There is worldwide concern about rising medical costs. The problem is particularly acute in the United States, which has led to multiple efforts to institute health care reforms. Health care expenditures constitute about 17% of the U.S. gross domestic product, compared to 6% to 11% for Canada, Germany, Japan, and the United Kingdom.[1] The cost of administration of U.S. health care is approximately one-fourth of the total national expenditure on health care. Health care administrative costs in the United States exceed those in many other developed countries. In 2002 the administrative cost of the federal Medicare program was 3% of the program's total budget, whereas the administrative costs of the federal and state Medicaid programs was 6.7% compared to 12.8% of total revenues for private health insurance plans. One reason for the low administrative cost of Medicare is its lack of advertising and marketing expenses. Medicare pays for roughly 1 employee for 10,000 beneficiaries, whereas most large private insurers hire 15 or more employees per 10,000 enrollees. The Kaiser Foundation Health Plan, one of the largest and best-known group-health maintenance organizations (HMOs), has self-reported administrative costs of 4%.[2]

According to the 2011 report of the Organisation for Economic Co-operation and Development, the average annual growth rate in health care spending between 2000 and 2006 ranged from 1.4% in Germany to 10.7% in Korea. With health expenditure of $6,714 per person per year, the United States largely outspent the other countries surveyed.[3]

Borger et al.[4] projected that in 2015 the United States will spend >$4 trillion, about 20% of the gross domestic product, on health care. Over the last 30 years overall inflation in the United States was 106%, whereas health care costs grew by 251%.[5] It is estimated that >$100 billion are devoted yearly to research, development, and regulatory approval of new technologies, but <$1 billion is spent on assessment of these new technologies.[6] Concern over the magnitude and continued growth of expenditures for health care in the United States has led to economic pressure on health service providers to contain costs.

Powerful forces affect the assessment of new technologies in radiation therapy. Inventors and developers, medical equipment manufacturers, corporate stock holders, and equipment salespeople seek rapid entry of new technologies into the marketplace at a minimum cost for as rapid a financial return as possible. Radiation oncologists desire new technology either for a real or perceived improvement in health care, career development, competitiveness with other practitioners, and/or personal profit. Patients and family members hope to see an improvement in clinical outcomes. Third-party payers seek cost reductions or stabilization, stable budgetary expenditures, and a plausible explanation of the "medical necessity" of the new technology. Finally, policy makers seek to balance the competing pressures that they feel from medical equipment manufacturers, physicians, and patients and the overall need for cost containment.[7]

Historically, regulatory approval of new drugs and devices was reliant on well-funded developers with a significant revenue stream conducting and funding randomized, prospective clinical trials. Many new technologies in radiation therapy, however, are introduced by small startup companies that are smaller, less well capitalized, and often single-product vendors. They are not capable of funding randomized, prospective trials and they have a powerful financial impetus to bring their product to market as quickly and as profitably as possible.

In 1985 the Blue Cross Blue Shield Association adopted criteria that required "adequate scientific evidence" to determine that technology improved health outcomes. This approach quickly became the norm among public and private payers. In an interesting development, in 2005, the Centers for Medicare and Medicaid Services (CMS) posted on its website draft guidelines describing a new approach to the determination of coverage policies called "Coverage with Evidence Development."[7] This proposal argued that Medicare coverage of promising technologies or services could be linked directly to a requirement that the beneficiary be a participant in a trial or registry and that the CMS had statutory or regulatory authority for that requirement. In the United Kingdom there was a similar proposal for funding "only-in-research" programs. Such programs were used for the evaluation of laparoscopic surgery for colorectal cancer, photodynamic therapy for age-related macular degeneration, the National Emphysema Treatment Trial to determine whether lung reduction surgery was superior to pulmonary rehabilitation without surgery, a comparison of balloon angioplasty plus carotid artery stenting versus carotid endarterectomy in patients at high risk for stroke, and the role of positron emission tomography scanning in suspected dementia.[8]

ECONOMIC EVALUATION IN HEALTH CARE

Economic evaluation is routinely becoming an important criterion for evaluation of therapeutic strategies. Unfortunately, consistent criteria are not followed for evaluation of the economics of treatment, which reduces the usefulness and credibility of comparative cost and other financial data/statistics across studies or over time.[9]

Health technology assessment (HTA) plays an essential role in modern health care by supporting evidence-based decision making in policy and practice. HTA involves addressing five questions[10]:

1. Can a health care intervention achieve its expected goal when used in optimal circumstances? (Efficacy)
2. Does the intervention do more good than harm when used in routine practice? (Effectiveness)
3. What is the balance between the health outcome obtained and the resources required to deliver the intervention? (Efficiency or Cost-Effectiveness)
4. Is the supply of services matched to locations where they are accessible to persons that need them? (Availability)
5. Who gains and who loses by choosing to allocate resources to one health care program instead of another? (Distribution).

A full economic evaluation typically involves quantitative examination of both costs and outcomes, or consequences, of competing interventions possible, including no intervention. An appropriately performed economic evaluation is incremental, that is, it measures the extra cost incurred to obtain the incremental improvement in outcome. Drummond et al.[11] identified different types of full economic evaluation based on the denominator chosen (Table 98.1). The most widely used approach, *cost-effectiveness analysis* (CEA), compares the incremental costs of a new technology or intervention to the incremental gain or loss of clinical outcome of the new intervention,

TABLE 98.1 LEVELS OF EVIDENCE AND GRADING OF EVIDENCE FOR RECOMMENDATIONS

	Type of Evidence
Level	
I	Evidence obtained from meta-analysis of multiple, well-designed, controlled studies or from high-power randomized, controlled clinical trials
II	Evidence obtained from at least one well-designed experimental study or low-power randomized, controlled clinical trial
III	Evidence obtained from well-designed, quasi-experimental studies such as nonrandomized, controlled, single-group, pre/post, cohort, time, or matched case–control series
IV	Evidence from well-designed, nonexperimental studies, such as comparative and correlational descriptive and case studies
V	Evidence from case reports and clinical examples
Grade	
A	There is evidence of type I or consistent findings from multiple studies of type II, III, or IV
B	There is evidence of type II, III, or IV and findings are generally consistent
C	There is evidence of type II, III, or IV but findings are inconsistent
D	There is little or no systematic empirical evidence

Adapted from Drummond M, Sculpher MJ, Torrance GW, et al. *Methods for the economic evaluation of health care programmes.* Oxford: Oxford University Press, 2005.

ideally measured in life-years gained (LYG). Other potential denominators in a CEA are disease-free survival or number of cancers prevented or detected, but the use of such intermediary outcome measures hampers comparison among different CEAs and should therefore be discouraged. The evaluation will result in a ratio of the cost/outcome, for example, cost/life-year gained ($/LYG, €/LYG), called the incremental cost-effectiveness ratio.

When the outcome of the evaluated interventions is expected to be the same, the economic evaluation will be limited to a cost comparison called *cost-minimization analysis* (CMA). Assuming a well-defined comparison of two radiation therapy (RT) approaches and a sufficiently long follow-up, prolongation of life, life-years gained, can be measured, but it can be questioned whether this is the metric that has most relevance to patients. The third type of full economic evaluation, *cost–utility analysis* (CUA), acknowledges quality of life after aninterventionby weighting the LYG with a "utility factor" typically ranging from 0 (death) to 1 (perfect health). For example, if a patient had a utility or preference for a health state of 0.5 and he survived in that state for 1 year, then he would have had a quality-adjusted survival of 6 months. A CUA employs quality-adjusted life years (QALYs) in the denominator, with the result expressed as cost/QALY. Utilities or patient preferences for a certain health outcome can be measured with instruments such as the Health Utilities Index III[12] and EuroQol[13] or tests such as Time-Trade Off or Standard Gamble.[14] CUAs are helpful in trying to compare nonsimilar health interventions, such as a prostate cancer–screening program with a child immunization program, for example.

The last type of full economic evaluation is *cost–benefit analysis,* in which both cost and outcome are valued in terms of currency. Where the benefit in monetary units is greater than the cost, the medical intervention is considered worthwhile. Putting a dollar value on the quantity and quality of a life is, however, a highly specialized and controversial area. Full economic evaluation in RT, requiring detailed input on short- and long-term costs and outcomes, can be difficult to perform. One such approach addresses costs and outcomes separately and leads to cost and outcome descriptions, respectively.[11] However, there are dangers with separating costs and outcomes, and one has to be cautious that the information generated will not be misused.

The most useful descriptions of outcome of a new treatment strategy, particularly from the patient's perspective, result from the conduct of clinical trials. Randomized and controlled phase III trials have been categorized as efficacy or effectiveness evaluations.[11] It can be argued, however, that such comparisons may indirectly lead to the increased cost of health care as funders come under pressure to broadly adopt new interventions with only marginal clinical benefit and no consideration of the opportunity cost. A pure cost comparison, in contrast, entails the opposite risk. If the tendency to reduce health care spending is strong, this might result in the simple choice of the cheapest approach, which may, in turn, lead to reduced quality, hence inferior outcome. Provided that there is sufficient evidence that the outcome of interest for the experimental treatment or intervention does not differ from the standard treatment, a CMA is undertaken (discussed earlier), that is, a mere cost comparison, with the intervention resulting in the lower cost being the favored one from a health economics' perspective.

In evaluating medical care, the term *efficacy* is not interchangeable with *effectiveness.* The maximum possible reduction in a disease due to the use of medical intervention is properly *termed efficacy,* which is generally measured with randomized, controlled trials, which will achieve the maximum possible benefit when patients are carefully selected and stratified, randomization arms are properly designed, compliance is high, and trial participants are often free of other diseases or conditions that might interfere with the intervention being evaluated. The benefits established in a randomized, controlled trial are only partially applicable to day-to-day practice in a general population. The value of a medical intervention in the general population is termed *effectiveness.* The difference between efficacy and effectiveness can be very large, and obtaining a realistic measurement of effectiveness is often difficult.[15]

There are three approaches to health economic evaluation for comparing two therapies: (a) cost minimization, in which one assumes or observes no difference in effectiveness, (b) incremental cost-effectiveness, and (c) incremental net benefit. The last can be expressed in units of either effectiveness or costs. When analyzing data from a clinical trial, expressing incremental net benefit in units of cost allows the investigator to examine all the approaches in a single graph, complete with the corresponding statistical inferences.[15a]

A computerized literature search of >14,000 articles published since 1994 having *cost* as a keyword was carried out. Criticisms of these costing studies focus on three areas:

1. Costs are not measured correctly[16–18] because most studies use charge or reimbursement dollars as a proxy for cost. This is an incorrect measure because neither value is representative of the resources consumed or foregone in the process of providing a good service; hence, it is not a cost; the former figure is a construct, and the latter is the result of a negotiation between a payer and a provider.
2. Costs are not compiled using a proper perspective and scope.[17,19] Most studies only tabulate the cost of the health care provider and not to the patient, the family, or society.
3. There is a lack of consistency in reporting results,[16,20,21] which prevents interstudy and interinstitutional comparison.[22]

As a result of these problems, the data and conclusions from many cost-based studies are suspect.[19]

Clearly, a better costing method is required. Russell[23] emphasized that to serve its purpose, a model must produce accurate predictions and low probability for substantial variation in the factors that influence costs and effects. He identified three aspects of modeling: validating effectiveness estimates, modeling costs, and the implications of common statistical forms. Validation procedures similar to those for effectiveness estimates are proposed for costs. Modelers need to pay more

attention to ensuring that the events described by a model represent costs and effects. Modelers can also help improve the epidemiologic and clinical research on which cost-effectiveness analyses depend by showing the implications for resource allocation of the statistical forms conventionally used in these fields.

Comparative effectiveness research (CER) aims to improve the quality, effectiveness, and efficiency of health care and to help patients, health care professionals, and purchasers make informed decisions regarding various treatment options, particularly for chronic illnesses or cancer. CER is moving forward, with recently defined priorities and a newly funded Patient-Centered Outcomes Research Institute, which, it is hoped, will survive cost cutting in the U.S. Congress. Economic analyses are most valuable to health policy analysts and health care managers who must allocate resources and establish benefit packages. An economic health care analysis tries to directly relate the incremental cost of an intervention to its potential benefit. The intervention is always evaluated relative to an alternative form of treatment.[9]

Technology assessment, cost–benefit outcome analysis, clinical trials supported by evidence-based medicine, and comparative effectiveness together can enhance the rationale and quality of medical care provided to patients at a competitive cost.

TECHNOLOGY ASSESSMENT

Technological change is the key driver of health care expenditure growth because it is generally associated with increased rather than reduced cost. As the economist Henry Aaron is quoted as saying, "Rapid scientific advance always raises expenditures even as it lowers prices. Those who think otherwise need only to turn their historical eyes to automobiles, airplanes, television, and computers. In each case, massive technological advance drove down the price of services, the total outlay soared."[2] A good example in medicine of this phenomenon is laparoscopic cholecystectomy. Although the price of a laparoscopic procedure is less than the price of an open cholecystectomy, after the introduction of the new technology the rates of both types of surgery increased, and the growth in the quantity of services overwhelmed the impact of per-unit reduction in price. Similar examples can be found in the widespread use of magnetic resonance imaging, computer tomography, coronary artery bypass grafting, angioplasty, cardiac intensive care units, neonatal intensive care units, and positron emission tomography and the growth of radiation oncology facilities. Technology may also increase costs by either premature adoption of the technology without adequate evidence that it improves outcome or overuse of technology, regardless of value, to provide a competitive market advantage or to generate revenues.[24]

Technology assessment is undertaken to determine (a) the appropriateness of adopting a new procedure consistent with the health care organization's mission and strategic plan; (b) the safety, efficacy, and cost-effectiveness of the new technology; (c) distinctions between appropriate and inappropriate use for the new technology; and (d) quality improvement methods to optimize the use of the new technology.[25] Technology assessment is a complex process that involves financial considerations, therapeutic outcome (locoregional tumor control, amelioration of symptoms and survival), treatment-induced morbidity, quality of life, impact on caregivers, family, and coworkers, and lost-opportunity costs.

When new technology emerges and priorities for allocation of increasingly scarce resources are considered, it is imperative to carry out economic analyses and also to assess the positive effects to the population who will benefit from the new technology compared with standard treatment techniques. The U.S. Center for Medicare Management concluded that cost-effectiveness should be considered in approving reimbursement by Medicare for new technology procedures.

Halperin[26] pointed out the importance of technology assessment in determining the merits of new devices or modalities and the impact they may have on the cost of health care. In a provocative editorial, Lee[27] pointed out that although technology is ubiquitous in radiation oncology, it is our professional responsibility to critically evaluate the merits of new technological developments. Yet, technology assessment can be a thorny and complex subject. Many of the technological advances in radiation oncology have not undergone a strict test of worthiness in formal clinical trials. Simulation, positioning techniques, computed tomography scanning for treatment planning, online imaging, and even intensity-modulated radiation therapy have had multiple dosimetric validations, but no randomized trial has documented their impact on outcome of large numbers of patients. However, lack of this evidence would not lead us to discontinue any of these procedures, which have been shown to improve in some way (i.e., less toxicity) the quality of care provided to patients.

The profusion of new technologies in medicine is related to the number of specialists in an area. Specialists receive income from new technologies and prompt hospitals to invest in them. A hospital that is constructing innovative facilities may attract specialists to the community and improve its revenue. It is also likely that public attitudes are influenced by medical providers and suppliers that advertise new technologies through the mass media.

Many nations have agencies to conduct health technology assessment, and there is an international network of agencies for health technology assessment that can share such data. The United States, however, has no national coordinating body on health technology assessment. Assessments are conducted through organizations such as the Veterans Administration, the Blue Cross Blue Shield Association, and professional organizations like the American College of Radiology, the Medicare Coverage Advisory Committee, and HMOs.

Health care organizations use a variety of models to assess and acquire technology, some of which include outcome. Reliable data for such benchmarking is frequently scarce. Some compare new and emerging technology against existing technology, although reliable outcome data are rare. Most institutions or individuals buy what physicians, advocacy groups, philanthropists, or governing boards want and use manufacturers and physicians as the primary sources of technology information. Cowan and Berkowitz[24] pointed out several key mistakes that occur during the diffusion of technology:

1. Technologies are adopted simply because they are new, without assessing their impact on outcomes.
2. Equipment is replaced solely because of its age. To avoid overuse of technology, health care organizations must carefully match the capacity of existing technology with projected utilization in a world of limited resources.
3. Applications of technology expand without adequate justification based on outcome or cost considerations.
4. Numerous vendors are used, and numerous models of products with duplicative specifications are purchased. Reducing the number of brands and models of devices used may provide an opportunity to reduce purchasing and inventory costs, as well as maintenance and repair costs. On the other hand, competitive pressures in the marketplace may provide downward pressure on equipment prices and argue in favor of the existence of multiple vendors.
5. Economies of scale in regionalizing technology decisions are missed because of lack of consolidation of services. This is sometimes related to inadequate systems for patient transport to treatment centers.
6. Duplication of services sometimes adds cost without significant increase in work volume.

A number of studies on the costs of treating cancer patients with radiation therapy[28–31] used either relevant costs defined in a number of ways or different proxies for actual costs (billed charges, revenue received, Medicare allowable). Recent reviews illustrate the wide variety of cost information and cost methods used in the literature and call for a consistent method for estimating site- and intent-specific treatment costs.[9,18,19,22,32] In estimating costs of health care interventions, several decision tools, including cost analysis, cost-effectiveness, and cost–utility and cost–benefit analysis, seek to define a unit of health outcome per unit input of cost. Before employing any of these decision tools, proper definition and calculation of cost is essential. The literature on the cost-effectiveness of particle therapy for cancer is scarce, studies are often not comparable, and many studies are not performed according to standard health assessment criteria. Evidence on the cost-effectiveness of particle therapy is, therefore, limited. One would hope that adequate reimbursement can be found to support innovative yet costly treatment to learn whether it is truly more efficacious.

TYPES OF COST IN HEALTH CARE

Costs During Treatment

Direct medical costs include the value of all the goods and services consumed in the provision of an intervention or dealing with the side effects of treatment. These costs include the consumption of all capital and human resources such as professional time, diagnostics, treatment, and medications.

Direct non–health care costs include all costs as a consequence of undergoing a treatment but not related to the treatment itself. Examples are the cost of transportation while patients are receiving treatment. Other costs sometimes included are *changes in use of informal caregiver time* (including the cost of family or other providers to provide health care in the home or continuous nursing care for disabled individuals) and *patient time costs* (referring to the time patients spend receiving care, including the value of the time consumed in receiving the treatment as well as travel and waiting time).

Indirect medical costs include all costs in the time after the treatment has been terminated and include costs of late toxicity or related diseases. In RT, these costs can differ quite substantially between different approaches if the side effects are very different or if one of the interventions has a higher curative potential. Typically, however, these costs occur many years after termination of the treatment.

Indirect nonmedical costs refer to costs that are important for society, in that they measure loss of productivity due to long-term disability or premature death. Costs to the family or society can be substantial. These include the patient's travel costs, the patient's or care provider's time off from work, and the considerable strain on caregivers. There may also be "downstream" effects. If a caregiver is devoting time to an ill spouse, he or she is taking time away from work or child care responsibilities, for example.

Global cost estimates of the cost of RT are the aggregate costs of the human and capital resources consumed in the delivery of a RT service. They do not contain the fine detail required when comparing, say, one RT protocol with another. However, they can have value as a background to allocating national health care budgets between different classes of medical intervention.

The data show that even in countries with optimal infrastructure, the budget assigned to RT is roughly 5% of the total amount spent on cancer care.[33] In the early 1990s, the European Union estimated the average cost per course of RT at about 3,000€, compared to roughly 7,000€ and 17,000€ for surgical and chemotherapy treatments, respectively. However, in spite of the perception of high capital costs, it is the personnel cost that dominates the cost of the provision of the service (about 70%), with capital investment typically representing <30% of the total RT budget.[3,14,34]

Reimbursement-Based Costs

Whereas economic evaluation theoretically advocates the use of cost figures that reflect actual resource consumption, this is frequently not achievable, and charges for service are used as a proxy. It should, however, be realized that large discrepancies may exist between the reimbursement of treatments and the costs of resources consumed while delivering a treatment. Due to the fact that reimbursement often lags behind the introduction of novel technologies, in many countries there is a tendency for high-tech treatments to be underreimbursed. The inverse seems to hold for the United States, where the reimbursement is likely to be higher for new technologies, although it decreases with time.

Besides numerical differences between costs and charges, other, more practical and theoretical problems may arise when utilizing reimbursement figures for economic evaluation. This was observed by the Radiation Therapy Oncology Group when performing an economic evaluation based on combining clinical trial data with cost data obtained from Medicare for each patient.[35] The first problem was that Medicare-managed care products do not have individual claims because managed care companies receive capitated payments and therefore may not record and/or report individual claims to Medicare. A more accurate estimation of costs would result from using administrative claims data to calculate costs, provided that they contain all claims of care a patient received. Another potential problem is that an underestimation of costs could occur if codes with only a cancer diagnosis were used, thus neglecting costs related to treatment toxicity or indirect medical costs occurring in the further follow-up of the patient. It may also be difficult to generalize the results of an analysis based on Medicare patients older than 65 years to the general population. Finally, it is apparent that obtaining administrative claims data from Medicare can be a costly procedure in itself.[36]

ACTIVITY-BASED COST ANALYSIS

Activity-based costing (ABC) is a system widely used in manufacturing but rarely in health care. ABC dissects the process of providing patient care into a series of microlevel tasks and assigns costs to these tasks. As a result, ABC directly identifies resources consumed by cost objects (treatments, patients, or health care providers).[12] Tabulating these tasks and resources consumed allows for comparison of cost values across institutions and time in a consistent and credible way. From this, the economic impact of differences in operating policies can be quantified and the comparison of cost to health outcome will be improved.

The traditional cost models that hospitals have used are outdated and ill equipped to provide accurate information on costs of a specific medical procedure or global cost of medical care for a patient from initial diagnosis to death. Cost models break organizations into departments for financial oversight and budgetary control; the focus of these cost models is departmental budgets, and they are not specific for a patient or a procedure, when it is really patients and procedures, not the department, triggering costs. For example, the accounting system of a hospital may be able to provide a fair assessment of the total budget (cost) of its radiation oncology department. However, the same system is of little help in assessing the actual cost of treating a patient with, for instance, prostate cancer using radiation therapy. This lack of applicability of cost information at the patient or the procedure level often leads to faulty decision making because analysis of the whole department does not necessarily translate into data about an individual patient.

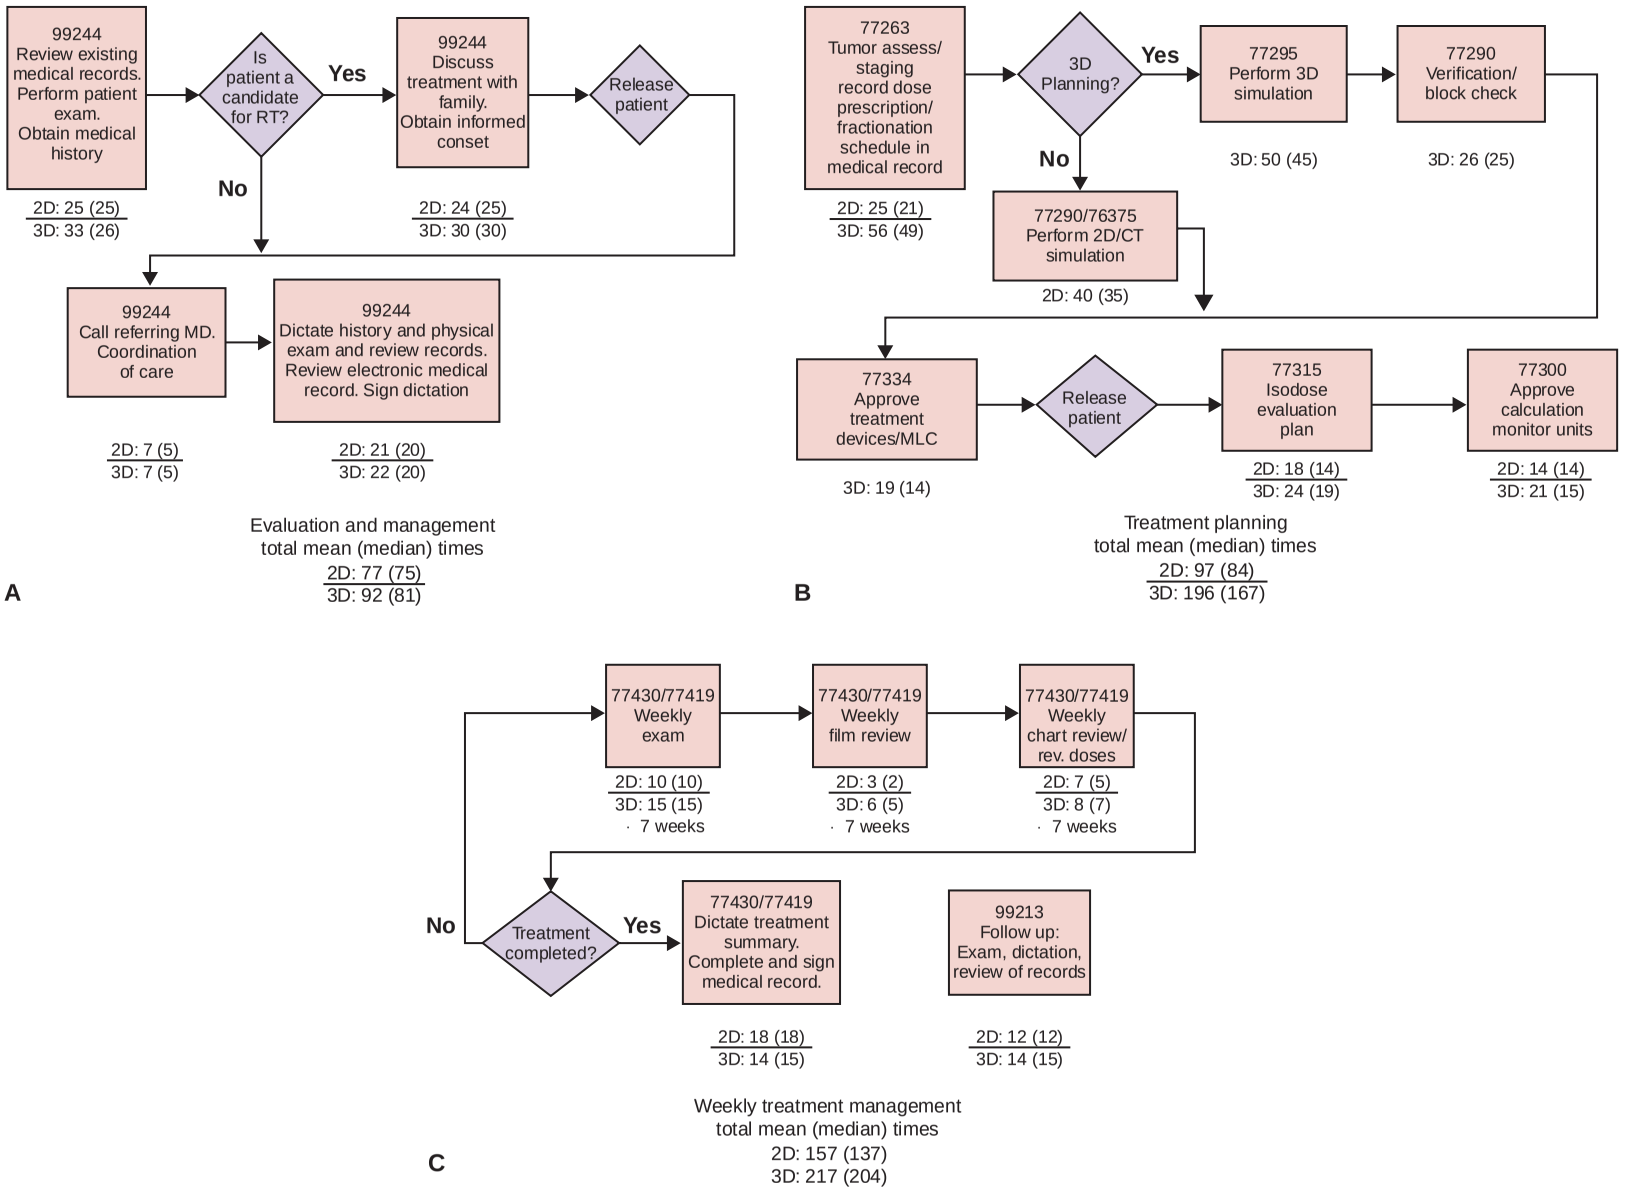

FIGURE 98.1. Process flow chart. Activity map and corresponding mean (median) times for definitive irradiation of cancer of prostate. **A:** Evaluation and management. **B:** Treatment planning. **C:** Weekly management.

ABC is concerned with measuring resource consumption by an individual patient. There are two general advantages of using ABC: increased accuracy of cost measurements and transparency of cost-incurring sections. The latter advantage—increased accounting transparency—means that there is a more lucid and readily apparent correlation between costs and actions. This allows managers to evaluate each step of the process, perceive inefficiencies in the system, and quantify economic benefits of process improvements.

The cost data of any technology should reflect the facilities and equipment costs (including depreciation and replacement), space (including housekeeping and utilities), and recorded time and effort of all professional staff on hospital payroll treating patients. Specific technical approaches should be identified, for example, in patients undergoing definitive radiation therapy, standard two-dimensional (2D) or three-dimensional (3D) conformal RT (CRT) or intensity-modulated RT (IMRT) or image-guided RT (IGRT). Time and effort observations for multiple tasks must be recorded by the respective staff members as they take place. The numbers of observations provide a representative sample of treatment procedures.

Technical cost is defined as the actual expenditures recorded in hospital accounting records. The total technical cost of a course of therapy includes staff time and effort, compensation including fringe benefits, space, utilities, maintenance, equipment depreciation, supplies, support services, liability cost, and administrative overhead. The ABC method[37–40] was used to derive technical (hospital) resource utilization costs for treatment procedures in treating localized prostate cancer.[9,30] The costing method consists of four major steps:

1. Creating a process flow map that identifies and defines all of the activities and steps associated with the treatment of patients with standard irradiation or with 3D CRT (Fig. 98.1).
2. Collecting and recording the staff time expended on each activity.
3. Identifying and accumulating all hospital costs from the general accounting ledger system related to the patients treated at a radiation oncology center in a given period.
4. Allocating actual cost to each activity to derive total specific costs of technical resource utilization for a course of 2D or 3D CRT, IMRT, or IGRT.

An example of an ABC cost-calculation model is the one developed in by Lievens et al.[34] Because it was felt that current RT protocols, with a shift toward more complex treatment planning and delivery techniques and more thorough quality assurance procedures, were no longer accurately captured within the original model, a novel version has recently been developed.[41] Because evolving technology over the last decade was more complex, it was found that the introduction of IMRT compared to 3D CRT translated into an almost doubling of procedure costs. ABC analysis allowed the authors to identify exactly where these extra costs were incurred. It was shown that the cost increase was the consequence not of the IMRT technique as such but of the combined effect of IMRT using more fields and delivering higher fraction numbers and, very important, the introduction of more, often daily, online imaging for position verification. If, however, techniques such as IMRT or gated radiotherapy delivery make it possible to reduce the number of fractions using simultaneous integrated boosts or accelerated hypofractionation, the resulting costs may decrease while yielding potentially improved treatment outcomes.[36]

Time and Effort Analysis

An integral phase of ABC is identifying process flow, listing each individual involved in the process and recording the actual amount of time spent to perform an activity by the staff using electronic or paper daily activity logs. Determining the participant's task time should follow the monopolizing rule: timing begins when a specific patient requires the participant's attention and stops when he or she is no longer doing so. Whether or not the patient is still present in the activity area is immaterial. For example, for an office visit, the nurse's time to prepare the patient's paperwork should be attributed to the patient, even before the patient arrives or after he or she has left the office. The actual activity time may be adjusted upward to recognize some normal unproductive time of activity participants, such as time spent in work breaks. Tables are generated to show the time and effort involved in each of the functions necessary to register and evaluate the patient, perform treatment planning, deliver external-beam irradiation, and supervise the management, as well as in preparation of the appropriate records to document all information, including quality assurance requirements.

Times are collected for each activity in the treatment process beginning with the initial consultation through the first follow-up visit after full treatment. These data points are analyzed and used to generate average times for patients treated with a specific technique along with the standard deviation of times.

RESOURCE UTILIZATION COSTS

Four types of resources should be catalogued and measured for each task:

1. Activity participants (e.g., radiation oncologists, physicists, therapists, dosimetrists, nurses, receptionists)
2. Physical resources (e.g., space, equipment, machines)
3. Supplies (e.g., x-ray films, office supplies)
4. Support services (e.g., administration, centralized information system)

Patient-related expenses include salaries and fringe benefits of the staff, Social Security contributions, retirement annuities, health, life disability and long-term care, dental insurance, tuition and childcare benefits, and disability insurance. Average hourly salary and related costs for each staff member are computed.

There are many supplies, such as office paper and latex gloves, for which the cost is trivial, and it is not economically worthwhile to track their specific use for individual patients. An average cost rate can be computed for such supplies by dividing their total cost by the total number of patients, which is applied to each patient. However, supplies used only by patients with specific diseases or procedures (e.g., contrast material, immobilization devices) need to be recorded for individual patients.

For hospital-based departments, indirect operating costs are classified into general hospital operating expenses and administrative overhead, which includes hospital liability insurance and administrative costs such as shared activities (administrative personnel for purchasing and payroll functions, human resources, public relations, and financial operations). The allocation of indirect operating costs among different departments of the hospital is complex. Models include allocating them as a proportion of personnel costs and many others. The allocation of cost among various units in a hospital can also be the source of pitched battles between different units. In many hospitals allocation of costs is a mechanism of cross-subsidization among different departments (e.g., the surgery department subsidizing primary care). Administrative cost can be determined by computing prorated allocation, dividing the total hospital indirect expenses by the proportion of the radiation oncology center technical budget to the total hospital annual budget.

Technical equipment expenses for treatment of patients are included using American Hospital Association standard depreciation schedules. The cost of depreciation of all equipment involved in the management of these patients, including

treatment planning and delivery, should be accounted for on a prorated basis.

COST BENEFIT

If all that matters is minimizing expense, then the lowest-cost treatment (or no treatment) would be preferred. However, cost benefit, which incorporates the incremental impact of a new technology on outcome, and cost utility, which also relates additional costs to impact on survival as well as on the patient's quality of life and productivity, are important parameters in the assessment of new technology.[9] The projected cost of treating a patient who initially has control of the local tumor and no distant metastases is about one-third of that for a patient who develops a treatment failure.[42]

As a concomitant to an increasing proportion of the health insurance market being controlled by managed care, with its cost-cutting pressures, there may be a tendency to de-emphasize the importance of quality of care. However, it is critical, for instance, to document the alleged decreased morbidity of treatment with 3D CRT, IMRT, or protons in comparison with treatment of patients with carcinoma of the prostate[43] with conventional external-beam radiation therapy. This benefit, if it is real, is of great financial significance because treatment of major therapy complications may be costly.

Owen et al.[44] conducted economic studies for two phase III Radiation Therapy Oncology Group studies that compared different irradiation fractionation schedules (1-04 and 90-03, brain metastasis and head and neck cancer, respectively). Expected quantities of current procedural terminology codes and relative value units (RVUs) were modeled. Institutions retrospectively provided procedure codes, quantities, and components, which were converted to RVUs used for Medicare payments. The median and mean RVUs were within the range predicted by the model for all arms of one study and above the predicted range for the other study. The model predicted resource use well for patients who completed treatment per protocol. Actual economic data can be collected for critical cost items. Some institutions experienced difficulty collecting retrospective data, and prospective collection of data is necessary to validate these studies.

We must move from a fee-for-service mentality to a more critical and fiscally responsible health care system delivering high-quality care at a competitive cost. Based on current trends, 70% of hospital revenues will be capitated in a not-too-distant future. A challenge for future health care initiatives will be to strive for the lowest (optimally speaking, most competitive) cost with the highest value for the patient, including decreased morbidity of treatment and enhanced quality of life.[45]

The potential contribution of more complex and expensive procedures to the outcome of cancer therapy needs to be carefully evaluated.[46] Obviously, a significant portion of the increase in health care costs is linked to new technology; a great deal of this technology is welcome, but cost benefit should be demonstrated. Some technologic advances improve health care and can be justified economically if we document a positive impact on tumor control, patient survival, morbidity of treatment, and quality of life. The efficacy of diagnostic and therapeutic procedures can be related to outcome studies, and costs should be carefully evaluated based on both monetary and health-related considerations. Doubilet et al.[47] cautioned against the indiscriminate use of "cost-effectiveness" as the criterion on which medical decisions should be made, and thus we must carefully define the endpoints on which these studies are based.

Models can be constructed using a Markov model and available data on the natural history of a tumor, prognostic factors, efficacy and morbidity of a given therapeutic modality (based on outcome analysis), and reimbursement data for treating a specific patient population. When patterns-of-failure data are used, the cost differential can be calculated for a patient treated successfully in contrast to one who fails in a specific anatomic site (locoregional failure, distant metastasis, or combination), incorporating expenditures related to management of the treatment failure. The model can be made more complete (and complex) by adding costs of the morbidity of therapy. With the information and epidemiologic data currently available in the United States, annual costs of care can be computed and compared for various therapeutic modalities. Using Monte Carlo simulation, sensitivity analysis of cost-effectiveness may be performed.

Total cost-of-care projections should be carried out using a Markov-type analysis based on clinical experience, which will provide more accurate cost data for different management options. Providing cost–benefit information to patients (consumers) will be necessary when evaluating diagnostic and treatment options, particularly in carcinoma of the breast and prostate, in which great controversy exists regarding the merits of various modalities.

This information also will be very helpful in contract negotiations with health care organizations and third-party payers and in setting policies for establishing therapy guidelines and justification of health care expenditures.

Cost–utility analysis calculates the value of an intervention as the ratio of its incremental cost divided by its incremental survival benefit, with survival weighted by utilities to produce QALYs. Many studies are at variance with current standards; only 20% of studies took a societal perspective, more than one-third failed to discount both the costs and QALYs, and utilities were often simply estimates from the investigators or other physicians. There remains much room for improvement in the methodologic rigor with which utilities are measured. Considering quality-of-life effects by incorporating utilities into economic studies is particularly important in oncology, when many therapies obtain modest improvements in response or survival at the expense of nontrivial toxicity.

Stinnett and Mullahy[48] introduced the concept of net health benefit as an alternative to cost-effectiveness ratios for the statistical analysis of patient-level data on the costs and health effects of competing interventions. Net health benefit addresses a number of problems associated with cost-effectiveness ratios by assuming a value for the willingness-to-pay for a unit of effectiveness. Willan[49] extended the concept of net health benefit to demonstrate that standard statistical procedures can be used for the analysis power and sample size determines cost-effectiveness data. He showed that by varying the value of the willingness to pay, the point estimate and confidence interval for the increment cost-effectiveness ratio can be determined.

The benefit of 3D CRT, IMRT, or IGRT is hypothetically linked to improved local tumor control because of better coverage of the target volume with a specific dose of irradiation, less acute and late morbidity, and possibility of carrying out dose-escalation studies if morbidity is held to an acceptable level, resulting in improved survival.[42] Several institutions, the Radiation Therapy Oncology Group, and 10 institutions under cooperative agreement with the National Cancer Institute conducted phase I/II dose-escalation studies in carcinoma of the prostate and are carrying out a study on carcinoma of the lung. Depending on the results, the cost benefit of 3D CRT, IMRT, or IGRT must be further evaluated in dose-escalation and in larger multi-institutional phase III studies, comparing it with standard techniques to justify its somewhat higher initial cost. Cases that are most likely to benefit from 3D CRT, IMRT, or IGRT include patients with (a) tumors in sites with complex anatomy, (b) irregular-shaped tumors, (c) tumors adjacent to radiation-sensitive normal structures, (d) tumors that undergo significant changes in volume during treatment, and (e) small-volume or high-dose treatment.

The introduction of protons and heavy ions (hadrons) into the radiation therapy armamentarium has brought additional controversy in technology assessment because of the higher cost of facilities, equipment, and operation, with diverse opinions as to the cost-effectiveness of these innovative modalities. A 2008 review of the literature showed that only 17 publications (out of 777 on particle therapy) dealt with economic aspects, and only 5 of them were on cost-effectiveness.[50]

Many articles have been published on the physical advantages of protons or heavy ions in comparison to photons, resulting in better dose distribution in the target volume with less radiation administered to normal tissues, which may decrease morbidity and eventually the risk of second malignancies.[51,52] However there is a lack of randomized trials documenting superior clinical outcomes with these particles.

Opinions on the need for or ethical considerations to subjecting patients to prospective trials have been expressed.[53,54] Perrier et al.[55] used an ABC approach similar to the examples discussed previously to evaluate the cost of carbon-ion therapy. It allowed an in-depth definition of the cost of treatment preparation and the actual irradiation, depending on various parameters such as actual treatment time and patient setup time. The approach of Peeters et al.,[56] conversely, was more aggregate, using a spreadsheet model that assumes that treatment costs scale linearly with the number of fractions. This, obviously, is a somewhat simple approximation of reality, which results in less accurate estimates.[34]

Implementing new technologies in radiation oncology with advanced engineering, such as linear accelerators, cone beams, tomotherapy, treatment planning and delivery techniques, and accessories that enhance the efficiency and accuracy of operation, may decrease overall cost of treatment computed over the lifetime of the patient.

The American Society for Therapeutic Radiology and Oncology maintains the position that new technologies and modifications of existing technologies representing significant paradigmatic shifts in treatment approach should be implemented into clinical practice in such a manner as to ensure safety, efficacy, and, ideally, cost-effectiveness.[57]

EVIDENCE-BASED MEDICINE AND EVIDENCE-BASED ONCOLOGY

There have been significant scientific advances in biologic sciences and health care. At the same time, there has been increased accountability and in some instances attempts to ration services; as a mechanism to accomplish this, arbitrary clinical practice guidelines have been promulgated. A more rational effort to define optimal heath care should be based on identification of innovative approaches, outcome analysis in properly designed clinical trials, and careful assessment of current practice; more important, we have a dire need for solid and credible clinical research and evidence-based decision making in medicine.

The growth in basic and translational research data to guide medical practice has made it critical for clinicians to appraise and use published data for medical decisions. Evidence-based medicine (EBM) is the compelling idea that any recommendation of a specific medical procedure should be supported by empirical evidence for its superior efficacy/toxicity ratio compared with alternative treatment options in a patient with a given presentation.[43,58,59]

Evidence-based medicine helps correct an imbalance in contemporary medicine in which clinicians are being trained to maintain high standards of critical consciousness in methodologic domains but not in the broader historic and sociocultural domains that surround them.[60]

Evidence-based health care is the conscious use of current best evidence in making decisions about the care of individuals or the delivery of health services. Current best evidence is up-to-date information from relevant valid research about the effects of different forms of health care, the potential for harm from exposure to particular agents, the accuracy of diagnostic tests, and the predictive power of prognostic factors.

Evidence-based clinical practice is an approach to decision making in which the clinician uses the best evidence available, in the context of consultation with the patient, to decide on which option suits the patient best. Evidence-based medicine is a conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients.

Evidence-based medicine or evidence-based practice aims to apply the best available evidence gained from the scientific method to clinical decision making. It seeks to assess the strength of evidence of the risks and benefits of treatment or lack of treatment and diagnostic tests. Evidence quality can range from meta-analysis and systematic reviews of double-blind, placebo-clinical trials at the top end down to conventional wisdom at the bottom.

The systematic review of published research is the major method used for evaluating particular treatments. The Cochrane Collaborations are among the best known and respected examples of systematic reviews. Like other collections of systematic reviews, it requires authors to provide a detailed and repeatable plan of literature search and evaluation of the evidence. Once all the evidence is assessed, treatment is categorized as "likely to be beneficial," "likely to be harmful," or "evidence did not support either benefit or harm."

Evidence-based medicine categorizes different types of clinical evidence and rates or grades them according to the strengths of their freedom from the various biases that have beset medical research. The strongest evidence for therapeutic intervention is provided by systematic review of randomized, triple-blind, placebo-controlled trials with allocation concealment and complete follow-up involving a homogeneous patient population and medical condition. In contrast, patient testimonials, case reports, or even expert opinion have little value as proof because of the placebo effect, the biases inherent in observation in reporting cases, and difficulty in ascertaining who is an expert.

Randomized, controlled trials are highly desirable to answer questions about technology assessment, but there are alternatives. Carefully controlled observational studies are good predictors of the outcome of randomized trials as long as enough essential information is collected to ensure that the patients are standardized. It is equally important in an observational series to understand which patients have been excluded.[61]

The American College of Radiology (ACR) created a Task Force on Appropriateness Criteria. This task force incorporates attributes for developing exceptional medical practice guidelines that have been used by the Agency for Health Care Research and Quality as designated by the Institute of Medicine. The ACR adopted the AQA's[62] definition of appropriateness: "The concept of appropriateness, as applied to health care, balances risk and benefit of treatment, test, or procedure in the context of available resources for an individual patient with specific characteristics. Appropriateness criteria provides guidance to supplement the clinician's judgment as to whether a patient is a reasonable candidate for the given treatment, test, or procedure."

The ACR Task Force on Appropriateness Criteria established 20 expert panels. Ten are concerned with diagnostic radiology and 10 with radiation therapy. In this latter group there are panels for bone metastases, brain metastases, breast, gynecologic, head and neck malignancies, Hodgkin disease, and lung, prostate, and rectal/anal malignancies. Each expert panel is chaired by an individual who is deemed by the College to have leadership capabilities and a national recognition of expertise

in the area of focus. Volunteer physicians are involved in the criteria development process. Expert panelists go through a process of literature searches, acquisition of scientific articles, drafting of evidence tables, dissemination of materials for the Delphi process, collation of results, conference calls, and documentation processing. For multiple radiation oncology treatments and procedures, there are published ACR appropriateness guidelines that one can consult to garner an opinion about the "consensus view."[62]

The Delphi methodology is a technique used to arrive at appropriateness ratings. A series of surveys is conducted to elicit members of the expert panel's interpretation of the evidence concerning the appropriateness of a therapeutic procedure for specific clinical scenario. The panelist receives a survey with an evidence table and narrative. Each panelist is asked to interpret the available evidence and rank each procedure. The survey is completed by each panelist without consulting fellow panel members. Ratings are done on a scale of 1 through 9, which is further divided into three categories, 1 to 3 is defined as usually not appropriate; 4 to 6 is defined as maybe appropriate; and 7 to 9 is defined as usually appropriate. Each panel member assigns one rating for each radiation therapy procedure or intervention per survey round. Surveys are collected and the results are tabulated, deidentified, and redistributed after each round. A maximum of three rounds is conducted. This modified Delphi technique enables each panelist to express individual interpretations of the evidence and his or her expert opinion without receiving bias from fellow panelists in a simple, standardized, and economical process. A consensus is defined as 80% agreement within a rating category.

Practicing evidence-based medicine requires recognition that, in most encounters with patients, questions arise that should be answered to provide the patient with the best available medical care. Appropriate and relevant clinical questions contain four elements: (a) a patient or problem, (b) an intervention, (c) a comparison intervention (if necessary), and (d) an outcome. Important practical steps in practicing evidence-based medicine include the following:

1. Formulation of the patient's clinical problem
2. Search of literature for relevant and reliable data
3. Evaluation of validity and usefulness of data
4. Integration of critical evaluation of evidence with clinical judgment
5. Implementation of useful information
6. Assessment of outcome to improve medical practice

Once the right questions have been formulated, the best source for finding most types of best evidence is by searching Medline (National Library of Medicine), PubMed (National Library of Medicine), OVID, the Cochrane Database, or a similar database by computer.

The quality (strength) of evidence is based on a hierarchy, proceeding from the most reliable results of systematic reviews of well-designed prospective clinical trials to results of one or more well-designed meta-analysis studies, results of large retrospective case series, expert opinion, and personal experience.[63] Once the best data have been found, the evidence-based medicine approach involves critically appraising the quality of the evidence, determining its magnitude and precision, and applying it to a specific patient.[64,65]

The Cochrane Collaboration was established in 1993 as an international network to help health care providers, policy makers, patients, their advocates, and their caregivers make well-informed decisions about health care by preparing, updating, and promoting the success of Cochrane reviews. More than 4,500 such reviews have been published so far online in the Cochrane Library.[66]

The Cochrane Collaboration traces its origins to a 1972 publication by the British epidemiologist A. Cochrane entitled *Effectiveness and Efficiency: Random Reflections on Health Services*.[67] This book called attention to the collective ignorance concerning the effects of health care. In 1979 Cochrane published an essay in which he suggested that "it is surely a great criticism of our profession that we have not organized a critical summary, by specialty or subspecialty, adapted periodically, of all relevant randomized controlled trials."[68] Responding to Cochrane's charge, the Cochrane Collaboration undertook such a crucial but enormous undertaking.

There are >28,000 people working within the Cochrane Collaboration in >100 countries. Its central functions are funded by royalties of its publisher, which comes from sales from subscription to the Cochrane Library. The individual entities of the Cochrane Collaboration are funded by a large variety of governmental, institutional, and private funding sources and are bound by organization policy limiting uses of funds from corporate sponsors.

Evidence-based medicine promotes rule-based behavior on the part of physicians in an effort, among other things, to eliminate variations in medical practice. However, professionals do not follow rules per se; they intuit what is right in a situation, including, sometimes, that it is right to defer to a rule.[69]

The practice of evidence-based medicine (careful clinical judgment in evaluating the "best available data") should be differentiated from the special collection of data regarded as "suitable evidence." The new collection of best available information has major constraints for the care of individual patients; derived almost exclusively from randomized trials and meta-analyses, the data do not include many types of treatments or patients seen in clinical practice, and the results show comparative efficacy of treatment for an "average" randomized patient, not for pertinent subgroups formed by such cogent clinical features as severity of symptoms, illness, comorbidity, and other clinical nuances. The intention-to-treat analyses in clinical trials reporting do not reflect important postrandomization events leading to altered treatment, and the results seldom provide suitable background data when therapy is given prophylactically rather than remedially. The authoritative aura given to the "collection of data" may lead to abuses that produce inappropriate guidelines or poorly supported doctrinaire dogmas for clinical practice.[70] There are a variety of mechanisms to apply evidence-based medicine to clinical practice, including formulation of treatment pathways, practice guidelines, appropriateness criteria, consensus conferences, patterns of care, and institutional peer review. A fundamental part of evidence-based medicine is the filtering of evidence through the clinical skill of the clinician. It is not easy to determine which level of evidence is required, and it is estimated that only 20% of medical procedures currently in practice can be justified by evidence-based medical standards. In addition, EBM has a dark companion: what Bentzen and Wasserman[58] called lack-of-evidence-based medicine (LEBM), a methodology used in the United Kingdom by the National Institute for Clinical Excellence to restrict access to a number of therapies on the National Health Service. Whereas evidence-based medicine is concerned with weighing level I evidence for or against a give intervention, LEBM is concerned with the systematic review of the lack-of-level I evidence on a given topic.

When does a new cancer therapy cease being experimental and become a component of the standard of care? This distinction is subject to powerful influences for for-profit pharmaceutical companies and medical equipment manufacturers wanting to increasing their sales and financial return to shareholders, advocacy groups, politicians, and a public anxiously awaiting the next "cancer breakthrough." A dispassionate set of systems for technology assessment of cancer therapies is essential to evidence-based oncology practice.

In 1993 in the United States the American Society of Clinical Oncology (ASCO) formed a Health Services Research Committee

(HSRC) to perform technology assessments and to develop guidelines for cancer treatment. The Committee is composed of clinical researchers and clinicians from academic centers and private practice and performs technology assessment after hearing from expert advisors. The committee does not develop guidelines; it assembles expert panels to develop guidelines.[71]

Among the most important initial tasks of the HSRC was to create an outcome working group to define the outcomes of cancer treatment that should be considered for technology assessment in forming cancer treatment guidelines. Not surprisingly, patients, physicians, researchers, payers, and policy makers all have different ideas about which outcomes of cancer treatment are important. The main purpose of ASCO's technology assessments and guidelines is to define what constitutes the best cancer treatment, not to inform policy development and payment decisions. The working group on outcomes, therefore, considered outcomes primarily from the perspective of the clinical investigators who produced evidence for the guidelines, individual doctors and patients who have to make decisions about treatment, and health services researchers who evaluate the quality and cost of care produced by the guidelines. Because it is clear that there are health policy implications of ASCO's technology assessments and guidelines, the working group also considered outcomes that would convince health policy makers that ASCO's technology assessment was sound and that its guidelines represented worthwhile treatment.[25,71] For technology assessment the ASCO working group is composed of members of the Health Service Research Committee and selected members. They conduct a literature review and analyze the outcomes-based evidence. Testimony is collected from invited experts and interested parties. After evaluating the information, the working group defines specific questions and provides a report outlining conditions under which the proposed procedures are warranted to assist both physicians and patients in making informed decisions regarding the technologist or procedures.

The working group identifies specific questions to be addressed by the technology assessment, develops a strategy for completing the assessment, and reviews the available literature and evidence. The process may include face-to-face meetings of available working groups and members, circulation of draft forms of the technology assessment, and opportunities for comment. Working groups do not attempt to codify established practice. They review the available evidence and add their best clinical judgment to make final recommendations.

Making a treatment selection involves defining the patient's condition, identifying management options and outcome, collecting and summarizing evidence, and applying value judgments or preferences to arrive at an optimal course of action.[45] The randomized, controlled clinical trial has become the "gold standard" for evaluating the efficacy of health care intervention. In the 30-year period starting in 1966, >80,000 journal articles from randomized, controlled trials results were registered in the Medline database. The first 5 years of that period contributed <1% of the total number of articles, whereas the last half-decade contributed more than the previous 25 years combined. (For more detailed review of the principles of design in clinical trials, the reader is referred to Bentzen.[72]) A proposal for structured reporting of randomized clinical trials was described in the consolidation of standards for reporting trials guidelines[73] that have been accepted by many medical journals. For instance, the journal *Radiotherapy and Oncology* adopted a set of guidelines for reporting clinical research (Table 98.2).[72] Linking management options to known outcomes in clinical trials or obtained through systematic reviews is becoming a common procedure (Fig. 98.2).

Clinical decisions are complex and based on many sources of information (Fig. 98.3).[73] Patient management decisions are always a function of both scientific evidence and individual preferences (physicians, health care providers, patients). A development to improve the basis for clinical decision making is an international movement to improve the reporting of clinical research results, particularly in randomized, controlled trials and method analyses. New data on current molecular biology and genetics investigations have broadened the scope of evidence-based oncology.

Hunt et al.[74] reported on an analysis of 68 controlled medical trials, 40 of which were published since 1992, to assess the effects of computer-based clinical decision support systems on physician performance and patient outcome. They observed that, in 43 of 65 studies (66%) on physician performance, a benefit was found, including drug-dosing systems, use of diagnostic aids, preventive care assistance, and other medical care procedures. Only 6 of 14 studies assessing patient outcome found a benefit, indicating that the impact of clinical decision support systems on patient outcome has been insufficiently studied. Furthermore, very few reports dealt with cancer-related treatment issues; most reports centered on prevention, activities, and cancer screening.[75,76]

Although oncologists, patients, and national organizations recognize that communication is very important in cancer care, evidence-based data on the subject are scarce. Oncologists should use a patient-centered interview approach, ask patients what level of involvement they want in medical decision making, develop a caring attitude, and consider that patient–physician encounters should provide both cognitive data of patient understanding and feelings.[77]

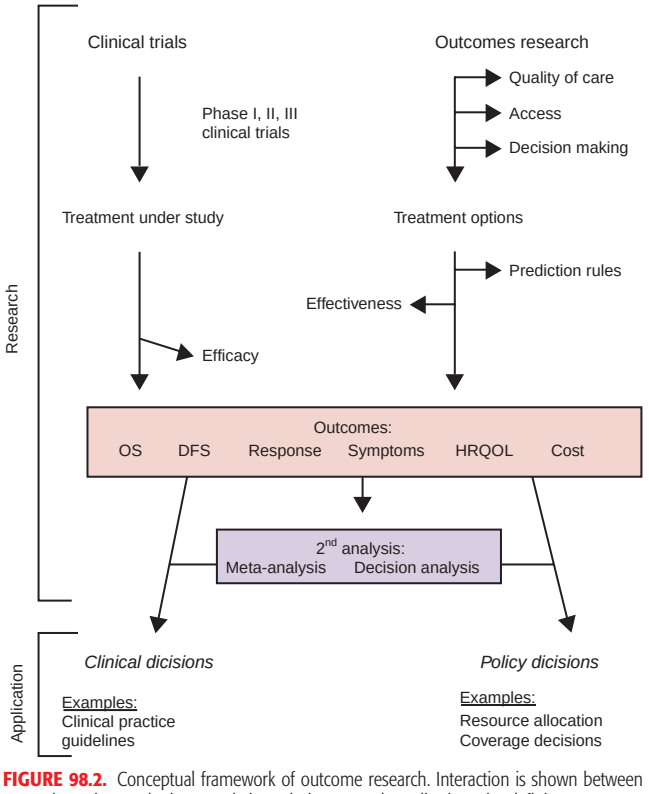

FIGURE 98.2. Conceptual framework of outcome research. Interaction is shown between research topics, endpoints, analytic techniques, and applications in defining outcomes research. Depicted in the upper left corner are the classic clinical trials and analytic techniques that are not outcomes research. In the upper right corner are shown the study topics, endpoints, and analytic techniques that are considered to be outcomes research. Outcomes depicted in the center box may or may not constitute outcomes research, depending on the context. For example, overall survival as measured in a phase III trial is not an outcomes study (efficacy), whereas it is if observed in a large community cohort (effectiveness). Symptoms have both efficacy and outcomes influences. Applications are indicated in italics and may emanate from either clinical trials or outcomes research. See text for further details. TABLE 98.2 GUIDELINES FOR REPORTING CLINICAL OUTCOME STUDIES IN THE JOURNAL *RADIOTHERAPY AND ONCOLOGY*

Heading	*Subheading*	*Item*	*Was It Reported? Yes/No/NA*[a]	*If Yes, on What Page Number?*
Title		1. Identify the study as a randomized trial		
Introduction		2. State the prospectively defined hypothesis, clinical objectives, and planned subgroup or covariate analyses		
Methods	Study design	3. Define the patient population, inclusion and exclusion criteria		
		4. Planned treatments and their timing		
	Radiotherapy	5. Radiotherapy dose prescription method, dose-planning procedure		
		6. Target volume definition, critical organs considered, simulation and verification procedures		
		7. Dose fractionation details		
		8. Planned radiotherapy quality assurance procedures		
	Endpoints and analysis	9. Primary and secondary endpoints, specific follow-up procedures, the minimum clinically relevant difference, the target sample size and how it was decided		
		10. Statistical analyses, their purpose and methods used, and whether the intention-to-treat principle was used.		
		11. Trial monitoring, early-stopping rules		
	Randomization	12. Method used for randomization		
		13. Method of concealment and time of randomization		
		14. Method to separate the generator of random treatment assignments from the treating physician		
Results	Masking patient flow and follow-up analysis	15. Describe any blinding procedures (if relevant)		
		16. Provide an overview of number of patients randomized, compliance with treatment, radiotherapy quality assurance results		
		17. State the effect of treatment on primary and secondary tumor outcome measures, including effect estimates with confidence intervals		
		18. Describe the incidence and grade of treatment-induced early and late toxicity by treatment group		
		19. State frequencies as absolute numbers when feasible (e.g., 10/20 and not just 50%)		
		20. Present summary data with appropriate statistics to permit alternative analyses or interpretations and comparisons with other trials on the same problem		
		21. Describe prognostic variables by treatment group, check, if they were balanced, and if not describe attempts to adjust for them		
		22. Describe protocol deviations from the study as planned, together with reasons		
Discussion		23. State the interpretation of the study findings, including sources of bias and imprecision, and discuss how this trial compares with other similar studies		
Conclusion		24. State the general interpretation of the trial in view of all available evidence in the literature		

These guidelines meet the minimum criteria defined in the CONSORT statement for reporting of randomized clinical trials.

[a]NA, not applicable; certain items apply to randomized studies only.

QUALITY OF MEDICAL CARE AND EVIDENCE-BASED MEDICINE

Continuous quality improvement emerged from the industrial sector as an effective means of reducing production errors. The quality of health care can be precisely defined and measured with a degree of scientific accuracy comparable to that of most measures in clinical medicine.[78] Health care quality problems can be classified into three categories:

1. *Underuse* is the failure to provide a health care service when it would have produced a favorable outcome for a patient, such as not administering irradiation in breast-conserving therapy.
2. *Overuse* occurs when a health care service is provided under circumstances in which its potential for harm exceeds the possible benefit—for example, prescribing postoperative pelvic irradiation to a patient with stage IA G1 endometrial carcinoma.
3. *Misuse* takes place when an appropriate service has been selected but a preventable complication occurs and the patient does not receive the full potential benefit of the service; avoidable complications of surgery, medications, or irradiation are important misuse problems.[79]

Other issues influencing the inadequate use of services include geographic variation in the rate of use, training of general practice or specialist physicians, the makeup of the nonphysician health care work force, and the effect of organization of medical services as a determinant of quality.

In health care, continuous quality improvement is most effective when used as an integral part of a scientific approach to improving clinical practice. A potential strength is the ability of motivate good performers to excel and to place emphasis on generating new methods for achieving improvement. Among its limitations are a too-narrow focus on administrative (as opposed to clinical) aspects of care and a lack of attention to problems of overuse or underuse. Several major strategies have been advocated to move the health care delivery system toward improving quality. The challenges are (a) to always provide effective care of those who could benefit from it, (b) to always refrain from providing inappropriate services, and (c) to eliminate all preventable complications.[80] Skeptics point out that no health care market currently competes on the basis of improving quality, and there is little theoretical basis in economics to predict that this success will occur.[79] Mendelson et al.[81] noted that there are many parties involved in outcome and effectiveness research (Fig. 98.4) and that payers and providers of health care may in the future use outcome research as a basis for coverage of services, including procedures, devices, or drugs.

OUTCOME RESEARCH

Outcome research focuses on identifying variations in medical procedures and associated health outcomes. Figure 98.2 illustrates the interplay of outcome research and clinical trials with clinical and policy decision making.

The term *outcome* is frequently used to describe a variety of endpoints or products of health care. Areas of specific focus of outcome analysis include the following:

1. Structure of care (such as features of health care facilities, staffing, equipment)
2. Process of care (such as type of studies performed, services provided)
3. Patient characteristics (gender, age, race, ethnic group)
4. Disease focus (such as location and type of tumor, histology, pathologic features)
5. Treatment-related factors (type of treatment, tumor response, disease-free survival, overall survival, morbidity of therapy)
6. Socioeconomics (such as cost benefit, quality of life, financial impact of the disease, recovery, and rehabilitation)

Meta-analysis is another mechanism to systematically research and collect published/unpublished randomized clinical trial data and quantitatively summarize results to obtain objective assessment of efficacy. The process should be (a) hypothesis driven, (b) protocol based, and (c) reproducible and comprehensive.

However, meta-analysis has some potential shortcomings, such as uncontrolled testing conditions, sample heterogeneity, unrecorded interventions, ambiguous endpoints, lack of independence of determinant factors, synergistic interactions, and sometimes contradictory experimental results.

Efforts have intensified during the last 20 years to promote outcome research in oncology, and there is a critical need to continue to support randomized, controlled studies. Patient and

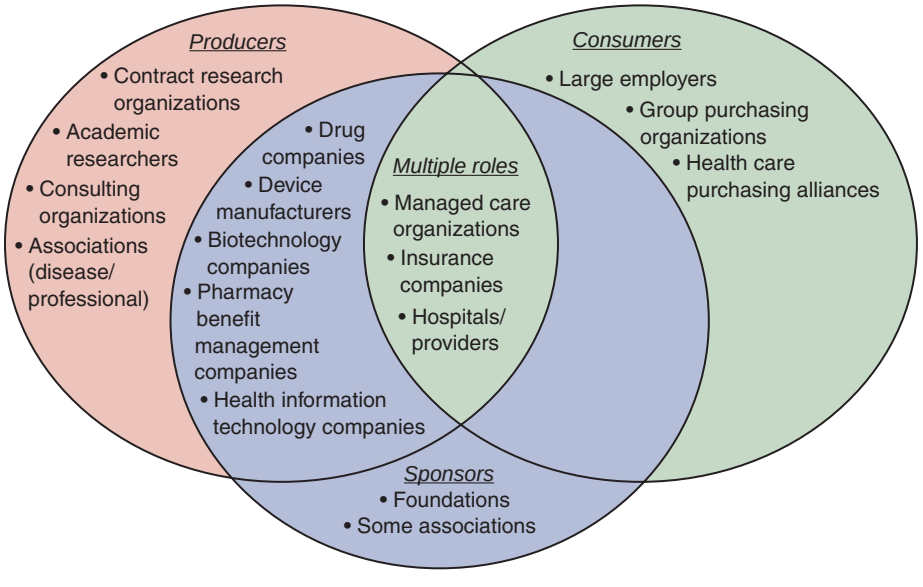

FIGURE 98.4. Stakeholders in outcomes and effectiveness research. (Adapted from Lewin Group. Outcomes and effectiveness research in the private sector: final report. Fairfax, VA: Lewin Group, 1997; and Mulrow CD, Cook DJ, Davidoff F. Systematic reviews; critical links in the great chain of evidence. In: *Systematic reviews: synthesis of best evidence for health care decisions.* Philadelphia: American College of Physicians, 1998:1–4.)

physician acceptance of participation in outcome research studies must be improved because only 10% to 20% of patients with newly diagnosed cancer participate in these important studies.[82] There is considerable variation in participation of patients in research studies as a function of patient age and disease site. In general, compliance with participation in studies is much higher among pediatric patients than adults.

Among the most commonly used data are those of the Surveillance, Epidemiology, and End Result (SEER) program. SEER is a continuing project of the biometry branch of the U.S. National Cancer Institute. The program draws data from several population-based cancer reporting systems covering approximately 14% of the total population of the United States. When linked to Medicare and other insurance administrative files, it has been extremely valuable in assessing the quality of care of the elderly and other insured populations. Although an excellent data source, SEER has been criticized as being inadequate to represent the diversity of systems of care throughout the country and in general does not have data that may more accurately define patient- or tumor-specific prognostic characteristics or treatment details.

The National Cancer Data Base, a joint project of the American College of Surgeons' Commission on Cancer and the American Cancer Society, holds information on more than half of all newly diagnosed cases of cancer in the United States and includes many of the demographic, clinical, and health systems data elements necessary to assess quality of care. A serious limitation of the National Cancer Data Base is the absence of complete information on outpatient care; its data have not been widely used to assess quality of care, but it has great potential for doing so.

An effective national system to collect this type of information should be established in the United States to collect data about the following:

1. Demographics of individuals with cancer (e.g., age, ethnic group, socioeconomic status, and insurance or health plan coverage)
2. Type of cancer (stage, histologic type, grade, comorbid conditions)
3. Treatment, including outcome of procedures, such as adjuvant chemotherapy and radiation therapy
4. Specialty training of care providers
5. Site of care delivery (such as community hospital or specialized cancer center)
6. Type of care delivery system (such as managed care, fee for service, government agency)
7. Outcomes (tumor control, survival, complications of treatment, quality of life, satisfaction with services provided)

THE WAYS TO MEASURE OUTCOMES INDICATIVE OF SURVIVAL AND TUMOR RESPONSE

Survival can be measured as overall survival, disease-free survival, progression-free survival, or event-free survival. It is clearly the most important outcome in cancer treatment. It is also clear, however, that survival alone is insufficient as a measure of outcome. The quality of survival and the cost of maintaining and improving survival must also be assessed.[83]

Making a choice between alternative treatment approaches often involves a tradeoff between length of survival and quality of life. A survival measurement alone might not answer the question of whether gains in survival justify toxicity. Quality-adjusted survival attempts to adjust the absolute length of life to reflect the patient's quality of life. Quality-adjusted survival provides a framework within which tradeoffs that influence treatment choices can be defined as in decision and cost-effective analysis to assess the effectiveness of alternative therapies.[71,73]

Quality-of-Life Outcome Measures

Quality of life considers the impact of cancer and its treatment on the physical, psychological, and social components of patient's lives. Cancer-related quality of life is a family of outcomes including the global quality of life as well as physical, psychological, and social dimensions, each one of which is a potentially separate outcome. Because of its subjective nature, the assessment of quality of life generally should include an evaluation by the patient. Quality-of-life measures should be characterized by reliability and validity.[73,81,84]

Toxicity Measures of Outcome

Toxicities are subjective, objective, or both. An example of a subjective toxicity would be a symptom such as nausea that is often not associated with overt signs or laboratory abnormalities. Evaluation of toxicities of this sort rest with the patient's report. Objective toxicities are measured by physical examination or laboratory tests. The common toxicity criteria use a system for categorizing toxicity from cancer treatment according to its severity. Such systems are widely used in cooperative group trials.

Measures of Cancer Response Outcomes

Measures of tumor response include complete response, response to radiation, and time to progression. Response may also be measured by biomarkers and changes in cancer-induced abnormalities and common blood tests. Some studies demonstrated the positive relationship between response rate and quality of life, but others did not. It is clear that freedom from progression may not be a convincing indication of the benefits of treatment if it does not predict significantly improved survival or cure. Freedom from progression is therefore not an adequate measure of quality of life.[82]

Comparative effectiveness research must be focused on patient outcomes. One cannot assume that a higher dose of radiation to a target field or a more conformal dose distribution will result in better survival or improved tolerance. Outcomes of significance to the patient such as survival, disease-free survival, quality of life, or specific side effects must be the focal points of research.[61] It is particularly important for radiation oncologists to remember that an improved dose distribution achieved through intensity-modulated radiotherapy, conformal techniques, or particle therapy is not the same as an improved outcome. The presence of an improved outcome as the result of a difference in dose distribution must be proven, not assumed.

Cost Effectiveness as a Cancer Outcome

Cost is not an outcome. It is, instead, what we spend to produce an outcome. Cost-effectiveness, in contrast, is often an important outcome. Cost-effectiveness may be reported in terms of cost per year of life saved or cost per quality adjusted year of life saved. Clinical practice guidelines are generally informed by cost-effectiveness considerations.[71,73]

HOW ONE MIGHT USE OUTCOMES FOR TECHNOLOGY ASSESSMENT AND GUIDELINE DEVELOPMENT

Priority of Outcomes

Patient outcomes are more important than cancer outcomes for technology assessment and development of cancer treatment

guidelines. If a new technology or therapy is not ultimately shown to make patients live longer or feel better, then its use cannot be justified. Gathering the necessary data is not easy. Randomized, controlled trials are the gold standard for these comparisons but often fail to accrue enough patients. The reasons for failure to accrue include physicians who refuse to enroll patients because they believe one technology is superior, patients who refuse to be randomized because they have a treatment/technology preference, and the extra work necessary to enroll a patient in a trial.[61]

The Need to Use Multiple Outcomes

There is no single outcome that can represent the results of cancer treatment. Each of the various outcomes provides an unique perspective on treatment and has its own limitations. In general, multiple outcomes should be used for technology assessment.

Barriers to Progress in Cancer Outcome Research

Despite growing interest, there are numerous obstacles to overcome in health care outcome research, including the need to apply scientific disciplines that are different from the biomedical sciences (survey research, psychology, health services research, statistics, economics), the need for resources to collect additional data and information beyond that of standard clinical care, and limited coordination and collaboration among researchers working in the field. Other barriers are intrinsic to a specific cancer, including heterogeneity of patients, type of tumor, phases of the disease, and ethnic and socioeconomic characteristics. Furthermore, many institutions do not give a high priority to or adequately fund outcome research because this activity is considered a cost, not a revenue center, and there is a lack of conviction that this effort will reduce health care spending.[79,85]

Data sharing and increased collaboration in data collection and analysis should be promoted among health care providers and the various groups conducting outcome research. Creative approaches to educating providers and patients about outcome studies are needed, as well as mechanisms to ensure that patients and health professionals have ready access to the results of outcome research.

Making a treatment selection involves defining the patient's condition, identifying management options and outcome, collecting and summarizing evidence, and applying value judgments or preferences to arrive at an optimal course of action.[46] The randomized, controlled clinical trial, the first of which was published in 1952, has become the "gold standard" for evaluating the efficacy of health care intervention. Clinical decisions are complex and based on many sources of information (Fig. 98.3).[34] Patient management decisions are always a function of both scientific evidence and individual preferences (physicians, health care providers, patients).

Although oncologists, patients, and national organizations recognize that communication is very important in cancer care, evidence-based data on the subject are scarce. Oncologists should use a patient-centered interview approach, ask patients what level of involvement they want in medical decision-making, develop a caring attitude, and consider that patient–physician encounters should provide both cognitive data of patient understanding and feelings.[71]

The Complexity of Randomized, Prospective Clinical Trials

Randomized, prospective, controlled trials are held forth as the gold standard for determining the appropriateness of introducing technology into clinical practice. One must be cognizant, however, of adverse influences upon the generalizability of randomized, controlled trials. If the age, gender, severity of the disease, risk factors, comorbidity, ethnicity, or socioeconomic status of the patients in the randomized, prospective trial are not representative of the general population, it may be inappropriate to generalize the results of the clinical trial to that population. Similarly, if the dose, timing of administration, duration of therapy, quality of care, or comedications of the patients in the trial are not similar to those of the general population, the results may not be applicable.[23]

There is a long-standing joke that one does not need a randomized, prospective trial to ascertain the efficacy of a parachute. In medicine, there are long lists of new technologies that were introduced into general practice based on historical controls without randomized, prospective trials. These include, for example, the use of thyroxin for myxedema, insulin for diabetes, vitamin B12 for pernicious anemia, sulfonamides for puerperal sepsis, penicillin for lobar pneumonia, streptomycin for tuberculosis, defibrillation for ventricular fibrillation, and cisplatinum, vinblastine, and bleomycin for disseminated testicular cancer. The analysis of a randomized clinical trial has traditionally been based on a hypothesis that presumes that there is no difference between treatments. The hypothesis is tested by estimating the probability of obtaining a result as extreme as or more extreme than the one observed if the hypothesis is true. The hypothesis may be irrelevant if there had been previous studies demonstrating that the treatment had some benefits. Those who criticize randomized, prospective trials will quickly argue that "no one ever did a randomized trial to prove that a linear accelerator was better than a cobalt machine, that port films were necessary, or that simulation was preferable to a clinical setup." These arguments are, to some extent, true. One must remember, however, that there is a considerable financial difference between using and not using a port film compared to using a linear accelerator versus a $200 million proton machine.[76]

Nonetheless prospective, randomized clinical trials have come to occupy a prominent role in clinical research in radiation oncology. The most commonly used clinical endpoints are summarized in Table 98.3. Unfortunately, many published reports have unclear definitions or lack some of the fundamental endpoints.

Clinical trials are time consuming and costly. Randomization is the only method that may guarantee that comparisons of treatment outcome are, on average, unbiased. Not all clinical trials yield positive results, and not all new therapies are improvements compared with the standard therapy.[58,64] As an example, a recent analysis of outcome data from 57 randomized, controlled trials, including a total of 12,734 patients, conducted between 1968 and 2002 by the Radiation Therapy Oncology Group[63] showed that overall, experimental and standard radiotherapy were equally successful (odds ratio for survival, 1.01; $p = .5$); however, treatment-related mortality was significantly greater in the experimental arm of the trials (odds ratio, 1.76; $p = .008$) A drawback of randomized trials for the evaluation of a new technology in radiation oncology is that to detect small improvements in morbidity from, for example, an alleged improved dose distribution, an enormous number of patients will need to be accrued and followed for a considerable length of time. Radiation oncologists must, therefore, give serious consideration to the development of novel paradigms for health technology assessments without meeting, in some cases, the ideal requirement of randomization.[63]

Practice Guidelines

Guidelines for health services resulting from valid and appropriate outcome studies have the potential to promote consistency

TABLE 98.3 MOST COMMONLY USED CLINICAL ENDPOINTS IN RADIATION THERAPY TRIALS

Endpoint	*Definition of Event*	*Comments*
Local control	No evidence of disease at the primary site (T position)	Statistically this is the absence of an event (i.e., local recurrence); estimated at a given time as the local-recurrence-free rate
Local failure rate	Recurrence in T position	Estimated as 1 minus the local-recurrence-free rate
Locoregional control	No evidence of disease in T and N positions	See above, but for T or N recurrence, whichever comes first; sometimes defined as in-field control (i.e., control within the treated volume)
Survival or overall survival	Death irrespective of cause	–
Cancer-specific survival or cause-specific survival	Death of cancer	Often defined as death of cancer or with active disease
Disease-free survival	Any recurrence or death from any cause, whichever comes first	A composite endpoint combining survival and disease control
Local recurrence-free survival	Local recurrence or death from any cause, whichever comes first	As above, but with local recurrence as the relevant event
Disease-free rate	Any recurrence	Death without recurrence is a cause of censoring
Local relapse-free rate	Local recurrence	As above
Early reactions	Signs or symptoms of a specific early reaction; defined by measuring scale	Typically defined inside a time window; actuarial methods normally not used
Late reactions	Signs or symptoms of a specific late reaction; defined by measuring scale	Actuarial methods should be used
Palliation	Typically defined by measuring scale	May require special statistical considerations
Quality of life	Typically defined by measuring scale	May require special statistical considerations

All definitions involving local recurrence are defined for nodal recurrence (N position) or distant recurrence (M) by analogy.

and quality of care. In the United States, clinical practice guidelines have been promulgated by the American Cancer Society, the American College of Radiology, the American Society of Clinical Oncology, the National Cancer Centers Network, and other professional organizations (Table 98.4).[61,84] Sisk[85] observed that for such guidelines to be successful, it is very important to involve local physicians in the process, to get their views and ultimately their support. The values of practice guidelines in medicine include minimizing inappropriate practice variations, providing reference points for education/practice, improving patient care and outcomes, providing criteria for self-evaluation, setting indicators for external quality review, assisting with service coverage and reimbursement, and decreasing overall cost of medical care. Perceived drawbacks to such guidelines include overregulation and loss of autonomy for both physicians and patients. The conflicting needs and motivations of physicians, patients, third-party carriers, and society bring into play a variety of ethical perspectives. Although contrasting ethical foundations likely will lead to significantly different solutions to the health care resource problem, it is only through educated and reasoned discussion that this problem can be tackled.[86]

Courts in the United States have ruled that guideline developers can be held liable for faulty guidelines and that doctors cannot pass off their liability by claiming that adherence to guidelines corrupted clinical judgment. Protocols and guidelines provide the courts with examples of clinical standards across a wide range of medical practice. However, adherence to guidelines has not automatically been equated with reasonable practice, and the courts seem unlikely to follow the standards enunciated in clinical guidelines without critically evaluating their authority, flexibility, and scope of application.[87]

TABLE 98.4 AMERICAN COLLEGE OF RADIOLOGY APPROPRIATENESS GUIDELINES LITERATURE EVIDENCE TABLE KEY

Strength of recommendation (quality of the study design)

- *Good* evidence to support recommendation that procedure be performed
- *Fair* evidence to support recommendation be performed
- *Poor* evidence to support recommendation, but may be made on other grounds
- *Fair* evidence to support recommendation not be performed
- *Good* evidence to support recommendation not be performed

The Patterns of Care Study in the United States

The basic concepts of the Patterns of Care Study are based on analysis of structure, process, and outcome.[88] Initially, all facilities in the United States that provided radiation therapy were identified, and a master list was developed; a statistically determined group of the facilities was selected to reflect the type of practice of radiation oncology throughout university hospitals, community hospitals, and free-standing facilities. Surveys were conducted to define the structure of the facilities, including equipment, staffing, and prevailing standards of practice. More than 1,000 institutions were surveyed in each period of study, and thousands of patients have been included in the database.

Ten diseases were chosen in which curative radiation therapy played a major role. Through extensive discussions with appropriate physicians, a consensus of the best current management was developed for each disease, and decision trees were designed that logically led to the appropriate application of radiation therapy. Process criteria were grouped into three categories, which included workup, treatment, and auxiliary services. Data were collected on individual patients (with appropriate safeguards of privacy), and later the institutions were resurveyed to record the results of treatment, including local/regional recurrence, disease outside the treated field, major complications of therapy, and so forth, leading to publication of several reports correlating process with treatment outcome. An example is a report on the practice of radiotherapy in carcinoma of the uterine cervix published by Eifel et al.[65]

Reports similar to those of the Patterns of Care studies in United States have been published in other countries, such as one by Ringborg et al.[31] in Sweden.

CONCLUSIONS

Technology assessment, outcome analysis, cost benefit, comparative effectiveness, and clinical trials supported by evidence-based medicine should be strengthened and fostered to enhance the rationale and quality of medical care provided to patients at a competitive cost. Basic and translational laboratory research and properly designed, relevant, and timely prospective clinical trials should be strongly promoted, and patient participation must be increased to acquire more accurate information to develop innovative therapeutic strategies in oncology. Methods for accurate cost accounting of medical care and comparative effectiveness studies need further development. Technology assessment will substantially contribute to better utilization of scarce health care resources and will be invaluable in determining the potential value of innovative therapeutic approaches.

Chapter 99
Ethics, Professional Values, and Legal Considerations in Radiation Oncology

Brian D. Kavanagh, Laurie J. Lyckholm, and Jeremy Sugarman

The medical profession experienced a rise in socioeconomic stature in the United States during the 20th century.[1] Physicians began to receive higher wages for their services and enjoy greater personal respect as providers of health. Although progress in medical science has improved the quality and duration of life for some patients with cancer and other serious illnesses, technical expertise alone does not fully account for the upsurge in the societal standing of medical doctors during the past 100 years.

High regard for physicians is contingent on the trust that doctors act unselfishly in a patient's best interests, a role sometimes called *moral fiduciary.*[2] Essential to this role are medical knowledge and a firm grasp of ethics. Derived from the Greek ήθος (*ethos*), meaning *character,* ethics refers to the process of applying values and principles in professional interactions and particularly in medical decision making on behalf of patients. The curriculum of most medical schools now includes coursework in ethics, but many physicians practicing today completed their training without formal instruction in this topic. To foster an appreciation for the intellectual underpinnings of modern medical ethics, this chapter begins with an overview of scholarly approaches to ethics. Next is a discussion of selected proclamations and codes of ethics published by professional societies, federal commissions, and other authorities as guidelines for medical practice and research. Finally, common ethical issues in radiation oncology are addressed, including relevant medicolegal considerations.

CONCEPTUAL APPROACHES TO MEDICAL ETHICS

The term *bioethics,* coined in the early 1970s, refers to the academic inquiry and public policy movement addressing the application of science and medicine from a humanistic perspective.[3] Medical ethics may be most accurately viewed as a branch of bioethics, but the terms are commonly used interchangeably. Among the more influential theoretical approaches to ethics that are used in bioethics are *utilitarianism, deontology, casuistry, virtue theory,* and *principlism.*

Utilitarianism is based on the premise that, in any situation, the best course of action is the one that produces the maximum net positive value (or least negative value). Utilitarianism can be applied to an individual patient's case or to matters of health policy, in which decisions might be made to achieve the greatest overall benefit for the largest number of people.

Unlike utilitarianism, deontology is an ethical theory based on the morality of actions themselves rather than their net result. Deontology, sometimes called *Kantianism* in recognition of the influence of Immanuel Kant,[4] calls for consistent standards of behavior at all times, regardless of the consequences. One simple example of the difference between utilitarianism and deontology is the issue of educating patients about their diagnosis, especially if the prognosis is very poor. Whereas a deontologist would always feel obliged to tell the truth even at the risk of causing distress, a utilitarian considers whether telling a patient the complete truth about the disease does or does not really benefit the patient. In practice, there is obviously a need to find the right balance between purely utilitarian and purely deontologic perspectives in a situation like this one. Respect for the patient's autonomy, for example, is one of the *prima facie* ethical principles discussed further in the next section. Truth-telling is an integral component, and overriding this principle requires justification.

Casuistry is an approach to ethics that emphasizes inductive reasoning based on established precedents, and it is a common practice in both law and medicine. The proper course of action in any individual case is decided by recalling decisions made in prior similar cases. The major weakness of casuistry is the lack of a reference benchmark or settled opinion on novel technologies.

Virtue theory focuses on the character of moral agents, in this case physicians and other health care providers, focusing less on actions or outcomes. As such, virtue theory captures the way in which correct moral actions occur. For example, it is not only important to tell patients the truth about their diagnoses, but it is also critical to do so in a compassionate manner. In this case, the virtue is compassion. Accordingly, while virtue is a critical part of assessing moral action, virtues themselves have little guiding force.

Principlism is a system of applied ethics through which core principles ideally govern behavior in the absence of compelling reasons to override them. Principlism can be integrated with the other philosophical approaches already mentioned and serves as a unifying influence. Key features of principlism are addressed in the next section.

ETHICAL PRINCIPLES

A *prima facie* obligation may be defined as one that is "binding unless overridden or outweighed by competing moral obligations."[4] Four *prima facie* principles of bioethics are highlighted here: *respect for autonomy, beneficence, nonmaleficence,* and *justice*.

Respect for a patient's autonomy is based on respect for the right to individual liberty. A patient's voluntary decision to seek medical care or comply with referral to a specialist is the starting point of most patient–physician relationships, and competent patients should remain free to forgo therapy or change physicians at any time. The responsibility to respect patients' autonomy is established not only in ethics but also in law. An example is the requirement to obtain a patient's informed consent for proposed medical therapy. In a landmark case involving postmastectomy chest wall radiation therapy, a patient who sustained soft tissue necrosis won a lawsuit against her radiation oncologist for negligence and for lack of proper disclosure regarding possible treatment-related toxicity. The Kansas Supreme Court ruled that doctors should explain "in language as simple as necessary" the side effects associated with any recommended therapy.[5]

The principle of *beneficence* is intertwined with that of *nonmaleficence*. Some authors have offered nuanced distinctions between the two principles,[4] but the key point is that physicians should act for the benefit of patients and should not harm their patients. Beneficence and nonmaleficence are typically concordant objectives, but sometimes an intervention that is helpful also entails a high risk of adverse treatment-induced sequelae. For example, administering high-dose morphine to a patient severely dyspneic from an incurable lung malignancy can relieve symptoms but at the same time risks fatally suppressing respiratory drive. Here the quality of remaining life might be improved by a measure that also hastens death. Such an action can sometimes be justified by the principle of double effect, the earliest expression of which is generally attributed to St. Thomas Aquinas.[6] According to this concept, the benefit of an action might be valuable enough to outweigh a simultaneous significant risk of serious adverse event, as long as achieving benefit is the primary intent. High-dose chemotherapy, bone marrow transplant, and some high-complexity surgeries, such as Whipple procedures, are examples of cancer therapies in which potential burdens and risks might militate against potential benefits.

The principle of justice refers to fairness, typically the equitable distribution of health care resources. Justice-related questions often arise in regard to matters of public policy. Two examples are determining the means to allocate scarce organs for transplantation and selecting what types of research merit government funding. More globally relevant in the United States is the challenge of allocating federal dollars for health care. Distributive justice implies that persons ought to be afforded medical care according to their medical needs and the ability of the system to provide.

FORMAL OATHS AND CODES OF ETHICS

There are many published declarations of medical ethics authored by physicians. Not surprisingly, the tone and language of each reflect the social mores and sometimes historical events of the era in which it was composed.

FIGURE 99.1. Early 19th-century engraving depicting a likeness of Hippocrates, closely resembling images of ancient coins found on the island of Cos bearing his likeness. (Courtesy of the National Library of Medicine.)

The Hippocratic Oath

> I will prescribe regimen for the good of my patients according to my ability and my judgment and never do harm to anyone

The *Corpus Hippocraticum* is a collection of medical treatises dating from around the fifth century BCE, believed to be the work of philosopher–physicians from the Greek island of Cos (Fig. 99.1). Contained within the *Corpus* is the well-known oath of Hippocrates, an ancient physician's pledge of professionalism. Curiously, the oath is inconsistent with some other sections of the *Corpus,* perhaps because it was added later. Comments about abortion and surgery, for example, are at variance with teachings elsewhere in the collected works.[7] Nevertheless, timeless themes are included, and the oath has survived in various modernized versions. The oath is often recited by medical students at the time of graduation—even if its contents are not always well remembered.[8,9]

Percival's Medical Ethics

> Hospital physicians and surgeons should minister to the sick, with due impressions of the importance of their office, reflecting that the ease, the health, and the lives of those committed to their charge depend on their skill, attention, and fidelity.

Thomas Percival (1740–1804) (Fig. 99.2) published *Medical Ethics* at a time when there were considerable tension among clinicians in his community.[10] In the 1760s, Manchester, England, was a prosperous urban society that comfortably supported public health initiatives, including an infirmary serving as a charity hospital and teaching institution. But as the city grew and became crowded by the 1790s, tensions arose between rival groups in the medical community. Percival was prompted to draft a code of ethics after a contentious dispute about enlarging the infirmary's staff, a threat to the controlling physician faction.[11]

FIGURE 99.2. Thomas Percival (1740–1804). (From Brockbank EM. *Sketches of the lives and work of the honorary medical staff of the Manchester Infirmary, from its foundation in 1752 to 1830 when it became the Royal Infirmary*. Manchester, UK: Manchester University Press, 1904, with permission.)

When he began writing *Medical Ethics,* Percival was already a well-known writer and moralist whose *A Father's Instructions to His Children,* published in 1775, included essays promoting personal virtues and social awareness to young readers. While completing *Medical Ethics,* Percival suffered devastating personal tragedies, bereaving the untimely deaths of two of his own sons. The finished work was dedicated to a third son studying medicine at the time.

Ultimately, *Medical Ethics* provided a template for the codes of ethics adopted by the American Medical Association (AMA) and other societies in the 19th century. Early 20th-century pundits criticized Percival's work as merely a book of medical *etiquette* rather than medical *ethics*. However, revisionist historians have subsequently argued that although Percival focused on interprofessional relationships, he also taught that a physician's duty toward the patient outweighs obligations of civility toward other health care professionals. Furthermore, Percival advanced the enlightened view that indigent patients should receive the same quality of care as affluent patients.[12]

The American Medical Association Code of Ethics

The AMA first adopted a code of ethics at its inaugural meeting in 1847. The initial code was modeled on the work of Percival, but subsequent updates have reflected societal changes and technological progress. The 2004 version includes four components[13]:

a. *Principles of Medical Ethics;*
b. *Fundamental Elements of the Patient–Physician Relationship;*
c. *Current Opinions of the Council on Ethical and Judicial Affairs;* and
d. *Reports of the Council on Ethical and Judicial Affairs.*

The seven *Principles* are general instructions for a physician to maintain competence and integrity in the context of individual patient care and also in the larger view toward enhancing the standard of care in the community. The *Fundamental Elements* expand the concept of a collaborative interaction between physicians and patients, specifically mentioning the need for good communication and the need to protect patients' confidentiality. The AMA here advocates that all patients have a right to "necessary care," regardless of their ability to pay for that care, and that physicians should play a role in safeguarding this right. The *Current Opinions* and the *Reports of the Council on Ethical and Judicial Affairs* provide situational interpretations of the *Principles* and *Fundamental Elements,* and they are often referenced in legal proceedings.

The Nuremberg Code and the Declaration of Geneva

During World War II, odious crimes were committed by Nazi physicians who conducted horrific experiments on concentration camp prisoners who were coerced to submit. The Nuremberg Code was a formal response to these World War II–era human rights atrocities disguised as medical experiments.[14] Issued from the military tribunal that tried some of the Nazi doctors who conducted these experiments, the Nuremberg Code acknowledges that medical investigations are important. However, for a medical experiment to be morally permissible, it must meet 10 criteria, paraphrased as follows:

- Voluntary consent of the human subject
- Necessity to yield results helpful to society
- Appropriate design based on knowledge of the disease under study
- Avoidance of unnecessary physical and mental suffering and injury
- Absence of reason to believe that death or disabling injury will occur
- Overall degree of risk in proportion to the nature of the problem to be solved
- Adequate precautions against the possibility of the subject's injury, disability, or death
- Qualified persons conducting the study
- Unrestricted freedom of the subject to end the experiment if he or she reaches the physical or mental state where continuation of the experiment seems impossible
- Willingness of the investigator to discontinue the study at any time if there is reason to believe that continuing the experiment is likely to result in injury or death to the subject.

In the aftermath of the war, the international medical community was especially sensitized to the need for universal adherence to high standards of ethical behavior. The Declaration of Geneva was adopted in 1948 by the World Medical Association and has been updated since then. The text includes the physician's vow to ignore "considerations of age, disease or disability, creed, ethnic origin, gender, nationality, political affiliation, race, sexual orientation, or social standing" in the treatment of a patient and to uphold "even under threat . . . the utmost respect for human life."

Case Study

Despite publicity about the Nuremberg Code and the Geneva declaration, controversial large-scale, government-sponsored medical studies took place in the years following World War II. Experimentation on the effects of radiation exposure on humans was conducted in the United States during the Cold War, when fears of nuclear warfare prompted inquiry into the carcinogenic and other adverse health effects of environmental exposure to ionizing radiation. In response to public concern about thousands of federally funded studies conducted from the 1940s through 1970s without consent of the subjects, in

1994 President Bill Clinton established the Advisory Committee on Human Radiation Experiments (ACHRE). ACHRE was comprised of ethicists, radiation oncologists, and others with relevant expertise. It was charged with evaluating the experiments' ethical and scientific standards and recommending actions to ensure that any mistakes of the past would not be repeated. ACHRE reviewed all available documentation and also conducted an oral history project in which scientists described prevailing sentiments regarding human research ethics during the era of interest.

ACHRE found that government officials and investigators were in some cases culpable "for not having had policies and practices in place to protect the rights and interests of human subjects who … could not possibly derive direct medical benefit."[15] One example was the observational study of uranium mine workers exposed to radon levels known to be hazardous, without warning and without efforts to reduce the radon levels by ventilating the mines. As a result, lung cancer developed in hundreds of workers, and appropriate compensation was recommended for the individuals affected.

The Belmont Report

In 1972 Jean Heller exposed the injustices of the U.S. Public Health Services (USPHS) Study of Untreated Syphilis in the Negro Male that was conducted in Tuskegee, Alabama.[16] During a 40-year period beginning in the 1930s, 399 indigent African American sharecroppers with syphilis and 200 without syphilis were subjects in a natural history study of the disease. The men mistakenly believed that diagnostic blood tests and lumbar punctures composed treatment for their "bad blood" when in reality these were done solely to monitor the course of the infection. Moreover, years later when penicillin was discovered and found to be effective in the treatment of syphilis, it was withheld intentionally from the men. Subsequently, public awareness of the USPHS study likely contributed to enduring reluctance among some members of minority groups to participate in clinical trials,[17,18] and the political backlash provoked action by the federal government.

The 1974 National Research Act established the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research. The commission met at the Belmont Conference Center in Maryland to develop ethical guidelines for the conduct of biomedical and behavioral research. In 1979 the commission published *Ethical Principles and Guidelines for the Protection of Human Subjects of Research,* commonly known as the Belmont Report.[19]

In the Belmont Report, a clear distinction is made between medical research and clinical practice. The term *practice* describes interventions intended "to enhance the well-being of an individual patient … that have a reasonable expectation of success," whereas *research* is "designed to test an hypothesis, permit conclusions to be drawn, and … contribute to generalizable knowledge." Sometimes a clinician uses good judgment and departs from standard methods for the benefit of an individual patient in special circumstances. However, if major innovations are proposed as replacement for standard techniques, then a formal investigation should be conducted to assess safety and efficacy. The National Commission embraced a principlist perspective in drafting the report, emphasizing in particular respect for persons, beneficence, and justice. The Belmont Report's definition of respect for persons incorporates respect for autonomy and special concern for individuals with diminished capacity to exercise their autonomy. Involving prisoners in research activity is cited as an example. Although it is inappropriate to deny prisoners the possible benefit of experimental interventions, any direct or indirect pressure on prisoners to participate in clinical studies must be avoided. For instance, a promise of clemency in return for study enrollment is unacceptable. The report also addresses the nature of justice in medical research, emphasizing that the process of selecting subjects for a research study must be carefully examined. Investigators should minimize the chance that socioeconomically disadvantaged groups are represented disproportionately as a result of a vulnerability to manipulation in the health care environment.

The American College of Radiation Oncology Code of Ethics

The American College of Radiation Oncology (ACRO) has published a code of ethics, contained within the organization's bylaws, which is available for review at the organization's website (www.acro.org). The principles expressed are concordant with accepted ethical standards and include respect of patient autonomy, the expectation that a radiation oncologist should always act in the best interests of the patient, and respect of patient confidentiality. The ACRO code also forbids deceptive billing arrangements, and members of ACRO who do not comply with the code of ethics are subject to disciplinary action by the organization.

National Electrical Manufacturers Association Code of Ethics

The makers of equipment and software used in the practice of radiation oncology are not required to demonstrate clinical efficacy of a new device or software through the same sort of clinical testing that is required by the U.S. Food and Drug Administration (FDA) for approval of a new drug or implantable medical device. Rather, most treatment devices are approved after demonstration of safety and substantial equivalence to an approved device that is already commercially available. A company that wishes to sell a new device submits a premarket notification to the FDA at least 90 days before commercial distribution is to begin, in accordance with Section 510(k) of the FDA Modernization Act of 1997. Because devices may be introduced into the market without proof of superiority in any given clinical situation, manufacturers may promote their products to physicians by emphasizing intuitively attractive features that might or might not provide meaningful clinical advantage to patients.

On January 1, 2005, members of the National Electrical Manufacturers Association (NEMA) adopted a code of ethics regarding interactions between makers of medical imaging and treatment equipment and physicians (www.nema.org). Individual sections of the NEMA code address member-sponsored product training and education, support for third-party educational conferences, sales and promotional meetings, arrangements with consultants, gifts, provision of reimbursement and other economic information, charitable donations, and research grants. The guidelines are essentially consistent with the AMA policy on gifts and applicable federal regulations. NEMA members are allowed to support educational conferences and advertise their wares in these venues, and also they may provide educational support for individual customers in the safe use of their products. However, hospitality provided by NEMA member at conferences and meeting should be "modest in value and … subordinate in time and focus to the purpose of the meeting." When it is necessary to demonstrate nonportable equipment, members may pay for reasonable travel costs of attendees with a *bona fide* professional interest but not for their guests.[20]

COMMON ETHICAL ISSUES IN RADIATION ONCOLOGY

> Doctors wear a lot of hats these days; besides the usual physician role, we are expected to be a researcher, financial counselor, administrator, gatekeeper, patient advocate in the medicolegal system, ethicist, and Lord knows what else.
>
> —Thomas J. Smith[21]

Financial Relationships with Hospitals and Referring Physicians

Reimbursement for radiation oncology services or other procedure-intensive subspecialties can be a major revenue source for hospitals. At the same time, subspecialists depend on other physicians to refer patients for evaluation and management. These situations can tempt hospital administrators to reward subspecialists for practicing in their facility and might tempt the subspecialists to induce referrals with financial incentives. In either case, a conflict of interests emerges: Treatment recommendations can be influenced not only appropriately by patient-centered beneficence but also inappropriately by the physician's interest in personal gain. In the United States, the Anti-Kickback Statute and the Stark Law make it illegal to engage in such unscrupulous medical business practices.

The Anti-Kickback Statute (42 U.S.C. §1320a-7b) includes criminal penalties for acts involving Medicare or state health care programs. Section (b) makes it a felony punishable by a fine up to $25,000 and up to 5 years in prison to solicit or receive "any remuneration (including any kickback, bribe, or rebate) directly or indirectly … in return for referring an individual to a person for … any item or service" reimbursed in whole or in part through Medicare or a state health care program. The Anti-Kickback Statute also bans other fraudulent transactions supported through the same funding sources.

Named for its leading congressional author, Rep. Pete Stark of California, the Stark Law (42 U.S.C. §1395nn; "Limitation on certain physician referrals") bans other misconduct involving Medicare and Medicaid patients. The Stark Law prohibits a physician from referring a patient for a "designated health service" to a clinic or other facility with which the physician or an immediate family member of the physician has a financial relationship. Radiation therapy is considered a designated health service, but it is clarified that a request by a radiation oncologist for radiation therapy is considered integral to the consultation request from the (nonradiation oncologist) referring physician and does not constitute a self-referral *per se* in most situations. Sanctions for violations of the numerous Stark Law regulations may include civil prosecution.

Managed Care

By the early 1990s, more than 70% of Americans with health insurance were enrolled in some form of managed care plan[22] in which patients are restricted in their choices of physicians and medical services for the purpose of limiting the cost of the health care.[23] The idea has existed in the United States at least since the time of the Great Depression of 1929, when Dr. Michael Shadid of Oklahoma organized a prepay and copay system for surgical, medical, and dental services. To maintain profitability, managed care organizations influence the behavior of patients and physicians through strategies to minimize expenditures. Tactics directed toward patients are promotion of preventive medicine, limitation of access to medical specialists unless approved by a "gatekeeper" primary care physician, and restricted selection of physicians to those willing to accept lower reimbursements. Physicians are prompted to lower costs by capitation-based compensation packages and financial rewards to avoid excess resource utilization.

Managed care is ethically defensible insofar as it can provide equal access for participants and promote well-being through an emphasis on preventive medicine. However, managed care can also threaten the physician–patient relationship by undermining the patient's autonomy and creating a conflict of interest for the health care provider.[24] If the physician gatekeeper shares financial risk with the managed care organization, a patient with a difficult medical problem might be less likely to be referred to a specialist where higher costs would be expected to result.

Physicians' attitudes about managed care reflect concerns about ethics. A survey of primary care physicians revealed that most of them believed that managed care has a negative impact on the patient–physician relationships by interfering with patients' choices and compromising the physicians' ability to put the patients' interests first.[25] Medical students and residents frequently receive negative messages about managed care from their faculty mentors.[26]

Oncology services are often still provided by managed care organizations through fee-for-service contracts with independent practitioners. Nonetheless, there remain challenging patient management issues with regard to delivering radiation therapy in the setting of managed care that include the sometimes fragmented care and inconvenience for the patient, whose managed care organization might have contracted with several centers for various aspects of oncology care, and the administrative burdens associated with obtaining documentation of preapproval for patients' radiation treatments.[27]

Electronic Record-Keeping and Billing Practices

The principles of respect for autonomy and nonmaleficence oblige confidentiality in physician–patient communications. Publicizing private details of a patient's condition can create social and economic harms for the patient. With the advent of electronic medical records and Internet communication, there is a greater need for vigilance in this respect.

In the United States, the Health Insurance Portability and Accountability Act of 1996 (HIPAA) empowered the Department of Health and Human Services to codify standards for storage and transmission of an individual patient's health information. Penalties for violations vary in proportion to their severity. In the worst case of wrongful disclosure of information with intent to sell it, a fine of up to $250,000 and a prison term of up to 10 years can be imposed.

Submitting fraudulent claims to the government for reimbursement of health care services is illegal. The False Claims Act (31 U.S.C. §3729) provides that any person who knowingly presents fraudulent claims to the U.S. government may be fined $5,000 to $10,000 and may be liable for three times the amount of any damages sustained by the government.

Applications of New Technology

Innovative treatment-delivery technologies such as intensity-modulated radiation therapy and stereotactic body radiation therapy provide radiation oncologists freedom to exercise creativity in customizing treatment plans for each individual patient. Ideally, it is best that such innovations are tested in formal research protocols in which a clinical problem is identified and the new technology is proposed as a solution so that toxicity and efficacy can be monitored closely. A prospective clinical trial approved and monitored by an institutional review board affords the opportunity to advance knowledge in the field with ethical oversight.[28] It is inappropriate to apply a novel, more expensive technology to generate higher revenue in the absence of a sound clinical rationale. The AMA code of ethics proscribes superfluous therapy of no benefit to the patient.[29]

Clinical Trial Conduct

Instances of flagrantly improper clinical research taint the annals of medical history. The USPHS study of syphilis mentioned earlier and the human radiation experiments conducted during the Cold War without the consent of the participants are dark reminders of the need for ethical oversight of research.

Obtaining a participant's informed consent is of paramount importance in conducting most clinical research. Despite the recognized importance of informed consent, precisely how much information should be conveyed to a potential clinical trial participant is debatable. The Belmont Report offers this

criterion: "the extent and nature of information should be such that persons, knowing that the procedure is neither necessary for their care nor perhaps fully understood, can decide whether they wish to participate" in the study. In certain situations the nature of a study requires that there is incomplete disclosure of information to the participant to sustain the integrity of the study. The Belmont Report condones such research only when "i) incomplete disclosure is truly necessary to accomplish the goals of the research, ii) there are no undisclosed risks to subjects that are more than minimal, and iii) there is an adequate plan for debriefing subjects, when appropriate, and for dissemination of research results to them." The federal rules governing research (45 CFR 46) reflect these arguments.

Advances in the biosciences, such as stem cell research, cloning, and manipulations of the human genome, have been associated with contentious public debate. Federal government and professional policies on such matters have sometimes been constructed as a compromise between scientific opportunity and political ideology.[30] Extra safeguards have been imposed in some settings; for example, the federal government requires an extra level of review for gene-transfer experiments.[31]

Genetics

The management of some cancer patients can involve assessment of genetic markers that might predict treatment response and also reveal a predisposition to the development of certain cancers among the patient's family members. The National Society of Genetic Counselors has published a guideline concerning genetic cancer risk assessment, counseling, and testing.[32] It is recommended that the process of obtaining informed consent for genetic testing should include, among other considerations, an explanation to the patient of possible implications on the ability to obtain health or disability insurance in the future.

Relationships with Industry Sponsors

Incentives from industry representatives to prescribe pharmaceuticals or purchase equipment threaten the fiduciary obligations physicians have to their patients. The AMA code of ethics allows that gifts of modest value with direct or indirect benefit to patients are acceptable.[33] Examples include textbooks or unrestricted educational grants for students or fellows. Subsidies for "modest meals or social events held as part of a conference" are permissible, as are honoraria for lectures or legitimate consulting services. However, cash or other valuable incentives intended to influence the decision to use a company's products are forbidden. Also unacceptable would be a blanket indemnification from liability for use of a product. Advertising items such as patient education pamphlets and anatomic models bearing a sponsor's name are commonly found in radiation oncology clinics.[34] Physicians should be aware of any real or perceived influence on the patient–physician relationships resulting from their tacit compliance with such marketing activities.

In recent years some pharmaceutical companies have been prosecuted for kickback schemes or other illegal enticements to physicians, and the civil and criminal penalties paid by the corporations held responsible have ranged up to hundreds of millions of dollars.[35] Brennan et al.[36] contend that voluntary self-regulation by physicians, industry, and government is an insufficient safeguard against the conflict of interests nurtured by close relationships between practicing doctors and sellers of pharmaceuticals and medical products. These authors argue that academic medical centers should set an example for the rest of the medical community by establishing policies that forbid gifts to physicians, funds for travel, unjustified consulting fees, participation in speakers' bureaus, and the practice of "ghostwriting" medical articles, among other things. Substantial attention has focused on implementing policies related to these issues.[37,38]

CASE-SPECIFIC DILEMMAS: THE ROLE OF AN ETHICS CONSULTANT OR COMMITTEE

The radiation oncology–related ethical issues discussed thus far relate primarily to general practice and research guidelines. However, individual cases can also pose uncertainties regarding the proper choice of action for a specific patient.

Case Study

A 37-year-old woman undergoes modified radical mastectomy for a pathologic T3N2M0 breast cancer; postoperative chemotherapy and locoregional radiation therapy are recommended. The patient wishes to receive the therapy only if she can periodically interrupt it to alternate with what she calls a "natural herbal" therapy.

In this case, respect for a patient's autonomy conflicts with what is believed to be in the patient's best interests, but a physician cannot ethically abrogate the fiduciary responsibility to a patient simply for reasons of unfamiliarity with alternative medicine or prejudice against its worth.[39] Similar situations may arise when patients are noncompliant with standard treatment recommendations because of a particular religious faith or cultural heritage. Although physicians must respect patients' choices, there is no strict obligation for a physician to accept a particular individual as a patient, especially if there are foreseeable personal conflicts that might adversely affect the patient–physician relationship.[40]

Pediatric oncology also requires special considerations. Parents are the chief decision makers, but sometimes their wishes can seem discordant with the best interests of the child. In a different context, what should be done if the adult children of a patient with a heritable trait for malignancy inquire of the patient's diagnosis, but the patient has instructed the physician not to reveal any information to them? The obligation to patient–physician confidentiality conflicts with a potentially overriding obligation toward the family members who might benefit from guidance toward screening.

In cases such as these in which it is difficult to choose between two defensible courses of action, individuals with experience in clinical medical ethics can provide the expertise needed to sort through the ethical, legal, and social issues involved.[41]

PALLIATIVE MEDICINE

Palliative medicine has become a well-established component of clinical practice, and numerous academic medical centers offer accredited fellowship programs in this field. Palliative medicine places emphasis on symptom management and on the goals of care, not only at the end of life but also in the treatment of serious illnesses. A palliative approach is ethically justified when fully aggressive therapy might be intolerable or futile.

Case Study

A 92-year-old woman presented with stage IVa maxillary sinus cancer. She complained of sinus fullness and a painful 4-cm neck node. Radical radiation therapy to the primary and neck was recommended, and the patient underwent placement of a percutaneous gastric feeding tube and full dental extraction. Midway through the course of treatment, the patient required a lengthy hospitalization for failure to thrive and severe mucositis.

In retrospect a less-aggressive course of radiation therapy intended to reduce the sinus and neck symptoms would have been a better choice for this patient, who was frail and unable to withstand intense treatment. Palliative medicine pays careful attention to a patient's individual needs, quality of life, and a discussion of goals of care. A recent randomized study demonstrated improved quality of life and overall survival when palliative care was given early alongside standard cancer treatment for metastatic lung cancer.[42] In many cases, aggressive symptom

management and good communication among patient, family, and provider may result in better quality and, perhaps, quantity of life than would antineoplastic therapy that has little expectation of efficacy but significant risk of morbidity.[43]

ETHICS AND MEDICAL ERRORS

Soon after the discovery of x-rays by Wilhelm Röntgen more than 100 years ago, the first cases of malpractice involving the clinical use of radiation therapy were tried in the U.S. court system.[44] During the early 20th century, severe dermatitis was a frequent plaintiff's complaint—not surprising in view of the physical limitations of the low-energy machines available at the time.

In 1999, the Institute of Medicine published a report on medical errors, elevating the level of public awareness and stimulating inquiry into this topic.[45,46] Estimates of the number of Americans who die each year as a result of medical error have ranged from 44,000 to 98,000,[47,48] and the annual cost of preventable adverse events has been projected to be $17 billion to $29 billion.[49] In addition to encouraging efforts to improve patient safety, the Institute of Medicine recommended the development of confidential self-reporting programs and legislation to prevent voluntary reporting from legal discovery.[50]

Physicians are often reluctant to discuss errors. It has been suggested that doctors and patients "harbor deep within themselves the expectation that the physician will be perfect."[51] Other reasons for reticence include uncertainty about whether an event really is an error, concern for the patient's well-being, and fear of litigation.[52] Each of these items warrants comment.

First, if a patient has an undesirable treatment outcome, careful review of the case can help distinguish error from untoward but unsurprising occurrence. For example, severe pneumonitis after breast radiation therapy is uncommon but not necessarily proof of negligence. Second, concern that disclosing an error causes a patient undue anxiety is contradicted by studies revealing that patients prefer physicians to acknowledge errors[53] and they might even sue for lack of apology.[54] Finally, in cases of alleged or suspected error leading to injury, the institutional risk-management service should usually be contacted for advice. However, fear of litigation should be mitigated by the fact that a low overall percentage of patients who suffer negligent injuries actually file malpractice claims.[25,52]

Nondisclosure of error can weaken the trust at the core of the patient–physician relationship. The argument for disclosure is especially strong when there is a specific preventive intervention that might lessen the severity of possible future injury. Nevertheless, the question still remains: Are physicians ethically obliged to disclose an error, even if there is no immediate harm to the patient?

Case Study

A patient with T3N1M0 squamous cell carcinoma of the left retromolar trigone received concurrent cetuximab plus intensity-modulated radiation therapy to the gross disease, with elective coverage of adjacent nodal echelons. The intent was to give 54 Gy to adjacent uninvolved lymph nodes at a rate of 1.8 Gy per day and 66 Gy to the gross disease at a rate of 2.2 Gy per day using a synchronous integrated boost technique, with all treatment completed in 30 fractions. After the spinal cord was contoured as an organ at risk, the structure was inadvertently deleted on all planning computed tomography slices below the level of the gross disease. As a result, when the intensity-modulated radiation therapy inverse planning software optimized the dose distribution according to the constraint of limiting the maximum dose to the spinal cord to 50 Gy, the entire cross-section of a 6-cm length of cervical spinal cord received the full prescription dose, with some areas of the cord located in a "hot spot" region receiving more than 70 Gy. The error was not detected until 1 week after the patient completed treatment, during a routine quality assurance check.

In this example, no injury has yet occurred, but the patient is at increased risk for radiation myelitis. Although there is currently no available proven preventive measure, if the escalated risk of myelitis is unknown to the patient, he or she might later undergo misguided management by another physician if symptoms develop. For instance, if the patient develops arm and leg weakness, a magnetic resonance imaging scan showing nonspecific enhancement and edema in the cervical spinal cord might be interpreted as evidence of metastatic intramedullary or epidural tumor rather than radiation change. Unaware of the prior treatment error, the patient would be unable to inform the other physician involved about the high risk for radiation injury. As a result, the patient might be given only minimal supportive care on the assumption of incurable recurrent disease rather than appropriate efforts toward rehabilitation.

Evans and Decker[55] have offered practical suggestions on how to address the issue of a medical error in radiation oncology once the event has been recognized. They advise disclosure for any errors that result in a perceptible clinical effect, change in diagnosis or treatment course, or a chance of future harm. Their two-phase response recommendation involves initial attention to the patient's immediate needs and an apology that avoids giving an impression of defensiveness. Later, after a more thorough analysis of the situation has been completed with the involvement of the hospital's risk management team, a carefully prepared discussion with the patient and other interested parties can occur. Evans and Decker also encourage radiation oncologists to maintain a proactive process of practice self-review as one component of fostering a culture of safety and quality in patient care.

CONCLUSION

Society's view concerning medical ethics has shifted over time to adapt to the forces of advancing knowledge. Ethical guidelines have sometimes been constructed as formal documents or mandated as law, but no single system comprehensively predicts and resolves all situational dilemmas. The core principles of medical ethics remain essential foundations for the practice of medicine.

Chapter 100
Economics of Radiation Oncology

Paul J. Schilling

ECONOMICS OF LOCOREGIONAL FAILURE

In 2012, 1,618,910 patients were diagnosed with cancer and 577,610 deaths were recorded.[1] Of those who succumbed to cancer, half had a component of local or regional failure. As systemic therapy improves, consequences of local failure become more pronounced.[2,3] Improving systemic therapy may lead to a longer lifetime free of systemic metastasis during which local failure can occur. This is one reason that postoperative radiation treatment improves survival in breast cancer, small cell lung cancer, prostate cancer, and rectal cancer.[1–3] The cost of regional failure in terms of human life and tragedy is staggering.

UNDERSTANDING MEDICARE

For patients who have Medicare as their primary insurance (these are the majority of radiation oncology patients), Medicare has a predetermined fee that is paid for each medical procedure, billed as a CPT (*Current Procedural Technology*) code. Medicare pays 80% of this allowable, and the patient's secondary insurance pays the remaining 20%. Charges are electronically billed, and turnaround time to receive payment can be as few as 14 days. Some secondary insurances will take between 6 and 9 months to pay the final 20%. Many secondary insurances must be billed using a paper claim sent through the mail instead of an electronic claim, thus delaying payment for up to 6 months.[4]

Hospital-owned, hospital-based radiation oncology practices bill under Medicare Part A. This provides for a technical component of radiation treatment delivery for the hospital; the professional component for physician services is billed separately by the radiation oncologist, also under Medicare Part A. The basis on which the technical component is paid to the hospital is called an ambulatory payment classification (APC). APC groups have different payments based on the complexity of radiation treatment delivery. The payments under the APC classification compared to those paid to outpatient free-standing facilities vary widely. For example, radiation treatment delivery for intensity-modulated radiation treatment, code 77418, is paid to the hospital under Medicare Part A at considerably less than the rate paid to free-standing centers under Medicare Part B. Alternatively, code 77370, special medical physics consultation, is paid to the hospital at approximately twice that paid to a free-standing facility.[4]

For a free-standing radiation oncology center, Medicare Part B is billed and a global fee is paid. This global fee combines both the professional fee to the physician and the technical fee to the equipment owner in one bundled payment. Some (CPT)

FIGURE 100.1. Medicare relative value units broken out by professional and technical classification per radiation treatment course.

codes have a professional component only, and some codes have a technical component only. Other codes have both professional and technical components, indicating that the physician and the equipment owner split this code based on their investment of physician time or equipment ownership. Calculating the professional/technical "split" in an outpatient facility can be difficult and depends on the payer mix, as well as the complexity of patients treated. The professional/technical split is calculated using the relative value units (RVUs) assigned to each CPT code. The RVUs are units of work assigned by Medicare, with each unit of work having a standard reimbursement. The RVUs in the professional/technical split are shown in Figure 100.1 and, as can be seen, vary depending on the complexity and objective of treatment. Calculating the professional/technical split is often difficult for physicians who are in free-standing centers and eligible to receive the professional component. In general, the professional component of global collections is approximately 11% to 35%, depending on the payer mix. If we consider equal rates of IMRT, 3D, and palliative treatment courses, the professional component of the global collections under Medicare Part B is 22%.

SUSTAINABLE GROWTH RATE VERSUS MEDICAL ECONOMIC INDEX

Medicare Part B (physician services) provides an annual update in allowable charges based on the gross domestic product called the sustainable growth rate (SGR). From the years 2000 through 2011, this has required a reduction in Medicare payment and thus Medicare-allowable fees. These cuts have been forestalled by Congress on multiple occasions.[5]

The Medicare Economic Index (MEI) is an annual update for Medicare Part A (hospital services) that is based on the rate of medical inflation. This has resulted in a yearly increase in payments to hospitals based on their self-reported rate of Medicare inflation.[6] If physician services were paid according to the MEI, we would be reimbursed at 40% more than we are now.

APPEALING DENIED MEDICARE CLAIMS FOR RADIATION ONCOLOGY

In January 2006 the Centers for Medicare and Medicaid Services (CMS) reduced the maximum time for adjudicating appeals for denied claims from a maximum of 1,000 days to 300 days. Nearly 20% of processed Medicare claims are denied. However, only 5% of denied Medicare claims are appealed.[7,8]

Physicians succeed in appealing payment denial in more than 60% of cases, indicating that the appeals process can be successful. If resubmitting the first rejection does not resolve the problem, the first level of appeal is called a *fair hearing,* and is usually conducted by telephone. You simply need to write a letter to the Medicare carrier requesting a fair hearing. The minimum denied amount needed to appeal a denied claim is $100. Multiple denied claims on different patients can be bundled together as long as the appeal amount is >$100. Include the appropriate documentation with the total amount appealed and CPT book definitions to describe what medical care was rendered and why you should be paid. Much to your surprise, most of the reviewers are not familiar with radiation oncology coding or the CPT coding books. Your job is to teach the reviewers to do their job and pay you.

For the carrier who habitually denies the same code, a previous favorable ruling may get the same code paid over and over again. In this situation, your goal is to use the last favorable ruling as evidence that the same denied code should be paid. This actually works, and sometimes the Medicare carrier will just pay the bill without the hearing as described earlier.[8]

For all fair hearings, the Medicare carrier is required to give you a written decision within 90 days. If the fair hearing process results in additional denial, the next step is a hearing before an administrative law judge. This is much more formal, and likely you should consider having legal representation. During the fair hearing process, the hearing officer will allow you to explain why a patient needed the (denied) care and provide documentation that you were able to help the patient based on available clinical evidence. During an administrative law hearing, the judge is only interested in whether the law allows you to be paid or not. Do not be afraid to try the appeals process if you feel the denial is inappropriate, and again, most often you will win.[7,8]

MEDICARE MEDICALLY UNLIKELY EDITS

A medically unlikely edit (MUE) is a limit on the number of units of a CPT code that would be reported for a patient in 1 day.[9] Medically unlikely edits were developed based on clinical judgment, and these were reviewed by insurance medical directors of Medicare and/or Medicare intermediary insurance companies. MUEs are used to screen out too many units of service done in a single day. For example, an appendectomy can only be done once on a patient in 1 day (or ever), and reporting two appendectomies in the same day of service would be impossible. Medicine as a profession can expect Medicare to pass more medically unlikely edits in the future.[9] These are often adopted by private insurance programs as well. MUEs apply to a number of procedures in radiation oncology, including dose calculations (code 77300), device charges (code 77334), and IMRT plans (code 77301), and for medical oncology limits in the total quantity of drugs that can be administered. If you find yourself the victim of not being paid due to medically unlikely edits, the first level of appeal as described earlier is a fair hearing, and the next level of appeal is an administrative law hearing. There is no prohibition for additional payments if clinically necessary.

BUNDLING EDITS

Medicare and some managed care organizations "bundle" procedures together so that only one charge is paid rather than two separate charges. For example, weekly physics management (code 77336) may not be able to be billed on the same day as special medical physics consultation (code 77370). The managed care organization may think that the special medical physics consultation is bundled into the weekly physics management.[10] It is essential to understand what these bundled codes are and where they conflict. Many times, this information is difficult to obtain during the contracting process. The best time to find out about bundling edits is before you sign an insurance contract. It is important to have a well-trained billing staff so that they can understand which codes are bundled, and decisions need to be made regarding a patient's care as to what specific service is required on a specific day. A sudden billing denial may herald new bundling edits.

Effective January 1, 2010, code 77338 replaced device charge 77334 used for each multileaf pattern for Medicare patients receiving IMRT. This code is used one time per IMRT plan (77301) and replaces multiple charges for multileaf patterns. Unfortunately, the reimbursement for this code is below what would be reimbursed under the prior system. Prior to 2010, if a head and neck cancer patient received a 10-beam, 10-gantry-angle IMRT treatment, code 77334 was billed for a quantity of 10 separate multileaf patterns used in treatment. Currently, code 77338 replaces *all* of these charges and can only be billed with a quantity of one, not 10. In Florida, in 2011, reimbursement for code 77338 is $459 and for code 77334 is $145. Thus, one charge of code 77338 represents 3.2 charges of code 77334, enough to pay for only 3.2 of the multileaf patterns for the aforementioned head and neck cancer patient.

INSURANCE REQUIREMENTS FOR PREAUTHORIZATION FOR RADIATION TREATMENT

A more recent feature of private insurers and Medicare HMOs is to require preauthorization for radiation treatment. This can be extraordinarily restrictive. Generally there are limitations on stereotactic radiosurgery as well as intensity-modulated radiation treatment. Often the patient will need to undergo simulation, and treatment can be delayed until a reviewer can decide if IMRT is warranted or three-dimensional (3D) conformal treatment will suffice. Needless to say, we do not get reimbursed for the treatment plans of both modalities, although they are requested by the insurer. There are various sets of guidelines developed by insurance companies to help their reviewers authorize or deny complex radiation oncology treatments. If denial occurs, again, it can be appealed, but the patient waits for treatment. Be sure to insist on a reviewer who is a board-certified radiation oncologist and not a retired general practitioner.

MEDICARE ADVANTAGE HEALTH MAINTENANCE ORGANIZATION INSURANCE PLANS

In 2007, Medicare Advantage Health Maintenance Insurance Programs were created. The insurance companies who administer Medicare HMOs are currently reimbursed up to 19%, more than traditional Medicare pays for each senior's care.[4,11] The seniors who sign up for Medicare Advantage plans often receive less care but pay higher copays and higher deductibles,

and more than half of Medicare plans pay physicians below traditional Medicare rates. Many seniors do not realize that with a Medicare Advantage plan they need secondary insurance to pay for the additional costs that Medicare Advantage does not cover. More than 2,000 physicians responding to an American Medical Association survey on Medicare HMOs noted that Medicare HMOs routinely denied services typically covered by traditional Medicare plans including colonoscopies, prostate-specific antigen (PSA) blood tests, and other cancer screening procedures. A survey of patients enrolled in Medicare Advantage HMOs reported that 80% of them did not understand their plans and 60% did not realize they were actually giving up traditional Medicare.[11] Some seniors are being sold Medicare HMO plans through abusive marketing practices. CMS singled out insurers including United, Humana, Coventry, and Cigna for abusive marketing techniques, and these companies were advised to take steps to more closely scrutinize their sales personnel. Medicare Advantage plans have created an incentive for insurance companies who sponsor these plans to enroll healthy new patients. The bottom 50% of Medicare recipients spend only 3% of Medicare health dollars.[11] Insurance companies have found ingenious ways to enroll healthy seniors while making enrollment inconvenient to patients with many chronic diseases who might cost more. These incentives include offering free gym memberships to those enrolled (this appeals to the healthiest, most ambulatory seniors) and holding dinner seminars for prospective enrollees after dark in locations without access to public transportation or that require ascending several sets of stairs. An investigation by the Medicare Payment Advisory Commission in 2004 found that Medicare HMOs were designing their plans to avoid paying for kidney dialysis, chemotherapy drugs, home care, and radiation treatment. A *New England Journal of Medicine* article noted that currently enrolled Medicare HMO members spent only 66% of the average cost of non-Medicare HMO patients during the year prior to joining the HMO. This may indicate selection of the healthiest seniors. Seniors departing from Medicare HMOs went on to spend 180% of this average, indicating that sicker patients were leaving Medicare HMOs possibly due to higher out-of-pocket costs. Cancer treatment, unfortunately, continues to be extraordinarily expensive. We must keep informed as to where cost shifting is going in the future and educate our seniors.[11]

PATIENTS REQUIRING RADIATION TREATMENT WHO RESIDE IN SKILLED NURSING FACILITIES

Skilled nursing facilities are paid for by Medicare for seniors who need more care than a nursing home can provide but less care than an acute hospital provides. The skilled nursing facility is reimbursed by Medicare at a fixed rate per day for a patient's care. When patients residing in a skilled nursing facility require radiation treatment, if the radiation facility bills under Medicare Part B (physician and outpatient services), the skilled nursing facility is responsible for reimbursing the radiation oncology facility and physician out of the fixed amount of money that is received each day by the facility. Conversely, if a radiation facility is owned by a hospital and bills under Medicare Part A, a separate payment by Medicare Part A is made to the radiation oncology facility and thus does not cost the skilled nursing facility any portion of their daily fee. Because of this, there is a financial incentive to refer or divert patients who need radiation treatment to a hospital-based facility billing under Medicare Part A. Of course, skilled nursing facilities do not wish to generate a bill that would require payment by them for referring patients to a Medicare Part B facility. This places outpatient facilities at a distinct disadvantage and is certainly unfair. The radiation oncology community is lobbying to change this practice.

RADIATION TREATMENT OF PATIENTS ENROLLED IN HOSPICE

It is not unusual for patients in hospice care to require palliative radiation treatment for pain control, palliation of neurologic symptoms, and so forth. Under Medicare Part B, the outpatient facility can directly bill Medicare with a GV modifier. The GV modifier indicates that the radiation oncology facility is separate from hospice and that the physician who is consulting and overseeing radiation oncology care is not directly employed by the hospice facility. Hospice benefits do include radiation treatment if this is included in the hospice plan of care. Thus, if the hospice facility includes radiation treatment in its plan of care for a patient, it must pay for it out of its daily reimbursement, a fixed amount per day. Currently hospice services are paid for by Medicare with a daily fee. This is paid 7 days a week for a maximum of 6 months. However, hospices usually only provide care 1 to 3 days per week. Hospices are among the few patient care providers that receive reimbursement from Medicare, depend on volunteer services to provide some of the care, and receive charitable donations from the public. Consider this when donating your time or money to a for-profit or not-for-profit hospice.

MEDICAL PHYSICISTS: SHOULD THEY BILL MEDICARE DIRECTLY FOR THEIR SERVICES?

Many medical physicists maintain that they are board-certified professionals so should be able to bill Medicare directly; however, if they did so, their paychecks would shrink considerably. In 1960, lists of providers who could bill Medicare directly were formulated, and physicists were not among these professionals. Because of this, a congressional act is required to give billing status to medical physicists.[12] Currently there are only two codes recognized for the contribution of medical physicists: code 77336, continuing medical physicist services, and code 77370, special medical physics consultation. There are no other CPT codes in Medicare Part A or Part B that identify any medical physicist component of work.[12] At Florida Medicare rates, code 77336 is reimbursed at $50.43, and code 77370 is reimbursed at $105.55. In a busy department with 30 patients under continuous radiation treatment, there would be 30 continuing medical physicist services provided at a Medicare reimbursement level of $50.93 for 50 weeks per year, for a total reimbursement of $75,645. If 50% (this is high) of patients under treatment required a special medical consultation, this would mean a yearly reimbursement of $15,833. The total for these services, $91,478, is dramatically below what the average medical physicist makes in the United States.[12] In 2007, CPT code 77336 was submitted to CMS 475,000 times at a reimbursement of $50.93. This would yield total reimbursement for medical physicists of $24,191,750. During the same year, CPT code 77370 was submitted 25,000 times at a reimbursement of $105.55 for a total Medicare payment of $2,638,750. When we combine these two numbers we get a total reimbursement for physicist services of $26,593,000. There are currently 4,700 members of the American Association of Physicists in Medicine. It is uncertain as to how many medical physicists practice exclusively in radiation oncology; most estimate approximately 25% of the total. If we use the number of 1,000 medical physicists in the United States splitting the total reimbursement for physicist services delivered to Medicare patients in the United States, we get a per physicist rate of $26,593. Again, this is rather dramatically below what the average medical physicist makes in the United States. Professional self-determination appears to be important to medical physicists. If we examine published literature available to the public on the process of radiation treatment, very little mention is made

to medical physicists being members of the patient care team. This is true of the National Cancer Institute's manual on radiation therapy and the American Cancer Society's publication on the process of care for radiation oncology. This is unfortunate. There is certainly room for improvement to include medical physicists in the process of care because they are an integral component. The patient should understand their role, and perhaps additional efforts can be directed toward recognizing the contributions of medical physicists in the care of our cancer patients.[12]

RADIATION ONCOLOGY NEGOTIATION WITH MANAGED CARE PLANS

In 1937, Dr. Sidney Garfield provided prepaid medical care for Henry J. Kiser's company in California, and this was the beginning of managed care in the United States. Managed care proliferated with the objective to reduce health care costs for workers covered by health care plans paid for by their employers.[4,10]

Many physicians have experience negotiating the rate of compensation for their contracts. However, a managed care company may be reluctant to disclose their fee schedule if other physicians in the area are contracted with them. Begin the negotiation by making an inquiry for 10 codes most commonly used for radiation oncology patients. Oftentimes, a managed care company will send the reimbursement for 10 codes total. From this it is possible to get an idea as to what the company's rate of payment is and whether you wish to continue the negotiation.[4,10]

Many private insurance contracts try to link reimbursement to a percentage of Medicare rates. Some managed care plans pay you based on 100% of the regional managed care company's usual and customary fees. Often, this is below Medicare rates, and it is imperative to know exactly how you are being paid.[4,10] Many managed care companies want you to take a fee reduction across the board for all radiation oncology CPT codes. Try to negotiate reduction in only a few codes (used less often), which may have a less deleterious effect on your practice. Always attach a comprehensive fee schedule to all contracts and make the insurance company sign off on this as an exhibit. This clearly prevents confusion later and locks in your rate of reimbursement instead of having it adjusted each year depending on Medicare rates.

Some managed care companies will try to get you to contract for a case-rate structure. In this scenario, for any patient who requires radiation treatment, a fixed dollar amount would be paid regardless of treatment complexity. Case-rate arrangements can sometimes be tiered, which allows two to three levels of complexity paid at a fixed rate. Case-rate reimbursements are difficult to manage and frequently do not increase year to year, while the complexity of treatment does increase. The physician is advised to use caution in accepting any case-rate structure.[10]

There are a few managed care companies that reimburse based on a capitation basis. Under this scenario, a certain amount of money is paid monthly to the radiation oncology group to provide services regardless of the covered population's average age or need for radiation treatment. These contracts are extraordinarily difficult to negotiate and manage. Ultimately, to remain solvent, you would need to know the age of the population insured, as well as their cancer incidence, cancer screening availability, and so forth. Unfortunately, this information usually resides with the insurer, and most likely they will not share this with the physician. Capitation rates can also be calculated from population-based data using Surveillance, Epidemiology, and End Results (SEER) data.[4] Nonetheless, these data underestimate the incidence of cancer and the volume of cancer treated with radiation.

For hospital-based practices, it may be necessary for the managed care company to have a contract with the hospital for the technical component of radiation treatment and a contract with the radiation oncologist for professional services. Pitfalls to watch out for include a provision that the codes with a professional/technical split must be billed on the same day by both the hospital and physician for either to obtain payment. This puts the physician in the position of auditing the hospital charge capture, a notoriously inefficient process.[4]

A contract with the managed care company should spell out emergency care provisions. Many times emergency treatment for spinal cord compression or brain metastasis, for example, will be provided and a managed care company will later indicate that this was a noncovered service, even on an emergency basis. Thus, an entire course of treatment may be denied in this way.[10]

The managed care organization may wish to retain the right to reduce current reimbursement to you for prior payments that were paid in error. Thus, they may "set off" current payments by past debts. Some states laws do not allow this. These clauses are often subject to abuse. For example, suddenly the managed care company decides that dose calculations (code 77300) are "bundled" or included in special medical physics consults (code 77370). They will be able to potentially audit the practices to disallow as many 77300 codes as you have and adjust the billing to create a debt for 3 years' worth of 77300 charges against which future payments are applied.

Audit provisions are similarly important to negotiate. Provisions on closing the claims process should apply equally to physician and managed care organizations. The time limit for auditing should be similar in time to which forfeiture of payment occurs. For example, if the managed care organization allows submission of bills up to 12 months after a service is rendered, you should negotiate an audit provision for only 12 months. Longer audit provisions may lead to abuse. Large-scale insurance companies routinely hire an auditing company on a contingency basis that is motivated to audit claims and recover payments. Occasionally audits are used to retaliate against physicians who request arbitration of unpaid claims.

It is important to assess your strengths and weaknesses during the negotiation process. Managed care companies realize that their contracts are subject to termination. Because of this, they usually do not depend on a single provider for medical care. Are you a second source of radioactive isotope therapy or radiopharmaceutical therapy? Are you one of only two providers of high–dose-rate brachytherapy in your area (which avoids a hospital stay)? Are you the only provider of intensity-modulated radiation treatment or the only practice that will treat children? All of these things count as strengths in negotiations and can be effective in setting the tone for negotiations with insurance companies.

SILENT PREFERRED PROVIDER ORGANIZATIONS

Because of the rise of managed care, a new process has been promulgated whereby a network in which a physician is contracted as a preferred provider is sold to another health plan without the physician's knowledge or consent.[13] This creates a *silent preferred provider organization (PPO)* in which a discount is extracted from the physician's usual and customary fees without the physician's consent. The net result is a secondary discount where an insurer (often with a low number of patients) pays the physician's discounted fee without the physician ever receiving the benefit of any additional patient volume. In most instances physicians become aware that they are victims of a silent PPO after providing services to a patient with indemnity insurance. When payment is made on behalf of an insurance company, the discount is applied even though the patient is not a member of the PPO and the physician is not a contracted member of that insurance organization. Unfortunately, there is

no Health Insurance Portability and Accountability Act (HIPAA) statute governing selling lists of physicians and their associated contracted discounts. The American Medical Association estimates that $750 million to $3 billion is lost annually in the United States by physicians to silent PPOs.[13,14] The American Medical Association was successful in banning silent PPOs from all federal employee health insurance benefits contracts. However, currently state insurance boards generally provide insurance regulations. A few states including North Carolina, Louisiana, Oklahoma, California, and Texas have passed legislation banning this practice.[14] One simple step to combat this practice is to carefully read all contracts. Many health insurance contracts contain provisions that allow them to enter contracts with "other payers on the physician's behalf." If this language appears in your contract, insist on striking it. Additional language to protect yourself might include the prohibition of selling, renting, or leasing networks providing any information about a fee schedule to anyone without your express permission.[13] Currently the only recourse after an inappropriate discount has been applied and you have been paid inappropriately is to use the legal system. As always, "an ounce of prevention is worth a pound of cure," so be sure to look for the aforementioned clauses and lobby your state medical association to pass legislation that protects physician information.

ECONOMIC PROFILING: INSURANCE COMPANIES DETERMINE WHO PROVIDES THE LEAST EXPENSIVE CARE

Economic profiling tracks physician care expenditures including specialty referrals, laboratory testing, and utilization of other costly resources. Physicians are allowed to continue on the panel of certain insurance plans based on their level of utilization and cost to the insurance plan. Yet, expenditures to provide care to individual patients are variable.[15] Patients who have complex cancers have a higher average cost of care, which may institute multiple inquiries from the insurance company about specialist referral, prescribing habits, and overall resource utilization. Higher average costs of care may lead to deselection from insurance plans for "outlier" utilization. When comprehensive care is provided in a single geographic setting, insurance companies know that patient compliance in the stated plan of disease management is enhanced, leading to fewer episodes of missed testing or treatment. This "dropout rate" is calculated as care prescribed by a physician but not undertaken by a patient.[15] Physicians with high dropout rates reduce costs to the insurance company, but only temporarily.

ECONOMIC CREDENTIALING: HOSPITALS SEEK TO PREVENT PATIENT CHOICE

Economic credentialing is defined by the American Medical Association as the "use of economic criteria unrelated to the quality of care or professional competency to determine an individual physician's qualifications for granting or renewal of medical staff privileges."[16] The goal of economic credentialing in radiation oncology is to capture a revenue stream by denying hospital privileges to a group or terminating hospital privileges and thereby limiting competition. Hospital bylaws are considered by many states to be a contract between a hospital and medical staff, serving as a guideline for actions against physicians, as well as outlining due process provisions for physicians.[16] Read your hospital bylaws carefully and watch for hospital proposed changes. The medical staff should have its own legal representation, separate from the hospital, when hospital bylaws changes are proposed.

Hospitals may seek to institute differential credentialing to keep qualified physicians from becoming members of the medical staff, and thus limiting competition. One example is requiring radiation oncologists to complete 4 years of residency, whereas before 1994 radiation oncology residencies were only 3 years.[16]

Contracts between physician groups and hospitals establish a business relationship to provide radiation oncology services. Traditionally, exclusive contracts ensured patient access to care that would otherwise not be available. Because of increased access to cancer treatment in the United States, this is almost never the case today. Most hospitals enter into an exclusive contract strictly for financial reasons, which puts the physicians in the position of being controlled by the hospital master financial plan. Exclusive contracts may deprive patients of choices and limit the establishment of new physician practices. Some exclusive contracts contain "clean sweep" provisions, which stipulate that when a group loses an exclusive contract with a hospital, each physician simultaneously forfeits clinical privileges without the benefit of due process afforded by the hospital bylaws.[16]

The peer review process may be misused to further a hospital's economic goals. Because in most states peer review proceedings are protected from legal discovery, peer review affords an opportunity for physicians to evaluate their care and remediate their knowledge if necessary. Protection from legal discovery also invites hospitals to target and eliminate physicians who are economic threats to their service lines. This is particularly true for hospital-based specialists including radiation oncologists. Some radiation oncologists find themselves excluded from equipment or facilities when a health care institution changes radiation oncology from a hospital inpatient service to an outpatient service. This may occur with no change in location of building, equipment, or staffing. There is an entire consulting industry that teaches hospitals how to displace existing radiation oncologists and put their replacement physicians on salary. We are not the only target; physical medicine, diagnostic radiology, and cardiothoracic surgery are also vulnerable to these tactics.[16]

The American Medical Association has a long, continuous interest in fighting economic credentialing and has a litigation department with years of accumulated information and experience and will assist physicians who challenge health care institutions about these issues.[16]

RADIATION ONCOLOGY'S SOCIOECONOMIC TIES WITH DIAGNOSTIC RADIOLOGY

In previous years, delivery of radiation treatment was both crude and considerably simpler. "Therapeutic radiology" was a discipline of diagnostic radiology. As radiation treatment became more sophisticated and as megavoltage linear accelerators became available, it was clear that separate training was necessary for radiation oncologists to treat cancer patients. Eventually new CPT codes were created for radiation oncology and governmental payers began to recognize us as being separate from diagnostic radiology. Diagnostic radiologists seem to be embroiled in a campaign to close the "in-office ancillary exemption," which allows nonradiologist physicians to perform imaging within their offices. Currently, obstetricians perform pregnancy-related ultrasounds, cardiologists perform cardiac catheterizations and nuclear cardiac procedures, and family physicians perform bone densitometry and plain films within their offices. With the advent of image-guided radiation treatment, positron emission tomography (PET)/computed tomography (CT) simulators, and magnetic resonance imaging (MRI) simulators for treatment planning, radiation oncologists continue to fight for the ability to image our patients for diagnosis, staging, and treatment planning related to cancer. Our objective should be to show CMS that imaging is necessary for treating cancer patients appropriately.

In 2009, Medicare proposed a 95% "usage rate" for diagnostic imaging equipment and then proposed extending this to all medical equipment costing more than $1 million. This proposal was advanced by the Medicare Payment Advisory Commission and was based on a sample size of only six urban diagnostic radiology centers but, because of the cost of linear accelerators, was extended to radiation oncology.[17] Data collected by U.S. Oncology show that 50% of linear accelerators installed in the United States operate at a 50% utilization rate or less.[17] If this usage rate were enacted for radiation oncology, the technical reimbursement would be reduced with the assumption that more patients are being treated per day on each linear accelerator. A reduction in technical reimbursement would force the closure of many rural practices, making patients travel longer distances for cancer treatment. Fortunately, this proposal was defeated because radiation oncologists like you told Congress that we are different from diagnostic imaging. Radiation oncologists need to continue to show CMS that we treat cancer patients and are separate from diagnostic radiology.[17]

HEALTH CARE REFORM

In 2011, 48.6 million Americans did not have health insurance. According to census data taken in 2007, approximately one-third of those uninsured held jobs that offered health insurance coverage and had salaries 300% above the poverty level. This group chose not to pay for health insurance due to cost considerations. The Affordable Care Act will enroll currently uninsured patients into the Medicaid program. This will be a payment windfall for hospitals, which would be paid for emergency room visits for which they now do not receive reimbursement. Private practice physicians may not see more Medicaid patients due to low reimbursement, thus encouraging the use of emergency rooms for primary care.

The Congressional Budget Office estimated that tort reform with a $250,000 cap on noneconomic damages would save the United States $54 billion over 10 years and reduce national health care spending by 0.5% annually and save $41 billion in tests ordered due to physicians' needs to practice defensive medicine.[18] Medicaid expansion during a time when fewer doctors accept Medicare patients may not be an answer that is palatable to many physicians. The government has studied bundled "bulk" payments for hospital and physician care. One proposal would be to negotiate a bundled fee paid to hospitals for an episode of care (i.e., lung cancer). This led to the creation of accountable care organizations as part of the Affordable Care Act. The physicians would then negotiate with the hospital for their component of pay. As always, greater bargaining power is in the hands of the entity that receives the check.

ACCOUNTABLE CARE ORGANIZATIONS

Expenditures for health care in 2011 totaled $2.6 trillion. In the United States, we spend 17.6% of our gross domestic product on health care, which comes to $18,344 per person, while Japan spends 8.5% of its gross domestic product, accounting for $2,872 per person. Accountable care organizations (ACOs) promise to improve medical care coordination, with reductions in fragmented care, improvement in outcomes, and reductions in the cost of health care. Their successful operation is a priority in cost savings for the new Healthcare Reform Law. Under the Affordable Care Act, the minimum size of the population for Medicare beneficiaries for an ACO is 5,000 patients. ACO founders can be primary care physicians or independent practice associations. ACO participation includes hospital and physician specialists (like radiation oncologists). Patients are assigned to an ACO *retrospectively.* Thus, physicians providing care in an ACO do not know which patients do or do not belong to the ACO. Ostensibly, this is to encourage cost savings for all patients, not just those patients assigned to an ACO. Any savings achieved in the ACO population (actual medical care costs compared to expected medical care costs) are shared between Medicare and the ACO at a rate of 50%. If the cost of care for the population is more than 2% higher than Medicare expected, the ACO may need to repay this loss. Patients may self-refer to another Medicare provider physician outside their ACO, and care provided by that physician or that hospital counts against the ACO's cost goals.

Because ACOs are controlled by primary care physicians whose missions are cost savings, this may not bode well for the specialty of radiation oncology. Most primary care physicians have a difficult time understanding the benefits of radiation treatment, especially in palliative cases as well as in cases where the cure rate is <50%. Primary care physicians may leave the decision for radiation treatment to medical oncologists. This decision making by medical oncologists may diminish once primary care physicians realize that delivering chemotherapy is by far the most expensive portion of cancer treatment with the extremely high cost of cancer drugs. It is possible that patients for whom palliation is a goal will automatically be enrolled in hospice. We may see more hip fractures, intractable pain from metastatic disease, and brain metastases go untreated, all with the goal of cost savings, which individually benefits Medicare and the physician partners in the ACO. Primary care physicians need to be educated as to the benefits of radiation treatment. We should let them know that treating a hip metastasis may actually prevent a total hip arthroplasty, which is a more costly event. Preventing or palliating a spinal cord compression might prevent paralysis and a prolonged episode of bedridden care. Radiation treatment is dramatically more cost-effective than Mohs microsurgery and reconstruction, which costs more than $1,000 per stage. This will be our mission for the future, and given the change in the health care landscape, this will be challenging.[19]

There has been a tremendous push for independent practice of nurse practitioners (without physician supervision) and for nurse anesthetists.[20] The former may be provided to close the gap in primary care resulting from fewer primary care physicians choosing primary care as a profession due to low reimbursement.

The American Medical Association has requested insurance market reform with elimination of denials for pre-existing conditions, health insurance for all Americans, and health care decisions remaining in the hands of patients and their physicians, as well as repealing the Medicare sustainable growth formula that triggers deep cuts in Medicare and threatens seniors' access to care. The American Medical Association also desires proven medical liability reforms to reduce the cost of defensive medicine.[21,22]

RADIATION ONCOLOGISTS' LOBBYING AND POLITICAL ACTIVITY

Americans place a high value on the quality and availability of medical care. In this country, we have massive government programs that provide the funds to pay for the health care of the poor, disabled, and elderly. Unfortunately, payment rules are created by the legislature for a large portion of all physicians' practices in the United States.[4,20] The importance of interfacing with governmental payers, as well as in influencing the process that benefits our patients and brings them new technologies, cannot be underestimated. This can be accomplished through membership and in financial support of organized medicine at all levels. Select the organizations that you support carefully and specifically with an eye toward those which provide lobbying power for you and for your patients.[23–26] There are multiple organizations that interact with CMS. These include the American College of Radiation Oncology, the American Brachytherapy Society, the Association of Freestanding Radiation Oncology

Centers, and the American Society for Therapeutic Radiology and Oncology.[23–27]

STARTING A FREE-STANDING CANCER CENTER

Starting a free-standing cancer center requires substantial time, effort, and persistence. The population area served by the free-standing center must be clearly defined by the radiation oncologist. In an area where there is no cancer program, the population data for the area can be gathered, complete with the age range of the population and the number of each potential patient within defined age ranges. SEER data can then be applied using population-based cancer incidence. In 2010, the age-adjusted incidence of new cancers diagnosed was 5.4 cases per 1,000 men and 4.1 cases per 1,000 women.[4,28,29] The raw cancer incidence provided by the SEER data does not tell us how many patients may undergo radiation treatment during the course of their illness. Take the number of estimated patients and then apply a yield ratio of approximately 50%, which should estimate the total number of patients that the new cancer center would serve. An additional 25% of patients will need to be retreated for other metastases or other new primary cancers.[29] Model radiation oncology courses of treatment must be developed to estimate reimbursement per course of treatment (see Fig. 100.1).[4] A certain percentage of patients will receive a palliative treatment course, 3D conformal treatment, and intensity-modulated radiation treatment. If an average length of treatment (including palliative treatment and definitive treatment) is approximately 5 weeks, to have 20 patients under continuous treatment per day will require 200 new patients per year.

A second way to estimate the population served is to count the number of occupied beds of hospitals serving the area. Each permanently filled hospital bed yields approximately one cancer patient per year, of which half will require radiation treatment.

For a cancer center in a competitive market, one must establish exactly how many patients would be treated in the new cancer center and specifically how the physicians plan to obtain these referrals. If a hospital-based group of physicians builds its own free-standing cancer center, some of the patients may follow because referring physicians will continue to refer. There are always surprises and changes in referral patterns when hospital-based radiation oncologists open a competing free-standing center.[4]

Once the numbers of patients to be treated are established, along with their treatment length, the reimbursement for an "average course of treatment" can then be calculated. This average course of treatment should take into account intensity-modulated radiation treatment, palliative treatments, and 3D conformal therapy. When one uses a conservative estimate and sets the total reimbursement at Medicare rates, this seems to be a reasonable approach to many lending institutions. Once total collections for the population to be served are established, the total expenses need to be established, as well. This includes the costs of debt service, interest, principle, sales tax on equipment when installed, electric bills, costs of physics and dosimetry, costs of personnel including nursing and therapists, costs of water, building maintenance, professional liability, building insurance, employee benefits, physics equipment, accelerator maintenance, and so forth.

All of this can be packaged together as a pro forma to take to your financial institution. Generally, banks require a down payment between 5% and 20% of the total amount borrowed. In addition, working capital will be needed for approximately 6 months of operation.[4] The pro forma should be conservative. The goal should be to exceed the numbers that are projected, not just to meet them. This will give the bank a substantial amount of comfort as well. The carrying costs of maintaining a center, maintaining a competitive edge with equipment, and attracting and maintaining high-quality personnel are substantial. If you have never run a free-standing radiation center, you may substantially underestimate the costs of running one.[4] If medical oncology is to be added, the costs of the monthly drug bill need to be calculated.

MARKETING A RADIATION ONCOLOGY PRACTICE

Marketing for radiation oncology is directed toward the referring physician. Determine the physicians most likely to refer to you and make a list. *Any* physician can be a referring physician.[4,29] I have received two referrals from psychiatrists who had cancer patients that were unhappy with their care, underscoring this premise.

Presenting patient cases at cancer conferences at your local hospitals is a time-honored and useful form of individual marketing for your practice.[4,29] Nursing staff usually attend, and they can be a referral source. Radiation oncology images can be rewarding to present at tumor boards. Outlines of isodose plans and other imaging studies, MammoSite depictions, high–dose-rate brachytherapy plans, and so forth, form an image in referring physicians' minds that medical oncologists cannot accomplish.[29]

Giving talks to civic organizations and cancer support groups is also beneficial but requires patience for the long term.[4,29] Although I give multiple talks to groups, there has never been an instance where someone in the audience decided that he or she would change to me as a physician as the result of my presentation. Nonetheless, there have been multiple times when family members of new patients have said that they have heard me give a presentation. This underscored another physician's referral choice.

Advertising to the public generally does not yield new patients on its own. Advertising advanced technology may be helpful but usually only bolsters the understanding and familiarity with your physicians and facility when another primary physician makes a referral. In some larger urban markets, advertising advanced technology may make a difference or get some patients to call, ask questions, and possibly self-refer.

If your hospital has a teaching program, it is often rewarding to give a lecture or two within this program.[29] Physicians who attend will soon become your referring physicians, especially if they stay in the area to practice.

Develop a telephone answering on-hold message that showcases your technology, as well as the talents of your physicians. Thus, when the patients and physicians call, they are given an explanation of exactly what your practice does while they are waiting for the receptionist. Developing an immediate fax or e-mail form to briefly let referring physicians know what is being done for a new patient facilitates communication and gives them immediate information about the workup and progress of a patient you have seen.[4]

Internet website development can also be helpful. Again, this usually does not yield new patients, but rather reinforces the choice that other physicians have made to refer patients. Patients can find out about your practice on the Internet, as well as fill out their intake forms, and so forth. Some of these techniques may be helpful. But none of these techniques will be useful unless outstanding patient care is delivered, both socially and medically.

SELLING A FREE-STANDING CANCER CENTER

In recent years there has been much interest by private or publicly traded groups in purchasing radiation oncology centers. Publicly held or private corporations may seek to purchase radiation oncology centers to induce an economy of scale,

dominate a certain region or state (and thereby exact additional reimbursement from the area insurers), or ultimately go public (issue stock certificates that can be purchased by the public). Generally a sale is based on earnings before depreciation, interest, taxes, and amortization (EBDITA). A multiple of this number is paid to the owner, generally in the 4 to 7.5 range. This range will decrease as cuts in reimbursement occur. Generally purchasers ask the owner to retain a minority percentage of the original cancer center he or she built. Sometimes this can be as small as a few percent, sometimes up to 49%. The purchasing entity may propose an automatic payout for the final percentage after 2 to 5 years of employment. It is important to negotiate how the buyout will be valued into the future. One potential problem is that an entity that owns more than 50% of your cancer center may dramatically reduce the profitability of this facility by allocating expenses incurred in the home office to your office, which actually is treating patients. This reduction in profitability likely will affect the buyout price in the end and will not adjust it upward. Sellers of radiation oncology practices should be aware of this potential and retain as small a percentage as possible or none at all. Some purchasers require a reduction in the ultimate purchase price based on the prospect of reduced reimbursement for some procedures. For example, an IMRT or stereotactic radiosurgery "earn-out" may be a reduction in payment price based on the future of reimbursement for these two modalities, with a portion of the purchase price paid at a later date. Predicting into the future of reimbursement is beyond the scope of most of our readers.

NONPROFIT HOSPITALS AND RADIATION ONCOLOGISTS

Earnings from many nonprofit hospitals have soared, with a combined income of the 50 largest nonprofit hospitals in the United States increasing eightfold to $4.27 billion between 2001 and 2006, according to a *Wall Street Journal* analysis updated from the American Hospital Directory. Nonprofit hospitals' "excess cash flow" (we call this profit in the for-profit sector) is spent on new facilities, generous executive pay, and often new and lavish cancer centers.[30] The largest nonprofit hospital chief executive officer pay ranged from $3.3 million to $16.4 million per year.[30] Historically, most nonprofit hospitals in America have been recognized as charitable organizations and exempt from taxes under Section 501(C)[3] of the U.S. tax code. In return for a generous tax exemption, the U.S. Internal Revenue Service (IRS) previously required nonprofit hospitals to provide a substantial amount of charity care for the poor. However, in 1965, when Medicare and Medicaid were created, the hospital industry felt there would not be enough demand for charity care to satisfy the IRS exemption standards. With substantial lobbying, the nonprofit hospital industry pushed for more flexible exemption that became known as the Community Benefits Standard adopted by the IRS in 1969. This allowed hospitals to provide local "community benefit" consistent with any other nonprofit hospital in their area.[30] Unlike for-profit hospitals, nonprofit hospitals do not pay dividends to shareholders. Instead, they use "excess cash flow" (profits), earned from operations, to pay for new facilities. Among these are proton treatment centers under construction in the Midwest, and located within minutes of each other, and various cancer centers being built by nonprofit hospitals without paying any taxes. These compete with those facilities that do pay taxes. While nonprofit hospitals have a charity obligation to the communities they serve, do they compete with physician practices by using an unfair tax advantage?

FEDERAL STARK REGULATIONS AFFECTING RADIATION ONCOLOGY

Current Stark laws prohibit self-referral to designated health services, which includes radiation oncology. Radiation oncologists who own their own facilities and equipment do not fall under violations of the Stark rule because it is not considered self-referral when the referring physician personally performs a designated health service in his or her own facility.[31]

There is also an in-office ancillary exemption, which applies to ownership and investment interest for ancillary services. The in-office ancillary service must be provided in a building in which the referring physician also furnishes substantial physician services.[31] This loophole has been exploited by some urologists to create a "group practice" with radiation oncologists and add a linear accelerator to their building. Curiously enough, the very radiation oncologists who join these ventures are often the displaced victims of hospital tactics of economic credentialing (see next section).

Congress made some of its conclusions and wrote portions of the Stark law based on studies that examined the effects of ownership of free-standing radiation oncology facilities by referring physicians who were not radiation oncologists and did not directly provide services. These "joint ventures" yielded a utilization rate 40% higher in these facilities than the rest of the United States, and a cost of radiation treatment that was 60% higher than the rest of the United States.[32] In addition, these studies showed that there was less access to poorly served populations without any reduction in mortality among cancer patients that indicated improved quality of care.[31,32] State laws may strengthen current existing federal laws, and it is important to understand the laws in your state concerning self-referral.[4,31,32]

"GROUP PRACTICES" INCLUDING RADIATION ONCOLOGY, UROLOGY, AND OTHER SPECIALTIES

Radiation oncologists have become increasingly concerned about the growing trend of self-referral for radiation treatment services by other specialty physicians seeking to create a group practice for apparent economic gain. Physician-driven financial arrangements may be consummated specifically to facilitate the delivery of intensity-modulated radiation treatment and have caused concern for the quality and cost of radiation treatment delivery. These arrangements have caused proliferation of "multispecialty groups" with the objective of delivering IMRT to prostate cancer patients that the group's urologist diagnoses. Prior to the initiation of the Stark laws, studies of radiation oncology facilities owned by referring physicians reported higher costs for cancer treatment without improved outcomes.[33] Radiation oncology is a designated health service under Section 1877 of the Social Security Act, which prohibits financial arrangements between the physicians and entities providing these services. Congress created an "in-office ancillary exemption" to protect medical services for which a service or test result is immediately needed for in-office patient care. As part of a program to address and study this growing trend, the American College of Radiation Oncology (ACRO) issued a physician statement on self-referrals specifically addressing the formation of urology and radiation oncology radiation groups for apparent financial reasons. ACRO then surveyed radiation oncologists who identified themselves as having a financial relationship with urologists. After telephone verification, there were 75 radiation oncologists who identified themselves as having a practice model that included urologists. The radiation oncologists were both employed in and a financial partner in the group. No radiation oncologists responded that their practice model included "block leasing" linear accelerator time to urologists. For all respondents, the radiation oncologists received the professional component of treatment. All 75 respondents either were economically displaced in a geographic region by an existing radiation oncology group or were economically displaced by a hospital in their region.[33]

All respondents were unable to achieve professional partnership status within a radiation oncology group, and 98.6% were unable to achieve any share of the technical component for radiation treatment within a radiation oncology group.

Sixty-six of 75 physicians provided a daily total of prostate cancer patients treated in their facility.[29] The range was one prostate cancer patient treated per day (newly started practice) to 48 patients per day (mature practice).[33] The mean was 17.1 prostate cancer patients treated per day. Eighty-six percent of radiation oncologists within this model were treating both prostate and nonprostate cancer patients. The average combined urology–radiation oncology practice treated 33 patients per day with nonprostate malignancies. Thus, the radiation oncologists responding to our survey who treated both prostate and nonprostate cancer patients treated 1.9 times more nonprostate cancer patients than prostate cancer patients.[33] This may possibly indicate that urologists seek radiation oncologists in an area where radiation oncologists already have an established referral base and bring nonprostate cancer referrals with them.[33] On August 19, 2008, the Office of the Inspector General (OIG) issued an opinion on the relationships between urologists and radiation oncologists that addressed leasing radiation equipment to provide IMRT to prostate cancer patients that urologists diagnose. The OIG expressed concern that urology groups are in a position to choose IMRT instead of other forms of radiation and ensure economic success of a joint venture while assuming minimal business risk. The radiation oncologist would then be able to reward the referring urologist with a profit. The opinion as written states, "We conclude the proposed arrangement could potentially generate prohibited remuneration under the anti-kickback statute."[33] Unfortunately, this opinion applies to equipment leasing arrangements only.

Some hospital medical oncologists, general surgeons, and neurosurgeons also choose a variation of this business model when they combine with radiation oncologists to provide radiation treatment including robotic radiosurgery.[33] Again, the radiation oncologist is in a position to reward the owners of equipment with a profit.

ECONOMIC ISSUES SPECIFIC TO NEW GRADUATES OF RESIDENCY PROGRAMS

Most new graduates are largely concerned about mastering the amount of medical knowledge necessary to become a specialist, as well as passing their radiation oncology boards. Few articles have been written on contracting specific to radiation oncology.[34] A contract is a promise between two parties that the law recognizes as a duty. Five elements are required to create a valid contract: two competent parties, mutual consent, consideration, a legal purpose and duty, and a mutual obligation. When evaluating a first contract, obtaining legal advice from a health care attorney is essential.

The terms and conditions of the contract should set forth working conditions, provision of nursing service, transcription, ancillary help, on-call arrangements, vacation time, and coverage. Arrangements should be spelled out for professional liability insurance coverage including term limits and a tail policy in the event that termination of employment occurs. Duties should be specific to the practice of radiation oncology and not be vaguely worded so the new physician is expected to "perform all duties as the board of directors may assign."[34] The employer should also spell out the terms of potential termination. Reasonable terms of automatic contract termination include loss of your medical license, loss of hospital privileges for patient care issues, loss of a drug enforcement agency license, loss of ability to prescribe controlled substances, conviction of a felony, and so forth. If there is a provision for termination of the contract prior to the end of the term, it should be clear and available to both parties. For example, "either party may terminate this agreement with 90 days written notice with or without cause."[34] Written performance reviews should be given at least quarterly. This assists the employer and the employee to identify potential areas of conflict and allow resolution.

Restrictive covenants protect employers by placing limitations on the rights of the employee to compete with the employer. They should include the period of time the restriction shall remain in effect, as well as the geographic restriction. Because some of these restrictive covenants are not enforceable in certain states, liquidated damages for terminating employment and remaining in an area to compete has also been used by some practices.[34] A liquidated damage clause provides a payment to the practice owner, negotiated in advance, that allows the employed physician to work in the area and compete after the contract is terminated.[34]

Associates are invited to become partners after some period of time, which varies from region to region. Traditionally, this has meant financial parody with the senior partners. Many physicians are being offered positions without a partnership track. Partnership has also traditionally meant voting and decision-making parody. Some groups offer graduated financial parody: the first 2 years may be salaried, and during the next 3 years they may gradually reach financial parody with senior partners in percentage increments. Formulas for buying into the practice are similarly variegated. In a hospital-based practice with an exclusive contract to provide professional services, the buy-in should be minimal, simply because the cost of maintaining the contract is minimal. There is no cost to maintain equipment. One should only purchase assets that have real value or cover the cost of maintaining the contract over time. The accounts receivable are usually generated by the physician during the years of nonpartnership. One questions a "buy-in" for these accounts receivable that the new physician helped to generate. Good will is augmented by the employed physician, who builds and contributes to practice expansion during the nonpartnership years. It is my opinion that accumulated practice goodwill is not worth a great deal financially.

Less than one-third of radiation oncologists are still in their first postresidency job 5 years later.[4,34] If negotiated into the contract, arbitration or mediation can be an effective and cost-efficient means to negotiate a dispute and avoid litigation between parties, should you decide to separate.[4,34]

ECONOMICS OF MEDICAL ONCOLOGY

As a way to achieve prescription drug coverage for our seniors, chemotherapy drug payments became the source of some revenue.[35] The target is huge: Medicare spends $70 billion each year for chemotherapy drugs. Compare that to the amount spent on radiation oncology professional and technical fees, which totals $7 billion per year, and our services appear very cost-effective.[35,36] Outpatient drug reimbursement has changed from paying a percentage of the average wholesale price (AWP) to paying a percentage of the average sales price (ASP). ASP is the sales price that is actually paid by outpatient practices with a tiny margin added, only 6%. Medical oncologists argue appropriately that the administration of chemotherapy does not cover the cost of nursing time, waste disposal, and supplies. Medicare responded to this reality by increasing the fee for administration of the first hour of chemotherapy infusion by over 270% between 2003 and 2004.[36] Because reimbursement for the first hour of chemotherapy has had the most dramatic increase in reimbursement for medical oncology, this makes any regimen that requires multiple days of therapy profitable for our medical oncology colleagues. These include daily or weekly chemoradiation protocols.[36] There is a new drug reimbursement update by Medicare every 12 weeks as the average sales price for chemotherapeutic drugs is recalculated by CMS. There continue to be proposals to reimburse chemotherapy drugs by Medicare at ASP plus 3%—a 50% cut in profit margin.

Consulting groups are letting medical oncologists know that they can profit from incorporating PET scanners, CT scanners, and radiation oncology equipment into their practices. Perhaps more realistically, medical oncologists will be looking for reduction in their overhead through combining with radiation oncologists and being able to enhance patient care by giving daily chemotherapy sensitization protocols within a combined cancer center. Do not build a new cancer center without at least considering adding space for medical oncologists.

MEDICAL ONCOLOGY SUPPLY AND DEMAND: HOW WILL THIS AFFECT RADIATION ONCOLOGY IN THE FUTURE?

The demand for medical oncologists will rise by 48% in the year 2020, but the supply will only rise 14%, creating a 34% shortfall in the number of medical oncologists needed in the workforce. These conclusions were drawn from a study performed by the American Association of Medical Colleges and reported in the *Journal of Oncology Practice*.[37,38] The number of patient visits for medical oncology was determined by the National Cancer Institute analysis of the SEER database. There was no adjustment for the ever-lengthening regimens of palliative or adjuvant chemotherapy, nor was there any adjustment for patients with metastatic cancer who may live longer as a result of palliative treatment and thus require increased patient visits in the future. In his article, Dr. Erickson Salsberg proposes increased use of nurse practitioners and physician assistants and delays in retirement for current medical oncologists. He also proposes increase use of primary care physicians to monitor patients during and after chemotherapy.[37,38] With the shortage of primary care doctors in the United States, this does not seem likely. One of our most respected mentors and long-time leader in radiation oncology, Dr. Luther Brady, teaches residents that we are first and foremost cancer physicians who use radiation as a tool to treat cancer patients. Radiation oncologists are trained in all aspects of solid tumor oncology and can easily direct medical care for cancer patients during their disease process. Given the need, there is every reason for radiation oncologists to see cancer patients for consultation and to design a program for biopsy, workup, and management of their malignancy, even if it does not include delivery of radiation treatment. We encourage radiation oncologists to step up to the plate and provide more consultative services, more direct patient care, more inpatient care, and more general oversight than ever before. This new role may be one of the most important challenges for our specialty. However, if realized, it will benefit countless cancer patients by the year 2020.[38]

PAY FOR PERFORMANCE

CMS continues to move toward pay for performance. Under this system, a physician practice meeting a certain benchmark of quality in patient care does not receive a reduction in Medicare payments. This movement, in its various combinations and permutations, including ACOs, started in 1999 when the Institute of Medicine released a report called *To Err Is Human*.[39] This report documented quality-of-care concerns in our health care system and pointed out that 98,000 people die each year due to preventable medical errors from health care professionals. Subsequently, a Rand study found that many hospital deaths were preventable.[40] In our legislators' minds, the findings of these studies sharpened their resolve to improve the quality of care delivered in our health care system. Pay for performance has the objective of improving the quality of care by linking physician reimbursement to quality measures and outcomes. Pay for performance was first instituted in hospitals. Under the Deficit Reduction Act of 2005, hospitals receive a 2% reduction if they do not report to CMS on 10 quality measures and have acceptable performance targets. This pilot project with hospitals has been viewed by Congress to be successful. The results of quality-of-care measures for these areas are available on the CMS website for any hospital that participates.

Certain specialties lend themselves better to pay-for-performance measures than others. For example, diabetic patients should have retina exams as a component part of their care, and not doing so would not be optimal care for them. The care of cancer patients is, however, quite variegated. As we all know, some patients with brain metastasis live only a few months, and others live for a year or more. Thus, outcome measures for patients who have cancer would probably not be appropriate. It is the physicians themselves within each specialty that should shape the compliance program linked to pay for performance. In this regard, likely the better measure of quality of care would be accreditation of radiation oncology practices. This has not been adopted by CMS to date but is currently required in several states in the United States.[41,42]

RADIATION ONCOLOGY DEPARTMENT: APPROPRIATE STAFFING AND PERSONNEL

Radiation treatment consists of a series of steps and involves a number of different professionals. Each radiation oncology department should establish a staffing program consistent with the level of patient care complexity and other factors within that department. Radiation oncologists can manage 30 to 40 patients per day under continuous radiation treatment. When considering new patient visits and simulation follow-up visits, this translates to 65 to 90 patient encounters per week and allows us sufficient time for treatment planning and clinical functions.[43] Medical physicists should be available when necessary for consultation with the radiation oncologists and to provide advice and direction of the technical staff when treatments are being planned or patient treatment initiated. Chart checks by the physicists should be performed at least once per week. Generally one medical physicist is needed for every 30 to 40 patients under continuous radiation treatment.[43] Medical dosimetrists act under the supervision of the radiation oncologist and medical physicist. There should be one full-time-equivalent dosimetrist per 40 patients under continuous treatment. More dosimetrists may be needed if a larger proportion of patients receive higher-complexity care. Radiation therapy technologists practice under the direction of the radiation oncologists. They should have achieved American Registered Radiologic Technologist (ARRT) certification in radiation oncology.[43,44] One radiation therapist is needed for 20 patients under continuous treatment.[43,44] It is ideal to have two therapists per treatment machine and to allow for vacations, meetings, absences, and so forth. Radiation oncology support staff may include radiation therapist treatment aides, who work under the direct supervision of the radiation therapist and radiation oncologist and are generally trained on site to assist and facilitate patient transport and patient flow.

RADIATION ONCOLOGY STAFF RECRUITING AND RETENTION

In the United States, currently there is a critical manpower shortage in radiation therapy personnel. Regional shortage of therapists, dosimetrists, and physicists creates a "musical chairs" job market: the bell rings and everyone changes position.[4] This situation is neither beneficial to patient care nor fiscally sound for our shrinking health care dollar. For those of us who have depended on temporary workers, we know that this is both an expensive proposition and seriously disruptive to employee morale.[44]

The U.S. Bureau of Labor statistics predicted that by the year 2010, there would be a shortage of 7,000 radiation

therapists.[4,44,45] A shortage of this magnitude did not seem to materialize. One way to stabilize your workforce, create good will, and create excellence in our field is to start a scholarship program for radiation therapy professionals. Currently, most scholarship programs support radiographers to take 1 additional year of training to become radiation therapists. During the time of training, the student can receive a stipend, as well as have his or her tuition and books paid for. In exchange, the candidate agrees to work for the cancer center for a period of years after graduation. One source of candidates can be a local radiography training program. Contact the director of the program and let him or her know that you are offering a scholarship program to qualified candidates. For students who receive monthly stipend support, the best way to ensure that they are serious about accepting the obligation is to have them sign a promissory note. If they fail to honor their contract or pass the registry within a specified period of time, the amount that the practice advanced them becomes immediately due with interest.[4,44]

Although many dosimetrists today are trained "on the job," there are 1-year programs that enroll therapists in full-time dosimetry training. If you have a candidate willing to relocate to one of the cities that has these programs, it is worth the investment to train them outside of your facility and hopefully bring back some fresh ideas. For a radiation therapist who may have a baccalaureate degree in radiation therapy, and for the right individual who wishes to train in medical physics, this may be an opportunity to train a medical physicist for your program.

Opening your practice to scholarship programs and scholarship support creates a unique marketing opportunity for your facilities.[4,44] This also augments cancer center morale, where the seasoned employees can teach the new graduates the tricks of the trade.[4,44]

PRACTICE ACCREDITATION

Practice accreditation is a way to demonstrate the quality of radiation oncology practice to the public, as well as third-party payers. Practice accreditation may be one avenue whereby a practice demonstrates quality and distinguishes itself. Currently, ACRO and the American College of Radiology (ACR) are the two practice accreditation bodies for radiation oncology practices. Some states (Alabama, New Jersey, and New York) require practice accreditation for state certification.[4,41,45]

Most importantly, practice accreditation constitutes a mechanism to accomplish quality assurance and assess compliance with recognized standards for hospital or free-standing radiation oncology practices.[4,41,45] Practice accreditation can also be a value-added qualification for third-party payers; some will require it in the future.

Standards for accreditation should include external review of randomly selected radiation oncology treatment courses, peer review, and quality assurance activities performed regularly; physics and dosimetry standards consistent with drafted standards for external-beam radiation treatment and brachytherapy; and medical physics quality assurance.[41,42,45] An onsite verification visit by both physicists and physicians is essential to practice accreditation.[45]

ECONOMICS OF RADIATION ONCOLOGY: SELECTED INTERNATIONAL PERSPECTIVES

The rate of installation of megavoltage radiation therapy equipment was compared in Canada, Germany, and the United States.[4,46] Rublee[4,46] concluded that the higher proliferation of radiation equipment in the United States promoted rapid access to advanced medical services but was not necessarily associated with improved outcomes, more patient utilization, or efficient use of health care funds. He noted an average rate of growth of 10.3 radiation therapy units per million persons in the United States, 4.6 units per million persons in Germany, and 4.8 units per million persons in Canada.

Canada's socialized health care system creates some access problems for cancer patients. During the years 1982–1991, the waiting times for radiation treatment in Canada, specifically documented in Ontario, deteriorated. Prostate cancer patients waited longer than 3 months and larynx cancer patients waited longer than 1 month for treatment. During this time, patients often advanced a stage or required treatment that was more extensive than initially planned. This was well documented in a series of published articles indicating the waiting times for breast, cervix, larynx, and prostate cancers. The Canadian Association of Radiation Oncologists Commission on Standards recommended that intervals between treatment and consultation not exceed 2 weeks' time. This led to a scoring system that scores the severity of curative cancer patients and urgency in starting radiation treatment. Curable head and neck cancers received the highest score, whereas curable prostate cancers received the lowest. This system sorts access to radiation treatment.[47,48]

Radiation oncologists in China note that they have a single governmental payer system with socialized medicine and staggering cost increases. Patients in China who require chemotherapy are required to pay cash up-front for their medication prior to its delivery. With respect to radiation oncology, radiation oncologists note a dearth of intensity-modulated radiation treatment, image-guided radiation treatment, and access to 3D conformal radiation treatment.

Calvo and Santos[49] describe monetary limits on the investment in innovative radiation treatment techniques in Western Europe. These authors note that the need for cost containment in the public health care system in Western European countries has slowed investment in stereotactic radiosurgery, conformal radiation treatment, high–dose-rate brachytherapy, and intraoperative radiation treatment. They reported on cost–benefit analysis of each of these technologies. Their conclusion was that Western Europe was not adopting new technology rapidly enough.[49]

Radiation oncologists responding to our survey in England felt that access to curative radiation oncology was good. However, access to palliative radiation oncology was suboptimal.[4]

Radiation oncologists in the Netherlands felt that their cancer programs limited neither access nor the development of new technology. Dutch radiation oncologists reported limited waiting times for patients to start radiation treatment.[4]

Radiation oncologists in South America and Latin America cited too few radiation oncology installations particularly in Mexico, Bolivia, and Venezuela. They also noted a rapidly growing number of radiation oncology installations especially in Argentina.[50] The latter have tended to be for-profit centers. Deficiencies in radiation oncology services in Latin America are attributed to a shortfall of equipment. Approximately 100 more teletherapy machines are needed, increasing equipment need by 14%. There is currently less than one radiation oncologist per teletherapy machine and less than one radiation oncologist for 1,000 new radiation oncology patients.[50] A 69% increase in radiation oncologists would be needed to fill the void, and the number of radiation therapists would need to increase by 109% across Latin America. Currently, 69% of Latin American installations have no fluoroscopic or CT simulation.[50] However, Latin American radiation oncologists point with pride to the Latin American Association of Therapeutic Radiation and Oncology. This organization currently serves their needs and is trying to augment staffing and physicians and enroll more Latin American patients in cooperative randomized trials.

Radiation oncologists in the Scandinavian countries of Denmark and Sweden showcase their innovative, large, and integrated cancer centers. They do point out that they are geographically distant from each other, but there appears to be minimal to no limit in their access to new technology, nor long waiting times for patient treatment.[4]

Practice accreditation is uncommon internationally. However, ACRO currently has accredited a number of international facilities, and practice accreditation in other countries continues to be in greater demand and is growing.[4,45]

In general, countries with socialized medicine have certain defined limits on capital investment each year. As our technology grows ever more costly, these issues will need to be dealt with both at home and in the international community.[4]
