- Trauma to soft tissues (eye, brain, tongue, salivary gland ducts, and neurovascular structures)
- Transposition of tooth/root fragments into the mandibular/infraorbital canal and nasal passages
- Iatrogenic jaw fracture

RECOMMENDED MONITORING

Vital pulp therapy and root canal therapy require follow-up radiography under sedation/anesthesia at 6 months postoperatively and yearly thereafter.

PROGNOSIS AND OUTCOME

- In periodontally sound teeth (teeth without concurrent periodontal pockets or bone loss), root canal therapy fails in only 6% of treated roots (dependent on skill of the operator).
- Animals likely to continue abusive chewing habits may benefit from placement of prosthodontic metal crowns.

PEARLS & CONSIDERATIONS

COMMENTS

- Functionally significant teeth (i.e., those teeth on which the animal depends for chewing, prehending, cosmesis, or other functions—the importance of which varies from patient to patient) should be preserved with endodontic therapy rather than being extracted.
- Although root canal therapy can be performed for almost any dog tooth, endodontic therapy in cats is often not feasible because of size, except for the canine teeth.
- Dental radiography is an important diagnostic tool in determining appropriate treatment.

PREVENTION

Appropriate chew toys will allow for decreased plaque and calculus accumulation without fracturing teeth. Owners should avoid very hard treats and toys such as real bones, nylon bones, ice cubes, cow hooves, and rocks.

TECHNICIAN TIPS

- Technicians can help prevent tooth fractures with proper education. Discuss appropriate chewing habits, treats, and toys during wellness visits.
- Technicians may be the first to notice subtle tooth fractures during professional dental cleanings. Bringing these fractures to the veterinarian's attention and becoming accustomed to taking dental radiographs of fractured teeth are important parts of oral health provision.

CLIENT EDUCATION

Root canal therapy causes less postoperative discomfort than tooth extraction.

Tooth Displacement Injuries

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

- Concussion and subluxation: injuries to the periodontal tissues, with little or no tooth loosening or displacement and with mild hemorrhage and edema in the periodontal space. Usually do not require treatment.
- Luxation: partial displacement of the tooth in an axial (intrusion, extrusion) or lateral direction, usually accompanied by extensive injury to the pulp and periodontal ligament and (except in case of extrusion) fracture of the alveolar bone as well as soft-tissue laceration
- Avulsion: complete displacement of the tooth out of the alveolus, with total tearing of periodontal fibers and shearing of the pulp neurovascular supply
- Replantation/reimplantation: replacement of the tooth in its alveolar socket

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Occasionally reported in dogs and cats
- More common in dogs than cats, with lateral luxation following fights with other animals most commonly reported
- Maxillary incisor and canine teeth are most commonly affected.

RISK FACTORS

- Loss of attachment due to periodontitis or other diseases causing alveolar bone lysis
- Young age: alveolar bone and periodontal ligament of teeth of young animals more resilient than the same tissues of older individuals

ASSOCIATED CONDITIONS & DISORDERS: Trauma: other oral, cranial, thoracic or abdominal injuries

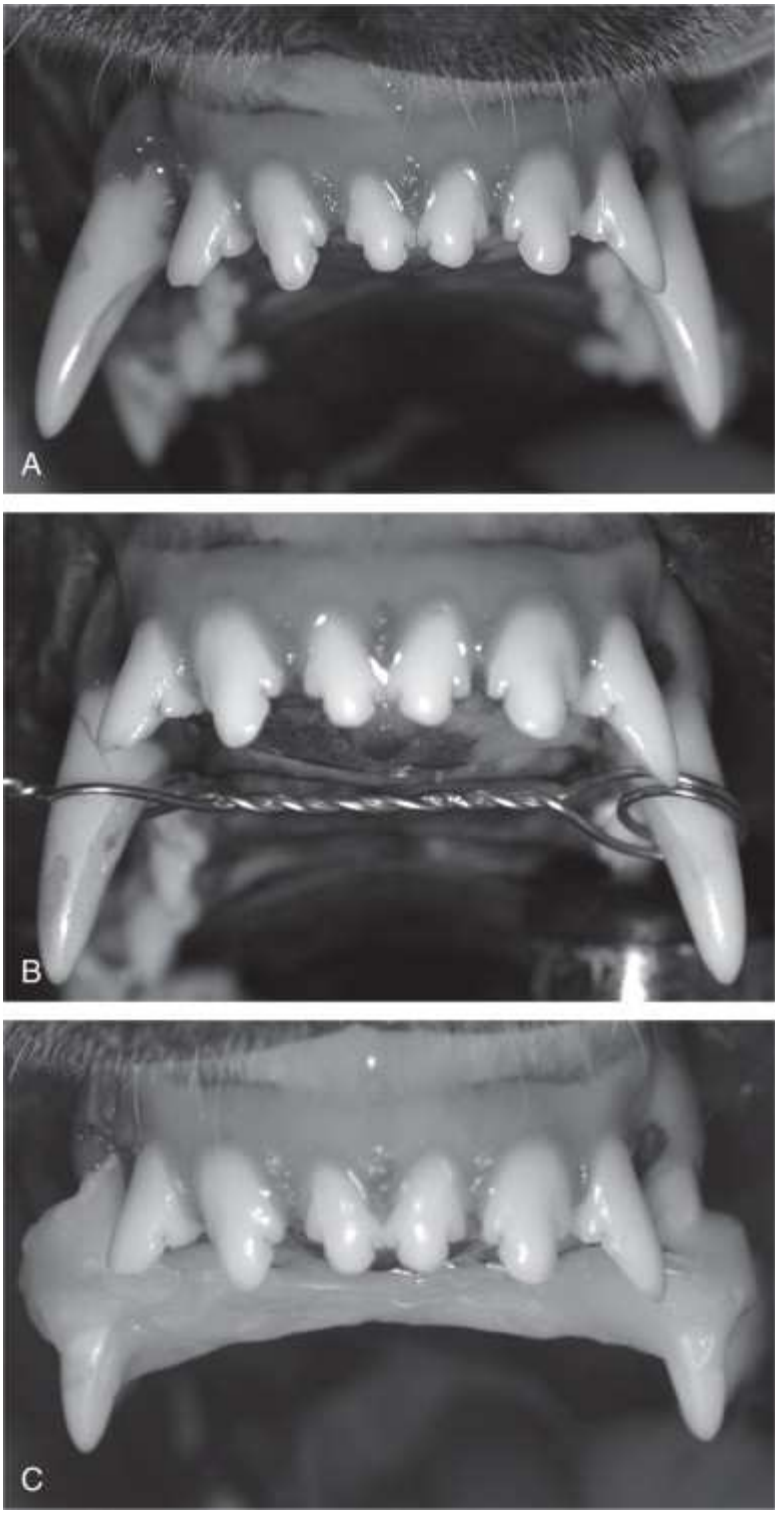
CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Owners usually report a recent traumatic event and oral hemorrhage.
- Anorexia, oral pain, continuous licking, and abnormal facial profile may be present.

PHYSICAL EXAM FINDINGS

- Lateral luxation: hemorrhage from the periodontal space, abnormal mobility and displacement of the tooth crown in a labial direction, laceration of gingiva and alveolar mucosa
- Extrusive and intrusive luxation: tooth elongation or shortening, with increased or decreased mobility; hemorrhage from the periodontal space
- Avulsion: empty alveolar socket, eventually filled with blood clots and debris
- All: evaluate teeth adjacent to a displaced tooth for structural defects or abnormal mobility, which may indicate periodontal trauma, root fracture, or bone fracture.



TOOTH DISPLACEMENT INJURIES A, Lateral luxation of right maxillary canine tooth in a dog, following a fight with another dog. **B**, Wire placement following replantation of luxated tooth. **C**, Completed splint after placement of cold-cured composite resin over the wire.

(Courtesy Dr. Margherita Gracis.)

ETIOLOGY AND PATHOPHYSIOLOGY

Energy and direction of impact determine type of displacement. A frontal impact may cause concussion or subluxation if mild to moderate, or cause luxation or avulsion if severe. A horizontal force usually causes lateral displacement, and an oblique force causes extrusion. Intrusion follows an impact in an axial direction.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis of more severe tooth displacement requires a thorough oral, periodontal, and radiographic examination. Diagnosis of dental concussion and subluxation may be difficult or impossible to make because clinical and radiographic signs may be mild or absent.

DIFFERENTIAL DIAGNOSIS

- Increased tooth mobility and displacement (lateral luxation): root fracture, bone fracture, neoplasia
- Decreased tooth mobility (intrusive luxation): incomplete tooth eruption, root replacement resorption, dentoalveolar ankylosis
- Tooth elongation (extrusive luxation): buccal bone expansion and idiopathic tooth extrusion
- Missing tooth (avulsion): congenital or acquired (postextraction) missing tooth, unerupted tooth, crown-root fracture with retained root tip

INITIAL DATABASE

Routine preoperative blood work; no specific associated abnormalities expected

ADVANCED OR CONFIRMATORY TESTING

Dental radiographs (see p. 1246) of the affected tooth and surrounding tissues; intraoral techniques are preferred over extraoral techniques, to avoid superimposition with other structures of the head.

TREATMENT

TREATMENT OVERVIEW

Treatment goals include prompt tooth replantation, bone fracture reduction (lateral luxation), and treatment of periodontal and pulpal injuries. Replantation requires a minimum level of surgical skills and competence and should be performed at the emergency visit. For endodontic treatment, the case should be referred to a veterinary dentist.

ACUTE GENERAL TREATMENT

- Keep avulsed tooth moist in commercial tissue culture media, cold low-fat milk, or egg albumin (raw egg white) until replantation.
- Start systemic tetracycline hydrochloride (20 mg/kg PO q 8 h for 4 weeks) or amoxicillin (22 mg/kg PO q 12 h for 4 weeks) immediately.
- Induce general anesthesia if patient is stable.
- Obtain dental radiographs to evaluate the extent of injury.
- Rinse alveolus and tooth root with sterile saline. To avoid damage to viable periodontal fibers, do not scrape the root surface, and do not use chlorhexidine solution.
- Soak the avulsed tooth in 5% doxycycline solution for 5 minutes before replantation.
- Gently replant the tooth manually, and confirm its position radiographically.
- Suture lacerated soft tissues with thin, absorbable suture material.
- After scaling and polishing, splint the replanted tooth to adjacent teeth with or without wire reinforcement using an acid-etch resin technique and cold-cured composite or acrylic resin applied to 1-3 teeth mesially and distally.
- Perform temporary root canal treatment with calcium hydroxide or anti-inflammatory medicaments (e.g., 1% triamcinolone) to inhibit inflammatory root resorption (optional).
- Smooth the splint, and check the occlusion before recovery from anesthesia.
- Orthodontically move an intruded tooth into position over a few weeks.

CHRONIC TREATMENT

- Remove the splint 1-2 weeks (avulsion and extrusion) or 4-6 weeks (lateral luxation and intrusion with extensive bone fracture) after replantation.
- Perform definitive root canal therapy at the time of splint removal.

BEHAVIOR/EXERCISE

Limit chewing activity on toys and other hard materials while a splint is in place.

POSSIBLE COMPLICATIONS

- Pulp necrosis, pulp infection, tooth discoloration, root canal obliteration
- Inflammatory root resorption, replacement resorption, dentoalveolar ankylosis
- Loss of marginal alveolar bone

RECOMMENDED MONITORING

Regular radiographic follow-ups for several years after replantation

PROGNOSIS AND OUTCOME

- Good prognosis after immediate replantation followed by proper endodontic treatment
- Poor prognosis after delayed replantation, long-term and rigid splinting, and delayed endodontic treatment
- In humans, concussion injuries have the best prognosis, followed by subluxation and extrusion. Lateral luxation, intrusion, and avulsion show the highest incidence of complications.

PEARLS & CONSIDERATIONS

COMMENTS

- Tooth luxation and avulsion are dental emergencies. Immediate replantation and splinting are mandatory for successful treatment.
- Severed pulp tissue may survive for 2 hours in an extraoral environment. Periodontal fibers survive 30 minutes if dry and 1-3 hours if kept moistened.
- In most instances, endodontic treatment is necessary after replantation.
- Displaced deciduous teeth should be extracted rather than replanted.
- Extraction of displaced permanent teeth is an alternative to replantation.

CLIENT EDUCATION

- Recommend soft diet and daily oral hygiene when an oral splint is in place.
- Discuss the need for endodontic treatment, radiographic follow-ups, and possible complications before tooth replantation is performed.

AUTHOR: MARGHERITA GRACIS

EDITOR: ALEXANDER M. REITER

Tonsillar Disorders

BASIC INFORMATION

DEFINITION

Abnormal structure or function of the palatine tonsils, usually manifest as increased size, often with protrusion from the tonsillar fossa

SYNONYM

Palatine tonsillar disorders

EPIDEMIOLOGY

SPECIES, AGE, SEX: Occasionally seen in dogs; less frequent in cats. No known sex predilection. Acute tonsillitis appears to be more frequent in animals <1 year of age.

CONTAGION & ZOONOSIS

- Group A *Streptococcus pyogenes* ("strep throat" in humans) does not cause signs of tonsillitis in dogs or cats.
- Rates of infection in dogs or cats from contact with infected humans appear low; in rare circumstances, infected dogs or cats not showing clinical signs may serve as a source of reinfection to humans in the household.

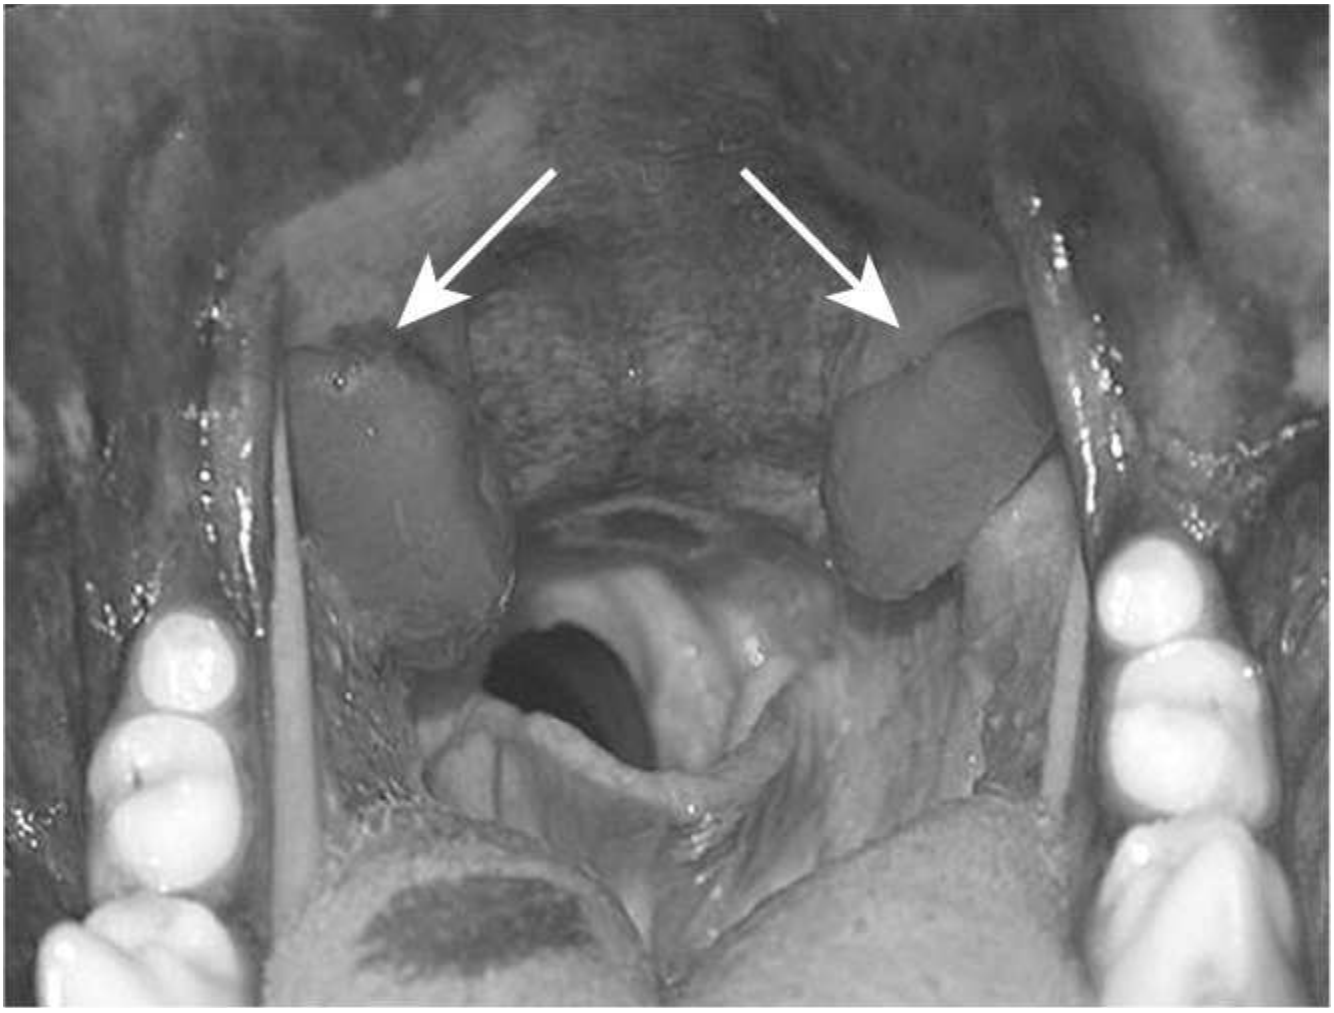
CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: Tonsillar enlargement often is an incidental finding; when present, signs may include dysphagia/retching, coughing, ptyalism, and inappetence. The clinical signs of the underlying disease may often be more clinically significant than the signs attributable to tonsillar enlargement.

PHYSICAL EXAM FINDINGS: Bilaterally or unilaterally enlarged palatine tonsils; with tonsillitis, the tonsils are often bright red and protruding from the tonsillar crypts. There may be petechiae or a purulent exudate on the tonsils or in the tonsillar crypts. Fever is common with infectious disease.

ETIOLOGY AND PATHOPHYSIOLOGY

- The palatine tonsils are sentinels for exposure to antigens that enter through the mouth and nose; unlike lymph nodes, they have no afferent drainage region and therefore, reactive tonsillar enlargement arises from exposure through the oral cavity.
- Primary tonsillitis: bacterial or viral colonization of the lymphatic tissue of the tonsils. The tonsils are a common portal of entry for enteric bacteria and viruses.
- Secondary tonsillitis: results from chronic pharyngeal irritation, such as recurrent vomiting, regurgitation, or coughing; may also result from chronic pharyngitis secondary to elongated soft palate, immunosuppression from feline immunodeficiency virus (FIV), chronic contamination of the oropharynx with pathogenic bacteria in cases of chronic periodontal disease, or licking of distant infected sites such as skin or anal sacs.
- Swallowed foreign bodies such as grass awns or wood splinters may become lodged in the tonsillar crypt.
- Tonsillar cyst: embryonic remnant
- Neoplasia: squamous cell carcinoma (SCC) or lymphoma may develop from the epithelial or lymphoid components of the tonsils, respectively.



TONSILLAR DISORDERS Intraoral view of a dog with marked bilateral enlargement of the tonsils *(arrows)*.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Most cases of bilateral tonsillar enlargement are benign and secondary to such processes as licking infected material. The diagnostic goal is to rule out neoplasia. If a single tonsil is irregular and enlarged, suspect squamous cell carcinoma or foreign body. If both tonsils are enlarged, along with other lymphoid tissues such as peripheral lymph nodes, suspect lymphoma. Suspected neoplastic cases can be confirmed with fine-needle aspirates or biopsy.

DIFFERENTIAL DIAGNOSIS

Symmetric/bilateral tonsillar enlargement:

- Primary tonsillitis:
  - Bacteria: streptococci, staphylococci, coliforms, canine infectious tracheobronchitis
  - Viruses: feline panleukopenia, canine distemper, infectious canine hepatitis, rabies
  - Parasites: *Pneumonyssoides caninum* nasal mites
- Secondary tonsillitis:
  - Pharyngeal irritation: chronic vomiting, regurgitation, or coughing
  - Anatomic abnormalities: elongated soft palate, cleft palate
  - Oropharyngeal contamination: anal sac disease (licking at distant site), pyoderma (licking at distant site), possibly periodontal disease
  - In racing greyhounds, lymphoid hyperplasia of the tonsils and tonsillar enlargement are associated with respiratory disease and poor performance.

TONSILLAR DISORDERS Intraoral view of tonsils in a normal dog for comparison.

Unilateral tonsillar enlargement:

- Foreign body (e.g., grass awn or splinter in tonsillar crypt)
- Tonsillar cyst

Unilateral or symmetric/bilateral tonsillar enlargement:

- Neoplasia: tonsillar lymphoma or SCC

INITIAL DATABASE

- CBC, serum biochemistry profile, and urinalysis to identify underlying systemic disease
- Feline leukemia virus (FeLV) and FIV testing of cats

ADVANCED OR CONFIRMATORY TESTING

- Bacterial culture and sensitivity (C&S) or virus isolation in cases of primary tonsillitis that fail to respond to routine antibiotics
- General anesthesia and tonsillar fine-needle aspirate (FNA) cytologic examination or biopsy:
    - Specific indications: unilateral tonsillar enlargement or tonsillar enlargement that does not resolve (or worsens) despite identification and treatment of underlying disease

TREATMENT

TREATMENT OVERVIEW

- Treat the underlying disease
- Tonsillectomy is only indicated with the following:
    - Chronic recurrent tonsillitis unresponsive to antibiotic therapy and elimination of source of antigen (e.g., licking infected area)
    - Marked tonsillar enlargement interfering with swallowing or breathing
    - Neoplasia

ACUTE AND CHRONIC TREATMENT

- Primary tonsillitis with no identifiable etiology: broad-spectrum antibiotics if necessary (e.g., ampicillin or amoxicillin at 20 mg/kg PO q 8-12 h, 10-14 days)
- Chronic tonsillitis: antibiotic therapy based on C&S results
- Foreign-body retrieval
- Tonsillar lymphoma: chemotherapy for lymphoma
- SCC: surgical excision followed by chemotherapy (e.g., doxorubicin or epirubicin and cisplatin or carboplatin) and radiation therapy
- Incidentally discovered bilateral/symmetric tonsillar enlargement is often most appropriately treated with only monitoring (watchful waiting) while the underlying cause is sought and treated.

PROGNOSIS AND OUTCOME

- Tonsillitis: good prognosis, usually resolves with underlying disease
- Neoplasia: poor long-term prognosis

PEARLS & CONSIDERATIONS

COMMENTS

- Therapeutic intervention for enlarged tonsils is rarely required.
- The most common cause of symmetric/bilateral tonsillar enlargement is a reactive change in response to oral exposure to antigen, such as the pet licking his/her anal sacs or genitalia. Therefore, diagnostic investigation and treatment should focus on these processes first, then on the tonsils only if necessary.

EDITOR: ETIENNE CÔTÉ

Toad or Lizard Intoxication

BASIC INFORMATION

DEFINITION

Toxicoses associated with exposure to toads of the genus *Bufo;* generally characterized by severe neurologic and cardiovascular effects (hypersalivation/foaming, head shaking, tremors, ataxia, collapse, seizures, cardiac arrhythmias, and death)

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs are more likely to mouth the toads than are cats.

GEOGRAPHY AND SEASONALITY

- In the United States, the greatest number of cases is seen in Florida. Cases occur across the United States (California to New England, Florida to Ohio), Hawaii and the Caribbean.
- Wet conditions (e.g. hurricanes, high rainfall) may predispose to increased *Bufo* numbers.
- Peak months are June through September.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Witnessed or suspected exposure (mouthing by the dog or cat; some dogs will swallow the toad)
- Hypersalivation, head shaking
- Sudden onset of collapse, seizures

PHYSICAL EXAM FINDINGS

- Hypersalivation/foaming
- Head shaking
- Vomiting
- Tachypnea
- Ataxia
- Seizures
- Stupor
- Pale mucous membranes or cyanosis
- Cardiac arrhythmias:
    - Sinus tachycardia
    - Bradycardia; atrioventricular (AV) block

ETIOLOGY AND PATHOPHYSIOLOGY

- Two species of toads have been associated with poisonings:
    - *Bufo marinus* (cane toad, marine toad, giant toad): sizes of 4-9.5 inches (10-25 cm); found in southern tips of Florida and Texas, much of the Caribbean, and Hawaii
    - *B. alvarius* (Colorado River toad): sizes 3-7 inches (8-18 cm); found in southeasternmost California, across the southern half of Arizona, and southwesternmost New Mexico
- Modified parotid glands (skin glands) of toads excrete several toxins known as *bufogenins,* including marinobufagin and bufotoxins. Clinical signs are likely caused by a combination of toxins
    - Action of bufogenins and bufotoxins is similar to that of cardiac glycosides (such as digitalis [see p. 175 and online chapter: Digoxin Toxicosis]), which inhibit Na+/K+-ATPase activity in myocardial cells; this process leads to increased intracellular calcium and blockage of sodium channels, resulting in cardiac anhythmias.
    - Secondary toxins in the parotid secretions may include bufotenins, serotonin, 5-hydroxytryptophan, powerful hallucinogenic tryptamines (found in *B. marinus* and *B. alvarius),* or catecholamines and could be responsible for such other signs as gastrointestinal (GI) upset, tremors, hyperthermia, and seizures

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Tentative diagnosis is based on observed or suspected exposure to a toad and acute onset of a startled, agitated, and hypersalivating patient. Digoxin irnmunoassay may aid confirmation of exposure in questionable cases.

DIFFERENTIAL DIAGNOSIS

- Cardiac glycoside toxicity (e.g., digoxin/digitalis, foxglove, lily of the valley)
- Illicit or prescription drug intoxication

INITIAL DATABASE

- Blood pressure (BP; see p. 1209):
  - Hypotension is common and may require treatment.
- Electrocardiogram (ECG; see p. 1253):
  - Various cardiac arrhythmias
- Serum potassium:
  - Hypokalemia or hyperkalemia may be present

TREATMENT

TREATMENT OVERVIEW

Management is based primarily on whether the toad has been merely mouthed and released (rinse the mouth immediately) or has been chewed and/ or swallowed (more aggressive intervention and cardiac and neurologic monitoring/management are indicated). Common effects requiring treatment include bradycardias or tachycardias, hypotension, electrolyte disturbances, and seizures.

ACUTE GENERAL TREATMENT

- Immediately rinse the patient's mouth with running water for 5 minutes.
- If a toad has been ingested and the animal is not showing overt clinical signs of toxicosis:
  - Induction of vomiting:
    - Hydrogen peroxide 3%, 0.25-0.5 mL/kg PO once; *or*
    - Apomorphine, 0.04 mg/kg IV, IM, SQ, or conjunctivally
  - Administration of activated charcoal:
    - Dose according to packaging label of product (e.g., 10 mL of activated charcoal suspension PO made from 2 g activated charcoal suspended in 10 mL tap water).
- IV fluids ± colloids to correct shock and hypotension
- Correct hyperkalemia or hypokalemia if present (see pp. 556 and 577).
- Control seizures with diazepam (0.5-1 mg/kg IV) or barbiturates as needed.
- Monitor and control anhythmias:
  - Atropine, 0.02-0.04 mg/kg IV or IM, for significant bradycardia. Do not use atropine to treat hypersalivation alone because it can predispose the patient to arrhythmias.
  - Propranolol, 0.02-0.06 mg/kg via slow IV, or other beta-blocker only for extremely rapid, sustained sinus tachycardia. Reflex tachycardia may occur secondary to hypotension and must not be suppressed; correct hypotension before treating tachycardia.
  - Lidocaine, 2 mg/kg IV bolus followed by 50-80 mcg/kg/min (constant rate infusion) for ventricular tachyarrhythmias
- Oxygen supplementation for severe cases (see p. 1318):
  - Address cerebral edema if suspected (collapsed or comatose patient: furosemide [dog, cat], 1-2 mg/kg IV; mannitol [dog, cat], 0.25-1 g/kg IV over 15-20 min).
- Digibind (Glaxo Wellcome), a digoxin-specific Fab fragment for poorly responsive or deteriorating animals:
  - Determine serum digoxin levels for dosing Digibind. Empirically, can use multiple vials with minimal risk (good safety profile; see online chapter: Digoxin Toxicosis).
  - High cost and large amounts needed for treatment may make Digibind impractical in many cases.

RECOMMENDED MONITORING

- ECG, blood pressure, oxygen tension

- Neurologic status
- Serum potassium

PROGNOSIS AND OUTCOME

Good if signs are mild; guarded if both neurologic and cardiac signs develop

PEARLS & CONSIDERATIONS

COMMENTS

- Exposure to other North American toads such as *B. americanus* (American toad), *B. boreas* (western toad), *B. cognatus* (Great Plains toad), *B. terrestris* (southern toad), *B. valliceps* (Gulf Coast toad), and *B. woodhousei*(Woodhouse toad) may result in only mild hypersalivation; severe systemic signs are unlikely.
- Several species of salamanders and newts (e.g., California newt) may contain tetrodotoxin in their skin and muscles. Ingestion can cause vomiting, muscle weakness, ataxia, hypotension, bradycardia, and an ascending paralysis with respiratory arrest. Treatment is centered on supportive care.
- Gila monsters *(Heloderma suspectum)* and the Mexican beaded *lizard (Heloderma horridum)* are two venomous lizards found in North America. Gila monsters are found in the southwestern part of the United States, while the Mexican bead lizard is found in the southwestern part of Mexico and Guatemala. The lizards' bites tend to be defensive; they will hang on after biting, so they can inflict considerable mechanical trauma in addition to envenomation. The venom can cause local pain, weakness, vomiting, muscle fasciculation, hypotension, and tachycardia or anaphylaxis. Treatment consists of wound irrigation, antibiotics, analgesia, management of hypotension if present, and monitoring for systemic signs. Antivenin is not commercially available.
- Blue-tailed skinks *(Plestiodon* [formerly *Eumeces]* spp., family Scincidae) are anecdotally reported to cause acute vocalization, ataxia, hypersalivation, labored respirations, and generalized weakness in cats; not all ingestions cause clinical signs. While this American lizard is endemic east of the Mississippi River from Michigan and Ontario southward, most reports are from Florida, and clinical cases appear to respond to general supportive treatment; little is known regarding a toxic principle

Ticks

BASIC INFORMATION

DEFINITION

Ectoparasites that feed on the blood of their hosts and can be divided into hard (ixodid) and soft (argasid) ticks. Ixodid ticks are highly parasitic, produce more progeny, and infest larger areas compared to argasid ticks.

EPIDEMIOLOGY

SPECIES, AGE, SEX: Ixodid ticks (*Ixodes*, *Dermacentor*, *Rhipicephalus*, *Amblyomma*, *Haemaphysalis* spp.) are more commonly found on dogs than on cats.

RISK FACTORS: Canine hunting breeds (greater environmental exposure)

CONTAGION & ZOONOSIS: Infected animals may act as a source of transmission to other animals and people.

GEOGRAPHY AND SEASONALITY: Ixodid ticks:

- *Ixodes scapularis* (black-legged tick): the Midwest and the northeastern and southeastern parts of the United States; borreliosis [Lyme disease] (also transmitted by *I. pacificus*)
- *Dermacentor variabilis* (American dog tick): throughout North America but most commonly found along the Atlantic Coast in areas of shrub and beach grass; Rocky Mountain spotted fever, tick paralysis, tularemia
- *Rhipicephalus sanguineus* (brown dog tick): widely distributed throughout North America; babesiosis, ehrlichosis, and tick paralysis
- *Amblyomma americanum* (lone star tick): found throughout the southeastern and south central states; tularemia
- *Haemaphysalis* spp. (yellow dog tick): Africa and Asia

Argasid ticks:

- *Otobius megninii* (spinous ear tick) in arid areas of North America, South America, India, and South Africa

ASSOCIATED CONDITIONS & DISORDERS

- Anaplasmosis
- Babesiosis
- Borreliosis (Lyme disease)
- Ehrlichiosis
- Rocky Mountain spotted fever
- Tick paralysis
- Tularemia

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES: Ticks can injure animals by producing tick paralysis through their secretions, causing localized irritation via bites, producing hypersensitivity reactions, and serving as vectors for bacterial, viral, protozoal, and rickettsial diseases.

HISTORY, CHIEF COMPLAINT: Owners note a tick infestation. Generally the patient is either in or has traveled to an area known to be tick-infested.

PHYSICAL EXAM FINDINGS: Presence of ticks noted on the skin. Clinical signs vary from none to the presence of a nodule at the site of tick attachment or systemic signs of tickborne diseases (ehrlichiosis, Lyme disease, Rocky Mountain spotted fever, babesiosis, tick paralysis, tularemia). Ticks are most commonly found on the pinnae of the ears or within the interdigital spaces.

ETIOLOGY AND PATHOPHYSIOLOGY

- Heavy infestations can lead to significant blood loss.
- Several types of neurotoxins produced by a variety of ticks affect the lower motor neurons of the spinal cord and cranial nerves and produce a progressive ascending flaccid paralysis (tick paralysis).

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis is based on noting the presence of ticks on the skin and then evaluating for localized and/or systemic disease if appropriate historical and/or physical signs exist.

DIFFERENTIAL DIAGNOSIS

Tickborne systemic disorders:

- Tick paralysis
- Rocky Mountain spotted fever: caused by *Rickettsia rickettsii*; causes a necrotizing vasculitis
- Ehrlichiosis: caused by *Ehrlichia canis* (other species exist also); vasculitis, hematologic disorders, and facial dermatitis
- Lyme disease: caused by *Borrelia burgdorferi*; in dogs: fever, neurologic signs, polyarthritis
- Tularemia: vectors are *D. andersoni*, *D. variabilis*, *D. occidentalis*, and *A. americanum*

INITIAL DATABASE

- Examine the entire skin for ticks, paying special attention in the ears and between the toes.
- Perform a complete physical examination; if clinical signs and history warrant, specific (serologic) testing should be done for the various tickborne diseases.

TREATMENT

TREATMENT OVERVIEW

Treatment should involve the efficient removal of attached ticks, performing proper environmental control measures, and treating localized reactions or transmitted diseases.

ACUTE GENERAL TREATMENT

- Tick removal as soon as possible:
  - Soak the tick in isopropyl alcohol while it is still attached to the animal's skin. Then, using a pair of hemostats, grasp the head parts at the surface of the skin and apply firm traction with a gentle twist.
- Effective approved antiparasitic treatments for dogs include Fipronil (Frontline) and acaricidal collars containing amitraz (Preventic). Fipronil (Frontline) may be effective for tick control in cats.
- Repeated spraying of the internal (kennel) and external environments with approved pesticides may be effective for controlling or eliminating infestations with *R. sanguineus*.

PROGNOSIS AND OUTCOME

Prognosis is good, but reinfestation can occur if preventive measures to prevent exposure are not undertaken.

PEARLS & CONSIDERATIONS

PREVENTION

- Avoid environments with large tick populations.
- May require strict indoor sequestration
- Selamectin (Revolution) is effective in control of *R. sanguineus* and *D. variabilis* on dogs and is safe to use on cats. Imidacloprid-permethrin (Advantix) is effective in controlling *D. variabilis* when applied monthly on dogs.
- Immunotherapy with a tick vaccine has been proposed.
- Tick habitats can be destroyed by cutting and burning brush and grass, cultivating land, and rotating pastures.
- Grassy and shrubbed areas can be treated with appropriately registered pesticides in urban areas; application is done in the spring and repeated once during midsummer.

CLIENT EDUCATION

- Inform clients that tick control/prevention can be challenging because ticks have long lifespans, are widely prevalent in the environment, have remarkable reproductive capabilities, and spend short time periods on their hosts.
- Infected animals may act as a source of transmission to people.

EDITOR: MANON PARADIS

Tick Paralysis

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

An acute, rapidly progressive generalized lower motor neuron (LMN) paralysis that results from neuromuscular blockade due to a salivary neurotoxin produced by certain gravid, female tick species

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Any age or breed; both sexes
- North American tick paralysis *(Dermacentor* ticks) affects dogs but not cats; Australian tick paralysis *(Ixodes* ticks) affects dogs and cats.

GENETICS & BREED PREDISPOSITION: Any species; incidence is rare in the cat.

RISK FACTORS: Tick exposure CONTAGION & ZOONOSIS: Some ticks may cause tick paralysis in humans; animal-to-animal or zoonotic transmission does not occur.

GEOGRAPHY AND SEASONALITY

- Recognized worldwide; most in-depth reports from the United States and Australia
- Incidence is most frequent in the summer months.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- History of hind limb and then forelimb stiff gait that progresses to flaccid paralysis
- Mentation, behavior, and ability to urinate and defecate remain normal.

PHYSICAL EXAM FINDINGS

North America *(Dermacentor* spp. ticks):

- Hind limb weakness rapidly progressing to generalized weakness, then complete flaccid paralysis. Tail wag often is preserved.
- Cranial nerve involvement is rare, but nystagmus or mild facial palsy may be observed.
- Pain sensation is preserved, but hyperpathia is rare.
- Voice change and intercostal muscle paresis can be observed, potentially leading to ventilatory failure (respiratory paralysis).

Australia *(Ixodes* spp. ticks):

- Hind limb weakness rapidly progressing to generalized weakness, then complete flaccid paralysis. Tail wag often is preserved.
- Pain sensation is preserved, but hyperpathia is rare.
- Signs of facial paralysis, dysphagia, and megaesophagus are common and may be profound.
- Autonomic signs (mydriasis, peripheral vasoconstriction, arterial and pulmonary hypertension) can be observed. If left undiagnosed, respiratory paralysis and death may ensue.

ETIOLOGY AND PATHOPHYSIOLOGY

- Gravid female tick of the species *D. variabilis* (Eastern wood or dog tick), *D. andersoni* (Rocky Mountain wood tick) in the United States, and *Ixodes holocyclus* in Australia.
- Adult *D. variabilis* and *D. andersoni* female ticks elaborate the neurotoxin; adult female, nymphs, and larvae of *Ixodes* ticks are incriminated.

- The neurotoxin is secreted by the engorged feeding female tick; the toxin either inhibits depolarization in the terminal portions of motor nerves or blocks the release of acetylcholine (ACh) from the motor nerve terminals at the neuromuscular junction.
- The toxin may affect both the motor and sensory nerve fibers by altering ionic fluxes that mediate action potential production.
- In most cases, hind limb weakness begins days after tick attachment, 5-9 rapidly followed by generalized weakness and complete flaccid paralysis as well as areflexia within 24-72 hours.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis rests entirely on finding tick(s) in an animal with compatible clinical signs. Delay to finding and removing tick(s) can affect prognosis markedly.

DIFFERENTIAL DIAGNOSIS

- Polyradiculoneuritis
- Early stages of botulism
- Fulminant myasthenia gravis

INITIAL DATABASE

- Response to tick removal is confirmatory: patient's rapid clinical improvement after tick removal (within 24 hours for *Dermacentor* spp. and return to normalcy in 48-72 hours; clinical signs may initially progress for 24-48 hours after tick removal for *Ixodes* spp.)
- Exclusion of other causes of rapidly progressive LMN diseases (see Differential Diagnosis, above)
- Hematologic and biochemical profiles are usually normal

ADVANCED OR CONFIRMATORY TESTING

- Chest and abdominal radiographs are usually normal (exception: megaesophagus *[Ixodes* spp.])
- Electromyography:
  - Shows no evidence of denervation
  - Amplitude of evoked motor potentials is markedly reduced.
  - Repetitive stimulation does not cause further decrement in amplitude.
- Nerve conduction velocity (motor and sensory) may be slightly slower; terminal conduction times may be prolonged.

TREATMENT

TREATMENT OVERVIEW

Since tick removal is both diagnostic and therapeutic, additional treatment consists of supportive care until the clinical signs resolve.

ACUTE GENERAL TREATMENT

- Tick removal can be curative; remember to remove the head, since the toxin resides in the salivary glands.
- Insecticide if ticks are not found
- Whole-body shaving if long-haired patient (tick search)
- Hyperimmune serum (0.5-1 mL/kg IV): recommended for binding circulating neurotoxin and preventing further progression in the dog; caution regarding anaphylaxis risk.
- Autonomic dysfunction can be treated with a combination of phenoxybenzamine hydrochloride, 1 mg/kg as a 0.1% solution given IV over 15 minutes q 12-24 h; and acepromazine, 0.05-0.1 mg/kg IV q 6-12 h.
- Oxygen and ventilatory support necessary for animals with respiratory compromise.

CHRONIC TREATMENT

- Supportive care
- Physical therapy
- Sanitation
- Provision of food and water
- Recurrence is possible with reexposure

DRUG INTERACTIONS

Avoid aminoglycosides (associated with neuromuscular blockade).

POSSIBLE COMPLICATIONS

- Respiratory paralysis (especially with recurrent exposure)
- Decubital ulcers
- Aspiration pneumonia

RECOMMENDED MONITORING

- Respirations
- Urination/defecation
- Progression of signs

PROGNOSIS AND OUTCOME

- Highly dependent on timely identification and removal of tick(s)
- Excellent if rapid removal of *Dermacentor* tick (in United States); fatal if undiagnosed/untreated
- Guarded with *Ixodes* ticks (Australia); fatal if undiagnosed/untreated

PEARLS & CONSIDERATIONS

COMMENTS

- Consider time of the year in the differential diagnosis.
- Note rapid (24-72 hours) progression to areflexic flaccid paralysis, which should raise the suspicion of tick paralysis and prompt a meticulous examination of the skin and coat.
- Make sure whole tick is removed, because the toxin lies in the tick's head (salivary glands).
- Make sure the animal is shaved if heavily funed so that identifying the tick(s) (if present) is easier.

TECHNICIAN TIP

Identifying and removing a tick (including mouth parts) from the skin of a patient with a presumptive diagnosis of another neuromuscular disease can be lifesaving.

PREVENTION

- Avoid tick exposure.
- Use insecticides at appropriate doses.
- Avoid reexposure.

EDITOR: CURTIS W. DEWEY

Thyroid Carcinoma

BASIC INFORMATION

DEFINITION

Most common malignant neoplasm of the thyroid gland. Thyroid carcinomas are uncommon in dogs, accounting for 1.2%-4% of all canine tumors. They are very rare in the cat.

SYNONYM

Thyroid adenocarcinoma

EPIDEMIOLOGY

SPECIES, AGE, SEX: Usually older dogs; median age at diagnosis is 9-10 years; no sex predilection.

GENETICS & BREED PREDISPOSITION: Any breed; beagles, boxers, and golden retrievers may be at increased risk.

RISK FACTORS: Radiation exposure; possibly iodine deficiency or excess

ASSOCIATED CONDITIONS & DISORDERS

- Hypothyroidism
- Hyperthyroidism
- May occur as part of multiple endocrine neoplasia syndromes

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Histologic classification:
  - Follicular cell origin; papillary, follicular, compact or anaplastic
  - Medullary tumors (parafollicular or C-cell carcinomas) are rare.
- Functional classification:
  - Hypofunctional (30%), normal function (60%), or hyperfunctional (10%)

HISTORY, CHIEF COMPLAINT

- Ventral cervical mass, cough, dysphagia, dysphonia, dyspnea, facial edema (see p. 263) are recognized chief complaints.
- With concurrent hypothyroidism, the patient may manifest lethargy, poor haircoat, or other signs of hypothyroidism (see p. 558).
- With concurrent hyperthyroidism, the patient may have polyphagia, polyuria and polydipsia, weight loss, restlessness, and tachypnea (see p. 558).
- With medullary carcinoma, the patient may manifest diarrhea and tetany (hypocalcemia).

PHYSICAL EXAM FINDINGS

- The normal paired thyroid glands lie lateral to the trachea and just caudal to the larynx. A thyroid carcinoma is generally palpable as a cervical mass that is subcutaneous and usually lateralized, firm, sessile/broad-based, asymmetric, irregular, and nonpainful; may be fixed or movable.
- With concurrent hyperthyroidism, tachycardia is possible.

ETIOLOGY AND PATHOPHYSIOLOGY

- Etiology is unknown.
- Metastasis to the lungs or regional lymph nodes is common: ≈30%-50% of affected animals have clinically detectable metastasis at the time of diagnosis.
- Local invasion of vital vascular and neurologic structures, including external carotid artery, external jugular vein, and

vagosympathetic trunk, are common. In these cases, full excision is impossible, contributing substantially to morbidity and mortality.
- Unilateral tumors are more common than bilateral tumors.
- Ectopic thyroid tissue can occur anywhere from the base of the tongue to the heart.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis of thyroid neoplasia involves confirming the abnormal tissue is of thyroid origin (cytologic/histopathologic evaluation and/or advanced imaging). This confirmation and appropriate staging allows the development of a comprehensive treatment plan.

DIFFERENTIAL DIAGNOSIS

Cervical mass:

- Other primary tumors: soft-tissue sarcoma, salivary gland adenocarcinoma, parathyroid neoplasia, lymphosarcoma
- Metastatic tumors: oral squamous cell carcinoma (SCC), oral melanoma
- Abscess or granuloma
- Salivary mucocele

INITIAL DATABASE

- CBC, serum biochemical profile, and urinalysis:
  - Usually normal
  - Mild anemia possible
  - If hypothyroidism: fasting hypercholesterolemia is common
  - If medullary carcinoma: hypocalcemia likely
- Serum total thyroxine (T4), free T4, and endogenous thyroid-stimulating hormone (TSH) concentrations: results depend on functional status of tumor (see p. 588 and 562)
- Thoracic radiographs (three views): possible metastasis
- Fine-needle aspirate (FNA) of regional lymph nodes: possible metastasis
- Cervical ultrasound: can help assess the extent of tissue invasion and vascularity

ADVANCED OR CONFIRMATORY TESTING

- FNA of the mass:
  - These are often difficult to assess cytologically because of heavy contamination with peripheral blood, and neoplastic cells may not exfoliate well. It is not possible to differentiate benign versus malignant thyroid tumors based on cell characteristics.
  - May help rule out nonthyroidal tumors such as lymphoma or metastasis from an oral tumor
  - Risk of persistent hemorrhage even with small-gauge needle
- Needle biopsy: greater diagnostic yield than an aspirate but high risk of hemorrhage. This biopsy should not be performed without ultrasound guidance, and even with such guidance, both the owner and animal should be prepared for immediate surgery if intractable bleeding occurs.
- Cervical exploratory surgery for incisional biopsy and histopathologic evaluation
- CT scan with contrast enhancement or MR imaging: helps differentiate thyroidal from nonthyroidal cervical masses; assesses tissue invasion and feasibility of surgical excision and can also be useful in planning radiation therapy.
- Thyroid scintigraphy (technetium-99m [^{99m}Tc]-pertechnetate scan): may identify ectopic or metastatic tissue, can help predict radioactive iodine (^{131}I) uptake, and can be used after surgery to identify residual disease.

TREATMENT

TREATMENT OVERVIEW

Surgical excision is the best treatment for freely movable tumors without deep tissue invasion. If complete surgical excision is not possible, halting/slowing tumor growth and metastasis become the primary goals. Any related thyroid dysfunction needs to be addressed with medications.

ACUTE GENERAL TREATMENT

- The best treatment option depends on tumor size, mobility, and functionality and whether metastasis is present.
- Nonfixed tumor without metastasis: thyroidectomy
- Fixed/locally invasive tumor without metastasis: surgical debulking (if debulking is not possible because of vascularity or extent of invasion, initial radiation therapy may shrink the tumor so that surgical debulking becomes possible), or radiation therapy can be used as definitive treatment.
- Fixed or nonfixed tumor with metastasis: surgical debulking, palliative or definitive radiation therapy
- Local residual disease: radiation therapy and/or chemotherapy (doxorubicin and/or cisplatin; consult a veterinary oncologist for treatment regimen details).
- Metastatic disease: chemotherapy as already described
- Use of ^{131}I: effectiveness in dogs controversial. Can be considered for residual and/or metastatic disease if the thyroid tissue is functional, but higher doses are required than those used for treating benign disease.

CHRONIC TREATMENT

- If hyperthyroidism is not present: T4 supplementation may be helpful insofar as T4 inhibits endogenous TSH secretion, and TSH may stimulate remaining tumor cells (see p. 588).
- If hyperthyroidism is present: methimazole, 2.5-5 mg PO q 8 h, to decrease systemic signs and treat thyrotoxicosis prior to definitive treatment.

POSSIBLE COMPLICATIONS

- Tumor alone: anemia, hypercalcemia (paraneoplastic—adenocarcinoma), hypocalcemia (paraneoplastic—medullary carcinoma), respiratory distress, disseminated intravascular coagulation
- Surgery: extensive hemorrhage, laryngeal paralysis, postoperative hypoparathyroidism and hypothyroidism (if bilateral excision)
- External beam radiation therapy: mucositis, dry to moist skin desquamation, and alopecia within the treatment field
- Chemotherapy: myelosuppression, cardiotoxicity (doxorubicin), nephrotoxicity (cisplatin)

RECOMMENDED MONITORING

- Bilateral thyroidectomy: monitor serum calcium concentrations for 7-10 days.
- Chemotherapy: monitoring dependent on protocol used
- General: physical examination, thoracic radiographs, and ± serum T4 concentrations every 3 to 4 months

PROGNOSIS AND OUTCOME

- Long-term prognosis usually guarded to poor because of tumor size, local invasion, and relatively high incidence of metastasis at the time of diagnosis; however, tumors with a volume <20 cm^3 are less likely to have metastasized, and surgery may be curative if the tumor is movable.
- Neither chemotherapy nor external beam radiation therapy is curative, but long-term progression-free intervals (>3 years) have been reported in some dogs treated with the latter.

TECHNICIAN TIP

Since prognosis and ease of excision improve with early detection, incidentally finding a mass in the cranial ventral neck can be very important and is always worth bringing to the attention of the attending veterinarian.

Thymoma

BASIC INFORMATION

DEFINITION

A benign or malignant primary tumor originating from the thymic epithelium. Clinically, the presenting complaints for animals with thymoma are signs caused by the space-occupying nature of the mediastinal mass or by paraneoplastic syndromes such as myasthenia gravis, megaesophagus, and hypercalcemia.

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Dog: average age is 8-10 years.
- Cat: average age is 9-12 years.

GENETICS & BREED PREDISPOSITION: Dog: large-breed dogs (Labrador retriever, German shepherd) may be more commonly affected.

ASSOCIATED CONDITIONS & DISORDERS

- Paraneoplastic syndromes associated with thymoma:
  - Myasthenia gravis (20%-50% of dogs with thymoma)
  - Hypercalcemia
- Immune-mediated syndromes (less common):
  - Polymyositis, dermatitis (e.g. feline thymoma-associated exfoliative dermatitis), and myocarditis
- Megaesophagus
- Cardiac arrhythmias: rare
- Cranial vena cava syndrome (see p. 263): rare

DISEASE FORMS/SUBTYPES: Epithelial-dominant, lymphocyte-dominant, and mixed forms exist and can make diagnosis by fine-needle aspiration difficult.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Respiratory signs: very common chief complaints (dyspnea, coughing); signs may be surprisingly mild given size of thymoma.
- Anorexia and weight loss also common
- Weakness: associated with myasthenia or hypercalcemia
- Regurgitation: if megaesophagus is present

PHYSICAL EXAM FINDINGS

- Respiratory system: muffled or absent lung and heart sounds due to pleural effusion and/or space-occupying nature of mass:
  - Increased, harsh lung sounds: aspiration pneumonia
- Weakness: episodic or sustained; associated with loss of muscle tone, decreased spinal reflexes. Can be focal, associated with the pharyngeal, laryngeal, or facial muscles.
- Decreased chest wall compliance noted with manual compression of the cranial thorax:
  - Important physical finding in cats with medium to large thymomas

ETIOLOGY AND PATHOPHYSIOLOGY

- Neoplastic transformation of thymic epithelial cells
- Cranial mediastinal mass ± pleural effusion:
  - Clinical signs of respiratory compromise
- Paraneoplastic syndrome of myasthenia gravis:
  - Result of aberrant immune stimulation

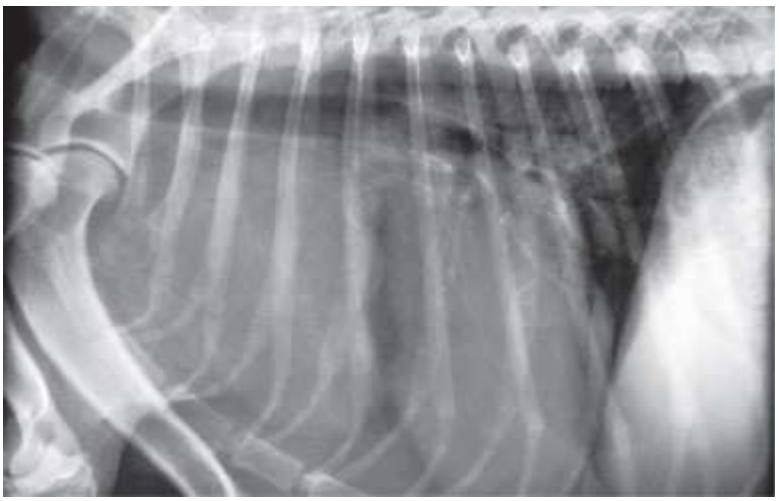
DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis of thymoma is suspected based on presenting history, physical examination findings, and the demonstration of a well-defined cranial mediastinal mass on thoracic radiographs. Ultrasound-guided fine-needle aspirates or needle biopsies are required to confirm the diagnosis and rule out other causes such as mediastinal lymphoma. CT scan helps determine whether the mass is surgically resectable.

DIFFERENTIAL DIAGNOSIS

- Thymic lymphoma
- Thymic hyperplasia
- Thymic hemorrhage
- Branchial cyst
- Ectopic thyroid or parathyroid neoplasia
- Neurogenic tumor
- Heart base tumor
- Mediastinal abscess or granuloma



THYMOMA Lateral thoracic radiograph. A large soft-tissue/fluid opacity mass occupies the entire cranial thorax of this dog, elevating the trachea.

(Courtesy Dr. Richard Walshaw.)

INITIAL DATABASE

- CBC, serum biochemical profile, and urinalysis:
  - Preoperative evaluation
- Feline leukemia virus (FeLV) and feline immunodeficiency (FIV) serologic testing in cats
- Survey thoracic radiographs (three views):
  - Extent of primary neoplasm
  - Evidence of metastasis
  - Evidence of megaesophagus and/or aspiration pneumonia (secondary to myasthenia gravis)
  - Pleural effusion
- Thoracic ultrasound:
  - Morphologic examination of mass, including association with/invasion of vascular structures, presence or absence of cysts
  - Fine-needle aspirate (FNA) cytologic examination/needle biopsy of mass:
    - Rule out lymphoma
  - Collection of pleural fluid (analysis, cytologic examination)
- Survey abdominal radiographs, ultrasound:
  - Rule out abdominal organ involvement:
    - Lymphoma

ADVANCED OR CONFIRMATORY TESTING

- MRI (see p. 1302) or CT (see p. 1233) scan: determine whether surgical excision is a viable treatment option. Evaluate compression, displacement, invasion, or incorporation of adjacent structures (e.g., vessels, esophagus, trachea) and metastasis. Evaluation of invasion of the cranial vena cava, however, is difficult. Contrast administration does not assist in determining cell type of mediastinal masses.
- Acetylcholine (ACh) receptor antibody titers: positive with thymoma-associated myasthenia gravis
- Flow cytometry of samples collected by fine-needle aspirate and stored in fetal bovine serum may be useful in differentiating thymoma from lymphoma. The test utilizes T-cell marker expression of CD4 and CD8 on T cells; >20% expression of CD4 and CD8 is consistent with thymoma, and lack of CD4 and CD8 expression rules out thymoma.

TREATMENT

TREATMENT OVERVIEW

Complete surgical resection is the recommended treatment for thymoma.

ACUTE GENERAL TREATMENT

- Complete surgical excision: often feasible with thymoma. May be carried out thoracoscopically (see p. 1340) for noninvasive thymoma.
- Incomplete surgical excision: more likely when thoracic ultrasonography reveals invasion into or attachment to local vessels. The size of thymoma is not necessarily predictive of complete versus incomplete resection
    - Chemotherapy:
        - Lymphoma protocol (see pp. 673 and 674)
    - Radiation therapy
- Nonresectable masses:
    - Radiation therapy ± chemotherapy
- Myasthenia gravis (see p. 736):
    - Resolution following complete resection of neoplasm
    - Prednisone, 2 mg/kg PO q 24 h for 4 weeks, then tapered
    - Hypercalcemia (see p. 553)
    - Aspiration pneumonia (see p. 1583):
        - Antibiotic therapy: based on culture and sensitivity (C&S) testing
    - Megaesophagus (see p. 709):
        - Consider tube gastrostomy for medical and nutritional support
- Therapeutic thoracocentesis (see p. 1338):
    - If respiratory compromise
    - Preanesthetic patient stabilization

THYMOMA Dorsoventral radiograph of same dog. Midline location suggests a mediastinal mass. Surgical excision and histopathologic analysis confirmed thymoma.

(Courtesy Dr. Richard Walshaw.)

CHRONIC TREATMENT

- Chemotherapy for nonresectable disease:
  - Lymphoma protocol (see pp. 673 and 674)

POSSIBLE COMPLICATIONS

- Inability to resolve the associated myasthenia gravis:
  - Persistent regurgitation
  - Recurring aspiration pneumonia
  - Intraoperative hemorrhage
- Regrowth of thymoma: occurs in some cases after complete surgical resection as well as cases with incomplete surgical resection. Monitoring is essential regardless of completeness of resection

RECOMMENDED MONITORING

- Following surgical resection (complete or incomplete):
  - Every 3 months (exam, thoracic radiographs) for 1 year, then every 6 months
- If patient is receiving chemotherapy:
  - As determined by protocol

PROGNOSIS AND OUTCOME

Dog:

- Resectable thymoma without megaesophagus: 70%-80% 1-year survival. 50% 3-year survival
- Nonresectable thymoma: poor
- Presence of myasthenia gravis or megaesophagus: guarded to poor; may resolve over a period of months

Cat:

- Resectable thymoma: 2-year median survival, 89% 1-year survival, 74% 3-year survival

PEARLS & CONSIDERATIONS

COMMENTS

- Adjuvant radiation therapy ± chemotherapy may benefit animals with nonresectable thymoma.
- Closely monitor animals for development of aspiration pneumonia and myasthenia gravis after surgery.

TECHNICIAN TIPS

- Knowledge of and experience in working with thoracostomy tubes is important in the postoperative management of patients who have undergone a thoracotomy.
- Patients with megaesophagus will require nutritional support (see p. 709):

SUGGESTED READING

Zitz JC, Birchard S, Couto GC, et al: Results of excision of thymoma in cats and dogs: 20 cases (1984-2005). J Am Vet Med Assoc 232:1186, 2008.

AUTHOR: MARYANN G. RADLINSKY

EDITOR: RICHARD WALSHAW

Thymic Hemorrhage

BASIC INFORMATION

DEFINITION

Accumulation of blood in the parenchyma of the thymus

SYNONYM

Thymic hematoma

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Generally an uncommon disease that occurs primarily in dogs; rare cases in cats have been reported.
- Thymic hemorrhage has been described predominantly in dogs <2 years of age, although it has been seen in older dogs.

GENETICS & BREED PREDISPOSITION: No sex or breed predilections have been identified, but in some reports, German shepherds have been overrepresented.

RISK FACTORS: Potential risk factors that have been identified include:

- Thoracic trauma or cervical stretching
- Exposure to anticoagulant rodenticides
- Thymic neoplasia (uncommon)

ASSOCIATED CONDITIONS & DISORDERS

- Hemothorax
- Hemomediastinum
- Hemopericardium (with heart base thymic remnants)

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Acute onset of lethargy, depression
- Tachypnea, respiratory distress
- Increased respiratory effort
- Sudden death

PHYSICAL EXAM FINDINGS

- Mucous membrane pallor
- Tachycardia
- Tachypnea
- Muffled heart sounds and decreased lung sounds ventrally are possible.
- Pain with compression of the cranial thorax

ETIOLOGY AND PATHOPHYSIOLOGY

- Intrathymic bleeding secondary to thymic trauma or a coagulation disorder, such as vitamin K rodenticide toxicity, will be the proximate cause identified in some cases.
- The initiating cause may not be identified in some animals.
- Another proposed cause includes bleeding from increased vessel fragility associated with normal thymic involution.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The initial key to the diagnosis of thymic hemorrhage is having suspicion for the disorder in young animals with unexplained anemia and respiratory distress.

DIFFERENTIAL DIAGNOSIS

- Other causes of hemothorax such as:
  - Trauma
  - Anticoagulant rodenticide toxicosis
  - Intrathoracic neoplasia
- Other causes of hemopericardium:
  - Heart base tumors
  - Right atrial hemangiosarcoma
  - Pericarditis
- Occult blood loss into other sites such as the gastrointestinal (GI) and urinary tracts.

INITIAL DATABASE

- CBC: anemia; thrombocytopenia has been described in some animals.
- Serum biochemical profile: hypoproteinemia (hypoalbuminemia and hypoglobulinemia)
- Thoracic radiographs/ultrasound: pleural effusion or a mediastinum widened by a soft-tissue density (hemorrhage)

ADVANCED OR CONFIRMATORY TESTING

- Thoracocentesis and fluid analysis will confirm hemothorax.
- Prolongations of one-step prothrombin time (PT) and activated partial thromboplastin time (APTT) will be expected in animals with anticoagulant rodenticide toxicity. These animals may also have increases in serum levels of proteins induced by vitamin K absence or antagonism (PIVKA); toxicologic analysis could reveal high concentrations of specific rodenticides identified in blood samples.
- Cardiac ultrasound and pericardiocentesis can rule out or document the presence of heart base masses/tumors and pericardial effusion (hemopericardium), respectively.

TREATMENT

TREATMENT OVERVIEW

Treatment goals are to identify an underlying cause whenever possible and provide hemodynamic support.

ACUTE GENERAL TREATMENT

- IV fluids (crystalloids, colloids)
- Blood products (whole blood, packed red blood cells [RBCs], plasma) or hemoglobin solutions (e.g., Oxyglobin).
- Vitamin K1 for animals with historic or laboratory features suggestive of anticoagulant rodenticide toxicity

POSSIBLE COMPLICATIONS

Complications of treatment or of the primary disease have not been described for those animals that survive.

RECOMMENDED MONITORING

- Clinical signs
- Packed cell volume (PCV), total protein
- PT, APTT, particularly as vitamin K1 therapy is discontinued

PROGNOSIS AND OUTCOME

- Most reported cases have been associated with fatal outcomes, possibly because of the low clinical suspicion of the disease and delay in diagnosis and treatment.
- Provision of timely, aggressive supportive care in the form of fluids and blood products and administration of vitamin K1 for animals with known or suspected rodenticide toxicosis have been associated with survival of some affected animals.

PEARLS & CONSIDERATIONS

COMMENTS

- Perform thoracic radiographs on young animals with an acute onset of respiratory distress and anemia of undetermined origin. Consider the diagnosis if there is evidence of a mass or density in the mediastinum or if the animal has pleural effusion (hemothorax).
- When hemorrhage is documented or suspected in the absence of a history of trauma, assess coagulation parameters to rule out coagulation disorders.

TECHNICIAN TIPS

- It may be difficult to place an IV catheter in patients with severe hemodynamic collapse; an intraosseous catheter (proximal humerus, proximal femur) is a viable substitute for initial fluid or blood component therapy.
- Patients that receive hemoglobin solutions will have discolored plasma and urine for a time after administration, and the free hemoglobin can interfere with a number of laboratory test results.

PREVENTION AND CLIENT EDUCATION

Avoid trauma and exposure to rodenticides.

AUTHOR & EDITOR: RANCE K. SELLON

Thrombocytopenia, Immune-Mediated

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

Thrombocytopenia resulting from idiopathic destruction of platelets. A causative etiologic agent cannot be identified.

SYNONYM

Idiopathic thrombocytopenic purpura (ITP)

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs are far more frequently affected than cats; reported in male and female dogs from 8 months to 15 years of age, with middle-aged females predisposed.

GENETICS & BREED PREDISPOSITION: Cocker spaniels, Old English sheepdogs, German shepherds, and poodles are overrepresented.

ASSOCIATED CONDITIONS & DISORDERS: Immune-mediated diseases may affect multiple body systems; for example, immune-mediated thrombocytopenia (IMT) may be associated with polyarthritis or proteinuria. Anemia may be due to blood loss (especially gastrointestinal [GI]) or concurrent immune-mediated hemolytic anemia (Evans syndrome).

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES: Primary IMT remains idiopathic despite investigation. Secondary IMT occurs in association with infection, drug therapy, or neoplasia.

HISTORY, CHIEF COMPLAINT: Owners commonly notice bleeding in the skin, from the nose or mouth, or associated with minor trauma. Frank blood in the stool or melena may be detected. The patient may continue to eat and act normally, although some cases present with lethargy and weakness. Signs caused by bleeding into vital organs (brain, spinal cord) are an uncommon presentation.

PHYSICAL EXAM FINDINGS

- Petechiae, ecchymoses
- Ocular hemorrhage/hyphema
- GI bleeding, manifesting as melena or hematochezia noted after defecation, on rectal examination, or on a thermometer
- Pale mucous membranes
- Fever: present in <20% of cases

ETIOLOGY AND PATHOPHYSIOLOGY

- Occurs when a stimulus triggers a patient with the appropriate susceptibility genes
- The identification and inheritance of predisposing genes are unknown.
- Triggering factors may include vaccination, drug administration, stress, or infection.
- Bleeding does not occur until the platelet count is less than 25,000/µL, although bleeding may occur in the face of higher platelet counts if the platelets are dysfunctional (thrombocytopathia; see p. 881).

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis is suspected in patients showing overt signs of bleeding in the history, physical exam, or both and is confirmed by demonstrating repeatable severe thrombocytopenia (<50,000/µL) in the absence of an identifiable cause.

DIFFERENTIAL DIAGNOSIS

- Breed-associated physiologic thrombocytopenia (greyhounds and Cavalier King Charles spaniels)
- Thrombocytopathia (drug-related, inherited, von Willebrand disease; see online chapter: Platelet Dysfunction)
- Tickborne disease (ehrlichiosis, anaplasmosis, Rocky Mountain spotted fever)
- Splenic disease (neoplasia, torsion, infarction)
- Drug administration (chemotherapy, antibiotics, estrogen, nonsteroidal antiinflammatory drugs [NSAIDs], albendazole, griseofulvin, propylthiouracil, ketoconazole)
- Recent vaccination
- Bacterial sepsis, vasculitis, disseminated intravascular coagulation
- Bone marrow disease (myelofibrosis, myelodysplasia, necrosis, myelophthisis)
- Severe hemorrhage (anticoagulant rodenticide, trauma)
- Cats: feline leukemia virus (FeLV), feline immunodeficiency virus (FIV) infections

INITIAL DATABASE

- CBC with manual differential: usually normal unless excess bleeding causes anemia
- Platelet count: low, usually <25,000 µL (severe thrombocytopenia)
- Biochemical profile: usually normal
- Urinalysis (voided):
  - Usually normal or may show hematuria
  - Avoid cystocentesis in any severely thrombocytopenic animal.
- Coagulation profile: usually normal
- Thoracic radiographs: usually normal
- Abdominal ultrasonography: usually normal or may show mild splenomegaly
- Titers for tickborne diseases in endemic

ADVANCED OR CONFIRMATORY TESTING

- Bone marrow cytologic examination is unnecessary in most cases (only necessary if the animal has concurrent leukopenia or nonregenerative anemia): may show increased (peripheral platelet destruction) or decreased (marrow-based destruction) megakaryocytes
- Testing for platelet-bound antibody is unnecessary in most cases.

TREATMENT

TREATMENT OVERVIEW

Severe bleeding may require transfusion (uncommon); cases with profound thrombocytopenia, signs of blood loss (e.g., lethargy, pallor), or owner inability to control activity require hospitalization. Stable patients may be treated as outpatients, with therapies aimed at raising the platelet count into the normal range and correcting the underlying cause if present. In some cases, it may be preferable to allow a low grade of thrombocytopenia to persist to decrease medications to tolerable levels.

ACUTE GENERAL TREATMENT

- Prednisone/prednisolone, 2.2 mg/kg PO q 24 h or divided q 12 h (alternative: dexamethasone, 0.2 mg/kg IV q 24 h or divided at q 12 h)
- Vincristine, 0.02 mg/kg (or 0.5 mg/m^2) IV once weekly
- Azathioprine, 2.2 mg/kg PO q 24 h
- Red blood cell (RBC) transfusions (fresh whole blood, packed cells) given as needed (see p. 1347)
- Platelet transfusions usually are impractical, since platelets are immediately destroyed.
- Human IV immunoglobulin (0.5 g/kg slowly IV q 24 h × 1-3 days) has been effective in refractory cases.

CHRONIC TREATMENT

- Discontinue vincristine once platelet count is >50,000 µL or if no response.
- Taper prednisone/prednisolone and azathioprine together once platelet count has normalized
- Decrease doses by half every month (in general) while monitoring platelet count.
- The minimum duration of therapy is 4-6 months.
- Increase to the previous dose, and attempt to taper more slowly if the platelet count falls during the drug tapering.

BEHAVIOR/EXERCISE

Activity and excitement should be minimized to avoid self-trauma until a normal, stable platelet count is achieved and all clinical signs

have resolved.

DRUG INTERACTIONS

- Extravasation of vincristine must be avoided because it causes severe skin necrosis; use an indwelling IV catheter.
- Avoid drugs such as aspirin or other NSAIDs.

POSSIBLE COMPLICATIONS

- Avoid the use of cyclophosphamide; hemorrhagic cystitis may be fatal.
- Prolonged administration of azathioprine may cause bone marrow suppression; monitor CBC and decrease dosage once platelet count returns to normal.
- Thrombosis has been rarely seen in patients after rapid rise of the platelet count. Patients with rapid (<3-5 days) rise of their platelet count to >200,000/ µL. may have their immunosuppressant medications tapered more quickly and/or antithrombotic medication administered (clopidogrel, 1 mg/kg PO q 24 h for 30 days).

RECOMMENDED MONITORING

- Platelet counts every other day until >50,000 µL, then weekly until normal
- CBC 1 week after starting azathioprine, then every 2 weeks while on daily dosing. Bone marrow suppression is unusual once azathioprine is tapered to 2.2 mg/kg every other day, so CBC need only be monitored every 2-3 months.

PROGNOSIS AND OUTCOME

- The prognosis is initially guarded, with fatal bleeding into the brain or spinal cord possible.
- Response often takes 3-10 days.
- Once the platelet count normalizes, the prognosis is fair to good.
- Many pets may be completely tapered from immunosuppressive medications, although relapse remains possible.

PEARLS & CONSIDERATIONS

COMMENTS

- The presence of severe thrombocytopenia (<25,000 µL in an otherwise healthy-appearing animal is most likely due to IMT.
- If bleeding is present when the platelet count >25,000 µL, an additional problem such as clotting factor deficiency, thrombocytopathia, or vasculitis must be present.
- Many animals are euthanized owing to adverse effects of glucocorticoids. Strategies to decrease glucocorticoid-induced adverse effects include avoidance of obesity, substituting prednisone with methylprednisolone or prednisolone, use of an additional immunosuppressive agent and lower glucocorticoid doses, and routine monitoring for infection of the skin and urinary tract.
- Combination immunosuppressive therapy with azathioprine is often more effective and has fewer adverse effects than prednisone or prednisolone alone.

PREVENTION

- Although a **link** has not been proven, future vaccinations should be limited to those considered absolutely essential.
- Stressful circumstances should be avoided if possible to avoid triggering relapse during remission and to reduce the risk of minimal but catastrophic self-trauma during severe thrombocytopenia.

TECHNICIAN TIPS

Venipuncture should be performed with the least possible trauma and pressure maintained over the vein for a full 60 seconds. Venipuncture from the jugular veins should be avoided to lessen the chance for cervical bleeding.

CLIENT EDUCATION

- Routine monitoring should be scheduled to detect relapse of disease and side effects of immunosuppressive medications.
- Weight must be carefully monitored and obesity avoided.

Third Eyelid Abnormalities/Protrusion

BASIC INFORMATION

DEFINITION

- Scrolled cartilage is an everted scrolllike malformation of the third eyelid.
- Third eyelid gland prolapse is a dorsal displacement of the gland from the base of the third eyelid.
- Protrusion of the third eyelid is a dor-solateral displacement of a normal third eyelid structure, typically as a result of alteration of ocular or orbital contents, orbital muscular tone, or globe position.
- Neoplasia of the third eyelid involves a smooth or irregular mass or diffuse thickening of the third eyelid; adenocarcinoma is reported to be most common; papilloma is second most common.

SYNONYMS

- Third eyelid: nictitating membrane, membrana nictitans
- Scrolled cartilage: everted cartilage, bent cartilage
- Third eyelid gland prolapse: cherry eye, Haws syndrome
- Third eyelid inflammatory disorders:
    - Plasma cell infiltration of the third eyelid: plasmoma, pannus, or chronic superficial keratitis of the third eyelid
    - Nodular granulomatous episclerokeratitis of the third eyelid: nodular episcleritis, nodular fasciitis (dogs)
    - Proliferative (eosinophilic) keratoconjunctivitis (cats)
    - Follicular conjunctivitis: lymphofollicular conjunctivitis
- Third eyelid protrusion: elevation of third eyelid

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Scrolled cartilage: congenital/early developmental disorder (dogs and cats)
- Third eyelid gland prolapse: generally occurs before 2 years of age (dogs and cats)

GENETICS & BREED PREDISPOSITION

- Scrolled cartilage: familial problem in large breeds including basset hound, bloodhound, English setter, German shepherd, Great Dane, Newfoundland, Rhodesian ridgeback, weimaraner; reported as simple recessive trait in Saint Bernard and German short-haired pointer dogs; uncommon in cats but reported in Burmese
- Third eyelid gland prolapse: predisposed breeds include American and English cocker spaniels, English bulldog, beagle, shihtzu (dogs); Burmese (cats)
- Third eyelid inflammatory disorders:
    - Breeds predisposed to plasma cell infiltration include German shepherds, Belgian sheepdog, Borzoi, Doberman pinscher, English springer spaniel.
    - Nodular granulomatous episclerokeratitis can involve the third eyelid of all dog breeds, with the collie apparently predisposed.
    - Follicular conjunctivitis: primarily large breeds, dogs typically <18 months of age.

ASSOCIATED CONDITIONS & DISORDERS: Third eyelid inflammation:

- Dogs:
    - Chronic superficial keratitis (see p. 825)
    - Nodular granulomatous episclerokeratitis (limbal lesions; see p. 356)
    - Follicular conjunctivitis (bulbar con-junctival lesions; see p. 239)
- Cats:
    - Proliferative (eosinophilic) keratoconjunctivitis (see p. 254)
    - Feline herpesvirus type 1 infection (see pp. 237 and 524)

Protrusion of the third eyelid:

- Conditions causing alteration of orbital contents: dehydration, loss of orbital fat from emaciation, temporal muscle atrophy,

orbital neoplasia, cystic disease in the orbit, and orbital cellu-litis, abscess, or hemorrhage (see p. 790)
- Conditions associated with alteration in globe size:
  - Microphthalmia (congenital smallness of the eye; see p. 778)
  - Chronic uveitis or glaucoma or ocular trauma causing phthisis bulbi (shrinkage of the eye; see pp. 448 and 1151)
- Conditions associated with alteration in orbital muscle tone: tetanus (see p. 1083), strychnine poisoning (see p. 1055), Horner's syndrome (see p. 543)
- Conditions associated with alteration in globe position:
  - Painful ocular disorders including: corneal ulceration (see p. 250), uveitis, and conjunctivitis
- In cats, also consider dysautonomia or a bilateral chronic idiopathic condition associated with gastrointestinal (GI) parasites, GI malfunction, or feline leukemia virus (FeLV) infection

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- “Membrane covering part of the eye” (layperson's description)
- Abnormal appearance of or position of third eyelid or gland of the third eyelid

PHYSICAL EXAM FINDINGS

- Scrolled cartilage: anterior (rostral) folding of the dorsal portion of the third eyelid
- Third eyelid gland prolapse appears as a smooth, moist (mucosa-covered) pink to red mass at the medial canthus, protruding over the free margin of the third eyelid; may be unilateral or bilateral.
- Third eyelid inflammatory disorders:
  - Plasma cell infiltration causes a thickened, pebbly, often depigmented, hyperemic third eyelid, especially along the free margin.
  - Nodular granulomatous episclerokeratitis lesions of the third eyelid are typically smooth, hyperemic subconjunctival tubular-like swellings along the palpebral surface of the third eyelid.
  - Animals with follicular conjunctivitis have an increased number of larger-than-usual follicles on the bulbar side of the third eyelid in addition to multiple small, pink follicles along the bulbar conjunctival surface.
- Neoplasia of the third eyelid: typically appears as a smooth to irregular, occasionally ulcerated, pink to red mass at the medial canthus, arising from the third eyelid; typically unilateral.

ETIOLOGY AND PATHOPHYSIOLOGY

- Scrolled cartilage: differential growth rate of the posterior (caudal) portion of the cartilage compared to that of the anterior (rostral) portion
- Third eyelid gland prolapse: may result from weakness of connective tissue attaching the base of the gland to the periorbital structures
- Third eyelid protrusion; movement of the third eyelid is passive and occurs with:
  - Changes in volume of globe or orbit
  - Secondary globe retraction via retractor bulbi muscle (e.g., ocular pain)
  - Changes in extraocular muscle tone (e.g., Horner's syndrome results in decreased sympathetic tone; tetanus produces increased extraocular muscle tone)
- Third eyelid inflammatory disorders:
  - Plasma cell infiltration is often associated with chronic superficial keratitis (see p. 825); the inflammatory infiltrate consists of plasma cells and lymphocytes.
  - Nodular granulomatous episclerokeratitis appears to be an immune-mediated disease; lesions are characterized by a chronic granulomatous inflammatory cell response.
  - Follicular conjunctivitis is thought to represent chronic antigenic stimulation.

DIAGNOSIS 

DIAGNOSTIC OVERVIEW

The diagnosis of many disorders of the third eyelid rests on careful physical examination of the third eyelid lesions; confirmatory testing is needed in a minority of cases.

DIFFERENTIAL DIAGNOSIS

- Scrolled cartilage is diagnosed based on ophthalmic examination revealing a curled or bent third eyelid.
- The differential diagnosis for a smooth, fleshy mass at the medial canthus in a middle-aged or older dog is neoplasia, versus

glandular prolapse in a young (<2 year) dog.
- Third eyelid protrusion (as described above)

INITIAL DATABASE

- Characteristic clinical examination findings exist for most lesions involving the third eyelid, as described above.
- Definitive diagnosis of mass lesions may require excisional biopsy and histologic examination.
- Complete physical and ophthalmic examinations (see p. 1313) to determine cause of third eyelid protrusion, including:
  - Pupillary light reflexes (PLRs) (e.g., miotic pupil in Horner's syndrome and uveitis)
  - Fluorescein dye application (positive fluorescein stain retention in corneal ulceration)
  - Evaluate globe size (e.g., if small: microphthalmia versus phthisis bulbi)
  - Retropulsion of globe (may be reduced with orbital disease; see p. 790)
  - Hydration status
  - Body condition
  - Signs of systemic illness (fever, lethargy, etc.)

ADVANCED OR CONFIRMATORY TESTING

- Variable depending on underlying abnormality
- Imaging studies (ocular or orbital ultrasound, CT scan, MRI) for retrobulbar space-occupying lesions, possibly in conjunction with fine-needle aspirates (FNAs) and cytologic examination and/or biopsy and histologic examination of the orbital mass

TREATMENT 

TREATMENT OVERVIEW

Goals of treatment are to:

- Improve the appearance and function of third eyelid structures to as normal as possible to minimize chronic low-grade corneal and conjunctival irritation and associated ocular discharge (scrolled cartilage and third eyelid gland prolapse).
- Preserve vital tear production from the gland of the third eyelid (third eyelid gland prolapse).
- Formulate specific goals according to the nature of the abnormality.

ACUTE GENERAL TREATMENT

- Scrolled cartilage: treatment is surgical, requiring removal of the folded/ scrolled portion of the cartilage through the bulbar conjunctival surface of the third eyelid.
- Third eyelid gland prolapse requires surgical replacement of the third eyelid gland, which involves:
  - Anchoring the prolapsed gland to the orbital periosteum
  - Burying the prolapsed gland in a pocket created under the conjunctiva of the third eyelid
  - Fixation of the prolapsed gland to the cartilage of the third eyelid
  - Contraindicated: excision of the gland of the third eyelid. It is associated with significantly decreased tear production and a high incidence of keratoconjunctivitis sicca (KCS) months to years postoperatively.
- Third eyelid inflammatory disorders:
  - Treatment of plasma cell infiltrate typically consists of topical (q 6-12 h), subconjunctival (q 2-4 weeks initially), or (rarely) systemic corticosteroids; topical cyclosporine A (q 12 h) used for a long period of time (see p. 825)
  - Nodular granulomatous episclerokeratitis is generally controllable with the long-term use of topical and/or systemic corticosteroids and/or systemic azathioprine (see p. 356).
  - Follicular conjunctivitis is often self-limiting. In severe cases or those cases that feature unacceptable hyperemia or ocular discharge, irrigation of the conjunctival cul-de-sac with saline and judicious use of topical corticosteroids are helpful. Mechanical débridement with a gauze square/sponge following instillation of topical anesthesia (e.g., 0.5% proparacaine ophthalmic solution) is described but seldom necessary.
  - Neoplasia of the third eyelid may necessitate surgical removal of the entire third eyelid.

CHRONIC TREATMENT

If the third eyelid and gland are removed for neoplasia of the third eyelid, long-term use of topical artificial tear supplements (q 6-12 h) with or without topical cyclosporine A or tacrolimus (q 12 h) may be required, especially if KCS develops.

POSSIBLE COMPLICATIONS

- Third eyelid gland prolapse: if uncorrected, chronic exposure of the gland results in glandular hypertrophy, decreased tear

production, chronic KCS, and ocular discharge.
- Use caution with deep passage of suture needle in orbital “tie-down” procedures, because perforation of the globe may cause devastating consequences.

PROGNOSIS AND OUTCOME

- Scrolled cartilage: following surgery, most third eyelids return to normal function and appearance; in some cases, surgical removal of the scrolled section still does not produce complete flattening against the globe.
- Third eyelid gland prolapse: although surgical failure (up to 20%) can occur, subsequent repositioning is typically successful.
- Most inflammatory conditions of the third eyelid can be controlled medically; however, recurrence may arise, and maintenance therapy is often necessary.
- Prognosis of third eyelid protrusion depends on the underlying disease process and ranges from excellent (e.g., orbital cellulitis) to grave (malignant orbital neoplasia).
- Neoplasia of the third eyelid: adenocarcinoma is the most common condition and is associated with recurrence following excision; the second most common is papilloma, for which local excision is typically curative.

PEARLS & CONSIDERATIONS

COMMENTS

- The only indication for surgical removal of the third eyelid is neoplasia.
- Be suspicious of neoplasia of the third eyelid gland rather than third eyelid gland prolapse in a middle-aged or older dog. Do not surgically replace the gland in a suspicious case until confirmed (by FNA and Cytologic examination or wedge biopsy and histologic examination) that it is not neoplastic.
- Check the bulbar surface (i.e., underside) of the third eyelid in cases with third eyelid protrusion and cases in which concurrent corneal ulcers are not responding to treatment.

EDITOR: CHERYL L. CULLEN

Thiamin (Vitamin B1) Deficiency

BASIC INFORMATION

DEFINITION

Inadequate intake of thiamin

SYNONYMS

Thiamine deficiency, Chastek paralysis (fox, mink)

EPIDEMIOLOGY

SPECIES, AGE, SEX: Cats and dogs of all ages. Thiamin requirement is higher in cats and increases during growth and reproduction. Thiamin is a heat-labile, water-soluble vitamin not synthesized in tissues of cats and dogs and therefore must be continually ingested in food.

RISK FACTORS

- Consumption of raw flesh and viscera of certain fish and shellfish containing thiaminases, which degrade thiamin. Thiaminases are inactivated by cooking.
- Feeding heat-processed foods without added thiamin or inadequately supplemented commercial diets. Pet food manufacturers overcome predictable losses by supplementation.
- Feeding sulfur dioxide- or sulfite-preserved cooked or raw meats. The U.S. Department of Agriculture (USDA) prohibits the use of sulfiting agents to preserve meats.

ASSOCIATED CONDITIONS & DISORDERS

- Feeding foods with active thiaminases or sulfiting agents at the same time with a thiamin source (e.g., commercial pet food) can inactivate thiamin and cause deficiency.
- Gastrointestinal disease causing malassimilation; inappetence or anorexia; polyuria/polydipsia; fluid diuresis.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Dietary history compatible with the risk factors listed above
- In dogs, nonspecific clinical signs include combinations of depression, inappetence, anorexia, weight loss, vomiting, reduced mentation, and failure to grow in puppies. Neuromuscular signs are progressive and consist of ataxia, circling, head tremor, thoracic limb hypermetria, stiff hind limb gait, increased muscle tone, paraparesis, tetraparesis, inability to walk, tonic-clonic convulsions, recumbency with opisthotonus, coma, and death.
- In cats, decreased food intake and salivation develop within 1-2 weeks of consumption of a deficient diet. Early clinical signs include combinations of inappetence, weight loss, vomiting, diarrhea, general weakness and mild ataxia. This stage may progress to spastic gate, spastic ventroflexion of the head and neck (so-called praying sign), and dilated unresponsive pupils. Severely affected cats may develop stupor, seizures, opisthotonos, and limb spasticity prior to death.

PHYSICAL EXAM FINDINGS

- In dogs, abnormalities may include tachypnea, tachycardia and weak femoral pulses. Neurologic examination (see p. 1311) may reveal reduced mentation, dilated and unresponsive pupils, positional horizontal or vertical nystagmus, deficits of postural reactions in all limbs, absence of deep and superficial pain in all limbs, hyperactive patellar and biceps reflexes, and hyperesthesia.
- In cats, sinus arrhythmia and bradycardia have been reported. Dilated unresponsive pupils, nystagmus, anisocoria or absence of menace responses may be present. Spastic ventroflexion of the head and neck is characteristic of disease. When suspended by the hind legs, affected cats keep their head ventroflexed instead of dorsiflexed. Cats may show abnormal behavior, abnormal postural reactions, hyperesthesia, or tetraparesis.

ETIOLOGY AND PATHOPHYSIOLOGY

- Thiamin plays essential roles in carbohydrate metabolism, energy production and neural function. Thiamin pyrophosphate (TPP) is a coenzyme in the conversion of pyruvate to acetyl coenzyme A, which enters the tricarboxylic acid (TCA) cycle to generate energy. It also catalyzes reactions in the oxidation of glucose by the hexose monophosphate shunt to produce NADPH for biosynthetic processes. Thiamin deficiency impairs the TCA cycle and generation of energy. Thiamin's role in neural function is unclear, but it is probably nonenzymatic, such as activation of ion channels.
- The mechanism by which thiamin deficiency results in observed clinical signs is unknown but may relate to dependence of neuronal and cardiac tissue on energy derived from glucose metabolism.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis is suspected based on the dietary history and consistent clinical signs. These findings justify prompt treatment with parenteral thiamin.

DIFFERENTIAL DIAGNOSIS

- Toxicity
- Inflammatory or infectious central nervous system diseases
- Multifocal neoplastic process
- Nutritional disease
- Metabolic disease

INITIAL DATABASE

- Review diet history to identify dietary risk factors.
- Question owners about possibility of toxin ingestion.
- CBC, serum biochemical profile, urinalysis, and CSF analysis are generally unremarkable.
- Neuroanatomic localization is consistent with multifocal central nervous system lesion.

ADVANCED OR CONFIRMATORY TESTING

- Treat with thiamin; expect rapid response within 12-48 hours.
- Erythrocyte transketolase activity assay (ETKA): limited availability
- MRI of the brain
- Analysis of the food for thiamin and sulfur dioxide concentration

TREATMENT

TREATMENT OVERVIEW

Clinical signs are rapidly progressive and fatal. Therefore treatment with parenteral thiamin must be initiated before results of advanced and confirmatory tests are obtained.

ACUTE GENERAL TREATMENT

- Supportive care (intravenous fluids)
- Control of seizures (anticonvulsant medications)
- Thiamin hydrochloride: recommended parenteral dose for cats and dogs varies from 5-250 mg IM or SQ q 12 h. Little clinical evidence exists other than case reports to identify an optimal dosage, so 5-20 mg per patient would likely be sufficient, as this is at least 4-30 times a patient's recommended daily allowance, depending on species and body weight. Follow-up oral treatment with 25-50 mg q 24 h is optional when enteric function is normal.

NUTRITION/DIET

- Nutritional support (enterally or parenterally) is indicated in all anorexic patients.
- Feeding a diet that is known to be nutritionally adequate for the life stage of the dog or cat. Diet change is preferred over thiamin supplementation of the inadequate diet.

PROGNOSIS AND OUTCOME

Excellent if recognized and treated before the animal reaches convulsive stage.

PEARLS & CONSIDERATIONS

COMMENTS

Response to treatment and improvement of clinical signs is rapid if deficiency of thiamin is the cause of the signs.

PREVENTION

Feed a properly formulated diet; avoid feeding foods that contain thiaminases and sulfiting agents.

CLIENT EDUCATION

Explain the dietary risk factors associated with thiamin deficiency and the importance of feeding a properly formulated complete and balanced diet.

AUTHOR: IVETA BECVAROVA

EDITOR: KATHRYN MICHEL

Tetraplegia/Tetraparesis

BASIC INFORMATION

DEFINITION

The suffix *-plegia* signifies complete paralysis; *-paresis* signifies incomplete paralysis. Either may manifest with upper motor neuron (UMN) or lower motor neuron (LMN) signs. *Tetraplegia* is complete paralysis of all limbs; *tetraparesis* is incomplete paralysis of all limbs.

SYNONYMS

Tetraplegia: quadriplegia. Tetraparesis: quadriparesis.

EPIDEMIOLOGY

GENETICS & BREED PREDISPOSITION

- Toy breed dogs: atlantoaxial instability
- Older Doberman pinschers, young Great Danes, and other large-breed dogs: cervical spondylomyelopathy
- Chondrodystrophic dog breeds: cervical intervertebral disk protrusion
- Burmese cats: hypokalemia
- Labrador retrievers: exercise-induced collapse
- Various dog breeds: breed-associated motor neuron diseases
- Various cat/dog breeds: breed-associated muscular dystrophies and myopathies

RISK FACTORS

- Exposure to carrion: botulism (dogs)
- Exposure to toxins (e.g., 2,4-D herbicide; organophosphates/carbamates)
- Penetrating wounds (tetanus)
- Areas endemic for coral snakes; black widow spiders *(Latrodectus* spp.); *Dermacentor* spp., *Amblyomma* spp., and *Ixodes* spp. of ticks (tickbite paralysis)

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: Tetraplegia:

- Inability to bear weight, voluntarily move limbs, or ambulate

Tetraparesis:

- Impaired locomotion, ranging from mild weakness or spasticity (usually with ataxia) to recumbency
- Ability to voluntarily move limbs even if recumbent
- Tetraparetic/tetraplegic animals with diseases involving the cerebral cortex and/or brainstem will typically show other abnormal neurologic signs:
    - Abnormal mentation and/or seizures (cerebral cortex or diencephalon)
    - Dullness, stupor, or coma (brainstem)
    - Cranial nerve disturbances (brainstem)
    - Abnormal respiratory character (brain, cervical spinal cord)

PHYSICAL EXAM FINDINGS

- Variable (see specific diseases)
- It is important to neuroanatomically localize the lesion (see p. 1311).
- Tetraplegia or tetraparesis can be seen with UMN and/or LMN signs.
- Symmetry or asymmetry of paresis should be noted because this finding may help narrow the differential diagnosis.
- Animals may have UMN or LMN bladder depending upon the neuroanatomic location of the lesion(s).
- Animals with tetraplegia or tetraparesis have a disease involving one of the following regions:

- Tetraplegia or tetraparesis with UMN signs (e.g., increased muscle tone and hyperreflexia) to all four limbs
  - Bilateral cerebral cortex
  - Bilateral brainstem (midbrain)
  - Bilateral cervical spinal cord
- Tetraplegia or tetraparesis with hind limb UMN (as above) and forelimb LMN signs (decreased muscle tone, hyporeflexia)
  - Bilateral C6-T2 spinal cord involvement
- Tetraplegia or tetraparesis with LMN signs to all four limbs
- Disease affecting motor neurons of C6-T2 and L4-S2
  - Disease affecting peripheral nerves (motor component) of all four limbs
  - Disease affecting the neuromuscular junction
  - Disease affecting the skeletal muscle
  - If one particular region cannot be logically identified, disease process is likely multifocal.

ETIOLOGY AND PATHOPHYSIOLOGY

- UMNs are found in the brain and control LMNs.
- LMNs transmit information from the central nervous system (CNS) to an effector organ-like skeletal muscle.
- Conditions affecting UMNs and/or their axons result in UMN signs:
  - Paralysis or paresis
  - Normal to increased spinal reflexes
  - Later onset muscle atrophy (disuse atrophy)
  - Normal to increased muscle tone
- Conditions that affect LMNs, their axons, and the neuromuscular junction result in LMN signs:
  - Paralysis or paresis
  - Decreased or absent spinal reflexes
  - Rapid, severe muscle atrophy (neurogenic atrophy)
  - Decreased muscle tone
- Primary or systemic diseases affecting skeletal muscle cause impaired muscular function and can manifest as tetraplegia or tetraparesis.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Tetraparesis/tetraplegia implies a neurologic syndrome; severe systemic disturbances (see p. 235) must be ruled out with physical examination. A neurologic exam is pivotal in establishing an anatomic diagnosis, which narrows the differential diagnosis and allows the clinician to choose specific diagnostic tests.

DIFFERENTIAL DIAGNOSIS

- Intracranial:
  - Neoplasia
  - Trauma
  - Encephalitis (various causes, including infectious and immune-mediated granulomatous meningoencephalitis [GME] diseases)
  - Hydrocephalus
  - Postictal state
- Cervical spinal cord:
  - Intervertebral disk prolapse
  - Trauma
  - Cervical spondylopathy
  - Atlantoaxial instability
  - Myelitis (various causes, including infectious and immune-mediated [GME] diseases)
  - Osteochondromatosis
  - Synovial or arachnoid cysts
- Peripheral nerves or neuromuscular junction:
  - Tickbite paralysis
  - Idiopathic polyradiculoneuritis
  - Snake or spider envenomation
  - Myasthenia gravis
  - Botulism
  - Hypothyroidism

- Various toxins
- Muscle:
  - Immune-mediated polymyositis (primary or secondary to another disease, such as neoplasia)
  - Hypokalemia
  - Endocrine disease (hyperthyroidism [cats], hypothyroidism, hyperadrenocorticism)
  - Various breed-related muscular dystrophies and myopathies

INITIAL DATABASE

- Assess patient stability (some may present with impaired respiratory function and/or cardiac anhythmias)
- Complete physical and neurologic examinations (see p. 1311)
- CBC, serum chemistry profile, and urinalysis for assessment of systemic causes and preanesthetic evaluation

ADVANCED OR CONFIRMATORY TESTING

- Plain skull or spinal radiographs
- Cerebral spinal fluid (CSF) analysis (see p. 1228)
- Myelography (see p. 1306)
- MRI (see p. 1233) or CT (see p. 1302) scan
- Electrodiagnostic and histopathologic evaluation of affected muscle and nerves
- Detection of antibodies to acetylcholine receptors in cases of fulminant myasthenia gravis

TREATMENT

TREATMENT OVERVIEW

Treatment goals are to eliminate the inciting cause and provide adequate supportive nursing care.

ACUTE GENERAL TREATMENT

- Treat underlying condition if possible.
- Intensity of nursing care depends on the individual needs of the animal.
- Some supportive therapies to be considered:
  - Assisted pulmonary ventilation (see p. 1362): if inadequate spontaneous ventilation
  - Caloric intake: handfeeding (see p. 1377), feeding via esophagostomy/gastrostomy tube (see p. 1270), or parenteral nutrition (see p. 1322)
  - Hydration: appropriate fluid therapy
  - Muscle contracture: passive range-of-motion exercises
  - Pressure sores: turn animals frequently, and treat the lesions early and aggressively if they occur.
  - Urinary bladder (e.g., catheterization) and bowel management (e.g., stool softener)
  - Hygiene: regular cleaning of perineum; ensure animals are kept on clean, dry bedding.

CHRONIC TREATMENT

Long-term supportive therapy may be necessary.

POSSIBLE COMPLICATIONS

Complications associated with tetraplegia or severe tetraparesis include:

- Pressure sores
- Urinary tract infections (with chronic bladder catheterization)
- Fecal impaction
- Pneumonia

RECOMMENDED MONITORING

- Complete physical examinations two times per day to identify complications from recumbency
- Regularly scheduled and frequent neurologic assessments to monitor disease progression
- Severe or progressive CNS or neuromuscular disease: regular assessment of respiratory function

PROGNOSIS AND OUTCOME

Variable, depending on underlying cause

PEARLS & CONSIDERATIONS

COMMENTS

- Referral to an appropriate treatment center is often necessary.
- Nursing care is often times intensive, extensive, and expensive.

TECHNICIAN TIP

Technicians caring for these patients should be able to turn the patients regularly to minimize the risk for pressure sores, be familiar with precautions to be taken when moving patients that have spinal cord disease, be familiar with urinary catheter management, and be able to perform range-of-motion exercises.

CLIENT EDUCATION

Diseases resulting in tetraplegia or tetraparesis can be costly to diagnose and treat.

Tetralogy of Fallot

BASIC INFORMATION

DEFINITION

A congenital heart malformation that consists of a large (unrestrictive) ventricular septal defect (VSD), pulmonic stenosis (PS), dextropositioned or overriding aorta, and secondary right ventricular hypertrophy. Ventricular outflow obstruction may be subvalvular or valvular.

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs and cats; present at birth; some survive to maturity (occasionally >5 years).

GENETICS & BREED PREDISPOSITION: Keeshond, West Highland white terrier, English bulldog, and French bulldog are often affected. In the keeshond, three distinct gene loci contribute to conotruncal malformations, the embryologic basis for tetralogy of Fallot (TF).

ASSOCIATED CONDITIONS & DISORDERS: Patent ductus arteriosus (PDA) or atrial septal defect (ASD) may be cofindings.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES: Most cases of TF manifest overt clinical signs resulting from hypoxemia or polycythemia. Right-sided congestive heart failure (CHF) is very rare.

HISTORY, CHIEF COMPLAINT

- Cardiac murmur in an apparently healthy puppy or kitten
- Exercise intolerance, often with tachypnea
- Exertional syncope
- Stunted growth

PHYSICAL EXAM FINDINGS

- Systolic murmur over the pulmonic valve area with radiation dorsally and to the right. A softer murmur may be evident with severe PS, marked polycythemia, or pulmonary atresia.
- Generalized cyanosis may be observed, particularly after exertion.
- Palpable right precordial heave, indicating ventricular hypertrophy.

ETIOLOGY AND PATHOPHYSIOLOGY

- TF is a cardiac malformation that causes bidirectional shunting across a large VSD, leading to hypoxemia, cyanosis, secondary polycythemia, and impaired exercise capacity.
- Hyperviscosity syndrome may develop from polycythemia.
- Increased blood flow through bronchial artery collateral vessels increases venous admixture and further lowers the arterial Po2.
- Sudden cardiac death is the typical outcome in untreated cases.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis is suspected when a young dog or cat either is noted to have a systolic murmur on routine examination, or is presented for evaluation of exercise intolerance, cyanosis, or both.

DIFFERENTIAL DIAGNOSIS

- PS with ASD or VSD

- Pulmonary or tricuspid valve atresia (with associated ventricular or atrial septal defect), as well as other complex malformations such as transposition of the great arteries.
- Double-chambered right ventricle with VSD proximal to the midventricular obstruction
- Severe pulmonary hypertension (Eisenmenger's physiology)
- Other causes of polycythemia (polycythemia vera, renal mass lesions)
- Respiratory diseases

INITIAL DATABASE

- Chest radiographs show right ventricular prominence, straight left auricular border on the dorsoventral projection, and pulmonary hypoperfusion. Radiographs also exclude primary pulmonary causes of cyanosis and respiratory distress.
- The electrocardiogram (ECG) usually shows a right ventricular hypertrophy pattern (or a cranially directed axis).
- CBC may demonstrate polycythemia.
- Pulse oximetry (or arterial blood gas [ABG]) testing quantifies oxygen saturation and functional status.

ADVANCED OR CONFIRMATORY TESTING

- Echocardiography with Doppler studies (± contrast echocardiography) is confirmatory, demonstrating the four principal lesions and associated shunting across the VSD.
- Cardiac catheterization and angiography are rarely needed.

TREATMENT

TREATMENT OVERVIEW

- Definitive therapy requires open heart surgery with cardiopulmonary bypass and is rarely done.
- Palliation involves preventing arterial desaturation by surgically creating a left-to-right, systemic arterial-to-pulmonary shunt to enhance pulmonary blood flow and left ventricular volume.
- Control of the hematocrit to prevent severe polycythemia is critical. A slightly higher than normal packed cell volume (PCV) is beneficial for increasing oxygen-carrying capacity and raising systemic vascular resistance.
- Avoid drugs that are vasodilators and reduce systemic vascular resistance (increasing right-to-left shunting).

ACUTE GENERAL TREATMENT

For bouts of dyspnea:

- Enforce rest, providing a cool, well-ventilated or fanned space (prevent overheating).
- Although supplemental oxygen has minimal benefits for patients with right-to-left shunting, it should be provided, and the effect on oxygen saturation should be measured by pulse oximetry.
- Sedation with butorphanol may be helpful, but avoid acepromazine.
- Treat severe bradycardia with atropine if necessary.
- If necessary, increase systemic vascular resistance with an alpha-adrenergic agonist (phenylephrine) to reduce right-to-left shunting.
- Once the patient is stable for handling, measure the PCV; if >68%, perform a phlebotomy, replacing the removed volume with a balanced crystalloid (100%-150% of volume removed).

CHRONIC TREATMENT

- Assuming definitive repair is not possible, long-term benefits can be achieved by referral for extracardiac thoracic surgery. A palliative left-to-right shunt between a systemic artery and the pulmonary artery (e.g., modified Blalock-Taussig shunt) increases pulmonary blood flow and usually raises arterial oxygen saturation to >90%.
- Alternatively, “partial” balloon valvuloplasty of the stenotic right ventricular outlet can be considered, provided a residual pulmonary obstruction is maintained to prevent severe left-to-right shunting across the unrestrictive VSD. Theoretically, catheterization of the aorta (through the VSD) may permit identification of excessive collateral vessels that may be occluded by coil embolization.
- Periodic phlebotomy, maintaining PCV < 68% (target 62%-65%, although lower values may be well tolerated).
- The nonspecific beta-blocker, propranolol (0.5-1 mg/kg PO q 8 h; begin low and titrate upward), can mitigate dynamic right ventricular outflow tract obstruction from hypertrophy while preventing drug-induced vasodilation.
- Consider a trial course of hydroxyurea (30-50 mg/kg PO q 24-48 h; titrate based on PCV) to suppress the bone marrow when frequent phlebotomies are needed.
- Prescribe low-dose aspirin to animals with surgically created palliative shunts (to impede thrombosis).
- Limit exercise, and avoid high heat/ humidity conditions; prevent dehydration.

- Consider pentoxifylline to improve red blood cell (RBC) flexibility in the micro-circulation (however, use in animals with TF is completely empirical).

POSSIBLE COMPLICATIONS

- Adverse effects of the aforementioned drugs
- Gradual spontaneous closure or thrombosis of a surgically created palliative shunt
- Acute pulmonary edema from creation of a large palliative shunt or overzealous balloon valvuloplasty for relief of PS
- Paradoxical (right-to-left) thromboembolic episode following venipuncture, causing stroke or coronary embolus. In cats with TF, atrial thrombi may result in arterial thromboembolism.

RECOMMENDED MONITORING

- Clinical signs: exercise capacity and respiratory effort at home
- Mucous membrane color and arterial oxygen saturation (oximetry)
- Hematocrit or full CBC with platelet count if the patient is taking hydroxyurea
- Resting heart rate, as bradycardia (<60 in dogs or <120 in cats) may indicate overdosage of propranolol.
- Pulmonary blood flow in surgically created shunts (by auscultation and echo-Doppler studies of the pulmonary artery)

PROGNOSIS AND OUTCOME

Guarded; most affected dogs and cats will succumb to complications of hypoxia or polycythemia (or will have to be euthanized because of clinical signs). Common findings include:

- Bouts of exertional dyspnea or respiratory distress
- Stroke or other signs of hyperviscosity syndrome
- Sudden cardiac death

PEARLS & CONSIDERATIONS

COMMENTS

- Systemic vascular resistance and pulmonary blood flow impact clinical outcome.
- Vigorous exercise, anemia, thyrotoxicosis, and vasodilator drugs reduce systemic vascular resistance, increasing right-to-left shunting.
- Mild PS or concurrent PDA may reduce clinical signs, leading to a “pink” tetralogy of Fallot.
- The magnitude of polycythemia may not correlate with clinical signs.
- Palliative surgery for TF can significantly improve clinical outcome and permit a relatively long life. This surgery is challenging and should be performed only by a surgeon with experience in vascular surgery.

PREVENTION

Do not breed dogs that have TF.

CLIENT EDUCATION

- Observe exercise capacity, effort and rate of breathing, and general well-being.
- Avoid environmental and exercise extremes.
- Report progressive signs or syncope.
- Provide ventilation (a fan) and water during periods of respiratory distress.

Tetanus

BASIC INFORMATION

DEFINITION

An infectious disease caused by a potent neurotoxin produced by the bacterium *Clostridium tetani,* resulting in a sustained tonic contraction of the muscles

SYNONYM

Lockjaw

EPIDEMIOLOGY

SPECIES, AGE, SEX: All domestic animals are susceptible; cats are more resistant than dogs.

RISK FACTORS: Open wounds; exposure to organism in feces or in the environment

GEOGRAPHY AND SEASONALITY: Ubiquitous in the environment; no seasonally

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES: Focal versus generalized dependent on inoculation site; the generalized form is more common.

HISTORY, CHIEF COMPLAINT

- Cutaneous/soft-tissue wound (cut, puncture, surgical [e.g., ovariohysterectomy])
- Progressively worsening gait stiffness

PHYSICAL EXAM FINDINGS

- Extreme sensitivity to tactile and auditory stimulation: mildly to extremely exaggerated reaction to sound or touch
- Characteristic facial expression due to facial muscle spasm: ears held erect, forehead wrinkled, lips drawn back (risus sardonicus)
- Trismus (teeth clenching)
- Protrusion of third eyelids, enophthalmos, strabismus, hypersalivation, laryngeal spasm, dysphagia
- Mild hyperthermia due to excessive muscular activity
- Dyspnea, coughing possible from aspiration pneumonia
- Progression to periodic generalized tonic muscle contraction possible
- Autonomic “storms”: cardiac arrhythmias, hypotension or hypertension
- Death can result from respiratory compromise.

ETIOLOGY AND PATHOPHYSIOLOGY

- *C. tetani* typically enters the body through wounds.
- A potent neurotoxin (tetanospasmin) is formed in the patient's body during vegetative growth of *C. tetani*
- Tetanospasmin enters the neuromuscular end plate of motor nerves and migrates to the neuronal cell body in the spinal cord or brainstem.
- Tetanospasmin blocks inhibitory neu-rotransmitter release (glycine, gamma-aminobutyric acid [GABA]), facilitating muscle contraction.
- Tetanospasmin's binding to presynaptic sites of inhibitory neurons is irreversible; recovery depends on sprouting of new axon terminals.
- Signs occur within 5-10 days of injury but can be delayed up to 3 weeks.
- Wounds close to the head are associated with a more rapid onset of signs than those in the extremities.

TETANUS Dog with fulminant tetanus. Contraction of facial muscles has drawn the ears dorsally, and a divergent strabismus is present. Canthi of the lips were drawn into a sardonic grin (not seen here); mouth could not be opened. Extreme rigidity of the limbs explains stiff, stilted posture.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Tetanus is diagnosed based on clinical signs and history of a recent wound; there is no practical clinical confirmatory test. The source of infection or wounds is not always immediately apparent.

DIFFERENTIAL DIAGNOSIS

Hypocalcemic tetany

TETANUS Same dog after having made a complete recovery.

(Courtesy John Sylvester.)

INITIAL DATABASE

All the following test results may be seen, but none is required for a diagnosis of tetanus:

- CBC: leukocytosis (neutrophilia with left shift)
- Serum biochemistry profile: elevated serum creatine phosphokinase (CPK)
- Cerebrospinal fluid (CSF) analysis: unremarkable
- Electrocardiogram (ECG): tachyarrhythmias or bradyarrhythmias (atrioventricular [AV] block, sinus arrest) possible
- Thoracic and abdominal imaging: megaesophagus with or without aspiration pneumonia possible; abdominal effusion possible if source of *C. tetani* is septic peritonitis (metritis, enteritis, ruptured abscess)
- Muscle biopsy: usually unremarkable
- Serum antibody titers to tetanus toxin may support the diagnosis (compared to control animals).
- Isolation of *C. tetani* from wounds is unrewarding.

TREATMENT

TREATMENT OVERVIEW

Treatment is mostly supportive and may be protracted: resolution of clinical signs may take days to weeks, depending on form (generalized or localized) and individual response.

ACUTE GENERAL TREATMENT

- As much as possible, keep the animal in a quiet, soundproof area with minimal stimulation.
- Wound débridement and resection of necrotic tissue; wounds are left open (avoid anaerobic conditions).
- Antitoxin: equine antitetanus serum (ATS) (given IM or IV) or human tetanus immunoglobulin (TIG) given IM. Equine ATS:
  - Give the initial test dose, 0.1-0.2 mL SQ or ID, 15-30 minutes before IV administration; monitor for anaphylaxis.
  - If no anaphylaxis, therapeutic dose is 2.5-25 IU/kg IV; continue to monitor for anaphylaxis during and immediately after administration.
  - Intralesional injection appears promising (experimental studies).
  - Antitoxin prevents further toxin binding to axons but does not eliminate currently bound toxin.
- Sedation (e.g., one of the following: diazepam [helps enhance GABA inhibition], phenobarbital, acepromazine,

chlorpromazine) is recommended.
- Antibacterial treatment *(C. tetani):* sodium or potassium penicillin, 20,000-50,000 IU/kg slow IV q 6 h for 10 days; and metronidazole, 10 mg/kg PO q 8 h for 10 days.

CHRONIC TREATMENT

- Physical rehabilitation (see p. 1329)
- Intensive nursing care to include IV fluids and nasogastric or percutaneous endoscopic gastrostomy (PEG) tube feedings (see p. 1269 and 1270)
- Prevention of decubital ulcers
- Indwelling urinary catheter

DRUG INTERACTIONS

- Narcotics can depress the respiratory center and may stimulate other areas of the central nervous system (CNS).
- Parasympatholytic drugs such as atropine should be avoided in routine cases.

POSSIBLE COMPLICATIONS

- Aspiration pneumonia
- Decubital ulcers
- Respiratory paralysis

RECOMMENDED MONITORING

- Heart and respiratory rates
- Temperature monitoring
- Seizure watch
- Urine output

PROGNOSIS AND OUTCOME

- Guarded; better with mild clinical signs and localized clinical signs
- In mildly affected animals, normal function usually returns within 3 weeks of the initial treatment.
- Survival rates have varied between 50% and 92% in the literature.

PEARLS & CONSIDERATIONS

PREVENTION

- Avoid exposure to potential sources of infection.
- Routine immunoprophylaxis (tetanus toxoid) not recommended in dogs and cats
- Appropriate (open) care of infected wounds and rational antibiotic therapy

TECHNICIAN TIP

These patients can be exquisitely sensitive to light and sound; any efforts to prevent stimulating them (e.g., signs to alert clinic staff, selection of an appropriate location in the hospital for housing and recovery) are important during convalescence.

CLIENT EDUCATION

- Treatment of the disease can take weeks, but a cure is possible.
- seek veterinary attention in cases of open wounds.

Testicular Tumors

BASIC INFORMATION

DEFINITION

Neoplasia arising from testicular germ cells or sex-cord stromal cells; common in dogs, uncommon in cats

SYNONYMS

Germ cell: seminoma

Mixed tumors: germ cell/stromal tumors Sex-cord stromal: Leydig (interstitial) cell tumor, Sertoli (sustentacular) cell tumor

EPIDEMIOLOGY

SPECIES, AGE, SEX

Dogs:

- Incidence: common (75% of all tumors affecting the male urogenital tract)
- Age: aged patients, most >7 years
- Equal incidence of seminoma, Leydig cell tumor, Sertoli cell tumor much less common

Cats: all tumor types are very rare.

GENETICS & BREED PREDISPOSITION

- Seminoma: all canine breeds; boxer is predisposed.
- Sertoli cell: miniature schnauzers with persistent Müllerian duct syndrome are predisposed.

RISK FACTORS

Dogs, cryptorchidism:

- Overall risk of testicular tumor development increased 13-14 times
- Risk of Sertoli cell tumor increased 20 times
- Approximately half of Sertoli cell tumors occur in cryptorchid testes.
- Approximately one-third of seminomas occur in cryptorchid testes.

Cats: none identified

ASSOCIATED CONDITIONS & DISORDERS: Sertoli cell tumor: hyperestrogenism occurs in approximately 20%-30% of affected dogs.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Primary: unilateral or bilateral, focal or multifocal
- Metastatic (rare)

HISTORY, CHIEF COMPLAINT

- Testicular enlargement ± atrophy of unaffected testis (most severe associated with Sertoli cell tumor but can occur with other neoplasms, especially larger tumors)
- Sertoli cell tumor: symmetric hair loss, feminization (gynecomastia, attractiveness to other male dogs, pendulous penile sheath, lethargy, loss of libido, redistribution of body fat)

PHYSICAL EXAM FINDINGS: Testicular enlargement ± atrophy of contralateral testis

- Seminoma: soft to slightly firm texture
- Sertoli cell tumor: very firm texture, discrete mass
- Leydig cell tumor: soft texture, discrete mass
- Mixed germ cell/stromal tumors: variable texture, generally discrete and focal
- Sertoli cell with hyperestrogenism: endocrine dermatopathy, gynecomastia, pendulous penile sheath, redistribution of body fat, marked contralateral testicular atrophy

ETIOLOGY AND PATHOPHYSIOLOGY

Cryptorchidism: altered testicular environment due to increased testicular temperature favors neoplastic transformation of Sertoli cells and (less commonly) germ cells.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis relies on palpation of an enlarged testis or abnormal firm area within a normal-sized testis. Ultrasound and cytologic evaluation may aid in diagnosis, but in most cases excision of the affected testis and submission for histopathologic evaluation will confirm neoplasia and allow classification of the tumor.

DIFFERENTIAL DIAGNOSIS

- Testicular torsion
- Abscess
- Cyst

INITIAL DATABASE

- CBC: rule out bone marrow suppression due to Sertoli cell tumor-associated hyperestrogenism.
- Semen evaluation and/or testicular biopsy with histologic examination of unaffected testis will aid in decision for unilateral or bilateral castration in breeding dogs.

TESTICULAR TUMORS Transscrotal ultrasonogram of left testis of a normal fertile male dog. Echotexture of the parenchyma is homogeneous, with the exception of the hyperechoic mediastinum (rete testis; *arrow).*

(Courtesy Dr. Michelle A. Kutzler.)

TESTICULAR TUMORS Transscrotal ultrasonogram of left testis of an infertile male dog. Two anechoic cystic structures are present within the parenchyma on either side of the mediastinum. Differential diagnoses include cystic neoplasia or testicular cyst.

(Courtesy Dr. Michelle A. Kutzler.)

ADVANCED OR CONFIRMATORY TESTING

- Ultrasound, all tumortypes: hypoechoic or mixed echotexture
- Gross pathologic examination of excised testis:
    - Seminoma signs include soft to slightly firm testis, homogeneous gray/white glistening appearance, areas of discoloration due to hemorrhage or necrosis possible, focal to multifocal.
    - Sertoli cell tumor signs include very firm testis, discrete, white or gray in color, tan or yellow hemorrhagic areas possible, usually focal.
    - Leydig cell tumor signs include soft testis, discrete, yellow/brown in color, bulges on section, areas of hemorrhage or cystic change common, focal to multifocal.
    - Mixed germ cell/stromal tumors signs include variable texture, pale white or gray, generally discrete and focal.
- Bilateral tumors are common, and multiple tumor types are often present within the same testis.
- Histopathologic examination: include spermatic cord to evaluate for local invasion; multiple tumor types can occur in the same testis.

TREATMENT

TREATMENT OVERVIEW

Therapy consists of surgical removal of the affected testis.

ACUTE GENERAL TREATMENT

- Testicular removal: unilateral castration if contralateral testis is normal to small in size, and future breeding with the dog is desired
- Supportive care for dogs with Sertoli cell tumor-associated bone marrow suppression

CHRONIC TREATMENT

For metastatic seminoma, both chemotherapy and radiation therapy have been described. Methotrexate, vincristine, and cyclophosphamide; cisplatin; bleomycin: and radiation therapy have been reported to have some degree of efficacy.

BEHAVIOR/EXERCISE

Avoid estrous females and restrict physical activity for approximately 1 week following surgery.

POSSIBLE COMPLICATIONS

- Bone marrow suppression (hyperestrogenism) from Sertoli cell tumors
- Behavioral changes (hyperandrogenism) from Leydig cell tumors

RECOMMENDED MONITORING

- Seminoma, Leydig cell tumor, nonactive Sertoli cell tumor, mixed sex cord/ stromal tumor: yearly physical examination
- Sertoli cell tumor with bone marrow suppression: close follow-up for evidence of bacterial septicemia; yearly physical examination

PROGNOSIS AND OUTCOME

- Seminoma: excellent following testicular removal; metastasis is rare. Sertoli cell tumor: excellent following testicular removal; metastasis is rare, but risk of metastasis is increased for tumors >2 cm diameter.
- Leydig cell tumor: excellent following testicular removal; metastasis is not expected.
- Mixed sex cord/stromal tumor: excellent following testicular removal; metastasis is not expected.

PEARLS & CONSIDERATIONS

COMMENTS

- Histopathologic examination is needed for determination of tumor type.
- Unilateral castration may result in up to 50% hypertrophy of the remaining testis. Return to fertility following unilateral castration depends on the severity of testicular atrophy secondary to hormonal downregulation and presence of underlying disease (testicular degeneration with loss of spermatogo-nia).

PREVENTION

Testicular removal, especially of cryptorchid testes

CLIENT EDUCATION

- Regular examination of testes and evaluation of the semen in breeding animals
- Prompt presentation for veterinary examination if an abnormality is detected

AUTHOR: BETH A. VALENTINE

EDITOR: MICHELLE A. KUTZLER

Tenesmus

BASIC INFORMATION

DEFINITION

Ineffectual or painful straining to defecate due to obstruction or inflammatory lesions of distal colon, rectum, or anus

SYNONYM

Straining to defecate

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Frequent posturing to defecate/urinate without producing feces/urine
- Turning around/looking at hind end while attempting to defecate
- Excessive licking/chewing of perineal region
- Flattened, ribbon-like stools
- Vocalizing (cats most often)
- Inappropriate defecation in the house/ outside litter box or refusal to defecate owing to severe pain and secondary constipation
- Common error in cats: overdiagnosis of constipation by owner or veterinarian; careful history/observation reveals lower urinary tract signs

PHYSICAL EXAM FINDINGS

- Observe the animal defecate/urinate; assess if the animal's tail between the legs, low carriage of the tail, resentment of tail elevation (discomfort), presence of an arched back (abdominal or back pain).
- Examine anus/perianal area: erythema of anal/perineal region, perineal fistulas, perineal masses, pseudocoprostasis (anal obstruction due to severe matting of fur with feces).
- Abdominal palpation: mass, signs of discomfort despite gentle palpation
- Rectal palpation may require sedation/ general anesthesia if patients have very painful perineal conditions. Assess for presence of perineal hernia, mass, prostatomegaly, pelvic fractures, fecal consistency (constipation, foreign material), stricture, foreign bodies (e.g., bones, rocks, grass, fur, food wrappers)
- Cytologic analysis (infection, inflammation)
- If origin of clinical signs are unclear, catheterize urethra/urinary bladder
- Palpation of anal sacs (mass, impaction, infection, abscess, or rupture)

ETIOLOGY AND PATHOPHYSIOLOGY

- Perianal (specifically adjacent to anus) and perineal (whole region between tail and pubis) disorders may be due to anal sac impaction, anal sacculitis, anal sac abscess, perianal gland tumors, perineal hernia, perianal fistula, neoplasia (anal sac adenocarcinoma), pseudocoprostasis.
- Large bowel: acute diarrhea (see p. 303)
- Genitourinary (GU) tract: in general, GU abnormalities produce disorders of urination rather than tenesmus (careful history and examination for accurate diagnosis). Prostatomegaly (benign prostatic hyperplasia/hypertrophy [BPH], prostatitis, abscess, neoplasia), paraprostatic cyst, GU neoplasia
- Caudal abdominal cavity disorders include mass (organ compression), pelvic fractures (misaligned healing of old pelvic fractures), pelvic osteosarcoma

DIAGNOSIS

DIAGNOSTIC OVERVIEW

- Tenesmus is a clinical sign, not a disease; successful management requires identifying the underlying cause.
- Diagnostic test selection is highly dependent upon obtaining a clear history, observing the animal urinate and defecate, and

performing a thorough examination of the rectum, perineal, and perianal areas.

DIFFERENTIAL DIAGNOSIS

see Etiology and Pathophysiology, above.

INITIAL DATABASE

- Observe the animal defecating/ urinating.
- Proper examination of the perineal, perianal area, anus, and rectum (may require sedation if very painful)
- Urogenital system: vaginal examination to exclude impostors for tenesmus (see p. 1360)
- Neurologic exam (see p. 1311): perineal reflex, and tone, presence of lumbosacral/back pain
- CBC, serum biochemical profile, urinalysis: elucidate possible urinary tract or systemic abnormalities
- Radiographs (abdominal/pelvic): constipation, megacolon, prostatomegaly, pelvic fractures, malunion of pelvic fractures, foreign bodies, masses, or sublumbar lymphadenopathy

ADVANCED OR CONFIRMATORY TESTING

- Abdominal ultrasonography: gastrointestinal (GI)/pelvic mass, ± lymphadenopathy, urogenital tract, GI motility, distension/wall thickening
- Intrarectal ultrasonography: specific probes required
- Colonoscopy: rigid and/or flexible to biopsy polyp/mass(es), strictures or infiltrative lesions
- Urogenital system (to exclude impostors for tenesmus): vaginal examination, ultrasonography and/or urinary tract contrast radiography, urethroscopy/cystoscopy, culture and sensitivity of urine/prostatic fluid, cytologic examination, and/or biopsies of urinary tract/prostate.

TREATMENT

TREATMENT OVERVIEW

Treatment should address the underlying cause and relieve any discomfort the animal is experiencing.

ACUTE GENERAL TREATMENT

- Clip fur and gently wash perineal area if needed.
- Hydrotherapy to affected area multiple times per day if indicated
- Enemas: soften impacted feces if constipation
- Topical cutaneous glucocorticoids/ anesthetics (creams, ointments, suppositories): reduce inflammation/pain
- Corticosteroid enemas if severe, non-infectious colitis: budesonide (Entocort) 2 mg dissolvable tablet. Give 0.5-1 mg (¼-½ tablet dissolved in enema diluent) per rectum (dose is for most small animals). Budesonide does not tend to reach high concentrations outside the GI-hepatoportal system (high first-pass metabolism), which minimizes systemic glucocorticoid effects.
- Drain/flush anal gland abscesses.
- Cyclosporine (3-5 mg/kg PO q 12 h) or topical tacrolimus ointment (0.03%-0.1%) for perianal fistula; cyclosporine more effective
- Surgery: perineal hernias (repair), colonic or rectal polyps (excision), colonic/rectal/anal sac tumors (resection), rectal strictures (rectal “pull-through”)
- Adjunctive chemotherapy and/or palliative therapy with piroxicam (0.3 mg/ kg PO q 24-48 h) for anal sac adenocarcinomas

CHRONIC TREATMENT

Dependent on the underlying cause

DRUG INTERACTIONS/SIDE EFFECTS

- Immunosuppressive therapy (azathioprine, chlorambucil): myelosuppression
- 5-aminosalicylates: keratoconjunctivitis sicca
- Iatrogenic hyperadrenocorticism with chronic glucocorticoid use
- Nonsteroidal antiinflammatories (e.g., piroxicam) can cause GI ulceration, renal failure. Blood work prior to initiation recommended to assess liver and renal function.
- Do not use glucocorticoids and nonsteroidal antiinflammatories concurrently: increased risk of GI ulceration.

POSSIBLE COMPLICATIONS

- Recurrent tenesmus, a colonic/rectal obstruction causing obstipation, or a rectal prolapse (uncommon; usually young patients <6 months old)
- Surgery: risk of postoperative fecal incontinence

PROGNOSIS AND OUTCOME

- Colonic/rectal inflammatory lesions: often successful (medical therapy)
- Anal sac disease, perineal hernias, wounds within and sunounding the anorectal area: better prognosis than strictures or neoplasia
- Perineal fistulas: improved prognosis with cyclosporine, but costly. Tacrolimus is less expensive, but not as effective.

PEARLS & CONSIDERATIONS

COMMENTS

- Stranguria is a common impostor for tenesmus, especially in cats. Thorough questioning during history taking, and observation of the animal's elimination process, are essential for avoiding misdiagnosis.
- Tenesmus is a clinical sign, not a disease. Therefore, an underlying cause must be sought.
- Workup is highly dependent upon obtaining a clear history and observing the animal urinate/defecate.

EDITOR: ETIENNE CÔTÉ

Temporomandibular Joint Luxation

BASIC INFORMATION

DEFINITION

Complete displacement of the mandibular condyle out of the corresponding mandibular fossa of the temporal bone. Subluxation of the temporomandibular joint (TMJ) occurs when the mandibular condyle is incompletely displaced.

EPIDEMIOLOGY

SPECIES, AGE, SEX: TMJ luxation can occur in dogs and cats of any age. TMJ luxation with regional fracture is more common in younger cats with head trauma. Cats have a higher incidence of TMJ luxation than dogs, owing to decreased mandibular symphyseal movement and shorter jaw length. GENETICS & BREED PREDISPOSITION: Any breed affected when associated with trauma. Breeds predisposed to TMJ dysplasia (shallow to flat mandibular fossa with flattening of mandibular condyle) are at risk for TMJ subluxation and luxation and open-mouth jaw locking (Basset hound, dachshund, Irish setter; Persian cats).

RISK FACTORS: Trauma, TMJ dysplasia, increased mandibular symphyseal laxity

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Subluxation: minimal displacement of the mandibular condyle, which is still situated in its corresponding mandibular fossa of the temporal bone
- Luxation:
  - Rostrodorsal: most common and usually unilateral
  - Caudoventral: rarely noted; usually associated with fracture of the retroarticular process of the temporal bone
- Open-mouth jaw locking (see Etiology and Pathophysiology, below)

HISTORY, CHIEF COMPLAINT: Owners present animals for head trauma or inability to close the mouth fully, pain on chewing/yawning, reluctance to play or chew on toys, inappetence, and/or an audible click when opening or closing the mouth. Depending on etiology, progression may be peracute, acute, or chronic.

PHYSICAL EXAM FINDINGS: In rostrodorsal luxation, the lower jaw is shifted and tilted ventrally to the unaffected side. This malocclusion results in abnormal upper and lower tooth contact, leading to inability to close the mouth fully. Other findings may include decreased range of lower jaw motion, decreased eye globe retropulsion on the affected side, swelling and discoloration of the ipsilateral glossopalatine region, swelling, crepitation and pain with affected TMJ palpation, dehydration, and hypersalivation.

TEMPOROMANDIBULAR JOINT LUXATION Skull of a cat, ventral view. Right mandibular condyle *(asterisk)* is luxated rostrally and dorsally, causing lower jaw to shift towards the left side *(arrows).* For comparison, note normal left temporomandibular joint *(dotted oval),* with mandibular condyle articulating with mandibular fossa of temporal bone.

ETIOLOGY AND PATHOPHYSIOLOGY

Relevant anatomy:

- Mandibular ramus: vertical part of mandible that lies medial to the zygomatic arch, caudolateral to the orbit
- Mandibular condyle: articular process of the mandible; articulates with mandibular fossa of the temporal bone to form temporomandibular joint
- Retroarticular process: process of the temporal bone preventing caudal dislocation of the mandibular condyle
- Coronoid process: dorsal protuberance of the mandibular ramus providing insertion for the temporal muscle

Luxation with/without regional fracture:

- Trauma is the most common inciting cause; TMJ dysplasia may predispose the animal to subluxation/luxation without obvious outside force.
- Luxation in a rostrodorsal direction is most common because the prominent retroarticular process prevents caudoventral movement of the mandibular condyle.
- More tightly seated mandibular condyle in the mandibular fossa of the temporal bone makes luxation in cats more common when there is an associated regional fracture. Dogs have a more loosely seated mandibular condyle, and luxations usually occur without regional fracture.
- In rostrodorsal luxation, the lower jaw will be shifted rostrally and laterally to the unaffected side.
- With complete luxation, the joint capsule is damaged; serious injury to the articular disk may be present.

TMJ dysplasia with/without coronoid process displacement:

- Rare congenital or acquired malformation: shallow mandibular fossa, underdeveloped/misshapen retroarticular process, flattened mandibular condyle, and periarticular osteophytosis; abnormal laxity in mandibular symphysis also reported as inciting cause of open-mouth jaw locking
- Open-mouth jaw locking: TMJ subluxation/luxation, rotational movement of the mandibular body and locking of the coronoid process ventrolateral to the zygomatic arch; mouth is locked wide open, and compared to TMJ luxation, there is no tooth-

to-tooth contact.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Clinical presentation and head radiographs (under general anesthesia) will provide conclusive diagnosis. If subluxation/luxation due to TMJ dysplasia is suspected, then CT scan with 3-D reconstruction or fluoroscopic imaging may be necessary for diagnosis. General anesthesia for diagnostic imaging also provides an opportunity for esophagostomy tube placement if prehension and chewing functions are unlikely to be reestablished immediately.

DIFFERENTIAL DIAGNOSIS

- TMJ luxation with/without regional fracture
- TMJ dysplasia with/without coronoid process displacement
- Mandibular neurapraxia (dysfunction of mandibular branch of cranial nerve V)
- Neurogenic atrophy of temporal, masseter, and digastricus muscles
- Mandibular ramus/zygomatic arch fracture
- Masticatory myositis
- Dental/skeletal malocclusion
- Periorbital/caudal mandibular/caudal maxillary neoplasia
- Foreign body

INITIAL DATABASE

- CBC and serum biochemistry panel: generally unremarkable; preanesthetic
- Head radiographs under general anesthesia: dorsoventral (ventrodorsal), right and left lateral oblique, and open-mouth views that show displacement of the mandibular condyle or coronoid process with/without fracture of associated bone structures

ADVANCED OR CONFIRMATORY TESTING

CT scan (see p. 1233):

- Excellent imaging modality for assessing TMJ disease
- Subtle abnormalities not identified on radiographs easily demonstrated on CT scan
- Three-dimensional (3-D) reconstruction beneficial for diagnosis and treatment planning and owner education

TREATMENT

TREATMENT OVERVIEW

Treatment goals are to alleviate discomfort and obtain functional lower jaw movement and occlusion.

ACUTE GENERAL TREATMENT

Acute TMJ luxation:

- Manual reduction of rostrodorsal luxation:
  - Chemical restraint (sedation or anesthesia)
  - Place a wooden dowel (pencil in small pets) between carnassial teeth of affected side only, and gently force the mouth closed until the joint is reduced. Remove the dowel/ pencil, but keep the mouth closed to maintain joint reduction.
  - Apply a slightly snug tape muzzle for 1-3 weeks. The muzzle should be sufficiently loose to allow the animal to lap up water and liquefied food.
  - Recovery from sedation/anesthesia, with particular attention to aspiration (e.g., remove muzzle immediately if vomiting appears imminent).
- Regional fractures (condylar process of mandible; mandibular fossa/retroarticular process of temporal bone) are usually treated conservatively without surgical intervention. Owners must be warned of possible complications such as TMJ ankylosis, which may become apparent 6-8 weeks after traumatic incident. Muzzling is contraindicated.

CHRONIC TREATMENT

Chronic TMJ luxation:

- Maxillomandibular fixation (applying a muzzle using white medical tape or inserting a composite bridge between upper and lower canines) for 4-6 weeks
- Condylectomy and bone fragment resection indicated for severe regional fractures resulting in TMJ ankylosis and arthrosis

NUTRITION/DIET

If normal prehension of food is not possible (e.g., complex jaw fractures, severe swelling), placement of an esophagostomy tube may be needed for nutritional support (see p. 1267).

PROGNOSIS AND OUTCOME

Excellent if no regional fracture; fair to poor if regional fracture ± ankylosis, particularly in immature/adolescent animals

PEARLS & CONSIDERATIONS

COMMENTS

- The most common form, rostrocaudal TMJ luxation, is usually unilateral.
- Do not force the mouth closed in patients presenting with the mouth wide open. Manual correction of open-mouth jaw locking is achieved by opening the mouth a little further, pressing the coronoid process medially, and closing the mouth. Definitive surgical treatment of open-mouth jaw locking is achieved with unilateral or bilateral partial zygomectomy, partial coronoidectomy, or a combination of both procedures.

TECHNICIAN TIPS

- Patients with tape muzzles may have compromised thermoregulation and should not be outdoors on warm or hot days. Restriction in mouth opening also bears the risk of aspiration in the regurgitating or vomiting patient, requiring extra vigilance during patient monitoring.
- To reduce the possibility of local pyoderma from a soiled muzzle, tape muzzles may be removed during drinking and eating and put back in place once feeding is completed.

Tear Film Abnormalities (Excluding KCS)

BASIC INFORMATION

DEFINITION

A relatively common ophthalmic condition characterized by abnormal mucin (produced by goblet cells of the conjunctiva) and/or lipid (produced by meibomian [tarsal] glands) component(s) of tears. Keratoconjunctivitis (KCS) is discussed separately on .

SYNONYMS

Qualitative tear deficiencies or abnormalities

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs and cats, any age, either sex

GENETICS & BREED PREDISPOSITION

- Cats predisposed to corneal sequestration (e.g., brachycephalic breeds) may be predisposed to tear film abnormalities (TFAs).
- Dogs predisposed to chronic eyelid and/or conjunctival irritation (e.g., breeds with inherited entropion and/or ectropion) are predisposed to developing qualitative tear deficiencies (see p. 348).

RISK FACTORS

- Disorders affecting the meibomian glands (e.g., alkali burns of the eye)
- Patients with diseases resulting in primary (e.g., feline herpesvirus-1 infection) or secondary keratoconjunctival (e.g., entropion/ectropion, keratoconjunctivitis sicca [KCS]) disorders

ASSOCIATED CONDITIONS & DISORDERS

- Conjunctivitis and TFAs commonly coexist (unclear which is causative).
- Superficial keratitis (nonulcerative or ulcerative)
- Eyelid disorders:
  - Entropion (common)
  - Ectropion (common)
  - Eyelid agenesis (rare)
  - Autoimmune disorders (rare)
  - Infectious marginal blepharitis (occasional)
- Chemical ocular burns (occasional)
- Primary or secondary skin disease involving eyelid mucocutaneous junctions (common)
- Keratoconjunctivitis sicca (common; see p. 628)
- Diabetes mellitus in dogs (common)

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES: Mucin tear deficiency, lipid tear deficiency

HISTORY, CHIEF COMPLAINT

- Swollen eyelids
- 'Red' eye
- Serous or mucoid to mucopurulent ocular discharge
- Previous bout(s) of conjunctivitis responsive to standard topical medication(s) but recurrent
- Squinting
- Corneal cloudiness (see p. 245)

PHYSICAL EXAM FINDINGS

- Systemic: generally unremarkable except in those cases where systemic disease is present (e.g., diabetes mellitus; generalized seborrhea)
- Ophthalmic:
  - Serous or mucoid to mucopurulent ocular discharge
  - Conjunctival hyperemia ± chemosis
  - ± Blepharospasm
  - ± Protrusion of the third eyelid
  - Signs of keratitis with chronicity:
    - Corneal vascularization (see p. 254)
    - Corneal pigmentation (see p. 246)
    - Corneal ulceration (see p. 250)
    - Blepharitis, usually marginal with associated meibomianitis with or without overt lipogranulomas/chalazia

ETIOLOGY AND PATHOPHYSIOLOGY

- Mucin tear deficiency:
  - Primary/spontaneous of unknown cause
  - Secondary to conjunctivitis; loss of the conjunctival goblet cells, diminished mucin production with unstable tear film
- Lipid tear deficiency:
  - Inflammation of the meibomian glands (which produce the lipid component of the tear film) directly or by extension from margins of the eyelids (marginal blepharitis):
    - Diseased meibomian glands produce highly polar lipids which destabilize the nonpolar lipid layer of the tear film, allowing rapid evaporation of the aqueous component of tears.
    - Dried lipid plugs meibomian gland ducts
    - Chronic meibomianitis can cause rupture and lipid release into palpebral tissue.
    - With eyelid agenesis: lack of meibomian glands

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis is suspected on presenting complaint and physical exam (e.g., recurrent conjunctivitis, “red” eye, ocular discharge) and confirmed with identification of abnormal meibomian glands (lipid tear deficiency) and/or abnormal tear film breakup time (TFBUT).

DIFFERENTIAL DIAGNOSIS

- Other keratoconjunctival disorders, including:
  - Keratoconjunctivitis sicca (see p.628), conjunctivitis (see pp. 237 and 239), chronic superficial keratitis (CSK/pannus, dogs; see p. 825), feline herpesviral keratitis (see p. 524), proliferative (eosinophilic) keratoconjunctivitis (cats), and corneal exposure/ineffectual blinking (e.g., lagophthalmos)
- Blepharitis

INITIAL DATABASE

- History ± bouts of conjunctivitis that were temporarily responsive to routine topical medications
- Complete ophthalmic examination () including:
  - Schirmer tear test (STT): normal or elevated STT values; normal STT value ≥ 15 mm/min in dogs; variable in cats.
  - Fluorescein dye application: secondary corneal ulceration is possible.
  - Intraocular pressures: normal IOP values; normal IOPs range from 15-25 mm Hg (dogs and cats).

ADVANCED OR CONFIRMATORY TESTING

- Meibomian gland examination using magnification lipid tear abnormalities: slight protrusions of meibomian gland ductal openings; swollen, rounded, hyperemic eyelid margins; yellowish subconjunctival masses [lipogranulomas/chalazia] possible)
- Evaluation of TFBUT: mean normal TFBUT = 19.6 seconds in dogs and 16.7 seconds in cats; TFBUT is rapid/ accelerated with mucin tear deficiency (i.e., TFBUT < 5-10 seconds):
  - Prior to instillation of topical solutions on the surface of the eye or a few hours following ophthalmic examination
  - Evaluates stability of the tear film
  - Performed by instilling one drop of fluorescein stain onto the eye, closing the eyelids to distribute the stain, and then opening them, using a cobalt-blue filter, and immediately commencing timing until the appearance of the first black/dark spot within the green fluorescein-stained corneal tear film
- Palpebral conjunctival biopsy and staining with periodic acid-Schiff (PAS) for quantification of epithelial goblet cells

(diminished to absent with mucin tear deficiency)

TREATMENT

TREATMENT OVERVIEW

The treatment goals are to stabilize the tear film and eliminate ocular pain. Identifying and treating the underlying cause of the TFA is essential.

ACUTE AND CHRONIC TREATMENT

- Variable depending on the underlying cause
- Lacrimomimetics (tear substitutes and stabilizers) q 4-8 h (e.g., viscous mucinomimetic [e.g., hyaluronic acid 0.4%]) for mucin tear deficiency; emollient/ oil-based tear supplement (e.g., Lacri-Lube ointment) for lipid tear deficiency) may be used for initial 3-4 weeks without concurrent lacrimostimulant if rapid improvement in clinical signs noted and no concurrent KCS.
- ± Lacrimostimulants:
  - Cyclosporine A (CsA) 0.2% ointment or 0.5%-2% solution q 8-12 h usually required for at least 4 weeks and possibly lifelong. May increase to q 8 h if TFBUT < 10 seconds after 3-4 weeks of treatment; some advocate increasing concentration of solution (e.g., 0.2%-2%). May decrease to q 24 h if TFBUT ≥ 10 sec and clinical signs improve/resolve.
  - Tacrolimus 0.02%-0.03% ointment or aqueous suspension q 12 h if no response to CsA after 3-6 weeks (unproven long-term safety).
- Antimicrobials if secondary bacterial conjunctivitis and/or corneal ulceration:
  - Topical broad-spectrum antibiotic (e.g., bacitracin-neomycin-polymyxin solution q 6-8 h for 7-14 days or until the corneal ulcer has healed)
- Antiinflammatories if severe conjunctivitis and/or corneal vascularization/ pigmentation:
  - Prednisolone acetate 1% suspension q 6-8 h if corneal ulceration is ruled out

NUTRITION/DIET

Consider L-lysine supplementation for feline herpesvirus 1 infection (see p. 524).

POSSIBLE COMPLICATIONS

- Corneal ulceration
- Vision impairment from progressive corneal vascularization/pigmentation (chronic uncontrolled qualitative tear deficiency)

RECOMMENDED MONITORING

- Complete ophthalmic examination with STT, TFBUT, and corneal fluorescein staining performed every 3-4 weeks initially
- Rechecks performed every 4-6 weeks until qualitative tear deficiency and associated disorder(s) (e.g., marginal blepharitis and meibomianitis) is/are controlled, then every 3-4 months

PROGNOSIS AND OUTCOME

- Variable depending on underlying cause
- Delayed diagnosis and treatment may result in permanent quantitative and qualitative changes in meibomian glands and/or goblet cell function.

PEARLS & CONSIDERATIONS

COMMENTS

- Response to lacrimomimetics may occur following 3-4 weeks; if not, instituting concurrent topical lacrimostimulants is advised and may be required lifelong.
- May take weeks to months of therapy before determining if favorable response to lacrimostimulants

PREVENTION

Breeds predisposed to eyelid disorders associated with qualitative tear deficiencies: avoid breeding affected or closely related dogs.

AUTHOR & EDITOR: CHERYL L. CULLEN

Taurine Deficiency

BASIC INFORMATION

DEFINITION

Inadequate intake or availability of dietary taurine

EPIDEMIOLOGY

SPECIES, AGE, SEX: Taurine is an essential nutrient for cats but not for dogs under most circumstances. Deficiency can occur in cats that cannot meet metabolic needs from dietary sources and occasionally in dogs, particularly if on restricted diets.

GENETICS & BREED PREDISPOSITION

- None reported in cats
- In dogs, isolated occurrences of taurine-deficient dilated cardiomyopathy have been identified in a variety of breeds, including American cocker spaniels, golden retrievers, and Newfoundlands.

RISK FACTORS

- Cats: inadequately supplemented commercial or home-prepared diets
- Dogs: breed predisposition, inadequate protein and sulfur-containing amino acid intake (restricted diets), possible impact of diet composition on intestinal availability

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Cats: central retinal degeneration (CRD), reproductive failure, growth retardation, and dilated cardiomyopathy (DCM)
- Dogs: DCM in susceptible breeds or individuals

HISTORY, CHIEF COMPLAINT

- Cats: compatible diet history (poorly formulated commercial or home-prepared diet) is suggestive but not pathognomonic; dyspnea, respiratory distress.
- Dogs: exercise intolerance and weight loss progressing to cough, respiratory distress, and eventually ascites; possible diet history of restricted diet (very low-protein diets, vegan diets, dry dog food with lamb meal, rice, or both as the primary ingredient)

PHYSICAL EXAM FINDINGS

- Cats: variable combinations of tachypnea, dyspnea, tachycardia, lethargy, dehydration, and hypothermia. Systolic murmur at the apex on the left side, with gallop rhythm in severe cases. Peripheral vasoconstriction may result in cold extremities.
- Dogs: similar to cats; tachyarrhythmia

ETIOLOGY AND PATHOPHYSIOLOGY

- Taurine is synthesized from methionine and cysteine. It does not occur in proteins but is required for a variety of cellular homeostatic functions. Synthesis occurs in cats too slowly to maintain taurine balance in the absence of adequate intake. Dogs have a greater ability to synthesize taurine than cats but occasionally develop taurine deficiency as well. Obligatory loss also occurs in cats and dogs, because only taurine can combine with cholesterol during bile salt synthesis, whereas most other species can substitute glycine for taurine.
- In cats, excessive taurine-conjugated bile salt loss in feces occurs secondary to variable combinations of type of diet processing, protein source, changes in location and/or numbers of intestinal microflora, and/or increased secretion of bile salts due to changes in the release of cholecystokinin.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The possibility of taurine deficiency should be considered in cats and dogs with a compatible diet history and signs of cardiac dysfunction (dogs, cats) or blindness (cats).

DIFFERENTIAL DIAGNOSIS

- Idiopathic DCM
- Other causes of myocardial failure

INITIAL DATABASE

- Cats: radiography to determine presence of heart failure (cardiomegaly plus pleural effusion, pulmonary edema, or both). Do not attempt to obtain radiographs of severely dyspneic, struggling patients, because the stress of the procedure may result in the death of the cat.
- Dogs: radiography, as for cats; electrocardiographic (ECG) signs include variable combinations of left-sided enlargement, sinus tachycardia, atrial fibrillation, and ventricular tachyarrhythmias.

ADVANCED OR CONFIRMATORY TESTING

- Echocardiography is the test of choice for diagnosis of DCM: dyskinesis (reduced systolic motion) of the left ventricular walls, increased end-diastolic diameter, and reduced shortening fraction.
- Blood and/or plasma taurine concentration (draw sample into heparin [green top] tube):
    - Animals with low taurine concentrations (whole blood: <200 nmol/mL in cats, <150 nmol/mL in dogs; plasma <40 nmol/mL in cats and dogs) should be switched to diets known to result in higher plasma concentrations or supplemented with taurine. Plasma taurine concentrations fluctuate with food intake, whereas whole blood taurine reflects long-term (weeks to months) intake.

TREATMENT

TREATMENT OVERVIEW

The goals of treatment are to restore taurine homeostasis and improve cardiac function.

ACUTE GENERAL TREATMENT

- Supportive care for congestive heart failure (CHF; see p. 470), inotropic support (digoxin, pimobendan) and arrhythmias
- Taurine supplementation pending confirmation of diagnosis

CHRONIC TREATMENT

- Cats: recommend switching the cat to a satisfactory diet and supplementing with taurine at 250-500 mg PO or in food q 12 h for 3-6 months or until echocardiographic parameters return to normal.
- Dogs: recommend 1000 mg taurine/ day PO (divided, or once a day). Change to a diet containing more protein and sulfur-containing amino acids and less fiber if possible.

RECOMMENDED MONITORING

- Clinical condition
- Taurine levels should be reevaluated in 1-2 months.
- Radiography, echocardiography

PROGNOSIS AND OUTCOME

- The prognosis is better when deficiency is identified and treated appropriately before extensive permanent change exists in the myocardium. Clinical signs of advanced heart failure, such as hypothermia or thromboembolism, suggest a poorer

prognosis.
- Dogs that improve in conjunction with taurine supplementation become more energetic after a few weeks; they then also show reduction in cardiomegaly, and improvement in echocardiographic parameters should be observed in 3-6 months.

PEARLS & CONSIDERATIONS

COMMENTS

Recovery of function and appetite occur within days to weeks after provision of taurine if deficiency of this amino acid is the cause of the signs. When they occur, reduction in cardiomegaly and improvement in echocardiographic parameters may require 3-6 months of supplementation; improvement may permit reduction or discontinuation of cardiac medications.

PREVENTION

Feeding a properly formulated diet

CLIENT EDUCATION

Explain the importance of feeding pets a properly formulated diet.

Tarsal Trauma

BASIC INFORMATION

DEFINITION

Includes ligament damage, luxation/subluxation of individual tarsal bones, fractures, or shearing injuries

SYNONYM

Tarsal breakdown

EPIDEMIOLOGY

GENETICS & BREED PREDISPOSITION: Racing greyhounds: central tarsal bone fractures. Border collies: central tarsal bone fracture with luxation. Shelties and collies: luxation of superficial digital flexor tendon.

RISK FACTORS: Racing or agility activities; distal hind limb trauma

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES: Sprains, fractures, and shearing or degloving wounds; coaptation-related injuries, including pressure sores from casts or splints, dermatitis from soiled bandages, and wound infection or dehiscence from contaminated dressings

HISTORY, CHIEF COMPLAINT: Hind limb trauma; lameness after competition or exercise

PHYSICAL EXAM FINDINGS

- Lameness
- Swelling
- Open wounds around the tarsus
- Pain or crepitation on palpation of the tarsus
- Gross instability characterized by a plantigrade stance
- Tarsal deformity

ETIOLOGY AND PATHOPHYSIOLOGY

- Racing animals on counterclockwise tracks are predisposed to right-sided injuries.
- In racing greyhounds, there is a classic triad of fractures involving the central tarsal bone, calcaneus, and base of metatarsal V.
- In border collies, unknown etiology for exercise induced subluxation with central tarsal bone fracture
- In pets, fractures often occur in the calcaneus.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Tarsal injuries are best diagnosed by physical and radiographic examinations.

DIFFERENTIAL DIAGNOSIS

- Autoimmune polyarthropathy (systemic lupus erythematosus [SLE], rheumatoid arthritis)
- Infectious (Lyme borreliosis, rickettsial disease)

INITIAL DATABASE

- Mediolateral and dorsopalmar radiographic projections of the tarsus

- CBC, chemistry panel, and urinalysis based on the animal's stability and the American Society of Anesthesiologists (ASA) classification (see p. 1372)
- Thoracic/abdominal radiographs, abdominal ultrasound, electrocardiogram (ECG) for animals that have undergone severe trauma

ADVANCED OR CONFIRMATORY TESTING

- Oblique radiography (nondisplaced fractures); skyline views (trochlea of the talus)
- Stress-film radiography (mediolateral radiograph with tarsus manually forced into dorsal and plantar extension and a dorsoplantar radiograph with a medial to lateral stress applied) to identify location of joint instability

TREATMENT

TREATMENT OVERVIEW

The goal of therapy is anatomic and functional restoration of tarsal functions:

- Fractures: stabilization and anatomic reduction
  - Buttress repair of comminuted tarsal bone fractures to prevent joint collapse
- Ligamentous injuries: reestablishment of joint support by repairing collateral ligaments or arthrodesis/ankylosis
- Shearing injuries: wound management

ACUTE GENERAL TREATMENT

- Minimally displaced, nonarticular fractures and grade I and most grade II sprains can be stabilized for 6-8 weeks with an external splint (see p. 1336):
  - Luxated joints, intraarticular fractures, and grade III sprains are supported in a modified Robert-Jones bandage until surgery.
- Shearing injuries require initial wound-management treatment (see p. 1016):
  - Gentle lavage of open wounds using warm saline, lactated Ringer's solution, and dilute chlorhexidine solutions to reduce gross contamination. (Animals are sedated and given analgesics.)
  - Coverage of tissues with moistened (above solutions) gauze sponges useful in débridement (wet-to-dry-bandages) as they are changed daily.
  - Alternatively, direct application of sugar or honey has been used for reducing infection and promoting healing for highly contaminated, traumatic open wounds, but the role of such treatment in the joint is unclear.
  - Final surgical débridement and joint lavage can be performed during orthopedic stabilization surgery.
  - Wounds with healthy granulation tissue, reduced contamination, and early epithelialization can be closed with sutures or covered with a non-adherent dressing and allowed to heal via second intention.

CHRONIC TREATMENT

- Surgical repairs to the tarsus require 6-12 weeks of external coaptation (splints or external fixatures) and exercise restriction.
- Collateral ligament disruption requires stabilization with tension-band principle (malleolar fractures) or replacement with prosthetic suture.
- Instability of the tarsocrural joint or complete (grade III) plantar tarsal disruption necessitates pantarsal arthrodesis.
- Individual tarsal bone fractures require lag screw fixation, except for lesions of the calcaneus (tension-band principle).
- Plantar intertarsal and plantar tarso-metatarsal subluxations are unstable in weight-bearing animals and require partial tarsal arthrodesis with pins or small plates (tension-band principle).
- Dorsal intertarsal and dorsal tarso-metatarsal subluxations are rare and stable (compressed) in weight-bearing animals:
  - Establishing the diagnosis requires stress film radiography.
  - Primary ligament repair or partial tarsal arthrodesis is performed.
- Luxation of the superficial digital flexor tendon is treated by suturing of torn retinacular tissues.

POSSIBLE COMPLICATIONS

- Reduction/implant failure
- Delayed or failed arthrodesis
- Plantar necrosis (vascular injury)
- Wound infection
- Coaptation-related morbidity
- Degenerative joint disease

RECOMMENDED MONITORING

- Lameness evaluation 1-3 months following injury and treatment
- Serial radiographic studies to evaluate fracture healing or progression of arthrodesis

PROGNOSIS AND OUTCOME

- Good to excellent for noncompeting dogs
- Variable for return to preinjury status for competing dogs
- Severe shearing injuries with neurovascular compromise may necessitate limb amputation.

PEARLS & CONSIDERATIONS

COMMENTS

- When conservatively managed, intraarticular fractures rarely heal with osseous bridging, thus leading to degenerative joint disease. Surgical treatment is recommended to reduce the risk of such adverse consequences.
- Severe shearing injuries are commonly due to motor vehicle trauma. Despite significant damage, acceptable function is possible with various reconstructive efforts.
- In noncompeting animals, solitary intertarsal joint fusion/ankylosis (i.e., calcaneotarsal, calcaneoquartal, quartalmetatarsal) can lead to near normal function.

AUTHOR: JOHN J. HABURJAK

EDITOR: JOSEPH HARARI

Tail Paralysis

BASIC INFORMATION

DEFINITION

Severe impairment or loss of tail motor function

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dependent on underlying cause

GENETICS & BREED PREDISPOSITION

- Pugs, bulldogs (spina bifida, sacrocaudal dysgenesis)
- Chondrodystrophic breeds (disk herniation)

RISK FACTORS

- Outdoor cats (trauma)
- Free-roaming dogs
- Cardiomyopathies in cats (aortic thromboembolism)
- Type I disk herniation with severe paraparesis
- Degenerative lumbosacral stenosis (cauda equina syndrome)

ASSOCIATED CONDITIONS & DISORDERS

- Cutaneous wounds of the tail:
  - Self-inflicted if sensation altered by neurologic disease
  - Secondary to external trauma (hit by car, falls, etc.)
- Tail fracture

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Trauma involving the hind quarters (hit by car, falls, stepped on, etc.)
- Trauma involving traction injury on the tail (exercise-related, malicious, caught in door, etc.)
- Unwillingness to jump up (e.g., lumbosacral diseases)
- Acute-onset vocalization and hind limb paresis/paralysis (aortic thromboembolism)

PHYSICAL EXAM FINDINGS

- Impaired tail motility with or without hind limb paresis
- Skin wounds (limbs, trunk, abdomen and/or tail)
- Concurrent fractures of the axial skeleton, pelvis, pelvic limbs, and/or thoracic limbs
- Urinary and/or fecal incontinence, urine- or feces-soiled tail
- Pain originating from the pelvic area
- Weakness, pale mucous membranes, dyspnea (if cat with thromboembolic disease)
- Shock if massive trauma
- Tachycardia, heart murmur, gallop, weak or absent pulses, cyanosis of the pelvic limbs (if feline cardiomyopathy)
- Transverse myelopathy (T3-L3 or L4-S3 or Cd1-Cd5 only)
- Large, distended bladder:
  - Easy to empty if spinal lesion involves lumbar intumescence (“lower motor neuron bladder”)
  - Difficult to empty if spinal lesion is cranial to lumbar intumescence (“upper motor neuron bladder”)
- Rectal exam: painful and might induce sacrocaudal instability if associated with trauma

ETIOLOGY AND PATHOPHYSIOLOGY

- Orthopedic:
  - Spinal/coccygeal fracture
  - Degenerative lumbosacral stenosis
- Neurologic:
  - Spinal malformations
  - Spinal fracture
  - Nerve root avulsion (lumbar intumescence/coccygeal)
  - Disk herniation (with or without paraparesis)
  - Tumor of the spine/spinal canal/cord
- Cardiac/vascular:
  - Feline thromboembolic disease
  - Vascular compromise secondary to trauma (arterial avulsion or thrombosis)
  - Fibrocartilaginous embolism

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Tail paralysis is apparent on physical exam. A complete neurologic exam helps identify the extent of the causative lesion, which in turn contributes to determining the prognosis, and whether or not treatment is likely to require tail amputation.

DIFFERENTIAL DIAGNOSIS

- Anomalous (spina bifida, hemivertebra, sacrocaudal dysgenesis, dermoid sinus)
- Degenerative lumbosacral stenosis (stenosis of vertebral canal, type II disk at L7-S1 space, sacral osteochondrosis, instability and misalignment of L7-S1, articular facet arthritis)
- Intervertebral disk disease (type I or type II)
- Spinal trauma/fracture/avulsion
- Vascular (feline thromboembolism, fibrocartilaginous embolism)
- Neoplasia
- Diskospondylitis

INITIAL DATABASE

- Rectal exam to document pain, swelling, instability, mass effect
- Complete neurologic examination to localize the lesion (see p. 1311)
- Radiographs of the spine, including sacrocaudal region (malformations, fracture/trauma/avulsion, diskospondylitis, osteolytic/osteoproliferative tumor, intervertebral disk disease)
- CBC, serum biochemistry panel, urinalysis depending on patient stability and systemic involvement
- Thoracic radiographs:
  - To evaluate the presence of thoracic lesions secondary to trauma
  - To assess for metastases if neoplasia is suspected
- Ultrasound:
  - Thoracic (for feline cardiomyopathy)
  - Abdominal if suspected pelvic canal tumor

ADVANCED OR CONFIRMATORY TESTING

- Advanced imaging modalities: myelography (see p. 1306), CT (see p. 1233), MRI (see p. 1302)
  - May be indicated for assessing underlying spinal abnormalities
- Electromyography (rare instances of neuromuscular disease)
- Fine-needle aspiration if possible for cytologic evaluation (masses, diskospondylitis)
- Ultrasound-guided biopsy (masses)

TREATMENT

TREATMENT OVERVIEW

- Orthopedic or neurologic:
  - Treatment limited to addressing underlying cause if no vascular compromise

    - Medical management of fractures, using pain management, bandages for immobilization
    - Amputate tail if vascular compromise:
        - Leave 3-4 coccygeal vertebrae if well vascularized.
        - Amputate to the level of the skin if tail is devascularized.
- Cardiac/vascular:
    - Tail amputation if tail is soiled by urine and/or feces or if tail has not revascularized well
    - Address underlying cardiac disease.
- Neoplasia:
    - Wide surgical excision if possible
    - Radiation therapy or chemotherapy if indicated and if possible
- Skin wound of the tail (see p. 1016):
    - With vascular compromise, amputate tail at appropriate level.
    - Without vascular compromise, treat accordingly by local débridement (wet-to-dry bandaging or surgical débridement).
    - Use second-intention healing (bandages with hydrogel).
    - If wound closure impossible via second-intention healing, use secondary closure (local skin flaps, free skin grafts).

ACUTE GENERAL TREATMENT

- Treat shock if present.
- Treat underlying cardiac cause.
- Administer corticosteroids if tail paralysis is secondary to spinal cord/nerve compression (controversial; see p.1039).
- Once patient is stable, treatment depends on underlying cause.

CHRONIC TREATMENT

- Hygiene and topical care to prevent urine/fecal contact dermatitis:
    - Bathing, keeping area dry and clean, clipping perianal region, and protective ointment if necessary
- Bladder catheterization if necessary
- Physical therapy for paraparetic patients
- As indicated by underlying cardiac disease

POSSIBLE COMPLICATIONS

- Dependent on therapeutic options
- Beware of corticosteroid administration:
    - Associated with gastrointestinal ulceration, colonic perforation

RECOMMENDED MONITORING

Dependent on primary cause and therapeutic options

PROGNOSIS AND OUTCOME

- Trauma:
    - Intact deep pain perception and normal vascularization: guarded. Generally these patients will regain enough motor activity to avoid lack of hygiene.
    - Absence of deep pain for more than 48 hours: poor prognosis for return of motor activity, but good if tau amputated and normal voluntary hind limb activity and bladder control
- Guarded to poor if feline thromboembolic disease (recurrence risk)

PEARLS & CONSIDERATIONS

COMMENTS

- The most common causes of tail paralysis are trauma and degenerative lumbosacral stenosis:
    - Prognosis depends on deep pain perception and vascular supply.
- In dogs and cats, the tail is not essential to life:
    - Tail amputation in patients with normal limb function and bladder control provides excellent quality of life.
- Beware: pain originating from the pelvic canal (e.g., prostatic abscess, degenerative lumbosacral stenosis) can mimic tail paralysis.

CLIENT EDUCATION

Variable: depends on primary cause of tail paralysis

SUGGESTED READING

De Lahunta A, Glass EC: Veterinary neuroanatomy and clinical neurology, ed 3, St Louis, 2009, Saunders Elsevier.

Uveitis

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

Inflammation of part or all of the uveal tract, including the iris, ciliary body, and choroid. May be associated with inflammation of adjacent structures such as the retina, vitreous, sclera, lens, and cornea.

SYNONYMS

Anterior uveitis: iridocyclitis, cyclitis, panuveitis (inflammation of the entire uveal tract)

Posterior uveitis: choroiditis, chorioretinitis, retinochoroiditis

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs and cats; any age or sex

GENETICS & BREED PREDISPOSITION: Many forms of uveitis have a significant immune-mediated component and thus may have a genetic/breed predisposition:

- Uveodermatologic syndrome/Vogt-Koyanagi-Harada (VKH) syndrome: causes granulomatous uveitis and depigmenting dermatitis in dogs, especially Akitas, Samoyeds, and Siberian huskies
- Pigmentary uveitis: associated with pigment dispersion in the anterior chamber in the golden retriever:
  - Uveal cysts (see p. 1149) are often seen in conjunction with pigmentary uveitis.

CONTAGION & ZOONOSIS: A few selected forms of uveitis associated with certain infectious diseases may have contagion and zoonotic potential: *Brucella* uveitis (dogs): both contagious and zoonotic implications (see p. 162); feline leukemia virus (FeLV, see p. 385), feline infectious peritonitis (FIP; see p. 383), and feline immunodeficiency virus (FIV; see) infections are contagious between cats; and toxoplasmosis could have zoonotic potential, but the majority of cats are not passing oocysts during clinical ocular disease (see p. 1105).

GEOGRAPHY AND SEASONALITY: Certain infectious disease etiologies may exhibit seasonality and/or geographic incidence.

ASSOCIATED CONDITIONS & DISORDERS

- Uveitis associated with infectious diseases frequently, but not invariably, may have associated systemic signs.
- Immune-mediated causes of uveitis may also have nonocular signs (e.g., dermatologic signs as noted in uveodermatologic syndrome/VKH).

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Portion of the uvea involved (anterior: iris and/or ciliary body; posterior: choroid; panuveitis: entire uveal tract)
- Acute versus chronic
- Type of inflammation (i.e., nongranulomatous versus granulomatous; nonsuppurative versus suppurative)
- Cause of the uveitis

HISTORY, CHIEF COMPLAINT

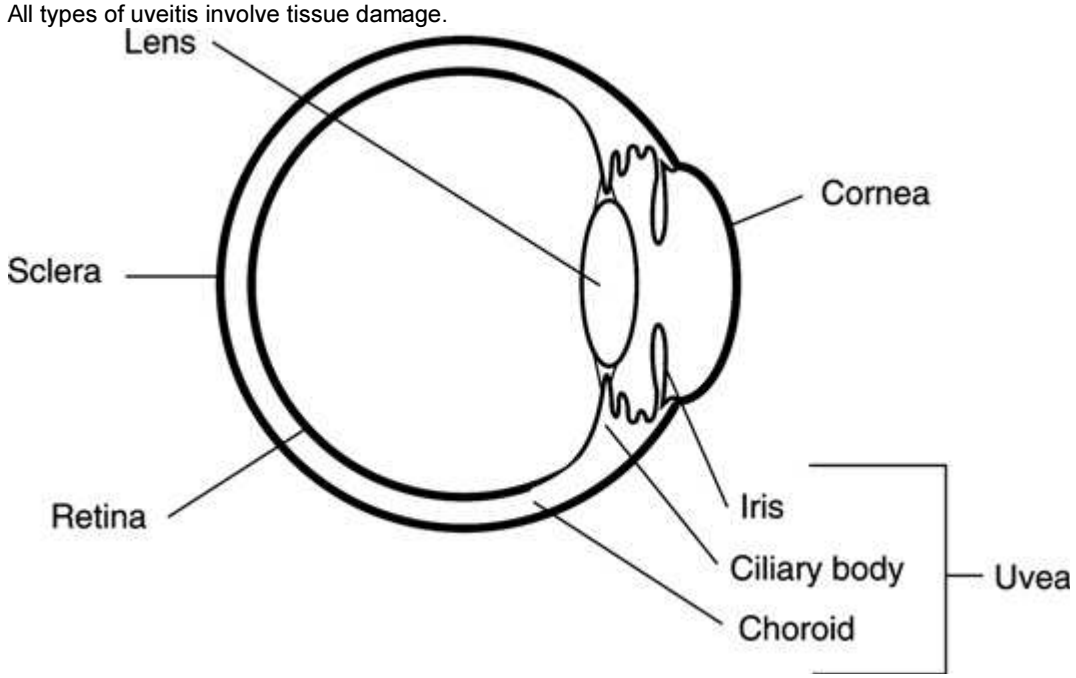
- Variable systemic complaints if caused by systemic disease
- “Red eye”
- Vision problem
- Photophobia
- Blepharospasm
- Color changes in interior of eye

PHYSICAL EXAM FINDINGS

- Conjunctiva and episclera:
  - Congestion/hyperemia of blood vessels
- Cornea:
  - Corneal edema of varying degrees
  - Corneal vascularization (deep) if more chronic
  - +/− Keratic precipitates (forms of white blood cell [WBC] aggregates in which multiple round to ovoid, gray to yellowish opacities are noted on the posterior cornea)
- Anterior chamber:
  - Aqueous flare (cloudiness of the aqueous humor caused by increased protein levels)
  - +/− Fibrin clots
  - +/− Hyphema
  - +/− Hypopyon
- Iris:
  - Color changes (e.g., blue iris becomes brown, brown iris becomes darker or depigmented).
  - Texture changes (e.g., thickened iris with possible visible neovascularization, such as in rubeosis iridis)
- Pupil:
  - Acute, often miotic; chronic, mid-range in size
  - Slow to dilate in response to or lack of response to mydriatics, such as to topical 1% tropicamide
  - Focal or diffuse posterior synechiae (adhesions of iris to lens; e.g., iris bombé, 360° pupillary synechia impairing aqueous drainage and causing iris to balloon forward)
  - Lack of consensual pupillary light reflex in opposite eye if involved eye is blind
- Lens:
  - +/− Varying degrees of cataract; if inflammation is secondary to cataract, the cataract is relatively diffuse; if the cataract is secondary to uveitis, the opacity is usually incomplete and on the capsule/anterior cortex.
- Intraocular pressure (IOP): low unless complicated by secondary glaucoma
- Posterior segment:
  - Posterior uveitis may be accompanied by effusive retinal detachments of varying degrees
  - +/− Vitreal haze due to inflammation in vitreous humor
  - +/− Diffuse or (more likely) multifocal color changes in the fundus, associated with inflammatory infiltrates
  - Optic nerve swelling and hyperemia in some cases

ETIOLOGY AND PATHOPHYSIOLOGY

- All types of uveitis involve tissue damage.



UVEITIS Sagittal section of the globe, showing the anatomic relationships of the uvea to the other parts of the eye.

- Clinical signs are attributed to disruption of the blood-ocular barrier (physiologic mechanism that prevents exchange of large molecular materials between the blood and chambers of the eye) and release of numerous chemical mediators following tissue damage.

Etiology:

- Primary ocular:
  - Blunt and perforating trauma (see p. 249), including surgical trauma
  - Corneal ulceration (see p. 250)
  - Lens-induced:
    - Rapidly developing or hypermature cataracts leaking soluble lens proteins into eye, causing uveitis
    - Lens capsule rupture, causing phacoclastic uveitis; often also have bacterial contamination if due to perforating injury such as cat claw
    - Lens luxation (see p. 644) o Scleritis (see p. 356)
  - Uveal cysts (see p. 356)
  - Primary intraocular neoplasia, such as uveal melanoma (see p. 1149)
  - Retinal detachment (see p. 985)
- Systemic:
  - Infectious diseases that are often species-specific:
    - Cats: toxoplasmosis, FIP, FeLV, FIV, systemic mycoses, bartonellosis, tuberculosis, herpesvirus
    - Dogs: infectious canine hepatitis, ehrlichiosis, Rocky Mountain spotted fever, toxoplasmosis, protothecosis, brucellosis, borreliosis, leptospirosis, leishmaniasis, systemic mycoses
  - Aberrant metazoan parasites: *Dirofilaria immitis,* ascarids, fly larvae
  - Secondary intraocular neoplasia (e.g., lymphoma most common)
  - Immune-mediated: uveodermatologic syndrome/VKH
  - Pigmentary uveitis in golden retrievers
  - Idiopathic: In the dog, roughly 50%-60% of uveitis workups fail to identify a definite cause and are probably immune mediated; in the cat, lymphocytic-plasmacytic uveitis of undetermined cause is common.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

A complete ocular examination of both eyes is warranted to help determine whether or not the uveitis affects the anterior segment (i.e., anterior uveitis), posterior segment (i.e., posterior uveitis), or both segments of the eye(s) (i.e., panuveitis), as this will help determine the possible underlying causes for the uveitis and an appropriate treatment protocol.

DIFFERENTIAL DIAGNOSIS

Other causes for ”red eye”:

- Glaucoma
- Conjunctivitis
- Episcleritis/scleritis
- Keratitis
- Orbital disease

INITIAL DATABASE

- Complete ophthalmic examination (p. 1313) of both eyes:
  - A patient may have anterior lesions in one eye and posterior lesions in the contralateral eye.
- IOP: glaucoma is a frequent complication of uveitis (see p. 448):
  - Normal range is 10-25 mm Hg.
  - A measurement of <10 mm Hg is consistent with uveitis; >30 mm Hg is consistent with glaucoma.
- Thorough general physical examination and history: systemic causes for uveitis are common.
- Ocular ultrasound is indicated when opaque ocular media preclude thorough examination.
- Unless the cause is obvious, a systemic workup beginning with CBC, serum biochemistry profile, and urinalysis is indicated.

ADVANCED OR CONFIRMATORY TESTING

- Selected infectious disease titers based on species, geography, and systemic signs
- Chest radiographs for neoplasia and systemic mycoses
- Fine-needle aspirate (FNA)/biopsy of enlarged lymph nodes, abnormal organs
- Anterior chamber/aqueous centesis in selective cases for culture, cytologic examination, and titers (referable procedure)

TREATMENT

TREATMENT OVERVIEW

Goals of treatment are to reduce the inflammation before inflammatory sequelae produce blindness, alleviate ocular pain, and eliminate the initiating cause if possible.

ACUTE GENERAL TREATMENT

- In general, topical therapies are used for anterior uveitis, whereas systemic therapies are required for effective treatment of posterior uveitis.
- Reduce ocular inflammation with anti-inflammatory drugs:
  - Corticosteroids:
    - Topical and/or systemic depending on severity and location of uveitis
    - Contraindicated with many infectious etiologies (i.e., systemic mycoses; acute bacterial) and corneal ulceration
    - Start with frequent dose q 4-6 h for topical (e.g., prednisolone acetate 1%, dexamethasone 0.1%) and antiinflammatory doses of systemic drug (e.g., prednisone 1 mg/kg PO q 24 h).
  - Nonsteroidal antiinflammatory drugs (NSAIDs):
    - Topical and/or systemic depending on severity and location of uveitis
    - Topical (flurbiprofen or diclofenac q 4-6 h, depending on severity of disease) and/or systemic (dog: meloxicam, 0.2 mg/kg SQ loading dose and 0.1 mg/kg PO q 24 h; cat: ketoprofen, 2 mg/kg SQ loading dose and 1 mg/kg PO q 24 h for 4 days).
  - Do not use systemic glucocorticoids and systemic NSAIDs concurrently (gastrointestinal [GI] ulceration).
  - Miscellaneous immunosuppressive drugs: severe recalcitrant forms of inflammation may necessitate systemic drugs such as azathioprine and cyclosporine.
- Control ocular pain and prevent synechiae:
  - Topical atropine 1% q 6-8 h to dilate the pupil (i.e., mydriatic) in acute cases to minimize posterior synechiae and prevent spasms of the ciliary body muscle (i.e., cycloplegic) that contribute to pain.
- Other therapies:
  - Specific therapies:
    - If an infectious agent is the initiating cause, specific antiinfective therapy, such as antibiotics, is indicated.
    - Usually administered by both topical and systemic routes
    - Broad-spectrum, bactericidal drugs are preferred until sensitivity is known.
  - Tissue plasminogen activator (tPA) injected into the anterior chamber (referable procedure): 25 mcg of tPA may release a posterior synechia and dramatically dissolve fibrin clots of anterior chamber in animals with acute uveitis.

CHRONIC TREATMENT

- After 7-10 days, antiinflammatory therapy is usually reduced in frequency if the uveitis is significantly reduced, but is continued for several weeks at a lower frequency and/or systemic dose.
- Some immune-mediated diseases (e.g., uveodermatologic syndrome/VKH) are treated indefinitely.
- Most infectious causes are treated for 3-4 weeks with antibiotics; some, such as those caused by *Brucella* spp. and *Leishmania,* may require prolonged therapy.

DRUG INTERACTIONS

Topical NSAIDs may elevate IOP and, if secondary glaucoma develops, may need reevaluation.

POSSIBLE COMPLICATIONS

Blindness (see p. 141), glaucoma (see p. 448), cataracts (see p. 181), synechiae resulting in pupil immobility, retinal detachment (see p. 985), corneal opacity (see p. 245), prolonged ocular hypotony (low IOP), phthisis bulbi (shrinkage of the eye)

RECOMMENDED MONITORING

- Animals with acute severe forms should be monitored daily until inflammation begins to subside, then weekly and biweekly.
- IOPs should be monitored:
  - At a frequency dependent on progress
  - As the uveitis subsides and aqueous production normalizes, any outflow restrictions from adhesions/synechiae may become manifest and require therapy (see Acute General Treatment, above).
- Certain infectious diseases may be monitored by repeat titers.

PROGNOSIS AND OUTCOME

- The prognosis is highly variable depending on severity of inflammation, stage at presentation, and underlying cause.
- Any significant inflammation of the interior of the eye should have a guarded prognosis for maintenance of ocular function.

PEARLS & CONSIDERATIONS

COMMENTS

- Despite extensive medical workups, more than 50% of cases of uveitis in the dog are idiopathic and, by default, thought to be immune-mediated conditions.
- In the younger cat, systemic infectious diseases are often implicated; in the older cat, uveitis is often idiopathic (i.e., lymphocytic-plasmacytic).
- Infectious etiologies *(Brucella,* systemic mycoses) may be difficult to clear from the eye despite specific therapy.
- Many of the infectious disease tests are antibody titers and are often only presumptive of exposure unless serial tests demonstrate rising titers.

PREVENTION

- Minimize infectious diseases through vaccination and restriction of environment.
- Surgical removal of primary cataracts (referable procedure) before the cataracts become mature to hypermature
- Removal of injured or displaced lenses in eyes with vision potential:
    - Perforating injuries that have created lens rupture (specifically, capsular tears of greater than 2 mm)
    - Lens luxation

CLIENT EDUCATION

- Any inflammation of the interior of the eye is potentially serious and can threaten vision.
- Causes of uveitis are multiple and often difficult to pinpoint; nevertheless, it is important to perform laboratory diagnostics in hopes of formulating a specific therapy and to determine the systemic prognosis.

Uveal Cysts

BASIC INFORMATION

DEFINITION

Generally benign/incidental, round to ovoid, pigmented intraocular structures arising from the iris or ciliary body. They may be seen attached at the pupillary margin and/or posterior iris, free-floating in the anterior chamber, and (rarely) in the vitreous.

SYNONYMS

Anterior chamber cysts, ciliary cysts, iridociliary cysts, iris cysts, pupillary cysts

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs, cats, and other domestic species; in dogs, mean age is 6.8-9.1 years.

GENETICS & BREED PREDISPOSITION

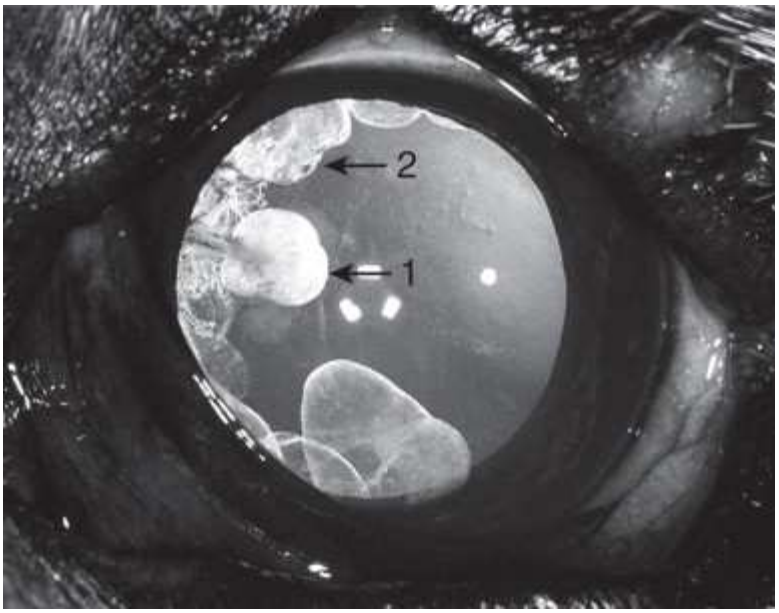
- Dogs: golden retrievers, Labrador retrievers, Boston terriers, Great Danes, rottweilers
- Cats: Siamese (one report)

RISK FACTORS

- Trauma
- Uveitis, especially lens-induced uveitis; uveal cysts may arise as a consequence of uveitis, or uveitis may result as a consequence of the cysts (see p. 1151)

ASSOCIATED CONDITIONS & DISORDERS

- Dogs: uveitis and secondary glaucoma (i.e., glaucoma results as a complication of the cysts) associated with iridociliary cysts in golden retrievers and Great Danes
- Cats: cysts may be associated with trauma or uveitis.



UVEAL CYSTS Dog with multiple uveal cysts in the anterior chamber *(1)* and posterior to the iris *(2)*.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Free-floating cysts within the anterior chamber
- Cysts attached to the pupillary margin
- Iridociliary cysts
- Rarely, cysts in the vitreous

HISTORY, CHIEF COMPLAINT

- Usually incidental findings
- Pigmented intraocular mass
- Signs of uveitis (see p. 1151) and glaucoma (see p. 448) in golden retrievers and Great Danes
- Intraocular bleeding (rare)
- Vision impairment

PHYSICAL EXAM FINDINGS

- Single or multiple pigmented masses in anterior chamber, along pupillary margin, posterior to the iris, or rarely in the vitreous
- Canine uveal cysts are often translucent such that they can be transilluminated (i.e., it is possible to see through them using a strong light source, such as a Finnoff transilluminator), whereas feline uveal cysts may be very dark and difficult to transilluminate.

ETIOLOGY AND PATHOPHYSIOLOGY

- Most are spontaneous in nature but may be associated with previous trauma or anterior uveitis.
- Generally arise from the pigmented epithelial layer of iris or ciliary body

DIAGNOSIS

DIAGNOSTIC OVERVIEW

An intraocular mass (noted by the owner or encountered incidentally on physical exam) raises the possibility of a uveal cyst. Definitive confirmation is possible in some cases with simple transillumination or with ocular ultrasound evaluation.

DIFFERENTIAL DIAGNOSIS

- Iridal or anterior uveal melanomas
- To differentiate uveal cysts (often translucent and thus can be transilluminated) from neoplastic tissue (more dense/opaque and cannot be transilluminated), a strong light source such as a Finnoff transilluminator is advised.

INITIAL DATABASE

- Neuro-ophthalmic examination (see p. 1311)
- Schirmer tear test, intraocular pressure measurement, and fluorescein staining
- Full ocular examination (see p. 1313) performed with and without mydriasis (topical tropicamide 1%)

ADVANCED OR CONFIRMATORY TESTING

- Ocular ultrasonography may confirm the diagnosis by revealing a cyst's anechoic (fluid-filled) center.
- Biopsy of cyst and its contents can be performed, but this is usually not necessary.

TREATMENT

TREATMENT OVERVIEW

- A true cyst is a benign structure that poses a risk only by its physical presence. Removal can be contemplated if the cysts are very large, obstruct the pupillary axis, cause corneal edema, or are associated with iris plateauing and glaucoma.

ACUTE GENERAL TREATMENT

- Laser ablation of cysts with Nd: YAG or diode laser
- Aspiration of the cyst with a 25-G to 27-G needle through a limbal paracentesis

CHRONIC TREATMENT

- Usually not necessary unless chronic uveitis or glaucoma is present. Therapy may entail topical steroidal ophthalmic preparations (prednisolone acetate 1% or dexamethasone 0.1%), topical nonsteroidal agents (diclofenac 0.1% or flurbiprofen 0.03%), as well as topical and oral antiglaucoma medications.

POSSIBLE COMPLICATIONS

- Cyst rupture, with adhesion to the corneal endothelium or anterior lens capsule
- Mechanical interference with iris function
- Aqueous outflow obstruction:
    - Secondary glaucoma

RECOMMENDED MONITORING

- For most cases diagnosed incidentally, monitor every 6-12 months.
- If the condition is associated with uveitis or glaucoma, recheck every 2-4 months or sooner.

PROGNOSIS AND OUTCOME

Generally benign condition; of concern in the golden retriever and Great Dane breeds. According to one report, 46% of affected eyes studied in golden retrievers became blind as a result of glaucoma.

PEARLS & CONSIDERATIONS

COMMENTS

A strong light source is advised for ocular examination and transillumination (Finnoff transilluminator) to differentiate uveal cysts (often translucent) from neoplastic tissue (more dense/opaque and cannot be transilluminated).

PREVENTION

- Breeds of dogs predisposed to uveal cysts: avoid breeding affected or closely related individuals.
- If associated with uveitis, topical anti-inflammatory medications are advised.

CLIENT EDUCATION

- Uveal cysts are typically a benign condition requiring no therapy. Periodic recheck evaluations are advised every 6-8 months.
- If the cysts become large, impair vision, or are associated with glaucoma, laser ablation can be considered.

AUTHOR: JOHN S. SAPIENZA

EDITOR: CHERYL L. CULLEN

Uterine Neoplasia

BASIC INFORMATION

DEFINITION

Benign or malignant cellular proliferations involving the uterus. Uncommon in dogs and cats.

SYNONYMS

Uterine mass, nodule, or polyp

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Most common in bitches >10 years of age and queens between 5 and 10 years of age
- Accounts for 1%-19% of all reproductive tumors in dogs and l%-2% of all reproductive tumors in cats

GENETICS & BREED PREDISPOSITION: Boxers may be overrepresented.

RISK FACTORS: Older age, intact reproductive tract

CONTAGION & ZOONOSIS: Transmissible venereal tumor (TVT) uterine metastases can result in TVT dysgerminoma.

ASSOCIATED CONDITIONS & DISORDERS: Uterine torsion and/or rupture may occur as a result of uterine neoplasia.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES: May involve the endometrium (polyp); myometrium (leiomyoma, fibroma, fibroleiomyoma, fibroadenoma, adenoma, leiomyosarcoma, adenocarcinoma, fibrocarcinoma); lipoma; or metastatic disease (lymphoma; transmissible venereal tumor dysgerminoma).

HISTORY, CHIEF COMPLAINT

- Bloody, mucoid, mucopurulent or mucohemorrhagic vulvar discharge
- Abdominal distension
- Ascites
- Depression or lethargy
- Vomiting
- Anorexia
- Dysuria
- Constipation
- Chronic low-grade fever: uncommon

PHYSICAL EXAM FINDINGS

- Bloody vulvar discharge
- Abdominal distension with palpable midcaudal abdominal mass
- Weight loss
- Depression
- Lymph node enlargement (especially inguinal): uncommon

ETIOLOGY AND PATHOPHYSIOLOGY

- Uterine tumors may be of endometrial, myometrial, serosal origin; may be primary or metastatic.
- Leiomyoma is the most common tumor and may be found incidentally or concurrent with pregnancy.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis is typically suspected with a history of bloody vulvar discharge with supportive cytologic findings and/or ultrasound evidence of a uterine mass. Histopathologic examination of a specimen from the mass is the confirmatory test of choice.

DIFFERENTIAL DIAGNOSIS

- Pyometra
- Segmental endometrial hyperplasia
- Uterine lithiasis
- Pregnancy
- Mummified fetus
- Subinvolution of placental sites (SIPS)
- Adenomyosis
- Granuloma
- Mural abscess
- Decidual reaction
- Remnant of the mesonephric duct
- Serosal inclusion cysts

INITIAL DATABASE

- CBC, serum biochemistry profile, urinalysis (avoid unguided cystocentesis): results may be normal with benign tumors to abnormal with metastatic disease, depending on metastatic location.
- Cytologic examination of vulvar discharge may demonstrate neoplastic cells.
- Radiographs may reveal an enlarged caudal abdominal viscus.
- Abdominal ultrasound examination reveals a mass in the uterine, cervical, or vaginal lumen:
    - If mass appears solid (homogeneous, minimally vascularized), fineneedle aspiration for cytologic examination is appropriate.
- Thoracic radiographs for evidence of metastasis

ADVANCED OR CONFIRMATORY TESTING

- Hysteroscopy may reveal a luminal or mural mass.
- Biopsy may be taken via transcervical endoscopic collection technique (TECT).
- MRI may better delineate the mass and provide further evidence of metastasis (rarely necessary).

TREATMENT

TREATMENT OVERVIEW

Ovariohysterectomy (OHE): either partial or complete

ACUTE GENERAL TREATMENT

- Typically, complete OHE is recommended to ensure that any small masses not palpable or visible are removed at the time of initial surgery.
- Abdominal inguinal lymph nodes may be submitted for assessment of metastasis.
- If the tumor is long-standing, necrosis of the uterine wall is possible, or adhesions to other abdominal tissues may require resection.

CHRONIC TREATMENT

Depending on tumor type and presence of metastasis, chemotherapy, immune modulators, or radiation therapy may be appropriate. Consultation with an oncologist is recommended.

POSSIBLE COMPLICATIONS

If malignancy is present, complications associated with tumor metastasis in other locations may occur.

RECOMMENDED MONITORING

If malignant, monitoring of other organ systems for metastasis may be required.

PROGNOSIS AND OUTCOME

Good for benign tumors; guarded to poor for metastatic or malignant tumors

PEARLS & CONSIDERATIONS

PREVENTION

Ovariohysterectomy will prevent uterine disorders from developing.

CLIENT EDUCATION

Brood bitches, regardless of their age, should be spayed after the last litter to prevent tumors from developing.

AUTHOR: CHERYL LOPATE

EDITOR: MICHELLE KUTZLER

Uterine Disorders, Non-Neoplastic

BASIC INFORMATION

DEFINITION

- Uterine torsion: an uncommon condition involving twisting of one or both uterine horns or the uterine body on its own axis
- Uterine prolapse: a rare condition where the uterus everts through the cervix and vagina (one or both horns may be involved)

EPIDEMIOLOGY

SPECIES, AGE, SEX: Either condition may occur at any age or parity. Uterine torsion may occur unrelated to pregnancy.

RISK FACTORS

- Large litter size may predispose to torsion.
- Any condition causing excessive straining may predispose to prolapse (dystocia, necrotic vaginitis, severe cystitis, diarrhea, constipation).

ASSOCIATED CONDITIONS & DISORDERS: Both uterine torsion and uterine prolapse may be associated with shock, sepsis, disseminated intravascular coagulation (DIC), multiple organ dysfunction syndrome (MODS), and systemic inflammatory response syndrome (SIRS).

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Torsion may involve one or both horns or the uterine body and may be from 90○ to 2160○ (6 complete turns described in one case).
- Prolapse occurs in the puerperal period and may involve one or both horns, be partial or complete, and occurs rarely prior to delivery of all fetuses.

HISTORY, CHIEF COMPLAINT

Torsion:

- History of no progression from stage 1 to stage 2 of labor, or cessation of ongoing stage 2 labor
- Acute abdominal pain
- Shock

Prolapse:

- History of prolonged straining (labor, other)
- Tissue protrudes from the vulvar lips.
- Queens may present up to 48 hours after delivery of last kitten.

PHYSICAL EXAM FINDINGS

- Acute abdominal pain and splinting
- Crying
- Hemorrhagic vulvar discharge
- Excessively vulvar licking
- Abdominal distension
- Tachycardia and tachypnea
- Pale mucous membranes with increased capillary refill time
- +/− Collapse
- +/− Devitalized prolapsed tissue

ETIOLOGY AND PATHOPHYSIOLOGY

- Torsion: unknown etiology; may be due to fetal or bitch activity or abnormal uterine motility (inertia) with continued fetal activity
- Prolapse: eversion of the tip of a uterine horn followed by excessive straining (due to any cause) during uterine involution or eversion of the tip of a horn due to uterine inertia followed by normal uterine contraction patterns

DIAGNOSIS

DIAGNOSTIC OVERVIEW

- Torsion: diagnosis is based on cessation of labor or acute abdominal pain. Ultrasound may be supportive, but the diagnosis is conclusively made on exploratory laparotomy.
- Prolapse: diagnosis is based on physical exam findings of prolapsed tissue from the vulvar lips following parturition. Inability to locate the uterus on ultrasound of the abdomen is confirmatory.

DIFFERENTIAL DIAGNOSIS

Uterine torsion:

- Pyometra
- Uterine rupture
- Uterine inertia (primary or secondary)
- Acute gastrointestinal disorders (bloat, gastric or mesenteric torsion), other causes of the acute abdomen

Uterine prolapse:

- Bladder or vaginal prolapse
- Vaginal, cervical, or uterine neoplasia

INITIAL DATABASE

- CBC: +/− leukocytosis +/− toxic neutrophils, evidence of dehydration
- Serum biochemistry profile: normal to increased renal and hepatic values and electrolyte disturbance depending on duration.
- Abdominal ultrasonography:
    - Hemorrhage into the uterine lumen and edema (hypoechogenicity) of the uterine wall adjacent to the torsion
    - Fetuses may be viable or dead.
    - Intraluminal gas may be present.

ADVANCED OR CONFIRMATORY TESTING

TREATMENT

TREATMENT OVERVIEW

Treatment goals are:

- Patient stabilization (IV fluid resuscitation, pain control)
- Exploratory laparotomy for correction of torsion, Caesarian section to deliver remaining fetuses if still viable, or ovariohysterectomy (OHE) if tissue is devitalized.
- Prolapsed tissue is cleaned and replaced with combination of manual manipulation externally +/− abdominal approach. OHE may be necessary if tissue devitalized.

ACUTE GENERAL TREATMENT

Torsion:

- Broad-spectrum antibiotics (ampicillin, 10-20 mg/kg IV q 6-8 h + enrofloxacin, 2.5-5 mg/kg IM q 12 h; maximum 5 mg/kg q 24 h in cats) as soon as the diagnosis is confirmed and when devitalized tissue is present.
- Do not detorse the affected horn(s), as this may result in reperfusion injury and allow systemic circulation of bacteria and

toxin.
- If only one horn is affected, a partial OHE may be performed, oversewing the uterine body at the level of the bifurcation.

Prolapse:

- Initially, digital pressure and inversion of the horn into itself starting distally and working towards the tip
- Care should be taken to invert the entire horn to its tip (ultrasound may be used to confimi this).
- Oxytocin may be administered after complete inversion.
- If manual reduction is impossible, uterine amputation is indicated.

CHRONIC TREATMENT

Long-term antibiotics (2 weeks) should be administered.

BEHAVIOR/EXERCISE

If the dam is stable, she may be allowed to nurse the neonates.

RECOMMENDED MONITORING

CBC, serum biochemistry profile

PROGNOSIS AND OUTCOME

- With early diagnosis, the prognosis is good for survival.
- With systemic illness, the prognosis for survival may be guarded to poor.
- Recurrence is unlikely.

PEARLS & CONSIDERATIONS

COMMENTS

- Caution should be taken when handling either condition, as the uterine wall may be friable.
- Do not administer calcium or oxytocin to patients suspected of torsion or prolapse.

PREVENTION

Ovariohysterectomy will prevent uterine disorders from developing.

CLIENT EDUCATION

- Failure of an animal to continue to progress through labor should instigate a veterinary examination.
- Bloody discharge or abdominal pain during or after delivery is abnormal.

AUTHOR: CHERYL LOPATE

EDITOR: MICHELLE KUTZLER

Urolithiasis, Urate/Biurate

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

Organized concretions within the urinary tract, composed of uric acid and its salts; these comprise approximately 5%-10% of uroliths in dogs (except dalmatians, which form mostly urate uroliths) and cats.

SYNONYMS

Biurate urolithiasis, purine urolithiasis, ammonium urate urolithiasis, uric acid urolithiasis, urate calculi/stones

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Urate uroliths account for ~6% of canine uroliths and 5% of feline uroliths.
- Urate uroliths are the most common urolith of dalmatian dogs (prevalence ~35%) and occur predominantly in middle-aged males.
- Most often seen in young to middle-aged adult dogs and young adult cats

GENETICS & BREED PREDISPOSITION

- All dalmatians are unique in their excretion of uric acid instead of allantoin as an end product of purine metabolism, but only a subset develop urate urolithiasis. The tendency to form uroliths is heritable, although genetics are incompletely understood.
- Predisposed non-dalmatian breeds include English bulldog and Russian black terrier. Miniature schnauzer, shih tzu, and Yorkshire terriers are over-represented (likely due to congenital portosystemic shunts).

RISK FACTORS

- Portosystemic shunt (PSS; see p. 905)
- Hepatic microvascular dysplasia
- Hepatic cirrhosis
- Acidic urine and/or urinary infection with urease producing bacteria

ASSOCIATED CONDITIONS & DISORDERS

- Urinary tract infection
- Ureteral or urethral obstruction

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: Clinical signs often absent. When apparent, signs may include:

- Hematuria
- Pollakiuria
- Inappropriate elimination (penuria)
- Dysuria
- Stranguria
- If congenital hepatic disease is present, growth retardation
- If hepatic dysfunction is present, encephalopathy and/or hypoglycemia (e.g., altered mentation, seizures)
- Rarely, systemic illness due to urinary obstruction

PHYSICAL EXAM FINDINGS: Physical exam is usually unremarkable. Abnormalities may include:

- Hematuria (stains on prepuce, vulva, hocks)
- Palpable cystic calculi
- Palpable urethral calculi (via digital rectal exam in dogs)

- Enlarged, turgid bladder if urethral obstruction present
- Renomegaly related to PSS or hydronephrosis
- Small body size if PSS present
- Neurologic deficits related to encephalopathy and/or hypoglycemia if due to congenital hepatic disease

ETIOLOGY AND PATHOPHYSIOLOGY

- Dalmatians:
  - During protein catabolism in non-dalmatian dogs, purine metabolism leads to uric acid oxidation by hepatic uricase, with resultant allantoin production.
  - Despite normal uricase activity, dalmatians convert uric acid to allantoin inadequately, resulting in increased urinary excretion of poorly soluble uric acid.
  - Contributing mechanisms may include decreased tubular resorption of uric acid and less activity of urinary crystal-inhibiting proteins.
- Dogs with hepatic dysfunction: reduced uricase production and increased renal excretion of uric acid and ammonia, resulting from reduced hepatic conversion/urea synthesis
- Non-dalmatian dogs and cats without hepatic dysfunction: unknown

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis is suspected in dogs with radiolucent uroliths and either a breed predisposition (dalmatian, English bulldog) or hepatic dysfunction. Diagnosis in cats and healthy dogs of other breeds is usually based on quantitative stone analysis.

DIFFERENTIAL DIAGNOSIS

- Urinary tract infection
- Other types of uroliths
- Urinary tract neoplasia

INITIAL DATABASE

- CBC: often unremarkable, but PSS is associated with microcytosis.
- Serum biochemical profile: often unremarkable, but may suggest hepatic dysfunction (low blood urea nitrogen [BUN], hypoglycemia, hypocholesterolemia, hypoalbuminemia; hyperbilirubinemia if cirrhosis present). Urinary obstruction leads to azotemia, hyperkalemia, and metabolic acidosis.
- Urinalysis: frequently aciduria; urate crystals sometime identified; physical irritation and/or secondary infection sometimes leads to hematuria, pyuria, or bacteruria
- Urine culture and sensitivity to rule out secondary infection
- Abdominal radiographs: urate uroliths are often radiolucent (radiopacity: struvite = oxalate = $CaPO_4$ = silica > cystine > urate).
  - If visible, often few smooth round uroliths identified
- Microhepatica is suggestive of PSS, cirrhosis
- Abdominal ultrasound: confirm urolithiasis, which may be missed on abdominal radiographs. Confirms location of uroliths within the urinary tract; may identify PSS, hepatic abnormalities.

ADVANCED OR CONFIRMATORY TESTING

- In non-dalmatian dogs or when appropriate: serum bile acids or other tests to rule out hepatic disease
- Contrast cystography/urethrography: alternative to ultrasound for confirmation/localization of radiolucent stones (see pp. 1237 and 1357)
- Urolith analysis: retrieved stones submitted for quantitative analysis (crystallography, x-ray diffraction, infrared spectroscopy) to determine urolith type
- Cystoscopy may facilitate urolith removal for analysis and therapy (see p. 1239).

TREATMENT

TREATMENT OVERVIEW

Although uncommon, urinary tract obstruction requires immediate removal of uroliths. In the absence of urinary obstruction, treatment consists of either medical stone dissolution or manual removal of stones, as well as treatment of underlying disorders (e.g., PSS) or preventive therapy.

ACUTE GENERAL TREATMENT

- Relieve urinary tract obstruction (see pp. 1353 and 1355).
- If present, treat hepatic encephalopathy (see p. 501).
- If present, treat urinary infection (see p. 276).
- Choose between medical dissolution (see Chronic Treatment, below) and mechanical removal:
    - Urinary tract obstruction should be relieved mechanically.
    - Mechanical removal allows for urolith analysis, culture.
    - Cats are poorly amenable to medical dissolution of urate uroliths.
- Mechanical removal of calculi:
    - Urohydropropulsion (voiding, retrograde; see pp. 1353 and 1355)
    - Avoid performing voiding urohydropropulsion in male cats.
    - Catheter-assisted retrieval
    - Cystoscopic-assisted retrieval (see p. 1239)
    - Cystotomy/urethrotomy/urethrostomy/pyelotomy/nephrotomy
    - Lithotripsy (see p. 1297; intracorporeal or extracorporeal shock wave lithotripsy)

CHRONIC TREATMENT

- Animals with hepatic disease:
    - Surgical correction of PSS prevents recurrence; cystotomy may be used to remove uroliths during surgical correction of hepatic shunt.
    - If hepatic disease cannot be corrected, institute medical management (including restricted protein diet), and monitor for recurrence.
- Promote water consumption to avoid concentrated urine (e.g., canned food, wetting dry food, use of cat water fountains).
- Feed low-purine calculolytic diet (see Nutrition/Diet, below).
- If urine remains acidic after diet change, consider adding sodium bicarbonate (25-50 mg/kg PO q 12 h) or potassium citrate (50-150 mg/kg PO q 12 h), with dose adjustment to maintain urine pH of 7.0 to 7.5.
- Allopurinol 10-15 mg/kg q 12 h PO, with dose reduction for azotemic dogs

NUTRITION/DIET

Reduced protein (therefore reduced purine) diet:

- Dogs: for example, Hills u/d, Royal Canin Urinary UC Low Purine, Royal Canin Vegetarian Formula. For English bulldogs, a renal diet may be preferred, as ultra low-protein diets have been associated with cardiomyopathy.
- Cats: for example, Hills l/d or k/d

POSSIBLE COMPLICATIONS

- Chronic use of low purine diets may result in cardiomyopathy, perhaps related to carnitine or taurine deficiency (esp. English bulldogs).
- Severely protein-restricted diets are inappropriate for growing, pregnant, or lactating animals.
- Xanthine urolith formation with allopurinol administration

RECOMMENDED MONITORING

- Serum biochemical profile and urinalysis 2 weeks after diet change. Goal is urine pH 7.0 to 7.5, specific gravity < 1.020, and absent crystals. Assuming adequate renal function and diet adherence, BUN should be < 10 mg/dL. Monitor urinalysis q 2-4 weeks until uroliths resolved and q 3-6 months thereafter.
- Monitor dissolution of uroliths q 2-4 weeks via lower urinary tract contrast studies or ultrasound. Monitor for recurrence in like manner q 3-6 months for a year, then q 6-12 months.

PROGNOSIS AND OUTCOME

- Prognosis for dissolution is good in dogs.
- Recurrence is common unless cause resolved (e.g., PSS corrected).

PEARLS & CONSIDERATIONS

COMMENTS

- Non-dalmatian dogs with urate uroliths should be evaluated for hepatic disease, even when showing no overt clinical signs of hepatopathy.
- Cats with urate urolithiasis have underlying hepatic disease less commonly than non-dalmatian dogs.

PREVENTION

- Avoid high-protein diets in at-risk dogs (e.g., dalmatian), but severely protein-restricted diets or allopurinol prior to a first episode of urate urolithiasis is not recommended.
- Heritability of tendency to form urate uroliths suggests breeding affected dalmatians should be avoided.
- Long-term dietary +/− allopurinol therapy is indicated for dalmatians after first episode of urolithiasis.

CLIENT EDUCATION

- Urethral obstruction is life threatening. Stranguria should prompt immediate veterinary attention.
- Adherence to dietary therapy must be strict.
- Implications for heritability in dalmatians should be addressed.
- Once dalmatians have formed urate uroliths, preventive therapy should continue lifelong.

Urolithiasis, Struvite

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

Organized concretions within the urinary tract composed of magnesium ammonium phosphate; struvite uroliths occur commonly in both dogs and cats.

SYNONYMS

Magnesium ammonium phosphate stones, struvite calculi/struvite stones, triple phosphate calculi/stones, urease calculi/stones

EPIDEMIOLOGY

SPECIES, AGE, SEX

Dogs:

- The most common urolith of dogs, canine struvite uroliths are usually associated with urinary tract infections (UTI) involving urease-producing bacteria.
- Sterile struvite urolithiasis is rare in dogs.
- Found at any age, they occur nearly twice as often in females as in males, as females are more likely to have UTIs.

Cats:

- The second most common urolith of cats, struvite uroliths are typically found in sterile, alkaline urine.
- Male cats may be at increased risk.
- Compared to calcium oxalate uroliths (most common in cats), cats with struvite uroliths are generally younger (4-7 years of age) and are more likely to be neutered.

GENETICS & BREED PREDISPOSITION

- Dogs: any breed can be affected, but miniature Schnauzers, shih tzus, bichon frises, miniature poodles, cocker spaniels, and Lhasa apsos are overrepresented. Cocker spaniels may form sterile struvite uroliths.
- Cats: commonly affected breeds include the domestic shorthair, foreign shorthair, ragdoll, Chartreux, Oriental shorthair, and Himalayan.

RISK FACTORS

Dogs:

- UTI
- Highly concentrated urine
- Infrequent urination

Cats:

- Highly concentrated urine
- Alkaline urine
- Diets high in magnesium

ASSOCIATED CONDITIONS & DISORDERS

- Dogs: UTI
- Cats: feline lower urinary tract signs/disease (FLUTS/D), urethral obstruction

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: Clinical signs often absent. When signs are apparent, they may include:

- Hematuria
- Pollakiuria
- Dysuria
- Stranguria
- Inappropriate elimination (penuria)
- Rarely, systemic illness due to urinary obstruction or to ascending infection causing pyelonephritis

PHYSICAL EXAM FINDINGS: Physical exam is usually unremarkable. Abnormalities may include:

- Hematuria (stains on prepuce, vulva, or hocks)
- Painful urinary bladder
- Palpable cystic calculi
- Palpable urethral calculi (via digital rectal exam in dogs)
- Enlarged turgid bladder, if urethral obstruction
- Renomegaly, if secondary hydronephrosis

ETIOLOGY AND PATHOPHYSIOLOGY

- Infection-associated struvite urolithiasis (mainly dogs):
  - Bacterial urease converts urea to ammonia and bicarbonate
    - The most common urease-producing pathogens are *Staphylococcus* and *Proteus* spp.
    - Other urease-producing pathogens include *Pseudomonas. Klebsiella,* and *Ureaplasma* (urease-producing *Mycoplasmd)* spp.
  - Ammonium binds to phosphorus and magnesium, forming struvite crystals.
  - Bicarbonate increases urine pH.
  - Alkalinity decreases solubility of magnesium ammonium phosphate crystals.
  - Crystals aggregate with organic material (including viable bacteria) and combine to form uroliths.
  - Decreased presence of glycosaminoglycans suggested as a cause in some cases of FLUTS/D.
- Sterile struvite urolithiasis (mainly cats): there appears to be a complex relationship between diet, water intake, individual predisposition and subsequent urine pH and relative supersaturation.
  - Diets high in magnesium, phosphorus, calcium, chloride, and fiber, with moderate protein content may predispose to struvite crystal formation.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis is suspected in dogs with radiopaque bladder stones, alkaline urine, and/or urinary infection. The diagnosis is suspected in cats with radiopaque bladder stones, alkaline urine, and/or struvite crystalluria. Quantitative stone analysis is necessary to confirm the diagnosis and provide an optimal treatment/prevention plan.

DIFFERENTIAL DIAGNOSIS

- Urinary tract infection
- Other types of uroliths
- Urinary neoplasia

INITIAL DATABASE

- CBC: unremarkable
- Serum biochemistry profile (including electrolytes): unremarkable unless urinary tract obstruction present (see p. 1131)
- Complete urinalysis: neutral or alkaline (common) urine pH, bacteria (especially likely in dogs), pyuria (especially likely in dogs), hematuria (inconsistent), and crystalluria (inconsistent) are possible.
  - Storage of urine may lead to precipitation of struvite crystals; therefore, urine sediment should be examined within 1 hour of collection.
- Urine culture (identify uropathogen) and susceptibility (influence antimicrobial therapy)
- Abdominal radiographs:
  - Struvite calculi are generally radiopaque (radiopacity: struvite = oxalate = $CaPO_4$ = silica > cystine > urate). o Often smooth or round in shape
  - Most commonly located in bladder, sometimes urethra, ureter, or kidney.

ADVANCED OR CONFIRMATORY TESTING

- Abdominal ultrasound: little benefit beyond abdominal radiography but will confirm location of stones, assess kidneys for evidence of pyelonephritis or hydronephrosis
- Urolith analysis: retrieved stones should be submitted for quantitative analysis (crystallography, x-ray diffraction, infrared spectroscopy) to determine urolith type.
- Urolith culture: retrieved stones can be cultured if urine culture obtained by cystocentesis is negative.

TREATMENT 

TREATMENT OVERVIEW

Although uncommon, urinary tract obstruction requires immediate removal of uroliths. In the absence of urinary obstruction, treatment consists of either a stone-dissolution diet or manual removal of stones as well as treatment of UTI.

ACUTE GENERAL TREATMENT

- Relieve urinary tract obstruction if present (see pp. 1353 and 1355).
- Antibiotics for urinary tract infection, based on culture and susceptibility results (dogs > cats; see see p. 276). Generally, antimicrobial therapy is continued until struvite urolith has dissolved or been removed.
- Choose between medial dissolution and mechanical calculi removal:
    - Urethral obstruction should be relieved mechanically.
    - Mechanical removal allows for urolith analysis, culture.
    - Even large struvite uroliths can be amenable to medical dissolution.
    - Provided urethral obstruction is absent, trial of medical dissolution prior to mechanical removal is reasonable; potential drawbacks include risk of obstruction prior to complete dissolution and ineffective dissolution.
- For medical dissolution, calculolytic diets (see Nutrition/Diet, below) and appropriate antimicrobials are required:
    - Mean time to dissolution is 3 months (less for sterile uroliths, longer time for nephroliths than for cystoliths).
    - Urinalysis and urine culture should be repeated 5-7 days after initiating medical therapy. Goals are urine pH < 7.0, urine specific gravity 1.010-1.020, and negative culture.
    - Medical therapy is continued 1 month beyond radiographic disappearance of uroliths.
    - Small urolith may become lodged in the urethra (especially males) during urolith dissolution.
- Mechanical removal of uroliths:
    - Urohydropropulsion (voiding, retrograde; see pp. 1353 and 1355)
    - Avoid performing voiding urohydropropulsion in male cats.
    - Catheter-assisted retrieval
    - Cystoscopic-assisted retrieval (see p. 1239)
    - Cystotomy/urethrotomy/urethrostomy/pyelotomy/nephrotomy
    - Lithotripsy (intracorporeal or extracorporeal shock wave lithotripsy)

CHRONIC TREATMENT

- Predisposing causes of UTI should be addressed (e.g., control glucosuria in diabetic animals, treat hyperadrenocorticism).
- For animals in which UTI is a recurrent problem, chronic prophylactic therapy may be considered after appropriate therapy of recognized infection (see p. 276).
- Promote water consumption to avoid concentrated urine (e.g., canned food, wetting dry food, use of cat water fountains; see p. 387).
- Dietary therapy is crucial; see Nutrition/Diet, below.
- Urinary acidifiers are seldom required if the pet is eating an appropriate diet and urinary tract infection is eliminated.

NUTRITION/DIET

- Many commercially diets designed to aid in struvite urolith dissolution (e.g., Hill's prescription diet s/d, Innovative Veterinary Diets dissolution formula, Royal Canin SO).
- Monitor urolith size periodically via radiographs (see monitoring).
- Some dissolution diets provide inadequate nutrition for long-term feeding. Calculolytic diet is continued 1 month past radiographic disappearance of uroliths.
- Other diets aid in the prevention of recurrent struvite urolithiasis and can be fed long-term (e.g., Hills Pet nutrition c/d and w/d, Royal Canin SO, Eukanuba Low pH/S/Feline)

POSSIBLE COMPLICATIONS

- Risk of urethral obstruction either from small stones or during medical dissolution as the stones become small enough to pass into the urethra (males):
  - Urinary tract obstruction
  - Hydronephrosis
  - Hydroureter
- Urinary tract infection
- Urinary polyp formation
- Uroliths inadvertently may be left behind during surgery (up to 20% of stones are not removed).
- Some diets appropriate for treatment/prevention of struvite urolithiasis may predispose to calcium oxalate urolithiasis.
- Malnutrition due to long-term feeding of certain dissolution diets

RECOMMENDED MONITORING

- Repeat radiographs every 2-4 weeks during medical dissolution to evaluate the size and number of uroliths.
- If no improvement is seen on radiographs after 4-8 weeks, mechanical removal is indicated.
- Repeat urinalysis 5-7 days after initiating medical dissolution therapy to ensure pH between 6.5 and 7, specific gravity between 1.010 and 1.020, absent struvite crystals, and absent bacteruria.
- Ideally, urine culture is repeated 5-7 days after initiating medical dissolution therapy to ensure sterile urine.
- Repeat urine culture 5-7 days after stopping antibiotics to evaluate for recurrence of infection, then again 3-4 weeks later.
- If predisposing causes of bacterial cystitis cannot be corrected, or in animals with sterile struvite urolithiasis, repeat urinalysis every 4-6 months.
- If predisposing causes of bacterial cystitis cannot be corrected, or in animals with sterile struvite urolithiasis, repeat abdominal radiographs initially every 3-6 months for 1 year, then every 6 months thereafter.

PROGNOSIS AND OUTCOME

- Prognosis for dissolution of uroliths is good.
- Recurrence of struvite urolithiasis is common.

PEARLS & CONSIDERATIONS

COMMENTS

- Struvite urolithiasis in dogs is routinely associated with a UTI. Elimination of infection is crucial for dissolution of stones with a calculolytic diet.
- Struvite urolithiasis in cats is rarely associated with UTI; long-term diet modification is often necessary to prevent recurrence.
- If uroliths fail to resolve with medical therapy, consider:
  - Inadequate infection control
  - Failure to comply with diet restrictions
  - Mixed or alternative urolith composition
- Struvite crystalluria can be found in normal urine and does not reliably predict struvite urolithiasis.

PREVENTION

- Dogs: if urinary infection can be eliminated, long-term diet change is usually not necessary.
- Cats: long-term use of canned struvite-management diets (e.g., Waltham SO or Hills Pet Nutrition c/d or w/d) is best if recurrence noted.
- The merit of supplementing with glycosaminoglycans is unknown.

TECHNICIAN TIPS

Any voided urinary stone should be saved for analysis.

CLIENT EDUCATION

- Adherence to dietary therapy must be strict.
- Urinary tract obstruction is life threatening. Stranguria should prompt immediate veterinary attention.

Urolithiasis, Oxalate

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

Organized concretions within the urinary tract composed of calcium oxalate; oxalate uroliths occur commonly in both dogs and cats.

SYNONYMS

Jackstones. Calcium oxalate dihydrate crystals: weddellite.

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs:

- The relative frequency of calcium oxalate urolithiasis has increased over the last 20 years. Since 2004, they have become the most common canine urolith analyzed at the Minnesota Urolith Center.
- Incidence is greatest in middle-aged to older castrated male dogs. Calcium oxalate uroliths tend to occur at a younger age in bichon frise dogs.

Cats:

- In recent years, calcium oxalate uroliths have become the second most common feline urolith analyzed at the Minnesota Urolith Center.
- Incidence is greatest between 7 and 10 years of age, with males accounting for ~60% of affected cats.

GENETICS & BREED PREDISPOSITION

- Dog breeds at increased risk for developing calcium oxalate stones include the miniature schnauzer, Lhasa apso, Yorkshire terrier, bichon frise, Pomeranian, shih tzu, and miniature poodle.
- Cat breeds at increased risk for forming calcium oxalate stones include the ragdoll, British shorthair, foreign short-hair, Himalayan, Havana brown, Scottish fold, Persian, and exotic shorthair.

RISK FACTORS

- Hypercalcemia
- Acidic urine
- Highly concentrated urine
- Infrequent urination
- Primary hyperparathyroidism
- Hyperadrenocorticism
- Chronic metabolic acidosis
- Obesity
- Diets designed to minimize struvite formation in cats

ASSOCIATED CONDITIONS & DISORDERS: Feline lower urinary tract signs/disease (FLUTS/D), urethral obstruction, chronic kidney disease, urinary tract infection

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: Clinical signs are often absent. When clinical signs are apparent, they may include:

- Hematuria
- Pollakiuria
- Dysuria
- Stranguria
- Inappropriate elimination (penuria)
- Rarely, systemic illness due to urinary obstruction

- Polyuria/polydipsia if concurrent hypercalcemia or renal failure

PHYSICAL EXAM FINDINGS: Physical exam is usually unremarkable. Abnormalities may include:

- Hematuria (stains on prepuce, vulva, or hocks)
- Painful urinary bladder
- Palpable cystic calculi
- Palpable urethral calculi (via digital rectal exam in dogs)
- Enlarged, turgid bladder if urethral obstruction
- Renomegaly if secondary hydronephrosis
- Findings associated with predisposing factors (e.g., hyperadrenocorticism: pot-bellied appearance, alopecia, hepatomegaly)

ETIOLOGY AND PATHOPHYSIOLOGY

- Hypercalciuria and/or hyperoxaluria promote formation of calcium oxalate urolithiasis.
- Hypercalciuria may result from increased intestinal absorption of calcium, increased renal excretion of calcium, or increased resorption of calcium from bone with or without hypercalcemia.
- Hypercalcemia is identified in ~35% of cats and ~4% of dogs with calcium oxalate urolithiasis.
- Hyperoxaluria in cats may be related to dietary sources, inadequate vitamin B6, and hepatic enzyme deficiencies.
- Urolith formation is potentiated by diminished concentrations of urinary crystallization inhibitors (e.g., citrate, pyrophosphate, glycosaminoglycans, Tamm-Horsfall mucoprotein).
- Diets with moderate fat and carbohydrate levels are associated with an increased risk of calcium oxalate stone formation, while diets high in moisture with a moderate magnesium, phosphorus, and calcium content result in a diminished risk.

DIAGNOSIS 

DIAGNOSTIC OVERVIEW

Diagnosis is suspected in animals with radiopaque bladder stones and acidic urine, or in animals with radiopaque nephroliths. Quantitative stone analysis is necessary to confirm the diagnosis and identify an optimal treatment/prevention plan.

DIFFERENTIAL DIAGNOSIS

- Urinary tract infection
- Other types of uroliths
- Urinary neoplasia

INITIAL DATABASE

- CBC: unremarkable
- Serum biochemistry profile (including electrolytes) typically unremarkable:
  - Hypercalcemia or evidence of endocrinopathy detected uncommonly
  - Urinary tract obstruction leads to azotemia, hyperkalemia, and metabolic acidosis.
- Urinalysis: acidic to neutral pH unless secondary bacterial infection present; crystalluria (inconsistent); hematuria and/or pyuria (occasional):
  - Storage of urine may lead to precipitation of oxalate crystals (artifact); urine sediment should be examined within 1 hour of collection.
  - Urine culture and sensitivity to rule out secondary infection
- Abdominal/pelvic radiographs: radiopaque calculi most commonly located in bladder, sometimes urethra, ureter, or renal pelvis:
  - Relative radiopacity of uroliths: struvite = oxalate = $CaPO_4$ = silica > cystine > urate
  - Shape varies from spiculated (dihydrate) to smooth (monohydrate), sometimes jackstone.
  - The perineum must be included in the radiographic field in order to see uroliths located in the urethra.

ADVANCED OR CONFIRMATORY TESTING

- Abdominal ultrasound: little benefit beyond abdominal radiography but will confirm location of stones, assess kidneys for evidence of pyelonephritis or hydronephrosis.
- Urolith (stone) analysis: retrieved stones should be submitted for quantitative analysis (crystallography, x-ray diffraction, infrared spectroscopy) to determine urolith type.
- Urolith culture: retrieved stones can be cultured if urine culture obtained by cystocentesis is negative.
- Cystoscopy may facilitate stone removal for analysis and therapy (see p. 1239).

- Specific diagnostic tests may be indicated to identify predisposing conditions (e.g., parathyroid hormone assay).

TREATMENT

TREATMENT OVERVIEW

Although uncommon, urinary obstruction requires immediate removal of uroliths. Oxalate stones cannot be dissolved through medical therapy, so uroliths in the bladder or urethra should be removed mechanically if they are causing clinical signs. Recurrence is common (up to 50% in 3 years in dogs).

ACUTE GENERAL TREATMENT

- Relieve urinary tract obstruction (see pp. 1353 and 1355).
- Antibiotics (choice based on culture and susceptibility) if secondary urinary tract infection is identified
- If uroliths are found incidentally in the absence of clinical signs, it is reasonable to institute preventive measures to minimize growth of uroliths and adopt a program of regular follow-up, including periodic urinalysis, urine culture, and radiography.
- Mechanical removal of bladder/urethral calculi producing clinical signs. Radiographs should be repeated afterwards to ensure complete removal:
  - Urohydropropulsion (voiding, retrograde; see pp. 1353 and 1355)
  - Avoid performing voiding urohydropropulsion in male cats.
  - Catheter-assisted retrieval
  - Cystoscopic-assisted retrieval (see p. 1239)
  - Cystotomy/urethrotomy/urethrostomy/pyelotomy/nephrotomy
  - Lithotripsy (see p. 1297; intracorporeal or extracorporeal shock wave lithotripsy)
- Calcium oxalate is the most common type of nephrolith/ureterolith. Because surgical removal of nephroliths may be associated with loss of renal function (see p. 760), it is not uniformly indicated.

CHRONIC TREATMENT

- Determine whether underlying disorder (e.g., hyperadrenocorticism, hyperparathyroidism) is present, and treat appropriately.
- For cats with idiopathic hypercalcemia, a diet high in fiber may be beneficial. To simultaneously alkalinize the urine, add potassium citrate (75 mg/kg PO q 12 h, adjusted to increase urine pH to 6.5-7.0).
- Initiate measures to prevent recurrence, as described (see Prevention, below).

NUTRITION/DIET

- Avoid calcium supplements.
- Avoid foods high in oxalate.
- Feed reduced protein diets which promote diuresis and formation of alkaline urine. For example, Hill's Pet Nutrition u/d or w/d, Royal Canine Urinary SO, CNM NF-Formula (dogs) or Hill's Pet Nutrition Feline c/d Multicare, Royal Canine Urinary SO, CNM NF-Formula (cats)
- Feed canned food when possible.

POSSIBLE COMPLICATIONS

- Urinary tract obstruction
- Hydronephrosis
- Hydroureter
- Chronic kidney disease (nephrolithiasis)
- Urinary tract infection
- Some diets appropriate for prevention of calcium oxalate urolithiasis may predispose to struvite urolithiasis.

RECOMMENDED MONITORING

- Repeat urinalysis q 2 weeks, starting 2 weeks after removal of stones and initiation of dietary changes until pH is between 6.5 and 7.0, specific gravity is between 1.010 and 1.020, and no calcium oxalate crystals are found. If goals are not met, consider adding supplementary therapies (see Prevention, below).
- Repeat abdominal radiographs and a urinalysis every 3-6 months for the first year, then every 6-12 months thereafter to evaluate for recurrence of uroliths.
- Monitor and treat any concurrent conditions such as hypercalcemia.

PROGNOSIS AND OUTCOME

- Recurrence is common; therefore, long-term monitoring and care are required.
- Nephrolithiasis may be associated with diminished renal function.

PEARLS & CONSIDERATIONS

COMMENTS

- Calcium oxalate urolithiasis frequently recurs. Therefore, long-term management and observation are necessary.
- Calcium oxalate crystalluria does not necessarily correlate with the presence of calcium oxalate uroliths.
- Calcium oxalate dihydrate crystals (square envelope or Maltese cross shape) are more commonly associated with nutritional or artifactual causes, whereas calcium oxalate monohydrate crystals (picket fence board or flattened hexagon shape) are sometimes associated with ethylene glycol intoxication. Calcium oxalate dihydrate crystalluria can be found in normal urine and does not reliably predict oxalate urolithiasis.
- Large quantities of calcium oxalate dihydrate crystals or large crystal aggregates should prompt evaluation of hyperoxaluric or hypercalciuric conditions.
- The appearance of calcium oxalate monohydrate crystals in a dog presenting with acute renal failure is strongly suggestive of ethylene glycol intoxication (see p. 369). Because it is an acute intoxication, ethylene glycol does not lead to oxalate urolithiasis.

PREVENTION

- Treat any identified cause of hypercalcemia/hypercalciuria.
- Initiate measures to prevent recurrence in a stepwise manner, adding the next measure when the first one is found to be insufficient to produce urine with a pH between 6.5 and 7.0, a urine specific gravity between 1.010 and 1.020, or prevent calcium oxalate crystal formation:
    - Promote water consumption (e.g., canned diet, wetted food, water fountains for cats).
    - Provide diet with restricted oxalate, sodium, and protein and which does not acidify the urine (see Nutrition/Diet, above). Potassium citrate can be added if the urinary pH remains acidic. Initial dose of 50-75 mg/kg PO q 12 h is adjusted to maintain urine pH 6.5-7.0.
    - If calcium oxalate crystalluria persists despite prior measures, hydrochlorothiazide (2-4 mg/kg PO q 12 h) or vitamin B6 (2 mg/kg PO q 12 h) can be added.
    - Avoid supplementation of vitamins C and D.
- For male cats with recurrent history of urethral obstruction, consider perineal urethrostomy.

CLIENT EDUCATION

- Adherence to dietary therapy must be strict.
- Urinary tract obstruction is life threatening. Stranguria should prompt immediate veterinary attention.

BASIC INFORMATION

DEFINITION

Organized concretions within the urinary tract composed of cystine, calcium phosphate (CaPO4), or silica; these are uncommon to rare in dogs and cats.

SYNONYMS

CaPO4: apatite uroliths. Cystine: cysteine

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Cystine: uncommon in dogs, rare in cats. Onset in middle age; occurs predominantly in males.
- CaPO4: uncommon in dogs, rare in cats. Middle-aged to older. Gender prevalence varies: brushite—mostly males; hydroxyapatite—either sex; carbonate apatite—female. Silica: very rare in dogs. Onset in middle age; males predominate.

GENETICS & BREED PREDISPOSITION: Several breeds are overrepresented for each urolith type:

- Cystine: many dog breeds, including Newfoundland and Labrador (autosomal recessive trait), English bulldog, Siamese cats. Prevalence greater in Europe than in the United States.
- CaPO4: Yorkshire terrier, miniature schnauzer, bichon frise, shih tzu, pug, springer spaniel, Pomeranian, miniature poodle, and cocker spaniel
- Silica: German shepherds, Labrador, boxer, Old English sheepdogs, rottweiler, miniature schnauzer, shih tzu, Lhasa apso, bichon frise, and Yorkshire terrier

RISK FACTORS

- Cystine: renal tubular transport defect
- CaPO4: primary hyperparathyroidism, distal renal tubular acidosis, hypercalcemia

ASSOCIATED CONDITIONS & DISORDERS

- Urethral obstruction
- Urinary tract infection
- Renal dystrophic mineralization
- A link between cystinuria and taurine-deficient dilated cardiomyopathy has been proposed in the Newfoundland dog but remains unproven (cystine is a precursor for taurine synthesis).

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: Clinical signs may be absent. If present, they may include:

- Hematuria
- Pollakiuria
- Dysuria
- Stranguria
- Inappropriate elimination (periuria)
- Rarely, systemic illness due to urinary obstruction

PHYSICAL EXAM FINDINGS: Examination is often unremarkable. Abnormalities, if present, may include:

- Hematuria (stains on prepuce, vulva, if present, or hocks)
- Painful urinary bladder
- Palpable cystic calculi

- Palpable urethral calculi (via digital rectal exam)
- Enlarged turgid bladder, if urethral obstruction
- Renomegaly, if secondary hydronephrosis

ETIOLOGY AND PATHOPHYSIOLOGY

- Cystine:
  - Inborn error of metabolism leads to defective renal tubular transport of cystine (± other amino acids) resulting in cystinuria, but not all animals with cystinuria form uroliths.
  - Cystine becomes insoluble in acidic urine.
- CaPO4:
  - Hypercalcemia is contributory but not necessary.
  - Hypercalciuria may occur without hypercalcemia.
  - Factors decreasing the solubility of calcium salts (e.g., urine pH) or promoting crystallization (e.g., deficient inhibitor substances, epitaxy [concentric layered formation of a stone of mixed composition]) also contribute.
- Silica:
  - Poorly understood. May be associated with ingestion of silica-rich feedstuffs such as rice or soybean hulls.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Radiolucent uroliths can be missed by routine abdominal radiography but are often identified via ultrasonography. Confirmation of the specific urolith type, which dictates optimal treatment and prevention, ultimately depends upon analysis of uroliths after removal.

DIFFERENTIAL DIAGNOSIS

- Other types of uroliths (struvite, calcium oxalate uroliths most common)
- Urinary neoplasia
- Urinary tract infection (UTI)

INITIAL DATABASE

- CBC: unremarkable
- Serum biochemical profile: hypercalcemia in some animals with CaPO4 uroliths. If urinary obstruction present, azotemia and electrolyte abnormalities (see p. 1131)
- Complete urinalysis: hematuria, bacteruria, pyuria are found inconsistently.
  - Cystine: aciduria to neutral urine pH; sometimes flat, hexagonal crystals
  - CaPO4: alkaluria (apatite/hydroxyapatite) to neutral to aciduria (brushite); sometimes amorphous or long, thin prism-like crystals
  - Silica: pH variable (solubility not linked to pH)
- Urine culture and susceptibility to rule out UTI
- Abdominal radiographs:
  - Cystine uroliths: radiolucent to slightly radiopaque, round to oval, typically smooth
  - CaPO4 uroliths: radiopaque, round or faceted, smooth
  - Silica uroliths: radiopaque, jackstone (radial spokes from round center)
  - Relative radiopacity: struvite ≥ oxalate = CaPO4 = silica > cystine > urate
- Abdominal ultrasound: confirm/identify radiopaque/radiolucent uroliths, assess kidneys for pyelonephritis, hydronephrosis.
- If urethral obstruction is suspected, catheterization to identify or rule out obstruction.

ADVANCED OR CONFIRMATORY TESTING

- Contrast cystography/urethrography for radiolucent uroliths
- Urolith analysis: retrieved stones should be submitted for quantitative analysis (crystallography, x-ray diffraction, infrared spectroscopy) to determine urolith type
- Cystoscopy may facilitate stone removal for analysis and therapy.
- Screening tests for cystinuria (Metabolic Screening Laboratory, Veterinary Hospital, University of Pennsylvania: www.vet.upenn.edu/penngen)
- Assay of urine calcium excretion rarely used to document hypercalciuria
- Specific tests to identify cause of hypercalcemia, if present (see p. 553)

TREATMENT

TREATMENT OVERVIEW

Although uncommon, urinary obstruction requires immediate removal of uroliths. Appropriate treatment depends upon identification; mechanical removal facilitates identification of these uncommon uroliths. Silica and CaPO4 uroliths are not amenable to medical dissolution.

ACUTE GENERAL TREATMENT

- Relieve urinary tract obstruction if present (see pp. 1353 and 1355)
- Antibiotics for documented urinary tract infection; selection based on culture and susceptibility
- Choose between medical dissolution and mechanical calculi removal:
    - Urinary obstruction should be relieved mechanically.
    - Mechanical removal allows for urolith analysis, culture.
    - Cystine uroliths are amenable to medial dissolution; CaPO4 and silica uroliths are not.
    - Medical dissolution: see Chronic Treatment, below.
- Mechanical removal of calculi:
- Urohydropropulsion (voiding, retrograde; see and)
- Avoid performing voiding urohydropropulsion in male cats.
- Catheter-assisted retrieval
- Cystoscopic-assisted retrieval (see p. 1239)
- Cystotomy/urethrotomy/urethrostomy/pyelotomy/nephrotomy
- Lithotripsy (see p. 1297; intracorporeal or extracorporeal shock wave lithotripsy)

CHRONIC TREATMENT

- Promote water consumption to avoid concentrated urine (e.g., canned food, wetting dry food, use of cat water fountains). Precipitation/concretion of minerals less likely in dilute urine.
- Cystine uroliths: dissolution may require 1-6 months
    - Limit dietary cystine with a restricted protein diet low in methionine (e.g., Hill's u/d). See Nutrition/Diet, below.
    - If urine remains acidic, add potassium citrate (50-150 mg/kg PO q 12 h; dose adjusted to maintain urine pH of 7.0-7.5). Avoid sodium bicarbonate.
    - Solubility of cystine in dogs is increased by administration of *N*-(2-mercaptopropionyl)-glycine (2-MPG)
    - A higher dose (15-20 mg/kg PO q 12 h) promotes urolith dissolution.
    - A lower dose (10-15 mg/kg PO q 12 h) is used to prevent recurrence.
- CaPO4: medical dissolution not possible. After mechanical removal, address conditions causing hypercalcemia when present.
- Silica: medical dissolution not possible. After mechanical removal, decrease consumption of vegetable materials and soil (see Nutrition/Diet, below).

NUTRITION/DIET

-
    - Cystine: Calculolytic diet with restricted protein and low in methionine (e.g., Hills Prescription Diet u/d) fed at least 1 month past dissolution.
    - If an ultra low-protein diet is not appropriate, consider a renal diet (e.g., Hill's k/d) with the addition of potassium citrate to keep the urine pH > 7.2.
    - Low purine diets (e.g., Royal Canine Urinary UC Low Purine, Hill's k/d) can be fed to reduce cystine recurrence.
    - Silica: although dissolution not possible, feeding a diet low in vegetable materials and soil may reduce recurrence (e.g., avoid rice, soybean hulls).

POSSIBLE COMPLICATIONS

- Risk of urethral obstruction (small stones or during medical dissolution of cystine uroliths)
    - Urinary tract obstruction
    - Hydronephrosis
    - Hydroureter
- Urinary tract infection
- Urinary polyp formation
- Uroliths may be left behind during surgery (up to 20% of stones are not removed).
- Cystinuric dogs (especially English bulldogs) fed ultra low-protein diets may be at risk of dilated cardiomyopathy.
- Although uncommon, 2-MPG can lead to aggression, dermatopathy, myopathy, proteinuria, spherocytic anemia,

thrombocytopenia, or increased hepatic enzymes.

RECOMMENDED MONITORING

- Repeat urinalysis 2 weeks after initiation of medical therapy or diet changes, and again every 2-4 weeks thereafter to assess for pH, crystals, specific gravity, or evidence of infection. When pH and specific gravity have met goals (specific gravity < 1.020, pH as appropriate for urolith type), monitoring frequency can be extended to q 3-6 months for a year, then q 6-12 months.
- Imaging (radiographs for $CaPO_4$ and silica; contrast or ultrasound for cystine) should be repeated after mechanical removal or q 2-4 weeks during dissolution (cystine). Thereafter, imaging should be repeated q 6-12 months.
- Urine should be cultured if signs/uroliths recur or an active urine sediment is identified on urinalysis.

PROGNOSIS AND OUTCOME

Because cystinuria is due to a persistent renal tubular defect, recurrence of cysteine urolithiasis is likely without dietary modification ± 2-MPG

PEARLS & CONSIDERATIONS

COMMENTS

All of these uroliths are rare, and only the cystine urolith can be medically dissolved.

PREVENTION

- Promote water consumption (e.g., canned food, wetted food, water fountains).
- Cystine: restricted protein diet, urine alkalinization as necessary, ± long-term use of 2-MPG. Avoid breeding carrier dogs.
- $CaPO_4$: address hypercalcemic disorders directly (e.g., surgical correction of hyperparathyroidism). Avoid low-calcium diets (paradoxic hypercalciuria). Other therapies (e.g., thiazide diuretics, dietary modifications, acidification of urine) may be warranted in cases with multiple recurrences.
- Silica: avoid feedstuffs high in silica (e.g., rice, soybean hulls).

CLIENT EDUCATION

- Adherence to dietary therapy must be strict for urolith dissolution.
- Animals with metabolic defects should not be bred. Genetic tests are available for cystinuria in Newfoundlands and Labradors (University of Pennsylvania).
- Urinary tract obstruction is life threatening. Stranguria should prompt immediate veterinary attention.

Uroabdomen

BASIC INFORMATION

DEFINITION

A condition characterized by accumulation of urine within the peritoneal and/or retroperitoneal spaces; caused by leakage of urine from the kidneys, ureters, bladder, or proximal urethra

SYNONYMS

Urinary tract rupture, uroperitoneum

EPIDEMIOLOGY

SPECIES, AGE, SEX: May affect all species and ages and both sexes; males may be slightly more predisposed due to anatomic characteristics.

RISK FACTORS: Preexisting compromise of the urinary tract owing to urinary obstruction (urolith[s], neoplasia, other), iatrogenic causes (urethral catheterization, aggressive bladder palpation, surgical complication [laceration or ligation of urinary tract]), or abdominal or pelvic trauma (hit by car, pelvic fractures of any cause, penetrating abdominal wounds)

ASSOCIATED CONDITIONS & DISORDERS

- Hyperkalemia
- Metabolic acidosis
- Septic abdomen (if urine was infected)
- Postrenal azotemia

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Nonspecific lethargy, anorexia, discomfort, vomiting
- Signs identifying or suggesting the underlying cause (e.g., witnessed being hit by a car; worsening pollakiuria due to obstruction)
- Urination: ability to pass urine does not rule out urinary tract rupture or uroabdomen; patient may or may not be hematuric.

PHYSICAL EXAM FINDINGS

- Dehydration
- Abdominal pain:
  - Lack of signs of abdominal pain does not rule out uroabdomen, but because of chemical peritonitis, most are painful.
- Lack of a palpable bladder:
  - Palpable bladder does not rule out urinary tract rupture/uroabdomen (small rupture, but still potentially life threatening).
- Bruising (perineum, ventral abdomen, and inguinal region)
- Depression
- Inappropriate bradycardia (from hyperkalemia):
  - Unlike dogs, cats may have severe hyperkalemia and maintain a normal or elevated heart rate.

ETIOLOGY AND PATHOPHYSIOLOGY

Accumulation of urine in the abdominal cavity results in the following consequences:

- Translocation of solutes that are normally higher in urine concentration (urea, creatinine, potassium, hydrogen) across the peritoneal lining into the extracellular fluid spaces and systemic circulation
- Postrenal azotemia
- Metabolic acidosis
- Hyperkalemia

- Chemical peritonitis

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Definitive diagnosis is based on demonstration of urine in the abdomen. Plasma-to-abdominal fluid gradients of creatinine and potassium are helpful to differentiate uroabdomen from other causes of azotemia and ascites.

DIFFERENTIAL DIAGNOSIS

- Acute abdomen
- Ascites of other causes (e.g., hypoalbuminemic, cardiogenic, hemorrhagic)
- Acute (oliguric/anuric) renal failure

INITIAL DATABASE

- CBC: generally unremarkable
- Serum biochemistry profile: moderate or marked blood urea nitrogen (BUN), creatinine, and potassium elevations as well as low $Hco3^{-}$ are common.
- Urinalysis: cystocentesis not feasible if bladder has collapsed; catheter acceptable if no urethral resistance. Hematuria is most common finding.
- Abdominal radiographs: loss of serosal detail
- Abdominal ultrasound: free abdominal fluid (anechoic); ultrasound contrast cystography may confirm bladder rupture (e.g., bladder bubble study).
- Abdominocentesis, with increased creatinine and potassium of fluid compared with serum

ADVANCED OR CONFIRMATORY TESTING

Positive contrast radiography (cystourethrography [bladder, urethra; see and] or IV excretory urography [kidneys, ureters; see]). The most sensitive method to confirm urine leakage and localize the site of leakage.

TREATMENT

TREATMENT OVERVIEW

The mainstay of treatment is normalization of perfusion and correction of hyperkalemia if present. Once the animal is stable, surgical exploration is usually required for definitive repair. Urethral and ureteral surgery is technically demanding, and transfer of the patient to a center with advanced surgical facilities should be considered.

ACUTE GENERAL TREATMENT

- Intensive fluid therapy to treat shock if present and correct severe dehydration:
  - Fluid without potassium is recommended as an initial choice (e.g., 0.9% NaCl)
  - High fluid rates are often necessary for dehydration correction or for management of postobstructive diuresis.
  - Fluid type and rate are continually reassessed based on physical monitoring and serial electrolyte levels.
- If the patient's potassium > 7-8 mEq/L and/or there are clinical (e.g., bradycardia) or electrocardiographic (ECG) (e.g., no P waves in all ECG leads) changes due to hyperkalemia, immediate medical therapy and stabilization is required (see p. 556).
- For animals with lower urinary tract injury and urine accumulation in the peritoneal space:
  - Placement of peritoneal drainage catheter (see p. 1192; simple and life-saving!).
  - Placement of urethral catheter (bladder decompression and prevention of further urine leakage)
  - Placement of prepubic tube cystostomy in animals with severe urethral trauma
  - Analgesia and sedation as indicated, nonsteroidal antiinflammatory drugs should be avoided until azotemia has resolved and renal function has normalized.
  - If urinary tract infection is suspected, broad spectrum antimicrobial drugs are indicated. Every effort should be made to collect urine for culture, and ongoing antimicrobial usage should be guided by culture and sensitivity.

CHRONIC TREATMENT

- Fluid therapy to replace ongoing losses, including the presence of postobstructive diuresis

- Surgical correction of the site of leakage

NUTRITION/DIET

All animals with uroabdomen, but especially cats, can have a long recovery from surgery. Consideration should be given to the placement of a feeding tube (nasoesophageal or esophageal; see and) at the time of surgery.

DRUG INTERACTIONS

Do not add potassium chloride (KC1) to IV fluids until serum potassium level is known to be normal or low.

POSSIBLE COMPLICATIONS

- Obstruction of the peritoneal drainage catheter with omentum
- Injury to other intraabdominal structures during placement of peritoneal drainage catheter
- Urethral stricture formation and urinary incontinence
- Persistent renal insufficiency

RECOMMENDED MONITORING

- Frequent monitoring of vital signs, including blood pressure (BP)
- ECG monitoring if hyperkalemia
- Fluid input and urine output from both peritoneal drainage and urethral catheters q 2-4 h
- Serum chemistry, venous blood gas (VBG), packed cell volume (PCV) q 8-12 h during initial stabilization
- Patient's weight q 12 h

PROGNOSIS AND OUTCOME 

- Prognosis is good with early diagnosis, aggressive emergency management, and definitive repair.
- The mortality rate is increased in animals with concurrent injuries or underlying neoplasia.

PEARLS & CONSIDERATIONS 

COMMENTS

- Consider uroabdomen in animals with a history of abdominal or pelvic trauma, urinary obstruction, or urethral catheterization.
- A palpable bladder and the ability to void urine do not rule out uroabdomen, because animals with urinary tract disruption may continue to urinate.
- The abdominal fluid obtained is serosanguineous and may not look like urine; creatinine and potassium concentrations of the fluid are diagnostic when compared to serum levels.
- Asepsis (urethral and peritoneal drainage catheters, sterile collection system) is essential for preventing complications secondary to infection.
- In dogs and cats, lower urinary tract injuries are more common than renal/ureteral injuries. Therefore, contrast cystography and retrograde urethrography take precedence over intravenous excretory urography.
- Surgical repair should not be attempted until the animal has been stabilized with fluid therapy and abdominal drainage.

TECHNICIAN TIPS

Fluid therapy is a challenge in these patients, and accurate recording of fluid administration and fluid output are crucial. Patients with uroabdomen often have concurrent disease or injuries and may have a long recovery period; adequate attention to analgesia and nutrition can be of huge benefit to their recovery.

Urinary Bladder and Urethral Rupture

BASIC INFORMATION

DEFINITION

Traumatic rupture of the urinary bladder and/or urethra.

EPIDEMIOLOGY

SPECIES, AGE, SEX: Urethral trauma more common in males

RISK FACTORS

- Ability to roam freely
- Blunt trauma (e.g., vehicular accident, kicks, falls)
- Penetrating injury (e.g., gunshot wound, cystocentesis)
- Pelvic fracture
- Fracture of the os penis
- Urolithiasis
- Lower urinary tract obstruction
- Urethral catheterization
- Urogenital surgery

ASSOCIATED CONDITIONS & DISORDERS

- Azotemia/uremia
- Hyperkalemia

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Precipitating event (e.g., trauma, penetrating injury)
- Dysuria or anuria (common); ability to produce urine stream does not rule out urinary bladder rupture.
- Hematuria (common)
- Vomiting (common)
- Depression (common)
- Anorexia (common)
- Abdominal pain (may not be noticed by owners)
- Urethrocutaneous fistula (uncommon; chronic)

PHYSICAL EXAM FINDINGS

- Abdominal effusion (especially with bladder rupture)
- Caudal abdominal pain (especially common with bladder rupture)
- Dehydration (common)
- Depression (common)
- Dysuria (especially common with urethral rupture)
- Halitosis (with uremia)
- Hematuria (especially common with urethral rupture)
- Hypovolemia secondary to urine peritonitis/uroabdomen
- Inability to palpate bladder (especially common with bladder rupture)
- Pelvic fracture (sometimes present when trauma causes urinary tract rupture)
- Stranguria (especially common with urethral rupture)
- Uremic oral ulcers +/−
- Ventral abdominal wall or perineal bruising +/−

ETIOLOGY AND PATHOPHYSIOLOGY

- Blunt external trauma, penetrating projectiles, perforation by fracture fragments
- Iatrogenic: secondary to catheterization, cystocentesis, or other diagnostic procedure errors; forceful bladder expression
- Intraperitoneal accumulation of urine results in chemical peritonitis, azotemia, hyperkalemia, and acidemia; death may occur in 3-5 days if animal is left untreated.
- Extraperitoneal accumulation of urine results in cellulitis and tissue death acutely and may result in formation of urethrocutaneous fistulas if the rupture is not treated.
- See Uroabdomen, .

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Urinary tract rupture should be suspected in animals with uremia and dysuria/oliguria, especially after either abdominal trauma or suspected urethral obstruction. Whereas animals with simple urethral obstruction often have large bladders, the bladder may be small or nonpalpable in animals with urinary bladder rupture.

DIFFERENTIAL DIAGNOSIS

- Bladder rupture:
  - Urinary tract infection
  - Urine leakage from upper urinary tract
  - Other causes of peritonitis
- Urethral rupture:
  - Urinary tract obstruction due to urolithiasis, neoplasia, granulomatous urethritis, or prostatic disease
  - Periurethral hematoma or abscess

INITIAL DATABASE

- CBC:
  - Initially unremarkable, progressing to neutrophilic leukocytosis, often with left shift as urinary peritonitis develops
- Serum biochemical profile:
  - Azotemia common
  - Hyperkalemia worsens with time (may be life threatening; i.e., >8 mEq/L)
  - Metabolic acidemia common
- Abdominal/pelvic radiographs:
  - Loss of serosal detail as urine accumulates in peritoneal space
  - Pelvic or os penis fracture occasionally identified
- Abdominocentesis (see p. 1193) or peritoneal lavage (see online chapter: Diagnostic Peritoneal Lavage) with fluid analysis:
  - Compare fluid and serum creatinine; fluid creatinine 2× greater than serum creatine is strongly supportive of urinary tract rupture.
  - Abdominal fluid potassium 4× greater than serum potassium also strongly supportive.
- Urethral catheterization should normally encounter no friction/resistance.

ADVANCED OR CONFIRMATORY TESTING

- Positive-contrast urethrocystogram (see pp. 1357 and 1237)
- Ultrasonography

TREATMENT

TREATMENT OVERVIEW

Rupture of the bladder or urethra represents an urgent problem. Immediate therapy is aimed at stabilization of fluid, electrolyte and acid-base disturbances, with a goal of restoring urinary tract integrity via surgical intervention or temporary urinary diversion while smaller tears in the urinary tract heal on their own.

ACUTE GENERAL TREATMENT

- Temporary urinary diversion by transurethral catheter or cystostomy tube
- Correct electrolyte and acid-base disturbances:

    - If potassium >7 mEq/L, consider one or more of the following (see p. 556):
        - Regular crystalline insulin (¼ unit/kg IV bolus) with IV dextrose (2 g dextrose/unit insulin over 6 hours IV; 50% dextrose is 0.5 g/mL, 5% dextrose is 0.05 g/mL. Generally administered as 5% dextrose infusion; dextrose concentrations >10% can cause phlebitis).
        - Sodium bicarbonate: 1 mEq/kg IV bolus
        - Calcium gluconate (10% solution): 1 mL/kg slow IV bolus (cardio-protective)
            - Monitor electrocardiogram (ECG) and stop infusion if new arrhythmia occurs.
    - If pH < 7.1, institute sodium bicarbonate therapy:
        - Calculate bicarbonate deficit: [(0.3) × (BW in kilograms) × (base deficit)]. Base deficit is (24 -patient's $Hco3^-$) in milliequivalents per liter.
        - Administer half of deficit in IV fluids over 6 hours.
- Provide crystalloid fluids at an adequate rate:
    - Rehydration: % dehydration* × body weight (kilograms) = deficit (liters); the asterisk sign* for this equation refers to dehydration entered as a decimal, so 10% is 0.1, 7% is 0.07, and so on.
    - Maintenance: 60 mL/kg per day
    - Ongoing loss: estimate loss from vomiting, third-space loss, and other such losses.
- Abdominocentesis (see p. 1193) or peritoneal lavage to decrease the effects of uroabdomen
- Primary repair of rupture or conservative management by urine diversion until adequate healing occurs:
    - Primary repair:
        - Bladder ruptures due to blunt trauma; complete abdominal exploration
        - Complete urethral transections
    - Conservative management by urine diversion:
        - Small bladder perforations (e.g., from catheter trauma)
        - Incomplete urethral lacerations
        - Bladder rupture: urethral catheter ± peritoneal lavage catheter
        - Urethral rupture: urethral catheter or cystostomy tube

CHRONIC TREATMENT

- Antimicrobial therapy for bacterial cystitis may be necessary after urinary diversion catheter is removed.
- Stricture formation or urethral dehiscence postoperatively may necessitate antepubic urethrostomy.

POSSIBLE COMPLICATIONS

- Cardiac bradyarrhythmia due to hyperkalemia
- Urinary tract infection as a result of urinary catheterization
- Continued leakage after surgical correction

URETHRAL STRICTURE RECOMMENDED MONITORING

- Positive-contrast urethrocystography after conservative management to assess adequacy of healing and identify formation of any strictures
- Observation of animal for dysuria or stranguria
- Urinalysis and/or urine culture after removing urinary diversion catheter

PROGNOSIS AND OUTCOME

- Good to excellent for bladder rupture and incomplete urethral transection
- Guarded to good with complete urethral transection, especially if complicated by urethrocutaneous fistula formation

PEARLS & CONSIDERATIONS

COMMENTS

- Emergency surgery to repair bladder or urethral rupture is rarely necessary if urinary diversion can be established.
- Address life-threatening shock and metabolic disorders prior to surgery.

PREVENTION

Avoid excessive force during bladder expression or catheterization.

TECHNICIAN TIPS

Urinary bladder rupture is possible with aggressive manipulation, especially when urinary obstruction is present. Do not attempt manual bladder expression against firm resistance.

CLIENT EDUCATION

- Do not allow pets to roam.
- Dysuria/stranguria can indicate a life-threatening problem and warrant rapid veterinary evaluation.
- Dysuria and/or stranguria after treatment of urinary tract rupture could indicate stricture formation.

Urethral Sphincter Mechanism Incompetence

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

Urethral sphincter mechanism incompetence is a common cause of involuntary voiding of urine (urinary incontinence). It is most frequently identified in ovariohysterectomized bitches.

SYNONYMS

Estrogen-responsive or hormone-responsive incontinence, hormone-responsive urethral incompetence

EPIDEMIOLOGY

SPECIES, AGE, SEX: Middle-aged female dogs predominantly affected, although hormone-responsive incontinence can occur in bitches of any age and occurs rarely in neutered males. Onset of incontinence may be months to years after ovariohysterectomy (OHE).

GENETICS & BREED PREDISPOSITION: Usually medium- to large-breed dogs. A positive association between tail docking and hormone-responsive incontinence has been demonstrated. Over-represented breeds include boxer, Doberman pinscher, German shepherd, Old English sheepdog, rottweiler, springer spaniel, weimaraner

RISK FACTORS: Intrapelvic bladder, short urethra, and obesity. Often occurs in association with ectopic ureter. Any cause of polyuria may initiate or exacerbate clinical signs.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Urinary incontinence, often most evident during rest (i.e., patients leave “puddles” after sleeping)
- Excessive licking of perineum
- Dogs retain ability to produce normal voluntary urine stream.

PHYSICAL EXAM FINDINGS

- Usually unremarkable. Complete neurologic examination should be conducted, including evaluation of tail and anal tone.
- Observed episode of urination is normal; bladder will empty nearly completely after voluntary voiding.
- Perineal urine staining or perivulvar dermatitis sometimes observed.

ETIOLOGY AND PATHOPHYSIOLOGY

- The vast majority of neutered dogs remain continent. It is unclear why only a minority of neutered bitches develop urethral sphincter mechanism incompetence.
- Sex hormones apparently sensitize the internal urethral sphincter to the effects of α-adrenergic stimulation.
- The bladder may be positioned in a relatively caudal position in neutered bitches, lessening the intraabdominal pressures on the urethra that help maintain urethral closure.
- Urethral sphincter mechanism incompetence is commonly found in intact dogs with ectopic ureter, and may account for continued incontinence after surgical correction of ectopia.

DIAGNOSIS

DIAGNOSTIC OVERVEIW

The diagnosis is suspected when an otherwise healthy neutered bitch develops urinary leakage, especially during sleep. Ruling out other causes of incontinence and response to therapy are usually used to confirm the diagnosis.

DIFFERENTIAL DIAGNOSIS

- For inappropriate urination, distinguish between urinary incontinence and pollakiuria, polyuria, or behavioral disorders.
- Differentials for urinary incontinence: lower motor neuron disease/peripheral neuropathy; upper motor neuron disease; dysautonomia; urge incontinence; partial urethral obstruction; and congenital and acquired urinary tract structural defects (ectopic ureter[s], vaginal stricture/stenosis, urethrovaginal fistula).

INITIAL DATABASE

- Complete neurologic examination (see p. 1311): normal
- CBC and serum biochemistry profile: unremarkable
- Complete urinalysis: occasionally reveals evidence of secondary urinary tract infection
- Urine culture: to rule out urinary tract infection
- Abdominal radiographs or ultrasound of urinary structures: unremarkable, or bladder may display intrapelvic positioning.

ADVANCED OR CONFIRMATORY TESTING

- Contrast studies (see p. 1357) and/or cystoscopy (see p. 1239): not routinely required, but can rule out structural causes of urinary incontinence.
- Urethral pressure profile (UPP) and/or leak point pressure (requires specialized equipment/expertise): not routinely employed for clinical diagnosis but can objectively identify urethral sphincter incompetence. May have prognostic utility in animals with ectopic ureter to predict resolution of incontinence after surgical correction.
- Positive response to therapy is often used for supporting the diagnosis, but interpretation of result should be cautious because optimal response may require dosage adjustment over weeks.

TREATMENT

TREATMENT OVERVIEW

Medical treatment with either phenylpropanolamine or hormone therapy usually results in control of incontinence. Endoscopic and surgical therapies are also options.

ACUTE GENERAL TREATMENT

- If polyuria is identified, the cause should be sought and treatment instituted (underlying cause is likely not hormone-responsive incontinence alone or at all).
- Medical therapy with phenylpropanolamine or estrogen compounds
- Treatment of secondary urinary tract infection with appropriate antimicrobials

CHRONIC TREATMENT

- Phenylpropanolamine is an α-agonist sympathomimetic used for increasing internal urethral sphincter tone. Available as chewable tablets or oral solution (1-1.5 mg/kg PO q 8-12 h) or as time-released 75-mg capsules (<40 lb: ½ capsule daily; dogs 40-100 lb: 1 capsule daily; >100 lb: 1.5 capsules daily). Discontinue if anxiety, hyperactivity, or tachycardia.
- Diethylstilbestrol (DES) is a synthetic estrogen that increases sensitivity of internal urethral sphincter to catecholamines. Dosage is empirical, with reduction in frequency and dose to least possible that controls clinical signs. Starting dose: 0.1 mg (small dog), 0.3 mg (medium dog), or 0.7 mg (large dog) total daily dose PO q 24 h for 3-5 days. Then the same dose is given q 5-8 days as needed to control incontinence.
- Conjugated estrogens (e.g., Premarin, 20 mcg/kg PO q 4 days) have been used in place of DES.
- Testosterone cypionate (2.2 mg/kg IM q 30 days) can be used in castrated males (but phenylpropanolamine is preferred).
- Gonadotropin releasing hormone (GnRH) analog can be used in place of DES but is less effective than phenylpropanolamine.
- Hormones may be administered concurrently with phenylpropanolamine when incontinence persists despite therapy (synergistic actions).
- Surgical therapies are usually reserved for refractory patients:
    - Cystoscopically administered periurethral injections of collagen or Teflon; may need to be repeated
    - Adjustable hydraulic urethral sphincter placed at surgery
    - Colposuspension, cystourethropexy, urethroplasty, or urethral intussusception

DRUG INTERACTIONS/CONTRAINDICATIONS

- Hormone therapy may cause adverse reactions: estrogen compounds (e.g., bone marrow suppression), testosterone (e.g., prostatomegaly, behavioral changes)
- AVOID estradiol cypionate because of increased risk of marrow suppression.

- Phenylpropanolamine may cause adverse reactions (e.g., lethargy, decreased appetite, GI upset, hyperactivity, hypertension). Use with caution or avoid if there is systemic hypertension, heart disease, cardiac arrhythmias, central nervous system disease, or if monoamine oxidase inhibitors or other sympathomimetic agents are used.

POSSIBLE COMPLICATIONS

Secondary urinary tract infection

RECOMMENDED MONITORING

- Periodic urinalysis with Gram stain of sediment and/or bacterial culture and sensitivity if incontinence persists
- Periodic monitoring of blood pressure in dogs treated with phenylpropanolamine
- Periodic monitoring of CBC in dogs treated with estrogen drugs

PROGNOSIS AND OUTCOME

Most dogs respond to medical therapy with improvement or resolution of clinical signs. Some dogs require more than a single type of medication, and ancillary surgical procedures may be required in some cases.

PEARLS & CONSIDERATIONS

COMMENTS

- Hormone-responsive urinary incontinence is a common cause of urinary incontinence.
- Diagnosis usually based on clinical presentation, ruling out other common causes of incontinence, and response to therapy.
- Minimal evaluation includes neurologic examination, observation of urination and palpation of bladder afterwards, urinalysis and urine culture, and imaging of the urinary tract with radiographs or ultrasound.

PREVENTION

Hormone-responsive incontinence occurs in only a small percentage of ovariohysterectomized bitches. There is little evidence that early neutering increases likelihood of developing incontinence.

AUTHOR & EDITOR: LEAH A. COHN

Urethral Prolapse

BASIC INFORMATION

DEFINITION

Prolapse of urethral mucosa from urethral orifice

EPIDEMIOLOGY

SPECIES, AGE, SEX: Young, intact male dogs

GENETICS & BREED PREDISPOSITION: English bulldog

RISK FACTORS

- Intact male dog
- Brachycephalic breed

ASSOCIATED CONDITIONS & DISORDERS: Brachycephalic airway syndrome

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Excessive licking of prepuce or penis
- Blood from preputial opening
- Stranguria

PHYSICAL EXAM FINDINGS

- Hemorrhagic discharge from prepuce
- Red or purple mass protruding from urethral orifice
- A prolapsed urethra typically appears as a small red bulb of smooth, congested (red) mucosa at the tip of the penis surrounding the urethral opening.

ETIOLOGY AND PATHOPHYSIOLOGY

Possible causes include:

- Excessive sexual excitement
- Masturbation
- Genitourinary infection
- Urolithiasis

Secondary swelling of the prolapsed segment prevents spontaneous reduction.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis is based on patient signalment, presenting history, and physical examination findings.

DIFFERENTIAL DIAGNOSIS

- Penile trauma
- Urethritis
- Neoplasia (transmissible venereal tumor [TVT])

INITIAL DATABASE

- Presurgical CBC, serum chemistry profile: generally unremarkable
- Urinalysis (cystocentesis) ± microbiologic culture:
    - Rule out associated urinary tract infection (UTI), prostatic disease.

ADVANCED OR CONFIRMATORY TESTING

- Impression smear of prolapsed tissue for cytologic examination:
    - Rule out TVT
- Abdominal ultrasound examination:
    - Rule out prostatic disease

TREATMENT

TREATMENT OVERVIEW

The prolapsed urethral mucosa requires surgical correction. Postoperatively appropriate measures should be taken to prevent recurrence of the problem.

ACUTE GENERAL TREATMENT

Surgical correction of prolapsed urethra:

- Urethropexy technique: inversion of urethral mucosa using several mattress sutures

CHRONIC TREATMENT

- Prevent masturbation in the immediate postoperative period.
- Treat UTI, prostatic disease, and urolithiasis if present.
- Consider castration to reduce sexual arousal:
    - Dog should not be used for breeding purposes because of genetic predisposition.

POSSIBLE COMPLICATIONS

Recurrence of prolapse after surgical correction

RECOMMENDED MONITORING

Observe animals for recurrence of bleeding from prepuce; the signs may indicate recurrence of prolapse.

PROGNOSIS AND OUTCOME

Excellent prognosis with appropriate surgical technique

PEARLS & CONSIDERATIONS

COMMENTS

The hallmark of diagnosis is the physical finding of a red bulb-like mass at the tip of the penis in a patient with stranguria or penile self-trauma.

PREVENTION

- Recognize genetic predisposition for the problem: English bulldog.
- Early castration to reduce sexual activity or excitement
- Prevention of masturbation
- Prevention of obesity

TECHNICIAN TIPS

Perioperative in-hospital care consists of:

- Preoperative prevention of additional trauma to prolapsed urethra
- Sedation, Elizabethan collar
- Postoperative prevention of trauma to surgical site (see above)
- Ensuring that adequate analgesia is provided in the postoperative period

CLIENT EDUCATION

- Early castration in predisposed breeds to reduce sexual activity or excitement
- Prevention of masturbation and self-trauma to penis
- Avoid circumstances that would exacerbate respiratory problems in brachycephalic dogs:
  - Obesity
  - Stress
  - Heat, humidity

SUGGESTED READING

Kirsch JA, Hauptman JG, Walshaw R: A urethropexy technique for surgical treatment of urethral prolapse in the male dog. J Am Anim Hosp Assoc 38:381–384, 2002.

AUTHOR & EDITOR: RICHARD WALSHAW

Urethral Obstruction

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

A common condition that involves obstruction of the lower urinary tract, usually due to urolith or matrix formation. Other causes (e.g., neoplasia, stricture, infections) are less common.

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Cats and less commonly dogs of any age
- Males are anatomically predisposed to obstruction.

GENETICS & BREED PREDISPOSITION

- Certain breeds predisposed to specific urolith formation (e.g., Dalmatians: urate uroliths)
- Other breed predisposed to urethral neoplasia (e.g., Scottish terrier)

RISK FACTORS

- Feline lower urinary tract signs/disease (FLUTS/D)
- Neoplasia
- Urinary tract infection
- Risk factors associated with urolithiasis (see pp. 1138, 1141, 1143, and 1145)

ASSOCIATED CONDITIONS & DISORDERS

- Hydronephrosis
- Azotemia/uremia
- Hyperkalemic cardiac dysrhythmia
- Urinary bladder rupture
- Bladder atonia/hypotonia
- Urinary tract infection
- Post obstructive diuresis

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Stranguria
- Anuria/oliguria
- Hematuria
- Lethargy
- Anorexia
- Vocalization
- Restlessness
- Dribbling urine
- Licking prepuce/vulva (urethral discharge)
- Dyschezia
- History of urinary infection or urolithiasis

PHYSICAL EXAM FINDINGS

- Enlarged, turgid urinary bladder (characteristic)
- Abdominal discomfort (common)
- Dribbling urine (occasionally)

- Bloody preputial/vulvar discharge (occasionally)
- Palpable urethral urolith or tumor (digital rectal exam in dogs) (occasionally)
- Bradycardia if severe hyperkalemia (in very advanced cases)

ETIOLOGY AND PATHOPHYSIOLOGY

- Urine supersaturation, urinary tract infection, certain disease states, and breed predisposition contribute to urolithiasis.
- In cats especially, urethral plugs may be composed of matrix (cellular debris, virus-like particles, +/− bacteria, urinary crystals).
- Uroliths or plugs can obstruct the urethra; urethral anatomy favors obstruction in males.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis of urethral obstruction is suspected in any patient that is straining to urinate and has an enlarged, firm urinary bladder present on abdominal palpation.

DIFFERENTIAL DIAGNOSIS

- Detrusor atony
- FLUTS/D
- Fungal granulomas
- Reflex dyssynergia
- Trauma (pelvic fracture) with urethral damage, bladder entrapment hernia, penile fracture
- Urethral neoplasia
- Urethral stricture
- Urethral tissue valve/flap
- Urethritis
- Urolithiasis

INITIAL DATABASE

- CBC: unremarkable
- Serum biochemical profile: possible azotemia, hyperkalemia, findings consistent with predisposing conditions
- Urethral catheterization: distinguish functional from structural urethral obstruction, localize structural obstruction, may relieve obstruction and provide urine for analysis
- Urinalysis: possible hematuria, crystalluria, pyuria, epithelial cells, dilute urine, bacteruria. Rarely, fungal hyphae or neoplastic cells
- Urine culture: if sample is obtained by catheterization, quantitative culture to distinguish contamination ($<10^3$ colony-forming units/mL) from infection
- Abdominal/pelvic radiographs: distended urinary bladder, possible radiopaque uroliths, renomegaly, ascites
- Abdominal ultrasound: possible uroliths, urinary bladder debris, pyelectasia, ascites
- Electrocardiogram: hyperkalemia signs (absent P waves, wide QRS complexes, bradycardia)

ADVANCED OR CONFIRMATORY TESTING

- Voiding cystourethrogram: determine location of urethral obstruction
- Retrieved uroliths: quantitative analysis, culture
- Other testing for conditions predisposing to urolith formation (e.g., bile acids as screen for portosystemic shunt)

TREATMENT

TREATMENT OVERVIEW

Treatment consists of relieving the urinary obstruction. This is generally done by passing a urinary catheter into the urinary bladder and draining the urine.

ACUTE GENERAL TREATMENT

- Intravenous catheter for crystalloid fluid therapy, correcting electrolyte disorders, and administering sedation/anesthesia:
  - Crystalloid fluids: 5-10 mL/kg/h during sedation/anesthesia
  - Thereafter, rate should provide maintenance (60 mL/kg q 24 h), correct dehydration, and match postobstructive diuresis losses.
    - Closed urine collection system to identify profound postobstructive diuresis, maintain sterility, and allow "ins-and-outs" fluid treatment plan
  - If serum potassium >7 mEq/L, consider calcium gluconate, sodium bicarbonate, or insulin/dextrose therapy (see pp. 31 and 556).
- Small plug/urolith at the tip of the penis: remove via gentle massage (cats)
- Urethral catheterization can be attempted without sedation in male dogs; in cats, bitches, or dogs resistant to catheterization, sedation/anesthesia is usually required (see pp. 1266, 1353, and 1355).
- Insert a sterile red rubber catheter or open-ended polypropylene catheter into the urethra to the point of obstruction. Once encountered, retropulse the urolith/debris into the urinary bladder using sterile saline or a 75% sterile saline and 25% sterile water-based lubricant mixture.
  - In male cats, a sterile 22-G, 1-inch intravenous catheter (without stylet) may be used to dislodge urethral plug.
  - The urinary bladder is emptied; if debris is identified, lavage with sterile saline.
- An indwelling urinary catheter attached to a sterile, closed urine collection system is often indicated (e.g., pending correction of anatomic or functional obstruction, in cats with FLUTS/D, or to prevent urolith movement back into urethra following retropulsion and pending cystotomy).
  - For indwelling purposes, polypropylene catheters should be replaced with red rubber or Foley catheters.
  - Ideally, radiographs are obtained to identify remaining radiopaque urethral/bladder uroliths and to evaluate appropriate catheter placement. The catheter should just enter the trigone.
- If a urinary catheter cannot be passed, periodic cystocentesis can be performed to temporarily empty the urinary bladder pending definitive treatment.
- See Urethral Obstruction (Canine): Medical Management, ; Urethral Obstruction (Feline): Medical Management, .

CHRONIC TREATMENT

- Maintain indwelling urinary catheter appropriately (sterile, closed collection system):
  - Typically for 24-72 hours in cats with crystalluria or FLUTS/D
- Phenoxybenzamine (dog: 0.25 mg/kg PO q 12 h; cat: 2.5 mg/cat PO q 12-24 h) may decrease urethral spasm.
- Antibiotic therapy based on urine culture/sensitivity; obtain culture when removing catheter.
- Address urolithiasis:
  - Diet/medical dissolution possible for some types, but risk of repeated obstruction
  - Consider cystotomy, urohydropulsion (voiding, retrograde), cystoscopic-assisted retrieval.
- Perineal urethrostomy considered for male cats (or dogs) with recurrent obstruction
- Tube cystostomy for urethral neoplasia while waiting for chemotherapy to work

POSSIBLE COMPLICATIONS

- Urethral tear
- Urinary bladder rupture
- Urethritis
- Iatrogenic urinary tract infection
- Urethral stricture
- Recurrent urinary tract infections with perineal urethrostomy and tube cystostomy

RECOMMENDED MONITORING

- Daily bladder palpation during hospitalization after removing urinary catheter
- Repeat urinalysis and urine culture when urinary catheter is removed and again 1 week later.
- Monitor as appropriate for urolith type or FLUTS/D (see p. 1555).

PROGNOSIS AND OUTCOME

- Urethral obstruction is rapidly life threatening.
- If obstruction is alleviated and electrolyte disorders are addressed, prognosis is good (exception: neoplasia).
- Risk for recurrence is present regardless of cause.

PEARLS & CONSIDERATIONS

PREVENTION

Dietary/medical therapy are indicated when uroliths are identified. Predisposing factors for urolith formation should be addressed directly whenever possible.

TECHNICIAN TIPS

- Overly aggressive attempts at manual expression of the bladder must be avoided because bladder rupture can result.
- Straining to urinate without producing a urine stream is highly suggestive of urethral obstruction.

CLIENT EDUCATION

- Urinary tract obstruction is life threatening. Stranguria or dysuria should prompt immediate veterinary attention.
- Adherence to dietary therapy for urolith dissolution must be strict.

AUTHOR: ANNE M. DALBY

EDITOR: LEAH A. COHN

Ureteral Obstruction

BASIC INFORMATION

DEFINITION

Obstruction of urine flow through one or both ureters. Ureteral obstruction is recognized with increasing frequency, especially in cats.

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs or cats of any age or sex

RISK FACTORS

- Intraluminal obstruction (e.g., urolith, trauma, inflammation, fibrosis/stricture, congenital stenosis, blood clots)
- Intramural obstruction (e.g., fibrosis/stenosis, ureterocele, fibroepithelial polyps, proliferative ureteritis, neoplasia)
- Extramural obstruction (e.g., retroperitoneal or pelvic masses, prostatic/bladder neoplasia, inadvertent ligation or fibrotic entrapment of ureter)

ASSOCIATED CONDITIONS & DISORDERS

- Renal failure +/− uremia
- Hydronephrosis/hydroureter
- Pyelonephritis
- Uroabdomen (associated with ruptured ureter)

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Partial or complete
- Unilateral or bilateral

HISTORY, CHIEF COMPLAINT: Clinical signs are often absent, especially with unilateral obstruction. When signs are present, they may be related to acute renal failure or to overt chronic kidney disease. Any of these may be seen:

- Lethargy/depression (due to uremia or renal pain)
- Anorexia/vomiting (due to uremia or renal pain)
- Polyuria and polydipsia (with chronic kidney disease)
- Dysuria, stranguria, pollakiuria, or hematuria
- Oliguria or anuria (bilateral obstruction)

PHYSICAL EXAM FINDINGS: Physical examination is often normal; abnormalities can include:

- Dehydration
- Poor body condition
- Enlarged kidney(s) (due to hydronephrosis)
- Abdominal mass
- Abdominal discomfort (severity related to rate of onset of obstruction rather than degree of obstruction)
- Halitosis and/or oral ulceration (due to uremia)
- Abdominal fluid wave (if rupture and uroabdomen)

ETIOLOGY AND PATHOPHYSIOLOGY

Urolithiasis is an especially common cause of ureteral obstruction. However, there are many other potential causes (see above).

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Ureteral obstruction may be discovered incidentally during imaging studies or (less often) may be identified as the cause of acute renal failure due to bilateral obstruction. Animals with subclinical or overt chronic kidney disease may be identified as having ureteral obstruction during imaging examinations.

DIFFERENTIAL DIAGNOSIS

Other causes of renomegaly (see p. 979), other causes of acute renal failure (see p. 31)

INITIAL DATABASE

- CBC generally unremarkable:
  - Normocytic, normochromic, nonregenerative anemia (if chronic kidney disease or chronic inflammation)
  - Leukocytosis with left shift possible if concurrent pyelonephritis
- Serum biochemical profile; abnormalities depend on degree of obstruction and/or nephron loss:
  - Azotemia
  - Hyperphosphatemia
  - Hyperkalemia
  - Metabolic acidosis
- Urinalysis may be normal or may reveal:
  - Isosthenuria
  - Hematuria
  - Pyuria
- Urine culture and sensitivity (C&S) indicated even if sediment is inactive (occult infection)
- Blood pressure (BP) to rule out hypertension (see p. 1209)
- Abdominal radiographs; renomegaly common; may identify:
  - Urolithiasis
  - Prostatomegaly
  - Abdominal mass
  - Loss of retroperitoneal/abdominal contrast
  - Distended ureter
  - Mass associated with ureter or bladder

ADVANCED OR CONFIRMATORY TESTING

- Abdominal ultrasound (sensitive and specific):
  - Pyelectasia (dilation of renal pelvis) common
  - Hydronephrosis common
  - Hydroureter common
  - Often allows identification of a cause of ureteral obstruction (e.g., urolithiasis, mass)
- Excretory urography (intravenous pyelography [IVP]; see), percutaneous nephropyelography:
  - Pyelectasia
  - Ureteral dilatation or lack of filling (IVP only)
- Renal scintigraphy or CT:
  - Affected kidney contributes little to overall glomerular filtration rate (GFR).
- Quantitative analysis and culture of uroliths

TREATMENT

TREATMENT OVERVIEW

When unilateral obstruction is believed to be long-standing, specific therapy may not be necessary. Acute bilateral ureteral obstruction requires intervention both to relieve obstruction and address consequences such as uremia, electrolyte, and acid-base disorders. Whenever possible, attempts should be made to prevent further obstruction (e.g., prophylaxis of urolithiasis, correction of anatomic defects, removal of obstructive masses).

ACUTE GENERAL TREATMENT

- Correct hydration, acid-base, and electrolyte disorders if present:
  - Crystalloid fluid therapy for azotemia, dehydration (see p. 31):
    - Initial rate of 120 mL/kg per day unless diuresis contraindicated

        - Postobstructive diuresis may require the “ins-and-outs” method of adjustment (rate based on measured urine output).
        - Diuresis may flush out ureterolith.
    - Address electrolyte disorders and acidosis (see pp. 1131 and).
    - Consider hemodialysis or peritoneal dialysis for stabilization.
- Percutaneous nephrostomy tubes may be used for preventing further renal damage while assessing renal function prior to surgical intervention:
    - Only possible if renal pelvis dilated
    - Placed with ultrasound guidance or via laparotomy
- Analgesia for abdominal pain (e.g., buprenorphine, 0.01 mg/kg IM, IV, or SQ q 6-8 h)
- Address uremic signs (see pp. 31 and 207).

CHRONIC TREATMENT

- Intervention is not always required if obstruction is partial, there is adequate renal function, and infection is absent.
- Ureteral surgery or stenting is indicated for bilateral obstruction or when function of contralateral kidney is impaired; major complication is postoperative ureteral stricture formation. Nuclear scintigraphy or CT provides quantitative assessment of each kidney's contribution to glomerular filtration rate:
    - Ureterotomy: for intraluminal or intramural obstruction in the proximal third of the ureter
    - Ureteroneocystostomy: for resection of distal ureter
    - Ureteroureterostomy: to repair ureter after resection or transection (anastomosis of proximal ureter to distal portion of ureter on ipsilateral side), usually when proximal third cannot be implanted directly into bladder neck
        - Highest incidence of postoperative obstruction
- Ureteral stent placed via interventional endoscopy or surgery should be considered, but has limited availability. Surgery is more widely available, especially if the patient is unstable to transfer to referral centers equipped to perform this noninterventional method.
- Nephrectomy: reserved for animals with unilateral obstruction, adequate function in contralateral kidney, and infection or loss of function in the affected kidney.
- Antibiotics if appropriate (e.g., pyelonephritis, bacterial cystitis) based on C&S.
- Therapeutic or prophylactic measures for urolithiasis if present (see pp. 1141, 1143, and 1138)
- Therapeutic measures for other identified causes of obstruction (e.g., removal of tumors obstructing urine flow)

POSSIBLE COMPLICATIONS

- Renal failure
- Postoperative ureteral stenosis
- Urinary rupture and uroabdomen

RECOMMENDED MONITORING

- Repeat ultrasound 10-12 weeks after initial evaluation. Remaining renal parenchymal changes are likely permanent.
- Animals with permanent hydroureter/hydronephrosis are monitored as for chronic kidney disease (see pp. 205 and 207). Azotemic animals are monitored more intensively than nonazotemic animals.

PROGNOSIS AND OUTCOME

- Dependent on underlying cause, duration of obstruction, extent of renal parenchymal damage, presence of concurrent infection, and ability to resolve underlying cause.
- Structural renal changes persisting 14-45 days or more after relief of ureteral obstruction are generally permanent.
- Complete bilateral obstruction of more than 3 days is fatal without appropriate treatment.

PEARLS & CONSIDERATIONS

COMMENTS

- Ureteral obstruction should be considered in the differential diagnosis for renal failure, especially in patients with evidence of nephrolithiasis or pyelonephritis.
- Bilateral ureteral obstruction is rare compared to unilateral obstruction but is life threatening.
- Ureteral obstruction can recur, especially in the presence of existing nephroliths.

PREVENTION

Strategies that limit the formation of urolithiasis (see pp. 1141, 1143, and 1138)

TECHNICIAN TIPS

Animals in acute renal failure should have urine output carefully quantified. One possible correctible cause of oliguria/anuria is bilateral ureteral obstruction.

CLIENT EDUCATION

Strict adherence to dietary recommendations can minimize the risk of ureteral or urethral obstruction due to urolithiasis.

Urachal Diverticulum

BASIC INFORMATION

DEFINITION

Embryonic remnant at the apex of the urinary bladder; although diverticula occur commonly, they seldom result in clinical problems.

SYNONYM

Vesicourachal diverticulum

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs and cats

RISK FACTORS: Microscopic diverticula in cats may create risk for developing macroscopic diverticula following urinary tract obstruction from any cause.

ASSOCIATED CONDITIONS & DISORDERS

- Urinary tract infection (UTI)/bacterial cystitis
- Urolithiasis (especially struvite)
- Feline lower urinary tract signs/disease (FLUTS/D)

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Macroscopic: intramural and extramural
- Microscopic
- Acquired macroscopic

HISTORY, CHIEF COMPLAINT: Clinical signs are often absent. When clinical signs are apparent, they may include any of the following:

- Hematuria
- Pollakiuria
- Dysuria
- Stranguria
- Inappropriate elimination
- Systemic illness due to urinary tract obstruction (rare)

PHYSICAL EXAM FINDINGS: Physical exam is usually unremarkable. When present, abnormalities are nonspecific and may include:

- Hematuria (stains on prepuce, vulva, or hocks)
- Painful urinary bladder
- Enlarged, turgid bladder with urethral obstruction

ETIOLOGY AND PATHOPHYSIOLOGY

The urachus is a canal connecting the fetal bladder with the allantois. The urachal lumen normally becomes obliterated during development, but on occasion the lumen remains patent (patent urachus) or the obliteration is incomplete, leaving a remnant diverticulum. Cause of incomplete urachal atrophy is unknown.

- Macroscopic:
  - Most common form in dogs
  - May not be associated with clinical signs

    - May be associated with or predispose the animal to chronic/recurrent UTI and urolithiasis
- Microscopic:
    - Most common form in cats
    - Remnants of urachus at bladder apex that can extend from the level of the submucosa to the subserosa
    - Not associated with clinical signs
- Acquired macroscopic:
    - Microscopic diverticula may become macroscopic secondary to sustained increase in bladder intraluminal pressure.
    - May spontaneously regress if the cause of increased bladder pressure is removed

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis of urachal diverticulum is based on imaging of the urinary tract through ultrasonography, contrast radiography, or visual inspection at surgery. Often, diverticula are incidental findings.

DIFFERENTIAL DIAGNOSIS

- Neoplasia
- Polyps
- Urolithiasis
- Blood clots

INITIAL DATABASE

- CBC: unremarkable
- Serum chemistry profile: unremarkable unless urinary obstruction exists; in these rare instances, azotemia, hyperkalemia, or acidemia are identified.
- Urinalysis: often unremarkable; sometimes shows pyuria, hematuria, bacteruria, or struvite crystalluria
- Urine culture and sensitivity (C&S) is used for identifying urinary tract infection.
- Abdominal radiographs to rule out radiopaque uroliths

ADVANCED OR CONFIRMATORY TESTING

- Contrast cystography:
    - Positive-contrast cystography
    - Double-contrast cystography
- Ultrasonography
- Cystoscopy
- Exploratory celiotomy and cystotomy

TREATMENT

TREATMENT OVERVIEW

Incidentally discovered urachal diverticula may not require therapy. Those associated with recurrent urinary tract infection or urolithiasis are surgically addressed.

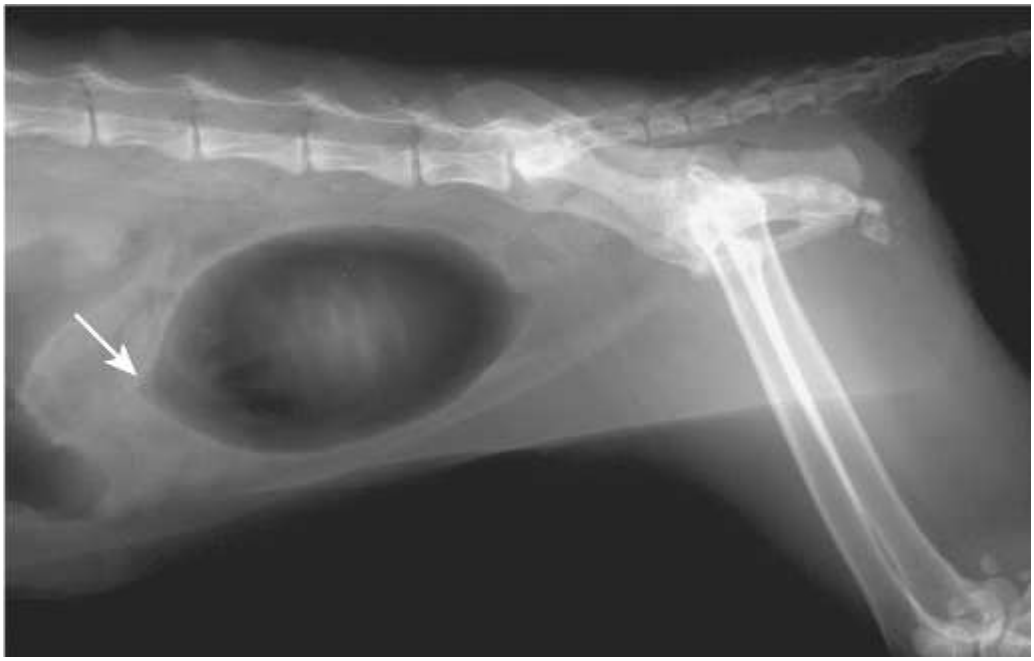
ACUTE GENERAL TREATMENT

- Relieve urethral obstruction if present (see 1353)
- Fluid therapy and correction of electrolyte disturbances if present (see pp. 1353 and 1555)
- Antimicrobial therapy for bacterial cystitis if present (see 276)

CHRONIC TREATMENT

- Animals with clinical signs or a urinary tract infection related to either congenital macroscopic diverticula or nonresolving acquired macroscopic diverticula should undergo surgical resection of the diverticulum:
    - Exploratory celiotomy
    - Ventral midline cystotomy

    - Identification of diverticulum at apex of bladder
    - Excision of diverticulum with elliptical incision
    - Routine closure
- Address chronic feline lower urinary tract signs/disease (see 387).
- Address urolithiasis (see 1143).



URACHAL DIVERTICULUM Lateral radiographic projection of a double-contrast cystogram performed on a 4-year-old male domestic shorthaired cat with a history of chronic urinary tract infections. A small "out-pouching" of the bladder wall is present at the apex *(white arrow)*. Diagnosis: bladder diverticulum predisposing the animal to chronic cystitis.

(Courtesy Dr. Stephanie Essman, University of Missouri.)

NUTRITION/DIET

Animals with urinary tract infection may develop struvite urolithiasis. Diets low in ash designed to acidify the urine may be used in conjunction with appropriate antimicrobial therapy to aid in dissolution of struvite calculi (see 1143).

POSSIBLE COMPLICATIONS

- Obstruction of the urinary tract as a result of struvite urolithiasis is a possible complication of urinary tract infection associated with urachal diverticula.
- Suture-line leakage with peritonitis is a possible complication following surgical excision of diverticula.

RECOMMENDED MONITORING

- Monitor cats with acquired macroscopic diverticula for regression of diverticulum by contrast cystography 2-3 weeks after treatment of obstruction and resolution of clinical signs.
- Monitor for recurrence of signs of FLUTS/D (see 387).

PROGNOSIS AND OUTCOME

- Surgical excision for congenital macroscopic diverticula is curative.
- Acquired macroscopic lesions that spontaneously resolve may recur with repeated episodes of lower urinary tract obstruction.

PEARLS & CONSIDERATIONS

COMMENTS

Patent urachus causes umbilical urine dribbling in neonates and should be corrected surgically.

PREVENTION

Prevention of lower urinary tract obstruction will prevent acquired diverticula formation.

CLIENT EDUCATION

- Recurrent UTI may be a sequela to uncorrected congenital macroscopic diverticula.
- Recurrent or persistent UTI may lead to struvite urolithiasis.

1ST EDITION AUTHOR: ERIC POPE

Upper Respiratory Infection, Cat

BASIC INFORMATION

DEFINITION

A complex of viral and bacterial agents can cause upper respiratory tract signs such as sneezing, nasal congestion, and nasal discharge in cats. Etiologies include feline herpesvirus (FHV), feline calicivirus (FCV), *Bordetella bronchiseptica. Chlamydophila felts,* and (less commonly) feline reovirus, cowpox virus, and mycoplasmas.

SYNONYMS

Feline infectious respiratory disease, feline respiratory disease complex

C. felts previously known as *Chlamydia psittaci*

Feline herpesvirus: feline rhinotracheitis

EPIDEMIOLOGY

SPECIES, AGE, SEX: The main causative infectious agents (herpesvirus and calicivirus) are confined to the family of Felidae and are typically found in young animals. Mycoplasmas are often found as normal flora in the upper respiratory tract of many species.

RISK FACTORS

- Poor husbandry and overcrowding in catteries or rescue shelters
- Exposure to free-roaming cats in high-density feral populations

CONTAGION & ZOONOSIS

- FHV and FCV are shed in ocular, nasal, and oral secretions and are passed via direct cat-to-cat contact. Both viruses spread easily through susceptible populations and are perpetuated by carrier animals not showing overt signs. Disease can be spread via fomites such as contaminated cages, bowls, and clothing. FCV can persist in the environment for up to 1 month.
- Direct aerosol transmission is actually an unlikely cause of respiratory disease spread, owing to the small feline tidal lung volume and lower numbers of pathogenic organisms in the respiratory volume. Sneezing of nasal/oral secretions, however, may disseminate a virus more readily over a radius of several feet (>1 m).

GEOGRAPHY AND SEASONALITY: Worldwide and no true seasonally; more cases may be noted in late spring and summer when many susceptible kittens are added to the population.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Herpesvirus: in young animals, usually acute, severe upper respiratory signs; in chronic adult cases, often manifests as a chronic conjunctivitis/keratitis without respiratory signs.
- Calicivirus: typical upper respiratory signs; isolated highly virulent strains that cause severe systemic disease and death have been noted.

HISTORY, CHIEF COMPLAINT

- General signs of respiratory disease complex include anorexia, lethargy, ocular and nasal discharges, sneezing, epiphora, blepharospasm.
- Specific to calicivirus (see p. 172), herpesvirus (see p. 524), and *C. felts* (see p. 193)

PHYSICAL EXAM FINDINGS: Respiratory disease complex:

- Serous to mucopurulent nasal and ocular discharge
- Epiphora, blepharospasm, chemosis, conjunctival hyperemia

- Fever
- Dyspnea, increased airway sounds, wheezes, cough

In addition:

- Herpesvirus: conjunctivitis, ± dendritic corneal ulcers
- Calicivirus: oral, nasal, lip ulcers, or generalized stomatitis and gingivitis
- Rare severe cases of very virulent calicivirus strains: facial/limb edema, dermal necrosis, vomiting, diarrhea, icterus, petechiae and ecchymoses from disseminated intravascular coagulation, or sudden death
- *B. bronchiseptica:* fever, submandibular lymphadenopathy, and cyanosis/dyspnea in cases of severe bronchopneumonia

ETIOLOGY AND PATHOPHYSIOLOGY

Feline herpesvirus:

- A double-stranded DNA alpha-herpes-virus specific to Felidae. It attacks mucosal epithelial cells of the soft palate, tonsils, turbinates, cornea, and conjunctiva, leading to multifocal epithelial necrosis and secondary clinical signs. Pulmonary involvement is rare.
- Incubation period is 2-6 days; disease usually runs its course in 10-20 days.
- Turbinate destruction due to herpesvirus infection may be permanent and can predispose the cat to chronic rhinitis, even in the absence of active infection.
- Chronic conjunctivitis/keratitis can lead to symblepharon (adhesion of bulbar conjunctiva to palpebral conjunctiva), corneal scarring, or keratoconjunctivitis sicca (KCS).
- Essentially all cats infected with FHV become chronic carriers; the virus remains latent in the trigeminal ganglia. However, a smaller proportion of cats are truly susceptible to recrudescence, and these animals act as the FHV reservoir for the feline population. Recrudescence and viral shedding often occur 1-3 weeks after a stressful event. Not all recrudescence is accompanied by obvious clinical signs.

Feline calicivirus: see p. 172

B. bronchiseptica: see

C. felis: see

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Usually the diagnosis is based on clinical presentation: a cat with signs of conjunctivitis, anterior uveitis, ocular or nasal discharge, gingivitis, faucitis, stomatitis, glossitis, fever, and lymphadenomegaly has an upper respiratory infection. Specific identification of a causative agent is not always necessary, but ruling out non-viral causes is important for treatment considerations.

DIFFERENTIAL DIAGNOSIS

- Nasal signs: nasal neoplasia, nasopharyngeal polyps, periodontal disease, foreign body, fungal infection, structural malformation of nasal passages/sinuses, esophageal motility dysfunction
- Ocular signs: corneal and/or conjunctival trauma, corneal foreign body, eosinophilic keratoconjunctivitis, neoplasia, KCS, uveitis, glaucoma
- Cough or dyspnea: feline asthma, intrathoracic neoplasia (pulmonary, lymphoid, mediastinal, or pleural), congestive heart failure (CHF), pleural effusion of other causes, feline heartworm disease

INITIAL DATABASE

- CBC: neutrophilia with left shift if secondary bacterial infection is severe. Stress leukogram is possible. Results are often normal.
- Serum biochemistry profile and urinalysis: may reflect dehydration but typically unremarkable. With virulent calicivirus infections, increases in alanine aminotransferase (ALT), creatine kinase (CK), and bilirubin levels; and decreased albumin level possible.
- Thoracic radiographs: assessing for signs of pneumonia in cats with lower respiratory tract signs
- CT scan of the skull, with rhinoscopy and nasal biopsy/culture can help rule out neoplasia, fungal infection, dental disease, nasopharyngeal polyps, and structural deformities as causes of chronic respiratory signs.

ADVANCED OR CONFIRMATORY TESTING

- Serologic testing for herpesvirus and calicivirus is unrewarding because of widespread vaccination.
- Virus isolation from nasal, conjunctival, or oropharyngeal swabs is the best diagnostic assay for FHV and FCV. Requires special swabs or media for transport; however, FCV is commonly isolated from the oral/respiratory mucosa of healthy cats, so positive viral culture should be supported by appropriate clinical presentation.
    - Feline upper respiratory disease panel: www.idexx.com or www.antechonline.net; requires swab samples depending on location of predominant clinical signs.
- Conjunctival scrapes may demonstrate basophilic intracytoplasmic inclusions indicative of *C. felis* infection.
- Culture or PCR on conjunctival swabs can also be used to rule out *C. felis.* Special transport medium is required for culture. Serologic testing may also be helpful in the unvaccinated cat, because affected animals typically have high titers.
- Transtracheal or bronchoalveolar washes with cytologic examination and culture and sensitivity (C&S) are helpful in isolating *B. bronchiseptica, C. felis,* or secondary bacteria as causative agents of pneumonia.
- Cryptococcal antigen titer to rule out cryptococcosis.

TREATMENT

TREATMENT OVERVIEW

Treatment is typically supportive, with the goal of controlling secondary bacterial infections and maintaining comfort and appetite.

ACUTE GENERAL TREATMENT

Most cats with upper respiratory infections can and should be managed at home by the owner to decrease pathogen dissemination in the hospital setting. Animals that are febrile, dehydrated, severely depressed, or compromised should be treated in the hospital until they are stable and can be sent home; they should be isolated from other cats. Acute treatment includes:

- IV crystalloids and colloids if patients are febrile and/or dehydrated or have evidence of hypovolemia
- Broad-spectrum antibiotics (one of the following):
    - Amoxicillin-clavulanate, 13.75 mg/kg PO q 12 h
    - Cefadroxil, 10-30 mg/kg PO q 8-12 h
    - Cephalexin, 22-30 mg/kg PO q 8-12 h
    - Enrofloxacin, 5 mg/kg PO q 24 h
- Antibiotics most effective against specific bacteria (see pp. 144 and 193):
    - Doxycycline, 5 mg/kg PO q 12 h; or tetracycline, 20 mg/kg PO q 8 h
- Topical ophthalmic preparations:
    - Artificial tears q 2-6 h
    - Tetracycline ophthalmic preparations are the treatment of choice for *C. felis* and *Mycoplasma* spp. conjunctivitis and in FHV cats to prevent secondary bacterial infections. Topical tetracyclines can be irritating. Chloramphenicol, erythromycin, or fluoroquinolone topicals are alternative options.
    - Topical or systemic corticosteroids should not be used in suspected FHV keratitis.
    - Most “triple-antibiotic” ophthalmic preparations (neomycin, polymyxin, and bacitracin/gramicidin) are typically ineffective against *C. felis, Mycoplasma* spp., and FHV-1.
- Topical and systemic antiviral drugs for FHV keratitis/conjunctivitis (see p. 524)
- Treatment duration with antibiotics and antivirals should be determined on an individual case basis, but typically 1-2 weeks is required while the viral disease runs its course.

CHRONIC TREATMENT

- Home nebulization (putting the cat on a dry surface in a steamy bathroom) may help ease nasal or airway congestion.
- Owners should be instructed to cleanse the face, mouth, and nares regularly to minimize accumulation of discharges or saliva.
- Herpesvirus carriers that have bouts of recrudescence can be treated on as-needed basis with L-lysine (250-500 mg PO q 12 h for life) to decrease severity of outbreaks.

NUTRITION/DIET

- Appetite stimulants may be necessary:
    - Cyproheptadine, 2 mg/cat PO q 12-24 h; *or*
    - Diazepam, 0.05-0.15 mg/kg IV q 24 h; may cause extreme sedation soon after administration. Paradoxically in some cats, may lead to hyperexcitability and fractiousness.
- Feed animals very pungent, highly palatable foods to overcome a decreased sense of smell from nasal infection (see p.

1377).
- Tube feeding may be necessary in chronic cases with prolonged anorexia.

POSSIBLE COMPLICATIONS

FHV keratoconjunctivitis can predispose the animal to KCS.

PROGNOSIS AND OUTCOME

Except in very young or compromised animals or in cases of virulent calicivirus, prognosis is usually good for recovery from acute bouts of respiratory disease. Some animals develop chronic rhinitis and/or keratoconjunctivitis and will have recurrent bouts of disease that may require lifelong management.

PEARLS & CONSIDERATIONS

PREVENTION

- Several modified live or killed vaccines are available for protection against herpesvirus and calicivirus. They offer good to moderate protection against clinical disease but are not guaranteed to prevent infection or development of a carrier state.
  - Modified live vaccines (MLV) may induce a mild form of respiratory disease.
- Vaccines are available for *B. bronchiseptica* and *C. felis,* but because these diseases are relatively benign and easy to treat, the benefit of immunization in most pet cats is questionable. Vaccination may be warranted in cattery or shelter situations.
- Dilute bleach (1 part bleach to 32 parts water) is the best disinfectant for preventing FHV and FCV spread in the hospital environment. FCV has shown resistance to common disinfectants such as quaternary ammonium compounds and chlorhexidine.

Upper Airway Obstruction

BASIC INFORMATION

DEFINITION

Inability to move air effectively through trachea, larynx, pharynx, or nose and mouth

SYNONYMS

Choking, occlusion of the upper airway

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Airway foreign body more likely in young dogs; neoplasia, laryngeal paralysis more likely in adult older dogs
- Young cats may have nasopharyngeal polyps.

GENETICS & BREED PREDISPOSITION: Short-nosed (brachycephalic) animals are predisposed to airway obstruction (see p. 151).

RISK FACTORS: Environmental factors: excitement, heat, and exercise, especially in animals with physical predisposition (e.g., elongated soft palate, laryngeal paresis)

GEOGRAPHY AND SEASONALITY: More common in warmer climates (heat stress)

ASSOCIATED CONDITIONS & DISORDERS: Brachycephalic upper airway syndrome, laryngeal paralysis, neoplasia

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Supraglottic structures: brachycephalic upper airway syndrome (see p. 151), laryngeal paralysis (unilateral/bilateral), foreign bodies (pharyngeal), laryngeal collapse, laryngeal edema, and nasopharyngeal polyps (cats)
- Subglottic structures: tracheal neoplasia, tracheal hypoplasia, tracheal collapse, foreign body aspiration, trauma

HISTORY, CHIEF COMPLAINT

- Owners often report that their pet appears anxious or agitated, that he or she is having difficulty breathing, and that they can hear loud respiratory noises or a honking cough.
- Clinical signs can occur more commonly after exercise, excitement, or on a warm day.
- Animals may have been witnessed aspirating a foreign object (e.g., ball/marble/acorn), although the mistaken belief that a foreign body has been aspirated is a common error that some clients believe passionately ("something stuck in the throat") even when the problem is clearly different (e.g., pulmonary edema, pleural effusion).

PHYSICAL EXAM FINDINGS

- Noisy and/or stridorous breathing
- Hyperthermia possible (excessive muscle activity from inspiratory effort)
- Conformation changes (e.g., short nose) raise the suspicion of associated malformations as the underlying cause.
- Loud sounds may be ausculted over the trachea and may be referred to the lower airways.

ETIOLOGY AND PATHOPHYSIOLOGY

- Most of the resistance to airflow occurs in the upper airways. Any fixed or dynamic obstruction in the upper airways will increase the resistance to breathing and, subsequently, the work of breathing.
- Inspiration against a partially or completely closed upper airway may cause flooding of pulmonary alveoli with plasma (i.e., noncardiogenic pulmonary edema due to negative pressure generated in the air space).

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis is based on physical exam findings, including difficulty breathing and/or stridorous breathing. Specifically, inspiratory dyspnea, often with the point of stridor audibly in the upper airway (making the site of obstruction manifestly clear on distant physical exam alone) helps localize the anatomic lesion. Oral examination, diagnostic imaging, and endoscopy are cornerstones for confirming the site (and sometimes nature) of the obstruction, and are selected based on suspected location of the obstruction, available means, and patient stability.

DIFFERENTIAL DIAGNOSIS

Occasionally, pleural effusion in cats will mimic upper respiratory obstruction.

INITIAL DATABASE

- Oral examination under sedation is the most important diagnostic test (see p. 1295). The clinician should be prepared for an emergent tracheostomy (and possibly positive-pressure ventilation, if noncardiogenic pulmonary edema is present; see and) if needed. Doxapram may be used for stimulating ventilation during oral examination in sedated dogs and cats.
- Other ancillary testing includes radiographs (thoracic and neck), ultrasound, CBC/serum biochemistry profile, and evaluation of oxygenation (pulse oximetry or arterial blood gas [ABG] analysis).

ADVANCED OR CONFIRMATORY TESTING

Bronchoscopy, fluoroscopy, or CT scan may be useful for evaluating focal lesions or obtaining biopsies or cytologic specimens.

TREATMENT

TREATMENT OVERVIEW

Minimize stress and address the clinical signs until a definitive diagnosis is made; sometimes the diagnosis and treatment occur simultaneously (e.g., foreign body is identified and removed).

ACUTE GENERAL TREATMENT

- Tranquilizers or analgesics, corticosteroids at antiinflammatory doses, and oxygen supplementation. Secure airway if necessary (see pp. 1292 and 1318).
- If hyperthermia is due to exertion or anxiety (i.e., muscle activity, not true fever), it can respond to physical cooling measures but not to antiinflammatory drugs (see p. 1564).

CHRONIC TREATMENT

Either medical or surgical management of the underlying problem:

- Medical: anxiolytics, antitussives, and environmental control
- Surgical: stenotic nares repair; soft palate resection; everted laryngeal saccule resection; abscess drainage; tracheal ring implants/stent placement; removal of foreign body, tumor, or polyp; permanent tracheostomy; or temporary tracheotomy

BEHAVIOR/EXERCISE

Ideally, pets that are at risk should be kept calm and in an air-conditioned area. At the least, exercise or exertion should be avoided in those animals that are predisposed.

POSSIBLE COMPLICATIONS

Postsurgical complications include the recurrence of clinical signs, aspiration pneumonia, noncardiogenic pulmonary edema, and/or respiratory arrest.

RECOMMENDED MONITORING

Monitor respiratory rate/effort and mucous membrane color.

PROGNOSIS AND OUTCOME

Depend on the actual underlying problem and the severity of clinical signs. For example, presence of noncardiogenic pulmonary edema substantially worsens prognosis.

PEARLS & CONSIDERATIONS

COMMENTS

- Up to half the diameter of the airway can be compromised without obvious clinical signs.
- Major errors in the initial treatment include underestimation of the patient's distress, overzealous examination, and performance of diagnostics that are detrimental to the condition of the patient at that time.
- A common radiographic misdiagnosis is the interpretation of a prominent or mineralized (but normal) larynx as a foreign body, especially if the neck is radiographed obliquely.
- Thoracic radiography and positive-pressure ventilation should be planned in case dyspnea and/or hypoxemia persist after relief of upper airway obstruction, as can occur when noncardiogenic pulmonary edema is also present.

PREVENTION

Avoid overexertion, prevent heat stress, and know the medical options that are available to help break the cycle of distress and resultant respiratory difficulty.

TECHNICIAN TIPS

When administering treatments to these pets, stress should be minimized (minimal restraint) and treatments should be conducted in a stepwise manner.

CLIENT EDUCATION

Explain to owners that a brachycephalic animal is predisposed to developing upper airway problems

Unerupted Teeth

BASIC INFORMATION

DEFINITION

Teeth that have not emerged into the mouth are unerupted. Clinically, the tooth appears to be missing. Radiographic diagnosis is required.

SYNONYMS

- Embedded teeth (teeth exhibiting a lack of eruptive force without physical obstruction)
- Impacted teeth (teeth not erupting owing to a physical barrier)

EPIDEMIOLOGY

SPECIES, AGE, SEX: Unerupted teeth occur more commonly in the younger dog and less commonly in cats. They may not be recognized until animals have reached adulthood.

GENETICS & BREED PREDISPOSITION: Familial delayed eruption does occur in Tibetan and Wheaten terriers, and toy breeds can have overall slower eruption times. Because erupting teeth can be influenced by internal and external causes, a genetic link is suspected but difficult to prove. Symmetrically unerupted or missing teeth are usually genetic in origin. Brachycephalic and toy dog breeds appear to be predisposed to unerupted and missing premolar and molar teeth.

RISK FACTORS

- Persistent deciduous teeth (see 282)
- Regional trauma
- Certain endocrine disorders
- Malnutrition
- Canine distemper

ASSOCIATED CONDITIONS & DISORDERS: Dentigerous (tooth-containing) cyst (also called follicular cyst)

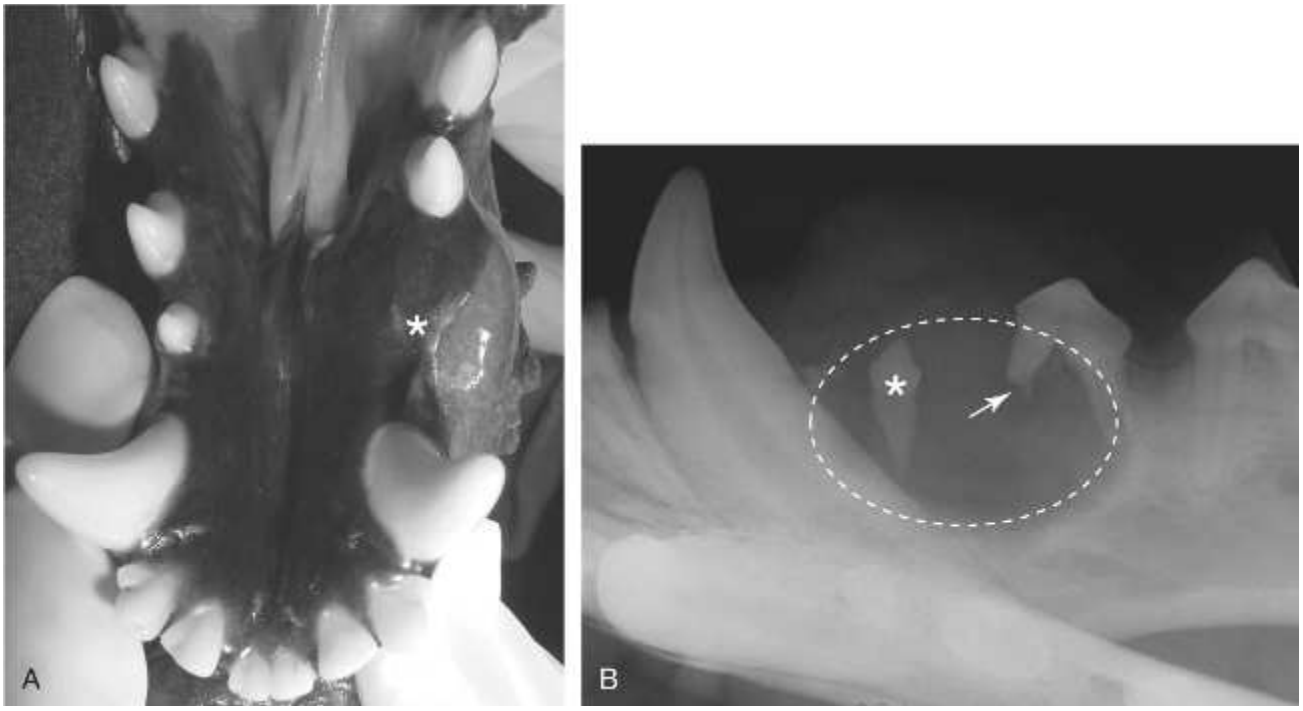
CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: Animals are sometimes presented for evaluation of missing teeth, but the majority of unerupted teeth are found incidentally on routine physical examination.

PHYSICAL EXAM FINDINGS: Most animals are in good health. Oral examination reveals an edentulous (toothless) region. Permanent premolars are the most common unerupted teeth, but any tooth can be affected. If a dentigerous cyst is present, a fluctuant soft-tissue swelling may be located in the edentulous region.

ETIOLOGY AND PATHOPHYSIOLOGY

- Complications leading to abnormal tooth eruption are many and varied: primary defects in the eruptive process, genetic/traumatic displacement of the tooth bud or surrounding bone, mechanical obstruction from adjacent structures, regional odontogenic and nonodontogenic neoplasia.
- The most commonly unerupted teeth in the dog are the mandibular first premolar and third molar teeth.
- Endocrine abnormalities (hypothyroidism, cretinism, hypogonadism, mongolism, hypopituitarism, hyperparathyroidism) can prevent or slow the eruption of teeth.
- Unerupted teeth can incite dentigerous cyst formation: an epithelial-lined soft tissue is attached to the cementoenamel junction of an unerupted tooth, with the crown protruding into the fluid-filled cyst, causing pressure resorption of alveolar bone, displacement of adjacent teeth, abscess, and fistulation.



UNERUPTED TEETH A, Clinical photograph of rostral lower jaw of an adult dog. Note swelling in the area of a missing left mandibular first premolar tooth *(asterisk)* and distally displaced left mandibular second premolar tooth. **B,** Radiograph of left rostral mandible of same patient arranged in labial mounting (rostral toward the left, caudal toward the right of image). Note that left mandibular first premolar tooth *(asterisk)* is unerupted, and a dentigerous cyst *(dotted oval)* has developed around the unerupted tooth, causing pressure resorption of the roots of the caudally displaced left mandibular second premolar tooth *(arrow)*. (Copyright 2010 Dr. Alexander M. Reiter.)

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Dental radiography is necessary to differentiate unerupted teeth from missing teeth.

DIFFERENTIAL DIAGNOSIS

Edentulous region:

- Partially erupted, ankylosed, embedded, and impacted teeth
- Presence of an operculum (tough gingival covering preventing tooth eruption)
- Anodontia and hypodontia resulting from a large variety of causes
- Fractured tooth ± retained tooth roots
- Previously extracted tooth

Edentulous region associated with soft-tissue swelling:

- Odontogenic tumor (e.g., compound or complex odontoma)
- Cyst (e.g., radicular, dentigerous)
- Abscess
- Neoplasia

INITIAL DATABASE

- CBC, serum biochemistry panel, urinalysis (preanesthetic): generally unremarkable
- Full-mouth (intraoral) dental radiography

ADVANCED OR CONFIRMATORY TESTING

CT scan (see): if associated cystic structure is large and to define surgical margins and/or regions for débridement

TREATMENT

TREATMENT OVERVIEW

Treatment goals are to preserve normal anatomic arrangement and structure, encourage complete tooth eruption or extract tooth if eruption impossible or impractical, and prevent cyst/abscess formation.

ACUTE AND CHRONIC TREATMENT

- No treatment if entire tooth is missing on radiographs
- Some unerupted teeth can be orthodontically coaxed into position if tooth, patient, and owner are willing.
- If an operculum is present, dissect gingiva to allow for tooth eruption (operculectomy).
- To prevent dentigerous cyst development, surgically extract unerupted teeth without eruption potential. Curettage of the extraction site is recommended to remove remnant odontogenic tissue. Postoperative radiographs ensure complete removal of all tooth structures.
- If a dentigerous cyst is present, the tooth and cyst are removed en bloc. If this is not possible, extensive curettage to remove all epithelial cyst lining is mandatory because small islands of remaining epithelium can lead to cyst reoccurrence or malignant transformation. The débrided cyst cavity need not be filled with osteopromotive materials; natural bone remodeling will likely be clinically adequate.
- Flaps should be closed with synthetic absorbable suture material.
- Administration of antibiotics is not usually necessary after the extraction procedure unless another medical condition or extensive tissue trauma at the extraction site is present.
- Pain management: regional nerve block (0.5% bupivacaine) intraoperatively, followed by nonsteroidal antiinflammatory drugs (e.g., carprofen, 2 mg/kg PO q 12 h in dogs) ± opioid medications (butorphanol, 0.2-0.4 mg/kg PO q 4-6 h) given postoperatively for 2-3 days.

POSSIBLE COMPLICATIONS

- Inability to locate the unerupted tooth
- Extraction of a healthy erupting permanent tooth
- Cyst recurrence
- Regional trauma due to improper extraction technique
- Infection

RECOMMENDED MONITORING

- Examination 1-2 weeks postoperatively to evaluate extraction sites
- Cyst: examination with radiographs in 6 months

PROGNOSIS AND OUTCOME

- Unerupted teeth with operculectomy: fair for tooth eruption (depends on tooth eruption potential)
- Extracted unerupted teeth: excellent for extraction site healing
- Dentigerous cyst: excellent if all cystic lining is removed

PEARLS & CONSIDERATIONS

COMMENTS

- No tooth should be considered “missing” without radiographic diagnosis.
- Extraction of unerupted teeth may be unnecessary in older pets (>8-9 years) if there is no radiographic evidence of associated lesions. The odds a dentigerous cyst will form at this age are low.

PREVENTION

- Removal of persistent deciduous teeth
- Early recognition of “missing” teeth in young animals
- Selective breeding

TECHNICIAN TIPS

Technicians are at the frontline for identifying unerupted teeth during professional dental cleanings and pointing them out to the veterinarian if they were not noted previously.

EDITOR: ALEXANDER M. REITER

Umbilical Hernia

BASIC INFORMATION

DEFINITION

Full-thickness congenital abdominal wall defect at the umbilicus

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Dogs and cats
- Greater incidence in females of predisposed breeds

GENETICS & BREED PREDISPOSITION

- Breed predisposition in dogs:
  - Airedale terrier, basenji, Pekingese, pointer, and weimaraner
- Could be an inherited defect:
  - Polygenic inheritance possible

ASSOCIATED CONDITIONS & DISORDERS

- Fucosidosis, an inherited lysosomal storage disease reported in English springer spaniels
- Cryptorchidism
- Incomplete caudal sternal fusion
- Peritoneopericardial diaphragmatic hernia
- Exstrophy of the bladder
- Hypospadias
- Imperforate anus

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Uncomplicated:
  - Single umbilical hernia without incarceration or strangulation of abdominal contents, concurrent anatomic abnormalities, or multiple hernias
- Complicated:
  - Presence of multiple hernias; other associated anatomic abnormalities, defects, or diseases; or strangulation or contamination of abdominal contents
- Omphalocele:
  - Large midline umbilical hernia and skin defect that allow abdominal organs to protrude externally. The umbilical sac is merely a thin transparent membrane (amniotic sac). The membrane is attached to the hernia edges and may rupture easily. Most affected puppies die or are euthanized before treatment is sought.
- Gastroschisis:
  - Grossly similar to omphalocele, but the defect is paramedian.

HISTORY, CHIEF COMPLAINT

- None; incidental finding (most common)
- Soft swelling at umbilicus may be noticed by some owners.
- Systemic signs of illness (anorexia, vomiting, lethargy) are possible if abdominal contents are strangulated (least common).

PHYSICAL EXAM FINDINGS

- Protruding mass at the umbilicus:
  - Soft, fluctuant, and reducible, especially if animal is placed in dorsal recumbency

- Large, firm, and irreducible if contents are incarcerated
- Acute intestinal incarceration or strangulation:
  - Firm, painful mass; vomiting, abdominal pain, signs of sepsis are possible.

ETIOLOGY AND PATHOPHYSIOLOGY

- Abdominal wall of the embryo normally is formed by migration of cephalic, caudal, and lateral folds.
- Umbilical aperture remains after normal migration and fusion of the folds.
- Umbilical hernia results when the lateral folds, principally the rectus abdominis muscle and fascia, fail to fuse or have delayed fusion after the midgut relocates in the sixth week of gestation.

DIAGNOSIS 

DIAGNOSTIC OVERVIEW

The diagnosis is made entirely on physical examination. In complex cases with entrapped viscera, the identity of herniated organs is confirmed at surgery.

DIFFERENTIAL DIAGNOSIS

Traumatic umbilical hernia: peripartum insult caused by traction on umbilical cord or cutting cord too close to abdominal wall

INITIAL DATABASE

Survey abdominal and thoracic radiographs: only needed if hernia is very large and if other anomalies (diaphragmatic hernia, incomplete sternal fusion, strangulation/incarceration) are present.

ADVANCED OR CONFIRMATORY TESTING

Ultrasound examination (uncommonly used): only considered with large and/or incarcerated hernia contents to determine contents of hernia.

TREATMENT 

TREATMENT OVERVIEW

- Resolve any existing visceral entrapment.
- Reduce or eliminate risk of herniation of abdominal viscera.

ACUTE GENERAL TREATMENT

- Conservative treatment:
  - Small hernia (less than the size of the intestine; i.e., the size of a fingertip)
  - Spontaneous closure may occur as late as 6 months of age.
- Surgical correction:
  - Large hernia but no associated clinical problems (incarceration of abdominal contents):
    - Elective surgical correction; also repaired when another elective surgical procedure (ovariohysterectomy, orchiectomy) is performed
- Large hernia with evidence of incarcerated or strangulated viscera:
  - Immediate surgical correction
- Omphalocele:
  - Immediate surgical correction to prevent further organ damage or contamination

POSSIBLE COMPLICATIONS

- Dehiscence of repair:
  - Large defect
  - Excess tension on repair
  - Friability of abdominal wall
- Gastroschisis and omphalocele may be associated with early neonatal death:

- Contamination of abdominal contents
- Inability to correct defect

RECOMMENDED MONITORING

Counsel owners to watch for enlargement of hernia or acute gastrointestinal (GI) signs in animals that are managed conservatively; onset warrants immediate evaluation and consideration of surgical correction.

PROGNOSIS AND OUTCOME

- Excellent with uncomplicated umbilical hernia and successful closure
- Guarded to poor with complicated or open hernia
- Status of animal at presentation and health of herniated contents determine prognosis

PEARLS & CONSIDERATIONS

COMMENTS

- There are usually no clinical signs associated with umbilical hernias. Correction is usually an elective procedure.
- Entrapment of abdominal contents can occur with larger hernias.
- Always examine animals with umbilical hernias for additional congenital abnormalities.

PREVENTION

- Consideration should be given to avoiding breeding affected dogs or cats, because this condition is usually an inherited defect.
- At the time of the animal's birth, carefully ligate and transect the umbilical cord—without excessive traction—at least 1-2 cm from the neonate's body wall.

CLIENT EDUCATION

- Treatment may be conservative, or a herniorrhaphy may be required to prevent complications.
- Veterinarians should train breeders in proper neonatal care.

EDITOR: RICHARD WALSHAW

1ST EDITION AUTHOR: ELLEN B. DAVIDSON DOMNICK

Ulcers, Oral Mucosal

BASIC INFORMATION

DEFINITION

Focal or multifocal loss of superficial epithelial integrity affecting the oral mucosa

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs and cats of either gender and all ages can be affected.

GENETICS & BREED PREDISPOSITION: Maltese, Cavalier King Charles spaniel, cocker spaniel, and Bouvier des Flandres dogs are predisposed to chronic ulcerative periodontal stomatitis (CUPS). Abyssinian and Somali cats are predisposed to lymphocytic/plasmacytic stomatitis (LPS).

CONTAGION & ZOONOSIS: Feline leukemia virus (FeLV), feline immunodeficiency virus (FIV), feline herpesvirus (FHV), and feline calicivirus (FCV) in cats are transmissible to other cats. Leptospirosis is transmissible to other animals and human beings.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Lethargy
- Anorexia
- Behavior change due to oral pain
- Halitosis
- Hypersalivation

PHYSICAL EXAM FINDINGS

- Gingivitis
- Faucitis (inflammation of the archway between the pharyngeal and oral cavities [formed by the tongue, anterior and posterior tonsillar pillars, and soft palate])
- Pharyngitis
- Dental plaque accumulation
- Oral mass
- Buccitis/buccal mucosal ulceration
- Lingual ulceration
- Kissing ulcers: mucosal ulceration (common in CUPS)
- Scar tissue formation on lateral margins of tongue (CUPS)

ETIOLOGY AND PATHOPHYSIOLOGY

- Metabolic causes: renal failure (uremia; common), diabetes mellitus, hypothyroidism, hypoparathyroidism
- Immune-mediated disease: oral ulcers occur with pemphigus vulgaris (90% of cases), bullous pemphigoid (80% of cases), systemic lupus erythematosus (SLE) (50% of cases), and discoid lupus erythematosus and can also be drug-induced (toxic epidermal necrolysis)
- Infectious: FeLV, FIV, FCV, FHV, leptospirosis (dogs), periodontal disease (dogs and cats)
- Neoplastic: melanoma, squamous cell carcinoma (SCC), fibrosarcoma
- Traumatic: foreign body, electric cord shock, malocclusion, “gum chewer's disease“ (chronic chewing of cheek)
- Idiopathic: eosinophilic granuloma (cats, Siberian huskies, Samoyeds), LPS, CUPS
- Miscellaneous: caustic burns (acids), thallium toxicity, protein-calorie malnutrition, riboflavin deficiency

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Oral mucosal ulcers may be easily noted on physical exam or may be subtle. A heightened index of suspicion is warranted with hypersalivating or anorexic patients. Features of the history and physical exam should guide the selection of diagnostic tests once ulcers have been observed.

DIFFERENTIAL DIAGNOSIS

- History, physical, and oral exam can differentiate foreign bodies, malocclusions, toxin/chemical exposure, and electrical burns.
- Breed predispositions and response to therapy can help identify idiopathic disorders.

INITIAL DATABASE

- Thorough oral examination (may require sedation or general anesthesia)
- CBC: inflammatory leukogram may be present with infectious or immunemediated diseases.
- Serum biochemical profile: evidence for metabolic disease (e.g., renal failure)
- Urinalysis: urine specific gravity may support a diagnosis of renal failure. Proteinuria may be present if immune-mediated, neoplastic, or infectious disorders cause secondary glomerular damage.

ADVANCED OR CONFIRMATORY TESTING

- Serologic titers or other tests (e.g., PCR for infectious agents such as FeLV, herpesvirus) or systemic immune-mediated disease (e.g., antinuclear antibody titer for SLE)
- Thyroid hormone assays
- Thoracic radiographs: evaluation for metastatic disease
- Oral radiographs: evaluation for concurrent osteomyelitis secondary to severe periodontal disease or bony involvement from malignant neoplasia
- Mucosal or gingival biopsy: support for diagnosis of idiopathic, immune-mediated, chronic inflammatory, and neoplastic diseases

TREATMENT

TREATMENT OVERVIEW

Correct underlying cause if possible.

ACUTE GENERAL TREATMENT

Supportive therapy:

- Soft diets
- Fluid support (SQ or IV) if the patient is dehydrated
- Nutrition: esophagostomy or gastrostomy feeding tubes (see pp. 1269 and 1270) may be required if oral disease or pain is resulting in steadfast and prolonged anorexia.

CHRONIC TREATMENT

- For idiopathic conditions (i.e., CUPS, LPS), meticulous dental care to prevent plaque accumulation is necessary. In addition, dental extractions (partial, caudal, or full mouth) may be necessary to remove the source of inflammation.
- Treat metabolic conditions if present.
- Immunosuppressive drug therapy (e.g., corticosteroids, azathioprine) may be required for immune-mediated diseases.
- Antimicrobial therapy may be required to treat secondary periodontal or oral infections.
- Topical solutions (e.g., chlorhexidine solution) to inhibit bacterial growth or promote improved dental health may be beneficial.

POSSIBLE COMPLICATIONS

Side effects from corticosteroid (e.g., polyuria and polydipsia [PU/PD]) or immunosuppressive medications (e.g., myelosuppression)

RECOMMENDED MONITORING

Dependent on cause and therapies employed

PROGNOSIS AND OUTCOME

- Dependent on underlying cause
- The idiopathic conditions (CUPS, LPS) can be difficult to treat and require considerable client commitment and compliance.

PEARLS & CONSIDERATIONS

CLIENT EDUCATION

For idiopathic conditions, clients should be encouraged to keep their pets' teeth as free from plaque as possible using both at-home (brushing, cleansing solutions; see) and veterinary (dental cleaning) therapies.

Ulcerative and Erosive Skin Disorders

BASIC INFORMATION

DEFINITION

A cutaneous erosion is a shallow epidermal defect that does not penetrate the basal membrane. Erosions are usually associated with self-trauma or mild epidermal affections. A cutaneous ulcer is produced by a break in the continuity of the epidermis, with exposure of the underlying dermis. Ulcers are usually a consequence of a deep and serious pathologic process. Healing ulcers typically result in scarring.

EPIDEMIOLOGY

SPECIES, AGE, SEX: Vary according to the underlying pathologic process:

- Some dermatoses are seen more frequently or strictly in one species rather than another (e.g., eosinophilic granuloma in cats).
- Young animals are predisposed to genetic defects or infectious diseases, whereas older animals are predisposed to immune-mediated diseases or neoplasia.

GENETICS & BREED PREDISPOSITION: Some diseases tend to have a genetic basis or are related to anatomic defects (e.g., intertrigo in such breeds as the Chinese shar-pei).

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: A thorough history of the animal is important, considering the extensive list of differential diagnoses. Some essential clues help define the condition:

- Travel history (e.g., leishmaniasis in dogs traveling to Europe), grooming and boarding (contagion risk; e.g., herpesvirus infection in cats), and similar environmental information may affect a patient's risk of developing a certain condition.
- Dietary history (e.g., food allergy)
- Presence of signs of systemic illness (e.g., lethargy, anorexia, lameness, etc.) may narrow the differential diagnosis, and diagnostic methods will be oriented differently (e.g., toward systemic lupus erythematosus [SLE], leishmaniasis, systemic mycoses).
- Prior treatments: response to prior therapy or therapy administered prior to onset of clinical signs allows the inclusion or exclusion of some dermatoses (e.g., drug eruption).

PHYSICAL EXAM FINDINGS

- Dermatologic examination for identifying erosive and ulcerative lesions, and general physical examination to detect signs of underlying systemic diseases.
- The clinician should take note of primary lesions such as vesicles, bullae, and pustules and the distribution of the lesions (e.g., involvement of the mucosa). This information can suggest a specific group of diseases.
- Secondary lesions such as crusts are common.
- Exact description of the lesions varies according to the underlying disease.

ETIOLOGY AND PATHOPHYSIOLOGY

Variable, depending on underlying cause.

- Congenital, hereditary, and conformational defects: for example, ulcerations can result from skin friction (e.g., intertrigo) or can be secondary to abnormal fragility of the dermoepidermal junction (e.g., epidermolysis bullosa).
- Infectious diseases (bacterial, viral, parasitic, fungal, rickettsial): some organisms infect and lyse keratinocytes (e.g., herpesvirus) or can cause epidermal necrosis secondary to either vasculitis (e.g., canine Rocky Mountain spotted fever) or a substantial inflammatory reaction, leading to ulcerative dermatitis.
- Immune-mediated disorders: ulcers may follow the rupture of vesicles and bullae caused by the action of antibodies.
- Drug-induced conditions
- Self-induced lesions
- Environmental injuries (e.g., coagulation necrosis of the epidermis/dermis associated with thermal or chemical burns results in ulcerations)

- Secondary to systemic diseases (e.g., uremia resulting from renal failure may cause oral ulceration).
- Ischemic disorders: any dermatopathy that interferes with vascular supply of the skin can potentially cause ulcers secondary to skin necrosis.
- Neoplasia: ulcerations noticed in skin tumors, such as cutaneous epitheliotropic lymphoma or squamous cell carcinoma (SCC), are usually secondary to the infiltration of the skin by neoplastic cells and often correlate with the aggressiveness of the tumor.
- Idiopathic condition

DIAGNOSIS

DIAGNOSTIC OVERVIEW

A definitive diagnosis is required in order to institute the appropriate treatment regimen.

DIFFERENTIAL DIAGNOSIS

- Congenital and hereditary: idiopathic facial dermatitis of Persian and Himalayan cats, aplasia cutis, epidermolysis bullosa (EB), familial canine dermatomyositis
- Infectious diseases: demodicosis, flea bite hypersensitivity, feline mosquito bite hypersensitivity, fly dermatitis; systemic mycoses, sporotrichosis, phaeohyphomycosis, zygomycosis, candidiasis, dermatophyte granuloma, pseudomycetoma, protothecosis, pythiosis, aspergillosis; deep pyoderma, mucocutaneous pyoderma, pyotraumatic dermatitis; feline leukemia virus (FeLV), feline cowpox, feline calicivirus (FCV), feline herpesvirus (FHV); canine Rocky Mountain spotted fever, leishmaniasis
- Immune-mediated disorders: pemphigus, bullous pemphigoid, erythema multiforme, toxic epidermal necrolysis, vasculitis, lupus erythematosus, EB acquisita, cold-agglutinin disease, cutaneous drug eruption
- Self-induced lesions: pruritic dermatoses, psychogenic dermatoses, neuropathies
- Environmental injuries: burns, frostbites
- Systemic diseases: superficial necrolytic dermatitis (hepatocutaneous syndrome), calcinosis cutis, uremia
- Neoplasia: SCC, cutaneous epitheliotropic lymphoma, mast cell tumor, paraneoplastic alopecia
- Conformational dermatoses: intertrigo, pressure sores
- Iatrogenic: radiation therapy, thermal or tissue injury
- Miscellaneous: feline indolent ulcer, feline eosinophilic plaque, feline plasma cell pododermatitis, feline ulcerative dermatitis with linear sub-epidermal fibrosis, snakebite

INITIAL DATABASE

- Patient history and physical examination are very important in the diagnostic process.
- Cytologic examination of any exudate contents: bacteria, inflammatory cells, acantholytic keratinocytes (pemphigus), fungal organisms
- CBC, serum biochemistry panel, and urinalysis if systemic signs are observed

ADVANCED OR CONFIRMATORY TESTING

- Skin biopsies for histopathologic examination are indicated in most cases of ulcerative dermatoses.
- Endocrine tests and serologic examination depend on suspected disease.
- Coombs' test: cold-agglutinin disease
- Antinuclear antibody (ANA) test: positive in virtually all animals with SLE
- Imaging, if relevant, to confirm systemic disease or stage tumors

TREATMENT

TREATMENT OVERVIEW

Varies considerably according to the disease. It must address the primary cause of the erosions or ulcers.

ACUTE AND CHRONIC TREATMENT

- Immunosuppressive treatments are required in immune-mediated diseases, whereas infectious diseases require proper antimicrobial treatment.
- Antiparasitic treatments as required

- Neoplastic diseases should be addressed according to the type of tumor.
- Some patients with conformational dermatoses may need surgery to correct the skin defect.
- Supportive care may be required, especially in animals with severe lesions or systemic illness.

PROGNOSIS AND OUTCOME

Ranges widely from good to poor, depending of the primary cause

PEARLS & CONSIDERATIONS

COMMENTS

- Considering the wide range of treatments, make a definitive diagnosis to correctly address the disease and prevent adverse effects of an improper treatment trial.
- Primary lesions (e.g., vesicles, bullae, and pustules) or skin surrounding erosion/ulcer should be sampled when skin biopsy is performed.
- Some of these diseases are life threatening.
- Be aware of the zoonotic potential of some of these diseases (e.g., sporotrichosis).

Vulvar Discharge

Additional Images Available on Website

BASIC INFORMATION

DEFINITION

Discharge of substance from the urogenital tract (most likely vagina or uterus). May be abnormal or physiologically appropriate. Very common in the bitch during the normal estrous cycle and periparturient period

EPIDEMIOLOGY

SPECIES, AGE, SEX: More common in dogs (spayed or intact)

RISK FACTORS

- Sexually intact bitch
- Post partum bitch or queen
- Vaginal stricture or septum, vaginal foreign body, vaginal neoplasia
- Ovarian remnant syndrome
- Urethral neoplasia, ectopic ureters, redundant lateral/dorsal vulvar fold
- Mibolerone treatment

CONTAGION & ZOONOSIS

- *Bruceila canis*
- Transmissible venereal tumor (TVT)

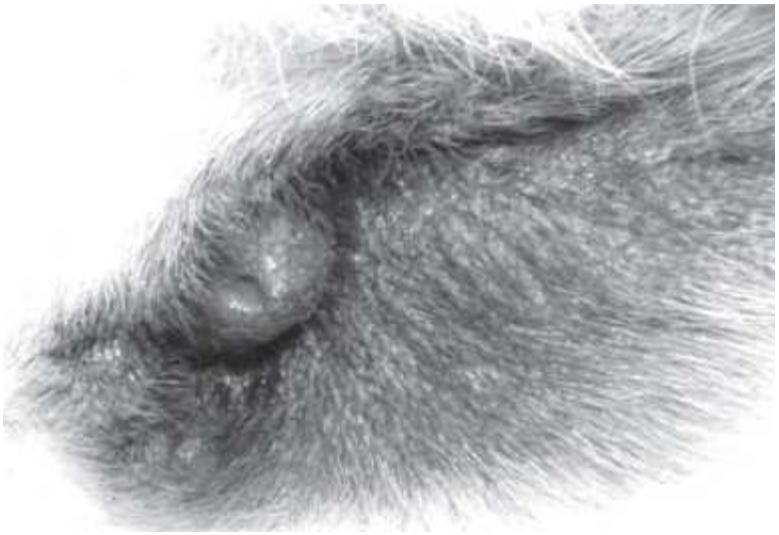
ASSOCIATED CONDITIONS & DISORDERS

- Frequently associated with pyometra
- Not uncommon in association with abortion/premature labor, metritis, or endometritis
- Rarely noted secondary to subinvolution of placental sites (SIPS) in the bitch
- Others: vulvar fold pyoderma, urinary tract infection (UTI), urinary incontinence, urethritis, pseudohermaphroditism, hermaphroditism

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Visible vulvar discharge
- Malodor
- Increased genital grooming
- Staining of carpet/bedding
- “Scooting” (rubbing perineum on floor)
- Pollakiuria
- Attracting males
- Hair staining in perineal area



VULVAR DISCHARGE Ulcerative perivulvar pyoderma typically seen in association with chronic vulvar discharge in dogs.

- Lethargy, inappetence in cases of sepsis or hypovolemic shock (e.g., pyometra)
- Polyuria and polydipsia with pyometra

PHYSICAL EXAM FINDINGS

- Generally, physical abnormalities are restricted to genital tract; exceptions: pyometra with sepsis, or coagulopathy
- Inflamed, moist, red perivulvar skin ± moist or ulcerative pyoderma
- Red ± ulcerated vulvar mucosa; clitoral enlargement
- Classification of discharge type assists diagnostic approach:
  - Color (colorless, brown, green, red, purulent)
  - Smell (malodorous or not)
  - Volume (mild, moderate, copious)
- Discharge associated with bacterial infection is typically purulent/mucosanguineous and malodorous with moderate to copious volume.
- Discharge due to inflammation is typically mucoid, white or clear, mild to moderate volume, and not malodorous.
- Rectal palpation may reveal foreign body or mass in the posterior vaginal vault and/or pelvic urethra.
- Digital vaginal examination (see p. 1360) may reveal discharge; small mucosal nodules (reactive lymphoid tissue) may be palpable with any inflammation and are not pathognomonic for any one cause.
- Most vaginal strictures are palpable at the level of the urethral papilla because of embryologic fusion of müllerian ducts and urogenital sinus.
- Fever, signs of septic shock, distended uterine horns, and/or abdominal discomfort: possible if pyometra
- Petechiae and bleeding of other mucous membranes (nose, gums) may be present when coagulopathy is the cause of vaginal discharge; may also be noted in association with sepsis.

ETIOLOGY AND PATHOPHYSIOLOGY

- Purulent vaginal discharge in adult intact animal (diestrous): commonly due to pyometra (see p. 954)
- Vaginal discharge in adult animals: commonly from secondary bacterial vaginitis due to anatomic abnormalities (lateral/dorsal vulvar fold dermatitis, vaginal stricture, septum), foreign body, urinary tract infection with urethritis/vestibulitis, or neoplasia
- Lymphoplasmacytic vaginitis and juvenile-onset “puppy” vaginitis: unknown etiology
- Strictures are associated with adult-onset vaginitis due to a change in vaginal mucus drainage.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

- Purulent vaginal discharge requires immediate evaluation for pyometra (or metritis/endometritis in the periparturient period).
- Hemorrhagic vaginal discharge warrants evaluation for systemic bleeding disorders (see p. 493).
- More chronic discharges should be initially evaluated with a thorough physical examination, including rectal and vaginal palpations, cytologic exam of the discharge, and routine database for detection of urinary tract infection, vulvar abnormalities, vaginal strictures, foreign body, and palpable neoplastic change.
- Additional imaging, culture, and biopsy sample acquisition for detection of uterine stump abnormalities, ovarian remnants,

urinary tract abnormalities, and vaginitis should be guided by preliminary findings and may require referral.

DIFFERENTIAL DIAGNOSIS

- Normal vaginal discharge; none should be malodorous:
  - Estrus: hemorrhagic, low volume
  - Parturition: moderate to large volume, hemorrhagic, green or brown
  - Postpartum: low to moderate volume for up to 4-6 weeks, green initially then brown
- Endometritis/metritis: purulent, mucosanguineous, malodorous, moderate volume in association with a febrile post partum bitch
- Subinvolution of placental sites (see p. 1060): hemorrhagic, moderate volume in association with periparturient period
- Juvenile-onset vaginitis: white, mucoid, moderate in volume
- Secondary bacterial vaginitis due to stricture, foreign body: mucoid, blood-tinged discharge; may be malodorous; scant to moderate in volume
- Herpesvirus, *Brucella canis* infection (abortion): abortion-associated discharge is typically brown, moderate in volume.
- Urogenital neoplasia: variable; may be hemorrhagic, serous, or mucoid; scant to moderate in volume
- Bleeding disorder: hemorrhagic; volume depends on degree of coagulation impairment
- Lymphoplasmacytic vaginitis: typically low volume, scant, and serous initially; may become mucoid with secondary bacterial infection; occasionally serosanguineous
- Primary bacterial vaginitis (uncommon)
- Urinary tract infection/urethritis
- Vulvar fold pyoderma: malodor is typically noted from the vulvar area; discharge may be mild to moderate in volume; mucoid and occasionally blood tinged
- TVT: vulvar mass typically noted; associated discharge is typically serosanguineous (see p. 1114).

INITIAL DATABASE

- Physical examination, including evaluation of vulvar lip conformation, mucosa, and digital rectal and vaginal examination
- Vaginal cytologic examination
- CBC: leukocytosis with left shift, toxic changes: common with pyometra; leukopenia possible with endometritis; anemia may be noted postpartum or in association with SIPS.
- Serum biochemical analysis: generally unremarkable unless systemic involvement
- Urinalysis, sediment examination, and culture: assess for concurrent UTI. Avoid cystocentesis if there is a possibility of pyometra or coagulopathy.
- Ultrasonographic evaluation of genitourinary tract: diagnostic test of choice for pyometra

ADVANCED OR CONFIRMATORY TESTING

- Guarded cranial vaginal aerobic/mycoplasma bacterial culture to evaluate bacterial population
- Retrograde double-contrast vaginocystourethrogram
- Cystoscopy and vaginoscopy, including examination of cervix if present: foreign body, congenital malformation, mass
- Vaginal biopsy ± mass biopsy
- Coagulation profile
- Urethral pressure profile

TREATMENT

TREATMENT OVERVIEW

Treatment goals are to restore patient's comfort, correct underlying cause, and prevent recurrence.

ACUTE AND CHRONIC TREATMENT

The nature and extent of treatment is determined by the underlying cause; vaginal discharge is simply a clue of underlying disease.

BEHAVIOR/EXERCISE

If discharge is associated with an infectious disease (e.g., *Brucella canis,* TVT), then bitch should be quarantined from other dogs to prevent transmission.

POSSIBLE COMPLICATIONS

Chronic estrogen supplementation may cause myelotoxicity.

RECOMMENDED MONITORING

- When diethylstilbestrol (DES) is used in high doses or for chronic therapy, regular evaluation of patient's CBC is advised (myelotoxicity).
- Patients with diminished renal function receiving cephalosporins may require more frequent renal monitoring.
- Baseline CBC, complete serum biochemistry, and urinalysis should be obtained prior to commencement of carprofen and rechecked on an ongoing basis during therapy.
- Nonsteroidal antiinflammatory drug (NSAID) use may be associated with hepatotoxicity, renal toxicity, and gastrointestinal disturbance.
- Clinical response for uncomplicated bacterial vaginitis
- Reexamination and reevaluation if complete resolution is not achieved after 14 days of therapy

PROGNOSIS AND OUTCOME

- Good prognosis for secondary bacterial vaginitis if underlying cause is identified and corrected.
- Idiopathic lymphoplasmacytic vaginitis is often recurrent but responsive to steroid therapy.

PEARLS & CONSIDERATIONS

COMMENTS

- Always rule out pyometra in an intact animal with vaginal discharge.
- Always perform digital vaginal and rectal palpation when initially evaluating a patient with vaginal discharge.
- Normal vaginal flora is mixed *(Escherichia coli, Pasteurella multocida,* β-hemolytic *Streptococcus* group G most common). Abnormal flora is typically a single isolate and/or heavy growth.
- Vaginal cytologic examination is always helpful to detect discharge due to estrus in the bitch and the presence of estrogen influence.
- Surgical correction of strictures is not advised; clitorectomy is advised in cases of clitoral hypertrophy.

PREVENTION

Pyometra may be avoided by ovariectomy/ovariohysterectomy.

TECHNICIAN TIPS

When taking a medical history, always ask owners when their bitch's last estrous cycle occurred or confirm previous ovariohysterectomy.

CLIENT EDUCATION

- Positive bacterial culture does not indicate disease is present.
- Prebreeding antibiotics do not prevent vaginitis or pyometra.
- Puppy vaginitis is usually self-limiting and does not require antimicrobial treatment; antimicrobial treatment of puppy vaginitis may prolong resolution of the problem.

AUTHOR: SOPHIE GRUNDY

EDITOR: MICHELLE A. KUTZLER

von Willebrand Disease

BASIC INFORMATION

DEFINITION

Hereditary primary hemostatic defect caused by a quantitative or functional deficiency of von Willebrand factor (VWF). VWF is an adhesive protein required for normal platelet-collagen binding at sites of small vessel injury. Clinical expression varies in severity from a mild bleeding tendency manifesting primarily after injury to more severe forms characterized by recurrent mucosal hemorrhage and prolonged bleeding from normal processes, such as deciduous tooth loss.

SYNONYMS

Factor-VIII related antigen (old terminology; protein is now referred to as *VWF),* VWD

EPIDEMIOLOGY

SPECIES, AGE, SEX

- von Willebrand disease (VWD) is the most common hereditary bleeding disorder of dogs. It is a rare hemostatic defect of cats.
- Severe forms typically manifest by 1 year of age, and milder forms may be inapparent unless the patient undergoes surgery or trauma.

GENETICS & BREED PREDISPOSITION

- Autosomal trait with three type classifications:
  - Type 1 VWD: mild to moderate; recessive or incomplete dominant inheritance
  - Types 2 and 3 VWD: severe; recessive inheritance
- Males and females express and transmit VWD with equal frequency.
- In recessive forms, affected pups inherit a VWF mutation from both dam and sire.
- Affected breeds:
  - Type 1 VWD: Airedale, Akita, Bernese mountain dog, dachshund, Doberman pinscher, German shepherd, golden retriever, greyhound, Irish wolfhound, Kerry blue terrier, Manchester terrier, miniature pinscher, Papillon, Pembroke Welsh corgi, poodle, schnauzer, and sporadic cases in any breed
  - Type 2 VWD: German short-haired pointer, German wirehaired pointer
  - Type 3 VWD: Chesapeake Bay retriever, Dutch kooiker, Scottish terrier, Shetland sheepdog, and sporadic cases (recent cases in Australian shepherd, border collie, cocker spaniel, Labrador retriever, Maltese)

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Type 1 VWD: quantitative protein deficiency. Low plasma concentration of VWF (von Willebrand factor antigen [VWF:Ag]) with proportionate reduction in VWF function; the VWF protein has a full distribution of multimeric forms.
- Type 2 VWD: both quantitative and functional protein deficiency; low plasma VWF:Ag has a disproportionate decrease in VWF function measured by collagen binding or support of platelet agglutination. VWF protein lacks the high molecular weight multimers.
- Type 3 VWD: severe VWF deficiency, no detectable plasma VWF

HISTORY, CHIEF COMPLAINT

- Severe forms: recurrent mucosal bleeds, prolonged bleeding from loss of deciduous teeth or minor wounds, blood loss anemia after surgery or trauma
- Mild forms: few spontaneous or severe bleeds; abnormal bleeding typically observed after surgical or traumatic injury

PHYSICAL EXAM FINDINGS

- Abnormal hemorrhage:
  - Mucosal bleeding

- Abnormal bleeding from traumatic/surgical wounds
- Pallor due to blood loss anemia

ETIOLOGY AND PATHOPHYSIOLOGY

- Distinct VWF mutations causative for type 3 VWD have been described in Scottish terriers and Dutch kooiker dogs.
- Homozygosity for a mutation located at a splice site of the VWF gene has been associated with low VWF protein in type 1 VWD.
- Types 2 and 3 VWD cause a moderate to severe bleeding tendency.
- The clinical severity of type 1 VWD generally correlates with decrease in VWF concentration.
- VWF is an adhesive protein required for normal platelet-collagen binding at sites of small vessel injury under high shear.
- A lack of VWF impairs platelet plug formation and causes bleeding despite normal in vitro platelet numbers, normal platelet aggregation, and normal coagulation cascade parameters (normal coagulation profile).

DIAGNOSIS 

DIAGNOSTIC OVERVIEW

Von Willebrand disease typically causes signs of mucosal hemorrhage and prolonged postsurgical/traumatic hemorrhage. Platelet count and coagulation screening tests are normal in dogs (or cats) with VWD.

DIFFERENTIAL DIAGNOSIS

- Primary hemostatic defects:
  - Thrombocytopenia
  - Acquired or hereditary platelet dysfunction (thrombocytopathias; e.g., patient taking aspirin)
- Coagulation factor deficiency
- Vasculopathy or erosive/infiltrative vessel defect causing mucosal hemorrhage

INITIAL DATABASE

- Thorough physical exam to define single versus multiple sites of hemorrhage
- Baseline hematocrit and plasma protein: normal or decreased if bleeding is severe and chronic
- Platelet count or platelet estimate from blood smear: usually normal
- Point-of-care coagulation screening tests: usually normal:
  - Activated clotting time (ACT)
  - Activated partial thromboplastin time (APTT)
  - Prothrombin time (PT)
- Bleeding time (buccal mucosal bleeding time): increased (see p. 1222)

ADVANCED OR CONFIRMATORY TESTING

Clinical diagnosis is based on specific measurement of plasma VWF concentration:

- VWF concentration (VWF:Ag):
  - VWF:Ag < 50% is evidence of VWF deficiency, but clinical bleeding tendency is usually seen in animals having more severe deficiency (<25%).
  - Types 1 and 2 VWD in dogs are characterized by the presence of low protein concentration, whereas type 3 VWD is characterized by a complete absence of VWF (VWF:Ag < 0.1%).
- Differentiation of types 1 and 2 VWD is based on the presence of dysfunctional and structurally abnormal protein in the type 2 form. Abnormal protein is identified based on the following tests:
  - VWF:CB = VWF collagen binding activity (functional assay)
  - VWF multimer analyses = Western blot to visualize VWF subunit structure
- Hereditary type 2 VWD has been identified only in two breeds: German wirehaired and short-haired pointers.
- An acquired type 2 VWD occurs in human beings with aortic stenosis. A recent study of mitral valve disease in Cavalier King Charles spaniels revealed abnormal VWF multimer distribution, compatible with classification of type 2 VWD.

TREATMENT 

TREATMENT OVERVIEW

- Control active bleeding with transfusion therapy and local wound care.
- Minimize frequency of induced bleeds by avoiding surgery, trauma, and any drug therapy that inhibits platelet function or coagulation factor activity.
- Correct any underlying medical conditions that might impair hemostasis.

ACUTE GENERAL TREATMENT

A patient that had a normal preoperative platelet count but bleeds persistently during a surgical procedure, shows no physical evidence of severe systemic illness (vasculitis), and is not known to have been exposed to anticoagulant (e.g., rodenticide) or antiplatelet (e.g., aspirin) substances should be suspected of having VWD and may be treated as follows pending the results of confirmatory tests (see Advanced or Confirmatory Testing above):

- Transfusion to supply hemostatic levels of VWF is the best strategy to control active hemorrhage refractory to local wound care. Patients with severe VWD (typically types 2 and 3 VWD) may require a second or third transfusion within the first 24 hours of presentation to sustain hemostasis after an initial response.
- Transfusion of plasma components reduces risk of volume overload or red cell sensitization while maximizing VWF replacement.
- Fresh frozen plasma (10-15 mL/kg IV):
  - Transfuse at the high end of dosage range for the initial transfusion.
  - Severely deficient patients may require repeated transfusions at q 8-12 h intervals.
- Cryoprecipitate (unit dosage varies for different suppliers):
  - Cryoprecipitate is prepared from fresh frozen plasma and contains a fivefold to tenfold concentration of VWF in approximately one-tenth the volume of the starting plasma.
  - Cryoprecipitate's low volume eliminates the risk of volume overload if repeated transfusion is needed for high-dose VWF replacement.
- Fresh whole blood (12-20 mL/kg) can be used as a source of VWF replacement if plasma components are unavailable or if replacement of red blood cells (RBCs) and VWF is desired to treat ongoing blood-loss anemia:
  - Risk of volume overload generally limits whole blood transfusion to q-24-h intervals (see p. 1347).
- Packed RBC transfusion (6-12 mL/kg) is indicated to treat severe blood-loss anemia.
- Use local wound care (suture, pressure wrap, tissue glue) to help control bleeding from cutaneous or superficial sites.

CHRONIC TREATMENT

- Intermittent transfusion may be needed to control hemorrhagic events in patients with severe (types 2 and 3) VWD.
- Preoperative transfusion to patients with type 2 or 3 VWD or severe expression of type 1 VWD to replace VWF before surgical procedures:
  - Fresh frozen plasma and cryoprecipitate are the best products for preoperative prophylaxis: same dose as described previously.
  - Transfusion is administered just before the surgical procedure. Peak VWF is obtained immediately post transfusion, and values fall to baseline by 24 hours.
  - Close monitoring is required during the first 24 hours after the operation. Repeat transfusion (at q 8-12 h) may be required during this period for severe VWD.
- Desmopressin acetate (DDAVP; deamino-8-D-arginine vasopressin) is a synthetic vasopressin analog that can be used preoperatively to enhance surgical hemostasis in patients with mild to moderate VWD (type 1 VWD); dosage is 1 mcg/kg SQ, given 30 minutes preoperatively.
  - The response to DDAVP varies, and transfusion should be available if hemorrhage develops despite DDAVP therapy.
- The development of endocrinopathy (e.g., hypothyroidism, hypoadrenocorticism) or thrombocytopenia may exacerbate the bleeding tendency of VWF-deficient patients. Identification and correction of these disorders are indicated to help reduce risk of clinical signs.

BEHAVIOR/EXERCISE

Von Willebrand disease, unlike hemophilia and other hereditary coagulopathies, does not cause hemarthrosis. Exercise restrictions are unwarranted, but sharp sticks or chew toys should be avoided to prevent oral mucosal injuries.

DRUG INTERACTIONS

Avoid drugs with anticoagulant or antiplatelet effects in animals with VWD:

- Nonsteroidal antiinflammatory drugs (NSAIDs)
- Sulfonamide antibiotics
- Heparin, warfarin (Coumadin)
- Plasma expanders
- Estrogens

- Cytotoxic drugs

POSSIBLE COMPLICATIONS

RBC sensitization causing transfusion reactions:

- Transfuse plasma components when possible.
- Dogs with severe VWD should be blood typed because repeated transfusion may be required. Choose type-matched donors for RBC or whole blood transfusions.
- Canine transfusion: after a first RBC transfusion, perform a cross-match before subsequent transfusions.

RECOMMENDED MONITORING

Adequate VWF replacement is demonstrated by:

- Cessation of active bleeding
- Stabilization of hematocrit/plasma protein

PROGNOSIS AND OUTCOME 

- Most dogs clinically affected with VWD have a good quality of life and require transfusions intermittently or rarely:
  - Animals with severe VWD (types 2 and 3 VWD) are most likely to develop spontaneous bleeds or require repeated transfusion. All dogs affected with types 2 and 3 VWD should receive a preoperative transfusion before surgical procedures.
  - Many dogs with type 1 VWD have mild disease expression. Clinical signs of abnormal bleeding are most likely to develop in dogs with VWF:Ag < 25%.
- Acute bleeding crises may require aggressive transfusion support to rapidly provide hemostatic levels of VWF protein. High-dose component therapy (fresh frozen plasma or cryoprecipitate) may be needed to control severe bleeds.

PEARLS & CONSIDERATIONS 

COMMENTS

- Specific diagnosis of VWD requires measurement of plasma VWF concentration (VWF:Ag):
  - The findings of normal coagulation panel and platelet count do not rule out VWD.
- Signs of mucosal hemorrhage (rather than petechiae) are typical manifestations of VWD.

PREVENTION

- Screen animals preoperatively to determine baseline VWF:Ag for breeds or lines with a high prevalence of VWD. The risk of abnormal bleeding is greatest for dogs with VWF:Ag that is <25%.
- Clinically affected dogs should not be used for breeding. Carriers of the VWD trait can be identified based on low VWF:Ag (<50%). The VWF protein assay is relatively fast and inexpensive and does not require knowledge of mutation type; however, values for carrier and clear dogs may overlap at the low end of the normal range (50%-70% VWF:Ag). A direct mutation detection strategy is offered for several breed variants of VWD (Vetgen), using DNA isolated from cheek swabs. Using this method, dogs are classified as “VWD affected” if they are homozygous for a mutation, or “VWD carrier” if they are heterozygous. DNA analyses provide unambiguous information on the presence, absence, and copy number of a specific mutation type.
- Selective breeding practices can reduce the prevalence or eliminate VWD from an affected pedigree. Breeding two clear parents is ideal and is expected to produce entire litters of clear pups. Breeding one carrier parent to a clear mate may be acceptable, and the clear pups produced from these matings can be used for subsequent generations. Carrier-to-carrier matings may produce affected pups and therefore should be avoided.

TECHNICIAN TIPS

Sample quality is important for obtaining valid VWF:Ag assay results. To avoid activation and depletion of VWF, blood samples should be drawn directly into tubes or syringes containing anticoagulant and centrifuged to separate plasma as soon as possible after collection.

CLIENT EDUCATION

Owners and breeders should be aware of VWD and be advised to screen their pets to prevent propagation of the trait.

Vomiting, Chronic

BASIC INFORMATION

DEFINITION

- Active expulsion of stomach and sometimes duodenal content preceded by nausea and retching
- Either intermittent course or persistent vomiting for more than 7 days
- Chronic vomiting is a very common clinical sign and can be associated with a variety of disorders.

SYNONYM

Chronic emesis

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Any animal can be affected; epidemiology depends on the underlying cause.
- Young animals are more likely to ingest foreign bodies.

GENETICS & BREED PREDISPOSITION

- Brachycephalic breeds: pyloric stenosis
- Airedale terrier: pancreatic carcinoma
- Shar-pei, rottweiler, German shepherd: inflammatory bowel disease (IBD)

RISK FACTORS

- Use of drugs such as nonsteroidal anti-inflammatory drugs (NSAIDs) and glucocorticoids, chemotherapy
- Numerous systemic diseases other than gastrointestinal (GI) disease can cause vomiting.

CONTAGION & ZOONOSIS: Zoonotic potential of *Helicobacter heilmanii* and *H. felis* unclear.

ASSOCIATED CONDITIONS & DISORDERS: Hypochloremic metabolic alkalosis initially; progression leads to dehydration and hypovolemia, and metabolic acidosis may emerge.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Owners may present animals that look healthy with no obvious signs of systemic disease.
- Owners may present animals that have signs of systemic disease (e.g., dehydration, icterus).

HISTORY, CHIEF COMPLAINT

- It is important to differentiate vomiting from dysphagia and regurgitation:
  - Vomiting involves forceful retching and abdominal contraction and may produce bile-stained contents.
- Administration of potentially ulcerogenic drugs such as NSAIDs or glucocorticoids
- The possibility of ingestion of a foreign body
- Dietary history, a description of the vomitus (e.g., possible hematemesis), and its time relation to food intake
- If vomiting of undigested or partially digested food occurs >7-10 hours after ingestion, a gastric outflow obstruction or gastric hypomotility is likely.

PHYSICAL EXAM FINDINGS

- A thorough physical examination is mandatory.
- Extra attention is warranted regarding:
  - Hydration status
  - Mouth inspection (sublingual linear foreign body in cats, ulcerations)

- Abdominal palpation (abdominal mass, thickened bowel loops)
- Rectal examination (presence of melena or hematochezia)

- In cats older than 6 years, palpation of the neck region for thyroid nodules is essential.

ETIOLOGY AND PATHOPHYSIOLOGY

- Stimulation of humoral (bloodborne substances) or neural (especially via receptors located throughout the GI tract) pathways can lead to activation of the vomiting center located in the brain (medulla oblongata).
- Certain drugs (e.g., apomorphine, xylazine), uremic toxins, and electrolyte, osmolar, or acid-base disorders can activate the chemoreceptor trigger zone (CRTZ), which is also in the medulla oblongata, and cause vomiting.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Differentiation of systemic causes from primary GI causes begins with history and physical exam; routine blood and urine tests and abdominal radiographs are warranted. If a cause is not found, abdominal sonography and specific tests (e.g., adrenocorticotropic hormone [ACTH] stimulation/resting cortisol in dogs, serum T4 in adult cats) should be considered. Prophylactic broad-spectrum deworming and diet trial are indicated at any time. Ultimately, failing a conclusive diagnosis from these measures, the structure of the proximal GI tract is assessed endoscopically and histologically.

DIFFERENTIAL DIAGNOSIS

Extra-GI causes:

- Extraabdominal disorders:
  - Azotemia/uremia
  - Hypoadrenocorticism
  - Especially in cats: hyperthyroidism, heartworm disease
  - Intoxications
  - Drugs o Neurologic disorders (especially vestibular)
- Intraabdominal disorders:
  - Hepatic disease
  - Pancreatitis
  - Peritonitis

GI causes:

- Gastritis (lymphocytic-plasmacytic, eosinophilic)
- Food intolerance/food allergy
- Foreign body
- Parasites *(Physaloptera* spp., *Ollulanus tricuspis)*
- Neoplasia
- Inflammatory bowel disease
- Bilious vomiting syndrome
- Motility disorders
- Colitis (up to 30% of dogs with colitis may vomit).
- Hiatal hernia

INITIAL DATABASE

- CBC, serum biochemistry profile (including sodium and potassium)
- Urinalysis
- Fecal examination
- Total thyroxine (older cats)
- Medical imaging: abdominal radiographs and/or abdominal ultrasound
- With hematemesis: check drug history, platelet count, coagulation profile, ACTH stimulation, and possibly serum gastriti concentration (gastrinoma); gastroduodenoscopy may be indicated.

ADVANCED OR CONFIRMATORY TESTING

- If clinically relevant, based on history, exam, and minimum database: liver function tests, ACTH stimulation test to rule out

hypoadrenocorticism, toxicologic testing, neurologic examination, canine or feline pancreatic lipase immunoreactivity, feline heartworm antibody testing.
- In some cases, especially to evaluate motility disorders or gastric outflow obstruction, GI contrast studies may be indicated.
- If all previous tests fail to identify a non-GI cause for chronic vomiting, gastroduodenoscopy or an exploratory laparotomy with GI and hepatic biopsies is indicated.

TREATMENT

TREATMENT OVERVIEW

Goals are supportive treatment if needed and elimination/treatment of the underlying cause.

CHRONIC TREATMENT

- Causative treatment is warranted, especially if the patient shows systemic clinical signs. If the patient seems otherwise healthy, dietary therapy alone can be tried if the initial database fails to identify abnormalities. If the response to this treatment is insufficient, further diagnostics are necessary, followed by specific treatment based on results.
- Antiemetics (e.g., maropitant [dogs only], 1 mg/kg SQ or 2 mg/kg PO q24 h; or metoclopramide, 0.2-0.4 mg/ kg SQ q 8 h) can be used empirically after the presence of a foreign body is ruled out. Maropitant should only been given 5 days maximum. Metoclopramide can cause lethargy and restlessness, especially in cats.
- Dietary manipulations (often low-fat, hypoallergenic diets containing a single and novel source of protein)
- Specific treatments (see specific information for individual disorders):
    - Foreign-body removal
    - Inflammatory bowel disease: diet, glucocorticoids, azathioprine
    - Antiparasitic treatments
    - Hypoadrenocorticism: mineralocorticoid and glucocorticoid replacement

DRUG INTERACTIONS

Cimetidine and ranitidine can interfere with hepatic metabolism of other drugs.

POSSIBLE COMPLICATIONS

- Weight loss due to malnutrition
- Dehydration
- Hypokalemia
- Sometimes metabolic alkalosis with hypochloremia if a pyloric (sub) obstruction is present

PROGNOSIS AND OUTCOME

Dependent on etiology

PEARLS & CONSIDERATIONS

COMMENTS

- Numerous causes of chronic vomiting exist. A first step is to rule out extra-GI causes with initial (imaging and laboratory-based) workup. If these results are not significantly abnormal, gastroduodenoscopy or exploratory laparotomy with hepatic and GI biopsies is recommended for animals that chronically vomit.
- Caution is warranted: often, concentrating only on the GI tract too early can lead to misdiagnosis and erroneous treatment.
- Some dogs or cats with vomiting due to IBD show no abnormalities on gastric endoscopy and biopsies. Therefore, endoscopy of the small intestine is important even with a history of chronic vomiting without diarrhea.
- The area under the tongue must be examined in every cat with a chronic vomiting condition; this area is most easily visualized by pressing dorsally on the skin of the underside (ventral surface) of the mandible, between the bodies of the mandible, while the mouth is open. This pressure elevates the sublingual tissues and tongue, exposing the region of interest.

Vomiting, Acute

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

Active expulsion of stomach and sometimes duodenal contents preceded by nausea and retching; duration is less than 7 days.

SYNONYM

Acute emesis

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Any animal can be affected; patient demographics depend on the underlying cause.
- Young animals are more likely to ingest foreign bodies or acquire infectious diseases (viral and parasitic).

RISK FACTORS: Use of drugs such as nonsteroidal antiinflammatory drugs (NSAIDs) and chemotherapy

GEOGRAPHY AND SEASONALITY: Infectious causes often are more prevalent in specific geographic regions.

ASSOCIATED CONDITIONS & DISORDERS: The most common cause of acute vomiting is dietary indiscretion; however, numerous gastrointestinal (GI) or systemic diseases can also cause vomiting.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Patients can be presented looking healthy with no concurrent signs of systemic involvement. These are classified as “nonserious cases.”
- Patients can be presented with concurrent systemic clinical signs (e.g., lethargy, dehydration, abdominal distension, icterus, fever). These are classified as “serious cases.”

HISTORY, CHIEF COMPLAINT: It is important to differentiate vomiting (active expulsion of GI contents) from dysphagia (difficulty swallowing) and regurgitation (passive movement of ingesta from the esophagus out the mouth). Important components of the history:

- Vaccination status (parvoviral enteritis and canine distemper are more likely in unvaccinated than vaccinated dogs).
- Administration or ingestion of potentially ulcerogenic drugs such as NSAIDs or glucocorticoids
- Possibility of ingestion of a foreign body (e.g., exposure to objects that could be ingested; individual propensity to such ingestions)
- Dietary history (e.g., recent changes; content and volume of recent and typical meals)
- Description of the vomitus (e.g., hematemesis) and productiveness (e.g., nonproductive with gastric dilatation/volvulus [GDV])
- Time relation of vomiting to food intake (if vomiting of undigested or partially digested food occurs >7-10 hours after ingestion, a gastric outflow obstruction or gastric hypomotility is likely).

PHYSICAL EXAM FINDINGS: A thorough physical examination is mandatory. Specific points requiring extra attention include:

- Hydration status
- Mouth inspection (e.g., linear foreign body in cats, ulcerations suggesting intoxication or uremia)
- Abdominal palpation (e.g., abdominal pain, abdominal distension, foreign body, mass, organomegaly)
- Rectal examination (e.g., presence of melena, foreign material)

ETIOLOGY AND PATHOPHYSIOLOGY

- Stimulation of humoral (bloodborne substances) or neural (especially via receptors located throughout the GI tract) pathways can lead to activation of the vomiting center located in the medulla oblongata.

- Certain drugs (e.g., apomorphine [dogs], xylazine [cats]), uremic toxins, and electrolyte, osmolar, or acid-base disorders can also activate the chemoreceptor trigger zone (CRTZ), which in turn triggers the vomiting center, causing vomiting.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

A large proportion of patients presenting with this disorder have benign, self-resolving illness. Therefore, the extent of diagnostic testing is determined from presence or absence or signs of systemic illness; known inciting causes (e.g., overeating might prompt minimal investigation, whereas intoxication could warrant tests to evaluate body systems likely to be affected); and the wishes of the pet's owner.

DIFFERENTIAL DIAGNOSIS

GI causes:

- Adverse food reactions (dietary indiscretion, intolerance)
- Gastritis: viral (parvovirus, coronavirus, distemper), bacterial
- Foreign body
- Parasites *(Physaloptera* spp., *Ollulanus tricuspis;* see online chapter: Gastric Parasites)
- Motility disorders
- GDV

Extra-GI causes:

- Extraabdominal disorders:
  - Azotemia/uremia
  - Hypoadrenocorticism
  - Diabetic ketoacidosis
  - Intoxications
  - Drugs (NSAIDs, chemotherapy, glucocorticoids)
  - Neurologic disorders (especially vestibular)
- Intraabdominal disorders:
  - Hepatic failure
  - Pancreatitis
  - Peritonitis
  - Pyometra

INITIAL DATABASE

- If the animal is classified as a nonserious case: history and thorough physical examination are most important; further workup is determined by status and response to treatment.
- If the animal is classified as a serious case and/or if vomiting was nonproductive: further diagnostic workup is always warranted:
  - CBC, serum chemistry profile (including sodium and potassium)
  - Urinalysis
  - Fecal examination
  - Medical imaging:
    - Abdominal radiographs: radiopaque foreign bodies, signs of intestinal obstruction, ileus, GDV, or loss of abdominal detail, suggesting pancreatitis or peritonitis
    - Abdominal ultrasound: changes associated with organomegaly, identification of origin and extent of masses and other such findings
- With hematemesis: review medication/drug exposure history, coagulation profile, adrenocorticotropic hormone (ACTH) stimulation, gastroduodenoscopy

ADVANCED OR CONFIRMATORY TESTING

- If clinically relevant: liver function tests, ACTH stimulation test to rule out hypoadrenocorticism, toxicologic testing, neurologic examination, canine or feline pancreatic lipase immunoreactivity.
- In some cases, especially to evaluate motility disorders or gastric outflow obstruction, GI contrast studies can be performed.
- If vomiting persists (for more than 3-4 days) or worsens, approach the animal as a chronic vomiting case (see p. 1175); endoscopy is warranted if previous tests fail to identify the cause.

TREATMENT

TREATMENT OVERVIEW

- Rehydrate the animal if needed.
- Implement treatment for acutely life-threatening cases (e.g., GDV, intoxications)
- Otherwise, allow the GI tract to "rest" by giving nothing per os (NPO).

ACUTE GENERAL TREATMENT

Nonserious cases (animals generally treated as outpatients):

- NPO for 12-24 hours. If vomiting resolves, initiate a small amount of water or ice cubes. Thereafter, initiate feeding with small quantities of a highly digestible, low-fat diet for several days. Gradually transition to using the regular food.

Serious cases: hospitalize the animal and perform further diagnostic steps as described above (Initial Database and Advanced or Confirmatory Testing).

- NPO, water, and food identical to non-serious cases
- IV fluid therapy (crystalloids)
- Antiemetics:
  - Indications: when vomiting is severe and animal is at risk for dehydration or developing electrolyte/acid-base imbalances or reflux esophagitis
  - Should only be used if the possibility of GI obstruction has been ruled out
  - Maropitant, 1 mg/kg SQ or 2-8 mg/kg PO q 24 h (selective neurokinin[1] receptor antagonist). Dogs only; not labeled for use in cats; *or*
  - Metoclopramide, 0.2-0.5 mg/kg IM or SQ q 8 h (dopamine antagonist; central and peripheral antiemetic agent); *or*
  - Chlorpromazine, 0.1-0.5 mg/kg IM or SQ q 8-24 h, based on response (phenothiazine derivate with central antiemetic activity, α-antagonist, can cause hypotension, especially in dehydrated animals). Avoid chlorpromazine in epileptic animals (may lower seizure threshold).

POSSIBLE COMPLICATIONS

- Dehydration
- Reflux esophagitis
- Aspiration pneumonia
- Electrolyte and acid-base imbalances (especially hypokalemia and sometimes metabolic acidosis)

RECOMMENDED MONITORING

- Signs of dehydration
- Abdominal pain
- Frequency of the vomiting

PROGNOSIS AND OUTCOME

Very good with dietary indiscretion; otherwise, depends on underlying etiology

PEARLS & CONSIDERATIONS

COMMENTS

- Most cases of acute vomiting are self-limiting and do not require further diagnostics, but it is important to not miss the more seriously sick animals and to recommend further workup and treatment if the vomiting does not subside within a few days.
- Use antiemetics carefully because they can mask progressive disease and response to primary therapy.

CLIENT EDUCATION

Avoid dietary indiscretion (whenever possible).

Tams TR: Gastrointestinal symptoms. In Tams TR, editor: Handbook of small animal gastroenterology. Philadelphia, 2003, WB Saunders, pp 1–50.

AUTHOR: SYLVIE DAMINET

EDITOR: ETIENNE CÔTÉ

Voice Change

BASIC INFORMATION

DEFINITION

Condition characterized by reduced vocalization and/or change in pitch of vocalization

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Canine and feline
- Apparent male predisposition (3:1) for idiopathic laryngeal paralysis

GENETICS & BREED PREDISPOSITION

- Hereditary laryngeal paralysis (Bouvier des Flandres, Siberian husky, pit bull terrier)
- Generalized polyneuropathy (dalmatian)
- Acquired laryngeal paralysis (giant and large breeds have been reported to be overrepresented)
- Laryngeal edema/eversion of laryngeal saccules (brachycephalic breeds)

CONTAGION & ZOONOSIS: If secondary to infectious diseases (e.g., infectious tracheobronchitis [kennel cough]), potential but rare zoonosis (e.g., immunocompromised persons) with *Bordetella bronchiseptica*

ASSOCIATED CONDITIONS & DISORDERS Dogs:

- Infectious tracheobronchitis (kennel cough)
- Laryngeal paralysis
- Brachycephalic airway syndrome Cats:
- Lymphoma
- Squamous cell carcinoma (SCC)
- Secondary to thyroidectomy
- Laryngeal paralysis

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: Voice change may be described as a change in pitch of bark or meow (dog/cat, respectively) or a persistent hoarseness.

- Variable voice change depending on condition:
  - Peracute if traumatic
  - Acute if infectious
  - Subclinical and subtle if associated with neoplasia or with laryngeal paralysis
- May be associated with:
  - Exercise intolerance if mild upper airway obstruction (structural or functional)
  - Inspiratory stridor and respiratory distress (dyspnea, cyanosis, syncope) if substantial upper airway obstruction (structural or functional)

PHYSICAL EXAM FINDINGS: Variable: dependent on primary cause

ETIOLOGY AND PATHOPHYSIOLOGY

- Anatomic cause: structure of the larynx affected
- Functional cause: innervation of the larynx affected

DIAGNOSIS

DIAGNOSTIC OVERVIEW

While most causes of voice change originate from a laryngeal/pharyngeal lesion (warranting a sedated laryngeal exam), systemic disturbances such as myasthenia gravis should be ruled out first, particularly if the history and physical exam are consistent with such disorders.

DIFFERENTIAL DIAGNOSIS

- Anatomic cause:
  - Laryngeal distortion:
    - Blunt trauma (e.g., choke chain, hit by car, kicked by horse)
    - Penetrating trauma (e.g., stick, gunshot, dog/snake bite)
  - Laryngeal edema (elongated soft palate, insect bite, chronic barking)
  - Eversion of the laryngeal saccules
  - Laryngeal/pharyngeal foreign body
  - Laryngeal inflammation (polyp, traumatic, infectious [viral, bacterial], granulomatous, immune mediated)
  - Laryngeal neoplasia (mast cell tumor, SCC, leiomyoma/sarcoma, rhabdomyoma/sarcoma, fibroma/fibrosarcoma, lymphoma)
- Functional cause:
  - Dysfunction of the recurrent laryngeal nerve:
    - Congenital/idiopathic laryngeal paralysis
    - Trauma to the nerve (direct or indirect):
      - Occurs after thyroidectomy in cats
    - Nerve compression (hematoma, abscess, tumor [thyroid carcinoma, lymphosarcoma])
    - Neuropathy, polyneuritis
  - Myopathy (including cricoarytenoid dorsalis muscle)
  - Neuromuscular disease (myasthenia gravis)

INITIAL DATABASE

- CBC, serum biochemistry panel, and urinalysis
- Cervical/thoracic imaging:
  - Radiographs: The normal larynx, especially if mineralized, should not be mistaken for a foreign body.
  - Ultrasound (mass lesions, laryngeal paralysis)
- Oral/laryngeal/pharyngeal examination (visual ± endoscopy); see require sedation depending on whether severe inspiratory dyspnea is present (with severe dyspnea, the laryngeal exam often may be performed while the patient is awake, because the patient is breathing with mouth and oropharynx maximally opened). In a study comparing three techniques for the diagnosis of laryngeal paralysis, direct per os laryngoscopy combined with the knowledge of the clinical history and physical examination was preferred over echolaryngoscopy and transnasal endoscopy (Radlinsky et al.).

ADVANCED OR CONFIRMATORY TESTING

- CT scan or MRI of larynx
- Serum acetylcholine receptor antibodies titer (myasthenia gravis)
- Electromyography (myopathies)
- Exploratory surgery ± biopsy and histopathologic examination

TREATMENT

TREATMENT OVERVIEW

- Stabilize the patient if upper airway obstruction/dyspnea.
- Determine cause of voice change.
- Address primary cause of the condition.

ACUTE GENERAL TREATMENT

- Stabilization of the patient:
  - If associated with mild inspiratory stridor:
    - Sedation of the patient, oxygen supplementation (see p. 1318)
  - If associated with severe inspiratory stridor and dyspnea:
    - Sedation of the patient, oxygen supplementation, intubation/ventilation if necessary, emergency tracheostomy

(see p. 1344) if indicated

- Addressing the primary cause:
  - If secondary to anatomic cause:
    - see Tracheobronchitis (Infectious): Dogs, p. 1109
    - Local trauma/inflammation: foreign-body removal, antiinflammatory drugs (e.g., carprofen, 2 mg/kg PO q 12 h; or meloxicam, 0.1 mg/kg PO q 24 h), antibiotics if indicated (penetrating wound; consider amoxicillin-clavulanate, 12.5 mg/kg PO q 12 h, then base the decision on aerobic and anaerobic culture and sensitivity [C&S]), soft palate resection
    - Eversion of laryngeal saccules: resection
    - Laryngeal mass: resection (ventriculocordectomy/partial laryngectomy), radiation therapy, or chemotherapy
    - If mass resection impossible: total laryngectomy with permanent tracheostomy
  - If secondary to functional cause:
    - Laryngeal paralysis: unilateral cricoarytenoid lateralization
    - Surgical decompression of recurrent laryngeal nerve (hematoma, abscess drainage, mass excision)
    - Acquired neuropathy/neuromuscular disease: treat according to primary cause

CHRONIC TREATMENT

Variable, dependent on primary cause

POSSIBLE COMPLICATIONS

Variable, dependent on primary cause:

- Laryngeal paralysis: aspiration pneumonia
- Tumor: recurrence, progression of disease (local, regional, systemic)
- Inflammation, infection, or foreign body: recurrence possible
- Trauma: potential irreversible nerve damage

RECOMMENDED MONITORING

Variable, dependent on primary cause

PROGNOSIS AND OUTCOME

Variable, depending on condition:

- Infectious tracheobronchitis: excellent
- Trauma, inflammation, or foreign body: good to guarded
- Laryngeal paralysis: good to guarded with surgery
- Resectable laryngeal mass: good if benign and clean resection; poor if malignant, nonresectable, and/or not responsive to chemotherapy or radiation therapy

PEARLS & CONSIDERATIONS

COMMENTS

A very common underlying dogs is laryngeal paralysis.

CLIENT EDUCATION

If the cause is infectious tracheobronchitis, the affected dog should avoid contact with other dogs, especially those that are unvaccinated.

EDITOR: ETIENNE CÔTÉ

Vitamin A Toxicosis

BASIC INFORMATION

DEFINITION

Usually a chronic toxicosis seen in dogs and cats after repeated ingestion of high doses of vitamin A. Characterized by lethargy, anorexia, weight loss, cervical neck pain, skin conditions, and possibly reproductive problems. Acute intoxication may present as vomiting, diarrhea, abdominal pain, and rarely hepatitis.

SYNONYMS

Retinoids are vitamin A derivatives.

EPIDEMIOLOGY

SPECIES, AGE, SEX: All mammals are susceptible, but vitamin A intoxication clinically occurs mainly in the cat.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Acute: very rare
- Chronic: after months of high levels of vitamin A ingestion

HISTORY, CHIEF COMPLAINT

- History of chronic exposure to excesses of a high vitamin A–containing product (capsules) or diet (mainly or exclusively raw liver diet: most common):
  - Intoxication is more likely with repeated exposures than with a single acute exposure.
  - Toxicosis can occur in cats 2-9 years of age that are fed a diet high in raw liver (e.g., 4 days per week).
- Acute (rare): self-limiting mild vomiting, diarrhea, anorexia, depression
- Chronic: lethargy, anorexia, weight loss, gingivitis, matted haircoat, irritability, resentment of handling; signs typically develop over several months.
- Pregnant animals: teratogenicity (cleft palate, hydrocephalus, microencephaly), reproductive failure

PHYSICAL EXAM FINDINGS

- Neck and limb rigidity due to exostosis (proliferation from bone)
- Tense musculature
- Neck ventroflexion possible:
  - In contrast to neck ventroflexion from hypokalemia or thiamine deficiency (characterized by a flaccid neck), in patients with vitamin A intoxication, the ventroflexion is stiff (caused by bony exostoses).
  - Exfoliation, matted coat

ETIOLOGY AND PATHOPHYSIOLOGY

Source:

- Vitamin A and its congeners are not produced endogenously and must be supplied exogenously through different sources (dietary or oral supplementation); beta-carotene is a plant pigment found in a number of foods. It is converted to retinal in the intestine and is further oxidized to retinoic acid and retinol.
- Acidic forms of vitamin A (*cis*- or *trans*-retinoic acid), vitamin A derivatives (retinol, *trans*-retinyl palmitate, retinyl stearate), synthetic retinoids (tretinoin, isotretinoin, etretinate), and vitamin A capsules, tablets, and injections all represent potential pharmaceutical sources of vitamin A.
- Liver (typically from chicken, beef, seal, or fish) is a common nutritional source of vitamin A.

Mechanism of Toxicosis:

- Vitamin A plays an essential role in normal night vision, reproductive processes, maintenance of epithelial and membrane structure, normal cellular growth, and immune functions.
- Hypervitaminosis A can inhibit keratinization of epithelial cells, which can lead to skin problems.
- High concentrations of vitamin A induce chondrocytes to produce more extracellular matrix, which forms a framework for mineralization (exostoses: abnormal bone growth, cervical spondylosis).
- In humans, neurotoxicosis is due to increased intracranial pressure.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Clinical diagnosis is based almost entirely on unusual nutritional/dietary supplement history and characteristic exostotic bony changes on radiographs (especially cervicothoracic vertebrae) and is confirmed by elevated serum levels of retinol.

DIFFERENTIAL DIAGNOSIS

Other causes of acute gastrointestinal (GI) signs (vomiting, diarrhea) or liver damage (rare because acute vitamin A toxicosis [hepatotoxicosis] is very uncommon)

INITIAL DATABASE

- CBC: nonspecific changes or no significant changes expected
- Serum chemistry profile: liver enzymes elevated with acute intoxication
- Urinalysis: generally unremarkable
- Cervical radiograph: may show bone-density cervical mass ventral to C1-C2 intervertebral space

ADVANCED OR CONFIRMATORY TESTING

- Cats: serum/plasma retinol level > 3145 mcg/L is considered toxic (normal: 200-1600).
- Toxic levels in feline liver (postmortem): 8590-39,570 mcg/g
- In dogs, serum/plasma retinol > 20,000 mcg/L is considered toxic (normal: 300-1000 mcg/L)

TREATMENT

TREATMENT OVERVIEW

With acute intoxication, general decontamination procedures (induction of vomiting and administrations of activated charcoal) are indicated, whereas with chronic toxicosis, treatment simply consists of removing the source of excess vitamin A and providing supportive care. There is no antidote.

ACUTE GENERAL TREATMENT

- Decontamination of patient:
  - Induction of vomiting (see 1364)
  - Activated charcoal: 1-2 g/kg PO if recent large ingestion (within few hours)
- Remove source (excess vitamin A).
- Supportive care:
  - IV fluids
  - Vomiting may be controlled with metoclopramide at 0.1-0.4 mg/kg body weight PO, SQ, or IM q 8 h; or maropitant, 1 mg/kg SQ q 24 h.
  - Management of liver damage (rare) as needed (see 503)

DRUG INTERACTIONS

Hypervitaminosis A can interfere with the action of other fat-soluble vitamins.

RECOMMENDED MONITORING

- Serum biochemistry profile
- Body weight

PROGNOSIS AND OUTCOME

- Excellent in acute cases
- Chronic: guarded prognosis; bony changes are permanent, and some cats that were fed only liver may refuse to eat anything else.

PEARLS & CONSIDERATIONS

COMMENTS

- Vitamin A deficiency far more common than intoxication
- Dogs can convert beta-carotene into vitamin A, but cats cannot.
- The amount of vitamin A needed to cause toxic effects is usually 10-1000 times the dietary requirements for most species.
- The vitamin A requirement for cats is 10,000 IU/kg of diet fed, with levels up to 100,000 IU/kg of diet tolerated.
- For dogs, the requirement is 3333 IU/kg of diet fed, with up to 33,330 IU/kg of diet tolerated.
- Vitamin A is fat soluble; 90% is stored in the liver and 10% in adipose tissue.

TECHNICIAN TIP

An owner may mention that a cat eats a diet composed mainly of raw liver, and this information is worth relaying to the attending veterinarian because of the possibility of vitamin A toxicosis.

PREVENTION

Do not overfeed raw beef liver to cats.

CLIENT EDUCATION

Teach owners the value of a balanced diet.

Vestibular Disease

BASIC INFORMATION

DEFINITION

Category of disorders affecting the central or peripheral vestibular system of dogs and cats; usually cause clinical signs of head tilt, nystagmus, and/or loss of balance

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Occurs in both dogs and cats
- Idiopathic vestibular disease occurs in older dogs (usually >8 years) but in cats of any age.

ASSOCIATED CONDITIONS & DISORDERS: Nausea, vomiting

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Peripheral vestibular disease (PVD): vestibular nerve lesion in inner ear
- Central vestibular disease (CVD): brainstem lesion (medulla)

HISTORY, CHIEF COMPLAINT

- Regardless of the underlying cause, most animals present with a peracute to subacute onset of clinical signs.
- The most common chief complaints are head tilt, nystagmus, and ataxia.
- Acute-onset vestibular disorders may produce such profound dysequilibrium and ataxia that owners are concerned about the animal's having “had a stroke.”

PHYSICAL EXAM FINDINGS

- Head tilt, nystagmus, and vestibular ataxia (possibly to the extent of causing recumbency and whole-body rolling) are the hallmarks of both peripheral and central vestibular disorders.
- The most important aspect in localization of a lesion to the central vestibular system is identification of neurologic signs that cannot be attributed to PVD.
- Mental status:
  - Central: often altered (depression, stupor, or coma)
  - Peripheral: animal should be alert and responsive and can often appear disoriented.
- Gait: vestibular ataxia (falling, veering, leaning, rolling, circling), usually toward the side of the lesion; seen with both CVD and PVD. Hypermetria, intention tremors, and truncal sway may be observed if the cerebellum is affected (central).
- Head tilt: usually toward the side of the lesion; seen with both CVD and PVD.
- Spontaneous nystagmus: occurs with both CVD and PVD. Vertical nystagmus occurs only in animals with CVD, while horizontal or rotary nystagmus can be seen with either PVD or CVD. The fast phase of the nystagmus is usually away from the side of the lesion. Change in direction of the fast phase with altered head positions suggests CVD.
- Cranial nerve deficits: cranial nerve VII (facial nerve) paresis is sometimes seen in animals with PVD, owing to its proximity to peripheral vestibular structures. Cranial nerves V, VI, IX, and XII ipsilateral to lesion may be affected in animals with CVD but not PVD.
- Horner's syndrome: possible with PVD but rare with CVD ipsilateral to lesion
- Postural reaction deficits are commonly seen with CVD but should not be observed with PVD.
- Paradoxical CVD: lesion location as suggested by clinical signs related to the head (head tilt, nystagmus, etc.) does not match the lesion location suggested by the postural reaction deficits; the latter indicate the true side of the lesion (same side as hopping/proprioceptive deficit).
- Bilateral PVD: head tilt and nystagmus may not be present; animals may walk with a crouched gait.
- Clinical signs related to disease in other central nervous system (CNS) locations, such as seizures, behavioral changes, hypermetria, intention tremors, and truncal sway, suggest multifocal central neurologic disease.

ETIOLOGY AND PATHOPHYSIOLOGY

- Basic neuroanatomy of the vestibular system:
  - Peripheral: vestibular receptors (semicircular canals, saccule, utricle) located within the petrous temporal bone and cranial nerve VIII (vestibulocochlear nerve)
  - Central: vestibular nuclei in the dorsal portion of the medulla oblongata, vestibular pathways of the brainstem and spinal cord (medial longitudinal fasciculus, vestibulospinal tracts), vestibular components in the cerebellum, and vestibular pathways through the caudal cerebellar peduncle
- Etiology for idiopathic vestibular disease in dogs and cats is unknown; an immune-mediated mechanism is suspected, but immunosuppressive drugs such as glucocorticoids have not been shown to help.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Clinical signs of vestibular disease are usually distinctive (see above). The diagnostic challenge consists of identifying peripheral versus central disease, which can be done on physical exam in most cases. The underlying cause is found using specific diagnostic tests ranging from hormonal assays (hypothyroidism) to advanced imaging (structural brain lesion).

DIFFERENTIAL DIAGNOSIS

Peripheral vestibular diseases:

- Otitis media/interna
- Idiopathic vestibular disease
- Nasopharyngeal polyps: cats >> dogs
- Hypothyroidism: dogs
- Neoplasia: squamous cell carcinoma (SCC), ceruminous gland adenocarcinoma, and other related conditions
- Ototoxicity: topical chlorhexidine or iodine; systemic aminoglycosides and other drugs

Central vestibular diseases:

- Canine distemper virus (CDV) encephalomyelitis
- Feline infectious peritonitis (FIP)
- Rickettsial encephalitis: Rocky Mountain spotted fever (RMSF), ehrlichiosis
- Fungal encephalitis: *Cryptococcus neoformans* most common; blastomycosis or coccidioidomycosis in certain regions of North America
- Granulomatous meningoencephalomyelitis (GME)
- Protozoal encephalitis: *Toxoplasma gondii, Neospora caninum*
- Neoplasia: meningioma, choroid plexus tumor, lymphoma, metastatic neoplasia
- Metronidazole toxicosis
- Cerebrovascular accident (infarct)

INITIAL DATABASE

- CBC, serum biochemical analysis, urinalysis: results often normal
- Thyroid hormone analysis: low total T^4 and free T^4 and elevated thyroid-stimulating hormone (TSH) in dogs with hypothyroidism
- Otoscopic examination: evaluate tympanic membranes for integrity.

ADVANCED OR CONFIRMATORY TESTING

- Bulla radiographs: dorsoventral, oblique lateral, and rostroventral-caudodorsal open-mouthed views. Abnormalities include soft-tissue or fluid opacity within the bulla and sclerosis of the tympanic bulla.
- Oropharyngeal and otoscopic examination under general anesthesia to identify nasopharyngeal polyps and otitis media. Abnormalities include soft-tissue or fluid opacity within and sclerosis of the affected tympanic bulla (see p. 1316).
- Brainstem auditory evoked response (BAER) test may be useful for distinguishing PVD from CVD (see p. 1216).
- CT scan (see p. 1233): useful for examination of the middle ear in patients with PVD. CT scans can also be used for CVD; however, beam-hardening artifacts in the caudal brain may preclude evaluation of the brainstem, and small lesions may not be visualized (MRI preferable for this location).
- MRI (see p. 1302): useful for examination of both the peripheral and central vestibular structures. It provides superior resolution of brain parenchyma.

- Cerebrospinal fluid (CSF) analysis (see p. 1228): used as an adjunct to advanced imaging, primarily to rule out encephalitis.
- Infectious disease titers may be required in certain cases to rule out infectious encephalitis. CSF is the preferred sample for CDV, FIP, and cryptococcosis. Serum titers are performed for *Toxoplasma* and *Neospora* spp.
- CSF culture and sensitivity (C&S) may be required for ruling out bacterial encephalitis.
- Histopathologic examination is required for definitive diagnosis in many diseases causing structural lesions (e.g., masses). Tissue samples can be obtained via surgical excision or stereo-tactic brain biopsy (see p. 1214).

TREATMENT

TREATMENT OVERVIEW

Definitive treatment for vestibular disease is based on diagnosis of the underlying cause.

ACUTE GENERAL TREATMENT

- Meclizine (25 mg PO q 24 h in dogs; 12.5 mg PO q 24 h in cats) or diazepam (0.1-0.5 mg/kg PO q 8 h in dogs) may help alleviate clinical signs of nausea and vomiting. Meclizine causes less sedation than diazepam and can be purchased as an over-the-counter drug. Oral diazepam should be used with caution in cats because of the reported incidence of idiosyncratic hepatic necrosis.
- Idiopathic vestibular disease: clinical signs improve spontaneously over 1-2 weeks; no treatment has been shown to accelerate natural resolution of the disorder.
- Otitis media/interna: systemic antibiotics ± antifungals for 4-6 weeks, ideally based on bacterial C&S. Surgical treatment (bulla osteotomy and total ear canal ablation) may be required to remove infected tissues.
- Nasopharyngeal polyps: bulla osteotomy
- Hypothyroidism: thyroid supplementation (see p. 588)
- Neoplasia: surgical excision may be possible for meningioma and choroid plexus tumors depending on lesion location. Surgical excision of tumors in the middle and inner ear may be possible but is difficult. Radiation therapy may provide some relief of clinical signs, and consultation with an oncologist is recommended in these cases.
- CDV and FIP encephalomyelitis: no specific therapy is available. Nonspecific supportive therapy with antibiotics and corticosteroids may alleviate signs temporarily (see pp. 317 and 383).
- Rickettsial encephalitis: doxycycline (5 mg/kg PO q 12 h) or chloramphenicol (50 mg/kg PO q 8 h) for 3-4 weeks.
- Fungal encephalitis: fluconazole (5 mg/kg PO q 12 h) penetrates the CNS to a greater degree than other antifungal medications. Itraconazole and amphotericin B can be used with blastomycosis. Oral treatment should be continued for at least 6 months, barring adverse reactions, and may be required long term to control clinical signs.
- GME: immunosuppressive dose of prednisone, initially at 2 mg/kg PO q 12 h for 1-2 days, then 1 mg/kg PO q 12 h for at least 2 weeks. Then slowly taper the drug over 4-8 months to reach the minimal effective dose (see p. 457).
- Protozoal encephalitis: clindamycin (10 mg/kg PO q 12 h to q 8 h) for 4 weeks; or combination of trimethoprim/sulfadiazine (TMS; 15 mg/kg PO q 12 h) and pyrimethamine (1 mg/kg PO q 24 h)
- Metronidazole toxicosis: discontinue metronidazole. In dogs, diazepam administration (0.5 mg/kg IV once, followed by 0.5 mg/kg PO q 8 h until resolution of signs) appears to shorten the duration of clinical signs. Oral diazepam should be used with extreme caution in cats, owing to the reported incidence of idiosyncratic hepatic necrosis.

POSSIBLE COMPLICATIONS

A permanent mild head tilt may persist after resolution of other clinical signs.

RECOMMENDED MONITORING

- Serial neurologic exam every 4 weeks
- Serial infectious disease titers if indicated

PROGNOSIS AND OUTCOME

- Prognosis for most PVDs is good with specific treatment, with the exception of neoplasia, which carries a guarded to poor prognosis.
- CDV and FIP encephalomyelitis: poor even with treatment
- Rickettsial and protozoal encephalitis: good with early and specific treatment
- Fungal encephalitis: fair to guarded. Long-term treatment may be required to control clinical signs.
- GME: fair to guarded. Many dogs respond initially to treatment; however, relapse is common. In some dogs, corticosteroids eventually can be discontinued.
- Neoplasia: generally poor long-term prognosis

- Metronidazole toxicosis: excellent

PEARLS & CONSIDERATIONS

COMMENTS

- Compensation for vestibular diseases will occur in many animals regardless of lesion location, and clinical signs may improve slightly if the lesion is slow growing.
- In general, animals with PVD carry a good prognosis for recovery following specific therapy.
- The long-term prognosis for animals with CVD is variable depending upon the specific cause; however, treatment should be attempted to alleviate clinical signs.

PREVENTION

- Thyroid supplementation in dogs with hypothyroidism
- Avoidance of high doses and/or prolonged courses of metronidazole treatment. A common error is to prescribe a high dose of the drug (e.g., 30-65 mg/kg PO q 12 h). The recommendation is to limit the maximum daily dose to 30 mg/kg/day, divided into two daily doses.

CLIENT EDUCATION

Head tilt may be persistent.

AUTHOR: MARK T. TROXEL

EDITOR: CURTIS W. DEWEY

Ventricular Septal Defect

BASIC INFORMATION

DEFINITION

Well-recognized, anomalous communication between the right ventricle (RV) and left ventricle (LV), resulting in interventricular shunting of blood

SYNONYMS

Interventricular septal defect, VSD

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Dogs and cats
- First or second most common congenital heart defect in cats
- Typically diagnosed at a young age
- No sex predilection

GENETICS & BREED PREDISPOSITION

- Hereditary in a family of English springer spaniels and keeshonden
- Predisposed breeds: Akita, basset hound, bloodhound, English bulldog, English springer spaniel, keeshonden, Lakeland temer, Old English sheepdog, West Highland white terrier

ASSOCIATED CONDITIONS & DISORDERS

- Aortic valvular insufficiency (AI) due to decreased support of aortic valve
- Pulmonic stenosis, overriding aorta, atrial septal defects

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- In small animals, ventricular septal defect (VSD) most commonly involves the high membranous septum below the aortic valve on left side and below the tricuspid valve on the right side (perimembranous VSD).
- Left to right (L→R) shunting across the VSD is most common.
- A very large VSD or VSD accompanied by other defects that increase RV pressure (e.g., severe pulmonic stenosis or pulmonary hypertension) may result in shunting of blood from right to left (R→L, “reverse shunting”).

HISTORY, CHIEF COMPLAINT

- Usually there are no overt clinical signs reported by the owner (incidental finding of heart murmur during routine exam).
- In the case of a large L→R VSD or in R→L VSD, the following may be observed:
  - Exercise intolerance
  - Dyspnea, tachypnea
  - Cough (L→R)
  - Cyanosis (R—>L)
  - Syncope

PHYSICAL EXAM FINDINGS

- Systolic murmur, loudest around the fourth intercostal space (ICS) on the ventral thorax to the right of the sternum (most common) or left base
- If substantial AI is present, a diastolic murmur may be heard on the left cranial thorax (heart base, third ICS).
- Tachycardia, dyspnea, tachypnea, crackles may be apparent if left-sided congestive heart failure (CHF) is present

- R→L shunt: cyanosis, generally no murmur unless another malformation is present (e.g., pulmonic stenosis)

ETIOLOGY AND PATHOPHYSIOLOGY

- Magnitude and direction of shunting and thus clinical consequences depend on size of defect, relative pulmonary and systemic vascular resistances, and presence of other cardiopulmonary defects.
- L→R shunting VSD causes volume overload of pulmonary circulation and left side of the heart; ultimately the result may be left-sided CHF and/or pulmonary hypertension.
- R→L shunting VSD (much less common) causes systemic arterial hypoxemia, which can lead to polycythemia and hyperviscosity syndrome.

DIAGNOSIS 

DIAGNOSTIC OVERVIEW

While very strong clinical suspicion of VSD may be based on physical examination alone (typically, systolic murmur with a point of maximal intensity on the right hemithorax), definitive diagnosis requires echocardiography.

DIFFERENTIAL DIAGNOSIS

- Other congenital causes of systolic murmurs: aortic/subaortic or pulmonic stenosis, atrio ventricular (AV) valve dysplasia, tetralogy of Fallot (of which VSD is one component)
- Acquired heart diseases: acquired AV valve regurgitation (dogs), dilated cardiomyopathy (dogs or cats), hypertrophic cardiomyopathy (cats)

INITIAL DATABASE

- CBC/serum biochemistry panel:
  - Typically normal
  - Polycythemia if R→L shunting
- Thoracic radiographs:
  - Normal with small VSD
  - Larger L→R VSD: left-sided cardiomegaly, pulmonary overcirculation, ± pulmonary edema, ± right ventricular enlargement
  - R→L VSD: right-sided cardiomegaly, variable pulmonary artery pattern (e.g., normal to enlarged if pulmonary arterial hypertension; normal or small if pulmonic stenosis)
- Electrocardiogram (ECG):
  - Often normal
  - Left atrial (LA) and/or LV enlargement if large L→R shunt or RV enlargement if R→L shunt
  - ± Wide and/or notched Q wave, representing abnormal septal activation
- Echocardiography:
  - A visible defect in the interventricular septum may be noted. Beware of artifactual defects (“septal drop-out”).
  - L→R VSD: turbulent jet from LV to RV with color Doppler, ± LA enlargement, ± LV enlargement
  - Peak velocity (V in m/s) of VSD jet with continuous wave Doppler reflects the pressure gradient (ΔP [mm Hg]) between LV and RV according to modified Bernoulli equation ($\Delta P = 4V^2$), which generally speaks to size of defect (small VSD: V > 4.5 m/s; moderate-size VSD: 3 < V < 4.5 m/s; large VSD: V < 3 m/s). Beware of underestimation of velocity due to erroneous/oblique alignment of Doppler sample.
  - R→L VSD: right ventricular hypertrophy, flattening of the interventricular septum, main pulmonary artery dilation
  - ± AI with color and spectral Doppler

ADVANCED OR CONFIRMATORY TESTING

- Contrast echocardiography (bubble study) to confirm R→L shunt
- Cardiac catheterization for angiography, shunt quantification, and measurement of cardiac pressures (virtually never used; mainly preoperative if open-heart surgery)

TREATMENT 

TREATMENT OVERVIEW

- Often no treatment is required, since the majority of VSDs are small and do not result in volume overload of the left ventricle or other significant clinical consequences.
- Treatment of large L→R VSDs is directed at decreasing the shunt volume and preventing or eliminating the signs of CHF.
- Treatment of R→L VSDs tends to be palliative only.

ACUTE GENERAL TREATMENT

- L→R VSD with significant left-sided volume overload (moderate to marked left ventricular enlargement):
  - Surgical repair via thoracotomy uncommon (requires cardiopulmonary bypass, which is available at very few referral institutions)
  - Percutaneous transcatheter repair using a variety of devices has been described and may be available at some referral institutions.
  - Pulmonary artery banding is a palliative surgical technique to decrease L→R shunt.
  - Arterial vasodilators used with caution to decrease L→R shunt; contraindicated if complex malformations or R→L shunt
  - If CHF present, may use angiotensin-converting enzyme (ACE) inhibitors, diuretics, ± pimobendan, ± digoxin (see p. 468)
- R→L VSD:
  - Surgical repair contraindicated
  - Phlebotomy to palliate signs and maintain PCV at 55%-65%

CHRONIC TREATMENT

- Treatment of CHF as already described (see p. 470)
- Periodic phlebotomy ± hydroxyurea as needed if R→L shunt

POSSIBLE COMPLICATIONS

- Left-sided CHF
- Pulmonary hypertension
- Shunt reversal (R→L) over time (Eisenmenger's complex); rare in dogs and cats

RECOMMENDED MONITORING

- Following diagnosis in puppies/kittens with no clinical signs, examination at 6 months, 1 year, then yearly thereafter
- Frequent monitoring for animals with overt decompensation and requiring treatment

PROGNOSIS AND OUTCOME

- Excellent prognosis for small, uncomplicated VSD
- Guarded prognosis for larger VSD (risk CHF and/or pulmonary hypertension)
- Concurrent substantial AI carries poor prognosis.
- Guarded to poor prognosis for R→L shunts; severe exercise limitations

PEARLS & CONSIDERATIONS

COMMENTS

- In L→R shunting VSDs, the RV and pulmonary arterial circulation essentially act as conduits for VSD flow. The LA and LV, however, receive increased venous return, resulting in increased diastolic pressures. In addition, effective forward flow into the systemic circulation is reduced as a result of the shunt flow. The latter two points account for the increased LV workload and predominant occurrence of left heart failure, not right heart failure, in L→R VSDs.
- VSD and tricuspid dysplasia are the two main differential diagnoses for a systolic murmur heard best on the right side of the chest in dogs or cats (murmurs due to subaortic stenosis may radiate prominently to the right side in some cases; hypertrophic cardiomyopathy is another common differential in cats).
- Most VSDs are relatively small, well tolerated, and do not require therapy.

PREVENTION

Genetic basis possible but unproven in the breeds listed previously. Consider discouraging breeding of affected animals.

Ventricular Arrhythmias

Additional Images Available on Website

BASIC INFORMATION

DEFINITION

- Ventricular arrhythmias are excessive electrical discharges occurring spontaneously and prematurely in the ventricles.
- By definition, the term *premature ventricular complex(es)* (PVCs) applies to one, two, or three consecutive premature ventricular impulses, whereas four or more in a row are defined as ventricular tachycardia (VT).
- By definition, ventricular tachycardia involves a ventricular rate of 180 beats per minute (bpm) or more in dogs and 240 bpm or more in cats.
- Strictly speaking, these are ventricular tachyarrhythmias (to distinguish them from ventricular escape rhythms); for simplicity, the term *ventricular arrhythmia* will be used here for designating PVCs and VT.

SYNONYMS

- Ventricular ectopy, extrasystoles, or tachyarrhythmias
- *PVCs* are synonymous with ventricular premature complexes or contractions (VPCs), premature ventricular depolarizations (PVDs), and similar variations.

VENTRICULAR ARRHYTHMIAS Lead II ECG in a dog with ventricular tachycardia, 50 mm/sec, 10 mm/mV. The ventricular tachycardia is monomorphic (PVCs all of the same shape) and extremely rapid (375 bpm) in this critically septic dog.

VENTRICULAR ARRHYTHMIAS Single-lead ECG in a dog with immune-mediated hemolytic anemia and an ausculted arrhythmia, 50 mm/sec, 5 mm/mV. The 5th beat is a normal sinus beat; the remaining beats are of ventricular origin. Despite the ventricular arrhythmia, the rate is not rapid (115 bpm) and likely only slightly faster than the underlying sinus rate. This is accelerated idioventricular rhythm, a benign rhythm that does not require therapy beyond proactive treatment of its inciting cause (here, anemia).

EPIDEMIOLOGY

SPECIES, AGE, SEX: Any can be affected.

GENETICS & BREED PREDISPOSITION

- Boxers: arrhythmogenic cardiomyopathy (see p. 90)
- Doberman pinschers and other breeds: dilated cardiomyopathy
- German shepherds: inherited ventricular tachycardia of young adults
- Large-breed dogs: splenic masses
- Large-breed dogs (Great Danes, setters, retrievers, and many others): gastric dilatation/volvulus (GDV)
- Cats (male > female): hypertrophic cardiomyopathy

RISK FACTORS: Outdoor, roaming dogs: traumatic myocarditis (hit by car). Primary heart disease or any systemic disturbance, if sufficiently severe, can cause ventricular arrhythmias.

GEOGRAPHY AND SEASONALITY: Chagas' disease: myocarditis (southern parts of the United States and Latin America)

ASSOCIATED CONDITIONS & DISORDERS: Syncope (rapid VT)

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Incidental finding
- Clinically overt (e.g., causing syncope)
- Accelerated idioventricular rhythm

HISTORY, CHIEF COMPLAINT

Incidental finding (more common):

- Animal is presented for evaluation of a disorder other than syncope.
- Arrhythmia is noted during physical examination or subsequent monitoring.

Clinically overt:

- Syncope/episodic collapse
- Episodic stumbling, disorientation, confusion
- Animal may be well (and even playful and active) before and after episodes or may be lethargic, weak, or anorexic.

PHYSICAL EXAM FINDINGS

Incidental finding:

- Physical exam findings reflect the underlying disorder; however, an arrhythmia is noted on physical exam.

Common Causes of Ventricular Arrhythmias

Hypokalemia*,†
Hypoxemia (e.g., due to cardiogenic pulmonary edema, pleural effusion, primary lung disease)*
Cardiomyopathy
Gastric dilatation/volvulus*
Traumatic myocarditis/hit by car
Abdominal mass, especially splenic or hepatic*
Advanced valvular heart disease
Hypomagnesemia*,†
Acidosis*
Intoxication (digitalis; oleander, foxglove, lily of the valley, azalea, and yew plants; many over-the-counter, prescription, or illicit drugs)

* Potentially correctable/curable.

† Presence makes ventricular antiarrhythmic drugs such as lidocaine, procainamide, and mexiletine ineffective.

- With ventricular tachycardia, the arrhythmia is rapid and may be irregular (usually polymorphic on electrocardiogram [ECG]) or regular (usually monomorphic on ECG).
- Pulse deficit:
  - Premature heartbeat ausculted, without a corresponding palpable pulse for that beat
  - Common with ventricular arrhythmias
  - Depends on the degree of prematurity of PVCs (“How underfilled are the ventricles when the PVC causes them to contract again?”)

- Clinically overt:
- Wide range of presentations, from clinically normal and alert if arrhythmia is intermittent, to profoundly weak and hemodynamically collapsed with very rapid, sustained ventricular tachycardia
- Regularity or irregularity and pulse deficit, as for incidental finding (above)

ETIOLOGY AND PATHOPHYSIOLOGY

- Enhanced or abnormal automaticity, microreentry, and triggered activity (early or delayed after depolarizations) are mechanisms that underlie ventricular arrhythmias.
- These mechanisms can be activated or potentiated by systemic disturbances such as those previously listed (see Associated Conditions & Disorders, above).
- The result is one or more spontaneous electrical depolarizations originating prematurely in the ventricles. The prematurity is manifested on the electrocardiogram (ECG) as a shorter R-R interval. The ventricular origin results in a QRS complex that is of a different shape than a sinus QRS complex.
- A greater degree of prematurity of PVCs (or a higher rate of ventricular tachycardia) reduces the time the ventricles have for filling prior to contracting. Therefore, faster ventricular arrhythmias compromise diastolic filling time more severely and are more likely to produce clinical signs or hemodynamic deterioration (e.g., poor pulse, cerebral hypoperfusion) than slower or infrequent ventricular arrhythmias.
- Accelerated idioventricular rhythms are seen commonly in hospitalized patients in association with noncardiac diseases (e.g., GDV surgery, splenic disease, immune-mediated hemolytic anemia, post trauma, and neurologic disease). These are often benign, the rate is not rapid, and they often do not require therapy.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Ventricular arrhythmias can be suspected on history (syncope), physical exam (premature beats), and ECG (classically, wide and bizarre QRS complexes occurring prematurely). Careful inspection of the ECG allows differentiation from other similar-appearing but clinically very different ECG deflections.

DIFFERENTIAL DIAGNOSIS

- PVCs can occur in many situations and do not automatically equate to an underlying serious cardiac disorder. Additionally, they can be seen in normal animals in low numbers (<50 per 24 hour period). They are very commonly associated with noncardiac disease, possibly secondary to myocardial ischemia, electrolyte abnormalities, or other factors surrounding the underlying disease.
- Physical examination:
  - Supraventricular premature beats, marked respiratory sinus arrhythmia
- ECG (wide, bizarre, and/or predominantly negative QRS complexes in lead II):
  - Right or left bundle branch block
  - Ventricular escape rhythm
  - Right ventricular enlargement
  - Motion artifact
  - Accelerated idioventricular rhythm (ventricular rhythm at a rate of ≈120-170 bpm). This is a fancy term for slow ventricular tachycardia, but it is an appropriate name because a ventricular myocyte is now firing as a pacemaker cell at an accelerated rate.

INITIAL DATABASE

ECG (see p. 1253) remains the gold standard for diagnosis of cardiac arrhythmias. Criteria for ventricular arrhythmias:

- PVC is substantially different from normal sinus QRS complexes:
  - Wide and bizarre QRS (<90% like the normal beat). This is because the impulse originates below the bundle of His and therefore cannot take advantage of the specialized conduction system. It therefore must travel through the ventricular myocardium muscle cell to muscle cell. This is slow and produces a wide, bizarre complex. QRS complexes can be positive in lead II or negative, depending on the site of origin within the ventricle.
- PVC occurs prematurely. The R-R interval from the preceding normal sinus beat to the PVC is shorter than the interval between two normal sinus beats.
- Large, bizarre T wave; because depolarization is abnormal, repolarization is also abnormal.
- P waves continue to occur regularly during ventricular arrhythmias, but they are not related to PVCs and often are lost within the PVCs.

ADVANCED OR CONFIRMATORY TESTING

- 10- or 12-lead ECG: improved visualization of certain features of ventricular arrhythmias (e.g., better ability to see P waves not associated with the wide, bizarre QRS complexes of PVCs)
- CBC, serum biochemistry profile, urinalysis: especially to assess systemic proarrhythmic abnormalities like hypokalemia
- Thoracic radiographs: particularly if suspicion of primary cardiac disease, hypoxemia, or thoracic trauma
- Echocardiogram: if a primary cardiac problem is suspected or if no other cause is identified
- Abdominal imaging: if there is suspicion of an abdominal problem or if a primary cause for the arrhythmia is not found
- Arterial blood gas (ABG) analysis: if acid-base or oxygenation abnormalities are suspected

TREATMENT 

TREATMENT OVERVIEW

- To control the arrhythmia to such a degree that adequate organ perfusion is present and there is a resolution or control of any arrhythmia-related clinical signs (e.g., syncope)
- Decisions regarding treatment for a ventricular arrhythmia should be made based on whether the patient is experiencing or will experience hemodynamic compromise due to the arrhythmia. The goal is to treat the patient, not the ECG!
- The goal is not to abolish every PVC or otherwise try to “normalize” the ECG, because overzealous treatment of arrhythmias may be detrimental.
- see algorithm, .

ACUTE GENERAL TREATMENT

- First, determine if the arrhythmia is a ventricular arrhythmia (PVC, VT) by ruling out common impostors (see Differential Diagnosis, above).
- Second, identify and address any relevant underlying causes (see table).
- Third, determine if there are overt clinical signs associated with the ventricular arrhythmia (e.g., syncope). If so, antiarrhythmic treatment is warranted.
- Fourth, if the ventricular arrhythmia is sustained at a rapid rate (>180/min in large-breed dogs, >220/min in smallbreed dogs, >260/min in cats) despite the three steps described so far, then antiarrhythmic treatment should be considered. The following are recognized treatments for ventricular arrhythmias:
    - Lidocaine, 1-2 mg/kg (dog) or 0.25-1 mg/kg (cat) IV bolus (can repeat up to three times in 10-15 minutes); can be followed with IV constant rate infusion (CRI) at 40-80 mcg/kg/min (dog) or 10-20 mcg/kg/min (cat)
        - To make lidocaine CRI: withdraw 25 mL from a 500-mL bag of crystalloid fluid (e.g., lactated Ringer's solution) and replace with 25 mL of 2% lidocaine. Concentration in bag is 1000 mg/mL. Administer IV at usual fluid maintenance rate *(66* mL/kg per day) assuming congestive heart failure (CHF) is not present. Infusion at this rate will be 50 mcg/kg/min.
    - Procainamide, 6-15 mg/kg (dog) or 1-2 mg/kg (cat) slow IV bolus; may follow with IV CRI at 25-50 (dog) or 10-20 (cat) mcg/kg/min. Usually administered instead of lidocaine if lidocaine was ineffective, but both may be given together.
    - see treatment algorithm, .

CHRONIC TREATMENT

- Ongoing management of the underlying cause
- Oral antiarrhythmic drugs may be used for treating rapid and/or clinically overt (syncopal) ventricular arrhythmia. Options include one of the following:
    - Sotalol, 0.5-2 mg/kg PO q 12 h (dogs); 10-20 mg per cat PO q 12 h
    - Mexiletine, 4-8 mg/kg PO q 12 h to q 8 h; and atenolol, 0.2-0.75 mg/kg PO q 12 h (dogs)
    - Amiodarone, 10 mg/kg PO q 12 h for 1 week (loading), then 5-8 mg/kg PO q 24 h (dogs)
    - Atenolol (cats), 6.25-12.5 mg per cat PO q 24 h to q 12 h
    - Procainamide sustained release (dogs) has been given at 10-20 mg/kg PO q 8 h to q 6 h, but variable dissolution of tablets makes pharmacokinetics unpredictable.

DRUG INTERACTIONS

Digoxin can cause ventricular arrhythmias (see p. 309).

POSSIBLE COMPLICATIONS

Uncontrolled ventricular arrhythmias may progress to ventricular flutter and ventricular fibrillation (cardiac arrest); however, normalization of the ECG to sinus rhythm using antiarrhythmic drugs alone has never been shown to improve the prognosis for

survival. Therefore, complications can be minimized by treating/correcting inciting factors (see table), reserving ventricular antiarrhythmic drugs for cases in which overt signs such as syncope are present or in which a very high rate (e.g., >220 bpm in dogs, >260 bpm in cats) is present despite management or correction of the underlying cause.

RECOMMENDED MONITORING

- ECG as dictated by clinical evolution; ranges from continuous ECG with ventricular tachycardia in an unstable animal to periodic ECG or Holter monitoring during visits in stable animals
- Follow-up tests as listed for initial diagnosis to monitor underlying condition

PROGNOSIS AND OUTCOME

- Ventricular arrhythmias that occur at a faster rate are more likely to produce clinical signs and carry a more guarded prognosis than slower ventricular arrhythmias.
- Ventricular arrhythmias that fail to respond to correction of the underlying problem (or for which the underlying problem cannot be corrected) usually indicate cardiac manifestations of a serious problem that carries a guarded short-term prognosis. Long-term prognosis depends on the exact nature of the underlying problem.

PEARLS & CONSIDERATIONS

COMMENTS

- Virtually any disease or disorder, if sufficiently severe to have systemic effects, can cause ventricular arrhythmias.
- Ventricular escape beats and PVCs often look identical. Ventricular escape beats occur at a rate of 40-100 bpm against a background of second- or third-degree AV block or asystole—they are saving the heart from arrest and should never be treated with ventricular antiarrhythmics. By contrast, PVCs are excessive, unwanted ventricular complexes that occur in addition to the heart's usual rhythm.
- The most common correctable underlying causes of ventricular arrhythmias are hypokalemia, hypoxia, GDV, abdominal masses, anemia, metabolic acidosis, and pain.
- The most common treatable but non-correctable causes of ventricular arrhythmias are cardiomyopathy, degenerative valvular heart disease, and traumatic myocarditis (hit by car).
- Ventricular arrhythmias most commonly are manifestations of an underlying disorder. Attempting to eliminate ventricular arrhythmias with antiarrhythmic drugs in a stable animal is analogous to “shooting the messenger.” Rather, the underlying cause needs to be found and addressed. Perhaps no antiarrhythmic drug is as beneficial to a patient with ventricular arrhythmias as correction of the underlying cause.

TECHNICIAN TIP

Impostors for ventricular arrhythmias are common on in-hospital telemetry monitors, but ventricular arrhythmias are an important signal requiring attention. Unusual-appearing heartbeats on an ECG monitor should be printed and reviewed with the attending veterinarian.

PREVENTION

Ventricular arrhythmias are clues to a primary cardiac or systemic disturbance; therefore, preventing them relies on identifying and managing the underlying disease whenever possible.

CLIENT EDUCATION

Ventricular arrhythmias are serious disturbances of the cardiac rhythm. Their impact can range from minimal to life threatening, and sudden cardiac death is always possible when an animal has a disorder that causes ventricular arrhythmias.

1ST EDITION AUTHOR: ETIENNE CÔTÉ

Vasculitis

BASIC INFORMATION

DEFINITION

Vasculitis is an uncommon pathologic syndrome of inflammation and necrosis of the vessel wall, characterized by purpura, edema, necrosis and ulceration, often involving the extremities. Vasculitis may be limited to the skin (see online chapter: Vasculitis, Cutaneous) or may be an early sign of systemic disease.

SYNONYMS

Inflammatory vasculopathy, angiitis

EPIDEMIOLOGY

SPECIES, AGE, SEX: Vasculitis is rare in cats and when it occurs, is often associated with neoplasia such as lymphangiosarcoma.

GENETICS & BREED PREDISPOSITION: Dogs: Jack Russell terriers, Scottish terriers, German shepherds, greyhounds (cutaneous and renal vasculopathy), dachshunds, rottweilers, beagles (rare: juvenile polyarteritis syndrome, [JPS], primary polyarteritis). Poodles, Maltese, bichon frise are reported to experience vaccine reactions more commonly.

RISK FACTORS

- Dogs: infectious diseases (Rocky Mountain spotted fever [RMSF], ehrlichiosis, babesiosis, bacteremia, canine corona virus, canine parvovirus, leishmaniasis, dirofilariasis, sarcocystosis, staphylococcal hypersensitivity); drug exposure, vaccination (rabies vaccine), blood component transfusions (human albumin), flea bite or food hypersensitivity
- Cats: infectious diseases (feline infectious peritonitis [FIP], feline leukemia virus [FeLV], feline immunodeficiency virus [FIV]), drug exposure, vaccination (rabies, herpesvirus/calicivirus panleukopenia)

CONTAGION & ZOONOSIS

- Dogs: canine corona virus (dog-to-dog only), canine parvovirus (dog-to-dog only) leishmaniasis (potential zoonosis)
- Cats: FIP, FeLV, FIV (cat-to-cat only)

GEOGRAPHY AND SEASONALITY: Regional variation in etiology (i.e., RMSF)

ASSOCIATED CONDITIONS & DISORDERS: Multisystemic clinical signs are uncommonly reported, including anemia, thrombocytopenia, polyarthropathy, myopathy, neuropathy, hepatopathy.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Cutaneous vasculitis is more common than systemic vasculitis.
- Vasculitis is more commonly secondary; a careful history including all medications/vaccinations received in the most recent 3 months is critical to identifying the etiology.
- Primary vasculitis is diagnosed by exclusion.

HISTORY, CHIEF COMPLAINT

- Nonspecific signs: lethargy, inappetence, or anorexia
- +/− Medications/vaccination in past 3 months
- Erythema, plaques, papules/pustules, necrosis/ulcers
- Bruising
- Ventral or dependent edema (limbs, ventrum, prepuce)

PHYSICAL EXAM FINDINGS

- Lesions in dependent/ventral regions, over pressure points, extremities (pinna, tail):

- Nonblanching erythema typically sharply demarcated from adjacent “normal” tissue; may be focal or generalized.
- Plaques, papules/pustules, necrosis/ulcers
- Petechia or ecchymotic hemorrhages
- Dependent edema
- +/− Fever
- +/− Peripheral lymphadenopathy

ETIOLOGY AND PATHOPHYSIOLOGY

- Toxic, immune-mediated, infectious, inflammatory and neoplastic disorders can all result in vasculitis.
- >50% of cases are idiopathic.
- Secondary vasculitis more common than primary vasculitis; search for underlying cause.
- Type III hypersensitivity is the predominant mechanism of cutaneous vasculitis.
- Vasculitis is characterized histologically by inflammatory cells in and around the vessel wall. Histologic classifications include neutrophilic, eosinophilic, lymphocytic, granulomatous, mixed and cell-poor forms. Neutrophilic vasculitis can be further classified into leukoclastic or nonleukoclastic (more common).
- Damage to vascular endothelium results in increased permeability, inflammation, and microvascular thrombosis.

DIAGNOSIS 

DIAGNOSTIC OVERVIEW

The diagnosis is suspected based on the presence of nonblanching dermal erythema with or without edema; diagnosis is confirmed by skin biopsy. Vasculitis is a clinical problem with many etiologic possibilities, rather than a diagnosis, and efforts should be directed at identifying the underlying etiology.

DIFFERENTIAL DIAGNOSIS

Coagulopathy, disseminated intravascular coagulation (DIC), systemic lupus erythematosus, cold agglutinin disease, discoid lupus, bullous pemphigoid, lymphoreticular neoplasia, hypersensitivity (primarily urticaria)

INITIAL DATABASE

- CBC: changes related to underlying disease +/− mild leukocytosis
- Serum biochemistry panel: changes related to underlying disease +/− hyperglobulinemia, mild hypoalbuminemia
- Urinalysis: +/− proteinuria if renal involvement
- Skin biopsy: confirmatory test of choice

ADVANCED OR CONFIRMATORY TESTING

- Rickettsial testing (dogs), viral serology (FeLV/FIV, cats)
- Coagulation testing (platelet count, prothrombin time (PT), activated partial thromboplastin time (APTT), fibrin degradation products (FDPs)
- Direct immunofluorescence, immunohistochemical testing: often not needed in diagnosis, short window for sampling (within 4-24 hours of lesion formation)

TREATMENT 

TREATMENT OVERVIEW

Vasculitis may be acute and nonprogressive or chronic and recurrent. The therapeutic goal is to identify the underlying cause and minimize end organ damage if there is systemic involvement. Treatment of idiopathic cases is immunosuppressive or immunomodulatory. For treatment to be successful, the underlying cause must be treated or removed if possible.

ACUTE GENERAL TREATMENT

- Discontinue all unnecessary drugs until the inciting cause is identified.
- Glucocorticoids: prednisone or prednisolone (cats), 2-4 mg/kg PO q 24 h:
  - Use caution with immunosuppressive doses if underlying infectious etiology
- Supportive care including IV fluids and analgesics, based on clinical judgment

- Sulfasalazine: 20-40 mg/kg q 8 h in dogs for cases refractory to glucocorticoids or if dermal involvement only:
  - Monitor for side effects: anemia, thrombocytopenia, KCS, elevated ALT, and more serious side effects such as neuropathy, nephropathy
- May require addition of second immunosuppressive if not responding or prednisone intolerant:
  - Azathioprine, chlorambucil, and cyclophosphamide have been reported.

CHRONIC TREATMENT

- Glucocorticoids: slowly taper to lowest effective dose.
- Pentoxifylline: 10 mg/kg q 8-12 h, tapered over 1-3 months to q 12-24 h:
  - May take 1-3 months for response, synergistic action with glucocorticoids
- Therapy may be able to be tapered and discontinued over 4-6 months.

NUTRITION/DIET

Vitamin E therapy has been reported, as has a combination of tetracycline and niacinamide.

DRUG INTERACTIONS

Immunosuppressive doses of glucocorticoids may complicate treatment of underlying infectious etiology and should be used with extreme caution in these cases.

POSSIBLE COMPLICATIONS

- Necrosis: predisposes to infection or necessitates surgical débridement or amputation
- Consumptive coagulopathy (DIC) in severe cases
- Glomerulonephritis (GN) if immune complex deposition in the kidneys
- Hypoalbuminemia with severe or diffuse vasculitis or GN
- Glucocorticoids: immunosuppression, iatrogenic hyperadrenocorticism
- Sulfasalazine: side effects (above)

RECOMMENDED MONITORING

- Recheck in 3-5 days to assess response to initial therapy (extent and severity of lesions); reassess blood work if abnormalities present.
- CBC and serum biochemistry profile in 7 days if using sulfasalazine; every 4-6 weeks during initial treatment
- Reassess potentially infarcted dermal regions daily for evidence of necrosis; surgically address when patient stable.

PROGNOSIS AND OUTCOME

- Open depending on the underlying cause
- Drug-induced vasculitis tends to have a favorable prognosis once the inciting cause is eliminated, but chronic therapy may be required to limit the recurrence of clinical signs.

PEARLS & CONSIDERATIONS

COMMENTS

- Most cases of vasculitis are secondary, so aggressive efforts to identify the etiology should be made; however, 50% of cases remain idiopathic.
- A skin biopsy including the junction between affected and normal skin is critical to diagnose vasculitis and may be helpful in identifying the possible underlying etiology.

PREVENTION

Mark patient charts with medications/vaccinations associated with vasculitis to prevent potential administration in the future.

TECHNICIAN TIPS

Obtain a detailed history from owners.

CLIENT EDUCATION

Medical therapy may involve combinations of medications and multiple dose adjustments until therapeutic goal is reached. Frequent reassessment is critical to treatment success.

AUTHOR: KRISTIN WELCH

EDITOR: ELIZABETH ROZANSKI

Vasculitis, Cutaneous

BASIC INFORMATION

DEFINITION

A well-recognized condition characterized by blood vessel damage that results in ischemia of the skin and resultant tissue necrosis

SYNONYM

Cutaneous vasculopathy

EPIDEMIOLOGY

GENETICS & BREED PREDISPOSITION: Any breed, but certain syndromes show breed predisposition:

- Familial cutaneous vasculopathy (autosomal recessive): Jack Russell terrier, Scottish terrier, German shepherd
- Alabama rot (see p. 491): greyhounds
- Thrombovascular pinnal vasculitis: dachshund, weimaraner
- Rabies vaccine injection-site vasculitis (see p. 610): rottweiler, miniature poodle, bichon frise, silky terrier, Yorkshire terrier, Pekingese, Maltese, and miniature pinscher
- Familial canine dermatomyositis (see p. 291): collie, Shetland sheepdog, and Beauceron shepherd

RISK FACTORS

- Drug therapy (oral or injectable)
- Malignancy
- Infection (viral, bacterial, fungal, rickettsial)
- Immune-mediated diseases
- Insect bites
- Food allergy/hypersensitivity

ASSOCIATED CONDITIONS & DISORDERS

- Systemic lupus erythematosus (SLE)
- Familial canine dermatomyositis

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Clinically the lesions can be localized, regional, or multifocal to generalized.
- They are classified as small-vessel necrotizing vasculitis, hypersensitivity vasculitis, and large-vessel vasculitis.
- They are categorized histologically as neutrophilic (leukocytoclastic, nonleukocytoclastic), eosinophilic, lymphocytic, granulomatous, or cell-poor.

HISTORY, CHIEF COMPLAINT: Patients may present with crusted or ulcerative macules or patches that may be a source of self-trauma. Patients with urticarial vasculitis may present with erythematous and often pruritic wheals. These patients are often anorexic and lethargic.

PHYSICAL EXAM FINDINGS

- Description of the lesions varies according to the disease. Fever is often present.
- Thrombovascular pinnal vasculitis: notching of pinnal margins at tip and/or well-demarcated ulcers on the concave aspect of the pinna.
- Idiopathic vasculitis: well-demarcated necrosis and ulceration, particularly at the extremities and pressure points; may include edema, alopecia, or crateriform ulcers on the central aspect of the footpads. Some of these cases could be a rare manifestation of rabies vaccine-induced generalized ischemic dermatopathy.
- Urticarial vasculitis: generalized pruritus associated with papules, purpura, and wheals

- Familial canine dermatomyositis: erythema, ulceration, and mild crusting in the young dog. Affected areas include face, pressure points, digits, and tail tip.

ETIOLOGY AND PATHOPHYSIOLOGY

- Suspected type III hypersensitivity, although multiple pathomechanisms likely play a role. Antigen-antibody complexes become trapped along the basement membrane of vessel walls and activate the complement cascade.
- Other mechanisms proposed include direct antibody binding to the vessel wall and the release of toxic mediators, leading to a bystander reaction.
- In many cases, the exact mechanism is not known.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Cutaneous vasculitis is first suspected based on the appearance of skin lesions. The definitive diagnosis is based on a detailed drug history and skin biopsy. Unremarkable hematologic and biochemical profiles help confirm that the problem is "skin deep." It is often wise to consider the option of submitting tissue samples for fungal and bacterial culture at the time of biopsy.

DIFFERENTIAL DIAGNOSIS

- Cold-agglutinin disease
- Disseminated intravascular coagulation
- Frostbite
- Demodicosis (focal lesions)
- Dermatophytosis (focal lesions)

INITIAL DATABASE

- Thorough history to assess risk of drug-induced vasculitis
- Routine CBC, serum biochemical profile, urinalysis: results are typically within normal limits.
- Skin scrapings for focal (not ulcerated) lesions
- Diascopy (hemorrhagic lesions [e.g., vasculitis] do not blanch when a glass slide is pressed over the top, in contrast to vascular dilation/congestion).
- Biopsy: histopathologic evaluation reveals varying degrees of neutrophilic, eosinophilic, lymphocytic, granulomatous, or cell-poor vasculitis.

ADVANCED OR CONFIRMATORY TESTING

Selected according to signalment and clinical features of case:

- Bacterial serologic titers (dogs: *Rickettsia rickettsii, Ehrlichia canis, Borrelia burgdorferi)*
- Viral serologic titers (cats: feline leukemia virus [FeLV], feline immunodeficiency virus [FIV])
- Coagulation profile, Coombs' test, antinuclear antibody (ANA) test, and rheumatoid factor test may be indicated based on history, physical exam, and initial database supporting immune-mediated disease.
- Blood culture if sepsis is suspected
- Tissue culture of nodular or granulomatous lesions
- Hypoallergenic dietary trial (urticarial form of food hypersensitivity)

TREATMENT

TREATMENT OVERVIEW

The goal of treatment is to improve circulation to the affected area (e.g., using pentoxifylline, which increases RBC plasticity), control self-trauma, and suppress the immune reaction (e.g., using corticosteroids or other immunosuppressors) while evaluating for the inciting cause.

ACUTE GENERAL TREATMENT

- Discontinue current drug therapies.

- Bandage pressure points and keep wounds clean.
- Prevent self-trauma (Elizabethan collar).

CHRONIC TREATMENT

One or more may be indicated:

- Pentoxifylline: 25-35 mg/kg PO q 12 h following a meal
- Tetracycline and macinarmele: >10 kg. 500 mg of each drug PO q 8 h (<10 kg, 250 mg of each drug) for a minimum of 3 months; tapering is based on a favorable response.
- Prednisone or prednisolone: 2-4 mg/kg PO q 24 h starting dose, tapering based on a favorable response
- Azathioprine (dogs): 2.2 mg/kg PO q 24-48 h (with prednisone or prednisolone)
- Chlorambucil (cats): 0.1-0.2 mg/kg PO q 24-48 h (with prednisone or prednisolone)
- Dapsone: 1 mg/kg PO q 8 h in dogs
- Sulfasalazine: 22-44 mg/kg PO q 8 h in dogs
- Cyclosporine: 5 mg/kg PO q 12-24 h
- Tacrolimus 0.1% topically q 12 h can be considered in cases with focal disease, especially as a substitute for topical corticosteroids. Wear gloves to apply.

POSSIBLE COMPLICATIONS

Tissue necrosis and secondary infection: septicemia

RECOMMENDED MONITORING

- Response to therapy
- Monitor as appropriate for adverse reactions to therapy.

PROGNOSIS AND OUTCOME

- Some cases resolve, whereas others are chronic or recurrent. Damage to other organs (renal, neurologic) will also affect prognosis.
- Thrombovascular pinnal vasculitis: variable response (may wax and wane)
- Idiopathic: may require long-term/indefinite treatment
- Urticarial: dependent on identification of underlying etiology; rule out food allergy (see p. 400).

PEARLS & CONSIDERATIONS

COMMENTS

- Multiple skin biopsies for histopathologic evaluation are the key to diagnosis.
- Do not use drugs of similar classes to those used prior to development of the disease (owing to possibility of drug reaction).
- Monitor closely for adverse reactions to therapy.

PREVENTION

Vaccinate dogs IM if there is a history of rabies vaccine-induced vasculitis; increased risk of an anaphylactic reaction has been suggested.

CLIENT EDUCATION

Long-term treatment (4-6 months, sometimes indefinitely) is often needed.

SUGGESTED READING

Nichols PR, Morris DO, Beale KM: A retrospective study of canine and feline cutaneous vasculitis. Vet Dermatol 12:255–264, 2001.

AUTHOR: STEPHEN WAISGLASS

EDITOR: MANON PARADIS

Vascular Ring Anomaly

BASIC INFORMATION

DEFINITION

Congenital malformation of one or more parts of the aortic arch during embryogenesis such that vessels encircle the esophagus and trachea, causing chronic compression

SYNONYMS

Vascular ring malformation, persistent right aortic arch (PRAA; most common vascular ring anomaly)

EPIDEMIOLOGY

SPECIES, AGE, SEX

- More common in dogs than in cats
- Clinical signs usually develop shortly after weaning.
- No sex predilection

GENETICS & BREED PREDISPOSITION

- The majority of dogs with PRAA are of large breeds (>15 kg expected adult weight).
- Heritability is suspected in German shepherds and greyhounds.

ASSOCIATED CONDITIONS & DISORDERS

- Persistent left cranial vena cava and patent ductus arteriosus (PDA) can be associated vascular anomalies.
- Megaesophagus and aspiration pneumonia are secondary problems associated with chronic partial esophageal obstruction.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT: Most dogs and cats develop clinical signs once they start to ingest solid food, because the vascular ring obstructs passage of food down the esophagus. Postprandial regurgitation is the usual presenting complaint, and the majority of cases are diagnosed before 6 months of age. Occasionally, animals may have coughing or respiratory distress due to aspiration pneumonia or tracheal compression.

PHYSICAL EXAM FINDINGS: Animals have a good appetite but may be thin as a result of chronic regurgitation. An enlarged esophagus may occasionally be palpated in the thoracic inlet, especially after eating. In dogs with a concurrent PDA (minority of cases), a continuous left basilar murmur is ausculted; however, in the absence of PDA, cardiac auscultation is normal. Animals with aspiration pneumonia may be febrile with harsh ventral lung sounds.

ETIOLOGY AND PATHOPHYSIOLOGY

- Normal embryogenesis:
  - In the embryo, the great vessels are formed from six aortic arches that connect paired ventral and dorsal aortas. During development, these vessels undergo regression and reconnection that normally result in a left-sided aorta, left-sided ligamentum arteriosum, and normal branching of the brachiocephalic trunk and left subclavian arteries off the ascending aorta.
- Pathophysiology:
  - Developmental anomalies of the great vessels appear to be relatively common; however, these anomalies are only clinically important when the vessels entrap the esophagus and trachea within a vascular ring.
  - Passage of food down the esophagus is impeded by the vascular ring, causing esophageal dilation, food stasis, and regurgitation. Regurgitation with aspiration can cause pneumonia.
- PRAA (most common in dogs):
  - The normal left aortic arch regresses, while the right aortic arch is retained. The left ligamentum arteriosum passes over the esophagus, connecting the right aortic arch to the left-sided pulmonary artery and compressing the esophagus at the base of the heart.
  - PRAA can also occur with an aberrant left subclavian artery. This causes an incomplete ring that dorsally compresses

the esophagus (the left subclavian arises from the right aorta and courses dorsally over the esophagus).

- Double aortic arch:
  - Both left and right aortic arches persist, encircling the esophagus and trachea as the two vessels merge to form the descending aorta.
- Persistent right ligamentum arteriosum with normal left aorta is an uncommon cause of a vascular ring anomaly. It is important to note that correction by a left lateral thoracotomy is more difficult for this malformation than for the other vascular ring anomalies.
- An aberrant right subclavian artery with a normal left aorta can cause an incomplete ring because the aberrant vessel courses over and dorsally compresses the esophagus.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

A history of regurgitation beginning immediately after weaning is highly suggestive; plain thoracic radiographs provide the basis for a diagnosis of vascular ring anomaly (e.g., ventral and leftward tracheal deviation, dilated cranial esophagus) and also screen for associated aspiration pneumonia.

DIFFERENTIAL DIAGNOSIS

- Differential diagnoses for regurgitation include congenital megaesophagus, stricture, foreign body, neoplasia, granuloma, hiatal disorder, and esophageal diverticulum.
- Esophageal stricture is the major differential diagnosis to consider for radiographic esophageal dilation that terminates at the base of the heart.

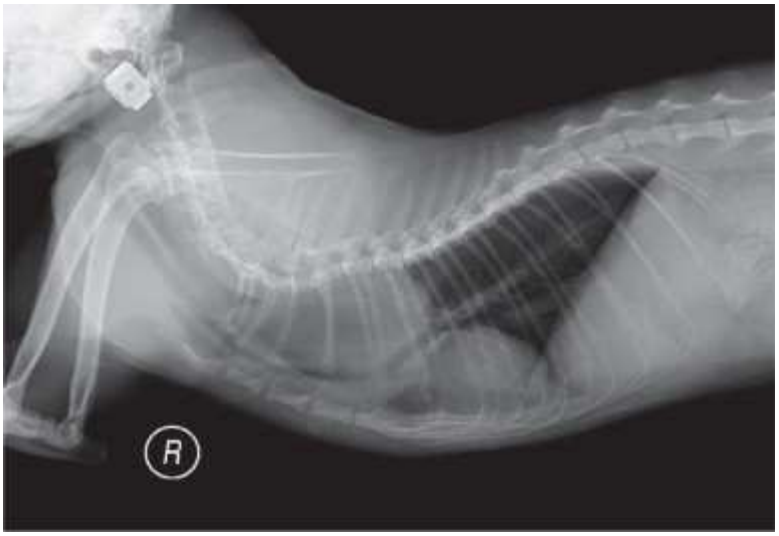
INITIAL DATABASE

- Thoracic radiographs:
  - The esophagus may appear dilated up to the base of the heart on plain films. Its visualization may be enhanced by residual food. Lateral radiographs often show ventral deviation of the trachea cranial to the heart, and the tracheal lumen may be narrowed in this deviated segment.
  - Leftward curvature of the trachea near the cranial border of the heart on the dorsoventral (DV) or ventrodorsal (VD) view reliably differentiates dogs with vascular ring anomalies from dogs with generalized megaesophagus. These radiographic findings may obviate the need for a barium esophagram.
- CBC is indicated if there is evidence of aspiration pneumonia.

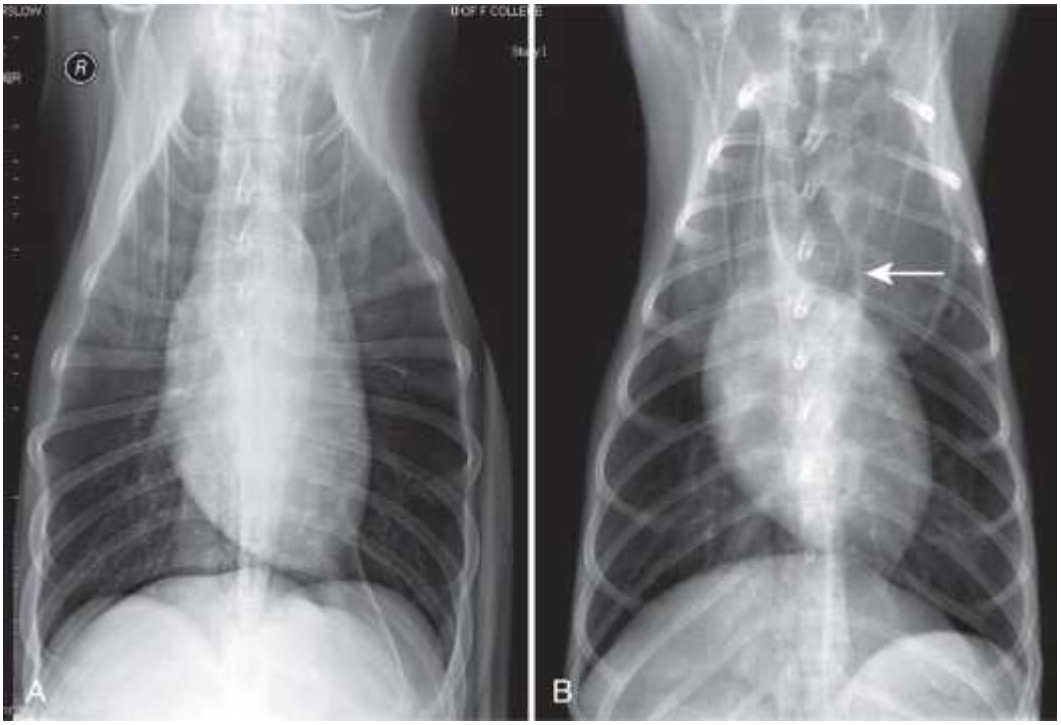
ADVANCED OR CONFIRMATORY TESTING

Often unnecessary when a working diagnosis is made from thoracic radiographs.

- Barium esophagram: barium given in food can be used to radiographically outline the focal dilation of the esophagus that narrows at the base of the heart. Although this finding is diagnostic for a vascular ring anomaly, it does not reveal the type of anomaly present.
- Nonselective CT angiography has been used for producing a 3-dimensional anatomic reconstruction of the anomalous vasculature for diagnosis and to assist in surgical approach.



VASCULAR RING ANOMALY Lateral thoracic radiograph demonstrating marked ventral deviation of the trachea and severe esophageal filling with fluid/soft-tissue opacity material cranial to the carina. The cause was a vascular ring anomaly.



VASCULAR RING ANOMALY A, Ventrodorsal thoracic radiograph of a normal dog. **B**, Ventrodorsal thoracic radiograph of a dog with vascular ring anomaly. Leftward deviation of the trachea *(arrow)* is characteristic of vascular ring anomaly.

TREATMENT

TREATMENT OVERVIEW

Esophageal constriction caused by vascular ring anomalies is treated surgically by ligation and division of the aberrant vessel, with the ultimate goal being a reduction or elimination of regurgitation. Intensive pre- and postoperative care may be required for debilitated patients.

ACUTE GENERAL TREATMENT

- Young malnourished animals may benefit from fluid therapy with dextrose.
- Animals with aspiration pneumonia require antibiotic therapy prior to surgical intervention.
- Surgical division of the vascular ring:

- For the vast majority of vascular ring anomalies, the preferred surgical approach is a left fourth intercostal thoracotomy.
- Ventilation is required after entering the thorax (thoracostomy tube after surgery for 24 hours to evacuate air).
- When the vascular ring is caused by PRAA, the left ligamentum arteriosum is ligated and divided, releasing the constriction on the esophagus.
- When the vascular ring is caused by an aberrant subclavian artery coursing over the esophagus, this artery is ligated and divided. No adverse effects are noted from this ligation, as the vertebral artery supplies adequate collateral flow.
- When a double aortic arch is present, the smaller arch is ligated and divided.
- Thoracoscopic ligation of a left ligamentum arteriosum (with PRAA) has been reported as a less invasive surgical option.

NUTRITION/DIET

- Severely malnourished animals may require nutritional support prior to surgery, including elevated feedings of slurried food or, in some cases, placement of a gastrostomy tube (see p. 1270).
- Give slurried food to the patient from an elevated position for several weeks after surgery. After feeding, the patient should be kept in a vertical position for 10 minutes. Then introduce solid food from an elevated position. If no regurgitation occurs, most dogs can be returned to a normal feeding regimen 1-2 months after surgery.

POSSIBLE COMPLICATIONS

- Most common complication: aspiration pneumonia. Regurgitation may continue after surgical disruption of the vascular ring because of loss of neuromuscular esophageal function. Some animals may never be able to ingest solid food and may need to be fed a slurry diet indefinitely.
- Other possible complications are related to thoracic surgery and include lung lobe laceration, intraoperative hemorrhage, or thoracic duct injury leading to postoperative chylothorax.

RECOMMENDED MONITORING

Thoracic radiographs should be used to monitor for postoperative aspiration pneumonia and document resolution of megaesophagus.

PROGNOSIS AND OUTCOME

- Prognosis is dependent on age at the time of surgical therapy, severity of malnourishment, presence of aspiration pneumonia, and degree of esophageal constriction.
- A study found that 6 months after surgery, the majority (92%) of dogs did not regurgitate, and the remainder regurgitated only occasionally.

PEARLS & CONSIDERATIONS

COMMENTS

- Oral passage of a stomach tube into the esophagus by an assistant during surgery can help locate the stricture and facilitates dissection around the esophagus.
- Intraoperative balloon dilation of the esophagus is particularly helpful to remove constricting fibrous bands after the ring has been resected.

CLIENT EDUCATION

Although the prognosis is good for most dogs following surgical therapy, counsel owners about the potential for continued esophageal dysfunction.

Vaginitis

Additional Images Available on Website

BASIC INFORMATION

DEFINITION

Inflammation/irritation of the vagina

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Spayed or intact bitches
- Prevalence <1%
- Juvenile onset: bitches 8 weeks to 1 year of age. Adult onset: bitches >1 year of age

RISK FACTORS: Anatomic abnormalities (strictures or septa), perivulvar dermatitis with atrophic juvenile vulva and excessive skin folds, perivascular dermatitis in overweight dogs with urinary incontinence, systemic illness (e.g., diabetes mellitus, hyperadrenocorticism)

CONTAGION & ZOONOSIS: *Bruceila cants,* canine herpesvirus

GEOGRAPHY AND SEASONALITY: Hot and humid climates may trigger or exacerbate vaginitis.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Juvenile onset versus adult onset
- Acute versus chronic

HISTORY, CHIEF COMPLAINT

- Vulvar discharge (chronic, if present for >1 month)
- In juvenile-onset vaginitis, bitches usually are not systemically ill.
- Pollakiuria, discomfort (e.g., excessive vulvar licking, pain when urinating)
- Clinical signs of concurrent disease (e.g., polyuria/polydipsia, urinary incontinence, pruritus, infertility) may be contributing causes of vaginitis.

PHYSICAL EXAM FINDINGS

- Vulvar mucoid, purulent, occasionally blood-tinged discharge
- Vulvar hyperemia
- Digital vaginal examination (see p. 1360) may reveal vaginal stenoses or septa
- Atrophic or juvenile vulva with excessive skin folds, with concurrent perivulvar dermatitis
- Overweight dogs with urinary incontinence, with excessive perivulvar skin folds and persistent moisture and urine scalding

ETIOLOGY AND PATHOPHYSIOLOGY

- Physical abnormalities impede normal evacuation of secretions, compromise natural barrier. Systemic diseases may compromise immunity (e.g., diabetes mellitus, hyperadrenocorticism) or infect reproductive tract directly (e.g., brucellosis).
- Many dogs have idiopathic vaginitis.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis is generally suspected as a result of vulvar discharge. Vaginoscopy +/− bacterial culture are used for confirming the

diagnosis.

DIFFERENTIAL DIAGNOSIS

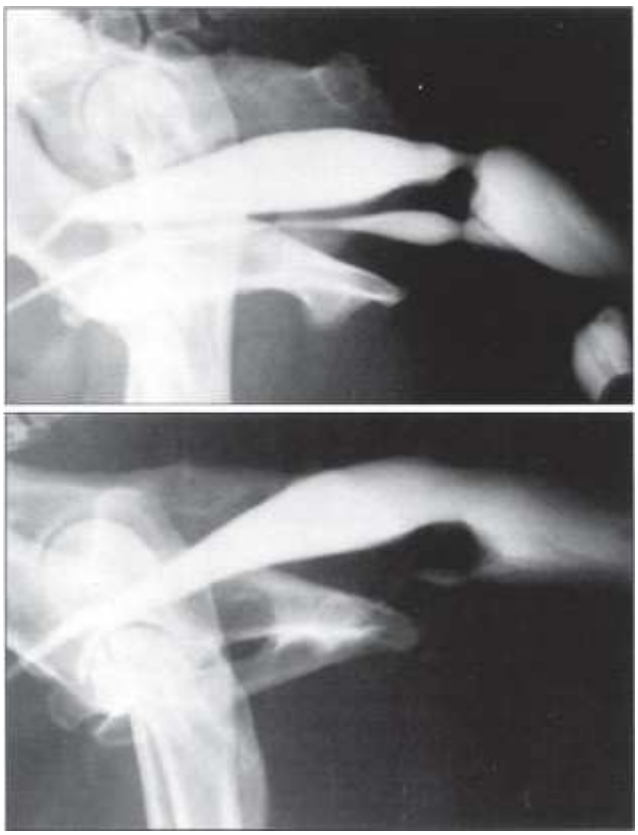
- Urinary tract infection
- Metritis
- Cystic endometrial hyperplasia/pyometra
- Uterine stump pyometra
- Vulvar, vaginal, or uterine tumor
- Brucellosis
- Canine herpesvirus infection

INITIAL DATABASE

- CBC, serum biochemistry profile: generally unremarkable
- Serologic titer for *Brucella canis* (see p. 162)
- Vaginoscopy assesses discharge present in the vagina; vesicular lesions (e.g., canine herpesvirus associated or lymphoid follicles) seen as nonspecific indicators of inflammation; urine pooling, masses, foreign bodies possible.
- Vaginal Cytologic examination shows WBCs with or without bacteria.

ADVANCED OR CONFIRMATORY TESTING

- Vaginal bacterial culture: moderate to heavy growth of 1 to 2 bacterial types (more might suggest normal flora).
- Urinalysis and bacterial culture: concurrent urinary tract infection (UTI) is common.
- Contrast radiography, biopsy: rarely if ever needed



VAGINITIS Contrast vaginogram showing vestibulovaginal stenosis with marked narrowing of vagina cranial to urethral papilla. *Top,* Preoperatively. *Bottom,* Five months after surgical resection of the stenosis and vestibulovaginal anastomosis.

(From Kyles AE, Vaden S, Hardie EM, et al: Vestibulovaginal stenosis in dogs: 18 cases (1987-1995). J Am Vet Med Assoc 209:1889-1893, 1996.)

TREATMENT

TREATMENT OVERVIEW

- Correction of the underlying cause is the cornerstone of effective long-term resolution. In adult-onset vaginitis, treatment of the underlying cause is usually curative.
- Most therapy for vaginitis is supportive and nonspecific because most cases are idiopathic. Many cases resolve spontaneously in both juvenile- and adult-onset vaginitis, particularly when there is no identifiable underlying cause.

ACUTE AND CHRONIC TREATMENT

- If the primary problem is UTI (up to 60% of cases with identifiable underlying cause):
  - Antibiotics based on culture and sensitivity testing (empirical antibiotics acceptable for first 48-72 h pending culture results)
  - Antibiotics, if used, should be administered for 4 weeks and based on a guarded sample collected from the cranial vagina and culture and sensitivity.
- Diethylstilbestrol (DES), 0.1-0.2 mg/kg PO, maximum dose = 1 mg, q 24 h for 5 days, tapering to 2× a week; or phenylpropanolamine, 1-1.5 mg/kg PO q 8-12 h. Note: Do not use DES in dogs that have not reached adult stature (may induce premature long-bone physeal closure).
- In overweight urinary-incontinent dogs with excessive perivulvar skin folds, vulvoplasty (episioplasty) is recommended.
- If the primary problem is vaginal anatomic anomalies (up to 36% of cases with identifiable underlying cause), surgical repair may be indicated.
- If the primary problem is systemic disease (up to 15% of cases with identifiable underlying cause): treat the underlying systemic disease.
- If the primary problem is idiopathic:
  - DES to treat subclinical urinary incontinence
  - Glucocorticoids may be beneficial in some bitches (do not use in cases of concurrent urinary incontinence).
- Treatment for atopic dermatitis if present concurrently (see p. 106)
- Vaginal douches with antiseptics or antibiotics have not been reported to be an effective treatment.
- Owners should be instructed to keep the perivulvar skin folds clean.

POSSIBLE COMPLICATIONS

- Ascending UTIs can result from chronic vaginitis.
- Self-mutilation can result from excessive licking of the perivulvar skin secondary to vaginitis.

RECOMMENDED MONITORING

Recheck animals showing any signs of systemic illness, and look for complications such as metritis.

PROGNOSIS AND OUTCOME

With spontaneous remission, future reproductive success is not compromised.

PEARLS & CONSIDERATIONS

COMMENTS

- Urethral sphincter mechanism incompetence (see p. 1134) may be misdiagnosed as vaginitis, especially when there is positive response to treatment for suspected vaginitis with DES or phenylpropanolamine.
- Daily record of the frequency and severity of clinical signs (e.g., vulvar discharge, vulvar licking) will help the veterinarian to assess response to therapy.
- Limited understanding of the causes of vaginitis makes it difficult to predict when and if clinical signs will resolve.

CLIENT EDUCATION

Owners should consider not breeding bitches with poor vulvar conformation or congenital vaginal defects to avoid perpetuating these problems in the female offspring.

Vaginal Hyperplasia and Vaginal Prolapse

BASIC INFORMATION

DEFINITION

Edematous swelling of the vaginal mucosa cranial to the urethral orifice; an uncommon disorder that occurs during estrogen stimulation in the intact bitch. It may progress to vaginal protrusion through the vulvar lips.

SYNONYMS

Vaginal edema, hypertrophy, hyperplasia, eversion, or protrusion

EPIDEMIOLOGY

SPECIES, AGE, SEX: Intact bitch, any age (7 months to 16 years old)

GENETICS & BREED PREDISPOSITION

- More common in large-breed dogs
- Breeds predisposed: bulldog, mastiff, boxer, dalmatian, German shepherd, Saint Bernard, Labrador and Chesapeake Bay retrievers, weimaraner, Walker hound, springer spaniel, Airedale terrier, and American pit bull terrier

RISK FACTORS

- Young bitch under the influence of estrogen during proestrus or estrus; may occur or recur during diestras, pregnancy, or parturition
- Can be observed as side effect of estrus induction with estrogen

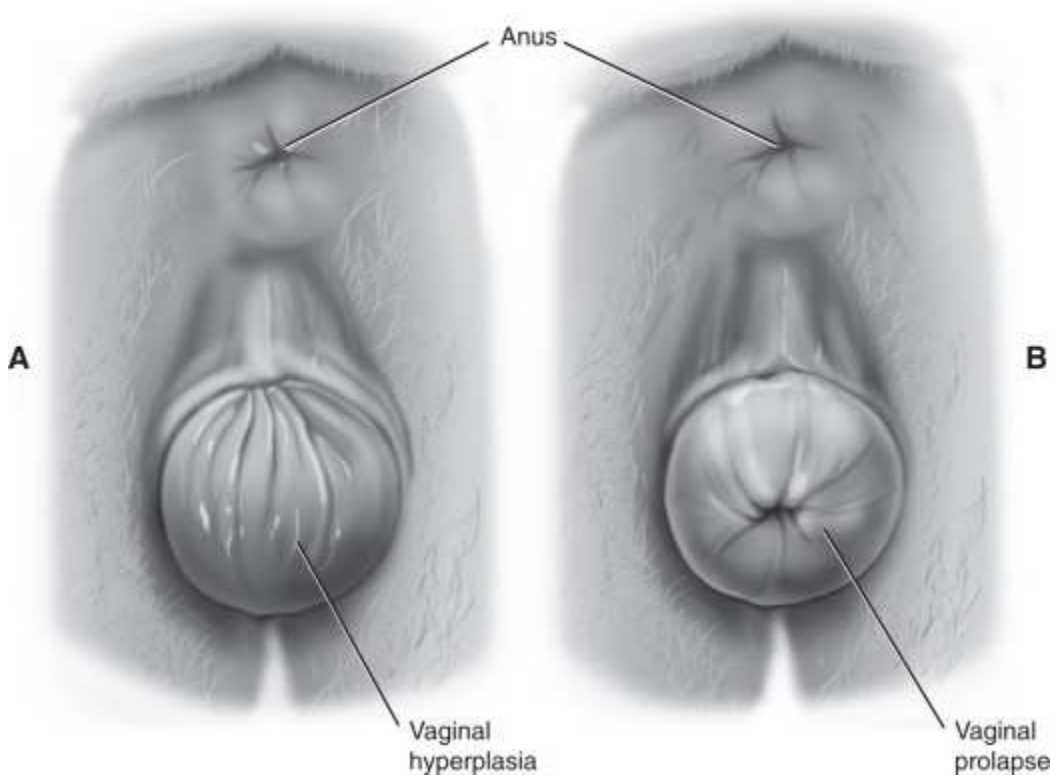
ASSOCIATED CONDITIONS & DISORDERS: Markedly prolapsed vaginal tissue is subject to self-mutilation and may be dry, ulcerated, necrotic, and devascularized; possible dysuria or pollakiuria.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

Vaginal hyperplasia:

- Type I: slight to moderate eversion of the vaginal floor cranial to the urethral orifice; confined to the vestibulum, appearing as a bulge at the perineum.
- Type II: well-developed swelling of the vaginal floor, which may include the lateral vaginal walls, protruding through the vulvar lips. The swelling appears dome shaped.



VAGINAL HYPERPLASIA AND VAGINAL PROLAPSE A, Well-developed swelling of vaginal floor, which may include lateral vaginal walls, protruding through vulvar lips. Swelling appears dome-shaped (type II vaginal hyperplasia). **B**, Well-developed protrusion of entire circumference of vaginal wall through vulvar lips. Swelling appears doughnut shaped (vaginal prolapse).

- Type III: well-developed protrusion of the entire circumference of the vaginal wall through the vulvar lips. The swelling appears doughnut shaped and is a vaginal prolapse.

HISTORY, CHIEF COMPLAINT

- Previous occurrence of vaginal hyperplasia
- Onset of proestrus or estrus
- Licking or irritation of the vulva
- Mass protruding from vulva or bulge at the perineum
- Dysuria or pollakiuria
- Failure to allow intromission during breeding
- Tenesmus

PHYSICAL EXAM FINDINGS: Bulge at the perineum or protrusion of a pink dome-shaped or doughnut-shaped mass from vulva; surface of protrusion may be dry, necrotic, or ulcerated. Vaginal examination reveals:

- A urethral orifice located ventrally in all three types of vaginal hyperplasia
    - A vaginal lumen located dorsally in types I and II but centrally located in type III
- By contrast, uterine prolapse is distinguished by the presence of tubular masses within the vagina or protruding from the vulva.

ETIOLOGY AND PATHOPHYSIOLOGY

- Vaginal hyperplasia: an exaggerated response of the vaginal mucosa to estrogen (hyperemia, edema, keratinization). The swelling begins as an eversion in the vaginal floor, cranial to the urethral orifice.
- With vaginal prolapse: histopathologic examination of affected vaginal tissue is consistent with submucosal edema rather than with hyperplasia or hypertrophy.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis is suspected based on the presence of a vulvar swelling or protrusion in a young intact bitch.

DIFFERENTIAL DIAGNOSIS

- Benign or malignant vaginal neoplasia
- Vaginal polyp
- True vaginal prolapse with concurrent entrapment of visceral organs (rare)
- Uterine prolapse
- Urethral neoplasia

INITIAL DATABASE

- Stage of hormonal cycle based on vaginal cytologic examination
- Vaginal examination to locate the urethral orifice, vaginal lumen, origin of the protruding mass, and the size of its base (see p. 1360)
- Ensure that the animal is able to urinate.

ADVANCED OR CONFIRMATORY TESTING

- Biopsy of vaginal mass confirms diagnosis in atypical bitches.
- In severe cases, survey radiographs can be used to evaluate for visceral organ involvement; contrast radiography can confirm the location of the urethral orifice and vaginal lumen.

TREATMENT

TREATMENT OVERVIEW

Treatment goals are to prevent drying, necrosis, and devitalization of exposed vaginal tissue, prevent future recurrence, and prevent urethral obstruction.

ACUTE GENERAL TREATMENT

- Insertion of a urethral catheter to relieve obstruction when present
- Ensuring that vaginal tissue is kept clean
- Topical application of sterile water-soluble lubrication or antibiotic ointment
- Application of an Elizabethan collar or protective pants
- Provision of a clean environment to minimize tissue trauma
- Scheduling an ovariohysterectomy, which prevents recurrence and may hasten resolution; regression of tissue is reported to occur within 21 days.
- Recognition that spontaneous regression at end of estrus is common

CHRONIC TREATMENT

- Ovariohysterectomy prevents recurrence in nonbreeding bitches.
- Surgical excision of prolapsed vaginal tissue in bitches intended for breeding or in those with severely inflamed or devitalized vaginal tissue:
    - May prevent recurrence during subsequent estrous cycles or at parturition
    - Various surgical techniques are described involving circumferential incision at the base of the prolapse.
    - Episiotomy may be needed.
- Manual reduction of prolapsed tissue and placement of stay sutures in the vagina do not prevent recurrence and may cause the bitch discomfort.
- Artificial insemination can be performed in breeding bitches.
- Induction of ovulation during a nonbreeding cycle may hasten regression of vaginal tissue by decreasing estrogenic stimulation: gonadotropin-releasing hormone (2.2 mcg/kg IM) or human chorionic gonadotropin (1000 IU IM, irrespective of body weight as a single injection, or 500 IU IM, irrespective of body weight and repeated in 48 hours); a 1-week regression follows ovulation. Treatment is ineffective if given after ovulation.

DRUG INTERACTIONS

Avoidance of progestational drugs that contribute to pyometra

POSSIBLE COMPLICATIONS

- Necrosis, infection, and devascularization of vaginal tissue
- Evisceration of abdominal organs
- Urination and defecation difficulties

RECOMMENDED MONITORING

- Monitor viability of prolapsed vaginal tissue.
- Evaluate ability to urinate.

PROGNOSIS AND OUTCOME

- Good prognosis with ovariohysterectomy
- Recurrence rate is 66% in untreated bitches

PEARLS & CONSIDERATIONS

COMMENTS

- Vaginal hyperplasia may progress to vaginal prolapse (type lll), but other disorders less commonly may also cause vaginal prolapse.
- If excision of vaginal tissue is performed in late estrus or early diestrus, bleeding is minimized.
- If ovariohysterectomy is performed in anestrus (serum progesterone concentrations <2 ng/mL), development of pseudopregnancy is minimized.
- Catheterize urethra during excision of vaginal tissue to help prevent inadvertent urethral trauma.

PREVENTION

- Ovariohysterectomy
- Surgical excision of redundant vaginal tissue may prevent recurrence during the following estrous cycle.

CLIENT EDUCATION

Discuss heritability and intended plans for the bitch; ovariohysterectomy is the recommendation for nonbreeding bitches.

Vaginal Congenital Abnormalities in the Bitch

BASIC INFORMATION

DEFINITION

Malformations that reduce the diameter of the vestibulovaginal junction (bands) and may cause secondary infertility, vaginitis, or cystitis include incomplete dissolution or fusion of the paramesonephric ducts (Müllerian), hymenal remnants, and hypoplasia of the vestibulovaginal junction.

EPIDEMIOLOGY

SPECIES, AGE, SEX: Congenital vaginal abnormalities are present at birth but are usually undetected until the appearance of clinical signs. Young-adult female dogs are most commonly affected.

GENETICS & BREED PREDISPOSITION: Large-breed dogs may be over-represented.

ASSOCIATED CONDITIONS & DISORDERS: Female dogs with ectopic ureters often have coincident congenital vaginal abnormalities.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Double vagina
- Hypoplasia of the vaginal vault
- Imperforate hymen
- Vaginal stenosis
- Vaginal stricture

HISTORY, CHIEF COMPLAINT

- Unsuccessful breeding attempts, obvious pain during breeding, avoidance of male during breeding attempts
- Purulent, often recurrent vaginal discharge
- Persistent urinary tract infection (UTI), urine dribbling

PHYSICAL EXAM FINDINGS

- Vaginal discharge may be present.
- Narrowing of vestibulovaginal junction may be apparent during manual vaginal exam (see p. 1360).

ETIOLOGY AND PATHOPHYSIOLOGY

- Incomplete fusion of the paramesonephric ducts can result in persistent dorsoventral bands.
- Vestibulovaginal hypoplasia causes concentric narrowing of the vestibulovaginal junction.
- Incomplete dissolution of the hymen can compromise the vestibulovaginal junction.
- Any type of vestibulovaginal stricture can interfere with breeding, owing to pain produced during penetration by a male dog.
- Anatomic abnormalities of the vestibulovaginal junction can inhibit drainage of vaginal secretions, which can lead to vaginitis or ascending UTI.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Clinicians should suspect vestibulovaginal abnormalities in bitches or queens with a history of difficult or unsuccessful breeding. The diagnosis is usually made during vaginal examination.

DIFFERENTIAL DIAGNOSIS

- Behavioral abnormalities in breeding bitches in estrus who are reluctant to stand for a male
- Urolithiasis is a much more common cause of chronic UTI.
- Vaginal discharge may be associated with juvenile-onset vaginitis or pyometra.

INITIAL DATABASE

- Vaginoscopy using a flexible or rigid endoscope (see p. 1361)
- Heavy sedation or general anesthesia is necessary.

ADVANCED OR CONFIRMATORY TESTING

Contrast radiography: retrograde vaginography (see p. 1158)

TREATMENT

TREATMENT OVERVIEW

Remove obstruction/narrowing at vestibulovaginal junction.

ACUTE GENERAL TREATMENT

- Digital dilation of vestibulovaginal junction (effective for treatment of hymenal remnants or mild [membranous] vestibulovaginal stenosis)
- Resection of dorsoventral paramesonephric duct remnants or bands if present
- For severe (fibrous) vestibulovaginal stenosis: resection and anastomosis of vestibulovaginal junction via an extended episiotomy

CHRONIC TREATMENT

After manual or surgical dilation, antibiotic therapy (based on culture and sensitivity [C&S]) may have to be extended up to 6 weeks for treatment of ascending UTI if present.

BEHAVIOR/EXERCISE

Bitches with previous painful breeding episodes may be reluctant to accept a male after treatment of vestibulovaginal abnormalities. Use of an experienced breeding male may be helpful.

POSSIBLE COMPLICATIONS

- Stricture secondary to resection and anastomosis
- Inadequate resection does not resolve clinical signs.

RECOMMENDED MONITORING

Observe the animal for recurrence of signs; initial treatment may have to be repeated if stricture occurs secondary to resection or traumatic dilation.

PROGNOSIS AND OUTCOME

- Prognosis is good if clinical signs are caused by hymenal remnants or mild vaginal stricture.
- Prognosis for resolution of clinical signs is fair to good for severe vaginal stricture treated by vestibulovaginal resection and anastomosis.

PEARLS & CONSIDERATIONS

COMMENTS

- Do not confuse normal narrowing at the vestibulovaginal junction with a pathologic condition:

    - The diameter of the vestibulovaginal junction must be less than 30% of the diameter of the maximal diameter of the vagina to be considered pathologic.
- Most congenital vaginal abnormalities do not cause clinical signs.

PREVENTION

Since most vestibulovaginal abnormalities are congenital but not hereditary, there are no recommendations against breeding affected bitches or queens once the abnormality is treated.

TECHNICIAN TIPS

Although digital vaginal examination is helpful in making a diagnosis of vestibulovaginal abnormality, direct visual inspection using vaginoscopy permits a much more accurate diagnosis.

CLIENT EDUCATION

- Breeding bitches that are reluctant to stand for a male may have vestibulovaginal abnormalities that cause painful breeding.
- Congenital vaginal anomalies may be present without causing clinical signs.

Vacuolar Hepatopathy

BASIC INFORMATION

DEFINITION

Benign, reversible hepatic lesion of glycogen accumulation that occurs commonly in dogs in response to excess glucocorticoids and/or as a reactive change secondary to systemic disorders

SYNONYMS

Glucocorticoid hepatopathy, hepatic glycogen accumulation, steroid hepatopathy

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs only; age and sex dependent on underlying cause. Older dogs may have spontaneous hyperadrenocorticism or idiopathic vacuolar hepatopathy.

GENETICS & BREED PREDISPOSITION

- Poodles, dachshunds, beagles, boxers, terrier breeds: pituitary-dependent hyperadrenocorticism
- German shepherd, Labrador retriever, poodle, dachshund, terrier breeds: functional adrenal tumor
- Scottish terriers: idiopathic vacuolar hepatopathy

RISK FACTORS: Glucocorticoid administration

ASSOCIATED CONDITIONS & DISORDERS: Hyperadrenocorticism including atypical forms (increased adrenal steroids other than cortisol, or aberrant adrenocortical disease [see p. 6]); secondary reactive change associated with stress from other systemic inflammatory, infectious, or neoplastic disorders.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Incidental finding of increased serum alkaline phosphatase (ALP) activity; subsequent fine-needle aspirate (FNA) and Cytologic examination or liver biopsy show vacuolar change
- Clinical signs of glucocorticoid excess
- Clinical signs of primary systemic disorder

HISTORY, CHIEF COMPLAINT

- For glucocorticoid excess, clinical signs reflect systemic effects of hyper-cortisolism rather than hepatic disease: polyuria and polydipsia (PU/PD), polyphagia, panting.
- If iatrogenic, a history of glucocorticoid administration (oral, injectable, topical: eyes, ears, skin) within last 3-6 months (depends on route, preparation, duration of therapy, and individual sensitivity) is expected.
- Other signs depend on primary systemic disorder.
- The patient may show no clinical signs (incidental finding) or mild polydipsia: idiopathic vacuolar hepatopathy, Scottish terriers.

PHYSICAL EXAM FINDINGS

- For iatrogenic or spontaneous hyperadrenocorticism: hepatomegaly (may be massive); abdominal enlargement, thin haircoat or truncal alopecia, thin skin
- Other findings dependent on primary systemic disorder
- May be unremarkable

ETIOLOGY AND PATHOPHYSIOLOGY

- Excess glucocorticoids (exogenous, or spontaneous hyperadrenocorticism):

    - Dogs are uniquely susceptible to hepatic effects of glucocorticoids.
    - Gradual hepatic glycogen accumulation and hepatomegaly occur within the first 2 weeks of daily prednisolone administration.
    - Preceded by increased serum ALP activity
    - Marked individual variation
    - Lesions identical with exogenous or endogenous corticosteroids
    - Hepatic function is typically normal.
    - Reversible
- Aberrant adrenocortical disease ("atypical hyperadrenocorticism;" see p. 6)
    - Increased adrenal steroid hormones other than cortisol (especially progesterone and 17-α hydroxyprogesterone)
    - Progesterone has glucocorticoid-like effects on the liver.
- Scottish terriers:
    - Increased serum ALP activity (predominantly steroid-induced isoenzyme)
    - No overt clinical signs; cause unknown
    - No association between progesterone or 17-α hydroxyprogesterone levels and serum ALP elevations
    - Reactive hepatopathy:
    - Common lesion in dogs with other systemic illnesses (including neoplastic, neurologic, immune-mediated, and gastrointestinal tract disorders) and severe dental disease.
    - Acute or chronic illness can be associated with stress-induced hypercortisolemia resulting in vacuolar hepatopathy.
- Hepatic nodular hyperplasia or regeneration:
    - Etiology unknown; may be associated with nutritional factors or the result of focal areas of ischemia
- Congenital or acquired hepatobiliary disease:
    - Acute and chronic inflammation, hepatotoxicity, and congenital portosystemic shunt may have vacuolar changes. With acquired hepatobiliary disease, necrotic or inflammatory lesions predominate.
- Idiopathic vacuolar hepatopathy:
    - Excess corticosteroids or other adrenal steroid hormones cannot be documented; absence of systemic disease; usually associated with no clinical signs; clinical significance unknown.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

- Initially suspected based on findings of increased serum ALP activity (steroid-induced isoenzyme predominates), normal liver function, and hepatomegaly.
- Abdominal ultrasound to evaluate for other causes of liver disease and to evaluate adrenal glands; FNA cytologic examination of liver shows characteristic vacuoles (though common false-positive finding with FNA).
- Screen for excess exogenous or endogenous glucocorticoids (endocrine testing for hyperadrenocorticism if compatible with history and physical exam), then evaluate for systemic disorders causing reactive change; if no diagnosis, consider liver biopsy to evaluate for primary hepatobiliary disorders.

DIFFERENTIAL DIAGNOSIS

- Other hepatopathies (inflammatory, neoplastic)
- Nodular hyperplasia or regeneration
- Hyperlipidemia:
    - Diabetes mellitus
    - Hypothyroidism
    - Familial in miniature schnauzers, Shetland sheepdogs, others
- Superficial necrolytic dermatitis (hepatocutaneous syndrome)
- Exocrine pancreatic insufficiency
- Chronic pancreatitis
- Tetracycline administration
- Glycogen or lysosomal storage disease

INITIAL DATABASE

- CBC: lymphopenia, eosinopenia (excess glucocorticoids), other abnormalities depending on primary systemic disorder
- Serum biochemistry panel: serum ALP activity increased, may be marked, predominantly due to steroid-induced isoenzyme of ALP. Serum alanine aminotransferase (ALT) activity shows mild to moderate increases (or levels may be normal). Increased serum cholesterol concentration (excess glucocorticoids). Other biochemistry values typically normal (bilirubin, albumin).
- Serum bile acids concentration normal to mildly increased
- Abdominal radiographs: hepatomegaly (may be marked)

- Abdominal ultrasound: diffusely hyperechoic liver; may also be mottled and/or nodular; adrenomegaly (hyperadrenocorticism)

ADVANCED OR CONFIRMATORY TESTING

- FNA and cytologic evaluation of liver:
  - Ballooned hepatocytes with decreased cytoplasmic density, commonly described as *vacuolar hepatopathy*
  - Vacuolar hepatopathy is a common false-positive finding with FNA
- Liver biopsy and histopathologic evaluation:
  - Patchy distribution of ballooned hepatocytes with decreased cytoplasmic density. Glycogen accumulation is characteristic. Glycogen accumulation can be differentiated from hydropic degeneration with periodic acid-Schiff (PAS) stains for glycogen; oil red O (ORO) stain to differentiate lipid vacuoles
  - No evidence of inflammation, necrosis, or cholestasis
- Rule out spontaneous hyperadrenocorticism:
  - Review clinical history and physical exam
  - Low-dose dexamethasone suppression test or adrenocorticotropic hormone (ACTH) stimulation test to screen for hyperadrenocorticism
  - Endogenous ACTH level, high-dose dexamethasone suppression test, and adrenal gland ultrasonography to differentiate pituitary from adrenal causes
  - Adrenal steroid profile before and after ACTH to diagnose aberrant adrenocortical disease
- Evaluate for other systemic disorders that could cause secondary reactive vacuolar hepatopathy.

TREATMENT

TREATMENT OVERVIEW

Focus therapeutic efforts on treating underlying disorder.

CHRONIC TREATMENT

- If the patient is receiving high doses of glucocorticoids and is showing clinical signs of hepatic disease (e.g., lethargy or depression, difficult to distinguish from underlying condition), other immunosuppressive drugs such as azathioprine or cyclosporine may be warranted to allow dose reduction of glucocorticoids.
- Idiopathic vacuolar hepatopathy:
  - If no clinical signs are present, treatment may not be warranted.
  - Necessity or clinical effectiveness of hepatoprotective drug therapy (*S*-adenosylmethionine, vitamin E) unknown.

POSSIBLE COMPLICATIONS

- Hyperadrenocorticism (see p. 548) and complications involving glucocorticoid excess
- Severe vacuolar hepatopathy has been associated with development of gallbladder mucocele.

RECOMMENDED MONITORING

Idiopathic vacuolar hepatopathy: because some dogs may eventually develop spontaneous hyperadrenocorticism, monitor for clinical signs and follow up with screening tests (low-dose dexamethasone suppression test or ACTH stimulation) as needed.

PROGNOSIS AND OUTCOME

- Idiopathic vacuolar hepatopathy; vacuolar hepatopathy of Scottish terriers:
  - Benign clinical course
  - Good long-term prognosis
  - Some dogs may eventually develop clinical hyperadrenocorticism
- Exogenous glucocorticoid therapy:
  - Vacuolar hepatopathy is reversible once glucocorticoids are discontinued; may require weeks to months.

PEARLS & CONSIDERATIONS

COMMENTS

- Diagnostic and therapeutic efforts should be directed at identifying and correcting causes of glucocorticoid excess or primary systemic disorders.
- Hepatic function is typically preserved. If serum ALT > ALP or if hypoalbuminemia, hyperbilirubinemia, or markedly increased serum bile acids concentration are present, a more serious primary hepatobiliary disorder may be present and should be identified and treated. In rare instances, severe vacuolar hepatopathy has been associated with overt hepatic dysfunction, which may be fatal.
- Presence of increased serum ALP activity and vacuolar hepatopathy does not preclude continued use of corticosteroids if their administration is necessary. Liver function is generally preserved; benign lesion. Whenever possible, make an attempt to minimize systemic effects of glucocorticoids with alternate-day therapy using lowest effective dose possible (prednisolone or prednisone), and/or use other immunosuppressive drugs (azathioprine, cyclosporine).
- Cats that are receiving glucocorticoids (or with hyperadrenocorticism) rarely develop vacuolar hepatopathy.

PREVENTION

If long-term glucocorticoid therapy is necessary, give oral prednisolone or prednisone (rather than oral dexamethasone or injectable long-acting forms) at the lowest dose possible on alternate days to minimize the systemic (including hepatic) effects of glucocorticoids. Also consider administering other immunosuppressive drugs (e.g., azathioprine, cyclosporine) to allow dose reduction of glucocorticoids.

CLIENT EDUCATION

Idiopathic vacuolar hepatopathy appears to be clinically benign.

AUTHOR: SUSAN E. JOHNSON

EDITOR: KEITH P. RICHTER

Wolff-Parkinson-White Syndrome

BASIC INFORMATION

DEFINITION

A cardiac disorder characterized by extremely rapid, inappropriate tachycardias. The underlying defect is an accessory pathway or additional conductive fiber connection between atria and ventricles, separate and parallel to the normal atrioventricular (AV) node-bundle of His connection. The accessory pathway can participate as one limb of a rapid re-entrant tachycardia.

SYNONYMS

Premature activation of the ventricles by the atria:

- Accessory AV pathway (or bypass tract)
- Ventricular pre-excitation

Macro re-entrant tachycardia:

- AV reciprocating tachycardia

EPIDEMIOLOGY

SPECIES, AGE, SEX: Any; most commonly identified in dogs <6 years old

GENETICS & BREED PREDISPOSITION: Labrador retrievers and brachycephalic breeds appear to be predisposed.

ASSOCIATED CONDITIONS & DISORDERS: In dogs, there is a possible association between tricuspid valve dysplasia and accessory AV pathways.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Manifest accessory AV pathway: capable of antegrade (atrioventricular) conduction, bypassing the AV node. The result is ventricular pre-excitation during normal sinus rhythm. Manifest accessory pathways can also participate as the antegrade or retrograde limb of a tachyarrhythmia.
- Concealed accessory AV pathway: capable of retrograde conduction (ventricle to atrium) only. Therefore, there is no ventricular pre-excitation. Concealed AV pathways can participate as the retrograde limb of a tachyarrhythmia.

HISTORY, CHIEF COMPLAINT: Related to resultant tachyarrhythmias:

- Decreased exercise tolerance/weakness
- Vomiting, inappetence
- Racing heart/pulsing ears or head
- Dyspnea/coughing
- Abdominal distension
- Acute collapse
- Sudden death

PHYSICAL EXAM FINDINGS: Patient may be normal at the time of exam or may show any of the following signs:

- Tachyarrhythmia
- Decreased femoral pulse quality
- Tachypnea/dyspnea
- Abdominal fluid wave
- Mucous membrane pallor

ETIOLOGY AND PATHOPHYSIOLOGY

- The accessory AV pathway is composed of working myocardial fibers that exist outside the confines of the normal conduction system and connect atrial and ventricular myocardium.
- The antegrade (atria to ventricles) conduction of an atrial impulse over the accessory AV pathway activates a portion of the ventricular myocardium early and then spreads in a myocyte-to-myocyte fashion. The result is a short PR interval and a wide, abnormal QRS complex (i.e., ventricular pre-excitation).
- Retrograde (ventricles to atria) conduction of a ventricular impulse over the accessory AV pathway activates a portion of the atrium and then spreads in a cell-to-cell fashion, eventually reaching the AV node. If the AV node conducts the impulse to the ventricles, this cycle can be repeated in a self-perpetuating loop and result in a narrow complex tachyarrhythmia.
- If a tachyarrhythmia is frequent or sustained, it can lead to tachycardia-induced cardiomyopathy, a dilated poorly contractile heart that is indistinguishable from idiopathic dilated cardiomyopathy, except that it can be reversible with control of the tachyarrhythmia. Pathways capable of rapid antegrade conduction can conduct atrial tachyarrhythmias rapidly to the ventricles, bypassing the normal delay imposed by the AV node.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Electrocardiographic identification of ventricular pre-excitation during sinus rhythm or an atrial tachycardia definitively identifies an accessory pathway. This will not be found with concealed accessory pathways. A narrow complex, regular tachyarrhythmia with specific ECG features is suggestive, but electrophysiologic study is required for confirmation.

DIFFERENTIAL DIAGNOSIS

- Electrocardiographic (ECG): narrow complex, regular tachyarrhythmias: automatic or re-entrant atrial tachycardias, AV re-entrant tachycardia, junctional tachycardias. Pre-excited tachyarrhythmias: ventricular tachycardias.
- Radiographic/echocardiographic (in cases progressing to tachycardia-induced cardiomyopathy): idiopathic dilated cardiomyopathy

INITIAL DATABASE

- ECG (see 1253):
  - Ventricular pre-excitation may be present during sinus rhythm: short PR interval (usually <0.06 seconds); initial portion of the QRS slurred (i.e., slowly rises or descends; “delta wave”); QRS duration prolonged (> 0.06 seconds); QRS axis may be abnormal
  - Tachyarrhythmias: tend to be narrow complex (QRS < 0.06 seconds), 250-400+ bpm; when patients are not on antiarrhythmic drugs, the ECG may have a visible deflection in ST segment (retrograde P wave); tachyarrhythmias are often intermittent, so they are not necessarily captured on a baseline ECG. Holter monitoring is more helpful than a single baseline ECG but may still be normal on a given day.
- Echocardiogram (see 1253):
  - May be normal
  - May mimic dilated cardiomyopathy
  - Assess for congenital heart defects, examine tricuspid valve
- Thoracic radiographs:
  - Assess cardiac silhouette (normal to severely enlarged)
  - Assess pulmonary vasculature and lung fields (for congestion and edema)
- Physical tests:
  - Vagal maneuver: may terminate a tachyarrhythmia by inducing AV nodal blockade but generally unsuccessful (see 1359)

ADVANCED OR CONFIRMATORY TESTS

- Holter monitoring: can be helpful in capturing intermittent pre-excitation or tachyarrhythmias.
- Drug administration: IV diltiazem can terminate AV reciprocating tachycardia by inducing AV block; however, it can terminate certain other tachyarrhythmias as well. Blood pressure (BP) monitoring and resuscitation equipment should be available.
- Electrophysiologic testing: definitively establishes the presence or absence of an accessory pathway and its location along the AV groove.

TREATMENT

TREATMENT OVERVIEW

Goals of treatment are to terminate any tachyarrhythmia present, control its reoccurrence, and control signs of congestive heart failure and hypotension.

ACUTE GENERAL TREATMENT

- Incessant narrow complex tachyarrhythmias: aimed at slowing AV nodal conduction or blocking the accessory pathway: diltiazem (0.125-0.35 mg/kg, slow IV over 3-4 minutes) or procainamide (6-20 mg/kg slow IV over 30 minutes) most commonly used.
- Synchronized direct current (DC) cardioversion can be used once the patient is anesthetized or unconscious if drugs are unsuccessful.

CHRONIC TREATMENT

- Antiarrhythmic drug therapy to control tachyarrhythmias
- Radiofrequency catheter ablation of the accessory pathway is a curative procedure.

BEHAVIOR/EXERCISE

Restricted exercise is recommended until antiarrhythmic control and control of congestive heart failure signs is achieved.

DRUG INTERACTIONS/CONTRAINDICATIONS

Potential interactions between digoxin and several antiarrhythmic and commonly used drugs. Beta agonists or other stimulants are contraindicated.

POSSIBLE COMPLICATIONS

- Tachycardia-induced cardiomyopathy
- Congestive heart failure (CHF)
- Sudden death
- Side effects of antiarrhythmic drugs

RECOMMENDED MONITORING

- Follow-up exam, ECG, and Holter monitoring: frequency dependent on the severity of the tachyarrhythmias documented
- Radiographic and echocardiographic monitoring for dogs with tachycar-dia-induced cardiomyopathy: with adequate control of tachyarrhythmias, myocardial function and chamber dilation should improve within 3 months.

PROGNOSIS AND OUTCOME

- Excellent with radiofrequency catheter ablation
- Fair long term with antiarrhythmic drug administration
- Poor if tachyarrhythmias are not controlled: progressive cardiomyopathic changes (eventually not completely reversible) and recurrent CHF result. Sudden death becomes more common.

PEARLS & CONSIDERATIONS

COMMENTS

- Should be a differential diagnosis in a young (<6 years old) dog presenting with dilated cardiomyopathy (DCM)-like signs
- May require repeated Holter monitoring for documentation
- Even dogs with tachycardiomyopathy and CHF can be cured with successful ablation of the accessory pathway.

CLIENT EDUCATION

- Monitor heart rate carefully at home.
- Sustained tachyarrhythmias are life threatening.
- Curative procedures are available.

Whipworm Infection

Client Education Sheet Available on Website

BASIC INFORMATION

DEFINITION

Infection of the cecum (and possibly ileum and colon) with *Trichuris vulpis* (canine); rare in cats *(T. campanula* or *T. serrata)*

SYNONYM

Trichuriasis

EPIDEMIOLOGY

SPECIES, AGE, SEX: Primarily in dogs; rarely a problem in cats

RISK FACTORS

- Roaming
- Exposure to feces or a contaminated environment

CONTAGION & ZOONOSIS: Humans are rare aberrant hosts.

GEOGRAPHY AND SEASONALITY

- Common in the eastern and southern United States
- Ova are extremely resistant in the environment, surviving 4-5 years and demonstrating no seasonality.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Large-bowel diarrhea (mucoid stool, hematochezia, tenesmus) of variable degrees of severity
- Hypoadrenocorticism-like syndrome: hyponatremia, hyperkalemia, azotemia, metabolic acidosis
- Rarely, typhlitis or cecocolic intussusception may occur.

HISTORY, CHIEF COMPLAINT

- None (incidental finding on fecal flotation)
- Clinical signs of large-bowel diarrhea: frequent, urgent defecation of loose or watery feces, possibly containing mucus or fresh blood (hematochezia). Tenesmus, flatulence possible.
- Occasionally associated with weight loss and protein-losing enteropathy
- In dogs with hypoadrenal-like illness, lethargy, vomiting, or severe diarrhea may be present.

PHYSICAL EXAM FINDINGS

- Commonly, animals with mild whipworm infections have a normal physical examination.
- Vague signs of midabdominal pain/tenderness, often characterized by flank licking, have been associated with granulomatous typhlitis.
- Rarely, physical signs of systemic disease are present (weight loss/cachexia) with hypoadrenal-like illness related to whipworm infection.

ETIOLOGY AND PATHOPHYSIOLOGY

- Direct life cycle begins with ingestion of embryonated eggs.
- Ova hatch in small intestine, and larvae burrow into mucosa for a 1-week period, not causing clinical signs.
- Young adults emerge, relocate to the cecum/colon, and deeply embed the thread-like head (the “whip”) into the mucosa to feed on blood and tissue fluids.
- 3-month prepatent period (range: 70-107 days) precedes appearance of ova in feces

- Host response varies from mild localized inflammation to mucosal hyperplasia to granulomatous inflammation, resulting in variable degrees of gastrointestinal (GI) clinical signs.
- Affected animals can develop large-bowel diarrhea that ranges in severity from intermittent soft stool to severe, copious mucoid or hemorrhagic diarrhea with tenesmus.
- Whipworm-related enteritis may produce biochemical changes falsely suggesting hypoadrenocorticism.
  - Hyponatremia: due to concurrent diarrhea-associated sodium loss, water consumption, and anorexia
  - Hyperkalemia: due to metabolic acidosis, decreased kaliuresis from reduced flow in the distal renal tubules, and/or laboratory artifact (normal platelet K^+ release when clotting)
  - Primary enteritis-associated hyponatremia and hyperkalemia are not caused by aldosterone deficiency (hypoadrenocorticism), as confirmed by normal adrenocorticotropic hormone (ACTH) stimulation test results.
- Whipworm infection has been suggested as a cause for cecocolic intussusception.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Whipworm infection should be suspected on any dog with clinical signs of chronic colitis. Multiple fecal analyses should be pursued but may yield negative results despite parasite infection (intermittent shedding). Therefore monitoring the initial response to two courses of anthelminthic treatment (2 weeks apart), even with negative fecal analysis results, is an important step prior to pursuing costly diagnostics in any patient with solitary signs of intermittent bloody and/or mucoid diarrhea.

DIFFERENTIAL DIAGNOSIS

- *Capillaria* spp. infection (ova appear similar, but *Capillaria* spp. do not cause enteritis)
- Dietary-responsive large-bowel diarrhea
- *Clostridium perfringens* enterotoxicosis
- Inflammatory bowel disease (large intestine)
- Chronic colitis (e.g., histiocytic ulcerative colitis)
- Eosinophilic colitis
- Histoplasmosis (large bowel)
- Neoplasia (carcinoma, lymphoma)
- Hypoadrenocorticism
- Protein-losing enteropathy
- Intussusception

INITIAL DATABASE

- Serial fecal flotations to identify characteristic golden-brown bioperculated smooth ova: they are dense and intermittently shed—often in low numbers—making multiple examinations necessary with adequately dense flotation solution (specific gravity >1.200; e.g., sugar or zinc sulfate).
- CBC: occasional eosinophilia and mild to moderate anemia
- Serum biochemistry profile: hyponatremia, hyperkalemia, azotemia, hypoalbuminemia, metabolic acidosis are occasionally seen.
- Rectal cytologic examination (see p. 1334): insensitive for ova but may demonstrate clostridial spores, inflammatory cells, neoplastic cells
- ACTH response testing is recommended to rule out hypoadrenocorticism in dogs with hyponatremia and hyperkalemia.

ADVANCED OR CONFIRMATORY TESTING

Colonoscopy is an expensive and complex way to detect the presence of adult worms in the cecum and proximal colon.

TREATMENT

TREATMENT OVERVIEW

Therapeutic goals are to eliminate parasites from the GI tract. Three treatments are needed to completely eliminate parasites, owing to prepatency period.

ACUTE GENERAL TREATMENT

- Anthelmintic therapy:
  - Fenbendazole, 50 mg/kg PO q 24 h × 3 days is the preferred treatment.
  - Febantel, 10 mg/kg PO q 24 h × 3 days is an acceptable alternative.
  - Drontal Plus (contains febantel) is also an appropriate therapy.
- Retreat in 3 weeks and again in 3 months because of the long prepatent period.
- Supportive care (e.g., intravenous fluids) for electrolyte abnormalities and azotemia in severe cases
- Typhlectomy for granulomatous typhlitis or cecocolic intussusception (rare)

CHRONIC TREATMENT

Milbemycin oxime is an effective preventive for chronic, recurrent trichuriasis.

DRUG INTERACTIONS

Dogs should be evaluated for presence of heartworm infection before instituting milbemycin oxime.

POSSIBLE COMPLICATIONS

Possible adverse reaction with milbemycin oxime in heartworm-positive dogs

RECOMMENDED MONITORING

Frequent fecal examinations for chronic infections

PROGNOSIS AND OUTCOME

- Excellent with appropriate therapy
- Reinfection likely as a result of environmental contamination with resistant ova.

PEARLS & CONSIDERATIONS

COMMENTS

- *T. vulpis* is a common cause of large-bowel diarrhea in dogs in the eastern and southern United States.
- Empirical treatment is recommended in uncomplicated cases before pursuing a lengthy, expensive diagnostic workup.
- The potential for hypoadrenocorticism-like findings with trichuriasis must be recognized when hypoadrenocorticism is suspected in any dog based on history, clinical signs, and serum biochemistry/electrolyte results.
- Seizures have been reported in dogs with trichuriasis, most likely associated with profound hyponatremia.

PREVENTION

Milbemycin oxime in endemic areas or with chronic infections is an excellent preventive against *T. vulpis* and *Dirofilaria immitis* infection. Because of the prepatent period, a three-treatment course regime with fenbendazole is recommended for acute infections.

CLIENT EDUCATION

Environmental contamination is the source for reinfection and is difficult to eliminate; monthly prophylaxis is recommended after treatment.

EDITOR: DEBRA L. ZORAN

1ST EDITION AUTHOR: E. KELLY NITSCHE

West Nile Virus Infection

BASIC INFORMATION

DEFINITION

Mosquito-borne virus that affects humans and animals but rarely causes clinically significant illness in dogs and cats

EPIDEMIOLOGY

SPECIES, AGE, SEX: Wild birds are the principal hosts of West Nile virus. More than 150 species of birds have been infected in North America. Horses and humans, particularly if older, may also develop clinical signs of infection. Dogs and cats appear to be more resistant to clinical illness, with lower morbidity and mortality.

RISK FACTORS: Infection in dogs and cats has been associated with being stray, residing exclusively outdoors, and not receiving heartworm medication. In humans, advanced age, alcohol abuse, diabetes mellitus, immunosuppression, requirement of mechanical ventilation, history of stroke, and being homozygous for a defective allele have been associated with increased risk of encephalitis, death, or a poor prognosis. In some studies, horses were at greater risk of death or euthanasia if they were older, had not received West Nile vaccination, or had collapsed or become recumbent.

CONTAGION & ZOONOSIS: Exposure to domestic animals is not considered a risk factor for acquisition or amplification of West Nile virus.

GEOGRAPHY AND SEASONALITY: Infections are more common during warm seasons in manmade and natural environmental conditions supportive of the transmitting mosquito species.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES: Most infections with West Nile virus are subclinical.

HISTORY, CHIEF COMPLAINT: Dogs or cats with clinical West Nile virus infection could present with signs related to joint, cardiac, or neurologic infection, as well as sudden death.

PHYSICAL EXAM FINDINGS: Lethargy, anorexia, weight loss, lameness, depression, neurologic involvement (central neurologic deficits), and myocarditis (e.g., cardiac arrhythmia on auscultation, pulse deficits) may be expected in advanced cases. The physical exam is likely often normal, and the infection is not suspected (nor necessarily of clinical concern).

ETIOLOGY AND PATHOPHYSIOLOGY

- West Nile virus is a mosquito-borne disease. The natural hosts are wild passerine birds (e.g., robins, sparrows, finches, blackbirds, warblers), which predominantly experience latent infection. However, high mortality has been reported in crows and blue jays. Mosquitoes (primarily *Culex* spp. in the United States) feed on infected birds and are vectors, transmitting disease to other animals and to people.
- Pathologic findings usually mirror clinical signs and can include gross brain hemorrhage; lymphoplasmacytic encephalitis; enlargement, necrosis, and hemorrhage of the spleen and liver; myocardial degeneration; and pancreatitis.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Clinical cases in dogs and cats are rare and will require submission of specimens to a veterinary diagnostic laboratory with capability of West Nile virus testing.

DIFFERENTIAL DIAGNOSIS

Causes of encephalitis, myocarditis, lameness

INITIAL DATABASE

Because dogs and cats are rarely clinically ill with West Nile infection, no routine diagnostic testing regimens are likely to be of value but should be considered to rule out other causes of clinical signs.

ADVANCED OR CONFIRMATORY TESTING

- For ill animals, serologic testing methods are most commonly used for diagnosis, particularly paired acute-phase and convalescent-phase serum samples.
- Tissues including brain, spinal cord, heart, liver and kidneys from animals that have died or been euthanized can be submitted for viral detection through cell culture, RT-PCR, and immunohistochemistry.

TREATMENT

TREATMENT OVERVIEW

Supportive care, which in horses has included administration of antiinflammatory drugs, vitamins, fluids, and antimicrobials to minimize co-infections

ACUTE GENERAL TREATMENT

- As determined by clinical manifestations of disease
- Neurologic manifestations (see pp. 314 and 1009)
- Myocarditis: treatment of arrhythmias if negatively affecting perfusion (see pp. 111 and 1165)

PROGNOSIS AND OUTCOME

For clinical cases, prognosis depends on severity of illness.

PEARLS & CONSIDERATIONS

COMMENTS

- West Nile virus is now the leading cause of human arboviral encephalitis in the United States.
- Domestic animal species, except for horses, are rarely ill with West Nile infection and do not develop sufficient viremia to serve as a source of infection for mosquitoes.
- Dead birds, particularly crows, may indicate that the risk of West Nile infection has increased in an area.

PREVENTION

- Control of West Nile virus is best accomplished by control of mosquito populations, particularly by removal of standing, stagnant water in artificial basins (pools, tires, pots).
- Keeping animals and people indoors at times of high mosquito activity (e.g., dusk and dawn) may help prevent infection.
- Topical application of insect repellents can be effective at repelling mosquitoes, but only products approved for specific species should be used.
- Vaccination appears to be effective in horses and has also been used in animals from zoological collections.

CLIENT EDUCATION

- Prevention of mosquito breeding grounds and mosquito exposure is the most effective method of preventing infection with West Nile virus.
- Domestic animal species are not a risk for transmitting West Nile virus to people.

Weight Loss

BASIC INFORMATION

DEFINITION

Decrease in body mass; may be intended (as in the treatment of obesity) or an unintended consequence of disease

SYNONYMS

Cachexia, emaciation

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dog or cat, any age, either sex

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

With or without localizing gastrointestinal (GI) signs

HISTORY, CHIEF COMPLAINT

- Thin appearance, lethargy, decreased appetite
- It is important to determine:
  - Quantity, quality, and appropriateness of the diet
  - Appetite (increased or decreased)
  - Daily activity/caloric expenditure
  - Presence of physiologic conditions that may increase energy requirements (e.g., growth, pregnancy, lactation)
  - Presence of localizing GI signs (dysphagia, regurgitation, vomiting, diarrhea)

PHYSICAL EXAM FINDINGS

Poor body condition (or decrease in weight in comparison to historic body weight) +/− poor haircoat, muscle atrophy

ETIOLOGY AND PATHOPHYSIOLOGY

- Body weight is affected by caloric intake, absorptive capacity, metabolic demand, and nutrient losses.
- Weight loss may result from (1) inadequate quantity or quality of diet, (2) inability to prehend or swallow food, (3) regurgitation or vomiting of ingesta, (4) anorexia (loss of desire to eat), (5) inability to digest or absorb ingested nutrients, (6) inability to utilize absorbed nutrients (e.g., diabetes mellitus), (7) increased metabolic rate, (8) increased catabolism, (9) loss of nutrients.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Weight loss is a nonspecific clinical sign. When it is confirmed to not be deliberate (i.e., no weight-loss diet), a broad systemic evaluation beginning with fecal flotation and routine blood and urine tests is indicated. The diagnostic approach is then adapted to results of these tests, the history, and the physical exam.

DIFFERENTIAL DIAGNOSIS

- Weight loss with localizing GI signs:
  - Inability to prehend or masticate food:
    - Dental disease
    - Head trauma
    - Temporomandibular joint disease

        - Masticatory myositis
    - Dysphagia:
        - Neuromuscular disorders
        - Oropharyngeal neoplasia
        - Nasopharyngeal polyp
    - Regurgitation:
        - Esophageal disorders
    - Vomiting (see p. 1175)
    - Small-bowel diarrhea (see p. 305; e.g., protein-losing enteropathies)
    - Large-bowel diarrhea:
        - Does not cause weight loss
- Weight loss due to anorexia/decreased appetite:
    - All GI causes of vomiting
    - Systemic diseases leading to anorexia
    - All systemic causes of vomiting
    - Neoplasia (anywhere)
    - Chronic infections:
        - Viral: feline leukemia virus (FeLV), feline immunodeficiency virus (FIV), feline infectious peritonitis (FIP)
        - Mycotic: blastomycosis, histoplasmosis, cryptococcosis, coccidioidomycosis
        - Bacterial: endocarditis, chronic pneumonia, rickettsial infections (e.g., chronic ehrlichiosis), mycobacterial infections
        - Protozoal: leishmaniasis, hepatozoonosis
    - Chronic pancreatitis
- Weight loss despite normal to increased appetite:
    - Unrecognized vomiting or regurgitation
    - Dietary:
        - Inadequate quantity
        - Poor-quality diet
    - Increased energy demand:
        - Pregnancy
        - Lactation
        - Increased exercise
        - Growth
    - Increased metabolic rate or increased catabolism:
        - Hyperthyroidism (cats)
        - Congestive heart failure
        - Chronic inflammation
    - Inability to utilize nutrients:
        - Diabetes mellitus
    - Nutrient loss:
        - Protein-losing nephropathies (see p. 926):
            - Rarely, protein-losing enteropathies cause weight loss without diarrhea

INITIAL DATABASE

- CBC, biochemistry panel, urinalysis
- FeLV/FIV testing (cats)
- T4 (cats >5 years old)
- Fecal flotation

ADVANCED OR CONFIRMATORY TESTING

- Trypsinlike immunoreactivity (TLI), if there is small-bowel diarrhea, to rule out exocrine pancreatic insufficiency (EPI)
- Fecal α1-protease inhibitor activity if PLE is suspected but no diarrhea
- Abdominal ultrasound to identify GI tract thickening or layer loss, neoplasms, granulomas, pancreatitis
- Upper GI endoscopy to rule out esophageal or gastric foreign body, ulcerations, or luminal neoplasms
- GI biopsies via endoscopy or exploratory laparotomy
- Bile acids to rule out liver failure (portosystemic shunt)
- Urine protein/creatinine (UPC) ratio to rule out protein-losing nephropathy
- Adrenocorticotropic hormone (ACTH) stimulation test to rule out hypoadrenocorticism
- Infectious disease testing when indicated

TREATMENT

TREATMENT OVERVIEW

Treat underlying disease and provide nutritional support.

ACUTE GENERAL TREATMENT

- Improve appetite/symptomatic therapy:
  - Diet change
- Antacids (H2 blockers [famotidine, ranitidine] or proton pump inhibitors [omeprazole])
- Antinausea medications (metoclopramide, ondansetron, maropitant) unless contraindicated
- Appetite stimulants (mirtazapine [dogs], cyproheptadine [cats])
- Increase caloric intake.

CHRONIC TREATMENT

Treat underlying disease and maintain adequate caloric intake.

NUTRITION/DIET

- Enteral nutrition is preferred in animals that have a functioning GI tract.
- Assisted feeding through a nasoesophageal, esophagostomy, gastrostomy, or jejunostomy tube may be required (see p. 1267).
- Parenteral nutrition may be necessary in animals that cannot tolerate enteral feeding or if enteral feeding alone cannot meet caloric requirements.
- Caloric requirements are estimated by calculating resting energy requirements (RER) and illness energy requirements (IER):
  - RER (in kilocalories) can be calculated as:
    - 70 × (body weight [BW] in kilograms)$^{0.75}$
  - IER is calculated by multiplying RER by an illness factor (1.2 to 1.4 for dogs; 1.1 to 1.2 for cats).

BEHAVIOR/EXERCISE

Exercise should not be encouraged until weight is controlled.

POSSIBLE COMPLICATIONS

- Refeeding syndrome if anorexia is chronic and/or severe
- Aspiration pneumonia in patients that are regurgitating, vomiting, or being force-fed

RECOMMENDED MONITORING

- Body weight
- Other testing based on underlying cause

PROGNOSIS AND OUTCOME

Weight stabilization occurs in the majority of surviving patients through treatment of the underlying disease and appropriate nutrition.

PEARLS & CONSIDERATIONS

COMMENTS

- If the patient has other clinical signs (e.g., vomiting, diarrhea, fever, etc.), the diagnostic approach should not focus on the weight loss alone.
- In the initial stages of therapy, changes in body weight often reflect changes in fluid dynamics.

PREVENTION

Dependent upon the underlying cause

CLIENT EDUCATION

Weight loss is caused by a wide array of diseases; many are treatable. Obtaining a diagnosis often requires extensive testing.

Zinc-Responsive Dermatosis

Additional Images Available on Website

BASIC INFORMATION

DEFINITION

Uncommon but well-recognized zinc-responsive scaling disorder of the skin; can be hereditary or secondary to a dietary imbalance

EPIDEMIOLOGY

SPECIES, AGE, SEX

- Syndrome I: age of onset is typically 1-3 years; range: 2 months to 11 years
- Syndrome II: most common in young, rapidly growing dogs

GENETICS & BREED PREDISPOSITION

- Syndrome I: northern canine breeds, such as Alaskan malamute, Siberian husky, and Samoyed; also reported in Doberman pinschers and Great Danes
- Syndrome II: any breed; Great Dane, Doberman pinscher, beagle, German shepherd, German short-haired pointer, Labrador retriever, Rhodesian ridgeback, and standard poodle may be predisposed.

RISK FACTORS: Rapidly growing puppies fed diets deficient in zinc or high in phytates (high plant/grain content) or calcium

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES

- Syndrome I: hereditary
- Syndrome II: dietary

HISTORY, CHIEF COMPLAINT

- Owner may note scaling and crusting dermatosis.
- Pruritus may precede development of other clinical signs and is present in nearly half of cases.

PHYSICAL EXAM FINDINGS

- Focal cutaneous erythema and alopecia progress to scaly and crusted lesions.
- Secondary microbial (bacterial and yeast) dermatitis
- Predilection sites: periocular, ears, bridge of the nose, perioral, footpads, pressure points on limbs. Scrotum, prepuce, perianal region, and vulva may also be affected.
- Dull, dry coat
- Some puppies with syndrome II present with depression, anorexia, delayed growth, fever, and lymphadenopathy.

ETIOLOGY AND PATHOPHYSIOLOGY

- Genetic defect involving zinc absorption reported in Alaskan malamutes.
- Diets high in calcium or phytates (plant/grain products) bind zinc, decreasing absorption.
- Zinc absorption is also negatively affected by essential fatty acid deficiency, high levels of iron in water, or prolonged diarrhea.
- It is suspected that low zinc levels cause poor lytic enzyme function (thus affecting epidermal maturation) or increased epidermal turnover rate (leading to hyperkeratosis).

DIAGNOSIS

DIAGNOSTIC OVERVIEW

The diagnosis is based on identification of lesions both clinically and histopathologically in an animal of a breed that is at risk, an animal that has a current history of nutritional inadequacy (high in phytates, high iron-content drinking water), or an animal with chronic diarrhea.

DIFFERENTIAL DIAGNOSIS

- Superficial necrolytic dermatitis (hepatocutaneous syndrome)
- Dermatophytosis
- Nutritionally deficient diets
- Demodicosis
- Pemphigus foliaceus

INITIAL DATABASE

- Skin scrapings: generally negative
- Fungal (dermatophyte) culture: expect negative result
- If diarrhea is noted, perform fecal flotation and any additional appropriate testing.

ADVANCED OR CONFIRMATORY TESTING

- Skin biopsy: epidermal parakeratotic hyperkeratosis is the most common finding, and follicular parakeratosis is highly suggestive.
- Zinc concentration in serum or hair: not used in small animal clinical dermatology. Overall, lower levels are present in zinc-responsive dermatosis patients, but substantial overlap exists with the normal range.

ZINC-RESPONSIVE DERMATOSIS Alopecia and crusting of the face in a Siberian husky with zinc-responsive dermatosis.

(Courtesy Dr. Stephen Waisglass.)

TREATMENT

TREATMENT OVERVIEW

The goals of treatment are to resolve the scaling +/− alopecia and inflammation, control the secondary microbial dermatitis, and ensure the patient is eating a nutritionally balanced diet.

ACUTE GENERAL TREATMENT

- Assess and correct dietary deficiencies.
- Treat secondary bacterial or yeast dermatitis (see pp. 682 and 951).
- Keratomodulating shampoos (e.g., salicylic acid/sulfur shampoos) to remove scales and crusts
- Syndrome I: Supplementation is recommended at 1-3 mg/kg of elemental zinc daily. Start at the lower dose, but in some cases doses in the order of 2-3 mg/kg may be needed. Zinc gluconate (generic) 5 mg/kg PO q 24 h, or zinc sulfate 10 mg/kg PO q 24 h. Response to treatment is usually noted within 6 weeks. Lifelong treatment is required.
- Syndrome II: Correct diet. Lesions improve within 2-6 weeks in most cases. Some animals require zinc supplementation, as

above.
- Essential fatty acid supplementation (omega-3 and omega-6) may aid zinc absorption.

CHRONIC TREATMENT

- Treatment for patients with syndrome I is usually lifelong.
- It has been suggested that low (0.15 mg/kg PO q 24 h) doses of prednisone or prednisolone can be added to the regimen to aid gastrointestinal (GI) absorption if response is inadequate. Improved response may also be due to an antiinflammatory effect on the skin.
- Different forms of zinc may be tried if there is poor response to therapy. It has been suggested that IV sterile zinc sulfate administration (10-15 mg/kg diluted 1:1 with saline and infused slowly) may help animals that do not respond to oral supplementation because of poor intestinal absorption. Treat weekly for at least 4 weeks (monitor with electrocardiogram [ECG] when administering), then every 1-6 months as maintenance.

DRUG INTERACTIONS

- Zinc salts may reduce the absorption of some fluoroquinolones and chelate oral tetracycline, reducing the absorption of zinc.
- Penicillamine and ursodiol may inhibit zinc absorption.

POSSIBLE COMPLICATIONS

- Emesis: zinc in the form of methionine or acetate may be less likely to cause stomach irritation. If vomiting occurs, lower the dose or give with food.
- Large doses of zinc can inhibit copper absorption in the intestine. Carefully consider the use of zinc in copper-deficient animals.
- IV zinc sulfate treatment may result in cardiac arrhythmias. Always monitor ECG during administration.

PROGNOSIS AND OUTCOME

- Syndrome I: fair to good prognosis in most animals
- Syndrome II: excellent prognosis if cause is of dietary origin

PEARLS & CONSIDERATIONS

COMMENTS

- Zinc chelated as an amino acid such as methionine offers greater bioavailability than sulfate or gluconate, but response has been noted using all forms. If one form is not working, try another.
- Zinc plus linoleic acid (e.g., safflower oil) has been shown to improve skin and coat condition in normal dogs eating a properly balanced diet.
- Avoid confusion regarding zinc formulations: note whether dosed as mg/kg of the compound or mg/kg elemental zinc. Zinc sulfate contains 1 mg element zinc/4.4 mg zinc sulfate; zinc acetate contains 1 mg elemental zinc/3.33 mg zinc acetate; zinc gluconate contains 1 mg elemental zinc/7.14 mg zinc gluconate.

CLIENT EDUCATION

- Syndrome I: animals should not be used for breeding purposes.
- Syndrome II: nutritional counseling on benefits of feeding good-quality diets

AUTHOR: STEPHEN WAISGLASS

EDITOR: MANON PARADIS

Zinc Toxicosis

BASIC INFORMATION

DEFINITION

Syndrome that occurs after ingestion of zinc-containing objects such as pennies, scrap metal pieces, wires, and hardware. Clinical signs arise due to acute gastrointestinal (GI) irritation or hemolysis (zinc-mediated red blood cell [RBC] injury) and possible renal and hepatic damage.

SYNONYMS

Elemental zinc; Zn

EPIDEMIOLOGY

SPECIES, AGE, SEX: Toxicosis is reported mostly in dogs (all breeds and ages, both sexes) from ingesting zinc-containing objects; cats are less likely cases.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Inappetence, lethargy, protracted vomiting, diarrhea
- Red-colored urine
- Animal occasionally may vomit pennies or other metallic objects or pass pennies in the feces
- Animal owners often are unaware of ingestion of any foreign metallic object by their pets
    - In these cases, zinc toxicosis becomes suspected based on hemolytic anemia and/or presence of metallic object in the GI tract on radiographs or in vomitus/feces.

PHYSICAL EXAM FINDINGS

- As already described
- Signs of abdominal discomfort or pain on palpation
- Pale mucous membranes
- Icterus
- Discolored urine (hemoglobinuria)

ETIOLOGY AND PATHOPHYSIOLOGY

Source:

- Metallic zinc is used in galvanizing, welding, and soldering. Zinc salts are used as astringents, antiseptics, deodorants; in galvanized nuts and cage wires; and in smoke generators, wood preservatives, pigments, and insecticides. Zinc gluconate is about 14% elemental zinc and is frequently found in cough drops. Zinc oxide (10%-40%) is found in ointments and sunblocks (see p. 1180).
- U.S. pennies minted after 1982 weigh 2.5 g and are 97.6% zinc and 2.4% copper. Canadian pennies prior to 1997 were approximately 98% copper and 1.75% zinc. From 1997 to 2001, Canadian pennies were made with 96% zinc and 4% copper. Since 2001, Canadian pennies have been made of copper-plated steel (94% steel, 1.5% nickel, 4.5% copper).

Mechanism of Toxicosis:

- Zinc has an antagonistic effect on copper and iron. It can interfere with iron absorption, making RBCs susceptible to hemolysis. Zinc also causes direct, severe GI mucosal irritation.
- Zinc leaches from metallic objects owing to an acidic gastric pH, providing continuous GI absorption. Toxicosis occurs when zinc-containing objects are retained or embedded in the GI tract.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Suspicion of zinc toxicosis arises in one of three contexts: observed ingestion or vomiting/defecation of metallic objects; incidental finding of metallic object on abdominal palpation or radiography; or investigation of hemolytic anemia. A patient in any of these categories should undergo a minimum database of a CBC (hemolytic anemia), serum biochemistry profile, urinalysis, and abdominal radiography. Protracted vomiting, lethargy, diarrhea, inappetence and hemoglobinuria lend further support to the diagnosis. Toxicosis should be confirmed (or ruled out) by measuring concentration of zinc in serum, whole blood or urine.

DIFFERENTIAL DIAGNOSIS

- Other toxicoses: onions/garlic, acetaminophen, mothballs (naphthalene), local anesthetics
- Immune-mediated hemolytic anemia
- Tickborne diseases

INITIAL DATABASE

- CBC: regenerative anemia, hemoglobinemia, reticulocytosis, spherocytosis; neutrophilic leukocytosis
- Serum biochemistry profile: azotemia; elevation in serum bilirubin, liver enzymes, amylase, lipase
- Urinalysis: hemoglobinuria, proteinuria

ADVANCED OR CONFIRMATORY TESTING

Definitive diagnosis: blood or tissue zinc levels

- For blood collection, use special tubes (royal-blue top) and syringes that contain no rubber grommets. Do not use traditional syringes, rubber grommets, and Vacutainer tubes, because the rubberized surfaces contain some amount of zinc and may give erroneous results.
- Toxic levels in dogs:
  - Serum: 10-54 ppm (adequate levels 0.7-2 ppm)
  - Whole blood: 45 ppm has been fatal
  - Liver: 130-436 ppm (adequate levels 30-70 ppm)
  - Kidney: 175-295 ppm (adequate levels 16-30 ppm)
  - Urine: 10-25 ppm (adequate levels 2-5 ppm)

TREATMENT

TREATMENT OVERVIEW

Life-threatening abnormalities, if present, must be identified and managed first: severe anemia may require transfusion, pigment nephropathy should be addressed with intravenous fluids, and GI tract perforation may require medical treatment with or without surgical correction. Then the source of zinc should be removed from the GI tract. Finally, general supportive care is indicated during recovery. Chelation with calcium EDTA or dimercaprol or D-penicillamine is rarely needed after the source of zinc has been removed.

ACUTE GENERAL TREATMENT

- Management of life-threatening abnormalities if present:
  - Anemia: if severe (e.g., hematocrit <20%), consider blood transfusion (see p. 1347).
  - Azotemia, if concurrent with severe hemolysis: brisk intravenous fluid therapy (e.g., 90-130 mL/kg/h, barring preexisting heart disease)
  - Peritonitis from GI tract perforation (see p. 865)
- Removal of zinc source from GI tract:
  - Emesis (see p. 1364): do not induce if animal is already vomiting; always feed the animal first (to avoid unproductive vomiting).
  - Removal through an endoscope: may be possible if the metallic object is small and present in the stomach, but difficult/impossible if there is food in the stomach or with smooth, slippery objects
  - Surgical removal (gastrotomy/enterotomy): last resort, weighing all the risks and benefits before performing surgery; stabilize the animal first (fluids, blood transfusion as needed).
  - Activated charcoal is not indicated because it does not adsorb zinc well.
  - Early and sustained use of antacids until source is removed (calcium carbonate, 70-185 mg/kg/d PO) and/or H2 blockers (famotidine, 0.5-1 mg/kg PO q 12-24 h) to decrease leaching and absorption of zinc.
- Chelation therapy: Note that most cases of zinc poisoning do not require chelation therapy. Animals with zinc toxicosis usually respond well to fluid therapy and other supportive measures once the source of zinc has been removed. In the rare case that

requires chelation, options for chelation therapy include one of the following treatments:
    - Calcium EDTA *(6.6%* solution, equals *66* mg/mL) in dogs: dilute to 10 mg CaEDTA/mL in 5% dextrose and give 25 mg/kg SQ at different sites q 6 h for 2-5 days. Do not exceed 2 g per day, and do not treat for more than 5 consecutive days. In cats: 27.5 mg/kg in 15 mL of 5% dextrose SQ q 6 h for 5 days. Use with caution and monitoring because of risk of nephrotoxicity.
    - Dimercaprol: 2-4 mg/kg SQ or IM q 8-12 h for 2 days
    - D-penicillamine: 27.5 mg/kg/d PO q 6-8 h for 7-14 days
    - Efficacies of dimercaprol and D-penicillamine have not been validated for zinc toxicosis.
- Supportive care:
    - As above. Control severe vomiting with maropitant, 1 mg/kg SQ q 24 h or 2 mg/kg PO q 24 h for 5 days; or metoclopramide, 0.2-0.5 mg/kg SQ q 8 h if needed, provided GI obstruction is ruled out.

POSSIBLE COMPLICATIONS

Liver and renal compromise

RECOMMENDED MONITORING

- CBC
- Serum biochemistry profile (serum bilirubin, renal, and liver values for 1-3 days or until resolution of signs)
- Hematocrit
- Urinalysis

PROGNOSIS AND OUTCOME

- Good with intensive supportive care after removing the source
- Poor if there is overt clinical evidence of multiple organ system damage or failure (liver, kidney, and/or pancreas)

PEARLS & CONSIDERATIONS

COMMENTS

- Toxicosis not likely to occur if zinc-containing objects move out of the GI tract quickly.
- The hematologic and clinical findings in animals with zinc toxicosis are similar to those found for immune-mediated hemolytic anemia (IMHA).
- Zinc toxicosis can cause a positive direct antiglobulin test (Coombs' test) result. Therefore, Coombs' test is not a reliable method of differentiating between IMHA and zinc toxicosis.
- The LD50 of zinc chloride is approximately 100 mg/kg PO.
- The greatest amounts of zinc are present in blood, liver, kidney, skin, lung, brain, heart, and pancreas. Excretion of zinc occurs through the bile and kidneys.

Zinc Phosphide Intoxication

BASIC INFORMATION

DEFINITION

Zinc phosphide is a metallophosphide rodenticide available as 0.5%-10% bait. Acute toxicosis occurs from ingestion of bait and is characterized by progressive bloody vomiting, agitation, discomfort, constant movement or running, vocalization, bruxism (teeth grinding), respiratory distress, muscle tremors, seizures, and death.

SYNONYMS

Gopher or mole killer; Zn3P2, trizinc diphosphide

EPIDEMIOLOGY

SPECIES, AGE, SEX: All species are susceptible; dogs are more frequently involved.

GENETICS & BREED PREDISPOSITION: Animals that do not vomit are at greater risk of toxic effects.

GEOGRAPHY AND SEASONALITY: Increased incidence during greater rodent activity and mobility following harvest.

CONTAGION & ZOONOSIS: Public health significance to veterinary personnel: human inhalation of phosphine off-gas during decontamination procedures can occur (risk of pulmonary and other effects in humans). Typical garlic or dead fish odor of phosphine may not be detectable at low yet hazardous concentrations to humans. If handling a phosphine-intoxicated animal, ensure good ventilation and contact regional hazardous materials authority for safest procedure guidelines; see Acute Treatment, below.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- History of exposure
- Vomiting, often with blood
- Agitation, discomfort, constant movement or running
- Vocalization, teeth grinding
- Muscle tremors, seizure

PHYSICAL EXAM FINDINGS

- As above
- Dyspnea, harsh lung sounds (due to pulmonary edema)
- Signs of cranial abdominal pain
- Cardiac arrhythmias
- Shock
- Slight garlic or rotten fish odor

ETIOLOGY AND PATHOPHYSIOLOGY

Source

- Baits are available as commercial grain-based pellet, tracking powder, or paste.
- Fumigants aluminum phosphide and magnesium phosphide are similar to zinc phosphide in toxicity.
- Some commercial names are Sweeneys Poison Peanuts Mole and Gopher Bait, Dragon Gopher and Mole Killer Pellets, and Dexol Gopher Killing Pellets 2.

Mechanism of Toxicosis

- Onset of clinical signs in most cases is 15 minutes to 4 hours after ingestion; occasionally delayed up to 18 hours.
- Corrosive effects of zinc phosphide can cause signs of cranial abdominal (gastric) pain and bloody vomiting.
- Gastric acid hydrolysis of zinc phosphide liberates highly toxic phosphine gas, which is rapidly absorbed by passive diffusion.

- Phosphine disrupts cellular respiration by interfering with electron transport (cytochrome C) in the mitochondrion, leading to cellular hypoxia, generation of reactive oxygen species, and lipid peroxidation, especially in tissues of high oxygen demand.
- Death is from cardiac arrest most commonly resulting from hypotensive shock, seizures, and pulmonary compromise.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Tentative diagnosis must be based on history of exposure and clinical signs (vomiting, agitation, vocalization, tremors, seizures), as timely testing is not available. Characteristic rotten fish or garlic smell supports diagnosis but poses risk of pulmonary toxicosis to humans. Diagnosis can be confirmed by presence of zinc phosphide in the stomach contents, liver, or kidney (collect samples in airtight jar) through a diagnostic laboratory.

DIFFERENTIAL DIAGNOSIS

- Strychnine intoxication
- Metaldehyde intoxication
- Organophosphate or carbamate insecticides intoxication
- Arsenic intoxication
- Primary central nervous system (CNS) disease (neoplasia, encephalitis, other)
- Hepatic encephalopathy

INITIAL DATABASE

- Chest radiographs: pulmonary edema
- Acid-base status: respiratory and metabolic acidosis
- Electrocardiogram (ECG): arrhythmias, nonspecific evidence of myocardial ischemia (e.g., ST segment elevation or depression)
- Baseline CBC and serum chemistries generally unremarkable:
  - Baseline electrolytes: possibly decreased Mg^{++}, Ca^{++}
- Coagulation profile: increased

ADVANCED OR CONFIRMATORY TESTING

- Freeze gastric contents, vomitus, liver, and kidney in airtight containers for zinc phosphide analysis.
- Silver nitrate paper qualitative screen of gastric fluid may help detect presence of phosphine gas. Phosphine reacts with silver nitrate, changing the test paper color to black and indicating a positive reaction (follow label directions).

TREATMENT

TREATMENT OVERVIEW

Because of human health risk of phosphine gas, owners or veterinary staff should feed the patient margarine/oil and magnesium hydroxide to help with toxin neutralization. Then treatment goals are early decontamination (induction of vomiting in a well-ventilated area and administration of activate charcoal) for patients not showing any clinical signs. Additional treatment is implemented based on the occurrence of signs: seizure control, treatment of noncardiogenic pulmonary edema, and supportive care to minimize or prevent renal/hepatic failure, while protecting the veterinarians and staff.

ACUTE GENERAL TREATMENT

- Reduce liberation of phosphine gas:
  - 1-3 tbsp (15-45 mL) margarine or olive/corn/vegetable oil (high in unsaturated lipids) fed on a piece of bread to an affected, conscious animal PO may help quench reactive oxygen species from phosphine in the stomach. Useful prior to presentation and vomiting induction.
  - Magnesium hydroxide 10-60 mL PO/animal prior to presentation and vomiting induction to increase gastric pH. A commonly available preparation of magnesium hydroxide is Milk of Magnesia.
- Decontamination of patient:
  - Emesis (see p. 1364). Indicated in patients not showing clinical signs. Apomorphine is preferred: 0.04 mg/kg IM or IV, or part of a crushed tablet dissolved in water instilled into conjunctival sac. Note: Use of 3% hydrogen peroxide, 1-2 mL/kg PO, maximum 45 mL in dog is not contraindicated. However, it is possible that its use may enhance liberation of

phosphine gas (weigh pros and cons before using in well-ventilated area).
    - Activated charcoal, 1-3 g/kg PO (Caution: aspiration risk in vomiting animal; see p. 1281).
- Control seizures. One of the following may be used:
    - Diazepam, 0.5-2 mg/kg IV; repeat as needed.
    - Pentobarbital, 10-30 mg/kg IV to effect, repeat as needed.
    - Propofol, up to 5-6 mg/kg slow IV to effect, then constant rate IV infusion 0.1-0.6 mg/kg/min titrated to effect
- Stabilize respiratory, cardiovascular, and neuromuscular systems:
    - Place endotracheal tube if needed, with proper gas evacuation.
    - Supplemental oxygen
    - Treat hypovolemic shock with crystalloid or colloid fluids; crystalloid dose 80-90 mL/kg/h for dogs, 40-60 mL/kg/h for cats. Synthetic colloid dose approximately 20 mL/kg/d for dogs, 10-20 mL/kg/d for cats (adjust based on case parameters).
    - Corticosteroids (dexamethasone, 0.1-0.2 mg/kg IV) if needed
    - Monitor acid-base status, and correct metabolic or respiratory acidosis with sodium bicarbonate as needed.
    - Monitor electrolytes; correct any deficiency (Ca^{++}, Mg^{++}, and K^{+}).
    - Control pain with narcotic analgesics (e.g., fentanyl transdermal patches 25-100 mcg/h; injectable opiates first if acute pain).
    - Monitor serum biochemistry profiles for 72 hours for delayed hepatic and renal injury.
- Exogenous scavengers:
    - *N*-acetylcysteine reduced myocardial injury in laboratory animals exposed to aluminum phosphide: loading dose 140-280 mg/kg PO or slow IV, then 70 mg/kg PO q 6 h for six treatments.

POSSIBLE COMPLICATIONS

Renal, cardiac, and/or hepatic compromise

RECOMMENDED MONITORING

Respiratory, cardiac, hepatic, and renal functions for 72 hours after exposure

PROGNOSIS AND OUTCOME

- Good for animals not showing clinical signs 8-16 hours after exposure
- Guarded to poor if cardiac arrhythmias, shock, or pulmonary edema develop; death usually within 6 hours
- Fair to good for cases surviving 24 hours

PEARLS & CONSIDERATIONS

COMMENTS

- Early vomiting may reduce risk of serious toxicity in dogs.
- Human inhalation of phosphine off-gas during decontamination procedures can occur and is hazardous. Typical garlic/dead fish odor of phosphine may not be detectable at low yet hazardous concentrations to humans.
- Baits may retain potency for 3 years in a dry environment.
- Toxic dose in dogs and cats is 20-40 mg/kg.
- Only 1 tbsp of 2% pellet bait contains approximately 180 mg zinc phosphide, a significant risk for a 10-kg dog.
- Delayed hepatic or renal injury is possible 48-72 hours following exposure.

TECHNICIAN TIPS

- As with any toxicosis, having the owner bring the container can confirm active ingredients (label and/or brand name search); technicians who speak to owners on the telephone should encourage this if the dog is likely to have ingested zinc phosphide, and technicians should also recommend the owner take immediate measures to reduce phosphine gas (see Acute General Treatment, above).
- Do not wash vomitus down drain, as water will liberate phosphine gas. Double-bag and dispose of in the trash.

CLIENT EDUCATION

- Keep all baits away from dogs.
- Dogs can dig mole/gopher holes and retrieve the bait in the yard/garden.

EDITOR: SAFDAR A. KHAN

1ST EDITION AUTHOR: MICHAEL W. KNIGHT

Zinc Oxide Toxicosis

BASIC INFORMATION

DEFINITION

Generally acute self-limiting vomiting, lethargy, and anorexia occurring after ingestion of concentrated (10%-40%) zinc oxide–containing products such as diaper rash ointments, creams, hemorrhoid preparations, calamine lotion, and some sun blocks

SYNONYMS

Zinc oxide: Chinese white, zinc white, ZnO

EPIDEMIOLOGY

SPECIES, AGE, SEX: All animals susceptible; cases commonly involve dogs.

RISK FACTORS: Younger, unsupervised pets are most likely to ingest products containing zinc oxide.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- Acute onset of vomiting
- White-colored material present in the vomitus (looks like product ingested) within hours of the ingestion
- Presence of teeth marks on the container
- Animals usually remain bright, alert, and responsive.

PHYSICAL EXAM FINDINGS: Unremarkable, aside from nausea, vomiting, and mild lethargy

ETIOLOGY AND PATHOPHYSIOLOGY

- Zinc oxide–containing ointments or creams are used as topical skin protectants, astringents, and bactericidal agents.
- Most zinc oxide ointments or creams contain 10%-40% zinc oxide.
- Some commercial zinc ointment preparations may also contain varying concentrations of vitamin A or D or local anesthetics (benzocaine), cod liver oil, beeswax, petrolatum, or mineral oil.
- Zinc salts are usually irritating to gastrointestinal (GI) mucosa.
- Mild to moderate vomiting occurs secondary to acute gastric irritation.
- Vomiting is self-limiting but may be exacerbated if unlimited water ingestion is allowed before resolution.
- Some dogs will occasionally show an allergic-type reaction (urticaria, angioedema).

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Evidence of exposure to zinc oxide–containing product and presence of self-limiting gastritis should be considered diagnostic.

DIFFERENTIAL DIAGNOSIS

- Dietary indiscretion/indigestion/garbage ingestion
- Pancreatitis
- Parvoviral enteritis
- Differentiation: zinc oxide characteristically gives vomit a white color.

INITIAL DATABASE

Not generally required; no systemic signs are expected, and diagnostic testing is rarely indicated (self-resolving problem)

TREATMENT

TREATMENT OVERVIEW

Withhold food and water for 2 hours. Control vomiting and maintain hydration as needed (rarely necessary).

ACUTE GENERAL TREATMENT

- Nothing by mouth (NPO) until 2 hours after last episode of vomiting
- Consider using antiemetics (rarely needed) such as maropitant, 1 mg/kg SQ q 24 h in dogs; or metoclopramide, 0.2-0.5 mg/kg SQ q 6-12 h in dogs, if vomiting is severe and no longer productive (zinc oxide-containing product has been expelled), and gastrointestinal tract obstruction (e.g., with the container as a foreign body) has been ruled out.
- Most cases do not require IV fluids, because clinical signs resolve within 12 hours. Allergic reactions may persist longer (24 hours).
- For allergic reaction: diphenhydramine (dogs: 2-4 mg/kg PO q 8-12 h or 1 mg/kg IM or SQ q 8-12 h; cats: 0.5-mg/kg PO q 12 h or 2 mg/kg IM q 12 h)

POSSIBLE COMPLICATIONS

GI foreign body if the container was ingested

PROGNOSIS AND OUTCOME

- Expect rapid and complete recovery within 24 hours.
- Ingestion is not expected to result in zinc toxicosis (hemolytic anemia, renal damage), because most dogs vomit. Unlike a solid zinc-containing object, which tends to remain in the GI tract long enough to allow absorption of zinc, ointment/cream is readily removed from stomach.

PEARLS & CONSIDERATIONS

COMMENTS

- Single acute ingestion of zinc oxide–containing ointments or creams is not likely to result in zinc toxicosis.
- Repeated use of concentrated zinc oxide–containing products can result in zinc toxicosis, however. Zinc toxicosis has been reported in a dog when 40% zinc oxide ointment was applied dermally for 4 days and dog licked most of the ointment after application.
- Cod liver oil in products containing zinc oxide makes them attractive to dogs.

TECHNICIAN TIP

Prevention of licking (via application of an Elizabethan collar, for example) helps reduce the likelihood of toxicosis when zinc oxide creams are applied to dogs' skin, such as in the treatment of superficial dermatitis or with sunscreen in dogs sensitive to ultraviolet light (immune-mediated skin disease, hairless skin).

PREVENTION

Keep diaper rash products out of pet's reach.

AUTHOR & EDITOR: SAFDAR A. KHAN

1ST EDITION AUTHOR: MARY M. SCHELL

Yew Toxicosis

BASIC INFORMATION

DEFINITION

Toxicosis resulting from accidental ingestion, typically by dogs, of dried or fresh yew plant material followed by development of vomiting, muscle weakness, seizures, cardiac arrhythmias, coma, and death

EPIDEMIOLOGY

SPECIES, AGE, SEX: Dogs are more likely to be involved than cats; all breeds, ages, and both sexes are susceptible.

RISK FACTORS

- Yews are toxic both as green and dried plant material.
- All parts of the yew are toxic except for the red, fleshy fruit surrounding the hard seed. The hard seed coat is resistant to digestive enzymes. Clinical signs are unlikely if the seed is swallowed whole, but absorption from a cracked or partly chewed seed is possible.
- *Taxus brevifolia* contains only minimal concentrations of toxic alkaloids and therefore has lower toxic potential than other yews.

GEOGRAPHY AND SEASONALITY

- The most common ornamental yews are *T. baccata* (English yew) and *T. cuspidata* (Japanese yew).
- In the eastern United States, *T. canadensis* (American yew) is the most common native yew; in Florida, *T. floridana* is the most common native species; and in the western United States, *T. brevifolia* (Western or Pacific yew) is most frequently seen.
- Taxine content is often higher in the winter than in the summer.

CLINICAL PRESENTATION

HISTORY, CHIEF COMPLAINT

- History of exposure to dried or fresh plant material.
- Recent history of vomiting, with the presence of plant material noted in the vomitus.
- The onset of systemic clinical signs is extremely rapid (within 30 minutes to 3 hours post ingestion), and progression to death may happen within a few hours.
- In increasing degree of severity over time, the spectrum of clinical complaints includes vomiting, muscle weakness, seizures, coma, and death.

PHYSICAL EXAM FINDINGS

- Signs of abdominal pain
- Mydriasis
- Tachycardia or bradycardia (both occur fairly commonly with yew toxicosis)
- Hypotension
- Respiratory distress or arrest

ETIOLOGY AND PATHOPHYSIOLOGY

- *Taxus* spp. (yew) are commonly used as ornamental evergreen shrubs (Japanese yew *[Taxus cuspidata],* English yew *[Taxus baccata],* American yew *[Taxus canadensis],* Chinese yew *[Taxus chinensis],* Pacific or Western yew *[Taxus brevifolia],* Florida yew *[Taxus floridana]*).
- Yew alkaloids (taxines) are calcium and sodium ion channel blockers that gradually induce bradycardia and ultimately cardiac arrest.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Generally based on known or possible ingestion of yew; confirmation is via identification of plant parts in vomitus. Extremely rapid course of toxicosis means that diagnosis is often retrospective (made at postmortem exam).

DIFFERENTIAL DIAGNOSIS

- Cardiac glycoside-containing plants (e.g., oleander, foxglove)
- Calcium channel blockers (diltiazem, verapamil) toxicosis
- Caffeine toxicosis (methylxanthines)

INITIAL DATABASE

- CBC, serum biochemistry profile, urinalysis: hypokalemia possible
- Electrocardiogram (ECG; see 1253): a wide variety of arrhythmias is possible and fairly common, most commonly atrioventricular (AV) block, ventricular tachycardia, and (ultimately with severe intoxications) ventricular fibrillation/cardiac arrest.
- Blood pressure (see 1209) (hypotension possible)

ADVANCED OR CONFIRMATORY TESTING

- Taxines (or metabolites) can be identified in vomitus and stomach contents by gas chromatography, mass spectrometry, and silica gel thin-layer chromatography, although the lengthy turnaround time of such advanced testing usually precludes its use clinically.
- Necropsy: the diagnosis of yew poisoning is generally based on the presence of yew plant in the gut. Taxine affects electrical activity of the heart, so no significant lesions are typically found on necropsy. Fatty degeneration of the kidney, congestion of lungs, and inflammation of the gastrointestinal (GI) tract are possible.

TREATMENT

TREATMENT OVERVIEW

Given the rapid course of progression and possibility of fatal intoxication, yew toxicosis is considered a medical emergency. Induction of vomiting, followed by administration of activated charcoal can be lifesaving, particularly if implemented within 2 hours of ingestion prior to the onset of clinical signs of toxicosis. If clinical signs are present, general treatment consists of managing cardiac arrhythmias, controlling seizures, and providing supportive care as needed.

ACUTE GENERAL TREATMENT

- Evacuation of ingested plant material: in animals not showing clinical signs:
  - Apomorphine, 0.03-0.04 mg/kg IV or IM, or crush tablet portion with water and instill into conjunctival sac and rinse following emesis; or hydrogen peroxide 3%, 2 mL/kg PO (max 45 mL [in large dogs]), repeat in 10 to 15 minutes if no vomiting. Emesis may not remove all plant material from the GI tract. If the ingestion was small and/or the patient has not eaten anything else, some clinicians feed a tasty meal immediately prior to inducing vomiting, to allow mixing and agglutination of plant material with food that is then vomited.
  - Gastric lavage (plant material not easily removed through tube)
  - Endoscopic removal of plant parts
  - Activated charcoal (1-2 g/kg PO) with a cathartic such as sorbitol (70%) 1-3 mL/kg; mix with charcoal; use labeled dose for commercial products.
- Treat cardiac arrhythmias as needed:
  - Ventricular tachyarrhythmias (see 1165): correct hypokalemia if present and consider lidocaine (dogs: 2 mg/kg IV; cats: use with caution), procainamide (dogs: 6-8 mg/kg IV; cats: 1-2 mg/kg IV), propranolol 0.1 mg/kg slow IV, or esmolol 0.2-0.5 mg/kg slow IV to effect.
  - Sinus bradycardia: atropine, 0.04 mg/kg IV
- Control seizures (see pp. 353 and 1009): diazepam (dogs/cats: 0.25-0.5 mg/kg IV) or phenobarbital (dogs/cats: 2-5 mg/kg IV, higher doses often used in dogs)
- IV fluids and oxygen as needed
- Correct electrolyte abnormalities as needed.

DRUG INTERACTIONS

Sodium channel blockers (proarrhythmia), calcium channel blockers may potentiate arrhythmias.

RECOMMENDED MONITORING

- ECG (arrhythmias)
- Blood pressure (hypotension)
- Serum electrolytes
- Central nervous system (CNS) signs
- Respiratory rate and effort

PROGNOSIS AND OUTCOME

- Good if treated early and aggressively (prior to onset of clinical signs)
- Poor if systemic effects are present, especially cardiac arrhythmias

PEARLS & CONSIDERATIONS

COMMENTS

- All species of yews should be considered toxic, but there is great variability in taxine content.
- Tetanic epileptiform seizures are reported clinically in dogs but not reproduced experimentally.
- Toxic dose for dogs is 30 g (approximately 2 tbsp) of plant material.

TECHNICIAN TIP

Ensure that vomitus and ingesta are disposed of safely, to avoid consumption and reintoxication by other dogs (or the same dog).

PREVENTION

Keep pets away from yew bushes and clippings.

CLIENT EDUCATION

Dried shrubbery and trimmings are still toxic.

EDITOR: SAFDAR A. KHAN

1ST EDITION AUTHOR: TINA WISMER

Xylitol Toxicosis

BASIC INFORMATION

DEFINITION

Xylitol is a 5-carbon sugar alcohol used as a sweetener in gums, candies, confectionery/baked goods, and in some medications. Toxicosis is characterized by hypoglycemia leading to weakness, lethargy, disorientation, seizures, and ataxia usually within 12 hours after ingestion. Hepatotoxicity can occur in 12-48 hours in some dogs and may be idiosyncratic (individual susceptibility). Toxicosis has been fatal in some dogs.

SYNONYMS

- Xylite, Eutrit, Newtol, Xyliton
- Chemical names are 1,2,3,4,5-pentapentanol or 1,2,3,4,5-pentahydroxypentane.
- Many “sugar-free” products contain xylitol as a sweetener.

EPIDEMIOLOGY

SPECIES, AGE, SEX: Toxicosis has been documented in dogs only. No known age, sex, or breed predisposition.

RISK FACTORS

- Animals with preexisting liver disease may be at increased risk for hepatotoxicosis.
- Young animals may be more prone to developing hypoglycemia.

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES: Xylitol toxicosis is an acute syndrome.

HISTORY, CHIEF COMPLAINT

- Evidence of chewed up package; gum or wrappers in the vomitus/stool
- Lethargy, vomiting, weakness, disorientation, ataxia, seizures, typically 30 minutes to 12 hours after ingestion.
- Some dogs develop both hypoglycemia and acute liver failure. Some dogs do not show evidence of hypoglycemia but may have signs of acute hepatic injury (see p. 503) in 12-48 hours.

PHYSICAL EXAM FINDINGS

- Nonspecific lethargy, vomiting, weakness
- With marked hypoglycemia: ataxia, disorientation, seizures
- Evidence of bleeding disorder is common: petechiae, ecchymoses, gastrointestinal hemorrhage, oozing from venipuncture sites.
- Vital signs usually within normal range (body temperature, respiratory rate and character, heart rate)

ETIOLOGY AND PATHOPHYSIOLOGY

- Toxicosis occurs acutely when dogs eat large amounts of xylitol-containing products.
- In humans, xylitol does not cause significant increase in insulin or blood glucose levels, but in dogs, xylitol causes a rapid and dose-dependent increase in blood insulin and concomitant decrease in blood glucose concentration.
- Mechanism of hepatotoxicosis in dogs may be necrosis of hepatocytes due to adenosine triphosphate (ATP) depletion, resulting in cell necrosis; or production of reactive oxygen species, resulting in damage to cell membranes and macromolecules.

DIAGNOSIS

DIAGNOSTIC OVERVIEW

Diagnosis rests on any combination of history (observed or suspected ingestion), physical exam (signs consistent with hypoglycemia and/or liver failure), and results of routine laboratory testing (hypoglycemia +/− signs of acute liver injury +/− coagulopathy). No specific confirmatory test exists.

DIFFERENTIAL DIAGNOSIS

- Rule out other causes of hypoglycemia:
  - Toxicologic: Insulin overdose, anti-diabetic medications overdose (sulfonylureas)
  - Nontoxicologic: Insulinoma, juvenile hypoglycemia, starvation, sepsis
- Rule out other causes of hepatotoxicosis:
  - Toxicologic: acetaminophen, blue-green algae, sago palm, mushrooms (*Amanita* type), zinc phosphide, mycotoxin (aflatoxins), nonsteroidal antiinflammatory drug (NSAID) toxicosis
  - Nontoxicologic rule outs: bacterial hepatitis, idiopathic chronic hepatopathy, viral hepatitis, leptospirosis

INITIAL DATABASE

- CBC: thrombocytopenia common; mean = 137 × 10^9 platelets/L
- Serum biochemistry profile, specifically including glucose, electrolyte, and liver enzyme levels (baseline on presentation):
  - Hypoglycemia (mild to severe; lowest reported = 26 mg/dL [1.5 mmol/L])
  - Marked liver enzyme elevations common (e.g., ALT: 1000 to >10,000 IU/L; normal <120 IU/L).
  - Hyperbilirubinemia common (mean 4.1 mg/dL; normal <0.6 mg/dL)
  - Mild to marked hyperphosphatemia
- Coagulation panel:
  - Prothrombin time (PT) often elevated (36 to >100 seconds)
  - Activated partial thromboplastin time (APTT) markedly elevated (>100 seconds) in many/most dogs

ADVANCED OR CONFIRMATORY TESTING

Necropsy findings include icterus, hepatic necrosis, peritoneal and gastrointestinal (GI) petechiae and ecchymoses, hemorrhage into the GI tract, and mediastinal hemorrhage.

TREATMENT

TREATMENT OVERVIEW

Mainstays of therapy are to treat seizures (likely due to hypoglycemia) if present; induce vomiting if ingestion occurred within 6 hours and patient is not yet showing clinical signs, to manage delayed hepatotoxicosis if present; and to address bleeding tendencies prophylactically. The clinical presentation and evolution of the case dictates which aspects of treatment are necessary.

ACUTE GENERAL TREATMENT

- Management of hypoglycemia and associated signs, including seizures:
  - 5% dextrose, 20 mL/kg IV bolus followed by 2 mL/kg/h IV; adjust according to blood glucose level measured q 2-4 h.
  - Oral source of dextrose (e.g., Karo syrup) to lick if dog is able to swallow; give small frequent meals.
- Decontamination in asymptomatic patient:
  - Induce vomiting with oral administration of 3% hydrogen peroxide or apomorphine (see p. 1364)
  - Activated charcoal: do not give; not expected to be effective.
- Gastric lavage (see p. 1281): only if large dose has been ingested and vomiting cannot be induced.
- Treat liver damage (see p. 503).
- Treat bleeding disorders:
  - Significant (>double, with or without overt bleeding) elevations in PT and/or APTT warrant fresh frozen plasma transfusion (see p. 1347).
  - Severe thrombocytopenia, especially if solely associated with bleeding (i.e., coagulation times are normal), may warrant replacement via whole-blood transfusion.

CHRONIC TREATMENT

S-adenosyl-L-methionine (SAMe), 18 mg/kg PO q 24 h for 1-3 months if evidence of hepatotoxicosis

NUTRITION/DIET

- Karo syrup, honey, or corn syrup, together with frequent feeding of small meals, may be helpful initially for hypoglycemia.

- Optimal protein diet for liver damage (see p. 513)

DRUG INTERACTIONS

Metabolism and pharmacokinetic parameters of many medications can change due to liver damage. Dose adjustments should be made accordingly.

POSSIBLE COMPLICATIONS

- Coagulopathy secondary to acute liver failure and/or disseminated intravascular coagulation
- Hyperthermia secondary to seizures

RECOMMENDED MONITORING

- Monitor blood glucose every 2-4 hours for 12-24 hours in all patients (whether showing overt signs of hypoglycemia or not).
- Recheck serum biochemistry profile (liver enzyme levels) at 24, 48 hours. If high, monitor until return to normal.
- Recheck coagulation profile at 24, 48 hours.
- Neurologic signs of hypoglycemia

PROGNOSIS AND OUTCOME

Prognosis is good with control of hypoglycemia. Guarded if hepatic necrosis and coagulopathy develops.

PEARLS & CONSIDERATIONS

COMMENTS

- Hypoglycemia can occur at doses of >75-100 mg/kg.
- Hepatotoxicity typically occurs at higher doses >500-1000 mg/kg, but since it is possibly an idiosyncratic reaction, monitoring liver enzymes is suggested in most cases, especially if hypoglycemia develops.
- Amount of xylitol in gums and candies varies widely; sugar-free gums can contain as little as 9 mg of xylitol per piece, and some brands may contain up to 2 g per piece.
- Some medications, rinses, toothpastes may also contain xylitol (variable amount).
- Sorbitol, maltitol, or maltitol syrup present in some sugar-free products are not believed to induce hypoglycemia or liver damage in dogs.
- Splenda (sucralose), Sweet'n Low (saccharin, dextrose, and cream of tartar), and Equal (aspartame, dextrose, and maltodextrin) do not contain xylitol.

PREVENTION

Keep xylitol-containing products out of reach of dogs.

TECHNICIAN TIPS

Label may provide information on the amount of xylitol or other sugar-free alcohols present in the product.

CLIENT EDUCATION

Keep xylitol containing gum, cookies, oral hygiene products, and other sources away from dogs.

Overview

This section, Diseases and Disorders, aims to summarize the most important clinical entities in small-animal practice. These entities include specifi c disease syndromes and general clinical signs. The following pages summarize several hundred of the most frequently encountered diseases and disorders. Over 100 more, which are encountered less frequently but are well recognized in veterinary practice and are equally complete and up to date, are accessible online in this same format at www. clinicalvetadvisor2.com.

BASIC INFORMATION

DEFINITION

a brief explanation of the meaning of this disease or disorder

SYNONYMS

where appropriate, other terms used interchangeably to name this disease or disorder

EPIDEMIOLOGY

SPECIES, AGE, SEX

the typical signalment of affected individuals

GENETICS & BREED PREDISPOSITION:

information regarding possible hereditary factors

RISK FACTORS

elements that might predispose a patient to this disease or disorder

CONTAGION & ZOONOSIS:

important information regarding infectious spread of certain diseases

GEOGRAPHY AND SEASONALITY:

features that would help to raise or lower the clinician's index of suspicion for a disease or disorder, based on environment and timing of occurrence

ASSOCIATED CONDITIONS & DISORDERS:

entities that occur simultaneously or as a result of this disease/ disorder

CLINICAL PRESENTATION

DISEASE FORMS/SUBTYPES:

if applicable, the different variants of a disease a clinician should consider

HISTORY, CHIEF COMPLAINT

the information provided by the owner or caretaker (history), together with the primary reason for seeking veterinary attention (chief complaint)

PHYSICAL EXAM FINDINGS

the relevant abnormalities—or, if important, relevant normal findings—associated with the disease/disorder

ETIOLOGY AND PATHOPHYSIOLOGY

The mechanisms and pathways according to which the disease or disorder begins and then evolves

DIAGNOSIS 

DIAGNOSTIC OVERVIEW

New to this edition, this segment is a brief summary that states what is appropriate to achieve a functional clinical diagnosis in most cases of the disorder. The goal of the Diagnostic Overview is to give direction to the reader/practitioner for applying the information provided subsequently. The result is diagnostic guidance, rather than just a list of possible diagnostic tests.

DIFFERENTIAL DIAGNOSIS

Other diseases or disorders that may mimic the one under discussion, and about which the reader should be aware

INITIAL DATABASE

A summary of basic clinical tests that are appropriate when this disease/disorder may be present. These are largely tests that should be accessible in most outpatient clinics or facilities.

ADVANCED OR CONFIRMATORY TESTING

Diagnostic tests that are performed if the initial database is insuffi cient for establishing the diagnosis. Some of these tests may be performed easily in any clinic or hospital, whereas others may require referral to a specialty center.

TREATMENT 

TREATMENT OVERVIEW

Like the Diagnostic Overview, a new section that summarizes the goals and priorities of treatment. The purpose is to offer guidance in the application of treatment information.

ACUTE GENERAL TREATMENT

Those forms of treatment that are instituted promptly, either because treatment is simple or because of immediate need

CHRONIC TREATMENT

When necessary, ongoing treatment typically provided at home

NUTRITION/DIET

Previously grouped within the preceding two segments, this area covers alterations of food intake or food type that may assist in treatment.

BEHAVIOR/EXERCISE

Information pertaining to deliberate changes in physical activity (increase, decrease, or new) and any forms of treatment related to behavioral modifications.

DRUG INTERACTIONS

Relevant information regarding incompatibility of two or more medications commonly used in the treatment of the disease/disorder. This section by necessity is perhaps one of the least comprehensive; the reader is advised to seek information from clinical pharmacology sources to assist in identifying potential or real problems..

POSSIBLE COMPLICATIONS

Selected, recognized problems that may occur as a result of the disease process alone or as a complication of treatment to be sought and addressed if it occurs

RECOMMENDED MONITORING

Methods the reader/practitioner should use for ensuring that treatment and/or resolution of the disease or disorder is proceeding as expected

PROGNOSIS AND OUTCOME 

The expected evolution of the disease or disorder, with or without treatment. Important elements include survival time, survival rate, and expected variations in clinical progression.

PEARLS & CONSIDERATIONS 

PEARLS

Single items of counterintuitive observations, pitfalls to avoid, and other important points

PREVENTION

Methods to avoid recurrence or reduce occurrence of new cases

TECHNICIAN TIPS

New to this edition, this segment provides information relevant to nursing care and the role of the veterinary technician in managing cases of this disease disorder.

SUGGESTED READING

Every disease and disorder has at least one outside source for additional consultation. In most cases, there are others as well. In addition to the Suggested Reading in the printed version of this text, be sure to check the online version for expanded lists at: www.clinicalvetadvisor2.com.

Artificial Insemination

OVERVIEW AND GOAL

To effectively deliver fresh, chilled, or frozen-thawed semen into the cranial vagina

INDICATIONS

Convenience (geographic separation of dam and sire), maximizing use of valuable semen, ineffective natural mating (e.g., inexperienced/uncooperative male)

CONTRAINDICATIONS

Poor timing/incorrect detection of estrus; systemic illness or other medical disorder likely to compromise successful fertilization; poor technique and/or materials and equipment; semen quality is not optimal, or the total number of viable sperm is not adequate (arbitrarily, <50 million motile sperm for small or toy breeds or <100 million motile sperm for medium, large breeds), which is a relative contraindication because acceptable results may be obtained, especially if switching to transcervical insemination (see p. 1346) or surgical intrauterine insemination.

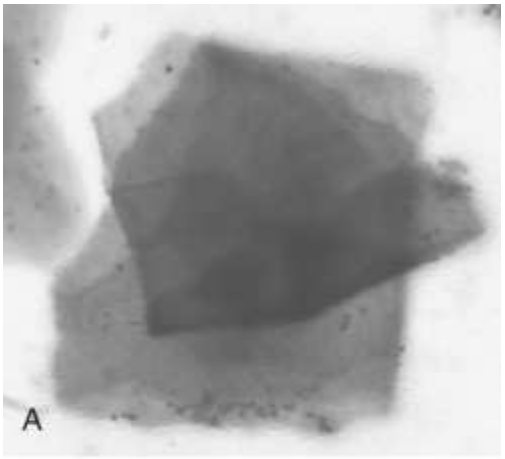
EQUIPMENT, ANESTHESIA

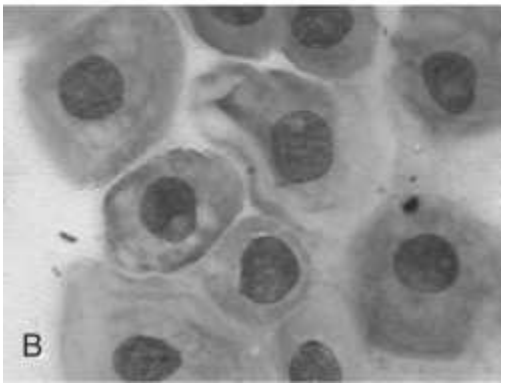
The procedure is generally performed awake. Required materials and equipment include:

- Latex examination gloves
- Sterile water-soluble lubricant
- Semen in sterile pipette or straw
- Sterile syringe for expelling the semen in the pipette

ANTICIPATED TIME

10 minutes

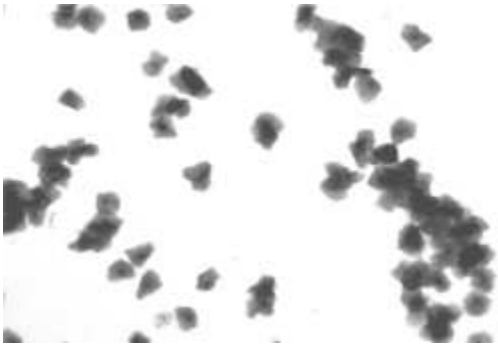




ARTIFICIAL INSEMINATION Vaginal smears stained with Romanowski stain and observed with bright-field microscopy. **A**, Estrus; superficial epithelial cells observed at 1000× magnification. **B**, Diestrus; parabasal epithelial cells observed at 400× magnification.

PREPARATION: IMPORTANT CHECKPOINTS

- Above all, the insemination process should be timed as optimally as possible. This means inseminating 1-4 days after ovulation.
- For optimal results, 2 inseminations should be planned 24-72 hours apart in this window of time.
- Methods for estrus detection and estimation of anticipated time of ovulation require hormonal assays, vaginoscopy, vaginal cytologic examinations (see figure), or a combination thereof (see pp. 155 and 1361).
- Semen which has been properly handled and is of good quality must be available.
- The help of one or two assistant(s) is very useful for basic restraint and handling of the bitch.



ARTIFICIAL INSEMINATION Vaginal smear depicting 100% cornification (superficial and large intermediate squames), consistent with estrus. Smear stained with Romanowski stain and observed with bright-field microscopy at 100× magnification.

POSSIBLE COMPLICATIONS AND ERRORS TO AVOID

- Urethral catheterization with the pipette; avoided by advancing the pipette along the lateral (left or right) aspect of the vagina
- Vaginal injury; avoided by concurrent gentle palpation of the vagina and cervix abdominally, and avoidance of pressure if resistance is met while advancing the pipette
- The semen should be deposited specifically in the cranial-most part of the vagina as close to the cervix as possible to increase the likelihood of success.

PROCEDURE

- The bitch is placed standing in a location that is comfortable for the inseminator, typically an examination table for small dogs and the ground for medium- to large-breed dogs.
- An assistant restrains the bitch and draws her tail to one side (or this can be done by a second assistant).
- The inseminator dons gloves and holds the semen-filled pipette in the right hand if the inseminator is right-handed.
- The inseminator parts the labia and elevates the vulva dorsally using the hand not holding the pipette.
- The pipette tip is placed in the vestibule and elevated dorsal to the brim of the pelvis, and lateral (left or right) to avoid the urethral papilla.
- The pipette is advanced gently. The inseminator releases the labia and uses the non-pipette hand now to palpate the abdomen and locate the cervix.
- The pipette continues to be advanced until its tip is felt with the fingertips, transabdominally, to be immediately caudal to the cervix.
- At this time, the bitches hindquarters are elevated at a 30- to 45-degree angle; the inseminator then delivers the semen by depressing the plunger on the syringe connected to the pipette.

POSTPROCEDURE

- With insemination into the cranial vagina, it is considered advantageous to maintain the bitch's hindquarters elevated for 5-10 minutes to improve delivery of semen to the uterus. In the dog, spermatozoa first reach the uterus 30-120 seconds after insemination into the cranial vagina when the bitch is positioned with elevated hindquarters, but this process is hindered when the bitch is left in a horizontal (normal) posture after vaginal artificial insemination.
- “Feathering” of the vulva and perineum may be performed while the bitch's hindquarters are elevated, to induce uterine contractions and further favor movement of spermatozoa into the uterus.

ALTERNATIVES AND THEIR RELATIVE MERITS

Fertile dogs experience normal pregnancy rates and litter sizes following intravaginal inseminations; however, intracervical or surgical uterine inseminations may be advised for breeding bitches with frozen-thawed semen or low sperm doses.

AUTHOR: CARLOS PINTO

Arthroscopy

OVERVIEW AND GOALS

Arthroscopy is the use of a rigid endoscope—fitted with a lens, a fiberoptic light source, a video camera, and a fluid ingress—to magnify, view, and assess the intraarticular anatomy of a joint. Assisted manipulation and structural alteration of intraarticular ligaments, tendons, joint capsule, and cartilage are routinely performed under arthroscopic visualization.

INDICATIONS

Diagnostic: confirmation of suspected joint trauma and degeneration initially assessed by palpation and imaging

- Forelimb:
  - Shoulder: osteochondritis dissecans (OCD) flap, biceps tendon avulsion/sprain, supraspinatus and subscapularis tendon trauma, medial and lateral glenohumeral ligament damage
  - Elbow: fragmentation of medial coronoid process, humeral trochlear OCD, ununited anconeal process, humero-ulnar conflict, radio-ulnar joint incongruity, condylar fracture, incomplete ossification of humeral condyle, cartilage damage secondary to elbow joint dysplasia
  - Carpus: intercarpal ligament damage
- Hindlimb:
  - Hip: acetabular labral avulsion, femoral head ligament rupture, cartilage damage secondary to hip dysplasia
  - Stifle: cranial and caudal cruciate ligament damage, medial and lateral meniscal avulsion and tearing, long digital extensor tendon avulsion, lateral femoral condylar OCD, femoropatellar and femorotibial cartilage degeneration
  - Hock: talar OCD, intraarticular tibiotarsal fracture

Therapeutic: débridement and removal of damaged and noncompetent ligament, tendon and osteochondral lesions under arthroscopic visualization

CONTRAINDICATIONS

Lack of comprehensive training, supervised initial exposure, and well-maintained modern arthroscopy equipment

EQUIPMENT, ANESTHESIA

Equipment:

- Rigid arthroscope; there is a wide range of scope diameters and length; the commonly used diameters in small animal arthroscopy are 1.9 mm, 2.3 mm, and 2.7 mm. Arthroscope length varies from short (6-10 cm) to long (12-18 cm). The most commonly used arthroscopes are the 2.3 mm and 2.7 mm short arthroscopes.
- Arthroscopic cannula and blunt trocar matched to arthroscope size and used for joint introduction
- Endoscopic video camera mounted to the arthroscope and connected by cable to a camera control box and video screen monitor
- Compatible tungsten-halogen or xenon lamp and intensity regulator
- Digital image collection system; video loop capability is optional and advantageous
- Fluid ingress system for joint distension and lavage. Gravity-assisted, pressure-bag, or mechanical pump systems are all used with success. Initial joint aspiration and distension achieved with 22- to 18-gauge needles and 6- to 12-mL syringes.
- Joint fluid outflow egress cannula-trocar or large-gauge needles (18-20 gauge)
- Hand instruments; a variety of probes, grasping forceps, cutting forceps, biting forceps, push and hook knives is needed to manipulate, débride and remove intraarticular structures.
- Motorized sheathed shavers and burrs with concurrent suction and adjustable rotatory speed allow for mechanical débridement of intraarticular fat pads, damaged ligaments, and cartilage defects.
- Intraarticular electrocautery and radio-frequency units enable accurate control of intraarticular bleeding and soft-tissue débridement.
- Instrument cannulas may be utilized to minimize periarticular trauma by repeated introduction of hand instruments through tissue ports.

Anesthesia:

- Routine induction and anesthesia maintenance of patient on airway-intubated gas anesthesia
- Regional local anesthesia often employed with axillary nerve block for thoracic limb procedures and epidural analgesia for pelvic limb procedures

- Intraarticular local anesthesia with lidocaine or bupivacaine is used by some surgeons to further analgesic coverage.

ANTICIPATED TIME

About 20-60 minutes depending on surgeon experience and skill level. Diagnostic joint exploration followed by significant intraarticular débridement and treatment may exceed 60 minutes in select cases.

PREPARATION: IMPORTANT CHECKPOINTS

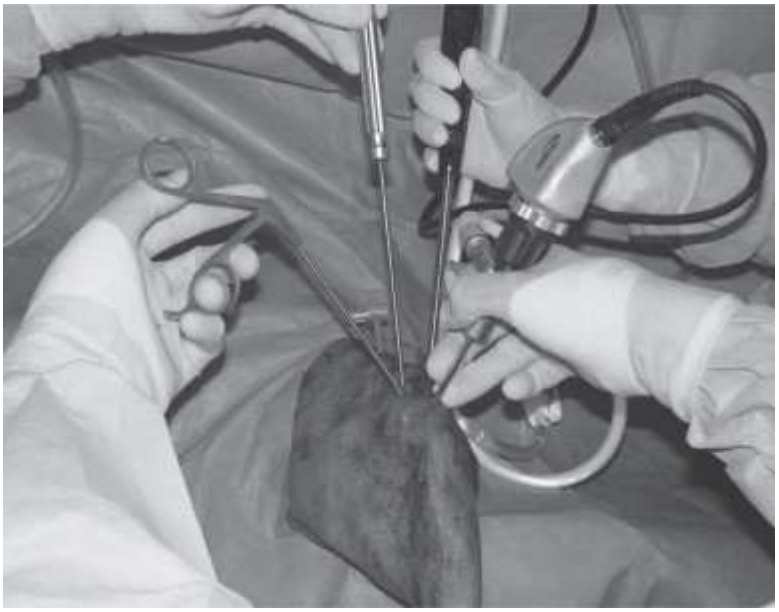
- To minimize the occurrence of technical difficulties, the video camera, video screen monitor, light source, image collection system, fluid supply, and their relevant control units should be connected and tested prior to patient induction. The components of the arthroscopic equipment are best stored and operated from a mobile equipment tower that can be easily moved to an optimal position.
- The arthroscopic control tower with the video monitor should be located in the surgical theater to allow easy access to the control units by nonsterile technical staff during the procedure and an uninterrupted view of the monitor by the sterile surgical team.
- Correct patient positioning on the surgical table is very important to minimize iatrogenic joint trauma during arthroscopic instrumentation and allow for maximal visualization of intraarticular structures.
- The use of arthroscopic positioning braces allows the examined joint to be placed in an optimal position and secured in that position for the duration of the procedure.
- All arthroscopic supplies and equipment should be available, sterilized as appropriate, and organized on the surgical table in a consistent and logical fashion.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Technical issues with endoscopic equipment are not uncommon, and it is imperative that technical staff be completely familiar with the various components of the arthroscopic tower and be able to troubleshoot technical issues as they arise during the procedure.
- Difficulty with initial distension, lavage, or instrumentation of the joint during the procedure, or loss of intraarticular visualization due to joint capsule collapse during prolonged procedures with multiple arthroscopic ports, may necessitate open arthrotomy to complete diagnostic and therapeutic goals.
- Pooling of arthroscopic ingress fluids in the periarticular tissues due to difficulties with egress ports and cannulas may make secondary procedures planned for the joint difficult due to alteration of standard tissue dissection planes.

PROCEDURE

- Patient positioning will depend upon the surgical joint and which aspect of the joint is being instrumented:
    - Shoulder: lateral or dorsal recumbency with lateral or hanging distal traction of the surgical limb
    - Elbow: dorsal recumbency with limb abduction and lateral bracing for medial instrumentation, medial bracing for lateral instrumentation
    - Carpus: dorsal or ventral recumbency with carpus hyperflexed
    - Hip: lateral recumbency with pelvic limb distally distracted
    - Stifle: dorsal recumbency with stifle flexed at table end and femur stabilized
    - Tarsus: ventral recumbency with tarsus flexed off table end
- The locations of the camera portal and instrument portals in each joint vary with the location of the intraarticular lesion of greatest interest, the overall aim of the individual procedure, and the arthroscopic surgeon's personal preference.
- Distension of the surgical joint with isotonic fluid and/or local anesthetic via an 18- to 12-gauge needle and 6-mL syringe allows for placement of the arthroscope cannula and trocar through a small stab incision directly adjacent to the distension needle.
- Care should be taken to not damage critical neurovascular tracts, transarticular ligaments, and tendons and to minimize periarticular and intraarticular trauma during the instrumentation procedure.
- Replacement of the arthroscopic trocar with the arthroscope and initiation of egress fluid flow should allow visualization of the cartilage surface and joint capsule.
- Establishing the location of the instrument portal into the joint will depend upon the ability to triangulate with the visual field of the arthroscope, the presence of vital structures that must be avoided, the instruments needed, and the specific intraarticular treatment planned.
- Crucial to effective ongoing visualization and manipulation of joint structures are stable limb position, reliable and adjustable ingress fluid flow, maintenance of an unobstructed and consistent visual field within the joint, a reliable and easily used instrument portal, lack of fluid leakage into the periarticular tissue, and minimal intraarticular hemorrhage.
- Following systematic examination of the joint, interventions may include removal of osteochondral flaps, debridement of damaged articular ligaments, partial meniscectomy and meniscal release, etc. Initial technical challenges are generally overcome with increased surgeon experience.



ARTHROSCOPY Left stifle arthroscopy with arthroscope in distal lateral portal, double instrumentation of medial portal, and joint distractor in second proximal lateral portal.

ARTHROSCOPY Left shoulder arthroscopic image with partially elevated osteochondritis dissecans (OCD) flap.

POSTPROCEDURE

- Articular ports are closed with skin sutures that should be removed in 10-12 days.
- Cold packing of the surgical joint area for 15-20 minute periods over the first 24-48 hours post surgery will assist in patient comfort and recovery.
- Placement of a light support dressing for the first 24-72 hours post surgery may assist in patient comfort, absorb postsurgical fluid leakage from the arthroscopy ports, and minimize early contamination of port sites.
- Use of postsurgical medications including opioids, nonsteroidal antiinflammatories, and sedatives may allow for better patient recovery and compliance with postsurgical exercise restriction.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Open arthrotomy and direct visualization of intraarticular structures is more invasive, causes more periarticular trauma, has a higher incidence of joint contamination and development of septic arthritis, provides less accurate visualization of joint lesions, allows less accurate treatment of articular lesions, and has a higher complication rate and slower patient recovery with potentially a less successful endpoint in treatment recovery.
- Open arthrotomy should only be employed in patients that do not have access to arthroscopic surgeons or in joint conditions that require an arthrotomy to achieve the surgical goal.

AUTHOR: IAN GORDON HOLSWORTH

Arthrocentesis

SYNONYMS

Joint tap, joint aspirate, synovial tap

OVERVIEW AND GOAL

To use a needle and syringe to obtain a sample of fluid from a synovial (joint) space for analysis

INDICATIONS

- Joint pain (arthralgia)
- Joint swelling, joint effusion
- Radiographic evidence of joint disease
- As part of evaluation of nonspecific systemic signs

CONTRAINDICATIONS

Severe bleeding disorder (risk of hemarthrosis)

EQUIPMENT, ANESTHESIA

- Generally performed with mild sedation but not local or general anesthesia
- Skilled clinicians sometimes use no sedation or anesthesia unless the animal shows signs of resentment or discomfort.
- The procedure may be performed during general anesthesia if the animal is anesthetized for another reason.
- Hair clippers
- Surgical scrub solution, rubbing alcohol, and gauze/sponge for prepping skin
- 6-10 4 × 4 gauze pads
- Microscope slides (at least 10), cleaned and spread out on a table or tray
- 5-10 sterile needles (20-, 22-, or 23-gauge, depending on the animal's size)
- 3-4 sterile syringes (1, 3, or 6 mL)
- Red-top test tube
- Lavender-top test tube
- Sterile culture swab
- Sterile gloves

ANTICIPATED TIME

About 10-30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- The joints to be aspirated should be clearly identified in the medical record.
- As a general rule, the carpi, tarsi, and stifles are the most easily accessed joints.

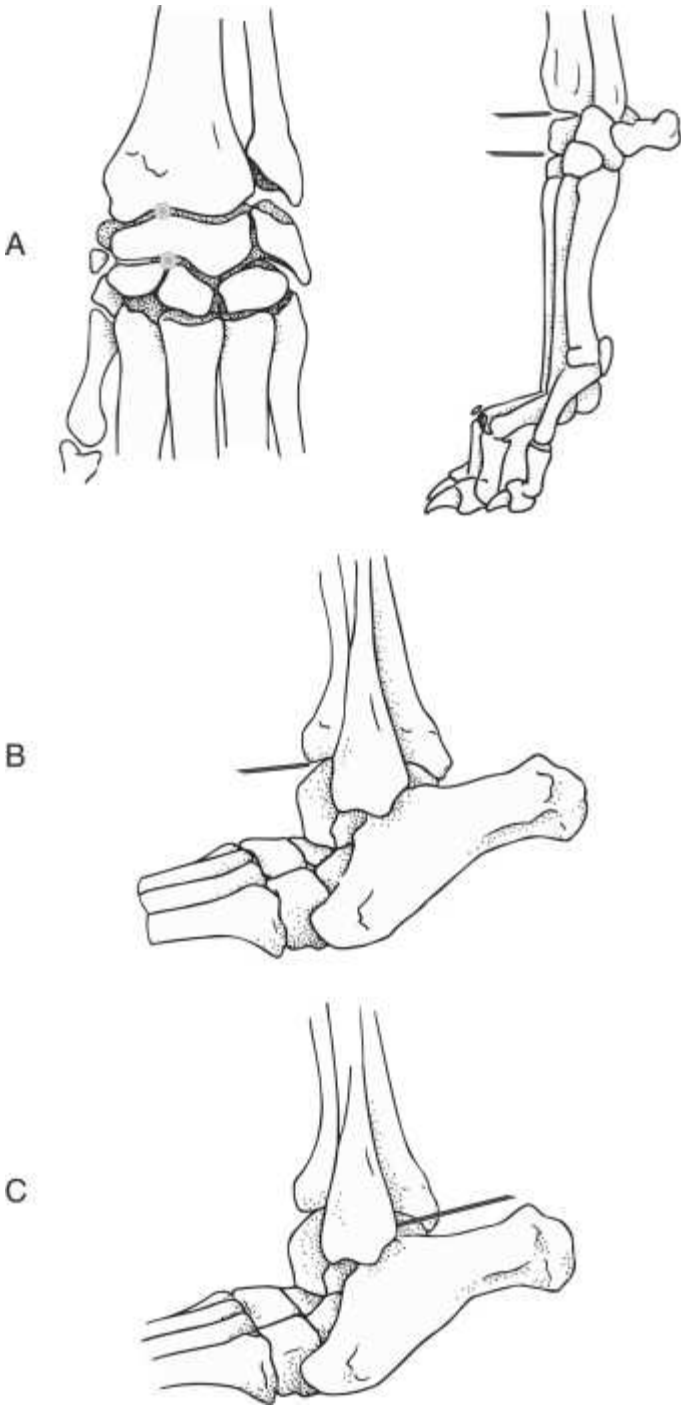
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Blood contamination of sample: very common and detrimental to obtaining an accurate diagnosis. Be sure to release negative pressure on syringe before withdrawing needle from joint.
- Iatrogenic hemarthrosis: very uncommon unless underlying bleeding disorder
- Lameness induced by procedure: very rare

PROCEDURE

- The skin is clipped and aseptically prepped over the relevant joint(s).
- Bony landmarks are palpated to have the most direct access to the joint space.

- Note: An important rule of thumb is to first palpate a joint in a gentle and superficial manner to find areas of gross joint swelling. When they occur, joint swellings can often be felt as soft, fluctuant, "puffy" subcutaneous pockets of synovial fluid and are the easiest source of access to a joint. This is especially true for the carpi, tarsi, and stifles.



ARTHROCENTESIS Schematic representation of recommended sites for arthrocentesis in the dog and cat. **A**, Carpus: partially flex joint. Palpate and enter craniomedial aspect of carpometacarpal or radiocarpal space. **B**, Hock: cranial approach. Palpate space between tibia and tibiotarsal bone on craniolateral surface of hock; insert needle in shallow, palpable space. **C**, Hock: lateral approach. Partially flex joint, and insert needle under (distal to) lateral malleolus of fibula.

(Reprinted with permission from Nelson RW, Couto CG: Small animal internal medicine, ed 4, St Louis, 2009, Mosby, pp 1122–1124.)

CARPUS:

- On the cranial-most surface of the flexed carpus, a space is delineated by the distal radius proximally, the carpal bones distally, and the tendons of the extensor carpi radialis and common digital extensor on either side.
- The space is 2-3 mm in diameter in a medium-size dog.

- It is a natural depression that is best felt when the carpus is flexed.
- An assistant maintains the carpus in a gently but fully flexed position to open the radiocarpal angle and increase access to the joint space during the procedure.

TARSUS:

- The tarsal joint is not excessively flexed or extended.
- The caudal aspect of the tarsus presents both medial and lateral access to the tarsal joint.
- The lateral and medial malleoli of the distal tibia are palpated; immediately medial and caudal to each one is a depression in which the joint space can be accessed.

STIFLE:

- The stifle joint is not excessively flexed or extended.
- From a cranial approach, the needle is passed laterally or medially to the patellar tendon and is directed caudally and toward the center of the tibial plateau.

Once the landmarks have been established for the chosen joint(s):

- Aseptically scrub the site once more.
- Open sterile syringes onto sterile field (e.g., onto opened paper wrapper for sterile gloves).
- Put on both sterile gloves.
- With the help of an assistant, attach sterile needle to sterile syringe.
- Have assistant hold joint in the desired position to maximize access with needle.
- Palpate landmarks once more.
- Advance needle and syringe, applying gentle negative pressure with syringe once the needle tip is below the skin until synovial fluid is seen in the needle hub and syringe.
- Often, the needle tip will strike bone. If so, the pressure should be released from the syringe, and the needle tip “walked” off the bone and further into the joint space. “Walking” refers to gentle probing using the needle tip, seeking out a path of lesser resistance within a few millimeters of the site where bone was encountered. The needle is partially withdrawn—but remains below the skin surface—and is redirected and readvanced during “walking.”
- When the needle tip advances without striking bone, negative pressure may be reapplied with the syringe until synovial fluid enters the hub of the needle and the syringe.
- If blood is encountered, the procedure should be stopped and then restarted with a new needle and syringe.
- At least 1 mL should be sought if possible, but many successful arthrocentesis procedures will produce < 0.5 mL of joint fluid.
- It is essential to release negative pressure from the syringe prior to withdrawing the needle to avoid blood contamination from vessels in the joint capsule and skin.

POSTPROCEDURE

- Immediate assessment of the synovial fluid includes:
  - Turbidity; the fluid should be clear and pale tan or pale yellow.
  - Viscosity test; a drop of fluid placed between two slides, which are then separated, should appear somewhat viscous or gummy. Synovial fluid that has little viscosity (like water) is abnormal.
  - Odor; none is expected in normal synovial fluid. Note: If an airborne zoonotic organism is part of the differential diagnosis, assessing the odor may be hazardous and should be avoided.
- Laboratory samples to be submitted include (in general order of priority because volume of fluid retrieved maybe small):
  - Fresh smears on microscope slides
  - Whole fluid in red-top tube
  - Whole fluid in lavender-top tube
  - Culture swab
- Routine sedation/anesthetic recovery as needed

ALTERNATIVES AND THEIR RELATIVE MERITS

- Radiographs:
  - Useful for detecting subchondral bone lesions
  - Do not replace synovial fluid analysis
- Bone scan:
  - Identifies multiple joint involvement
  - Identifies relative degree of severity between joints
  - Does not give etiologic diagnosis

- Synovial biopsy:
    - Appropriate if joint capsule is thickened or deformed (grossly, radiographically) and synovial fluid analysis is unrewarding

AUTHOR: ETIENNE CÔTÉ

Arterial Blood Sampling and Arterial Catheterization

SYNONYMS

Arterial phlebotomy, arterial puncture

OVERVIEW AND GOALS

To access the peripheral artery with a needle or catheter, typically for arterial blood gas (ABG) analysis or for arterial blood pressure (BP) monitoring, respectively

INDICATIONS

- Assessment of ABG and acid-base status, usually in animals with systemic illness or a respiratory problem
- Placement of an arterial catheter for BP measurement, usually in critically ill or anesthetized animals

CONTRAINDICATIONS

Bleeding disorder: assess for overt signs of bleeding or history of bleeding

EQUIPMENT, ANESTHESIA

Sedation or general anesthesia not usually required; manual restraint only; one or two assistants may be needed and:

- Hair clippers
- Sterile scrub material
- 6-10 3 × 3 gauze squares
- Arterial catheter (standard over-the-needle IV-type catheter):
  - Cats, dogs < 10 kg: 24- or 25-gauge
  - Dogs 10-25 kg: 22-gauge
  - Dogs > 25 kg: 20-gauge
- White tape, 2 cm (1 inch) width
- Heparinized sterile saline flush
- Pressure transducer and monitor (if continuously monitoring direct arterial pressure)

For arterial blood sample (one time):

- 1-mL heparinized syringe
- Needles (guidelines for size same as for arterial catheters, above)

ANTICIPATED TIME

- About 5 minutes (arterial blood sample)
- About 10-15 minutes (arterial catheter)

PREPARATION: IMPORTANT CHECKPOINTS

- Thoracic radiographs are indicated prior to or concurrently with ABG sampling when the purpose of arterial sampling is to assess arterial oxygen or CO2 levels.
- Samples for venous blood gas measurement generally are easier to obtain and may be useful for measuring certain parameters in arterial blood (e.g., pH, Pco2, $Hco^{-}3$).
- Confirmation of normal platelet count
- Confirmation of absence of overt signs of bleeding disorders or history of bleeding

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Pressing excessively firmly on the artery when palpating for the pulse to locate the proper site for puncture; excessive pressure abolishes the pulse and makes accurate puncture virtually impossible
- Inserting the needle or catheter without having convincingly identified the course of the artery (by repeated palpation of the arterial pulse)
- Crossing both artery and vein with the needle, resulting in venous contamination of arterial sample (artifactual low Po2 result)
- Mistakenly advancing the needle or catheter with the bevel up rather than down
- Inadequate manual pressure on the site after the procedure:
  - Hematoma possible if inadequate direct pressure is applied after the procedure or if animal has a bleeding disorder or vasculitis.
- Artery may not be patent after arterial catheterization, but the effect of this loss of patency on the animal typically is minimal (limits the source of access for arterial blood samples in the immediate future but rarely causes ischemia distal to the site of puncture).

PROCEDURE

- Clip hair over the area of interest (dorsal metatarsus: dorsal surface of distal hind limb, from hock to beginning of phalanges; inguinal area: femoral triangle, from inguinal crease [medial side of proximal hind limb where thigh meets caudal abdomen] toward stifle).
- Restrain animal in lateral recumbency (example here: left lateral):
  - Dorsal metatarsal arterial approach:
    - Right-handed clinician: fully extend animal's hock by drawing paw of upper hind limb (right paw if animal is in left lateral recumbency) toward self using the left hand.
    - While keeping leg extended using traction on the right hind paw with the left hand, palpate the dorsal metatarsal pulse with the tips of the index and middle fingers of the right hand on the dorsal surface of the right metatarsus. The artery lies between the third and fourth metatarsal bones.
    - Palpating the dorsal metatarsal pulse simultaneously with two fingers reveals the course of the dorsal metatarsal artery.
    - Caution: The course of the metatarsal artery must be identified convincingly by repeated palpation of the dorsal metatarsal pulse before beginning to insert the needle or catheter.
    - Then proceed as described further below (after “Femoral arterial”): “Both dorsal metatarsal and femoral approaches.”
  - Femoral arterial approach:
    - Right-handed clinician: Fully extend the animal's dependent hind limb (e.g., left hind leg, if in left lateral recumbency) to expose the medial inguinal area of that leg. In cooperative (or anesthetized) cats and dogs, the leg may be restrained minimally or not at all. In recalcitrant animals, a second restrainer is needed to hold the leg in an extended stable position.
    - Palpate the femoral pulse at its dorsal-most location, near the inguinal crease. It should be palpated with the tips of the index and middle fingers of the right hand (for a right-handed clinician). The femoral artery lies midway between the cranial-most and caudal-most aspects of the thigh, at the usual location for palpation during physical examination.
    - Palpating the pulse of a femoral artery simultaneously with two fingers 1-2 cm apart reveals the course of the femoral artery, namely a straight line between the two points on the artery where the pulse is palpated (i.e., between the two fingers).
    - Caution: This line (the artery) must be identified convincingly by repeated palpation of the femoral pulse before beginning to insert the needle or catheter.
  - Both dorsal metatarsal and femoral approach:
    - Repeat brief aseptic scrubbing procedure once pulse has been palpated satisfactorily.
    - There is no need for the assistant to “hold off” or “raise” the vessel, as is done for venous samples, because of the normal arterial pressure.
    - Break the seal in the syringe by withdrawing and depressing the plunger once. The syringe (with needle) is held in the right hand like a pen. It enters the skin obliquely at 45°. If placing an arterial catheter, the 45° angle between skin and catheter is also necessary, but the catheter is held the same way an IV catheter is normally held.
    - The bevel of the needle/catheter points down, not up (contrary to venous blood samples and IV catheters).
    - The needle is introduced under the skin and into the artery, again advancing while maintaining a 45° angle between the syringe and the vessel.
    - A flashback of blood indicates successful entry into the artery. Pulsatile flow is visible when an uncapped catheter is used. With a needle and syringe, arterial pressure will slowly but steadily “self-fill” the syringe, and negative pressure (as with a venous blood sample) is not necessary.
    - Typically, a sample for ABG analysis requires approximately 0.5 mL of blood, which should be placed in an ice bath if analysis in the following 10 minutes is not possible.
    - An arterial catheter should be fixed in place, capped, and flushed, or it should be connected to a pressure transducer for pressure measurement. It should be identified clearly with a label as being arterial.

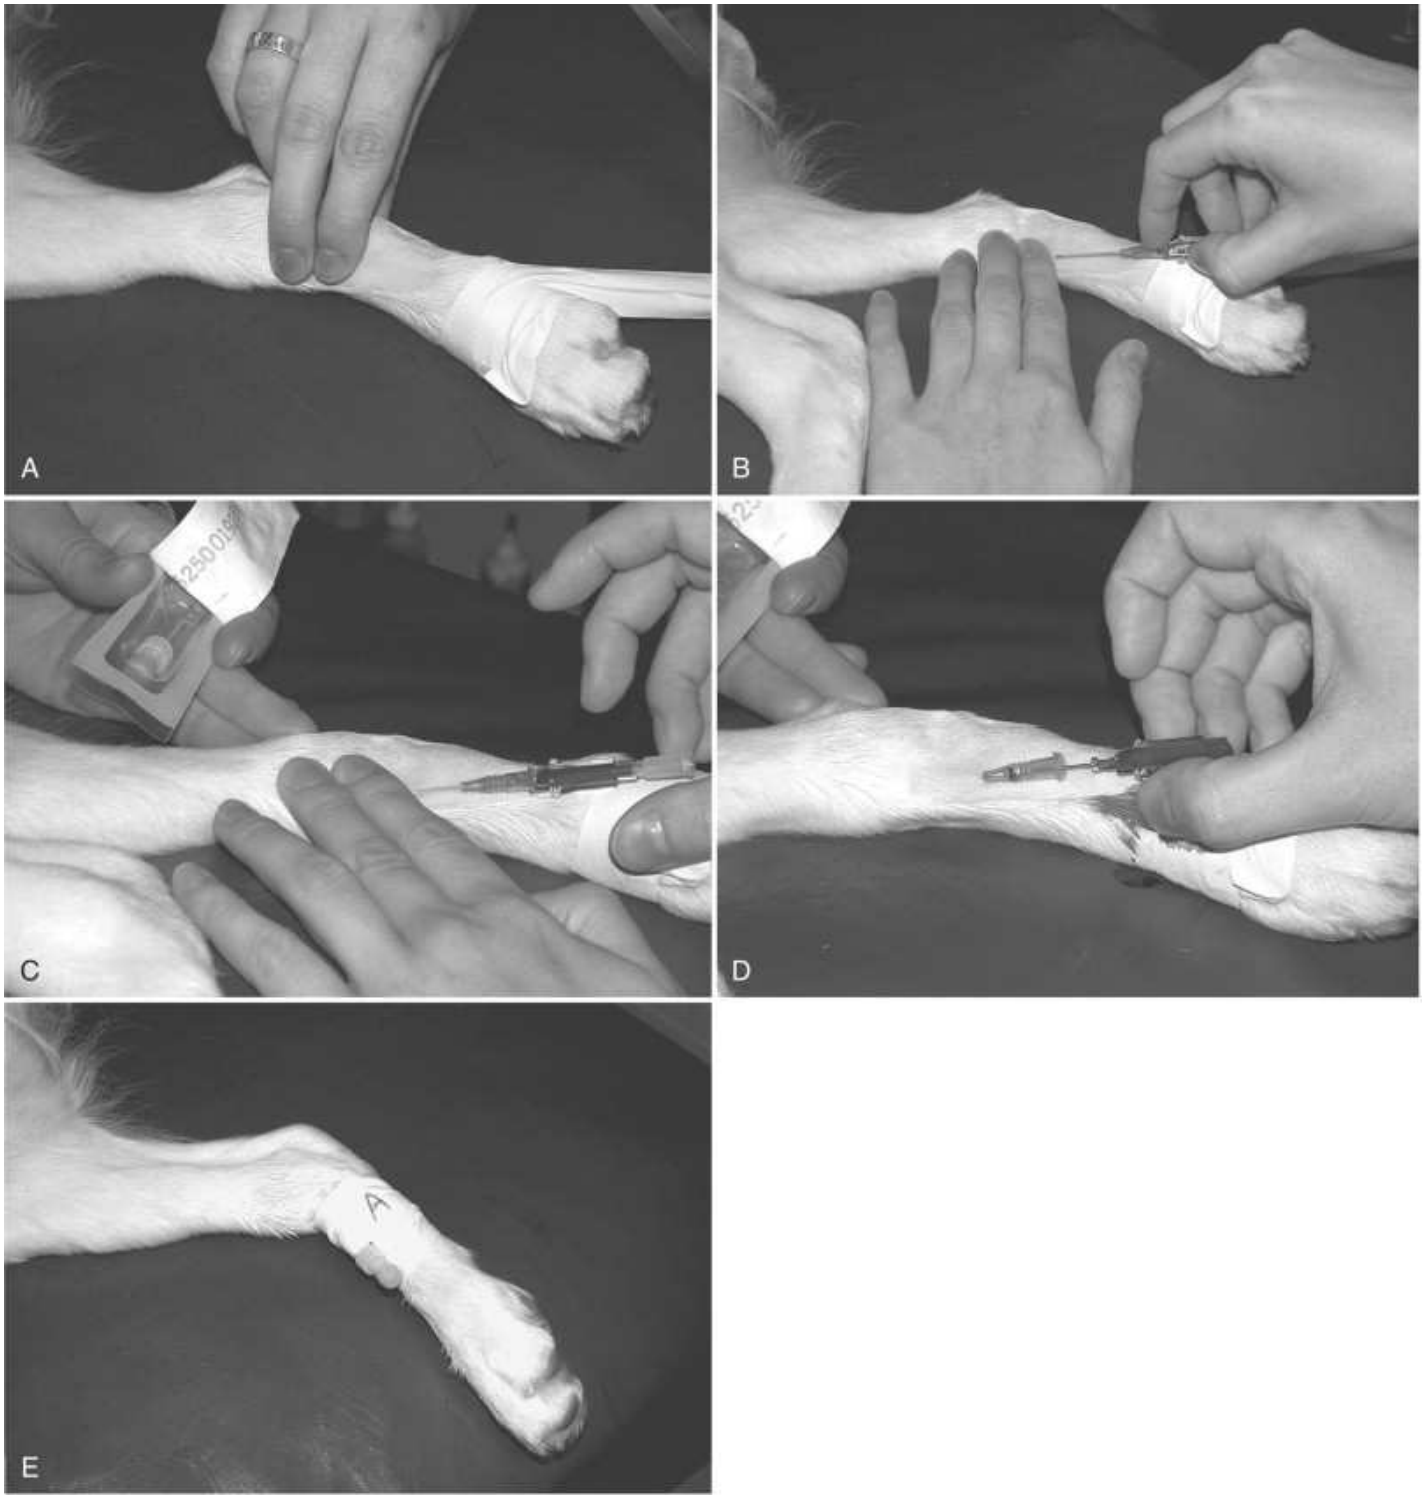
ARTERIAL BLOOD SAMPLING AND ARTERIAL CATHETERIZATION Blood sampling from femoral artery, dog in left lateral recumbency. Cranial is to lower right. Assistant holds right hind limb elevated and prepuce retracted. Phlebotomist identifies course of left femoral artery between middle and index fingers by palpation of femoral pulse with both fingers and prepares to enter artery, needle bevel down.

POSTPROCEDURE

Successful outcome:

- Successful arterial puncture for blood gas measurement improves animal care via treatment adjustments.

- Successful arterial catheter placement improves animal care via minute-by-minute adjustments of factors that influence arterial BP (e.g., IV fluids, pressor drugs, anesthetic agents) in anesthetized or critically ill animals.



ARTERIAL BLOOD SAMPLING AND ARTERIAL CATHETERIZATION Placement of arterial catheter in a dog's right metatarsal artery. **A**, Palpation of arterial pulse. **B**, Introduction of catheter, using right hand while simultaneously palpating arterial pulse for orientation using left hand (right-handed clinician). **C**, Flashback of blood confirms proper placement. **D**, Removal of stylet in preparation for placement of catheter cap. **E**, Capped catheter is flushed with heparinized saline, wrapped, and clearly marked as arterial.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Repeat thoracic radiographs:
  - Noninvasive; provides information on lesions of respiratory system only. Minimal usefulness for assessing subtle, moment-by-moment changes.
- Venous blood gas analysis:
  - Sampling is easier.

    - Few other advantages over arterial blood, unhelpful regarding Po2
- Arterial cutdown for arterial blood sampling:
    - Easier access to vessel
    - More invasive

AUTHOR: ETIENNE CÔTÉ

Angiogram, Nonselective

SYNONYMS

Nonselective radiographic contrast study of the heart

OVERVIEW AND GOAL

To perform an IV contrast study that highlights the venous return to the heart and the right-sided cardiac structures

INDICATIONS

- Suspected venous obstruction (see p. 263)
- Ill-defined abnormalities of the right side of the heart when echocardiography is equivocal or unavailable
- Pulmonary thromboembolism: rarely diagnostic as a nonselective procedure (often requires power-injected contrast through large-bore catheter in pulmonary artery)

CONTRAINDICATIONS

- Lesions that are equally or better defined without the administration of contrast (i.e., via echocardiography)
- Hypersensitivity to contrast material
- Acute renal failure (decreased ability to excrete contrast material and/or risk of contrast-induced renal failure)
- Arteriovenous (AV) fistulae are not an indication for this procedure. AV fistulae shunt from artery to vein and require selective arteriography.

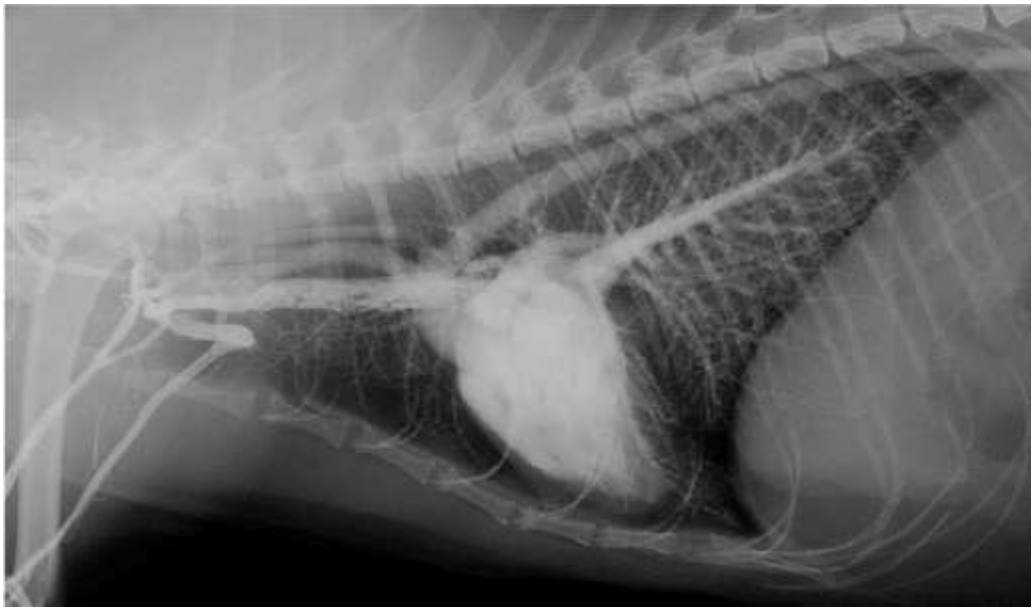
EQUIPMENT, ANESTHESIA

- Can be done with or without anesthesia; sedation in most patients (see end pages inside text cover).
- Hair clippers
- Surgical scrub solution, rubbing alcohol, and gauze/sponge for prepping skin
- IV catheter (jugular or peripheral)
  - A 19- or 20-gauge catheter for cats or small dogs; a 16- or 18-gauge catheter for medium or large dogs
- The catheter cap or T-port should be a screw tip to avoid detachment under high pressure of contrast injection.
- ± Sterile surgical gloves if using a nonsheathed jugular catheter
- ± Lidocaine for local anesthesia if large-bore jugular catheter (e.g., 18 gauge or larger)
- Routine tape and bandage material for catheter fixation to skin
- ± Suture material (e.g., 3-0 nylon), needle holders, and suture scissors if anchoring jugular catheter to skin of neck
- Syringe for IV contrast material. A syringe with a screw tip is recommended to avoid pressure-induced separation of the syringe from the T-port or catheter cap during high-pressure injection of contrast.
- Transparent, aqueous IV contrast material (iodinated, ionic; e.g., Renografin-76, Renovist 69%, Hypaque-M75, Conray 60%); maximal total cumulative dose given during procedure, assuming maintenance IV fluid administration to promote diuresis: 3 mL/kg
- Radiographic facility, including radiographic machine, films and cassette, and developer and/or fluoroscopic unit

Adapted from Wise M: Nonselective angiocardiography in the normal dog and cat, Vet Radiol 23:144–151, 1982.

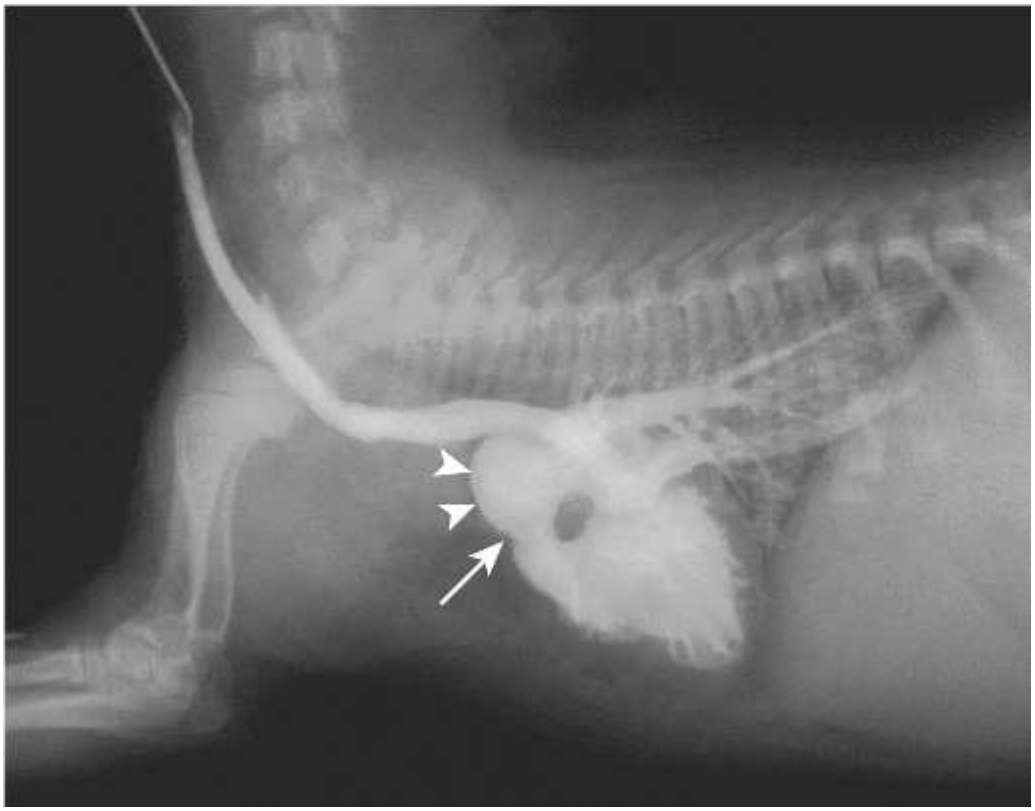
	DOG	CAT
Site Enhanced by Contrast	**Time (sec) from Start of Injection**	**Time (sec) from Start of Injection**
Cranial vena cava	1–2.5	0.5–1.5
Right ventricle	2–3	1.5–2.5
Pulmonary arteries	2–3	1.5–2.5
Left atrium	4–5.5	4.5–7
Left ventricle	4.5–6	5–7

	DOG	CAT
Site Enhanced by Contrast	**Time (sec) from Start of Injection**	**Time (sec) from Start of Injection**
Aorta	4.5–6.5	5–7



ANGIOGRAM, NONSELECTIVE Lateral nonselective angiogram in a normal cat. Contrast was injected in a cephalic vein; right side of the heart and pulmonary circulation are opacified, and early opacification of left side of the heart and aorta is also seen.

(Courtesy Dr. Brett Kantrowitz.)



ANGIOGRAM, NONSELECTIVE Lateral nonselective angiogram in a dog with valvular pulmonic stenosis. Contrast was injected in a jugular vein. Narrowing (stenosis) is seen at the level of the pulmonic valve *(arrow)*. Marked poststenotic dilatation of the pulmonary trunk is apparent *(arrowheads)*.

(Courtesy Dr. Brett Kantrowitz.)

ANTICIPATED TIME

About 15-30 minutes after catheter placement

PREPARATION: IMPORTANT CHECKPOINTS

- Thoracic radiographs: must precede contrast study, because a diagnosis may be apparent from these alone.
- Congestive heart failure must be controlled prior to procedure.
- Clipping of hair over vein to be catheterized (typically jugular or cephalic); jugular may be preferable in small animals (<10 kg) because the cephalic can be too small to allow easy flow of viscous contrast solution through catheter.
- A 12-hour fast if sedating animal
- Placement of IV catheter
- Discuss possible complications with owner as indicated in the following paragraphs (see p. 1293).

POSSIBLE COMPICATIONS AND COMMON ERRORS TO AVOID

Nondiagnostic study; improve likelihood of diagnostic result by:

- Using large-diameter catheter
- Using fluoroscopy instead of serial radiographs
- Injecting contrast rapidly
- Injecting adequate volume of contrast

PROCEDURE

- Catheter patency is checked.
- Animal is placed on radiographic table, usually in lateral recumbency.
- Position of radiographic beam is set over area of interest (usually thorax, neck, or limb).
- Contrast is injected IV by hand as quickly as possible (maximal manual pressure). Recommended single dose is 1-2 mL/kg (440 mg iodine/kg).
- Radiographic views are obtained at the appropriate times, or the flow of contrast is observed in real time with fluoroscopy.

POSTPROCEDURE

IV fluid diuresis is provided if appropriate. The goal is to increase excretion of contrast medium, but excessive volume load must be avoided if heart disease exists.

ALTERNATIVES AND THEIR RELATIVE MERITS

- An echocardiogram and thoracic radiographs should be performed prior to angiography:
  - Noninvasive, excellent diagnostic yield
- Vascular ultrasound:
  - Noninvasive but limited by lungs: poor visualization of intrathoracic vessels
- Arterial blood gas (ABG) analysis:
  - If pulmonary vascular disease
- Selective angiography/cardiac catheterization:
  - If cardiac or pulmonary vascular lesion still unclear

AUTHORS: ETIENNE CÔTÉ, BRETT KANTROWITZ

Acupuncture

Additional Images Available on Website

OVERVIEW AND GOAL

- Acupuncture may be used in concert with other methods of integrative pain management for the control of acute or chronic pain.
- Most clinicians report that acupuncture either resolves the clinical problem or serves well as a maintenance therapy for a lifelong condition in 80% of cases.
- There are several indications for the use of acupuncture as an adjunct treatment for specific visceral organ diseases.
- The many different techniques used for stimulating an acupuncture point may be a source of confusion (e.g. heat, ultrasound, laser, or implant). Each method has its purpose and particular virtues in a given clinical setting.
- There are several neurophysiologic mechanisms which describe acupuncture effects. Spinal gates, central nervous system (CNS) endorphin release, and viscerocutaneous reflex arcs are a few of these.
- The teaching and clinical applications of acupuncture may be based on any of several different methodologies. The principle systems are known as *traditional Chinese medicine (TCM); the eight principles;*and *medical, empirical,*and *French energetic acupuncture.*The essential differences between them are matters of history and clinical philosophies. Each system uses the same needles and inserts them into the same acupuncture points. Differences of clinical outcome between these methodologies are difficult to measure and appear to be slight.

INDICATIONS

- Chronic orthopedic pain, especially:
  - Hip dysplasia
  - Cranial cruciate ligament injury
  - Elbow dysplasia
  - Other degenerative joint disease
- Postoperative (acute) pain
- Back pain (including nonsurgical intervertebral disk disease [IVDD])
- Asthma syndromes
- Demodectic mange
- Acral (lick) granuloma
- Malaise of chemotherapy
- Inflammatory bowel disease

Note: In the abstract, acupuncture is capable of influencing virtually any disease process or organ system in the body. Although we may accept the theoretical basis for this point of view, there are numerous medical and practical reasons to avoid considering acupuncture as an isolated treatment modality. Acupuncture may be helpful as the sole treatment for hypothyroidism, for example, but thyroid supplementation is known to be successful, cost-effective, and safe.

The use of particular acupmuncture points and related techniques (tongue and pulse diagnosis) to suggest or confirm a diagnosis is established in TCM of human beings. While the development of this aspect of acupuncture clinical science in animals is progressing, there is less validated information to advocate its use for this purpose on a routine basis.

CONTRAINDICATIONS

- Pregnancy and tumors are often cited as relative contraindications. Use of acupuncture therapy in patients with these conditions should be reserved for clinicians with advanced knowledge of safe protocols.
- There are specific cautions for the use of electroacupuncture, which should be understood by practitioners who use this modality.

EQUIPMENT, ANESTHESIA

- Needles, 28-38 gauge, sterile, disposable, solid, acupuncture needles
- Microamperage electrostimulator
- Moxa (an herbal product)
- Milliwatt diode laser equipment is useful for younger animals, birds, ferrets, and pocket pets.
- Anesthesia is not indicated; sedation is rarely needed.

ANTICIPATED TIME

- Varies from 15-60 minutes for each treatment session
- Particular problems may be resolved following a single treatment, but most will need from 3-8 treatments.
- Maintenance treatments for chronic conditions (e.g., hip dysplasia, epilepsy) may be performed at intervals from 1-6 months.

PREPARATION: IMPORTANT CHECKPOINTS

- Acupuncture may be performed on the sedated or anesthetized patient, but this is seldom indicated and may cause more problems than it prevents.
- Acupuncture will almost always be less difficult and more acceptable when performed without physical restraint.
- Medium- and large-breed dogs typically will be more relaxed when treated on a low bench or on a blanket on the floor instead of the typical exam table.
- Quiet surroundings and the presence of the owner can provide reassurance, especially for cats.
- There is no requirement for preparation of the skin at the site of needle insertion, even in immunosuppressed patients.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO BE AVOIDED

- Clinically relevant complications of acupuncture in animals are rare, and patients do not require hospitalization.
- It is common for patients to experience somnolence for 12-24 hours following treatment.
- A stuck or “frozen” needle (resists removal) will often occur: this is easily resolved by further manipulation of the needle for a few more minutes.
- Immediately following the first treatment, patients may show a transient increase in disease signs of the condition being treated.
- Concurrent use of pharmaceuticals is not a contraindication for acupuncture.
- Local infection or seizures occur in <0.1% of patients.

PROCEDURE

- Acupuncture is normally performed on an outpatient basis.
- While some practitioners find simple (minimal) methods of restraint to be needed for some cases, most patients will be treated without forceful or unpleasant restraint.
- Most patients do not feel most needles; when they do, the clinician may elect its removal.
- Needles remain in place for an average of 10-20 minutes before removal.
- Treatments are repeated at intervals from 24 hours to several weeks.
- Following the appearance of a useful response to treatment by the patient, supportive or maintenance treatments may be needed in some cases, especially for chronic pain conditions in older animals.
- For a number of visceral organ, immune system, dermatologic, and cases of back pain, there may not be a requirement for maintenance treatments.

POSTPROCEDURE

- Other than occasional somnolence, there are few postprocedure considerations following routine acupuncture.
- It is common to find that the requirement for systemic analgesic or antiinflammatory drugs is reduced following acupuncture.

ALTERNATIVES AND THEIR RELATIVE MERITS

- The relative merit of pharmaceutical alternatives varies widely with the disease being treated.
- For treatment of pain, nonsteroidal antiinflammatory drugs (NSAIDs) can be equally effective but carry the risk of a number of adverse drug reactions in a significant percentage of patients.
- Treatment of chronic orthopedic pain is best accomplished with multimodal therapies, and the combination of a low-dose NSAID and acupuncture is often very effective and reduces the likelihood of renal or gastrointestinal injury from the use of NSAIDs alone.
- For conditions likely to persist for the rest of the patient's life (e.g., osteoarthritis), it may be appropriate to place a permanent implant in the acupuncture points which have been successful in treatment of the problem. Small rods or spheres of sterile metallic 0.999 gold are often used in this way for long-term treatment of degenerative joint disease, for example.
- When acupuncture fails to provide adequate clinical results or cannot be continued for other reasons, it may be necessary to consider pharmaceutical or surgical options.

AUTHOR: ARTHUR I. ORTENBURGER

Abdominocentesis

SYNONYMS

Abdominal paracentesis, abdominal tap, belly tap

OVERVIEW AND GOAL

To use a needle and syringe to obtain a sample of abdominal fluid

INDICATIONS

- Visible abdominal distention with palpable fluid wave
- Ultrasound-detected ascites
- Generally diagnostic, not therapeutic (versus abdominal drainage as already described, p. 1192)

CONTRAINDICATIONS

- Abdominal enlargement due to mass or organomegaly, without ascites, because of risk of organ damage without benefit of fluid retrieval for analysis
- Bleeding disorders

EQUIPMENT, ANESTHESIA

- Procedure is done with manual restraint only and without anesthesia (local or general), except in fractious or excited animals.
- Note: Pressure of large-volume ascites on the diaphragm may distress animals during restraint. In such cases, sedation should not be administered, but rather the procedure may be performed with the animal in lateral recumbency or in standing position.
- Hair clippers
- Surgical scrub solution, rubbing alcohol, and gauze/sponge for prepping skin
- 6-10 4s × 4 gauze pads
- Needles (1-5; 2 inches long; 20-, 22-, or 25-gauge based on animal size and body wall thickness); a 22-gauge needle is generally preferred.
- Syringes (1-3, 6 mL or greater)
- Sterile tubes for cytologic examination and fluid analysis (red and lavender tops)
- Ultrasound guidance optional

ANTICIPATED TIME

About 1-10 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Assess for risk of bleeding disorder if indicated overtly (e.g., epistaxis, hematuria, melena, petechiae/ecchymoses) or suspected via primary diagnosis (e.g., hepatopathy).
- Use ultrasound guidance if necessary for small volumes of ascites.
- Advise owner of possible complications, as listed in the following paragraphs.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- “Dry tap,” no fluid withdrawn: insufficient abdominal fluid (check with ultrasound); fluid is too viscous or particulate (change needle and syringe because clot may be in needle; check fluid appearance with ultrasound); wrong area was sampled (change animal's posture—e.g., try with animal standing—or site of centesis).
- Centesis not representative of underlying process: assess for extraabdominal causes of ascites such as cardiovascular, hypoalbuminemia, and vasculitis as indicated, and pursue primary intraabdominal causes further, beginning with abdominal ultrasound. If negative, consider nonexfoliating intraabdominal disease.
- Laceration of organ with needle tip. Decrease risk with:

    - Good animal restraint (sedation if animal is fractious or excited)
    - Ultrasound guidance if volume of ascites is small
    - Single-dimensional, in-out motion of needle, with minimal or no redirecting
- Pooling of ascitic fluid subcutaneously postprocedure; usually resolves on its own

PROCEDURE

- Place animal in dorsal recumbency or lateral recumbency. If dyspnea is present, lateral recumbency is preferable. Very small, dyspneic animals (cats, toy-breed dogs) that are cooperative may be restrained in an upright sitting position ("begging" posture) in a technician's arms; muzzling is recommended owing to proximity to technician.
- Aseptically scrub and prepare the clipped area, which typically will be on the midline just cranial or just caudal to the umbilicus. Position adjusted according to any known risk (e.g., cavitated abdominal mass in that location).
- Connect needle to syringe and advance needle through skin and body wall, directing the needle cranially and dorsally into the abdomen. The needle is meant to pass through the linea alba/body wall slightly obliquely, such that the tract left when the needle is removed can close on itself. The obliquity comes from the dorsocranial orientation of the needle on the midline instead of direct dorsal orientation.
- Once tip of needle is just under the skin, pull back on syringe plunger intermittently or continuously and observe for fluid "flashback" into syringe.
- Depth of penetration (2-3 mm to 3 cm) is relative to the animal's size and amount of body fat.
- Once fluid flow is established, the desired amount of fluid can be aspirated, and then the needle is withdrawn from the abdomen smoothly and quickly.
- Immediate tests that can be performed include:
    - Visual inspection for turbidity and color. Note: Hemorrhagic samples with hematocrit > 5% appear as red as blood.
    - Odor; foul smell commonly associated with anaerobic infections. Note: Be aware of the possibility of airborne zoonoses if applicable (e.g., systemic fungal, other), and avoid assessing odor in such cases.
    - Hematocrit: compare to peripheral blood to rule out hemorrhage.
    - Total protein: compare to peripheral blood to rule out hemorrhage, exudative process.
    - Creatinine, potassium: compare to peripheral blood to rule out uroabdomen.
    - Cytologic evaluation
- The fluid should be fractionated into two tubes (EDTA [lavender-top tube], and sterile glass [red-top tube]), and a sample should also be saved on a sterile swab for bacterial culture. The two tubes are submitted for standard fluid analysis including cytologic evaluation. The bacterial swab can be submitted for culture immediately if bacterial infection is suspected clinically, or it can be saved for later submission in case cytologic results indicate the possibility of bacterial infection.

POSTPROCEDURE

Subcutaneous pooling of ascitic fluid is common with partial drainage of large-volume ascites; may resolve spontaneously or require abdominal wrap (barring dyspnea).

ALTERNATIVES AND THEIR RELATIVE MERITS

- Repeat centesis under ultrasound guidance:
    - Better ability to reach small pockets of ascites
- Diagnostic peritoneal lavage (see online chapter: Diagnostic Peritoneal Lavage):
    - Increases ability to sample small volumes of ascites
    - Often poorly diagnostic, somewhat cumbersome
    - Generally replaced by ultrasound-guided centesis
- Laparoscopy (see p. 1298) or exploratory laparotomy for nonexfoliating, primary intraabdominal disorders causing ascites:
    - Definitive diagnosis for abdominal masses, mesothelioma/carcinomatosis, and other similar conditions

AUTHOR: ETIENNE CÔTÉ

Abdominal Drainage

SYNONYMS

Large-volume abdominal paracentesis, peritoneal drainage

OVERVIEW AND GOAL

To evacuate large-volume ascites via percutaneous placement of a sterile tube into the abdomen

INDICATIONS

- Tense ascites caused by chronic passive congestion (right heart failure, chronic hepatopathies)
- Abdominal compartment syndrome

CONTRAINDICATIONS

- Hemoabdomen: voids autotransfusion; delays control of cause of hemoabdomen
- Coagulopathy: risk of hemorrhage if laceration of abdominal organ occurs with needle tip

EQUIPMENT, ANESTHESIA

- Local anesthesia
- Manual restraint; sedation needed only rarely. Note: Animals often are restless during restraint owing to pressure of ascites on diaphragm; in such cases, the procedure may be preceded by large-volume needle centesis or may need to be performed with the animal in standing position.
- Hair clippers
- Surgical scrub solution, rubbing alcohol, and gauze/sponge for prepping skin
- Use 0.5-15 mL 2% lidocaine for local anesthesia. The volume is based on body weight, 1-70 kg. Discomfort from lidocaine infusion can be reduced by adding 0.05-0.2 mL sodium bicarbonate for injection (8.4% = 84 mg/mL = 1 mEq/L) and by warming solution to body temperature (armpit method).
- Alligator forceps (preferable) or mosquito hemostats, 1 pair
- Red rubber feeding tube: sterile 5-16 Fr tube, based on body size
- Sterile surgical gloves
- Suture material (e.g., nylon 2-0) and needle
- A#11 sterile scalpel blade
- Sterile needle holders
- Sterile suture scissors
- Elizabethan collar
- Sterile gauze squares (postprocedure)
- Tissue glue (postprocedure)

ANTICIPATED TIME

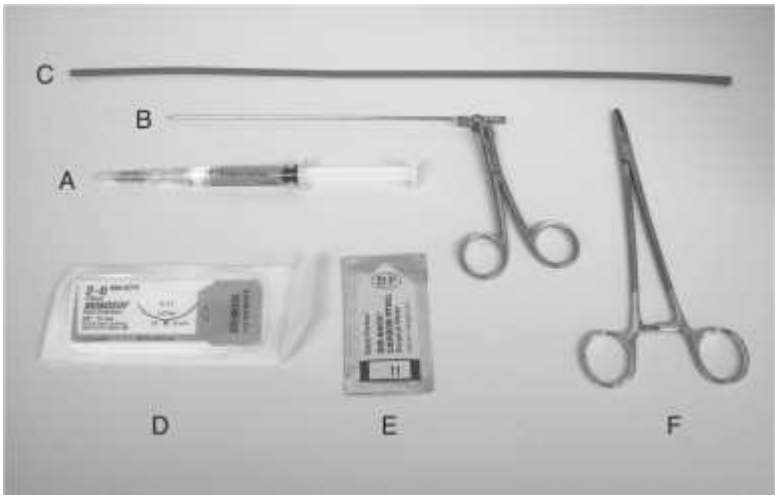
15-40 minutes, plus drainage time

PREPARATION: IMPORTANT CHECKPOINTS

- Weigh animal immediately before procedure (to quantify volume of fluid lost).
- Advise owner of possible drawbacks:
    - Hair clipping required
    - Procedure generally palliative; underlying problem not corrected
    - Low risk of infection or other complications
- Have Elizabethan collar ready to place on the animal as soon as tube placement is complete.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Overall, complications very uncommon; approximately 5%-10% incidence of irritation or dehiscence of incision, responding to topical treatment. Major complications are <1%.
- Concerns for hypovolemia, hypotension, hypoalbuminemia, and ascending bacterial peritonitis appear unjustified, given lack of occurrence in large case series (unpublished data).
- Elizabethan collar must be on the animal at all times during drainage to avoid self-induced damage to the tube.
- Once in place in the standing animal, the tube ± stopcock may be caught in the grate flooring of the cage when the animal lies down. Covering the grate on the floor of the cage with towels helps prevent this complication.

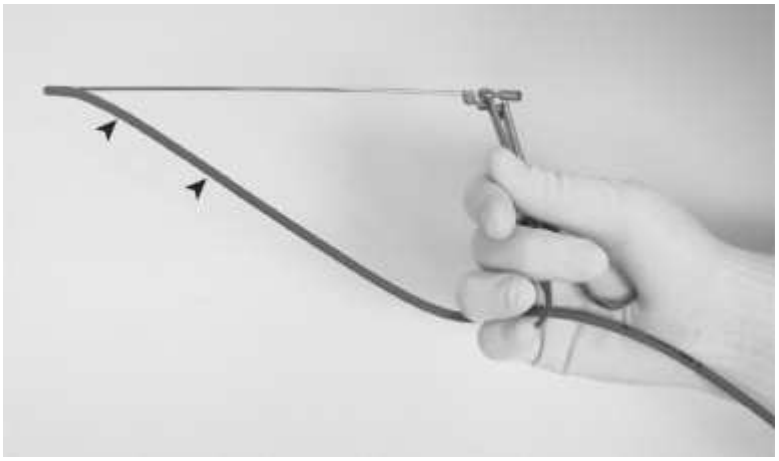


ABDOMINAL DRAINAGE Equipment and materials used for abdominal drainage. **A**, 0.5-15 mL 2% lidocaine for local anesthesia. **B**, Alligator forceps. **C**, Sterile red rubber feeding tube, 5-16 Fr gauge. **D**, Suture material (e.g., nylon 2-0) and needle. **E**, #11 sterile scalpel blade. **F**, Sterile needle holders.

PROCEDURE

- Clip hair widely (ventral abdomen), with umbilicus approximately at center of clipped area. Since the procedure does not require surgical draping, long hair must be trimmed back extensively.
- Restrain in lateral recumbency.
- Wide surgical scrub and prep, centered on ventral abdominal midline and just cranial to the umbilicus.
- Lidocaine infusion at planned point of entry; on abdominal midline, generally just cranial to the umbilicus. Use multiple (e.g., 6-8) small subcutaneous boluses.
- Note: More cranial is better in most males (greater distance from prepuce, so less risk of contamination), but it is important to avoid too cranial in animals with hepatomegaly (right-sided heart failure, some liver diseases).
- Note: Lidocaine infusion must be wide (cranial-caudal, left-right) and deep (reaching all layers, including peritoneum) and involves injecting many small pockets of lidocaine throughout the region of the planned incision.
- Caution: When redirecting, avoid subcutaneous tissue laceration with the needle tip. After each infiltration of a small pocket of lidocaine, partially withdraw the needle, redirect it, and then readvance it for the next infiltration. The multiple infiltrations can all be accomplished via a single point of needle entry (i.e., radial redirection of the needle).
- After opening the sterile gloves, keep the paper wrapper flat and use as a sterile surface. Wear the sterile gloves from this point onward. Use the suture scissors for making three to five additional drainage holes in the red rubber feeding tube to avoid omental plugging during drainage.
- Note: To make extra holes prior to inserting the tube into the abdomen, kink the red rubber feeding tube with thumb and forefinger and snip off the corner of the folded edge; unfolded edge reveals a small oval hole (needs to be <50% of tube's circumference to prevent weakening it). Repeat to make several holes along the distal half of the tube. The suture scissors are kept sterile for later in the procedure.
- Using the #11 scalpel blade, make a stab incision cranial to the umbilicus on the ventral abdominal midline at the center of the lidocaine-infiltrated area.
- Note: To avoid an excessively large incision, hold the #11 scalpel blade between the thumb and forefinger. The point at which the blade is held between the thumb and forefinger leaves a maximal width of the exposed blade that is the same as, or just slightly greater than, the diameter of the red rubber feeding tube to be inserted; that is, the fingertips act as a guard to prevent excessive insertion of the blade. For example, if a 10 Fr red rubber feeding tube will be used (approximate outer diameter of tube is 6 mm), then the scalpel blade should be held such that the maximum exposed width of the blade (at the fingertips) is 6 or 7 mm.
- The blade is set aside but kept sterile in case enlargement of the incision is necessary.
- The tube is inserted into the abdomen. Tube insertion is facilitated by grasping the tip in the lower jaw of an alligator forceps, closing the forceps, and advancing tube and forceps through the hole. Mosquito forceps are an acceptable alternative. Often the hole in the skin and the hole in the body wall are not exactly aligned because of imperceptible shifting of the tissue planes. Blunt probing with the tube and forceps may be necessary to find the hole in the abdominal wall. If excessive

pressure is required, the incision may need to be enlarged using the #11 scalpel blade.
- Any sign of discomfort on the animal's part is an indication for additional lidocaine infiltration at and around the insertion site.
- Once the tube is inserted appropriately (a release of pressure may be apparent as the tube pierces the peritoneum and initiates voluminous flow of ascites), it is advanced until it protrudes from the abdominal wall by only 1-2 inches (several cm).
- The tube is sutured in place, using 2-0 or 3-0 nylon, with both a circumferential purse string and a transfixation (suture through the tube) ligature.
- If a rapid flow of fluid occurs, a clamp or partially closed three-way stopcock (usually requiring a “Christmas tree” type of adapter to fit most red rubber feeding tubes) can be used for moderating the rate of flow.
- Complete drainage is possible in minutes (often 15-20 minutes) or 2-6 hours (animal is placed in a cage with a grated floor to allow drainage; towels are placed on top of the grate to prevent a clamp/stopcock from becoming caught in the grate).
- Caution: An Elizabethan collar is essential for preventing the animal from chewing at and transecting the tube.
- The system may be closed (drainage bag) or open; if open, as is done most commonly, the animal must be monitored for ongoing drainage, and the tube should be removed immediately when flow ceases to reduce the risk of ascending infection.
- When drainage has ended, the animal is again restrained in lateral recumbency, and the nylon ligatures are cut. The tube is removed, taking care not to withdraw omentum. The skin incision may be dried with a sterile gauze, and tissue glue may be applied to close it. If the incision is >5 mm, a skin suture or staple may be placed.



ABDOMINAL DRAINAGE Sterile red rubber feeding tube with additional holes in its distal part *(arrowheads)*. Tube is grasped in jaws of alligator forceps and passed into abdominal cavity through a small incision on ventral abdominal midline.

POSTPROCEDURE

- Weigh the animal; record weight of lost fluid (for future reference and also to know accurate lean body weight for medication dosages).
- Dripping of ascitic fluid from incision is common despite tissue glue and generally resolves in minutes to hours. If it is persistent, a skin suture or staple may be necessary.
- Dripping and any subcutaneous pooling of ascitic fluid are minimized by allowing complete rather than partial drainage during procedure.

ALTERNATIVES AND THEIR RELATIVE MERITS

Abdominocentesis with needle and syringe:

- Less invasive
- Very time-consuming for large volumes (e.g., 1 l or more)
- Generally ineffective at removing most or all of ascites

Abdominocentesis with suction/vacuum:

- Faster
- May aspirate omentum or other abdominal structure
- Drainage less complete

AUTHOR: ETIENNE CÔTÉ

Buccal Mucosal Bleeding Time

SYNONYMS

Bleeding time, BMBT

OVERVIEW AND GOALS

To quickly and easily assess primary hemostasis and evaluate formation of a platelet plug

INDICATIONS

Presence of mucosal hemorrhage (petechiae/ecchymoses, gingival bleeding, epistaxis, melena, hematuria) in animals with a normal platelet count. May also be used for assessing primary hemostasis in preoperative animals.

CONTRAINDICATIONS

Thrombocytopenia

EQUIPMENT, ANESTHESIA

- Anesthesia is generally not required in dogs.
- Sedation or general anesthesia necessary in cats
- Template bleeding device (device with a spring-loaded blade that creates a standard incision in the buccal mucosa)
- Filter paper or gauze for blotting blood
- Muzzle gauze (or equivalent)
- Stopwatch

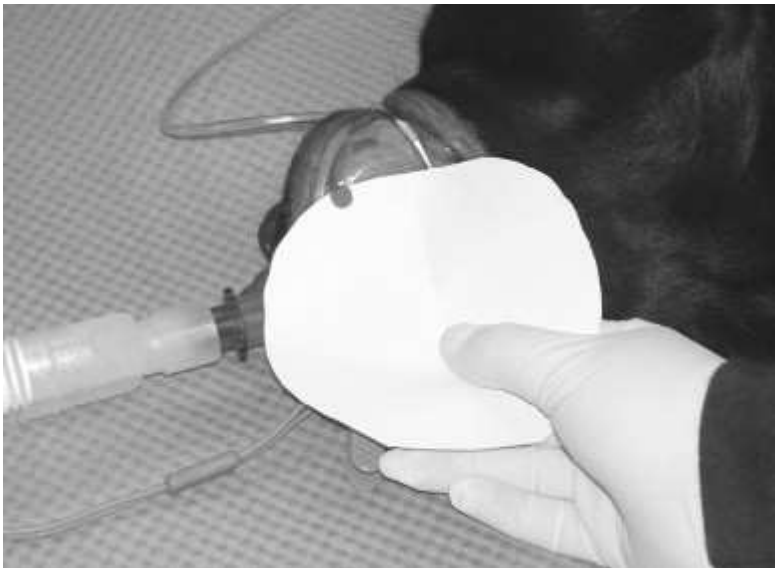
BUCCAL MUCOSAL BLEEDING TIME Template bleeding device placed against buccal mucosa.

ANTICIPATED TIME

A total of 5-10 minutes

PREPARATION: IMPORTANT CHECKPOINTS

Evaluate platelet count prior to evaluating buccal mucosal bleeding time (BMBT).



BUCCAL MUCOSAL BLEEDING TIME Blotting blood below the incision.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Animal may become agitated; use sedation as needed to keep animal still for entire test.
- Do not manually disrupt clot while assessing clotting time.

PROCEDURE

- Place animal in lateral recumbency.
- Evert upper lip and secure in everted position with muzzle gauze. This allows exposure of the buccal mucosa and causes the vessels to become slightly engorged.
- Place template firmly on mucosa, and activate the blade.
- Begin timing when the incision is made.
- Hold filter paper beneath the incision to absorb blood.
- Continue timing until a clot has formed and bleeding has ceased.
- Normal BMBT is about 3 minutes in cats and about 4 minutes in dogs.

POSTPROCEDURE

After the clot has formed and the test is completed, it may be necessary to apply pressure as needed if the clot becomes disrupted and bleeding resumes.

ALTERNATIVES AND THEIR RELATIVE MERITS

Cuticle (“toenail”) bleeding time; less reliable as a measure of primary hemostasis and more painful to the animal.

AUTHOR: ERIKA DE PAPP

Bronchoscopy

OVERVIEW AND GOALS

To view and assess both the anatomy (mucosal, structural) and function (dynamic collapse) of the airways from larynx to distal bronchi and to obtain samples from the distal airways for analysis

INDICATIONS

- Diagnostic: evaluation of lower airway and parenchymal disease (culture/cytologic examination, biopsy) and documentation of airway caliber disorders (malacia, collapse, compression, bronchiectasis, bronchial stenosis)
- Therapeutic: foreign body/secretion removal

CONTRAINDICATIONS

- Major: severe hypoxemia, unstable cardiac arrhythmias, heart failure
- Minor: significant resting expiratory effort, bronchomalacia, inexperience

EQUIPMENT, ANESTHESIA

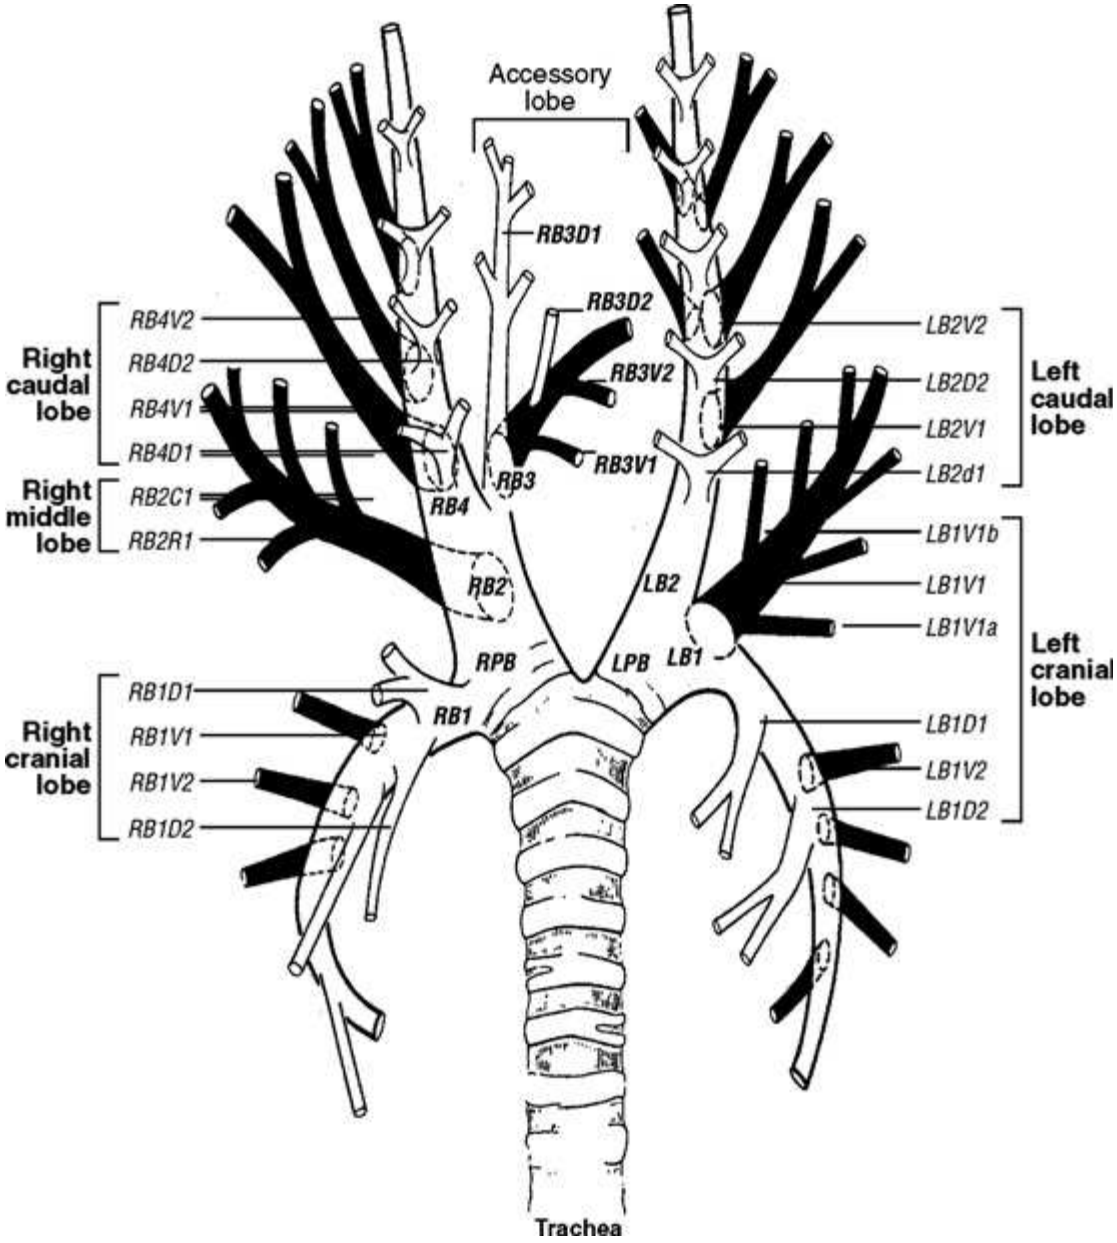
- Equipment:
  - Flexible endoscope: 3-5 mm in diameter, 55-85 cm in length
  - Mouth gag, sterile gauze, suction capabilities
  - Sterile saline:
    - Preloaded in 3 or 4 10- to 20-mL syringes for bronchoalveolar lavage (BAL)
    - For rinsing and cleaning
  - Sterile, water-soluble lubricant
  - Forceps: if foreign body removal or mucosal biopsy is required
- Anesthesia:
  - Pretreatment with a bronchodilator is recommended, especially in small dogs and all cats; use injectable terbutaline, 0.01 mg/kg SQ at least 15 minutes prior to the procedure.
  - IV catheter for administration of a short-acting injectable anesthetic protocol: either atropine, 0.02-0.04 mg/kg IM; or glycopyrrolate, 0.01-0.02 mg/kg IM; in addition, butorphanol, 0.05-0.1 mg/kg IM and diazepam, 0.1 mg/kg IV followed by propofol, 3-6 mg/kg, slow IV titrated to effect, with repeated miniboluses of propofol (1 mg/kg) as needed over the duration of the procedure to maintain anesthetized state.
  - Intubation is rarely used for the procedure; an anesthesia “T” piece is required if the scope will be passed through the tube; jet ventilation can be used if available.
  - Provide oxygen before, during, and after the procedure; insufflate oxygen through the endoscope channel or via a 3-8 Fr urinary catheter passed alongside the scope during the procedure; use an endotracheal tube or a face mask for oxygen administration before and after.
  - Topical 2% lidocaine if needed to decrease pharyngeal/laryngeal sensation, excessive coughing, and movement
  - Doxapram HCl, 2.2 mg/kg IV once to assist with the evaluation of intrinsic laryngeal function
  - Electrocardiogram (ECG), oximetry, blood pressure (BP) cuff, and other monitoring equipment

ANTICIPATED TIME

A complete bronchoscopy and bronchoalveolar lavage can be completed within 10-20 minutes by an experienced endoscopist; animal recovery time is additional and varies with the type of anesthetic used.

PREPARATION: IMPORTANT CHECKPOINTS

- The bronchoscopist must have a good understanding of normal bronchial mucosa and lung anatomy to diagnose subtle airway abnormalities.
- The bronchoscope should be cleaned and ready for use.
- All supplies and equipment should be available before starting the procedure; anesthetic monitoring and image capture equipment should be turned on and ready to use.
- Antibiotics should be discontinued at least 72 hours prior to the procedure for accurate culture results.
- Chest radiographs are useful to help select specific lung regions for examination and for BAL.



BRONCHOSCOPY Diagrammatic representation of the normal canine tracheobronchial tree.

(Reprinted with permission from Amis T, McKiernan BC: Systematic identification of endobronchial anatomy during bronchoscopy in the dog, Am J Vet Res 47:2649–2657, 1986.)

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Contamination of the BAL sample is possible if care is not taken to avoid touching the upper airways during insertion of the scope. Guarded catheters may be used for decreasing the potential for BAL contamination, although catheter cost limits their use.
- Pulmonary barotrauma (tracheobronchial or lung rupture) is possible if the oxygen insufflation rate exceeds the ability of the gas to exit the lungs; this is of concern in smaller animals when the bronchoscope diameter is close to the tracheal size and pressure builds up in the lungs as active insufflation continues.
- Airway collapse during recovery can result in severe hypoxemia; anticipate when active expiratory effort is noted prior to anesthesia; slow recovery from anesthesia helps minimize this concern.

PROCEDURE

- Sternal recumbency is the recommended position in cats and dogs.
- Topical anesthesia (1%-2% lidocaine) may be applied to the pharyngeal/laryngeal mucosa to minimize laryngospasm or excessive coughing.

- Provide oxygen as already outlined.
- Evaluate the oropharyngeal/laryngeal region; use IV doxapram HCl (2.2 mg/kg once) to stimulate intrinsic laryngeal motion.
- Insert the bronchoscope into the airways, noting changes in shape (stenosis, stricture), dynamic caliber (malacia, collapse), and mucosa (secretions, erythema, edema, masses).
- In the normal animal, the dorsal tracheal membrane is taut so that there is little if any redundancy (no visible protrusion or collapse into the airway).
- The healthy tracheobronchial mucosa is a smooth, light-pink surface with a rich supply of submucosal capillaries; if these capillaries are not visible, mucosal edema or cellular infiltration is likely present.
- Healthy mucosa has a slightly glistening appearance; mucosal edema is readily apparent because it imparts a gelatinous appearance to the epithelial surface.
- The clinician should examine the carina for abnormalities (widening, compression, mucosal infiltration) before evaluating each lobar and as many segmental and/or subsegmental bronchi as possible (as both the animal and endoscope size will allow).
- Airway bifurcations beyond the carina are referred to simply as a *spur.* Like the carina, these should also form a sharp V, but they become widened and appear U shaped with chronic airway inflammation and/or mucosal edema.
- Small polypoid mucosal nodules are commonly encountered in the bronchi of dogs with chronic bronchitis.
- Small amounts of white or slightly opaque mucus may be noted in a healthy animal, but larger accumulations or secretions of unusual color are abnormal.
- The normal monopodial branching system results in a gentle, smooth tapering of the airways. Changes may be focal or generalized and include those of shape and size of the airway lumen, such as an intraluminal stricture/tumor, external compression (tumor or lymphadenopathy), bronchiectasis, or dynamic collapse (malacia).
- Whether or not abnormalities are noted, samples should be obtained for culture and cytologic examination. Following the initial airway evaluation, the endoscope is removed from the animal and cleaned by alternatively suctioning the channel with sterile saline and air immediately prior to reinsertion.
- The BAL site (lobe and bronchus) is chosen based on both radiographic and gross bronchoscopic findings. If no site is clearly abnormal, BALs from both “middle” lung lobes should be collected.
- To perform a BAL, the bronchoscope is first gently wedged into a segmental or smaller bronchus. Aliquots of 10-20 mL sterile saline (depending on the size of the animal) are instilled into the airway (via the suction channel or a washing pipette) and then immediately aspirated using slow, gentle hand suction.
- Ideally, at least two different sites (lung lobes) should be lavaged, with two aliquots per site.
- A 40%-90% return of the volume instilled is expected. Difficulty in fluid recovery results when a proportionately large endoscope is used (prevents wedging into a small bronchus) or if malacic airways collapse when suction is applied.
- If there is enough time and anesthetic depth is appropriate, the nasopharynx should also be examined.

POSTPROCEDURE

- Provide supplemental oxygen until fully recovered.
- Crackles are commonly noted on auscultation for a short time following a BAL procedure.
- Process samples immediately.
    - Quantitated aerobic cultures should be made if possible.
    - *Mycoplasma* and anaerobic cultures are processed using Amies transport media, or submit fluid in a sterile tube.
    - Cytologic analysis:
        - Total white blood cell (WBC) and differential cell counts should be done.
        - The predominant cell in all species should be the alveolar macrophage (70+%), with usually less than 3%-8% of all other cell types (except the cat, which may have up to 20+% eosinophils and still be normal).
- Handling the scope:
    - Immediately rinse/wipe the scope down when finished to prevent secretions from drying.
    - Clean and sterilize the scope as outlined in the manufacturer's manual.
    - Store the scope hanging up (to fully dry it) in a protected space/closet.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Tracheal wash procedures are less expensive and easier to perform, but they lack the ability to direct sampling into specific sites, provide no information regarding anatomic, structural, or functional airway abnormalities, and have no therapeutic capability.
- Fine-needle lung aspiration biopsy has been used successfully to sample consolidated lung lobes and larger masses.

AUTHOR: BRENDAN C. MCKIERNAN

Breeding Soundness Exam: Male Dog

OVERVIEW AND GOAL

Evaluate the physical and physiologic parameters of the breeding male

INDICATIONS

- Prior to breeding, especially with a virgin male, a male with a history of systemic disease or when the male has not been used for breeding for several months
- Less than 50% whelping rate
- Prepurchase evaluation of a male intended for breeding

EQUIPMENT, ANESTHESIA

- Scrotal calipers
- A semen collection vessel such as:
  - 15-mL centrifuge tube and plastic cone
  - Sterile urine cup
  - Whirl-Pak bag
- Microscope
- Morphology stain (eosin-nigrosin) and Diff-Quik stain for cytologic analysis
- Hemocytometer and WBC Unopette
- Ultrasound

ANTICIPATED TIME

30-90 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- 1 week sexual rest recommended prior to a breeding soundness exam (BSE)
- It is recommended to fill out an evaluation form when performing a BSE, as this will help ensure all important points are covered and provide a valuable record. An evaluation form is available from the Society for Theriogenology.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO BE AVOIDED

- It is important to prevent thermal, mechanical, or chemical injury to the semen once collected.
- A poor-quality semen sample, especially one with low sperm numbers, should be interpreted with caution, as it may be an incomplete ejaculate. Seminal alkaline phosphatase (ALP; of epididymal origin) can be used to distinguish between an incomplete ejaculate and true azoospermia. Normal ALP of a complete ejaculate would be between 5000 and 40000 IU/L. An incomplete ejaculate usually would usually measure <1000 IU/L.

PROCEDURE

- History:
  - Obtain a general health history including nutrition, vaccination history, systemic diseases and previous illnesses with attention to anything that may have resulted in thermal injury (fever) or trauma to the penis or scrotum. Include all previous medications, especially corticosteroids, anabolic steroids, chemotherapeutics, anthelminthics, and antifungal agents.
  - Obtain a thorough reproductive history including libido, presence of a tie at each breeding, and the details for all bitches bred. This would include their age and parity, type of breeding management used, dates bred, method of pregnancy diagnosis, their whelping dates, and litter sizes. The results from any previous semen evaluations, cytologic evaluation, and cultures should also be included.
- Perform a general physical exam, noting any musculoskeletal pain that may affect mating ability and potential hereditary or congenital defects. Chronic conditions such as obesity, skin disease, and endocrine disorders can also negatively impact fertility.
- Scrotal width should be measured by calipers. This correlates with testicular volume and sperm production.

- The testes and epididymides should be palpated for symmetry and consistency. The testes lie horizontally in the scrotum, with the tail of the epididymis at the caudal pole; the body and head of the epididymis lie along the cranial-dorsal aspect. It is abnormal for the testes to be either soft or hard, which may indicate degeneration, hypoplasia, neoplasia, fibrosis, or abnormal development.
- Prostate evaluation involves rectal and abdominal palpation. For rectal palpation, it may be necessary to simultaneously exert dorsal pressure on the abdomen to lift the bladder and prostate higher into the pelvic inlet. On rectal exam, the prostate should be smooth and bilobed and lie 2-3 cm caudal to the brim of the pelvis. Size, texture, and pain should be evaluated:
    - An ultrasound exam is warranted if any abnormalities are noted. If the prostate cannot be reached by rectal exam, it may be evaluated by transabdominal ultrasound or radiography.
- The prepuce is examined for discharge and the presence of paraphimosis. Preputial discharge may be the result of posthitis or balanoposthitis. The penis is best examined during semen collection. If semen collection is not to be performed, the prepuce should be reflected and the penis evaluated.
- Semen collection:
    - Before starting, the collection vessels should be prepared and within reach of the collector.
    - If possible, the male and teaser bitch should be allowed to interact. When the male becomes sexually excited, the collector should step in and begin to stimulate the penis through the prepuce.
    - The bulbus glandis is stimulated inside the prepuce until an erection is established, then the prepuce is retracted caudal to the bulbis glandis to expose the penis.
    - The collector encircles both hands around the base of the bulbus glandis. To simulate the tie, the dog may want to step over the collector's arm. The dorsal aspect of the penis remains dorsal as the collector turns the penis 180° until it is directed caudally.
    - The ejaculate should be fractionated such that each fraction is collected in a separate vessel. The first fraction is the pre-sperm fraction consisting of 1-2 mL of clear prostatic fluid. The second fraction is the sperm-rich fraction and consists of 1-3 mL of an opaque to creamy white fluid. The third fraction is clear prostatic fluid and will continue to be produced as long as the erection is maintained.
    - After the collection is complete, placing a small amount of water-soluble lubricant around the bulbus glandis will aid retraction into the prepuce.
- Semen evaluation:
    - Color:
        - The first and third fractions should be colorless, and the second should be slightly white to cream colored. In cases of prostatic disease, such as benign prostatic hyperplasia, the third fraction maybe pink, red, or brown colored. A yellow color indicates urine contamination; an Azostix can be used to confirm the presence of urea.
    - Semen analysis:
        - Motility is evaluated by placing a drop of semen on a warm slide and adding a cover slip. Gross motility is evaluated at low power (10-20), and individual motility is evaluated at 40. Normal motility is >70% with good forward progression.
        - A morphology slide is prepared by placing a drop of semen on a warm slide along with a drop of an eosin-nigrosin morphology stain. The two drops are mixed together, spread evenly across the slide and allowed to air dry. Alternatively, the slide can be prepared by smearing the semen drop across the slide and stained using Diff-Quik. If this method is used, the slide should remain in the purple and red stain for 10 minutes each to ensure stain penetration of the sperm cells. The slide must be evaluated under oil immersion (100×). Normal morphology should be >70%. Primary defects should not be greater than 10%, and secondary defects should not be greater than 20%.
        - A concentration is obtained by creating a 1 : 100 dilution, either using a WBC Unopette or by manually pipetting 20 L of semen into 2 mL of distilled water, and counting the central square on a hemocytometer. This is the concentration in million per milliliter.
        - Volume should be between 1 and 30 mL total, with the sperm rich fraction comprising 1-12 mL.
        - Total sperm/ejaculate should be between 200 million and 2 billion. This is dependent on the body weight of the dog but should be greater than 22 million per kilogram of body weight.
    - Cytologic analysis:
        - Normal cytologic examination should contain <2000 WBC/mcL. There should not be more than 6 leukocytes per high-power field in any portion of the ejaculate.
        - Abnormalities include red blood cells, tumor cells, and spermatocytes.
    - Culture:
        - >105 gram-negative organisms/mL and an inflammatory cytologic profile indicates bacterial infection (typically prostatitis).
    - pH: between 6.3 and 6.7
- Blood should be collected for a baseline database including *Brucella canis*titer, CBC, serum biochemistry, and thyroid function tests.

POSTPROCEDURE

- If there is a high number of morphologically abnormal sperm, the semen analysis should be repeated in ~60 days.
- Additional tests not part of a routine BSE but which can be performed to further investigate an infertility problem include:

- Staining for intact acrosomes
- Endocrine assays
- Karyotype
- Testicular ultrasound
- Testicular biopsy

AUTHOR: BRONWYN CRANE

Breeding Soundness Exam: Female Dog

OVERVIEW AND GOAL

Evaluate the physical and physiologic parameters of the breeding female to determine her likelihood for normal fertility.

INDICATIONS

- Prior to breeding, to ensure general health and likelihood of a healthy litter
- Prepurchase evaluation of a female intended for breeding
- A breeding female with a history of abnormal estrous cycles or failure to conceive when bred to a fertile male with appropriate breeding management

EQUIPMENT, ANESTHESIA

- Canine vaginal speculum
- Pediatric protoscope and a penlight
- Cotton-tip swab, slides, and Diff-Quik stain for vaginal cytology
- Culturette for vaginal culture, if needed. Double-guarded swabs for mares will work well.
- Blood collection supplies
- Ultrasound
- If vaginoscopy is required:
    - Rigid endoscope
    - Sedation/anesthesia

ANTICIPATED TIME

30-90 minutes

PROCEDURE

- The reproductive history will often outline a cause for infertility or reveal an area for improvement in the breeding management. A complete reproductive history should be obtained and include the following:
    - Fertility of dam, sire, and littermates
    - Date and age at first estrus
    - Duration of estrus
    - Duration of interestrus intervals
    - Progesterone/vaginal cytologic analysis results and dates from previous estrous cycles
    - Insemination dates and semen evaluation (if performed)
    - Date(s) and method(s) of pregnancy diagnosis
    - Whelping dates and litter sizes
    - Dates and results of *Brucella canis* tests
    - Vaccination and general health history: general health history should take into account factors and diseases that could potentially alter fertility. This would include thyroid disorders, prolonged treatment with corticosteroids (e.g., for skin problems), and potential exposure to reproductive pathogens such as canine herpesvirus.
- The following diagnostic samples should be collected:
    - Serum progesterone: result should coincide with the expected stage of the estrous cycle
    - Vaginal cytologic sample: result should also coincide with the stage of the estrous cycle and could potentially reveal inflammation.
    - *Brucella canis* serologic test (see p. 162): initial screening test is usually a highly sensitive test. This will result in a higher number of false positives but fewer false negatives. The rapid slide agglutination test (RSAT), the modified RSAT (MERSAT) and the tube agglutination test (TAT) are the most common screening tests performed. Antibodies for *Bordetella* spp. may cross-react with the *Brucella canis* tests. A positive test should be followed up with a more specific test such as agar gel immunodiffusion, blood culture, or histopathologic examination of tissue.
    - CBC and serum biochemistry profile
    - Thyroid function tests
- A complete physical exam should be performed. This includes careful palpation of the mammary glands and a digital vaginal exam. Physical factors which may reduce fertility include abnormal vulvar conformation, vaginal strictures, and a persistent median septum. Potential hereditary disorders such as orthopedic disorders (hip dysplasia, elbow dysplasia, cranial cruciate

ligament rupture), ophthalmic disorders, and heart conditions should be evaluated and brought to the attention of the breeder if present.

- Vaginal speculum exam is performed using a canine vaginal speculum and/or the pediatric proctoscope (if available). This will allow visualization of the caudal vagina only. The degree of vaginal crenulation as well as the presence or absence of vaginitis can be observed.
- Vaginoscopy requires a rigid or flexible endoscope at least 30 cm long (depending on the size of the bitch). This will allow visualization of the entire vagina and external cervical os. Strictures, persistent median septa, and other abnormalities may be observed.
- Vaginal culture should be obtained after a sterile prep of the vulva and careful retraction of the vulvar lips or insertion of a sterile vaginal speculum:
    - Contamination can be prevented by using a double guarded swab.
    - Careful interpretation of the vaginal culture is required, as most cultures will be positive for one or more bacteria considered part of the normal flora. If high numbers of potentially pathogenic bacteria are cultured, this result may be considered significant.
    - Vaginal culture should be interpreted together with the history and vaginal cytology:
        - If there is no evidence of infertility or inflammation, a positive culture—even with a potential pathogen—is most likely insignificant.
    - If *Mycoplasma canis* is a concern, the diagnostic lab receiving the sample should be contacted regarding the culture procedures and shipping requirements prior to obtaining a sample.
- Ultrasonography of the uterus and ovaries should be part of a complete breeding soundness exam. In larger bitches, it can be difficult to image the ovaries consistently. The uterus is located dorsal to the bladder and should be followed to the horn tips:
    - The features of the uterus will vary with the stage of the estrous cycle. During proestrus and estrus, the uterus will be edematous and appear have a heterogenous echotexture. There may be a small amount of fluid present in the lumen at this time. During diestrus, the uterus will have a more homogenous echotexture and may have a convoluted course. Cystic structures within the endometrium are abnormal at any stage of the estrous cycle and may indicate cystic endometrial hyperplasia. The presence of luminal fluid in diestrus is also abnormal and indicates mucometra or pyometra. Ovarian structures should coincide with the stage of the estrous cycle. Follicles larger than 8 mm are most likely anovulatory follicles. These could be significant if signs of prolonged proestrus exist (estrogen exposure) and may be estrogen-producing cysts. During diestrus, the ovaries will contain corpora lutea and some small follicles. During anestrus, the ovaries will have only small follicles and may be difficult to locate.

POSTPROCEDURE

Additional tests:

- An abnormal or unexpected progesterone or vaginal cytologic analysis should be followed by serial tests every 2 days.
- A positive *Brucella* RSAT or TAT should be followed by a more specific test such as agar gel immunodiffusion or culture.
- Suspected vaginal abnormalities can be further evaluated by a vaginography or vaginoscopy.
- Karyotyping should be performed on females with abnormal external or internal genitalia, with irregular estrous cycles or failure to cycle.

AUTHOR: BRONWYN CRANE

Brainstem Auditory Evoked Response (BAER) Test

SYNONYMS

Hearing test, auditory brainstem response (ABR)

OVERVIEW AND GOALS

- A noninvasive way of evaluating hearing and brainstem function by recording the electrical response in the brainstem to an external auditory stimulus.
- An average of 256 and 1000 time-locked recordings result in a characteristic waveform with five to seven discernable waves (I-VII).
- Wave I is generated by the ipsilateral cochlear nerve. Waves II-V are generated by nuclei within the medulla, pons and midbrain.
- The brainstem auditory evoked response (BAER) test does not actually assess conscious perception of hearing; however, because there are very few diseases that would interrupt the hearing pathways after they have left the brainstem, it is accepted as a valid test of hearing.
- Conductive (obstruction to sound in the ear canal or middle ear) and sensorineural (abnormality with the nerves or receptors in the inner ear) deafness both can result in an abnormal BAER test.
- Congenital sensorineural deafness typically results in a flat BAER recording.
- With conductive disorders, the latency from stimulus to the appearance of wave I is delayed, and there is often decreased amplitude which increases when the intensity is raised from 80 to 100 dB.
- With brainstem lesions, the interpeak latencies (I-III, I-V) may be prolonged relative to normal reference range or the opposite side, and the wave V/I amplitude ratio may be reduced.
- Brainstem death results in a BAER that is either flat or has only a wave I.
- Although BAER testing is commonly used for identifying congenital deafness (an absolute yes/no assessment), it can also be used for assessing the level of hearing function by performing threshold analyses. Most dogs can hear sounds at a level of sound intensity of 0-5 dB. By gradual reduction of the sound intensity during testing (from an initial level of 80 dB), the examiner can establish whether the threshold is abnormally increased.

INDICATIONS

- Suspected deafness or hearing loss (unilateral or bilateral). Screening for congenital deafness is the most common reason for BAER testing. It is frequently performed in puppies of those breeds commonly affected with congenital deafness (e.g., dalmatian, bull terrier, English setter).
- Suspected brainstem disease (neoplasia, encephalitis, infarction)
- Confirmation of brainstem death (complete loss of brainstem function)

EQUIPMENT, ANESTHESIA

- A computer with a signal averager and software capable of labeling and analysis of waveforms
- Subdermal electrodes
- Foam insert microphones, headphones or a bone conductor
- Otoscope
- Sedation may or may not be required, depending on how quiet the animal is and if it will lie still for 10-15 minutes. If sedation is required, light sedation is usually sufficient, and it will not significantly alter the characteristics of the recorded waveforms.

ANTICIPATED TIME

Usually 15-30 minutes depending on the animal's temperament and behavior

PREPARATION: IMPORTANT CHECKPOINTS

- Computer check to see that established protocols have been loaded appropriately and settings are correct.
- Impedance check (via computer software program) to ensure that all the electrodes are operating effectively.
- Otoscopic examination (see p. 1316): to ensure that ear canal is open and free from significant amounts of debris or exudate. A stenotic or occluded ear canal will not transmit sound to the tympanum and will result in subnormal waveform amplitudes and prolonged wave I latency. Ear canals may need to be cleaned thoroughly prior to the BAER test. Clinicians should

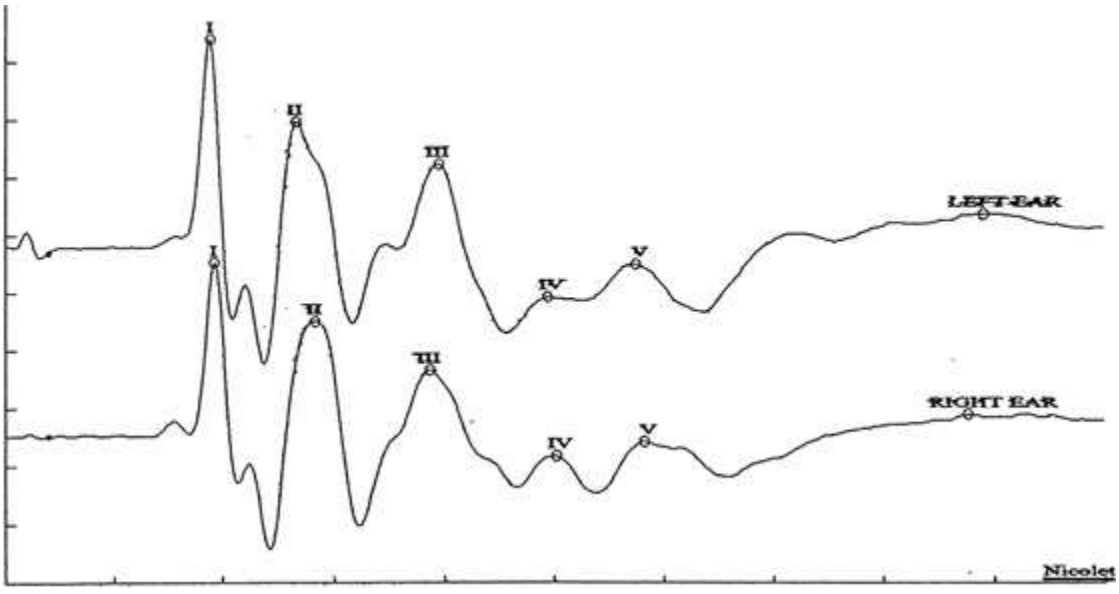
visually assess the integrity of the tympanic membrane.
- Ensure that right and left ear electrodes are appropriately placed and noted correctly on the computer.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Ear canals filled with exudate, cerumen, or debris
- Testing puppies that are too young. Puppies should be at least 6 weeks of age when tested.
- Although general anesthesia has little effect on the BAER, hypothermia will prolong latencies.
- Inserted microphones: not placed sufficiently deeply in the ear canal, or positioned such that the sound is directed into the wall of the ear canal instead of down the lumen
- Subdermal electrodes become dislodged.
- If flatline or grossly abnormal recording is obtained, always do a thorough technical check (e.g., computer working, sound is actually generated in the microphones, subdermal electrodes in place and not dislodged, inserted microphones placed appropriately in the ear canal) to ensure that the result is real. In some cases, a known normal dog should be checked to ensure there is not a technical problem and prevent incorrectly diagnosing deafness.

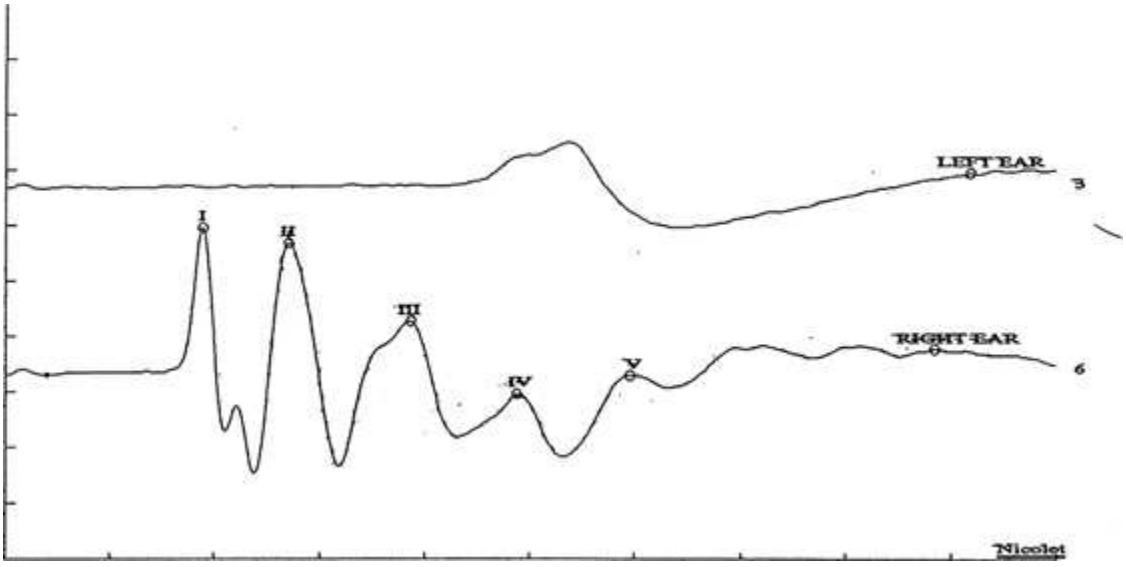
PROCEDURE

- Place animal in sternal recumbency or in a sitting position.
- Turn on computer, load appropriate software and protocols, and set up animal record.
- Perform an otoscopic examination and clean ears if necessary.
- Insert subdermal electrodes:
    - Reference: mastoid. Place electrode subcutaneously adjacent to where the horizontal ear canal begins just rostral to the base of the ear (usually at the caudal end of the zygomatic arch). The T1 reference may also be used just dorsal to the spinous process of T1.
    - Recording electrode: vertex. Place the electrode midline, halfway between the occipital crest and orbits.
    - Ground electrode: place the electrode midline over the second to fourth cervical vertebra.
- Check electrode impedance (usually in the computer software) to ensure that electrodes are working appropriately.
- Place foam insert microphones in right and left ear canals; place them so they are well seated in the upper (distal) third of the vertical ear canal. If using headphones, ensure that the pinnae are not obstructing the headphones and a snug seal is established over the ear canal.
- Set sound intensity at 80 dB. There is no established appropriate sound intensity to do initial screening, but this level has been determined to be comfortable for the animal and effective at identifying potential hearing deficits.
- Set signal averager to average 1000 signals (256 may be adequate for cats or uncooperative dogs if the waveform is clearly normal), and select right or left ear to begin recording.
- Each ear should be recorded twice, and the recorded waveforms should be compared. They should be very similar. If not, do a technical check and repeat the test.
- Once good-quality recordings have been recorded for both ears, the waveforms should be labeled and amplitudes and latencies calculated.
- Subdermal electrodes and inserted microphones are then removed, and the animal can be discharged.



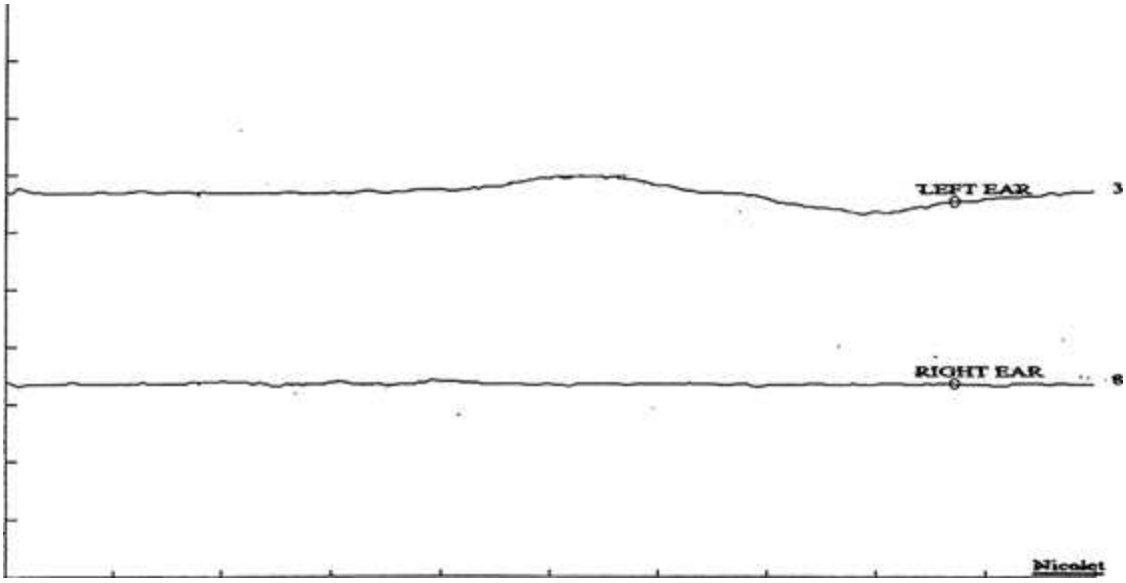
BRAINSTEM AUDITORY EVOKED RESPONSE (BAER) TEST Normal study.

(Courtesy Dr. Peter Foley.)



BRAINSTEM AUDITORY EVOKED RESPONSE (BAER) TEST Unilateral deafness in the left ear.

(Courtesy Dr. Peter Foley.)



BRAINSTEM AUDITORY EVOKED RESPONSE (BAER) TEST Bilateral deafness.

(Courtesy Dr. Peter Foley.)

POSTPROCEDURE

If the animal has been sedated, allow it to recover sufficiently before discharge.

ALTERNATIVES AND THEIR RELATIVE MERITS

There are no practical and accurate alternatives to establishing unilateral or bilateral deafness in dogs and cats. Bilateral deafness can usually be suspected but not confirmed by subjective assessment of the animal's response to loud noises.

Brain Biopsy, CT-Guided Stereotactic

OVERVIEW AND GOAL

Neoplastic, vascular, infectious, or inflammatory diseases of dogs and cats frequently result in focal brain involvement. Although CT and MRI are sensitive in determining location, extent, and relationships of brain lesions to adjacent structures, both have limited specificity. For example, non-neoplastic lesions (such as those seen in association with infection, inflammation, or vascular diseases) may mimic the CT or MRI appearance of a neoplasm. In most instances, results of CT or MRI provide only a broad list of differential diagnoses for a focal brain lesion. Accurate histologic diagnosis of an intracranial lesion is critical before recommending a specific management or treatment strategy.

INDICATIONS

This procedure is used for obtaining tissue samples of areas within the brain that have CT or MRI imaging characteristics consistent with a neoplasm or an infectious/inflammatory lesion. The main indications for stereotactic biopsy are deep-seated focal lesions, multiple lesions, or disseminated lesions of the brain.

CONTRAINDICATIONS

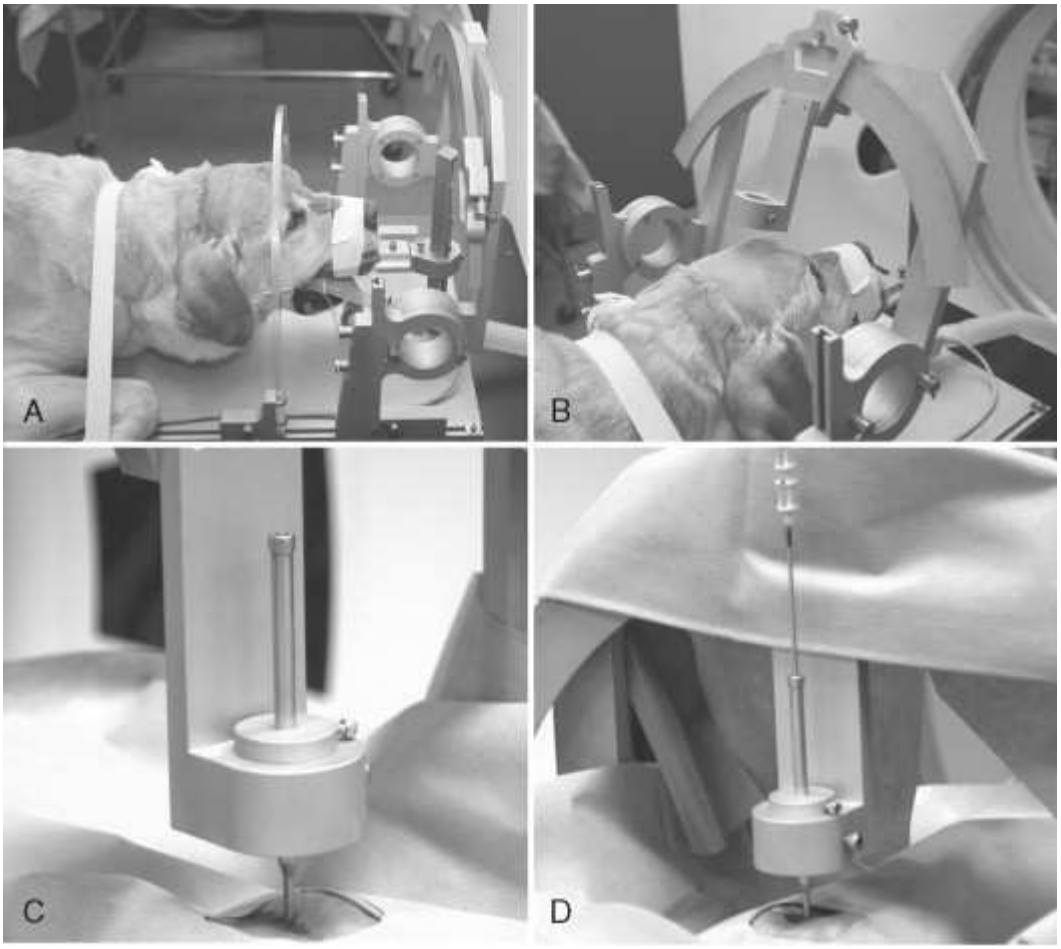
Brain biopsy should be approached with caution in animals with underlying bleeding disorders, clinical signs consistent with increased intracranial pressure (ICP), brainstem lesions, or systemic problems that result in increased anesthetic risk.

EQUIPMENT, ANESTHESIA

- Essentially all closed stereotactic brain biopsy methods rely on the three-dimensional CT-generated coordinates identifying the lesion location. These coordinates are used for plotting an optimal trajectory and depth needed for a biopsy needle to reach a target and obtain a diagnostic tissue sample.
- Technical impediments exist to the direct application of most human stereotactic systems to dogs and cats. Most commercially available systems use a cumbersome head frame and localizing system designed specifically for the human skull, and they require dedicated expensive computer software for the planning phase. Several different systems for image-guided stereotactic brain biopsy have been reported for use in dogs and cats.
- General anesthesia is required for stereotactic brain biopsy. Typically, pre-medication utilizes an opioid (a pure mu agonist because of using fentanyl in the maintenance phase). The dose and use of this drug will depend on the concern over changes in ICP and the mental status of the patient. General anesthesia usually is induced with propofol (± a benzodiazepine). Propofol (0.1-0.4 mg/kg/min to effect) and fentanyl (0.3-0.7 mcg/kg/minute to effect) are recommended for maintenance. Animals should be ventilated to maintain ETco2 at a value of 30-35 mm Hg. For recovery, the fentanyl should be stopped about 30 minutes before the end of the procedure.

ANTICIPATED TIME

2-3 hours, depending on the number of biopsy specimens collected and the number of trajectories planned



BRAIN BIOPSY Center-of-the-arc CT-guided stereotactic brain biopsy system. **A**, Dog positioned in biopsy frame. **B**, Biopsy frame positioned in appropriate trajectory for biopsy. **C**, Drill guide in place. **D**, Biopsy needle positioned in needle guide.

PREPARATION: IMPORTANT CHECKPOINTS

- Stereotactic biopsy begins with proper patient selection. The possibility of non-neoplastic disorders such as infection, cerebral infarction, or vasculitis must be considered and investigated, with other tests as appropriate prior to (or instead of) biopsy.
- When the differential diagnosis list is long and may include neoplasms and inflammatory lesions, the appropriate handling of tissue samples should be discussed with a neuropathologist in advance of the procedure.
- All patients should be tested for coagulation parameters (prothrombin time [PT], partial thromboplastin time [PTT]) prior to the procedure and should have a platelet count >100,000 mcL.
- Patients should not receive aspirin products for 1 week before surgery.
- Ideally, MRI or CT images should be completed within 10 days prior to completion of the biopsy procedure.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO BE AVOIDED

Although stereotactic brain biopsy is minimally invasive compared with open biopsy techniques, complications rarely may occur. Morbidity may include seizures, hemorrhage, development of biopsy-induced neurologic deficits, brain infection, tumor seeding, and lack of a definitive diagnosis.

PROCEDURE

- Biopsy generally is done on the CT-scanner table. For those lesions not well identified on CT images, MRI images that demonstrate a lesion may be used for localizing the lesion on CT images, using well-defined anatomic landmarks (e.g., lateral ventricles).
- Transverse CT images are used for defining the CT coordinates of reference markers and the biopsy target. Dorsal or sagittal images may be used for trajectory planning.
- An entry point should be selected that is associated with a low risk for neurologic deficit or hemorrhage (e.g., avoidance of dorsal sagittal sinus). Ependymal puncture should be avoided where possible.

- A small craniotomy (2-mm diameter) is made by means of a twist drill, the dura mater is punctured with an 18-gauge needle, and biopsies may be done with a side-cutting aspirator biopsy needle (Nashold Biopsy Needle [Integra Radionics, Burlington, Mass.]) with a 10-mm side opening. On average, one to three specimens are harvested.
- The intraoperative goal should be to confirm by means of smear or touch preparations whether tissue satisfactory for an eventual diagnosis has been obtained. A specific histologic diagnosis may require routine formalin fixation and paraffin embedding of the biopsy tissue.
- At the conclusion of the biopsy procedure, the needle is withdrawn in increments to assess any possibility of hemorrhage. In the case of hemorrhage, blood should be permitted to egress from the needle spontaneously until bleeding stops.

POSTPROCEDURE

- A series of CT images of the brain should be obtained immediately after completion of the biopsy procedure in order to assess the possibility of intracranial hemorrhage.
- Animals should be recovered in sternal recumbency with the head elevated slightly above the level of the heart.
- Animals should be observed for 12 hours postbiopsy before being discharged from the hospital.

ALTERNATIVES AND THEIR RELATIVE MERITS

Open (surgical) brain biopsy may be appropriate in certain clinical situations in which cortical architecture needs to be preserved, for leptomeningeal sampling, for superficially located lesions, and when a decompressive craniectomy with good cortical visualization may be helpful in addition to obtaining a biopsy sample.

AUTHOR: RICHARD A. LECOUTEUR

Bone Marrow Aspiration/Core Biopsy

OVERVIEW AND GOALS

To obtain a sample of bone marrow cells for cytologic (aspiration) and/or histologic (core biopsy) analysis

INDICATIONS

- Cytopenias without identifiable underlying cause
- Unusual blood cell morphologic abnormalities on blood smear
- Staging of neoplasia (notably lymphoma and mast cell tumor)

CONTRAINDICATIONS

- Contraindications to sedation or anesthesia
- Infection of overlying soft tissues
- Not a contraindication: thrombocytopenia

EQUIPMENT, ANESTHESIA

- Either sedation plus analgesia and local anesthesia may be used, or general anesthesia can be used.
- Typical protocol: butorphanol, 0.2 mg/kg IV, plus lidocaine 2% local infiltration (1-8 mL SQ for cats to large dogs, respectively); and propofol, 3-6 mg/kg IV to effect. Propofol and local anesthesia are inadequate without an analgesic such as butorphanol, because neither propofol nor lidocaine provides systemic analgesia, and aspiration is painful.
- Clippers for hair
- Antiseptic scrub solution, isopropyl alcohol, and gauze squares for preparing the skin
- Sterile surgical gloves
- A #11 scalpel blade.
- Bone marrow aspiration/biopsy needle, typically 18-gauge
- Microscope slides and/or laboratory container with anticoagulant and/or sterile test tube. The preferred method of submission varies from laboratory to laboratory.
- Tissue glue
- A 10% formalin and biopsy jar (if core biopsy)

ANTICIPATED TIME

About 20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- For larger patients (large-breed dogs, obese animals), the needle guard should be removed; otherwise, the exposed amount of needle shaft may not reach the marrow cavity.
- A whole-blood sample for CBC should be drawn before the procedure and submitted at the same time as the cytologic examination slides/biopsy specimen.
- The laboratory to which the sample is being submitted should be consulted beforehand. Some clinical pathologists require fresh smears, others require anticoagulated samples, and still others require clotted samples. Depending on the desired sample submission, anticoagulant may be placed in the aspirating syringe.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

Aspirate:

- Inadvertent clotting of sample; preventable by reducing the time between aspiration and smearing to a few seconds
- Sliding off the bone on initial approach, causing soft-tissue trauma; prevented with good anatomic landmarking, firm but not excessive pressure when advancing the needle, perpendicular positioning of the needle tip against the bone surface, and keeping one's hands close to one's own body for greater control when advancing the needle into bone.
- Submitting all slides for routine staining; it is worthwhile to keep one or two slides unstained because there may be additional indications (e.g., feline leukemia immunofluorescence, antimegakaryocyte antibody testing) that emerge later in the case and

for which additional slides would be useful.

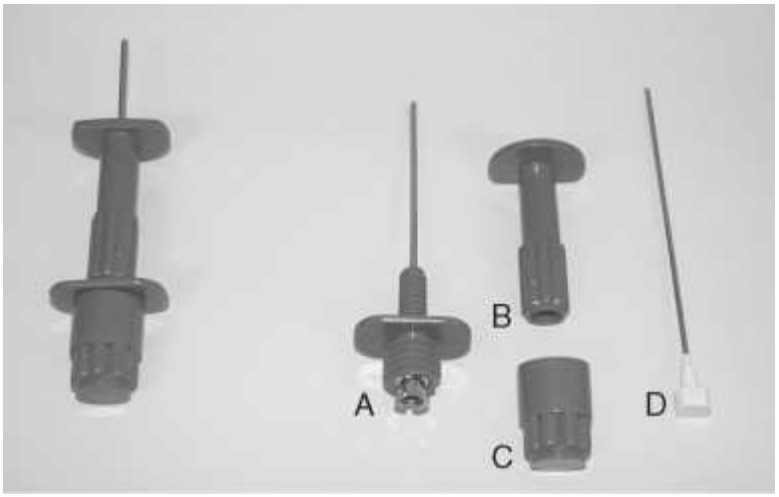
Core biopsy:

- Assumption that a core biopsy is superior to a marrow aspirate/cytologic examination. In most cases, a cytologic examination is as informative, if not more so.
- Sliding off the bone on initial approach, causing soft-tissue trauma: as already described.
- For core biopsies, failing to slightly rock the biopsy needle when it is fully embedded before withdrawing. This rocking motion breaks off deep attachments to the core and prevents the biopsy sample from remaining attached to bone and sliding out of the needle on withdrawal.

PROCEDURE

A humeral or ilial approach may be used. Aspirate: humerus:

- Sedation or general anesthesia is induced.
- For a right-handed clinician, the animal's left humerus is easiest. The animal is placed in right lateral recumbency on a table, and the clinician stands behind (dorsal to) the animal.
- The area over the animal's left shoulder is clipped of hair and aseptically scrubbed. Generally, a hairless, disinfected surface of skin that is a minimum of 3 × 3 inches (8 × 8 cm.) is necessary, centered on the point of the shoulder.
- Unless the animal is under general anesthesia, a local anesthetic is infiltrated (SQ and through the soft tissues to the level of the periosteum) according to the following landmarks:
    - The site of entry into the marrow cavity is the craniolateral proximal humerus, just distal to the joint space of the shoulder.
    - On palpation of the cranial aspect of the shoulder, a depression is felt (shoulder joint), and the site of entry with the needle is 3-10 mm (cat to large dog) distal and lateral to this point.
    - A broad surface of bone with little overlying muscle—the lateral, distal aspect of the greater tubercle—is the target. The needle should not enter the joint space.
- A brief aseptic scrub of the site is repeated after local anesthesia injection.
- The clinician puts on sterile gloves.
- Using his or her left hand, the clinician takes the animal's proximal left humerus firmly, holding the limb just distal to the aseptically scrubbed area. In this way, the left hand is no longer sterile but the right hand is still sterile.
- The landmarks just described are palpated again with the right hand; using the scalpel blade, the clinician makes a 2-3 mm skin incision over the lateral, distal greater tubercle.
- Using the right hand, the clinician places the bone marrow needle in the skin incision, exactly perpendicular to the bone surface, and advances it using a clockwise-counterclockwise rotatory motion and firm forward pressure. The bone marrow biopsy needle must be held firmly in the right hand, with the butt of the needle seated in the palm of the hand.
- If properly directed, the bone marrow needle should be difficult to advance and should feel firmly seated in bone.
- The needle is advanced 0.5-2 cm (cat to small dog/big dog) to reach the marrow cavity.
- The needle cap and stylet are then removed, a syringe is attached to the needle, and negative pressure is created by drawing back on the syringe plunger.
- Marrow (looks like blood) enters the syringe; 1-2 mL should be harvested if possible.
- As soon as marrow is in the syringe, the syringe and needle are withdrawn together, and the sample is instantly prepared for submission according to the laboratory's specifications.
    - Fresh smears: with the needle and syringe still connected to each other, a sample of marrow is expelled such that it partially (20%-50% of slide surface) floods the microscope slide. The sample is then reaspirated into the needle and syringe. This process leaves behind marrow spicules (1-2 mm specks) on the slide, and spicules contain the greatest concentration of marrow cells.
    - Anticoagulated samples: marrow is placed in a purpose-made dish with anticoagulant or in a lavender-top tube.
- The skin incision is closed with tissue glue, and mild direct pressure is applied for hemostasis.



BONE MARROW ASPIRATION/CORE BIOPSY Assembled *(left)* and disassembled *(right)* bone marrow needles. **A**, Needle. **B**, Needle guard. **C**, Cap. **D**, Stylet.

BONE MARROW ASPIRATION/CORE BIOPSY Position for bone marrow aspiration from the proximal humerus, using a skeleton for demonstration. This right-handed clinician is standing dorsal to the recumbent animal and is holding the humerus firmly. The needle tip is on the distal, lateral surface of the greater tubercle, ready to be advanced.

Aspirate: ilium:

- Sedation or general anesthesia is induced.
- The animal is placed in sternal recumbency.
- The skin over the dorsal-most aspect of the right or left ilial wing is clipped of hair and aseptically scrubbed. Generally, a hairless, disinfected surface of skin that is a minimum of 3 × 3 inches (8 × 8 cm) is necessary, centered on the palpable dorsal-most aspect of the wing of the ilium.
- Unless the animal is under general anesthesia, local anesthetic is infiltrated SQ and through the soft tissues to the level of the periosteum. The site of entry, and therefore the site requiring local anesthesia, is the dorsal-most/slightly medial aspect of the ilial wing.
- A brief aseptic scrub of the site is repeated after local anesthesia injection.
- The clinician puts on sterile gloves.
- Standing over the animal, the clinician palpates the dorsal wing of the ilium and makes a small (2-3 mm) skin incision using the scalpel blade.
- Using the right hand, the clinician places the bone marrow needle in the skin incision until it touches ilial bone and then advances it using a clockwise-counterclockwise rotatory motion and a moderate amount of forward (downward) pressure. The bone marrow biopsy needle must be held firmly in the right hand, with the butt of the needle seated in the palm of the hand.
- If properly directed, the bone marrow needle should be difficult to advance and should feel firmly seated in bone.
- The needle is advanced 0.5-2 cm (cat to small or big dog) to reach the marrow cavity.
- The needle cap and stylet are then removed, a syringe is attached to the needle, and negative pressure is created by

drawing back on the syringe plunger.
- Marrow (looks like blood) enters the syringe; 1-2 mL should be harvested if possible.
- As soon as marrow is in the syringe, the syringe and needle are withdrawn together, and the sample is instantly prepared for submission according to the laboratory's specifications.
    - Fresh smears: with the needle and syringe still connected to each other, a sample of marrow is expelled such that it partially floods the microscope slide. The sample is then reaspirated into the needle and syringe. This process leaves behind marrow spicules (1-2 mm specks) on the slide, and spicules contain the greatest concentration of marrow cells.
    - Anticoagulated samples: marrow is placed in a purpose-made dish with anticoagulant or in a lavender-top tube.
- The skin incision is closed with tissue glue, and mild direct pressure is applied for hemostasis.

Core biopsy: humerus or ilium:

- The same procedure as for bone marrow aspiration is followed, up to the point of advancing the needle into bone.
- When the needle is initially in bone (first few rotations, but before having advanced the full 0.5-2 cm), the procedure is stopped, the needle cap is unscrewed, and the stylet is removed.
- In this way, the cortex is not included in the sample (in contrast to bone biopsy, p. 1211).
- The cap is then replaced on the needle, and the procedure is continued, advancing the needle into the marrow cavity.
- No aspiration is involved. Rather, when the needle has been advanced a total of 0.5-2 cm (cat to small or big dog, respectively) without a stylet, a core of marrow should be in the shaft of the needle. The twisting and advancing motion is stopped, and the needle is gently tilted or rocked very slightly (perhaps 10° side to side) to break the core of marrow free from its attachments.
- The needle is then withdrawn and examined; a white plug of marrow should be obstructing the tip of the needle. This plug is expelled into 10% formalin using the stylet inserted in the normal (normograde) direction.

POSTPROCEDURE

Routine recovery from sedation/anesthesia and submission of samples for analysis

ALTERNATIVES AND THEIR RELATIVE MERITS

- Repeated CBC: assesses trends in cytopenias and morphologic blood cell abnormalities but does not show precursors and maturation sequence of blood cells
- Buffy coat examination: unreliable for malignant mast cell disease (poor sensitivity, poor specificity compared to bone marrow evaluation)

AUTHOR: ETIENNE CÔTÉ

Bone Grafting

SYNONYMS

Autogenous cancellous bone grafts (used most frequently in animals), allogenous corticocancellous bone grafts, allogenous cortical bone grafts, biosynthetic and synthetic bone graft substitutes

OVERVIEW AND GOALS

- Adjunct to surgical bone repair
- Autogenous cancellous bone grafts:
  - Enhance bone healing by osteogenesis, osteoconduction, and osteoinduction:
    - About 10% of donor cells survive and contain osteoblastic progenitor potential (osteogenesis).
    - Grafted cells serve as a trellis for ingrowing recipient vascular and cellular elements (osteoconduction).
    - Bone morphogenic proteins in graft stimulate recipient mesenchymal cells to form bone (osteoinduction).
- Allogenous corticocancellous and allogenous cortical bone grafts:
  - Enhance bone healing by osteoconduction and induction
  - Allogenous cortical bone provides structural support with cortical graft placed in bone defect.
  - Processed and banked
  - Derived from cadavers
- Biosynthetic and synthetic bone graft substitutes:
  - Consist of demineralized bone matrix, collagen, hydroxyapatite, tricalcium phosphate, calcium sulfate, or a combination of these minerals, special glass ceramics (bioactive glasses), and polymers
  - Serve as a structure on which new bone can grow
  - Many of these materials then dissolve over time, leaving only new bone behind
  - The degree to which the bone graft substitutes provide an osteoconductive structural framework or matrix for new bone ingrowth differs among implants

INDICATIONS

- Fractures
- Delayed unions or nonunions
- Osteomyelitis:
  - Infection of the recipient site is not a contraindication to autogenous cancellous bone grafting and selected synthetic and biosynthetic bone grafts.
  - The selected site from which the graft is harvested (donor site), however, must be aseptic.
- Arthrodesis
- Corrective osteotomies
- Ablation of bone cysts
- Limb-sparing surgery
- Minimize surgical time and donor site morbidity (allografts and bone graft substitute)

CONTRAINDICATIONS

- Prolonged anesthesia/operative time in compromised animal (autografts)
- Donor site comorbidity (autografts)

EQUIPMENT, ANESTHESIA

Standard orthopedic equipment and anesthesia are used during fracture repair, osteotomy, or arthrodesis.

ANTICIPATED TIME

An additional 15-30 minutes of operative time (autogenous cancellous bone grafting)

PREPARATION: IMPORTANT CHECKPOINTS

- Donor site for cancellous autograft
  - Common locations: proximal lateral humerus, proximal lateral femur, proximal medial tibia, or dorsolateral ilial wing
  - Needs to be aseptically prepared preoperatively

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

Cancellous autografts

- Hematoma formation
- Loss of graft by inadvertent discard of graft-laden sponge
- Contamination of donor site by infection or neoplasia from recipient site
- Inadequate graft harvest
- Iatrogenic fracture at donor site
- Iatrogenic physeal damage at donor siteAllografts and bone substitute
- Sufficient volume or size

PROCEDURE

For autogenous cancellous bone graft:

- Primary orthopedic procedure is performed, and then fresh graft is obtained from a separate (donor) site in the animal.
- Skin incision carried through subcutaneous tissues directly to bone at donor site
- Proximal cortex is penetrated by pin or drill bit
- Curette is used for collecting intramedullary contents: cancellous bone graft
- Material is collected in sterile container or gauze sponge and soaked with blood to prevent desiccation
- Graft is transferred to, and placed in, recipient site around implants and fracture(s)
- Routine closure of primary operative site and then donor site
- For autogenous corticocancellous graft from ilium:
    - Rongeurs or bone cutters are used for resecting ilium and collecting cortical and cancellous bone.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Commercial allograft preparations and bone substitutes eliminate donor site morbidity.
    - Unlimited supply, easy sterilization, and storage

AUTHOR: JOSEPH C. GLENNON

Bone Biopsy

OVERVIEW AND GOAL

Percutaneous sampling procedure using a minimally invasive approach to obtain cortical and cancellous bone for histologic analysis

INDICATIONS

Investigation of primary bone lesions, most commonly suspected neoplasms or bony infections:

- Focal, palpable, hard bone swellings
- Radiographic evidence of lytic and/or productive focal bone lesions
- Pathologic fractures

CONTRAINDICATIONS

- Bleeding disorders
- If iatrogenic/pathologic fracture appears likely as a result of the procedure (radiographic appearance of severe osteolysis)

EQUIPMENT AND ANESTHESIA

- General anesthesia
- Clippers for hair
- Routine antiseptic surgical scrub material and isopropyl alcohol
- A 22-gauge needle
- A #11 scalpel blade
- Sterile surgical gloves
- Bone biopsy needle, either a purpose-made Jamshidi-type needle or a routine bone marrow aspiration needle and stylet

ANTICIPATED TIME

About 20-30 minutes plus anesthesia induction and recovery

PREPARATION: IMPORTANT CHECKPOINTS

- Radiographs of the region to be biopsied always are indicated first to confirm bony nature of enlargement.
- Thoracic radiographs (three views, metastasis check) if bony mass is cause for biopsy
- Platelet count; severe thrombocytopenia (<25,000 platelets/µl and/or overt systemic clinical signs of hemorrhage) is a contraindication for the procedure.
- Discuss risks with owner, including possible need for amputation if iatrogenic pathologic fracture occurs in the long bone of a limb.

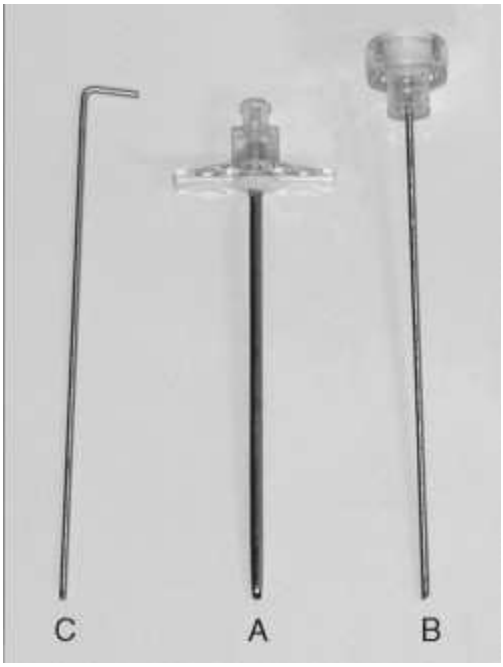
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Bone biopsy tends to be unrewarding in cases of diffuse osteopenia. These animals benefit more from review of signalment and history and assessments of serum ionized calcium, phosphorus, parathyroid hormone (PTH), and vitamin D levels.
- Iatrogenic pathologic fracture: best avoided by ensuring that if serial samples are taken, they are taken at multiple different angles and positions on the bone to avoid circumferential or linear sets of biopsy punch holes.
- Iatrogenic nerve damage, vessel trauma: the course of regional nerves, veins, and arteries needs to be known and properly identified before proceeding. Doing so may require a “mini-cutdown” or keyhole (1-cm) skin incision and blunt dissection through the soft tissues to reach bone while avoiding these structures.

PROCEDURE

- The area of greatest bony abnormality is identified on the radiographs, and the hair over that area is clipped widely (usually at least 3 × 3 inches [8 × 8 cm]).
- An approximate measurement of the thickness of the lesion should be made from the radiographs (distance from skin to

marrow cavity) to anticipate the desired depth of needle penetration.
- General anesthesia is induced.
- The skin overlying the area of greatest radiographic abnormality is aseptically scrubbed. Surgical draping often can be avoided, provided a sufficiently wide area of hair has been clipped.
- The clinician puts on surgical gloves and pinch-elevates the skin to make a small (2-3 mm) stab incision using the scalpel blade. Caution: Be sure that nerves and vessels do not course in the chosen area.
- The biopsy needle is advanced into the lesion using gentle, consistent forward pressure and a rotatory, clockwise-counterclockwise twisting motion. Caution: The resistance of the abnormal tissue may be variable, and a sudden push could damage the bone or deeper structures on the other side of the lesion; the biopsy needle should therefore be “palmed” (butt of the needle in palm, needle shaft held firmly between index finger and thumb) so that the fingertips of the thumb and index act as a buttress.
    - The stylet is generally removed from the biopsy needle and set aside after the soft tissues have been passed and the needle first reaches bone.
- The biopsy needle has been sufficiently advanced when the cortex and marrow of one side of a bone (and its lesion) have been traversed (i.e., when the marrow cavity is reached, as estimated from the radiographs).
- Before withdrawing the needle, a gentle rocking of the needle (a few millimeters at most) side to side will break off any attachments of the biopsy core to deeper bone. Not doing this could cause the core biopsy to be retained in the bone rather than coming out with the needle.
- The needle is withdrawn, again with a rotatory clockwise-counterclockwise motion to decrease friction.
- The sample is expelled from the shaft of the needle. The stylet is inserted normograde (usual direction) if using a bone marrow aspirate–type needle; however, the stylet is inserted retrograde (up the tip of the needle) if using a Jamshidi-type needle, because these usually are tapered at the tip.
- Multiple (two or three) samples often are obtained during one procedure to increase diagnostic yield. The samples are obtained away from each other to reduce the risk of weakening/fracturing the bone.
- If a very small skin incision was made, then direct pressure alone (or possibly tissue glue) usually is sufficient for closure; larger incisions (rare) may require skin sutures or staples.



BONE BIOPSY Jamshidi-type needles for bone biopsies. **A**, Needle. **B**, Stylet that remains inside the needle while crossing the soft tissues but is removed before entering bone. **C**, Second stylet that is inserted retrograde into the needle after procedure is finished to expel biopsy specimen from the needle shaft.

POSTPROCEDURE

- Sedation/prolongation of recovery if animal flails its biopsied limb (to reduce risk of self-induced pathologic fracture)
- Radiograph biopsied limb if the animal experiences markedly worse lameness after the procedure (rule out pathologic fracture).
- Evaluate site several minutes later. If a hematoma is present, direct pressure is indicated.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Open biopsy; more invasive, but specimen is larger.
- Amputation (if area being biopsied is on a limb); indicated if pathologic fracture is present.

AUTHOR: ETIENNE CÔTÉ

Blood Pressure Measurement

OVERVIEW AND GOALS

- The goal of noninvasive blood pressure (BP) assessment in animals in a veterinary setting is to accurately measure arterial BP and detect abnormal BP, particularly systemic hypertension.
- Doppler sphygmomanometric methods or automated oscillometric methods may be used.
- Doppler methods deliver systolic BP values.
- Oscillometric methods deliver systolic, diastolic, and mean BP values.
- Systolic BP is the value of interest in most clinical cases of systemic hypertension (see p. 1068).

INDICATIONS

- Presence of clinical signs of systemic hypertension
- Presence of systemic disease known to be associated with systemic hypertension (e.g., renal disease, hyperthyroidism, hyperadrenocorticism, diabetes mellitus, pheochromocytoma)
- Random BP screening in young healthy animals is not recommended.

EQUIPMENT, ANESTHESIA

Doppler method (used in dogs and cats; the preferred method for cats):

- Commercial Doppler amplifier with attached piezoelectric crystal for detection of blood flow
- Sphygmomanometer previously calibrated for accuracy
- A variety of cuff sizes based on animal limb circumference
- Pliable measuring tape to measure animal limb circumference
- Ultrasound coupling gel
- Hair clippers and isopropyl alcohol, if desired, for preparation of site of piezoelectric crystal application

Oscillometric method (automated system; used in dogs, less reliable in cats):

- Commercial automated oscillometric BP monitor with either print or data storage capability
- A variety of cuff sizes based on animal limb circumference
- Pliable measuring tape to measure animal limb circumference

ANTICIPATED TIME

- Doppler method: approximately 10 minutes
- Oscillometric method: approximately 20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Be sure the animal has acclimated to the clinic's environment and is calm and comfortable in lateral or sternal recumbency or sitting. BP values may be obtained in standing animals only if a tail cuff is used. Owner presence and assurance may help calm the animal.
- Be sure the cuff size used is appropriate and noted in the record for future reference. The width of the cuff should be (40% of the circumference of the limb or tail at the cuff site.
- During measurements with either method, the cuff should be at the level of the right atrium. This may involve elevating a forelimb during measurement if the animal is sitting.
- BP should be measured by well-trained individuals in the practice to maximize consistency. This is especially important when Doppler methods are used.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Erratic oscillometric readings may be obtained if an arrhythmia or very high heart rate is present.
- Turn volume knob to low or zero before turning Doppler amplifier on; then gradually increase volume to search for the pulse after contact is established between the crystal and the patient's skin. Failing to do this can produce extremely loud static noise that is startling to the patient (if using speakers) or deafening to the operator (if using headphones).

- For maximal accuracy in Doppler readings, be sure the audible signal is strong before beginning cuff occlusions.

PROCEDURE

Doppler method:

- Restrain the animal in a comfortable position, and allow time and reassurance for acclimation. The position of the animal is dependent on the animal's temperament and mobility and on the planned position of the cuff.
    - Cuff on forelimb at level of radius: sternal or lateral recumbency or sitting position
    - Cuff on hind limb proximal to hock (tibial level): lateral recumbency preferred; sternal recumbency may be used if leg is in gentle extension during measurement.
- Measure the circumference of the limb or tail at the intended cuff site, and select an appropriately sized cuff (as already described when preparing the animal).
- Wrap the cuff snugly around the limb, and attach to sphygmomanometer.
- Clip or dampen hair as needed at site of Doppler crystal application distal to the cuff (palmar or plantar arterial arch, proximal to the metacarpal/metatarsal pad and slightly medial); apply coupling gel, and hold or tape crystal in position.
- The crystal is placed against the skin concave side down; the flat aspect of the crystal faces out.
- Turn volume knob to low setting, and turn amplifier on. Verify correct position of crystal by listening for clear pulsatile sounds of flow in the artery beneath the crystal. Adjust the crystal position or angle as necessary to improve signal strength if sounds are soft, distant, or muffled.
- Gently position limb so cuff is at the level of the right atrium during readings.
    - Sternum level if animal is in lateral position
    - Thoracic inlet level if animal is sternal or sitting
- While listening to sound of flow, inflate the cuff using the bulb manometer to approximately 20 mm Hg greater than the pressure needed to cut off flow sounds.
- Slowly deflate the cuff (1-3 mm Hg per second), and note the pressure at which pulsatile sounds of flow recur. This pressure is recorded as the systolic pressure.
- Completely deflate the cuff, and count the heart rate in the approximately 30 seconds between pressure readings. A contemporary heart rate can be recorded with each BP reading.
- Record at least 6 measurements in succession, allowing approximately 30 seconds to 1 minute between measurements to allow for limb reperfusion.
- Discard the first reading, and average the results of the remaining readings to obtain a representative number of systolic pressure and heart rate. High heart rate may indicate that increased levels of stress have affected readings.

Oscillometric method:

- Restrain the animal in a comfortable position, and allow time and reassurance for acclimatization. The position of the animal is dependent on animal's temperament and mobility and on the planned position of the cuff.
    - Cuff on forelimb at level of radius: sternal or lateral recumbency or sitting position
    - Cuff on distal hind limb at level of metatarsus (median artery): lateral recumbency preferred; sternal recumbency may be used if leg is in gentle extension during measurement.
    - Cuff on proximal tailhead: sternal or lateral recumbency or standing if animal is relatively immobile during readings (tailhead is preferred cuff site for oscillometric measurement technique in cats).
    - Limb cuffs should not be used in standing animals.
- Measure the circumference of the limb or tail at the intended cuff site, and choose an appropriately sized cuff (as already noted when preparing the animal).
- Wrap the cuff snugly around the limb, with the center of the inflatable bladder of the cuff positioned over the artery, and attach to the BP monitor.
- Gently position limb so cuff is at the level of the right atrium during readings (no repositioning required if tail cuff is used).
    - Sternum level if animal is in lateral position
    - Thoracic inlet level if animal is sternal or sitting
- Record at least 6 measurements in succession, allowing approximately 30 seconds to 1 minute between measurements to allow for limb reperfusion.
- Discard the first reading and any readings with clearly spurious results, and average the results of the remaining readings to obtain a representative number for systolic, diastolic, and mean pressures, respectively.
- Note the heart-rate readings associated with the BP readings. If heart rate is clearly incorrect, BP values may be spurious. In addition, high heart rate during recording may indicate high animal stress levels and possible elevated BP due to stress of procedure.

BLOOD PRESSURE MEASUREMENT Doppler method is used for estimating blood pressure (BP) in a cat. Note that animal is restrained in a calm, comfortable position. Cuff is applied to a distal forelimb, and limb is elevated such that cuff is at level of right atrium during readings. Coupling gel is applied to Dopple crystal (shown). After Doppler crystal is positioned over palmar arterial arch and a strong audible signal is obtained, bulb sphygmomanometer is used for inflating cuff and occluding arterial flow, then slowly deflated. Pressure at which arterial flow is again audible is recorded as the systolic BP.

BLOOD PRESSURE MEASUREMENT Automated oscillometric method used with a forelimb cuff to obtain systolic, diastolic, and mean blood pressure in a dog. Dog is restrained in a comfortable position, with intended cuff-site limb gently extended. Cuff is positioned at mid-radius level, and limb is positioned such that cuff is at level of right atrium during readings.

POSTPROCEDURE

- Record the average values in animal's record, with notation of method, cuff size, and cuff site used.
- Evaluate BP values in light of clinical findings and level of anxiety or excitement during BP measurement.

ALTERNATIVES AND THEIR RELATIVE MERITS

Invasive BP measurement involves acute arterial puncture (typically femoral artery) with a small-gauge needle attached to a pressure transducer, or catheter placement in a distal artery (typically dorsal pedal) and attachment to pressure tubing and a pressure transducer. A BP tracing is printed out, and systolic and diastolic pressure can be determined from the pressure tracing.

- Highly accurate information, since direct measure is used
- Local anesthesia is used for minimizing discomfort.
- Arterial puncture or arterial catheter placement requires more technical skill than noninvasive methods (see p. 1196).
- Bleeding may occur at site of femoral puncture if care is not taken to apply pressure for at least 5 minutes after the needle is withdrawn.
- Invasive methods are rarely used in conscious clinical patients, but indwelling arterial catheters are frequently used for continuous BP assessment in anesthetized or critically ill patients.

AUTHOR: REBECCA L. STEPIEN

Biopsy: Ultrasound-Guided Percutaneous

SYNONYMS

Tissue core biopsy, Tru-Cut biopsy

OVERVIEW AND GOAL

Procedure to obtain tissue core sample using ultrasound guidance and real-time monitoring of needle instrument placement

INDICATIONS

- Ultrasonographic detection of focal mass lesion
- Physical, ultrasonographic, or biochemical detection of diffuse or focal parenchymal organ abnormalities

CONTRAINDICATIONS

- Cavitated mass or bleeding disorder: risk of hemorrhage
- If abscess possible: risk of leakage, sepsis
- Intrathoracic masses not in contact with the chest wall: poor visualization
- Diffuse lung disease: risk of pneumothorax

EQUIPMENT, ANESTHESIA

- Biopsy instrument:
  - Automatic:
    - Manually advanced to a point 1.5-2 cm superficial to lesion
    - When triggered, cutting needle and external shaft automatically advance a specific distance
  - Semiautomatic:
    - Inner cutting needle manually advanced to desired depth
    - When triggered, external shaft automatically advances over cutting needle
  - Manual:
    - Operator controls depth of needle and length of tissue sampled.
    - Requires two hands to operate device
- Formalin container
- A #11 scalpel blade to incise skin
- A set of 25-gauge standard injection needles
- Hair clippers
- Surgical scrub, rubbing alcohol, gauze
- Sector or linear-array ultrasound transducer:
  - Sector transducers allow sampling of deep structures.
  - Linear-array transducers provide better resolution of superficial structures.
- ± Biopsy guide: easiest method, but angle of needle insertion fixed
- Anesthesia: IV or gas anesthesia required.

ANTICIPATED TIME

The procedure time is 10-15 minutes, plus anesthesia preparation/recovery time.

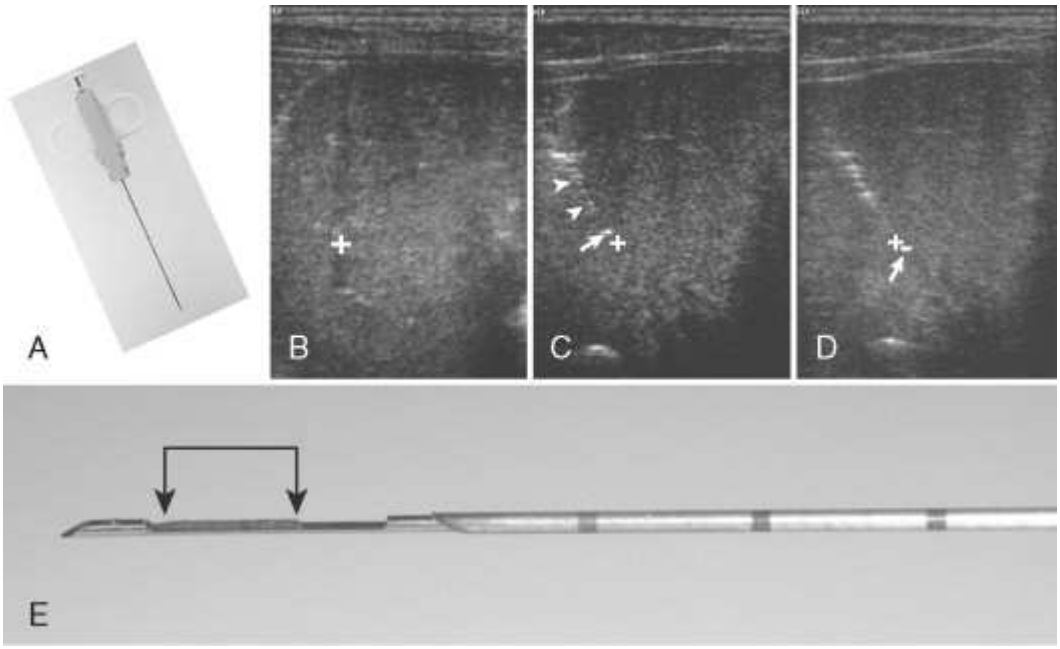
PREPARATION: IMPORTANT CHECKPOINTS

- Perform coagulation profile, platelet count, and blood pressure (BP) measurement.
- Place IV catheter.
- Ensure proper function of biopsy instrument.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Avoid overly rapid advancement and activation of the instrument:
  - A common, serious error of inexperienced veterinarians is to both advance and activate the instrument in one motion, which is contraindicated (poor placement/control of instrument tip).
  - The full extent of the instrument must be observed and monitored carefully and advanced with caution to the area to

be sampled.
- Identify and avoid large vessels in the organ being sampled or in those adjacent to the structure to minimize hemorrhage.
- Avoid penetrating bowel lumen, especially with larger-gauge instruments, owing to risk of peritonitis.
- Ensure that the ultrasound beam captures the full length and orientation of the instrument in the animal (see p. 1275).
- Sample the left aspect of the liver when possible to avoid the gallbladder and hilar vessels on the right. If the liver is small or cranially located, consider a caudal intercostal approach.
- In cases of bilateral renal abnormalities, the left kidney should be sampled because of its more caudal location.
- Sample the caudal cortex of a kidney to avoid the medulla and arcuate and hilar vessels.
- Do not pass through an organ other than the one being aspirated.
- Avoid using preanesthetic drugs that cause splenomegaly or panting whenever possible (e.g., acepromazine/phe-nothiazines, hydromorphone/opiates, respectively).



BIOPSY, ULTRASOUND-GUIDED A, Semiautomatic-type instrument used for ultrasound-guided core biopsy. **B**, Ultrasound of a dog's liver in preparation for core biopsy. Targeted area chosen for biopsy is marked (+). **C**, Ultrasound of same dog's liver, biopsy underway. Semiautomatic instrument shown in panel A has been advanced *(arrowheads)* until its tip *(arrow)* is immediately above the target. **D**, Internal stylet advancing. With instrument held immobile, internal stylet is slowly advanced, crossing through the targeted area or lesion. Once stylet is in the fully advanced/deployed position shown here, the instrument can be triggered, which obtains the sample. **E**, Core of liver tissue *(between arrows)* is shown within chamber of stylet.

PROCEDURE

- Restrain the animal in dorsal or lateral recumbency. A padded V-trough can be used.
- Clip hair from the ventral abdomen.
- Thoroughly evaluate area of interest sonographically, characterize lesion, identify adjacent or internal vessels to be avoided, and determine least traumatic location and direction of needle placement.
- Prepare skin with surgical scrub.
- Obtain ultrasound image of area to be sampled.
- Ensure that probe marker location on screen corresponds with desired needle course.
- Prepare biopsy instrument.
- Make a small skin incision with a scalpel blade at the site needle will be introduced.
- Introduce needle parallel to plane of ultrasound beam, visualizing it as it is advanced.
- Slowly fan transducer side to side to identify needle as necessary.
- Automatic:
    - Note the *throw length* of the biopsy device before triggering it. This is the additional distance the instrument advances when triggered.
    - Manually advance the needle, stopping at this distance superficial to desired biopsy site. Caution: When triggered, needle will advance the full predetermined throw length to obtain biopsy.
    - Trigger needle: cutting needle and external shaft will advance the predetermined throw length to obtain sample.
- Semiautomatic:
    - Manually advance the inner cutting needle to desired biopsy depth.
    - Trigger needle: external shaft will automatically advance over cutting needle to obtain sample.
- Manual:

    - Manually advance the inner cutting needle to desired biopsy depth.
    - Manually advance the external shaft over the cutting needle to obtain sample.
    - Requires two hands to operate, so two people are required for biopsy procedure.
- Withdraw needle from animal.
- Use a 25-gauge needle to gently lift sample from biopsy needle.
- Place sample in formalin container.
- Two to three samples of each organ or lesion are obtained.

POSTPROCEDURE

- Scan to evaluate for hemorrhage. A very small amount of hemorrhage is not uncommon.
- If small amount of hemorrhage is noted, reevaluate after several additional minutes, ensuring that the patient is monitored (mucous membrane color, blood pressure) and is kept recumbent with the biopsied side down (e.g., sternal recumbency if a liver biopsy was near or on the ventral midline).
- Hematuria is common following renal biopsy.

ALTERNATIVES AND THEIR RELATIVE MERITS

Laparoscopic (see p. 1298) and surgical biopsies are more invasive but have higher diagnostic quality in some cases.

AUTHOR: WENDY D. FIFE

Behavioral Assessment

SYNONYMS

Behavioral problems: misbehavior, aggression, house soiling, destructiveness, barking

OVERVIEW AND GOALS

- To reestablish the owner/animal bond
- To protect the owner and the public from injury or loss of property

INDICATIONS

- Owner requests information on behavior.
- Better yet, practitioner asks the client how satisfied he or she is with the animal.
- It is often too late if the owners are already contemplating getting rid of the pet.

CONTRAINDICATIONS

If the dog or cat is very aggressive, the animal should probably be euthanized. Finding a new home for this animal is not an option. If the original owner cannot live with the animal, no one should have to.

EQUIPMENT, ANESTHESIA

- Assess-a-Hand
- Child-sized doll
- Closed-circuit television (camera and time-lapse video recorder)

ANTICIPATED TIME

About 1 hour for cats or 2 hours for dogs, including diagnosis and treatment

PREPARATION: IMPORTANT CHECKPOINTS

- Have a history form, preferably one for each species.
- Pictures of dogs and cat in various moods are very helpful.
- Have the most commonly used tools available, as appropriate:
    - Basket muzzle
    - Gentle Leader
    - Kong dog toy
    - Catalogs or websites of less commonly recommended products

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

Dealing with aggressive animals is a hazard, so liability is great. However, it is also essential to address an owner's problems correctly, or a life will be lost when the animal is euthanized.

PROCEDURE

The specific overall goal is to determine the exact nature of the problem, resulting in appropriate intervention and prognosis when possible. With the increased use of electronic communication, sending and receiving histories before the consultation is a convenient and time-saving strategy. A sample set of history forms can be found at www.vet.cornell.edu/abc. Note: Many owners are more willing to divulge behavioral information to technicians than to veterinarians. In addition, the technician can demonstrate training procedures and behavior modification techniques.

- Rule out medical disorders (e.g., urinary tract infection, feline lower urinary tract signs/disease, or ectopic ureters for soiling an area in the house; metabolic, central neurologic, endocrine, or pain-producing conditions for aggression), and treat appropriately if present.
- Clarify the nature of the environment surrounding the behavioral problem:
    - Number of people and animals in the household
    - Amount of space at the animal's disposal, both with owners at home and when absent

    - For cats, the location, type, and contents of litter boxes
    - Change in the people or pets in the household or their schedules
    - If the presenting problem is destructive behavior, soiling an area in the house, or barking, an important step is to determine whether these events occur when the owners are at home or only when they are gone.
- Clarify the reaction of the owners and others to the animal's misbehavior. Do they punish or soothe the animal?
- Help the owner to avoid misdirected intervention, such as punishing after the fact, physically punishing the dog for aggressive behavior, or rewarding jumping up.
- The owner should be given a reasonable treatment plan that does not involve risk to the owner or the public.
- A detailed history should be taken carefully. A destructive dog can be used as an example:
    - When is the animal destructive?
    - Where is the animal destructive?
    - With what methods have the owners tried to address the problem?

Note: It is always important to maintain a neutral attitude when taking a history, because any criticism of the owners' methods at this time will probably inhibit owners from volunteering any additional information as the interview continues. The dog's early history often gives clues regarding the cause of misbehavior:

- If the dog was obtained from a kennel at 6 months of age, it may neither have been house broken properly nor socialized to people during the socialization period of 7-14 weeks of age.
- If the dog was obtained as a 3-week-old puppy or was hand raised, it may be too dependent on people and not properly socialized with dogs.
- If the dog was obtained from a pound or an animal shelter, it may have been placed there because it was destructive or aggressive in the original home.

The owners should be able to supply this information and to indicate why they obtained the animal. Hand-raised kittens are frequently presented for aggression as adults, and feral or free-ranging cats may be reluctant to remain indoors and may vocalize, claw, or spray when confined.

- Note: Canine aggression is much more complicated. The victim, time, place, and circumstances of the aggressive episode must be known. The owner should be asked to describe the dog's posture: the position of its ears and tail as well as its vocalization and mouth position. Pupillary dilation and raised hackles indicate sympathetic stimulation. A temperament test should be performed. A toddler-sized doll can be walked toward the dog. Although some dogs are frightened, aggressive ones will bark at, and even bite, the doll. An artificial hand (Assess-a-Hand) can be used for determining how responsive the dog is to touching of its head, abdomen, paws, and tail. The artificial hand can also be used for pulling food from the dog in a safe manner.

BEHAVIORAL ASSESSMENT Bite marks on a doll's arm inflicted by an aggressive dog during a behavioral assessment.

Behavior history forms for cats can be shorter than those for dogs because cats rarely are trained and do not require the attention that dogs do. Because cats are much less likely to demonstrate their misbehavior during an interview, a video recording of the cat when it is aggressive is very helpful. If the problem is soiling an area in the house, time-lapse video recording can elucidate which cat in a multicat household is soiling and what its preelimination and postelimination behaviors are. Many cats visit the litter box but eliminate elsewhere, indicating an aversion to the litter or the box.

POSTPROCEDURE

Recheck the animal at 3 and 6 weeks to determine the success of the treatment and compliance of the owner.

ALTERNATIVES AND THEIR RELATIVE MERITS

Behavioral problems can be referred to trainers, but there is no quality assurance. Herbal remedies also lack quality control or controlled studies of their efficacy.

AUTHOR: KATHERINE ALBRO HOUPT

Barium Esophagram, Dynamic

SYNONYMS

Barium swallow, fluoroscopic esophagram

OVERVIEW AND GOAL

To administer a contrast agent per os (PO) and observe the oral and pharyngeal phases of swallowing and esophageal transit using fluoroscopy. The goal of the study is to define abnormalities of swallowing and/or esophageal transit.

INDICATIONS

Functional abnormalities of swallowing (dysphagia, abnormal esophageal motility). Can be used for evaluating mechanical abnormalities (mass, foreign body, extrinsic compression), but a static esophagram is usually sufficient for this purpose.

CONTRAINDICATIONS

- Evidence or risk of esophageal perforation
- Megaesophagus (not an absolute contraindication, but the study is not needed for diagnosis).

EQUIPMENT, ANESTHESIA

- Contrast agent:
  - Liquid barium (30% weight/volume and higher density)
  - Iodinated contrast agent:
    - Nonionic (iohexol, iopamidol, ioxaglate compounds)
    - Diluted 1:1 with water
- Highly palatable canned food
- Syringes for barium administration
- Bowl and utensil for mixing barium and food
- X-ray unit:
  - Fluoroscopic capability
  - Spot film capability
  - Video recording capability
- Protective clothing (lead aprons, gloves, thyroid shields) for personnel
- Paper towels or similar for cleanup of barium on animal and x-ray table

ANTICIPATED TIME

15-20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Survey films of thorax and cervical region:
  - If contraindications are present (as previously mentioned), study should not be performed.
  - If plain films are diagnostic (i.e., megaesophagus), the study is unnecessary.
- Prepare contrast agents:
  - Barium:
    - Liquid barium in appropriately sized syringe
    - Liquid barium mixed with canned food. Only a small amount of barium ((5 mL) is needed, which also will keep the solid consistency of the food.
  - Nonionic iodinated contrast agent:
    - Iohexol, iopamidol, ioxaglate compounds
    - Liquid diluted 1:1
    - Diluted liquid is mixed with canned food.
- Personnel needed for procedure (restraint and administration of contrast). This may require two to three people, depending on animal's size and temperament.
- All personnel should have appropriate lead protective apparel (aprons, thyroid shield, gloves).
- Paper towels or other barrier drapes to limit excess contrast agent on table and animal

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Aspiration of contrast agent: study is always begun with a liquid contrast agent and no food. Animals with disorders requiring these evaluations may be prone to dysphagia and aspiration of contrast. If a small amount of liquid contrast agent is aspirated, it can be coughed up. If the animal aspirates a substantial amount of liquid contrast agent, the study should be aborted.
- Ionic iodinated contrast agents: these agents should not be used because clinically significant (potentially fatal) pulmonary edema can occur if they are aspirated. Ionic agents include diatrizoate, iothalamate, and iodamide compounds. All must be avoided.
- Nonionic iodinated contrast agents: these agents can be used if esophageal perforation is suspected.
- Leakage of contrast agent: evidence or risk of esophageal perforation is considered a contraindication for this study. If contrast agent leakage is suspected at any time, the study should be aborted.
- Assuming the procedure is not stopped because of aspiration of contrast agent or evidence of leakage of contrast agent, it is important to perform the study with both liquid contrast agent and liquid contrast agent mixed with food to give as full an assessment of esophageal function as possible.
- Fluoroscopic procedures involve a substantial radiation dose to the animal and to personnel. Radiation safety (e.g., proper protective clothing, collimation so that personnel are not included in the primary beam) is paramount.

PROCEDURE

Dynamic esophagram, barium:

- Survey films of thorax and cervical region (already described in preparation)
- Position animal in right lateral recumbency (if a C-arm fluoroscopy unit is used, it may be possible to place the animal in sternal recumbency and use a horizontal beam) with appropriate restraint.
- Activate fluoroscopy unit briefly to determine correct positioning and collimation.
- Activate the video recorder.
- Administer liquid barium PO (~5 mL for a cat and 5-10 mL depending on the size of the dog), and activate fluoroscopic unit. Image the oral and pharyngeal phases of swallowing (progression of barium from mouth to esophagus) and esophageal transit (progression from upper esophageal sphincter to stomach). Repeat two to three times even if no abnormality is defined.
- Spot film any areas of abnormality; lateral views are generally sufficient.
- Repeat above procedure with barium paste (optional).
- Administer barium and canned food mixture PO. Appropriately sized food balls (1-3 cm in diameter) may be fed to the animal or placed in the mouth. Activate fluoroscopic unit, and image the oral and pharyngeal phases of swallowing (progression of barium and food from mouth to esophagus) and esophageal transit (progression from upper esophageal sphincter to stomach). Repeat two to three times even if no abnormality is defined.
- Spot film any areas of abnormality; lateral views are generally sufficient.

Dynamic esophagram, iodinated contrast agent:

- This study may be performed if esophageal rupture is suspected or if endoscopy is to be performed immediately following the esophagram. If an esophageal perforation is suspected, a static esophagram is usually performed instead, using a nonionic iodinated compound.
- The dynamic esophagram using an iodinated contrast agent follows the same procedure as the barium esophagram.

POSTPROCEDURE

None

ALTERNATIVES AND THEIR RELATIVE MERITS

Static esophagram: a static esophagram (administration of barium and obtaining routine films) can be used in place of a dynamic study for certain indications. A static study does not require the use of a fluoroscopy unit and is generally sufficient for most suspected mechanical abnormalities of the esophagus (e.g., esophageal foreign body, esophageal mass, esophageal stricture). However, subtle abnormalities of swallowing and esophageal transit are rarely identified in this study, and it provides no information on the pharyngeal phase of swallowing.

SUGGESTED READING

AUTHOR: PATRICIA L. ROSE

Barium Enema

SYNONYM

Large bowel/rectal contrast study

OVERVIEW AND GOAL

To perform a radiographic contrast procedure that provides information on the gross structure of the colon and rectum. This information generally is not available by other routine imaging means: abdominal ultrasound is limited by the presence of gas in the colon, and plain radiography cannot evaluate the mucosal surface of the colon and cannot evaluate colonic distensibility.

INDICATIONS

- Persistent tenesmus
- Pelvic canal/rectal mass effect on rectal palpation and/or on plain radiographs
- Severe constipation/obstipation not responsive to simple medical management

CONTRAINDICATIONS

Note: Organic iodine contrast material (e.g., sodium iothalamate, sodium diatrizoate, diluted 1 : 1 with water) should be used instead of barium if rectal or colonic perforation is suspected; contrast effect will be reduced, however (see p. 1284).

EQUIPMENT

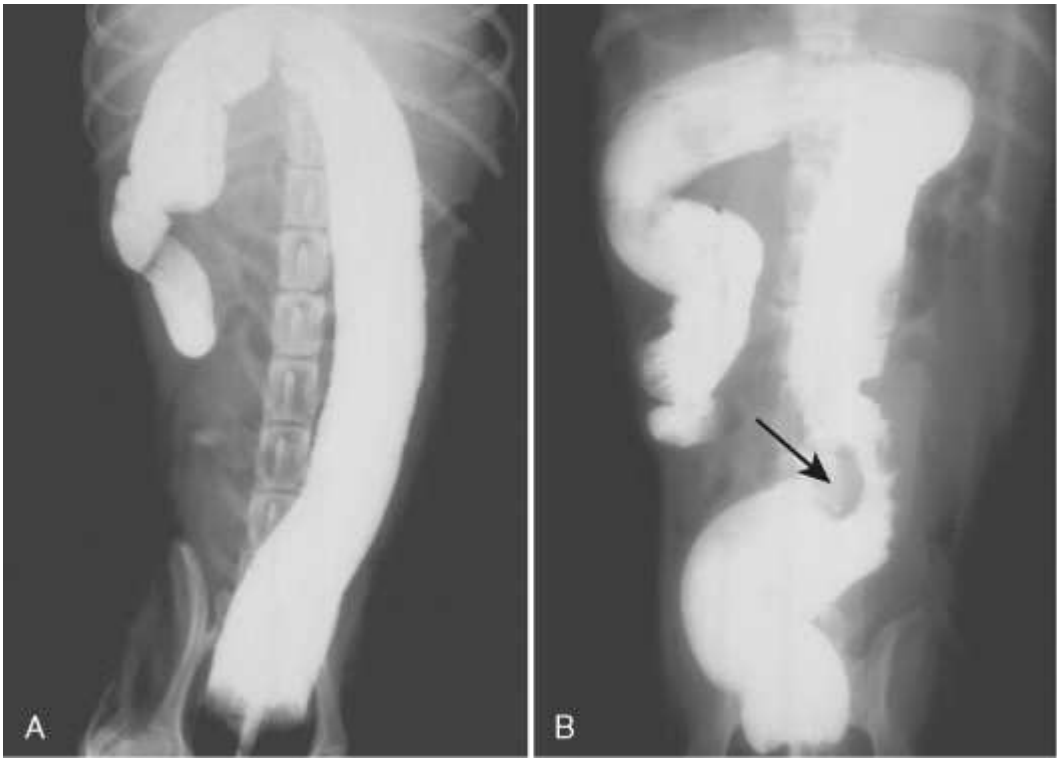
- General anesthesia is usually required; otherwise, barium is often expelled from the rectum by the animal's straining.
- Enema bag/set; for smaller animals, large syringes may be used instead.
- Barium sulfate suspension with concentration 15%-20% weight per volume
- Foley urinary catheter (e.g., 10-18 Fr tube for body range of cats to large dogs, respectively) or Bardex catheter
- Sterile, water-soluble lubricant

ANTICIPATED TIME

Approximately 40-60 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Fecal occult blood testing is highly specific using O-tolidine-based test kits and may be performed to further increase an index of suspicion for a colonic abnormality.
- Prepare an adequate volume of barium. Using too low a barium dose is a very common problem, causing pseudolesions or missing lesions altogether.
- Barring excessive anal pain, any dog weighing 6 kg or more needs to have a simple but complete rectal palpation prior to barium enema to better localize any focal lesions.
- Animal fasted 24 hours
- A maximum amount of feces is evacuated from the colon prior to the administration of the barium enema.
- Metastasis imaging (three-view thoracic radiographs; abdominal ultrasound to assess liver, lymph nodes, etc.) is indicated if malignancy is part of the differential diagnosis.



BARIUM ENEMA A, Ventrodorsal projection, normal study. **B**, Ventrodorsal projection, abnormal study. Large filling defect in distal colon *(arrow)* causes marked narrowing of lumen, suggesting a mass lesion.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

Perianal trauma and iatrogenic colonic perforation are very rare; use Foley catheter instead of rigid enema tube.

PROCEDURE

- Obtain preliminary abdominal radiographs to confirm adequate animal preparation (colon is as empty as possible) and to set radiographic technique. The barium contrast dose of 10 mL/kg is placed into enema reservoir.
- Lubricate catheter and insert sufficiently such that Foley balloon is well beyond the anus and within the rectum.
- Inflate Foley balloon to reduce or prevent outflow of contrast from the anus, and gently tug on catheter to bring Foley balloon to seal caudally and prevent contrast leakage from anus.
- Slowly administer barium, with the animal in right lateral recumbency, using gravity for colonic filling (raise the reservoir above the animal).
- Once the colon has been distended, clamp the infusion tubing to prevent backflow of the contrast material.
- Obtain both lateral and oblique views (45 degrees) and a ventrodorsal view.

POSTPROCEDURE

- Routine anesthetic recovery
- The clinician should tell the client that it is normal for the stools to be loose and grey or pale brown in color for several defecations after the procedure.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Endoscopy has largely replaced barium enemas.
- Abdominal ultrasound: the potential for visualizing the structure of the colonic wall is often severely restricted by the pelvis and by presence of air in the colon.
- Plain radiographs: diagnostic test of choice for bony obstruction of the pelvic canal (fracture, malformation, mass); poor sensitivity for soft-tissue lesions of the colon
- Colonic biopsy: diagnostic test of choice once a focal or diffuse mucosal lesion is suspected or identified

AUTHOR: LEEANN PACK

Cystoscopy

SYNONYMS

Transurethral cystoscopy, urethrocystoscopy, uroendoscopy

OVERVIEW AND GOALS

Transurethral cystoscopy (TUC) involves the use of rigid or flexible endoscopes for examination of the urinary bladder via passage through the urethra. Most anatomic structures of the lower urinary tract can be visualized: vulvar vestibule, vagina, urethral orifice, urethra, urinary bladder, and ureteral orifices. This procedure is done relatively commonly in specialty practice.

INDICATIONS

TUC is most often used in chronic conditions, but it may also be beneficial in cases with severe acute presentations. A differential diagnosis list for any of the following disorders or clinical signs could be an indication for transurethral cystoscopy:

- Anatomic abnormalities: vaginal strictures, persistent vaginal membranes, ectopic ureters
- Cystitis: chronic infectious, idiopathic, interstitial
- Posttraumatic or postsurgical assessment: pelvic fractures, abdominal trauma, prior surgery
- Hematuria: examination to identify origin of bleeding and observation of ureteral orifices (unilateral versus bilateral hematuria of renal origin)
- Urethritis: infectious, inflammatory, granulomatous (also known as proliferative)
- Stranguria
- Urinary incontinence: diagnostic identification of possible causes; therapeutic periurethral submucosal injections of glutaraldehyde cross-linked collagen for urethral sphincter mechanism incompetence
- Pollakiuria
- Calculi: urethral or cystic calculi retrieval and identification
- Tumor: urethral, urinary bladder, prostatic, vaginal
- Obstruction: tumor, stricture, calculi, hyperplasia (vaginal)
- Urethral stricture: diagnosis and dilations
- Removal of small polyps and tumors
- Ureteroscopy: for advanced endoscopists; requires concurrent fluoroscopy
- Holmium-doped yttrium, aluminum, garnet (Ho:YAG) laser: used for laser lithotripsy (see p. 1297); this is of growing interest and of proven benefit for the fragmentation of urinary calculi. These lasers have also been used for ablative treatment of intraluminal tumors and ectopic ureteral openings. As of 2009, the cost and advanced training involved have left the use of this laser as a procedure available at a few veterinary teaching hospitals and larger referral centers.

CONTRAINDICATIONS

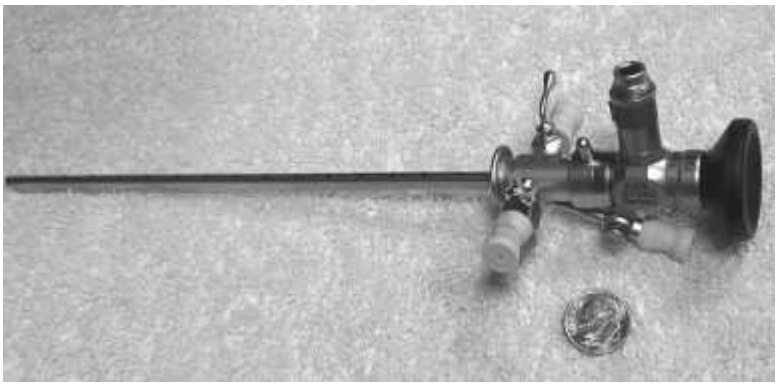
- Animal size and sex are the most common limiting factors; the exact limitations depend on endoscope size (external diameter) relative to the patient, as described in the following paragraphs.
- Known severe bacterial urinary tract infection is a relative risk factor.
- Known perforation or rupture of bladder or urethra

EQUIPMENT, ANESTHESIA

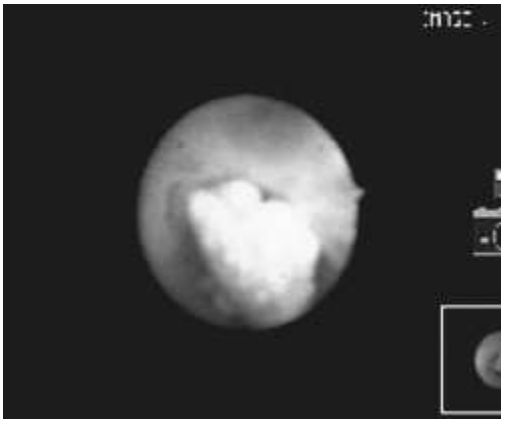
There is a wide array of possible equipment to use for transurethral cystoscopy. The marked differences between the male anatomy and female anatomy and between dogs and cats lead to the common veterinary statement “You can never have enough scopes.” To be prepared for any size and sex of animal may require a mix of six to seven flexible and rigid scopes.

- Review of the normal anatomy of the lower urinary tract
- Preparation of the preputial or perineal area by clipping interfering hair and gentle cleansing
- General anesthesia with tracheal intubation is required
- Between 1 and 2L of body-temperature sterile saline for flush and infusion during procedure via IV infusion set. A second IV infusion set is used for drainage and collection from the opposite port.
- Water-soluble sterile lubricant with or without lidocaine jelly
- Bacterial culture tubes
- Biopsy jars with 10% buffered formalin

- Flexible-tipped ureteral guide wires can be helpful for bypassing obstructions, strictures, and tears (serving a stylet-type function), then allowing catheters to be passed over them. Human ureteral dilation catheters can be used with the guide wires if urethral stricture is present.
- Accessory implements include sterile brushes, guide wires, biopsy forceps, balloon catheters, sterile catheters, stone retrieval baskets, and polypectomy snares (with or without electrocautery).
- Appropriate light source and light cable
- Documentation equipment (videocassette, digital video, prints)
- Flexible endoscopes:
    - Size of scopes varies by both anticipated length of the urinary tract segment to be assessed (cranial tip of filled bladder extending to perineum or preputial opening) and diameter of the urethra.
    - As examples: A larger female dog may be examined cystoscopically using a 5-mm, two-way deflecting fiberendoscope (e.g., bronchoscope), while a small male cat may only allow passage of a 1.2-mm pediatric ureterocystoscope.
    - Ancillary catheters, brushes, stone retrieval baskets, and biopsy forceps
    - Flexible endoscopes may require more positioning and manipulation of the animal because they tend to be deflected easily by external pressures.
- Rigid endoscopes:
    - A wide array of rigid endoscopes from human medicine can be used for transurethral cystoscopy, including purpose-designed cystoscopes, small laparoscopes, and adapted arthroscopes.
    - Rigid telescope sizes most commonly used range from 2.7-5 mm in diameter, with respective cannula (sheath) diameters ranging from 3.8-6 mm; length of the scopes ranges from 7-30 cm. The cannula usually includes the associated biopsy and infusion ports. Smaller scopes may have the outer cannula and ports combined into one single unit.
    - A 0° viewing angle may be better for viewing the urethra, and a 30° viewing angle may be preferred for viewing the bladder.
    - A "bridge" is used for connecting some scopes with their cannulas (cannula-bridge-scope) and to provide additional access ports (generally one or two) for flushing or infusion of saline and passage of other instruments.
    - The Albarrán lever is a "deflecting bridge" that forces flexible biopsy instruments to exit the bridge at an angle; this facilitates biopsy and grasping of structures that are almost parallel to the scope.
    - The Ellik evacuator allows for rapid saline lavage to provide for collection of small calculi when attached to a rigid cystoscope cannula.
    - Rigid scopes tend to provide superior images.

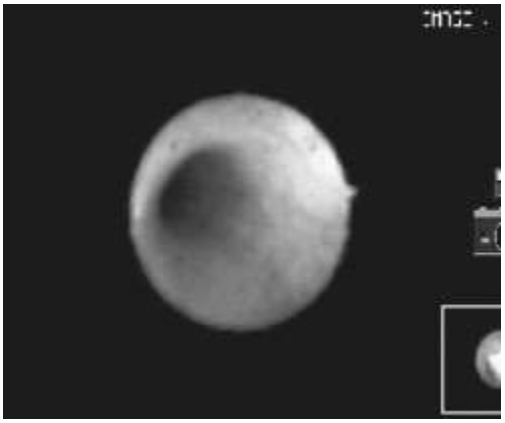


CYSTOSCOPY Assembled cystoscope and cannula/sheath.



CYSTOSCOPY Endoscopic view of urethra of a dog with severe stranguria and hematuria. A large urolith is occluding most of the lumen.

(Courtesy Dr. Etienne Côté.)



CYSTOSCOPY Endoscopic view of same site in same dog. Using an older set of dull biopsy forceps, urolith was fragmented into several pieces within the urethral lumen, and fragments passed easily through urethra during procedure. Moderate mucosal erythema remains (bottom half of image), but dog's recovery was uneventful and complete.

(Courtesy Dr. Etienne Côté.)

ANTICIPATED TIME

- About 30-75 minutes, depending onease of passage, extent of lesion(s), and whether the procedure is diagnostic or also therapeutic (e.g., stone retrieval)

PREPARATION: IMPORTANT CHECKPOINTS

- Have clear goals for the procedure based on case assessment.
- Know the appearance of normal structures in the lower urinary tract via textbooks and continuing education/training.
- Plan ahead for staff involvement with setup, procedural assistance, and cleaning the equipment.
- Discuss with owner that repeated procedures can be required (e.g., stone retrievals, stricture dilation, reassessments, etc.).
- Make alternative plans for surgery if goals are not achieved.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Mistaking the fossa clitoridis in female dogs for the urethral orifice
- Prior digital- or catheter-induced trauma to the urethral tubercle (papilla), thereby hindering entry of the endoscope into the urethra
- Iatrogenic urinary tract infections (UTIs)
- Rupture of the urinary bladder or urethra as a result of inappropriate technique (overfilling) or existing disease. Care should be taken while biopsying pathologic or thin areas of bladder wall (e.g., the site of remnant diverticula, intramural cancer).
- Urethral mucosal edema due to inherent trauma from endoscopy can be a limiting factor in uroendoscopy, particularly in the urethra of male dogs.
- Operator reliance on visual impressions rather than histopathologic or cytologic evaluation of samples

PROCEDURE

- If using small-diameter flexible endoscopes, if the urine is turbid and dark, or if there is gross hematuria, it may be best to empty the bladder prior to the procedure via urethral catheterization (see p. 1226).
- Transurethral cystoscopy can be done with the animal in either ventral or dorsal recumbency; the author prefers dorsal recumbency, but it can be necessary to reverse the selected position.
- Pre-procedure enemas can be done to reduce interference by colorectal feces (lessen mechanical depression of adjacent urinary structures, risk for fecal leakage contamination of perivulvar region during procedure).
- The perineum and prepuce or vulva are cleansed; it is preferable that an aseptic technique be the goal and any procedure-related materials be kept sterile (away from surrounding hospital-related contamination). However, it is expected that contamination from the animal will occur via the urethra, vulva, or prepuce.
- For female dogs and cats, the fiberendoscope or cannula with a rigid scope assembly is placed in the vulva, and the vulvar skin is gently pinched externally (by an assistant) to create a seal; then a saline infusion is started until the vault is distended. When the vulvovaginal area has been examined and the urethral orifice identified, the urethra is cannulated with the scope and distended with saline as the scope is passed to the bladder. The bladder is then emptied via the biopsy channel of the

fiberscope or cannula (remember that the rigid scope slides through the cannula) and then refilled with saline. It is important to visualize the appearance of mucosa both when the bladder is empty and when it is filled.

- For male dogs and cats, the technique is similar, except that the prepuce is held to form a seal around a flexible fiberendoscope. Male dogs may also have the pelvic and proximal urethral segments examined using a rigid urethrocystoscope via a temporary prepubic perineal urethrostomy.
- The bladder is examined in a methodical pattern inclusive of the apex of the bladder.
- The ureteral orifices are identified, and in many cases, pulsatile flow of urine can be observed. Then the trigonal area is examined. Biopsies are taken for histopathologic evaluation and culture. Calculi may be examined and samples taken for analysis. Calculi may be larger than the lumen of the cannula channel. If smaller than the urethral limitation, these larger stones may be drawn up to, and held against, the end of the scope. Then the scope and stone are withdrawn simultaneously. The size of the stone or stone fragments can limit the usefulness of this technique.
- The endoscope is withdrawn slowly while the clinician observes for abnormalities. Visualization of the urethral mucosa is often superior during withdrawal of the endoscope.
- Ectopic ureteral openings in the urethra can be identified in most cases with more accuracy than with the use of contrast radiography; multiple sites of ectopic openings might be identified.
- In the male dog, the colliculus seminalis is located dorsally and can be seen more prominently in intact dogs, as well as the associated prostatic and deferent duct openings into the proximal urethra.
- The vaginal area is then examined for irregularities to the level of the cervical os. Biopsies, brush cytologic analysis, and other procedures are done as warranted.
- The goals of the procedure should be reviewed prior to final withdrawal.

POSTPROCEDURE

- Consider antibiotic use when it is appropriate for the case.
- Postprocedural urethral obstruction can occur but is infrequent. It is usually correlated to the severity of the pathology present. Monitoring of micturition is advised until normal voiding is seen.
- Use appropriate pain management for the patient.

ALTERNATIVES AND THEIR RELATIVE MERITS

Laparoscopic-assisted suprapubic (pre-pubic) percutaneous cystoscopy can be done but is more involved with equipment and invasiveness. It may be used when larger tumors obstruct the trigonal region or urethra, for collection of greater numbers of small calculi, or for placing a retrograde guide wire to facilitate ante-grade catheterization of the urethra.

AUTHOR: MARK E. HITT

Cystogram

OVERVIEW AND GOALS

- On survey radiographs, the urinary bladder is often visualized. However, if further evaluation of the urinary bladder is needed or if the urinary bladder is not adequately seen on survey films, a cystogram may be needed.
- A cystogram is a radiographic study of the urinary bladder obtained following intraluminal administration of a positive contrast medium, negative contrast medium, or both. Evaluation of the urinary bladder with ultrasound has largely replaced many functions of the cystogram.

INDICATIONS

- Dysuria, pollakiuria, hematuria, stranguria
- Evaluation of caudal abdominal masses
- Increased or decreased opacity associated with the bladder
- Nonvisualization of the bladder after abdominal or pelvic trauma; suspected bladder rupture
- Abnormally-shaped or abnormally-located bladder
- Congenital abnormalities
- Recurrent or nonresponsive urinary tract infection (UTI)
- Suspected neoplasia
- Suspected polyp(s)
- Suspected radiolucent calculi
- Posturethral/cystic surgical evaluation

SPECIFIC STUDY FOR SUSPECTED DISEASE

- Negative-contrast cystogram: bladder position
- Positive-contrast cystogram: bladder rupture, bladder position
- Double-contrast cystogram: mucosal thickness (cystitis), mucosal margination, luminal contents (calculi), neoplasia

EQUIPMENT, ANESTHESIA

- General anesthesia or heavy sedation
- Agents:
    - Negative-contrast cystogram: room air, carbon dioxide, nitrous oxide
    - Positive-contrast cystogram: iodinated contrast medium (sodium iothalamate, sodium diatrizoate) or noniodinated contrast medium (iohexol, iopamidol) if clinically warranted
- Urinary catheter with inflatable bulb (Foley catheter) appropriately sized for the animal
- Tomcat catheter used for male cats
- Sterile lubricating jelly
- Surgical gloves
- Sterile syringe for contrast
- Sterile syringe for withdrawing urine from bladder
- Sterile syringe to inflate Foley balloon
- Mild surgical scrub solution and gauze/sponges for prepping the penis/vulva
- Sterile three-way stopcock
- Sterile catheter adapter (Christmas tree)
- Enema bag/set
- Sterile saline

ANTICIPATED TIME

Approximately 30 minutes

PREPARATION

- Animal fasted 24 hours
- Water ad libitum
- Enema given at least 2 hours prior to study to remove a maximum of fecal material from the colon to allow visualization of the

urinary bladder
- Sterile gloves should be worn from this point forward.
- Positive-contrast cystogram:
  - Dilute positive contrast agent to 15%-30% with sterile saline.
  - Dose of diluted contrast is 10 mL/kg.
  - Draw appropriate dose into a syringe.
- Negative-contrast cystogram:
  - Use 10 mL/kg of chosen negative agent (cats: 4-50 mL generally adequate).
  - Draw appropriate dose into a syringe.
- Double-contrast cystogram:
  - Use 10 mL of undiluted positive-contrast agent (cats: 2-4 mL).
  - Use 10 mL/kg of chosen negative-contrast agent (cats: 40-50 mL generally adequate).
  - Draw appropriate doses into syringes.
- Remove Foley catheter from packaging, using aseptic technique.
- Attach catheter adapter (Christmas tree) to Foley catheter.
- Attach three-way stopcock to catheter adapter.
- Draw appropriate amount of air into a syringe to inflate the Foley bulb.
- Attach syringe containing air to the three-way stopcock.
- Open three-way stopcock to allow air flow into the catheter bulb to ensure the bulb is intact. Fill the bulb to the recommended level, and close the three-way stopcock.
- Once it is clear the bulb will hold air, release the air from the bulb, leaving the air in the syringe.
- Attach the syringe filled with selected contrast onto the three-way stopcock (and fill the catheter with positive contrast if performing a positive contrast study).
- Close the stopcock to the contrast material, and open to the syringe filled with air for bulb inflation.
- In male cats, a sterile tomcat catheter is used. Contrast material is drawn into the syringe, and the syringe is attached directly to the catheter.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Urinary bladder rupture
- Cystitis: hemorrhagic, emphysematous
- Bacterial contamination: iatrogenic UTI
- Bladder or urethral trauma
- Catheter kinking or knotting
- Positive-contrast media reaction (rare)
- Negative-contrast: possibility of air embolism with severe mucosal disease (rare)

PROCEDURE

- Preliminary abdominal radiographs are made to determine adequate animal preparation and set radiographic technique.
- The kilovoltage peak (kVp) should be set between 65 and 75 to maximize contrast due to the photoelectric effect (K edge of iodine).
- Milliampere seconds (mAs) may need to be increased 25%-50% compared to settings for survey radiographs.
- The animal should be placed in left lateral recumbency.
- An assistant should extrude the penis in the male.
- The penis/vulva should be prepped with mild surgical scrub solution.
- Sterile lubricating jelly is placed on the Foley catheter.
- The catheter is then gently advanced into the urinary bladder (a stylet can be used with the Foley if necessary; see p. 1226).
- Inflate the catheter bulb with air, and then close the stopcock to maintain inflation.
- Attach a syringe onto the stopcock, and open the stopcock to this syringe.
- Remove as much urine as possible from the bladder (repeat as necessary to allow total emptying).
- Close stopcock to this syringe and discard syringe.
- Turn stopcock open to the contrast medium, and inject the dose of chosen agent.
- Palpate the bladder periodically to ensure it is not overdistended.

CYSTOGRAM Positive-contrast cystogram, lateral projection. Normal study.

CYSTOGRAM Positive-contrast cystogram, lateral projection. Large filling defect seen along caudodorsal aspect of urinary bladder later diagnosed as transitional cell carcinoma.

CYSTOGRAM Double-contrast cystogram, lateral projection. Normal study.

- Stop if back pressure is felt, if reflux is seen around the catheter, or if the bladder feels full.
    - Positive: once the contrast is in the bladder, images can be obtained.
    - Negative: once the contrast is in the bladder, images can be obtained.
    - Double: inject the positive contrast, then roll the animal to ensure good mucosal coating; follow this with injection of the negative contrast, then images can be obtained.
    - Note: If a double-contrast study is desired after a positive-contrast study, the majority of the positive contrast is removed from the bladder, leaving only a small puddle; then negative contrast is injected.
- Ventrodorsal and lateral radiographs are made immediately after injection.

POSTPROCEDURE

- Once the study is complete, the recoverable volume (majority) of contrast is withdrawn from the urinary bladder.
- Air should be removed from the catheter bulb before the catheter is withdrawn.
- If anesthesia used, expect a routine anesthetic recovery.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Plain abdominal radiographs: inexpensive means to survey the abdomen. Radiopaque cystic calculi can be visualized. Size and shape of the bladder often obvious.
- Abdominal ultrasound: noninvasive and readily available; excellent for visualization of bladder, especially wall thickness, luminal contents, and trigone region. Urinary bladder rupture not definitive with ultrasound.
- CT scan and MRI: provide excellent study of the bladder; however, these are costly and rarely performed for this indication.
- Urethrogram: see p. 1357

AUTHOR: LEEANN PACK

Cystocentesis

OVERVIEW AND GOAL

To obtain a sample of urine from the bladder

INDICATIONS

- Urinalysis
- Urine culture and sensitivity (C&S)
- Diagnostic evaluation of vaginal or preputial discharge or of discolored urine

CONTRAINDICATIONS

- Bleeding disorder
- Ascites
- Peritonitis
- Dyspnea, back/hip pain, or other conditions causing distress during dorsal recumbency
- Bladder neoplasia (tumor seeding in needle tract)

EQUIPMENT, ANESTHESIA

The procedure is generally performed awake, but sedation or general anesthesia does not preclude it. The following equipment should be available:

- A 22-gauge, 1½-inch (4 cm) needle
- A 12-mL syringe
- Cotton balls or gauze squares (e.g., 3 × 3 inches [8 × 8 cm])
- Isopropyl alcohol

ANTICIPATED TIME

<5 minutes

PREPARATION: IMPORTANT CHECKPOINTS

Identify contraindications on physical examination, and perform any diagnostic tests, including (as applicable) abdominal radiographs, abdominal ultrasound, CBC with platelet count, coagulation profile.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

The bladder is variable in its exact location from one individual to the next as well as in its degree of fullness in every individual. Therefore, it should be identified by palpation prior to cystocentesis.

CYSTOCENTESIS Ventral abdomen of a female dog in dorsal recumbency; cranial is to the right. A natural depression occurs on the ventral midline of the caudal abdomen of female dogs *(arrow)*, where isopropyl alcohol pools.

PROCEDURE

- The animal is placed in dorsal recumbency. The help of one or more assistants may be necessary to keep the animal in this position. In addition, a U-shaped trough may be used for keeping the animal comfortably recumbent. The examiner stands or kneels beside the animal (either side).
- The right-handed examiner palpates the animal's caudal abdomen with the left hand and holds the syringe—with needle attached—in the right hand.
- Landmarks:
    - General guidelines: ventral midline; cranial to the brim of the pelvis, caudal to the umbilicus
    - A commonly used landmark in female dogs, especially obese dogs, is the natural depression that forms on the caudal abdominal surface just cranial to the inguinal mammary glands on the ventral midline. Cystocentesis performed with the needle entering perpendicularly at this point is generally successful if the bladder is moderately or markedly full of urine.
    - In general, the urinary bladder is more easily palpated in cats than dogs and in thinner animals.
- With cystocentesis in male dogs, an assistant can retract the prepuce laterally. Alternatively, the prepuce may be drawn to one side by the examiner in the palm of the palpating hand.
- With the bladder encircled with the fingers of the left hand, the right-handed examiner cleans the overlying skin on the ventral midline with isopropyl alcohol–soaked gauze or cotton.
- With the right hand the examiner then introduces the needle through the overlying skin on the ventral midline, directed perpendicular to the skin (i.e., vertically downward when the dog is in dorsal recumbency). The examiner pulls back on the syringe plunger, creating negative pressure from the moment the needle is through the skin. Doing so helps identify penetration of the bladder as soon as it occurs.
- If no urine is obtained, it is important to NOT redirect the needle while it is in the abdomen; doing so could cause laceration of abdominal structures with the needle tip. When no urine is obtained, the needle may be withdrawn until only the needle tip remains (2-3 mm in the skin), redirected to a new angle, and then readvanced.
- Once urine flows into the syringe, the examiner withdraws the desired amount of urine and then withdraws the needle and submits the sample for analysis.

POSTPROCEDURE

No discomfort, gross hematuria, or other abnormality is expected after a properly performed cystocentesis.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Free-catch: atraumatic, but the sample is contaminated with urethral, preputial/vulvar, and cutaneous bacteria.
- Urethral catheterization: minimally invasive; may be more uncomfortable than cystocentesis in many animals and is not

practical for urine sampling in cats.

- Ultrasound-guided cystocentesis: useful when the bladder is small, when the animal is very obese, or when there is ascites or any mass lesion in the caudal abdomen.

CYSTOCENTESIS U-shaped foam trough used for comfortably maintaining an animal in dorsal recumbency.

AUTHOR: ETIENNE CÔTÉ

Cross-Match and Blood Typing

SYNONYMS

- Blood typing: determines the presence or absence of antigens on the red blood cell (RBC) membranes of the recipient and donor. Of major clinical interest are the blood types DEA 1.1 in dogs and the AB system in cats.
- Major cross-match: evaluates for antibodies in the recipient's plasma against the donor's RBCs, which is of greatest clinical significance.
- Minor cross-match: evaluates for antibodies in the donor's plasma against the recipient's RBCs.

OVERVIEW AND GOALS

- Cross-matching and/or blood typing eliminates most immunologic transfusion reactions.
- Maximize longevity of posttransfusion RBCs

INDICATIONS

- Blood typing: performed prior to administering a blood transfusion on all donors and recipients to minimize sensitization and avoid severe hemolytic transfusion reactions (i.e., AB mismatch in cats)
- Cross-match: performed prior to a whole-blood or packed RBC transfusion on animals that received a transfusion more than 4 days previously (even if blood typed) or have an unknown transfusion history:
    - First-time transfusions to dogs are considered safe without prior crossmatching, as dogs do not possess clinically significant naturally occurring antibodies.
    - Pregnancy does not appear to sensitize dogs to RBC antigens; consequently, dogs with prior history of pregnancy can safely be used as blood donors and can safely receive a first transfusion without a crossmatch as long as they are properly blood typed.
    - Ideally recommended in all cats, even with first transfusion, as cats have naturally occurring antibodies to the AB system and newly identified Mik red blood cell antigen. Transfusing cats without prior blood typing and/or cross-matching is dangerous; an AB mismatch can be lethal to a type B recipient. AB blood typing will not detect Mik-related incompatibilities.

EQUIPMENT, ANESTHESIA

Blood typing:

- Commercially available canine DEA 1.1 and feline AB system blood-typing cards (DMS Laboratories, Flemington, New Jersey)
- Approximately ≥ 0.4 mL EDTA anticoagulated (purple-top tube) whole blood

Cross-match:

- 1 mL EDTA-anticoagulated (purple-top tube) blood from recipient and donor (or cross-match segments from units of blood being considered)
- Tabletop centrifuge
- 3-mL test tubes (red-top tubes can be used)
- 0.9% saline
- Disposable pipettes or 1-mL syringes
- Test tube rack

ANTICIPATED TIME

- Blood typing: 2 minutes
- Major and minor cross-match: 40 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- The stability and expiration of components of blood typing kits vary: ensure proper storage and check expiration dates.
- EDTA blood samples should be blood typed or cross-matched within 2-3 days of collection, as the physical integrity of the

RBCs is essential for correct results.
- Breed and geographic prevalence of blood types for dogs and cats are listed online (see web tables: Blood Type Frequencies, Dogs and Blood Type Frequencies, Cats).

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Dogs or cats that are autoagglutinating due to underlying disease (e.g., immune-mediated hemolytic anemia) cannot be accurately blood typed (false positive) and will always appear incompatible on cross-match.
- A patient cannot be accurately blood typed following recent blood transfusion using in-house blood-typing cards.
- Severely anemic cats or dogs (<10% hematocrit) may not show agglutination when using blood-typing cards (prozone effect). After a brief centrifugation, some of the plasma is withdrawn to concentrate the RBCs before adding a drop to the test cards.
- Feline blood-typing cards may not detect type AB cats.

PROCEDURE

Blood typing: commercially available blood-typing cards (see package inserts) **Cross-match:** Recently a gel-based major cross-match test kit (DMS Laboratories, Flemington, New Jersey) was commercialized for in-practice use (see figure), which may decrease the subjectivity of interpreting results, although no published data are available at this time (see package inserts).

STANDARD CROSS-MATCH (MAJOR AND MINOR):

Step 1:

- Collect 1-2 mL of donor blood in an EDTA tube, or use an equivalent 1-2 mL of cross-match segments from unit of blood being considered.
- Collect 1-2 mL of recipient blood in an EDTA tube.
- Centrifuge both donor and recipient blood in separate labeled tubes for 5 minutes (1000 *g*).
- Remove plasma using a pipette and save in separate labeled tubes for later use (use different pipettes for donor and recipient).
- Wash the remaining packed RBCs three times by filling tubes with 0.9% saline, gently resuspending, centrifuging (1000 *g)* for 5 minutes, and decanting off the saline (discard the saline).
- After a third wash, add 0.2 mL of washed packed RBCs from the donor red-top tube to 4.8 mL of 0.9% saline (in a separate tube), and gently mix to obtain a 3%-5% RBC solution (bright cherry red). Make a similar 3%-5% RBC solution with the washed recipient RBCs.

Step 2:

In a test tube:

- Mix 2 drops of recipient plasma and 1 drop of donor RBC suspension (major cross-match).
- Mix 2 drops of donor plasma and 1 drop of recipient RBC suspension (minor cross-match).
- Mix 2 drops of recipient plasma and 1 drop of recipient RBC suspension (auto-control).
- Incubate at 37°C (ideally, but room temperature is acceptable) for 15-20 minutes.
- Centrifuge for 30 seconds.
- Observe the plasma for hemolysis. Gently resuspend the RBC button by tapping the tube, and examine for agglutination clumps.
- Hemolysis or agglutination indicates incompatibility.

POSTPROCEDURE

- Administer type-specific blood to the patient. DEA 1.1+ dogs can receive DEA 1.1+ or DEA 1.1-blood, but DEA 1.1-dogs should only receive DEA 1.1-blood.
- When the recipient autocontrol shows hemolysis or agglutination (common in IMHA cases), the cross-match cannot be interpreted. In such cases, use DEA 1.1-blood or “universal blood” (determined by extensive blood typing), or use hemoglobin-based oxygen carriers (i.e., Oxyglobin).
- If all available units are incompatible, the least reactive unit may need to be administered.
- Cats that show a positive result in both wells of blood-typing cards should be retested in a reference laboratory for the rare AB blood type.

ALTERNATIVES AND THEIR RELATIVE MERITS

An EDTA-collected blood sample can be sent to commercial laboratories for extensive blood typing of dogs and cats: advised for

blood donors. Consultation with the laboratory is advised because different labs test for different canine erythrocyte antigens.

CROSS-MATCH BLOOD-TYPING Gel-based major cross-match test kit. (DMS Laboratories, Flemington, NJ)

AUTHORS: SØREN R. BOYSEN & MARIE-CLAUDE BLAIS

Computed Tomography Scan

SYNONYMS

CT Scan, CAT Scan, computed axial tomography

OVERVIEW AND GOALS

Computed tomography (CT) is a method of cross-sectional imaging that involves ionizing radiation. When compared to radiography, CT allows improved evaluation of areas of complex anatomy by avoiding superimposition of multiple structures, and it provides improved contrast resolution of tissues. CT can be used for assessing any area of the body. In veterinary medicine, common uses include assessment of the head (brain and nasal cavity) and thorax. It is also often used for surgical and radiation therapy planning.

INDICATIONS

- Disease of the central nervous system
- Disease of the nasal cavity/upper airway
- Determine the extent of tumor involvement for surgical planning
- Radiation therapy planning (used with specialized planning software)

CONTRAINDICATIONS

- Inability to tolerate general anesthesia
- Presence of large metallic implants in the area of interest. This does not contraindicate the procedure, but the information offered by the study will be limited by the presence of artifact.

EQUIPMENT, ANESTHESIA

- CT scanner
- Anesthesia equipment:
    - General anesthesia is required. CT studies are relatively brief, and either gas anesthesia or a constant rate infusion of intravenous anesthetic agent—generally propofol—can be used for the study. The equipment needed will be determined by the type of anesthesia used:
        - Gas anesthesia:
            - Endotracheal tube and laryngoscope for placement
            - Anesthesia machine: no special requirements (unlike MRI)
        - Constant rate infusion:
            - Endotracheal tube and laryngoscope for placement
            - Infusion pump
    - Monitoring equipment
    - Pulse oximeter
    - Electrocardiogram (ECG)
    - Emergency kit: as with any procedure performed under general anesthesia, the equipment and drugs necessary for emergency resuscitation of the patient should be immediately available.
    - Intravenous contrast agent:
        - Iodinated contrast agent labeled for intravenous use (i.e., diatrizoate/metrizoate compounds such as Renografin 60, iohexol [Omnipaque], iopamidol [Isovue])
    - Intravenous fluids (optional)
    - Heating pad/blankets (optional)

ANTICIPATED TIME

The time required to perform the study will depend on the CT scanner used and the study to be performed and is therefore quite variable. Most scans will be completed in 30 minutes or less.

EXAMPLE: CT scan of the brain:

- Two scans are performed, one prior to contrast injection and one following contrast injection.
- The time for each of these studies may vary from 5-10 minutes (older, single-slice translational scanners) to less than 30

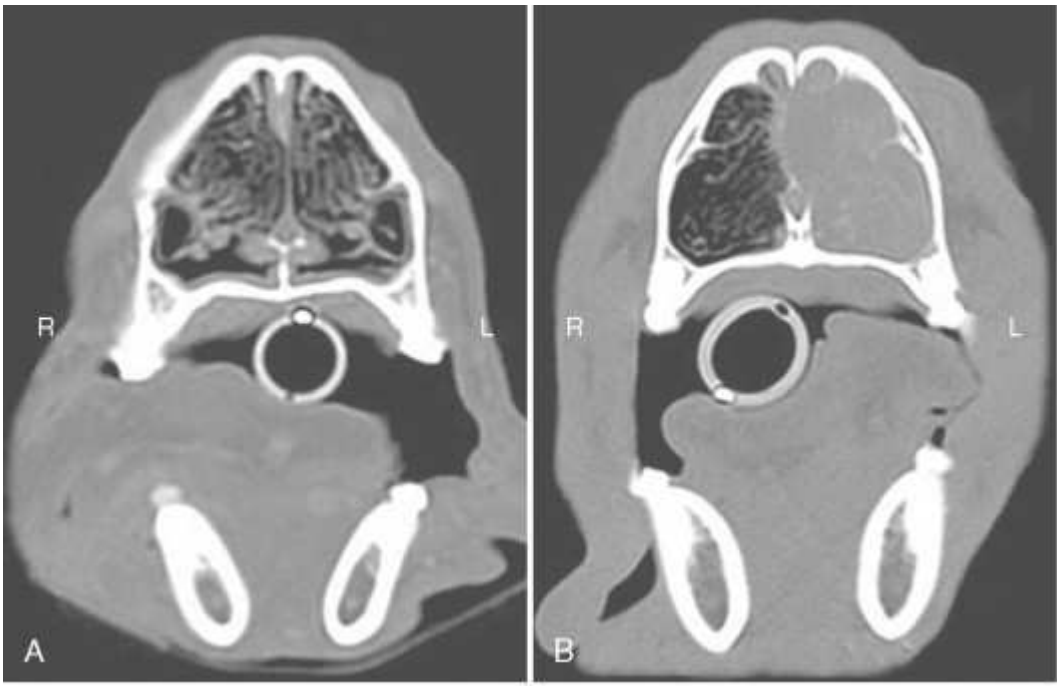
seconds (new multislice helical scanners).

Complex scans of large areas (abdomen or entire body for example) may require a pause in the scanning to allow the x-ray tube to cool. Generally this pause is relatively short (e.g., 2-3 minutes), but it must be considered when estimating the total general anesthesia time for the patient.

PREPARATION: IMPORTANT CHECKPOINTS

Preparation for general anesthesia:

- Routine preanesthetic fasting
- Place IV catheter: when placing the catheter, the anticipated position of the patient within the CT gantry must be considered, and the catheter should be placed to allow easy access to it during the procedure. For example, in patients undergoing CT scan of the head, it is convenient to have the IV catheter placed in the saphenous vein, although the forelimb can be extended caudally for ease of access if the catheter is in a cephalic vein.
- Make sure all needed equipment is available and functional. This is especially important if the study is to be performed at an outside (nonveterinary) facility.



COMPUTED TOMOGRAPHY SCAN NASAL CAVITY CT images from a normal **(A)** and abnormal **(B)** canine nasal cavity. CT is based on the principle of differential attenuation of tissues and, as in radiographs, bone appears white, air appears black, and soft tissues are intermediate in appearance. The term *density* is used for describing the appearance of tissues in CT images. In the normal patient, the nasal turbinates and nasal septum are present and surrounded by air. In the abnormal patient, the left half of the nasal cavity is filled with material of soft-tissue density, and there is loss (destruction) of the nasal turbinates. The nasal septum is thinned and deviated to the right. The right half of the nasal cavity is normal in appearance. This appearance is considered evidence of an aggressive process within the left half of the nasal cavity. Differentials for aggressive processes include neoplasia and fungal rhinitis. In this case, neoplasia is considered likely based on the mass effect within the nasal cavity.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Complications associated with general anesthesia
- Complications associated with the administration of intravenous contrast agent (rare in animals)

PROCEDURE

- Anesthetize the patient.
- Position the patient within the CT gantry; positioning depends on the area of interest and, in some cases, the size of the patient:
    - Connect IV fluids, place heating pad or blankets, and so forth.
- Scan

- Inject intravenous contrast agent: 600-800 mg iodine/kg of body weight as a bolus:
    - The concentration of iodine varies with the contrast agent used.
    - Sample calculation: 20-kg patient using a dosage of 700 mg iodine/kg:
        - Total dose = 14,000 mg iodine:
            - Renografin 60 (292.5 mg iodine/mL) = 14,000 ÷ 292.5 = 47.9 mL
            - Omnipaque 240 (240 mg iodine/mL) = 14,000 ÷ 240 = 58.3 mL
- Re-scan
- Briefly review images:
    - Rarely, the images obtained will identify an additional area of concern that should be scanned before the patient is allowed to recover from general anesthesia.

POSTPROCEDURE

No additional considerations beyond routine monitoring of the patient during recovery from general anesthesia

ALTERNATIVES AND THEIR RELATIVE MERITS

Magnetic resonance imaging (MRI): Advantages:

- Far superior contrast resolution
- No beam-hardening artifact (this artifact occurs in CT and severely limits evaluation of structures surrounded by dense bone such as the brainstem)

Disadvantages:

- Longer imaging times (and therefore, longer time under general anesthesia)
- Poor imaging of bone
- If available, MRI is the preferred imaging method for evaluation of the central nervous system.

AUTHOR: PATRICIA L. ROSE

EDITOR: ETIENNE CÔTÉ

Chest Tube Placement

SYNONYM

Thoracostomy tube placement

OVERVIEW AND GOALS

To provide means for frequent or continuous drainage of fluid or air from the pleural cavity

INDICATIONS

- Pyothorax
- Rapidly forming pleural effusion
- Recurring pneumothorax requiring repeated thoracocentesis
- Tension pneumothorax
- Postoperative thoracotomy management

CONTRAINDICATIONS

Severe bleeding disorder

EQUIPMENT, ANESTHESIA

- General anesthesia with intubation (ideally) or sedation
- Clippers
- Surgical scrub
- #11 scalpel blade
- Local anesthetic (e.g., 2% lidocaine, 0.2-0.5 mL/kg, SQ; maximum 7 mL)
- Small surgical pack or sterile hemostats
- Suture material (e.g., 2-0 to 4-0 nylon)
- An assistant (if possible)
- Thoracostomy tube
- Catheter adapter
- Three-way stopcock
- Injection caps
- ± Continuous drainage device
- 20-gauge orthopedic wire or plastic zipties
- Wire twister and cutter if using orthopedic wire

ANTICIPATED TIME

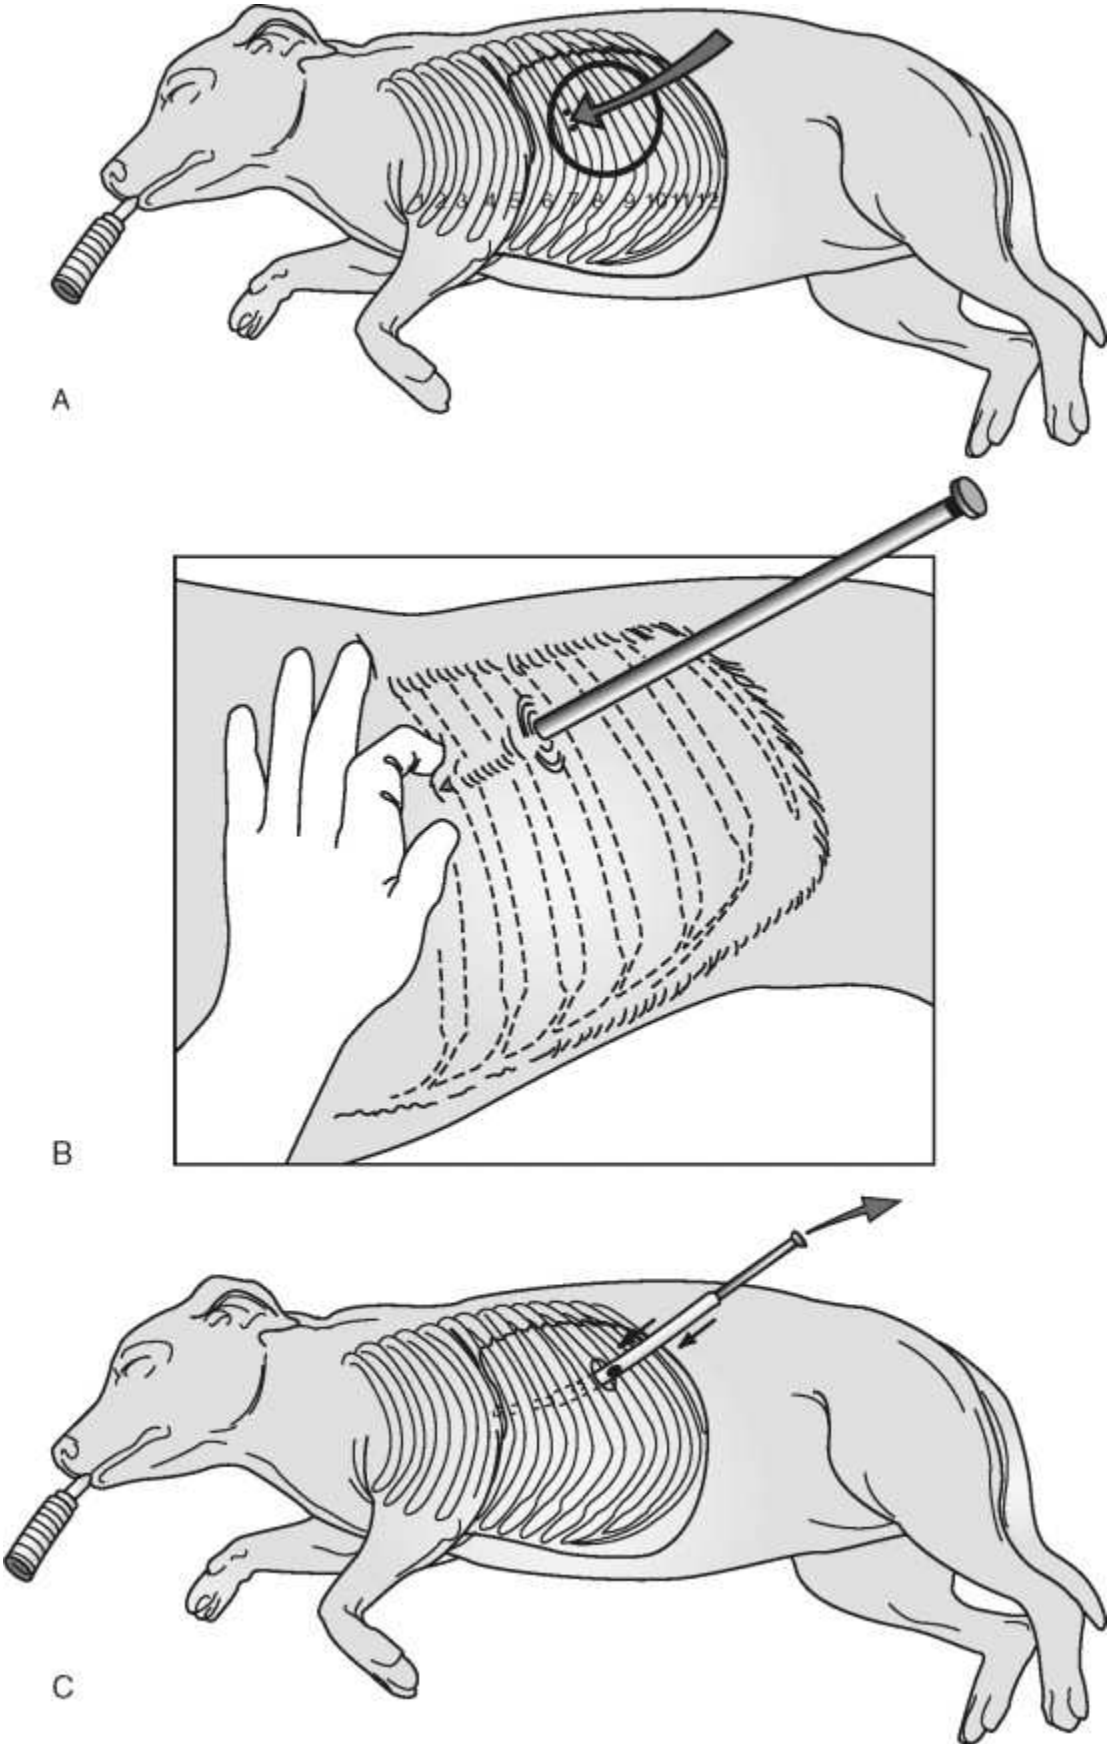
About 15-45 minutes

PREPARATION: IMPORTANT CHECKPOINTS

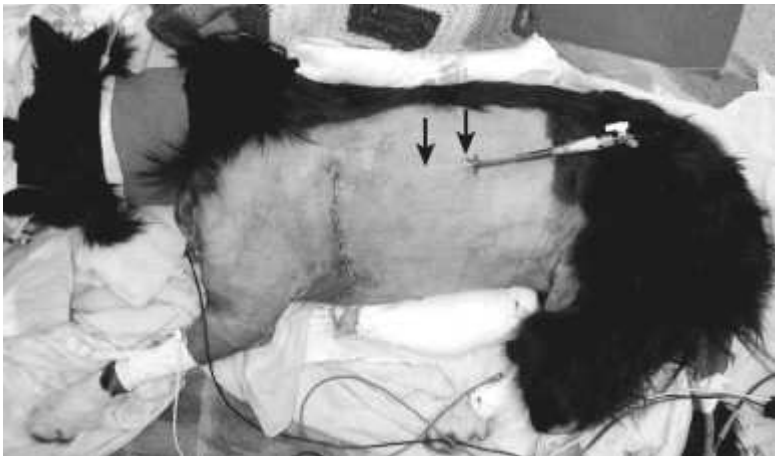
- Make 3-5 extra drainage holes in chest tube with scalpel blade if thick or purulent fluid is present in pleural space (< 50% of the diameter of tube). Be sure not to compromise the integrity of the tube with extra holes.
- Monitor animal's oxygenation with pulse oximetry during anesthesia and placement.
- If tension pneumothorax is present, continuous evacuation of pleural space by thoracocentesis until chest wall is opened will help stabilize animal.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Improper (SQ) placement of tube
- Impaling the heart or lungs with the tube's stylet/trocar
- Pulmonary contusions



CHEST TUBE PLACEMENT A, For placement of a chest tube, animal is in lateral recumbency, and an incision is made in the skin at least two intercostal spaces (ICS) caudal to planned site of entry into thorax. **B**, Chest tube and trocar within it are tunneled together SQ to the appropriate ICS, and chest is entered with the tube. **C**, Tube is then advanced off the trocar *(small arrows)* such that all side holes of the chest tube are within the pleural space, and trocar has not advanced farther into chest. Trocar is then withdrawn *(larger arrow)*, and chest tube is capped and secured.



CHEST TUBE PLACEMENT Chest tube in place after lateral thoracotomy for a penetrating wound. Tube enters skin at approximately the tenth intercostal space (ICS) *(large arrow)*, tunnels under skin for three rib spaces, and enters thorax *(small arrow)* through seventh ICS. Note "Chinese finger trap" suture pattern to secure tube and use of wire to secure tube-to-adapter and adapter-to-stopcock connections.

- Placement of the tube into the abdominal cavity, with abdominal organ trauma
    - Aforementioned complications are more common with the trocar method
- Tube migration or premature removal of tube by animal
- Development of life-threatening pneumothorax if tube becomes open to atmosphere

PROCEDURE

- General anesthesia (preferable); can be done with sedation for an emergency case
- Lateral recumbency
- Clip hair from lateral thorax, extending from axilla cranially to the last rib caudally, and from dorsal spine to ventral midline.
- Aseptically prep and drape area.
- Using scalpel blade, make a small stab incision in the skin over the highest point of the thorax at the ninth or tenth intercostal spaces (ICS).
- The assistant then pulls the skin cranially several centimeters and holds the skin in that position. The chest tube will be placed into the thorax via seventh or eighth ICS. When the skin is released after placement of the tube, there will be an SQ tunnel of 2-3 ICS over the tube. This helps prevent air or fluid leakage around the tube.
- Lidocaine can be injected into intercostal muscle at the tube insertion site, or an intercostal block can be performed, injecting lidocaine just ventral and caudal to the transverse processes of the thoracic vertebrae/head of ribs one space cranial and caudal and at the site of insertion. Before injecting, aspirate back to determine that needle is not in the intercostal artery or vein.
- If the patient is anesthetized, stop manual ventilation while actually inserting tube into thorax to deflate lungs and decrease risk of trauma to lungs.
- With the skin still drawn cranially, hemostats are used for bluntly dissecting vertically into the pleural space, spreading the jaws wide enough for the tube to snugly fit through the opening. The tube is inserted and advanced cranially and ventrally along the chest wall, making sure that all side holes in the tube are well within the thorax. The distance the tube is advanced can be measured with the stylet. The tip of the tube should be at the second or third ICS.
- Connect tube to a three-way stopcock and injection caps or a pleural drainage system.
- Secure to skin with a purse-string suture around the tube at the entry site and a "Chinese finger trap" suture pattern to reduce sliding of the tube.
- Place sterile dressing and light bandage.
- Tube connection sites can be secured with orthopedic wire in figure-eight patterns or plastic zip ties.

Alternate method, trocar technique:

- Sedation or anesthesia should be provided if possible.
- Initial prep as previously described
- Tube and trocar/stylet within it are tunneled SQ by 2-3 rib spaces and then positioned perpendicular to the chest wall and grasped tightly 1-2 inches from distal tip.
- Top of the tube will be hit bluntly with the palm of other hand, popping the tube through into pleural space; the other hand, grasping tube and trocar 1-2 inches from the distal tip, acts as a guard to prevent the tube from entering the thorax excessively.
- Tube is slid off the trocar/stylet cranially and ventrally, then connected and secured as described previously.
- This very rapid placement technique is only recommended in dogs in emergency situations, owing to increased risk of

iatrogenic trauma, and is never recommended in cats because of their very compliant chest walls.

POSTPROCEDURE

- Thoracic radiographs (lateral and ventrodorsal or dorsoventral) to check tube(s) placement
- Bandage to secure tube(s)
- Pain management: injectable opioids versus intrathoracic bupivacaine (both modalities can be used for optimal pain control).
    - Bupivacaine can be given at a dose of 1.5 mg/kg through tube every 6-8 hours.
- Continuous monitoring as long as the chest tube is in place because of the risks of disconnection and development of pneumothorax.

ALTERNATIVES AND THEIR RELATIVE MERITS

Repeat thoracocentesis: may become difficult to manage animal if pleural evacuation is needed frequently.

AUTHOR: LORI S. WADDELL

Cerebrospinal Fluid Collection

SYNONYMS

Spinal tap, CSF tap

OVERVIEW AND GOALS

- To safely collect an uncontaminated sample of cerebrospinal fluid (CSF) from an animal with suspected central nervous system (CNS) disease.
- CSF analysis is the single most valuable diagnostic test for evaluating inflammatory CNS disorders and it aids in the diagnosis of other encephalopathies and myelopathies.

INDICATIONS

- Clinical signs consistent with CNS or nerve root dysfunction
- Monitoring treatment efficacy of confirmed inflammatory CNS disease
- Intrathecal administration of contrast material (myelography)

CONTRAINDICATIONS

Absolute:

- Increased intracranial pressure (depressed mental status, bradycardia, hypertension, miosis, anisocoria)
- Any condition in which general anesthesia is contraindicated

Relative:

- Advanced imaging results identifying a noninflammatory disease process, which explains the animal's clinical signs

EQUIPMENT, ANESTHESIA

- General anesthesia and endotracheal intubation
- A few 20- or 22-gauge, 1½-inch spinal needles (2½ - or 3½-inch needle may be needed for large dogs or for lumbar approach).
- Hair clippers
- Surgical scrub solution, isopropyl alcohol, and gauze
- Sterile surgical gloves
- Sterile collection tubes (do not use tubes containing EDTA [lavender-top tubes])
- An assistant to position the animal and stabilize the animal's head and neck
- Level stationary or locked table

ANTICIPATED TIME

About 30 minutes of anesthesia

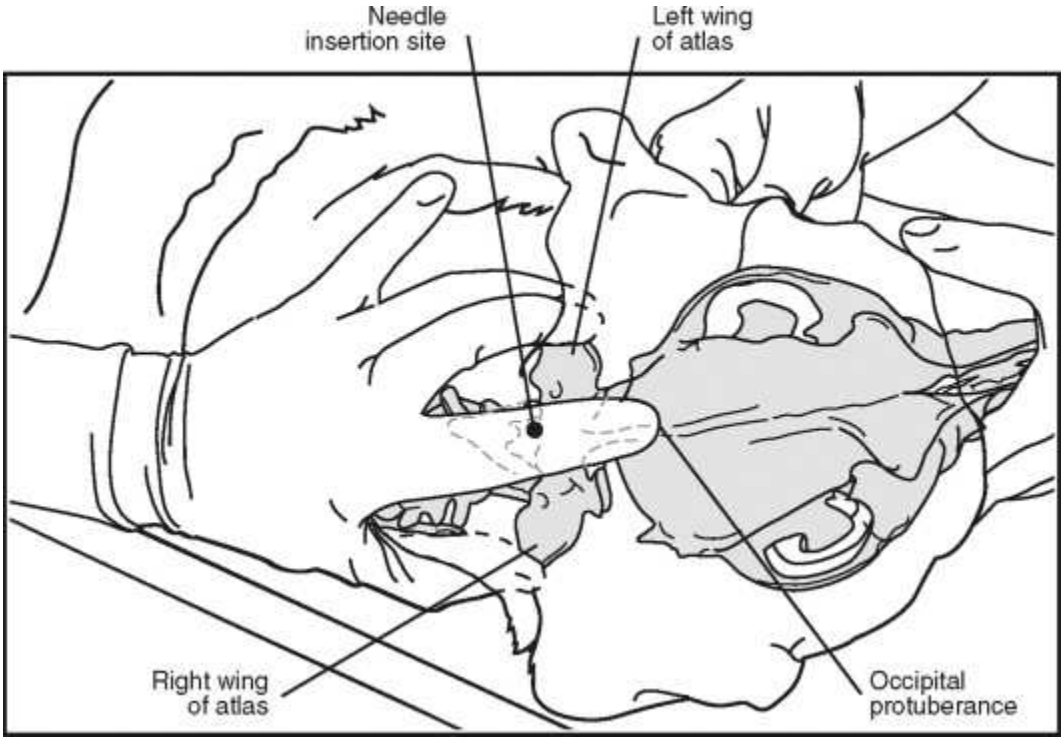
PREPARATION: IMPORTANT CHECKPOINTS

- Performed preferably after advanced imaging has ruled out both noninflammatory processes (neoplasia, malformation, vascular) and obvious increased intracranial pressure (coning and caudal displacement of the cerebellum, flattening of gyri, loss of sulci).
- Make arrangements for laboratory transport within 30 minutes of collection, or have in-house analysis equipment prepared and calibrated.
- If immediate analysis of the CSF is not possible, special preservation techniques may be required (prior laboratory consultation is recommended).
- Warn owners of hair clipping and low risk of complications. Complications associated with the procedure, although rare, can be fatal.

PROCEDURE

- General anesthesia and intubation
- Preparation and positioning for centesis from the cerebellomedullary cistern (preferred for ease and lower risk of blood contamination):
    - Shave and surgically scrub the skin from the occipital protuberance rostrally to the dorsal spine of C3 caudally and to the base of each pinna laterally.
    - Sterile gloves are worn, but the field is not usually draped.
    - Lateral recumbency: right lateral for the right-handed clinician and left lateral for the left-handed clinician.
    - An assistant holds the head flexed at a 90° angle to the neck and parallel to the table. Care must be taken to not overflex the neck, which could result in obstruction of the endotracheal tube or compress the jugular veins and increase intracranial pressure. For the head to be parallel to the table, the assistant must hold the nose slightly elevated from the table.
    - The assistant positions the dorsal aspect of the neck at the edge or slightly over the edge of the table.
    - The clinician should sit on a stool or kneel to be at eye level with the animal's head.
- Landmarking and puncture:
    - The right-handed clinician places the left thumb on the right wing of the atlas and the left ring or middle finger on the left wing of the atlas.
    - The left index finger is used for identifying the midline by palpating the occipital protuberance and the dorsal spine of C2, drawing an invisible line between these points.
        - Many cats and toy-breed dogs do not have a well-defined occipital protuberance. In these cases, the dorsal spine of C2 should be used as the sole landmark for identifying the midline.
    - The orientation of the needle's path will be parallel to the table's surface and toward the angle of the animal's mandible.
    - For dogs, using the right hand, the needle with stylette in place is inserted through the skin along the midline just cranial to the wings of the atlas.
    - In cats, the skin is tough, and the distance between the skin and subarachnoid space is very small. Therefore, although the same point of insertion is identified, the skin should be tented prior to inserting the needle through the skin into the subcutaneous tissues.
    - The needle is directed through subcutaneous fat and muscle toward the subarachnoid space, taking care to avoid lateral, caudal, or cranial deviation of the spinal needle.
    - Occasionally a loss of resistance to the needle insertion is felt as the needle passes through the fascial planes of the muscle and, eventually, the dorsal atlantooccipital membrane; this so-called pop is not reliable and should not be used as an indicator of appropriate depth of the needle.
    - While maintaining a grip on the hub of the needle with the right hand, the clinician uses the left hand to grasp the needle near its insertion into the skin.
    - The stylette is withdrawn with the right hand, and the hub of the needle is examined for the presence of CSF.
    - If no CSF is present, the needle is first withdrawn a few millimeters while watching for the appearance of CSF to ensure the needle has not been inserted too deep (into nervous tissue), and then the needle is advanced. The stylette need not be replaced at this point. (Although advancing the needle without the stylette creates a slight risk of creating a tissue plug in the needle, it decreases the risk of advancing the needle too deeply, as CSF will appear as soon as the subarachnoid space is entered.)
    - As the needle is advanced one of three things will happen:
        - CSF appears in the hub of the needle and will begin to drip out. The needle should then be advanced 1 mm to place the entire bevel in the cerebellomedullary cistern, and the needle is grasped firmly against the skin. The slight advancement and firm hold on the needle reduce the risk of blood contamination from meningeal vessels.
        - The needle hits bone. This is usually the occipital bone, and the needle should be redirected caudally to enter the cerebellomedullary cistern; if it strikes the atlas, the needle must be redirected cranially. The needle may be walked along the bone to find the cistern, bearing in mind that it will be only millimeters deeper, but this may result in blood contamination from trauma to the periosteum.
        - Frank blood appears in the hub. This most likely indicates that the needle is off midline and has punctured a venous sinus. In this case, the needle is removed and discarded, gloves are changed, the surgical prep is repeated, and the procedure is started again. Note: If blood is encountered, it is typically from a location outside the subarachnoid space and does not limit the ability to obtain an uncontaminated sample when the procedure is repeated.
    - Once CSF begins to drip from the hub, it is collected into two plain, sterile red-top tubes. Ideally, an assistant collects the sample, and the examiner does not release the needle during collection.
    - In general, 1 mL of CSF is required for assessment of the white blood cell (WBC) count, protein determination, and cytologic examination (1 mL/5 kg of body weight can be obtained safely).
    - If the animal weighs more than 5 kg, additional CSF can and should be collected for possible culture or ancillary diagnostics, such as infectious titers or immunoglobulin indices.

CEREBROSPINAL FLUID COLLECTION Landmarks. Dog is in right lateral recumbency, head pointing to right of photo. Right-handed clinician is using left hand to identify the occipital protuberance (index finger) and wings of the atlas (right wing of atlas: thumb; left wing of atlas: middle and ring fingers). Patient's neck is appropriately flexed (90°), and nose is elevated by an assistant so muzzle is parallel to table surface.



CEREBROSPINAL FLUID COLLECTION Diagram of same dog, showing bony landmarks and site of needle insertion.

CEREBROSPINAL FLUID COLLECTION Same animal. While clinician holds the needle, an assistant collects the cerebrospinal fluid.

  - Once the appropriate amount of CSF has been collected, the needle is removed.
  - Note: If during the procedure the heart rate acutely decreases or if fluid streams rather than drips from the hub when the subarachnoid space is entered, the needle should be removed and the procedure aborted.
- Preparation and positioning (for centesis from the lumbar subarachnoid space) is technically more difficult, yields less fluid, and is more likely to involve blood contamination but is more sensitive for focal thoracolumbar lesions:
  - The skin is shaved and surgically scrubbed over the dorsal midline from L3 cranially to the midsacrum caudally and the wings of the ilium laterally.
  - Sterile gloves are worn, but the field is not usually draped.
  - The animal is positioned in lateral recumbency with the hindlimbs and lumbar spine flexed (“tucked” posture).
- Landmarking and puncture:
  - The needle enters the L5-L6 or L6-L7 interspace in dogs, or the L7-S1 interspace in cats.
  - Except in very small or thin animals, the L6 dorsal spine is typically the most caudal and can be palpated just cranial to the wings of the ilium.
  - If the L7 dorsal spine is palpable, it is usually much smaller than that of L6 and lies between the wings of the ilium.
  - Radiographs can demonstrate individual differences in anatomy.
  - The needle is inserted into the skin just caudolaterally to the caudal dorsal spine of the space to be entered (i.e., caudolaterally to L6 for puncture between L5 and L6).
  - The needle is directed craniomedially to puncture the interarcuate space between the vertebrae.
  - If bone is encountered, the needle is redirected (usually cranially) until the space is identified.
  - If the needle is inserted to the hub and no bone is encountered, the needle is either too short or directed too far laterally.
  - Fluid can be collected from the dorsal subarachnoid space, but more often the needle is passed through the nervous tissue to the floor of the vertebral canal.
  - The stylette is removed, and if CSF is not recovered, the needle is withdrawn slightly to enter the ventral subarachnoid space while the examiner watches for the appearance of fluid in the hub of the needle.
  - CSF typically flows much more slowly from this site compared with the cerebellomedullary cistern.

POSTPROCEDURE

- Routine postanesthetic monitoring
- Monitor for neurologic deficits due to iatrogenic trauma (respiratory difficulty or vestibular ataxia with puncture from the cerebellomedullary cistern; paresis and proprioceptive ataxia with lumbar puncture).

ALTERNATIVES AND THEIR RELATIVE MERITS

MRI or CT scan (see pp. 1302 and p1233):

- Advanced imaging superior for the diagnosis of structural lesions
- May be strongly suggestive of inflammatory disease
- Typically used in addition to CSF analysis to fully evaluate disorders of the CNS

Serum infectious titers:

- Systemic disease not necessarily reflective of CNS disease
- For most inflammatory nervous system diseases, no infectious agent is identified.

AUTHOR: GREG KILBURN

Central Venous Pressure Monitoring

OVERVIEW AND GOALS

Central venous pressure (CVP) is a measurement that reflects the ability of the heart, and specifically the right side of the heart, to accept and pump blood through the circulatory system. The CVP reflects the interaction of the heart, vascular tone, and blood volume. Monitoring of CVP allows a better understanding of the circulatory status of the body and of the impact of fluid therapy.

INDICATIONS

- Monitoring the administration of large volumes of fluids in animals that are in shock or have impaired urine production
- Diagnostic help in difficult-to-diagnose right heart failure cases (e.g., constrictive pericarditis)

CONTRAINDICATIONS

Only those of jugular catheter placement (e.g., hypercoagulable or hypocoagulable states, skin infection over jugular site; see p. 1293)

EQUIPMENT, ANESTHESIA

- IV jugular catheter (Mila or Arrow double-lumen catheters)
- Sterile 500-mL saline bag with IV drip set
- CVP set (Universal CVP set [Abbott Laboratories]). Alternatively, if a purpose-made kit is not available, use the following: a sterile three-way stopcock, sterile IV fluid-type tubing, and a ruler (centimeter grading and at least 30 cm long). The sterile tubing is taped to the ruler, and it is held vertically, creating a simple pressure manometer.

ANTICIPATED TIME

- About 15 minutes to install the set
- About 2 minutes for each CVP reading

PREPARATION: IMPORTANT CHECKPOINTS

- The prerequisite is the placement of an IV jugular catheter (see p. 1293):
  - The distal tip of this catheter should be in the cranial vena cava, just cranial to the right atrium, which allows accurate measurement of CVP without inducing premature atrial contractions. Confirm position radiographically.
  - Mila or Arrow catheters are the most commonly used because their double lumen allows CVP measurement and/or blood sampling through one port and fluid delivery through the other.

PROCEDURE

Before connecting CVP set to patient's jugular catheter:

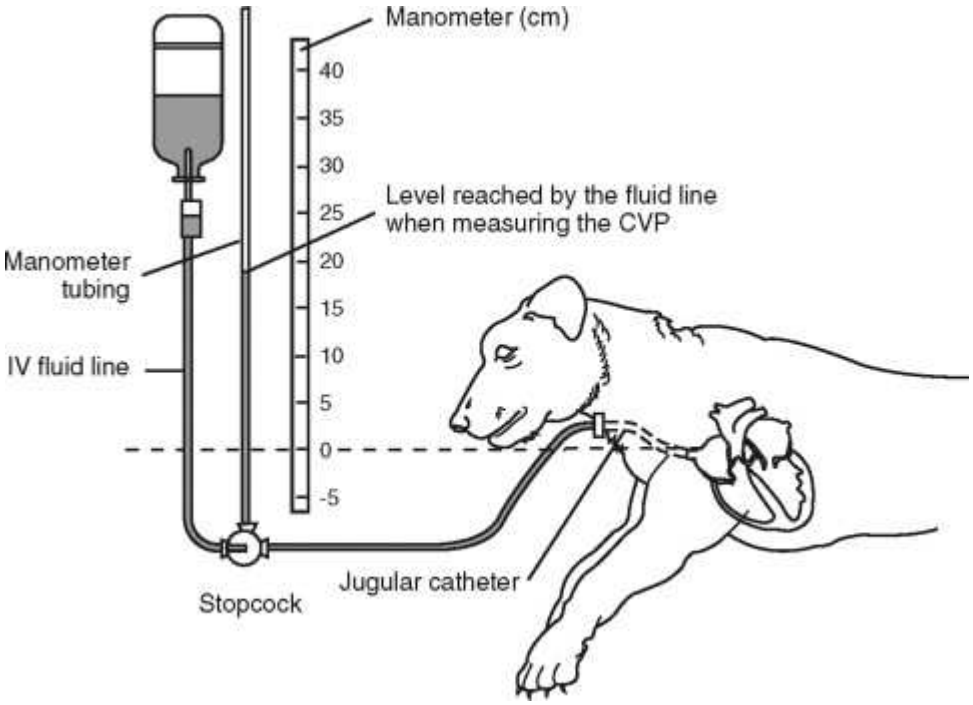
- One end (female end) of the CVP set goes to a suspended IV fluid bag. The line on that end should be closed using a clamp.
- A second end connects to tubing that is fixed to a scale (e.g., manometer scale or ruler). This line also should be closed using a clamp.
- The manometer tubing is pressed into the scale groove:
  - If using individual materials, tape the sterile IV fluid-type plastic tubing to the ruler.
- Using adhesive strips, fix the manometer on a vertical surface, such as the wall of a cage or a vertical stand, next to the animal and at a height such that the 0 on the scale of the manometer/ruler is at the level of the animal's heart (right atrium).
- Unclamp the fluid line coming from the fluid bag:
  - Fluid should run through the line until the line contains only fluid and no air.
- Then unclamp the manometer tubing and turn the three-way stopcock such that flow exists between the fluid line from the fluid bag and the fluid line of the manometer.
- Fill the manometer line with fluid to within 3 cm of its extremity.

Connecting CVP set to patient:

- Next, connect the remaining end (male end) of the CVP set to the jugular catheter. The stopcock is usually integral to the set.
    - If using individual materials rather than a purpose-made set, connect the male end of the three-way stopcock directly to the jugular catheter.
- Finally, turn the stopcock so that a column of fluid exists between the jugular catheter and the manometer.
- The fluid in the manometer will fall until it reflects the CVP (measured in centimeters of water).

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- One must allow fluid to flow frequently through the IV line to avoid plugging of the catheter by a blood clot. Periodic flushing with heparinized saline is desirable.
- Cardiac function needs to be factored in when interpreting results. For example, animals with tricuspid regurgitation may have elevated CVP irrespective of intravascular volume loads.
- The CVP level represents mostly loading conditions of the right side of the heart (right ventricular preload), not afterload.



CENTRAL VENOUS PRESSURE MONITORING CVP monitoring. Dashed line represents the level of the right atrium, the zero point for setting the manometer. The stopcock is closed to the IV fluid line; the jugular catheter and manometer tubing are in continuity. The dog's CVP reading is markedly elevated at 19 cm H2O.

(Reprinted with permission from Sattler FP: Shock. In Kirk RW, editor: Current veterinary therapy III, Philadelphia, 1968, Saunders.)

INTERPRETATION

- Normal CVP: variable; oscillates between -1 and +5 cm H2O.
- Values between +5 and +10 cm H2O are borderline.
- Values above +10 cm H2O may indicate too much blood volume expansion. IV fluids should no longer be administered.
- Values above +15 cm H2O may indicate right-sided congestive heart failure.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Blood pressure (BP) monitoring: easier to use and represents another way to monitor cardiovascular status and the impact of IV fluids. This is the best alternative to CVP monitoring. It does not require an IV jugular catheter.
- Weight: can be used for documenting rehydration; excessive weight gain could be a signal to slow/stop IV fluids.
- Packed cell volume/total solids (PCV/TS): a drop in the PCV/TS may indicate hemodilution.
- Urine specific gravity: a drop in the specific gravity could document successful restoration of plasma volume but is very dependent on kidney function.
- Pulmonary capillary wedge pressure/Swan-Ganz catheterization: accurately measures left-sided heart pressures, which CVP does not; however, this technique is much more technically demanding.

AUTHOR: ERIC DE MADRON

Catheterization, Urethral

SYNONYM

Urinary catheterization (see p. 1355 for catheterization of cats)

OVERVIEW AND GOAL

To pass a sterile catheter from the urethral orifice into the urinary bladder to obtain a urine sample or to evacuate the bladder

INDICATIONS

- Urine sample for urinalysis/urine culture
- Temporary management of urinary retention syndromes

CONTRAINDICATIONS

- Urethral pain
- Preputial/vulvar mass
- An animal that might otherwise be eligible for renal transplantation can be eliminated from the transplant list on the basis of prior urethral catheterization.

EQUIPMENT, ANESTHESIA

- Sterile polypropylene or red rubber-type catheter (or Foley catheter if indwelling); size ranges from 5-14 Fr, depending on the animal's size.
- Sterile lubricant
- Sterile syringe (3-20 mL)
- Sterile gloves
- ± Sterile tubing and urine collection bag (if indwelling catheter)

ANTICIPATED TIME

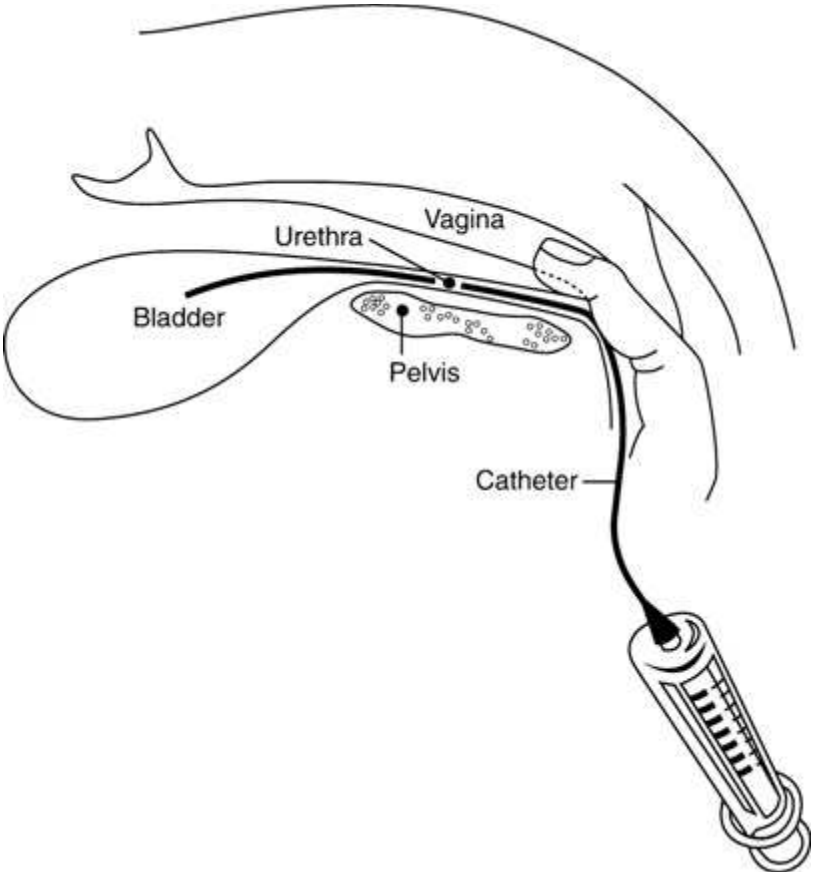
About 10 minutes

PREPARATION: IMPORTANT CHECKPOINTS

Rectal palpation is indicated as part of the physical examination of any adult dog, particularly prior to passing a urethral catheter (identify masses, sources of pain, or other factors that would affect passage of the catheter).

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Incorrect orientation (female): to enter the vulva, the directing (index) finger must be oriented dorsally, not cranially.
- Incorrect catheter position (female): clitoral fossa externally and vagina internally must be avoided in catheterizing female dog.
- Forceful advancement of the catheter: catheter should pass with no resistance and no discomfort. Otherwise, consider free catch, cystocentesis, or sedation/anesthesia (if placing indwelling catheter).



CATHETERIZATION, URETHRAL Cross-sectional anatomy of the female urogenital tract, demonstrating the proper position of catheter and index finger.

- Excessive advancement of the catheter: risks include bladder perforation and catheter looping/knot formation (requiring laparotomy).

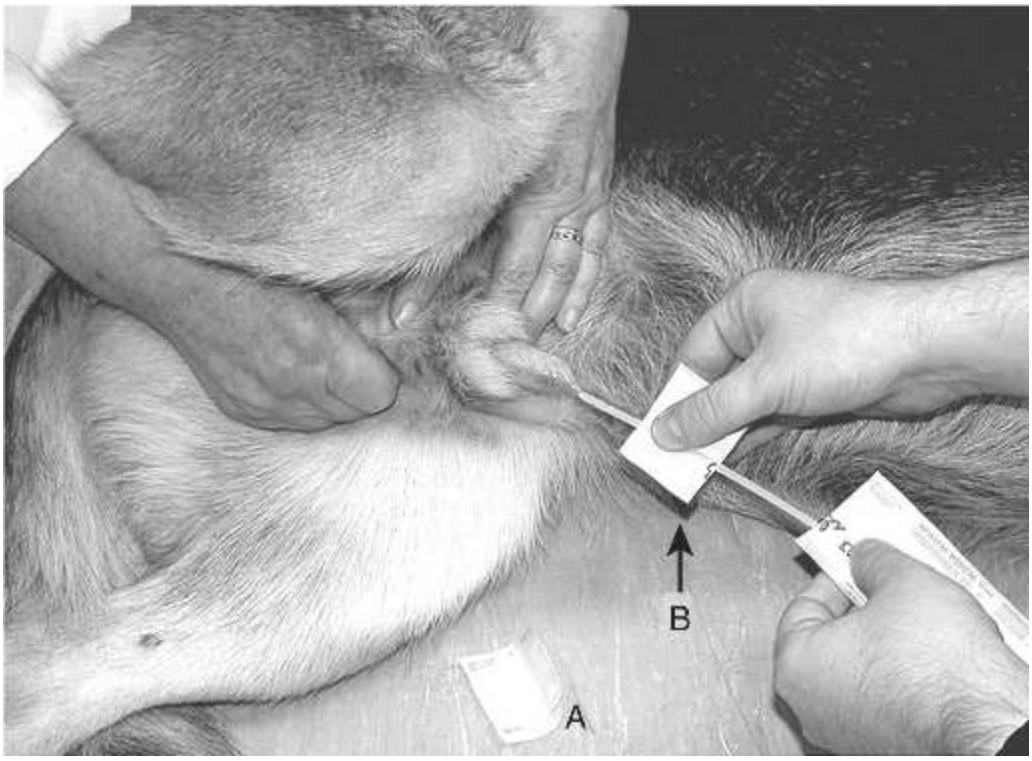
PROCEDURE

Female:

- The dog stands on an exam table or on the ground (giant-breed dogs). The procedure is also easily performed on the laterally recumbent (e.g., anesthetized) dog.
- While an assistant holds the dog's head, the examiner opens the sterile catheter wrapper, applies sterile lubricant to the catheter tip, and ensures that the catheter remains in a sterile field (e.g., the opened catheter wrapper).
- The right-handed examiner puts on sterile gloves, lubricates the right index finger, and takes the urinary catheter under his or her right index finger (palmar surface of finger), catheter tip at fingertip.
- The examiner lifts the dog's tail with the left hand and places the index finger on the vulva, pointing dorsally, and then enters the vulva by gently everting the vulvar lips and pressing cranially.
- The examiner advances the index finger and catheter directly dorsally (i.e., toward the ceiling in the standing dog) to a narrowing, which is the vestibulovaginal junction. The ischial arch also is palpable cranially.
- The urethral opening is on the cranial/ventral surface in this region, immediately adjacent to the ischial arch. Therefore, the catheter is advanced under the index finger such that the index finger blocks off the vestibulovaginal route and directs the catheter ventrally into the urethra. There should be no palpable resistance when advancing the catheter.
- Once urine flows from the catheter, it is advanced 2-3 cm (small dog) to 10-15 cm (large dog) into its final position.

Male:

- An assistant positions himself or herself dorsal to the laterally recumbent dog, elevates the dog's nondependent leg, and retracts the prepuce to expose the penis (see figure). A second assistant is usually needed to restrain the dog's head.
- The sterile catheter is kept within its sterile wrapper except for the distal end of the wrapper, which is cut off.



CATHETERIZATION, URETHRAL Urethral catheterization of the male dog. **A,** Distal end of wrapper cut off. **B,** Segment of sterile wrapper functioning as a sliding cuff for advancing the catheter.

- The next 3-5 cm of sterile wrapper is then cut and left overlying the catheter; it will serve as a sliding sterile cuff for advancing the catheter out of the wrapper and up the urethra, while keeping the clinician from touching the catheter directly with the fingers. This approach minimizes contamination without requiring sterile gloves.
- The catheter is placed into the urethral opening and is advanced until urine is obtained. Minor resistance may be felt at the ischium or prostate, but the procedure should be aborted if force seems necessary or if the animal seems uncomfortable.

POSTPROCEDURE

If an indwelling system is used, the catheter is fixed in place, and the extension tubing and collection bag are connected to the catheter.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Free-catch urine sample: simple and noninvasive but contaminates sample with urethral and genital bacteria and cells
- Cystocentesis: more invasive but may be less uncomfortable than catheterization; avoids urethral contamination

AUTHOR: ETIENNE CÔTÉ

Cardiopulmonary Cerebral Resuscitation

SYNONYMS

Cardiopulmonary resuscitation, CPCR, CPR

OVERVIEW AND GOALS

Cardiopulmonary cerebral resuscitation (CPCR) is instituted for cardiorespiratory arrest or near arrest. The goal is return of spontaneous and effective circulation (ROSC) and, ultimately, unassisted ventilation and appropriate cerebral function.

INDICATIONS

Cardiopulmonary arrest or near arrest; signs of impending arrest may include bradycardia, hypoventilation, hypothermia, hypotension, and progressive obtundation. These indicate that action should be taken to ensure continued effective circulation and ventilation. There are four cardiac rhythms that enter the definition of cardiac arrest: asystole, ventricular fibrillation, pulseless ventricular tachycardia (VT) or ventricular flutter (VF), and other pulseless electrical activity.

EQUIPMENT

- Endotracheal tube and laryngoscope
- Ambu-Bag, Bain Circuit, or mechanical ventilator
- Blood pressure (BP) measuring device (Doppler preferable)
- Electrocardiogram (ECG) (monitor preferable to printer)
- Defibrillator; internal and external paddles
- End-tidal carbon dioxide monitor
- Pulse oximetry
- Oxygen source
- Fluids: crystalloids (e.g., lactated Ringer's solution, 0.9% NaCl) and colloids (e.g., Hetastarch)
- Blood products (e.g., whole blood, packed red blood cells, polymerized bovine hemoglobin)
- Lubricant for eyes
- Point of care testing for blood glucose, electrolytes, packed cell volume, total solids, lactate, blood gases
- Other items that should be nearby: lidocaine jelly, suction tubing and means of generating suction, IV and urethral catheters, thoracotomy tubes, laceration packs
- Items for doing open thoracic cardiac massage and vascular cutdown procedures, self-retaining retractors
- Sterile gloves, means of warming fluids

The data collection sheet for record keeping should include:

- Date and time of arrest and institution of CPCR
- Animal name and medical record number, body weight, signalment and underlying disease, as well as assumed cause of the arrest
- A table or another quick and clear way to list which drugs are given, at what time they are given and at what dosage, and their effects
- Listing of fluid type and volume administered
- Time and energy of any defibrillation
- Pertinent laboratory results as tests are run during the procedure
- Personnel present during the event
- Time of return to spontaneous circulation or ending CPCR efforts
- Outcome
- Data that should be noted as well include size of endotracheal tube, time and settings if mechanical ventilation is instituted, changes in status of mentation, presence or absence of urine output, and BP measurement results.

PREPARATION: IMPORTANT CHECKPOINTS

- The owners of any critically ill animal should be consulted at the time of the animal's admission regarding their resuscitation wishes for the pet. In many cases of advanced or aggressive disease, advanced age, and financial limitations of the family, CPCR may not be appropriate, and the pet should be allowed to pass away peacefully.
- Successful CPCR is a team effort. The team consists of the clinician leading the arrest and individuals who are keeping a record of the event, acquiring the requested drugs or materials, administering the drugs and therapies, providing the chest compressions, and communicating with the animal's family. The team may contain any number of people, from few to many, with some having multiple roles.
- A senior knowledgeable individual must take charge in fostering a calm environment during CPCR, directing the other team members in their tasks, and keeping the team informed of progress. One responsible team member should be in communication with the owners to keep them apprised of progress and inform the team of changes in the family's wishes.
- Team members must be fully trained and prepared ahead of time concerning their responsibilities.
- All of the equipment that was previously listed (e.g., endotracheal tubes, breathing circuits, IV catheters, defibrillation paddles, sterile gloves, etc.) should be available in sizes appropriate for a wide variety of animals.
- Drug boxes should be checked weekly at least to ensure all drugs are available and have not reached their expiration dates.
- Equipment should be checked regularly for malfunctions and cleaned immediately after each use so that each piece is ready to be used again without notice.
- Data sheets should be kept nearby so that events, drug administration, animal information, and responses to treatments can be recorded in a timely and accurate fashion.
- After every CPCR event, the team should review the process to assess whether changes in plan, arrangement, or protocols are necessary for improvement of efforts in the future.

Emergency Drugs

Aminophylline: 25 mg/mL

Atropine*1: 0.54 mg/mL

Calcium gluconate*: (10% = 100 mg/mL [calcium: 27.2 mg/mL or 1.36 mEq/mL])

Dextrose*: 5% (50 mg/mL) or 50% (500 mg/mL)

Dobutamine*: 12.5 mg/mL

Dopamine*: 40, 80, 160 mg/mL

Doxapram: 20 mg/mL

Epinephrine*1: 1 : 1000 (1 mg/mL) or 1 : 10,000 (0.1 mg/mL)

Esmolol: 10 mg/mL

Furosemide*: 5% (50 mg/mL)

Lidocaine*: 2% (20 mg/mL)

Magnesium sulphate*: 10% (100 mg/mL, 0.8 mEq/mL), 12.5% (125 mg/mL, 1 mEq/mL), 50% (500 mg/mL, 4 mEq/mL)

Mannitol*: 5% (50 mg/mL, 275 mOsm/L), 10% (100 mg/mL, 550 mOsm/L)

Norepinephrine*1: 1 mg/mL

Phenylephrine: 10 mg/mL

Procainamide*: 100 mg/mL

Sodium bicarbonate*: 8.4% (1 mEq/mL)

Glucocorticoids:

Dexamethasone: SP (4 mg/mL)

Prednisolone sodium succinate: (10 or 50 mg/mL)

Methylprednisolone sodium succinate: (62.5 mg/mL)

Reversal Agents*:

Flumazenil: 0.1 mg/mL Naloxone: 0.4 or 1 mg/mL

Atipamezole: 5 mg/mL

Yohimbine: 2 mg/mL

Sample concentrations are listed; it is essential to check the actual concentration of available product.

* Indicates drugs that should be in all basic emergency kits. The others may be beneficial, and their use is dependent on clinician knowledge and familiarity.

1 Indicates that the drug can be administered intratracheally using a long catheter, generally at double the dose and followed by several deep breaths.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Inaccurate drug dosage administration
- Hyperventilation
- Inadequate fluid resuscitation
- Incorrect assessment of ECG, especially false interpretation of bad contact between ECG machine and animal as “ventricular fibrillation”
- Inadequately trained personnel
- Delayed defibrillation. The success of defibrillation in an experimental setting approaches 100% when instituted within 1 minute of onset of fibrillation and falls precipitously to virtually 0% after 10-15 minutes.
- Inadequate/infrequent monitoring of electrolytes, blood glucose, and physiologic parameters
- Malfunctioning or unavailable equipment
- Delayed decision to perform open-chest CPR in a patient for which it is appropriate
- Acute renal failure, diarrhea, liver dysfunction, and altered mentation and reflexes are common sequelae to inadequate oxygen delivery and tissue perfusion. Organ function must be closely monitored to take preemptive action should parameters deteriorate.

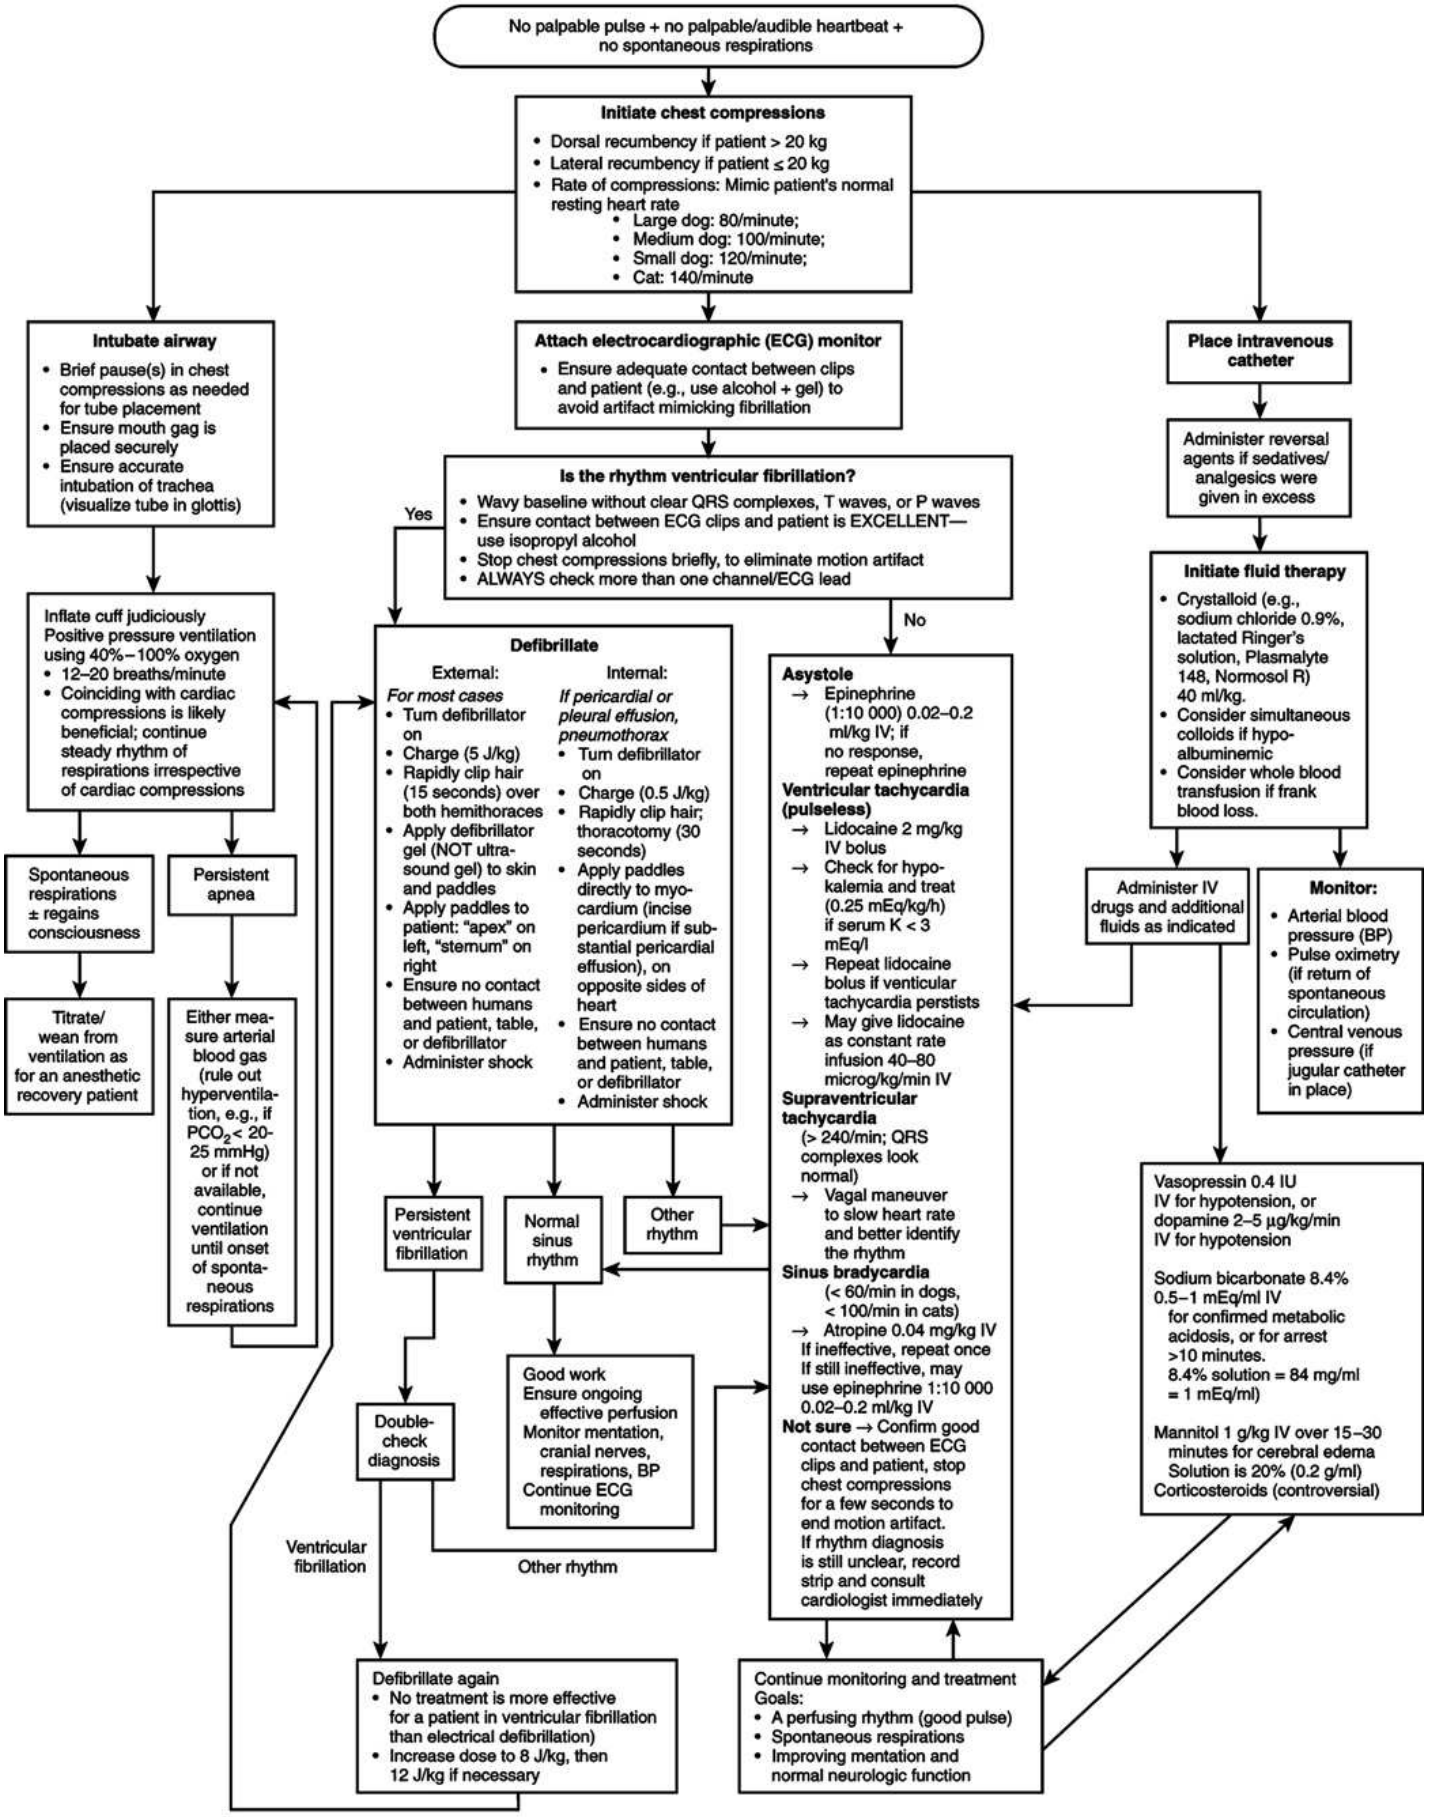
Prognosis overall is guarded to grave depending on the underlying disease process, age, and overall state of debilitation of the animal. The number of successful resuscitations (i.e., survive to discharge) may approach approximately 4% in dogs and possibly greater than 4% in cats; however, the fact that they occur with good critical care management means that every effort should be made to resuscitate animals when appropriate.

PROCEDURE

Most of the initial tasks listed here should be occurring simultaneously:

- Identify lack of effective spontaneous circulation and ventilation.
- Initiate chest compressions at 80-100 compressions/minute, compressing approximately 30% of chest diameter, with a 1:1 ratio of compression to relaxation. Hands should be placed over the widest part of the chest for patients > 10 kg. Hands should be placed over the heart for patients < 10 kg. Interruption of chest compressions should be minimized to <10 seconds until ROSC occurs.
- Intubate the airway, and place ECG leads on limbs.
- Begin assisted ventilation with 100% inspired oxygen at 10-12 breaths/minute, higher if pulmonary disease preventing effective oxygen transfer exists, or the patient was already hypoxemic.
- Identify cardiac rhythm if any.
- Establish vascular access (IV catheter) if not already established.
- If anesthetized, turnoff inhalant anesthetics, and reverse any injectable drugs that have reversal agents.

CARDIOPULMONARY CEREBRAL RESUSCITATION



- If thoracic compromise exists (e.g., pleural effusion, pneumothorax) or arrest is due to pericardial effusion, open-chest CPR must be instituted immediately. With pericardial effusion, open the pericardium ventral to the phrenic nerve to improve diastolic function of the heart and remove effusion.
- Fluid administration: IV (or intraosseous [IO], especially in pediatric animals). Shock rate administration (90 mL/kg in dogs, 45 mL/kg in cats, with constant monitoring and adjustments as needed) is appropriate if the patient was hypovolemic prior to the CPA. Otherwise, consider an initial bolus of 20 mL/kg in dogs, 10 mL/kg in cats if the patient was euvolemic; use caution with cardiac or renal disease. Hypertonic saline can also be considered (4-6 mL/kg of 3% saline IV slowly over 5 minutes).
- Administer epinephrine (low dose: 0.02 mg/kg IV; high dose: 0.2 mg/kg IV). Consider starting with the low dose, repeat with high dose if initial dose is unsuccessful.
- Vasopressin (0.2-0.8 U/kg IV) can be considered instead of or in combination with epinephrine.
- Defibrillate electrically (e.g., starting with 2-5 J/kg if closed chest, 0.2-0.5 J/kg if open chest) if ventricular defibrillation is present. Repeat defibrillation if ventricular fibrillation persists.
- Additional medications to consider to treat arrhythmias: atropine (0.04 mg/kg IV) followed by epinephrine again if asystole unresponsive to initial epinephrine; amiodarone (5 mg/kg IV or IO over 10 minutes) for refractory ventricular fibrillation, atrial fibrillation, supraventricular tachycardia (SVT), ventricular tachycardia (VT); lidocaine (2-3 mg/kg IV in dogs) for ventricular tachycardia or flutter; atropine for persistent bradycardia; magnesium (0.15-0.3 mEq/kg IV slowly over 10 minutes) for refractory ventricular arrhythmias.
- Start vasopressors (e.g., dopamine 2-10 mcg/kg/min IV) if BP not adequate once appropriate fluid resuscitation is administered.
- Assess metabolic condition with repeated blood gas analysis and electrolyte and blood glucose monitoring: treat abnormalities accordingly.
- Use ETco2 and Doppler transducer on the cornea to assess efficacy of CPCR attempts.
- Monitor body temperature, cranial nerve reflexes.

POSTPROCEDURE

MONITOR, MONITOR, MONITOR: ideally continuously; otherwise very frequent intermittent monitoring is required. A majority of critically ill animals that have been resuscitated will arrest again within a few hours. Clinicians should monitor the following:

- BP
- Ventilation
- Oxygenation
- Cranial nerve reflexes
- Mentation
- Blood gases
- Organ-specific chemistries
- Urine output
- Electrolytes
- Blood glucose
- Central venous pressure
- Lactate
- Packed cell volume (PCV)
- Coagulation deficits
- Body temperature

Clinicians should also consider the following during the monitoring period:

- Administration of mannitol at 1-2 g/kg IV over 30 minutes is useful to reduce cerebral edema secondary to hypoxic brain injury, as well as to support renal perfusion and improve circulation to tissues.
- Until the animal is conscious and mobile, recumbent animal care protocols must be used. Frequently turning the animal, lubricating its eyes, keeping it clean of eliminations, and keeping the oropharynx clean and/or suctioning the endotracheal tube are imperative. Monitor for pressure-induced sores and blood flow impairment.
- If postarrest recumbency lasts hours or more, passive range-of-motion exercises may help with improving ultimate recovery as well as helping assess the progress of the animal's muscle strength.

ALTERNATIVES AND THEIR RELATIVE MERITS

There are many approaches to and controversies associated with CPCR. Many books and/or articles list different drug dosages and indications or contraindications. The reader is advised to be prepared by reading multiple sources and generating a customized flow chart that takes into consideration the personnel, drugs, and equipment available at a particular practice. If the animal is stable to move, post-resuscitation management should ideally be handled in a well-staffed 24-hour facility.

Diagnostic Peritoneal Lavage

SYNONYMS

Abdominal lavage; DPL

OVERVIEW AND GOAL

Instillation and subsequent evacuation of lavage fluid to evaluate suspected intraabdominal disease

INDICATIONS

Animals with suspected abdominal disorders for which other noninvasive/less invasive testing has been inconclusive or unavailable. Animals that might benefit from diagnostic peritoneal lavage (DPL) include those with:

- Abdominal trauma
- Acute abdomen
- Sepsis with no source identified
- Shock with no source identified

CONTRAINDICATIONS

- Cardiovascular/respiratory compromise that may be exacerbated by lavage fluid administration
- Coagulopathy
- Recent abdominal surgery
- Diaphragmatic hernia

EQUIPMENT, ANESTHESIA

- Minimum of two assistants
- Sedation may be necessary; local anesthesia and manual restraint may be sufficient for some animals.
- Hair clippers
- Surgical scrub solution
- Isopropyl alcohol
- Sterile gauze for scrubbing skin
- Local anesthesia (2% lidocaine)
- Sterile drape
- Sterile surgical gloves
- Sterile needle holders
- Sterile scissors
- A #11 blade for stab incision of skin
- Sterile drainage catheter—various devices can be used:
    - Peritoneal dialysis catheter (recommended)
    - Over-the-needle large-gauge IV catheter: may be prone to kinking
    - Abdominal drainage catheter
    - Red rubber feeding tube
- Sterile collection system consisting of “Christmas tree” adapter, three-way stopcock, IV drip set, and collection bag
- 2-0 or 3-0 nylon suture to anchor the catheter to the skin
- Bandage material:
    - Nonadhesive absorbent sterile pad
    - Cast padding
    - Kling-type bandage roll
    - Protective outer layer (Vet-wrap, etc.)
- Elizabethan collar
- Lavage fluid (typically lukewarm saline) and administration supplies that depend on the volume of lavage infused (syringe/needle versus fluid bag with drip set, 22 mL/kg)

ANTICIPATED TIME

About 15-40 minutes for placement. Additional time required for drainage depends on type of catheter selected, degree of flow obstruction encountered, and variation between animals.

PREPARATION: IMPORTANT CHECKPOINTS

- Ensure adequate manual or chemical restraint. Excessive struggling by the animal may result in contamination of the sterile field or increased risk of abdominal trauma during catheter placement.
- Maximize cardiovascular stability prior to the procedure.
- Receive owner approval for invasive procedure.
- Perform all abdominal imaging prior to the procedure, because lavage fluid instillation will affect future imaging interpretation.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Care must be taken during placement to avoid internal organ damage. Possible traumatic injury includes:
  - Vessel or organ laceration leading to hemoabdomen
  - Gastrointestinal (GI) tract perforation leading to septic peritonitis
  - Urinary tract laceration leading to uroabdomen
- Obstruction of catheter drainage holes with omentum is a frequent occurrence and can limit complete retrieval of lavage fluid. Repositioning the animal and flushing the catheter may help relieve the obstruction. Use of commercially available peritoneal dialysis catheters with numerous (50-100) small-diameter side holes may minimize complete omental plugging. Cutting additional side holes (never more than one-third the circumference, because tube breakage may occur) into a nonperitoneal dialysis-specific catheter can be performed to decrease plugging of a single distal opening.
  - If sufficient lavage fluid cannot be retrieved, complications such as animal discomfort, cardiovascular or respiratory compromise, or overhydration may ensue.
- Subcutaneous or external leakage of lavage fluid may occur, especially if the body wall incision is large. Tunneling the catheter at least 2 cm through the subcutaneous space will help minimize external leakage. Keep the body wall and skin incisions small; the tube should be inserted with a snug fit through the incisions.
- Ascending infection into the peritoneal cavity is infrequent but possible. Sterile technique must be maintained during placement and when manipulating the lavage materials. A bandage should be maintained over the catheter site, and the catheter should be removed when the procedure has been completed.

PROCEDURE

PATIENT PREPARATION:

- Sedate the patient if it is fractious or likely to struggle, or if the clinician's ability to maintain a sterile technique throughout the procedure is questionable.
- Empty urinary bladder through catheterization or manual expression (decreases potential for bladder trauma or laceration during catheter placement).
- Place in dorsal recumbency. (Left lateral recumbency is also possible but not preferred.)
- Clip hair from abdomen, from xiphoid to pubis.
- Surgical scrub
- Determine catheter insertion sites for the skin and body wall:
  - Recommended skin insertion site is 1-2 cm to the right of the umbilicus.
  - Recommended body wall insertion site is 1.5-3 cm caudal to the skin insertion site.
- Administer lidocaine injection at skin and body wall insertion sites, penetrating all tissue layers to be incised. Note: Pain with lidocaine injection can be minimized by mixing lidocaine with one-tenth the volume of 8.4 mEq/L sodium bicarbonate (adjusts to a more neutral pH) and by warming to body temperature (e.g., once filled, keep syringe tucked in clinician's axilla).
- Repeat surgical scrub.
- Wear sterile gloves.
- Drape sterile field.

PLACEMENT: The technique will vary depending on the chosen catheter device.

- Trocar-type peritoneal dialysis catheter:
  - Incise skin using a #11 blade: incision should be no larger than the catheter diameter.
  - Tunnel the catheter through the subcutaneous space to the desired body wall entry site.
  - Insert trocar and catheter through the body wall at a 45° angle, directed caudally.
    - A turgid abdomen allows easier placement.
    - With a flaccid abdomen, insertion may be facilitated by grasping and “tenting” the abdomen with one free hand while advancing the catheter with another hand.
  - After passage through the body wall, advance the catheter off the trocar to minimize the potential for trauma with the sharp trocar.

    - Final catheter placement should be within the abdominal cavity, along the ventral midline adjacent to the urinary bladder.
- Seldinger-type peritoneal dialysis/abdominal drainage catheter:
    - Insert using the same anatomic markers.
    - Use the Seldinger technique of initial guide wire placement, dilation, and subsequent catheter insertion along the guide wire.
- Over-the-needle IV catheter:
    - Make 2-4 additional side holes < 30% of the diameter of the catheter using a #10 blade.
    - Insert using the same anatomic markers, and advance the catheter off the stylet once the body wall has been fully penetrated.
- Red rubber feeding tube: see p. 1192.

ANCHORING:

- Anchor the catheter in place using 3-0 or-2-0 nylon suture. A purse-string suture should be placed in the skin, followed by a Roman-sandal/Chinese-finger-trap suture pattern.
- Attach the sterile collection system to the catheter port.
- Apply a sterile dressing at the insertion site, followed by a bandage.
- Caution: An Elizabethan collar should be used if the animal is left unsupervised at any time with the tube in place.

LAVAGE:

- Instill 22 mL/kg of warm saline into the abdominal cavity through the three-way stopcock. Closely monitor the cardiovascular and respiratory status of the animal during infusion for early detection of deterioration, warranting termination of the procedure. Place a sterile male adapter into the port when completed to maintain a closed system.
- Gently rock the animal from side to side, and gently massage the abdomen to promote fluid dispersion. Reduce or avoid this step if the patient's abdomen is painful.
- Attach a 6- to 20-mL syringe (dependent on body size and fluid volume instilled), and slowly (to avoid omental plugging) aspirate to obtain the fluid sample for analysis. Replace male adapter when completed.
- Open stopcock to the collection system, and allow gravity to drain the remaining lavage fluid. Incomplete retrieval is likely owing to partial absorption and ineffective retrieval. Maximum retrieval should be attempted.

REMOVAL:

- Cut the purse-string suture and remove the catheter.
- Place a skin suture if the incision > 5 mm.
- Maintain a sterile dressing and bandage over the incision site for 12-24 hours.

ANALYSIS:

- Evaluate color: clear fluid is not expected when peritonitis exists. Flocculent fluid indicates possible peritonitis. Red fluid indicates hemoabdomen. Green fluid likely contains bile.
- Perform packed cell volume (PCV) count: > 5% indicates significant hemoabdomen.
- Perform white blood cell (WBC) count: normal is approximately 1000 cells/mm^3.
- Perform cytologic examination of fluid for degenerative neutrophils, toxic change, intracellular bacteria, bilirubin crystals, neoplastic cells, and other such abnormalities.
- Consider aerobic/anaerobic culture if septic peritonitis is suspected.
- Consider chemistry evaluation of lavage fluid, with comparison to peripheral blood:
    - Elevated creatinine in lavage fluid indicates ruptured urinary tract.
    - Elevated bilirubin indicates ruptured biliary tree.
    - Elevated amylase indicates pancreatitis.

POSTPROCEDURE

- Monitor recovery from sedation/anesthesia.
- Supportive care as indicated for condition.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Percutaneous needle abdominocentesis (see p. 1194):
    - Technically easier to perform
    - Requires less equipment
    - Higher probability of a negative tap with small fluid volumes or pocketed areas of disease

- Abdominal ultrasonography:
  - Noninvasive
  - Allows visualization of the entire abdomen and detection of small or pocketed areas of fluid accumulation
  - Ultrasound-guided aspiration allows fluid collection without risk of side effects secondary to instillation of lavage fluid.
  - Diagnostic accuracy is operator dependent.
  - Not available at all veterinary facilities
- Abdominal CT scan (see p. 1233) or MRI (see p. 1302):
  - High diagnostic accuracy rate
  - Typically requires anesthesia
  - Limited to referral institutions
  - Expensive
- Laparoscopy (see p. 1298):
  - High diagnostic accuracy rate
  - Requires anesthesia
  - Expensive
  - Not available at many veterinary facilities
- Exploratory laparotomy:
  - High diagnostic accuracy rate
  - Requires anesthesia
  - Highly invasive

AUTHOR: LILLIAN I. GOOD

Dermatologic Diagnostic Procedures

SYNONYMS

Diagnostic techniques in dermatology, diagnostic testing in dermatology

OVERVIEW AND GOALS

- Tests that are performed to confirm a diagnosis and/or to rule out differential diagnoses for skin lesions
- The most common diagnostic procedures in dermatology are examination of the haircoat and skin with a good light source and magnifying lens, flea combing, acetate tape preparation, skin scrapings, skin cytologic examination, Wood's lamp examination, fungal culture for dermatophytes, and skin biopsies.

INDICATIONS

- Skin scrapings: used primarily to find mites and occasionally nematode infestation
- Skin cytologic examination: extremely useful diagnostic procedure indicated in almost every dermatology case. It can rapidly and inexpensively detect the presence of inflammation, infection (bacteria, fungi), autoimmune disease (acantholytic keratinocytes in pemphigus), or neoplasia.
- Wood's lamp examination: useful screening tool when dermatophytosis caused by *Microsporum canis* is suspected
- Dermatophyte culture: indicated when a dermatophytosis is suspected. In fact, it is indicated in virtually any cat with undiagnosed skin disease.
- Trichography is the microscopic examination of forcefully plucked hairs. This test is most useful for finding ectoparasites (particularly louse ova and *Demodex),* identifying hair shaft fracture, and finding large melanin clumps (macromelanosomes) causing hair shaft distortion in color dilution alopecia and black hair follicular dysplasia. It can be a useful tool in evaluating alopecic dogs, but normal anagen/telogen ratios have not been established for most breeds.
- Skin biopsies: performed to confirm a diagnosis or to provide direction (without always receiving a definitive diagnosis). Skin biopsies are recommended with any neoplastic or suspected neoplastic lesion, any persistent or unusual lesion, any vesicular dermatosis, and any undiagnosed alopecia.

CONTRAINDICATIONS

Virtually none

EQUIPMENT, ANESTHESIA

Simple equipment is required to perform veterinary dermatologic tests. Standard equipment and materials consist of:

- Biopsy kit, including biopsy punches
- One or two dull #10 scalpel blades
- Glass microscope slides and coverslips (20 × 40 or 22 × 50 mm)
- Mineral oil
- Cotton-tipped applicators
- Acetate tape (clear adhesive tape)
- Microscope
- Hemostat
- Handheld magnifying lens
- Flea combs
- Otoscope and several otoscopic cones
- Cytologic examination stain
- Wood's lamp
- Dermatophyte test media
- Sterile toothbrushes
- Syringes
- A few 22-, 23-, and 25-gauge needles
- Biopsy kit
- Local anesthetic (e.g., lidocaine 2%)
- Biopsy jars containing 10% neutral buffered formalin

ANTICIPATED TIME

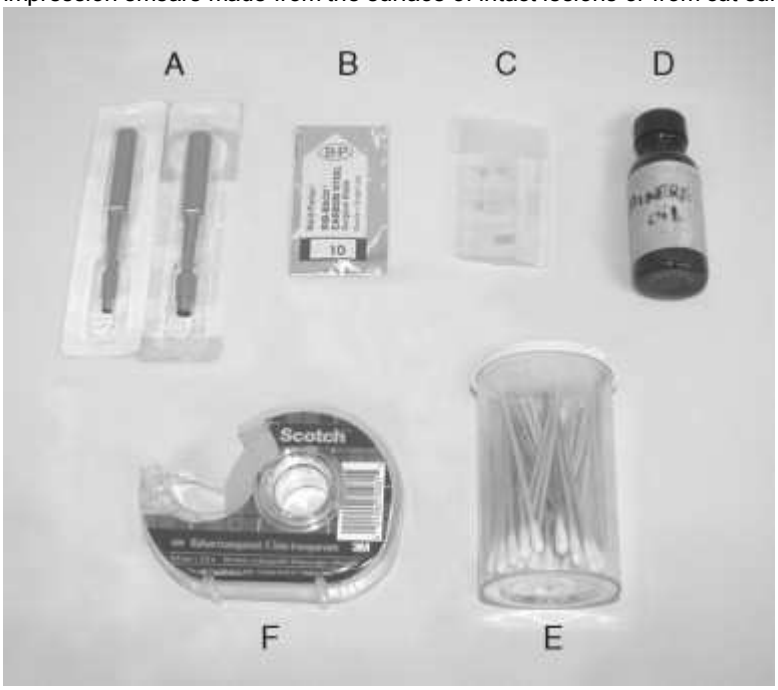
The procedure takes a few minutes.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Skin scrapings: to avoid false-negative results, it is important to clip hair before performing skin scrapings. However, it is preferable to use scissors when surface mites such as *Cheyletiella* are suspected, because they can be lost if electric clippers are used. Note: A positive scraping allows the clinician to find and identify a parasitic infestation, but its sensitivity in ruling out a diagnosis depends on the parasitic disease and the aggressiveness of sampling.
- Skin biopsies: do not scrub—or wipe or rub with alcohol or antiseptic—the surface of a biopsy site prior to performing punch biopsies; pathologic changes on the skin surface, which often are critical in making a diagnosis, may be altered or removed. For the same reason, do not shave the area of interest; gently clip the hair with scissors if necessary.

PROCEDURE

- Skin scrapings:
  - Apply a few drops of mineral oil to the area of skin selected for scraping or coat the dull scalpel blade that is used for performing the scraping with mineral oil. Broad superficial scrapings that collect scales and crusts should be performed when looking for mites living on the surface *(Cheyletiella)* or in the superficial layers of the skin *(Sarcoptes, Notoedres).* Deeper skin scrapings must be performed when suspecting the presence of deep-dwelling mites *(Demodex).* In the latter case, the skin must be squeezed to help extrude the mites from the hair follicles first, and the scrapings should be deep enough to create capillary oozing.
  - The skin scraping material that is collected on the scalpel blade is then smeared on a glass slide; additional mineral oil is added, and a cover slip is applied. The specimen is then examined with 40× *(Cheyletiella, Sarcoptes, Notoedres)* or 100× *(Demodex)* magnification.
  - *Demodex* mites are part of the skin's normal flora, but it is extremely rare to find them on skin scrapings. If one or a few mites are found, more deep skin scrapings should be taken to confirm the diagnosis of demodicosis. Conversely, numerous negative skin scrapings from appropriate areas should reliably eliminate demodicosis and notoedric mange. In addition, in areas that are difficult to scrape, hair can be plucked and the proximal ends examined under a microscope for the presence of *Demodex* mites.
  - Negative skin scrapings (even if several are performed) do not eliminate the possibility of sarcoptic mange or cheyletiellosis.
- Skin cytologic examination:
  - Allows microscopic examination of fluid or material collected from nodules, tumors, cysts, plaques, draining tracts, ulcers, pustules, vesicles, papules, and surface of the skin or ears. Several techniques may be used for obtaining samples. Specimens may be collected by:
    - Impression smears made from the surface of intact lesions or from cut surfaces of surgically



DERMATOLOGIC DIAGNOSTIC PROCEDURES Materials used for performing dermatologic diagnostic tests.

A, Biopsy punches. **B**, #10 scalpel blades. **C**, Glass microscope slides. **D**, Mineral oil. **E**, Cotton-tipped applicators. **F**, Acetate tape (clear adhesive tape).

excised lesions, such as nodules or tumors
- Impression smears made after lancing pustules or papules
- Fine-needle aspiration (FNA) of cells or material from lesions
- Smears made by rolling the cotton-tipped applicator across a glass slide (particularly useful for ear specimens)
- Scrapings of superficial epithelial cells with a dry, dull scalpel blade. This cellular material is then pressed firmly onto a glass slide.

- After the specimen has dried, the slide is stained with a modified Wright's stain (e.g., Diff-Quik) and examined microscopically. When a drop of mineral oil is put on the stained dried specimen and then covered with a large coverslip (22 × 40 or 22 × 50 mm), visualization of cells and most microorganisms at 400× is enhanced, so there is no need to perform an examination under oil immersion (1000×) in most cases.

- Wood's lamp examination:
  - This ultraviolet light's wavelength of 253.7 nm is temperature dependent, and the lamp should be turned on for 5-10 minutes before use. Certain dermatophytes (mainly *Microsporum canis* in veterinary medicine) may cause infected hairs (not scales or crusts) to fluoresce an apple green color. This occurs in about 50% of cases with *M. canis*.
  - It is a fast and inexpensive screening tool for dermatophytosis. False positives are unfortunately frequent. Glowing hair should be plucked and the proximal end further examined with the Wood's lamp or used for culture or direct examination for fungal elements under microscope. A negative examination does not rule out dermatophytosis.
- Dermatophyte culture (see p. 292):
  - Generally performed in clinics on commercial dermatophyte test medium (DTM), available in either glass jars or flat plates. The culture medium consists of Sabouraud's dextrose agar, antibacterial and antifungal agents to inhibit growth of contaminants, and phenol red (pH indicator).
  - Select hairs and scales for culture along the edge of newly developing lesions. Broken or frayed hairs and those that fluoresce with Wood's lamp are the best specimens. The plucked hairs should be firmly pressed onto the surface of the medium. Alternatively, vigorous brushing of the animal's haircoat with a sterile toothbrush or a small piece of sterile carpet can be used for collecting hairs and scales (more useful to identify carriers not showing obvious lesions). This material can be removed from the toothbrush with a sterile hemostat and placed into the culture medium. Alternately, if plates are used, the DTM is inoculated by gently embedding or repeatedly dabbing the toothbrush into the medium.
  - Ideally, the culture medium should be incubated at 22○C-30○C (72○F-86○F) and at about 30% of relative humidity for 2-3 weeks, and it should be checked daily for fungal growth. Desiccation hinders growth. It is recommended to keep the culture medium for up to 3-4 weeks in animals with antifungal pretreatment or suboptimal culture environment fungal growth.
  - A red color change with visible mycelial growth (typically cream color) is seen with dermatophytes on DTM. Contaminants (environmental molds) will eventually turn the media red; however, colony growth is usually well established before any color change appears in the medium. In addition, most saprophyte colonies are pigmented. Nonetheless, identification of the fungi is essential if a suspected dermatophyte is grown on culture.
  - Macroconidia must be collected from the mycelial surface by gently applying the sticky side of clear acetate tape to the aerial surface. The tape with sample is then pressed onto a glass slide over a drop of methylene blue or lactophenol cotton blue stain and examined under microscope for characteristic macroconidia.
- Skin biopsies:
  - The biopsy technique selected (punch biopsy, wedge biopsy, excisional biopsy) varies according to the type of lesions.
  - Site selection is crucial. Choose several representative lesions that may represent various stages of the same pathologic process or multiple problems, with emphasis on primary lesions if possible (e.g., pustules, vesicles).
  - Punch biopsy specimens (usually 6 mm) can be obtained under local anesthesia (1 mL of 2% lidocaine per site, injected subcutaneously beneath the specimen; do not exceed 1 mL per 5 kg of body weight). If a papule, pustule, vesicle, or any small lesion is selected, the lesion should be centered in the biopsy specimen. The biopsy punch should be rotated in only one direction to minimize shearing artifact. Handle the specimen carefully. The forceps should grasp either the hairs of the biopsy sample or its deepest surface (e.g., subcutis), never the core of the biopsy sample itself. The specimen must be put rapidly in 10% neutral buffered formalin. Skin biopsy punch sites can be sutured with one or two interrupted sutures.
  - Skin biopsies, along with a detailed history and animal description, should be submitted to a veterinary dermatopathologist.

ALTERNATIVES AND THEIR RELATIVE MERITS

Therapeutic trials (e.g., antiparasitic, antimicrobial) are frequently performed in veterinary dermatology and represent very useful diagnostic tools. For example, therapeutic trials with acaricidal agents such as macrocyclic lactones are often required when sarcoptic acariosis or cheyletiellosis is suspected but skin scrapings are negative.

AUTHOR: MANON PARADIS

Dental Radiography, Basic

OVERVIEW AND GOAL

To obtain diagnostic images of the teeth and surrounding structures using x-rays.

INDICATIONS

- Diagnosis, treatment planning, and postoperative assessment of treatment efficacy for various dental, oral, and maxillofacial conditions
- Dental radiographs should be obtained prior to tooth extraction to evaluate alveolar bone health and variations in root anatomy, and to determine the presence of dentoalveolar ankylosis or root replacement resorption that could potentially complicate the extraction procedure. They are essential when performing endodontic procedures.

Specifically, to diagnose and monitor:

- Regressive changes of the dentition including: caries, attrition, abrasion, and tooth resorption
- Dental (change in number or shape of teeth) and jaw size anomalies, including malocclusion, supernumerary teeth, and developmentally missing teeth
- Infection and inflammation of teeth, alveolar bone, and maxillofacial bones, including periodontitis, endodontic disease (pulp necrosis), periapical disease (apical granuloma, cyst or abscess, condensing osteitis, osteosclerosis), and osteomyelitis
- Oral and maxillofacial cysts and tumors
- Oral and maxillofacial trauma
- Disorders of joints of the head: mandibular symphysis separation; temporomandibular joint osteoarthritis, luxation, fracture, and ankylosis; open-mouth jaw locking
- Diseases of bone with manifestation in the jaws: craniomandibular osteopathy, calvarial hyperostosis, secondary hyperparathyroidism, fibrous osteodystrophy
- Diseases of the nose, orbit, and ear
- Partial or full-body imaging studies in small mammals and exotics

CONTRAINDICATIONS

Because dental radiography requires chemical restraint, it is contraindicated in patients that cannot undergo sedation or general anesthesia.

EQUIPMENT, ANESTHESIA

- Sedation or general anesthesia
- Radiolucent positioning and film-holding devices (e.g., bite blocks, foam rolls, syringe cases, gauze pads, paper towels, rubber bands) to keep the mouth open and the dental film packet in position without superimposition of maxillary and mandibular dental arches
- Dental x-ray machines:
  - Either handheld, stand-supported, or (more commonly) wall-/ceiling-mounted
  - Extension arm allowing vertical, horizontal, and rotational movement of the tube head without changing the patient's position
  - Adjusting exposure time based on patient size and tissue thickness to be imaged (between 0.1-0.6 seconds for teeth and jaws when using non-screen dental films and 1/10 of that time when using digital sensors)
- Dental x-ray films:
  - Nonscreen (providing greater detail than screened film used with standard x-ray machines)
  - Sizes 0, 1, 2, 3 and 4 (0, 2 and 4 most commonly utilized). Most jaw lesions can be satisfactorily assessed with size 2 and 4 dental film and intraoral imaging techniques.
  - Dot in corner of packet and also on the film: convex (raised) surface facing x-ray beam during exposure; after developing, dimple is used for distinguishing right side of mouth from left.
  - Contents of moisture resistant dental film packet:
    - Outer plastic wrap
    - Black paper on either side of the film
    - Layer of lead foil located at back of packet next to tab opening (protecting film from secondary radiation, which may cause fogging)
    - X-ray film
  - Types of film:
    - Ultra-speed (group D): most commonly utilized
    - Ekta-speed (group E): faster (reducing patient exposure and radiation), but image of slightly lesser quality than that obtained with ultra-speed film
  - Dental x-ray films can also be used with standard x-ray machines, using a technique of 100 mA, a film focal distance of 12 to 16 inches, and an exposure time of 1/10 second, with the kVp varying from 60 to 70 dependent on patient size.
- Other equipment:
  - Chairside darkroom (or automatic film processor) with small containers for the following solutions (from left to right): rapid developer, water, rapid fixer, and again water (or fixer, dependent on number of radiographs obtained)
  - Film clips and hangers
  - Dental view box
  - Envelopes or other storage system
- Digital imaging:
  - Most modern dental x-ray machines compatible with most digital hardware and software packages
  - Sensor pads (sizes 0 and 2) or photostimulable phosphor plates (size 4 also available) transferring images to a computer
  - Less radiation required to produce images
  - Digital image improvable with software programs

ANTICIPATED TIME

Obtaining a full-mouth dental series:

- Cats (8-10 films): 10-15 minutes

- Dogs (10-14 films): 15-20 minutes

Processing a full-mouth dental series:

- Cats: 5-10 minutes
- Dogs: 10-15 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Observe radiation safety guidelines:
  - Be protected against three sources of radiation: primary beam, secondary radiation emitted from the patient, and radiation leakage from the machine housing.
  - Wear film badges that monitor occupational exposure to radiation.
  - Keep amount of radiation exposure to a minimum.
  - Have x-ray machine accurately collimated and equipped with an accurate exposure timer.
  - Leave the room when radiographs are obtained.
  - If leaving the room is not possible, wear protective lead-lined gear, use a protective barrier, or stand at least 6 feet from the x-ray source and at an angle of 90°-135° to the central ray of the x-ray beam when the exposure is made.
- Film-processing solutions (rapid developer and fixer) should be disposed of properly in accordance with regional/local law, and lead foil from film packets should be separated and stored for recycling.
- Patient positioning varies; lateral recumbency allows for easy rotation of the head if needed and is a good starting position for obtaining most dental radiographs in cats and dogs.
- A full-mouth dental series may contain the following views:
  - Right maxillary premolars and molars
  - Right maxillary canine (lateral or lateral oblique view)
  - Right and left maxillary canines and incisors (occlusal view)
  - Left maxillary canine (lateral or lateral oblique view)
  - Left maxillary premolars and molars
  - Left mandibular premolars and molars
  - Left mandibular canine (lateral or lateral oblique view)
  - Right and left mandibular canines and incisors (occlusal view)
  - Right mandibular canine (lateral or lateral oblique view)
  - Right mandibular premolars and molars

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO BE AVOIDED

POSITIONING ERRORS:

- Elongation: abnormally long teeth due to tube angle too perpendicular to apico-coronal axis of teeth when bisecting angle technique is used
- Foreshortening: abnormally short teeth due to tube angle too perpendicular to film when bisecting angle technique is used
- Superimposition: summation effect due to tube head aligned too far in rostral or caudal direction
- Clear circular perimeter: cone cut
- Blurred image: movement of patient, tube head, or film during exposure
- Image distortion: excessive bending of film during positioning
- White crescents or lines: sharp bend or pressure on film prior to exposing
- Dark crescents or lines: sharp bend or pressure on film after exposing but before processing
- Area of interest not on image: tube head misaligned
- Blurry, magnified image: film too far from subject to be imaged
- Stipple pattern on light film: film placed backward

EXPOSING ERRORS:

- Dark film: overexposed
- Light film: underexposed
- Double image: double exposure

PROCESSING ERRORS:

- Entire film clear: emulsion detached from film or unexposed film
- Clear area along one edge: processing solution level too low
- Incomplete variable processing: paper stuck to film during processing
- Dark film (not overexposed): overdeveloped
- Light film (not underexposed): underdeveloped
- Black spots: contamination of film with developer prior to processing
- Yellow or brown stains: inadequate fixation, inadequate rinsing (incomplete removal of fixer)
- White spots: contamination of film with fixer before processing
- Green discoloration: films in contact during processing
- Fingerprints: film touched with contaminated fingers
- Frosted film surface: inadequate rinsing (incomplete removal of fixer)
- Small white circles: bubbles in processing solutions
- Thick white lines: scratched emulsion during processing
- Streaks: inadequate processing, solution contamination, contaminated hanger clips
- Mottled areas (too light or too dark): poorly mixed processing solutions, with temperature variances (too low or too high)
- Fogged film: light contamination or overprocessing

PROCEDURE

OBTAINING DENTAL RADIOGRAPHS:

- Parallel technique:
  - Film placed parallel to apico-coronal axis of the teeth
  - X-ray beam directed perpendicular (90○) to the film and the teeth
  - Used for imaging the molars and caudal premolars of the mandible and the nasal cavity
- Bisecting angle technique:
  - Film placed as close to the teeth as possible
  - Angle formed by the apico-coronal axis of the teeth and the plane of the film bisected by an imaginary line, with the tube head (x-ray beam) positioned perpendicular to this imaginary line
  - Used for imaging all maxillary teeth and the rostral premolars, canines, and incisors of the mandible
  - Peculiarity in cats: radiographs of the maxillary premolars and molars utilizing the bisecting angle technique results in superimposition of the zygomatic arch over the root apices of the teeth. To eliminate this superimposition:
    - An extraoral technique may be utilized; *or*
    - Premolars and molars may be intentionally elongated slightly when using the intraoral technique to eliminate the superimposition of the zygomatic arch by decreasing the vertical angulation of the tube head.

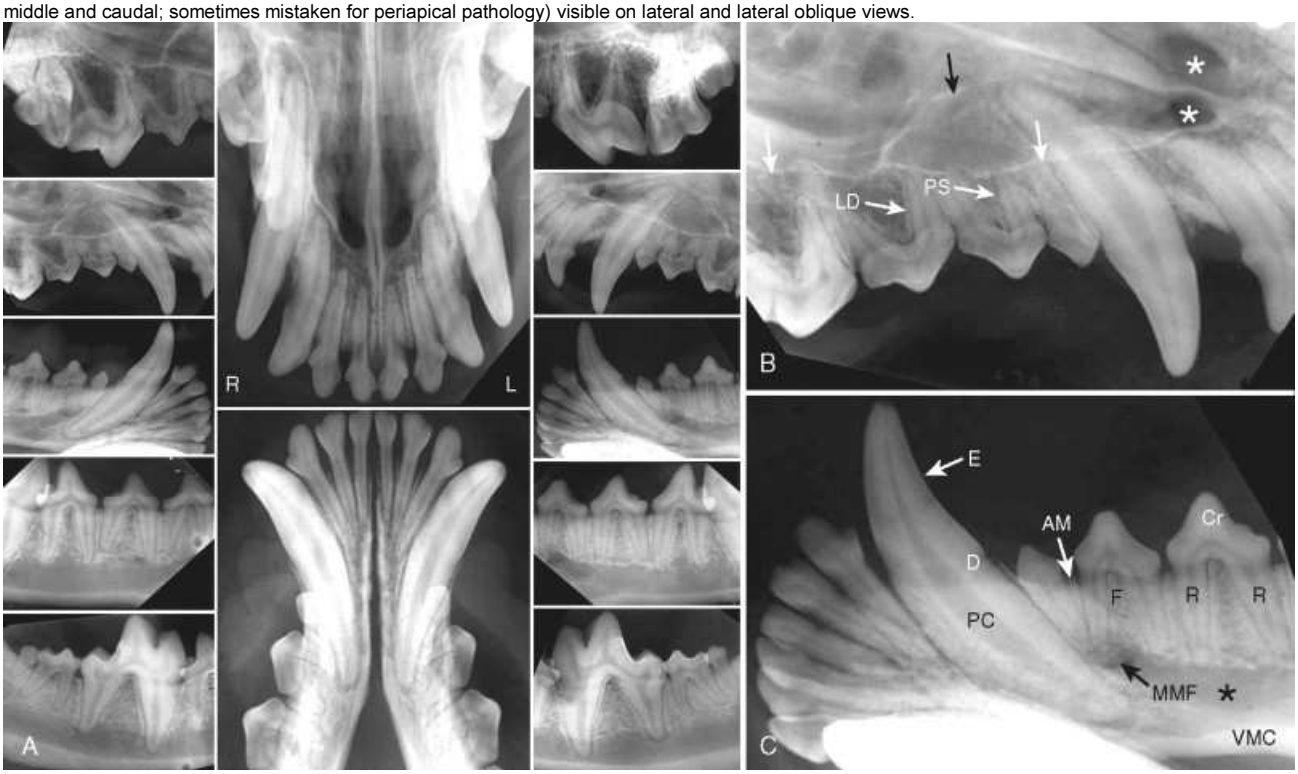
PROCESSING EXPOSED FILMS:

- Chairside darkroom:
  - Close lid of the chairside darkroom.
  - Hold film packet in one hand and a film clip in the other.
  - Slide both hands through front sleeves into the chairside darkroom.
  - Remove exposed x-ray film from packet, and place it in film clip.
  - Place film first into developer for about 30 seconds.
  - Briefly (few seconds) rinse in water.
  - Then place film into fixer for at least 60 seconds before viewing.
  - After a final water rinse, view film using a dental view box to make a diagnosis.
  - After viewing, place film for another 15 minutes into fixer, followed by thorough rinsing in water for 20 minutes and air drying.
  - Store completely dry films in a labeled envelope (or other storage system), and keep as part of the patient's medical record.
- Automatic processor:
  - Automatic processors designed for dental films can deliver processed film in a fully fixed, dried condition within 5 minutes.
  - Dental film can also be processed if taped to a larger film that serves as a leader by dragging the dental film through a large automatic processor.

POSTPROCEDURE

INTERPRETING PROCESSED FILMS:

- Labial mounting:
  - Place processed film on view box so that raised dot is projecting toward the viewer.
  - Determine if image is of upper or lower jaw.
  - Rotate film so that maxillary tooth crowns point downward and mandibular tooth crowns point upward.
  - View image as if one is looking from outside at a closed mouth whose maxillary and mandibular teeth are made visible after raising upper and lower lips.
- Radiographic landmarks:
  - All three-rooted teeth are located in the upper jaw.
  - Palatine fissures are also located in the upper jaw.
  - Upper jaw will often have white lines visible on lateral and lateral oblique views that are superimposed on teeth (indicating maxillary conchal crest and line of conjunction between body and palatine process of the maxilla).
  - Lower jaw will often have ventral mandibular cortex, mandibular canal (radiolucent tubular structure in the mandible), and mental foramina (rostral, middle and caudal; sometimes mistaken for periapical pathology) visible on lateral and lateral oblique views.



DENTAL RADIOGRAPHY, BASIC A, Full-mouth dental radiographic series in a 2-year-old dog with complete permanent dentition: radiographs are arranged in labial mounting (with raised dot facing the viewer). Maxillary tooth crowns point downward, and mandibular tooth crowns point upward. *L,* Left side; *R,* right side. **B**, Lateral radiographic view of right maxillary incisors, canine, and premolars in a dog (labial mounting). Note the palatine fissures *(asterisks)*, the line of conjunction between the body and palatine process of the maxilla *(large white arrows)*, and the conchal crest *(large black arrow)*. *LD,* Lamina dura; *PS,* periodontal space. **C**, Lateral radiographic view of left mandibular incisors, canine, and premolars in a dog (labial mounting). Note the mandibular canal *(asterisk)*. *AM,* Alveolar margin; *Cr,* crown; *D,* dentin; *E,* enamel; *F,* furcation; *MMF,* middle mental foramen; *PC,* pulp cavity; *R,* root; *VMC,* ventral mandibular cortex.

(Copyright Dr. Alexander M. Reiter.)

- Components of the tooth and its supporting structures:
  - Crown and root(s)
  - Enamel (covering the crown) and dentin (core hard tissue of the tooth)
  - Cementum (covering the root), periodontal space (containing the periodontal ligament), and lamina dura (cortical bone extending into the alveoli)
  - Pulp cavity (pulp chamber in crown and root canal in root)
  - Furcation (area where two roots meet at the crown)
  - Alveolar margin (most coronal extension of the alveolar bone)

ALTERNATIVES AND THEIR RELATIVE MERITS

The largest dental films (size 4) may also find use for radiographic evaluation of the nasal cavity, orbit, zygomatic arch, mandibular ramus, temporomandibular joint and tympanic bulla in cats and small dogs and for partial or full-body imaging studies in small mammals and exotics.

AUTHOR: ALEXANDER M. REITER

Dental Prophylactic Treatment

SYNONYMS

Dental cleaning and polishing, dental prophylaxis

OVERVIEW AND GOALS

- Complete oral examination
- Removal of calculus and plaque buildup on teeth to create a healthier dentogingival environment
- Polishing teeth surfaces to make them less prone to calculus accumulation

INDICATIONS

- Accumulation of bacterial plaque (soft) or dental calculus (hard) on the dental surface
- Treatment of gingivitis
- Prevention of periodontal disease
- Annual dental examination
- Part of the maintenance phase in the treatment of periodontitis

CONTRAINDICATIONS

- Established periodontitis: animal should receive more involved diagnostic and treatment procedures rather than prophylactic treatment. Diagnosis includes dental examination, periodontal probing and full-mouth intraoral radiographic examination. The first stage of treatment is aimed at controlling the infection; it includes dental cleaning and polishing, root planing, dental extractions and antimicrobials as needed. It is followed by a period of maintenance with home care and reevaluation. The second stage of treatment, periodontal surgery, is done a month later once the periodontium has healed, if the level of compliancy of the owner with home dental care is adequate and if the periodontium still needs to be restored to help prevent reinfection.
- When general anesthesia is contraindicated because of systemic illness
- Old age is not a contraindication.
- Note: Dogs with mitral valve endocardiosis have not been shown to have a greater risk of dental procedure–associated bacterial endocarditis than dogs with normal heart valves.

EQUIPMENT, ANESTHESIA

- General anesthesia and tracheal intubation
- Hand instruments:
  - Scalers (H 6-7)
  - Curettes (Gracey 3/4, Gracey 13/14, Mini-five 1/2)
  - Dental explorer and periodontal probe (XP-17/0W)
  - Dental mirror
  - Instrument tray
  - Ceramic sharpening stone
- Power instruments:
  - Ultrasonic (magnetostrictive with metal stack, magnetostrictive with ferrite rods, or piezoelectric) or sonic scaler
  - One tip for removal of gross and moderate calculus buildup
  - One perio (or universal) tip for removal of subgingival calculus and debris. The energized water spray at the end of the tip also kills bacteria with what is referred to as the *cavitation effect.*
  - Dental unit, either air or electric powered, with low-speed handpiece and contra-angle attachment. Since the speed of the prophy cup should be around 4000 rpm, a contra-angle-attachment with a 4:1 gear ratio is usually necessary with air-driven units.
  - Prophy head, multi-use or single-use
  - Rubber prophy cups; prophy paste (jars or unidose cups) or flour pumice medium grit
- Chlorhexidine solution 0.12%
- Good lighting conditions, magnifying glasses
- Dental chart

ANTICIPATED TIME

About 20 minutes for a cat and 45 minutes for a dog

PREPARATION: IMPORTANT CHECKPOINTS

Operator protection:

- Surgical mask, gloves, eye protection, scrub top or gown
- Instill 0.12 % chlorhexidine solution in the animal's mouth before starting the procedure to reduce bacterial counts in the aerosols generated during power scaling.

Animal protection:

- Keep the animal warm because of the cooling effect of the water spray during power scaling. Protect the eyes (lubrication, towel), and sterilize the instruments. Appropriately inflate the cuff of the endotracheal tube, and use lubricating gel.
- Administer antibiotics only if animal is immunosuppressed, has an internal prosthesis, or has a severe infection: 20 mg/kg ampicillin IV 1 hour prior to the procedure; or clindamycin, 5 mg/kg, or clavulanic acid-amoxicillin, 13.5 mg/kg, PO 12 hours prior to the procedure.
- Place cotton gauze in the oropharynx to catch pieces of calculus that could otherwise enter the trachea after extubation.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Forgetting to remove the cotton gauze in the oropharynx before extubation
- Causing thermal damage to the dental pulp by staying too long over a tooth during power scaling or polishing or inadequate water spray during power scaling
- Damaging the tooth surface by being heavy-handed during scaling and polishing or by using burs (Rotosonics) to remove calculus
- Dental cusp (tip) fracture caused when using extraction forceps to chip away the calculus (not recommended)
- Power instrumentation: use the lowest effective intensity (power) setting; use a light touch; work with the last 3 mm at the end of the tip; keep the tip moving, with adequate water spray. Use a gauge to check tip wear, and replace when 2 mm has been lost (50% loss of efficacy).

PROCEDURE

- The anesthetized, intubated animal is placed in lateral recumbency, and all stages of the procedure described here are performed on the lingual side of the teeth on the recumbent side and the labial side of the teeth on the non-recumbent side. Then the animal is turned over, and the procedure can be repeated (avoids turning the animal multiple times).
- Remove very heavy calculus deposits with a dental scaler or hoe.
- Remove gross and moderate supragingival calculus using hand instrumentation (dental curette, scaler) or power instrumentation (sonic or ultrasonic with a heavier tip at moderate- to high-intensity setting).
- The working surface of the power scaler should be held parallel not perpendicular to the tooth surface.
- Remove light supragingival and subgingival calculus with hand instrumentation (dental curette) or power instrumentation (sonic or ultrasonic with slim perio or universal tip at low-to moderate-intensity setting).
- A disclosing solution can be used for checking for the presence of dental plaque, or an air spray from an air/water syringe for the presence of calculus.
- The teeth are polished with prophy paste or flour pumice.
- Dental examination with dental explorer; periodontal examination with periodontal probe. Chart all the findings.
- Flush the gingival sulcus with an atraumatic needle and saline to remove the prophy paste or flour pumice, calculus debris, and bacteria.
- Perform final rinse with 0.12% chlorhexidine.

POSTPROCEDURE

- Discuss home oral care with owners, and find appropriate regimen.
- Provide the owner with information about the postoperative treatment plan, including the date of the next dental appointment.

ALTERNATIVES AND THEIR RELATIVE MERITS

- The wrong alternative to preventing periodontal disease with dental prophylactic treatment and home dental care is to wait until periodontal disease has progressed, and periodontal treatment is necessary to help control disease progression. This is

obviously not an option that benefits the animal or owner.
- Brushing the teeth will not remove existing calculus.
- Dental prophylactic treatment performed without general anesthesia provides some cosmetic improvement but no long-term benefit.

AUTHOR: YVAN DUMAIS

Dental Preventive (Home) Care

Client Education Sheet Available on Website

OVERVIEW AND GOALS

A regimen of home dental care is designed to help keep the periodontium healthy in between professional oral prophylactic or therapeutic treatments.

INDICATIONS

- Accumulation of bacterial plaque (soft) or dental calculus (hard) on the dental surface
- Prevention of gingivitis and periodontal disease
- Part of the maintenance phase in the treatment of periodontitis

CONTRAINDICATIONS

- When the animal needs professional dental prophylactic treatment (gingivitis, calculus, or plaque buildup) or periodontal treatment (periodontitis, loss of dentogingival attachment)
- Oral hygiene complements and does not replace professional dental care.

EQUIPMENT, MATERIAL

- Soft-bristle toothbrush; pet toothpaste
- Food that is specially designed to reduce dental plaque or calculus formation
- Oral rinses to help reduce dental plaque formation
- Chew toys

ANTICIPATED TIME

The home dental care regimen is discussed during regular visits or as part of a comprehensive oral prophylactic treatment or periodontal treatment. Once the regimen is well accepted by the pet and the owner, it is a daily routine that takes only 1 or 2 minutes.

PREPARATION: IMPORTANT CHECKPOINTS

- The home dental care regimen should be selected after considering the animal's needs; the will, availability, and dexterity of the owner; and the compliance of the animal.
- The implementation may require some form of training or behavior positive reinforcement before the pet associates home dental care with something fun.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- The desire to achieve thorough oral hygiene right at the beginning is often a deterrent for the owner and the animal. Most pets will not tolerate more than 20 seconds of toothbrushing and will not allow brushing the aspect of the teeth facing the palate or the tongue.
- In pets that have minimal calculus buildup, an annual thorough dental examination/cleaning under anesthesia often is not recommended. As a result, these animals may end up having severe dental or periodontal problems for an extended period of time before the problem gets noticed. It is sad that after investing a lot of effort in home dental care for prevention, these owners are not getting the success they were expecting because the recommendation for professional dental care was never made until it was clinically obvious that a problem was present. Pets, just as humans, need both: home dental care and professional dental care.
- Many chew toys have a round cross-sectional shape and are so hard that the carnassial teeth are prone to break when the pet bites down on them.
- There are so many products on the market and so many claims, most unsupported by credible independent research, that it is difficult to choose what to recommend to clients. A credible and independent source of information on the efficacy of dental products is the Veterinary Oral Health Council website (www.vohc.org), and products bearing the council's seal are recommended.

PROCEDURE

Training for toothbrushing; instructions for the owner:

- Start with a bare finger and apply pet toothpaste on the rostral (front) teeth.
- Massage the gingiva for a few seconds. Repeat many times a day.
- As the pet gets used to it, go farther caudally in the mouth until the pet tolerates the procedure being done up to and including the molars.
- Once the pet is comfortable with the procedure, start using a toothbrush with soft bristles, and apply the toothpaste again on the rostral teeth, brushing for a few seconds.
- Go farther caudally as the pet tolerates the procedure. Give praise and rewards immediately after. Brush daily.
- Movement: for the incisors, brush from the gingiva toward the tip of the teeth. For the other teeth, brush with a circulatory movement with the bristles slightly oriented toward the gingiva of the upper jaw, then lower jaw, so that the action is focused on the area next to the gingival margin. With the mouth closed, the last teeth of the lower jaw are hidden behind the teeth of the upper jaw; however, the area next to the gingiva can still be brushed.

Other alternatives:

- Food specially designed to prevent calculus or plaque formation either mechanically (fibers) or chemically. Fibers help clean the caudal teeth.
- Rinses: chlorhexidine 0.12% for treatment and prevention of gingivitis (not for periodontitis, because it is ineffective on organic material, cannot reach bottom of periodontal pockets); zinc and ascorbic acid, mainly for their action on epithelium and connective tissue post treatment.
- Products containing enzymes that enhance the antimicrobial action of saliva and leukocytes
- Products that stimulate oral exercise, production of saliva, and removal of plaque and calculus

POSTPROCEDURE

Professional dental care once a year to allow complete oral examination, removal of plaque and calculus in areas where they still build up despite home dental care, and tooth polishing

ALTERNATIVES AND THEIR RELATIVE MERITS

In absence or ineffectiveness of home dental care, the frequency of professional dental care is adjusted to prevent or control periodontal disease.

AUTHOR: YVAN DUMAIS

Dental Extraction

SYNONYM

Exodontics

OVERVIEW AND GOALS

- Removal of a tooth in a way that ensures complete removal of the root(s) and rapid healing of the dental alveolus and oral soft tissue
- Simple extraction is indicated for simple rooted teeth, except canine teeth or any tooth that has already lost most of its attachment. Canines and multirooted teeth usually require surgical extraction.

INDICATIONS

- Nonvital (dead) teeth; teeth with exposure or contamination of the endodontic system
- Moderate to severe periodontal disease
- Nonrestorable dental lesions: dental resorptions, dental fractures
- Persistent primary teeth, retained roots or impacted teeth, some teeth involved in jaw fracture
- Dental malocclusions
- Oral surgery, removal of oral tumors, oral cysts

CONTRAINDICATIONS

- When general anesthesia is contraindicated because of severe uncontrolled metabolic disease
- Animals with a bleeding disorder
- Animals undergoing chemotherapy or radiotherapy

EQUIPMENT, ANESTHESIA

- General anesthesia, preemptive pain control, and regional or local anesthesia are utilized as needed.
- Simple extraction:
  - Dental radiograph (see p. 1246)
  - A #11 or #15 scalpel blade
  - Dental elevator(s)
  - Dental forceps
- Surgical extraction: as above, plus:
  - Periosteal elevator
  - Dental unit with high-speed handpiece and FG dental burs (No. 699-701, regular, long shank, and surgical lengths)
  - Bone rongeurs or bone rasp
  - Bone curette
  - Sterile saline with syringe and atraumatic needle
  - Soft-tissue scissors (LaGrange)
  - Tissue forceps
  - Needle holder, 4-0 resorbable suture material with swaged-on needle

ANTICIPATED TIME

About 5 minutes for most simple extractions and 20 minutes for most surgical extractions

PREPARATION: IMPORTANT CHECKPOINTS

Dental radiographs: check for the number of roots, their shape, and their structural integrity (root resorption); the condition of the surrounding bone; and the presence or absence of a periodontal ligament with possible root ankylosis.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Oronasal fistula: if occurs, should be closed with a mucoperiosteal flap, either at the time the extraction is done or as a delayed surgery if the gingival tissue is so inflamed that its capacity to hold sutures is questionable.
- Root fracture:
    - Most easily prevented by examination of the preoperative radiographs and proper treatment planning. If the root is in advanced stage of resorption, is ankylosed, and has no evidence of periodontal or endodontic infection, it could be left in place for continued resorption.
    - Although the clinician should try to remove as much root material as possible in an animal with root fracture, the risk of damaging surrounding tissue should be weighed against the benefit of finding the last piece of root material.
    - When a root fragment is left in situ, the owner should be informed of that aspect of the surgery, and follow-up radiographs should be included in the treatment plan. The risk of causing an abscess is higher when the root fragment has been mobilized and its blood supply severed during its attempted extraction.
- Jaw fracture: usually the result of a blind attempt at extracting a tooth on the mandible without preoperative dental radiographs and appropriate treatment planning. Small-breed dogs with severe periodontal disease of the first lower molars and cats during extraction of the mandibular canines are the most likely to be at risk for jaw fracture during dental extraction.
- Root fragments in the nasal cavity or the mandibular canal should be retrieved.

PROCEDURE

Simple extraction:

- Incision of the gingival attachment around the tooth with a scalpel blade
- Mobilization of the tooth with dental elevators using first-class lever, wheel-and-axle, or wedge types of forces:
    - The tip of the elevator is used circumferentially as a wedge between the root and the bone to stretch the periodontal ligament, or as a wheel and axle with the side of the blade engaged under the enamel bulge mesial or distal to the tooth, to elevate the tooth out of the alveolus.
    - Use light forces over a longer period (at least 10 seconds each time) to break the attachment without fracturing the root.
    - Extend the index finger (of the hand holding the elevator) along the shaft of the elevator to protect deeper structures in case of slippage.
- Extraction with dental forceps once the tooth is mobile. Light rotation force may help.
- Check that extraction is complete; perform a postoperative radiograph if needed.
- Brief digital pressure to help hemostasis, reduce expansion of the alveolar wall caused by the extraction, and approximate the gingival margins
- Suture if needed

Surgical extraction:

- Incision of the gingival attachment around the tooth with a scalpel blade
- Elevation of a mucoperiosteal flap with a periosteal elevator
- With a dental bur, buccal cortical bone and alveolar bone is removed to expose the root surface up to half its length.
- On a multirooted tooth, the crown is sectioned between the roots.
- Each individual root with its attached piece of crown is elevated.
- Check that the extraction is complete.
- Smooth the edge of the alveolar bone with a bone rongeur or rasp; curette and flush debris out of the alveolus.
- Trim the border of the soft tissue if needed (LaGrange scissors).
- Suture with a simple suture pattern.
    - After a surgical extraction, the gingiva is sutured back in place, even in the case of an abscess.
    - It is important to cover the bone exposed during elevation of the soft tissue.

POSTPROCEDURE

- Surgical extractions: pain medication for 4 days, soft food for 10 days
- Antibiotics are used if the animal shows systemic clinical signs (fever, loss of appetite, etc.) or if the condition has progressed to osteomyelitis.
- Recheck in 10-14 days.

ALTERNATIVES AND THEIR RELATIVE MERITS

Endodontics, periodontics, and orthodontics are other alternative treatments. They have the advantage of preserving the teeth and are often a better option when the owner is interested in doing the necessary aftercare and home dental care.

AUTHOR: YVAN DUMAIS

Defibrillation, Electrical

OVERVIEW AND GOALS

Electrical defibrillation is the treatment of choice for cardiac arrest characterized by ventricular fibrillation. It consists of application of an electric shock to the heart, causing massive depolarization; when defibrillation is successful, this massive depolarization is immediately followed by spontaneous resumption of sinus rhythm.

INDICATIONS

Ventricular fibrillation

CONTRAINDICATIONS

- Conscious animal
- Normal cardiac rhythm but electrocardiographic (ECG) artifact mimics ventricular fibrillation
- Poor or inappropriate contact between defibrillation paddles and animal
- Inability to electrically isolate animal from surrounding animals or humans (e.g., in contact with same pool of water/urine/other conductive medium)
- Ventricular fibrillation > 10 minutes' duration

EQUIPMENT, ANESTHESIA

- Clippers for hair
- Defibrillator; ideally, combined defibrillator-electrocardiograph to avoid risk of electrical damage to stand-alone ECG machine
- Defibrillation coupling gel

ANTICIPATED TIME

About 1 to 10 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Is it ventricular fibrillation?
  - ECG shows coarse or fine patternless electrical activity with no synchronized activity (no QRS complexes) when ventricular fibrillation is present.
  - If the animal is conscious, the rhythm is not ventricular fibrillation.
  - If a pulse is palpable, the rhythm is not ventricular fibrillation.
- Is the animal prepared correctly?
  - Dorsal or lateral recumbency on a dry, insulated surface (e.g., foam mat or linoleum floor)
  - Hair clipped from both hemithoraces over heart (fourth through sixth intercostal spaces [ICS], right and left)

Note: The limbs of the animal will flail when the shock is administered, and any objects (e.g., monitoring instruments, drug bottles, etc.) in their trajectory must be removed prior to shock delivery.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Electric shock can be transmitted to bystanders. Note: This complication can cause cardiac arrest in human or animal onlookers. This result is best avoided by ensuring that no one is in contact with the animal or anything the animal is touching before delivering a shock. It is also important to ensure that no indirect contact from urine, saline, or any other fluids that may be trickling from the animal is occurring between the animal and the shoes of surrounding individuals. Shouting "clear" is not enough, since most people do not know what to do in response.
- Defibrillation is too late. The success of defibrillation approaches 100% when it is performed within the first minute of ventricular fibrillation, then decreases by 10%-15% per minute. Defibrillation is the most important treatment when there is ventricular fibrillation, and some have suggested revising the "ABCs" of resuscitation to the "DABCs," with *D* for defibrillation.
- Poor application of paddles on animal
  - Paddles must be set widely apart (i.e., one on each side of the thorax); if too close, an electric arc between them can cause severe skin burns and operator injury.

- Defibrillator gel must be applied between the defibrillator paddles and the animal's skin. Note: Any facility that owns a defibrillator must also own a tube of defibrillator gel, because alternatives are inadequate: ultrasound gel is contraindicated (nonionic/nonconductive), alcohol is flammable, and bare skin without a coupling agent can be burned by electric arcs.

PROCEDURE

- The animal is placed in lateral or dorsal recumbency.
- Rapid clip of hair over the left and right precordia (area of chest overlying the heart): 20 seconds.
- The ECG diagnosis of ventricular fibrillation is confirmed:
  - Animals with ventricular fibrillation are always unconscious (nonperfusing rhythm) and pulseless.
  - Alcohol or gel must be present at all points of contact between the ECG wires/clips and the animal (to rule out poor connection artifact/"pseudofibrillation").
  - Click from leads I to II and then to III on the ECG monitor to check for organized electrical cardiac activity in any lead. If present, defibrillation is contraindicated.
- The defibrillator is charged: 5 J/kg.
- Defibrillator gel is smeared on the surface of both paddles.
- The paddles are applied to the thorax: paddle marked "Left" or "Apex" is on left hemithorax, and paddle marked "Right" or "Sternum" is on the right.
- All onlookers and assistants must stand back and be neither in direct nor indirect contact with the animal. The only contact point between the animal and the person administering the shock is the paddles.
- The shock is delivered.
- The ensuing ECG rhythm is assessed immediately.

DEFIBRILLATION, ELECTRICAL Typical defibrillator. Paddles are clipped to side of unit, and screen displays both electrocardiographic (ECG) information and defibrillation charge (at 200 J in image). Controls for energy selection, charging, and shock administration on front panel are also present as finger controls directly on the paddles (not shown).

DEFIBRILLATION, ELECTRICAL Tube of defibrillator gel.

POSTPROCEDURE

If the rhythm still appears to be ventricular fibrillation, it should be quickly confirmed (check other ECG leads on the monitor, and

ensure ECG connection between animal and machine is good); if confirmed, defibrillation is immediately warranted once again at 8 J/kg. Up to 12 J/kg may be administered. When the rhythm is any other than defibrillation, standard cardiopulmonary resuscitation procedures are followed (see p. 1223).

ALTERNATIVES AND THEIR RELATIVE MERITS

- Precordial thump (physical blow to the chest): theoretically delivers physical “equivalent” of electrical shock; unproven value, many potential drawbacks, and never preferred over electrical defibrillation.
- Pharmacologic defibrillation (bretylium, potassium chloride/calcium chloride, etc.): unproven and not known to be widely successful in the clinical setting.

AUTHOR: ETIENNE CÔTÉ

Excretory Urogram

SYNONYMS

IVP, intravenous (IV) pyelogram, IV urogram

OVERVIEW AND GOALS

When the kidneys are difficult to assess by plain-film radiography or when qualitative renal functional information is needed, an excretory urogram could be performed. On survey abdominal radiographs, the renal silhouette may not be visualized in animals that have decreased abdominal detail (young, thin, peritoneal fluid).

INDICATIONS

- Identify kidneys (if poor abdominal detail)
- Mass lesions of kidneys (or mass in region of kidney)
- Qualitative assessment of renal function
- Patency, continuity of urinary tract
- Prior to nephrectomy
- Abnormal renal size, shape
- Persistent hematuria
- Suspected renal or ureteral calculi
- Suspected hydronephrosis
- Suspected ureteral ectopia, ureterocele
- Suspected ureteral rupture
- To evaluate the urinary bladder when it cannot be catheterized
- Postoperative assessment of urinary tract (patency, strictures, leakage)

CONTRAINDICATIONS

- Dehydration
- Previous reaction to iodinated contrast medium (a nonionic medium should be used)
- Caution should be used in animals with the following conditions:
    - Diabetes mellitus
    - Multiple myeloma
    - Congestive heart failure
    - Hypertension
    - Concurrent drug administration (cardiac glycosides)
    - Severe debilitation

EQUIPMENT, ANESTHESIA

- Many recommend the use of general anesthesia or heavy sedation; however, an excretory urogram can be performed in an unanesthetized animal.
- IV catheter
- Hair clippers
- Surgical scrub solution, rubbing alcohol, and gauze/sponges for prepping skin where catheter is placed
- Tape/releasing elastic (Vetrap-type) bandage
- Iodinated contrast medium (sodium iothalamate, sodium diatrizoate)
- Nonionic contrast medium (iohexol, iopamidol) if clinically warranted
- Syringe
- Heparin/saline for flush
- Enema set
- Antianaphylactic agents (e.g., diphenhydramine, 2-4 mg/kg for IM injection)
- Oxygen and a drug cart to address any possible complication during the procedure.

ANTICIPATED TIME

Approximately 1 hour

PREPARATION: IMPORTANT CHECKPOINTS

- The owner should be advised that hair will be removed from the site of IV catheter placement.
- Animal should have fasted 24 hours.
- Water given ad libitum
- Enema given at least 2 hours prior to study to remove a maximum of the fecal material from the colon to allow visualization of kidneys and ureters
- Assess hydration: proceed only if normal.
- Clip the hair where the IV catheter is to be placed.
- The site for the catheter placement should be prepped with surgical scrub solution, rubbing alcohol, and gauze sponges.
- Place an IV catheter in a cephalic or jugular vein; it is imperative that the catheter be properly placed.
- Secure the catheter in place with tape or releasing elastic (Vetrap-type) bandage.
- Add 900 mg iodine per kg body weight contrast material into syringe.
- Add an appropriate amount of heparin/saline flush into syringe.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Vomiting: this often occurs immediately after injection of the contrast medium. If the animal is muzzled, the muzzle should be removed immediately to avoid aspiration.
- Systemic hypotension, bradycardia
- Anaphylaxis (airway edema, vascular collapse, bronchospasm)
- Perivascular injection may result in sloughing of surrounding tissue.
- Contrast media–induced renal failure
- The administration of iodinated contrast media may affect urine specific gravity, urine sediment, and urine culture results for 24 hours following administration.
- Blood values (blood urea nitrogen [BUN], creatinine, prothrombin time [PT], partial thromboplastin time [PTT], activated partial thromboplastin time [APTT], thromboplastin time [TT], and hematocrit) might also be affected for up to 24 hours after contrast administration.

PROCEDURE

- Preliminary abdominal radiographs are made to determine adequate animal preparation and to set radiographic technique.

EXCRETORY UROGRAM Excretory urogram, ventrodorsal view. Normal study. Both kidneys and both ureters are clearly seen; contrast material is also seen in urinary bladder (right of midline). *L*, Left.

EXCRETORY UROGRAM Excretory urogram, ventrodorsal view. Ectopic ureter (left side), normal ureter (right side). Ectopic ureter is diffusely enlarged (hydroureter), especially distally where it inserts in an ectopic location *(arrow)*. *L*, Left.

EXCRETORY UROGRAM Excretory urogram, ventrodorsal view. Pyelonephritis (right side). Right-sided hydronephrosis and severe hydroureter are apparent. *L*, Left.

- The kilovoltage peak (kVp) should be set between 65 and 75 to maximize contrast due to the photoelectric effect (K-edge of iodine).
- Flush the catheter to again ensure patency.
- Inject contrast material rapidly as a bolus.
- Flush the catheter of residual contrast material.
- A ventrodorsal view is obtained at 20 seconds.
- Ventrodorsal and right lateral views are obtained at 5 minutes, 20 minutes, and 40 minutes.
- Oblique views are obtained at 5 minutes to visualize ureteral termination at the urinary bladder.

POSTPROCEDURE

- If anesthesia is used: routine anesthetic recovery
- Maintain adequate hydration.
- The IV catheter should remain in place for at least 15-20 minutes after the study is completed. The port for venous access might be necessary should a contrast media adverse reaction occur.
- Remove the catheter > 20 minutes after the procedure.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Plain abdominal radiographs: inexpensive means to survey the abdomen. Radiopaque renal or ureteral calculi can be visualized. Size and shape of the kidneys can be assessed if abdominal detail is adequate and fecal material is not obscuring their visualization.
- Abdominal ultrasound: excellent potential for visualization of kidneys, especially in animals that show poor radiographic abdominal detail. Renal size, shape, position, and echogenicity relative to the liver and spleen can be assessed. The size of the renal pelvis can also be evaluated. The internal architecture of the kidneys can be assessed. Ultrasound can determine if

masses are solid or cystic in nature. Resistive index can be calculated.

- CT scan: provides excellent detail of the size, shape, and margination of the kidneys. IV contrast media can also be used to enhance findings in the kidneys and or ureters. This imaging modality can also be used for assessing renal vascular anatomy when screening feline renal transplant donors. CT scans, however, are more costly to perform than other studies already listed and require general anesthesia.
- Nuclear scintigraphy:
    - Diethylenetriaminepentaacetate (DTPA): to determine global and individual kidney glomerular filtration rates; to evaluate the animal's response to treatment; to evaluate function of contralateral kidney prior to surgery and possible removal of diseased kidney; to identify and determine the severity of subclinical renal disease in an animal receiving nephrotoxic agents; and to examine renal perfusion by obtaining rapid serial images during first pass circulation
    - Mercaptoacetyltriglycine (MAG3): to determine global and individual kidney effective renal plasma flow

AUTHOR: LEEANN PACK

Ethanol Ablation of Thyroid and Parathyroid Tumors

SYNONYMS

Percutaneous ethanol injection, PEI, chemical ablation

OVERVIEW AND GOALS

Ethanol ablation, under ultrasound guidance, has been used most commonly in veterinary medicine for the minimally invasive treatment of parathyroid tumors. Additional reported uses of this procedure include benign thyroid tumors in cats, as well as other tumors, and renal, liver, and pancreatic cysts. The goal of this procedure is to eliminate the detrimental secretory function of a benign endocrine tumor in a minimally invasive fashion.

INDICATIONS

For parathyroid ablation in cases of primary hyperparathyroidism (PHPT). For thyroid ablation, consider in cases of feline unilateral hyperthyroidism or feline thyroid cysts.

CONTRAINDICATIONS

- There are few contraindications to percutaneous ethanol injection (PEI) therapy in hyperparathyroid dogs. Successful therapy does require a large enough nodule (typically over 3-4 mm in diameter), a skilled ultrasonographer, and advanced ultrasound equipment. It should not be attempted if these criteria are not met.
- It should also not be attempted in multiple nodules at the same time, especially bilaterally, for fear of transient laryngeal swelling and dysfunction after the injection.
- PEI has not worked well in cats with bilateral thyroid disease and should also never be performed bilaterally in cats. It can be considered as an alternative to surgery, radioiodine therapy, or methimazole in cats with unilateral hyperthyroidism.

EQUIPMENT, ANESTHESIA

- Intravenous or inhalant general anesthesia
- High-quality ultrasound equipment with a high-frequency probe (at least 10 MHz) and an ultrasonographer experienced at evaluating cervical structures and aspirating small nodules in an accurate fashion
- 96% ethanol
- At least one 2.5- to 3-mL syringe
- Low-flow extension set
- 25- to 27-gauge 1½-inch needles

ANTICIPATED TIME

The procedure itself lasts seconds once the needle has been properly inserted into the parathyroid nodule. Depending on the experience and expertise of the ultrasonographer, the size of the nodule, and the ultrasound equipment, 30 minutes to an hour are a reasonable time frame for completion of the procedure.

PREPARATION: IMPORTANT CHECKPOINTS

- The diagnosis of primary hyperparathyroidism should be confirmed utilizing ionized calcium and PTH testing and by ruling out other causes of hypocalcemia.
- The dog's neck should then be examined ultrasonographically, and the parathyroid nodule should be definitively located and measured.
- The dog should then be anesthetized and placed in dorsal recumbency for the procedure, with the ventral aspect of the neck clipped.
- 1 mL of 96% ethanol should be prepared with no air bubbles and attached to a 25- to 27-gauge 1½-inch syringe, and a low-flow extension set should be placed between the needle and syringe and primed with ethanol prior to injection.
- In the case of a hyperthyroid cat, unilateral hyperthyroidism should be confirmed based on hormonal testing and nuclear scintigraphy. Once confirmed, the preparation is identical to dogs with PHPT.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO BE AVOIDED

Possible errors include:

- Not offering owners surgery as an alternative to injection. This is especially true if there is concurrent urolithiasis or another reason to have surgery.

- Attempting to inject a nodule that is too small, without the right equipment, experience, or expertise and without proper anesthesia or sedation
- Not properly identifying the parathyroid nodule and differentiating it from the carotid artery, which can look very similar in a cross-section ultrasonographic view of the cervical region. The nodule must be round or elliptical in the longitudinal plane as well and ideally should also be documented to have no laminar flow using color-flow Doppler.
- Assuming the tip of the needle is in the nodule and the injection will be successful without a proper test injection. Once the area has been infiltrated with a large amount of ethanol around the nodule, it becomes very hard to visualize the nodule or the needle, and the attempt often must be aborted.

PROCEDURE

- The parathyroid or thyroid nodule is definitively identified and differentiated from the carotid artery.
- A 25- or 27-gauge needle attached to an extension set and syringe and filled with 96% ethanol is carefully advanced into the nodule under ultrasound guidance.
- Once the tip of the needle is thought to be in the center of the nodule, a small test dose of alcohol (less than 0.1 mL) is given. This should produce a small, white, hyperechoic "cloud" within the nodule that should not be seen dispersing rapidly along tissue planes. If there is a doubt that the tip is not in the nodule, the needle should be removed from the nodule and repositioned and the test dose repeated.
- If the tip of the needle appears to be within the nodule, the ethanol should be injected until all parts of the nodule become hyperechoic. This may require slight repositioning of the needle in a large nodule.
- Within approximately 10 minutes, the injected area will become hypoechoic, so the decision whether the nodule has been completely filled with ethanol or not must be done within that time frame after starting the injection.
- When the filling is complete, the needle is removed, and the animal can be recovered.

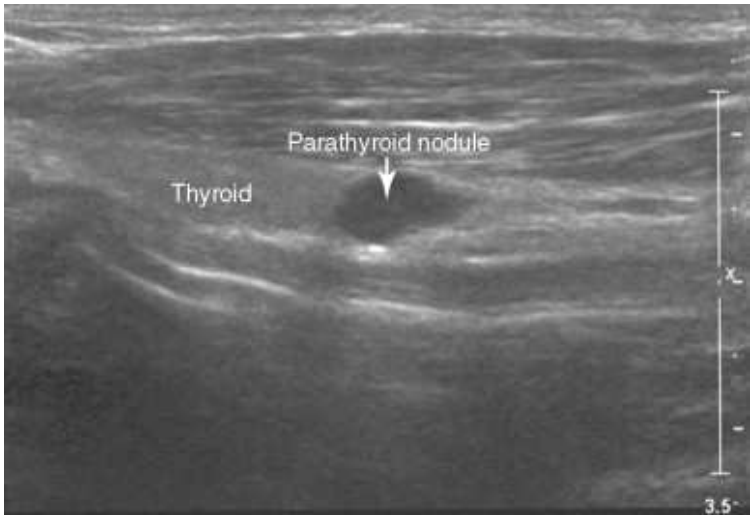
POSTPROCEDURE

No life-threatening or persistent complications have ever been observed following this procedure in dogs. Transient unilateral laryngeal swelling/paresis and Horner's syndrome can occur and tend to resolve within 1-4 days. Bilateral injections should not be attempted due to the risk of bilateral postprocedure laryngeal swelling. Dogs with PHPT should be monitored closely for 5-10 days after ablation for signs of hypocalcemia and should be supplemented as necessary with calcium and vitamin D. Clinical decision-making regarding calcium and vitamin D supplementation, as well as postinjection calcium monitoring, is the same as when surgical parathyroidecto mies are performed for the definitive treatment of PHPT.

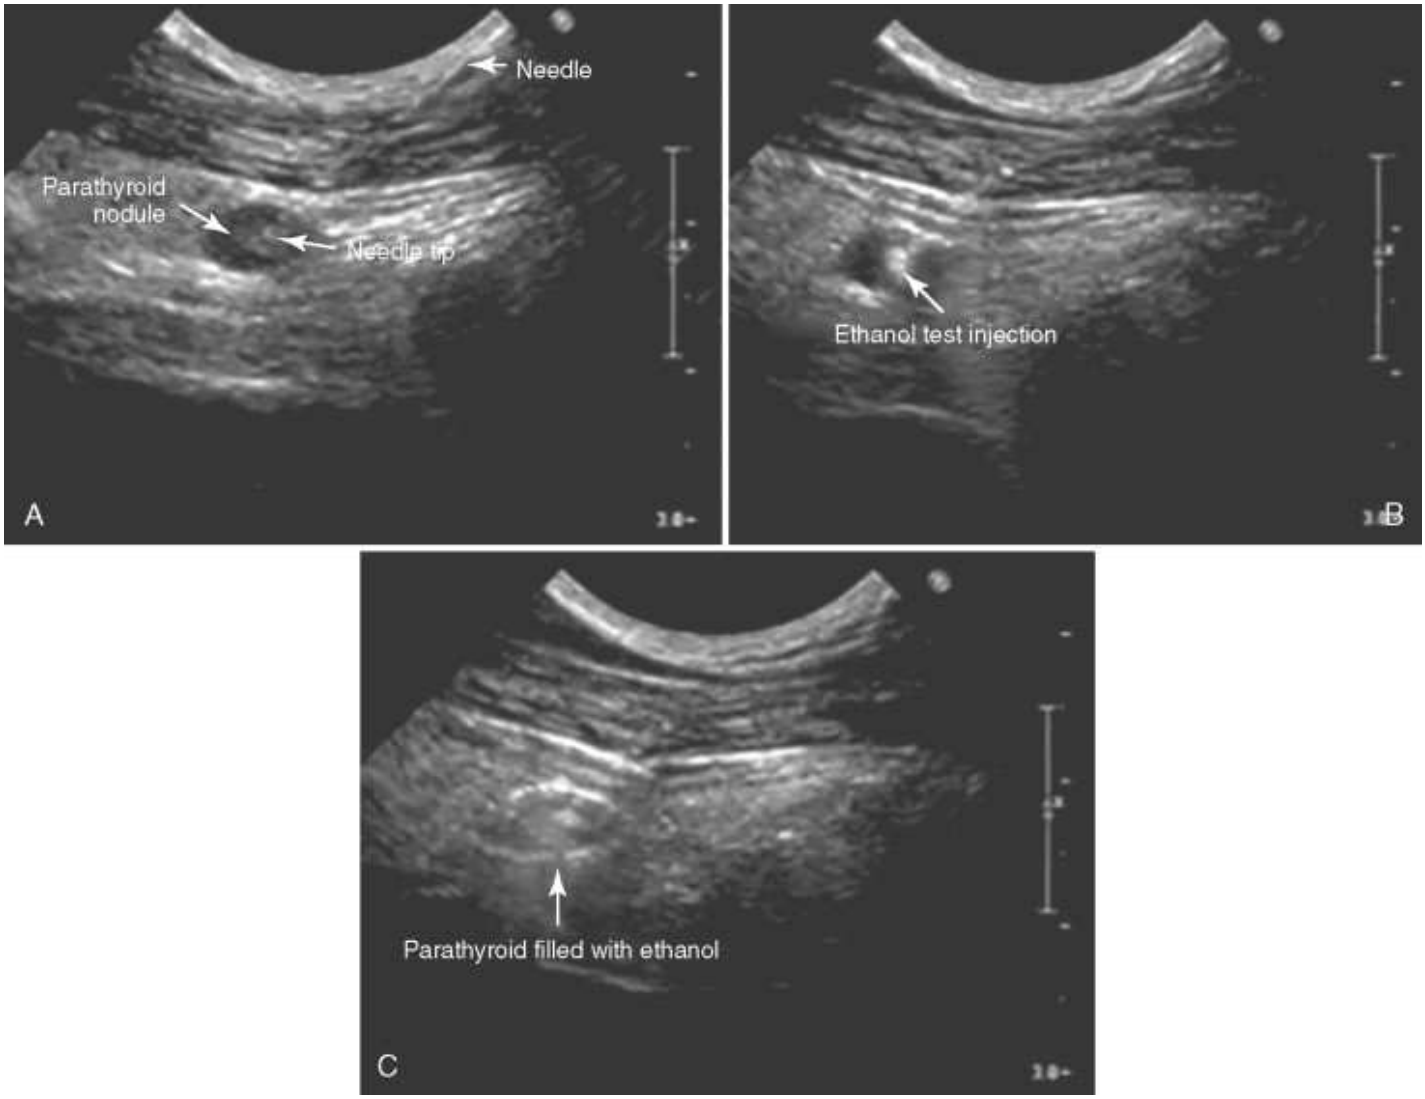
ALTERNATIVES AND THEIR RELATIVE MERITS

PEI is only one way to definitively treat PHPT. Alternatives are surgical removal of the parathyroid nodule or nodules and percutaneous heat ablation, which is performed in a similar fashion to PEI, but heat rather than ethanol is used to necrose the tissue via the inserted needle. Surgery is still the gold standard and should always be offered as such to the owner. Heat ablation may be superior to ethanol ablation in terms of fewer transient effects of the leakage of ethanol into the surrounding tissue but does require additional specialized equipment. The advantages of both heat ablation and PEI over surgery include shorter anesthetic time, a more rapid recovery, and less surgical healing or scar formation. Their disadvantage, in addition to the occasional transient local side effects of PEI, is the potential to fail, meaning the needle will not be properly inserted or the nodule will not be completely destroyed. Another disadvantage to the two less invasive options is that no tissue is obtained; hence the tumor cannot be classified histologically. Since almost all parathyroid tumors behave in a benign fashion regardless of their histopathologic features, this is not as severe a disadvantage as it would be in the case of other neoplasms.

ETHANOL ABLATION OF THYROID AND PARATHYROID TUMORS Anesthetized dog properly positioned in dorsal recumbency and prepared for percutaneous ethanol injection.



ETHANOL ABLATION OF THYROID AND PARATHYROID TUMORS Ultrasound image of a parathyroid nodule, with the thyroid gland, in a dog with primary hyperparathyroidism.



ETHANOL ABLATION OF THYROID AND PARATHYROID TUMORS Ultrasonographic images of percutaneous ethanol injection (PEI) therapy in a dog with primary hyperparathyroidism. **A**, Needle entering the parathyroid nodule, with tip clearly visible within the nodule. **B**, Test dose of ethanol being injected, and hyperechoic material remaining within the nodule. **C**, Parathyroid nodule has been completely infiltrated with ethanol immediately following successful PEI therapy.

Epidural Analgesia/Anesthesia

SYNONYM

Extradural blockade

OVERVIEW AND GOALS

Administration of drugs into the epidural space to provide decreased sensory and sympathetic pain transmission modulation (analgesia) and/or complete motor blockade (anesthesia). Drugs can be administered in one dose (single shot) repetitively or by continuous infusion:

- Epidural analgesia: injection of an opioid a phencyclidine an alpha-agonist or a nonsteroidal antiinflammatory drug (NSAID)
- Epidural anesthesia: injection of a local anesthetic

INDICATIONS

Caesarean section thoracostomy pelvic or hind limb orthopedic manipulations amputations (forelimb and hind limb) abdominal procedures tail or perineal procedures diaphragmatic repair pancreatitis peritonitis intervertebral disk disease (IVDD) thoracic trauma Advantages:

- Lengthy quick-onset analgesia
- Few systemic side effects for acute/chronic medical or surgical pain
- Reduced requirements for parenteral and inhalant drugs
- Alternative to general anesthesia for animals at high risk (American Society of Anesthesiologists III IV V E categories; see p. 1372)
- Adjunct to balanced anesthesia regimes

CONTRAINDICATIONS

Absolute contraindications:

- Coagulopathy/bleeding disorder
- Localized infection/inflammation over entry to epidural space
- Increased intracranial/intraspinal pressure (head trauma space-occupying mass)
- Risk of or present severe respiratory depression (phrenic nerve injury tentorial herniation)

Relative contraindications (requires alteration of dose frequency drugs or placement site):

- Urinary retention
- Meningitis encephalitis diskospondylitis
- Severe anatomic/neurologic disturbance or obesity at landmarks
- Inexperienced administration

Contraindications for use of local anesthetics in epidurals:

- Uncorrected hypovolemia
- Vasodilatory shock
- Severe clinical cardiac disease or liver impairment (third-spaced fluid disease ascites)
- Acute renal failure
- Sympathetic disturbance (e g autonomic disease dysautonomia)
- Use of potent systemic vasodilators

EQUIPMENT, ANESTHESIA

Most animals that receive an epidural are heavily sedated or under general anesthesia at the time of administration. Premedication with both anxiolytic and analgesic drugs (opioid, alpha-agonist) is recommended even if continued progression into general anesthesia is not anticipated, owing to the pain of positioning, approach, and administration of epidural agents. Equipment:

- Hair clippers
- Surgical scrub solution, isopropyl alcohol or saline, gauze/sponge

- Epidural or spinal needle (Quincke, Husted, or Tuohy needles); 22- to 20-gauge, 1½- to 3½-inch small hypodermic needles (22 gauge, ½-1½ inch) can also be used for tiny animals.
- Sterile gloves
- Sterile saline
- "Test syringe" for saline and air mix
- Syringe for administration of combination of local and/or opioid
- A few 20-gauge needles (used for withdrawing drugs from vials)
- Local anesthetics for epidural injection: 0.5% bupivacaine, 2% lidocaine, or 0.75% ropivacaine (all must be preservative- and epinephrine-free)
- Opioids for epidural injection: morphine, preferably preservative free (Duramorph, Astramorph, preservative-free morph), but parenteral morphine has been used for single-dose injection without complications anecdotally; buprenorphine, oxymorphone, hydromorphone, dexmedetomidine, and ketamine may also be utilized.
- A second operator (assistant) to allow strict attention to aseptic technique

For epidural catheterization, the following will also be required:

- Blunt-tipped, lateral-faced opening needle with curved bevel (Tuohy needle)
- Continuous or indwelling epidural catheter
- Injection port with screw or lock fitting to avoid inadvertent disconnection
- Sterile scissors to tailor-cut the catheter to proper length
- Microfilter
- Sterile covering for site and/or part/total catheter (Tegaderm)
- Suture material (3-0 nylon or other monofilament, nonabsorbable suture)
- Needle holders
- Suture scissors

ANTICIPATED TIME

- Experienced operator: 3-5 minutes
- Inexperienced operator, anatomic/animal positioning issues, dermatologic uncleanliness: 20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Base doses on lean body weight.
- Review anatomy for placement of entrance needle: most epidurals are performed at the lumbosacral junction because the cord terminates cranial to this area in dogs and near this area in cats; however, epidurals can be administered at any intervertebral space if lumbosacral (LS) access is limited.
- Consider ratio of each component: opioid, local anesthetic, alpha agent, ketamine, and/or others.
- Positioning of animal: sternal with hind legs pulled fully cranially under body or else flexed and stable under pelvis ("frog-legged"). Aged, debilitated, or traumatized animals may be uncomfortable in either position, so lateral positioning is also used. Obese animals are best placed in sternal, not only because of ease in identifying LS space but also because oxygenation and ventilation may be optimal.
- Premedication:
    - Medetomidine, 0.005-0.01 mg/kg (5-10 mcg/kg) IM or IV
    - Can also instead use a combination of anxiolytic plus analgesic: anxiolytic (acepromazine, 0.02-0.05 mg/kg IM or IV; or midazolam, 0.2-0.5 mg/kg IM or IV), plus analgesic (hydromorphone, 0.1 mg/kg IM or morphine 0.5-2 mg/kg IM)

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO BE AVOIDED

- The following can be seen with technical difficulty in prepping or identifying (finding) the epidural space: infection, hemorrhage, spinal or nerve root trauma.
- The following can be seen with use of certain agents: respiratory depression, urinary retention, pruritus, nausea and vomiting (opioids), motor paralysis, systemic vasodilation (lidocaine or high doses of bupivacaine/ropivacaine).
- Subarachnoid injection frequently results in superb analgesia but can cause respiratory and cardiac arrest or seizures with cranial advancement of drugs.

PROCEDURE

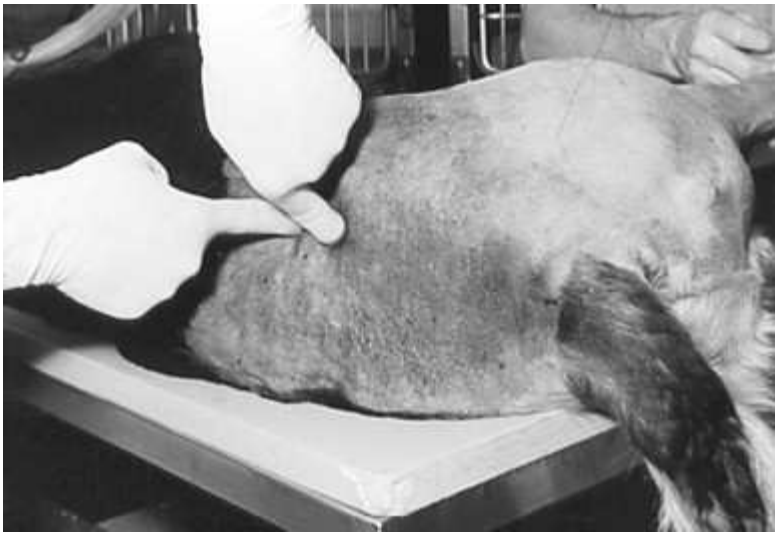
- The lumbosacral space is identified by palpating the most cranial dorsal aspects of each ilial wing, drawing an imaginary line between wings, and palpating the spinous process of L7 caudal to this line. The spinous process of L7 is smaller and shorter than that of L6 and, as such, is often more difficult to find. Staying directly on midline, the site of entry (LS space) is identified by placing a fingertip on the spinous process of L7 and gently rocking the finger caudally into the depression behind the process. The needle entry site is within this depression.
- The animal is positioned appropriately, the approximate LS area clipped, then aseptically prepped three times using

alternating chlorhexidine scrub and saline.

- Sterile gloves are unwrapped, and the paper sleeve is used as a sterile field; syringes, needles, and instruments are opened on the sleeve around the gloves.
- Epidural drugs are aseptically drawn into a syringe; dosages: some clinicians prefer combined local anesthetic bupivacaine, 0.1-0.3 mg/kg (motor sparing at 0.5%), with morphine, 0.02-0.1 mg/kg, for canine patients. This combination can be diluted to a total volume of 0.1-0.15 mL/kg with saline if advancement of the solution into the thoracic area is needed (thoracotomy, forelimb amputation, diaphragmatic repair, etc.). Total volume rarely exceeds 6 mL of saline, local, and opioid combined for canine patients for an injection made from the lumbosacral space. Injections made more cranially are reduced in volume by 25% per four to five vertebral bodies. Saline addition to the mixture is dictated by need for cranial spread of the agents.
- For cats, 0.02-0.1 mg/kg morphine is diluted with saline to a total volume of 0.1-0.2 mL/kg. Local anesthetic is rarely used because of the propensity to administer this into the subarachnoid space and the increased toxicity potential in this species.
- Both species: 0.5-2 mL saline with 0.5-2 mL of air are drawn into another syringe, which will act as an epidural space “tester” or identifier.

TECHNIQUE OF EPIDURAL INJECTION:

- Clinician approaches the patient from behind (facing in the same direction as the patient) if sternal recumbency, or from either behind or dorsal (the side of the table/hip against the patient's back, facing caudally) when the patient is in lateral recumbency.
- Brace the hand holding the needle on the patient's back. Use the other hand to identify the LS space as outlined above.
- The needle is then advanced transcutaneously at a 90○ angle to the skin surface over the LS site.
- The primary source of resistance is the dorsal spinous ligament, the ligamentum flavum. This is the hardest layer to penetrate and millimeter depth pushes are required to realize first, entry into the ligament, and second, the classic “loss of resistance” or “pop” as the epidural space is entered ventral to the ligament. Many clinicians will remove the stylet from the needle once ligamentum resistance is palpated, and add a small amount of saline to the hub of the needle in order to ascertain entry below the ligamentum.
- Once the ligamentum is penetrated, the hub of the needle is inspected for presence of blood or cerebrospinal fluid (CSF):
    - If blood is seen, the needle tip is partially redrawn and redirected.
    - If CSF is encountered, the needle is probably within the subarachnoid space, and should be withdrawn slightly.
    - If no blood or CSF is seen, assurance of epidural space is made by:
        - Loss-of-resistance technique: the syringe containing the saline and air is attached to the hub of the needle. The syringe plunger is then depressed. If there is no increase in resistance to pushing the plunger, the needle is correctly positioned in the epidural space. If the air bubble in the syringe is compressed or pushed against the saline as the plunger is depressed, the needle tip lies in the paraligamentous tissue, and the placement is incorrect.
        - Hanging drop technique: when the ligamentum flavum is encountered—the first sign of resistance—the stylet is withdrawn and the hub is filled with saline so the liquid forms a meniscus. As the space is entered, the normally negative pressure will cause aspiration down the needle shaft, and the fluid and meniscus will disappear.
- Once the correct positioning is confirmed, the injection proceeds over a 30-60 second time frame. Often, respiratory and cardiac rate increase during injection.



EPIDURAL ANALGESIA/ANESTHESIA Lumbosacral region of dog in left lateral recumbency. On the dorsal midline, the caudal-most dorsal spinous process, L7, is palpated (clinician's left hand). This process, shorter and smaller than that of L6 (clinician's right hand), is located caudal to an imaginary line that joins the most cranial dorsal aspects of both iliac crests. The point of epidural entry is the lumbosacral space, which is directly caudal to the dorsal spinous process of L7.

TECHNIQUE OF EPIDURAL CATHETERIZATION:

- Once the needle enters the space, the bevel of the needle must face cranially.
- The catheter is then threaded down the needle.
- Catheter advancement should proceed without resistance. The catheter should never be withdrawn into the needle because of the possibility of shear/breakage.
- Once the catheter is advanced to the appropriate space, the needle is then withdrawn over the catheter.
- A section of skin adjacent to the site of entry is then penetrated with the needle. The needle is tunneled parallel to the surface of skin for 1.5-2 cm and then exits the skin.
- The catheter's free end is then fed retrograde up the needle.
- The needle is then withdrawn, and the catheter is effectively “tunneled” away from the epidural site. This provides for decreased chances of bacteremia/infection in the epidural space.
- Excess catheter length is cut from the catheter, using sterile scissors.
- The filter and injection port are secured.
- The epidural medications are then administered through the catheter, with the amount reduced to accommodate for placement of catheter tip.
- The catheter cap and filter are secured with suture. A protective sterile covering is placed over the catheter and LS space.

POSTPROCEDURE

- Onset of analgesia varies from immediate for lidocaine epidurals, to 30-60 minutes for bupivacaine epidurals, to 2-4 hours for morphine and oxymorphone epidurals.
- Duration of analgesia varies from 1 hour for lidocaine epidurals, to 3-6 hours for bupivacaine epidurals, to 12-15 hours for morphine epidurals.
- Pain of injection is severe with local anesthetics and ketamine. Some clinicians strongly suggest utilizing each as diluted solutions only and administering bupivacaine only if the animal is under the influence of heavy sedation/analgesia or is anesthetized.
- Vomition, nausea, and drooling are common when catheters are placed in the thoracic spinal canal, when heavy volumes or concentrated morphine is used, or when pain/sudden hypotension is sensed during an injection (“awake bupivacaine epidurals”).
- The injection cap, filter, and dressing should be replaced every 72-96 hours using aseptic technique in catheters that are routinely used (q 12 h to q 8 h treatments).
- Swelling or pain over the tunneled site or, more importantly, over the catheter entry site warrants removal of the catheter. Replacement should then be questioned; alternative analgesic methods are suggested instead.

ALTERNATIVES AND THEIR RELATIVE MERITS

- General inhalant anesthesia: cardiorespiratory depression; expense
- Systemic narcotic administration: side effects of gastrointestinal (GI) stasis, respiratory depression, and mild anxiety; expense
- Recent electrostimulation and ultrasound techniques have allowed placement of blockades very close to nerves, nerve roots, and plexi; these may afford safe, economical, and less technically challenging means to providing analgesia without sympathetic blockade, although they do frequently include motor blockade.

AUTHOR: ANDREA L. LOONEY

Enema: Scintigraphic (Radionuclide)

SYNONYMS

Nuclear portogram, per rectum portal scintigraphy, transcolonic portal scintigraphy

OVERVIEW AND GOAL

Portosystemic shunts (PSS) are a relatively common congenital disorder in dogs and cats. Scintigraphy provides a rapid, noninvasive screening test for this disorder.

INDICATIONS

- Confirm the presence of a macroscopic PSS
- Evaluate the effectiveness of previous surgical shunt vessel attenuation
- Provide limited information regarding the number (single versus multiple) and location (intrahepatic versus extrahepatic) of the PSS vessel(s)

CONTRAINDICATIONS

Critical animal condition precluding relative isolation necessary to comply with regulatory requirements

EQUIPMENT, ANESTHESIA

Gamma camera and either an analog recorder (microdot) or preferably a nuclear medicine computer are necessary for calculation of shunt fraction.

ANTICIPATED TIME

- Procedure time of 5 minutes
- Isolation time (varies by local regulatory agency) of 6-60 hours

PREPARATION: IMPORTANT CHECKPOINTS

Animal:

- No animal preparation is required.
- Ideally, animals are fed the morning of the procedure.
- Discontinuation of oral lactulose for 36 hours prior to procedure may improve rectal uptake.
- Evacuation enemas are encouraged as a form of preparation by some clinicians but may not be routinely used by other clinicians.

Radionuclide setup:

- Prepare a dose of sodium ^{99m}T-pertechnetate (37-74 MBq/kg) in a small volume (<1 mL) in a shielded syringe case.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Delivery of isotope into transverse colon
- Poor positioning of animal on camera relative to location of radionuclide delivery in colon
- Inadequate radionuclide uptake

PROCEDURE

Technique, initial:

- Position the animal in right lateral recumbency on a Plexiglas table positioned over the gamma camera.
- Place the lubricated end of a pediatric feeding tube or IV extension set into the distal rectum (with the tip just inside the anal sphincter).
- Connect a three-way stopcock to the end of the delivery tubing.

- Connect a syringe containing 5-10 mL of air to the three-way stopcock.
- Connect the shielded syringe containing the sodium ^{99m}T-pertechnetate dose.

Technique, main:

- Introduce dose into feeding tube.
- Begin dynamic image acquisition.
- Flush dose into colon using room air flush.

Dynamic image acquisition parameters:

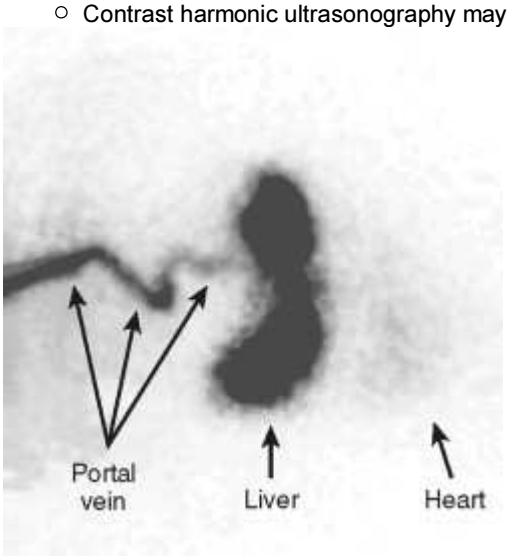
- Analog (microdot): 16 dynamic images of 5-second duration
- Digital (computer): 100 dynamic images of 2-second duration using 128 × 128 matrix

POSTPROCEDURE

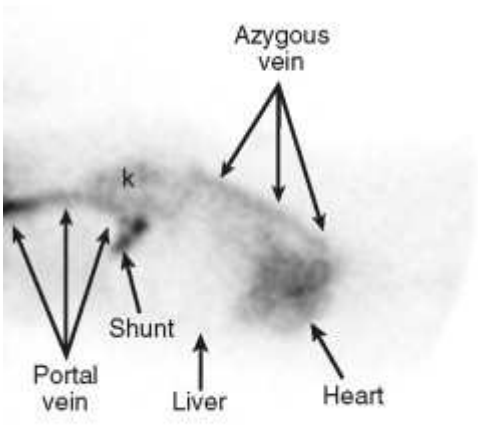
Isolation of animal in a radiation safety area is required until animal monitoring consistent with local release criteria. Collection of animal waste produced during isolation; the waste is treated as radioactive and typically held for decay before disposal.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Transsplenic portal scintigraphy:
  - Requires sedation or anesthesia
  - Requires concurrent use of ultrasound for guidance of splenic injection
  - Overcomes poor rectal absorption that occurs sporadically in some patients
  - May produce false negative results for portosystemic shunting occurring caudal to the portal vein
  - Increased count density is possible, allowing more accurate characterization of the morphology of the PSS vessel.
- Ultrasound:
  - More readily available
  - Very operator dependent
  - Good success for diagnosis of intrahepatic shunts, limited by overlying ribs and lungs
  - Limited success for diagnosis of extrahepatic shunts, owing to interference by adjacent gas-filled intestines
  - Contrast harmonic ultrasonography may reduce operator dependence.



ENEMA, SCINTIGRAPHIC (RADIONUCLIDE) Composite image of early phase of a scintigraphic enema in a normal dog. Lateral projection; cranial is to right. Note clear visualization of portal vein and liver, with incomplete visualization of heart.



ENEMA, SCINTIGRAPHIC (RADIONUCLIDE) Composite image of early phase of a scintigraphic enema in a dog with a surgically confirmed portoazygous shunt. Same orientation as in other figure. Note visualization of portal vein, shunt vessel at level of right kidney (k), and visualization of azygous vein. Minimal visualization of liver is due to reduced portal blood flow.

- Helical CT scan contrast portography:
  - Requires anesthesia
  - More expensive
  - Provides global perspective of entire abdomen with excellent anatomic detail
  - Generally used in cases of confirmed PSS when additional anatomic information is desired prior to surgical intervention
- MRI angiography:
  - Least available
  - Requires anesthesia
  - More expensive
  - Provides global perspective of entire abdomen, with excellent anatomic detail
  - Generally used in cases of confirmed PSS when additional anatomic information is desired prior to surgical intervention
- Intraoperative mesenteric portography:
  - Generally considered the gold standard for diagnosis of PSS
  - Requires anesthesia
  - Invasive
  - Expensive
- Liver biopsy:
  - Requires anesthesia
  - Invasive
  - Unable to confidently distinguish between macroscopic shunt and intrahepatic microvascular dysplasia (otherwise known as portal vein hypoplasia)

SUGGESTED READING

Koblik PD, Komtebedde J, Yen CK, et al: Use of transcolonic ^{99m}technetium pertechnetate as a screening test for portosystemic shunts in dogs. J Am Vet Med Assoc 196:6, 1990.

AUTHOR: MICHAEL R. BROOME

Enema (Evacuation, Retention)

OVERVIEW AND GOALS

Emptying of colonic content (evacuation) and/or colorectal administration of substrates (retention)

INDICATIONS

Evacuation enema:

- Treatment of colonic impaction/constipation
- Preparation of the animal for colonoscopy

Retention enema:

- Treatment of severe hepatic encephalopathy

CONTRAINDICATIONS

Painful anus, rectal mass/obstruction

EQUIPMENT, ANESTHESIA

- Enema solutions:
  - Warm tap water or isotonic saline (5-10 mL/kg)
  - Docusate (emollient enema promoting water penetration within the feces)
  - Mineral oil (lubricant enema; 5-10 mL for small dogs and cats, 10-20 mL for medium-sized dogs, 20-30 mL for larger dogs)
  - Lactulose (hyperosmotic laxative; 5-10 mL for cats)
- Preparation of the animal for flexible colonoscopy: to perform a successful colonic examination, thorough preparation of the animal is mandatory. Enema administration alone is often not enough to obtain a fully clean colon. Therefore, the following should also be performed in those animals to ensure a successful colonoscopy:
  - The animal should be fasted for 24-36 hours preceding colonoscopy.
  - The use of an oral gastrointestinal (GI) isosmotic lavage solution such as Golytely, Colopeg, or Colyte is recommended two times, a few hours apart, in the afternoon preceding colonoscopy:
    - Dogs: 30 mL/kg through an orogastric tube
    - Cats: 30 mL/kg through a nasoesophageal tube
  - One or two enemas is/are administered the afternoon before and the morning of the colonoscopy until the animal is evacuating watery fluid. Often “larger” quantities of water are necessary to obtain an adequately cleaned colon (dogs > 20 kg: 1 L; dogs > 40 kg: 2 L). Use a funnel and a large tube.
- Treatment of severe acute hepatic encephalopathy:
  - First perform a cleansing enema to evacuate all remaining colonic content.
  - Retention enema (total amount of 15 mL/kg): allows the delivery of fermentable substrates or colonic pH modification:
    - Lactulose (1:2 dilution with water)
    - Neomycin in water (10-20 mg/kg)
    - An alternative is to use diluted povidone iodine (1:10, rinse thoroughly after 15 minutes).
- See also Hepatic Encephalopathy, p. 501.

ANTICIPATED TIME

About 15-30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Fluid therapy is an essential part of the management of colon impaction.
- Animals should be well hydrated.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Some enemas, such as docusate, can promote GI water loss and should be used with caution if the animal is dehydrated.
- If enemas are administered too quickly, they can lead to discomfort and vomiting.
- Enemas should be administered after they are warmed to body temperature.
- Do not administer mineral oil with docusate.
- Do not administer sodium phosphate enemas to small dogs or cats, because such enemas can induce dehydration, neurologic signs, and severe hyperphosphatemia, hypernatremia, and hypocalcemia.
- If the animal has much anal or rectal pain, enemas should be replaced by an extra administration of an oral GI lavage solution.
- If the animal is not cooperative, sedation or general anesthesia can be necessary.

ENEMA (EVACUATION, RETENTION) Enema tube that is well lubricated before going into the anus. Distal end of tube must be smooth and rounded and not have sharp edges. It is generously lubricated, passed into the anus, and advanced to a maximum point that corresponds to the distance from the anus to the last rib.

ENEMA (EVACUATION, RETENTION) Large volumes of fluid instilled using gravity, a funnel, and tube. This procedure is performed either for preparation for colonoscopy or as a treatment for constipation.

PROCEDURE

- Slowly insert a very well-lubricated catheter or feeding tube through the anus (10-14 Fr). In cats, a 60-mL syringe and a urinary catheter can be used.
- Enema solution should be warmed and administered slowly. It may be administered by syringe, or larger volumes may be instilled more easily using a funnel and gravitational flow.
- When there is no resistance, the tube is inserted for a total length equal to that from the anus to the last rib (pre-measure the tube).

POSTPROCEDURE

- Animals usually have diarrhea.
- If enema administration was unsuccessful, animals with colon impaction may require manual extraction of impacted feces (under anesthesia).
- After the administration of an oral GI lavage solution, the animal should be kept quiet in a cage to avoid the potential risk of developing gastric dilatation/volvulus.
- Dogs should be regularly walked on a leash to allow defecation.

ALTERNATIVES AND THEIR RELATIVE MERITS

Pediatric suppositories (dosage is 1 to 3, according to body weight [cat/small dog to large dog]) such as glycerol, docusate (Colace), or bisacodyl (Dulcolax) can be used as an alternative to enemas. These are safer than the use of phosphate enemas, especially for cats or smaller dogs.

AUTHOR: SYLVIE DAMINET

Electroretinogram

SYNONYM

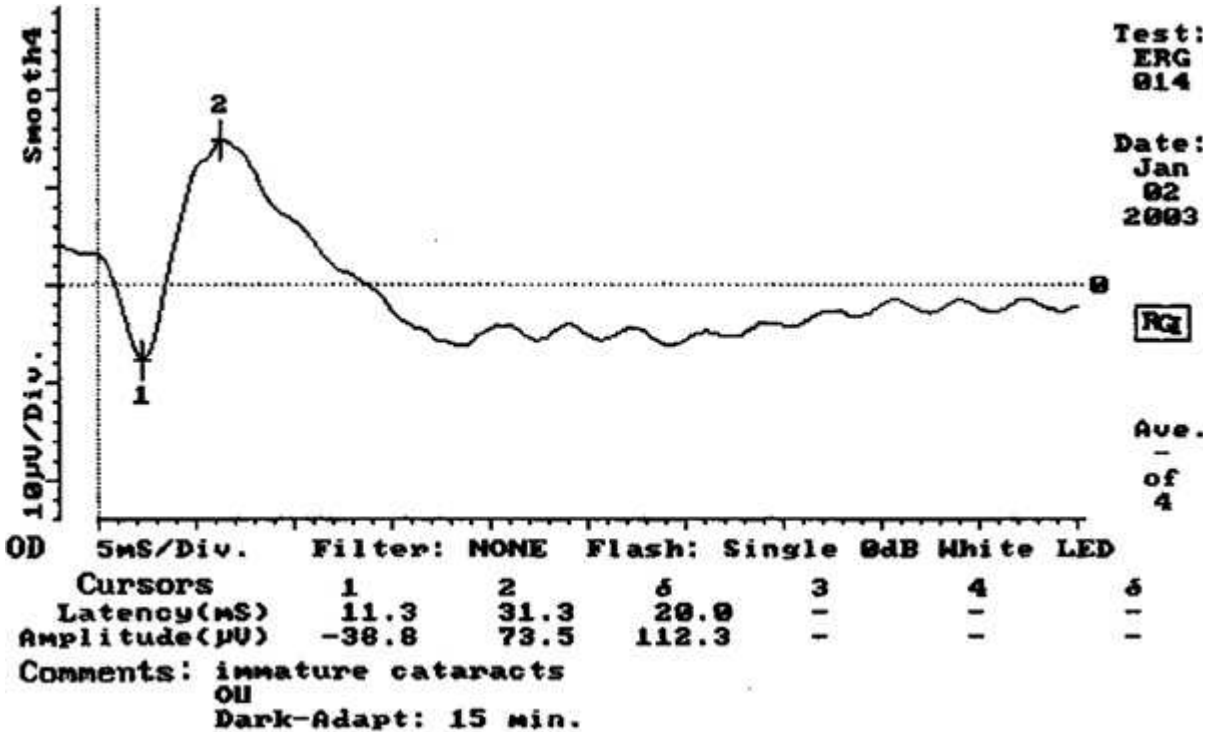
ERG

OVERVIEW AND GOALS

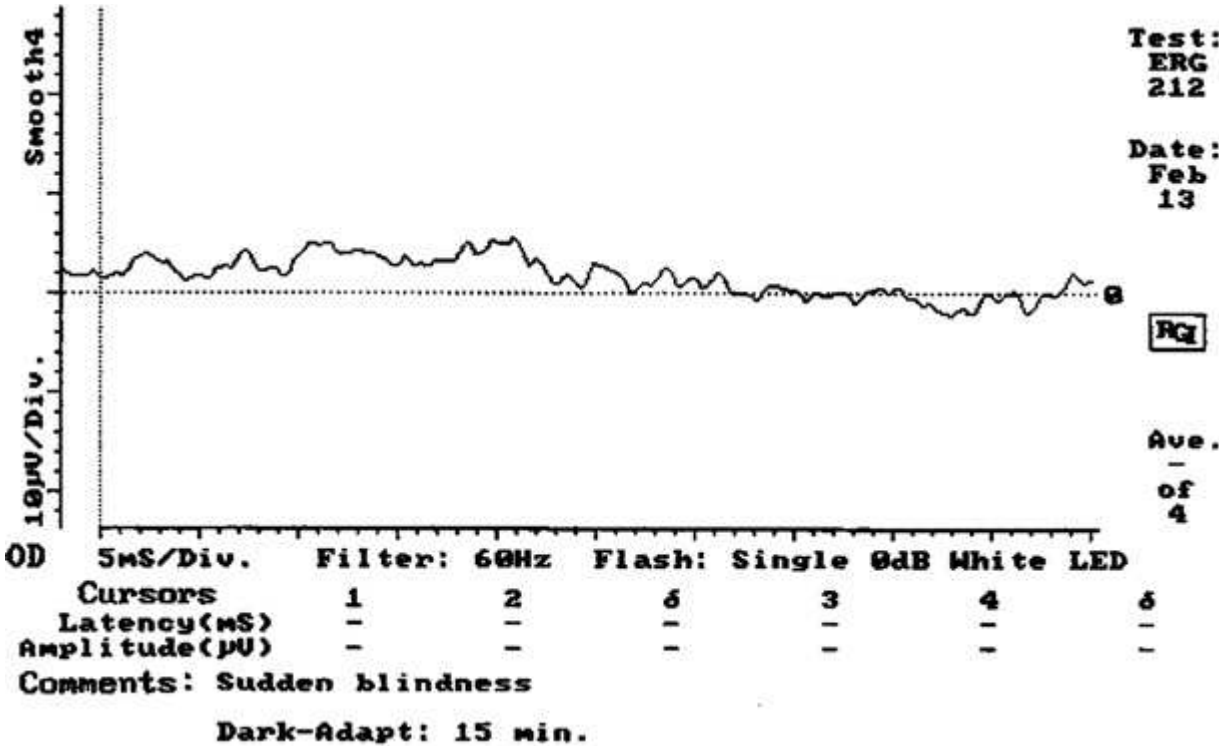
- Evaluation of retinal function (quantitative or qualitative) through measurement of the electrical response generated after the photoreceptors receive a light stimulus
- An electroretinogram (ERG) by itself does not determine whether an animal can see; the retina is only one part of the visual system.

INDICATIONS

- Differentiation of causes of sudden blindness (i.e., sudden acquired retinal degeneration syndrome [SARDS] and optic neuritis)
- Evaluation of retinal function to determine cataract surgery suitability
- Identifying inherited retinal disease (i.e., progressive retinal atrophy [progressive rod-cone degeneration] or progressive rod-cone dysplasias) at an early age well before clinical signs and gross retinal changes occur
- Evaluation of damage incurred by glaucoma or toxic effects of drugs
- Evaluation of the effects of optic nerve hypoplasia on retinal function



ELECTRORETINOGRAM Normal ERG. The number 1 marks the nadir of the a-wave, and the number 2 marks the peak of the b-wave.



ELECTRORETINOGRAM ERG from dog with SARDS. No normal waves are detectable.

CONTRAINDICATIONS

- Panuveitis
- Corneal ulcer
- Any contraindication for general anesthesia or sedation

EQUIPMENT, ANESTHESIA

Equipment:

- Gold-foil contact lens electrode or an atraumatic wire electrode (placed in conjunctival cul-de-sac). Contact lens electrodes are used most often.
- Reference and ground electrodes
- Standardized light source for light stimulus
- “Safe” light, red light, or small red penlight
- Timer for dark adaptation
- Conducting agent to facilitate electrical contact between the contact lens electrode and the eye; methylcellulose (Gonak) or GenTeal Tear Gel
- Table; if stainless steel, cover with nonconducting material (rubber padding).
- Optional: head rest for elevation and positioning of head; this may be made of foam, rolled-up blankets, or sandbags.

Anesthesia or sedation:

- General anesthesia or sedation; some animals will tolerate the procedure with topical anesthesia only (and contact lens electrode), but the risk of artifact is increased.
- General anesthesia prevents animal movement (artifact source) and allows more precise direction of the light stimulus into the eye via fixation of the eye.
- Sedation; one of these three protocols can be considered:
  - Acepromazine (0.03 mg/kg IV) and hydromorphone (0.05 mg/kg IV):
    - Observe precautions/contraindications, especially with acepromazine.
  - Diprivan (propofol) 4-6 mg/kg IV to effect (low doses will be sufficient in most cases).
  - Medetomidine (0.005-0.01 mg/kg [dogs, cats] IM) combined with butorphanol (0.2 mg/kg [dogs, cats] IM)
- Other anesthetic or sedation protocols may be employed; be consistent to aid in correct interpretation of the recordings.
- General anesthesia and sedation depress the ERG response.
- Butorphanol is the sedative most likely to depress ERG response.
- Topical anesthetic (i.e., proparacaine)

Personnel (two people):

- One to monitor anesthesia or sedation, position the animal's head, ensure that light stimulus is directed into the eye during the flash, cover the fellow eye, and check to see that all electrodes are in position during test
- One to run the computer program during the test

ANTICIPATED TIME

About 1-1½ hours, including time for pupillary dilation

PREPARATION: IMPORTANT CHECKPOINTS

- Knowledge of retinal physiology
- Familiarity with ERG equipment
- Control of inflammation; especially important in a precataract surgery evaluation. Lens-induced uveitis will decrease ERG amplitudes.
- Dilation of pupils
- Bleaching of retinal pigments in rods by exposure to bright light before dark adaptation
- Dark adaptation (4 minutes minimum, 20 minutes desirable)
- Lock room to avoid inadvertent exposure to light and necessity of starting procedure again.
- Use grounded outlet to decrease/eliminate 60-cycle interference.
- Take off wristwatch to decrease 60-cycle interference.
- Set up computer, supplies, equipment before dark adaptation.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

POSSIBLE COMPLICATIONS:

- Corneal ulcers, especially in diabetics with decreased corneal sensitivity and increased risk of corneal ulceration
- Hypoxemia or death due to failure to monitor animal during general anesthesia

COMMON ERRORS:

Preparation errors:

- Failure to dilate pupils fully Procedural errors:
- Failure to direct light stimulus directly into eye
- Failure to prevent “light spill” into fellow eye while recording “first” eye; this decreases amplitude of “second” eye by bleaching retinal pigments.
- Error in labeling which eye is which on recordings
- Lack of standardized protocol for specific model of equipment on premises
- Lack of standardized anesthesia/sedation, leading to difficulty in interpretation of results
- Excess noise due to failure to use signal averaging and filters
- Excess muscle fasciculations in eyelids due to inadequate sedation, leading to excess noise in the readings. The use of an eyelid speculum exacerbates muscle activity due to muscle stretching.
- Dull electrode needles
- Gap in gold-foil electrode ring on contact lens electrode, leading to inaccurate reading or artifact
- Expulsion of contact lens or reference electrodes during procedure, leading to artifact or inaccurate reading
- 60-cycle interference caused by lights, appliances in same room, using a non-insulated table
- “Stray” light stimulus from computer monitor during procedure, leading to lower amplitude readings

Animal-derived errors:

- Eyes are closed, leading to very low amplitude readings.
- Blinking during light stimulation, leading to low amplitude readings
- Third eyelid is prolapsed, expelling the contact lens or leading to very low-amplitude readings due to the failure of light to reach retina.

Interpretation errors:

- Misinterpretation of findings due to lack of knowledge of retinal physiology and basis of the test

PROCEDURE

- Dilate pupils with short-acting mydriatic (i.e. tropicamide) 30 minutes before sedation.
- Sedate or induce general anesthesia as necessary.
- Place reference electrode in skin over ipsilateral zygomatic arch, 5 cm distal to lateral canthus.
- Place ground electrode in skin over top of muzzle. If dog must be muzzled, place ground electrode in skin on forehead. If electrode needles do not go into skin easily, discard and use new electrodes to avoid discomfort to animal and increase accuracy of reading.
- Dark adapt patient for minimum of 4 minutes, optimum of 20 minutes.
- Place topical anesthetic in eye.
- Place conducting gel on concave surface of contact lens.
- Place contact lens in eye, ensuring that the lens is centered on the cornea and not on top of the nictitating membrane.
- Perform standardized protocol. Protocols are available in ERG units' software. To determine rod function, important in progressive rod-cone degeneration, a blue filter under scotopic conditions must be used.
- Use signal averaging. This produces an averaged response after a predetermined number of flashes (5-10) and enhances the signal-to-noise ratio.
- Use band-pass filters to screen out unwanted frequencies.
- A normal ERG consists of a low-amplitude negative a-wave 10-12 msec after the light stimulus, followed by a large positive b-wave. In some tracings, the c-wave (a third wave) is seen as a positive deflection.
- The a-wave is produced by the photoreceptors and the b-wave by movement of potassium in and out of Müller cells and indirectly by bipolar cells.

POSTPROCEDURE

- Remove electrodes from eye and skin.
- Soak contact lens electrode in distilled water; do not rub the inside surface of the lens to clean it, because this action will remove the gold-foil circle, rendering it useless.
- Flush eye with sterile eye wash and stain for corneal ulcer.
- Partially reverse butorphanol sedation with naloxone, or recover from general anesthesia.
- Measure amplitude of recordings, the amplitude from the nadir (lowest point) of the negative a-wave to the peak of the positive b-wave.
- Record findings on a separate disc or CD for a backup copy, and print hard copy for animal's record.

ALTERNATIVES AND THEIR RELATIVE MERITS

Genetic testing for inherited retinal disease:

- Many tests are available for specific dog breed–related inherited retinopathies but not for all breeds.
- Only requires blood test, so simpler than ERG

Maze test under photopic and scotopic conditions:

- May be gross screening test for retinal atrophy
- Unable to determine anatomic source of defect in sudden blindness cases

AUTHOR: NANCY B. COTTRILL

Electromyography (EMG) and Motor Nerve Conduction Velocity (NCV)

SYNONYMS

Electrodiagnostics; EMG, NCV

OVERVIEW AND GOALS

- Integral component of diagnostic evaluation of animals suspected of having neuromuscular disorders (neuropathy, myopathy, neuromuscular junctional disease).
- May confirm and characterize the presence of nerve, neuromuscular junction, or muscle disease in these animals.
- If the EMG is abnormal, a neuromuscular disease is present but a normal EMG does not rule out the possibility of a neuromuscular disease.
- Useful for differentiating denervation from disuse atrophy.
- Is very sensitive but not very specific.
- Generally part of a diagnostic workup that may also involve nerve and muscle biopsy, cerebrospinal fluid (CSF) analysis, laboratory testing (serology, endocrine testing, measurement of metabolites), radiographs and advanced imaging (MRI or CT).

INDICATIONS

- Animals with clinical signs and neurologic examination suggestive of neuromuscular disease (diffuse or focal).
- Animals with peripheral nerve injuries.
- May help confirm the presence of endocrine disease (hyperadrenocorticism-pseudomyotonia).

CONTRAINDICATIONS

Electrodiagnostics require general anesthesia, so relative contraindications include megaesophagus or severe weakness (hypoventilation).

EQUIPMENT, ANESTHESIA

- General anesthesia and tracheal intubation are required. For sensory nerve conduction studies in which paralysis with atracurium is required, a ventilator is needed.
- Should ideally be performed in electrically shielded room to minimize background noise.
- Differential amplifier, computer with appropriate software for labeling and calculations, needle electrodes for stimulating and recording impulses (concentric needle electrode preferred for electromyography [EMG]), isopropyl alcohol, and measuring tape.
- Surgical pack: often, muscle and nerve biopsies (see p. 1305) are done following electrodiagnostics.
- In some cases, percutaneous endoscopic gastric (PEG) tube placement (see p. 1270) is beneficial while animal is anesthetized (providing nutritional support, administering medications, etc.).

ANTICIPATED TIME

- EMG: 10–20 minutes
- EMG + nerve conduction velocity (NCV): 40-60 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Monitor body temperature and prevent hypothermia, which prolong nerve conduction times (1.8 m/s drop for every 1°C drop in limb temperature).
- Draw blood for chemistries prior to procedure, as EMG will cause a transient increase in CK.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Complications related to anesthesia
- Regurgitation and aspiration pneumonia in animals with megaesophagus/ esophageal dysfunction or dysphagia

PROCEDURE

- Animal is premedicated, anesthetized, intubated, and then maintained with inhalational anesthetic (isoflurane, sevoflurane).
- Placed in lateral recumbency
- EMG:
  - Needle electrodes are used for recording electrical activity in major muscle groups in appendicular muscles and in epaxial and masticatory muscles; rarely esophageal, laryngeal muscles, and tongue.
  - Evaluation is performed both by listening for characteristic sounds of electrical potentials and visually examining the waveforms produced by the potentials on the monitor.
  - Sensitivity is greatly increased by increasing the number of “passes” through the muscle (by continually redirecting the needle within the muscle) and by increasing the number of muscles sampled, as denervation potentials may be present in only a few areas.
  - A short burst of electrical activity occurs during needle placement is normal due to temporary disruption of muscle fibers (insertional activity). Other normal electrical potentials called miniature end plate potentials and endplate spikes may occur as a result of spontaneous depolarization of part or all of a myofiber.
  - Normal healthy muscle is otherwise electrically silent at rest.
  - Other spontaneous electrical discharges in resting muscle (i.e., anesthetized animal) are abnormal and indicate neuromuscular disease.
  - Abnormal EMG activity includes fibrillation potentials, positive sharp waves, complex repetitive discharges, or myotonic discharges. In general, the type of waveform is not specific for neuroanatomic location (nerve versus muscle) or pathophysiologic mechanism of disease.
  - Abnormal EMG activity confirms the presence of neuromuscular disease and helps localize which muscle groups are affected; however, abnormal EMG activity cannot differentiate between myopathic or neuropathic disease.
  - EMG changes due to denervation may not be detected for 5 to 10 days after initial injury.
  - Severity of clinical signs does not always correlate with severity of EMG changes.
- Motor NCV:
  - Using stimulating needle electrodes, a nerve is stimulated at various accessible points along its anatomic pathway.
  - Needle or surface electrodes within or over a muscle innervated by the nerve record a compound muscle action potential (CMAP), which results in a simple biphasic waveform.
  - Measurements made include the nerve conduction velocity (NCV), as well as the CMAP, amplitude, duration and area
  - Nerves commonly tested in domestic animals include the sciatic, peroneal, cranial tibial, radial, musculocutaneous, and median.
  - The recurrent laryngeal, facial nerve, and trigeminal nerves are rarely tested.
  - Nerve conduction velocity along various segments of axon may be determined by measuring the distance between points of stimulation (ideally at least 100 mm to decrease the effect of human measurement error) and difference in latency of waveforms (velocity [meters per second] = Ddistance/D time).
  - The amplitude of the waveform is proportional to the number of available axons. Axonal disease results in a decreased number of axons and decreased CMAP amplitude and may also cause secondary EMG changes due to denervation.
  - Nerve conduction velocity measures the speed at which action potentials travel down the axon.
  - Decreases in NCV may be due to demyelination or due to loss of the large, fastest conducting axons.
  - Demyelinating diseases, in addition to causing decreases in NCV, cause a widening and distortion of the CMAP waveform, and temporal dispersion or distortion of the waveform over the time axis.
  - Many peripheral nerve diseases result in both axonal loss and demyelination, causing decreased amplitude, temporal dispersion, and decreased conduction velocity in addition to abnormal EMG activity due to denervation.
  - Measuring nerve conduction velocity is helpful in determining whether disease is demyelinating, axonal, or both, as well as whether the nerves are more affected proximally or distally. It is also helpful in determining which nerves are affected.
  - Pathophysiologic mechanism of disease cannot be determined using NCV.
  - Nerve and muscle biopsies are often necessary to determine the etiology of disease, although EMG and nerve conduction velocity help determine the nature of disease (demyelinating versus axonal versus myopathy) and optimal biopsy sample site.

ELECTROMYOGRAPHY (EMG) AND MOTOR NERVE CONDUCTION VELOCITY (NCV) Motor nerve conduction studies recorded from the plantar interosseous muscles following stimulation of the sciatic-tibial nerve at the hock, stifle, and hip in a normal dog **(A)** and in a dog with generalized muscle disease **(B)** (mitochondrial myopathy). Note marked generalized decrease in compound muscle action potential (CMAP) amplitudes (3.12, 3.37, and 4.51 mV) from all sites of stimulation in the myopathic dog when compared with the normal dog (23.02, 19.86, and 20.34 mV). Despite CMAP amplitude reduction, the dog with myopathy has normal MNCVs (101 and 85 m/sec). Generalized CMAP amplitude decrease can also be observed in prejunctional neuromuscular diseases such as botulism, as well as in primary axonopathies. (Recording parameters: **A,** 5 mV/div and 2 msec/div; **B,** 1 mV/div and

2 msec/div.)

(Reprinted with permission from Cuddon PA: Electrophysiology in neuromuscular disease, Vet Clin North Am Small Anim Pract 32:31-62, 2002.)

POSTPROCEDURE

- Monitor recovery from anesthesia.
- Nerve and muscle biopsies are often indicated after electrodiagnostic testing to determine the pathophysiology of disease (e.g., inflammatory, infectious, neoplastic, degenerative, toxic, endocrine).
  - See Muscle and Nerve Biopsy, .
  - For additional details, consult recommended methods for submission of samples in Shelton and Engvall, 2002.
- In some cases, PEG tube placement is indicated while the animal is anesthetized.

ALTERNATIVES AND THEIR RELATIVE MERITS

Muscle and nerve biopsies as already described

AUTHOR: GREG KILBURN

Electrocardiography

SYNONYMS

- Electrocardiogram: ECG, EKG
- Electrocardiograph: ECG machine

OVERVIEW AND GOALS

- To obtain a tracing that represents the rhythm of the heartbeat
- Electrocardiography is the diagnostic test of choice for evaluating cardiac arrhythmias.
- Electrocardiography may also provide some limited information regarding cardiac structure (sizes and proportions of waves and complexes sometimes indicate chamber enlargement) and systemic disturbances (e.g., hyperkalemia, hypoxemia).

INDICATIONS

- Evaluation of a cardiac arrhythmia noted during physical examination
- Part of routine cardiovascular monitoring during general anesthesia or intensive care
- Monitoring of a cardiac arrhythmia noted during anesthesia or hospitalization
- Evaluation of an animal with clinical signs suggesting syncope
- Evaluation of an animal with suspected or confirmed hyperkalemia

CONTRAINDICATIONS

Severe dyspnea contraindicates restraint in lateral recumbency for ECG.

EQUIPMENT, ANESTHESIA

- Electrocardiograph (ECG machine). Each ECG wire should end in an atraumatic clip that connects the machine to the animal's skin.
- A table with a waterproof foam-core pad on which the animal can lie comfortably (to reduce electrical interference emerging through the table)
- Isopropyl alcohol for improving contact between ECG clips and skin

ANTICIPATED TIME

- Basic tracing: 5 minutes
- Ongoing monitoring: any duration
- For prolonged monitoring, see Holter/Cardiac Event Monitoring, .

PREPARATION: IMPORTANT CHECKPOINTS

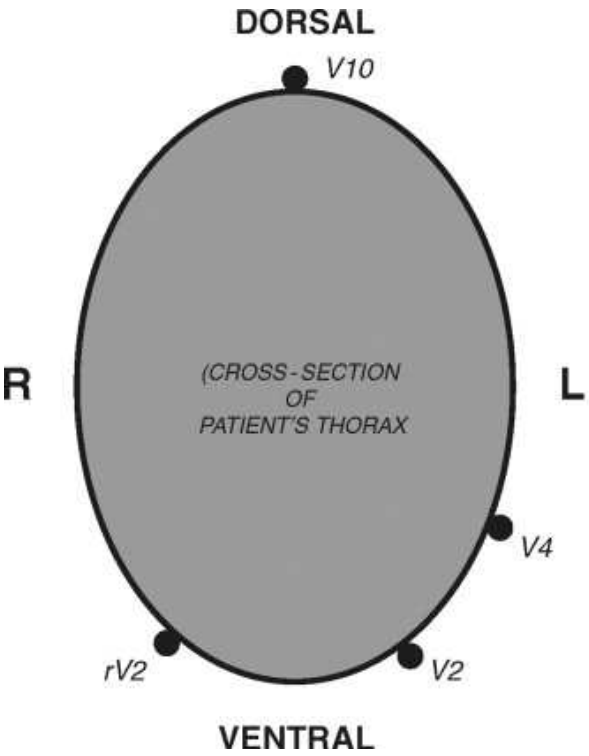
Check that the electrocardiograph has sufficient paper supply and is functioning. There is no ink in most electrocardiographs (heat-sensitive paper and thermal stylus).

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Animals that are in respiratory distress should not be restrained for electrocardiography; these animals should be assessed while they are standing (or in any other position in which they are not distressed), or the ECG should be postponed until dyspnea has improved or resolved.

- Artifact can be minimized by:
  - Using enough isopropyl alcohol at the point of contact between the skin clips and skin
  - Avoiding metal-on-metal contact between clips; often, with smaller dogs and cats, the wires need to be held apart by the person performing the ECG to avoid wire-to-wire or clip-to-clip contact during the procedure.
  - Choosing a quiet, comfortable environment to perform the tracing; a cold or stressful environment may trigger shivering (and motion artifact), whereas an excessively warm or stressful environment can induce panting in dogs (and motion artifact).
  - Replacing the ECG wire set every 5 years under all circumstances or annually with heavy use (e.g., used multiple times weekly) because the wires tend to fracture internally with age
  - Evaluating multiple ECG leads rather than just one lead; each lead provides a different perspective on the electrical activity of the heartbeat, and lead II is not necessarily the lead in which the clearest P waves, QRS complexes, T waves, and minimal artifact are seen.
- Overinterpretation of the dimensions of P waves and T waves as indicating cardiac chamber enlargement is a common pitfall; echocardiography is much more sensitive and specific than electrocardiography for assessing cardiac structure.
- Motion artifact may mimic abnormal cardiac activity and cause misdiagnosis.
- In-hospital monitoring that lasts for hours or more should involve the use of atraumatic or minimally traumatic skin clips: either (1) a small patch of skin can be shaved on each side of the thorax and stick-on, human ECG patches can be used or (2) loops of small-gauge steel suture may be passed through the skin in the usual locations on the four limbs, and the ECG wires are clamped to these loops instead of directly to the skin.

ELECTROCARDIOGRAPHY Patient is comfortably restrained in right lateral recumbency, with proximal long bones of the limbs perpendicular to long axis of body. Insulating (waterproof, foam core) pad and fleece blankets are under patient to reduce the influence of electrical interference.



AS WRITTEN ON CABLES (= HUMAN*)	VETERINARY TERMS (and previous vet nomenclature)	LOCATION ON THE PATIENT'S CHEST
V1	rV2 (CV5RL)	RIGHT 5TH INTERCOSTAL SPACE, JUST TO RIGHT OF STERNUM
V2	V2 (CV6LL)	LEFT 6TH INTERCOSTAL SPACE, JUST TO LEFT OF STERNUM
V3	V4 (CV6LU)	LEFT 6TH INTERCOSTAL SPACE, AT THE COSTOCHONRAL JUNCTION
V4	V10	DORSAL MIDLINE, DIRECTLY DORSAL TO V4 (APPROXIMATELY @ 7TH THORACIC VERTEBRA

* V5 and V6 are not used in veterinary medicine.

ELECTROCARDIOGRAPHY Placement and utility of precordial leads.

ECG Clip/Electrode Placement for Standard Limb Leads (I, II, III, aVR, aVL, aVF)

RA, white	Right forelimb; clip to skin just proximal to the olecranon (caudal triceps region).
LA, black	Left forelimb; clip to skin just proximal to the olecranon (caudal triceps region).
RL, green	Right hind limb; clip to skin just proximal to the stifle (cranial thigh); ground wire.
LL, red	Left hind limb; clip to skin just proximal to the stifle (cranial thigh).

PROCEDURE

- The procedure is the same for cats and dogs.
- Performing an ECG requires two people (clinician and assistant), unless animal restraint is not necessary (anesthetized or unconscious

animal).

- The assistant restrains the animal in right lateral recumbency. Sitting, sternal, and dorsal positions are equally acceptable; determination of the mean electrical axis from these other positions is inaccurate, but this has no effect on assessing the cardiac rhythm.
- The assistant stands or sits behind (dorsal to) the right-laterally recumbent animal and holds the animal's limbs perpendicular to the long axis of the animal's body. Note: For the humeri and femurs to be truly perpendicular to the long axis of the body, the assistant needs to extend the limbs sometimes quite substantially. Fore-limbs (at the level of the carpi) are held in the assistant's right hand and hind limbs (at the level of the tarsi) in the left.
- The clinician attaches the ECG clips (electrodes) to the appropriate points on the animal for the limb leads as well as the precordial leads.
- A standard ECG includes representative recordings from all six limb leads, usually 3-15 seconds each for I, II, III, aVR, aVL, and aVF, and will provide further information if precordial leads are also recorded.
- A standard ECG also includes a “rhythm strip,” which is a continuous tracing of the same lead for 12 seconds to 1 minute or more:
    - The most commonly used lead for the rhythm strip is lead II, but the lead that is chosen should be the one that shows the clearest P waves, QRS complexes, and T waves.
    - The duration of the rhythm strip depends on the reason for performing the ECG and can be as long as is needed (several minutes) when an intermittent arrhythmia is being sought.
- Generally, if an abnormality has not been detected over a period of 1-4 minutes of ECG recoding on paper, then the procedure is terminated. The tracing obtained thus far is reviewed meticulously, and if further ECG evaluation is needed, ongoing ECG monitoring either with an in-hospital display monitor (e.g., oscilloscope) or portable telemetry (see p.1287) can be used.

POSTPROCEDURE

The clips are carefully detached from the skin prior to releasing the animal's restraint.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Thoracic radiographs: provide some information on cardiac structure (e.g., chamber enlargement), but this information is limited by substantial overlap between normal and mild to moderate abnormalities. Also indicated when ST-segment elevation or depression is present (assess for pulmonary or airway lesions).
- Echocardiography: the clinical gold standard for assessing cardiac chamber size; indicated if cardiac enlargement is suspected based on ECG and/or radiographs
- Pulse oximetry/arterial blood gas measurement: if ST segment elevation or depression is noted in the absence of structural heart disease (e.g., cardiomyopathy, advanced valvular disease, congenital heart disease)
- Serum potassium measurement: if lack of P waves is noted, especially in an animal with a history and/or physical findings suggesting a reason for hyperkalemia (urgent)

AUTHOR: ETIENNE CÔTÉ

Echocardiography

SYNONYMS

Cardiac ultrasound; echo; transthoracic echocardiography

OVERVIEW AND GOALS

A complete echocardiographic study should:

- Reveal the pertinent acquired or congenital cardiac lesions
- Evaluate valvular function
- Quantify ventricular systolic and diastolic function
- Estimate the hemodynamic burden through quantification of chamber size (dilation, hypertrophy)

INDICATIONS

- Congenital or acquired cardiac disease (valvular, myocardial, pericardial), cardiac neoplasia, pulmonary hypertension, systemic hypertension, and pleural effusion or respiratory distress of uncertain etiology
- Limited echo studies can be useful in selected emergency situations (e.g., pericardial effusion, estimation of atrial size, or ventricular ejection fraction during initial stabilization if other initial diagnostic modalities are hazardous or nondiagnostic).

CONTRAINDICATIONS

- Animal should be stable enough to handle restraint.
- Animals with life-threatening problems (e.g., pleural effusion, pulmonary edema, and other causes of respiratory distress) need to be stabilized (limited echo study might be warranted or postponed).

EQUIPMENT, ANESTHESIA

- Scanning table with holes cut out because examination from beneath the animal improves image quality
- Ultrasonic transmission gel
- Isopropyl alcohol
- Hair clippers might be needed.
- Ultrasound equipment; sector-scanning transducers preferred:
    - For cats and small dogs (usually 7.0-8.0-MHz transducer), medium-sized dogs (5.0-MHz transducer), large dogs (2.5-3.5-MHz transducer)
    - It may be necessary to use two different probes during one examination.
- The echocardiography machine should have M-mode, two-dimensional (2D), Doppler (pulsed-wave, continuous-wave, and color-coded), and electrocardiogram (ECG) capabilities.
- Sedation/anesthesia is neither required nor desired except in very uncooperative animals.

ANTICIPATED TIME

Variable due to experience and case complexity (5-40 minutes).

PREPARATION: IMPORTANT CHECKPOINTS

- Dogs and cats usually require little preparation for echocardiographic examination.
- Fasting is not needed.
- Hair might be clipped over the right third to the sixth intercostal spaces (ICS) and left at the fourth to the seventh ICS (precordial transducer locations); however, in most dogs and cats, satisfactory images can be obtained by parting the haircoat, applying isopropyl alcohol liberally over area of interest, and finally applying transmission gel.

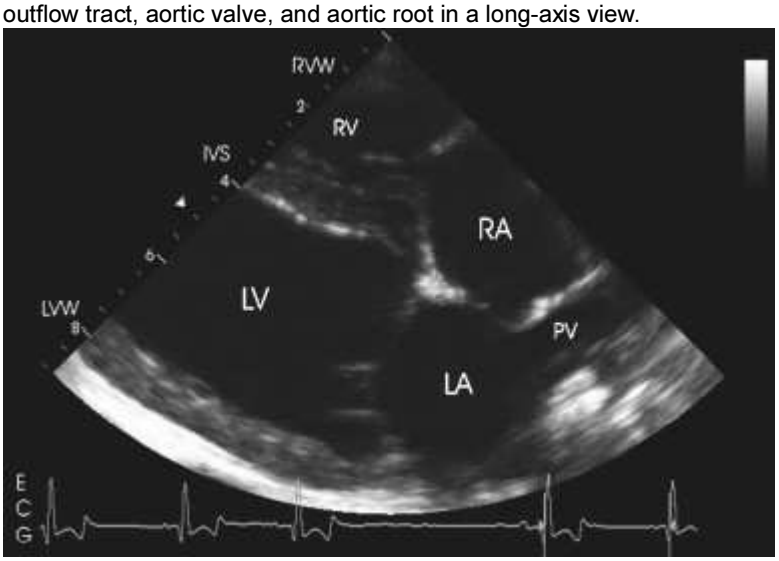
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Although the technique has no known physical hazard, there are risks associated with the improper interpretation or use of the results of the ultrasound.
- Use high-frequency transducers to obtain quality images of near-field structures.
- Use low-frequency transducers for quality Doppler (color, pulse wave, continuous wave) signals.

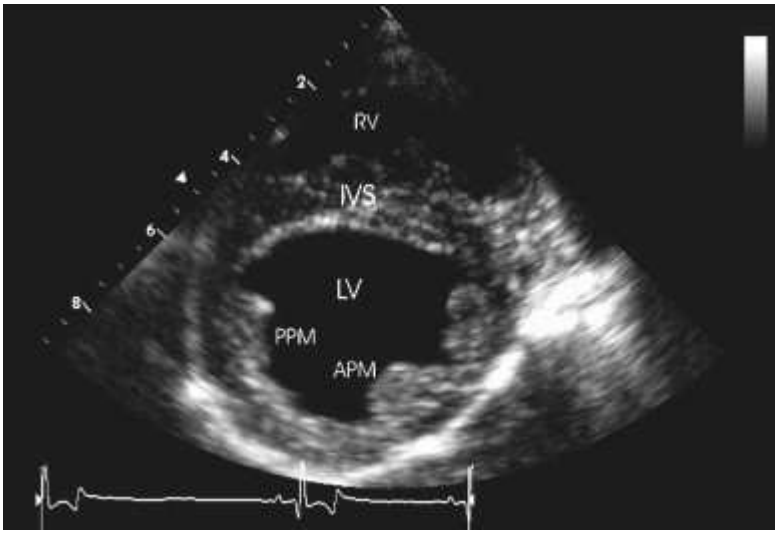
- Adjust depth of the real-time image to fill the field of view (reduce amount of lung field).
- Adjust gain to avoid producing a white, distorted image due to a high setting; too low a setting will produce a weak signal.
- Remember the concept of blue/away and red/toward (BART) for color-flow Doppler studies.

PROCEDURE

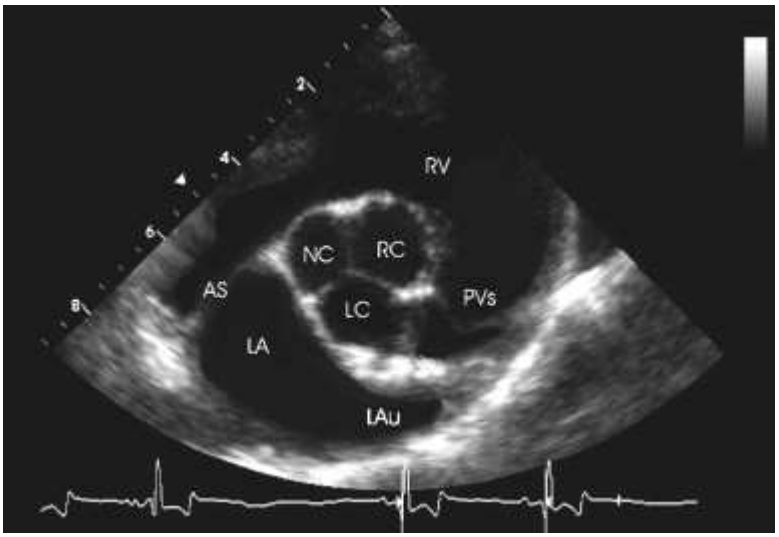
- Image quality is improved in lateral recumbency; however, dogs and cats may be examined in a standing, sitting, or sternal position.
- The ultrasound machine's ECG clips are attached to the legs as recommended by the manufacturer (ECG is used for measurements and timing within the cardiac cycle).
- Starting in right lateral recumbency (animal's legs toward the examiner), the right parasternal location (window) is between the right third and sixth ICS, between the sternum and costochondral junctions (landmark: palpate right precordial heartbeat and place transducer at this location to start). Attention is paid to having the assistant restrain the animal, with the forelegs drawn cranially to open the axilla/acoustic window.
- **Long-axis views**: The beam plane is oriented slightly clockwise from perpendicular to long axis of the body, parallel to the long axis of the heart, and with the transducer index mark pointing toward the heart base (craniodorsal, approximately toward the animal's shoulder). The following two views are obtained: first, a four-chamber view with the ventricles displayed to the left and the atria to the right; second, a view obtained by slight clockwise rotation of the transducer from the four-chamber view into a slightly more craniodorsal orientation revealing the left ventricular outflow tract, aortic valve, and aortic root.
- **Short-axis views:** Rotate the transducer about 90○ toward the sternum from the four-chamber view (keep probe in same position except for the rotation) such that the beam plane is oriented perpendicular to the long axis of the heart, with the transducer index mark now pointing cranially toward the animal's elbow (proper orientation identified by circular symmetry of the left ventricle or aortic root). There are five standard transverse images (left ventricle with papillary muscles, left ventricle at mitral chordae tendineae level, left ventricle at mitral valve level, heart base–aorta/left atrium level, and heart base–pulmonary artery) obtained from this position by pivoting the transducer from the apex to the base of the heart (caudal/ventral to cranial/dorsal).
- Turn animal over into left lateral recumbency, with the animal's legs still toward the sonographer.
- **Left caudal (apical) parasternal location:** The location is between the left fifth and seventh ICS, as close to the sternum as possible (landmark: palpable left apical heartbeat):
    - **Left apical two-chamber views:** The transducer index mark is pointing toward the heart base (dorsal), and the beam plane parallel to the long axis of the heart—the left side of the heart—is visualized (left atrium, left ventricle, and mitral valve). Slight rotation of the transducer into a craniodorsal to caudoventral orientation reveals left ventricle, outflow tract, aortic valve, and aortic root in a long-axis view.



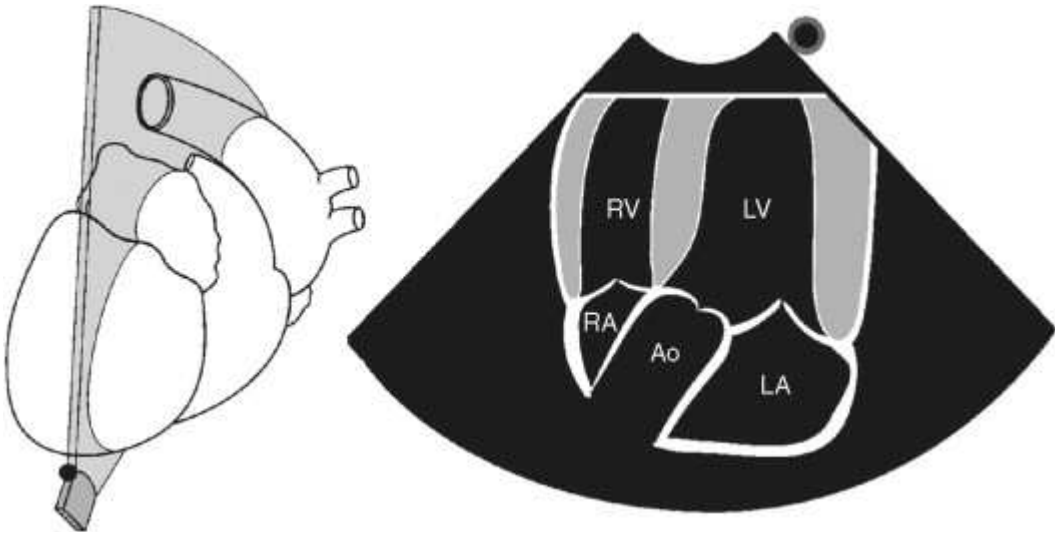
ECHOCARDIOGRAPHY Right parasternal four-chamber long-axis view in a normal dog (obtained without shaving). *IVS,* Interventricular septum; *LA,* left atrium; *LV,* left ventricle; *LVW,* left ventricular wall; *PV,* pulmonary vein; *RA,* right atrium; *RV,* right ventricle; *RVW,* right ventricular wall.



ECHOCARDIOGRAPHY Right parasternal short-axis view at the left ventricular papillary muscle level in same dog. From this view, gentle pivoting motion (caudal/ventral to cranial/dorsal) of the transducer beam toward the base will reveal the other four standard views obtained from this location. *APM,* anterior papillary muscle; *IVS,* interventricular septum; *LV,* left ventricle; *PPM,* posterior papillary muscle; *RV,* right ventricle.



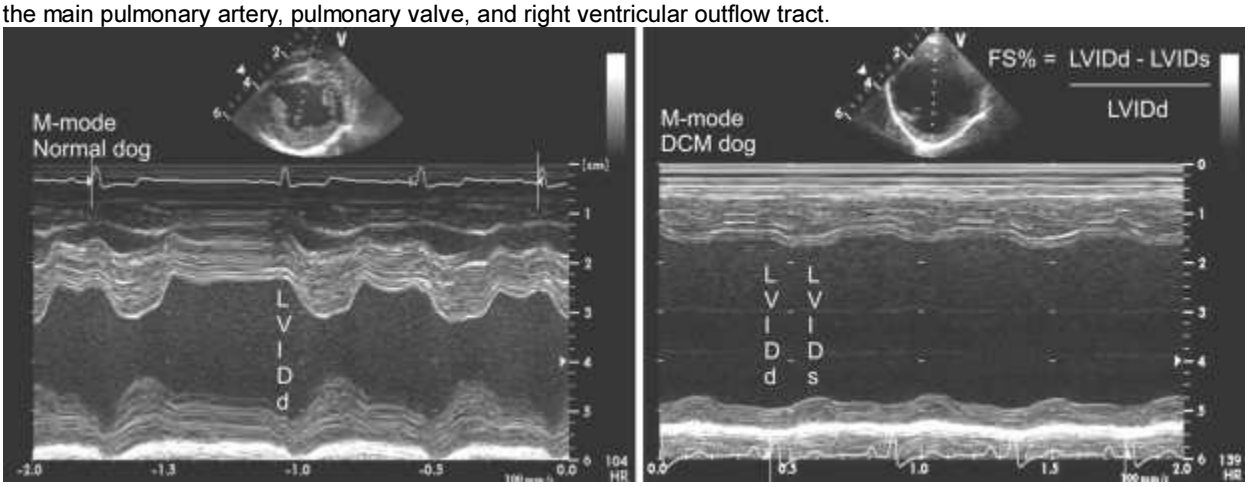
ECHOCARDIOGRAPHY Remaining in the same right parasternal window as the two previous views, gently pivoting toward the heart base, the right parasternal short-axis view at the left atrium/aorta level was obtained in the same dog. *AS,* atrial septum; *LA,* left atrium; *LAu,* left auricle; *LC,* left coronary cusp; *NC,* noncoronary cusp; *PV,* pulmonary vein; *PVs,* pulmonic valve; *RC,* right coronary cusp; *RV,* right ventricle.



ECHOCARDIOGRAPHY Five-chamber view is obtained at left apical parasternal location. Left apical parasternal location is the only time during echocardiographic examination when index mark on head of transducer is directed caudally. *Ao,* aorta; *LA,* left atrium; *LV,* left ventricle; *RA,* right atrium; *RV,* right ventricle.

- **Left apical four-chamber views:** This is the only view in which the transducer index mark is pointing to the left and caudally, opposite of all other views. Note: The transducer should be as far back toward the apex of the heart as possible, often around the seventh ICS, and tilted to point cranially. The beam plane is in a left-caudal to right-cranial orientation and then directed dorsally toward the heart base, revealing the ventricles in the near field closest to the transducer and the atria in the far field (heart is oriented vertically; left ventricle, mitral valve, and left atrium should appear to the right). Modest cranial tilting of the beam from the above view will bring the left ventricular outflow region into view (five-chamber view).

- **Left cranial parasternal location:** The location is between the left third and fourth ICS, between the sternum and costochondral junctions.
  - **Long-axis views:** With the transducer index mark pointing cranially and the beam plane oriented parallel to the long axis of the body and heart, a view of the left ventricular outflow tract, aortic valve, and ascending aorta is obtained (left ventricle will be displayed to the left and aorta to the right). From this position, angling of the beam ventral (toward the sternum) to the aorta brings out the right atrium/right auricle, tricuspid valve, and inflow region of the right ventricle (displayed to the right, while the left ventricle will be noted to the left). Finally, angling the transducer dorsally (transducer will almost be horizontal and parallel with the table) in relation to the ascending aorta produces a view of the main pulmonary artery, pulmonary valve, and right ventricular outflow tract.



ECHOCARDIOGRAPHY Two M-mode studies of left ventricle. *Left,* Normal dog shows vigorous excursions of the interventricular septum *(above)* and left ventricular free wall *(below)* from systole to diastole. The absolute diameter of the left ventricle is within normal limits. *Right,* Dog with dilated cardiomyopathy has visibly poor left ventricular systolic function (almost no difference between systole and diastole) and a very enlarged left ventricular diameter compared to normal.

LVIDd, left ventricular internal diameter in diastole; LVIDs, left ventricular internal diameter in systole; FS%, fractional shortening.

  - **Short-axis views:** Remain in the same location as for the cranial long axis, and rotate the transducer until the transducer's index mark is toward the thoracic spine (dorsally, about 90○ from the location of long-axis view; aorta should appear circular in the center of the image). The right ventricular inflow tract should be to the left, and outflow tract and pulmonary artery to the right.

POSTPROCEDURE

- Remove ECG clips.
- Wipe gel and alcohol from animal.

ALTERNATIVES AND THEIR RELATIVE MERITS

Transesophageal echocardiography:

- Semi-invasive procedure
- Requires general anesthesia in animals
- Provides superb clarity and resolution

Foreign-Body Removal, Esophageal (Endoscopic)

SYNONYM

Minimally invasive removal of esophageal foreign bodies

OVERVIEW AND GOALS

- Objects causing esophageal obstruction are most commonly found in one of three locations: at the thoracic inlet, at the level of the base of the heart, or immediately cranial to the gastroesophageal sphincter.
- About 90% of foreign bodies obstructing the esophagus can be removed without performing a thoracotomy. An attempt should be made to try to remove these foreign bodies via esophageal endoscopy in order to avoid surgery and its complications (e.g., difficult access, limited healing ability, and associated morbidity). Removal of these objects is achieved by making use of rigid or flexible endoscopes.
- If a foreign object cannot be removed via the oral route, an attempt can be made to pass the object through into the stomach using a large-bore stomach tube and copious lubrication, provided complications such as esophageal perforation (from a sharp-edged foreign body, esophageal wall devitalization, or overly aggressive forward pressure) are avoided. Objects passed from the esophagus into the stomach may then be removed via a gastrotomy or left to be digested (in the case of bones and other digestible objects).

INDICATIONS

Presence of foreign objects lodged in the esophagus (e.g., bones, fishhooks, needles, toys, partially regurgitated hair balls)

CONTRAINDICATIONS

Esophageal perforation is an absolute contraindication to minimally invasive approaches; thoracotomy is indicated in these cases.

EQUIPMENT, ANESTHESIA

- General anesthesia
- Cuffed endotracheal tube
- Mouth gag/speculum
- Rigid tube for esophageal dilation (optional); typical external diameters are 2 cm (cat, small dog), 3 cm (medium-size dog), and 4 cm (large dog). The end of the tube should have smooth edges (may heat with flame, then trim edges when cool before using).
- Rigid proctoscope or flexible fiberoptic endoscope
- Endoscopic basket or grasping forceps (recommended) or endoscopic biopsy forceps (second choice)
- Water-soluble lubricating jelly
- Polyethylene catheter or feeding tube (optional)
- Suctioning apparatus

ANTICIPATED TIME

Approximately 20-90 minutes, depending on size of object and ease with which it can be grasped, atraumatically dislodged, and retrieved

PREPARATION: IMPORTANT CHECKPOINTS

- Assess for location of foreign body, presence of signs of aspiration pneumonia, and evidence of esophageal perforation by performing survey and contrast radiography using low osmolality, nonionic contrast medium. Radiographs should be performed or repeated immediately prior to induction of general anesthesia to avoid anesthetizing an animal in which a foreign body has spontaneously passed into the stomach.
- Endoscopic evaluation of location of foreign body and state of esophageal mucosa
- Ensure adequate hydration and perfusion.
- Antibiotic therapy if indicated by complications (described in following paragraphs); often empirically at first (e.g., ampicillin, 22 mg/kg IV q 8 h; and enrofloxacin, 5 mg/kg diluted 1:1 in 0.9% saline and given slowly IV q 24 h [cats] or q 12 h [dogs]) and then guided by results of culture and sensitivity (C&S).

- Advise the owner of possible complications.
    - There may be a need for emergency thoracotomy if perforation occurs or if removal via the oral route is impossible; possible gastrotomy may result if the foreign body has to be pushed through into the stomach and is unlikely to be digested.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Esophageal mucosal trauma (erosion, ulceration)
- Esophageal perforation, pyothorax, pleuritis, mediastinitis
- Aspiration of esophageal contents and aspiration pneumonia
- Tension pneumothorax (associated with esophageal insufflation when using flexible fiberoptic endoscope)
- Bradycardia due to vagal stimulation
- Sepsis (due to aspiration or to esophageal rupture)
- Esophageal stricture (first clinical manifestations usually >2 weeks postoperatively)
- Bronchoesophageal fistulation (rare)
- Failure to radiograph immediately prior to induction (foreign body may have passed spontaneously)

PROCEDURE

- General anesthesia
- Place endotracheal tube and inflate cuff to prevent aspiration of esophageal contents.
- Animal in sternal or left lateral recumbency (allows the esophagus to lie over the aorta)
- Examine the mouth (especially the sublingual region) for the presence of objects such as thread, needles, or fishhooks.
- Suction esophagus to remove any liquid contents and contrast medium.
- Insert mouth gag/speculum.
- Rigid proctoscope technique:
    - Lubricate proctoscope.
    - Pass the proctoscope orally and into the esophagus to the level of the foreign body, visualizing the foreign body and any evidence of perforation that would contraindicate further endoscopic manipulations.
    - Lubricant can be placed at the site of the foreign body, using a polyethylene catheter with the tip placed at the level of the foreign body, between the foreign body and esophageal mucosa.
    - Using grasping forceps, bring the foreign body close to the end of the proctoscope.
    - If the foreign body is small enough, it can be partially or entirely pulled into the lumen of the proctoscope.
    - The foreign body, proctoscope, and grasping forceps are pulled out together via the mouth by gentle manipulation and with adequate lubrication. Continuous visualization and gentleness of traction are essential through this process. This is to ensure that complications such as esophageal laceration or perforation are noticed immediately if they occur, that the retrieval can be stopped immediately, and that the foreign body be repositioned or the procedure be aborted in favor of thoracotomy if serious complications are noted.
    - If retrieval is not possible, an attempt should be made to gently push the foreign body through to the stomach using a well-lubricated stomach tube, provided no evidence of esophageal devitalization (e.g., deep mucosal lacerations and discolorations or other signs of possibly imminent perforation) are seen.
    - Careful examination of the esophageal wall after foreign body removal; any suspicion of possible esophageal perforation warrants close radiographic and clinical monitoring.
- Flexible fiberoptic endoscope technique:
    - For medium-size or larger dogs, a rigid tube can first be placed to assist in dilating the esophagus. The endoscope can then be passed through this tube.
    - Lubricate the endoscope.
    - Pass the endoscope to the level of the foreign body, visualizing the foreign body and assessing the integrity of the adjacent esophagus.

FOREIGN-BODY REMOVAL, ESOPHAGEAL (ENDOSCOPIC) A 1-m flexible fiberoptic endoscope. This endoscope is adequate for esophageal procedures in dogs and cats of all body sizes.

FOREIGN-BODY REMOVAL, ESOPHAGEAL (ENDOSCOPIC) Large *(top)* and two small *(below)* rigid proctoscopes, used for retrieving esophageal foreign bodies, and small proctoscopic stylet *(bottom)*. Stylet is placed into proctoscope for advancing into esophagus. Once desired degree of insertion is achieved, stylet is withdrawn, and glass port (seen in the open position in the large proctoscope, *top*) may be closed for most effective visualization.

FOREIGN-BODY REMOVAL, ESOPHAGEAL (ENDOSCOPIC) Operator *(left)* examines esophagus of an animal, using a flexible fiberoptic endoscope; assistant adjusts endoscope's insertion and rotation according to operator's instructions.

- Insufflation of air will allow dilation of the esophagus around the foreign body. This may also be useful in dislodging foreign bodies such as bones that are embedded in the esophageal wall.
- Lubrication can also be placed at the site of the foreign body, using a catheter or feeding tube as already described.
- Grasping forceps or biopsy forceps can be passed through the endoscope biopsy channel. The use of biopsy forceps is a last resort, because dulling and damage to the instrument are possible.
- Grasp the foreign body, and pull it close to the endoscope.
- The endoscope, forceps, and foreign body are gently pulled out together via the mouth while ensuring adequate esophageal dilation and lubrication.
- If the foreign body is lodged to the extent that it cannot be retrieved easily, an attempt could be made to either slightly push it aborally or to rotate it gently. If the maneuvers result in dislodging the object, another attempt can be made to retrieve it.
- If retrieval is not possible, an attempt should be made to push the foreign body through to the stomach.
- The esophageal mucosa is carefully examined endoscopically after removal of the foreign body.

POSTPROCEDURE

- If esophageal mucosa is damaged (e.g., suspected on endoscopic observation of darkened/discolored esophageal mucosa, deep mucosal lacerations, or after prolonged, difficult procedure; confirmation comes from intraprocedure or postprocedure radiographs):
  - Clean lacerations that do not extend through the full thickness of the esophageal wall can be left to heal by epithelialization.
  - Full-thickness tears and areas of esophageal necrosis require immediate surgical resection or repair.
- Withhold food and water for 24 hours.
- Maintain hydration and electrolyte balance.
- Pain management: antibiotics (as already described), prokinetic agents, corticosteroids, and/or gastric antacids may be indicated (see pp. 365 and p. 367).
- Gastrostomy feeding tube placed distal to the site of the foreign body if prolonged withholding of food is indicated (such as in cases of esophageal mucosal damage).
- Once the animal has recovered, first introduce liquids, followed by gruel if no adverse reactions are noted once liquids have been introduced.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Advancement of foreign body into stomach followed by gastrotomy:
  - If a foreign body is too large or awkward to grasp, an attempt could be made to gently push it through into the stomach. Digestible objects such as bones could be left in the stomach to digest, but sharp objects and objects such as toys should not be pushed into the stomach (risk of esophageal perforation). Follow-up radiography is advised to ensure that foreign bodies were either digested or passed through the digestive tract.
- For cases in which esophageal perforation and its complications have already developed (see p. 363), surgical removal of the foreign body via thoracotomy is the only alternative.

AUTHOR: MIRINDA NEL (VAN SCHOOR)

Fistulogram

SYNONYM

Positive-contrast fistulogram

OVERVIEW AND GOAL

Fistulograms are radiographic contrast procedures that may be utilized in the evaluation of a cutaneous draining tract.

INDICATIONS

- Identify soft-tissue foreign bodies (e.g., splinters, plant awns, glass)
- Locate potential source of a draining tract (e.g., orthopedic implants, sutures)
- Identify communication of tract with body cavity or organ

CONTRAINDICATIONS

Known sensitivity to contrast media

EQUIPMENT, ANESTHESIA

- Contrast media:
  - Ionic or nonionic organic iodinated contrast agents
- Catheters:
  - Variable length and size depending on extent of lesion
  - Preferably semirigid without balloon tip, such as a tomcat catheter; no stylets
- Sedation/anesthesia may be required for fractious animals.

FISTULOGRAM Lateral radiographic projection of torso of a dog prior to contrast injection. There is a suggestion of minor radiopacity in dorsal body wall dorsal to location of a draining tract.

(Courtesy Dr. Phil Gill.)

ANTICIPATED TIME

About 5–20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Sedation/anesthesia if required
- Hair clipped and area scrubbed/disinfected
- Survey radiograph of region

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Systemic reaction to contrast agents (rare)
- Local irritation from hypertonic contrast agents (rare; can dilute with saline or sterile water for prevention)
- Leakage of contrast into fascial planes leading to nondiagnostic study (common)
- Inability to follow full extent of draining tract (common)
- Masking of small foreign bodies by opacity of contrast agent (common)

PROCEDURE

- Catheter is placed retrograde into draining tract as far as possible.
- Injection (usually 1-12 mL) while catheter in place or while drawing it back out
- Appropriate radiographic projections; two views at right angles are usually sufficient.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Ultrasound:
  - Easy to perform
  - Variable information obtained; may detect foreign bodies
  - Difficult to follow extent of tract
- CT scan and MRI:
  - Expensive
  - Variable information obtained

FISTULOGRAM Lateral radiographic projection of same dog after contrast injection into a cutaneous draining tract on lateral thorax. Study shows extent of draining tract, with pooling of contrast media in dorsal body wall. Filling defect in contrast-filled tract created by catheter.

(Courtesy Dr. Phil Gill.)

AUTHOR: BRETT KANTROWITZ

Fine-Needle Sampling for Cytologic Analysis: Lung

OVERVIEW AND GOALS

Minimally invasive diagnostic tool with a good diagnostic yield for focal lesions. Good technique increases the diagnostic yield and reduces complications.

INDICATIONS

- Pulmonary masses and nodules
- Areas of pulmonary consolidation
- Lower diagnostic yield and greater risk to animal for diffuse (interstitial) pulmonary diseases

CONTRAINDICATIONS

Bleeding disorders (coagulopathy, thrombocytopenia, thrombocytopathia)

EQUIPMENT, ANESTHESIA

- A few sterile 22-gauge needles (1-3½" [2.5-9 cm])
- A 12-mL syringe
- A standard 33" (84-cm) flexible extension set for IV lines
- Glass slides
- Blow dryer
- Image guidance if possible (ultrasound, CT scan, fluoroscopy, radiology)
- General anesthesia is recommended to reduce risks of pulmonary lacerations and pneumothorax.

ANTICIPATED TIME

About 30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Warn owners that hemorrhage and pneumothorax are possible complications, warranting intensive care and sometimes presenting a life-threatening situation.
- Rule out bleeding disorders.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Hemorrhage (pulmonary, pleural, airways)
- Pneumothorax
- Proceeding too slowly. While the procedure must be prepared for and carried out carefully, time is of the essence during fine-needle sampling. Tissue trauma activates coagulation, which can rapidly plug the needle or degrade the quality of the sample.
- Short and slow needle passes. A slow or timid back-and-forth motion does not detach a sufficient number of cells. The needle tip, however, must remain within the target tissue during this part of the procedure to avoid contamination by, or damage to, surrounding tissues.
- Changing directions while the needle is deep in the lesion causes shearing of tissue, lung lacerations, bleeding, and pain. The needle should always be withdrawn to the skin's surface (almost out but not quite) before being redirected.
- Aspiration. When aspiration is used in the lungs, air is aspirated as soon as the bevel enters an air-filled space, and the sample is lost in the syringe or extension set. A vigorous back-and-forth motion without aspiration is sufficient to detach cells, create mild bleeding, and fill the needle with a diagnostic sample.
- Multiple sites. An important point is to obtain three to five cellular biopsies of different areas of large lesions, because masses or large lesions may contain a mixture of necrotic, inflamed, hemorrhagic, neoplastic, and normal tissues.
- Nondiagnostic samples. With experience, a clinician can identify cellular smears with the naked eye. If the smear does not appear cellular, the procedure should be repeated. If there is any doubt, the sample can be evaluated immediately by in-house microscopic examination.

PROCEDURE

- Induce general anesthesia, including endotracheal intubation.
- Clip the hair from the sampling site(s), and prepare the site with surgical scrub.
- Connect extension set between syringe and needle.
- Fill syringe with 5-10 mL of air.
- The clinician hangs the syringe and extension tubing around his or her neck (like a stethoscope) and holds the needle like a pen to allow precise manipulations.
- Localize lesion with diagnostic imaging. Fine-needle procedures guided only by radiographs can be performed on large masses or when large areas of the lungs are affected. Note: Sonographic guidance works only if the mass, nodule, or consolidated lobe is in contact with the thoracic wall.
- Rapidly position the needle tip within the lesion. Avoid keeping the needle tip close to pleural surfaces, to reduce lacerations during respiratory motion.
- Move the needle rapidly back and forth using long needle passes (away from major blood vessels), and try staying within the lesion. Do not use negative pressure.
- Rapidly withdraw the needle.
- Immediately expel the sample on glass slides using the air-filled syringe.
- Make smear using the standard blood smear technique or a gentle squash technique.
- Immediately air-dry the smear with a blow dryer.
- Repeat the procedure to obtain two to three cellular smears of the lesion(s).

POSTPROCEDURE

Risks of pneumothorax are significantly reduced (5% versus 40%-50%) if the animal is kept in lateral recumbency (biopsy side down) for 30-60 minutes following the procedure. If the animal is stable, keep under anesthesia 15-20 minutes after the procedure. This simple precaution takes advantage of recumbency atelectasis to rapidly seal any lung perforations or lacerations.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Tru-Cut or core biopsy:
  - May be associated with more complications
  - May be more accurate for diffuse pulmonary diseases
- Bronchoscopy/bronchoalveolar lavage:
  - Minimally invasive: lowest risk of iatrogenic pneumothorax
  - Requires disease process that is exfoliating cells into the alveoli or airways (e.g., useful for lung consolidation due to pneumonia), so false negatives are possible.
- Surgical biopsy:
  - More costly
  - More invasive
  - Most definitive diagnostic sampling technique for diffuse (interstitial) pulmonary diseases

AUTHORS: MARC PAPAGEORGES, MICHÈLE MENARD

Fine-Needle Aspirate, Ultrasound-Guided

SYNONYM

Needle biopsy

OVERVIEW AND GOAL

Procedure to obtain small tissue or fluid samples using ultrasound guidance and real-time monitoring of needle placement

INDICATIONS

- Ultrasonographic evaluation of focal mass lesion or nodule
- Ultrasonographic evaluation of diffuse or focal parenchymal organ abnormalities
- Drainage of cysts, abscesses, or fluid

CONTRAINDICATIONS

- Cavitated mass: risk of hemorrhage
- Bleeding disorder: risk of hemorrhage
- Suspected transitional cell carcinoma: possibility of seeding tumor along needle tract

EQUIPMENT, ANESTHESIA

- A few 22- or 25-gauge standard sterile injection needles, 1½ inches (4 cm) in length:
  - Longer needle (3½ inch [9 cm]) required if using biopsy guide
- A few 6-mL syringes
- Glass microscope slides
- Hair clippers
- Surgical scrub, rubbing alcohol, gauze
- Sector or linear-array ultrasound transducer
  - Sector transducers allow sampling of deep structures
  - Linear-array transducers provide better resolution of superficial structures.
  - ± Biopsy guide: easiest method, but angle of needle insertion is fixed.
  - Sedation often not needed for fine-needle aspirate (FNA)
  - Occasionally, IV or gas anesthesia required (e.g., anxious animal, small structure in close proximity to large vessel)

ANTICIPATED TIME

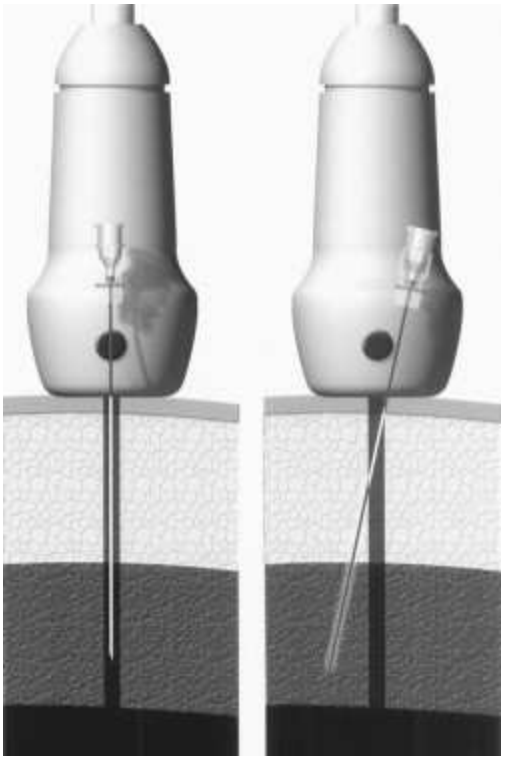
About 5-10 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Perform coagulation profile, platelet count, and arterial blood pressure (BP) measurement if animal is at an increased risk of bleeding.
- Determine if sedation is required; place IV catheter if needed.
- Ensure proper animal restraint.

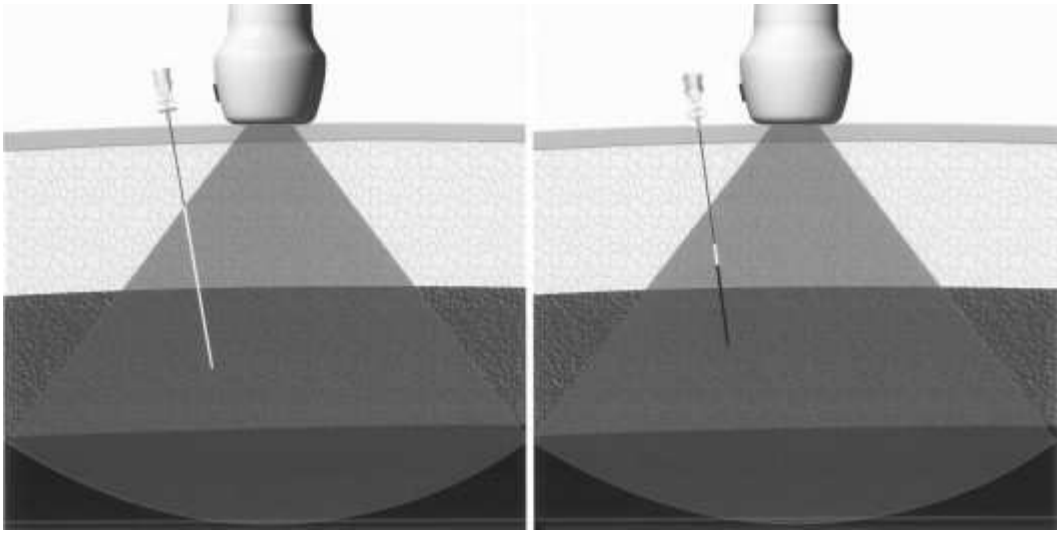
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- To decrease hemodilution, avoid the suction method in sampling vascular organs (e.g., spleen).
- Identify and avoid large vessels within the organ being sampled or those adjacent to the structure (e.g., aorta adjacent to lymph node).
- Hemorrhage is uncommon if 22- or 25-gauge needle is used and the movement of the needle through the entire procedure is one-dimensional (in and out only, with no side-to-side motion).



FINE-NEEDLE ASPIRATE, ULTRASOUNDGUIDED Importance of correct alignment between needle and ultrasound probe. *Left*, Correct alignment is present, and full extent of needle is seen. *Right*, Needle is not aligned with ultrasound beam, and only proximal portion of needle is seen. Here, trauma to deeper tissues is possible because location of needle tip is unknown.

(Reprinted from Fife WD: Abdominal ultrasound: aspirations and biopsies. In Ettinger SJ, Feldman EC, editors: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders, pp 271-275.)



FINE-NEEDLE ASPIRATE, ULTRASOUND-GUIDED Views as seen on monitor of ultrasound machine, perpendicular to other figure. *Left*, Correct alignment produces complete visualization of needle. *Right*, Probe/needle malalignment underrepresents depth of needle.

- Do not move the needle side to side within an organ, because this will cause tissue trauma.
- If redirecting needle orientation, withdraw needle tip to subcutis and then reinsert. Redirecting with needle fully advanced is ineffective (position changes little or not at all) and dangerous (shearing of tissue with needle tip).
- Cells may dry and clot in the needle very quickly. Therefore, when the needle is withdrawn, the expulsion of needle contents onto a microscope slide and the slide smearing technique should all be completed within seconds.
- Avoid penetrating bowel lumen, especially with larger gauge needles, because of risk of peritonitis.
- Sample the left aspect of the liver when possible to avoid the gallbladder and hilar vessels on the right. If the liver is small or cranially located, consider an intercostal approach.
- With renal aspirates, sample the caudal cortex of the kidney to avoid the medulla and hilar vessels.

- In cases of bilateral renal abnormalities, the left kidney should be sampled owing to its more caudal location.
- Do not pass through an organ other than the one being aspirated.
- Avoid administering drugs that cause splenomegaly or panting (e.g., phenothiazines, some opiates).
- If aspirating an adrenal gland mass, be aware of possible BP alterations and severe hemorrhage in the case of pheochromocytoma.

PROCEDURE

- Restrain the animal in dorsal or lateral recumbency. A padded U-shaped trough can be used for the animal so that it is more comfortable when lying down (see p. 1236).
- Clip hair from the ventral abdomen.
- Thoroughly evaluate area of interest, characterize lesion, identify adjacent or internal vessels to be avoided, and determine least traumatic location and direction of needle placement.
- Prepare skin with surgical scrub.
- Obtain ultrasound image of area to be sampled.
- Ensure probe marker location on screen corresponds with desired needle course.
- Freehand technique: hold transducer in one hand, and insert needle with other.
- The suction technique is useful in aspirates of less vascular structures (e.g., lymph node) but often results in hemodilution when aspirating vascular organs like the spleen.
    - Without syringe suction:
        - Introduce a 22- or 25-gauge needle parallel to plane of ultrasound beam, visualizing needle as it is advanced.
        - Slowly fan transducer side to side to identify entire needle length to tip.
        - Advance and retract needle three to four times to fill needle shaft with tissue cells. If using a spinal needle, remove the stylet before beginning the advancing and retraction of the needle.
        - Withdraw needle from animal, and quickly attach a 6-mL syringe prefilled with 5 mL room air.
        - Expel contents onto microscopic slide(s) immediately, and lightly smear using standard blood smear technique.
    - With syringe suction:
        - Attach 6-mL syringe to 22- or 25-gauge needle.
        - Introduce needle parallel to plane of ultrasound beam, as already described.
        - Apply suction to syringe three to four times while gently advancing and retracting needle.
        - Disconnect syringe and withdraw needle from animal.
        - Retract plunger to fill syringe with air, and reconnect syringe to needle.
        - Expel contents onto microscopic slide(s) immediately, and lightly smear using standard blood smear technique.
- Multiple samples of each organ or lesion should be obtained.

POSTPROCEDURE

Scan to evaluate for hemorrhage (very uncommon with this procedure).

ALTERNATIVES AND THEIR RELATIVE MERITS

Tissue-core and surgical biopsy are more invasive but of greater diagnostic quality because of the ability to collect larger tissue samples.

Feeding Tube Placement: Percutaneous Endoscopic Jejunostomy (PEJ)

Client Education Sheet Available on Website

SYNONYMS

Percutaneous endoscopic-assisted placement of jejunostomy feeding tube; percutaneous gastrojejunostomy feeding tube

OVERVIEW AND GOALS

Placement of a jejunal feeding tube using endoscopic assistance, rather than laparotomy or laparoscopy, to provide postgastric enteral feeding to nutritionally deficient or debilitated animals. The jejunostomy tube is placed using a concurrent/existing percutaneous gastrostomy (PEG) tube. Use of percutaneous endoscopic jejunostomy (PEJ) is uncommon because of the relative cost and stocking of supplies, inexperience, and infrequency of needs that are not accommodated by surgical or laparoscopic-assisted placement of jejunal feeding tubes. Enteral feeding provides the advantage of improved overall metabolism and health of the intestinal tract. Enteral feeding reduces intestinal bacterial translocation, maintains glutamine synthesis, and improves and maintains gut immunologic barrier functions.

INDICATIONS

- Postgastric feeding is advised for animals with uncontrolled vomiting from any cause.
- Following gastric or biliary surgery
- Pancreatitis
- Disorders causing persistent gastroparesis (e.g., following intestinal surgery)
- Animals at increased risk of active or passive gastroesophageal reflux and aspiration (e.g., prolonged recumbency, pharyngeal dysfunction, laryngeal paralysis, altered mentation)

CONTRAINDICATIONS

- Unresolved peritonitis
- Anesthetic risks
- Large-volume peritoneal effusion

EQUIPMENT, ANESTHESIA

- General anesthesia is required, with endotracheal intubation.
- Postprocedural analgesia
- Mouth gag
- Sterile water-soluble lubricant for endoscope passage
- Supplies as needed to place percutaneous endoscopic gastrostomy (PEG) tube (see p. 1270)
- 2-0 monofilament suture material
- Iohexol as water-soluble radiographic contrast agent
- Flexible video or fiberoptic endoscope and ancillary equipment appropriate to size of animal (generally 7-9 mm diameter with 100 cm length is acceptable for most cases).
- Endoscopic snare or grasping forceps
- Vacuum source for endoscopic suction
- PEG tube that is 18-24 Fr in diameter, as a kit with PEJ or as a separate item (e.g., Pezzer mushroom-tip catheter)
- PEJ tube that is 6-12 Fr in diameter (e.g., Wilson-Cook Medical, Global Veterinary Products, Compat brand by Novartis) and 35-150 cm in length; PEJ kits with gastrostomy tubes are also available (e.g., Mila International Inc. Medical Instrumentation for Animals); variable diameters and lengths based on supplier and animal size; internally coated catheters have an internal lubricant that activates when flushed with sterile water; 1 mm = 3 Fr.
- Weighted PEJ tubes are less commonly used; they have a tungsten bulb at the tip that adds weight to help prevent migration of the tube back to the stomach; these are preferred by some endoscopists and not by others.
- A 0.021- to 0.037-mm (50-150 cm) flexible guide wire matched to selected PEJ feeding tube
- Fluoroscopy is preferred to be available, especially while staff is learning the technique. Flash (then saved) images on the preview monitor of digital radiographic equipment can help in identifying the location of the distal tip of the PEJ if fluoroscopy is not available.
- Elizabethan collar or other restraint to prevent patient's removal of PEJ or PEG tubes
- Orthopedic stockinette appropriate to size of animal to create a “sweaterlike” effect

ANTICIPATED TIME

About 40-80 minutes (including placement of PEG tube)

PREPARATION: IMPORTANT CHECKPOINTS

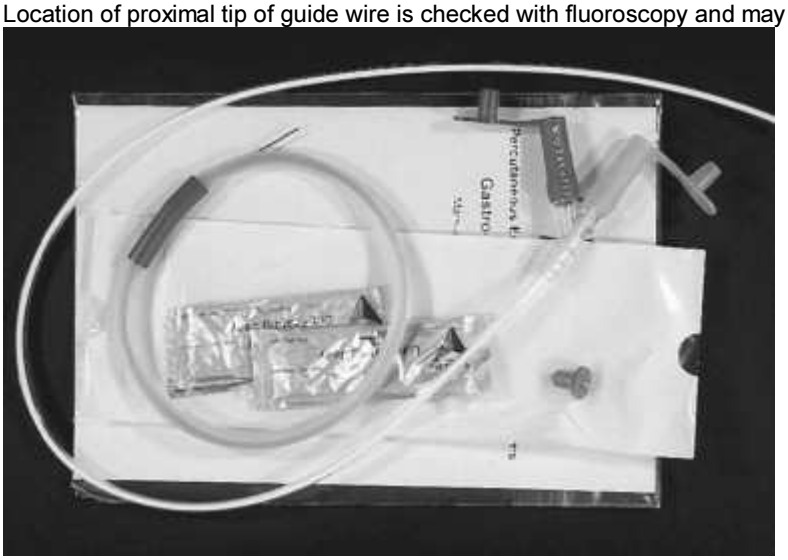
- Test or check integration of guide wire, PEG tube, and PEJ tube for compatibility of diameters and lengths.
- Plan for coordination of staff regarding anesthesia, endoscopy, and fluoroscopy/radiography.
- Discuss with client the potential that the PEJ tube may become occluded or may migrate back to stomach despite best efforts and cost of catheters.
- Check or estimate the fill volume of catheter prior to placement.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Stoma site infection
- Premature removal by animal of tube (teeth, rubbing on objects in environment)
- Peritonitis if adhesion of body wall to stomach breaks down
- Diarrhea induced by feeding enteral formula
- Reflux of enteral feeding product aborally
- PEJ tube migration back to the stomach and possible vomition of the tube aborally
- Complications occur with about the same frequency as with use of PEG tubes.

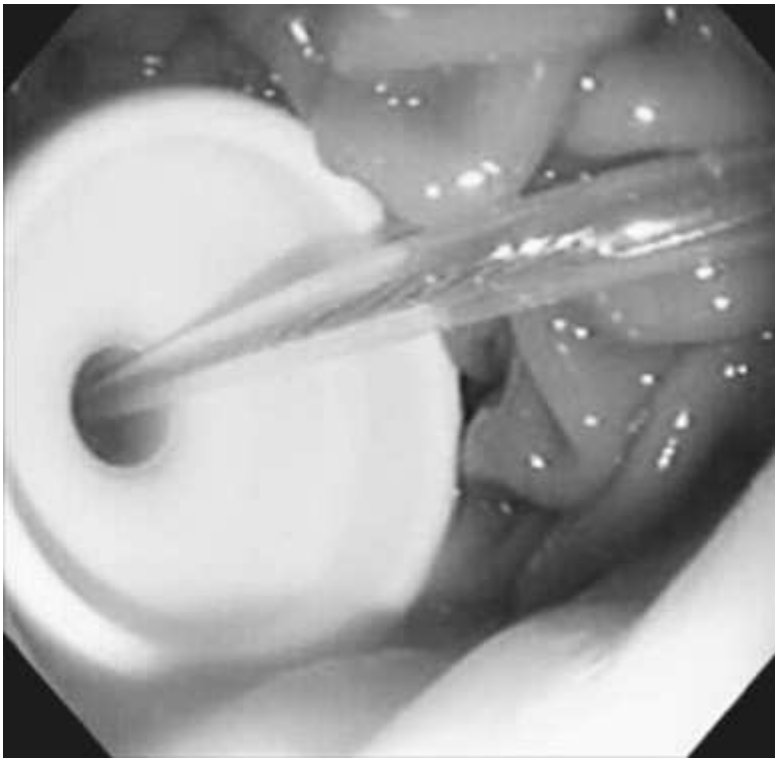
PROCEDURE

- Clip and prep left side of animal from approximately the eighth intercostal space (ICS) to just cranial to the stifle and from dorsal spinous process to ventral midline.
- General anesthesia, with endotracheal intubation
- Animal is positioned in right lateral recumbency.
- A PEG tube is placed (see p. 1270).
- Endoscope is passed to stomach from oral cavity.
- A snare or retrieval basket is passed via the gastrostomy (PEG) tube to the stomach.
- Endoscope is then maneuvered through the snare or basket.
- Pylorus is then visualized, and the endoscope is passed through to the mid-duodenum.
- Guide wire is passed via the operating channel of endoscope and continued forward blindly along the lumen of the small intestine until it is estimated that the tip is located in the proximal third of the jejunum.
- Guide wire is fed through the endoscope while the endoscope is slowly withdrawn from the body; the position of the guidewire in the body remains the same.
- Guide wire should then be in the center of the snare or basket. This is tightened and withdrawn via the gastrostomy (PEG) tube to the exterior so as to pull guide wire through the gastrostomy (PEG) tube (proximal tip is in jejunum, and distal end extends out the gastrostomy tube).
- Location of proximal tip of guide wire is checked with fluoroscopy and may be adjusted in position.



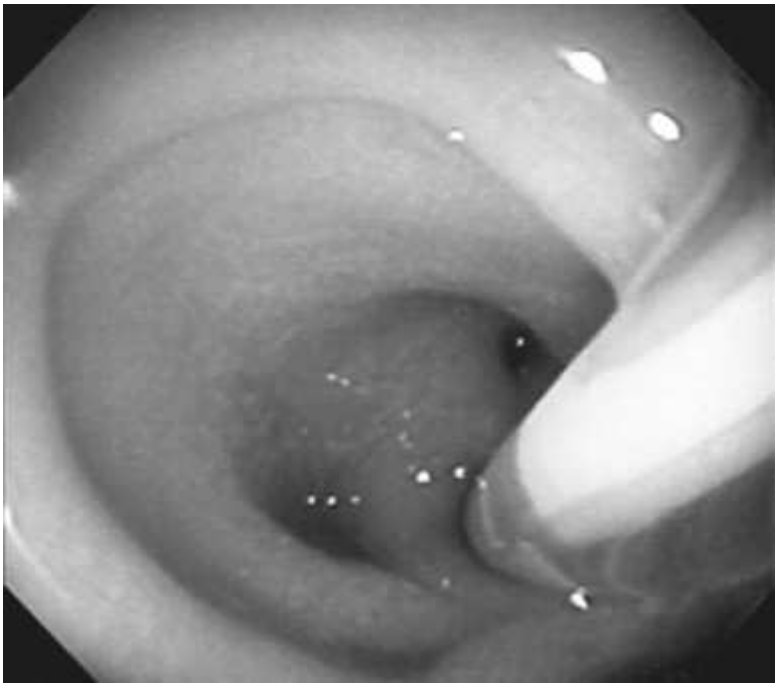
FEEDING TUBE PLACEMENT: PERCUTANEOUS ENDOSCOPIC JEJUNOSTOMY (PEJ) Endoscopic image. Luminal view of stomach, showing gastrostomy/PEG tube with jejunostomy/PEJ tube inserted.

(Courtesy Dr. Al Jergens.)



FEEDING TUBE PLACEMENT: PERCUTANEOUS ENDOSCOPIC JEJUNOSTOMY (PEJ) Gastrojejunostomy combined kit from Wilson-Cook.

(Courtesy Dr. Al Jergens.)



FEEDING TUBE PLACEMENT: PERCUTANEOUS ENDOSCOPIC JEJUNOSTOMY (PEJ) Endoscopic image. Luminal view of duodenum, showing jejunostomy/PEJ tube over the guide wire (guidewire not seen).

(Courtesy Dr. Al Jergens.)

- PEJ tube is flushed with copious amounts of water to activate lubricant.
- PEJ tube is passed over the guide wire until it extends a length adequate for the proximal tip to be in the proximal third of the jejunum.
- PEJ tube location is assessed with fluoroscopy or radiography with test infusion of a few milliliters of water-soluble contrast agent (iohexol); the PEJ tube may be repositioned as needed.

- Guide wire is removed slowly while the PEJ is held stable.
- PEJ tube is secured to animal's body or to the PEG tube as it exits the left side of the abdomen.

POSTPROCEDURE

- Place Elizabethan collar on the animal to prevent removal of both PEG and PEJ tubes.
- To protect tubes, place and adjust orthopedic stockinette “sweater” over animal's body, including two holes cut for the forelegs; this should be “comfortable” to reduce stimulus for premature removal by animal.
- Monitor recovery from anesthesia.
- Instill the volume of sterile water needed to fill tube every 2 hours to keep tube patent.
- Begin enteral nutrition via the PEJ tube 12 hours following PEG tube placement.
- Monitor stoma site; expect mild inflammation and swelling; discharge from stoma may appear serous or mildly purulent, but cytologic analysis should reveal no bacteria; cleanse stoma gently with sterile saline and gauze squares as needed; surgical scrub can be used if needed but should be rinsed off completely.
- PEJ tube may be used as long as it remains functional and needed; often used for days to many weeks.
- Enteral feedings, either as boluses or constant drip infusion, are started with goal of one-third of daily caloric requirements being given the first day, two-thirds the second day, and full feedings by the third day.
- After removal of the PEJ tube, the remaining gastrostomy (PEG) tube may be used for nutrition if appropriate.
- The gastrostomy tube is left in place a minimum of 10 days to ensure adequate adhesion of stomach to the abdominal wall.
- The gastrostomy tube is removed by gentle progressive traction in a caudal direction that is also directed slightly away from the body; the remaining stoma will often close over within 4 to 8 hours after tube is removed.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Nasojejunostomy tubes are placed with endoscopic or fluoroscopic assistance. These have the advantage of not requiring a gastrostomy tube. However, they have problems with nasal irritation, short duration of use (often a few days), difficulty in placing the tip distally enough in the jejunum, and problems with postprocedural retrograde migration back to the stomach or being vomited aborally.
- Laparoscopic-assisted jejunostomy tubes can be placed at the end of a diagnostic or therapeutic laparoscopy. This technique involves exteriorizing a loop of jejunum, which then is held with four stay sutures while a pursestring suture is placed in the antimesenteric side. The jejunostomy tube is placed through an incision in the center of the purse-string suture. This suture is tightened when the tube has been placed successfully (using fluoroscopy to confirm location and aboral direction). A box suture technique is used for creating an adhesion of the intestine to the body wall that secures the safe position of the jejunostomy tube. Problems can involve aboral migration or confusion in the direction for placement of the tube. Other complications include those that would be possible with surgically placed jejunostomy tubes.

AUTHOR: MARK E. HITT

Gastroscopy/Duodenoscopy

SYNONYM

Upper gastrointestinal (GI) endoscopy

OVERVIEW AND GOALS

Minimally invasive endoscopic method of visualizing the mucosal surface of the stomach and proximal duodenum. This procedure offers the possibility of retrieving foreign bodies, performing mucosal biopsies, and placing a gastrostomy or jejunostomy tube.

INDICATIONS

- Chronic or acute vomiting
- Gastric foreign body
- Suspicion of gastric or duodenal ulcer
- Suspicion of gastric or duodenal neoplasia
- Suspicion of inflammatory bowel disease
- Placement of percutaneous endoscopic gastrostomy (PEG) tube for enteral feeding

CONTRAINDICATIONS

- Food in stomach
- Large and/or sharp foreign body

EQUIPMENT, ANESTHESIA

- General anesthesia required
- Endotracheal intubation required
- Mouth gag/speculum
- Flexible fiberoptic or video endoscope with monocular or video display:
    - Diameter of 9-10 mm and length of 1000-1250 mm are sufficient for both gastroscopy and duodenoscopy of most medium- to large-sized dogs and for only gastroscopy of cats and small dogs.
    - A diameter of 5.5 mm or less is usually necessary to enter the duodenum of cats or small dogs. A length of 900-1000 mm is usually sufficient for cats and small dogs.
- Vacuum source for endoscopic suction
- Endoscopic biopsy forceps
- Endoscopic foreign body retrieval forceps, snares, or baskets
- Biopsy jar with 10% buffered formalin

ANTICIPATED TIME

- Usually 60-90 minutes anesthesia time (30-60 minutes endoscopy time)
- Complex foreign body retrieval may take >60 minutes.

PREPARATION: IMPORTANT CHECKPOINTS

- Animal should have fasted for 12 hours prior to the procedure if possible.
- Simpler, less invasive diagnostic procedures are performed prior to endoscopy (e.g., CBC, serum biochemistry profile, urinalysis, abdominal radiographs in all cases, abdominal ultrasound, fecal flotation, adrenocorticotropic hormone stimulation test, and others as indicated by the specific features of each case).

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

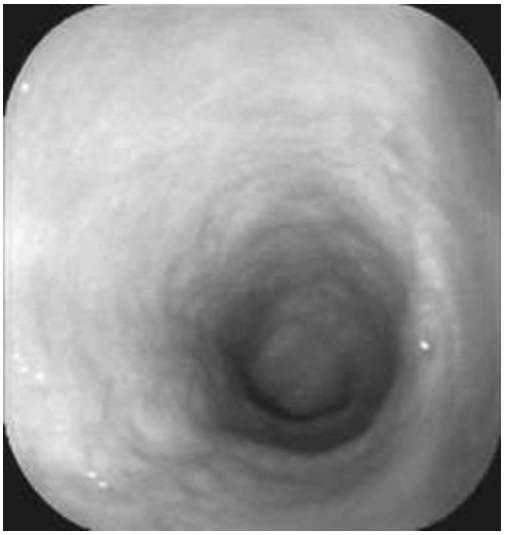
- Narcotic analgesics (e.g., morphine, meperidine, and butorphanol) increase motility of the pyloric antrum and may make passage of the endoscope into the duodenum difficult.
- Gastric or duodenal rupture:

    - Usually only occurs when the wall is compromised by a deep ulcer or neoplasia.
- Overinsufflation, usually of the stomach, may cause potentially severe bradycardia due to abdominal compartment syndrome (see p. 4) and creates the risk of gastric rupture.
- Prior administration of barium may make visualization difficult, and aspirating it with suction through the endoscope may be damaging to the suction channel of the endoscope.
- Failure to recognize the major duodenal papilla as a normal structure (major and minor duodenal papillae in cats) could lead to inadvertent biopsy, which in turn presents the potential for fibrosis and obstruction of the pancreatic and common bile ducts.

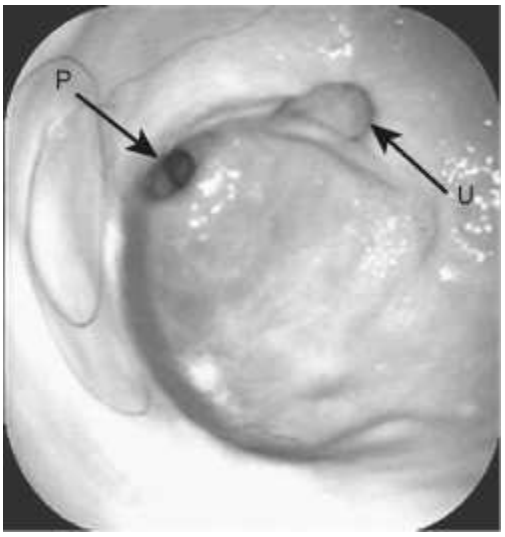
PROCEDURE

- Induce general anesthesia.
- Position the animal in left lateral recumbency. This is the position in which the pylorus is most easily entered.
- Place a mouth gag to keep the jaws open.
- Lubricate the endoscope with water-based lubricating jelly.
- Introduce the endoscope into the mouth, and feed it gently through the upper esophageal sphincter.
- Examine the esophageal mucosa as the scope is advanced down to the lower esophageal sphincter.
- Insufflate the esophagus with enough air to prevent the walls from collapsing on the scope and reducing visibility. An assistant may be required to gently occlude the upper esophagus by gently squeezing the cervical region externally, immediately cranial to the larynx, to prevent insufflated air from escaping out of the mouth. This will not be necessary once the tip of the endoscope is in the stomach.
- Whenever the scope is traveling down a tubular structure such as the esophagus or duodenum, it is important to keep repositioning the scope so the lumen of the tube is kept in the center of the screen. This maximizes visibility and minimizes trauma to the gut wall.
- Thread the scope through the lower esophageal sphincter by keeping the opening to the stomach in the center of the screen/view piece while gently advancing the scope.
- Once the distal end of the endoscope is in the stomach, insufflate the stomach with air to separate the walls and improve visibility. Insufflate until the rugal folds of the stomach are less prominent but still present. If the rugal folds are completely flattened, the stomach is so inflated that there is risk of compromising respiration or rupturing the stomach.
- If duodenoscopy is to be performed, it is best to proceed directly to the pylorus while it still may be relaxed. Prolonged insufflation or other activity in the stomach stimulates pyloric tone and motility, making threading the scope through the pylorus more difficult.
- Advancing the scope through the pylorus is usually the most difficult part of this procedure. The tone and degree of patency of the pylorus can be quite variable.
- If it is difficult to advance the scope to the opening of the pylorus (i.e., the scope is fed into the animal but advances no closer to the pylorus), suction some air out of the stomach—it may have been overinflated. This is common in large-breed dogs.
- If the pylorus is open, immediately advance the scope into the duodenum. If the pylorus is closed, maintain the opening to the pylorus in the middle of the screen while gently advancing the scope. If resistance is encountered, do not force the scope. Sometimes insufflating some air at the opening of the pylorus will stimulate it to open.
- If the pylorus is impossible to thread, try feeding a closed pair of endoscopic biopsy forceps through the pylorus. Use the threaded forceps as a stylet to feed the scope into the duodenum. If the scope still will not pass through the pylorus, consider using a smaller scope.
- Once the distal end of the endoscope is in the duodenum, advance the scope down to the limit of its length.
- Identify, if possible, the major duodenal papilla where the pancreatic duct and common bile duct empty into the duodenum. Do not biopsy this structure accidentally.

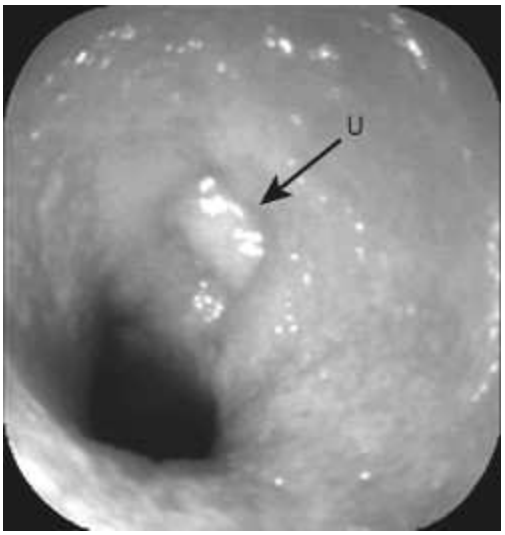
GASTROSCOPY/DUODENOSCOPY Endoscopic view of the normal pylorus (P).



GASTROSCOPY/DUODENOSCOPY Endoscopic view of the normal duodenum.



GASTROSCOPY/DUODENOSCOPY Endoscopic view of the pylorus (P) and a large craterlike gastric ulcer (U).



GASTROSCOPY/DUODENOSCOPY Endoscopic view of a duodenal ulcer (U).

- Examine and identify any irregularities to the duodenal mucosa and any foreign bodies.

- Obtain multiple (6-12) mucosal biopsies using biopsy forceps. Store these biopsies in 10% formalin. Any brushings or fluid samples for cytologic analysis or culture may be obtained now as well.
- Slowly withdraw the endoscope from the duodenum while obtaining mucosal biopsies and deflating the duodenum.
- Once the tip of the endoscope is back in the stomach, examine the entire stomach, including obtaining a retroflexed view to visualize the gastric cardia. This maneuver requires maximal flexion of the endoscope tip such that the endoscope itself is seen emerging through the cardia. Identify any mucosal irregularities, masses, ulcers, or foreign bodies.
- Obtain multiple (6-12) biopsies of any irregular structures and normal mucosa. Be cautious about taking a biopsy of deep gastric ulcers, because this could cause perforation of the stomach wall.
- Deflate the stomach before withdrawing the endoscope into the esophagus.
- Deflate the esophagus while slowly continuing to withdraw the endoscope from the esophagus. Suction any fluid in the esophagus, because it may be refluxed gastric acid that may ulcerate the esophagus if left behind.
- Take the scope out of the animal, remove the mouth gag, and recover the animal from anesthesia.

POSTPROCEDURE

- This procedure is minimally invasive, and the animal rarely requires analgesics after the endoscopy.
- Anesthetic recovery is usually routine.
- Clean the endoscope (internal and external surfaces) immediately before secretions and fluid have dried and are difficult to remove.

ALTERNATIVES AND THEIR RELATIVE MERITS

Exploratory laparotomy:

- Large, full-thickness biopsies may be taken from anywhere in the GI tract.
- All the abdominal organs may be visualized and biopsied if needed.
- Virtually any foreign body may be retrieved anywhere in the stomach or intestine.
- Serosal surfaces and wall thickness can be evaluated.
- Gastrostomy tube or jejunostomy tube may be placed.
- Tumors or abnormal tissue may be surgically excised.
- More invasive
- May be more costly
- May be more time consuming
- More painful for the animal/longer recovery time
- Greater risk of peritonitis and incisional dehiscence
- Unable to visualize the esophagus
- Unable to visualize the mucosal surface of stomach or intestines unless a gastrotomy or an enterotomy is performed

AUTHOR: PETER FOLEY

Gastric Intubation, Gavage, Lavage

SYNONYMS

Gastric decompression, orogastric feeding, orogastric intubation

OVERVIEW AND GOAL

Passage of a hollow tube into the mouth and through the oropharynx into the stomach to facilitate decompression of gas, removal of stomach contents (lavage), or administration of large volumes of liquid, food, or medication (gavage)

INDICATIONS

- Gastric intubation:
  - Preoperative stabilization of gastric dilatation/volvulus (GDV); allows evacuation of gas and fluid, resulting in an improved hemodynamic state
  - Relief of discomfort associated with gaseous dilatation (without torsion) of the stomach
- Gavage:
  - Administration of large volumes of liquid medication, including:
    - Activated charcoal after toxin ingestion
    - Barium for gastrointestinal (GI) contrast radiography
    - Hyperosmotic laxative agent prior to colonoscopy
  - Administration of formula to neonatal animals that are not nursing on their own
- Lavage:
  - Preoperative stabilization of GDV. Removal of stomach contents may help decrease the speed of gas reaccumulation while the animal is being prepared for surgery, thus slowing or preventing cardiovascular deterioration.
  - Removal of stomach contents with suspected intoxications

Note: Gastric lavage may not be indicated in all cases of toxin ingestion. Substance ingested, consistency, time since ingestion, and animal status will influence whether gastric lavage is appropriate.

CONTRAINDICATIONS

- Esophageal disease that could lead to tube-induced trauma or perforation. Conditions of concern include esophageal stricture, neoplasia, ulceration, megaesophagus, and recent esophageal surgery.
- Gastric disease that could lead to tube-induced trauma or perforation. Conditions of concern include neoplasia, ulceration, and recent gastric surgery.
- Any swallowing disorder (megaesophagus, esophageal motility disorder, etc.), pharyngeal disorder, or laryngeal disorder (paralysis, previous tie-back surgery, etc.) that could predispose a nonendotracheally intubated animal to aspiration.
- If even one of these conditions is present, the risk of the procedure versus its benefits must be considered (and will vary from case to case) before deciding whether to perform the procedure.

EQUIPMENT, ANESTHESIA

Gastric intubation:

- Two assistants (minimum)
- Flexible plastic tubing of various length and diameter. The distal end must be smooth and atraumatic; smoothing may be achieved by brief heating of the end of the tube over a flame, cooling, and trimming edges with a scalpel blade. One to three side holes may facilitate evacuation of stomach contents by minimizing obstruction of a single distal hole with gastric mucosa or ingesta.
- A roll of clinic-type white cloth tape
- Water-soluble lubrication jelly
- Mouth gag/speculum

If gastric lavage, all of the above, plus:

- Funnel or stomach pump
- Container (e.g., bucket) to collect stomach contents and lavage fluid

- Lavage fluid: usually warm (body temperature) water

ANTICIPATED TIME

Dependent on cooperation of animal; additional time may be needed for sedation or general anesthesia:

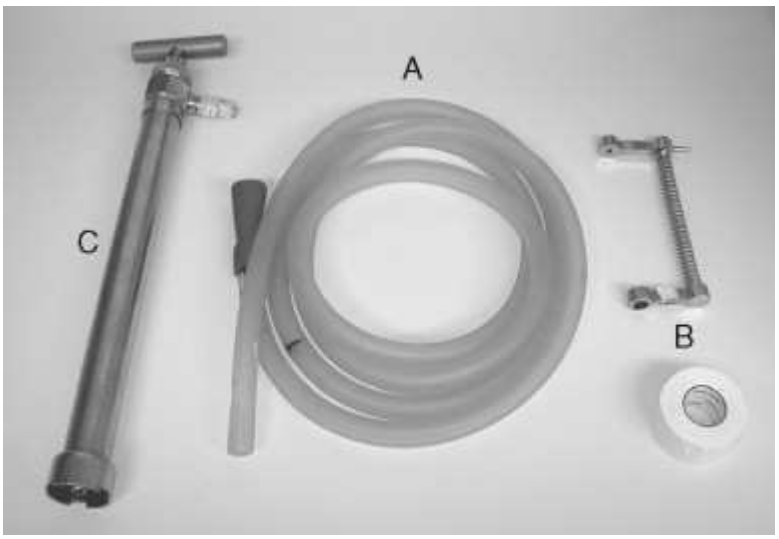
- Gastric intubation: 2-5 minutes
- Gavage: 3-10 minutes
- Lavage: 10-60 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Ensure that adequate manual or chemical restraint for the procedure is planned. Personal preference and animal stability may dictate the degree of sedation or anesthesia chosen. Note: Some clinicians prefer to ensure a patent and protected airway to minimize the potential for aspiration pneumonia through the use of general anesthesia and a cuffed endotracheal (ET) tube when gastric lavage is performed.
- Maximize cardiovascular stability prior to the procedure.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Inadvertent passage of the orogastric tube into the trachea can result in mild to severe complications:
  - Tracheal irritation leading to transient coughing or mucosal bleeding is possible.
  - Tracheal or bronchial placement of the gastric tube can result in airway obstruction until the tube is repositioned.
  - Tracheal or bronchial tearing can result in pneumomediastinum, pneumothorax, and death.
  - Tracheal or bronchial administration of gavage or lavage fluids can result in severe aspiration pneumonia and death.
  - See procedure (as explained in following paragraphs) for avoidance of this complication.
- Oral, pharyngeal, laryngeal, esophageal, or gastric trauma can result if excessive force is used for passing the gastric tube. Full-thickness tearing is possible, especially with a preexisting underlying disease.
- Inability to pass the tube into the stomach may be due to the choice of a tube with a diameter that is too large, esophageal obstruction (foreign body, stricture, neoplasia), torsion of the stomach, or excessive lower esophageal sphincter (LES) tone. Discontinuation of metoclopramide prior to elective gastric intubation is recommended to minimize LES tone.
- Inadequate sedation of an uncooperative animal will lead to longer procedure times and increased risk of injury to the animal and veterinary staff.
- Inability to effectively remove gastric contents through lavage may be related to excessive size or adhesive nature of gastric contents, gastric compartmentalization, or other factors.
- Regurgitation during lavage, gastric overfilling, or esophageal administration of large volumes of lavage fluid can result in aspiration if a cuffed ET tube is not in place.
- Excessive tube advancement can cause occlusion of the distal end of the tube against stomach mucosa. Palpation of the tube pressing against the stomach wall may indicate a need for partial retraction.



GASTRIC INTUBATION, GAVAGE, LAVAGE Materials and equipment used for gastric intubation and lavage. **A**, Orogastric tube. **B**, Metal speculum or roll of tape to be used as a mouth gag. **C**, Stomach pump for lavage.

PROCEDURE

- Manual restraint, sedation, or general anesthesia as indicated
- Position animal in sternal recumbency. If animal is uncomfortable, alternate positions may be better tolerated (sitting, standing, lateral, etc.).
    - Placement of the animal on an elevated surface will allow gravity-assisted efflux of stomach contents and lavage fluid once the tube is in place.
- Choose appropriate tube diameter for esophageal size and procedure planned. Example: A tube with an outer diameter of 1.5 inches (3.5 cm) is appropriate for most medium-sized dogs (45 lb [20 kg]). A larger tube size may be necessary for effective lavage versus gas decompression.
- Measure the length of tube necessary to pass from the nose to the xiphoid. Mark this distance on the tube with a piece of tape or nontoxic marker.
- Place a mouth gag (speculum) to prevent the animal from chewing on the tube.
    - A roll of 2-inch (5 cm)-wide clinic-type white cloth tape works well in many animals. The tube will pass through the hole in the tape roll. Place tape roll on top of the tongue and behind all 4 canine teeth.
    - Have an assistant hold the mouth closed around the mouth gag.
    - Avoid using a gag that will damage the teeth.
- Generously lubricate the distal portion of the stomach tube.
- Pass the tube into the mouth through the mouth gag.
- Advance the tube through the oropharynx and into the esophagus. Steps to promote and confirm esophageal and subsequent gastric intubation include:
    - Choice of a larger gastric tube size than appropriate ET tube size will lessen the possibility of tracheal intubation.
    - A neutral or very slightly ventro-flexed position of the head (i.e., avoiding extension of the neck) will reduce the opportunity for the tube to pass into the trachea.
    - In the awake animal, allow the swallowing reflex to facilitate tube passage through the pharynx.
    - If substantial coughing occurs, reassess placement, because the orogastric tube may be in the trachea.
    - Palpate the tube in the esophagus (separate from the tracheal rings).
    - Direct visualization of tube passage through the esophagus along the left side of the neck (lean, short-haired patients).
    - Small amounts of air infused into the stomach tube result in a gurgling sound when the stomach is ausculted.
    - Mild suction applied to the tube should reveal negative pressure, stomach contents, or odorous gastric gas with proper gastric intubation, whereas air flow and absence of negative pressure suggest that the tube is in the airways.
- Pass the tube up to the marked point that indicates where the tube should have entered the stomach. Relief of gas pressure can be assessed through auditory, tactile, and olfactory observations.
    - Certain conditions such as GDV may inhibit tube passage into the stomach. Choice of a smaller tube, gentle rotational pressure on the tube, repositioning of the animal, or percutaneous needle gastric decompression may facilitate passage.

DECOMPRESSION:

- Place the external portion of the stomach tube lower than the animal's head and body to allow gravity-assisted evacuation of stomach contents.
- Gentle massage of the stomach through the body wall may help to increase efflux.

GAVAGE:

- Using syringe, funnel, or stomach pump, instill the desired medication through the tube into the stomach.
- With administration of viscous materials, dilution with water may facilitate passage through the tube.
- Coughing, dyspnea, or cyanosis at any point suggests the tube may be in the respiratory tree. The procedure is terminated immediately, with kinking of the proximal tube (to avoid leakage of tube contents during withdrawal), tube removal, and animal care (physical examination, thoracic radiography as warranted, etc.).

LAVAGE:

- Using a funnel or stomach pump, instill approximately 5-10 mL/kg of lukewarm (body temperature) water into the tube.
- Acute onset of coughing, dyspnea, or cyanosis warrants immediate termination, as already described.
- Hold the tube higher than the animal's head to prevent efflux of the lavage fluid until desired.
- Gently massage the stomach to facilitate mixing of the stomach contents with the lavage fluid.
- Lower the stomach tube below the level of the head to allow the lavage fluid to efflux. Gentle manipulation of the tube forward or backward 1-3 cm may improve efflux.
- If the tube obstructs with stomach contents, flushing or manual breakdown may relieve the obstruction. If this is unsuccessful, the tube should be removed and the entire process repeated.
- Repeat lavage administration and efflux until the efflux is clear and the stomach contents have been removed.

REMOVAL:

- Kink the tube during removal to prevent laryngeal/pharyngeal contamination with liquid remaining in the tube lumen.
- Remove the mouth gag.

POSTPROCEDURE

- Monitor recovery from sedation/anesthesia.
- Supportive care as indicated for the condition.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Nasoesophageal/nasogastric intubation:
  - May be less stressful to the animal than orogastric intubation
  - Tube can be left in place for repeated aspirations/instillations.
  - Small tube diameter prevents administration of viscous substances and effective lavage. Withdrawal of large volumes of gastric contents is not possible.
- Percutaneous needle decompression/gastrocentesis:
  - May be easier to perform in a fractious animal
  - Allows gastric gas decompression when degree of torsion or another esophageal obstruction prevents tube passage
  - Potential for splenic puncture/laceration, gastric vessel or wall laceration, or other abdominal trauma
  - Ineffective for removing ingesta or large volumes of gastric contents
- Manual oral administration of medications or formula (pediatric animals):
  - Decreased chance of complications associated with orogastric intubation and gavage
  - Administration of large volumes to an uncooperative animal is labor intensive.
  - Risk of aspiration with force feeding
- Induced emesis to clear gastric contents:
  - Often more effective at removing stomach contents than lavage
  - Risk of aspiration, especially with decreased mentation or laryngeal/pharyngeal dysfunction
  - Not indicated with caustic ingestions
  - Not effective in all animals

Holter/Cardiac Event Monitoring

Video Available on Website

SYNONYMS

Ambulatory electrocardiography, cardiac telemetry

OVERVIEW AND GOALS

Goal: to assess the cardiac rhythm during an extended period of time. The monitor may record the cardiac rhythm continuously for 24-48 hours (Holter monitor) or only when triggered to record over a period of days to weeks (event monitor). With both devices, the pet is able to be in their home environment, and the owner is able to observe pet behavior.

INDICATIONS

- Syncope
- Episodic clinical signs of uncertain type but that might represent syncope
- Screening of breeding or at risk animals (boxers, Dobermans) for latent arrhythmia (arrhythmia not causing overt clinical signs)
- Monitoring of antiarrhythmic drug effects (Holter monitor only)

CONTRAINDICATIONS

- Animal thought to be likely to damage a portable monitor
- Animal that will be bathed or will be swimming
- Animal too small to carry monitor (monitoring may still take place, but animal stays mainly in pet carrier or cage for recording period)

EQUIPMENT, ANESTHESIA

- Clippers for hair
- Isopropyl alcohol
- Gauze squares or cotton balls
- Cardiac electrode adhesive patches (cutaneous)
- Ultrasound gel
- Bandage material: roll gauze, Esmarch-type bandage material (e.g., Vetrap), stretch adhesive-type cotton bandage (e.g., Elastikon, Elastoplast), 2-inch white medical tape, +/− cast padding
- Holter or event monitor, including wires to connect to animal, new batteries, and a blank digital card (Holter only), +/− Holter vest
- Interpretation system and printer or access to such a system

Note: Monitors are expensive systems not routinely owned by general practices. They are available for rental from many sources, including www.labcorp.com, www.vetheart.com, www.idexx.com, and www.pdsheart.com. Additionally, many veterinary college cardiology services have mail-out Holter programs. Veterinary sources are preferred because knowledge of common veterinary diseases (boxer dogs with arrhythmogenic right ventricular cardiomyopathy [ARVC], miniature schnauzers with sick sinus syndrome [SSS]), normal veterinary findings (sinus arrhythmia, sinus tachycardia, sinus pauses during daytime rest), and common veterinary artifacts (purring, panting, shaking) are important parts of interpretation. The monitor itself is sent by courier to the hospital for placement on the animal. Instructions for placement and patient daily diaries are usually sent with the monitor. When the monitoring period is over, the monitor is mailed back or transmitted via transtelephonic signal (event monitor), and findings and interpretations are reported back. Some mail-out programs (mostly veterinary colleges) will also provide consultation on the case as part of the service, along with the written Holter/event monitor report.

ANTICIPATED TIME

- Installation: 10 minutes (event monitor) or 20 minutes (Holter)
- Monitoring period: 24 or 48 hours (Holter); 7-30 days (event monitor, longer if battery is replaced; weeks to many months for surgically implanted event monitors)

PREPARATION: IMPORTANT CHECKPOINTS

If the reason for using cardiac monitoring is the occurrence of sporadic clinical signs, a complete medical evaluation is usually indicated first:

- CBC, serum biochemistry panel, urinalysis: all cases, hypoglycemia, hypocalcemia
- Serum preprandial and postprandial bile acids (if consistent with case): hepatic encephalopathy
- Electrocardiogram (ECG; standard, in-hospital): all cases; the diagnosis may be apparent without the need for Holter or cardiac event monitoring.
- Thoracic radiographs, echocardiogram: all cases; assessment of cardiac structure, presence or absence of signs of congestive heart failure.

The monitor itself is checked for proper function before preparing to install it on the animal. These instructions are usually sent with the monitor. Discussion of care of the monitor with the owner: the monitor must stay dry, clean, intact, and undamaged. It is customary to have the owner leave a deposit in the sum of the replacement cost of the monitor before leaving the hospital with the machine.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Wet monitor: no swimming or bathing during the recording period. In the rain, a plastic bag should be placed over the monitor by the owner.
- Damaged/chewed monitor or wires: if the owner observes the animal damaging the monitor, an immediate recheck is warranted. The equipment can be examined, and subsequently the monitor may simply be more heavily wrapped to prevent damage, or the monitoring period may be terminated and the monitor removed.
- Unstuck electrode patches: prevented by cleaning and preparing the skin with isopropyl alcohol prior to patch placement. Although not routine, in very active patients, a small amount of tissue glue can be used to prevent this.
- Poor electrode patch contact with skin: prevented by cleaning and preparing the skin with isopropyl alcohol prior to patch placement and adding a small amount of ultrasound gel to the center of the patch before applying it to the skin (see following paragraphs).
- Monitoring period is inexplicably shorter than expected: prevented by using new batteries every time. In addition, for audiotape Holter monitors, it is important to be sure that the audiotape is not put into the monitor backwards.
- Poor triggering of event button (Holter) or record button (event monitor): prevented by carefully showing the owners how to trigger the event and record buttons on the monitor at the time of installation.
- Letting batteries run out, causing the captured events to be deleted (event monitor): clients need to return 1 day prior to expected end of battery life to replace battery.

PROCEDURE

HOLTER MONITOR:

- The animal's apex beat (heartbeat on the thorax) is palpated on both the right and left side of the chest. These will be the sites of electrode patch placement.
- The hair is clipped over these areas bilaterally, starting close to the sternum and working upwards ensuring a generous clip: There must be room for the electrode patches and a few centimeters of space separating them.
- The hairless skin is wiped clean with isopropyl alcohol–soaked gauze or cotton and allowed to dry before placing the electrodes. Technician Tip: The patient should be standing during the application of the Holter or event monitor to ensure proper positioning of the leads and for taping purposes.
- Some cardiologists prefer to attach the patches to the wires of the monitor prior to placing the patches on the animal, which is acceptable. The following method will describe the alternative approach.
- Patch preparation: a very small dollop of ultrasound gel is placed on the center of each electrode patch. For very active patients, a tiny amount of tissue glue (<1 full drop) can be placed on opposite ends of the adhesive band of each electrode patch.
- The patches are attached to the animal's skin: three patches on the left (starting just left of the sternum) and two patches on the right, leaving a half inch to an inch between each electrode. For taping ease, make sure electrode snaps are all facing in the same direction.
- Secure electrodes with either 1-inch or 2-inch white tape. Wrap the tape all the way around the chest, covering the electrodes on both sides but leaving snaps exposed.
- The leads are attached to the patches according to the color scheme usually shown in the inside of the Holter recorder or within the instructions. Pressing the wire attachments directly onto the patches on the thorax can be painful to the animal and is not recommended. Rather, after the patch is attached to the skin, the patch and underlying skin are elevated with the finger, and the electrode is pressed in using thumb and forefinger.
- Once the leads are connected, the wires are gathered on top of the spine, with the cable exiting to the right side (most Holter vests have the recorder pocket on the right side) and taped with 2-inch tape to the tape around the chest. The only wire now left exposed is the cable that attaches to the recording system. This should come out over the left side of the patient's spine.
- The monitor is attached to the animal as follows:

    - The monitor is held in a dorsal midline location and 2-inch tape is wrapped around the chest, incorporating the wires and monitor such that they emerge at the dorsal midline.
    - Gauze is then wrapped over the tape, around the thorax, as well as cranial to the shoulders in a figure-eight pattern, creating a “vest” of bandage material. The monitor is included in this layer.
    - Esmarch-type (e.g., Vetrap) is then wrapped over the gauze in a similar fashion.
    - Occasionally, elastic cotton adhesive (Elastikon-type) bandage material is used along the cranial and caudal borders of the Vetrap to secure to the animal.
    - The Vetrap and Elastikon can be replaced with the use of a dog backpack (available in stores that sell equipment for outdoor activities) or a purpose-made Holter vest for dogs (see online video for description of application).
    - The monitor's event button should still be visible and accessible to the owner, but connections onto the thorax, loops of wire, and the rest of the monitor itself should be protected.
- If a clock setting can be adjusted on the monitor, it is set to the current time. If not, the times at which the battery was installed and the recording began are noted as time zero in the medical record.
- Instruct the owner to keep a diary of the dog's activities, including the time of the observed activity. This includes both normal activities and events thought to be of clinical relevance. They also may press the event button on the monitor if an episode of apparent significance (e.g., collapse) occurs; it will be flagged on the Holter recording.

After the recording period (24-48 hours):

- The bandage material, monitor, wires, and electrode patches are removed without the use of scissors. The entire system is unwrapped to avoid cutting of the leads and wires. Removal of the skin patches may be facilitated with isopropyl alcohol.
- The cassette or digital card is analyzed or sent back for analysis along with the recorder.

EVENT MONITOR:

- Animal preparation and patch preparation are the same as for Holter monitors (as already described).
- There are only two wires/electrodes and therefore only two electrode patches. The right-sided electrode (white) is connected to the electrode patch on the right hemithorax, and the left-sided electrode is connected to the patch on the left, as described previously.
- The monitor is wrapped onto the animal also as described above. It is essential to leave the record button visible and accessible.
- When the animal has an episode, the owner must press the record button. Doing so captures the ECG preceding and following the time the button was pressed. Typically, the monitors are set to store the preceding 45-second time period of ECG and the subsequent 15 seconds, for a total of 1 minute of ECG spanning the clinical episode.
- Event monitors typically have a total memory of 5 minutes (i.e., five 1-minute episodes), though newer models can store 18 minutes or more.
- Newer models can also be programmed to automatically store events if the owner is not present to witness the event. For example, the monitor can be programmed to record any heart rate lower than 40 bpm or higher than 200 bpm.

After the recording period (anywhere from 6 days to 8 weeks!):

- The bandaging, wires, and monitor are removed. The monitor is either returned to the supplier or in some models, the stored information can be transmitted transtelephonically to the receiving station. If this is not done very soon after a recorded event, the batteries continue to be drained, and the information eventually will be lost.

ALTERNATIVES AND THEIR RELATIVE MERITS

- In-hospital ECG: less motion artifact but generally shorter and under artificial conditions
- Holter monitor instead of event monitor: for screening for occurrence of latent arrhythmia; for antiarrhythmic drug monitoring
- Event monitor instead of Holter monitor: for long-term (days) monitoring; for smaller animals; for transtelephonic transmission of recorded information
- Implantable event monitor (Reveal Plus [Medtronics]): Allows an extended period of monitoring (up to 10 months). Devices are very small (size of a cigarette lighter), and implantation is achieved with a subcutaneous pocket and local anesthesia in many cases. Devices are now donated to a veterinary cardiology group (CANPACERS) and are inexpensive. Access to a Medtronic programmer is necessary, however, to retrieve the stored information.

Hemodialysis

SYNONYMS

Blood purification, renal replacement therapy

OVERVIEW AND GOALS

Hemodialysis is a blood purification procedure used for correcting azotemia and normalizing the fluid, electrolyte, and acid-base imbalances resulting from kidney disease. In this procedure, the animal's anticoagulated blood circulates through an artificial kidney (hemodialyzer) and is exposed to an electrolyte solution (dialysate) across a semipermeable membrane. Metabolic waste products, exogenous toxins, and excess water are removed from the bloodstream by diffusion (concentration gradient) and convection (hydrostatic gradient) through the dialysis membrane. The combination of these two basic blood purification principles define different treatment modalities, including hemodialysis (HD: diffusion), hemofiltration (HF: convection), and hemodiafiltration (HDF: combined diffusion and convection).

In acute uremia, hemodialysis restores metabolic stability and is provided for a finite period of time to allow animals to use their potential of recovery from acute kidney injury. Hemodialysis itself has no direct effect on renal recovery. Although hemodialysis can also be used for indefinite renal replacement in end-stage chronic kidney disease, chronic kidney disease is rarely a true indication because of the associated costs and the limited availability.

INDICATIONS

- Acute uremia: worsening azotemia and clinical signs of uremia despite adequate conventional therapy, anuria, fluid overload, severe refractory hyperkalemia, severe azotemia (blood urea nitrogen [BUN] > 100 mg/dL, creatinine > 10 mg/dL)
- Chronic kidney disease: acute decompensation, preanesthetic stabilization, pretransplant conditioning, chronic renal replacement
- Miscellaneous: fluid overload, acute poisoning, drug overdose (small-molecular-weight toxins or drugs with minimal protein binding capacity)

CONTRAINDICATIONS

- Small animal size (<2 kg) (relative contraindication)
- Severe pulmonary or cerebral hemorrhage (due to required anticoagulation)
- Cardiovascular instability and hypovolemia (should be corrected first)

EQUIPMENT, ANESTHESIA

Sedation/anesthesia: required for the placement of a vascular access but not for the hemodialysis procedure itself.

- Vascular access: short-term, temporary large-bore double-lumen catheter (7 Fr for cats and small dogs; up to 14 Fr for larger dogs); long-term, permanent double-lumen or twin-lumen catheter with subcutaneous tunneling; typically placed surgically in the external jugular vein
- Hemodialysis delivery system (hemodialysis machine)
- Disposable extracorporeal circuit and dialyzer (artificial kidney)
- Water purification system: particulate filter, carbon sorbent, water softener, deionization bed, and reverse osmosis
- Dialysate concentrates
- Replacement fluids for convective therapies (HF, HDF): on-line preparation or specific hemofiltration replacement fluids
- Monitoring equipment: blood pressure (BP) monitor, coagulation timer (e.g., activated clotting time [ACT]), in-line blood volume and oxygen saturation monitor (e.g., Critline), electrocardiogram (ECG)
- Emergency cart: cardiopulmonary resuscitation drugs, oxygen, endotracheal tube
- Protamine (for excessive heparinization and active hemorrhage)
- Physical restraint (i.e., harness and table straps)

ANTICIPATED TIME

- Acute treatments: depending on the degree of azotemia and the selected therapeutic schedule, initial treatments can be provided as intermittent (treatment of 1-8 h) or continuous therapy; treatments are provided daily until normalization of azotemia; a schedule of three times a week is then maintained until recovery of renal function.
- Chronic treatments: 4-5 hours, three times a week
- Every treatment necessitates 2 additional hours for setup, animal preparation, and completion.

PREPARATION: IMPORTANT CHECKPOINTS

- Initial database for animal evaluation and formulation of the dialysis prescription: body weight, physical exam, body temperature, heart rate, BP, hematocrit/total solids, serum chemistry profile (especially BUN, creatinine, electrolytes, Tco2 [$Hco3^-$]), coagulation time (e.g., ACT)
- Adequacy of vascular access: should deliver between 15 and 50 mL/min in cats and very small dogs and 200-500 mL/min in large-breed dogs
- Preparation of the dialysis system: alarm testing, priming and refreshing of the extracorporeal circuit
- Dialysis prescription: type and size of dialyzer and extracorporeal circuit, total volume of blood to be processed, duration of the treatment, ultrafiltration (fluid removal), dialysate composition and profiling (Na^+, K^+, bicarbonate, additives), dialysate flow rate and temperature, anticoagulation (type, prime, infusion rate), type of fluid used to prime the extracorporeal circuit (crystalloid, colloid, blood), and special procedures (e.g., single-needle operation, bypass time)

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Intradialytic complications: hemorrhage, hypotension, vomiting (hypovolemia, dialyzer reaction), dialysis disequilibrium (osmotic fluid shift into the intracellular compartment due to rapid correction of the azotemia; cellular edema can progress to cerebral edema and death), malfunction of vascular access, clotting of the extracorporeal circulation.
- Interdialytic complications: hemorrhage, delayed dialysis disequilibrium, catheter complications (thrombosis, vascular stenosis, infection, chylothorax)
- Other complications: related to severe uremia (i.e., uremic pneumonitis, encephalopathy, ulcers), its treatment (i.e., fluid overload, drug toxicity), or to the underlying etiology precipitating the renal failure (i.e., sepsis, hypovolemic shock)

PROCEDURE

Establishment of vascular access:

- A temporary or permanent dialysis catheter is placed aseptically in the external jugular vein, with the tip reaching the cranial vena cava or the right atrium. Permanent catheter placement requires general anesthesia for venotomy and subcutaneous tunneling. Proper placement is confirmed by adequate blood flow and thoracic radiographs. The dialysis catheter is strictly dedicated to dialysis therapy, and it is never used for other indications. It is prepared and handled aseptically for each use.

Anticoagulation:

- Animals require anticoagulation for extracorporeal circulation, typically with unfractionated heparin (initial bolus of 50 U/kg IV, followed by a constant rate infusion [CRI] of 50 IU/kg/h). Target: doubling of coagulation time (e.g., ACT 160-190 seconds).
- Alternative protocols have been established for animals with hemorrhagic risk: regional anticoagulation with citrate, special filters with anticoagulant membrane, and other modifications to provide low-heparin or heparin-free therapy.

Initiation of dialysis therapy:

- The dialysis machine is equipped with appropriate disposables (extracorporeal circuit, hemodialyzer), and its function is tested according to the manufacturer's protocols. Animals are equipped with a harness and strapped to the table to loosely restrain their activity.
- The catheter is connected to the extracorporeal circuit using aseptic techniques, and the extension lines are secured to the animal's body to avoid accidental catheter removal. The extracorporeal circulation is established under close monitoring of cardiovascular and respiratory status, and it is progressively increased to reach the prescribed blood flow.

Monitoring:

- Cardiovascular parameters (heart rate, BP, venous oxygen saturation, relative blood volume change), general condition (mentation, pupillary light reflexes), anticoagulation (ACT), and machine function (extracorporeal blood flow, dialyzer clearance) are monitored and recorded every 15-30 minutes for the duration of the treatment.
- Initial dialysis treatments commonly necessitate additional monitoring, including ECG and pulse oximetry.

End of therapy:

- The blood circulating in the extracorporeal circuit is returned to the animal, and the disposables are discarded.
- The dialysis catheter is locked with a solution of concentrated heparin (50-500 U/mL in cats; 500-5000 U/mL in dogs) and protected with a neck bandage until the next treatment.

POSTPROCEDURE

- Monitor for hemorrhage and dialysis disequilibrium (neurologic changes).
- Because of the persistent effect of systemic heparinization: no needle stick (IV, IM, SQ), no placement or removal of IV or arterial catheters, and no procedure that could potentially cause mucosal or internal hemorrhages up to 12 hours following discontinuation of dialysis.
- Assessment of dialysis adequacy: treatment adequacy implies global control of all the individual problems of renal failure, of which dialysis only addresses a few directly. Nutrition; pain control; treatment of renal hyperparathyroidism, anemia, and metabolic acidosis; and further supportive care are critical for successful therapy and are not corrected by hemodialysis. Blood volume processed, time on dialysis, convective fluid removal (ultrafiltration), normalization of chemistry parameters, and reduction ratios of urea and creatinine are commonly used for describing treatments. However, dialytic adequacy is more accurately described using kinetic modeling of urea removal and generation. The insight gained into the nutritional adequacy of the animal renders this analysis central for the global assessment of animals undergoing dialysis.
- Maintenance of the dialysis equipment is critical for adequate operation and safety of the procedure: Before each treatment, dialysate is controlled for traces of residual chlorine; at the end of each treatment, the machine is rinsed with acid and bleach to remove bicarbonate and protein deposits, respectively. At the end of every dialysis day, the machine is disinfected with a chemical or heat cycle. A quantitative bacteriologic culture of the dialysate water is scheduled once a month and a chemical water analysis for trace elements once a year.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Continuous renal replacement therapy (CRRT): a slower but extended form of dialysis therapy with more gradual correction of hydration and metabolic imbalances; lower blood and dialysate flow rates imply fewer treatment interruptions and alarms and, potentially, a technically less demanding form of therapy. Safe treatment still requires a thorough understanding of renal pathophysiology and dialysis technology, especially when used for treating severely uremic animals. After initial correction of the azotemia, maintenance of uremic animals with CRRT is hampered by the low efficiency of the treatments and the need for continuous therapy. The requirement for continuous anticoagulation may also be a relative contraindication in some uremic patients.
- Renal transplantation: offers the potential of long-term replacement of all renal functions when recovery can no longer be expected; however it requires surgical expertise and experience with the management of the long-term immunosuppression to avoid graft rejection; its availability is limited.

Intubation, Endotracheal

SYNONYM

Placement of a tube into the tracheal lumen via an oral approach

OVERVIEW AND GOAL

Endotracheal intubation is performed routinely in dogs and cats undergoing general anesthesia and is also a fundamental technique in emergency/critical care situations.

INDICATION

- To establish and maintain airway patency in animals under general anesthesia
- To protect respiratory tract from aspiration of foreign material during anesthesia
- To facilitate delivery of supplemental oxygen and volatile inhalant anesthetic agents
- To minimize exposure of hospital personnel to waste anesthetic gases
- To minimize anatomic dead space and optimize respiratory efficiency
- To facilitate delivery of positive-pressure ventilation

CONTRAINDICATIONS

Oral approach may not be possible with mandibular/maxillary trauma, temporomandibular disorders, oropharyngeal lesions, or oropharyngeal surgery where endotracheal tube placement would interfere with the surgical field.

EQUIPMENT, ANESTHESIA

Primary equipment:

- Appropriate endotracheal tube
- Adequate lighting
- Roll gauze to secure tube

Supplemental equipment:

- Laryngoscope
- Local anesthetic
- Stylet or guide tube
- Sterile water-soluble lubricant
- Mouth speculum

ANTICIPATED TIME

- Routine: <30 seconds in an adequately anesthetized animal
- Difficult airway: <3-4 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Adequate anesthetic depth required to provide good muscle relaxation and inhibit airway reflexes
- Preoxygenation indicated in select animals
- Measurement of tube length and trimming if necessary (see Procedure, below)

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Laryngospasm
- Trauma to larynx/trachea
- Vagal reflex activity

- Unrecognized esophageal intubation
- Bronchial intubation
- Postextubation upper airway obstruction

PROCEDURE

- Place anesthetized/unconscious animal in sternal recumbency.
- An assistant opens the animal's mouth by placing one finger and thumb behind the maxillary canine teeth. Lips are pulled upward and out of oral cavity. The animal's head and neck are extended to form a straight line.
- Do not support or put pressure under animal's neck.
- Grasp the animal's tongue, and use gentle pressure to extend it rostrally and ventrally. Excessive traction on the tongue should be avoided.
- With laryngoscope: place tip of blade at base of tongue underneath epiglottis, and exert downward (ventral) pressure. This disengages the epiglottis from the soft palate and directs it rostrally, allowing the laryngeal opening to be visualized. Note: Do not place laryngoscope blade on top of epiglottis.
- Without a laryngoscope: use the endotracheal tube to disengage the epiglottis from the soft palate and expose laryngeal opening.
- If local anesthetic is used for desensitizing the larynx, apply it to vocal folds using spray dispenser, cotton swab, or hypodermic needle and syringe for topical application.
- Advance endotracheal tube between the vocal folds into trachea. In cats, wait until the folds separate during inspiration before attempting to advance tube.
- Do not force tube. If resistance is encountered, back out slightly, maneuver tip of tube's bevel between the vocal folds, and gently rotate tube while advancing.
- Ensure that distal portion of tube lies at level of thoracic inlet and proximal end terminates at level of animal's incisors. Tubes may need to be shortened to appropriate length before placement.
- Tie piece of roll gauze tightly around tube, without constricting lumen, at a point caudal to animal's incisor teeth. Secure gauze around maxilla or back of animal's head.
- Connect endotracheal tube to breathing system, and begin delivery of oxygen.
- Close pop-off valve, and gently squeeze reservoir bag until a pressure of 20 cm H^2O is reached in breathing system, while listening for sound of leaking air exiting oral cavity around tube. Incrementally inflate cuff on tube using an “air syringe” until sound of leak is terminated. Avoid cuff overinflation, and remember to open pop-off valve once cuff is inflated.

INTUBATION, ENDOTRACHEAL Intubation of an anesthetized dog. An assistant extends the dog's neck and retracts the lips. The right-handed clinician is holding both a laryngoscope and the dog's tongue in the left hand and is placing the endotracheal tube using the right hand.

- Correct tube placement may be confirmed by:
  - Palpation of single tubular structure in cervical region (as opposed to two tubes, representing an intubated esophagus alongside a trachea that is not intubated)
  - Movement of reservoir bag corresponding to thoracic wall movements associated with animal inspiration/expiration
  - Auscultation of good breath sounds bilaterally during positive-pressure ventilation
  - Detection of carbon dioxide in animal's exhaled gases and evidence of normal capnographic tracing

POSTPROCEDURE

- Extubate when animal's oral/pharyngeal reflexes have returned.
- In brachycephalic animals, endotracheal tube should be left in place as long as possible during recovery.
- In animals undergoing procedures associated with accumulation of blood/fluid in oral cavity, cuff may be left partially inflated during extubation.

ALTERNATIVES AND THEIR RELATIVE MERITS

Tracheostomy or pharyngostomy: oral approach preferred in routine cases (no tissue trauma and technically simple to perform)

AUTHOR: LEIGH A. LAMONT

Intravenous Catheter Placement

SYNONYM

Peripheral venous catheterization. Jugular venous catheter placement is discussed separately (see p. 1293)

OVERVIEW AND GOAL

To obtain intravenous (IV) access for the administration of fluids, medications, anesthetic agents, and blood products

INDICATIONS

- Fluid resuscitation (dehydration, shock)
- Seizures
- Renal failure
- Cardiopulmonary cerebral resuscitation (CPCR)
- General anesthesia
- Chemotherapy
- Anemia

CONTRAINDICATIONS

- Injury or infection at site of catheter placement

EQUIPMENT, ANESTHESIA

- Sedation usually not required but dependent on disposition and health of animal
- IV catheter (type selected depends on size and location of vein, patient requirements, cost):
    - Winged infusion set (“butterfly” catheter)
    - Over-the-needle catheter (most commonly used for peripheral catheterization)
    - Through-the-needle catheter
    - Over-the-wire-guided catheter
- Clipper with No. 40 blade
- White tape
- Surgical scrub
- Alcohol
- Gauze sponges
- Syringe with heparinized saline
- T set/injection cap
- Bandaging material (required for long term catheter):
    - Roll gauze
    - Cast padding
    - Bandage wrap (e.g., Vetrap)
    - Bandage scissors

ANTICIPATED TIME

5-10 minutes

PREPARATION: IMPORTANT CHECKPOINTS

Determine site of catheter placement:

- Usually placed in the cephalic and lateral saphenous (canine) or medial saphenous (feline)
- Other sites include the accessory cephalic vein (distal to the carpus), dorsal common digital vein (over the metatarsals), auricular, jugular, and femoral veins.

Determine the type and size of the catheter required:

- Butterfly catheters are best used for blood collection and short-term infusion of nonirritating drugs or fluids.
- Use the largest bore catheter possible if needing to give a large amount of fluids rapidly.
- To avoid trauma to the vein in patients requiring multiple catheterizations, choose the smallest-gauge catheter possible.

A full/mini cutdown may be required in emergencies where the vessel cannot be visualized. Specifically, animals with tough skin or that are dehydrated may require a small 1- to 2-mm skin incision with a 20-gauge needle to prevent crimping or burring of the catheter.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

Complications:

- Phlebitis
- Thrombosis
- Sepsis
- Extravasation resulting in edema/necrosis at the catheter site
- Blood loss (catheter becomes disconnected from fluids/T set)
- Catheter embolism

Common errors:

- Avoid using the saphenous vein in animals with diarrhea or polyuria, and the cephalic vein in vomiting animals, due to risk of contamination.
- Catheter is placed too proximal on the limb, and flow is occluded when leg is flexed.

PROCEDURE

For over-the-needle catheters:

- Clip area and prepare aseptically.
- Occlude the vein, and insert the catheter at a 15-30○ angle, with bevel facing up.
- Advance the catheter until you see a flash of blood in the catheter hub. To get the catheter tip fully into the vein, advance the catheter an additional 1-3 mm; otherwise, only the stylet tip, and not the catheter itself, is in the vein. If blood flow stops, back the catheter out to a point where there is blood flow, and reattempt to seat the catheter in the vein.
- With the hand that is holding the leg, stabilize the hub of the needle; with your other hand, advance the catheter over the needle. (If the catheter does not advance smoothly, do not reinsert the needle into the catheter while in the leg. Further attempts can be made more proximal or at a different site.)
- Have the assistant apply pressure over the tip of the catheter to prevent blood from contaminating the site. Attach the injection cap or T set/T port.
- Dry the site with gauze and secure the catheter in place with tape.
- Flush the catheter with saline. If the catheter is properly placed, the flow of fluid in the vein can be palpated above the tip of the catheter, and blood can be aspirated.
- Wrap catheter with bandage material.

POSTPROCEDURE

- Inspect bandage and catheter site daily and monitor for pain, inflammation, edema, and infection.
- Flush catheter with heparinized saline every 4-6 hours if not administering an infusion.
- Apply an Elizabethan collar or catheter guard if necessary to avoid self-trauma.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Central venous catheter: used for administering total parenteral nutrition, monitoring central venous pressure, and obtaining repeated blood samples
- Intraosseous catheter placement: useful in neonates or in patients where IV access attempts have failed
- Subcutaneous fluid administration: inexpensive and convenient but only useful in stable patients with good peripheral perfusion

AUTHOR: ELAINE REVELER

Intraosseous Catheter Placement

OVERVIEW AND GOALS

- Insertion and maintenance of a patent catheter in the marrow cavity of a long bone for purposes of administering parenteral fluids, drugs, blood, or virtually any other agent that is routinely given IV.
- The technique is most commonly used in debilitated neonatal and pediatric animals, in which peripheral veins may be very small and difficult to access but also in which the bone is soft and entered fairly easily.

INDICATIONS

- Urgent fluid replacement in a severely dehydrated/hypovolemic kitten or puppy (most common indication)
- Plasma or blood transfusion in an animal that has poor peripheral or jugular venous access
- Administration of drugs when IV access is not available

CONTRAINDICATIONS

- Osteopenia (nutritional or metabolic bone disease) or fracture affecting the target bone
- Infection of the overlying soft tissues
- Sepsis is a relative contraindication. The benefit of fluid administration must be felt to outweigh the risk of osteomyelitis.

EQUIPMENT, ANESTHESIA

Sedation or general anesthesia is necessary for animals that are otherwise well. However, intraosseous catheters are often placed in severely debilitated animals; local anesthesia with 2% lidocaine (typical kitten/puppy dose: 0.25 mL) is sufficient for these animals, provided all tissue layers are intiltrated (subcutis, muscle, periosteum).

- Clippers for hair
- Isopropyl alcohol, surgical scrub supplies, and sterile gauze squares
- Spinal needle: typically 20 gauge, 1½ or 2½ inches (4-6 cm) long
- T-port-type injection cap with side connector
- Sterile gloves
- Tissue glue
- Heparinized saline flushes
- Bandage material: roll gauze, cast padding, stretch and release bandage (e.g., Vetrap), white medical tape
- Suture scissors and bandage scissors
- ± Splint material (e.g., wooden tongue depressor in pediatric patients) to protect the spinal needle after placement

ANTICIPATED TIME

About 20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Review anatomic landmarks.
- Consider alternatives (e.g., IV catheter).

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Damage to nerves (especially sciatic) or vessels. Risk is minimized by manipulating the limbs as described in the following paragraphs.
- Spinal needle kinking, causing obstruction; common. Minimized by using a needle that is not excessively long, that is not overly thin (a 22-gauge needle should probably be the smallest used in even the smallest animals), and by bandaging the proximal/protruding part of the needle in a way that reduces the lateral forces applied to it when the animal bumps against the cage wall, lies down, or rolls over.
- Using a regular 18-gauge needle (hypodermic/injection-type) instead of a spinal needle has been described, but this approach is not recommended. The procedure involves “coring out” a path by placing an 18-gauge needle in the appropriate place, immediately removing it (since, without a stylet, it will be plugged with bone), and placing a second, new 18-gauge

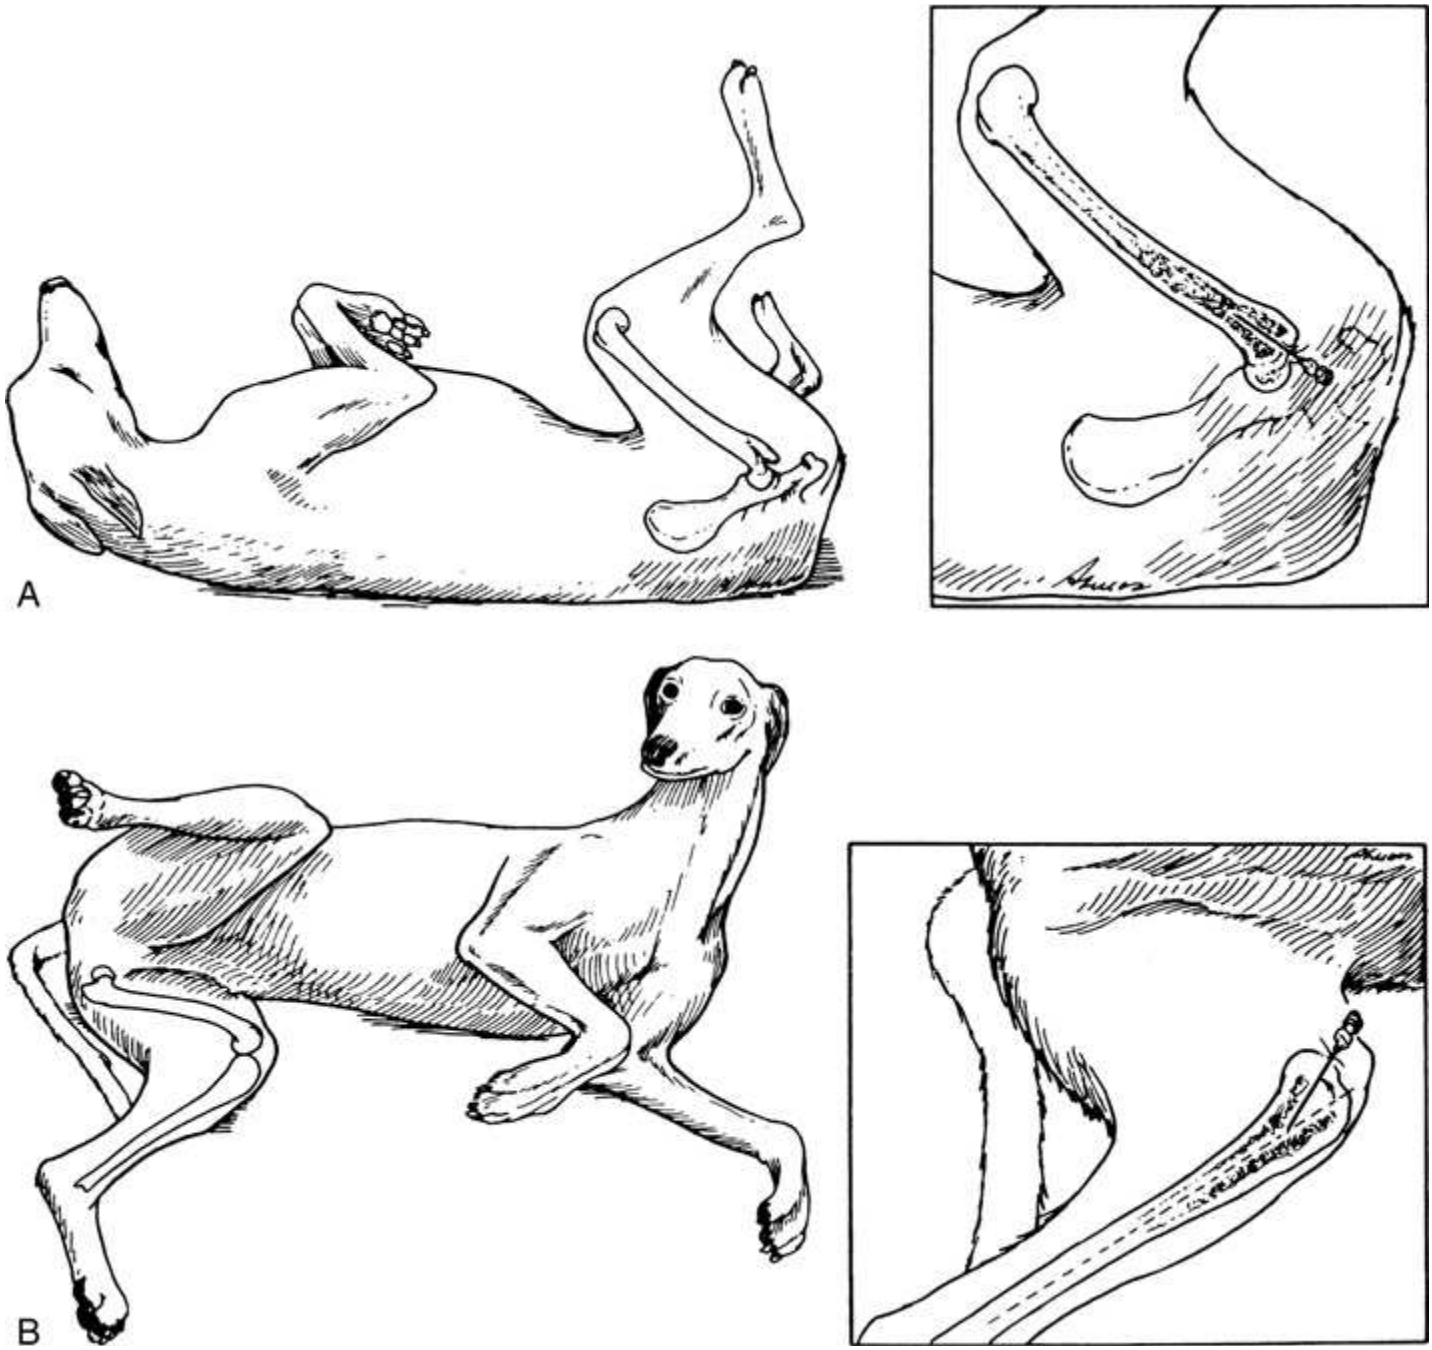
needle in the tract just created by the previous needle. Complications, including replugging with bone in the second needle, inability to find the hole when placing the second needle, and leakage of fluid around the needle, are extremely common. Therefore, only spinal needles (with stylets) should be used, not regular hypodermic needles.

PROCEDURE

FEMORAL APPROACH:

- Sedation/general anesthesia is administered if deemed necessary based on animal parameters (e.g., mentation, extent of illness, vital signs).
- The animal is placed in lateral recumbency, and the nondependent leg is used.
- The clinician palpates the hip; the greater trochanter of the femur is the outer/lateral landmark, and the trochanteric fossa medial to the greater trochanter is the target.
- The overlying skin is clipped of hair and aseptically prepped.
- If no sedation or general anesthetic has been administered, local anesthetic is infiltrated into the trochanteric fossa at this time.
- A 2-mm stab incision is made in the skin overlying the trochanteric fossa.
- The femur is rotated internally and adducted and is held in this position during needle placement to reduce the risk of traumatizing the sciatic nerve.
    - The sciatic nerve courses medial to the trochanteric fossa, dorsal to the acetabulum. Therefore, entering the trochanteric fossa from its lateral-most aspect minimizes the risk of sciatic nerve damage.
- The spinal needle is placed through the stab incision in the skin and onto the greater trochanter (lateral to target). It is then moved gradually in a medial direction until it enters the trochanteric fossa.
- Once in the trochanteric fossa, the needle is advanced parallel to the long axis of the bone, with the hub of the needle held firmly to allow a burrowing, clockwise-counterclockwise rotating motion to facilitate advancement of the needle. A mild loss of resistance is usually felt when the needle reaches the marrow cavity. NOTE: It is important not to advance the needle the length of the entire bone and into the distal cortex, because this could block flow through the needle.
- When the needle is sufficiently advanced, the stylet is withdrawn. The T-port is filled with heparinized saline, fitted onto the spinal needle hub, and flushed with heparinized saline.
- The spinal needle is sutured in place (to prevent migration outward) using a Chinese-finger-trap suture pattern. This may be further solidified by applying tissue glue to the suture as it courses over the hub of the spinal needle and the T-port.
- Cast padding, roll gauze, and bandage material are rolled around and over the needle hub and T-port in a way that protects the needle from becoming kinked or damaged with the animal's movements. Wooden tongue depressors or other splint materials can be useful for protecting the part of the needle that protrudes from the femur.
- The T-port can be connected to an IV fluid set, a blood transfusion set, or other, based on the animal's needs.
- There should be no outward signs of discomfort; if there are, nerve damage or other complications should be suspected, and the spinal needle may need to be withdrawn.

INTRAOSSEOUS CATHETER PLACEMENT Different views of two 20-gauge, 2½-inch spinal needles used for intraosseous catheterization.



INTRAOSSEOUS CATHETER PLACEMENT Intraosseous catheter placement. **A,** Femoral approach. **B,** Tibial approach.

(Reprinted with permission from Otto CM, Crowe DT Jr: Intraosseous resuscitation techniques and applications. In Kirk RW, Bonagura JD, editors: Kirk's current veterinary therapy XI, Philadelphia, 1992, Saunders, pp 107–112.)

TIBIAL APPROACH:

- The preparation is as described for the femoral approach, but the target area is the medial proximal tibia.
- The spinal needle enters the tibia on the medial surface of the tibial tuberosity and is directed laterodistally, as shown.
- The protocol is otherwise the same from the removal of the stylet to the end of the procedure.

POSTPROCEDURE

- Catheter care includes flushing with 0.2-0.4 mL sterile saline every 6-8 hours if an infusion is not being administered through the needle. It is important not to overflush the system in small animals, causing systemic heparinization.
- Catheter obstruction is a common problem. Most cases are prevented by proper placement (not too deep in the bone, causing blockage from the distal cortex), and proper securing and protection of the spinal needle so the animal does not bend it; prevention also is possible by regular flushing or infusion to keep the catheter patent.

- If the spinal needle becomes obstructed or bent and needs to be replaced, a different bone should be chosen for intraosseous catheter placement because a minimum of 24-48 hours are needed for the bone to heal. Otherwise, leakage from the original needle site of entry and subcutaneous pooling of the administered fluid/blood/drug commonly occur.
- The spinal needle can usually be removed without sedation or general or local anesthesia and without eliciting signs of pain from the animal.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Venous cutdown for peripheral or jugular catheter: acceptable alternative but more invasive, possibly with a greater risk of local infection.
- Intraperitoneal administration: acceptable in mildly/moderately ill pediatric animals, including for blood transfusion. Lack of direct access to the circulation is a substantial drawback compared to intraosseous catheterization.

AUTHOR: ETIENNE CÔTÉ

Inhalant Medication Administration

OVERVIEW AND GOAL

To deliver medication to the respiratory tract with maximal efficacy and minimal side effects

INDICATIONS

Virtually any disease of the respiratory tract for which oral or injectable corticosteroids are indicated:

- Lymphocytic-plasmacytic rhinitis
- Allergic rhinitis
- Laryngeal edema secondary to laryngeal paresis/paralysis or mass
- Reverse sneeze
- Chronic bronchitis
- Asthma
- Eosinophilic pneumonia

Any disease of the respiratory tract for which oral or injectable bronchodilators are indicated:

- Asthma
- Chronic bronchitis (occasional)
- Bronchial compression secondary to left heart enlargement (occasional)

CONTRAINDICATIONS

Prior known sensitivity to inhaled medications

EQUIPMENT, ANESTHESIA

- Face mask: specific to species and size of animal's muzzle
- Spacer: specific to size of animal
- Metered dose inhaler (MDI)

ANTICIPATED TIME

- Inhalation time is usually 7-10 seconds, q 24 h to q 12 h or as needed (bronchodilator).
- Preparation time for animal may be a matter of seconds if animal is trained and comfortable with the device or may last weeks if training is required.

PREPARATION: IMPORTANT CHECKPOINTS

- Approximately 90% of dogs and 65% of all cats will tolerate the placement of the mask and spacer apparatus the very first time.
- Animals that will not tolerate this device initially still can be trained to acceptance. This usually takes a few days to a few weeks.
- Approximately 5% of dogs and 20% of cats will not accept this form of medication delivery even after weeks of training.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Some animals cough immediately after inhaling the medications. No treatment for this is required.
- Mild conjunctivitis occasionally occurs if the top of the mask is in contact with the lower conjunctival lid margins.
- Contact dermatitis of the muzzle occasionally occurs.
- “Thrush,” a yeast infection within the posterior pharynx, is a frequent complication in humans. This has not been reported in dogs or cats using inhaled corticosteroids.
- Growth retardation is a potential concern in children using inhaled corticosteroids. This has not been reported in dogs and cats.
- Cats with respiratory distress due to bronchoconstriction will very quickly benefit from inhalation of bronchodilator drugs. The

temporary restraint required to administer these drugs has not been reported to result in clinically significant complications in this setting.
- Some cats will hold their breath. If this occurs, it is essential to wait until the animal begins breathing for 7-10 breaths.
- Some dogs and cats have nasal congestion that prevents inhalation by this method. In these cases, it is useful to instill a drop of a topical nasal decongestant (e.g., phenylephrine drops [Neo-Synephrine]) into either or both nostrils and wait 10-15 minutes before using the inhaled medications.

INHALANT MEDICATION ADMINISTRATION Spacer device connected to a face mask.

PROCEDURE

Technique, initial:

- Shake MDI three to five times vigorously.
- Attach MDI to spacer.
- Position the animal for gentle restraint and to prevent side-to-side movement.

Technique, main:

- Place the mask over the animal's nose (cats) or muzzle (dog). If right-handed, use left hand to place mask.
- Use right hand to actuate (spray) medication, one puff into spacer.
- MDI for albuterol comes as one dose only (90 mcg/actuation).
- MDI for fluticasone comes as 44, 110, and 220 mcg/actuation.
- Watch animal breathe for 7-10 breaths by watching the chest wall/abdomen.
- Alternatively, count 7-10 condensations of breath within the plastic mask.
- If an animal is resistant and in respiratory distress, it is usually safe to administer the medication with two people involved to temporarily restrain the animal. This is true even in the case of respiratory distress due to asthma.

POSTPROCEDURE

- Wipe patient's face/muzzle with washcloth.
- Maintain cleanliness of spacer according to manufacturer's recommendations.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Nebulization does not offer superior drug-delivery results compared to the simple mask/spacer combination.
- Long-acting corticosteroids cannot be administered by inhalation.
- Oral prednisone/prednisolone should be considered when the animal requires immediate antiinflammatory treatment. Inhaled corticosteroids may take 7-10 days to reach full effect. In these cases, prednisone/prednisolone should be administered for the first week concomitantly with the inhaled corticosteroid.
- Parenteral bronchodilators can be used (e.g., terbutaline, subcutaneously [SQ]) if an animal is fractious and cannot be easily restrained.
- Topical medications: no current or prior objective data that document the effectiveness of transcutaneously-administered corticosteroids or bronchodilators in the treatment of respiratory disorders in dogs or cats.

- Alternative therapies: many unproven alternative, evolving, and experimental approaches to treating respiratory disease in the canine and feline species.

AUTHOR: PHILIP PADRID

INHALANT MEDICATION ADMINISTRATION Spacer connected to a metered dose inhaler (MDI) and a self-sealing mask of the type commonly used for induction of anesthesia. Spacer acts as a reservoir for inhaled medication, so animal breathes the drug into its airways whenever it breathes through the face mask.

Jugular Catheter Placement and Management

OVERVIEW AND GOALS

Jugular venous access is essential in small-animal critical care and general medicine for a variety of therapeutic and diagnostic reasons.

- The duration of catheter patency and function tends to be longer with jugular catheters compared to peripheral catheters.
- Higher osmolar solutions (parenteral nutritional solutions, glucose solutions) may be administered more safely through these catheters compared to peripheral venous catheters.
- Jugular venous catheters allow for easier through-the-catheter blood sampling and are necessary for measuring central venous pressure.
- Jugular catheter sites are less likely to be contaminated from vomit and diarrhea in animals with those problems.

INDICATIONS

- When multiple/serial blood samples are required (e.g., diabetic ketoacidotic animals)
- Measuring central venous pressure (CVP)
- Constant rate infusions of hyperosmolar solutions (e.g., dextrose solutions > 5%)
- Total/partial parenteral nutrition (T/PPN) administration
- In animals with severe vomiting and diarrhea that require IV access

CONTRAINDICATIONS

- Hypercoagulable states (e.g., protein-losing nephropathy)
- Increased intracranial pressure (holding off jugular vein may increase intracranial pressure)
- Hypocoagulable states (e.g., liver failure, rodenticide anticoagulant intoxication)
- Thrombocytopenia
- Thrombocytopathia
- Skin infection over site of jugular catheter placement

EQUIPMENT, ANESTHESIA

- Sedation generally not necessary in critically ill animals but may be needed in fractious animals
- Clippers
- Sterile surgical gloves
- Surgical scrub soap
- Gauze squares for surgical prep of site
- Heparinized saline flushes
- Suture material
- White cloth-type tape
- Bandaging material (e.g., roll gauze, cast padding, and Elastikon/Elastoplast-type adhesive roll bandage)
- Injection cap
- Triple-antibiotic ointment
- Guide-wire technique: the following four items are available in kits manufactured by Cook, Mila, and Arrow:
    - Hypodermic needle
    - Guide wire
    - Dilator
    - Polyurethane IV catheter
- Other materials:
    - A #11 scalpel blade
    - Suture material (e.g., 2-0 to 4-0 nylon)

ANTICIPATED TIME

About 20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

Check coagulation profile (prothrombin time [PT], partial thromboplastin time [PTT], platelet count, platelet function)

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

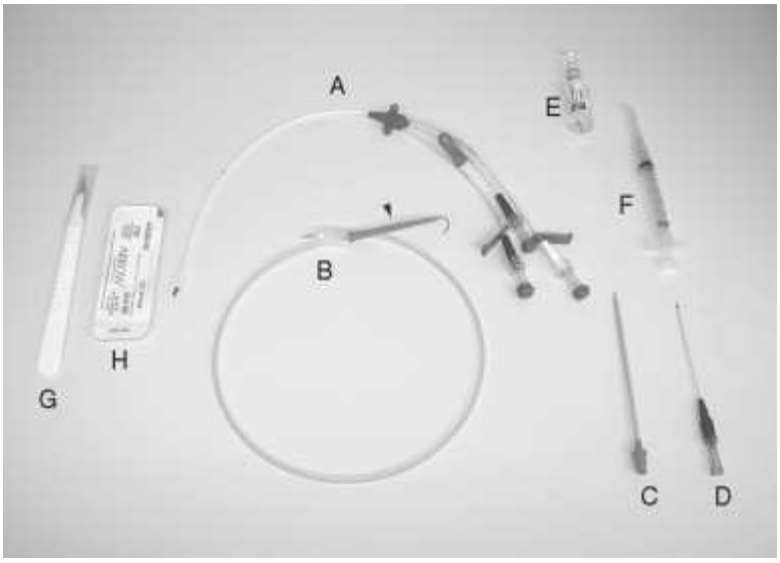
- Do not use leashes that go around the neck (neck leads) when a jugular catheter is in place.
- Place needle guard when using through-the-needle catheters before removing the stylet. Otherwise, the needle can lacerate or transect the catheter.
- Avoid excessively tight neck bandaging.

PROCEDURE

- Catheter placement should always be done aseptically.
- Animal should be in lateral recumbency, with the nonrecumbent side being the side with the jugular to be catheterized.
- Clip hair from site. Centered over the jugular furrow, the clip and aseptic prep extend approximately as follows:
    - From slightly beyond the ventral midline of the neck ventrally to halfway between the ventral and dorsal midlines dorsally
    - From the thoracic inlet caudally to the angle of the mandible cranially
- Prepare site aseptically with complete surgical scrub.

GUIDE-WIRE TECHNIQUE:

- Use sterile surgical gloves when placing the catheter.
- Drape site with sterile drape.
- Check that catheter or needle about to be used for venipuncture can accept guide wire (compatible diameters).
- Insert needle in vessel (jugular venipuncture):
    - Catheter (generally needs to be larger than 20-gauge) may used in place of needle.
    - In thick-skinned animals, a two-step approach may be better:
        - Raise the jugular vein.
        - Lift (tent) the skin overlying the jugular vein.
        - Enter only the skin with the needle/catheter, or make a small stab incision in the skin with a sterile scalpel blade.
        - Gently return the skin to a normal position (keeping the needle in place in the skin).
        - Advance the needle into the raised jugular vein.
- Place guide wire into vessel through needle or catheter, J-tip (not straight tip) first. To do so, the guide wire is retracted into the J-tip straightening device (a small, tapered sleeve), and the device with the straightened J-tip is placed into the catheter. The guide wire may then be advanced easily through the catheter and into the jugular vein, with the J shape emerging from the peripheral catheter in the jugular vein to avoid trauma from a straight guide wire tip.
- After advancing the guide wire a few cm into the jugular vein (4-10 cm, depending on the patient's size), do not move the guide wire for the rest of the procedure until the catheter is in place.
- While holding the guide wire firmly with one hand (guide wires are Teflon-coated and slippery), remove needle or catheter from vessel and off the wire while ensuring the guide wire stays in the vessel.
- Maintain digital pressure over the catheter placement site to minimize hemorrhage.
- Measure length of guide wire protruding from skin; it should be a few cm greater than the length of the dilator (withdraw guide wire slightly as needed).
- Place dilator over the wire into the vessel (this dilates the vessel insertion site so the catheter can be placed more easily into the vessel). Expect some bleeding around the site, which should be controlled with direct pressure. Some jugular catheter kits have a combined catheter-dilator configuration, which allows the dilation step and the catheter placement step to occur simultaneously.
- While holding the guide wire firmly in place, remove the dilator back over the wire, making sure that wire stays in the vessel. Apply pressure over the site to minimize hemorrhage.
- Thread IV catheter over the wire, and advance catheter into the vessel.
- Remove wire, making sure the catheter stays in place.
- Remove air in the catheter line with the use of a 3-mL syringe that contains heparinized saline.
- Flush catheter with heparinized saline without administering air to animal.
- Suture catheter to skin.
- Cover site with nonadhesive bandage.
- Bandage catheter in a stable position (neck wrap).



JUGULAR CATHETER PLACEMENT AND MANAGEMENT Guide wire–type jugular catheter kit. **A**, Triple-lumen jugular catheter. **B**, Flexible Teflon-coated stylet with J-tip straightening sleeve *(arrowhead)*. **C**, Vessel dilator. **D**, Peripheral IV catheter (large-bore needle may be used instead, but guide wire must fit through it). **E**, Local anesthetic. **F**, Syringe for injecting anesthetic. **G**, Disposable scalpel for making skin incision. **H**, Suture material.

THROUGH-THE-NEEDLE CATHETER TECHNIQUE:

- Insert needle into vessel. The two-step technique may help (as just described).
- Advance catheter through the needle into the vessel.
- Lock catheter into needle hub.
- Withdraw needle from vessel and skin (i.e., withdraw needle by 3-4 cm, ensuring catheter remains well in the jugular vein), and place the needle guard over needle.
- Remove stylet from catheter.
- Cap catheter and flush catheter with heparinized saline.
- Suture catheter to skin.
- Cover site with nonadhesive bandage.
- Bandage catheter in a stable position (neck wrap).

JUGULAR CATHETER PLACEMENT AND MANAGEMENT Through-the-needle jugular catheter. Inside the kit *(left)* are the catheter *(center)* and needle guard *(right)*. Note plastic sheath of catheter, which allows catheter to be advanced through needle into

the patient without wearing sterile gloves; also note large needle that remains with the patient and must be covered with needle guard.

POSTPROCEDURE

- Assess tightness of bandage around animal's neck after each layer is placed. A finger should easily pass between skin and bandage.
- For walks, leashes should be placed around shoulders, or use a harness.
- If using multiple-lumen catheters, be sure animal cannot chew lumen lines.
- When using multiple lumens, designate one for TPN (usually the most distal).
- Flush line(s) with heparinized saline every 6 hours to maintain patency.

ALTERNATIVES AND THEIR RELATIVE MERITS

Peripheral catheter: technically simpler and cheaper but does not allow jugular catheter functions as already described.

AUTHORS: ELISA A. PETROLLINI ROGERS, KENNETH DROBATZ

Luxation Reduction (Closed): Shoulder, Elbow, or Hip

SYNONYMS

Coxofemoral luxation (hip); dislocated shoulder, elbow, hip; scapulohumeral luxation (shoulder)

OVERVIEW AND GOALS

- Severe joint trauma can cause ligament/joint capsule damage, resulting in displacement of the bones of a joint.
- Closed reduction aims to restore the normal alignment of the joint without surgical intervention, and to maintain stability until these soft tissues heal.

INDICATIONS

- Traumatic luxation of normal shoulder, elbow, hip joints
- Acute luxation (<5 days)

CONTRAINDICATIONS

- Luxation associated with severe ligament damage or avulsion fractures that impede normal joint function and/or leave the joint unstable after closed reduction
- Failure of closed reduction due to interposed soft tissue, hematoma, or recurrent luxation necessitates open (surgical) reduction
- Chronic luxation (>5 to 7 days)
- Dysplastic joint:
    - Glenoid dysplasia
    - Total hip replacement may be a better option in cases of severe hip dysplasia.
- Femoral head and neck ostectomy (FHO) may be an acceptable alternative to closed/open hip reduction in a small dog or cat.

EQUIPMENT, ANESTHESIA

- General anesthesia
- Rope or leash to provide counterpressure (hip luxation)
- Assistant
- Bandage material

ANTICIPATED TIME

About 10-30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Advise owner of aftercare and possible drawbacks:
    - Recurrence
    - Degenerative joint disease
    - Decreased range of motion
    - Possible need for open reduction
    - Postreduction bandage care
    - Postreduction exercise restriction

After anesthetic induction:

- Minimum of two views of the joint to confirm luxation versus fracture
- Animal in lateral recumbency, affected limb up (affected limb on the nonrecumbent side)
- Hanging the affected limb can be useful (elbow luxation) for 5-10 minutes: secure the carpus, and hoist the limb vertically with traction. Be sure to secure the limb proximal to the metacarpi, and use a thick, soft rope (or roll gauze) in a double-loop technique, rather than single loop, to distribute pressure evenly on the distal limb. These measures reduce the risk of

iatrogenic damage.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- If there is excessive instability following closed reduction, open reduction should be performed.
- Failure to critically evaluate plain radiographs to assess joint anatomy or damage, avulsion fragments, and intraarticular debris
- Trying to reduce a luxation with sedation alone
- Failure to appropriately bandage the luxation
- Removal of bandage too soon
- Inadequate patient exercise restriction
- When hanging the forelimb to help with elbow luxation reduction: be sure to secure the limb proximal to the metacarpi, and use a thick, soft rope (or roll gauze) in a double-loop technique to distribute pressure evenly on the distal limb. These measures reduce the risk of iatrogenic damage.

PROCEDURE

All luxation reductions are performed with the animal under general anesthesia and in lateral recumbency, affected side up (nondependent).

- Shoulder:
  - Forelimb held in extension (in a ventral direction perpendicular to the long axis of the body, as in the standing animal)
  - For lateral luxation of the humeral head, apply medial pressure to the head at the same time as lateral pressure on the scapula.
  - Check range of motion and stability.
  - Place leg in a Spica splint.
  - For medial luxation of the humeral head, apply lateral pressure to the head at the same time as medial pressure on the scapula.
  - Check range of motion and stability.
  - Place the leg in a Velpeau sling.
  - Splint or sling can be removed after 2 weeks.
  - Passive range-of-motion exercises can begin after bandage removal, but restricted exercise is essential for another 2-4 weeks.
- Elbow:
  - Radius and ulna are usually luxated laterally relative to the distal humerus.
  - With the elbow in flexion, inwardly rotate the antebrachium.
  - Combined with elbow flexion, this movement enables the anconeal process of the ulna (caudal-most extent of the trochlear notch in the ulna) to hook into the olecranon fossa of the humerus. This maneuver is followed by careful extension of the elbow.
  - Hook the anconeal process of the ulna between the humeral condyles, and carefully extend the elbow. With this part of the maneuver, the joint should now be reduced.
  - Passive range-of-motion exercises can begin after bandage removal, but restricted exercise is essential for 4-6 weeks, followed by 2 weeks of leash exercise only.
- Hip:
  - Assistant stands on opposite side of animal, holding the ends of a padded rope or leash placed in the animal's groin to provide counterpressure.
  - Craniodorsal hip luxation (more common):
    - The tarsus is grasped and externally rotated while the femur is pulled caudally.
    - The head of the femur rides up (moves laterally and then caudally) and over the dorsal acetabular rim.
    - Internal rotation while maintaining distal traction on the femur, together with direct pressure on the greater trochanter, will seat the head in the acetabulum.
    - Place hip in an Ehmer or modified Ehmer sling for 2 weeks.
  - Caudoventral luxation:
    - The femur should be abducted and externally rotated to seat the femoral head in the acetabulum.
    - Hobbles may be applied for 10-14 days.
  - Medially-directed pressure can be applied to the reduced proximal femur as the hip is passively flexed and extended in an attempt to drive debris from the acetabulum.

POSTPROCEDURE

- Radiograph to evaluate the reduction.
- Toes should be accessible or visible to monitor for heat, cold, swelling, or pain.
- Bandage needs to be protected from moisture and kept clean and dry.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Open reduction:
  - Requires surgical intervention
  - Greater cost
  - Carries a higher rate of success than closed reduction for the shoulder, elbow, and hip
- FHO may be worth considering for cats and small dogs, as the possibility of hip reluxation is eliminated.
- Arthrodesis can provide pain relief for a chronically unstable joint. Aside from cost, complications include nonunion, stress fractures, implant failure and infection.
- Excision glenoid arthroplasty for the shoulder joint. There are few reports of glenoid arthroplasty, but an abnormal gait is to be expected.
- Amputation

AUTHOR: NICHOLAS J. TROUT

Local and Regional Anesthesia

SYNONYM

Local blocks

OVERVIEW AND GOALS

- *Local anesthesia* and *regional anesthesia* refer to a broad range of techniques that utilize local anesthetic agents delivered to a discrete anatomic area (as opposed to systemic delivery).
- With these techniques, the local anesthetic agent inhibits pain by blocking transmission of noxious input (and other types of sensory input) before it ever reaches the brain. The animal's level of consciousness is not affected.
- This contrasts with general anesthesia, during which nociceptive processing continues to occur, but the animal is not able to perceive pain owing to the unconscious state.

INDICATION

- Infiltrative anesthesia:
  - Incisional block: supplemental analgesia for a variety of surgical procedures (e.g., abdominal wall incisions, total ear canal ablation incisions)
- Peripheral nerve blocks:
  - Dental nerve block: supplemental analgesia for tooth extractions, maxillary/mandibular surgeries
  - Brachial plexus block: supplemental analgesia for surgical procedures involving the forelimb distal to shoulder
  - Distal radial, ulnar, and median nerve blocks: supplemental analgesia for feline onychectomy or any surgical procedure involving the distal forepaw
  - Intercostal nerve blocks: supplemental analgesia after lateral thoracotomy or desensitizing area around isolated rib fractures
- Epidural anesthesia/analgesia:
  - Lumbosacral injection of local anesthetic: indicated for caudal procedures/injuries only (e.g., involving hind limb, tail, perineum, caudal abdomen)
  - Lumbosacral injection of opioid: hydrophilic opioids (i.e., morphine) indicated to supplement analgesia for a variety of procedures (e.g., hind limb, tail, abdominal, forelimb, thoracic, cervical procedures)
- Other regional techniques:
  - Intraarticular anesthesia/analgesia: supplemental analgesia for procedures involving the joint space (stifle most common)
  - Interpleural anesthesia: supplemental analgesia for thoracic and cranial abdominal pain (especially pancreatitis)
  - IV regional anesthesia: desensitization of a distal limb to facilitate surgery

CONTRAINDICATIONS

- Infiltrative anesthesia, peripheral nerve blocks, others:
  - Injection into infected tissue
- Epidural anesthesia/analgesia (see p.1260):
  - Injection into infected tissue (at lumbosacral junction)
  - Coagulopathy
  - Septicemia
  - Uncorrected hypotension (especially with local anesthetics)
  - Significant trauma/lesion at lumbosacral junction

EQUIPMENT, ANESTHESIA

- Infiltrative anesthesia:
  - Incisional block:
    - Hypodermic needle (22, 25 gauge), syringe, sterile gloves, local anesthetic
    - Dosages (total per animal): lidocaine, ≤5 mg/kg (dog), ≤3 mg/kg (cat); bupivacaine, ≤2 mg/kg (dog), ≤1 mg/kg (cat)
    - Animal is usually under general anesthesia, and block is done either before incision is made or at the end of the surgery prior to complete closure.
- Peripheral nerve blocks:

- Dental nerve block:
  - Hypodermic needle (22, 25 gauge), syringe, local anesthetic
  - Dosages (total per animal): lidocaine, ≤5 mg/kg (dog), ≤3 mg/kg (cat); bupivacaine, ≤2 mg/kg (dog); ≤1 mg/kg (cat)
  - Animal is usually under general anesthesia.
- Brachial plexus block:
  - Hypodermic needle (22 gauge) or spinal needle (22 gauge, 2-3 inches [5-8 cm]), syringe, local anesthetic
  - Dosages (total per animal): lidocaine, ≤5 mg/kg (dog), ≤3 mg/kg (cat); bupivacaine, ≤2 mg/kg (dog), ≤1 mg/kg (cat)
  - Specialized insulated needle (22 gauge, 3 inches) required if a nerve locator is to be used.
  - Animal is usually sedated or under general anesthesia.
- Distal radial, ulnar, median nerve blocks:
  - Hypodermic needle (22, 25 gauge), syringe, local anesthetic
  - Dosages (total per animal): lidocaine, ≤5 mg/kg (dog), ≤3 mg/kg (cat); bupivacaine, ≤2 mg/kg (dog), ≤1 mg/kg (cat)
  - Animal is usually under general anesthesia, and block is done prior to surgical procedure.
- Intercostal nerve block:
  - Hypodermic needle (22, 25 gauge), syringe, local anesthetic.
  - Dosages (total per animal): lidocaine, ≤5 mg/kg (dog), ≤3 mg/kg (cat); bupivacaine, ≤2 mg/kg (dog), ≤1 mg/kg (cat)
  - Animal is usually sedated or under general anesthesia.

- Epidural anesthesia/analgesia (see p.1260):
  - Spinal needle (18, 20, 22 gauge; Quincke or Huber point, 1½-3½ inches [4-9 cm]), syringe, sterile gloves, local anesthetic (preservative-free lidocaine, bupivacaine), ± opioid (preservative-free morphine)
- Other regional techniques:
  - Intraarticular anesthesia/analgesia:
    - Hypodermic needle (22 gauge), syringe, sterile gloves, local anesthetic (lidocaine, bupivacaine) ± opioid (morphine)
    - Dosages (total per animal): lidocaine, ≤5 mg/kg (dog), ≤3 mg/kg (cat); bupivacaine, ≤2 mg/kg (dog), ≤1 mg/kg (cat)
    - Animal is usually sedated or under general anesthesia.
  - Interpleural anesthesia:
    - Butterfly catheter (22 gauge) or through-the-needle catheter (20 gauge, 2 inches); preplaced chest tube or commercial interpleural anesthesia tray, syringe, sterile gloves, local anesthetic
    - Dosages: lidocaine, ≤5 mg/kg (dog) q 2-4 h; ≤3 mg/kg (cat) q 4h. Bupivacaine, ≤2 mg/kg (dog) initially, then ≤1 mg/kg q 6 h; ≤1 mg/kg (cat) initially, then ≤0.5 mg/kg q 6 h
    - Animals are usually sedated or under general anesthesia.
  - IV regional anesthesia:
    - Cling-and-release bandage material (e.g., Vetrap), IV catheter (22 gauge), tourniquet, hypodermic needle (22 gauge), syringe, local anesthetic (lidocaine)
    - Dose: lidocaine, 2.5-5 mg/kg (dog only)
    - Animal is usually sedated.

ANTICIPATED TIME

This time period does not include clipping of hair and preparation of the site where indicated.

- Infiltrative anesthesia:
  - Incisional block: <1-2 minutes
- Peripheral nerve blocks:
  - Dental nerve blocks: <1-2 minutes
  - Brachial plexus block: <5-10 minutes
  - Distal radial, ulnar, median nerve blocks: <1-2 minutes
  - Intercostal nerve blocks: <1-2 minutes
- Epidural anesthesia/analgesia: <5-10 minutes
- Other regional techniques:
  - Intraarticular anesthesia/analgesia: <1-2 minutes
  - Interpleural anesthesia: <5-10 minutes
  - IV regional anesthesia: <5-10 minutes

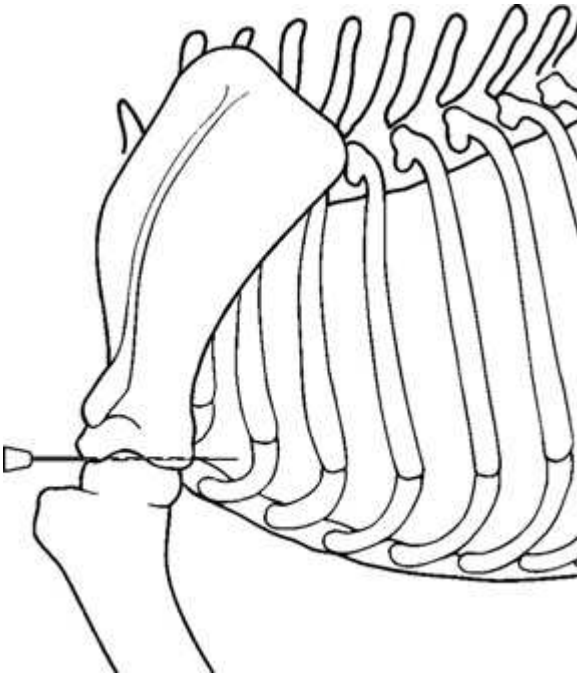
PREPARATION: IMPORTANT CHECKPOINTS

- Ensure that injection site(s) is clipped (if applicable) and aseptically prepared.
- Adhere to strict aseptic technique during all procedures—doing this is mandatory.

- Ensure that drug solutions are free from contamination (especially for epidural and intraarticular techniques).

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Systemic local anesthetic toxicosis is possible with any technique and is usually associated with inadvertent IV injection/excessive drug doses.
- Infiltrative anesthesia:
  - Incisional block: inadvertent IV or intraarterial injection, penetration of body cavities/organs
- Peripheral nerve blocks:
  - Dental nerve block: self-mutilation following sensory loss to tongue and lips (rare)
  - Brachial plexus block: inadvertent IV or intraarterial injection or injection into the thoracic cavity with possible pneumothorax/pulmonary laceration
  - Distal radial, ulnar, median nerve blocks: self-mutilation following sensory loss to distal paws (very rare)
  - Intercostal nerve block: inadvertent intrathoracic injection with possible pneumothorax/pulmonary laceration
- Epidural anesthesia/analgesia: inadequate block, hypotension, urinary retention, transient neurologic deficits (rare)
- Other regional techniques:
  - Intraarticular anesthesia/analgesia: articular cartilage damage
  - Interpleural anesthesia: pneumothorax, pulmonary laceration
  - IV regional anesthesia: ischemic limb damage; systemic local anesthetic toxicosis due to tourniquet failure



LOCAL AND REGIONAL ANESTHESIA Brachial plexus nerve block. Place needle medial to scapulohumeral joint, lateral to thoracic wall, toward costochondral junction, parallel to vertebral column.

(From Fossum TW, et al: Small animal surgery, ed 2, St Louis, 2002, Mosby.)

PROCEDURE

For selected techniques only:

- Peripheral nerve blocks:
  - Dental nerve blocks:
    - Infraorbital: palpate infraorbital foramen rostral and ventral to medial canthus of eye; insert needle into foramen and aspirate. If there is negative pressure (no blood), inject local anesthetic.
    - Mandibular: palpate mandibular foramen intraorally on the medial surface of the mandible, and insert needle percutaneously from the ventromedial aspect of the mandible toward the foramen and aspirate. If there is negative pressure (no blood), inject local anesthetic.
  - Brachial plexus block:
    - From a cranial approach, insert the needle medial to the scapula just ventral to the body of the sixth cervical vertebra; advance until the tip of the needle is just beyond the first rib and aspirate. If there is negative pressure (no blood), inject one-fourth dose of a local anesthetic; withdraw needle partially and aspirate. If

there is negative pressure (no blood), inject another one-fourth dose of anesthetic; repeat until needle is completely withdrawn and all drug has been injected.
    - Distal radial, ulnar, median nerve blocks; three injections required per paw:
        - On dorsal aspect, insert needle just proximal to the first phalanx and aspirate; if negative pressure (no blood), inject local anesthetic.
        - On palmar aspect, insert needle just medial to accessory carpal pad and aspirate; if negative pressure (no blood), inject local anesthetic.
        - Remove needle and insert just lateral and proximal to accessory carpal pad and aspirate; if negative pressure (no blood), inject local anesthetic.
- Epidural anesthesia/analgesia (see p.1260):
    - Place animal in lateral or sternal recumbency, and locate the lumbosacral space as follows: palpate the cranial edges of the ilial wings (this is at the level of the sixth lumbar vertebra), palpate the dorsal process of the seventh lumbar vertebra caudal to this area, and then palpate a large depression corresponding to the lumbosacral space farther caudally.
    - Insert spinal needle directly over the lumbosacral space at an angle perpendicular to the skin, and advance needle slowly through the ligamentum flavum until a loss of resistance and characteristic “pop” is appreciated, indicating that the epidural space has been penetrated.
    - Remove stylet, and ensure that blood or cerebrospinal fluid (CSF) is not evident in needle hub.
    - Inject 1 mL of air, using a glass syringe to confirm lack of resistance, and correct needle placement; inject local anesthetic, opioid, or other analgesic.
- Other regional techniques:
    - Interpleural anesthesia:
        - Insert catheter in the ninth intercostal space on the midlateral aspect of thorax.
        - Aspirate to remove air/blood.
        - Inject local anesthetic (lidocaine should be injected first in conscious animals to minimize discomfort and can be followed by bupivacaine if a long-duration block is desired).

POSTPROCEDURE

- If local/regional anesthesia is being used for supplementing analgesia in conjunction with general anesthesia, injectable and inhalant anesthetic requirements may be markedly reduced.
- Animals must be monitored for adequacy of analgesia and treated accordingly.

ALTERNATIVES AND THEIR RELATIVE MERITS

Pain associated with surgery, trauma, and a variety of medical conditions can usually be managed using systemic analgesics (e.g., opioids, nonsteroidal antiinflammatory drugs [NSAIDs]); however, these agents are not able to block peripheral nociceptive input. The inclusion of a local or regional technique constitutes a multimodal approach to anesthesia and pain management and is simply good medical practice.

AUTHOR: LEIGH A. LAMONT

Liver Biopsy, Laparoscopic

OVERVIEW AND GOALS

- Allows visualization of entire organ in order to obtain biopsy samples from appropriate lobe/lobes
- Easy access to gall bladder for examination/aspirate
- In most cases, pancreas can be examined/biopsied as well.
- Samples superior in size/number in most cases (compared to ultrasound-guided samples)
- Can be performed safely in dogs and cats

INDICATIONS

- Abnormal results of liver function tests (bile acids/ammonia)
- Persistently elevated serum liver enzyme levels
- Abnormal liver size or architecture ultrasonographically
- Ascites of unknown origin
- Elucidation of etiology in cases of suspected triaditis

CONTRAINDICATIONS

- Bleeding disorder
- Hepatic encephalopathy
- Surgical disease (e.g., bile duct obstruction/biliary mucocele)
- Peritonitis (septic/neoplastic)
- Diaphragmatic hernia
- Very small patient (<2 kg)

EQUIPMENT, ANESTHESIA

Instrumentation:

- Telescope: 5 mm (0 degrees)
- Veress needle
- Trocar cannulas: two sufficient for most liver biopsies
- Biopsy forceps: punch and oval
- Palpation probe
- Light source and cable: 130- to 300-watt xenon bulb
- Video camera and monitor
- CO2 insufflator

ANTICIPATED TIME

An experienced laparoscopist can perform the procedure in less than 20-30 minutes in most instances.

PREPARATION: IMPORTANT CHECKPOINTS

- Coagulation profile and buccal mucosal bleeding time
- Blood pressure
- Packed cell volume/total solids (PCV/TS)
- Bladder must be emptied prior to Veress needle insertion
- Sterile surgical prep from the 10th intercostal space to pubis

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Lack of insufflation: Veress embedded in omental fat, poor placement for insufflation based on CO2 flow. Withdraw Veress and replace.
- Laceration of spleen: usually not an emergency. Place patient in slight left lateral recumbency to avoid.
- Bladder impalement: empty bladder prior to procedure.
- Gall bladder leakage post aspiration: attempt aspiration of full contents to avoid.
- Postoperative seroma formation at trocar sites: avoid with double layer closure.

- In rare cases, patients showing respiratory compromise due to abdominal distension require ventilator support.

PROCEDURE

Ventral approach:

- Establish pneumoperitoneum: ventral midline placement of Veress needle into the abdomen, 1-2 cm caudal to the umbilicus.
- Insufflate the abdomen with CO_2 to set pressure maximums and flow rates based on the patient's size.
- Remove Veress needle once sufficient insufflation achieved, place first trocar at the Veress incision site, replace CO_2 flow to the trocar flow port.
- Place telescope through trocar, examine abdominal contents.
- Under telescopic guidance, place a second trocar in a right or left lateral position, depending on liver access/size/distribution of lesion(s).
- Transfer CO_2 line to the second trocar to prevent moisture accumulation on telescope lens.
- With telescope in central port, biopsy/probes in the lateral port, a liver biopsy can be obtained.
- Multiple lobes should be sampled from the edge of a given lobe or from the middle of a lobe of interest. Areas should be examined for excessive bleeding. Should this occur, pressure can be applied with a blunt probe, or gel foam can be inserted at the site.

POSTPROCEDURE

- Remove telescope and biopsy/blunt probes from trocars.
- Discontinue CO_2 flow.
- Open trocar flow ports, and gently place pressure on the abdomen to release gas via the trocars.
- Once abdomen is sufficiently deflated, trocars can be withdrawn from the abdominal wall.
- Each incision is closed in a two-layer fashion of the laparoscopist's choice.
- In most cases, patients can be sent home the same day, provided postoperative parameters (PCV/TS/blood pressure) are within normal and expected range.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Ultrasound-guided liver biopsy: less invasive, quicker procedure time, smaller sample
- Open liver biopsy via laparotomy: benefits are those associated with full abdominal exploratory surgeries but more invasive, longer healing.

AUTHOR: MAUREEN CARROLL

Lithotripsy

SYNONYMS

Stone fragmentation, electrohydraulic lithotripsy (EHL), laser lithotripsy (holmium-doped yttrium, aluminum, garnet [Ho : YAG] laser)

OVERVIEW AND GOALS

Removal of urinary tract stones through natural orifices

INDICATIONS

Treatment of bladder and urethral stones in dogs

CONTRAINDICATIONS

Untreated coagulopathy

EQUIPMENT, ANESTHESIA

General anesthesia, flexible ureteroscope (males), rigid cystoscope (females), saline, protective eyewear, Ho : YAG laser or EHL probe, stone basket, 60-mL syringes

ANTICIPATED TIME

Variable (mean 60 minutes). Depends on stone location (longer in bladder than in urethra), sex of the patient (longer in males than in females), number, size and shape of the stones (longer for smooth and large stones)

PREPARATION: IMPORTANT CHECKPOINTS

- Urine culture and sensitivity 5 days before the procedure and appropriate antibiotic therapy if needed
- Coagulation profile:
    - The following breeds are predisposed to von Willebrand disease: Doberman pinscher, standard poodle, Shetland sheepdog, German shepherd, German shorthaired and wirehaired pointers, Scottish terrier, Chesapeake Bay retrievers. Factor measurement may be indicated.
- Protective eyewear
- Gauze squares on the eyes of the patient

POSSIBLE COMPLICATIONS

- Most complications occur either during or within 24 hours of the procedure.
- Complications related to cystoscope-guided laser lithotripsy occurred in 5 of 28 female dogs and 6 of 45 male dogs (Adams, 2008).
- Common: hematuria, stranguria usually self-limiting within 48 hrs
- Rare: urethral or bladder perforation (due to laser contact with the mucosa or secondary to voiding urohydropulsion [VUH]), urethral obstruction, indwelling urinary catheter for 1-5 days after the procedure, urinary tract infection
- Scope damage: probe activated within the scope
- Precautions:
    - Avoid firing laser against the mucosa or closer than 1 mm, flush abundantly, use rigid cystoscope in female whenever it is possible.
    - VUH the day after the lithotripsy if remaining fragments
    - Selection of candidates depending on the sex, the size/shape/location of the stones

LITHOTRIPSY Endoscopic image demonstrating 2 uroliths in the bladder of a dog. The probe is seen emerging from the bottom of the image and contacting the urolith on the right in preparation for fragmentation.

PROCEDURE

- Performing lithotripsy requires at least 2 people (clinician and assistant).
- Patients are put under general anesthesia. Females are positioned in dorsal recumbency and males in lateral recumbency. The vulva or prepuce is aseptically prepared. The scope is passed through the urethra. Saline is injected through the scope to distend the bladder and localize the stones.
- The probe is passed through the working channel of the scope until it contacts the stone. As soon as the stones are broken (small enough to pass through the urethra), VUH is performed (saline) to remove the fragments from the urinary tract.
- The scope can then be reintroduced to check for remaining fragments and if needed, a new series of fragmentation and urohydropulsion is performed. A stone basket can be used to remove fragments more rapidly. Stone fragments should be sent for culture and mineral analysis.

POSTPROCEDURE

- Analgesia (opioids and nonsteroidal antiinflammatory drugs)
- Radiographs or ultrasound to check for the presence of stones/fragments
- Stone analysis
- 5 days of broad-spectrum antibiotics (amoxicillin or cephalexin)
- If remaining fragments, repeat lithotripsy and/or VUH depending on their size. These fragments could serve as a nidus for future stone formation.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Surgery is the standard of care for urocystoliths in dogs and cats. Cystotomy allows the removal of bladder stones, but the sutures can serve as nidus for new stone formation.
- Obstructive urethral stones may sometimes be retropulsed into the bladder and removed by cystotomy. Lithotripsy is an excellent minimally invasive alternative to urethrotomy.
- Extracorporeal shock wave lithotripsy (ESWL) consists of fragmenting urinary tract stones by delivering external shock waves through a water bath or a specific fluid-filled cushion. It has been very successful in fragmenting nephroliths and ureteroliths in dogs but less successful with cystoliths and urethroliths. Feline nephroliths and ureteroliths are more resistant to fragmentation, and fragments may obstruct small feline ureters.
- A laparoscopic approach to cystolith removal can be used in male cats and small male dogs (<5 kg) when the scope is too large to pass through the urethra.

Laryngeal, Pharyngeal, and Oral Examination

SYNONYMS

Laryngoscopy, pharyngoscopy

OVERVIEW AND GOAL

Complete examination of oral cavity, oropharynx, larynx, and part of the nasopharynx

INDICATIONS

- Anorexia (secondary to oral discomfort)
- Oronasal fistula evaluation
- Mandibular/maxillary fracture assessment
- Cervical/oral/facial trauma
- Precise occlusion evaluation
- Ptyalism/hypersalivation
- Gagging
- Halitosis
- Facial deformity
- Voice change
- Dysphagia
- Noisy respiration, especially inspiratory stridor with a radiographically normal trachea
- Respiratory distress, especially inspiratory

CONTRAINDICATIONS

Severe respiratory distress necessitating oxygen supplementation, endotracheal intubation, or emergency tracheostomy

EQUIPMENT, ANESTHESIA

VENOUS ACCESS:

- Hair clippers with a #40 blade
- Surgical skin scrub preparation materials
- IV over-the-needle catheter of appropriate size for the animal (18-24 gauge)
- T-port or PRN to cap catheter
- White cloth tape, 1½ inches (3.5 cm) and 1 inch (2.5 cm), for catheter fixation
- 5 mL heparinized saline

ANESTHETIC AGENTS:

- Premedication:
  - It may be preferable to avoid premedication when evaluating laryngeal function. The use of thiopental without premedication significantly increases arytenoid motion before recovery, which is optimal when compared to other protocols (propofol, ketamine, and diazepam; acepromazine and thiopental; acepromazine and propofol). This is the recommended protocol for evaluating laryngeal function (Tobias et al., 2004).
  - If the lack of premedication when potentially evaluating laryngeal function is unacceptable to the clinician, an alternative is glycopyrrolate (0.01 mg/kg IV, IM, or SQ) and butorphanol (0.1 mg/kg IV, IM, or SQ).
  - If no evaluation of laryngeal function is judged necessary, a standard sedation or premedication protocol is acceptable if the animal is stable. Examples (see also inside back cover of book):
    - Glycopyrrolate (0.01 mg/kg IV, IM, or SQ) + acepromazine (0.05 mg/kg IM or SQ) + butorphanol (0.1 mg/kg IM or SQ); *or*
    - Glycopyrrolate (0.01 mg/kg IV, IM, or SQ) + hydromorphone (0.1 mg/kg IM) ± acepromazine (0.05 mg/kg IM or SQ)
- Induction:
  - For evaluation of laryngeal function, thiopental (20 mg/kg IV, give half the volume as a bolus and then "to effect") or propofol (2 mg/kg with premedication, or 6 mg/kg if no premedication) are preferred over ketamine-diazepam (Gross et al., 2002).
  - If no evaluation of laryngeal function is judged necessary, routine agents are appropriate. Examples in stable animals

include:
    - Thiopental (as above); *or*
    - Propofol (as above); *or*
    - Ketamine (10 mg/kg) + diazepam (0.5 mg/kg) IV
- Stimulation of respiration:
    - The use of doxapram HCl helps differentiate normal dogs from dogs with laryngeal paralysis. In these dogs, administration of doxapram seems to enhance paradoxical arytenoid motion:
        - Doxapram HCl, 5-10 mg/kg IV

POSITIONING:

- To maintain head in the upright position:
    - Conformable roll gauze (e.g., 2-inch [5 cm] Kling)
    - Two poles (of the type used for IV fluid administration, optional)

ORAL EXAMINATION:

- Oral speculum (mouth gag)
- Light source/transilluminator
- Laryngoscope
- Dry gauze sponges:
    - For manipulating the tongue
    - To dry up secretions

LARYNGEAL EXAMINATION:

- Oral speculum
- Light source/transilluminator
- Laryngoscope
- One or two tongue depressors taped end to end for dorsal retraction/elevation of the soft palate

OROPHARYNGEAL AND NASOPHARYNGEAL EXAMINATION:

- As for oral and laryngeal examination (above) + spay hook for cranial retraction of soft palate
- Small mirror used in dentistry, with antifogging agent or immersed in warm (38○C) water/saline
- Small flexible endoscope (see Alternatives section, below)

FINE-NEEDLE ASPIRATION/BIOPSIES:

- A set of 10-mL syringes, 22-gauge needles, and microscope slides for fine-needle aspiration and cytologic examination
- Biopsy kit:
    - A #15 scalpel blade
    - Adson forceps
    - Needle holder
    - Small scissors
    - Suture scissors
    - Appropriate size resorbable suture (surgeon's preference)

ENDOTRACHEAL INTUBATION:

- Appropriate size tube (see p. 1293)
- Conformable 1- or 2-inch tape or gauze for tube fixation
- A 5- to 10-mL empty syringe for cuff inflation
- Anesthesia machine verified with appropriate circuit for the animal (semiopened or semiclosed):
    - Functional
    - Oxygen
    - Inhalant anesthetic agent

ANTICIPATED TIME

About 15-30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Use preoxygenation with a mask if possible.
- Always perform this examination on animals that have been fasted, because the airway is not always protected during the exam. There is the possibility of regurgitation of gastric contents and subsequent aspiration pneumonia.
- Always be prepared for orotracheal intubation of animal and possible ventilation with oxygen through an anesthetic circuit.
- In animals in respiratory distress, always be prepared to perform an emergency tracheostomy (see p. 1344).
- In animals with moderate or marked inspiratory stridor or any degree of upper airway distress, owners must pre-emptively hear and understand options to consider (surgical intervention if problem correctable, euthanasia on the table if noncorrectable obstructive disorder) in case severe laryngeal infiltration, a nonresectable mass, or other equally serious problem is identified.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Incomplete examination
- May give a false-positive diagnosis of laryngeal paralysis because animal is too heavily sedated or not enough time is given for animal to come out of light anesthesia. To minimize the occurrence of this situation, prepare doxapram HCl and administer if needed.

PROCEDURE

When dogs are extremely dyspneic due to laryngeal paralysis, the diagnosis often can be made on the awakened animal: a bright light source (e.g., Finnoff transilluminator) is directed into the oral cavity during the severe dyspnea, and failure of the arytenoid cartilages to abduct is clearly apparent in the conscious animal. Otherwise, proceed as follows:

- Venous access:
  - Prepare site for IV catheter insertion (clip, clean, and prep skin).
  - Insert IV catheter.
  - Close catheter with a T tube or a PRN.
  - Fixation of catheter to skin
  - Flush catheter with heparinized saline.
- Premedication:
  - Administer premedication if judged necessary.
- Preoxygenation:
  - Animal in sternal recumbency
  - If possible, use a mask to preoxygenate animal for 5 minutes.
- Induction of anesthesia:
  - IV administration of predetermined anesthetic agent:
    - Very light anesthetic plane is used for evaluation of laryngeal function:
      - If anesthetic plane is too deep, give time (5-10 minutes) for animal to partially recover from anesthesia, and then continue to evaluate.
    - Deeper anesthetic plane is used for evaluation of oral cavity and pharynx and anatomic evaluation of the larynx.
- Positioning of the head:
  - Assistant holds head upright using a piece of conformable roll gauze (Kling) passed behind the upper canine teeth.
  - Alternatively, two IV poles, one on each side of the table, can be used; the conformable gauze is passed behind the upper canine teeth, and the gauze is attached to each IV pole, thus supporting the head in the upright position.
  - Place oral speculum of appropriate size.
- Oral examination:
  - All structures of the oral cavity should be evaluated:
    - Lips, cheeks, teeth (abscess, fracture, occlusion), gingiva, tongue (under and at the base), hard palate, soft palate (mass, elongation), tonsillar crypts/tonsils.
- Oropharyngeal examination:
  - Soft palate should be palpated for thickness, mobility.
  - Elevate soft palate dorsally with a tongue depressor or two depressors taped end to end in a large dog.
  - Depress base of the tongue ventrally with a laryngoscope. This permits evaluation of the upper esophageal sphincter.
- Laryngeal examination:
  - After the evaluation of the oropharynx, it is appropriate to evaluate the anatomy of the larynx: epiglottis, aryepiglottic folds, arytenoid cartilages (cuneiform and corniculate processes) vocal cords, laryngeal ventricles.
  - Then evaluate the function of the larynx:
    - Normal:
      - Observe active abduction of the arytenoid cartilages synchronized with inspiration.
      - Observe passive adduction of the arytenoid cartilages synchronized with expiration.
    - Abnormal:
      - Observe no movement of cartilages:
        - Is it significant? Animal is usually too deeply anesthetized; wait until motion returns or

administer doxapram HCl (seep. 635).
- Observe paradoxical movement of arytenoid cartilages, indicating laryngeal paralysis:
  - Adduction at inspiration
  - Abduction at expiration

- Nasopharyngeal examination:
  - Palpate the soft palate, then press firmly to detect masses that could be in the nasopharynx (e.g., a nasopharyngeal polyp could deform the soft palate and could be palpated).
  - Use a spay hook to retract the caudal edge of the soft palate cranially, permitting the visualization of part of the nasopharynx.
  - Use a small, dental-type mirror to “look back” into the nasopharynx.
  - Use a small flexible endoscope if available.

LARYNGEAL, PHARYNGEAL, AND ORAL EXAMINATION Typical appearance of glottis of a healthy, anesthetized cat. Tongue is depressed with a laryngoscope, revealing epiglottis ventrally (tip appears as a white triangle in center of image), soft palate dorsally, and arytenoid cartilages laterally *(asterisks)*. Slightly deeper and ventral to arytenoid cartilages, vocal cords are seen (slight obliquity; animal's left vocal cord is seen more clearly here than right one).

POSTPROCEDURE

- Airway protection:
  - When the examination is completed, perform orotracheal intubation, inflate cuff, and secure tube to avoid complications secondary to regurgitation/aspiration pneumonia.
- Administer oxygen via anesthesia circuit.
- Monitor recovery from anesthesia.
- Extubation of animal when reflexes are reestablished, especially the deglutition reflex.

ALTERNATIVES AND THEIR RELATIVE MERITS

In a study comparing three techniques for the diagnosis of laryngeal paralysis, direct per os laryngoscopy combined with the knowledge of the clinical history and physical examination was preferred over echolaryngoscopy and transnasal endoscopy (Radlinsky et al., 2009).

NASOPHARYNGEAL ENDOSCOPY:

- The use of a small flexible endoscope can permit a more precise evaluation of the nasopharynx because it can be retroflexed 180○ over the soft palate and advanced in the nasopharynx, permitting visualization of the nasal choanae.

- Involves a substantial investment (endoscope, monitor, camera, image processor, light source).

TRANSNASAL ENDOSCOPY:

- The use of transnasal endoscopy has been reported in large dogs (over 20 kg) for the evaluation of the nasopharynx and of laryngeal structure and function. General anesthesia is not required, which might be an advantage. Dogs are heavily sedated, and topical anesthesia (2% lidocaine) is used in the left nasal passage.
- This technique does not permit evaluation of the oral cavity and oropharynx, so it is of limited use for a complete evaluation as described here.
- Involves a substantial investment (endoscope, monitor, camera, image processor, light source)

ULTRASOUND:

- Sonographic evaluation of laryngeal paralysis has been evaluated in 40 dogs (30 with laryngeal paralysis and 10 normal). Results have shown a high degree of sensitivity and specificity with this technique.

Myelography

Additional Images Available on Website

OVERVIEW AND GOALS

Myelography is the introduction of positive-contrast media into the subarachnoid space. It is used for demonstrating lesions in the spinal cord or lesions extrinsic to the spinal cord that may be causing cord compression. This procedure is used for supplementing or confirming information obtained with plain-film radiography.

INDICATIONS

- Clinical signs of spinal cord disease (± spinal trauma)
- Spinal pain or neurologic deficits without diagnosis on plain films or laboratory tests
- Confirmation of suspected lesion on plain films
- Aid in surgical planning (define exact location of lesion)
- Determine amount of spinal cord swelling
- Exclude compressive lesions of the spinal cord; by process of elimination, make presumptive diagnosis of non-compressive spinal disorder
- Rule out intraspinal lesion
- Disparity between clinical signs and plain radiographs
- Recurrence of clinical signs after decompressive spinal surgery

CONTRAINDICATIONS

- Cerebrospinal fluid (CSF) analysis indicates inflammation or infection: condition aggravated by irritation from contrast medium.
- Increased CSF pressure: possible herniation of cerebellum through foramen magnum
- Known hypersensitivity to contrast medium

EQUIPMENT, ANESTHESIA

- General anesthesia
- Intrathecal contrast material: low osmolar, nonionic, water-soluble iodines, such as iohexol or iopamidol (180-300 mg iodine/mL most commonly used):
    - Full spine dose is 0.45 mL/kg; regional dose is 0.30 mL/kg.
- A 20- to 22-gauge spinal needle with stylet and short bevel, 1½-3½ inches (depending on size of animal)
- Appropriately sized syringe (3-35 mL)
- Flexible extension tubing or T-port (catheter cap with side line and port)
- Hair clippers
- Surgical scrub solution, rubbing alcohol, and gauze/sponge for prep-ping skin
- Sterile surgical gloves

ANTICIPATED TIME

About 45-60 minutes, not including pre-procedural anesthesia time

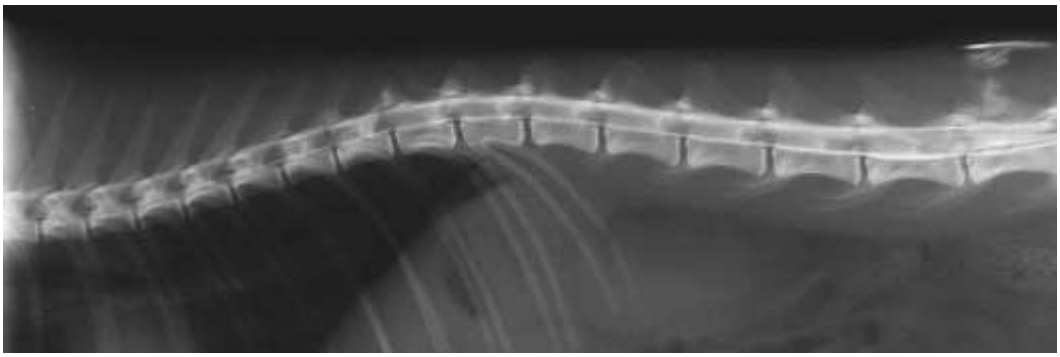
PREPARATION: IMPORTANT CHECKPOINTS

- Perform CSF analysis to ensure no evidence of infection or inflammation.
- Ensure adequate hydration status to decrease risk of neurotoxicity. Administer IV fluids as appropriate.
- Metastasis imaging (three-view thoracic radiographs are also indicated if malignancy is part of the differential diagnosis for the spinal problem).
- Advise owner the hair will be clipped in a large area near the injection site(s).

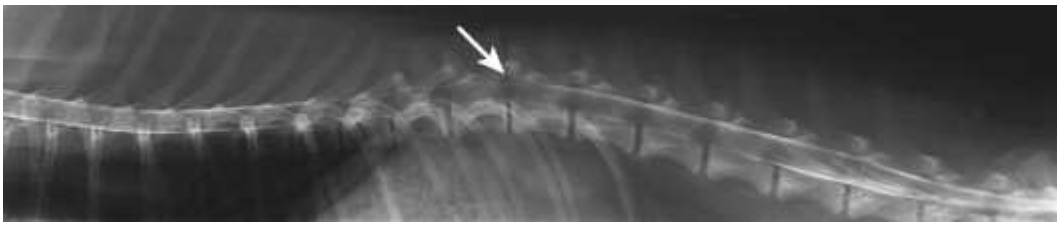
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- The most common complication of myelography is postprocedure seizures. Recover the animal with head elevated to minimize risk. If directly induced by contrast, seizures are expected to occur during anesthetic recovery. Seizures occurring thereafter are virtually never caused by the contrast injection.

- Bradycardia is sometimes seen in animals during injection of the contrast material.
- Epidural injection may occur with lumbar puncture: wavy pattern is apparent radiographically both dorsally and ventrally.
- Subdural injection:
    - Central canal filling: thin line in center of cord
- Administration of air bubbles
- Use of the incorrect type of contrast agent can be fatal. Ionic contrast agents (e.g., diatrizoate or any other product) should never be used in any amount in myelography; only low-osmolar, nonionic, water-soluble iodines are indicated.
- Lumbar puncture: inability to enter the space is commonly due to a nonmidline location of the needle (needle is inadvertently located parallel and lateral to dorsal midline).
- Extension of the neck for neck-extended views can cause permanent cord injury, especially in animals with neck pain prior to the procedure and animals with severe cervical intervertebral disk disease (IVDD). These views should be preceded by nonextended views (diagnosis may be apparent without extension) or avoided altogether.



MYELOGRAPHY 1 Myelogram of cat, lateral projection. Lumbar and caudal thoracic portion. Normal study. Incidental finding is a small amount of intramuscular and subcutaneous accumulation of contrast material at site of lumbar injection.



MYELOGRAPHY 2 Myelogram of dog, lateral projection. Mild dorsal deviation of ventral subarachnoid contrast column and attenuation of dorsal contrast column, most pronounced at T12-T13 *(arrow)* are seen, identifying lesion as extradural. Mineralization of T11-T12 intervertebral disk is an incidental finding.

MYELOGRAPHY 3 Myelogram of dog. Attenuation of both dorsal and ventral contrast columns over L4 on this lateral projection is consistent with either an intramedullary lesion or a lateralizing extramedullary lesion *(arrow)*.

PROCEDURE

- Obtain survey radiographs of the area of interest (ventrodorsal and lateral views).
- Clip a large area of hair near the injection site (depending on cisternal or lumbar puncture).
- Aseptically prepare the site for injection with surgical scrub solution, isopropyl alcohol, and gauze/sponges.
- Sterile surgical gloves should be worn from this point on, and a sterile technique should be used (nonsterile materials will need to be handled by an assistant).
- Draw correct contrast dose into syringe.
- Attach flexible extension tubing to the syringe, and fill with contrast so no air bubbles are present.
- Cisternal puncture (see p. 1228):
    - Commonly used for evaluating suspected cervical spinal cord lesions

- Animal is placed in lateral recumbency with neck fully flexed at atlanto-occipital joint.
- Insert needle on midline, with bevel directed caudally, at the center of the triangle formed by the external occipital protuberance and the wings of the atlas.
- Advance needle slowly until ligamentum flavum and dorsal dura are punctured. Since the puncturing may not be apparent, a good approach is to advance 1-2 mm at a time, removing the stylet and checking for CSF in the hub of the needle each time before replacing the stylet and advancing further.
- Once the subarachnoid space is entered and CSF flows, obtain a CSF sample for immediate analysis.
- If CSF analysis does not provide a diagnosis, the procedure may be continued.
- Attach tubing to the needle and inject contrast material slowly.
- Once contrast material is injected completely, the needle is removed.
- Elevate head prior to obtaining radiographs to allow contrast material to flow caudally from the atlanto-occipital site of injection.
- Standard radiographic views (lateral, ventrodorsal, 45° obliques) are then obtained.
- Optional views (lateral, neck flexed, neck extended, and traction views). Caution with neck-extended views, which may cause permanent damage to the spinal cord in some animals, particularly those with severe cervical IVDD.

- Lumbar puncture:
  - Commonly used for evaluating suspected thoracolumbar lesions
  - More technically difficult—fluoroscopy beneficial (see p. 1228).
  - Animal in lateral recumbency.
  - Sixth lumbar spinous process is palpated. For anatomic localization of this spinous process, see p. 1260.
  - With bevel directed cranially, introduce needle at 30-60° angle at this site just to the side of the spinous process.
  - Reposition needle until tip enters interarcuate space between L5 and L6. It may be necessary to flex the spine—especially in older animals with degenerative bony changes.
  - The tail or hind limbs may twitch as the needle enters the spinal cord.
  - Advance needle to canal floor.
  - Remove stylet and check for CSF; if no CSF is visualized, withdraw needle slowly until flow is obtained.
  - Compressing the jugular veins may increase CSF pressure, allowing CSF to flow more readily.
  - Once CSF is obtained and no contraindications have been identified on CSF analysis, attach tubing to the needle, and inject contrast material slowly into subarachnoid space.
  - Once contrast material is injected, the needle is removed.
  - Standard radiographic views (lateral, ventrodorsal, 45° obliques) are then obtained.

POSTPROCEDURE

- The animal's head should be elevated so contrast material does not accumulate around the brain.
- The animal should be monitored for seizure activity.
- If seizures are encountered, diazepam (0.5-1 mg/kg IV) can be administered.
- Many clinicians recommend keeping the animal under general anesthesia for 30 minutes to 1 hour after myelography to decrease the incidence of seizures.
- Myelographic effect on CSF: increased cell count (pleocytosis), increased percentage of neutrophils, increased protein, false-positive Pandy score, and high specific gravity. These effects are transient, and the normal state usually returns in 24-48 hours.
- Maintain adequate hydration status: IV fluids ± fluid diuresis.

ALTERNATIVES AND THEIR RELATIVE MERITS

- CT scan:
  - Requires general anesthesia and knowledge of cross-sectional anatomy
  - Provides axial images without superimposition of other structures, more detailed than standard radiography, ability to postprocess
  - Equipment and CT scan examination more costly than myelography and CT often requires intrathecal injection of contrast prior to the scan
- MRI:
  - Requires general anesthesia and knowledge of cross-sectional anatomy
  - Provides axial images without superimposition of other structures; more detailed than standard radiography
  - Sensitive, accurate, noninvasive, and does not involve the use of ionizing radiation
  - Equipment and MRI examination more costly than myelography or CT scan.

AUTHOR: LEEANN PACK

Muscle and Nerve Biopsy

OVERVIEW AND GOAL

Minimally invasive procedure for collection of muscle specimens for histologic, histochemical, immunohistochemical, and ultrastructural analyses. Nerve biopsy should only be performed by persons trained in the procedure.

INDICATIONS

- Chronic muscle atrophy, hypertrophy
- Weakness, hypotonia
- Exercise intolerance
- Nonorthopedic gait abnormalities
- Contractures
- Chronically elevated creatine kinase activity, myoglobinuria
- Myalgia, cramping
- Clinical evidence of muscle or peripheral nerve disease

CONTRAINDICATIONS

- Bleeding disorder
- Poor anesthetic risk

EQUIPMENT, ANESTHESIA

- General anesthesia usually required; muscle biopsies can be taken under heavy sedation and local anesthetic if indicated.
- General surgical pack including self-retaining retractors
- Containers for biopsy specimens:
  - Plain red-top tubes (5-10 mL) for unfixed biopsy specimens
  - Biopsy jars containing fixatives: 10% formalin for routine histopathologic evaluation, 2.5% glutaraldehyde in phosphate buffer or Karnovsky's fixative for electron microscopy
- Tongue depressors or wooden sticks and suture material or pins: for maintaining length of nerve specimens
- Method of refrigeration prior to shipping specimens
- Styrofoam containers for shipping refrigerated specimens to a specialized laboratory

ANTICIPATED TIME

- About 60-90 minutes if the biopsy is combined with electrophysiologic examinations (see online chapter: Electromyography and Nerve Conduction Velocity)
- About 30-45 minutes if nerve and muscle biopsy only

PREPARATION: IMPORTANT CHECKPOINTS

- It is essential that details of fixation and transportation be obtained from the laboratory that processes the tissues prior to taking biopsies.
- Determine if problem is generalized or localized to specific muscle groups: this will help in the selection of which muscle and nerve should be biopsied.
- Knowledge of anatomic localization of specific muscle groups
- It is critical that unfixed biopsy specimens are kept refrigerated and shipped by courier for processing within 24-36 hours. Do not ship biopsy specimens on a Friday.

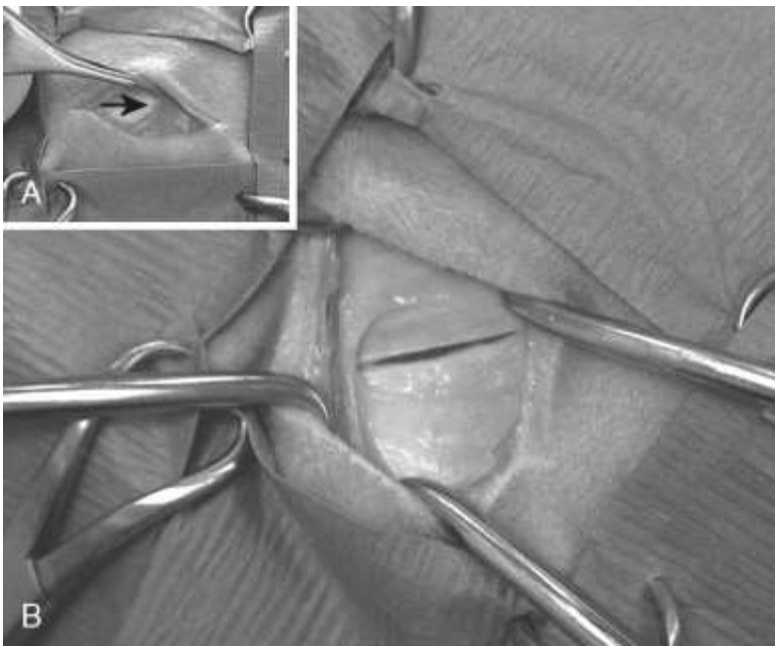
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Complications (hematoma, swelling) are rare following muscle biopsy.
- Transient neurologic dysfunction (knuckling, proprioceptive deficits) possible on the side of a nerve biopsy. The owner should be warned before the procedure of the expected short-term deficits.
- Artifacts in histologic specimens due to poor fixation or traumatic collection; handle tissue carefully.
- Biopsy of wrong muscle (e.g., frontalis instead of temporalis for masticatory muscle myositis)

PROCEDURE

For biopsy of muscle (biceps femoris) and nerve (common peroneal) through the same incision, an open biopsy procedure is necessary:

- Palpate the location of the common peroneal nerve on the lateral aspect of the distal femur just caudal to the proximal tibia.
- Clip hair, aseptic scrub/prep.
- Incise skin and overlying fascia to expose muscle.
- Establish orientation of the muscle fibers.
- Make parallel incisions along the longitudinal direction of the muscle fibers.
- Collect biopsy specimens 0.5 cm (width) × 0.5 cm (depth) × 1 cm (length).
- Transect the ends of the biopsy, handling carefully to minimize artifact.
- Wrap tissue in a saline-moistened gauze sponge (only moistened, not dripping wet).
- Place in dry, watertight container and keep chilled (not frozen).
- Collect a second smaller piece of muscle from same site, and place freely in 10% buffered formalin.
- Locate the nerve as it passes over the lateral head of the gastrocnemius muscle.
- Isolate the nerve carefully by blunt dissection.
- A 5-0 or 6-0 silk suture is placed through the caudal one-third to one-half of the nerve at the proximal end of the biopsy site, allowing minimal gentle traction.
- A 3-4 cm fascicular biopsy is excised using fine iris scissors.
- Lay nerve specimen on a tongue depressor or stick, and either pin or tie ends with suture to maintain length. Do not stretch.
- Immerse nerve biopsy into either 10% buffered formalin or Karnovsky's fixative.
- The fascial layer is closed with absorbable suture (e.g., polydioxanone).
- Skin closure with monofilament nylon or staples.



MUSCLE AND NERVE BIOPSY Biopsies obtained from temporalis muscle for diagnosis of masticatory myositis. **A**, Frontalis muscle *(arrow)*, first muscle encountered after making skin incision. Muscle should be incised and retracted, allowing visualization of the thick fascia that overlies temporalis muscle. **B**, Fascia has been incised and retracted, allowing access to temporalis muscle.

(For a more complete description of anatomy of the masticatory muscles, refer to Melmed et al, 2004.)

Open muscle biopsy procedures are also recommended if a peripheral nerve biopsy is not collected at the same time. For collection of temporalis muscle, make sure that the frontalis muscle is not collected by mistake.

Percutaneous needle/core biopsy is not recommended for routine muscle biopsy collection in dogs and cats:

- Inadequate sample size
- Difficult to orient tissue
- Artifact

Needle biopsies may be beneficial in research situations where sequential biopsy samples may be required over time; may be guided by ultrasonographic localization of specific lesions.

POSTPROCEDURE

- Treatment of hemorrhage, swelling, or hematoma if these occur (rare)
- External dressings are not normally required.
- Animals should be monitored to prevent interference with the sutures.
- Proprioceptive deficits as already described; usually self-resolving in 3-4 days; long-term deficits are extremely uncommon.

ALTERNATIVES AND THEIR RELATIVE MERITS

- For muscle diseases, there is no alternative to the muscle biopsy for determining the specific diagnosis and therapeutic options.
- MRI studies may help localize focal lesions and allow for guided muscle biopsies.
- Electrophysiologic examinations can provide important information on peripheral nerve diseases, but a peripheral nerve biopsy should still be collected for histologic evaluation.

AUTHOR: G. DIANE SHELTON

Magnetic Resonance Imaging Scan

SYNONYMS

MRI, MR

OVERVIEW AND GOALS

- Magnetic resonance imaging (MRI) is a method of cross-sectional imaging that does not involve ionizing radiation. When compared to radiography, MRI allows improved evaluation of areas of complex anatomy by avoiding superimposition of multiple structures. The contrast resolution of MRI is vastly superior to that of radiography and computed tomography (CT).
- Magnetic resonance imaging can be used for assessing any area of the body. In veterinary medicine, common uses include assessment of the brain and spinal column. Musculoskeletal imaging (scapulohumeral joint, stifle etc) is also increasing in popularity in small animal practice.

INDICATIONS

Disease of the central nervous system; best method available for imaging of the brain

CONTRAINDICATIONS

- Inability to tolerate general anesthesia
- Presence of a pacemaker: in a minority of patients, the MRI magnetic field may alter the pacemaker program or cause the pacemaker to oscillate in the patient. In human medicine, MRI suites bear warnings forbidding entry to any person with a pacemaker, so it is unlikely that an MRI technician will allow a veterinary patient with a pacemaker to be scanned.
- Presence of ferrous (iron-containing) metal including implants and intestinal foreign bodies:
    - Movement of the metal when in the magnetic field, causing soft-tissue trauma
- Presence of large metallic implants (nonferrous) in the area of interest:
    - Heating of the metallic implants → tissue damage
    - Imaging artifact severely limits the value of the study.

GENERAL MRI SAFETY CONSIDERATIONS:

- Injury to the patient and/or damage to the MRI magnet can occur if careful attention is not paid to basic MR safety as regards the presence of metallic objects within the MRI suite.
- The MR magnet is the core of the MRI unit, and the magnet is always “on,” 24 hours a day. Therefore, it is never safe to have loose metallic objects in the vicinity of the magnet—that is, anywhere in the same room as the MRI unit (MRI suite).
- Since the chemical composition of metal objects (ferrous or nonferrous) may not be known, all metallic objects should be regarded as potential safety hazards and excluded from the MRI suite.
- All equipment used in the area of the MRI magnet must be constructed of plastic and/or nonferrous metal or must be kept a safe distance from the magnet and secured. Recorded instances where this guideline was not followed have produced injury and death in patients and hospital personnel through blunt trauma caused by large objects which transform into projectiles owing to their strong attraction to the magnet.
- The safe distance from the magnet will depend on the field strength of the magnet, the shielding of the magnet and the amount of ferrous metal in the object. A distance of 36 inches (3 meters) is generally sufficient for a magnet of 1.0 tesla or less field strength.
- Because of the safety hazards associated with MRI imaging, it is best to limit the number of personnel in the MRI suite to the minimum necessary to perform the study and monitor the patient.

EQUIPMENT, ANESTHESIA

General anesthesia is required. MRI studies are prolonged and generally performed using gas anesthesia. Constant rate infusion of intravenous anesthetic agents can be used, but gas anesthesia is preferred because of the duration of the procedure.

- Endotracheal tube, NOT wire reinforced:
    - A laryngoscope can only be used if the patient is intubated in an area isolated from the MRI magnet.
- Gas anesthesia:
    - Anesthesia machine:
        - Unit specified as being MRI safe (nonferrous metals and plastic used in construction)

        - Generic anesthesia unit with long breathing circuit; minimum distance to magnet ~3 feet (1 meter)
- Constant rate infusion:
    - Infusion pump:
        - Unit specified as being MRI safe (nonferrous metals and plastic used in construction)
        - Generic infusion pump with extension tubing; minimum distance to magnet ~3 feet (1 meter)

Monitoring equipment:

- Pulse oximeter:
    - The patient attachment and cables must be specially constructed of nonferrous metal and/or plastic:
        - Fiberoptic technology is employed; an example is the Nonin 7500 FO unit.
- Blood pressure/CO2 measurement:
    - The patient attachment and cables must be specially constructed of nonferrous metal and/or plastic:
        - Surgivet monitors
- Electrocardiogram (ECG):
    - ECG electrodes for MRI use are available:
        - Because of radiofrequency interference, usable ECG tracings cannot be acquired during image acquisition.
- Emergency kit:
    - As with any procedure performed under general anesthesia, the equipment and drugs necessary for emergency cardiopulmonary cerebral resuscitation (CPCR) should be immediately available.
    - Great care should be exercised to ensure that metallic objects are not introduced near the magnet during CPCR. In the case of emergency, the patient will need to be removed from the MRI suite and resuscitative efforts performed at a safe distance from the magnet.

Intravenous contrast agent:

- Paramagnetic agents:
    - Gadolinium diethylenetriamine penta-acetic acid (Gd-DTPA): Magnevist
    - Gadodiamide: Omniscan
        - Nephrogenic systemic fibrosis has been reported as a sequela to the injection of intravenous paramagnetic contrast agents in human patients with renal insufficiency. This syndrome has not been reported in veterinary patients, but care should be taken when administering these agents to patients with renal dysfunction. Gadodiamide has a higher safety ratio than Gd-DTPA.
- Intravenous fluids
- Blankets/heated fluid pads or bags

ANTICIPATED TIME

The time required to perform the study depends on many factors:

- Field strength of the magnet: the higher the field strength of the magnet, the more quickly the study can be performed.
- Configuration/size of the radiofrequency coils
- Size of the area to be scanned
- Number and type of imaging sequences performed: unlike CT, MRI involves multiple separate image acquisitions. Images are obtained in multiple planes and using multiple different imaging parameters; the more acquisitions performed, the longer the study.

APPROXIMATE TIMES (Based on use of a 1.0-tesla magnet):

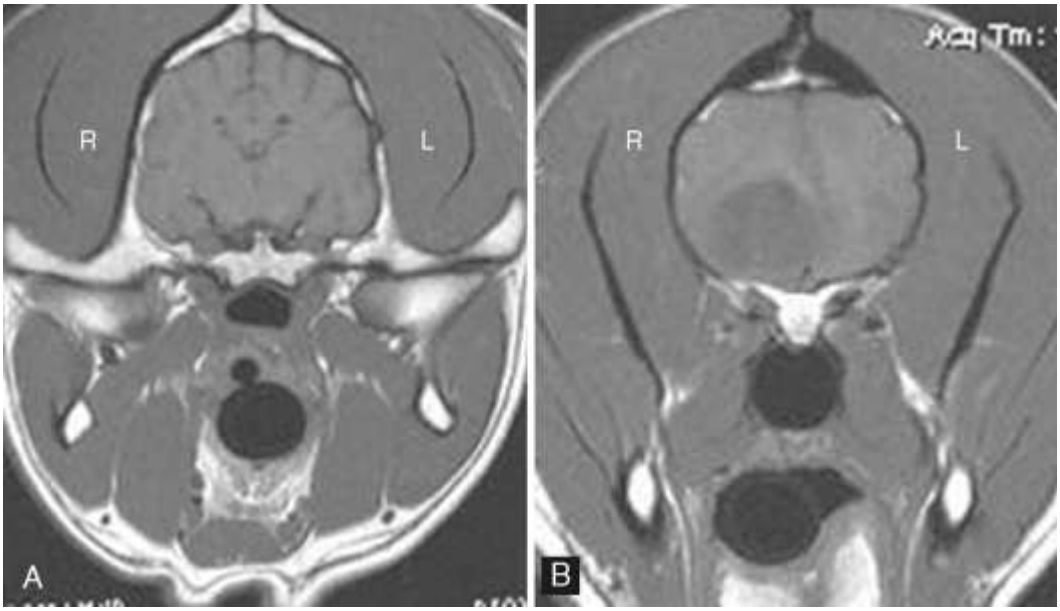
- Brain: 1-1.5 hours
- Spinal column:
    - Cervical: 1-1.5 hours
    - T3-L3: 1.5-2 hours
    - Lumbar: 1-1.5 hours

Because of long scan times, it is important to determine neuroanatomic localization of spinal lesions so that only the affected area of the spinal column is scanned, particularly in large dogs.

PREPARATION: IMPORTANT CHECKPOINTS

- Obtain thorough patient history: pacemaker? nonferrous metallic implants/foreign bodies? ferrous metallic implants/foreign bodies?
- Routine laboratory evaluation: CBC, serum biochemistry panel

- +/− Thoracic radiographs
- +/− Abdominal radiographs or ultrasound
- Many patients undergoing MR imaging are older and may have multiple diseases. Routine laboratory evaluation and thoracic and abdominal screening may be indicated in these patients for two reasons: to rule out the presence of concurrent disease that may affect the patient's ability to tolerate general anesthesia and to identify the presence of any potentially life-shortening disease process unrelated to the primary complaint (e.g., “incidental” splenic mass).
- Make sure all needed equipment is available and functional. This is especially important if the study is to be performed at an outside (e.g. nonveterinary) facility.
- Preparation for general anesthesia:
    - Routine preanesthetic fasting
    - Place IV catheter: when placing the catheter, the anticipated position of the patient within the MRI unit must be considered, and the catheter should be placed to allow easy access to it during the procedure. For example, in patients undergoing MR scan of the head, it is convenient to have the IV catheter placed in the saphenous vein. This is, however, not an absolute requirement, because the forelimb can be extended caudally for ease of access if the catheter is in a cephalic vein.
    - Clipping of hair in areas where monitoring devices are to be applied (dependent on type of monitoring devices used)



MAGNETIC RESONANCE IMAGING SCAN A-B, T1-weighted magnetic resonance images from a normal **(A)** and abnormal **(B)** canine brain. Images are from rostral to midcerebrum. In MRI, the imaging characteristics of tissues are determined by the imaging sequence used. To define the tissue characteristics of a lesion, multiple different imaging sequences are performed, and the appearance of the lesion in these images is compared. The term *intensity* is used for describing the appearance of tissues in MRI.

In the normal patient, there is a subtle difference in intensity between gray matter and white matter of the brain, and intensity of muscle is different from that of brain. This illustrates the level of soft-tissue contrast achieved with MRI.

In the abnormal patient, note the large, round hypointense lesion with a slightly hyperintense rim within the right ventral cerebrum; the lesion causes left deviation of falx cerebri. Differential diagnoses for mass lesions within the brain include neoplasia, granuloma formation, and abscess formation. In this case, the appearance of the lesion in multiple imaging sequences was consistent with a diagnosis of neoplasia with a central necrotic component.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Complications associated with general anesthesia
- Burns induced by placement of cables
    - Objects within the magnet can become hot due to the effect of radiofrequency pulses. Monitoring cables within the magnet should not be coiled and should not be placed on the patient. Wrapping the cables in fabric (towels, blankets, etc.) will provide further protection.
- Injury to the patient and/or damage to the magnet can occur if careful attention is not paid to basic MR safety as regards the presence of metallic objects within range of the magnet. See above.

PROCEDURE

- Anesthetize and intubate the patient.

- Move the patient to the MR area and position within the MR gantry; positioning of the patient depends on the area of interest and the configuration of the radiofrequency coils.
- Connect IV fluids and monitoring devices, place blankets and water bottles.
- Scan.
- +/− Inject intravenous contrast agent:
    - Contrast is routinely used in brain imaging but rarely used for imaging of the spinal column.
    - Gd-DTPA: Magnevist:
        - 0.2 mL/kg IV bolus
    - Gadodiamide: Omniscan:
        - 0.2 mL/kg IV bolus
- Rescan for postcontrast images.
- Briefly review images:
    - Evaluation of the images may suggest additional imaging sequences of the area being examined that may be useful in the particular case (e.g., obtaining T2-weighted images in suspected hemorrhagic lesions).
    - Rarely the images obtained will identify an additional area of concern that should be scanned before the patient is allowed to recover from general anesthesia.

POSTPROCEDURE

No additional considerations beyond routine monitoring of the patient during recovery from general anesthesia

ALTERNATIVES AND THEIR RELATIVE MERITS

CT:

- Advantages:
    - Shorter imaging time (and therefore, shorter time under general anesthesia)
    - Better imaging of bone
- Disadvantages:
    - Far inferior contrast resolution
    - Image acquisition is in only one plane.
    - Reformatted images have much lower spatial resolution than original images or MR images.

If available, MRI is the preferred imaging method for evaluation of the central nervous system.

AUTHOR: PATRICIA L. ROSE

Neurologic Examination

OVERVIEW AND GOAL

To evaluate a patient's neurologic function through clinical physical assessment of mentation, gait, posture, postural reactions, spinal nerve reflexes, and cranial nerve examination. Specifically, the goal in an animal with a nervous system lesion is to establish the anatomic location of that lesion. The anatomic diagnosis will determine the differential diagnosis and the choice of ancillary studies to be recommended.

INDICATIONS

Reasons for an owner to present an animal for a neurologic examination include:

- Seizures, abnormal spontaneous uncontrolled movements, pacing, circling, head pressing, tremors
- Abnormal mentation: depressed to unresponsive, no recognition of owner, loss of trained habits, excreting indoors
- Abnormal gait: lame, paretic, ataxic, paralyzed, collapsing
- Loss of balance, hearing, vision
- Head tilt, unable to close eyelids, unable to prehend food or swallow, protruded third eyelid, pupil asymmetry, eye deviation
- Regurgitation, dyspnea

CONTRAINDICATIONS

- Aggressive patient
- Injured patient where manipulation may exacerbate the nervous system lesion and the examination is limited to the recumbent patient

EQUIPMENT, ANESTHESIA

- Quiet area
- Outdoor area or a room large enough to evaluate the gait
- Nonskid floor surface; indoor-outdoor carpet works well.
- Plexímeter, source of bright light, small forceps

ANTICIPATED TIME

About 10-20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Assess for contraindications (as already noted).
- Note: To avoid introducing bias, review existing diagnostic test results (lab tests, radiographs, etc.) *after* performing the neurologic examination.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Do not be biased by a single abnormality.
- Do the same methodical, thorough evaluation on every patient regardless of the complaint or the signs that are evident.

PROCEDURE

There are five main components to the neurologic examination: sensorium, gait, postural reactions, spinal reflexes, and cranial nerves. The order in which the five components are evaluated depends on the animal's behavior and chief complaint.

- Sensorium: owners are best able to evaluate subtle changes in their animal's behavior or sensorium. In increasing severity, sensorium changes are depression, lethargy, obtundation, semicoma (stupor), and coma.
- Gait: diagnosis of gait disorders is based on pattern recognition for specific anatomic sites in the nervous system (and musculoskeletal system). These are best evaluated with the animal moving on grass or a rug where slipping is not a problem.

As a rule, changes are best seen with the animal walking slowly and taking numerous slow turns. There are two qualities of paresis and three qualities of ataxia that are considered in gait analysis:

- Paresis (neurogenic abnormality of muscle tone/strength):
  - Lower motor neuron (LMN) paresis causes a loss of ability to support weight, reflected in rapid short strides with collapsing on the affected limb. The animal walks with a “lame” gait.
  - Upper motor neuron (UMN) paresis interferes with gait generation, delaying the protraction of the affected limb and lengthening the stride. This form of paresis cannot be separated from general proprioceptive (GP) ataxia because of the close association of the caudal projecting upper motor neuron tracts and cranial projecting general proprioceptive tracts in any transverse section of the spinal cord.
- Ataxia (“incoordination”):
  - GP ataxia creates the appearance of the animal not knowing where its limb(s) is/are located in space. This also results in a delay in protraction of the limb, and the animal may show an excessive medial (adduction) or lateral (abduction) excursion of the limb as it is protracted. The stride may also be prolonged. Both UMN and GP deficits can cause the animal to occasionally stand on the dorsal aspect of its paw.
  - Vestibular ataxia is evident when the animal has a head tilt and drifts or stumbles to the side from loss of balance.
  - Cerebellar ataxia is characterized by a delay in protraction and an excessive response, a dysmetric abrupt gait generation that usually is associated with some balance loss.

- Postural reactions: normal postural reactions require that most components of the peripheral and central nervous systems be intact. The most reliable of the postural reactions is the hopping response.
  - Hopping response: each limb is tested by holding the animal so that most of the weight is borne on the limb to be tested, and the animal is moved laterally on that limb:
    - First, straddle the animal so that both you and the animal are facing in the same direction.
    - Palpate the thoracic limbs to determine if any denervation or disuse atrophy is present.
    - Flex and extend the limbs to determine range of motion and muscle tone.
    - Place the paw on its dorsal surface—the paw replacement test—and observe how quickly it is replaced. Note: This is not just a test of conscious proprioception (CP), because disorders of the UMN, LMN, and/or general somatic afferent cutaneous receptors all can result in a delay in this response. A sole CP deficit cannot be determined, and that term should be discarded from the neurologic examination. Be aware that many normal animals may delay in replacing the paw to its supporting position.
    - Brace your own elbow on your ipsilateral knee and support the abdomen so that most of the animal's weight is on its thoracic limbs.
    - With your other arm, pick up the animal's thoracic limb on that side, and push the animal laterally away from that limb. This will force the animal to hop on the opposite thoracic limb.
    - After three or four hops, do not move, but just reverse both arms so that you can pick up the opposite forelimb and hop the animal back on the contralateral thoracic limb.
    - Compare one forelimb with the other only when it is being hopped laterally.
    - Move back to the pelvic limbs, and repeat the muscle palpation, range of motion, and paw replacement.
    - At that time, check the tail and anus for tone and reflex response.
    - Stand beside the animal, and with one arm placed under the sternum, pick the animal up so it is standing on its pelvic limbs.
    - Pick up the closest pelvic limb, and push the animal away so that it hops laterally on the opposite pelvic limb.
    - Repeat this maneuver on the opposite side.
    - Always compare the thoracic limbs with each other and then the pelvic limbs with each other, because the pelvic limbs normally tend to be slower than the thoracic limbs.
    - For very large dogs, it is easier to make the same observations while the dog is “hemiwalked.”
    - For hemiwalking, stand beside the dog and pick up both limbs so they are located at your side; then push the animal gently away.
    - These hopping responses are much more reliable than the paw replacement test.
- Spinal reflexes; for spinal reflex testing, the animal should be placed in lateral recumbency:
  - Manipulate the limbs to assess muscle tone.
  - With the animal relaxed and the stifle slightly flexed, elicit the patellar reflex by tapping on the patellar tendon. If it is not present in one or both limbs, always place the dog in the opposite recumbency, and repeat the patellar reflex before concluding that it is absent. Some old dogs with no neurologic complaints lack the patellar reflex. This is the only reliable tendon reflex, because the other myotactic reflexes (triceps, biceps, extensor carpi radialis, etc.) may not be present in some normal animals.
  - The withdrawal-flexor reflex is routinely tested by gently compressing the base of the claw in each paw with forceps and observing the strength of the limb flexion and the animal's response (e.g., abrupt turning, vocalization) to the noxious stimulus. Note: The sensory modality that is tested is not pain. It is a noxious stimulus that is used, and what is observed is the animal's reaction to this conscious perception (nociception). Pain is the animal's response to a noxious stimulus. It is difficult to determine an animal's response to a minimal noxious stimulus, and there is no practical value to differentiating light and deep pain.
- Cranial nerves: sitting down on the floor with your back against the wall and knees flexed is the best position from which to evaluate small dogs and cats. Place the animal between your thighs and hold its head while testing the function of the cranial nerves. You can perform this cranial nerve exam on larger dogs by straddling them so that you and the dog are both looking

in the same direction. Proper evaluation requires a relaxed, nearly motionless animal. Use a regional approach, starting with the eyes:

- Menace response:
  - The menace response assesses vision and facial nerve function as long as the stimulus of the hand thrust at the animal's face does not touch the face or whiskers, or create excessive air movement.
  - If there is no response, be sure the eyelids are able to close (i.e., there is no facial paralysis).
  - If there is a normal palpebral reflex or spontaneous eyelid closure but still no menace response, then tap the eyelids or face gently to get the animal's attention, and then repeat the menace gesture.
  - Failure to close the eyelids to a menace in an animal > 10 weeks old with normal facial nerve function, or the lack of eyeball or head retraction in a patient with facial paralysis, indicates a lesion in some part of the visual pathway from the eyeball to the occipital lobe.
  - Animals with significant cerebellar disorders that have no menace response are still visual.
  - Assessing the menace response prior to shining a light in the animal's eyes avoids falsely compromising the menace response with the glare of the light.
- Pupil size and pupillary light reflex:
  - With a strong light source, assess the size and symmetry of the pupils from a distance.
  - Bring the light to about 1-2 cm from the eye, and swing it from one eye to the other and back again.
  - Repeat this to be sure that with the light in one eye, the pupils of both eyes are constricting.
  - Deficits in this light reflex implicate a lesion in the eye/optic nerve (optic chiasm or tracts) and/or the general visceral efferent component of the oculomotor nerve.
- Ocular position and movement:
  - Observe the position of the eyeballs for strabismus, and test abduction (abducent, VI) and adduction (oculomotor, III) nerve function by moving the head side to side while observing the eyes.
  - Look for a resting nystagmus. If not present, then look for a positional nystagmus with the head held flexed laterally to either side and then extended dorsally. Occasionally, it is worthwhile to look for this sign with the animal placed in dorsal recumbency.
- Trigeminal nerve (V):
  - Palpate the muscles of mastication (motor V) for denervation atrophy.
  - Recheck the palpebral reflex by stimulating the lateral and medial canthi with blunt forceps (sensory V; motor VII).
  - Place the blunt forceps against the nasal septum on each side to assess ophthalmic V and the nociceptive pathway to the opposite somesthetic cortex.
  - Observe for ear movement and lip symmetry and tone (VII).
  - Open the jaw to assess muscle tone (motor V) and range of motion.
- Glossopharyngeal (IX), vagus (X), and hypoglossal (XII):
  - Observe the tongue for its size and movements (XII).
  - Place one finger in the oropharynx to determine the muscle tone and the animal's response to the presence of the finger—the gag reflex (IX and X).

POSTPROCEDURE

By establishing the anatomic diagnosis (the location of the lesion in the nervous system), the results of the neurologic exam will allow a differential diagnosis to be established and a diagnostic plan to be created.

Nebulization, Coupage, and Respiratory Therapeutics

Client Education Sheet Available on Website

SYNONYMS

- Aerosolization and percussion
- Pulmonary (chest) physiotherapy or bronchial drainage/positioning
- Early ambulation
- Vibration/shaking
- Airway suctioning

OVERVIEW AND GOALS

- Nebulizers are used for aerosolizing saline in order to humidify airway secretions or to aerosolize drug solutions to obtain high local concentrations of medication in the respiratory tract while minimizing systemic absorption and toxicosis.
- Coupage or chest wall percussion aids in the removal of secretions from the tracheal bronchial tree.
- Pulmonary (chest) physiotherapy or bronchial drainage/positioning is a therapeutic modality that utilizes gravity-assisted positioning to improve pulmonary hygiene through the mobilization of airway secretions.
- Early ambulation facilitates mobilization and clearance of airway secretions, changes the lung regions being ventilated, and maintains muscular tone and strength.
- Thoracic wall vibration/shaking is a modality used for moving loosened secretions from small airways to larger airways so they can be coughed up or suctioned from the airway.
- Airway suctioning, as the name implies, is the active removal of airway secretions to clear the airway in patients with impaired mucociliary clearance. Reduces the risk of lower-airway contamination from oropharyngeal contamination as well as formation of airway mucus plugs leading to atelectasis.

INDICATIONS

Patients with inhalation injury (e.g., smoke inhalation) or retained secretions (recumbent patients, bacterial or fungal pneumonia, asthma, eosinophilic bronchopneumopathy, mechanically ventilated patients/intubated patients)

CONTRAINDICATIONS

- Percussion and vibration/shaking may not be suitable in patients with significant thoracic wall damage (i.e., fractured ribs or recent thoracotomy).
- Currently, nebulized antibiotics are only recommended in humans for multidrug-resistant gram-negative infections that are susceptible to aminoglycosides or polymyxin E (colistin); gram-positive bacterial infections are relative contraindications.

EQUIPMENT, ANESTHESIA

Three types of nebulizers:

- Jet nebulizers: employ oxygen under high pressure to generate the aerosol. The rate of droplet generation and the droplet size distribution are dependent on the jet flow rate.
- Ultrasonic nebulizers: the aerosol is produced by the vibration of a piezoelectric crystal. Drug output and droplet size are determined by the frequency and vibration amplitude.
- Vibrating mesh nebulizers: use a mesh or plate with multiple openings to generate the aerosol. These are the newest nebulizers, with reported better lung parenchymal penetration.

*Note: most aerosolized drugs listed are extrapolated from experimental and human clinical studies and are considered off-label use for dogs and cats.

Drugs that are specifically formulated or reported to be aerosolized*:

- Antibiotics: aminoglycosides (amikacin, tobramycin/tobramycin solution for inhalation [TSI], and gentamicin), polymyxins (colistin or polymyxin E), and vancomycin
- Airway humidification: sterile 0.9% saline
- Antifungals: amphotericin B
- Bronchodilators: racemic epinephrine, β2-agonist
- Antiinflammatory: corticosteroids
- Mucolytic drugs: *N*-acetylcysteine
- Oxygen free-radical scavengers: heparin/*N*-acetylcysteine combination

ANTICIPATED TIME

- Nebulization time of 15-30 minutes is recommended to allow sufficient time for adequate drug delivery/effect. Longer times are generally not tolerated by the patient or the operator (poor compliance). Nebulization and coupage should be performed every 6-12 hours.
- Chest physiotherapy, ambulation, vibration/shaking, and airway suctioning should be performed every 2-4 hours initially and gradually tapered as secretions improve.

PREPARATION: IMPORTANT CHECKPOINTS

- Ensure equipment used for nebulization and airway suction is maintained sterile. Ideally, sterile gloves or, at minimum, clean gloves should be worn when manipulating the equipment. Nebulization reservoirs should be replaced or cleaned daily and a new suction tip used for each suction.
- In-line suction units for mechanically ventilated patients can reduce the risk of iatrogenic infections.
- Equipment should be cleaned and disinfected between patients. Any replaceable part (e.g., nebulization reservoirs) should be exchanged daily if contaminated and always between patients.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Nebulization and coupage:
  - Bronchoconstriction: most common and serious side effect arising during nebulization. The use of nonaerosolized drug formulations increases the risk of clinically significant bronchoconstriction. Pretreatment or concurrent use of a bronchodilator may reduce the risk of bronchoconstriction.
  - Environmental waste: many nebulizers will continuously aerosolize drug even if the patient is not inhaling, allowing significant drug to be lost to the ambient air.
  - Operator exposure: owing to environmental contamination, operators may inhale some of the aerosolized drug or saline; use of a protective facemask can reduce the risk of exposure.
  - Low deposition of certain drugs: to allow deep penetration to the lower airways, the majority of the droplets produced should be within the range of 1-5 micrometer. Nebulizer type, use of nonaerosolized drug formulations, and highly viscous solutions are causes of poor drug penetration.
- Airway suctioning:
  - Reported complications following suctioning include tracheal irritation and bleeding, abrupt drop in partial pressure of oxygen, vagal stimulation, and bradycardia. Preoxygenating and limiting suction time have been shown to reduce the risk of hypoxemia.

PROCEDURE

- Nebulization and coupage:
  - Manufacturer instructions should be carefully followed to ensure proper use with each individual type and model of nebulizer. In general, sterile 0.9% saline or the specific drug diluted with sterile 0.9% saline to the required volume is instilled in the nebulizer reservoir. The nebulizer is turned on, and the reservoir is placed approximately 2-3 inches (5-8 cm) from the patient's nose for a minimum of 15-30 minutes. Certain nebulizers can be attached to the inspiratory limb of the ventilation circuit, facilitating nebulization in mechanically ventilated patients.
  - Immediately after nebulization, coupage is performed by repeatedly percussing both sides of a patient's chest wall simultaneously, typically while standing above and behind the patient (i.e., facing in the same direction as the patient) and using cupped hands and gentle force. Duration is typically 15-30 seconds, or less if coupage triggers repeated coughing.
- Pulmonary (chest) physiotherapy:
  - In the true sense, this involves 12 basic positions for postural drainage. The simplest and most practical form for clinical practice is to turn patients side to side every 2 hours to aid in mobilization of airway secretions.
- Early ambulation:
  - Involves assisting and encouraging patients to ambulate even for short distances. In the author's experience, this is essential in the successful treatment of pneumonia in recumbent large-breed dogs (e.g., wolfhounds).
- Thoracic wall vibration/shaking:
  - Manual or mechanical vibrations can be used to vibrate the thoracic cage.
- Airway suctioning:
  - The patient should be hyperoxygenated with 100% oxygen for a minimum of 1 minute prior to suctioning. The patient should be positioned with the head raised at a 45○ angle, and the catheter inserted into the trachea/endotracheal tube. Suction should begin while the catheter is gradually withdrawn from the airway. The patient should not be suctioned for more than 15 seconds without reoxygenation. Also, oropharyngeal secretions should be suctioned following tracheal suctioning.

POSTPROCEDURE

Patients should be monitored closely after the application/administration of any of the above therapies, because desaturation and worsening hypoxemia may occur. Decompensation may occur as a result of bronchoconstriction, incomplete mobilization of mucus causing airway obstruction, tracheal irritation or exhaustion.

ALTERNATIVES AND THEIR RELATIVE MERITS

Metered dose inhaler (MDI; see p. 1289): is a more practical alternative for at home delivery of specific medications. Unfortunately, only certain medications are routinely available in MDI form.

Nasal Infusion of Clotrimazole

OVERVIEW AND GOAL

Intranasal infusion of clotrimazole is a minimally invasive technique for treating confirmed nasal aspergillosis in dogs. Treatment is performed for 1 hour. Resolution of clinical signs is achieved in one half to two thirds of dogs with fungal rhinitis after a single treatment.

INDICATIONS

Dogs with confirmed nasal aspergillosis; confirmation requires either histopathologic confirmation of fungal hyphae in nasal tissues or at least two of the following: positive *Aspergillus fumigatus* serum titer, positive *Aspergillus* culture, radiographic/CT scan findings suggestive of fungal rhinitis (turbinate loss, fungal granulomas; see p. 96).

CONTRAINDICATIONS

- Cribriform plate erosion/damage secondary to fungal rhinitis. If advanced imaging (CT scan or MRI) of the cribriform plate is not available, owners should be warned that cribriform integrity has not been assessed. Topical therapy in animals with known cribriform damage has not been reported.
- Bulky fungal granulomas within the frontal sinus. Massive fungal disease within the frontal sinuses often recurs following topical therapy. It is assumed that the treatment does not adequately penetrate the center of these granulomas. Either rhinoscopic or surgical (sinusotomy) removal of bulky disease, followed by topical clotrimazole, should be considered.

EQUIPMENT, ANESTHESIA

- General anesthesia is required.
- A cuffed endotracheal tube (mandatory)
- Two 12 Fr Foley catheters, one 24 Fr Foley catheter, and two 10 Fr polypropylene or red rubber catheters
- Laparotomy sponges
- Two 60-mL syringes, one 12-mL syringe
- One pack of 3-0 nylon suture
- Suction canister and tubing
- Three hemostats
- One pair operating scissors
- One long-handled needle holder
- Four 30-mL vials of 1% clotrimazole in a polyethylene glycol base

ANTICIPATED TIME

About 2 hours total: 30 minutes for setup and anesthetic induction, 1 hour for treatment, and 30 minutes for recovery

PREPARATION: IMPORTANT CHECKPOINTS

Imaging studies are followed by rhinoscopic evaluation and then clotrimazole infusion during the same anesthetic episode if diagnostic results are highly suggestive of fungal rhinitis.

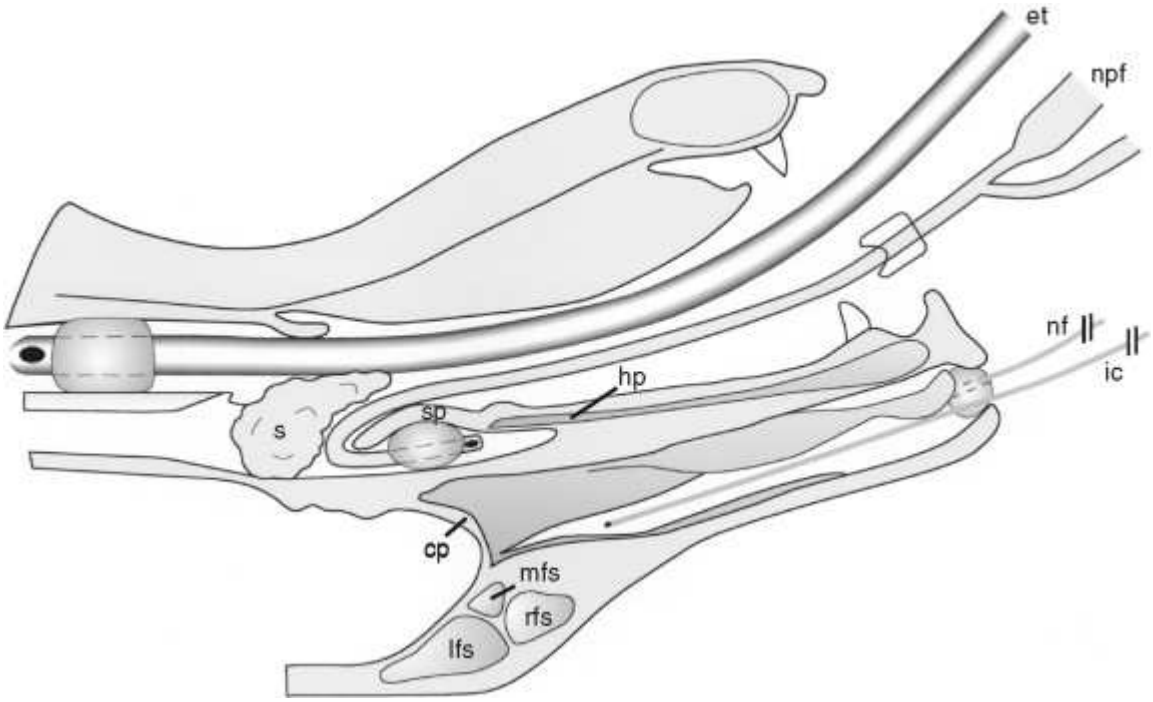
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

The inflated balloon of the nasopharyngeal Foley catheter must be palpated through the soft palate, just caudal to the hard palate. The balloon is initially held in place with a finger, which is then replaced with laparotomy sponges. Failure to fully inflate the balloon or ensure proper positioning will result in leakage of clotrimazole into the oropharynx.

PROCEDURE

- Place animal into lateral recumbency.
- Pass a 24 Fr Foley catheter orally and then into the nasopharynx with the aid of a long needle holder. Bend the Foley catheter tip 180○ so that the tip flips and comes to be seated dorsal to the soft palate. While palpating through the soft palate, fill the Foley balloon with air. Withdraw the balloon if necessary until it is just caudal to the hard palate. Place laparotomy sponges in the oropharynx to prevent caudal migration of the balloon.
- Pass a 10 Fr polypropylene or red rubber infusion catheter through each nostril and into each dorsal meatus (premeasure to the medial canthus).

- Place a 12 Fr Foley catheter into each nostril to prevent solution from leaking out the nostrils. Place a single nylon suture in each nostril to prevent rostral balloon migration. Fill balloons with air until obstruction occurs.
- Roll animal into dorsal recumbency.
- Fill two 60-mL syringes with the 1% clotrimazole solution (Lotrimin solution [Schering Corp., Kenilworth, New Jersey]). Administer 60 mL per side each hour via the infusion catheters.
- Place hemostats across any Foley if fluid is present within the catheter.
- Position the animal's head during infusion: 15 minutes dorsal, 15 minutes left lateral, 15 minutes right lateral, and again 15 minutes dorsal. The animal's body should remain in dorsal recumbency.



NASAL INFUSION OF CLOTRIMAZOLE Sagittal section of an anesthetized dog in dorsal recumbency. Image shows position of endotracheal tube *(et),* nasopharyngeal Foley catheter *(npf),* pharyngeal sponges *(s),* infusion catheter *(ic),* and rostral nasal Foley catheter *(nf)* in relation to the hard palate *(hp),* soft palate *(sp),* cribriform plate *(cp),* rostral frontal sinus *(rfs),* medial frontal sinus *(mfs),* and lateral frontal sinus *(lfs).*

(Reprinted with permission from Mathews KG, Koblik PD, Richardson EF, et al: Computed tomographic assessment of noninvasive intranasal infusion in dogs with fungal rhinitis, Vet Surg 25:309–319, 1996.)

POSTPROCEDURE

Following treatment, the animal is placed in sternal recumbency. All catheters and sponges are removed and counted. Clotrimazole is allowed to drain out of the nares by tilting the animal's nose downward at the edge of the treatment table. Suction and dry sponges are used for ensuring that the pharynx is dry prior to recovery from anesthesia. Repeat treatment if nasal discharge does not cease by 2 weeks after treatment. Additionally, new evidence suggests that affected dogs should be rhinoscopically reevaluated approximately 1 month post treatment to determine if any fungal plaques persist.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Orally administered antifungal drugs may be used in place of intranasal infusion of clotrimazole or as an adjunct to topical therapy. Itraconazole (5 mg/kg, q 12 h PO with food, for at least 2 months) has been associated with the greatest response rate (60%-70%) and requires intermittent monitoring of liver enzymes. A single 1-hour infusion of clotrimazole is equally effective if the medication is injected via catheters placed in dorsal sinusotomies.
- Enilconazole can also be applied topically via dorsal sinusotomy catheters but requires daily administration of small volumes (5-10 mL per side) for 10-14 days.
- There is new evidence that shows fungal granulomas can be adequately débrided by trained rhinoscopists, without the need for sinusotomy. Endoscopic placement of sinus catheters followed by 1-hour infusion with 1% clotrimazole has a similarly high success rate.
- Instillation of 1% clotrimazole cream into the frontal sinuses following fungal débridement may improve outcome by acting as an antifungal drug depot (increased antifungal contact time), but the number of cases reported at this time is limited.

AUTHOR: KYLE G. MATHEWS

Nasal Flush

SYNONYM

Nasal lavage

OVERVIEW AND GOALS

- To obtain cells and/or tissue for diagnostic sampling of intranasal inflammation, infection, or neoplasia
- To remove small nasal foreign bodies

INDICATIONS

- Chronic nasal discharge (unilateral or bilateral)
- Intranasal obstruction
- Chronic sneezing
- Nasal foreign body
- Epistaxis with normal coagulation profile and blood pressure (BP)
- Maxillary mass/deformity

CONTRAINDICATIONS

- High-risk anesthetic animals (i.e., severely compromised metabolic, cardiac, or neurologic disease)
- Documented loss of integrity of cribiform plate (relative contraindication)
- Coagulopathy/bleeding disorder

EQUIPMENT, ANESTHESIA

- General anesthesia
- Endotracheal intubation
- Bowl of lukewarm tap water
- Rolls of gauze to pack the pharynx (one to three rolls, depending on size of animal)
- A 60-mL feeding tip syringe; the larger the diameter of the syringe tip, the more forceful the water jet can be generated by pushing on the plunger.
- Sterile saline solution for flush (1-L bag)
- Two bath towels
- Sterile water-soluble lubricant

ANTICIPATED TIME

- Time for general anesthesia
- Actual procedure takes <10 minutes per nostril.

PREPARATION: IMPORTANT CHECKPOINTS

- Thoroughly soak the rolled gauze in tap water, and then wring it out just before using it.
- Fill the 60-mL syringe to capacity with sterile saline solution.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Improper placement or insufflation of the cuffed endotracheal tube, thus allowing water to enter the trachea of the anesthetized animal.
- Unevenly distributed or insufficient gauze, allowing the diagnosis (cells and tissue) to be flushed back into the esophagus.
- Forgetting to remove the gauze from the pharynx once the flush procedure is finished.
- Excessive force of flushing in patients with uncertain or compromised cribiform plate structure
- Using loose 4 × 4 gauze sponges—some may be forgotten after the procedure is finished and occlude the larynx or trachea.
- In case of severe nasal destruction, epistaxis may develop.

NASAL FLUSH Large-bore syringe is inserted into nostril of anesthetized patient to perform nasal flush procedure. End of gauze roll can be seen protruding from mouth.

PROCEDURE

- General anesthesia induction and maintenance; endotracheal intubation:
  - Verification of appropriate endotracheal tube cuff inflation
- Sternal recumbency, head and neck extended
- Unwind gauze and soak in water, and then retrieve and wring out excess water.
- Place damp gauze dorsal to and on both sides of the endotracheal tube as far caudally as possible, past the caudal edge of the soft palate.
- Gently insert lubricated end of syringe into the ventral meatus of the nose as far as it will go. This is most easily achieved by pushing the philtrum of the nose dorsally while aiming the tip of the syringe toward the septum. Slide into the nasal passage without using force.
- Place towel over the head and nose of the dog to avoid a spray of back flush onto the operator.
- While holding the syringe firmly in place, briskly empty the 60 mL of saline into the nasal passage using moderate pressure on the plunger.
- A powerful stream of fluid is required to dislodge foreign bodies or pieces of abnormal tissue.
- Repeat several times for each nostril; other towel may be used to control spillage if saline flows from mouth.
- When finished, gently pull gauze from the pharynx, and examine carefully for foreign bodies or tissue clumps.

POSTPROCEDURE

- Remove the gauze from the caudal pharynx.
- Once the gauze is removed, examine the animal's mouth and pharynx for any material that was flushed out of the nose but not trapped into the gauze.
- Observe the animal for sneezing and bleeding after termination of general anesthesia.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Rhinoscopy, nasal radiography series, CT scans, or MRIs normally precede nasal flush.
- Nasal radiography series, CT scans, and MRIs provide specific information on intranasal structure that is not obtained with nasal flush.

Oxygen Supplementation

SYNONYM

Oxygen therapy

OVERVIEW AND GOALS

Supplemental oxygen is easily administered, readily available, and if used correctly, safe. There are very few contraindications to oxygen supplementation. Oxygen therapy is often used in emergency and critical care medicine because hypoxic cellular metabolism is less efficient and may lead to organ dysfunction and death. The critical care supplier must understand the physiology of oxygen delivery and recognize cases that will benefit from oxygen therapy. A worthwhile rule of thumb is if there is uncertainty about whether to supplement oxygen, supplementation should be initiated pending clarification.

INDICATIONS

- Clinical situations in which oxygen therapy may be of benefit include respiratory distress, sepsis, pyometra, severe bite wounds, hyperthermia, pleural space disease, congestive heart failure, anemia, all forms of shock, pulmonary contusions, pulmonary hypertension, seizures, and head trauma.
- Clinical signs caused by hypoxemia include an anxious expression, extended head and neck, open-mouth breathing, abducted elbows, tachypnea, tachycardia, cyanosis, cardiac arrhythmias, and syncope.
- The hallmark clinical sign of diminished arterial oxygen content is cyanosis. For cyanosis to be detected, there must be >5 g/dL of unoxygenated hemoglobin in the peripheral capillaries (corresponds to SpO2 75%-80%); therefore, cyanosis indicates severe hypoxemia, and anemic animals may have critical hypoxemia without cyanosis.

CONTRAINDICATIONS

Causing distress to an already compromised animal is a contraindication. Several methods of oxygen delivery are available. Selection of the optimal technique depends on the animal's respiratory status, desired inspired O2 content, anticipated duration of therapy, equipment available and its size, and conformation and temperament of the animal.

EQUIPMENT, ANESTHESIA

See description for placement of devices.

ANTICIPATED TIME

Less than 10 minutes for any of the procedures

PREPARATION: IMPORTANT CHECKPOINTS

Pretreat animal with an anxiolytic that is not hypotensive and does not decrease respiratory effort. Most of these cases are in respiratory distress, so the less anxiety the better. Low-dose benzodiazepines or morphine, buprenorphine, or fentanyl are feasible choices.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

Excessive oxygen supplementation: Administration of 100% oxygen for 12 hours or 80%-90% for 18 hours can lead to alterations in pulmonary function and signs of oxygen toxicosis. Oxygen toxicosis is often difficult to recognize because the clinical signs can be similar to those seen with hypoxemia. However, oxygen toxicosis is relatively uncommon, takes at least 12 hours to occur, is preventable, and is reversible in the early stages if oxygen is discontinued. Supplementation with 50% oxygen appears safe in the dog.

PROCEDURE

Emergency oxygen supply: holding an oxygen-delivery tube so a high flow occurs directly into the animal's mouth is an option that can be used in an emergency situation until more optimal oxygen-delivery methods are instituted.

MASK: The mask is perhaps the easiest and least invasive technique for oxygen supplementation. Purpose-made veterinary masks are preferable (better fit). These masks come in an assortment of sizes that range from pediatric size to large dog size and are designed to fit over the muzzle. It is often awkward to administer oxygen via mask to brachycephalic dogs and some cats. The mask can be connected via tubing to a 100% oxygen source, and if used for long periods of time, the oxygen should be humidified. With a well-fitted mask, flow rates of 8-12 L/min achieve a fraction of inspired oxygen (Fio2) of 0.4 to 0.5 (room air 0.2). The advantages of a mask are related to ease and speed of administration, and no specialized equipment is required. In addition, during oxygen administration, the animal can be closely monitored. Disadvantages of this technique include lack of tolerance by some animals and the requirement of constant manual application of the mask unless the animal is moribund or otherwise immobile.

INTRANASAL CANNULA: There are various types of tubes available for nasal catheterization, including feeding tubes and urinary catheters. Some clinics use flexible feeding tubes or Foley catheters with multiple fenestrations to avoid mucosal jet lesions. The largest tube size possible should be passed. These tubes are placed in the conscious animal, but local anesthesia is recommended. Topical 2% lidocaine is used. The toxic lidocaine dose is 4 mg/kg in the cat, and one-fourth to half this dose is usually sufficient therapeutically.

- The tube is premeasured to the medial canthus of the eye, and the level of the external nares is marked on the tube to indicate the maximal distance of insertion.
- The animal's head is tilted with the muzzle pointing upwards. A few drops of lidocaine are applied to the external nares to desensitize the nasal mucosa.
- The tube is advanced until the tip is at the level of the medial canthus of the eye (until mark on tube is at nares). Insertion is usually easier if the nostril is pushed dorsally and the tube is directed medially.
- Once placed, the tube can be secured as close to the nostril as possible with suture or methacrylate glue (superglue).
- The tube should also be attached on the muzzle, below the eye and on the neck.
- These animals should also be fitted with an Elizabethan collar to prevent self-directed removal of the tube.

The advantages of this technique include ease of application, no special equipment required, versatility in animals that are different sizes, and lack of interference with animal monitoring. Disadvantages include lack of animal tolerance, variable flow rates required to provide oxygen, nasal mucosal irritation, and gastric distention at high flow rates (rare). Recommended flow rates to achieve a specific Fio2 are listed in the table.

TRANSTRACHEAL: Oxygen may be administered transtracheally via a nasal catheter, which is advanced through the nasopharynx to the proximal trachea or through a catheter placed percutaneously through the cervical trachea. A long, flexible IV (jugular-type) catheter can be placed percutaneously into the trachea through the cricothyroid membrane or between tracheal rings. These catheters can be over-the-needle types or through-the-needle types. The entry area should be infiltrated with a local anesthetic prior to catheter introduction. In an emergency situation (e.g., cat with critical laryngeal spasm), a hypodermic needle or an over-the-needle catheter attached to a fluid extension set can be used for administering oxygen intratracheally. Oxygen lines used with this technique should be humidified. The disadvantages of this technique include difficulty with tube placement and poor animal tolerance when it awakens or is more alert.

Reproduced with permission from Drobatz KJ, Hackner S, Powell S: Oxygen supplementation. In Bonagura JD, editor: Kirk's current veterinary therapy XII: small animal practice, Philadelphia, 1995, Saunders, pp 175–179.

Intranasal flow rates of >3l per minute often are not tolerated by animals; these rates may cause the animal to close its oropharynx in response to rapid air/O2 flow. If a hissing sound is heard because oxygen is mostly or entirely refluxing from the nostrils, common sense dictates that the tube and apparatus be checked; if no defects are found, the clinician should try a lower flow rate.

Approximate Oxygen Flow Rates for Supplementation Administration Via Nasal Catheter

OXYGEN FLOW RATES (L/MIN) REQUIRED TO DELIVER AN Fio2 OF:			
	30%-50%	**30%-75%**	**75%-100%**
Weight (kg)			
0-10	0.5-1	1-2	3-5
10-20	1-2	3-5	>5
20-40	3-5	>5	?

OXYGEN CAGE: Oxygen-cage equipment usually involves a chamber that can be flooded with oxygen to provide an oxygen-enriched environment. The advantage of this equipment is a controlled environment. The disadvantages include poor access to animal, difficulty in monitoring the animal, and inadvertent uncontrolled environmental conditions (especially overheating). Alternative oxygen-enriched environments include oxygen tents or a cage with a “fitted door” into which O2 is pumped. These systems are inefficient and generally have no way to remove or scavenge CO2. This works well for cats that present in acute congestive heart failure or status asthmaticus, because the clinician can supplement oxygen for a period of time without the stress of nasal oxygen. Human neonatal incubators have also been used for supplementing oxygen in small animals, and kits to modify normal clinic cages into oxygen cages are available. Covering some of the carrier holes with cellophane and providing a humidified oxygen source can

convert pet carriers into emergency oxygen cages. Elevated temperatures and carbon dioxide levels may be a problem with this technique, however.

OXYGEN SUPPLEMENTATION Animal receiving oxygen supplementation via an intranasal Foley catheter.

OXYGEN SUPPLEMENTATION Animal receiving oxygen supplementation via a tent.

OXYGEN SUPPLEMENTATION Animal receiving oxygen supplementation via an Elizabethan collar partly covered with cellophane, creating an oxygen canopy. Note the oxygen tube entering through the caudal edge of the collar.

MISCELLANEOUS: With an Elizabethan collar, cellophane, and a humidified oxygen line, it is possible to easily create an oxygen

canopy.

- The animal is fitted with an Elizabethan collar (E-collar), and the lower 50%-75% of the collar diameter is covered with cellophane.
- The oxygen line is run inside the E-collar and provides oxygen into the cellophane-covered area.
- In this way, the animal's head is essentially within an oxygen tent.
- In areas with high ambient temperatures, this device is poorly tolerated.
- The advantages of this technique include ease of application and no special equipment requirements.
- The major disadvantage is animal intolerance.

Note: Oxygen can also be administered in acute situations via a transparent plastic bag placed over the animal's head.

POSTPROCEDURE

- Most animals requiring oxygen supplementation will be hospitalized in an intensive care unit and observed closely because of the nature of the underlying disease. In addition, it is important to closely monitor the typical vital parameters, including temperature, pulse, and respiratory rate. Specific evaluation for animals on oxygen supplementation includes thoracic auscultation, observation of respiratory effort, evaluation of mucous membrane color, capillary refill time, blood gas analysis, and/or pulse oximetry.
- Knowing when and how to discontinue oxygen therapy can present the clinician with a dilemma. Generally it is worthwhile to slowly wean animals off oxygen supplementation. The rate of tapering should be based on the animal's condition and response but is generally done over a 24-48 hour period. It is also important to remember that oxygen is often an adjunctive therapy, and treatment directed toward the underlying disease process is paramount.

AUTHOR: DAVID MILLER

Otoscopy (Video)

OVERVIEW AND GOALS

- Minimally invasive examination technique for the external ear canal, tympanic membrane, and middle ear
- Allows excellent visualization, sampling, and documentation during ear flushing, myringotomy (deliberate perforation of the tympanum), removal of feline ear polyps, and biopsy procedures

INDICATIONS

- When clinical signs of ear disease are present: otic discomfort, pruritus, discharge, swelling or erythema, head-shaking, Horner's syndrome, vestibular signs, deafness
- Ear flushing using video otoscopy is indicated in unresponsive or recurrent otitis or if otitis media or a mass in the ear canal is suspected.

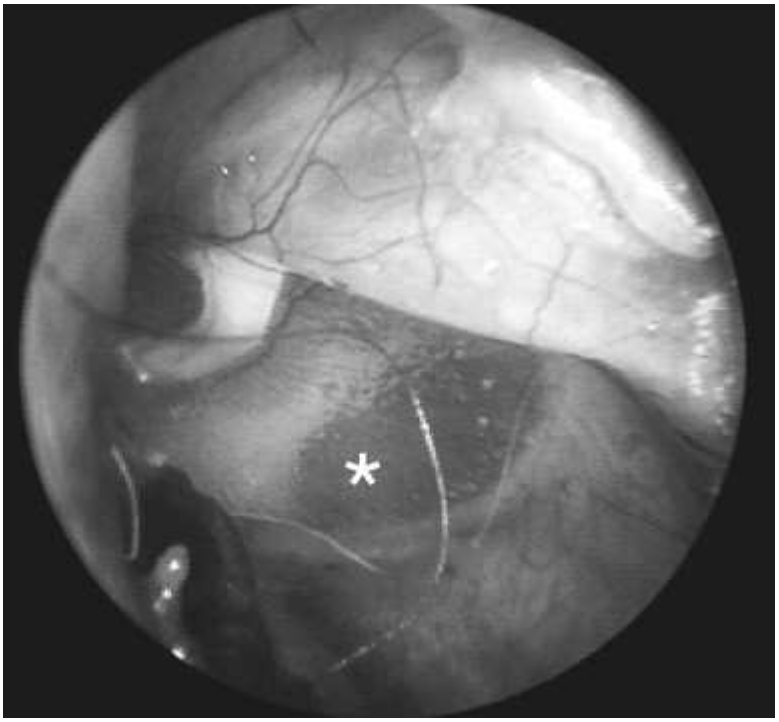
CONTRAINDICATIONS

- Very painful ears (in conscious animal)
- Severely stenotic ear canals

EQUIPMENT, ANESTHESIA

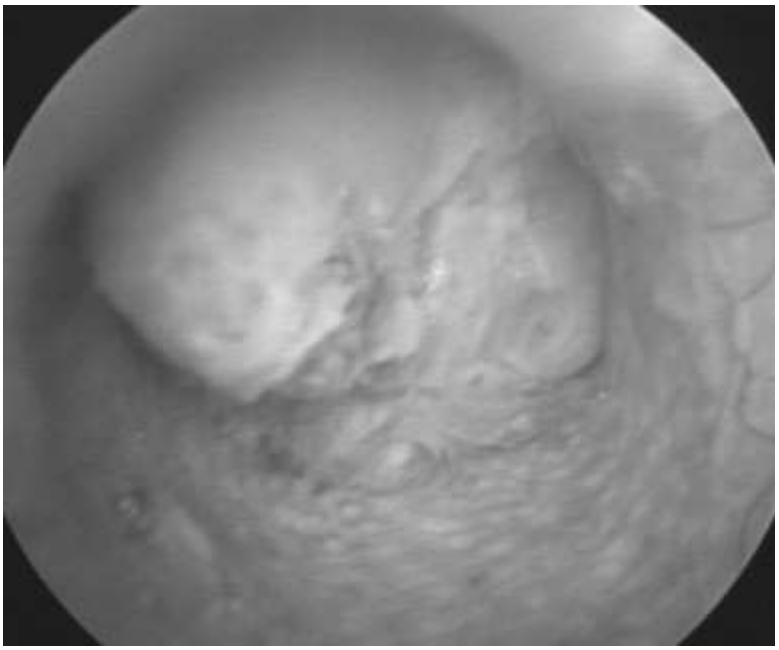
The main piece of equipment for the procedure is a video otoscope.

- Ear examination:
  - The examination can be performed in a conscious animal if the ear is not too painful.
  - Manual restraint by an experienced handler is required.
  - A small amount of isopropyl alcohol is needed for cleaning the otoscope tip; a commercial antifog solution improves visualization.
- Ear flushing:
  - Ear flushing, myringotomy, and biopsy procedures require general anesthesia and endotracheal intubation to prevent lower respiratory tract contamination.
  - Analgesia is essential and should be part of the anesthetic protocol.
  - Ceruminolytic agent (dogs only)
  - Bulb syringe
  - Sterile physiologic saline solution, approximately 1 L in bowl (may be warmed to body temperature)
  - A 5 Fr, 22-inch (56 cm) polypropylene urinary catheter, red rubber feeding tube or Tomcat catheter, tip dulled by heating briefly over a flame
  - Two 30-mL syringes
  - Three-way stopcock valve
  - Culturette tubes
  - Video otoscope: compatible biopsy and grasping instruments and ear curettes are available.
  - Optional: suction unit and flushing and suction apparatus



OTOSCOPY (VIDEO) Otoscopic view of a normal ear canal and tympanum. The asterisk indicates the optimal site for myringotomy.

(Courtesy Dr. Louis N. Gotthelf.)



OTOSCOPY (VIDEO) Otoscopic view of an external ear canal partially obstructed by a large polyp in a dog.

(Courtesy Dr. Michel Chenier.)

ANTICIPATED TIME

- Ear examination: <5 minutes in conscious animal
- Ear flushing: 10-30 minutes per ear, 30-60 minutes for anesthesia

PREPARATION: IMPORTANT CHECKPOINTS

Ear examination:

- Avoid having topical medication or cleaning solution instilled in the ears for 12 hours prior to procedure.
- Use adequate restraint to prevent harm to pet and handler.
- Sedation and analgesia are recommended in painful ears.

Ear flushing:

- Revision of the ear anatomy of cat and dog, localization of the myringotomy site
- Collect cytologic analysis and culture samples before instilling fluids or cleaning solutions in the ear.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

Ear examination:

- Discomfort, trauma to ear canal

Ear flushing:

- Vestibular signs, deafness, Horner's syndrome, facial nerve injury, pain, tympanic membrane rupture:
  - Usually temporary but may persist
  - More common in cats; therefore, the use of strong ceruminolytic agents should be avoided in this species
- Flushing very inflamed ears may increase discomfort and induce a rapid return of debris to the ear canal.
- Should not be attempted in extremely stenotic ear

PROCEDURE

Ear examination:

- Use a disinfected otoscope head for each animal (follow manufacturer's recommendation for disinfection).
- Wipe otoscope tip with isopropyl alcohol.
- Pull pinna gently away from skull.
- Slowly introduce otoscope into ear canal, using video image for guidance.
- If thorough examination is not possible because of swelling of the ear canal, the procedure may be attempted after 1-2 weeks of topical therapy, cleaning, ± oral corticosteroids (no topical medication on day of recheck).

Ear flushing:

- Many techniques have been described.
- General anesthesia
- Inflate endotracheal tube cuff.
- Sternal recumbency, head may be tilted to each side slightly as needed.
- Tilt head down (neck ventroflexion) so solutions exit from the nose if the tympanic membrane is ruptured.
- Collect cytologic analysis and culture samples.
- For tenacious or waxy debris, instill ceruminolytic agent, massage, and remove using saline and bulb syringe (dogs only) or a 30-mL syringe.
- Introduce catheter through otoscope so tip is visible, and attach one 30-mL saline-filled syringe and one empty 30-mL syringe on a three-way stopcock valve.
- Assistant flushes saline solution, using small pulses, and aspirates using the three-way stopcock valve.
- Direct catheter tip as needed to dislodge debris.
- Removal of debris reveals area of tympanic membrane at end of ear canal.
- If tympanic membrane is ruptured, the catheter can be advanced a short distance ventrally into the middle ear cavity.
- If tympanic membrane is intact but abnormal or if otitis media is suspected, myringotomy may be performed by introducing a fine instrument (open-ended Tomcat catheter cut to create a beveled edge, or a small culture swab) through the otoscope and directing it through the caudoventral portion of the pars tensa.
- May collect samples for cultures and cytologic analysis from middle ear
- Gently flush middle ear with saline solution at body temperature.
- Suction excess saline solution from the ear canal, and instill topical medication if appropriate.

POSTPROCEDURE

- Oral ± topical corticosteroids reduce the inflammation induced by otoscopy and flushing.
- Ear medications should be started immediately after flushing; start cleaning ear the following day.
- Analgesic protocol

ALTERNATIVES AND THEIR RELATIVE MERITS

Handheld otoscopes are adequate for cursory examination of the ear canal but much less useful for ear-flushing procedures. Advantages of handheld otoscope:

- Less expensive
- Convenient and portable
- Less prone to condensation
- Smaller plastic tip may be better tolerated.

Advantages of video otoscope:

- Greatly improved optics and magnification
- Increase client's compliance to treatments by allowing them to view the ear lesions when used in the examination room
- Allows documentation
- Vastly superior for ear flush procedures, because the ear canal can be visualized very well through saline solution during the flush procedure, allowing for a very thorough cleaning with minimal trauma
- Allows for much more precise and thus safe placement of instruments for biopsy, myringotomy, foreign-body removal, and polyp removal

Orthopedic Examination

OVERVIEW AND GOAL

To identify and localize an orthopedic disorder by performing a thorough and reproducible examination of the axial and appendicular skeleton, joints, and musculature

INDICATIONS

Any animal with abnormal musculoskeletal function due to injury, joint, muscle, or bone-related disease

CONTRAINDICATIONS

In trauma cases, life-threatening problems should be addressed and animal stabilization ensured before performing a detailed orthopedic evaluation.

EQUIPMENT, ANESTHESIA

- Specialized equipment is usually not required.
- Goniometer to measure joint angles is optional.
- Sedation/general anesthesia is rarely necessary.

ANTICIPATED TIME

About 20-30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

Detailed history tailored to the individual case, including:

- Signalment:
  - Breed-specific orthopedic disorders
- Owner assessment of problem
- Duration of problem
- Speed of onset
- Relationship to trauma, exercise, or time of day
- Course of problem
- Influence of rest or medications
- Associated or independent systemic disease
- Previous orthopedic problems and associated treatments and outcomes
- “Family” history
- Diet and exercise regimen
- Observation in the examination room noting how the animal sits, stands, and moves around
- Observation of different gaits in an open area

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Do not overinterpret breed-specific disorders.
- Beware of misinterpretation of neurologic disorders for orthopedic problems and vice versa:
  - Postural reactions such as proprioceptive testing and tactile placement responses, together with spinal cord reflexes, can help differentiate between orthopedic and neurologic disorders.
- Perform neurologic examination after orthopedic examination (see p. 1311).

PROCEDURE

- Strive to palpate entire musculoskeletal system.
- Palpate all joints for swelling, thickening, crepitus, pain, and instability.

- Palpate all muscles for swelling, atrophy, pain, and asymmetry.
- Palpate bones for irregularity, pain, and instability.
- Palpate entire spine (including flexion, extension, and lateral deviation of the head and neck; tail head flexion and flexion and extension of the lumbosacral joint) for pain and sensitivity.
- Place all joints through a full range of motion.
- Know normal range of motion for all joints.
- When appropriate, use opposite limb as "normal" for comparison, best achieved in a standing position.
- Specific orthopedic tests include an Ortolani maneuver for hip joint laxity and a cranial drawer/sign test or a tibial thrust test for stifle joint instability.
- Ortolani maneuver:
    - The femur is forced dorsally and perpendicular to the spine in an attempt to subluxate the hip joint.
    - Slow abduction of the limb allows the femoral head to return to the acetabulum.
    - An audible or palpable "clunk" is a positive sign, suggesting hip laxity.
- Cranial drawer/sign test (see p. 261):
    - The examiner places a finger and thumb of one hand on the patella and lateral fabella proximal to the joint; the finger and thumb of the other hand are placed on the fibular head and tibial crest distal to the joint.
    - Cranial translation of the tibia can be applied to the joint in stifle flexion and extension. A torn cranial cruciate ligament will produce cranial subluxation (cranial movement) of the tibia relative to the femur.
- Tibial thrust test (see p. 261):
    - Evaluates the same instability as a cranial drawer test (i.e., tests mainly for cranial cruciate ligament integrity)
    - Dorsiflexion of the hock while the stifle is in slight flexion
    - Positive result consists of a tibial thrust motion (cranial movement of the tibial plateau relative to the rest of the stifle), appreciated by placement of an index finger on the tibial crest.
    - Animal cooperation will determine whether the examination requires sedation or even general anesthesia.
- Perform a rectal examination in cases of pelvic trauma.

POSTPROCEDURE

- Inform owner that some animals may be sore or painful after an orthopedic examination.
- Use nonsteroidal antiinflammatory drugs (NSAIDs) if the animal shows evidence of discomfort or pain (e.g., lameness) after manipulation.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Plain radiographs:
    - May require sedation
    - Minimum of two views of the localized region
    - Normal opposite limb can be useful as a control for comparison
    - In trauma patients, thoracic radiographs should precede orthopedic radiographs as part of a minimum database.
    - Initial radiographic assessment of spinal injuries should ideally be performed without sedation.
    - Radiographic information and clinical/physical examination are complementary; one cannot entirely replace the other, because some animals with radiographically severe lesions are clinically mildly affected and vice versa.
    - Specific radiographic studies may be indicated (e.g., PennHIP, dorsal acetabular rim [DAR] view of pelvis, hyperflexed or hyperextended view of joint).
- Arthrocentesis (see p. 1199):
    - Where joint swelling is palpated, arthrocentesis may be indicated for cytologic evaluation of synovial fluid.
- CT scan (see p. 1233) and MRI (see p.1200) techniques can be extremely useful in specific cases:
    - Rule in or rule out diagnosis that is unclear from examination and routine testing
    - CT scan is usually preferred for bone analysis, and MRI is usually preferred for soft-tissue analysis, including ligament and articular cartilage damage.
    - Requires general anesthesia
    - Cost or availability may be prohibitive.
- Bone scan and nuclear scintigraphy:
    - Helpful to localize an occult orthopedic lameness
    - Highly sensitive yet nonspecific
    - Requires sedation and hospitalization of "hot" animal, and cost or availability may be prohibitive.
- Diagnostic ultrasound:
    - Limited uses in identifying orthopedic disorders
    - In skilled hands, can identify biceps, triceps, infraspinatus, and Achilles and iliopsoas tendon lesions
- Arthroscopy (see p. 1200):
    - Allows minimally invasive visualization and diagnosis ± surgical repair of a joint disorder
    - Requires general anesthesia, and cost or availability may be prohibitive.

AUTHOR: NICHOLAS J. TROUT

Ophthalmic Examination

OVERVIEW AND GOAL

Basic examination of the structure and function of the eyes and adnexa (surrounding structures) to establish an ophthalmic diagnosis, prognosis, and treatment plan and evaluate the need for additional diagnostic testing or referral

INDICATIONS

- An abnormal appearance to the eye(s) or adnexa
- Ocular discomfort or trauma
- Vision impairment/loss
- Systemic disease that may have ocular manifestations

CONTRAINDICATIONS

A very aggressive patient, particularly with a fragile eye, that will not tolerate eye examination may not be examinable awake.

EQUIPMENT, ANESTHESIA

- Exam table in a quiet room that can be darkened
- Bright focal light source (Finnoff transilluminator or otoscope without a cone)
- Schirmer tear test (STT) strips (optional)
- Fluorescein dye–impregnated strips
- Sterile saline/irrigating solution
- Topical anesthetic (e.g., proparacaine)
- Tonometer (Schiøtz, TonoPen)
- 1% tropicamide (optional)
- Condensing/fundic or magnifying lens (lens strength of 20-28 D is best for general use)
- Direct ophthalmoscope (optional)
- Muzzle for aggressive dogs
- Sedation and/or anesthesia are generally not necessary and may in fact hinder a good examination, owing to globe position, reduced alertness, and anesthetic drug effects.

ANTICIPATED TIME

About 10-20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Adequate restraint will greatly aid examination and is generally best performed by an assistant, not the owner. Muzzle dogs if necessary.
- Examine the animal at eye level (on exam table); large dogs may be examined on the floor, sitting up, and if cooperative, backed into a corner.
- Cats especially can become enophthalmic during examination; occasional repositioning is often necessary to stimulate the cat and reduce enophthalmos.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Fragile eyes (ruptured eyes, descemetoceles) should be handled extremely gently if at all. Note: Do not palpate, retropulse, or measure intraocular pressure in these eyes.
- Perform STT before any solutions are applied (solutions alter fluid content of tears), assess fluorescein staining before tonometry (tonometry may give false appearance of corneal lesions), assess pupillary motion before pharmacologic mydriasis (mydriatic drugs block miotic response).

PROCEDURE

- Grossly assess functional vision as the animal walks to the exam room: does the animal show signs of adequate vision, such as confidently maneuvering and successfully avoiding objects? Or does it walk slowly and cautiously with head down, using its whiskers and other senses to navigate? Is it easily frightened by obstacles? Does vision appear to be worse on one side than the other?
- Looking at the face head-on in normal room light, assess the overall appearance and symmetry of the head and orbits; resting pupil size; and globe size, position, and motility. Note any ocular discharge or tear staining:
    - Evaluate the eyelid shape and conformation before manipulating the head and eyes.
    - Palpate the muscles of mastication, and assess the degree of globe retropulsion through the closed lids. Palpate both eyes simultaneously to best assess symmetry.
    - Retropulsing each eye individually also elevates the nictitans, which can then be evaluated for presence, shape, coloration, and abnormalities.
- Assess the cranial nerves bilaterally (see):
    - Menace response (II afferent, VII efferent): covering one eye, perform a menacing gesture to the open eye to elicit a blink, without stimulating the vibrissae (whiskers) or face. Hold your hand flat and vertical with its lateral aspect toward the animal's eye to allow testing of different areas of the visual field while minimizing air motion:
        - Note that diffuse cerebellar disease may cause absence of the menace response without loss of vision.
        - Note that very young puppies and kittens normally do not menace.
    - Palpebral reflex (sensory V afferent, VII efferent): lightly touch the lateral and medial canthi to stimulate blinking. Observe for completeness of blinking:
        - Note that facial paralysis disables blinking, in which case globe retraction and nictitans elevation (± III, IV, VI efferent) or head withdrawal may be seen instead.
    - Dazzle reflex (II afferent, VII efferent): rapidly apply a very bright focal light to one eye. This should cause the eye to blink (subcortical pathway). An intact dazzle does not alone signify vision so much as some degree of retinal and optic nerve function.
    - Pupillary light reflex (PLR; II afferent, III efferent): apply a bright light to one eye, and observe ipsilateral (direct PLR) and contralateral (indirect or consensual PLR) pupillary constriction. Also note degree of pupillary constriction.
- Test vision by tossing cotton balls or gauze into the visual field:
    - Functional vision can also be tested utilizing an obstacle course in an enclosed area. The best obstacles are relatively large, safe to bump into, and free of odor. Vary the course during the test. Do not provide excessive nonvisual guidance (sound, food). Repeat in dim light if indicated.
- If significant mucoid ocular discharge is present, measure tear production:
    - Gently wipe away very large clumps of discharge without touching the lid margins or ocular surface.
    - Keeping the proximal end of the STT strip in the package, fold at the notch. Place the folded tip between the lower lid and globe. Close lids if necessary; keep strip in for 60 seconds, and immediately replace if blinked out.
    - Low is <10 mm/min, borderline is 10-15 mm/min, normal is >15 mm/min wetting in dogs and cats (even lower for many normal cats).
- If corneal ulceration is suspected, apply fluorescein. Place a drop of sterile saline on a fluorescein strip, and lightly touch the strip to the bulbar conjunctiva. Allow the lids to blink. Flush excess fluorescein with saline to prevent false-positive results. Examine in a darkened room, ideally with cobalt light/Wood's lamp:
    - In 1-5 minutes, fluorescein may appear at the nostril(s) or mouth, indicating nasolacrimal patency (positive Jones test). Note that a negative Jones test does not necessarily indicate nasolacrimal duct obstruction.
- Retroilluminate the eyes to identify opacities in the visual axis:
    - Hold the transilluminator above your ear and shine it into the animal's eyes. Adjust your position (usually to below the level of the animal) until you see the fundic reflection, and then scan from side to side to visualize opacities in the clear ocular media, which will appear silhouetted.
- Carefully examine the surface and anterior segments of the eyes in dim light with the transilluminator. Note the lid margins, nasolacrimal puncta, bulbar and palpebral conjunctiva, cornea and anterior chamber, iris surface, pupil, and anterior lens:
    - Holding the light from the side will aid greatly in accentuating the three-dimensionality of anterior chamber structures.
- Examine the fundus, noting the optic nerve, retinal vessels, tapetum, and nontapetum:
    - A drop of 1% tropicamide may be given for mydriasis if there is no suspicion of glaucoma. Wait 20-30 minutes after applying; the effects will last for 2-4 hours.
    - Indirect ophthalmoscopy: the preferred method, as it provides a wider view that is easier to interpret, allows three-dimensional visualization, and is safer for the examiner:
        - Using a fundic lens and transilluminator, position yourself as for performing retroillumination (as described above) an arm's length away from the animal. The assistant should hold the lids open. If using an aspheric lens, hold the lens' flatter side (white rim) toward the animal. Place the lens 1-2 inches from the animal's eye, and then move it toward you slightly until the fundic view appears (inverted and backwards) to fill the lens. Examine the whole fundus, adjusting as if the “fulcrum” of the line of sight is at the animal's lens (e.g., move laterally for a more medial view).
    - Direct ophthalmoscopy: provides a highly magnified view of very small areas of the fundus:
        - To allow the widest area to be examined, use your right eye to examine the animal's right eye, and use your left eye to examine the animal's left eye.
        - With the largest white circle setting and the diopter dial set on 0, focus on the fundus by viewing the eye from 2-6 inches (5-15 cm) from the animal. View as many areas as possible, adjusting the focus if needed by changing diopter settings. These lenses allow for focusing at different depths (for a fixed distance from the

animal) and also can adjust for any correction required by your eyes. The view through the direct ophthalmoscope is a direct image (not reversed).
    - If the light causes blepharospasm or resistance on the part of the animal, dim the light, apply the polarizing filter, or use a smaller circle size.
    - The slit beam (thin rectangle) setting may help in detecting three-dimensionality and depth in anterior segment or fundic lesions.
    - The crosshairs in the fixation aperture may be used for measuring very small retinal lesions. Size comparison may also be made to the size of the optic nerve head (optic disc).
    - The red-free (green) filter allows for differentiation between fundic blood, which appears black, and melanin, which appears brown.
    - An optional cobalt filter may be used for detecting fluorescein-positive corneal lesions.
- If the eye is red or cloudy, the pupil is abnormal, or there is vision loss, perform tonometry. Note that "digital tonometry" (mere globe palpation with the fingers) is inadequate to measure intraocular pressure. Apply a drop of topical anesthetic (may not be necessary with TonoVet). Avoid pressure on the ventral neck.
    - Schiøtz: assemble the tonometer and clean the footplate. Test the tonometer by placing it on the included test block (gives a scale reading of 0). Position the animal with iris plane parallel to floor (dorsal recumbency or sitting up with nose pointed to the ceiling). Holding the tonometer by the handles and keeping it vertical, gently rest the footplate on the central cornea (not the third eyelid or sclera) until a single reading is produced. Repeat two to three times, and use included chart to get actual intraocular pressure (IOP). If IOP is >25 mm Hg, repeat with next additional weight. Record IOP in mm Hg (not as scale readings). Clean tonometer after use.
    - Tono-Pen: Properly fit a clean tip cover, turn on, and calibrate if necessary. Gently touch the instrument tip to the cornea, keeping it perpendicular to the eye; it does not need to be horizontal. Repeat several times until a long beep is heard. A bar over the "5%" at the bottom indicates a statistically significant reading (mean given in mm Hg).
    - TonoVet: Properly insert a new probe tip. Turn on and ensure that proper species calibration is on. Holding the instrument horizontal with the tip 4-8 mm from the cornea, repeatedly press the button to take readings until a long beep is heard. A nonblinking "d" before the reading indicates a statistically significant, dog/cat-calibrated reading.
    - Normal IOP in dogs and cats is 15-25 mm Hg.

OPHTHALMIC EXAMINATION Equipment and materials that may be used during an ophthalmic examination. **A**, Finnoff transilluminator. **B**, STT strips. **C**, Fluorescein dye–impregnated strip. **D**, Lens. **E**, Sterile eye irrigating solution. **F**, 1% tropicamide solution. **G**, 0.5% proparacaine solution. **H**, Tonometer—Tono-Pen. **I**, Tonometer—Schiøtz. **J**, Direct ophthalmoscope.

POSTPROCEDURE

Flush corneas of excess fluorescein if necessary. Protect eyes from light if mydriatics were used.

AUTHOR: JANE CHO

Prostatic Sampling Techniques

SYNONYMS

- Prostatic fine-needle aspiration (FNA)
- “Tru-cut”: automated needle biopsy
- Prostatic massage
- Traumatic catheter biopsy

OVERVIEW AND GOAL

Nonsurgical techniques for obtaining prostate tissue samples for culture and cytologic and histopathologic examination in practices with ultrasound capabilities

INDICATIONS

- Pyuria
- Hematuria
- Penile/urethral discharge
- Prostate enlargement
- Prostatic mineralization
- Asymmetric/irregular/nodular prostate

CONTRAINDICATIONS

- Inadequate restraint
- Bleeding disorder
- Prostate abscess (for automated needle biopsy and large-needle FNA)
- Acute prostatitis

EQUIPMENT, ANESTHESIA

FNA:

- 18-gauge needle
- 12-mL syringe
- Usually does not require sedation
- Ultrasound machine

Automated needle biopsy:

- Automated biopsy needle (14-20 gauge)
- General anesthesia
- Ultrasound machine

Prostatic massage:

- Urinary catheter that is long enough to reach the urinary bladder
- Two 5-mL syringes
- Two 5-mL aliquots of sterile saline
- Two sterile sample containers capable of holding at least 5 mL of fluid
- Manual restraint to general anesthesia, depending on the demeanor of the patient

Traumatic catheterization:

- Urinary catheter that is long enough to reach the prostatic urethra
- 12-mL syringe
- Sedation pending patient

- Ultrasound or x-ray machine are helpful.

ANTICIPATED TIME

- Abdominal ultrasound time will take between 10 and 40 minutes depending on operator expertise.
- FNA takes about 5 minutes.
- Automated needle biopsy with anesthesia, prostatic massage, or traumatic catheterization will take about 20-30 min.

PREPARATION: IMPORTANT CHECKPOINTS

- The patient can be in lateral or dorsal recumbency.
- These procedures usually require the attending veterinarian and one to two assistants.
- Needle aspiration can be performed on a fully awake animal, provided the animal is adequately restrained.
- Automated needle biopsies require heavy sedation with analgesia or general anesthesia.
- For prostatic massage and traumatic catheterization, both digital rectal palpation and urethral catheterization are necessary. If the patient resists these procedures, sedation is advised.
- A soft red rubber (Sovereign type) feeding tube is less traumatic than a polypropylene catheter.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- FNA and automated needle biopsy procedures require the placement of a needle or biopsy instrument directly into the prostate. Adjacent large vessels such as the distal abdominal aorta and caudal vena cava can be lacerated with patient movement or a biopsy miss.
- These procedures should not be performed on animals with inadequate coagulation systems.
- If acute bacterial prostatitis is present, the prostatic massage could result in release of bacteria into the bloodstream, and septicemia.
- Traumatic catheterization and automated needle biopsy may lacerate the urethra.
- If an abscess or cyst is present, rupture is possible secondary to all of these procedures.

PROCEDURE

Fine-needle aspiration, guided:

- The animal should undergo a full abdominal ultrasound evaluation, and an appropriate area for aspiration should be identified.
- The skin is clipped of hair and aseptically prepared with surgical scrub.
- The needle with a syringe attached is then advanced through the skin into the prostate under ultrasound guidance.
- The prostate gland is aspirated, and the sample is handled for evaluation (as already described)

Fine-needle aspiration, nonguided:

- If the prostate is sufficiently enlarged that it can be palpated externally (abdominally) and stabilized by caudal abdominal palpation, then the procedure can be performed nonguided (without the use of ultrasound).
- The external surface of the skin over the prostate is clipped of hair and aseptically prepared with surgical scrub.
- The needle is affixed to the syringe, the needle tip is placed through the prepared skin, and the tip is advanced into the prostate gland.
- Material is aspirated into the needle by drawing on the syringe plunger to create negative pressure in the syringe.
- Negative pressure is released before withdrawing the needle.
- The needle and syringe are then withdrawn quickly, the syringe is detached from the needle and filled with air, and then the syringe is reattached to the needle; the contents are vigorously expelled onto a microscope slide to make fresh smears for cytologic analysis.
- A portion of the material can be placed in appropriate media for culture and sensitivity (C&S) instead of being smeared, or else the procedure can be repeated to obtain more material for this purpose.

Automated needle biopsy:

- Automated needle biopsies are attained either guided or nonguided as described above for needle aspiration. As this is a more invasive and painful procedure, general anesthesia is recommended.
- Care must be taken not to transect the urethra with this full-thickness biopsy procedure. With this in mind, the biopsy should be taken in an orientation parallel to the urethra, not perpendicular to the urethra.
- A portion of the biopsy is taken for culture. The biopsy is then rolled on a slide for cytologic analysis. The sample is then placed in formalin and processed for histopathologic examination.

Prostatic massage:

- The tip of the penis is extended from the prepuce and cleaned with a mild disinfectant.
- A urinary catheter is placed into the bladder, and the urine is completely removed.
- Sterile saline (5 mL) is instilled into the bladder. This fluid is then aspirated back and placed in a sterile tube labeled *tube #1*.
- The veterinarian then places an index finger in the rectum and palpates both the prostate and the catheter. The catheter is retracted until the tip can be felt caudal to the prostate. The prostate is then massaged for 1 minute.
- The palpating finger is retracted until it is caudal to the holes in the catheter. Pressure is applied to the catheter rectally so that fluid injected into the catheter will not leak out of the penis but will move forward into the bladder.
- Another 5 mL of sterile saline is then injected into the catheter. The fluid flows across the prostatic urethra into the bladder.
- The catheter is then pushed into the bladder, and the fluid is aspirated into a syringe and placed into a sterile tube labeled *tube #2*. Both tubes are presented for fluid analysis and culture.
- Sample #1 will have only bladder material, whereas sample #2 will have both prostate and bladder material. Comparing the two samples allows the clinician to localize the disease process to the prostate and/or the urinary bladder.

Traumatic catheterization:

- Prepare the penis and empty the bladder as above.
- The urinary catheter is placed into the prostatic urethra. Correct catheter placement can be verified by digital rectal examination, by radiograph, or by ultrasound.
- A 12-mL syringe is attached to the end of the catheter, and negative pressure is applied so that prostate tissue is aspirated into the holes of the catheter.
- While maintaining negative pressure on the syringe, remove the catheter from the urethra. This will tear tissue from the prostate that is aspirated into the catheter. This prostatic tissue can be evaluated by cytologic analysis, and sometimes a large enough piece is obtained for histopathologic evaluation.

POSTPROCEDURE

- These are outpatient procedures, and the client may be sent home the same day provided that its clinical condition allows.
- The patient should be sent home on an antibiotic for 5 days or longer if the culture comes back positive.
- The client should be counseled that there may be hematuria transiently postprocedure.

ALTERNATIVES AND THEIR RELATIVE MERITS

A technique for performing a needle aspiration biopsy of the prostate per rectum using a guarded needle has been described. This technique has the problem of injecting bacteria directly into the prostate, as the colon cannot be sterilized. The advent or ultrasound-guided techniques has made this procedure obsolete.

AUTHORS: DONALD KRAWIEC, LENORE MOHAMMADIAN

Prostatic Massage

SYNONYMS

Expressed prostatic fluid sampling by urethral catheter, prostatic wash or washing, traumatic catheter biopsy

OVERVIEW AND GOALS

Nonsurgical technique for obtaining prostate tissue samples for practices without ultrasound capabilities. This technique can also be performed when needle aspiration of the prostate has provided inconclusive or inadequate results.

INDICATIONS

- Pyuria
- Hematuria
- Penile/urethral discharge
- Prostate enlargement
- Asymmetric, irregular, or nodular prostate

CONTRAINDICATIONS

- Inadequate restraint
- Bleeding disorder
- Acute prostatitis
- Prostatic or rectal pain (contraindication to performing the procedure awake)

EQUIPMENT, ANESTHESIA

- Urinary catheter of sufficient length to reach the urinary bladder. A soft, red rubber (Sovereign-type) feeding tube is preferable because it is less traumatic than a polypropylene catheter.
- Two 5-mL syringes
- Two 5-mL aliquots of sterile saline solution
- Two sterile sample containers capable of holding at least 5 mL of fluid
- Routine surgical scrub soap and gauze squares for disinfecting the distal penis
- Manual restraint to general anesthesia, depending on the demeanor of the animal

ANTICIPATED TIME

Approximately 20-30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- The patient can be standing or in lateral recumbency.
- The procedure usually requires three people: the veterinarian and two assistants.
- The procedure requires both digital rectal palpation and urethral catheterization. If the animal resists these procedures, sedation or anesthesia is advised.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- This procedure requires digital massage of the prostate. If acute bacterial prostatitis is present, the prostatic massage could result in release of bacteria into the bloodstream, and septicemia.
- If an abscess or cyst is present, rupture is possible secondary to this procedure.
- The urinary bladder must be completely empty before starting the procedure, or the prostate sample will be diluted by the excess urine.
- Premeasuring the catheter makes it possible to place the catheter into the urinary bladder without causing catheter-induced bladder trauma or allowing it to loop back on itself to form a knot.
- Bladder infections will make the prostate wash difficult to interpret. Animals with bacterial cystitis should be treated with an

appropriate antibiotic before undergoing a prostatic wash.

PROCEDURE

- While one assistant restrains the animal, the other assistant retracts the prepuce to expose the penis and cleans the distal penis with a mild surgical disinfectant.
- The veterinarian passes a urinary catheter into the urethra until the tip is in the bladder and completely removes the urine.
- The veterinarian instills 5 mL of sterile saline via the catheter into the bladder.
- This fluid is then aspirated back with a syringe and placed in a sterile tube labeled *tube #1*.
- The veterinarian then places an index finger in the animal's rectum and palpates both the prostate and the catheter.
- The catheter is retracted until the tip can be felt to be distal (caudal) to the prostate.
- The prostate is then gently massaged for 1 minute.
- The palpating finger is retracted until it is distal/caudal to the holes in the catheter, and gentle pressure is applied to the catheter rectally so that fluid injected into the catheter will not leak out of the penis but will move cranially into the bladder.
- A total of 5 mL of sterile saline is then injected into the catheter so the fluid flows across the prostatic urethra into the bladder.
- The catheter is then advanced into the bladder, and the fluid is aspirated into a syringe and placed into a sterile tube labeled *tube #2*.
- Both tubes are presented for fluid analysis and culture.

If the above procedure yields either inadequate sample size or equivocal results, a traumatic catheter biopsy can be performed. General anesthesia or sedation with systemic analgesia is indicated.

- The urinary catheter in placed into the urethra as already described. The tip of the catheter should be in the prostatic urethra. Correct catheter placement can be verified by digital rectal examination or by radiograph.
- A 12-mL syringe is attached to the catheter, and negative pressure is applied so that prostatic tissue is aspirated into the holes of the catheter.
- While maintaining negative pressure on the syringe, the catheter is withdrawn from the urethra. Doing so will tear tissue from the prostate that is then aspirated into the catheter. This prostatic tissue can be used for cytologic evaluation, and sometimes a sufficiently large piece is obtained to allow histopathologic examination.

POSTPROCEDURE

- The animal should be discharged with an antibiotic for 5 days to reduce the risk of inducing a bladder infection.
- Sample #1 will have only bladder material, whereas sample #2 will have both prostate and bladder material. Comparing the two samples allows the clinician to localize the disease process to the prostate and/or the urinary bladder.

ALTERNATIVES AND THEIR RELATIVE MERITS

Prostatic washings are done infrequently since the advent of ultrasound-guided prostate biopsy procedures; however, washings do provide a representative prostate tissue sample.

AUTHOR: DONALD R. KRAWIEC

Porcupine Quill Removal

OVERVIEW AND GOAL

To safely remove all porcupine quills embedded in the tissues of a patient (almost always dogs). Although most patients are brought to veterinary attention within 24 hours of exposure to quills, extensive migration can occur in just 1-2 days; therefore, immediate removal is appropriate.

INDICATIONS

- Any witnessed or unwitnessed encounter with a porcupine
- Suspected prior porcupine encounter, presenting with signs of quill migration (ocular, thoracic, abdominal, or other site of discomfort, possibly with draining tract). In regions where porcupines are part of the natural fauna, a history of prior porcupine quill trauma should always be investigated when evaluating a patient weeks or months later for vague, nonspecific signs.

CONTRAINDICATIONS

None

EQUIPMENT, ANESTHESIA

General anesthesia is almost always required both for accessing remote (oral) quills and for pain control during the procedure. Quills routinely penetrate the mouth and pharynx; therefore, complete oral exam under general anesthesia is required even if quills initially appear to be confined to the muzzle.

ANTICIPATED TIME

30 minutes to 3 hours or more, depending on number of quills and depth of penetration

PREPARATION: IMPORTANT CHECKPOINTS

- Prior to beginning the procedure, advise owners that even with diligent removal of all visible quills, some may have penetrated beyond the point where they can be seen and can cause health problems in the future.
- Prior to induction, the clinician should be sure to inspect the surface of the face/body on which the dog will be lying once anesthetized to avoid having quills inadvertently driven more deeply into tissue during anesthesia.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Failing to remove all quills:
  - Remaining quills can migrate to deeper tissues and body cavities, including lungs and heart.
  - The number and location of quills at initial presentation do not appear to be associated with the risk of quill retention and infection.
  - Time from quill injury to the development of complications can range from days to months.
- Quill breakage during extraction. Requires dissection to remove the retained fragment.

PROCEDURE

- It is important to perform a full oral exam on the patient, as quills can be embedded in the oropharyngeal region and hard palate (see p. 1295).
- Quills are extracted one at a time with hemostats or needle drivers, beginning on the exterior (skin) and working into the mouth and pharynx.
- Removal is safest when grasping the quill as close to the skin as possible and pulling straight out. Doing so minimizes the likelihood of breaking the quill. If the quill should break, careful dissection to retrieve the remainder of the quill should be performed while attempting to minimize soft-tissue trauma.
- Placing quills in a bowl with gauze and water facilitates the removal process and minimizes risks of injury to those removing the quills.
- Quill removal in locations other than skin depend on the location:
  - Thoracoscopy or thoracotomy is needed to remove quills from the thoracic cavity.
  - An ophthalmologist should be consulted if there are quills embedded in the ocular or periorbital areas.
  - Ultrasonography can be useful in identifying migrating quills in the eye, joint space, thorax and abdomen. A quill appears as two distinct hyperechoic lines.

- Additional diagnostic tests such as thoracic radiographs, echocardiography, MRI, and complete blood work may be indicated on a case-by-case basis, generally if a chronically retained quill is suspected to be causing persistent problems.

POSTPROCEDURE

- Many dogs do not learn from their previous encounters with porcupines. Therefore, it is important to educate owners to avoid repeat events.
- After quill removal, antibiotic administration may be indicated (e.g., amoxicillin-clavulanate, 13.75 mg/kg PO q 12 h):
  - Porcupine quills themselves possess antibiotic properties, and infections after quill removal are not common. However, if significant trauma of the skin or subcutaneous tissues has occurred secondary to dissection, or if the quill has migrated to an atypical location, broad-spectrum antibiotics may be warranted.
  - A longer course of antibiotics is indicated in certain situations, such as migration to the pleural space or central nervous system.
- Analgesia: opiates (e.g., buprenorphine, 0.01-0.02 mg/kg IV or IM) and/or nonsteroidal antiinflammatories (e.g., meloxicam, 0.1 mg/kg PO q 24 h)

ALTERNATIVES AND THEIR RELATIVE MERITS

There are no humane alternatives to removing the quills.

Physical Rehabilitation

SYNONYMS

Physical therapy, physiotherapy Note: In some U.S. states, the *term physical therapy* (and possibly physiotherapy) is a protected term reserved only for human physical therapists. Therefore, claiming to practice such therapy without being a licensed physical therapist is potentially misleading and illegal. The term *physical rehabilitation* is safe and recommended for veterinary medicine.

OVERVIEW AND GOALS

Using modalities, manual therapies, and therapeutic exercises to increase function by strengthening an animal's muscles, accelerating the healing of damaged tissues, increasing flexibility and ranges of motion, and decreasing pain. These therapies are becoming more common in veterinary medicine.

INDICATIONS

- Postoperative orthopedic/joint surgery (e.g., fractures, cranial cruciate ligament tears, total hip replacements, femoral head and neck ostectomy)
- Postoperative laminectomy/hemilaminectomy or other spinal surgery
- Acute neurologic diseases (fibrocartilaginous embolism/stroke, trauma, intervertebral disk disease [IVDD])
- Osteoarthritis/spondylosis
- Vestibular disease and other balance/proprioceptive problems
- Postoperative amputation
- Soft-tissue injuries (e.g., sprains and strains, tendon repairs, muscle tears)
- Obesity/conditioning

CONTRAINDICATIONS

- Unstable and/or infected fractures and joints
- Therapeutic ultrasound is contraindicated over metal implants, tumors, growth plates, eyes, heart, and pregnant uteruses.
- Neuromuscular electrical stimulation may be contraindicated in animals with seizure disorders.
- Heat is contraindicated over acutely inflamed tissues.
- Swimming and underwater treadmill exercise are contraindicated in animals with diarrhea.

EQUIPMENT, ANESTHESIA

Physical rehabilitation can be successfully performed with a minimal amount of equipment. The practitioner's hands are the greatest asset. The following are, however, recommended for optimal results, depending on the case:

- Manual restraint at times
- Goniometer to measure angles of joints
- Gulick II tape measure (to measure limb circumference/muscle mass)
- Heat packs
- Cold/ice packs
- Inflatable exercise/yoga balls and/or rolls
- Therapeutic ultrasound unit (with ultrasound gel)
- Neuromuscular electrical stimulation (NMES) unit
- Treadmills (underwater or land)
- Swimming area (pools for larger animals, tubs for smaller animals)
- Canine life vests
- Various slings and carts
- Cavaletti rails (horizontal bars or poles at varying heights for the animal to walk over; a ladder lying flat works well)
- Stairs
- Balance boards (“wobble” and “rocker” boards)
- Elastic resistance bands
- Leg weights
- Extracorporeal shockwave therapy unit (usually requires sedation)
- Low-level (“cold”) lasers
- Various splints and orthotics

ANTICIPATED TIME

- About 20-90 minutes
- Usually performed several times a week
- Note: Most postop orthopedic cases require an average of 1 month of rehabilitation, neurologic cases average 2-3 months, and osteoarthritis cases may continue indefinitely (or may benefit from intermittent rehabilitation such as 1-2 month stints several times a year).

PREPARATION: IMPORTANT CHECKPOINTS

- Be sure that any surgical repair is stable.
- Watch for any swelling or signs of infected tissues, which could contraindicate treatment.
- Be sure that the animal's condition is not deteriorating with rehabilitation.
- Exercise animals on an empty stomach (subjectively, doing so may decrease risk of gastric dilation/volvulus).
- Take joint range-of-motion measurements (goniometry) in flexion and extension using a goniometer:
    - Normal values are published for some breeds.
    - The measurements should be rechecked every 2-4 weeks to monitor progress.
- Measure thigh or forearm circumference as a rough measure of muscle mass.
    - The measurement of this circumference is done with a tape measure, preferably the Gulick ll to decrease margin of error.
    - This measurement also should be monitored every few weeks for progress.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Do not institute hydrotherapy (e.g., swimming, underwater treadmill) until skin incisions have successfully sealed (at least 5 days).
- It is easy to overwork the animal, especially in the initial treatments. Be sure the animal can easily handle the work regimen in the beginning. As a general rule, exercise can be increased about 20% per week if the animal is improving.
- Do not stress the tissues too much (remember time frames for tissue healing):
    - For example, bone healing (fracture, surgical osteotomy) takes 8-12 weeks to be complete under ideal conditions. A classic pitfall would be applying too much force too early or allowing the dog to apply too much via inappropriate exercise. Signs of pain and palpable instability could be warning signs. Consultation with the surgeon on the stability of the repair is recommended.
- In the immediate postoperative period, therapeutic exercise may be contraindicated. These animals may still benefit from cryotherapy and gentle passive range-of-motion exercises three to four times daily.

PROCEDURE

- Thermal treatments (cryotherapy, heat therapy) are applied to the affected area and should not create discomfort.
- If acute inflammation is present (e.g., first few days after surgery, flare-up of chronic conditions), initiate cryotherapy with an ice pack or cold pack first. Apply for 10-15 minutes over the site of the inflammation. Cryotherapy aims to decrease edema, inflammation, and pain.
- For chronic situations, heat therapy is indicated. This is accomplished by massage, warm packs for superficial areas, or therapeutic ultrasound for deeper tissues (2-5 cm under the skin). Heat will increase blood flow to the tissues, increasing flexibility and decreasing the chance of injury with exercise. It can also reduce pain.
- After the warm-up period, stretching can be instituted if the procedure does not contribute to tissue injury. Tissue injury is avoided through precautions, including heeding the normal time frame of bone healing if relevant (as already described) and using an appropriately limited degree of force during healing, such as avoiding excessive force (animal vocalizes or resists).
- If the animal is vocalizing, then the practitioner may be going too far. Of course, some animals will squirm or vocalize without even being touched, so individual personalities are taken into consideration.
- The individual joints are brought to a comfortable end range in flexion and then extension for 10-15 seconds each. This is repeated 6-15 times.
- Passive range-of-motion (PROM) exercises are also instituted at this point. The entire limb is cycled through its ranges of motion, being sure to incorporate all desired joints. This will increase flexibility and minimize adhesions and contractures.
- NMES can be used for artificially eliciting a muscle contraction:
    - Electrical current is delivered by pads through the skin to the motor end plate, thereby causing the muscle belly to contract.
    - NMES is primarily used for strengthening muscles and increasing endurance as well as to attenuate atrophy.
    - This modality is most helpful in animals that are paralyzed and paretic.
- After successfully undergoing such treatments, the animal (depending on the individual case) may now be ready for therapeutic exercises. These are designed to increase strength, balance, and proprioception as well as encourage weight bearing on affected limbs as indicated. Therapeutic exercise is also helpful in improving active range-of-motion (AROM) in joints, flexibility, and overall function. Therapeutic exercises include the following:
    - Assisted standing exercises, using slings or exercise balls and rolls, are used in the early stages, especially for patients that are paralyzed or paretic.
    - These exercises are designed to encourage the patient to bear as much of his/her own weight as possible.

- The patient is supported in a standing position with the assistance of either slings or yoga balls under the trunk.
- The patient can be rocked side to side or front to back. If the patient begins to collapse, he/she is then lifted back up to the original position, and the exercise begins anew.
- Weight-shifting exercises are designed to shift the patient's weight onto the affected limb(s) to encourage weight bearing. This is achieved with balls and rolls, balance boards, wheelbarrowing and dancing exercises, or simply discouraging use of the contralateral limb in a normal standing position.
- Sit-to-stand exercises are used for increasing ranges of motion and strength in the hind limbs. The dog is commanded to sit squarely on its rear end and then to stand up. Small treats can be used.
    - Note: To get the dog to flex the hind limb squarely, the affected limb can be positioned against a wall to prevent “cheating.”
- Stair climbing is used for improving strength, coordination, and flexibility.
- Underwater treadmills are valuable tools that can be used in most cases:
    - Water height can be adjusted to different levels to change the animal's buoyancy and thereby the amount of weight the limbs are bearing.
    - Changing water heights also changes the active ranges of motion for all the joints of the limbs, depending on which ones are breaking the plane of the water.
    - Most units will also allow variations in speed, time, and incline.
    - Resistance jets can be installed.
    - Life vests and slings for assistance should be used as needed.
- Land treadmills can also be used.
- Cavaletti rails are used for increasing AROM, strength, balance, and coordination:
    - These are typically created with traffic cones with holes drilled through at different heights.
    - PVC pipes can then be inserted at the desired heights to create an obstacle course for the dog to negotiate.
    - The dog must lift its limbs to walk over these rails, thus encouraging active range of motion.
    - The cones and poles can be arranged to also force the dog to weave in and out of the cones, further strengthening the patient's balance and coordination skills.
- Elastic resistance bands and leg weights can be used to further challenge the dog with many activities. Be careful where these are placed—do not put undue stress or torque on susceptible tissues; usually reserved for advanced cases, when a patient has progressed from simpler exercises:
    - Can be used for a postoperative patient with cranial cruciate ligament repair toward the end of its treatments or a patient with osteoarthritis that has successfully progressed to a point that it needs to be further challenged
- Balance boards are used for increasing proprioceptive awareness and balance as well as strength:
    - These are typically flat wooden boards with a fulcrum underneath, on which the dog stands and tries to balance itself.
    - Indications in some animals with vestibular disease, ataxia of various causes, amputees.

PHYSICAL REHABILITATION Dog on underwater treadmill. Treadmill speed and depth of water can be adjusted to optimize level of activity.

POSTPROCEDURE

- Stretching after exercise is usually indicated.
- Cryotherapy (10-15 minutes) is also frequently indicated after the treatment to reduce muscle spasms, pain, and swelling.
- Any progression of lameness or signs of pain must be noted. If observed, reduce the next treatment by about 50%. Note: Be

careful to differentiate orthopedic pain from muscle soreness. Muscle soreness is expected after the first few treatments.
    - Palpate the muscle bellies and move the joints to identify the source of pain.
- Antiinflammatory medications can be used as needed:
    - Carprofen: 2.2 mg/kg PO q 24 h to q 12 h
    - Deracoxib: 1-2 mg/kg PO q 24 h
    - Firocoxib: 5 mg/kg PO q 24 h

ALTERNATIVES AND THEIR RELATIVE MERITS

- Acupuncture (see p. 1195) may also be helpful with pain control and neurologic diseases.
- Chiropractic therapy may be helpful in some cases.

Phlebotomy

SYNONYM

Venipuncture

OVERVIEW AND GOAL

To obtain blood with minimal stress to the patient for diagnostic or monitoring purposes, treatment of certain blood disorders, transfusion, or to administer medications

INDICATIONS

- Diagnostic testing
- Blood transfusion
- Polycythemia
- Hemochromatosis

CONTRAINDICATIONS

- Infection or injury at the sampling site
- Jugular venipuncture in animals with coagulopathy

EQUIPMENT, ANESTHESIA

- Alcohol
- Clippers (+/−)
- Needle and syringe/Vacutainer collection system:
  - Method used depends on vessel size, blood volume required, operator's preference.
- Tourniquet (+/−)
- Sample tubes
- Gauze and tape/bandage wrap (+/−)
- Sedation is dependent on the disposition and the health of the animal.

ANTICIPATED TIME

1-5 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Ensure that the proper criteria have been meet prior to diagnostic testing (e.g., animal fasted) and the required sampling containers are on hand.
- Using jugular veins spares the cephalic veins for IV catheterization and allows for a larger volume to be collected faster.
- Experienced restrainers reduce the stress to the patient and improve the chance for successful venipuncture.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Hematoma
- An insufficient amount of sample can produce an incorrect blood-to-anticoagulant ratio and result in erroneous values:
  - Use 0.5-mL pediatric containers for neonates/exotics (e.g., BD Microtainer tubes)
- Blood collection for coagulation profiles should be drawn with minimal trauma (first attempt) to prevent tissue thromboplastin from entering the sample.
- Improper handling of the specimen can alter results.

PROCEDURE

- Positioning of the patient depends on the ability to restrain the patient and operator preference.

- Apply isopropyl alcohol to the area. In animals with dense hair coats, it may be necessary to clip the area if the vein is neither visible or palpable.
- Jugular vein:
  - Occlude the vein by inserting pressure with your thumb at the thoracic inlet. Using the same hand, palpate the vein with your index finger.
- Cephalic or saphenous vein:
  - Hold the leg and apply slight traction to help stabilize the skin and vein while the restrainer uses one hand to create a tourniquet effect at the elbow. Placing your thumb alongside the vein may prevent it from moving.
- Insert the needle through the skin with bevel up:
  - If using a syringe, apply gentle negative pressure. If you do not have blood in the hub of the needle, draw back your needle (do not come out of the skin) and advance towards where you can palpate the vein. After obtaining the sample, release the pressure on the vein before withdrawing the needle.
  - If using a Vacutainer collection system, push in the Vacutainer tube with your thumb after you have penetrated the skin. Carefully watch for blood while you are advancing, and stop when blood enters the tube. If you get a flashback of blood and then it stops, you may have gone through the vein. Slowly back your needle out until blood flows. When changing Vacutainer tubes (needle still in the vein), be sure to firmly stabilize the plastic Vacutainer holder. Often the act of changing the tubes will push the needle ahead. If no blood flows after changing tubes, slowly back the needle out 1-2 mm until you see blood flow. If this is unsuccessful, withdraw (not out of the skin) and redirect the needle. After obtaining the sample, remove the tube and release the pressure on the vein before withdrawing the needle from the skin.
  - In veins that roll laterally and are difficult to penetrate, an assertive forward movement will aid in successful venipuncture.
  - If blood flow stops during aspiration, rotate the needle slightly in the vein.
  - Excessive negative pressure can cause the vein to collapse and hemolysis to occur.
- After the desired amount of blood has been drawn and the needle is removed, the restrainer applies digital pressure until hemostasis occurs.
- Marginal ear vein prick:
  - Puncture marginal ear vein with a needle or lance. Some apply a thin film of petroleum jelly or other hydrophobic substance to the surface being pricked, which can help the blood bead rather than run. Collect blood onto test strip or capillary tube. Apply pressure to puncture site afterwards to aid hemostasis.

POSTPROCEDURE

Patients with coagulopathy require that pressure be applied to the vein for at least 5 minutes after venipuncture.

ALTERNATIVES AND THEIR RELATIVE MERITS

Central venous catheter: technically challenging, expensive, facilitates multiple blood draws for monitoring in clinic patients

AUTHOR: ELAINE REVELER

Peritoneal Dialysis

OVERVIEW AND GOAL

Exchange of dialyzable solutes and fluid between the peritoneal capillary vessels and the dialysate solution. Exchange occurs across the semipermeable peritoneal membrane as a result of diffusion, ultrafiltration, and convection.

INDICATIONS

- Acute renal failure unresponsive to conventional medical management
- Hyperkalemia or hypercalcemia (severe)
- Intoxication from dialyzable toxin or drugs (e.g., ethylene glycol <24 hours post ingestion, barbiturates, ethanol)
- Hypothermia or hyperthermia
- Resistant metabolic acidosis (severe)

CONTRAINDICATIONS

- Peritoneal fibrosis (impaired semipermeable membrane)
- Pleuroperitoneal leak (predisposed to pleural effusion)
- Recent thoracic or abdominal surgery (including percutaneous endoscopic gastrostomy [PEG] tubes)
- Inguinal or abdominal hernia
- Severe hypercatabolic states (e.g., burn patients)

EQUIPMENT, ANESTHESIA

- General anesthesia (stable patient) or sedation and regional anesthesia (critical patient)
- Clippers
- Surgical scrub
- A #15 scalpel blade
- Local anesthetic (e.g., 2% lidocaine at 1-2 mg/kg)
- Small surgical pack
- Suture material
- Sterile surgical drapes
- Adhesive dressing (e.g., OpSite)
- Closed “Y” connection system or a three-way stopcock with one attachment to dialysate line and the other to sterile collection system
- Dialysate solution (see below)
- Peritoneal dialysis (PD) catheter (see below)

ANTICIPATED TIME

About 30-45 minutes of anesthesia for placement

PREPARATION: IMPORTANT CHECKPOINTS

- Catheterize and drain the urinary bladder prior to PD catheter placement to reduce the risk of iatrogenic puncture.
- Ensure patient is rehydrated prior to anesthesia, and carefully monitor and correct hypotension to minimize further renal compromise.
- Peritoneal dialysis catheters:
  - Regardless of method of placement or catheter type, all catheter types should be tunneled subcutaneously to decrease the risk of dialysate leak and the incidence of peritonitis.
  - Percutaneous placement options include silicone tube catheter with trocar or guidewire-inserted silicon tube (e.g., MILA chest tube) for use in emergency situations or for short-term use, as omental obstruction is a common occurrence.
  - Mini-surgical approach options include fenestrated modified silicone catheters with or without Dacron cuffs such as Tenckhoff catheters, fluted T catheters, Blake surgical drains, or Jackson Pratt surgical suction drains. Dacron cuffs facilitate fibrous attachments, decreasing the risk of dialysate leakage and incidence of peritonitis.
- Dialysate solution:
  - Commercial dialysate prepared as 1.25%, 2.5%, or 4.5% glucose solutions or alternatively, a homemade solution using lactated Ringer's solution (LRS), 0.9% NaCl, or 0.45% NaCl with dextrose added can be used.
  - Homemade solutions are more cost effective, but strict aseptic technique (mask and sterile gloves) must be followed

during preparation to reduce the risk of contamination. Use only single-use or new vials for adding medications or electrolytes to the dialysate. Wipe all injection ports with alcohol prior to injection.
    - Add the following to the solution:
        - Dextrose to act as an osmotic agent; concentration is dependent on patient's hydration status. A 4.5% solution (85 mL of 50% dextrose/L) should be used in fluid overloaded patients, whereas a minimum 1.25% solution (30 mL of 50% dextrose/L) must be used in normovolemic patients to approximate a normal patient's osmolality.
        - Unfractionated heparin (250 to 1000 U/L) for the first few days to reduce the risk of catheter obstruction by fibrin clots
        - Electrolytes should be added based on regular serum electrolyte monitoring.
    - Prophylactic antibiotics are not routinely added. In the event of suspect peritonitis, empirical therapy using cefazolin can be added to the dialysate solution while awaiting confirmation from cytologic analysis and bacterial culture and sensitivity. A one-time loading dose of 1000 mg/L of dialysate followed by a maintenance dose of 250 mg/L of dialysate is recommended.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Hypoalbuminemia
- Dialysate retention (obstruction by omentum or fibrin, improper placement, kinking of catheter)
- Peritonitis (septic)
- Subcutaneous leakage/limb edema
- Electrolyte imbalances (hypochloremia, hypokalemia, hyponatremia, hypomagnesemia, hypocalcemia, hyperkalemia, hyperglycemia)
- Overhydration and pleural effusion
- Hemorrhage
- Dialysis dysequilibrium

PROCEDURE

- General anesthesia for mini-laparotomy approach in stable patients or sedation and regional anesthesia in critical patients or percutaneous technique
- With the animal in dorsal recumbency, clip the abdomen from the xiphoid to the pubis.
- Aseptically prep and drape the area.
- Administer a prophylactic dose of a first-generation cephalosporin (e.g., cefazolin) 30 minutes prior to PD catheter insertion.
- *Mini-surgical approach for catheter placement* (author's preference):
    - At the level of the umbilicus make a small 2-3 cm paramedian skin and subcutaneous incision.
    - Place a small stay suture in the rectus sheath to facilitate manipulation of the body wall.
    - Tent the abdominal wall, and make a small stab incision into the peritoneum.
    - Grasp the PD catheter using a curved hemostat, and advance the catheter into the abdomen towards the pelvic inlet. Release the catheter and remove the hemostat.
    - Secure the Dacron cuffs (if present) within the rectus muscle (inner cuff) and within the subcutaneous tissues (outer cuff), using a pursestring suture.
    - Tunnel the distal end of the catheter through the subcutaneous tissues, and exit the skin 2-5 cm away from the abdominal insertion site. If no Dacron cuffs are present, begin tunneling under the external sheath of the rectus abdominis muscle prior to tunneling subcutaneously.
    - Before closure, connect the PD catheter to the dialysate solution in a sterile manner, and infuse a small volume of dialysate (2-5 mL/kg) into the abdomen to verify proper placement. The dialysate should be readily retrieved via the collection system if no occlusion is present. If unable to retrieve the solution, redirect the PD catheter.
    - Close the entry site through the external sheath of the rectus abdominis muscle over the PD catheter with a simple interrupted pattern using an absorbable monofilament.
    - Close the skin incision with a simple interrupted pattern using nonabsorbable monofilament.
    - Secure the catheter to the exit site using a purse string and fingertrap suture.
    - Apply a sterile gauze and adhesive dressing (e.g., Opsite) over the catheter exit site.
- *Percutaneous catheter placement:*
    - Make a paramedian incision at the level of the umbilicus small enough to form a tight seal around the chosen catheter.
    - Tunnel the trocar subcutaneously for several centimeters before penetrating the abdominal muscles and into the abdomen.
    - Advance the PD catheter off the trocar, directing it caudally into the pelvic inlet until completely in the abdomen.
    - Secure the catheter to the skin with a pursestring suture or with fixation provided in the PD kit (if available).
    - Apply a sterile adhesive dressing over the catheter exit site.
- Dialysate exchange:
    - *Inflow:* initial infusion volumes should be small (10-20 mL/kg) to reduce the risk of leakage. After the first 24 hours, increase the volume to 30-40 mL/kg if tolerated. Dialysate solutions should be warmed to body temperature and infused over 10 minutes either by gravity flow or IV infusion pump. Monitor for signs of nausea, discomfort, or

respiratory compromise, and reduce infusion volumes as needed.
    - *Dwell time:* initial dwell times should be short (30-40 minutes) until the patient improves and uremia stabilizes, and then extend to 4-6 hours.
    - *Outflow:* dialysate removal can be done by gravity over 15 minutes, by placing the collection system below the patient. Alternatively, a negative suction drain can be installed to actively remove the effusate. Effusate volume should equal infused volume when using a 1.25% dextrose solution and exceed infusion volume when using a 2.5% or 4.5% dextrose solution to correct overhydration.
- The entire exchange process is repeated every 1-2 hours until the patient improves clinically and the uremia stabilizes, and then every 4-6 hours.

POSTPROCEDURE

Patient care:

- Analgesia and excellent nursing care should be provided to minimize stress and discomfort.
- Adequate nutritional support (parenteral, enteral or combination of both) is essential to reduce the risk if hypoalbuminemia and peritonitis.
- Careful monitoring of hydration status (frequent body weights, packed cell volume/total solids [PCV/TP], central venous pressure [CVP], dialysate inflow/outflow volume) is essential.
- Assessment of PCV/TP, electrolytes, venous blood gas, blood glucose, blood urea nitrogen (BUN), creatinine, and serum albumin should be performed every 8-12 hours initially and then once daily after stabilization. Adjustments in dialysate and IV fluid composition may be required pending serum chemistry values.

Catheter care:

- Strict aseptic technique (washing hands, wearing sterile gloves) during handling and delivery of dialysate is essential to minimize risk of peritonitis. All line connections should be covered with either chlorhexidine or povidoneiodine soaked sponges/gauzes.
- The PD catheter insertion site should be examined daily for any signs of discharge, swelling, redness, or discomfort to indicate possible infection.
- The dialysate should be monitored daily for signs of cloudiness suggesting peritonitis. If a cloudy dialysate develops, cytologic analysis, Gram stain, and culture and sensitivity on the dialysate should be performed.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Pleural dialysis is technically less demanding than other alternatives, but it is the least effective, with greater complication risks.
- Intermittent hemodialysis (IHD; see p. 1286) is a reliable alternative for the treatment of uremia, but it is limited to specialized centers equipped and trained to offer this service.
- Continuous renal replacement therapy (CRRT) similar in efficacy to IHD, but CRRT is proposed to result in less complications. Specialized equipment, training, and higher cost limit its widespread availability.

AUTHOR: MICHAEL ETHIER

Pericardiocentesis

SYNONYMS

Pericardial drainage, pericardial tap

OVERVIEW AND GOAL

A catheter is used for removing a volume of pericardial effusion for diagnostic and/or therapeutic purposes.

INDICATIONS

- Pericardial effusion causing cardiac tamponade
- Pericardial effusion of unknown etiology

CONTRAINDICATIONS

Small volume of pericardial effusion (difficult to safely enter the pericardial space)

EQUIPMENT, ANESTHESIA

- Local anesthesia (2% lidocaine)
- Manual restraint; sedation needed only rarely.
- Hair clippers
- Surgical scrub solution, rubbing alcohol, and gauze/sponge for prepping skin
- 0.5-12 mL 2% lidocaine for local anesthesia; volume based on body weight 1-70 kg. Note: Discomfort of lidocaine infusion can be reduced by adding 0.05-0.2 mL 8.4% sodium bicarbonate and warming to body temperature (armpit method).
- Sterile surgical gloves
- A #11 scalpel blade
- A 14-gauge over-the-needle catheter (e.g., equine IV catheter)
- A 6-mL syringe
- Two 35- or 60-mL syringes
- Kidney bowl for effusion
- Lavender- and red-top tubes for sample
- Tissue glue

ANTICIPATED TIME

About 15-40 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Ultrasound guidance: not usually used during the procedure. Immediately prior to the procedure, however, ultrasound-based localization of an area with maximal pericardial effusion and minimal lung is extremely useful.
- Electrocardiogram (ECG) may be used during the procedure; appearance of premature ventricular complexes (PVCs) suggests catheter/stylet is touching heart and should not be advanced farther. However, such contact with the heart is generally palpable (heartbeat hitting catheter tip), and PVCs may occur independently of the catheter in animals with pericardial effusion.
- Clinicians should tell clients that the procedure is often palliative, and effusion can recur, with the likelihood and speed of recurrence depending on the underlying cause. Rapid re-effusion or even hemodynamic collapse postcentesis is possible with atrial tear and with malignancies such as hemangiosarcomas.

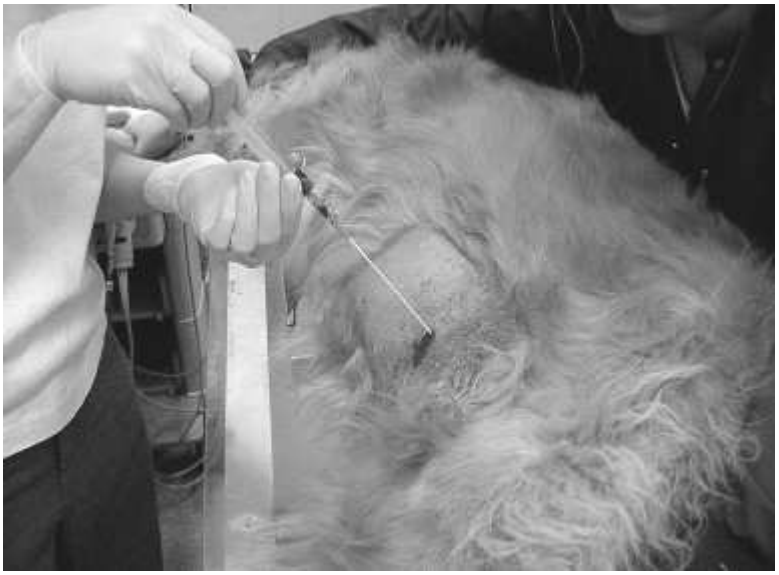
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Inability to obtain pericardial fluid. Ultrasound guidance is useful before reattempting.
- Effusion that clots in the syringe, either due to excessive advancement (catheter tip is in the heart) or to a rapidly bleeding pericardial effusion. Differentiation: disconnect syringe from catheter/stylet. If catheter is intracardiac, flow should be pulsatile

± vigorous.
- Coronary artery laceration; unlikely with right-sided approach

PROCEDURE

- The animal is restrained in left lateral recumbency for the whole procedure. The approach will be via the right side of the thorax to minimize the risk of catheter-induced coronary artery laceration.
- Ultrasound is used for confirming that pericardial effusion is present in sufficient volume to allow safe centesis (width of effusion on echocardiogram > 1 cm). In the absence of ultrasound guidance, the site of entry is at the level of the costochondral junction, right fifth intercostal space.
- The area is widely clipped of hair and aseptically prepared. The wide clipping of hair should allow the procedure to be done without a sterile drape.
- The designated site of centesis is again confirmed with ultrasound.
- Lidocaine is infused subcutaneously, intramuscularly (intercostal muscle), and subpleurally. Doing so requires that the needle be repeatedly withdrawn until almost out of the skin and then redirected and reinserted until a region at least 2 cm square and spanning the entire thickness of the chest wall has been infiltrated.
- The clinician puts on sterile gloves and makes a 3-mm skin incision in the center of the site using the scalpel blade.
- The catheter, which covers a metal stylet, is attached to the 6-mL syringe, and the tip of the catheter-stylet combination is inserted into the skin incision.
- The clinician advances the syringe-catheter-stylet combination (which is grasped in the palm as a handle to advance the catheter and stylet) while drawing back on the syringe plunger to create negative pressure. The orientation is perpendicular to the chest wall and is neither cranially nor caudally directed.
- When a flashback of effusion is seen to enter the syringe, the syringe-styletcatheter apparatus is advanced only 2-3 mm farther into the chest.
- With continuing negative pressure on the syringe (effusion flowing into syringe), the syringe and stylet are kept in the same position, while the catheter is advanced several centimeters farther. In this way, the catheter is seated well within the pericardial space.
- Using a large-volume syringe (35 or 60 mL), the effusion is withdrawn. Ideally, an assistant helps by emptying one syringe while the clinician is filling the other with pericardial effusion; thus, two syringes can aseptically be traded back and forth until the pericardium is empty.
- When the effusion has partially or completely been removed, the catheter is withdrawn, and the skin incision is closed with tissue glue.



PERICARDIOCENTESIS Pericardiocentesis in a dog with severe cardiac tamponade and hemorrhagic pericardial effusion. Left lateral recumbency; head is beyond the lower right corner of the image. The syringe-catheter-stylet combination has been advanced to the point of entering the pericardium, and effusion is seen in the hub of the stylet and the syringe. Next, the catheter will be advanced off the stylet.

POSTPROCEDURE

- Ascites caused by cardiac tamponade should resolve spontaneously over the 12- to 36-hour period following pericardiocentesis.
- A recheck echocardiogram immediately post centesis and another echocardiogram 12-24 hours later are recommended

(assess remaining volume, and note in record). Rapid reaccumulation of effusion suggests malignancy, atrial rupture from stretch, or coagulopathy.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Pericardiectomy: long-term palliation
- Diuretic: contraindicated in acute treatment (does not mobilize effusion but does deplete circulating blood volume, worsening cardiac filling); advocated by some for chronic treatment to delay of recurrence of idiopathic or malignant effusions

AUTHOR: ETIENNE CÔTÉ

Parenteral Nutrition

SYNONYMS

PN, partial parenteral nutrition (PPN), total parenteral nutrition (TPN)

OVERVIEW AND GOALS

- Parenteral nutrition (PN) is nutrition delivered by the IV route.
- It can be life saving in animals that cannot tolerate enteral feeding.
- Used when no other feeding option exists, and the need for nourishment is a critical factor in clinical outcome.

INDICATIONS

Animals in need of nutritional support when:

- Enteral nutrition is contraindicated (e.g., gastrointestinal [GI] dysfunction or risk of pulmonary aspiration).
- Sufficient nutrition cannot be provided by the enteral route alone (e.g., severe malabsorptive disease).

CONTRAINDICATIONS

- Animals that can be fed safely and effectively by the enteral route
- Animals that are at risk with catheter placement:
  - Central venous catheters in animals at high risk of thromboembolic disease (e.g., protein-losing nephropathy or enteropathy, hyperadrenocorticism, disseminated intravascular coagulopathy)
  - Jugular catheters in animals with increased cerebral pressure (e.g., head trauma)
- Animals experiencing fluid overload (e.g., animals with heart failure, oliguria, or severe hypoproteinemia)

EQUIPMENT, ANESTHESIA

- Venous access:
  - A dedicated catheter is required for delivery of the nutrient solution to avoid septic complications and drug-nutrient interactions.
  - Treat catheter placement as a surgical procedure (surgical prep, draping, and the use of sterile gloves) (see p. 12935/19/2011).
  - Place a central venous catheter to deliver TPN, because the nutrient solution is hyperosmolar. Solutions that are more dilute can be prepared, but the resulting large volume that must be infused can become a limiting factor.
  - Catheters made of nonthrombogenic materials (polyurethane or silicone) are preferred, particularly for peripheral infusion.
  - Multilumen central or peripherally placed central catheters (PICC lines) can be used if one of the ports is dedicated for PN.
- Nutrient admixture:
  - Amino acid solutions (3%-10%) are used for providing protein. These solutions come with and without added electrolytes.
  - Nonprotein calories can be provided by a combination of lipid emulsions (10% or 20%) and dextrose (10%-50%) or dextrose alone.
  - Electrolytes can be added to the nutrient solution as needed or provided separately in the animal's crystalloid fluid therapy. The latter allows greater flexibility. Alternatively, a combination amino acid and electrolyte solution can be used.
  - Special parenteral vitamin and mineral preparations are available. However, because most companion animals receive PN for relatively short periods of time (<2 weeks), only certain vitamins and minerals are commonly added to the nutrient admixture (B complex, ± potassium phosphate, magnesium sulfate, and trace elements [zinc, copper, manganese, and chromium]).
- Monitoring and nursing care:
  - PN is best delivered continuously (although this is not absolutely necessary), so 24-hour nursing care is desirable both for administration and for catheter vigilance/catheter care.
  - Many of the complications of PN can be life threatening, so careful monitoring of the animal is mandated. This includes frequent checking of serum glucose and electrolyte concentrations; hence, the ability to do some in-house serum chemistry analyses is necessary.

PREPARATION: IMPORTANT CHECKPOINTS

- Venous access:
  - Reserve a dedicated venous catheter (or port of a multilumen catheter) for PN. Insert the catheter under aseptic conditions, and do not use for any other purpose.
- Nutrient admixture:
  - Prepare PN solutions under aseptic conditions. In addition, solutions must be compounded in a specific sequence and carefully mixed.
  - Use the services of a home infusion service or a human hospital pharmacy to compound PN solutions when the veterinary practice lacks the facilities and expertise.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Common metabolic complications:
  - When addressing electrolyte abnormalities, delivering supplements in the IV fluids rather than in the PN solution allows greater flexibility. Later, when the amount of supplementation for maintenance is established, it can be included in the PN formulation.
  - Hyperglycemia: if present, reduce the percentage of nonprotein calories from dextrose, or give regular insulin.
  - Hypokalemia: if present, supplement IV fluids with potassium chloride. Monitor for hypomagnesemia (see online chapter: Refeeding Syndrome).
  - Hypophosphatemia: if present, supplement IV fluids with potassium phosphate, or add potassium phosphate to PN formulation.
  - Hypomagnesemia: if present, supplement IV fluids with magnesium sulfate or add magnesium sulfate to PN formulations.
  - Hyperlipidemia: if present, reduce or omit the lipid emulsion.
- Catheter complications:
  - Loss of venous access secondary to catheter malposition or thrombosis: if occurs, replace catheter.
  - Thrombophlebitis: if occurs, replace catheter. Select peripheral catheters that are long and made of nonthrombogenic materials.
  - Infection: if occurs, remove catheter and culture the tip. Replace with a new catheter in a new location.

PROCEDURE

PN PRESCRIPTION FORMULATION:

- Choose between central or peripheral venous administration.
  - Central venous administration is preferred because smaller volumes of PN solution are required, and thrombophlebitis is less likely to occur.
  - Peripheral venous administration is possible when central venous access is not available, but the animal must be fluid tolerant because required lower tonicity means larger volume of infusate.
  - Note: For peripheral venous infusion, long catheters made of nonthrombogenic materials reduce the likelihood of thrombophlebitis.
- Calculating the caloric goal:
  - Calculate the resting energy requirement (RER) using the animal's current body weight (or the animal's estimated ideal weight if overweight).
  - Formula: RER = 70 + 30 × (body weight in kilograms) for animals weighing 2-30 kg; use 70 × (body weight in kilograms)$^{0.75}$ for animals that weigh outside this range.
  - Start with a caloric goal of RER, and adjust based on animal response.
- Decide what percentage of calories will be delivered as protein depending on the animal's level of protein tolerance or deficiency.
  - Dogs: provide 15%-25% of goal calories as protein.
  - Cats: provide 25%-30% of goal calories as protein.
  - Amino acid solutions: provide 4 kcal/g.
  - To calculate the volume of amino acid solution required:
    - Divide the protein calories by 4 kcal/g = grams of amino acids required.
    - Divide the grams of amino acids required by the grams of amino acids per milliliter in the solution = volume of amino acid solution.
  - Note: For peripheral infusion, use =6% amino acid solutions because of high osmolarity.
- Decide what percentage of nonprotein calories will be delivered as dextrose with the remainder to be delivered as lipid:
  - 100% of the nonprotein calories can be delivered as dextrose, but hyperglycemia is a common sequela; 50% dextrose provides 1.7 kcal/mL.
  - Alternatively, lipid emulsions can be used for delivering 50%-70% of the nonprotein calories; 20% lipid emulsions provide 2 kcal/mL.
  - Note: For peripheral venous infusion, a high percentage of nonprotein calories from lipid is preferred because the lipid emulsions are isoosmolar. They are also more calorically dense than dextrose solutions that can be safely infused peripherally (=20% dextrose).

- Add 0.2 mL/100 mL total infusate of vitamin B complex.
- Decide whether electrolytes and minerals will be added.
    - Supplementation may not be necessary if amino acid solutions containing additional electrolytes are used.
    - Caution: Supplementation is contraindicated in animals with kidney disease/renal failure.
    - Potassium phosphate: 8 mEq/1000 kcal
    - Magnesium sulfate: 0.8 mEq/100 kcal
    - Zinc: 1 mg/kcal
- Calculate the hourly infusion rate by dividing the total volume by 24.

PARENTERAL NUTRITION Lipid, dextrose, and amino acid solutions.

Sample PN Worksheet for a 17.5 kg (39 lb) Dog: Centrally Administered PN Calculation

CANINE HIGH-PROTEIN REGIMEN

Weight: 17.5 kg	Resting energy requirement (RER) = 600 kcal/day
Day 1 goal	50% RER = 0.5(600) = 300 kcal
Day 2 goal	100% RER = 600 kcal
% Protein calories	25%
Nonprotein calories	50% from lipid, 50% from dextrose

- **Solutions:**
- 8.5% Amino acids (without electrolytes)
- 50% Dextrose
- 20% Lipid emulsion
- MTE-4 trace element solution containing 0.8 mg zinc/mL
- Potassium phosphate (3 mM/mL)
- Injectable B complex

- **Day 1 Calculations:**
- ***Amino Acids***
- (0.25 × 300 kcal) = 75 kcal from protein
- There are 4 kcal/g protein; therefore, the animal needs 18.75 grams of protein: (75 kcal ÷ 4 kcal/g = 18.75 g).
- 8.5% amino acid solution = 0.085 g protein/mL; therefore, the animal needs 220 mL 8.5% amino acid solution: (220 mL = 18.75 g ÷ 0.085 g/mL).

- ***Nonprotein Calories***
- (0.75 × 300 kcal) = 225 kcal
- 50% dextrose to provide 50% nonprotein calories = 112.5 kcal. 50% dextrose solution = 1.7 kcal/mL; therefore, the animal needs 66 mL 50% dextrose solution: (66 mL = 112.5 kcal ÷ 1.7 kcal/mL).
- 20% lipid emulsion to provide 50% nonprotein calories = 112.5 kcal. 20% lipid emulsion = 2 kcal/mL; therefore, the animal needs 56 mL 20% lipid emulsion: (56 mL = 112.5 kcal ÷ 2 kcal/mL).

- ***Trace Elements***
- Dosed at 1 mg zinc/kcal delivered
- MTE-4 contains 0.8 mg zinc/mL; therefore, the animal needs 0.37 mL: (0.37 mL = 300 kcal ÷ [0.8 mg/mL × 1000]).

- ***Potassium Phosphate***
- Dosed at 8 mM/1000 kcal delivered; therefore, the animal needs 2.4 mM potassium phosphate: (2.4 mM = [8 mM × 300 kcal] ÷ 1000 kcal).
- Potassium phosphate solution = 3 mM/mL; therefore, the animal needs 0.8 mL potassium phosphate: (0.8 mL = 2.4 mM ÷ 3 mM/mL).

- ***Vitamin B Complex***
- Dosed at approximately 2 mL/L infused
- Total infusate for day 1 = 343 mL; therefore, 1 mL B complex should be sufficient.

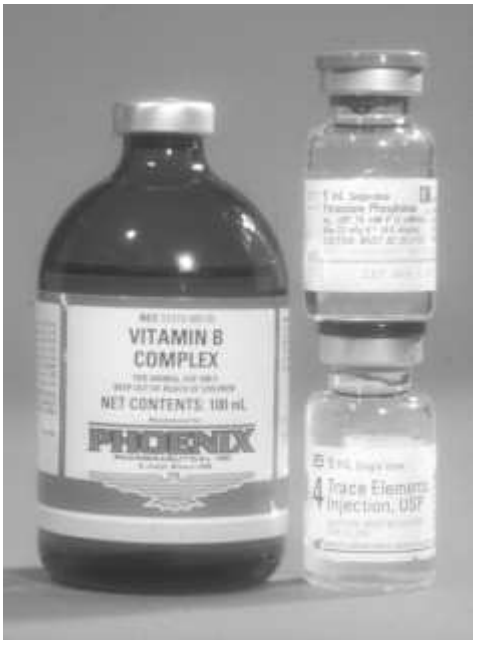
- ***Infusion Rate***
- 343 mL ÷ 24 h = 14 mL/h

- ***Day 2 Calculations:***
- Same calculations as those for day 1, but substitute 600 kcal for 300 kcal.

CANINE HIGH-PROTEIN REGIMEN

POSTPROCEDURE

- Delivery:
  - Deliver the solution at a constant rate using an infusion pump if possible.
  - Administer 50% of the goal infusion, and monitor for metabolic complications the first day, advancing to the goal rate the next day if no problems occur that cannot be addressed.
  - Do not discontinue PN abruptly, especially in animals that are not eating. If an animal cannot be weaned, monitor for hypoglycemia.
- Catheter care:
  - Examine the catheter site at least daily for signs of phlebitis or infection, changing the dressing as needed.
  - Change the drip set at least every other day.
  - Never use the catheter for any purpose other than the delivery of PN (no blood sampling, administering medications, fluid therapy, or measuring central venous pressure).
- Monitoring:
  - In addition to the routine monitoring appropriate for any animal on IV fluid therapy, animals receiving PN should be monitored for metabolic complications.
  - Animals should have blood glucose monitored at least every 12 hours and serum electrolytes at least once daily depending on circumstances and whether any PN supplementation is required.
  - When a packed cell volume (PCV) is performed, the serum should be examined for evidence of lipemia.
  - A complete serum chemistry profile and CBC should be performed as indicated but at least once weekly.



PARENTERAL NUTRITION Vitamin, electrolyte, and mineral solutions.

PARENTERAL NUTRITION Animal receiving PN.

ALTERNATIVES AND THEIR RELATIVE MERITS

Enteral nutrition:

- In general, nutrient delivery by the enteral route is safer and less costly than PN.
- Enteral nutrition has trophic effects on the GI tract and supports both the structure and function of the mucosa and the barrier function of the gut.
- Preferred over PN whenever feasible.

AUTHOR: KATHRYN E. MICHEL

1ST EDITION AUTHOR: C.A. TONY BUFFINGTON

Pacemaker: Transthoracic Cardiac Pacing

SYNONYM

Temporary cardiac pacing

OVERVIEW AND GOALS

Noninvasive, rapidly implemented temporary cardiac pacing system used for support of heart rate and blood pressure (BP) in animals that are under anesthesia and that have medically refractory bradyarrhythmias. Typical applications are stabilization for permanent pacemaker implantation and emergency treatment of life-threatening bradyarrhythmias.

INDICATIONS

- Support of heart rate and BP during general anesthesia for dogs with medically refractory bradyarrhythmias undergoing permanent pacemaker implantation or another surgery unrelated to pacemaker implantation
- Emergency treatment of hemodynamically unstable, medically refractory, complete atrioventricular block until more definitive therapy can be instituted
- Bradyasystolic arrests (e.g., digoxin overdose)

EQUIPMENT, ANESTHESIA

- General anesthesia and tracheal intubation required
- Continuous electrocardiogram (ECG) and transthoracic pacing system required, including disposable adhesive transthoracic patch electrodes. Newer versions of transthoracic patch electrodes are available that allow not only noninvasive cardiac pacing but can be used for defibrillation, synchronized cardioversion and ECG monitoring.
- A No. 10 clipper blade (to shave the hair from the left and right precordia (area of the thorax overlying the heart)
- Occasionally, a neuromuscular blocker (and hence mechanical ventilation) may be desirable to limit jerking of skeletal muscles during surgical procedure.

ANTICIPATED TIME

Pacing system can be attached and pacing implemented in just a few minutes, especially in urgent situations.

PREPARATION: IMPORTANT CHECKPOINTS

- Have pacing system prepared (patch electrodes on chest and ECG monitoring ongoing) at induction of general anesthesia in dogs undergoing permanent pacemaker implantation or other dogs at risk for bradyarrhythmic complications with general anesthesia. This is a precaution in the event of bradyasystole during induction.
- Ensure clear ECG tracing to allow accurate sensing of dog's intrinsic heartbeat before starting transthoracic pacing.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Most common complications are skeletal muscle twitching and pain associated with pacing stimulus.
- Pain or distress experienced in awake dogs requires rapid induction of general anesthesia for continued use of the temporary pacemaker. Analgesia (opiate or nonsteroidal antiinflammatory drug [NSAID]) is also recommended.
- Skeletal muscle twitching, more pronounced in smaller dogs, may require neuromuscular blockade to lessen the jerking of forelimbs and chest during surgical procedure.
- Most common error is suboptimal placement of patch electrodes, causing inconsistent pacing. Ensure placement directly over the palpable cardiac impulse beats. Readjustment of patch electrodes may be necessary.
- Obese dogs or dogs with pleural space disease may require higher than expected pacing threshold.

PROCEDURE

The procedure is typically performed in dogs undergoing anesthesia for permanent pacemaker implantation. ECG and pacing patch electrodes are in place prior to induction. The pacing system is usually turned on shortly after induction of anesthesia.

- ECG leads are connected to the dog, and a good-quality ECG tracing is obtained.
- Patch electrodes are placed directly over cardiac impulse on left and right hemithorax. The fur on the chest is shaved, and a small dollop of ECG paste is placed on the surface of the patch electrode facing the skin. Dogs ideally should be placed in lateral recumbency.
- Ensure accurate ECG sensing of dog's intrinsic cardiac rhythm by adjusting ECG gain and lead selection. A sensing marker will appear on the animal's QRS complex, signaling accurate sensing.
- After setting the pacing rate (range 40-170 beats per minute), the pacing current (range 0-200 mA) is gradually increased until ventricular capture is confirmed on the ECG monitor and by palpation of a corresponding arterial pulse. Ventricular capture is recognized by a wide QRS complex and T wave following a pacing spike on the ECG. The pacing current is maintained just above the capture threshold.
- Pacing rate and current usually range between 60 and 80 beats per minute and from 50-110 mA, respectively.

POSTPROCEDURE

Pacing patch electrodes are removed from skin. Adhesive remover can be used.

ALTERNATIVES AND THEIR RELATIVE MERITS

Transvenous pacing:

- Specialized transthoracic pacing system not required (very expensive)
- No skeletal muscle twitching or pain associated with pacing stimulus
- Procedure is more invasive, and implementation requires more time and expertise.
- Can be associated with infection, bleeding, lead wire displacement, lead wire-induced arrhythmia, cardiac perforation, and thromboembolism.

Transesophageal pacing:

- Same merits as with transvenous pacing in terms of no pain or twitching associated with pacing stimulus and less expensive pacing system
- Less invasive and less expertise needed as compared to transvenous pacing
- However, based on limited clinical experience in dogs, only the atria can be paced. No ventricular pacing is possible.

(Courtesy DeFrancesco TC, et al: Noninvasive transthoracic temporary cardiac pacing in dogs. J Vet Intern Med 17:663–667, 2003.)

PACEMAKER: TRANSTHORACIC CARDIAC PACING Animal undergoing transthoracic pacing while the neck is aseptically prepared for permanent transvenous pacemaker implantation.

Rhinoscopy

OVERVIEW AND GOALS

Minimally invasive, endoscopic approach to the nasal cavity for visual evaluation and swab, flush, and biopsy procedures

INDICATIONS

- Chronic nasal discharge
- Intranasal obstruction
- Chronic sneezing
- Nasal foreign body
- Epistaxis with normal coagulation profile and blood pressure (BP)
- Maxillary mass/deformity

CONTRAINDICATIONS

Coagulopathy/bleeding disorder

EQUIPMENT, ANESTHESIA

General anesthesia and endotracheal intubation with optimal endotracheal tube cuff seal are required. The following equipment is recommended:

- Mouth gag (speculum)
- Sterile, water-soluble lubricant
- Sterile saline solution for flush
- Gauze squares for packing off pharynx
- Flexible, fiberoptic endoscope (small; 3-mm diameter maximum for patients <20 lb [9 kg])
- Vacuum source for endoscopic suction
- Microbial culture swab
- Biopsy forceps (intraendoscopic or separate, such as Jackson mare 2, 4, or 6 Fr endometrial biopsy forceps)
- Biopsy jar with 10% buffered formalin
- Phenylephrine (e.g., Neo-Synephrine drops) for postoperative epistaxis

ANTICIPATED TIME

- Usually 60-90 minutes anesthesia time (about 30-60 minutes endoscopy time)
- Up to 3-4 hours possible with complex foreign bodies

PREPARATION: IMPORTANT CHECKPOINTS

- Warn owners that epistaxis is common, sometimes for 1-3 days after the procedure.
- Check that current coagulation profile (prothrombin [PT], activated partial thromboplastin time [APTT], platelets) and BP are normal.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Biopsy sample not representative of entire process (very common with small through-the-endoscope pinch forceps, especially if dull)
- Inability to see beyond first few millimeters of nasal passages (common, especially in cats and small dogs; an endoscope that is too big can be a contributing factor).
- Hemorrhage after biopsy (rarely before biopsy, although blood from scraping mucosa with scope can obscure view).
- Inability to see choanae during retroflexed view of nasopharynx (common in large dogs)
- Anesthetic complications

PROCEDURE

TECHNIQUE, INITIAL:

- General anesthesia
- Endotracheal intubation; check good seal on cuff (but not excessive inflation pressure)
- Ventral recumbency
- Animal facing endoscopist; head at edge of table elevated on folded towels
- Fill caudal pharynx with gauze (one to two 3 × 3 [8 × 8 cm] squares for cats, several for dogs; count number to ensure complete retrieval after procedure).
- Swab with sterile culture swab for microbial culture (usually aerobic bacterial).
- Measure length from tip of nostril to medial canthus of eye:
    - This is the maximal length of insertion of the endoscope.
    - Going farther than this measurement can perforate cribriform plate if diseased and enter the brain.

TECHNIQUE, MAIN:

- Advance endoscope into one nostril.
- Easiest route is medial and very dorsal.
    - Push dorsal edge of nostril caudally and dorsally with thumb.
    - Enter just alongside nasal septum for easiest access.
- Begin saline infusion through endoscope for better visualization.
- Catch outpouring of saline in waste bucket or on towels on floor.
- Examine dorsal, middle, and ventral nasal meatus systematically.
- If lesion noted, biopsy after completing visualization (otherwise, blood obscures field).
- Repeat process for contralateral nostril.
- When finished with both nostrils, prop mouth open with speculum.
- Enter oral cavity with endoscope.
- Curve endoscope tip to about 160° so that it reaches behind edge of soft palate.
- Examine choanae.
- Pull body of endoscope gently forward (cranially) to better observe choanae.
- Biopsy lesions if applicable.
- Withdraw endoscope.

RHINOSCOPY Endoscopic view, retroflexed behind the soft palate to show the choanae. Dog's right is on left side of the image. A fleshy mass is present in the right choana.

TECHNIQUE, COMPLETION:

- Suction caudal pharynx as necessary.
- Remove gauze sponges in caudal pharynx. Count number to confirm all removed.
- Instill phenylephrine (few drops in each nostril) if voluminous epistaxis.
- Anesthetic recovery:
    - Neck elevated/nose down to reduce inhalation of blood
    - Extubation as late as safely possible to avoid inhalation of blood.

POSTPROCEDURE

- Epistaxis common; treatment options:
    - Instill 2-5 drops of phenylephrine in bleeding nostril (best time is prior to complete anesthetic recovery—deeper instillation).
    - Tranquilization (butorphanol IV and/or low-dose acepromazine IM)
    - Very rarely, large-volume arterial epistaxis requires carotid ligation (bilateral carotid ligation can safely be done without risking hypoperfusion).
    - Phenylephrine nasal drops may be tried at home.
- Sneezing is common (often decreases to the same intensity as sneezing prior to procedure—if any—within 48 hours after the procedure).

ALTERNATIVES AND THEIR RELATIVE MERITS

- Nasal swab:
    - No anesthesia
    - Possibly acceptable for culture and sensitivity (C&S) of nasal discharge but commonly contaminated with normal flora
    - Poor cytologic yield because animal is awake
- Nasal flush (see online chapter: Nasal Flush):
    - Minimal tissue disruption means less epistaxis but also fewer cells for diagnosis.
    - Can flush out foreign material/foreign body
- Blind nasal biopsy:
    - Quick
    - Location nonspecific
    - May provide good yield if large sample (e.g., with Jackson forceps) and if oriented based on imaging results (radiographs, CT scan, MRI)
- Open-mouth transpalatal biopsy:
    - Caudal nasal biopsy possible without rhinotomy
    - Nasopharyngeal biopsy possible
    - Palatine artery must be avoided.
- Rhinotomy:
    - Most likely to give definitive diagnosis of nasal disease
    - Most invasive: incision through maxillary bones, disruption of large amounts of nasal mucosa
    - Often delayed until lesser invasive means have failed
- CT scan or MRI (see pp. 1233 and 1302):
    - Imaging techniques: no therapeutic value by themselves
    - More specific localization of lesion (CT scan usually preferred because of bone)

AUTHOR: ETIENNE CÔTÉ

Rectal Scraping

SYNONYMS

Rectal scrape, rectal cytologic analysis

OVERVIEW AND GOAL

The goal of rectal scraping is to obtain samples of mucosal tissue for cytologic examination.

INDICATIONS

Animals with signs of disease of the rectum or distal colon, such as hematochezia and tenesmus, especially when rectal mucosa has a diffusely thickened or cobblestone feel per rectal palpation. Most commonly indicated for the diagnosis of rectal histoplasmosis, protothecosis, pythiosis, or neoplasia.

CONTRAINDICATIONS

Suspicion of rectal perforation or deep ulceration

EQUIPMENT, ANESTHESIA

- Often performed without anesthesia or sedation. Sedation may be required for animals with pain on rectal palpation or for animals with an uncooperative temperament.
- Wooden tongue depressor (alternatively, cotton tipped applicator or blunt-tipped metal spatula like those for pharmacy use)
- Exam glove
- Lubricant
- Microscope slides

ANTICIPATED TIME

5-10 minutes

PREPARATION: IMPORTANT CHECKPOINTS

The rectum should be empty of formed fecal matter. Allowing the animal to defecate shortly before the procedure or manual evacuation of the rectum is sufficient (i.e., bowel cleansing or enemas are not required).

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Rectal perforation is possible with vigorous scraping or overzealous insertion of the instrument.
- Splintered or sharp edges of the tongue depressor should be smoothed or covered with a gloved finger.

PROCEDURE

- The rectum should be emptied before the procedure.
- Depending on the size of the patient, the tongue depressor may be left intact or broken lengthwise to a smaller width.
- The depressor is held in a gloved hand to the length of an outstretched index finger. If the depressor has been broken, the finger should cover the roughened edge.
- Lubricant is applied to the finger but not to the tongue depressor.
- The finger and depressor are inserted approximately 2 inches (5 cm) into the rectum.
- The finger is used to apply gentle but firm pressure to the tongue depressor while making two to three sweeping motions covering 20%-50% of the circumference of the rectum.
- The gloved finger and tongue depressor are removed.
- The edge of the tongue depressor is scraped against a microscope slide.
- Gentle smears are made from the material gathered during the scraping. Try to minimize the amount of lubricant which contaminates the slide.

- Slides are processed for cytologic examination in a routine fashion.
- For animals with extremely friable rectal tissue or for very small animals, a cotton-tipped applicator can be used in place of the tongue depressor.

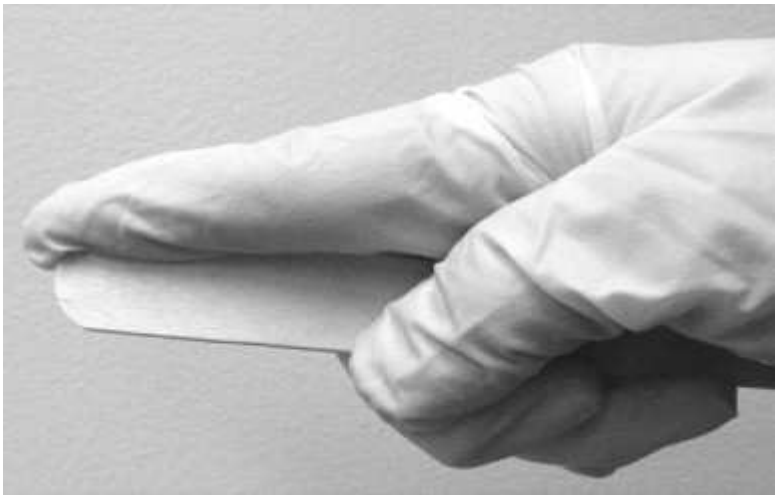
POSTPROCEDURE

Special care is not required afterwards but the animal should be monitored for worsened pain or evidence of new systemic illness which might indicate rectal perforation.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Noninvasive fecal flotation or examination of direct fecal smear may detect intestinal parasites responsible for large-bowel signs.
- Tissue biopsy provides larger samples with intact architecture but requires general anesthesia and bowel cleansing.
- Serologic tests, with varying sensitivity and specificity, are available for both histoplasmosis and pythiosis.

AUTHOR: LEAH COHN



RECTAL SCRAPING One side of a tongue depressor is covered with a gloved finger prior to insertion of both the lubricated finger and the depressor approximately 2 inches (5 cm) into the rectum. Once in the rectum, gentle pressure is used to move the depressor in an arcing motion to obtain tissue for cytologic examination.

Rectal Palpation

SYNONYMS

Digital palpation, rectal exam, transrectal palpation

OVERVIEW AND GOALS

Tactile assessment of the urethra, caudal aspect of the trigone of the urinary bladder, bony pelvic canal, aortic trifurcation, pelvic diaphragm, anal sacs, rectal mucosa, and either the prostate gland (males) or vagina (females)

INDICATIONS

Part of any complete routine physical exam in adult dogs; generally not feasible in puppies or cats

CONTRAINDICATIONS

- Animals weighing <5 kg
- Relative contraindication: anal/rectal pain. Requires that the rectal exam be performed under sedation or general anesthesia.

EQUIPMENT, ANESTHESIA

- Sedation or anesthesia only if required for patient comfort
- Latex or other clean, nonsterile exam glove
- Lubricant (e.g., K-Y Jelly or Vaseline)
- Cotton wool or other absorbent material to receive contents expressed from anal sacs
- Microscope slide with drop of saline

ANTICIPATED TIME

About 30-60 seconds

PREPARATION: IMPORTANT CHECKPOINTS

Review elements of animal's history (dysuria, hematuria, tenesmus, hind limb lameness, etc.), remainder of physical exam, and any diagnostic findings (e.g., hypercalcemia) that could be pertinent to rectal examination findings.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Rectal perforation: extremely uncommon when gentle technique is used.
- Anal sac rupture: also uncommon; however, impacted, infected/abscessed sacs may be more fragile. If anal sacs are large and/or painful, and gentle pressure is unrewarding or distressing to the patient, anesthesia is recommended, and anal sac cannulation may then be performed.
- Perianal fistulae may make it difficult to assess the exact location of the anal opening; time and caution are warranted to avoid exacerbating a fistula through blunt probing.
- Rectal peristalsis may be confused with perineal hernia or rectal stricture. If uncertainty exists, the rectal exam can be prolonged by 1-2 minutes; a wave of peristalsis will pass, but a stricture will not.

PROCEDURE

- Animal is restrained in a standing position by technician holding the head and neck.
- The right-handed examiner puts a glove on his or her right hand; the right index finger is lubricated.
- The examiner stands behind the animal and lifts its tail with the left hand to expose the anus.
- The right index finger is placed on the anus, and then after a few seconds of accommodation by the animal, the finger is gently introduced through the external anal sphincter.
- The tail may be released; most dogs will hold the tail elevated during the rectal exam.
- The left hand, no longer holding the tail, reaches under to the animal's caudal abdomen and cups the ventrocaudal abdomen.

- In addition to this cupping motion, the examiner draws the hand caudally toward his or her body to elevate the viscera of the caudal abdomen toward the right index (palpating) finger. With sufficient upward pressure, and without discomfort to the animal, it is possible to palpate the prostate of even giant-breed dogs this way.
- The palpation reaches to the maximal depth allowed by the examiner's finger and the animal's comfort; the examiner can also turn the finger circumferentially to assess both left and right walls of the pelvic canal and the roof of the pelvic canal.
- Once the exam is completed, the examiner withdraws the index finger, ensuring to first palpate the integrity of the pelvic diaphragm (assess for perineal hernia) and, if necessary, to express the anal sacs located at the 4 and 8 o'clock positions if the anus is pictured as a clockface.
- Finally, the feces coating the glove are examined grossly for blood or other abnormalities and smeared on a microscope slide for cytologic examination.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Fecal flotation and fecal occult blood test: identifies microscopic abnormalities (parasites, blood) but is of little use regarding structural malformations of the rectum and perirectal area.
- Abdominal ultrasound: excellent visualization of many organs of caudal abdomen and cranial pelvic canal; however, the bony pelvis and colon severely narrow the acoustic window and compromise ultrasound assessment of urethra, distal colon, and much of the pelvic canal, which is the area that a rectal examination accesses best.

AUTHOR: ETIENNE CÔTÉ

Slings, Casts, and Other Forms of Immobilization

Client Education Sheet Available on Website

SYNONYM

External coaptation

OVERVIEW AND GOAL

To provide appropriate temporary support and allow healing of musculoskeletal injuries, either alone or as augmentation of surgical repairs

INDICATIONS

- Robert Jones bandage: temporary immobilization of unstable fractures; control of edema and swelling. Appropriate for open fractures following wound dressing.
- Splints: temporary immobilization of fractures or peripheral joint luxations; also used following surgery for joint injuries, arthrodeses, or tendon injuries
- Casts: immobilization of distal limb fractures when mechanically stable; also appropriate following surgical repair—similar to splints
- Slings: partial immobilization of all joints of the limb and prevention of weight bearing. Ehmer sling is used primarily following reduction of hip luxation to prevent recurrence.

CONTRAINDICATIONS

Excessive duration of immobilization may lead to muscle and joint contracture and permanent loss of mobility. Use with caution, especially in pediatric animals.

EQUIPMENT, ANESTHESIA

Sedation may be required for appropriate placement of splints and bandages if animal is in pain or uncooperative. General anesthesia is required for reduction of fractures or joint luxations prior to immobilization. Materials required (amounts and material widths depend on animal size):

- Appropriate wound dressing, if needed
- A 0.5- or 1-inch (1.25 2.5-cm) wide roll of tape
- Rolls of cast padding, 2-6 inches (5-15 cm) width
- Rolls of conforming gauze, 2-6 inches (5-15 cm) width
- Rolls of self-adherent stretch tape

Additional materials:

- Roll of cotton, 12-inch (30-cm) width (for Robert Jones bandage)
- Fiberglass resin or plaster-impregnated casting tape, 2-4 inches (5-10 cm) in width for casts
- Stretch stockinette (for casts, optional)
- Rigid Mason metasplint, lateral plastic limb splint, fiberglass or thermoplastic splint (for splints)

ANTICIPATED TIME

About 10-30 minutes for application of most casts, splints, and slings

PREPARATION: IMPORTANT CHECKPOINTS

Wounds should be treated and an appropriate dressing applied before splinting or bandaging.

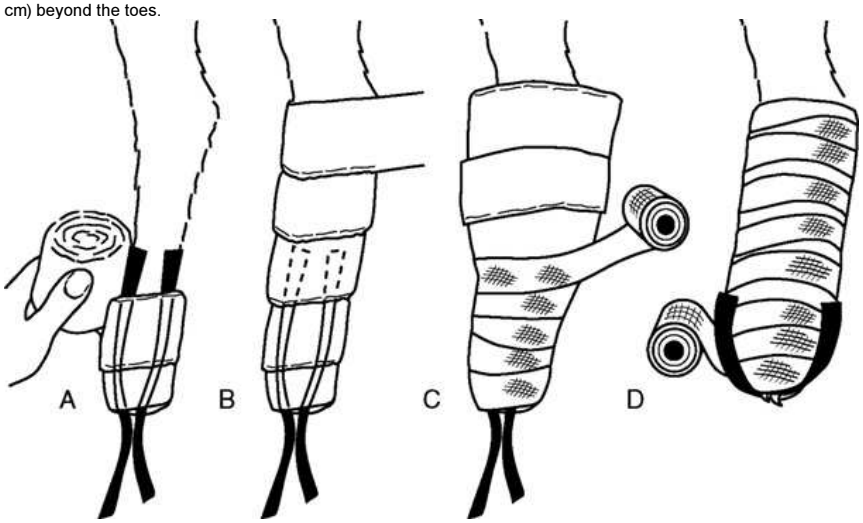
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Toes of the third and fourth digits should be left visible whenever possible to allow monitoring for coolness, swelling, cyanosis, or discharge, any of which warrants removal of the splint, cast, or bandage for closer evaluation of the soft tissues.
- All bandages, splints, slings, and casts should be checked frequently for limb swelling or discoloration, skin abrasions, loosening or slippage, moisture, or odor.
- Severe ischemia can result from poor application or management.

PROCEDURE

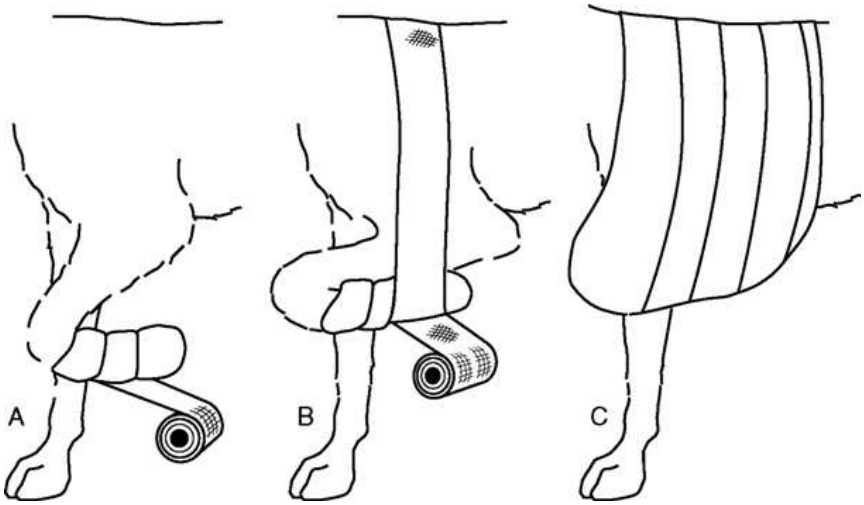
ROBERT JONES BANDAGE:

- Divide bulky roll cotton lengthwise and in thickness; reroll to create several smaller, narrower rolls.
- Apply adhesive tape stirrups directly to the skin of the medial and lateral or cranial and caudal surfaces of the distal limb, extending from the carpus or tarsus distally 4-6 inches (10-15 cm) beyond the toes.



SLINGS, CASTS, AND OTHER FORMS OF IMMOBILIZATION Robert Jones bandage. **A**, Adhesive tape stirrups (shown in black) are applied to skin on opposite sides of distal limb. Wound dressing is applied as needed. Roll cotton (or for small patients, cast padding) is wrapped evenly around foot. **B**, Cotton is continued proximally well above site of injury, with

overlap of about 50% at each turn, to create the full length of the bandage. **C**, Conforming gauze is applied in same manner from distal to proximal but pulled tight at each turn. Cotton should be evenly compressed. **D**, Tape stirrups are reflected proximally and stuck to bandage. An outer tertiary layer of conforming elastic tape is applied over the cotton. Finished bandage should be firm with even compression over entire surface. Toes must be visible for monitoring.



SLINGS, CASTS, AND OTHER FORMS OF IMMOBILIZATION Velpeau sling. **A**, Conforming gauze bandage material is wrapped loosely around the paw, with direction of wrapping causing the gauze to pass from medial to lateral on the dorsal surface of the paw, as shown. **B**, With carpus, elbow, and shoulder all flexed, gauze is brought from paw over lateral aspect of limb and shoulder, over chest and back, and caudal to the opposite axilla. It then continues across the ventral chest, back to the starting point. **C**, Several more layers of gauze are applied in a similar manner, and a few layers are brought around (cranial to) the flexed carpus to prevent extension of the elbow. Such extension could force the distal limb out of the bandage. Wide elastic tape is used for covering the gauze in a pattern similar to that used for the gauze application which completes application of the splint.

- Apply cotton, winding it around the leg from distal to proximal as far as possible into the axillary or inguinal space.
- Each turn of the cotton should overlap the last layer by 50%.
- Wrap the cotton as evenly as possible.
- Apply conforming gauze around the cotton as tightly as possible, working from distal to proximal.
- Cotton should be evenly compressed until the bandage is firm to the touch.
- Pull the tape stirrups proximally, and apply them onto the bandage. Their purpose is to prevent the bandage from slipping off the limb.
- Cover with a tertiary layer of conforming tape.
- Goal of this bandage is even compression and firm support over the entire limb.
- Properly applied, the finished bandage should make a thumping sound like a ripe melon when it is percussed.
- Tips of toes must be visible for monitoring. Owing to the high compression, this bandage can cause severe ischemic injury if applied poorly.

SPLINTS:

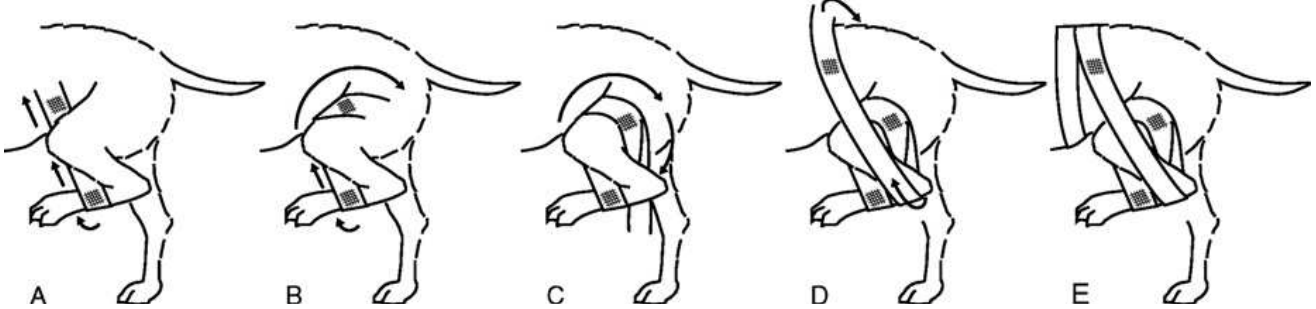
- Apply tape stirrups as for the Robert Jones bandage.
- Apply cast padding, starting distally and winding around the limb as far proximally as needed.
- Apply a layer of conforming gauze from distal to proximal area.
- Place rigid splint material, usually on the caudal or lateral side of the limb.
- Repeat another one to two layers of conforming gauze.
- Cover with an outer layer of conforming tape.

CASTS:

- Apply adhesive tape stirrups.
- Roll stockinette over the limb, allowing extra length proximally and distally. Stockinette is optional but does give the cast a more finished appearance.
- Apply a light layer of cast padding over stockinette.
- Apply roll gauze with light and even compression.
- Apply casting tape over the gauze in distal-to-proximal direction, overlapping by 50% and avoiding digital pressure and wrinkles during application. Layer as needed for appropriate strength.
- Support the limb at multiple points while hardening to avoid dents or incorrect alignment.
- Roll stockinette ends over the cast ends.
- Apply the stirrups to the cast. Their purpose is to prevent the cast from slipping off the limb.
- Cover with an outer tertiary layer of elastic conforming tape.

SLINGS:

- *Velpeau sling (forelimb):*
  - Lightly pad the foot and carpus with cast padding to prevent excessive flexion.
  - Wrap conforming gauze around the foot from medial to lateral.
  - Hold the limb adducted against the body wall with the carpus, elbow, and shoulder in flexion.
  - Roll the conforming roll gauze around the limb and thorax, passing caudally to the opposite forelimb to prevent slipping.



SLINGS, CASTS, AND OTHER FORMS OF IMMOBILIZATION Ehmer sling. **A**, Adhesive tape is passed around the lightly padded metatarsal region, coming up the lateral side of the metatarsus. **B**, Tape is twisted 180○, and stifle and tarsus are held in flexion. Adhesive side of tape is applied to medial side of stifle, continuing up and over thigh as

proximal into inguinal space as possible. **C**, Tape is again twisted 180○ to keep adhesive side against skin and is applied to medial side of hock, then around to starting point on lateral side of metatarsals. Tape is continued for another 1-2 layers over same pattern for greater support. **D**, To support hip reduction, tape may be continued over the back, with the hip in slight abduction. **E**, Tape is passed once around the body and stuck to itself as a belly band.

- Continue on the same pattern for two to three layers, incorporating the entire carpus and foot.
- Apply a light tertiary layer of conforming tape over the gauze in the same pattern.
- The easiest way to perform these steps is with the patient awake and standing.
- To avoid joint contracture, the sling should not be used for more than 2 weeks.

- *Ehmer sling (hind limb)*:
  - Lightly pad the metatarsal region with cast padding.
  - Hold the stifle and tarsus in flexion.
  - Pass adhesive tape around the padded metatarsal region, coming up the lateral side of the metatarsus.
  - Twist tape 180○ to keep the adhesive side against the skin, and pass medially to the stifle.
  - Pass the tape over the lateral thigh as far proximally into the inguinal region as possible.
  - Again twist the tape to keep the adhesive against the skin, and pass distally medial to the hock.
  - Continue tape back up to the starting point at the lateral side of the metatarsal region.
  - Repeat the pattern two to three times to layer the tape.
  - If maintaining hip reduction, following the last pattern, pass the tape over the lateral side of the flexed leg over the back and around the abdomen as a belly band; stick the tape to itself on the abdominal wall, taking care to exclude the prepuce in males. Note: Adhesive tape must be stuck directly to haired skin to avoid slippage.
  - To avoid joint contracture, the sling should not be used for more than 2 weeks.
  - The limb must be monitored frequently for swelling or skin abrasion.

POSTPROCEDURE

- Check toes and distal limb at least q 12 h for any signs of ischemic injury.
- Monitor contact points of bandage materials, especially around bony prominences and joints.

Transtracheal Wash

SYNONYM

Tracheal lavage, tracheal wash, tracheal wash via endotracheal tube

OVERVIEW AND GOAL

Minimally invasive method of obtaining specimens from the trachea for cytologic examination and culture; done frequently

INDICATIONS

- Chronic cough
- Suspicion of tracheal infection or inflammation
- Alveolar and bronchial radiographic lung patterns

CONTRAINDICATIONS

Compromise of unstable animal with respiratory disease via stress, sedation, anesthesia, or restraint

EQUIPMENT, ANESTHESIA

- May only need restraint in depressed animal, or use minimal sedation/anesthesia to avoid suppressing the cough reflex and to minimally depress respiration.
- Administration of supplemental oxygen is possible through a catheter placed in trachea via oral cavity or endotracheal tube. Ensure that the patient cannot bite/sever the catheter or tube.
- Both the transtracheal wash and the tracheal wash via endotracheal tube require:
    - Sterile saline 0.5-2 mL/kg (often separated into two syringes to allow repetition)
    - Additional sterile syringe (empty) for aspiration:
        - Should be larger than infusion syringe for better aspiration
    - Sterile tube designated for aerobic and fungal cultures
    - Microscope slides (for fresh smears/cytologic analysis)
    - Sterile tube designated for aliquot of sample for cytologic examination:
        - EDTA (purple top) tube for aliquot of sample for cytologic analysis may improve cell preservation or cell counts. Fill tube completely to avoid crenation artifact of cells.

TRANSTRACHEAL WASH

- Clipper for hair
- Sterile scrub supplies and isopropyl alcohol
- Sterile paper/cloth drape if desired
- 2% lidocaine for local subcutaneous injection (0.5-1 mL)
- A sterile #11 scalpel blade for small nick in skin (<1 mm)
- A sterile 18- to 22-gauge through-the-needle (introducer) jugular catheter of appropriate length
- Roll cast padding and Vetrap-type releasing elastic bandaging for cervical wrap

TRACHEAL WASH WITH USE OF STERILE ENDOTRACHEAL TUBE

- Topical 2% lidocaine solution applied by spray or swab as needed to laryngeal and pharyngeal regions (notably in cats)
- Sterile endotracheal tube
- Sterile red rubber catheter, 5 Fr, preferably long enough to reach fourth through sixth intercostal space (ICS)

ANTICIPATED TIME

About 15-20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Recent thoracic radiographs
- Supplemental oxygen available
- Advise owner of risks of techniques, including possible nondiagnostic findings.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

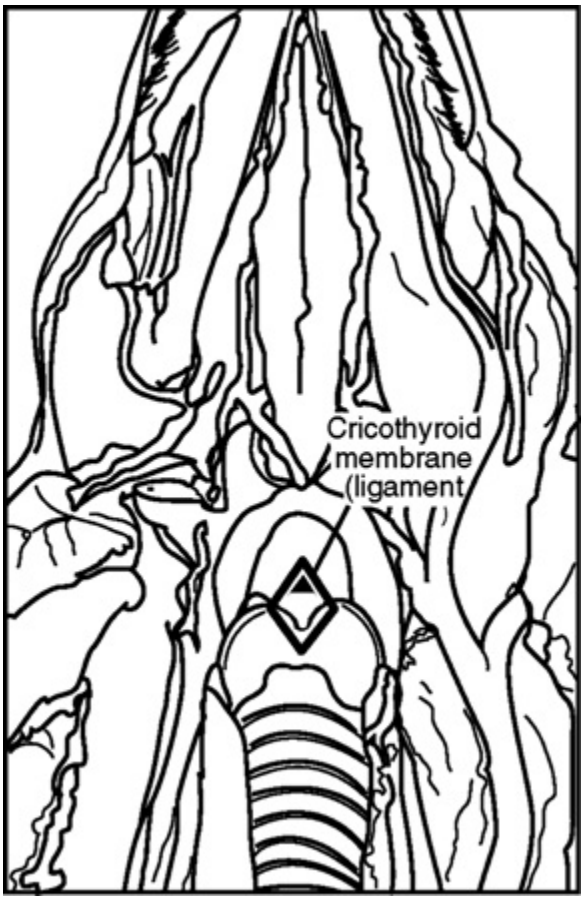
- Contamination of specimens via oral cavity if using endotracheal tube technique
- Subcutaneous emphysema or pneumomediastinum with transtracheal approach
- Being too hesitant (inadequate) in volume of saline instilled
- Withdrawal of catheter against the insertion needle can cut catheter off in the tracheal lumen.
- Cyanosis/hypoxemia in animals with borderline hypoxemia prior to procedure

PROCEDURE

Decide between techniques based on value of sample purity versus patient risk factors; transtracheal approach lessens contamination but slightly increases risk of complications.

TRANSTRACHEAL WASH:

- Patient in sitting or sternal position, ideally at the front end of a table to have the site of entry into the trachea at operator's eye level
- Head and neck elevated to horizontal or further vertical (45○ toward ceiling); if one side of the lungs is of greater interest, then have this be the dependent (down) side, using lateral recumbency.
- Palpate the small cricothyroid membrane at the caudal aspect of the ventral larynx.
- Clip and prepare the area using sterile technique.
- Infiltrate 0.5-1 mL lidocaine in SQ tissue overlying the cricothyroid membrane.
- Make a small (<1 mm) incision with the #11 scalpel blade.
- Prepare jugular catheter.
- Insert jugular catheter needle at oblique angle caudodorsally through the small incision in the skin, then through the cricothyroid membrane.
- When the needle is in the tracheal lumen, a slight cough upon entry is common. Take care to avoid lacerating the dorsal wall of the trachea with the needle tip.
- Slide the catheter down into the tracheal lumen in a caudal direction; remove the stylet partially.
- Back out the insertion needle so it is outside the trachea and skin, hold catheter steady (catheter position stays unchanged), and apply the needle guard.
- Remove stylet and flush initial volume. It is important to aspirate immediately after flushing and to not aspirate against negative pressure (catheter tip lodged against respiratory mucosa; release negative pressure and reposition). May switch to larger syringe to aspirate as much fluid sample as possible; if no specimen is obtained, the second volume is flushed and aspirated again. Saline that passes down the trachea is expectorated or coughed back toward the catheter; mucus and turbidity are seen in the fluid. Often, only 1-2 mL will be retrieved out of every 10 mL infused.
- Withdraw catheter.
- Gently wrap neck over insertion site with cast padding, roll gauze, and Vetrap to reduce risk of SQ emphysema. Keep the neck wrap in place preferably 12 hours, ensuring that it is not too tight.



TRANSTRACHEAL WASH Anatomic diagram of ventral neck of dog; dissected specimen (cranial is toward top of image). Diamond-shaped outline identifies the cricothyroid membrane, through which a catheter is introduced for performing transtracheal wash.

TRACHEAL WASH VIA ENDOTRACHEAL TUBE:

- Sedate or anesthetize animal, and place oral speculum to hold mouth open.
- Pass sterile endotracheal tube to an appropriate level while trying to avoid gross contamination of its lumen and sides; use topical lidocaine on larynx if needed.
- Pass sterile red rubber catheter through the endotracheal tube to level of thoracic inlet or bronchial bifurcation; lavage with same technique as already described.
- Can follow flush procedure with covered endoscopic cytology brush if desired.

POSTPROCEDURE

- Provide supplemental oxygen if needed (see p. 1318).
- Divide specimen into aliquots for cytologic analysis and cultures and fresh slides for cytologic analysis; can request routine staining and Gram stain.
- If respiratory distress occurs, tilt the animal's body (head down, allowing fluid to flow cranially), perform coupage, consider reintubation and oxygen supplementation/positive-pressure ventilation.
- Radiographs to assess for pneumomediastinum if needed

ALTERNATIVES AND THEIR RELATIVE MERITS

Tracheobronchoscopy:

- Visualization of airways to bronchi
- Provides reduced contamination and superior estimate of cell numbers from lavage specimen
- Catheter lavage and brush cytologic analysis can both be performed.
- Requires additional equipment, expertise, and longer procedural time
- Tracheobronchoscopy is more accurate than tracheal wash if both options are available.

AUTHOR: MARK E. HITT

Transfusion Therapy

SYNONYM

Blood transfusion, component therapy

OVERVIEW AND GOALS

Safely collect and administer blood products

INDICATIONS

FRESH WHOLE BLOOD:

- Improve oxygen delivery:
  - Hemolysis
  - Blood loss
  - Nonregenerative anemia
- Provide clotting factors:
  - Anticoagulant rodenticide toxicity
  - Liver disease
  - von Willebrand disease (VWD)
  - Disseminated intravascular coagulation (DIC)
  - Hemophilia A
  - Other factor deficiencies
- Support oncotic pressure:
  - Protein-losing disease (enteropathy, nephropathy, massive skin wounds or burns, serosal inflammation)
- Fresh whole blood is not recommended for treatment of thrombocytopenia unless significant active hemorrhage and anemia exist.

STORED WHOLE BLOOD: Same as for fresh whole blood except for VWD, liver disease, hemophilia A, and DIC: After 6 hours of storage, platelets, factors V and VIII, and von Willebrand factor all decrease.

PACKED RED BLOOD CELLS (PRBCs):

- Improve oxygen delivery:
  - When oncotic support and clotting factors are not required
  - When volume overload is a concern (cardiac disease, renal failure, chronic anemia)

FRESH FROZEN PLASMA:

- Provide clotting factors (same as fresh whole blood)
- Support oncotic pressure (same as fresh whole blood)
- Pancreatitis (controversial) or colostrum replacement
- Must be separated and frozen within 6 hours of collection

FROZEN PLASMA (plasma frozen more than 6 hours after collection or fresh frozen plasma stored more than 1 year):

- Anticoagulant rodenticide toxicity and hemophilia B (factors II, VII, IX, and X preserved)
- Support oncotic pressure
- Pancreatitis (controversial) or colostrum replacement

OTHERS: Platelet-rich plasma and platelet concentrate are rarely used in private practice (labor intensive, 2 to 3 day storage times, special storage conditions).

CONTRAINDICATIONS

- Animals with normal to increased packed cell volume (PCV)
- Administer cautiously in patients with volume overload, heart disease, or renal failure.

- Incompatible recipients:
  - Cross-match dogs that have received a transfusion more than 4 days previously, even if using the same previously cross-matched compatible donor.
  - Cats: all require blood typing and/or cross-matching prior to transfusion (cross matching will detect Mik incompatibilities in cats while AB blood typing will not).
- First-time transfusions to dogs are usually safe without prior blood typing and/or cross-matching, although compatibility testing is still recommended to decrease future incompatibilities.

EQUIPMENT, ANESTHESIA

BLOOD COLLECTION: Hair clippers and material for sterile prep

Dogs:

- Donor dogs should be healthy adults, weigh >30 kg, and have a normal physical exam and negative heart-worm and rickettsial serologies.
- Butorphanol, 0.1-0.2 mg/kg for IV use
- Sterile 450-mL collection bag with tubing, needle, and anticoagulant (commercially available)
- Digital gram scale
- Hemostat forceps
- Scissors
- Hemoclips and stripper sealer (optional)

Cats:

- Donor cats should be healthy adults, weigh >4 kg, have a normal physical exam and normal blood smear, and be negative for feline leukemia and feline immunodeficiency virus serologies.
- Ketamine HCl, 1-2 mg/kg for IV use
- Two 35-mL syringes (a 60-mL syringe may collapse the vein).
- Anticoagulant (citrate-phosphate-dextrose-adenine-1 or adenine-citrate-dextrose)
- A 19-gauge butterfly needle
- Note: Heparin (300 units per 50 mL blood collected) can be used as an anticoagulant in an emergency.
  - Dilute heparin in 3 mL of saline to facilitate mixing.
  - Heparin contains no preservatives: administer blood within 24 hours.
  - Heparin activates platelets: avoid in thrombocytopenic animals.

BLOOD ADMINISTRATION:

- IV or intraosseous (IO) catheter
- Transfusion set with filter (dogs)
- A 170-µm syringe filter and an IV extension set (cats)

ANTICIPATED TIME

- Whole blood collection: 20-40 minutes
- Administration: minutes to maximum of 4 hours, depending on animal's condition

PREPARATION: IMPORTANT CHECKPOINTS

- Check PCV of recipient and donor prior to transfusion.
- Save hematocrit tube containing recipient plasma for future comparison if hemolytic reactions occur.
- Aseptic technique is essential.
- See Cross-Match and Blood Typing, .

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

TRANSFUSION REACTIONS (see p. 1111):

- Monitor temperature, heart rate, and respiratory rate every 10 minutes for 30 minutes, then every 60 minutes until transfusion completed.
- Uncommon (3%) and rarely fatal (<1%) if cross-matched
- Stop transfusion.

- Evaluate signs: if mild without evidence of hemolysis or bacterial contamination, restart transfusion at a slower rate and monitor closely.
- Risk of reactions is reduced by:
    - Using donor dogs negative for DEA 1.1 and preferably negative for DEA-1.2 and DEA 7
    - Cross-matching all donors with recipients
    - Using proper collection, administration, and storage techniques
    - Not adding anything other than 0.9% saline to blood products

Hemolytic transfusion reaction; may be acute or delayed:

- Acute:
    - Can see signs within 20 minutes
    - Restlessness, fever, tachycardia, vomiting, hemoglobinuria, hemoglobinemia
    - Very rarely: renal failure, collapse, shock, and death
    - Stop transfusion.
    - Look for hemolysis: check plasma color of a spun hematocrit tube (compare to pretransfusion plasma color).
    - Check blood pressure (BP) and urine output.
    - Administer fluids (address shock, prevent DIC).
    - Corticosteroids and antihistamines will not prevent acute hemolytic reactions.
- Delayed:
    - Can occur 3-14 days after transfusion
    - Decreases transfusion efficacy but usually produces no clinical signs

Anaphylactic reactions:

- Usually mild
- Fever, urticaria, erythema, pruritus
- Stop transfusion.
- Administer antihistamines (e.g., diphenhydramine, 1-2 mg/kg IM) and glucocorticoids (e.g., dexamethasone SP 0.1-0.2 mg/kg IV).
- Can usually restart transfusion at a slower rate

Volume overload:

- Cough, dyspnea, jugular distention
- Stop transfusion.
- Administer furosemide (e.g., 2 mg/kg IV) ± oxygen supplementation.

Bacterial contamination: examine blood for discoloration, and submit blood for culture and Gram stain if animal is febrile.

OTHER CONCERNS:

- Dogs that receive a first-time crossmatched compatible transfusion can develop antibodies against the donor blood in 1-2 weeks, and any subsequent transfusion (even if using the same donor) should be cross-matched.
- Microembolism
- Hypothermia
- Acidosis
- Citrate toxicity

PROCEDURE

BLOOD COLLECTION FOR BANKING:

Blood donor dogs:

- Administer butorphanol, 0.2 mg/kg IV.
- Place in lateral recumbency on an elevated surface.
- Clip ventral neck (center over jugular furrow).
- Perform sterile scrub.
- Place collection bag on the scale at a level below the animal (blood collects via gravity).
- Zero the scale (collection bag + anticoagulant ≈ 85 g).
- Note: If less than 450 mL of blood is to be collected, anticoagulant must be expressed from the collection bag to maintain the 1 : 7 anticoagulant-to-blood ratio (e.g., to collect 225 mL blood, discard half the anticoagulant [32 g]).
- Clamp tubing with hemostat (near needle).

- Hold off jugular vein for visualization.
- Remove needle cap and insert needle (16-17 gauge) into jugular vein.
- Remove hemostat; collection begins.
- During collection, gently rock the bag intermittently to mix blood with the anticoagulant.
- Rotate/adjust needle delicately if flow stops.
- Continue collection until scale reads 450 g (± 45 g).
- Release jugular vein pressure.
- Reclamp tubing near needle.
- Remove needle from jugular vein.
- Recap needle.
- Strip blood from tubing into bag to mix with anticoagulant.
- Allow tubing to refill.
- Tie/hemoclip tubing at 6- to 10-cm intervals for storage and cross-match.
- Remove hemostat.
- If collection technique is questionable, blood should be used within 24 hours.

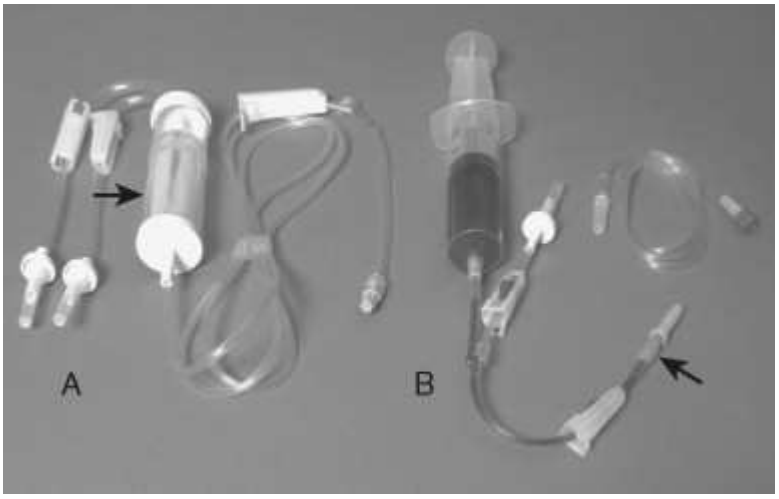
Blood donor cats:

- Sedate (1-2 mg/kg ketamine IV; may add diazepam, 0.1 mg/kg IV if necessary).
- Clip ventral neck (center over jugular furrow).
- Perform sterile scrub.
- Use a separate needle to put 4 mL ACD or CPDA-1 into each sterile 35-mL syringe.
- Connect one 35-mL syringe to a butterfly needle.
- Hold off jugular vein to visualize.
- Remove needle guard.
- Insert butterfly needle into jugular vein.
- Gently aspirate 27 mL of blood while slowly rocking the syringe to mix anticoagulant and blood.
- Disconnect syringe from butterfly catheter.
- Cap syringe with a sterile needle.
- Attach second anticoagulant-filled syringe, and gently aspirate 27 mL of blood as already described.
- Release jugular pressure.
- Remove needle from jugular vein.
- Note: A similar technique can be used in dogs (60-mL syringe with 7 mL ACD or CPDA-1) if collection bags are unavailable; refrigerate and use within 24 hours.

ADMINISTRATION:

- For all blood products:
  - Always use a filter.
  - Start slowly (0.5 mL/kg/h) for 15-20 minutes.
  - Monitor for reactions.
  - Increase rate if no reactions occur.
  - Complete transfusion by 4 hours (decreases bacterial contamination).
  - Normal rate is 5-10 mL/kg/h.
  - Can increase to 20 mL/kg/h in unstable hypovolemic animals
  - Can administer as rapidly as possible in a severe crisis
  - For heart disease, renal failure, or potential volume overload, administer at 1-4 mL/kg/h, and monitor for volume overload (as already described).
  - Can divide dosage into smaller aliquots and refrigerate up to 24 hours (allows slower administration with minimal risk of bacterial contamination)
- From a syringe:
  - Attach syringe filter to syringe.
  - Attach IV extension set to filter.
  - Prime system with blood product.
  - Connect extension set to IV catheter.
  - Use syringe pump or intermittent administration (i.e., healthy cats: 5 mL over 5 minutes then wait 6-12 minutes and repeat).
- From a collection bag:
  - Use blood administration set with filter (see manufacturer instructions).
  - Prime administration set with blood product.
  - Attach to IV catheter.
  - Set drip rate.
  - Some infusion pumps can be used; check manufacturer specifications.
- Dosages:
  - Whole blood: 10-20 mL/kg:

        - Generally: 2 mL/kg increases PCV ≈ 1%
    - PRBCs: 5-10 mL/kg:
        - Generally: 1 mL/kg increases PCV 1%.
        - Can dilute with 50-125 mL of 0.9% saline to decrease viscosity
    - Alternatively: PRBCs or whole blood (milliliters) dose = BW (kilograms) × 90 × (PCV desired — PCV recipient)/PCV of donor blood; substitute 90 with 60 for cats.
- Warming whole blood or PRBCs is not essential; indications to warm:
    - Multiple transfusions
    - Hypothermic animals
    - Neonates
    - Warm by room air or water bath.
    - Do not exceed 37○C (hemolysis).
- Fresh frozen/frozen plasma, 10-20 mL/kg:
    - Plastic is fragile when frozen; handle frozen units delicately.
    - Thaw in 37○C water bath in a waterproof plastic bag.
    - Give within 4 hours for clotting factors.
    - Can store 24 hours in refrigerator after thawing if clotting factors not required
    - Repeat dosage if coagulopathy persists.



TRANSFUSION THERAPY AND COLLECTION TECHNIQUES FOR BLOOD BANKING Two blood transfusion systems; arrows indicate filters. **A**, A transfusion set with filter chamber typically used for larger volumes (medium- and large-breed dogs). **B**, A 170-µm syringe filter and IV extension set typically used for cats and toy breed dogs.

TRANSFUSION THERAPY AND COLLECTION TECHNIQUES FOR BLOOD BANKING Materials for blood collection. A blood collection bag, tubing, and needle *(right)* are shown, with a hemostatic clamp placed on the tubing to prevent leakage of the anticoagulant. Hemoclips and a stripper-sealer *(left)* are also shown.

POSTPROCEDURE

- Blood donors: administer fluids if hypovolemic (tachycardia, pale mucous membranes, prolonged capillary refill time) or if the fluid equivalent of more than 2% of the body weight in kilograms is collected.
- Patients/recipients: check PCV 2 hours after the transfusion is complete, and check coagulation profile after administering plasma for coagulopathies.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Polymerized hemoglobin (Oxyglobin):
  - Improves oxygen delivery
  - Provides colloidal support but no other plasma benefits
  - Dogs: 10-30 mL/kg at a maximum of 10 mL/kg/h
  - Cats: 5-10 mL/kg at a maximum of 5 mL/kg/h
  - Monitor closely for signs of volume overload, especially in cats.
- Synthetic colloids:
  - Hypoalbuminemia requires large volumes of whole blood or plasma to correct.
  - Synthetic colloids should be considered instead to support colloidal pressure (bolus 5-20 mL/kg then 10-20 mL/kg/day; use lower doses for cats).
  - Human albumin: role is controversial; use with caution, as fatal reactions reported. Further studies are required before recommendations can be made (suggested guidelines if used: dogs, 2-7 mL/kg of 25% or 10-35 mL/kg of 5% over 4-6 hours).

AUTHOR: SØREN R. BOYSEN

Transcervical Insemination

SYNONYM

TCI

OVERVIEW AND GOAL

- Transcervical insemination (TCI) involves the endoscopic visualization of the cervix and its catheterization. Semen is then injected through the catheter and into the uterine lumen.
- The two primary methods of intrauterine insemination are catheterization of the cervix by TCI or injection of semen into the uterine lumen by laparotomy.
- TCI requires specific equipment and careful breeding management.

INDICATIONS

- Intrauterine insemination is required when using frozen-thawed semen.
- Female subfertility
- Cases where the semen is reduced in viability or dose (<150 million progressively motile, morphologically normal sperm)
- TCI can be used to rule out vaginal or cervical abnormalities through visualization of these areas and catheterization of the cervix.

CONTRAINDICATIONS

If the bitch is not in late estrus, the vaginal wall is more sensitive, and the procedure will be uncomfortable and more likely to require sedation.

EQUIPMENT, ANESTHESIA

- Endoscope:
  - Extended-length rigid cystourethroscope with a working length of 29 cm and 22 Fr diameter; ideal for dogs 25-75 lbs (12-35 kg). It should have a 30○ viewing angle with a sheath and a bridge. Use with urinary catheters 6-8 Fr diameter.
  - Cold light source and cable
- Camera and video tower system
- Adjustable-height exam table with nonslip surface
- Anesthesia or sedation is not usually required; a bitch in estrus will tolerate the procedure very well. Smaller breeds are more likely to require sedation.

ANTICIPATED TIME

10-40 minutes

PREPARATION: IMPORTANT CHECKPOINTS

Breeding management (see online chapter: Breeding Management) and insemination timing:

- The ideal timing for TCI is days 5 to 7 after the luteinizing hormone (LH) surge (LH surge = day 0). This is based on both oocyte viability and the degree of cervical relaxation required for catheterization. Secondary oocytes are only present after day 4-5, and by day 8, the oocytes become senescent. Prior to day 4, the cervix will be difficult to catheterize.
- The LH surge can be timed either directly by testing LH or indirectly by monitoring serum progesterone and looking for the rise above 1.5-3 ng/mL.
- When timing the insemination, it is also important to consider the longevity of the semen based on its handling and state (fresh versus cooled shipped versus frozen).
- Typical breeding management with any type of semen would include 2 inseminations between days 4 and 7:
  - The frequency of insemination using TCI is limited only by the ability to catheterize the cervix. Once daily inseminations, though not usually necessary, are possible from day 4-7 or as long as the cervix can be catheterized.

Semen preparation and evaluation:

- The minimum intrauterine dose of semen is 75 million.
- Since the space in the uterine lumen is limited, the volume of semen used is reduced. The maximum volume should be less than 3 mL. The size of the bitch and the capacity of the uterus will determine the ideal insemination volume.
- If using freshly collected semen, every effort should be made to fractionate the collection to separate the sperm-rich portion. The volume of the sperm-rich fraction is usually less than 3-5 mL. If TCI is scheduled to occur within a short time, the unextended sperm-rich fraction can be used. If additional volume is needed, the prostatic fluid can be used to follow the semen into the uterus and “flush” the catheter.
- If using cooled shipped semen or semen extended to a volume greater than 5 mL, the semen should be centrifuged at 900g for frac12; min/mL. The supernatant should be drawn off until the ideal volume is achieved, and the remaining pellet is resuspended.
- Frozen semen should not be thawed until the cervix is successfully catheterized. Thaw instructions and procedures should be followed. It is recommended to prepare for thawing in advance to ensure that insemination occurs with a few minutes of catheterization of the cervix.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Occasionally, it will not be possible to catheterize the cervix. This is affected by factors such as the stage of the estrous cycle, size of the female, and parity. The natural angle of the cervical canal is craniodorsal. Adjusting the angle of the endoscope can straighten the vagina and cervix. It may also be necessary to use a catheter with a narrower diameter.
- Inadequate insufflation can result in poor visualization of the external cervical os.
- Excessive discharge, especially in early estrus, can hinder visualization.

PROCEDURE

- To limit the time the animal is restrained on the table, equipment and semen should be prepared in advance.
- The dog is restrained in a standing position on a table. Restraint should include a person or device to limit forward movement, side-to-side movement, and prevent sitting or lying. The table is adjusted to a comfortable height for the operator/inseminator.
- The rigid endoscope is placed at the vulvar lips and advanced, noting important anatomical landmarks:
    - The caudal vagina of the bitch has a steep incline as it extends over the pubic bone (see p. 1360).
    - The scope should be held against the dorsal surface of the caudal vagina to avoid the sensitive clitoris and urethra.
    - In the cranial vagina, the vaginal folds become longitudinal, and the prominent dorsal vaginal fold or pseudocervix can be visualized.
    - The cervix is located on the dorsal vaginal wall at the cranial extent of the dorsal vaginal fold. It typically angles in caudal ventral direction. The tissue of the cervix will appear more fibrous and sharply creased than the surrounding vaginal tissue.
    - The vaginal fornix extends cranial to the cervix and is a blind pocket.
    - Location within the vagina can also be determined by transabdominal palpation.
- It is often necessary to insufflate the vagina to improve visualization as the scope is advanced:
    - The vulvar lips may need to be held shut to prevent air from escaping.
- Once the cervix is visualized, the catheter is advanced, and the external os of the cervix is probed. A twisting motion may help the catheter penetrate the cervix.
- The catheter should be visualized as it is advanced through the cervix. It should be placed as far as it will go into the uterine lumen, as long as no pressure is felt.
- Once the catheter is in place, the semen is injected. If backflow is observed through the cervix, the catheter should be repositioned and the injection of semen continued. The catheter should be flushed with an appropriate amount of air, extender, as prostatic fluid to ensure all has entered the uterine lumen.
- The catheter is withdrawn, and then the rigid endoscope is retracted.

POSTPROCEDURE

It has been recommended to elevate the hind quarters for 10 minutes to facilitate movement of the semen from the uterus into the uterine tubes.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Surgical insemination involves the direct injection of semen through the uterine wall into the lumen. This method is precise but invasive and should only be performed once per estrous cycle.
- The Norwegian intrauterine insemination catheters are rigid catheters 20-50 cm long with a tip diameter of 0.5-1 mm. These catheters are advanced into the cervix blindly relying only on transabdominal palpation for correct placement. This procedure requires a significant level of operator experience and risks traumatizing the vagina and cervix, but it does eliminate the need for expensive equipment.

AUTHOR: BRONYWN CRANE

Tracheostomy

OVERVIEW AND GOALS

The creation of a temporary hole through which a tube or a permanent stoma in the trachea can be placed. Tracheostomy facilitates airflow into the trachea distal to the nose, mouth, nasopharynx, and larynx.

INDICATIONS

Temporary tube tracheostomy:

- Emergency procedure to establish airflow in situations of acute upper respiratory distress or upper respiratory obstruction that does not allow stabilization with supplemental oxygen or oral intubation; occurs with trauma, neoplasia, laryngeal edema/collapse, certain foreign bodies
- Elective procedure to provide alternative airflow for surgical procedures of the oropharynx
- Long-term ventilatory support

Permanent tracheostomy:

- Salvage or palliative procedure
- Upper respiratory obstructions causing respiratory distress that cannot be treated otherwise; occurs in neoplasia, hemorrhage, laryngeal collapse

CONTRAINDICATIONS

Respiratory distress due to intrathoracic disease

EQUIPMENT, ANESTHESIA

- Anesthesia:
  - General anesthesia if elective procedure
  - Local anesthesia if too unstable for general anesthesia ± analgesia/sedative
  - If the animal is unconscious due to upper airway obstruction, tracheostomy is generally indicated in the absence of general or local anesthesia. Anesthesia is then administered/titrated if necessary after the tracheostomy has been performed but prior to the return of consciousness.
- Aseptic surgical preparation if elective procedure (and if time allows in cases of emergency tracheostomy):
  - Hair clippers
  - Surgical scrub solution, alcohol, gauze sponges
- Instruments:
  - Sterile gloves
  - A #11 sterile scalpel blade
  - Scalpel handle
  - 2-0 to 4-0 polydioxanone/polypropylene suture on a taper needle
  - Needle holders
  - Brown-Adson forceps
  - Kelly hemostat forceps
- Tracheostomy tubes:
  - Diameter: tubes should be no larger than half the size of the trachea. Intratracheal length: tube should extend six to seven tracheal rings. Composition: tubes should be made of autoclavable, nonreactive material (silver, silicone, nylon).
  - Single-lumen tubes must be removed and replaced for cleaning.
  - Double-lumen tubes have a removable inner cannula for cleaning, which is more convenient and is comfortable for the animal, but they may be too large for smaller animals, and mucus can still accumulate distal to the inner cannula.
  - Cuffed tubes are used for ventilator support. High-volume, high-compliance cuffs that are able to inflate with low pressures and less blood flow compromise are indicated.
  - The Shiley tracheostomy tube is the most common, and the company offers many varieties for treating veterinary patients.

ANTICIPATED TIME

- Temporary: 10 minutes
- Permanent: 30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Have all supplies at hand before beginning procedure.
- Label stay sutures to aid in replacement of tube.
- Inform owner of potential complications of procedure and long-term prognosis of condition.

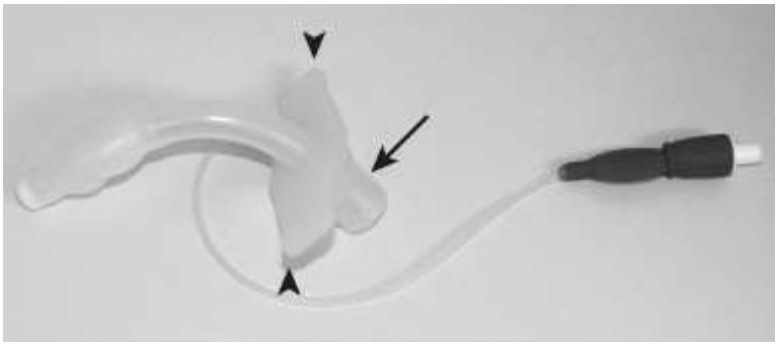
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Tracheostomy emergencies: obstruction, extubation, and cuff leakage
- Tube "cleaning" cannot involve pushing secretions and debris back into the trachea. Proper suctioning and, if double-lumen tube, removal of the inner cannula are essential.
- Infection
- Hemorrhage
- Subcutaneous emphysema, pneumomediastinum, pneumothorax
- Tracheal malacia
- Tube tracheostomy:
    - Gagging, vomiting, and coughing, especially during suctioning
    - Tube obstruction
    - Tube dislodgement
    - Tracheal irritation causing tracheocutaneous or tracheoesophageal fistulas
    - Vascular erosions
    - Stricture or stenosis from pressure necrosis and mucosal erosions
- Permanent tracheostomy:
    - Stomal occlusion by mucus, skin folds, stenosis
    - Mucus accumulation
    - Coughing and gagging from tracheal irritation

PROCEDURE

TEMPORARY TRACHEOSTOMY:

- Place animal in dorsal recumbency, and clip hair from ventral and lateral neck.
- Surgically prep the skin if time permits (all elective procedures and as much as possible with emergency cases).
- Make a ventral, cervical midline skin incision extending caudally from the distal aspect of the larynx. A typical length for the incision is 2-3 cm in a medium-sized dog.
- Expose the trachea by bluntly dissecting on the midline between the paired sternohyoid muscles and retracting the muscles and skin laterally.
- Either a horizontal (transverse) or a vertical (midline) incision can be made into the trachea.
- Prior to incising the tracheal cartilages/rings, stay sutures should be placed, encircling cartilages proximally and distally (horizontal tracheostomy) or laterally (vertical tracheostomy) to the proposed tracheal incision.
- A horizontal tracheostomy can be made by incising through the annular ligament between the third and fourth tracheal cartilages, with the incision not extending more than half the circumference of the trachea.
- A vertical tracheostomy can be made by incising through the ventral midline of the third through the fifth tracheal cartilages.
- Insert a tracheostomy tube by placing tension on the sutures to temporarily enlarge the tracheal opening and using a hemostat to manipulate the tube through the incision.
- Alternatively, a tracheal flap tracheostomy can be performed by making a U-shaped incision into the cartilage based at the second tracheal ring and extending distally two to three rings. The cartilage flap is raised, and the endotracheal or tracheostomy tube is inserted. This technique is best for long-term intubation or ventilation, because it decreases pressure on the tissue and granulation tissue formation.
- Secure the tube by suturing it to the skin or tying it with gauze around the neck.
- If necessary, skin cranial and caudal to the tube can be sutured together.
- Leave stay sutures in place while tracheostomy tube is present to aid in tube replacement should it become dislodged or obstructed.



TRACHEOSTOMY A single-lumen, cuffed tracheostomy tube. Curved and cuffed portions are inside the patient. External plate *(arrowheads)* is sutured to the skin of the ventral neck or tied around the neck with umbilical tape. Proximal extremity of tube *(arrow)* either is left open or attached to a ventilator.

PERMANENT TRACHEOSTOMY:

- Place animal in dorsal recumbency, and clip hair of the ventral and lateral neck.
- Surgically prep the skin.
- Make a ventral cervical midline skin incision extending caudally from the distal aspect of the larynx. A typical length for the incision is 6-8 cm in a medium-sized dog.
- Expose the trachea by bluntly dissecting between the paired sternohyoid muscles and retracting laterally.
- Identify the third through sixth tracheal cartilages/rings.
- Create a tunnel dorsal to the trachea in this region through gentle blunt dissection and, using this tunnel, place several horizontal mattress sutures with 2-0 or 3-0 polydioxanone/polypropylene through the tunnel and sternohyoid muscles to deviate the trachea ventrally and decrease tension.
- Make an incision through the ventral aspect of the third to sixth tracheal cartilages to the mucosal level, and remove a rectangular segment with a length of three to four cartilages and a width one-third of the tracheal circumference. The size of the segment removed should be approximately 50% larger than the size of the desired stoma.
- Using thumb forceps and the blunt edge of the scalpel blade, dissect free the edges of the incised cartilage from the underlying mucosa.
- Resect a rectangular segment of skin from the edges adjacent to the tracheostomy site similar to the size and shape of the tracheostoma. Excise excess skin or fat if present.
- Using interrupted intradermal sutures of 3-0 polydioxanone/polypropylene, suture the skin around the tracheostoma to the peritracheal tissues laterally and the annular ligaments proximally and distally. These sutures will promote skin adhesion to the trachea and decrease seroma formation and suture tension.
- Make an I- or H-shaped incision into the tracheal mucosa.
- Fold the mucosa over the cartilage edges, and suture it to the skin edges using simple interrupted sutures at the corners and a simple continuous pattern of 4-0 polypropylene for the remainder of the area.

POSTPROCEDURE

TEMPORARY TRACHEOSTOMY TUBE CARE:

- Proper care is necessary to prevent airway infection and occlusion.
- Inner cannulas are removed and cleaned or replaced at least every 24 hours or as needed. The inner cannula is soaked in 2% chlorhexidine solution and rinsed before replacement.
- Aseptic technique and sterile equipment should always be used when clearing the airways.
- Preoxygenation is performed for 2-5 minutes prior to suctioning to minimize hypoxemia.
- A sterile suction catheter no larger than half the size of the tracheostomy tube, with a blunt end and side suction holes, should be used. The catheter should be inserted without vacuum until obstruction is encountered, and then intermittent suction is performed while rotating the catheter as it is removed. The catheter should not remain in the airway for more than 15 seconds.
- Frequency of suctioning is determined by the amount of secretions produced by the animal and may range from every 15 minutes to 6-8 hours.
- Humidification or instillation of 0.1 mL/kg (minimum 1 mL, maximum 5 mL) sterile saline every 1-2 hours as well as coupage to aid in clearing secretions

CUFFED TUBES:

- Cuffs are inflated for airway sealing to prevent air leakage during ventilatory support.
- A stethoscope is placed over the trachea adjacent to the cuff to auscultate leaks.
- Air is removed in 0.25-mL increments until a small leak is detected at maximal airway pressure, which is considered minimal

occluding volume.
- Cuff deflation is not recommended unless there is evidence of difficulty achieving positive-pressure ventilation or airway pressure.

PERMANENT TRACHEOSTOMY CARE:

- Frequent cleaning of the opening (often every few hours for an indefinite period of time) is necessary to remove mucus, hair, and foreign material.
- Application of ointment, such as petroleum jelly, decreases mucosal drying and aids in removal of debris.
- Monthly clipping of the hair around the stoma to prevent matting.
- No swimming; avoidance of environments that may allow aspiration of particulate debris.

TEMPORARY TRACHEOSTOMY TUBE REMOVAL:

- The tube should be removed as soon as upper airway airflow has been reestablished. The original tube is removed and replaced with a smaller tube, the cuff is kept deflated, and respirations are observed for 10 minutes for appropriate ventilation through and around the smaller tube. If respiratory effort is satisfactory, the tube is then occluded, and the animal is observed for appropriate ventilation via oral-nasal respirations. If the animal continues to breathe comfortably, the tube is removed.
- The surgical site should be allowed to heal by second intention.
- For flap tracheostomy, the site should be débrided of granulation tissue and the flap sutured back into its original area, using interrupted sutures of absorbable suture to align the cartilages.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Oral/endotracheal intubation (seep. 1292): always attempted first in patients with acute-onset severe upper airway obstruction. Advantages over tracheostomy are speed of mobilization of the airway, technical simplicity, and minimal invasiveness. When such intubation is not possible (e.g., upper airway obstruction cannot be relieved, and patient is suffocating), tracheostomy is the procedure of choice.
- Oxygen supplementation (seep. 1318): sufficient as initial management in patients with mild upper airway obstruction but often inadequate as sole therapy in cases of moderate or severe obstruction.

Tracheal Stent Placement

SYNONYM

Self-expanding tracheal stent placement, endo-/intraluminal tracheal stent placement

OVERVIEW AND GOAL

- Tracheal stent placement is most often utilized for the management of tracheal collapse in dogs. Tracheal stents may also be utilized for the management of tracheal neoplasia or other causes of tracheal obstruction. The following information will describe the technique for tracheal stent placement for the management of tracheal collapse.
- Conservative management of tracheal collapse is centered on medical management including cough suppressants, corticosteroids, and management of concurrent problems including but not limited to pneumonia, bronchitis, obesity, and heart disease.
- When conservative management cannot adequately control the clinical signs, medications are poorly tolerated, or quality of life is compromised, palliative interventions including surgery for prosthetic ring placement or image-guided tracheal stent placement must be considered. It is critical for the client to accept that these interventions are palliative and will not cure the problem. Instead, the goal of these procedures is a significant improvement in clinical signs and less reliance on medical therapies.
- Tracheal stent placement offers a rapid, minimally invasive, image-guided technique for the management of tracheal collapse.

INDICATIONS

- Tracheal collapse no longer amenable to conservative therapy as described above, involving extrathoracic and/or intrathoracic segments of the trachea
- Emergency management of dogs presented in crisis due to tracheal collapse that cannot be extubated due to recurrent airway obstruction
- Palliation of airway obstruction due to tracheal neoplasia

CONTRAINDICATIONS

- Dogs with tracheal collapse and concurrent laryngeal obstruction and/or dysfunction
- Dogs with severe mainstem bronchial collapse and only mild signs of tracheal collapse

EQUIPMENT, ANESTHESIA

- Fluoroscopic guidance is most often utilized for tracheal stent placement. Digital radiography systems have been employed but lack the “real-time” image acquisition that allows for optimal stent placement. Bronchoscopic guidance has been described.
- General anesthesia is required for tracheal stent placement. Most often, a premedication that includes an opioid for its antitussive effects is utilized. Propofol induction and inhalant anesthetic in oxygen are appropriate in most patients undergoing tracheal stent placement.
- Endotracheal tubes with a radiopaque marker extending to the tip of the tube
- Bronchoscope adapter allows for maintenance of the anesthetic circuit during tracheal stent deployment.
- Inventory of various lengths and diameters of self-expanding metallic stents. Most commonly utilized brands include the Vet-Stent Trachea (Infiniti Medical LLC, Malibu, Calif.) and the Wallstent or Ultraflex (Boston Scientific, Natick, Mass.). A complete inventory allows the veterinarian to transition smoothly from diagnosis to treatment during a single anesthetic event.
- Shortening charts for the brand of stent utilized. These charts provide information about stent length when the stent does not open to its nominal diameter.
- Standardized marking device (marker catheter) placed at the level of the trachea during imaging to allow for accurate measurements of the tracheal dimensions such that the effects of magnification can be minimized. The marker catheter has radiopaque markings that are spaced 1 cm apart.
- Two 0.035-in standard-stiffness, hydrophilic angled guide wires (HGW)
- Basin with 0.9% NaCl (500 mL)
- Software package for making measurements from fluoroscopic images or calculator for manual measurements

ANTICIPATED TIME

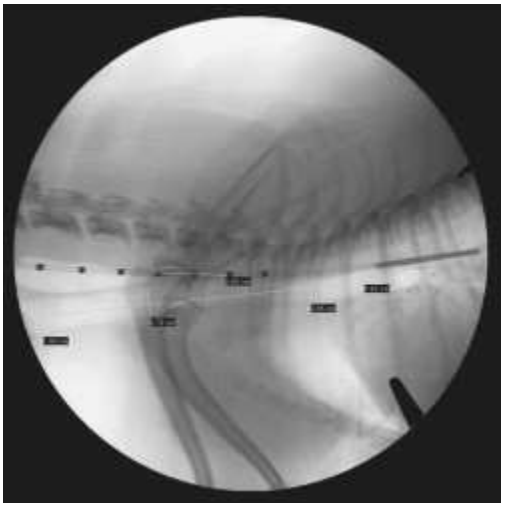
30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Perform fluoroscopy on the patient with tracheal collapse prior to anesthesia induction to determine the length of the airway obstruction relative to anatomic landmarks. Note the presence of concurrent mainstem bronchial collapse.
- Perform a laryngeal exam at anesthetic induction. If structure or function is abnormal, these problems will require management.
- Perform tracheobronchoscopy to assess the severity of tracheal and mainstem bronchial collapse. Contrast with fluoroscopic assessment to definitively determine the location and severity of the tracheal collapse.
- Position the patient in lateral recumbency such that the airway is in a straight line from nose to carina.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Acute complications of tracheal stent placement are very rare when the technique is performed appropriately.
- Without a marker catheter or similar measurement standardization device placed at the level of the trachea, magnification could significantly (and adversely) affect measurements.
- Undersizing of the tracheal stent may occur if the trachea is not appropriately distended with positive pressure (20 cm H2O) during measurement. Undersizing results in stent migration.
- Foreshortening is a property of many woven self-expanding metallic stents. When constrained on the delivery system, the stent will appear longer than its nominal (relaxed) diameter. As the stent is deployed, it will shorten towards its nominal length. Conversely, if the stent does not fully expand within the trachea (as expected owing to oversizing), it will be longer than the nominal length. Failure to recognize the properties of the stent can result in choosing a stent longer or shorter than is needed.
- Tracheal stents may be accidentally deployed into the carina, endotracheal tube, or larynx if inappropriately sized for the length of the tracheal collapse.



TRACHEAL STENT PLACEMENT Measurements of the trachea are taken at the cervical, thoracic inlet, and intrathoracic trachea. Magnification is accounted for through calibration against the marker catheter.

PROCEDURE

- Position the endotracheal tube to terminate just beyond the larynx.
- Advance a saline moistened HGW down the esophagus.
- Advance a lubricated 5 Fr marker catheter over the HGW.
- Anesthetist is asked to hold a positive pressure breath at 20 cm H2O in the anesthetic circuit while a radiograph is acquired. This maneuver is critical to determine the maximal tracheal diameter. Measurements of the tracheal diameter are then performed in the cervical and intrathoracic trachea.
- The stent diameter should be chosen to exceed the maximal tracheal diameter (usually a cervical measurement) by 10%-20%. As an example, if the cervical trachea measures 10 mm and the thoracic trachea measures 8 mm, then a 12-mm stent is chosen (10%-20% larger than the maximal tracheal diameter).
- The length of the stent is chosen based on the known extent of the collapse as viewed fluoroscopically during spontaneous breathing. An actual measurement of this distance is also acquired (using anatomic landmarks) from the image taken during the positive pressure breath as described above. Example: if the trachea collapses from the thoracic inlet to just in front of the carina, this distance should be measured on the image acquired during the positive pressure breath. As a general rule, the collapsed area should be spanned by 1 cm on either side. If the entire trachea is to be spanned with the stent, the stent should extend from 1 cm caudal to the cricoid cartilage to 1 cm cranial to the carina.
- Consult shortening charts to determine the expected length of the chosen stent when it is deployed, recognizing that it will not open completely (because a diameter was chosen that was 10%-20% larger than the actual tracheal diameter).
- Advance a sterile, wet HGW down through the working channel of the bronchoscope adapter to the level of the carina.
- Flush the hub (cannula) and Y-piece (sheath) of the stent delivery system with sterile saline to facilitate smooth passage over the guide wire and deployment. Advance the stent over the guide wire and into position.

- In order to deploy the stent such that its position does not change, it is critical to smoothly move the hub and the Y piece (sheath) towards each other in equal increments. This maneuver should be practiced prior to attempting it in clinical patients. If the stent is only partially (50%-70%) deployed and the positioning is not optimal, the reverse motion may be performed to recon-strain the stent within the delivery system. The stent is then repositioned and redeployed. Note that the endotracheal tube may have to be withdrawn over the delivery system into the larynx during deployment to avoid deployment of the stent into the endotracheal tube.
- Withdraw the delivery system and guide wire under fluoroscopic guidance. The endotracheal tube may be very gently advanced into the lumen of the stent under fluoroscopic guidance to maintain a patent airway if needed.
- Acquire lateral and VD images to determine expanded stent dimensions.
- Remove marker catheter and guide wire from esophagus.

POSTPROCEDURE

- Hospitalize for one night after the procedure.
- Medical management is ongoing and will include a cough suppressant (hydrocodone, 0.22 mg/kg PO q 6-12 h), prednisone (0.2-0.5 mg/kg PO q 12 h × 14 days then gradual weaning to lowest possible dose), and an antibiotic effective against *Mycoplasma* spp.
- A dry cough is expected for approximately 1 month.
- If mainstem bronchus (MSB) collapse is present, coughing related to MSB collapse will persist. Persistent coughing should be treated aggressively. Persistent coughing may apply considerable forces to the stent and these forces may be involved in stent fracture.
- Complications that may be encountered in the weeks to years after stent placement include bacterial tracheitis, stent fracture, and granulation tissue formation within the stent.
- Recheck exam including radiography is usually performed 3-4 weeks after placement and then every 6 months thereafter.

ALTERNATIVES AND THEIR RELATIVE MERITS

Placement of extraluminal prosthetic rings is the most commonly utilized surgical technique for the management of tracheal collapse. This technique is most often utilized in dogs with extrathoracic tracheal collapse and collapse at the thoracic inlet. Extraluminal prosthetic ring placement is technically challenging and associated with significant surgical morbidity.

Thoracoscopy

SYNONYM

Thoroscopy, video-assisted minimally invasive thoracic surgery

OVERVIEW AND GOAL

- A procedure for endoscopic exploration, biopsy and surgical procedures of the thorax (pericardial window, vascular ring surgery, patient ductus arteriosus ligation, thoracic duct ligation, lung lobectomy)
- Thoracoscopy is performed almost exclusively on dogs; size limitations limit visualization and safe manipulation in patients < 7 kg.
- Goals depend on the specific indication.
- Most commonly used for creating a pericardial window, allowing pericardial biopsy and alleviating recurrent cardiac tamponade; and for performing pleural biopsies (idiopathic pleural effusion)

INDICATIONS

- Recurrent pericardial effusion: common
- Idiopathic pleural effusion: occasional
- Idiopathic pneumothorax: rarely done, may be done as adjunctive step for surgical planning for thoracotomy
- Vascular ring anomaly: rarely done
- Patent ductus arteriosus: rarely done
- Idiopathic chylothorax: rarely done
- Primary pulmonary disease: rarely done
- Biopsy of mediastinal, pulmonary masses: rarely done

CONTRAINDICATIONS

- Clotting hemothorax
- Uncorrected bleeding tendencies (coagulopathies, thrombocytopenia, platelet function disorders)
- Small patients < 7 kg (approximately)

EQUIPMENT, ANESTHESIA

Equipment needs:

- Mechanical respirator (desirable but not absolutely required)
- Rigid endoscopic telescope (0○, 5-mm diameter scope)
- Endoscopic camera
- Xenon light source
- Video display
- Endoscopic trocars (5-mm diameter, one needs to be a minimum of 15 cm long)
- 12 Fr soft suction tubing (to use as chest tube)
- Endoscopic instruments. For basic pericardial window or pleural biopsy: 360○ rotatable Metzenbaum scissors, Babcock atraumatic grasping forceps, cup biopsy instrument
- Bipolar cautery (administered via the endoscopic instruments)
- Basic surgical supplies (towels, drapes, towel clamps, bowl, sterile saline, suction tubing)
- Basic surgical instruments (#12 blade, Brown-Adson forceps, needle holders)
- Suture (3-0 absorbable monofilament suture, 2-0 nonabsorbable monofilament suture)

Anesthesia:

- Premedication with opioid (e.g., hydromorphone, 0.1-0.2 mg/kg IM or IV) and benzodiazepine (e.g., midazolam, 0.2-0.4 mg/kg IV or IM); anticholinergic agents administered only as needed.
- Anesthetic induction with either propofol (e.g., 3-6 mg/kg slow IV to effect) or etomidate
- Anesthetic maintenance with oxygen/isoflurane inhalation
- Anesthetic monitoring including pulse oximetry, capnography, blood pressure and ECG monitoring

ANTICIPATED TIME

30 minutes or more, depending on procedure, experience of endoscopic team

PREPARATION: IMPORTANT CHECKPOINTS

- The entire ventral and lateral thorax and abdomen should be clipped and aseptically prepared to facilitate quick conversion to an open thoracotomy or laparotomy in an emergency setting.
- Be sure all video equipment is working properly prior to anesthetizing the patient.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Main complication is hemothorax.
- Inadvertent puncture of intraabdominal or intrathoracic structures
- Insufficient procedural analgesia will result in “bucking” of the ventilator (voluntary breaths, not coordinated with mechanical ventilation). This results in rapid oxygen desaturation.
- The rigid endoscopic telescope should be prewarmed in very warm saline for >5 minutes to avoid fogging of the lens.

PROCEDURE

Anesthetic induction and maintenance; dorsal recumbency; aseptic preparation of the whole ventral and lateral thorax; mechanical ventilation. The following describes the procedures using typical (nonselective two-lung ventilation) intubation:

- A Duke's trocar is used for inducing pneumothorax and to allow the threading of a 12 Fr suction tube into the left approximately 10th intercostal space (ICS) just dorsal to the mid-left thorax. After placing a three-way stopcock, additional room air is introduced into the thorax (≈10-20 mL/kg) to create a space in which to work, but being mindful of excess (e.g., overinsufflation causing inadequate oxygen saturation/hypoxemia).

Pericardial window:

- The long (=15 cm) trocar is introduced through an approximately 8-mm stab incision through the skin and subcutaneous tissues approximately 5 cm caudal and to the left of the xiphoid process. The trocar is introduced at a downward angle (i.e., craniodorsally) and then positioned parallel to the abdominal body wall and aimed toward the left shoulder joint. The trocar is removed and the endoscope placed through the trocar when the sensation of crossing the diaphragm is felt or at any point to monitor progress. The trocar is almost fully inserted when traversing the diaphragm of large dogs.
- Two additional instrument ports are placed on the left hemithorax in a triangulated orientation: approximately at the eighth ICS 5-10 cm below (dorsal to) the costochondral junction, and the seventh ICS 2-5 cm below the costochondral junction. Exact location depends on chest conformation and heart size. Prior to introduction of the trocars, the selected intercostal locations are palpated and visualized internally with the endoscope to decide if they are suitable, considering heart and lesion location. If so, an 8-cm stab wound is made into the skin to allow placement of a 5-mm endoscopic trocar with a closed valve.
- With ports created and instruments in place, the heart is visualized, and the forceps (in the cranial port) and scissors (in the caudal port) are visualized within the thorax. The pericardium is grasped. This may be difficult in patients with pericardial effusion at the time of the procedure or in patients with a very thick pericardial sac. The pericardial sac must be grasped—not just the fatty layer adjacent to it—to allow for adequate manipulation. One clue is the apex beat of the heart that can be felt on the forceps when the pericardium, but not pericardial fat, is contacted.
- When the pericardium is grasped, a small incision should be made into it, close to the tips of the forceps and with the pericardium tented up and away from the underlying heart. Care should be taken to not inadvertently clip any pulmonary tissue. Upon successful entry of the pericardium, fluid will be released in patients with pericardial effusion. The pericardium can then be repositioned with one jaw of the forceps within the pericardial sac for better control. The goal with a pericardial window is to make an opening approximately 4-5 cm in diameter for a large-breed dog. This will result from a small incision in a normal elastic pericardium, or a larger amount of tissue removed in multiple pieces when the pericardium is diseased and more rigid. The pericardial window should be made on the sternal surface of the heart to avoid the phrenic nerves coursing craniocaudally along the dorsal third of the pericardium.
- After the pericardial window is completed, the pericardium is tented to attempt a brief look inside the pericardial sac for mass lesions at the heart base. Tumors may be visualized in this position occasionally, but care should be taken to not induce arrhythmias or cause tumor bleeding. Tumor biopsy may be considered.
- Limited exploration of the thorax is made, looking for pulmonary metastatic lesions.
- The instrument ports are removed, using internal visualization of the sites for hemorrhage suggesting transection of an intercostal artery. Once adequate hemostasis is confirmed, the camera and transabdominal port are removed.
- The incisions are closed with a single cruciate suture in the subcutis (3-0 absorbable) and a single staple or cruciate suture in the skin. The chest tube is anchored with a modified Chinese-finger-trap suture (2-0 nonabsorbable suture). The air and any fluid are evacuated from the thorax. For local analgesia, bupivacaine (0.2 mL/kg) is diluted 1 : 1 with saline and placed into

the thorax through the chest tube, with the patient in left lateral recumbency. The chest tube is additionally secured with a light chest wrap.
- The patient is weaned off mechanical ventilation and recovered routinely.
- Postoperatively, hydromorphone is administered for a minimum of two doses as dictated by patient recovery.

For patients with idiopathic pleural effusion, the transabdominal approach is not used in order to avoid possible neoplastic contamination of the abdominal cavity:

- Induce pneumothorax as previously described.
- A short, 5-cm diameter endoscopic trocar is introduced in the approximately ninth intercostal space just dorsal to the costochondral junction. The camera is introduced and facilitates preliminary exploration of the thorax.
- A second trocar is introduced approximately in the fourth to fifth intercostal space just dorsal to the costochondral junction. Care is taken to introduce the trocar just through the chest wall, and then remove the sharp inner cannula to further introduce only the blunt outer cannula. The camera is positioned carefully across the mediastinum to the right hemithorax.
- A biopsy instrument is manipulated over (ventral to) the heart and toward the field of vision of the endoscope, using the transillumination of the skin as a guide to facilitate biopsy selection of the pleura. In patients with a normal-appearing parietal pleura, attempts are made to select biopsy samples from the diaphragmatic pleural reflection, which may be a place where occult mesothelioma cells may be easier to find.
- If the disease process appears lateralized, the procedure may be repeated on the other side of the thorax (from the right side to biopsy the left hemithorax).

Patients requiring more sophisticated surgical techniques and/or better surgical exposure to the heart base will require single-lung anesthesia using either a bronchial blocking tube (placed with bronchoscopic guidance into the surgical side) or selective intubation (using special endotracheal tubes and bronchoscopic guidance of the contralateral side).

POSTPROCEDURE

- Repeat chest tube aspirations to collect residual effusions/air and to monitor for bleeding complications.
- Oxygen supplementation until awake and ventilating fully
- Repeat opioid administration as needed for pain control.
- Nonsteroidal antiinflammatory drug (NSAID) generally started the first postoperative day after patient starts eating (unless contraindicated) and continued for 2-3 days (e.g., carprofen, 1 mg/kg PO q 12 h).
- Chest tube is removed 6-12 hours post procedure unless there are large amounts of ongoing fluid or air drainage.
- Monitor packed cell volume/total solids (PCV/TS) in patients with hemorrhagic pleural fluid.
- Patients generally discharged on postoperative day 1

ALTERNATIVES AND THEIR RELATIVE MERITS

For recurrent pericardial effusion:

- Repeat pericardiocentesis:
  - Advantage: technically easier, relatively inexpensive initially
  - Disadvantage: recurrent cardiac tamponade may be dangerous, frequent, unpredictable and cumulatively expensive.
- Thoracotomy:
  - Advantage: complete thoracic exploration, easier hemorrhage control, and facilitates full subtotal pericardectomy in patients with restrictive pericardial disease. Less specialized equipment required.
  - Disadvantage: patient morbidity, longer recovery time, higher cost. This is a particularly significant disadvantage in patients with malignant causes of disease.

AUTHOR: NANCY J. LASTE

Thoracocentesis

SYNONYM

Chest tap, pleural tap, thoracentesis (human medicine)

OVERVIEW AND GOALS

Rapid and technically easy procedure that is both therapeutic (removing air or fluid from the pleural space) and diagnostic (confirming the presence of air or fluid and obtaining samples of fluid for further analysis)

INDICATIONS

- Animals with respiratory distress (increased respiratory rate and effort) and dull lung sounds on auscultation
- Animals that present after trauma (hit by car, bite wounds, falling from height) and those that have undergone positive-pressure ventilation have increased risk for pneumothorax and may require thoracocentesis
- May also be used in the evaluation of smaller volume pleural effusions that are not causing significant clinical signs (diagnostic only; generally more challenging and greater risk of iatrogenic lung laceration)

CONTRAINDICATIONS

Severe coagulopathy; fractious behavior

EQUIPMENT, ANESTHESIA

- Clippers
- Antiseptic scrub (e.g., chlorhexidine)
- Sterile gloves
- Large syringe (10-60 ml, depending on size of animal)
- Three-way stopcock
- Sterile extension tubing and a sterile needle, catheter, or butterfly catheter:
  - Large dogs: 1frac12;-inch (4-cm) needle or longer catheter, 18-22 gauge
  - Medium dogs, large cats: 1-inch (2.5-cm) needle or catheter, 20-22 gauge
  - Cats, small dogs: frac34;- to ⅞-inch (2- to 3.5-cm) butterfly needle, 22-23 gauge; 25-gauge needle can be used for diagnostic centesis.
- Bowl (for fluid)
- Red- and purple-top tubes for fluid sample submission
- Sedation may be needed depending on animal's disposition and stability.

THORACOCENTESIS Materials used for thoracocentesis for a cat or small dog. **A**, Sterile gloves. **B**, Butterfly-type catheter. **C**, Three-way stopcock. **D**, Large syringe. **E**, Bowl.

THORACOCENTESIS Thoracocentesis for removal of septic pleural effusion from a Chihuahua. A butterfly catheter with three-way stopcock and a 60-mL syringe are in use. The entry site is at the right seventh or eighth intercostal space, approximately at the level of the costochondral junction. An open muzzle is placed loosely for protection of staff without compromising the animal's respirations.

ANTICIPATED TIME

Procedure is relatively fast (<5 minutes) although can be prolonged (45-60 minutes) if a large amount of fluid or air (i.e., several liters) must be removed or if effusion is viscous, contains fibrin clumps or blood clots, or is compartmentalized.

PREPARATION: IMPORTANT CHECKPOINTS

- If the patient is in severe respiratory distress and has dull lung sounds on auscultation, thoracocentesis should be performed prior to thoracic radiographs.
- In cases where respiratory signs are less severe, thoracic radiographs can be used for confirming the presence of fluid or air in the pleural space prior to thoracocentesis.
- Discuss possible complications with owners.
- Rule out coagulopathy as likely cause of respiratory signs first (from history, physical examination, ± coagulation screening).
- Prepare equipment and supplies.
- Be able to keep animal relatively still, either with restraint or sedation, to minimize risk of iatrogenic pneumothorax or hemothorax.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Iatrogenic pneumothorax
- Intrathoracic hemorrhage
- Reexpansion pulmonary edema in situations of chronic pleural space disease
- Acute death from stress of restraint in animals with severe respiratory com promise

PROCEDURE

- Position animal, preferably in sternal recumbency or standing, but lateral recumbency is also acceptable for pneumothorax.
- Have assistant available to restrain animal or give sedation as needed:
    - Consider brief, quiet rest in oxygen cage if patient is anxious and extremely dyspneic (any restraint or sedation appears hazardous).
    - With mild or no dyspnea, butorphanol, 0.05-0.1 mg/kg IV may be used for light sedation; protocols for heavy sedation or anesthesia (e.g., propofol) will likely require intubation.
- Clip and aseptically prepare appropriate rib space:
    - If expecting fluid or if unsure (fluid versus air), clip at the seventh or eighth intercostal space (ICS), about at the level of the costochondral junction.
    - If expecting air, clip at the eighth or ninth ICS space, approximately one-third of the way down the chest.
- Wear sterile gloves for the insertion of the appropriate-size needle or butterfly catheter.
- Attach needle to syringe.
- Insert needle slowly, bevel side up, just cranial to the rib to avoid intercostal blood vessels. When through skin (beveled edge of needle is no longer visible), begin aspirating with a few tenths of 1 mL of negative pressure for a cat or small dog to 1-2 mL

of negative pressure for larger patients, respectively.

- Observe hub of needle for signs of fluid ("flashback"):
  - If a small amount of frank blood is aspirated or if lungs can be felt rubbing against needle, needle should be moved to a different location.
  - If large amount of blood is obtained, place 1-2 mL in a red-top tube to see if it clots.
  - Blood from hemothorax should not clot, whereas blood from the heart or a blood vessel should clot normally if the animal does not have significant coagulopathy.
- For any other fluid, aspiration should continue until no more fluid can be removed.
- Directing the needle ventrally, rolling the animal slightly to the side on which thoracocentesis is being performed, and reaspirating from a more ventral location can facilitate removal of as much fluid as possible.
- Ultrasound guidance can be beneficial in finding small fluid pockets for diagnostic thoracocentesis.
- Fluid is submitted for fluid analysis and cytologic examination and is saved for future bacterial culture and sensitivity (C&S) (aerobic, anaerobic) if cytologic examination suggests septic exudate.
- Aspiration of air will turn the tubing a slightly foggy white color as the warm air from the thoracic cavity encounters the room temperature tubing:
  - Aspirate until negative pressure is reached.
  - If negative pressure is never obtained, a tension pneumothorax may be present, and chest tubes with continuous suction are needed (see p. 1230).

POSTPROCEDURE

Monitor for returning signs of respiratory distress: could represent return of underlying pleural disease or iatrogenic pneumothorax or hemothorax.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Chest tube placement: continuous removal of fluid and air but is more invasive and is associated with a greater risk of iatrogenic complications.
- Diuretics: slow mobilization of modified transudates (e.g., heart failure) compared to thoracocentesis and ineffective with other causes (e.g., exudates, hemorrhage).

Urethrogram

SYNONYM

Retrograde urethrogram

OVERVIEW AND GOALS

- The urethra cannot be seen on survey radiographs; therefore, a positive-contrast examination is necessary for radiographic evaluation.
- Ultrasound can be used for seeing small portions of the urethra in the male; however, adequate diagnostic imaging of the entire urethra requires radiographic assessment with the injection of water-soluble organic iodide contrast material.
- A simple urethrogram is quick and easy to perform.
- A vaginocystourethrogram is usually performed in the female because of the difficulty of catheterizing the female urethra.

INDICATIONS

- Clinical signs:
  - Dysuria, stranguria
  - Difficulty catheterizing, urethral obstruction
  - Trauma to pelvis or os penis
  - Hematuria in a voided or catheterized urine sample but normal urine on cystocentesis
  - Hemorrhagic preputial discharge with a normal penile/preputial physical exam
- Differential diagnosis:
  - Urethral calculi (especially important with radiolucent calculi)
  - Urethral tear/rupture
  - Urethral stricture
  - Iatrogenic urethral trauma
  - Urethral neoplasia
  - Urethral fistula
  - Other urethral mucosal abnormalities
  - Penile or extrapelvic urethral disease
  - Congenital anomalies
  - Postoperative evaluation of urethra to assess patency and completeness of healing (prostatic disease with communication with urethra)
  - Evaluation of perineal or caudal abdominal masses

EQUIPMENT, ANESTHESIA

- Heavy sedation is often all that is needed to perform the study in male dogs. General anesthesia can be used if necessary. The male cat should be under general anesthesia for the study.
- Mild surgical scrub solution and gauze/sponges for disinfecting the penis prior to catheterization
- Urinary catheter (preferably with inflatable bulb), such as a Foley catheter
- Iodinated contrast medium (sodium iothalamate, sodium diatrizoate) or low-osmolar, nonionic, water-soluble iodines such as iohexol or iopamidol (180-300 mg iodine/mL most common) can be used.
- Sterile lubricating jelly
- Sterile syringe for contrast (e.g., 12 mL)
- Sterile syringe for inflating the catheter bulb.
- Sterile catheter adapter (Christmas-tree type)
- Sterile three-way stopcock
- Sterile saline
- Sterile gloves
- Enema bag/set
- Open-ended Tomcat catheter (e.g., 3.5 Fr) used for male cats

ANTICIPATED TIME

Approximately 20 to 30 minutes

PREPARATION: IMPORTANT CHECKPOINTS

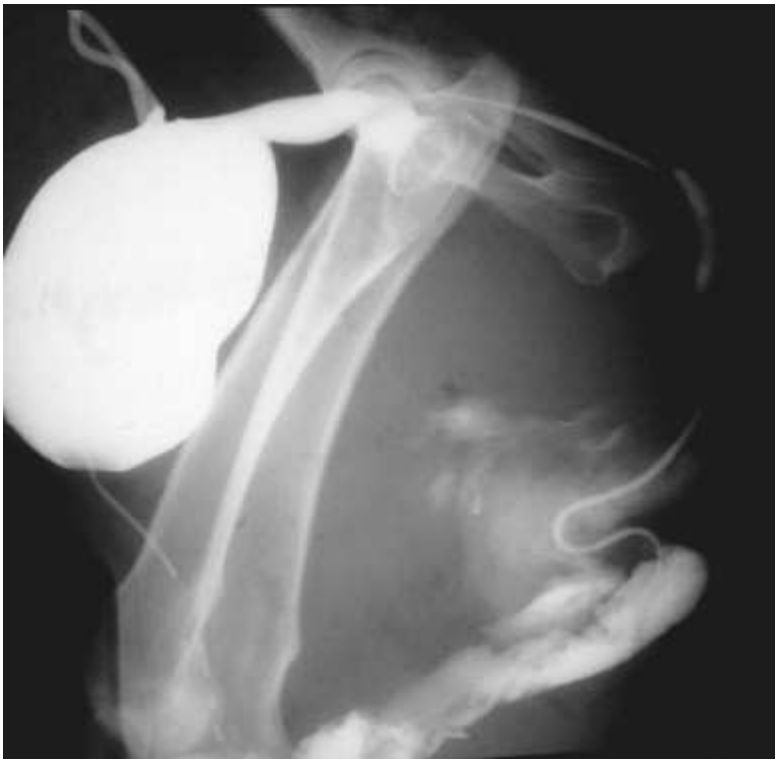
URETHROGRAM Normal male urethrogram (lateral view, cranial to left). Small air bubbles are seen in the pelvic urethra and distal urethra *(small arrow)*, and the inflated bulb of the Foley catheter is also seen *(large arrow)*.

- An enema is given approximately 2 hours prior to the study to ensure the removal of fecal material from the colon. Fecal material may compromise visualization of the urethra.
- Dilute organic iodinated contrast media to 50% solution with sterile saline.
- Sterile gloves should be worn from this point forward in the preparation.
- Draw 12 mL of diluted contrast material into the 12-mL syringe.
- Remove Foley catheter from packaging in a sterile manner, and remove guide wire.
- Attach catheter adapter (Christmas tree) to the open port (lumen) of the Foley catheter.
- Attach three-way stopcock to catheter adapter.
- Load syringe with air for inflating cuff later by drawing appropriate amount of air into the syringe (based on recommendation of Foley bulb size).
- Test integrity of the bulb.
    - Attach syringe containing air to side port (going to bulb, not the catheter lumen).
    - Infuse air into the bulb, filling it to the recommended level to ensure bulb is intact, and hold for a few seconds (test inflation).
    - Once it is clear the bulb will hold air, withdraw the air from the bulb back into the syringe.
- Attach syringe filled with contrast material onto the three-way stopcock, and fill the Foley catheter with contrast material. If this step is bypassed, air bubbles will be injected, resulting in a suboptimal study.
- Close the stopcock to the contrast material.
- In male cats, a sterile Tomcat catheter is used. Diluted contrast material is drawn into the syringe, and the syringe is attached directly to the catheter.

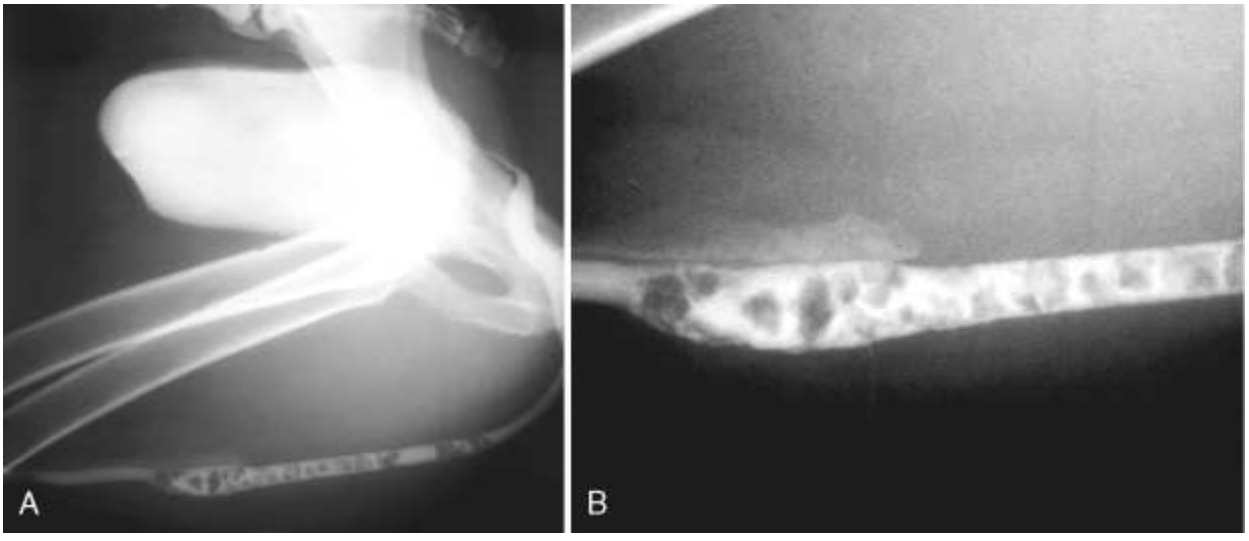
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Trauma due to overdistention of the cuff.
- Rupture of the urethra; forceful injection when the urethra is obstructed can lead to urethral rupture.
- Mild transient submucosal hemorrhage secondary to balloon (try not to leave urethral catheter in place longer than 15 minutes [urethral trauma caused by local ischemia and mechanical trauma]).

- Urinary bladder-associated complications (hemorrhagic cystitis, catheter kinking or knotting in the bladder lumen, pulmonary air embolism, bladder rupture secondary to overdistention of the bladder) are extremely rare because the catheter remains in distal urethra.
- Bacterial contamination
- False results: catheter in too far (past lesion site), too little contrast, air bubbles
- Contrast media reactions (absorbed systemically though mucosa)
- Anaphylactic reactions: very rare



URETHROGRAM Male dog with urethral rupture (lateral view, cranial to left). Contrast material has leaked widely throughout the soft tissues of the prepuce as a result of the ruptured urethra (bottom right of image).



URETHROGRAM A, Male dog with urethroliths (lateral view, cranial to upper left). **B**, Zoomed view, showing multiple urethroliths.

PROCEDURE

- Preliminary caudal abdominal radiographs (lateral and oblique ventrodorsal) are made to set radiographic technique and ensure adequate preparation of the animal.
- The kilovoltage peak should be set between 65 and 75 to maximize contrast due to the photoelectric effect (K-edge of iodine).
- The animal should be placed in left lateral recumbency (to reduce the risk of air embolism going to the lungs).

- An assistant should then extrude the penis from the prepuce.
- The penis should be prepped with a mild surgical scrub solution.
- Sterile lubricating jelly is placed onto the tip of the Foley catheter.
- Insert Foley catheter into the distal urethra until the bulb can no longer be seen, but no further; the procedure is conducted with the catheter inserted into the urethra a very short distance to avoid passing beyond the site of the lesion.
- Inject air into bulb to inflate bulb, and then close the stopcock to maintain inflation. A suitable volume of air should meet little resistance and yet should provide enough of a seal to prevent backflow of contrast out the urethra during injection.
- Tug very lightly on the catheter to ensure the bulb seal is tight, and adjust bulb inflation (increase or decrease) accordingly.
- With the animal's hind limbs pulled forward to allow an unobstructed radiographic projection of the urethra, inject 12 mL of contrast material rapidly into the urethral catheter. Note: The contrast material should flow smoothly and with no resistance; if resistance is met, stop the injection and make the radiographic exposure.
- Make radiographic exposure just before the end of injection.
- Close the stopcock to the syringe that contained the contrast material, and remove syringe.
- Refill syringe with diluted contrast material in preparation for second injection, and reattach syringe to stopcock; open stopcock to allow contrast flow.
- Place animal in an oblique ventrodorsal position, and inject 12 mL of contrast rapidly. Note: Here again, the contrast material should flow smoothly and with no resistance; if resistance is met, stop the injection, and make the radiographic exposure.
- Make radiographic exposure just before the end of injection.
- For male cats, the animal preparation and survey radiographs are the same as the dog. The penis is extruded and prepped, a lubricated Tomcat catheter is placed just inside the distal urethra, and contrast material is injected.

POSTPROCEDURE

- Once the study is complete, the air should be removed from the Foley bulb before the catheter is withdrawn from the penis.
- If general anesthesia was used: routine anesthetic recovery.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Plain abdominal radiographs: inexpensive means to survey the urethra for radiopaque urethral calculi. Otherwise, contrast medium is needed to visualize the urethra and most of its associated lesions.
- Abdominal ultrasound: can be used for assessing a portion of the urethra; however, ultrasound should only be used in certain instances (e.g., proximal urethral disorders).

AUTHOR: LEEANN PACK

Urethral Obstruction (Feline): Medical Management

OVERVIEW AND GOALS

Complete urethral obstruction is a potentially life-threatening event, culminating in death from uremia within 2-5 days if untreated. Although most causes for urethral obstruction are intraluminal (e.g., urethral plugs, urethroliths, foreign material), mural (e.g., tumors, urethral strictures) and extramural causes (e.g., pelvic fractures, iatrogenic urethral ligation) result in identical clinical consequences.

INDICATIONS

- Matrix-crystalline urethral plugs (common)
- Urethroliths (common)
- Blood clots
- Intraurethral foreign bodies (i.e., buckshot)

EQUIPMENT, ANESTHESIA

- The type and degree of sedation/anesthesia vary depending on patient status and veterinarian's preference.
- Cardiovascular stabilization:
  - Heating pad
  - IV catheter
  - Lukewarm IV replacement fluids
  - Sodium bicarbonate
  - Insulin and glucose to manage hyperkalemia
  - Calcium gluconate to manage hyperkalemia; see p. 556.
- Decompressive cystocentesis:
  - Sterile 1½-inch, 22-gauge needle
  - IV extension tubing
  - Three-way stopcock
  - Several syringes (size: 3-20 mL)
- Retrograde urethral flushing:
  - Sterile isotonic nonirritating solutions (e.g., normal saline, lactated Ringer's solution)
  - Sterile open-ended catheter (e.g., Minnesota olive tip catheter)
  - IV extension tubing
  - Large syringe (12-35 mL)
  - Moistened gauze sponges
- Indwelling urinary catheter placement:
  - Nonabsorbable suture and needle holders
  - Soft, flexible, inert sterile urinary catheter
  - Elizabethan collar

ANTICIPATED TIME

About 20 minutes to 1 hour

PREPARATION: IMPORTANT CHECKPOINTS

- Ensure cardiovascular stabilization prior to general anesthesia or urethral flushing.
- Prevalence of potentially life-threatening abnormalities in cats with urethral obstruction:
  - Hypothermia (<100°F [37.8°C]) = 39%
  - Acidemia (pH <7.2) = 16%
  - Bradycardia (<149 bpm) = 12%
  - Hyperkalemia (>8 mEq/L) = 12%
  - Hypocalcemia (<0.8 mmol/L) = 6%-12%
- Inform owners of the possibility of urinary bladder rupture and guarded short-term prognosis with and without therapy.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Cats with urethral obstruction and cardiovascular collapse rarely show overt signs referable to the urinary system at the time of presentation. Therefore, assessment of urinary bladder size (i.e., palpation or medical imaging) is essential to avoid overlooking urethral obstruction as the primary cause for cardiovascular or respiratory distress.
- Survey radiography is essential to verify, localize, and search for the underlying cause of obstruction; radiographs should be performed early in the diagnostic process prior to initiation of therapy. Nonobstructed dysuric cats usually have small urinary bladders.
- Unsuccessful transurethral insertion of urinary catheters is an unreliable and sometimes unsafe (i.e., urethral tear, rupture, and subsequent stricture) method of confirming and localizing urethral obstruction.
- Caustic, strongly acidic flushing solutions are contraindicated.

PROCEDURE

- Sedate or anesthetize the patient.
- To fragment urethral plugs, gently massage the distal urethra and cautiously compress the urinary bladder with the goal of promoting expulsion of plugs. This is easy to perform but not commonly effective.
- Decompressive cystocentesis:
    - Attach a 1½-inch, 22-gauge needle, IV extension tubing, and a three-way stopcock. Then use a large-volume syringe (20-35 mL) to remove urine from bladder inserting the needle at the center of the bladder with the needle directed obliquely (caudodorsally).
    - By using the IV extension tubing and three-way stopcock between the needle and syringe, the urinary bladder will not have to be repunctured to empty a syringe full of urine.
    - Excessive digital pressure should not be applied to the bladder wall while the needle is in the lumen, to prevent urine from being forced around the needle into the peritoneal cavity.
    - Attempting complete evacuation of the bladder lumen is undesirable, because the sharp point of the needle may then damage the bladder wall; the authors recommend that 5-15 mL of urine remain in the bladder.
    - Properly performed cystocentesis should not contribute to bladder rupture. Any excessive manipulation of a devitalized, overdistended bladder wall may promote rupture.
    - Advantages of decompressive cystocentesis:
        - Obtaining urine sample for analysis and culture
        - Temporarily halting the adverse effects of obstruction
        - Reducing intraluminal bladder pressure to facilitate retropulsion
        - Reducing pain associated with bladder overdistention
    - Disadvantages of decompressive cystocentesis:
        - Potential extravasation of urine into peritoneal cavity
        - Bladder wall trauma
- Flushing plug contents out the external urethral orifice:
    - Attach open-ended catheter, IV extension tubing, and large (35-mL) fluid-filled syringe in that order. Displace air in the tubing by filling tubing and catheter with fluid from the syringe prior to insertion in the urethra.
    - Insert tip of catheter into distal urethral opening.
    - Flush a large quantity of sterile isotonic solution into the urethral lumen, allowing it to reflux out the external urethral orifice.
    - Subsequent application of steady but gentle digital pressure to the bladder wall may result in expulsion of a urethral plug.
- Retrograde urethral flushing (to propel intraluminal contents into urinary bladder):
    - Attach open-ended catheter, IV extension tubing, and fluid-filled syringe (3-20 mL) in that order. Displace air in the tubing by filling tubing and catheter with fluid from the syringe prior to insertion in the urethra.
    - Insert tip of catheter into distal urethral opening.
    - With a moistened gauze sponge, occlude the distal urethra around the catheter.
    - Pull the penile urethra caudally to extend it parallel to the vertebral column.
    - Flush fluid vigorously by emptying syringe.
    - Repeat urethral flushing if needed while also remembering to repeat decompressive cystocentesis if bladder lumen becomes distended with flushing solution.
    - The greatest pressure to retrograde hydropropulse is achieved with the smallest syringe.

URETHRAL OBSTRUCTION (FELINE): MEDICAL MANAGEMENT Assembled catheter, IV extension tubing, and syringe to facilitate removing obstruction in the urethra of cats.

POSTPROCEDURE

In some cases, radiographs are indicated to verify return of uroliths into urinary bladder.

INDWELLING TRANSURETHRAL CATHETERS

- Not always indicated
- When indicated, 3 Fr or 5 Fr flexible feeding tubes composed of material that minimizes foreign body inflammatory response are preferred.
- To minimize urethral trauma, avoid open-end catheters with sharp stylets.
- Indications:
    - Inadequate/poor urine stream following urethral flushing:
        - Urethral spasm/swelling (~1-3 days)
        - Excessive urinary precipitates (~1-2 days)
    - Assist correction of postrenal azotemia (~1-2 days).
    - Promote recovery of detrusor contractility (~1-5 days).
    - Promote repair of urothelial urethral tear (~3-10 days).
- Care and management:
    - Place as atraumatically and cleanly as possible.
    - Maintain a closed collection system.
    - Remove indwelling catheters as soon as possible.
    - If urine is initially sterile, avoid antimicrobial therapy until catheter is removed.
    - If urine is initially infected, treat the infection (see p. 276).
    - Treat potentially life-threatening infections.
    - Do not give the cat corticosteroids.
- Pain medication (buprenorphine, butorphanol, etc.) is indicated for a short duration (1-4 days). Nonsteroidal antiinflammatory drugs (NSAIDs) are contraindicated in cats with compromised renal function or dehydration.
- Prevent negative fluid balance associated with postobstructive diuresis by giving parenteral fluids.
- Not recommended: routine use of urethral smooth-muscle relaxants (e.g., phenoxybenzamine, prazosin), urethral antispasmodics (e.g., propantheline, oxybutynin), and parasympathomimetics (e.g., bethanechol) following urethral manipulation. The efficacy of these agents has not been established by properly controlled clinical trials.

URETHRAL OBSTRUCTION (FELINE): MEDICAL MANAGEMENT Perineum of an anesthetized cat undergoing medical management of urethral obstruction. Cat is in dorsal recumbency; cranial is to right of photo. Occluding the distal urethra around the catheter and pulling the urethra caudally and dorsally to displace urethral kinking will facilitate retrograde flushing of plugs and stones into the urinary bladder.

ALTERNATIVES AND THEIR RELATIVE MERITS

Urethrostomy may be indicated if obstruction cannot be corrected. Contrast urethrography is indicated to localize the site(s) of obstruction and to select the location of surgery.

AUTHORS: JODY P. LULICH, CARL A. OSBORNE

Urethral Obstruction (Canine): Medical Management

OVERVIEW AND GOALS

Complete urethral obstruction is a potentially life-threatening event, culminating in death from uremia within 2-5 days if untreated. Although most causes for urethral obstruction are intraluminal (e.g., urethroliths, foreign material, urethral plugs), mural (e.g., tumors, urethral strictures) and extramural causes (e.g., pelvic fractures, iatrogenic urethral ligation) and functional disorders (e.g., detrusorsphincter dyssynergia) result in identical clinical consequences.

INDICATIONS

- Urethroliths (common)
- Urethral/prostatic neoplasia
- Blood clots
- Intraurethral foreign bodies
- Matrix-crystalline urethral plugs (uncommon)

EQUIPMENT, ANESTHESIA

The type and degree of sedation/anesthesia varies depending on patient status and veterinarian's preference.

- Cardiovascular stabilization:
  - Heating pad
  - IV catheter
  - Warm IV replacement fluids
  - Sodium bicarbonate
- Decompressive cystocentesis:
  - A sterile 1½-inch, 22-gauge needle
  - IV extension tubing
  - Three-way stopcock
  - Large syringe (20-60 mL)
- Retrograde urethral flushing:
  - Sterile isotonic nonirritating solutions (e.g., normal saline, lactated Ringer's solution)
  - Long, flexible large-bore sterile catheter (e.g., 8 Fr, 22-inch red rubber feeding tubes)
  - Large sterile syringe (12-60 mL)
  - Moistened gauze sponges
- Indwelling catheter placement:
  - Nonabsorbable suture and needle holders
  - Soft, flexible, inert sterile urinary catheter

ANTICIPATED TIME

About 20 minutes to 1 hour

PREPARATION: IMPORTANT CHECKPOINTS

- Inform owners of the possibility of urinary bladder rupture and guarded short-term prognosis with and without therapy.
- Inform owners that in many cases, surgery or lithotripsy will be needed to correct intraluminal causes for obstruction; urethral stenting may be needed to manage mural and extramural neoplasia

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Survey radiography is essential to verify, localize, and search for the underlying cause of obstruction. Therefore, radiographs should be obtained early in the diagnostic process prior to initiation of therapy.
- Unsuccessful transurethral insertion and passage of urinary catheters is an unreliable and sometimes unsafe (i.e., urethral tear, rupture, and subsequent stricture) method of confirming and localizing urethral obstruction.

PROCEDURE

- Sedate or anesthetize animal.
- Decompressive cystocentesis:
  - Attach a 1.5-inch, 22-gauge needle, IV extension tubing, and three-way stopcock; then use a large-volume syringe (20-60 mL) to remove urine from bladder, entering at the center of the bladder with the needle directed obliquely (caudodorsally).
  - By using the IV extension tubing and three-way stopcock between the needle and syringe, the urinary bladder will not have to be repunctured to empty a syringe full of urine.
  - Excessive digital pressure should not be applied to the bladder wall while the needle is in the lumen, to prevent urine from being forced around the needle into the peritoneal cavity.
  - Attempting complete evacuation of the bladder lumen is undesirable because the sharp point of the needle may then damage the bladder wall. We recommend that 10-15 mL of urine remain in the bladder.
  - Cystocentesis should not contribute to bladder rupture. Excessive manipulation of a devitalized, overdistended bladder is usually the cause of bladder rupture.
  - Advantages:
    - Obtaining a pretreatment urine sample for analysis and culture
    - Temporarily halting the adverse metabolic consequences of obstruction
    - Reducing intraluminal bladder pressure to facilitate retropulsion
    - Reducing pain associated with bladder overdistention
  - Disadvantages:
    - Potential extravasation of urine into peritoneal cavity
    - Bladder wall trauma
- Retrograde urethral flushing:
  - Lubricate around the urethroliths:
    - Fill one 12-mL syringe with 5 mL of saline and another 12-mL syringe with 5 mL of sterile water-soluble lubricant.
    - Attach these two syringes with a three-way stopcock.
    - Mix the contents of both syringes by emptying one syringe into the other several times.
    - After inserting a urethral catheter, inject 3-8 mL of mixture to lubricate around uroliths.
    - This step is not always necessary.
  - Insert a lubricated large-bore flexible catheter into the distal urethra. The tip of the catheter should remain distal to urethroliths.
  - Occlude pelvic urethra proximal to urethroliths: insert a gloved index finger into the rectum, and occlude the urethral lumen by compressing the urethra against the floor of the bony pelvis.
  - Occlude distal urethra: with a moistened gauze sponge, occlude the distal urethra by compressing the distal tip of penis around the catheter.
  - Forcefully flush fluid through catheter:
    - Fill a large syringe (20-60 mL) with sterile isotonic solution (e.g., saline, lactated Ringer's solution, etc.). The normal bladder holds approximately 7-11 mL/kg of the patient's weight.
    - With the syringe attached to the catheter, turn it upside down, and place the top of the plunger against the tabletop.
    - Hold the syringe by the barrel, and forcefully push it down over the plunger with the goal of rapidly and forcefully emptying the syringe and subsequently dilating the urethral lumen with saline.
  - Relieve occlusion of pelvic urethra: once the urethra becomes dilated, digital pressure applied to the pelvic urethra (but not the penile urethra) should be rapidly released.
  - Continue flushing:
    - Continue flushing fluid through the catheter and urethral lumen to propel urethroliths into the urinary bladder. Use caution not to over-distend the bladder lumen with saline.
    - If the technique is repeated, accumulation of saline in the bladder lumen necessitates repeating decompressive cystocentesis.
  - To perform this technique in female dogs, insert the index finger into the vagina, and apply digital pressure and occlude the distal urethra over the catheter at the urethral papilla. Inserting the index finger in the rectum and applying digital pressure over the catheter in the pelvic urethra can also achieve distal urethral occlusion.

POSTPROCEDURE

- Medical imaging:
  - Radiography provides an appropriate method of assessing whether all radiopaque uroliths have been flushed into the bladder lumen.
  - Transurethral catheterization is not a reliable method of verifying that all uroliths have been flushed out of the urethra.
- Pain medication (i.e., butorphanol, hydromorphone, etc.) is indicated for a short duration (1-2 days). Nonsteroidal antiinflammatory drugs (NSAIDs) are contraindicated in animals with compromised renal function or dehydration.
- Prevent negative fluid balance associated with postobstructive diuresis by administering parenteral fluids.

ALTERNATIVES AND THEIR RELATIVE MERITS

To minimize surgical disfigurement of the urethra (e.g., urethrotomy, urethrostomy), consider lithotripsy to shatter obstructing urethroliths if retrograde urohydropropulsion is not successful.

AUTHORS: JODY P. LULICH, CARL A. OSBORNE

Upper Gastrointestinal Radiographic Contrast Series

SYNONYMS

Barium series, UGI

OVERVIEW AND GOALS

- To identify abnormalities of the stomach and/or small intestinal tract. Morphologic and/or functional abnormalities may be identified.
- The upper gastrointestinal (UGI) radiographic contrast series is most commonly performed using barium, which gives the best mucosal detail and therefore the best evaluation of morphology. The study may be performed with an iodinated contrast agent; these do not give good mucosal detail and are most useful for evaluating gastrointestinal (GI) integrity and patency.

INDICATIONS

- Severe or protracted vomiting
- Hematemesis or melena
- Abdominal pain
- Abnormalities of survey radiographs requiring further investigation
- Determine location of GI structures (i.e., herniation)

CONTRAINDICATIONS

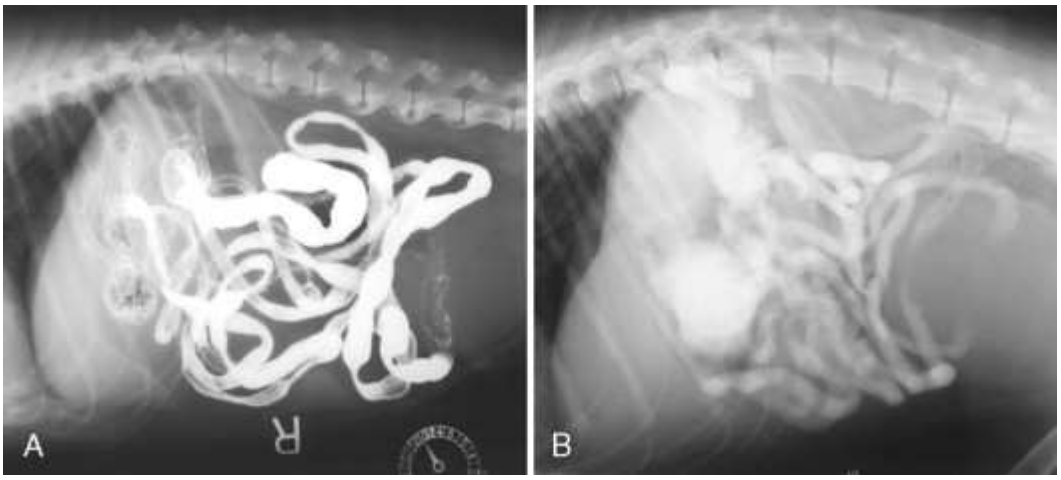
- Survey radiographic evidence of perforation:
  - If perforation is suspected, the study may be performed with an iodinated contrast agent; however, because of their relatively poor opacity, iodinated contrast agents may fail to demonstrate GI leakage.
- Survey radiographic evidence of obstruction:
  - Not an absolute contraindication, but the study is not needed for diagnosis.
- Projectile vomiting:
  - Not an absolute contraindication, but the risks involved in performing the study may outweigh the potential benefits.

EQUIPMENT, ANESTHESIA

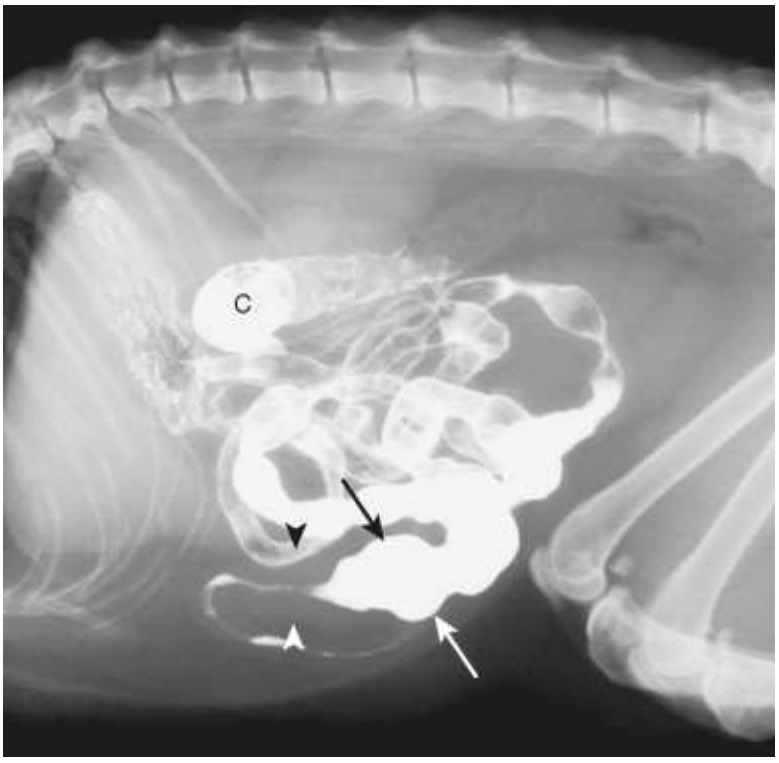
- Contrast agent:
  - Liquid barium (30% weight/volume):
    - 10 mL/kg PO
    - In very obese patients, it may be preferable to dose for desired/lean body weight, not actual weight.
  - Ionic iodinated contrast agent:
    - Gastrografin/Renografin: 2-7 mL/kg PO; total dose not to exceed 50 mL
    - Gastrografin is a contrast agent that was marketed for oral use only; this product is no longer available. Renografin is a contrast agent used for IV injection and may be given orally instead of Gastrografin.
  - Nonionic iodinated contrast agent:
    - Iohexol (Omnipaque):
      - 10 mL/kg PO of diluted iohexol (240-875 mg I/mL, diluted 1:1 to 1:3 with tap water)
      - The greater the iodine concentration of the iohexol, the better the mucosal detail.
      - Administration of undiluted iohexol causes vomiting.
- Syringes for contrast administration
- Orogastric tube of the appropriate size
- X-ray unit
- Protective clothing (lead aprons, gloves, thyroid shields) for personnel
- Paper towels or similar material for cleanup of barium on animal and x-ray table
- Drugs for restraint (used only if absolutely necessary). The following agents have been shown to have the least effect on motility and should be used if a motility disorder is suspected. The effect on gastrointestinal motility of other newer sedative drugs has not been proven, so these agents cannot be recommended:
  - Dogs: acepromazine, 0.055-0.1 mg/kg IV; avoid if animal is elderly or systemically ill.
  - Cats: midazolam, 0.44 mg/kg; ketamine, 13.2 mg/kg:
    - These drugs are given in separate syringes IM approximately 20 minutes prior to the procedure. If a motility abnormality is not of concern (i.e., determining if obstruction is present), the following combination is recommended for cats; this will give better and more consistent restraint than the midazolam/ketamine combination. The following drugs are also given IM approximately 20 minutes prior to the procedure and

should be avoided if animal is elderly or systemically ill:

- Acepromazine, 0.22 mg/kg
- Ketamine, 13.2 mg/kg



UPPER GASTROINTESTINAL RADIOGRAPHIC CONTRAST SERIES A, Right lateral radiograph obtained 30 minutes after administration of liquid barium. Note high opacity of contrast agent and good mucosal detail. **B**, Right lateral radiograph obtained 30 minutes after administration of iohexol. Contrast agent is much less opaque, and mucosal surface is poorly defined.



UPPER GASTROINTESTINAL RADIOGRAPHIC CONTRAST SERIES Right lateral radiograph obtained 2 hours after administration of liquid barium. Distended segment of small intestine *(arrows)* suddenly narrows at an area of intramural thickening *(arrowheads)* caused by a circumferential soft-tissue mass in this cat. Barium is present in cecum (C), indicating bowel is patent.

ANTICIPATED TIME

- About 6 hours to complete the study (barium); actual time spent performing the study is approximately 1.5 hours.
- About 2-3 hours to complete the study (iodinated contrast agents); actual time spent performing the study is approximately 1 hour.
- ± Additional film at 24 hours post contrast administration

PREPARATION: IMPORTANT CHECKPOINTS

Empty GI tract (see Common Errors, below):

- Fasting to empty the stomach
- Remove excess fluid from stomach via tube if present
- Enema: only if colon is very full

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

Complications:

- Vomiting and aspiration of barium: if the animal has projectile vomiting and/or radiographic evidence of severe gastric fluid retention, the risks involved in performing the UGI radiographic contrast series may outweigh the potential benefits.
- Aspiration of iodinated contrast agents: ionic iodinated contrast agents can cause severe (and fatal) pulmonary edema if aspirated. These agents should be administered only via orogastric intubation.

Common errors:

- Administration of too low a volume of barium:
  - This is the most common technical error in this study (occurs more often than administration of the proper volume of barium)
  - Accurate evaluation of gastric emptying time is not possible, and full distension of the intestinal segments is not achieved if the volume of barium is too low. This can lead to serious misinterpretation of the study.
- Failure to empty the stomach of food prior to administration of barium:
  - The presence of food in the stomach makes accurate assessment of gastric emptying time impossible.
- Administration of barium prior to abdominal ultrasound or endoscopy may interfere with visualization; however, sequence of testing may make this unavoidable.

PROCEDURE

- Obtain survey (plain) right lateral and ventrodorsal radiographs of the abdomen.
- Administer contrast:
  - Barium dosage: 10 mL/kg PO. If too low a volume of barium is used, artifactual delayed gastric emptying can occur and distension of the intestinal segments will not be achieved. Administration via orogastric tube is preferred, but barium may be administered per os; *or*
  - Iodinated contrast agent: Gastrografin/Renografin, 2-7 mL/kg PO, with total dose not to exceed 50 mL; *or* iohexol, 10 mL/kg PO of diluted iohexol (240-875 mg I/mL diluted 1:1 to 1:3). Administration via orogastric tube is necessary with the use of ionic iodinated agents (to avoid aspiration); administration via orogastric tube is preferred with the use of nonionic iodinated contrast agents.
  - Obtain films:
    - Film sequence and views for barium. This sequence is a routine timetable. The timing of films can be altered as the study progresses, based on what is found in the study:
      - Immediate: right and left lateral, ventrodorsal and dorsoventral
        - The dorsoventral view provides better evaluation of the body and pyloric region of the stomach and it is important to obtain this view in the immediate film series. However, it can be difficult to position the patient for a dorsoventral view, and ventrodorsal views are preferred for the remainder of the film series.
      - 30 minutes: right lateral and ventrodorsal
      - 60 minutes: right lateral and ventrodorsal
      - 90 minutes: right lateral and ventrodorsal
      - 3 hours: right lateral and ventrodorsal
      - 5 hours: right lateral and ventrodorsal
      - ± 24 hours: right lateral and ventrodorsal
    - Film sequence and views for iodinated contrast agents. This sequence is a routine timetable. The timing of films can be altered as the study progresses, based on what is found in the study:
      - Immediate: right and left lateral, ventrodorsal and dorsoventral:
        - The dorsoventral view provides better evaluation of the body and pyloric region of the stomach, and it is important to obtain this view in the immediate film series. However, it can be difficult to position the patient for a dorsoventral view, and ventrodorsal views are preferred for the remainder of the film series.
      - 15 minutes: right lateral and ventrodorsal
      - 30 minutes: right lateral and ventrodorsal
      - 60 minutes: right lateral and ventrodorsal
      - 2 hours: right lateral and ventrodorsal
- By definition, the UGI radiographic contrast series is considered to be complete when contrast has both emptied from the

stomach and has entered the large intestine.
- Films may be taken beyond this point if an abnormality has been noted during the examination. For example, in an animal with retention of barium in the stomach, the UGI radiographic contrast series should be continued until the stomach empties or an abnormality to account for the barium retention is noted.
- If an abnormality (i.e., obstruction) is identified, the study is considered to be complete even if barium is still present in the stomach and/or has not entered the large intestine.

POSTPROCEDURE

- There are no postprocedure considerations for a routine UGI radiographic contrast series other than informing the client that stools may have a paler color for several defecations after the procedure.
- The findings of the UGI radiographic contrast series may lead to an additional diagnostic test such as exploratory laparotomy or endoscopy.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Endoscopy:
  - Endoscopy allows visualization of the mucosal surface of the stomach and duodenum and allows tissue biopsies to be performed.
  - However, endoscopy does not evaluate the entire small-intestinal tract and requires the use of general anesthesia.
- Abdominal ultrasonography:
  - Ultrasonography is rapid and noninvasive and does not involve ionizing radiation.
  - However, ultrasonographic evaluation of the GI tract can be severely limited by gas in the tract. Interpretation of ultrasound images of the GI tract requires an experienced sonographer, and many GI disease processes do not cause significant changes in the ultrasonographic appearance of the intestine.
- Exploratory laparotomy:
  - Allows assessment of the entire length of the GI tract and full-thickness gastric and intestinal biopsies. However, general anesthesia, invasiveness, and recovery/incision healing time make laparotomy a second-order diagnostic modality after lesser invasive evaluations such as plain radiography, UGI radiographic contrast series, ultrasonography, and/or endoscopy.

Vomiting, Induction of

SYNONYM

Emesis, induction of

OVERVIEW AND GOAL

Deliberate induction of vomiting for elimination of ingested noxious materials

INDICATIONS

Confirmed or suspected ingestion of toxic substance

CONTRAINDICATIONS

- Ingestion of alkaline toxic substances: risk of reflux esophagitis
- Ingestion of oily substances: risk of aspiration pneumonia
- Ingestion of sharp or pointed foreign bodies: risk of gastrointestinal (GI) tract perforation
- Ingestions having occurred too long in the past to be effectively offset by vomiting (time is dependent on substance ingested)
- Sedated, mentally depressed, or comatose animal: risk of aspiration pneumonia

EQUIPMENT, ANESTHESIA

- No anesthesia; the procedure is performed awake.
- 3% hydrogen peroxide (Note: Not 30% hydrogen peroxide used for hair bleaching)
- Sterile or nonsterile syringe
- Gastric gavage tube and oral speculum/mouth gag (rarely necessary)
- Alternative for dogs or cats: syrup of ipecac
- Alternative for cats: xylazine, 0.44 mg/kg IV, IM, or SQ single dose

ANTICIPATED TIME

About 5 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Identification of the ingested substance is essential. Note: Vomiting should not be induced unless a known substance was ingested or exam findings are indicative of such an ingestion (e.g., antifreeze on muzzle, lead pellets in stomach on radiograph).
- If the animal has not eaten recently, canned food corresponding to approximately half a meal can be fed prior to induction of emesis to avoid nonproductive vomiting/dry heaving. If no appetite, simply proceed with emesis.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Aspiration pneumonia: monitor for dyspnea, coughing, fever, and lethargy postemesis. If present, proceed to thoracic radiographs.
- Gastric irritation: common and usually benign
- Esophagitis: usually benign and self-resolving if secondary to vomiting induction alone; may be more serious (e.g., esophageal perforation or stricture) if caused by ingestion of corrosive substance or lacerating foreign body

PROCEDURE

- Calculate appropriate dose of emetic (choose one):
  - Hydrogen peroxide 3%: 0.25-0.5 mL/kg PO once
  - Syrup of ipecac: 2-6 mL total dose PO once
  - Xylazine: 0.44 mg/kg IV, IM, or SQ once (cats only)

- Note: 1 teaspoon = 5 mL; 1 tablespoon = 15 mL; 1 fluid ounce = 28 mL
- Administer once. For orals (hydrogen peroxide or ipecac), it is best to administer via cheek pouch:
    - With animal in sitting position, elevate animal's chin (mouth closed) so neck is extended.
    - Insert tip of syringe into canthus of lips on one side (corner of mouth), with mouth still closed.
    - Infuse peroxide or ipecac over several seconds, watching for swallowing motions.
    - If not swallowed (e.g., if entirely spit up), may redose once immediately.
    - If a syringe is not available, alternatives include plastic human dosing cups, turkey basters (large volumes of peroxide for big dogs), or teaspoons/tablespoons.
- Vomiting should occur within 5-10 minutes; if not, repeat.
- The patient must not have his/her head raised and should not be wearing a muzzle when vomiting is expected; either of these factors would greatly increase the risk of aspiration pneumonia.

POSTPROCEDURE

- Oral emetics: may administer a total of three doses
- Persistent vomiting usually subsides in 15-30 minutes; otherwise, an anti-emetic may be given (very uncommon).
- Treatment for ulcerative gastritis (e.g., H2 blocker) may be instituted prophylactically.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Table salt for emesis: not recommended; risk of critical hypernatremia if emesis does not occur.
- Activated charcoal:
    - Reduces bioavailability of many overdosed drugs and toxic substances
    - Often coadministered 30 minutes after induction of emesis or instead of induction of emesis if vomiting is contraindicated
    - Minimal or no efficacy with corrosive alkalis, mineral acids, or petroleum distillates
- Gastric lavage:
    - Best approach if animal is unconscious (emesis contraindicated)
    - No proven benefit over induction of emesis in terms of efficacy of purging gastric ingesta

AUTHOR: ETIENNE CÔTÉ

Ventilation, Positive Pressure

SYNONYMS

Artificial ventilation, assisted ventilation, mechanical ventilation

OVERVIEW AND GOALS

- Positive-pressure ventilation (PPV) requires intensive 24-hour monitoring and nursing care but can be lifesaving.
- Owner communication and highly trained staff are essential.
- Manual PPV requires a person to manually deliver breaths continually to the animal.
- Mechanical PPV involves a machine that takes the place of the person to deliver breaths.
- Manual PPV is only practical for short-term use (up to several hours), whereas mechanical PPV is required for long-term cases (>6-12 hours).
- The objective of PPV is to maintain normal arterial oxygen (Pao2) and carbon dioxide pressure (PaCO2) until an underlying disease can be identified and treated.
- Therapeutic goal:
  - Pao2 is >60 mm Hg (minimum; >80 mm Hg preferred).
  - PacO2 is <50 mm Hg.
  - End-tidal CO2 is <50 mm Hg.
  - Arterial oxygen saturation (SaO2) is >90% (minimum; >96% preferred)
  - Measure Pao2 and PacO2 with arterial blood gases (ABGs); measure end-tidal CO2 with capnometry (inserted between endotracheal tube and breathing device) and oxygen saturation (SaO2) with pulse oximetry (attached to the tongue).
- Prognosis varies with underlying disease:
  - A reasonable goal is to discharge 25%-40% of mechanically ventilated cases.
  - Animals with ventilatory failure and normal lung function (i.e., opioid or barbiturate overdose, certain toxins, tick paralysis, botulism) have the best prognosis.

INDICATIONS

Early intervention has the greatest chance of success.

- Ventilatory failure: PacO2 is >50 mm Hg and pH is <7.3.
  - Some can be managed with short-term PPV (e.g., reversible opioid overdose).
- Respiratory failure: Pao2 is <50 mm Hg, or SaO2 is <88% despite supplemental oxygen.
  - Often requires >12 hours of PPV
- Animals with sustained extreme respiratory distress: increased work of breathing
  - Often requires >12 hours of PPV

CONTRAINDICATIONS

- Irreversible underlying disease
- Lack of trained personnel
- If >6-12 hours of PPV is anticipated, initiating manual PPV is questionable if mechanical PPV is not available.
- There should be a trained technician with the animal and a veterinarian on the premises around the clock.

EQUIPMENT, ANESTHESIA

- Intubation:
  - Animals can be ventilated via inflated endotracheal (seep. 1292) or tracheostomy (seep. 1344) tubes.
  - Low-pressure, high-volume cuffs are preferred.
  - Endotracheal intubation is more common owing to familiarity, ease of procedure, and minimal risk of tissue damage.
  - If PPV exceeds 24 hours or when heavy sedation is not desired, a tracheostomy may be preferred (allows some dogs to eat and drink).
- Sedation (IV, as needed; more common with endotracheal intubation); options include:
  - Pentobarbital: 2 mg/kg boluses to effect (up to 12 mg/kg) q 4-6 h or as needed to maintain sedation
  - Fentanyl: 5 mcg/kg boluses to effect up to 50 mcg/kg, then 5-7 mcg/kg/h constant-rate infusion (CRI) (can add diazepam)
  - Propofol: 2-8 mg/kg bolus to effect, then 0.1-0.3 mg/kg/min CRI
  - Close cardiovascular monitoring is required in animals under heavy sedation.

- Minimum recommended monitoring:
  - Vital signs
  - Level of consciousness
  - ABGs or pulse oximetry and end-tidal CO2
  - Arterial blood pressure (BP)
  - Continuous ECG
  - Volume of fluids in and out (urinary catheter)
  - Hematocrit, total solids, glucose, and urine specific gravity
  - Ventilator setting should be recorded every hour

MANUAL:

- Ambu bag and attached oxygen:
  - Inexpensive
  - Readily available
  - Pediatric-size bag most common (typically 450-950 mL volume)
  - Can be used without supplemental oxygen (not ideal)
  - Excellent for short-term use (i.e., during cardiopulmonary resuscitation [CPR])
  - Can add positive end-expiratory valves, which create positive end-expiratory pressure (PEEP) to recruit collapsed alveoli and improve oxygen exchange (typically in 0-10 cm or 0-20 cm H2O sizes)
  - Some Ambu bags have a removable safety valve that will open when a specific airway pressure is exceeded (typically 40 cm H2O).
  - Difficult to determine tidal volume and airway pressures delivered (vary with size and degree of manual pressure applied to the bag)
- Anesthesia machine with manual ventilation:
  - Readily available
  - Estimate tidal volume delivered with the size of the reservoir bag
  - Can monitor airway pressure with attached pressure gauge
  - Can apply adjustable PEEP valves (typically range from 0-40 cm H2O)

MECHANICAL:

- Anesthesia ventilators:
  - Limited choice of ventilator modes
  - Typically deliver only 100% inspired oxygen concentrations (Fio2)
  - Increased risk of oxygen toxicosis if ventilating > 12 hours
- Mechanical ventilators:
  - Allow greatest control over type of breath delivered (pressure, volume, flow rate, Fio2, respiratory rate, sensitivity to trigger a breath, and PEEP)
  - Supply humidified oxygen
  - Can be used for long-term care (days to weeks)
  - Relatively expensive

ANTICIPATED TIME

- It can take several minutes to set up mechanical ventilators.
- Initiate manual PPV (takes seconds to initiate) while mechanical ventilators are being set up.
- The overall duration of ventilation time varies with the underlying disease and animal's response.

PREPARATION: IMPORTANT CHECKPOINTS

- Ensure oxygen source, monitoring equipment, and suction devices are available.
- Nutritional support should be available for long-term cases.
- Pleural-space disease (pneumothorax, pleural effusion) should be identified and treated prior to ventilation.
- Perform thoracocentesis (see p. 1338) in suspected cases; untreated pleural space disease is associated with higher incidence of ventilatory complications.
- Check that valves on Ambu bag are functioning properly (not sticking) between uses.
- Check anesthetic machine and anesthesia ventilator, and check that mechanical ventilator tubing is correctly connected, valves are functioning, humidifiers are full, and there are no leaks in the system.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Barotrauma: avoid exceeding 30 cm of H2O airway pressure.
- Cardiovascular effects: PPV increases intrathoracic pressures, which may impede venous return to the heart and can

subsequently decrease cardiac output; at a minimum, monitor heart rate and BP closely.
- Oxygen toxicosis: significant risk after 12 hours if Fio2 remains above 60%.
- Ventilator-associated pneumonia: monitor for deterioration of respiratory function or unexplained fever.
  - Confirm diagnosis with radiographs and endotracheal wash.
- Pneumothorax: more common with high airway pressures (>30 cm H2O):
  - Can cause acute deterioration in ventilatory parameters
  - Auscultation usually reveals dull breath sounds in upper parts of thorax (i.e., dorsally when animal is in sternal recumbency).
  - The absence of a “glide sign” with thoracic focused assessment of sonography for trauma (TFAST) is strongly suggestive of pneumothorax.
  - Perform thoracocentesis in suspected cases.
  - Tension pneumothorax is associated with a severe decrease in cardiac output and hypotension; check for tension pneumothorax in ventilated animals that suddenly develop shock.
- Oral and ocular ulcers: usually avoided with good nursing care:
  - Lubricate eyes with sterile eye lubricant, and cleanse mouth with 0.1% chlorhexidine solution–soaked gauze sponges every 4 hours.

PROCEDURE

Note: Step-by-step guidelines to initiate PPV are beyond the scope of this text, and clinicians should consult more extensive reviews to become familiar with different ventilator modes and their indications. The following are suggested guidelines for starting PPV. Most cases do better in sternal recumbency.

- Ambu bag:
  - Bag size (in milliliters) should be at least 15 × BW (kilograms) to be able to deliver adequate tidal volumes.
  - Set oxygen flow rates at 10-15 L/min (delivers 50%-90% oxygen levels).
  - Attach adjustable PEEP valve to exhaust limb if PEEP desired (requires compatible attachment site). Adjust PEEP by turning valve to the desired level (start with 5 cm H2O).
  - If an oxygen reservoir bag is used, higher (90%-100%) inspired oxygen levels can be achieved.
  - Animals can breathe spontaneously while connected to Ambu bags, although airway resistance is higher.
- Anesthetic machine with manual ventilation:
  - Insert adjustable PEEP valve in the expiratory limb of tubing (bidirectional valves eliminate the risk of occlusion associated with backward insertion of unidirectional valves) if PEEP is desired.

SUGGESTED INITIAL PPV SETTING GUIDELINES (see figure):

- Inspired oxygen concentration (Fio2):
  - Start with 100% Fio2.
  - For long-term (many hours) use, decrease to the lowest Fio2 that maintains desired Pao2/SaO2 to reduce the risk of oxygen toxicosis.
- Respiratory rate (RR):
  - 8-20 breaths per minute (bpm)
  - Increase the RR to decrease the PacO2 if >50 mm Hg.
  - New RR = RR × PacO2/desired PacO2
  - RR often >20 breaths/minute if underlying pulmonary disease is present.
- Oxygen flow rates:
  - Start with 0.5-1 L/kg/min.
  - Often need to increase if underlying pulmonary disease is present.
- Tidal volume:
  - Amount of air delivered with each breath
  - Normal values: 10-15 mL/kg
  - Values of 4-6 mL/kg are associated with fewer lung injuries in people.
  - Volumes in excess of 20 mL/kg are likely to cause lung injury (barotrauma and volutrauma).
  - May need to increase tidal volume if PacO2 does not respond to increased RR
  - General rule: use lowest volume possible to achieve oxygen and carbon dioxide goals.
- Airway pressure:
  - If pressure gauge available
  - Normal airway pressures reach 15-20 cm H2O.
  - Values that are >30 cm H2O are to be avoided (likely to result in lung injury).
- Inspiratory time:
  - Inspiratory time is normally between 1.5 and 2.5 seconds.
- Inspiratory to expiratory (I:E) ratio:
  - Start with values of 1:2-1:4.
  - Try to stay >1:2 to prevent the next breath being delivered before exhalation is complete.
  - Increasing RR or tidal volume will decrease I:E ratio.

- Increasing oxygen flow rates will increase I:E ratio.
- Changing one parameter may require a change in another to maintain desired I:E ratio.

- PEEP:
  - Healthy lungs do not require PEEP.
  - Adding PEEP to diseased lungs often improves oxygenation, prevents further alveolar collapse, and reduces ventilator-induced lung injury.
  - A common starting value is 3 cm H2O.
  - If 3 cm H2O does not achieve desired results (based on Pao2/SaO2), increase the PEEP by 2-4 cm H2O until desired values are achieved.
  - Exceeding 15 cm H2O of PEEP increases the risk of lung injury and may decrease cardiac output.

VENTILATION, POSITIVE PRESSURE Potential ventilator settings for a 40- to 60-kg animal. Volume control ventilation (VCV) with synchronized intermittent mandatory ventilation (SIMV) is shown. The inspired oxygen content is 21% (room air). The peak inspiratory pressure (PIP) is high (34 cm H2O), and efforts should be made to decrease this value by decreasing tidal volume, increasing peak flow rate, or decreasing positive end-expiratory pressure (PEEP).

VENTILATION, POSITIVE PRESSURE Ventilator in use.

POSTPROCEDURE

- Supplemental oxygen is often required after weaning from ventilation (seep. 1318).

- Oxygen supplementation should be set up prior to extubation (nasal oxygen is frequently used).

ALTERNATIVES AND THEIR RELATIVE MERITS

Liquid ventilation using perfluorocarbons shows promise in managing some forms of respiratory failure in people but is cost prohibitive to most veterinary practices and clients.

AUTHOR: SØREN R. BOYSEN

Vaginoscopy

OVERVIEW AND GOAL

Visual inspection of the surface of the vaginal mucosa. This can be accomplished through a plastic or metal speculum, or is most rewarding with a fiberoptic endoscope.

INDICATIONS

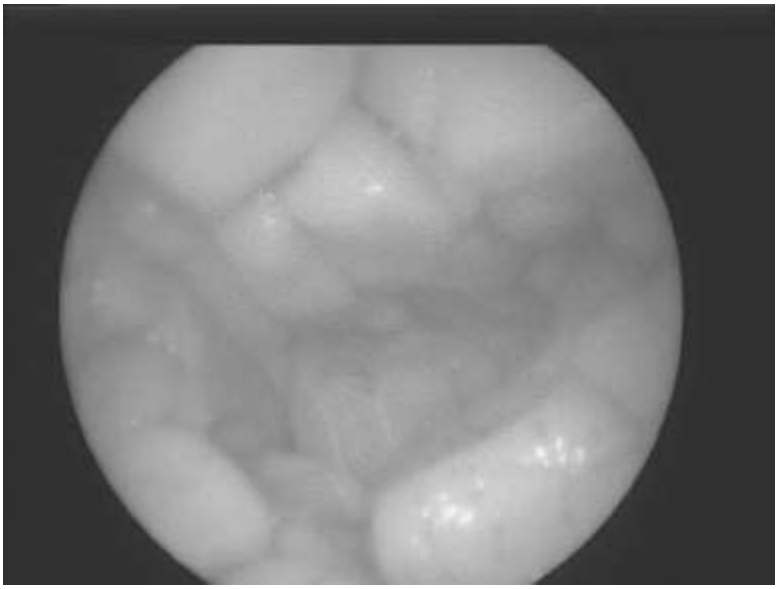
- Examining the physical changes associated with hormonal events of the canine reproductive cycle
- Evaluating abnormal conditions of the caudal reproductive tract (vestibule, vagina, and caudal cervix). Common disorders of the caudal reproductive tract include vaginal septa, vestibulovaginal stenosis (strictures), paramesonephric septal remnants, tumors, foreign bodies, lymphoid inflammation or hyperplasia, and ectopic ureters.
- To facilitate catheterization of the cervix for intrauterine artificial insemination

EQUIPMENT, ANESTHESIA

Bitches in estrus tolerate vaginal procedures well; bitches in early proestrus or anestrus may need sedation or even general anesthesia, depending on the medical reasons to perform the vaginoscopy.

Equipment:

- Endoscope or speculum: if using a rigid endoscope, its size should be compatible with the size of the bitch.
- Sterile water-soluble lubricant
- Light source if not integral part of endoscope/speculum
- Swabs
- Microscope slides



VAGINOSCOPY Endoscopic view of the canine vagina in midestrus.

ANTICIPATED TIME

5-20 minutes

PREPARATION: IMPORTANT CHECKPOINTS

- Be sure to apply lubricant copiously to the endoscope before introducing it.
- Position: if in estrus, most bitches will remain standing while vaginoscopy is being performed, especially if transcervical insemination is to be performed. In anestrous or spayed dogs, care should be taken to not traumatize the vaginal walls,

especially if a rigid endoscope is being used.
- Anesthetized dogs may be positioned in lateral, ventral, or dorsal recumbency; the latter prevents inadvertent fecal contamination of the perineovulvar area.

PROCEDURE

- Once the perineum is cleansed and excessive hair clipped, the vulvar labia are separated, and the instrument is introduced at a craniodorsal angle to avoid the clitoral fossa until the vestibule and vagina are visualized.
- Areas to be inspected: urethral opening, vestibulovaginal junction, vagina, vaginal dorsal median fold that leads to the narrow cranial vagina, vaginal fornix and paracervical area, and cervical caudal os (ostium uteri externum)
- Physical changes due to circulating hormones cause dramatic changes in the appearance of the vaginal mucosa, especially during proestrus and estrus:
    - Under the influence of estrogens produced by ovarian follicles, the vaginal epithelium undergoes hyperplasia and metaplasia during proestrus. The vaginal mucosa becomes edematous, swollen, and appears smooth, round, and plump.
    - As the bitch advances into late proestrus and estrus, declining concentrations of serum estrogens result in a wrinkling and shrinking of the vaginal mucosal folds, progressing to a markedly angulated and crenulated outline during mid to late estrus.

POSTPROCEDURE

Submission of samples, microscopic review of smears

ALTERNATIVES AND THEIR RELATIVE MERITS

- Digital vaginal palpation (see p. 1292): conveys the changes in texture of the vaginal mucosa but does not demonstrate lesions
- Serum progesterone assay: often used in conjunction with vaginoscopy; the appearance of the mucosa (and cornification of cells; see p. 1202) indicate when to begin measuring serum progesterone.

AUTHOR: CARLOS PINTO

Vaginal Palpation in the Bitch

SYNONYM

Digital vaginal examination

OVERVIEW AND GOALS

Minimally invasive digital examination of the vagina to evaluate the vaginal anatomy. Possible lesions in bitches include:

- Vaginal strictures
- Vaginal tumors
- Trauma during breeding
- Congenital anatomic anomalies

INDICATIONS

- Vaginal discharge
- Poor breeding experience
- Urinary incontinence (urine pooling)
- Dystocia

CONTRAINDICATIONS

There are relatively few contraindications to this procedure.

- If infection of the reproductive tract is a consideration:
  - Vaginal culture should be taken first.
  - Culture is followed by vaginal cytologic analysis before a digital examination is performed.

EQUIPMENT, ANESTHESIA

- Minimal restraint usually required
- Antiseptic cleanser
- Sterile exam glove
- Sterile water-soluble lubricant

ANTICIPATED TIME

With a cooperative bitch, the procedure should take less than 5 minutes, from gentle cleansing of the vulvar lips to finishing the exam.

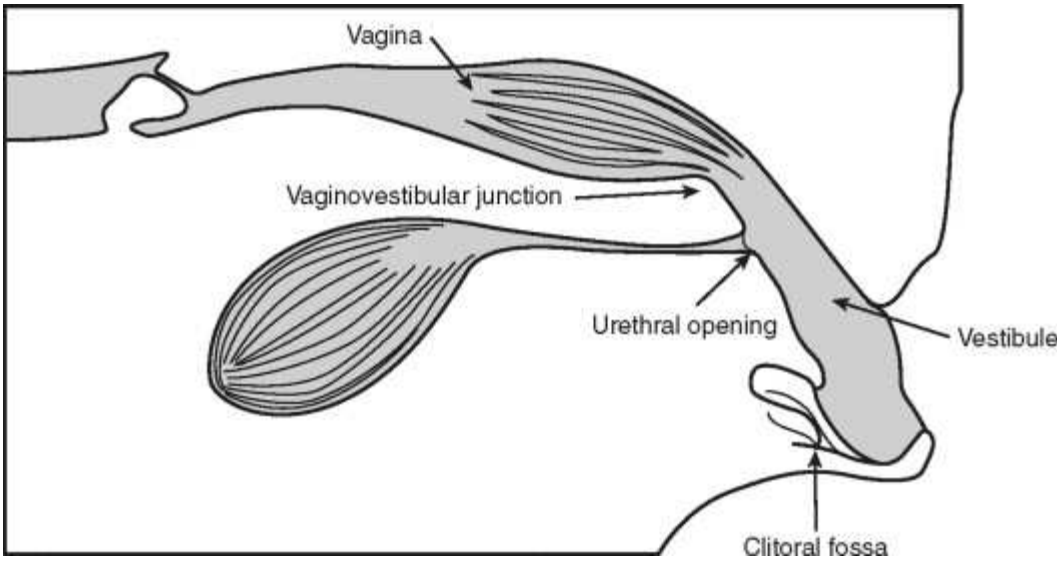
POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Urethral opening lies on the ventral surface of the vestibule and should be avoided:
  - This is not difficult if the finger is passed up to the vestibulovaginal junction perpendicularly to the ground in the standing bitch.
- Vestibulovaginal junction is one barrier to the entrance of the uterus and should not be mistaken for the cervix or a stricture:
  - The canine vagina is very long (up to 12 inches [29 cm] in giant-breed dogs), and thus the cervix is unlikely to be palpated on digital examination of the vagina.
  - The junction acts a barrier to pathogens and will be narrower than the vestibule or vagina. If the examiner proceeds slowly, he or she should be able to pass the finger beyond the junction in most bitches (depending on the size of the bitch and the size of the finger).

PROCEDURE

- Animal should be restrained in standing position.

- Vulvar lips should be gently wiped with a mild antibacterial cleanser.
- Examiner should wear sterile gloves.
- After coating the gloved index finger with the sterile lubricant, the finger is passed into the vulva and turned directly upward (90° angle to the floor in the standing animal). The upward direction is important so the urethral opening is avoided.
- When the finger cannot go any farther dorsally, it is turned directly cranially (parallel to the floor) and advanced over the ischium and into the vaginal vault:
    - As the finger passes over the ischium into the vagina, there may be a slight tightening at the vestibulovaginal junction. Depending on the size of the bitch and the size of the hand, most fingers should pass through this junction.
    - If the finger is well lubricated and it does not pass this point, a vaginal stricture should be considered.



VAGINAL PALPATION Anatomic relationship of vestibule and vagina in the bitch. Dorsal is toward top of image, cranial to left.

ALTERNATIVES AND THEIR RELATIVE MERITS

- Speculum examination (vaginoscopy; see p. 1361) may be performed for the visualization of the vaginal walls and vault:
    - Inflamed walls in vaginitis cases
    - Urine on the floor of the vagina in urine-pooling disorders
    - Evidence of trauma in difficult breeding
    - Evaluation of vaginal folds and mucosa for timing of estrus
- Vaginoscopy with an endoscope to visualize vagina and potentially the cervix

AUTHOR: CAROL A. MCCLURE

Vagal Maneuver

SYNONYMS

- Carotid sinus massage
- Ocular pressure
- Valsalva maneuver

OVERVIEW AND GOALS

A physical manipulation that temporarily increases parasympathetic tone, mainly for diagnostic—and occasionally therapeutic—cardiac rhythm effects

INDICATIONS

Tachycardia in which the rate is so rapid that it is unclear on the electrocardiogram (ECG) whether the rhythm is ventricular or supraventricular (e.g., heart rate is >260 bpm)

CONTRAINDICATIONS

- Ocular disease (for ocular pressure)
- Disorders of the ventral neck (for carotid sinus massage)
- Bradycardia, including the bradycardia-tachycardia syndrome (sick sinus syndrome)

EQUIPMENT, ANESTHESIA

No anesthetic requirement; procedure is performed when the animal is awake. Procedure requires ECG machine with printer to assess and record initial cardiac rhythm and to record effect of vagal maneuver.

ANTICIPATED TIME

<1 minute

PREPARATION: IMPORTANT CHECKPOINTS

A printed ECG tracing of the rhythm prior to the vagal maneuver is necessary.

POSSIBLE COMPLICATIONS AND COMMON ERRORS TO AVOID

- Inadequate vagal response. Subjectively, carotid sinus massage appears to be more effective than ocular pressure in some patients and vice versa in others, but some supraventricular tachycardias (and essentially all cases of ventricular tachycardia) are resistant to both.
- Concerns regarding vagal maneuver. Related harm due to carotid artery atherosclerosis is based on human cardiology but is not expected to be relevant to small animal medicine.

PROCEDURE

- Patient may be standing or recumbent.
- ECG leads are connected, and a good ECG signal should be seen.
- The prevagal-maneuver ECG is traced/printed; about 20-30 seconds of tracing should be recorded.
- The *vagal* maneuver is applied, with the ECG printing continuously. The ECG paper should be marked at the time of onset of the vagal maneuver. Usually, only one maneuver is performed. The ECG should be allowed to continue to run (printing) throughout the duration of the vagal maneuver and for at least 15 seconds after its termination.

VAGAL MANEUVER Placement of fingers for performing carotid sinus massage in a dog.

OCULAR PRESSURE:

- The patient's eyelids are closed, and using the thumb and middle finger of the same hand, both globes are depressed caudally into the orbit.
- A small, smooth massaging motion may be applied to the eyes along with the direct pressure.
- The degree of pressure should be sufficient that the eyes are substantially retracted caudally without, however, provoking any sign of discomfort or resentment. The exact extent of retraction will vary depending on orbit shape and size.
- Pressure is maintained until a substantial decrease in heart rate is noted and the rhythm can be identified or until the maneuver has been applied for 15 seconds.

CAROTID SINUS MASSAGE:

- The target area is the base of the internal carotid artery, which is not palpable as such but is located dorsocranially to the larynx, medial to the angle of the mandible.
    - For localization: the larynx is palpated using the thumb and forefinger. The thumb and forefinger are moved dorsally and cranially from the larynx until resting in the natural depression medial to the angle of the mandible and ventral to the occipital bone.
- Gentle, pincer-like pressure is applied in this area with the thumb and forefinger.
- Pressure is maintained, and a small, smooth, circular massaging motion may be performed.
- The pressure exerted is often sufficient to elicit a gag reflex but should not be so great as to cause discomfort or resentment.
- Pressure is maintained until a substantial decrease in heart rate is noted and the rhythm can be identified or until the maneuver has been applied for 15 seconds.

POSTPROCEDURE

- A vagal maneuver can routinely be terminated abruptly.
- Failure to slow tachycardia with a vagal maneuver should prompt a search for the tachycardia's possible causes, including anxiety/stress of hospitalization, respiratory compromise, structural cardiac disease, and systemic illness.

ALTERNATIVES AND THEIR RELATIVE MERITS

Pharmacologic slowing of tachycardias, such as with injectable propranolol, verapamil, or adenosine, should only be considered

once the aforementioned possible inciting factors have been ruled out or addressed.

Azotemia: Blood Urea Nitrogen/Creatinine Mismatch

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

BUN, Blood urea nitrogen; *GI,* gastrointestinal; *PU/PD,* polyuria and polydipsia.

Increased BUN Plus Normal Serum Creatinine

- ***Increased BUN***
  - Early prerenal azotemia (decreased urine flow rate)
  - High-protein diet
  - GI hemorrhage
  - Tetracycline or corticosteroid administration
  - Fever
  - Loop diuretic administration (e.g., furosemide)
  - Severe tissue trauma(?)
- ***Decreased Creatinine***
  - Decreased muscle mass (severe cachexia needed to cause significant changes)

Increased Serum Creatinine Plus Normal to Low BUN

- ***Decreased BUN***
  - Hepatic insufficiency
  - PU/PD
  - Low-protein diet
- ***Increased Creatinine***
  - Myositis/muscle trauma (unlikely)
  - Cooked meat diet (mild, transient changes)
  - Ketonemia (falsely increased)

Azotemia

Modified from Slatter D: Textbook of small animal surgery, St Louis, 2003, Elsevier.

*Urine specific gravity may be in the normal range in cases of acute anuric renal failure.

Differentiation and Anticipated Metabolic Changes

Parameter	Prerenal	Primary Renal	Postrenal
Creatinine	Increased	Increased	Increased
Blood urea nitrogen (BUN)	Increased	Increased	Increased
Urine specific gravity	Increased	Decreased*	Increased
Urine sediment	Normal	Often abnormal	Often abnormal
Urine production	Decreased	Variable	Decreased
Hematocrit	Increased	Variable	Increased
Serum potassium	Normal or low	Variable	Increased
Serum phosphorus	Normal	Variable	Increased
Metabolic acidosis	Mild	Mild to severe	Mild to severe
Common causes	Dehydration, hypovolemia, heart failure	Nephrotoxins, infectious disease, glomerulonephritis	Urethral obstruction, ruptured bladder

Azoospermia

From Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

*Decreased libido often associated with these disorders.

Potential Causes for Azoospermia

- **May Be Transient**
- Drugs, hormones*
- Environmental insult
- Systemic illness (current or previous)
- Testicular trauma, hyperthermia
- Infectious orchitis, prostatitis
- Retrograde ejaculation
- Hypothyroidism*
- Hypopituitarism*
- Hyperadrenocorticism*
- Estrogen-secreting Sertoli cell tumor*

- **Usually Permanent**
- Idiopathic testicular degeneration
- Lymphocytic orchitis
- *Brucella canis*
- Duct obstruction
- Bilateral testicular neoplasia
- Congenital defect

Arrhythmias: Ventricular Versus Supraventricular

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Comparison of Ectopic Beats of Supraventricular or Ventricular Origin

Feature	Supraventricular	Ventricular
Wide, bizarre QRS complexes	Rare (concurrent aberrancy)	Common
QRS complex shape	Same as sinus QRS complex	Different from sinus QRS complex
P wave for every QRS complex	Yes; often of different shape (consistent PR interval)	No; P waves occur regularly throughout tracing but independently of QRS complexes (often buried inside QRS complexes or T waves)
T wave	Same as sinus T wave	Different from sinus T wave
Postextrasystolic pause	Usually noncompensatory	Usually compensatory
QRS complex fusion beats as hallmark	No	Yes
Positive response to vagal maneuver	Possible	Virtually never

Arrhythmias: ECG Characteristics

From Kittleson M, Kienle RD: Diagnosis and treatment of arrhythmias (dysrhythmias). In Small animal cardiovascular medicine, St. Louis, 1998, Mosby, p 454.

Electrocardiogram Characteristics

Rhythm	P Wave Rate (bpm)	P Wave Rhythm	P Wave Configuration	QRS Complex Rate	QRS Complex Rhythm	QRS Configuration	P-QRS Relationship
Sinus	Normal	Regular	Normal	Same as P wave	Regular	Normal	1:1
Sinus bradycardia	<Normal	Regular	Normal	Same as P wave	Regular	Normal	1:1
Sinus tachycardia	>Normal	Regular	Normal	Same as P wave	Regular	Normal	1:1
Sinus arrhythmia	Normal	Irregular	Normal or wandering	Same as P wave	Irregular	Normal	1:1
Supraventricular tachycardia	>Normal	Regular	Positive, negative, absent, or buried	Same as P wave	Regular	Normal	1:1
Atrial flutter	>300	Regular	Positive (F waves; sawtooth baseline)	Same or less than P wave rate	Regular or irregular	Normal	Generally more P waves than QRS complexes
Atrial fibrillation	>500	Irregular	None to baseline undulation (F waves)	Less than P wave rate (100-280)	Irregular	Normal	No P waves; more undulations than QRS complexes
Accelerated idioventricular rhythm	Normal	Regular	Normal (often buried in QRS complex)	70-150	Fairly regular; may be irregular	Wide	Dissociated; more QRS complexes than P waves
Ventricular flutter	Not discernable	Not discernable	Not discernible	>350	Regular	Sine wave	Dissociated; more QRS waves than P waves
Ventricular fibrillation	Not discernable	Not discernable	Not discernible	>400	Grossly irregular	No QRS complexes	Dissociated; no QRS complexes
Second-degree AV block	Normal	Regular	Normal	<P wave rate	Irregular	Normal or wide	More P waves than QRS complexes
Third-degree AV block	Normal	Regular	Normal	20-60 (dog), 50-130 (cat)	Regular	Normal or wide	Dissociated; more P waves than QRS complexes; irregular P-R interval

Arrhythmias, Ventricular: Triggers

Causes of or Predisposing Factors for Ventricular Arrhythmias (Premature Ventricular Complexes, Ventricular Tachycardia)

- Hypokalemia
- Hypoxemia (e.g., from pulmonary edema, other causes)
- Anemia
- Structural heart disease (valvular heart disease, cardiomyopathy, congenital heart disease, others)
- Blunt chest trauma (e.g., hit by car)
- Gastric dilatation and volvulus
- Abdominal mass (splenic, hepatic, others)
- Sepsis
- Acidosis
- Systemic inflammatory response syndrome (SIRS)
- Intoxications (digitalis, pseudoephedrine, many other pharmaceuticals; oleander, yew, many other plants)
- Excess catecholamines
- Myocarditis (diagnosis of exclusion)

Antidotes and Reversal Agents in Small Animal Poisoning

CNS, Central nervous system; *GI,* gastrointestinal; *OP,* organophosphate.

Reversal Agent/Antidote	Toxicant/Main Indications	Comment(s)
N-acetylcysteine (Mucomyst)	Acetaminophen/paracetamol overdose	Can be used PO; injectable (Acetadote) available; in addition, can also use SAMe
Flumazenil (Romazicon)	Benzodiazepines (diazepam, alprazolam, lorazepam, clonazepam) overdose	Can help reverse severe CNS depression/coma; short half life; repeat in 1-3 hours if needed.
Pamidronate (Aredia)	Cholecalciferol; calcipotriene; calcitriol	Treats hypercalcemia and hyperphosphatemia; can cause transient azotemia
Cyproheptadine (Periactin)	Serotonin syndrome caused by serotonergic substances	Can be tried per rectum in animals that cannot receive oral medications; can repeat once or twice in 6-8 hours
Methocarbamol (Robaxin)	For tremor control in permethrin toxicosis in cats; can also be tried in cats/dogs for tremors resulting from other pyrethrins/pyrethroids	Not an anticonvulsant; works well in permethrin, metaldehyde, tremorgens, and strychnine toxicosis; injectable preferred for acute treatment; orally may be helpful for mild cases
Atipamezole (Antisedan)	To treat α2-adrenergic agonist effects of amitraz, xylazine, clonidine, and brimonidine overdose	Atipamezole and yohimbine have α2-adrenergic antagonist properties; atipamezole more specific/preferred.
Fomepizole (4-methyl pyrazole; Antizol-Vet)	Ethylene glycol (antifreeze) toxicosis in dogs; some benefit if used within 3 hours of exposure in cats	Good safety margin; does not contribute to acidosis and CNS depression as ethanol does.
Calcium disodium EDTA (Calcium Disodium Versenate)	Lead, zinc, cadmium	Injectable; can cause GI signs and nephrotoxicity; do not use if metal still present in GI tract.
BAL (British antilewisite; Dimercaprol)	Lead, arsenic, mercury	Injection can be irritating and painful; difficult to obtain; helps remove lead from CNS
Atropine sulfate	For treating muscarinic signs in OPs and carbamate toxicosis; certain muscarinic mushrooms	Avoid atropinization (hyperthermia, tachycardia, mydriasis)
2-PAM (Pralidoxime)	For treating nicotinic signs in OP toxicosis in dogs, cats	Not useful for most carbamate toxicoses; most beneficial within 24 hours of exposure but may be useful beyond this time; discontinue after 3 doses if no benefit
D-penicillamine (Cuprimine)	Zinc, cadmium; lead, copper, mercury	Used PO; can cause GI signs; do not use when metal is still present in the GI tract.
Digoxin immune Fab (Digibind)	Digitalis; cardiac glycosides	Expensive but rapid acting and efficacious; can be used in Bufo toad toxicosis
Deferoxamine (Desferal)	Iron chelator; useful in iron toxicosis	Urine color may turn wine color after chelation with iron.

Reversal Agent/Antidote	Toxicant/Main Indications	Comment(s)
Succimer (2-3-dimercaptosuccinic acid; Chemet)	Lead poisoning in dogs; cats, birds	Used PO; anecdotal reports of renal failure in cats; monitor renal values when using in cats; can be used when ingested lead is still present in the GI tract.
Yohimbine (Yobine)	To treat α2-adrenergic agonist effects of amitraz, xylazine, clonidine, and brimonidine overdose	Shorter half-life and less specific than atipamezole; use yohimbine as a second choice if atipamezole is not available.
S-adenosyl-L-methionine (SAMe; Denosyl)	General hepatoprotective agent	Used as an aid in hepatic damage from various causes (mushroom, xylitol, cycad, acetaminophen, etc.)
Naloxone (Narcan)	Opioids/opiates	Can help reverse respiratory/CNS depression; short half life; repeat in 1-3 hours if needed.
Vitamin K1 (phytonadione)	Anticoagulants (warfarin, brodifacoum, bromadiolone)	Parenteral use can cause allergic reaction; use PO for 2-4 weeks or more as needed; works better with fatty food and in divided doses.
Pyridoxine (vitamin B6)	Isoniazid toxicosis in dogs	Difficult to obtain; can be used 1 : 1 ratio (dose of isoniazid: dose of pyridoxine); 5%-10% IV infusion over 30-60 minutes; use in conjunction with diazepam to control CNS effects
Prussian blue	Thallium toxicosis	Used PO; difficult to obtain; thallium toxicosis not common anymore
Leucovorin	Methotrexate overdose	Leucovorin is active form of folic acid; 25-250 mg/m^2 q 6 h IV, IM for up to 72 h

Anticoagulant Rodenticides in Common Usage

Active Ingredient	Common Brand Names	Comments

Brodifacoum	• D-Con bait pellets
	• D-Con bait pellets II
	• D-Con bait pellets II place pack
	• D-Con Kills Rat
	• D-Con Lim-N8 Rat killer
	• D-Con Mouse Killing station
	• D-Con Mouse Prufe II
	• D-Con Ready Mixed Baitbits
	• De-Mize Kills Mice and Rats
	• Enforcer Mouse Kill II
	• Enforcer Mouse and Rat Bars
	• Enforcer Rat and Mouse Bars II
	• Enforcer Rat and Mouse Killer Pellets
	• Enforcer Rat Kill II with Bitrex
	• Final Blox All Weather
	• Final Blox All Weather Commercial (Canada)
	• Final Rodenticide Place Pack (Canada)
	• Final Rodenticide Ready to Use
	• Havoc Chunks
	• Havoc Rodenticide Bait Pellets
	• Havoc XT Blok
	• Jaguar 50 Bait Chunx (Canada)
	• Jaguar 50 Rodenticide place pack (Canada)
	• Jaguar 50 All Weather Blox (Canada)
	• Jaguar Rodenticide
	• Ratak Plus Rodenticide (Canada)
	• Ratak Plus Rodenticide Place pack (Canada)
	• Ropax Bars
	• Ropax Pellets
	• Ropax Rodenticide

	• Talon G Rodenticide mini pellets
	• Talon Liquid Concentrate
	• Talon Plus Rodenticide
	• Talon-G mini pellets
	• Talon-G rodenticide bait pack
	• Talon-G Rodenticide with Bitrex
	• Weather Block bait
	• Weatherblok Bait with bitrex
	• Weatherblok XT bait (Canada)
	• Zep commercial rat and mouse bars
		• One of the most widely used anticoagulants
		• Available as 0.005% or 0.0025 % or 0.25% or 0.28% w/w bait
		• Available as pellets, blocks, bait chunks
		• Some baits also contain bitrex (denatonium benzoate, a bittering agent) to deter nontarget animals.
		• No toxicity concern from bittering agent
		• Mostly available as 1-oz blocks
		  ○ (28.5-g); 1.5-oz
		  ○ (45-g) or 3-oz
		  ○ (85-g) packages

Bromadiolone	• Boot Hill Kills Rats and Mice • Boot Hill Rat and Mice pellets • Boot Hill Rat and Mice place packs • Boot Hill mini block • Boot Hill pellets • Contrac all weather blox • Contrac all weather cake • Contrac blox all weather (Canada)	• A widely used anticoagulant available as 0.005% bait • Available as pellets, blocks, bars, cake, chunks, trays, meal bait • Sometimes baits impregnated with seeds • Some formulations contain bitrex (bittering agent) to deter nontarget species

Active Ingredient	Common Brand Names	Comments
	• Contrac II • Contrac II cake • Contrac Rat and Mouse Bait • Contrac Rodenticide (Canada) • Contrac Rodenticide Place Pac • Contrac Super Size Blox • Contrac Super Size Blox Commercial (Canada) • Enforcer Mouse Kill III • Green Cross Rodentex Block (Canada) • Green Cross Rodentex Pellets (Canada) • Hawk All Weather Rodent Block • Hawk Bait Chunx • Hawk Bait Chunx Commercial (Canada) • Hawk Integrator All Weather Block • Hawk Rodenticide • Hawk Rodenticide Domestic (Canada) • Hawk Rodenticide Ready To Use • Just One Bite II Bait Chunk • Just One Bite II Bait Pellets • Just One Bite Pellets • Just One Bite Place Pack • Just One Bite Mouse Bars • Maki Mini Block Rodenticide • Maki Paraffinized Pellets • Maki Rat and Mouse Meal Bait • Maki Rat and Mouse Place Packs • Maki Rodenticide Bait Packs • Maki Rodenticide Pellets Place Packs (Canada) • Purina Mouse A Rest Pellets • Purina Rat A Rest Pellets • Rat X Dura Block (Canada) • Rat XB Meal Bulk Rodenticide (Canada) • Rat XB Bait Pack (Canada) • Ratoxin Bromadiolone Rodenticide Bait Pack (Canada) • Ratoxin Dura Block Domestic (Canada) • Ratoxin Meal Bait Pack (Canada) • Rattoxin Mouse and Rat bait (Canada) • Sanex Brobone Meal bait (Canada) • Snare rodenticide (Canada) • Snare Rodenticide Bait Blox (Canada) • Tomcat All Weather Ultra Block bait (Canada) • Tomcat Ultra • Tomcat Ultra Block Bait • Tomcat Ultra Feeder Pack • Tomcat Ultra Pelleted Bait • Tomcat Ultra Prebaited Bait Station • Victor Bait Station • Victor Kills Mice and Rat Bait Block • Victor Kills Mice and Rat Pellets	

Active Ingredient	Common Brand Names	Comments
	• Victor Mouse and Rat Block with Bitrex (Canada) • Wilson Super Mouse Treat (Canada) • Wilson Super Rat and Mouse Killer (Canada) • Wilson Wilsarin Rat and Mouse Bait (Canada)	
Chlorophacinone	• AC Formula 90 place packs or ready-to-use bait • Bonide No Escape rat and mouse place packs • Enforcer rat and mouse killer • Enforcer rat bait • Enforcer rat and mice bait (indoor outdoor use) • Green Cross mouse bait (Canada) • Ground Force field rodent bait (Canada) • Ground Force rat and mouse pellets or place packs (Canada) • JT Eaton feeder box rat bait • JT Eaton Answer for mice • JT Eaton Answer for chipmunks • JT Eaton Rozol Bait blocks • Rat XC bait pack (Canada) • Ratol Superbags I rodenticide (Canada) • Rozol Canary Seed Mouse Bait • Rozol Liquid Rodenticide Concentrated (Canada) • Rozol Mineral Oil Concentrated Rodenticide (Canada) • Rozol Pellets for Voles • Rozol Gopher bait • Rozol Rat and Mouse Killer • Rozol Tracking Powder • Super Bloc II Rodenticide (Canada) • Super Bloc I Rodent Bait (Canada) • Wilco Ground Squirrel Bait • Wilson Bait Bloks (Canada) • Wilson Ready to Mice Rodenticide (Canada) • Wilson Riddex Rat and Mouse Killer Pellets (Canada) • Wilson Riddex Rat and Mouse Killer Meal (Canada)	• Mostly available as 0.005% w/w bait • Sometimes 0.01%, 0.07%, or 0.28% w/w rat or mouse bait • Occasionally used for gophers, moles, chipmunks, voles, and squirrels • Available as pellets, paraffin blocks, tracking powder, or feeder station • Can be used indoors or outdoors • Tracking powder can be more concentrated (up to 0.28%). • Bait sometimes may be impregnated with bird seeds.
Difethialone	• D-Con Bait Paste Pouch • D-Con Rat and Mouse Mini Block • D-Cease Mini Bars • Enforcer Mouse Max Killer • Enforcer Rat Max Killer • Generation Blue Max Meal Bait • Generation Blue Max Block • Generation Blue Max Mini Block (Canada) • Generation Blue Max Rodenticide Pellets (Canada)	• Relatively new compared to other anticoagulants • Available as 0.025% w/w bait • Available as pellets, mini blocks, bars, meal, paste • Sometimes bait available with bittering agent

Active Ingredient	Common Brand Names	Comments
	• Generation Mini Block • Generation Block Commercial (Canada) • Generation Pellets Placepacks • Hombre Block • Hombre Pellets Place Packs • Hombre Pellets Ready to Use • Ortho Home Defense Max Bait Block • Ortho Home Defense Max Bait Station • Sweeneys Bait Block Rodenticide • Sweeneys Mice Bait Pack Pellets • Sweeneys No Mess Paste Bait • Wilson Predator Rat and Mouse Blok (Canada) • Wilson Predator Rat and Mouse Pellets Place Pack (Canada)	
Diphacinone	• Black Jack Ratonicide Rat & Mouse Killer • Ditrac All Weather Blox • Ditrac All Weather Cake • Ditrac Rat & Mouse bait • Ditrac Rat and Mouse Bait Place Pack • Eatons All Weather Bait • Eatons All Weather Blocks • Eaton Answer for Pocket Gophers • Enforcer Rat & Mouse Killer II • Enforcer Rat & Mouse Weather Bars • Greenlight Gopher Killer • JT Eaton Bait Blocks • Promar Blox All Weather Rodenticide • Ramik Green • Ramik Green Bait Pack • Ramik Green Mini Bait • Tomcat All Weather Rodent Block • Tomcat All Weather Bait • Wilco Gopher Getter • Wilco Ground Squirrel	• Available for indoor/outdoor use • Used for rats, mice, gophers, and squirrels • Available as 0.005% w/w bait • Available as bars, pellets, blocks, cake, tracking powder, chunks • Also used with bitrex (bittering agent) • Baits sometimes flavored with peanut butter or molasses
Warfarin	• Apo Rat and Mouse Bait • Bolt Rodenticide (Canada) • Bonide Tomcat • Contrac Rodenticide Kills Rats (Canada) • D-Con Pellets • D-Con Pellets Kills Rats and Mice • D-Con Ready Mixed Kills Rats and Mice • Ferret Rodenticide • Final Pelleted Rat and Mouse Bait • Final Rat and Mouse Bait • Hopkins Rodex Blox I • Kaput Mole Gel Bait • Kaput Mouse Block • Rat Control Pellets	• Not used commonly anymore, owing to availability of second- generation anticoagulants • Available as 0.025% w/w bait • Used as bars, meal, cakes, pellets • Used for rats, mice, moles, and occasionally for wild ferrets

Active Ingredient	Common Brand Names	Comments
	• Rid-A-Rat Rat & Mouse Killer • Rodex Blox I • Rodex Mole Gel Formula • Rodex Pelleted Bait • Warfarin Rat & Mouse Killer Meal (Canada)	

Anorexia: Tips for Coax Feeding

- Minimize stress at mealtimes.
- Approximate the patient's routine feeding management as much as possible.
- Recognize the signs of food aversion and modify/temporarily suspend feeding accordingly.
- Choose complete and balanced, energy-dense foods that are appropriate for the patient's medical condition.
- When medically appropriate, choose foods the patient is familiar with.
- Warm the food slightly.
- Offer modest portions of fresh foods frequently.
- Offer one food item at a time.
- Do not leave food with the patient for extended periods of time.
- Try novel foods if the patient seems averse to his/her typical diet.
- Give clear feeding instructions that include the specific diet to be fed, portion size, and meal frequency.

AUTHOR: KATHRYN MICHEL

Anorexia

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

- **Psychogenic (especially cats)**
- **Inability to smell food**
- **Dysphagia (especially when it causes pain)**
- **Inflammation**
  - Because of an infectious agent
  - Because of immune-mediated disease
  - Because of neoplasia
  - Because of necrosis
  - Because of drugs
- **Alimentary and abdominal diseases (especially those causing nausea or abdominal pain)**
- **Neoplasia**
  - Because of the neoplasm itself
  - Because of secondary bacterial infection when neoplasia impairs natural defense mechanisms
- **Toxins**
  - Exogenous (various ones)
  - Endogenous (e.g., renal failure, hepatic encephalopathy)
- **Endocrine disease**
  - Diabetic ketoacidosis
  - Hypoadrenocorticism
  - Hyperthyroidism
- **Central nervous system (CNS) disease**
  - Primary
  - Secondary

Anisocoria

Modified with permission from Oliver JE, Lorenz MD: Blindness, anisocoria, and abnormal eye movements. In Oliver JE, Lorenz MD: Handbook of veterinary neurology, Philadelphia, 1994, Saunders, p 261.

*Unilateral lesions of these structures are rare.†Possibly loss of sight in left visual field, with partial sparing of right visual field.

Anisocoria and Other Signs of Lesions in the Visual Pathways

	VISION	PUPIL SIZE	PUPILLARY LIGHT REFLEX IN CONTRALATERAL EYE			
Complete Lesion on Right Side	**Right Eye**	**Left Eye**	**Right Eye**	**Left Eye**	**Light in Right Eye**	**Light in Left Eye**
1. Retina or optic nerve	Absent	Normal	Slightly dilated	Normal	No response	Both constrict
2. Orbit (CN II, III)	Absent	Normal	Dilated	Normal	No response	Left constricts
3. Optic chiasm (bilateral)*	Absent	Absent	Dilated	Dilated	No response	No response

Anemias: Characteristics

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Conclusions That May Be Drawn from Hematologic Data

Hematologic Conclusion	Typical Evidence
Regenerative anemia	Appropriate degree of increased reticulocytes or polychromasia for severity of the anemia
Nonregenerative anemia	Insufficient increase in reticulocytes for the severity and duration of the anemia
Hemolytic anemia	Regenerative anemia with additional evidence such as hemoglobinuria, normal plasma protein, hyperbilirubinemia, and documentation of one of the causes of hemolysis
Blood-loss anemia	Regenerative anemia with normal to decreased plasma protein, evidence of iron deficiency, or proof of blood loss
Immune-mediated hemolytic anemia (IMHA)	Moderate to marked spherocytosis, autoagglutination, and/or positive Coombs' test
Oxidant-induced hemolytic anemia	Increased numbers of Heinz bodies, eccentrocytes, and methemoglobinemia
Fragmentation anemia	Increased number of keratocytes, schizocytes, or acanthocytes
Iron-deficiency anemia	Microcytic hypochromic anemia with variable regeneration

Anemias: Evaluation

Approach to Anemia Diagnosis

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

I. **Determine severity of anemia.**
- Mild anemia (PCV > 30% dog, >20% cat)
  - Consider age, breed, and statistical chance of normality.
  - Check for laboratory or sample error; repeat venipuncture.
  - For a secondary problem, go to step IV.
- For moderate to severe anemia, go to step II.

II. **Determine bone marrow responsiveness.**
- No reticulocytosis or polychromasia expected during first 2-3 days or in mild anemia (PCV > 30% dog, >20% cat).
- Reticulocytosis and polychromasia peak at 4-5 days if bone marrow function normal.
  - Marked canine reticulocytosis > 500,000/mcL
  - Marked feline aggregate reticulocytosis > 200,000/mcL
- Later-stage responsiveness at 7-14 days:
  - Feline punctuate reticulocytosis, marked > 1,500,000/mcL
  - Dogs: increase in macrocytic hypochromic RBCs
- Classification by RBC indices and hematology instrument graphics
  - Macrocytic hypochromic: regenerative anemia
  - Normocytic normochromic: nonregenerative or preregenerative anemia
  - Microcytic hypochromic: iron-deficiency anemia
  - Macrocytic normochromic: regenerative or nonregenerative
- If adequately regenerative, go to step III; if inadequately regenerative, go to step IV.

III. **Regenerative anemia diagnosis**
- Blood smear analysis critical in hemolytic anemia diagnosis
  - Spherocytes, autoagglutination, Heinz bodies, polychromasia, blood parasites, eccentrocytes, RBC fragmentation
- Hemoglobinuria is best proof of intravascular hemolytic anemia.
- Internal blood loss resembles hemolytic anemia.
  - Document hemorrhage with gross evidence of melena, ultrasound evidence of blood in body cavities, etc.
- External blood loss
  - Often in history
  - Tendency toward hypoproteinemia, hypoalbuminemia, or both
  - Check for thrombocytopenia or bleeding tendency.

IV. **Nonregenerative anemia diagnosis**
- Way to a diagnosis varies with case presentation.
- Use history and severity of anemia to reevaluate reticulocyte numbers to see if anemia is truly nonregenerative; duration exceeding 3-4 days excludes preregenerative anemia; reticulocyte response is weak or absent 2 weeks after the cause of an anemia ceases; mild anemia will not stimulate much reticulocytosis.
- Evaluate rest of the hematology report.
  - Microcytic hypochromic RBCs usually indicate iron-deficiency anemia
    - RBC cytograms and histograms more sensitive than MCV and MCHC
    - Half of iron-deficiency anemia cases regenerative
  - Normocytic normochromic anemia most common but nonspecific
  - Macrocytic normochromic feline RBCs without reticulocytosis suggests FeLV-induced myelodysplasia (see text)
  - Evidence of inflammation; anemia of inflammatory diseases is very common (i.e., mild, normocytic normochromic anemia).
  - Evidence of leukemia or dysplastic hematopoiesis usually indicates bone marrow evaluation; go to H.
  - Thrombocytopenia; consider *Ehrlichia* or other infections.
  - Pancytopenia or bicytopenia indicates bone marrow disease and bone marrow evaluation; go to H.
- Clinical chemistry profile
  - Renal or hepatic failure causes secondary anemia.
  - Systemic diseases have variable causes of anemia.
- Virology, serology if infection is likely (e.g., fever, lymphadenopathy)
- Endocrinologic examination for hypothyroidism or other dysfunction (e.g., mild, normocytic normochromic anemia)
- Toxicosis
  - Check for testicular neoplasm or access to estrogen.
  - Withhold any current drug therapy and monitor for recovery.

        - Check for toxicants in environment.
    - Bone marrow examination reveals many diagnoses.
        - Myelofibrosis, aplastic pancytopenia, dyserythropoiesis, leukemia, myelodysplasia, refractory anemia with excessive blasts, etc.

FeLV, feline leukemia virus; *MCHC,* mean corpuscular hemoglobin concentration; *MCV,* mean corpuscular volume; *PCV,* Packed cell volume; *RBC,* red blood cell.

Anemia: Causes

Causes

Modified with permission from Bonagura J: Kirk's current veterinary therapy XII: small animal practice, ed 12, St Louis, 1995, Saunders, p 448.

Hemorrhage

- ***Surgery/Trauma***
- ***Bleeding Disorder:***
  - von Willebrand disease/thrombopathia
  - Thrombocytopenia
  - Hemophilia A, B; decreases in other factors
  - DIC
- ***Ectoparasitosis (fleas, ticks, lice)***
- ***GI (hookworms, neoplasia, ulceration)***
- ***Neoplasia (hemangiosarcoma)***

Hemolysis

- ***Antibody-Mediated:***
  - Neonatal isoerythrolysis
  - Warm-reactive IgG IHA
  - Cold-reactive IgM IHA
  - Transfusion reaction
- ***Congenital:***
  - Phosphofructokinase deficiency (English springer spaniels, American cocker spaniel)
  - Familial nonspherocytic, hemolytic anemia (poodles)
  - Elliptocytosis (one crossbred dog)
  - NADH methemoglobin reductase deficiency (several breeds of dogs)
  - Hemolytic anemia secondary to RBC membrane defect (beagles)
  - Pyruvate kinase deficiency (beagles, basenjis, West Highland white terriers, giant schnauzers, Abyssinians)
  - Vitamin B12 deficiency (giant schnauzers)
  - Predisposition to oxidant injury, high erythrocyte potassium and low glutathione levels (Akitas, Shiba Inus)
- ***Toxin/Drug-Induced:***
  - Propylthiouracil
  - Lead
  - dl-methionine
  - Cephalosporins
  - Fenbendazole
  - Dapsone
  - Gold salts
  - MLV vaccines
  - Oxidants
  - Onions
  - Acetaminophen
  - Methylene blue
  - Phenacetin
  - Propylene glycol
  - Phenol compounds (mothballs)
  - Benzocaine
  - Hydroxyurea
  - Vitamin K3
- ***Parasites:***
  - *Mycoplasma haemofelis* and *M. haemominutum* infection
  - *Cytauxzoon felis*
  - Babesiosis (*Babesia canis, B. gibsoni*)
  - Ehrlichiosis (*Ehrlichia canis*)
- ***Microangiopathic:***
  - Splenic torsion

- Cranial vena cava syndrome
- Hemangiosarcoma

Decreased Production

- ***Bone Marrow Disorder:***
  - Hematopoietic malignancy
  - Myelofibrosis
  - Idiopathic aplastic anemia
  - Irradiation
  - Myelodysplasia
- ***Systemic Disease:***
  - Anemia of chronic disease/inflammation
  - FeLV
  - Parvovirus
  - Renal failure
  - Liver disease
  - Endocrine disease (hypothyroidism, hypoadrenocorticism)
  - Neoplasia
- ***Toxin/Drug:***
  - Estrogen
  - Chemotherapy
  - Phenylbutazone
  - TMS
  - Griseofulvin
  - Quinidine
  - Thiacetarsemide
  - NSAIDs
- ***Nutritional:***
  - Mineral deficiency (iron)
  - Vitamin deficiency (B complex)
  - Inadequate protein intake

DIC, Disseminated intravascular coagulation; *FeLV,* feline leukemia virus; *GI,* gastrointestinal; *IHA,* immune-mediated hemolytic anemia; *MLV,* modified live virus; *NSAIDs,* nonsteroidal antiinflammatory drugs; *TMS,* trimethoprim/sulfadiazine.

Anemia, Immune-Mediated

Examples of Underlying Disorders and Triggers

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Infectious

- Viral: FeLV, FIV, FIP infection, transient or chronic persistent upper respiratory or GI viral diseases
- Bacterial: leptospirosis, feline mycoplasmosis, various acute and chronic infections (e.g., abscess, pyometra, diskospondylitis)
- Parasitic: babesiosis, leishmaniasis, dirofilariasis, ehrlichiosis, *Ancylostoma caninum*
- Other emerging infectious diseases (e.g., bartonellosis), bee stings

Drugs

- Sulfonamides
- Cephalosporins
- Penicillins
- Vaccines
- Propylthiouracil (cats)
- Methimazole (cats)
- Procainamide

Neoplasia

- Hemolymphatic: leukemias, lymphoma, multiple myeloma
- Solid tumors

Immune Disorders

- SLE
- Hypothyroidism
- Primary and secondary immunodeficiencies

Genetic Predisposition

- American cocker spaniel (one-third of all cases)
- English springer spaniel
- Old English sheepdog
- Irish setter
- Poodle
- Dachshund

FeLV, Feline leukemia virus; *FIP,* feline infectious peritonitis; *FIV,* feline immunodeficiency virus; *GI,* gastrointestinal; *SLE*, systemic lupus erythematosus.

Anemia, Hemolytic

Adapted from Bonagura J, Twedt DC, editors: Kirk's current veterinary therapy XIV: small animal practice, St Louis, 2009, Saunders.

Causes of Hemolytic Anemia in Dogs and Cats

Inherited Causes

- Pyruvate kinase deficiency
- Phosphofructokinase deficiency
- Chondrodysplasia/anemia
- Nonspherocytic hemolytic anemia

Immune-Mediated Causes (Primary)

- Primary (idiopathic) immune-mediated hemolytic anemia (IMHA)
- IMHA associated with systemic lupus erythematosus
- Neonatal isoerythrolysis
- Incompatible transfusions

Metabolic Causes

- Hypophosphatemia

Neoplastic Causes

- Microangiopathic anemia associated with hemangiosarcoma or lymphoma

Infectious Causes

- *Babesia canis*
- *Babesia gibsoni*
- *Mycoplasma haemominutum*
- *Mycoplasma haemofelis*
- *Mycoplasma haemocanis*
- *Dirofilaria immitis*
- Bacterial endocarditis
- Feline leukemia virus
- Leptospirosis
- *Cytauxzoon felis*
- *Ehrlichia canis*

Toxin- or Drug-Related Causes

- Onion toxicity
- Zinc toxicity
- Methylene blue
- Copper toxicity
- Propylthiouracil
- Methimazole
- Sulfa drugs
- Penicillins and cephalosporins
- Quinidine
- Acetaminophen (cats > dogs)
- Benzocaine (cats)
- Dapsone
- Nitrofurantoin
- Phenacetin (cats > dogs)
- Phenazopyridine
- Propofol (cats)
- Vaccinations
- Vitamin K3 (cats)

Anemia, Aplastic

Modified with permission from Kirk R, Bonagura J, editors: Kirk's current veterinary therapy Xl: small animal practice, St Louis, 1993, Saunders, p 481. *D,* Dog; *C,* cat.

Causes

Cause	Dog/Cat	Type of Aplasia	Outcome
Idiopathic	D,C	Chronic	Irreversible
Drug-Associated			
Estrogen	D	Acute/chronic	Reversible/irreversible
Chemotherapy	D,C	Acute	Reversible
Phenylbutazone	D	Acute	Mostly irreversible
Meclofenamic acid	D	Acute	Irreversible
Trimethoprim/sulfadiazine (TMS)	D	Acute	Reversible
Quinidine	D	Acute	Reversible
Thiacetarsemide	D	Acute	Reversible
Griseofulvin	C	Acute	Reversible
Infectious			
Ehrlichia	D	Acute/chronic	Reversible/irreversible
Parvovirus	D,C	Acute	Reversible
Feline leukemia virus	C	Chronic	Irreversible

Anaphylaxis

Causes

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Venoms

- Insects of the *Hymenoptera* order: bees, wasps, ants
- Spiders: black widow, brown recluse
- Lizards: Gila monster, Mexican beaded lizard
- Snakes: pit vipers (rattlesnakes, copperheads, water moccasins), coral snakes

Hormones

- Insulin
- Corticotropin
- Vasopressin
- Parathyroid hormone
- Betamethasone
- Triamcinolone

Antibiotics

- Penicillins: amoxicillin, ampicillin, procaine penicillin
- Chloramphenicol
- Lincomycin
- Gentamicin
- Tetracycline
- Sulfonamides
- Cephalosporins
- Polymyxin B
- Doxorubicin

Nonsteroidal Antiinflammatory Drugs (NSAIDs)

- Aspirin
- Ibuprofen

Anesthetics and Sedatives

- Acepromazine
- Ketamine
- Barbiturates
- Lidocaine and other local anesthetics
- Narcotics
- Diazepam

Parasiticides

- Dichlorophen
- Levamisole
- Piperazine
- Dichlorvos
- Diethylcarbamazine
- Thiacetarsemide

Miscellaneous

- Blood products

- Aminophylline
- Asparaginase
- Calcium disodium edetate
- Iodinated contrast media
- Neostigmine
- Amphotericin B
- Vaccines
- Allergen extracts: pollens, molds, foods
- Enzymes: chymotrypsin and trypsin
- Vitamins: vitamin K, thiamine, and folic acid
- Dextrans and gelatins
- Sulfonamides

Foods

- Milk
- Egg white
- Shellfish
- Legumes
- Fruits: citrus
- Chocolate
- Grains

Physical Factors

- Cold
- Heat
- Exercise

Amyloidosis

Diseases Reported in Association With Amyloidosis in Dogs

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Systemic Disease (Glomerular Disease)

Infectious

- ***Bacterial***
  - Pyelonephritis (A)
  - Pyometra (A, G)
  - Pyoderma (A, G)
  - Other chronic bacterial infections (A, G)
- ***Protozoal***
  - Leishmaniasis (A, MN, P-E, and M)
- ***Rickettsial***
- ***Viral***
  - Canine adenovirus type 1 (P-M)
- ***Fungal***
  - Blastomycosis (A)
  - Coccidioidomycosis (A, G)

Inflammatory

- Chronic dermatitis (A, G)
- Pancreatitis (A, G)
- Periodontal disease (A, G)
- Polyarthritis (A, G)
- Shar-pei fever (A)
- Systemic lupus erythematosus (A, MN, P-E, and M)

Neoplastic

- Lymphoma (A, G)
- Primary erythrocytosis (MCD?)
- Other neoplasms (A, G, MN)

Miscellaneous

- Hyperlipidemia (?)
- Chronic insulin infusion (A)
- Cyclic hematopoiesis in gray collies (A)

Familial

Idiopathic (A, G, MN, MCD, P-E, or M)

A, Amyloidosis; *E,* endocapillary; G, glomerulonephritis, uncharacterized; *M,* mesangial; *MCD,* minimal change disease; *MN,* membranous nephropathy; *P,* proliferative.

American Society of Anesthesiologists Classification System

From Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

CBC, Complete blood cell count; *PCV,* packed cell volume; *TP,* total protein; *U/A,* urinalysis.*Minor is duration less than 60 minutes.†Major is duration longer than 60 minutes or concerns patients older than 7 years.‡Surgical panel: urea, creatinine, alkaline phosphatase, alanine aminotransferase, glucose, sodium, potassium, chloride, total protein.§Biochemical panel: full panel includes surgical panel tests plus bicarbonate, anion gap, calcium, phosphorus, cholesterol, total bilirubin, γ-glutamyltransferase, and albumin.

American Society of Anesthesiologists: Classification System for Physical Status and Recommended Tests for Each Class

			RECOMMENDED LABORATORY TESTS		
Physical Status	**Definition**	**Examples**	**Minor***	**Major†**	**Prognosis**
I	Healthy with no organic disease	Elective procedures not necessary for health (e.g., ovariohysterectomy)	PCV, TP, urine specific gravity	CBC, U/A, surgical panel‡	Excellent
II	Local disease with no systemic signs	Healthy nonelective surgery (e.g., skin laceration, simple fracture)	PCV, TP, urine specific gravity	CBC, U/A, surgical panel‡	Good
III	Disease causes moderate systemic signs that limit function	Heart murmur, anemia, pneumonia, mild chest trauma, moderate dehydration	CBC, U/A, surgical panel‡	CBC, U/A, biochemical§ panel	Fair
IV	Disease causes severe systemic signs that threaten life	Gastric torsion, diaphragmatic hernia, severe chest trauma, severe anemia or dehydration	CBC, U/A, biochemical panel§	CBC, U/A, biochemical§ panel	Guarded
V	Moribund, not expected to live for more than 24 hours with or without surgery	Endotoxic shock, severe trauma, multiorgan failure	CBC, U/A, biochemical panel§	CBC, U/A, biochemical§ panel	Grave
E	Emergency	Qualifier of above classes	PCV, TP, urine specific gravity	Depends on facilities available	Variable

Alopecia, Canine Symmetrical

ACTH, Adrenocorticotropic hormone; *FSH,* follicle stimulating hormone; *GH,* growth hormone; *hrTSH,* human recombinant thyroid stimulating hormone; *LH,* luteinizing hormone; *PU/PD,* polyuria/polydipsia; *T4,* thyroxine; *TgAA,* antithyroglobulin antibodies; *TSH,* thyroid stimulating hormone.

Disorders Causing Symmetrical Alopecia in Dogs

Disorders	Cutaneous and Systemic Signs Apart from Alopecia	Common Clinicopathologic Abnormalities	Diagnostic Tests
Alopecia X	Skin hyperpigmentation, hair regrowth at the biopsy site	None	Signalment, rule out other causes, skin biopsies (large number of flame follicles suggestive)
Anagen defluxion	Related to severe systemic disease or to cytotoxic therapy	Related to the underlying disorder	History, trichogram
Breed-specific follicular dysplasia	Secondary pyoderma	None	Signalment, trichogram, skin biopsy
Canine recurrent flank alopecia	None	None	Signalment, history, skin biopsy
Color dilution alopecia	Comedones, secondary pyoderma	None	Signalment, trichogram, skin biopsy
Congenital alopecia	Anomalies of dentition	None	Signalment, skin biopsy
Hyperadrenocorticism	• Atrophic skin, calcinosis cutis, comedones, prominent cutaneous blood vessels, phlebectasia • PU/PD, polyphagia, panting, pot belly, muscle atrophy, lethargy, testicular atrophy, abnormal estrus	Stress leukogram, increased serum alkaline phosphatase, hypercholesterolemia, hyposthenuria, urinary tract infection	History, physical findings, ACTH stimulation test, low-dose dexamethasone suppression test, high-dose dexamethasone suppression test, ultrasonography, urine cortisol/creatinine ratio
Hyperestrogenism	• Skin hyperpigmentation, linear preputial dermatosis • Enlarged vulva, gynecomastia • Abnormal estrus, abnormal sexual behavior	Bone marrow suppression	Signalment, physical findings, ultrasonography/radiography, histopathology (gonads)
Hypothyroidism	Dull haircoat, scaling, myxedema, lethargy, obesity	Hypercholesterolemia, mild nonregenerative anemia	Total T4, free T4, TSH, (+/− TgAA, TSH stimulation test with hrTSH)
Pattern alopecia	None	None	Signalment, skin biopsy
Pituitary dwarfism	• Skin hyperpigmentation, secondary pyoderma • Proportionate dwarfism, clinical signs of hypothyroidism (if concomitant TSH deficiency), hypogonadism (if concomitant LH and FSH deficiency)	None	Signalment, physical findings, basal and poststimulation GH measurement, total T4 or free T4
Sebaceous adenitis	Scaling, follicular casts	None	Skin biopsy, trichogram

Disorders	Cutaneous and Systemic Signs Apart from Alopecia	Common Clinicopathologic Abnormalities	Diagnostic Tests
Telogen effluvium	Only if systemic disease or physiologic stress is present	None	History, trichogram, skin biopsy

AUTHOR: MANON PARADIS

Alkalosis, Respiratory

Causes

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2006, Saunders.

Hypoxemia (stimulation of peripheral chemoreceptors by decreased oxygen delivery)

- Right-to-left shunting
- Decreased Pio2 (e.g., residence at high altitude)
- Congestive heart failure (CHF)
- Severe anemia
- Hypotension
- Pulmonary diseases (causing ventilation/perfusion inequality)
    - Pneumonia
    - Pulmonary embolism
    - Pulmonary fibrosis
    - Pulmonary edema
    - Acute pulmonary distress syndrome (ARDS)

Pulmonary Disease (stimulation of nociceptive receptors independent of hypoxemia)

- Pneumonia
- Pulmonary embolism
- Interstitial lung disease
- Pulmonary edema
- ARDS

Central Nervous System (CNS)–Mediated Hypocapnia (direct stimulation of medullary respiratory center)

- Liver disease
- Gram-negative sepsis
- Drugs: salicylate intoxication, progesterone, xanthines (e.g., aminophylline)
- Recovery from metabolic acidosis
- Central neurologic disease
    - Trauma
    - Tumor
    - Infection
    - Inflammation (e.g., granulomatous meningoencephalitis)
    - Cerebrovascular accident
- Exercise
- Heatstroke

Mechanical Ventilation

Alkalosis, Metabolic

Causes

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2006, Saunders.

Chloride Responsive

- Vomiting of stomach contents
- Diuretic therapy
- Post hypercapnia

Chloride Resistant

- Primary hyperaldosteronism
- Hyperadrenocorticism

Alkali Administration

- Oral administration of sodium bicarbonate or other organic anions (e.g., lactate, citrate, gluconate, acetate)
- Oral administration of cation exchange resin with nonabsorbable alkali (e.g., phosphorus binder)

Miscellaneous

- Refeeding after fasting
- High-dose penicillin
- Severe potassium or magnesium deficiency

Adrenal Mass/Nodule

List of Possibilities in the Differential Diagnosis of an Incidentally Discovered Mass in the Adrenal Region

From Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Adrenal Cortex

- Nodular hyperplasia
- Adenoma
- Carcinoma

Adrenal Medulla

- Pheochromocytoma
- Ganglioneuroma

Extraadrenal Masses

- Extraadrenal pheochromocytoma (paraganglioma)

Other Adrenal Masses

- Myelolipoma
- Granulomatous disease (fungal, feline infectious peritonitis [FIP])
- Teratoma
- Adrenal cyst
- Hematoma

Metastasis

- Mammary gland tumors
- Lymphoma
- Leukemia
- Pulmonary adenocarcinoma
- Other carcinomas (prostate, bladder, gastric)

Pseudoadrenal Masses

- Arising from kidney, pancreas, lymph nodes, and blood vessels

Technical Artifacts

Acute Respiratory Distress Syndrome (ARDS)

Causes, Predispositions, and Risk Factors*

*Risk factors may apply to veterinary patients, human patients, or both.

- Electrocution
- Near drowning
- Neurologic insult (e.g., brain injury)
- Noxious gas inhalation (e.g., phosphine toxicosis)
- Oxygen toxicity
- Pneumonia (aspiration, other)
- Pulmonary contusions
- Pulmonary embolism
- Sepsis (e.g., secondary to parvoviral enteritis or other processes)
- Smoke inhalation
- Strangulation
- Trauma (massive)
- Upper airway obstruction (laryngeal paralysis, elongated soft palate, foreign body, mass)
- Vasculitis/systemic inflammatory response syndrome (SIRS) (e.g., secondary to necrotizing pancreatitis or other generalized inflammatory states)

Acute Renal Failure

Causes

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Prerenal

- Anesthesia
- Dehydration*
- Heatstroke
- Hemorrhagic shock
- Hypoadrenocorticism*
- Hypoalbuminemia
- Hypotensive shock
- Hypovolemic shock
- Septic shock
- Surgery
- Trauma
- Vasculitis

Intrinsic Renal

Nephrotoxins

- Aminoglycosides
- Amphotericin B
- Cisplatin
- Ethylene glycol
- Heavy metals
- Hemoglobinuria
- Lilies
- Myoglobinuria
- Nonsteroidal antiinflammatory drugs (NSAIDs)
- Radiocontrast agents
- Raisins/grapes
- Snake venom

Hemodynamic

- Anesthesia
- Cardiovascular shock
- Hemorrhagic shock
- Hypotensive shock
- Hypovolemic shock
- Septic shock
- Surgery

Other Conditions

- Borreliosis
- Glomerulonephritis
- Hemoglobin/myoglobin
- Hypercalcemia
- Leptospirosis
- Lymphoma
- Pyelonephritis
- Renal arterial thromboembolism
- Rickettsial infections
- Trauma

Postrenal

- Bilateral renal calculi
- Bilateral ureteral calculi
- Extraluminal obstruction
- Prostatic disease
- Rupture of outflow tracts
- Urethral calculi
- Urethral neoplasia

*Hypoadrenocorticism, diuretic treatment, and diabetes mellitus may cause azotemia with isosthenuria in the absence of kidney disease.

Acute Abdomen

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

DE, Definitely requires emergent surgery; *DS,* definitely surgical; *NS,* nonsurgical (urgency of medical treatment depends on specific problem and condition of the patient; some nonsurgical acute abdomen cases may eventually require surgery on a nonemergent basis); *PE,* potentially requires emergent surgery; *PS,* potentially surgical (some conditions designated as PE may require surgery, although not on an emergent basis).

Differential Diagnoses and Immediate Triage Strategies for the Acute Abdomen

Body System: Cause of Acute Abdomen	**Treatment**
Gastrointestinal Digestive System	
Gastric dilatation	PS
Gastric dilatation/volvulus	DS, DE
Gastroduodenal ulceration	NS
Gastroduodenal perforation	DS, PE
Gastroduodenal rupture	DS, DE
Gastroduodenal dehiscence	DS, DE
Gastroenteritis (viral, bacterial, toxic; i.e., garbage)	NS
Hemorrhagic gastroenteritis	NS
Intestinal obstruction (foreign body, intussusception, neoplasia)	DS, PE
Functional intestinal obstruction; ileus	NS
Intestinal ulceration	NS
Intestinal perforation	DS, DE
Intestinal rupture	DS, DE
Intestinal dehiscence	DS, DE
Intestinal volvulus	DS, DE
Cecal inversion	DS, PE
Obstipation	NS
Colitis	NS
Colonic ulceration	NS
Colonic perforation	DS, DE
Colonic rupture	DS, DE
Colonic dehiscence	DS, DE
Hepatobiliary Digestive System	
Acute hepatitis (toxic, infectious)	NS
Hepatic abscess	DS, PE
Hepatic trauma	PS, PE
Hepatic rupture	PS, PE
Hepatobiliary neoplasia	PS, PE

Body System: Cause of Acute Abdomen	**Treatment**
Biliary obstruction (calculi, neoplasia, pancreatitis—abscess)	PS, PE
Biliary rupture	DS, DE
Cholecystitis	PS, PE
Cholangiohepatitis	NS
Pancreatic Digestive System	
Acute pancreatitis	NS
Pancreatic abscess	DS, PE
Pancreatic neoplasia	DS, PE
Urinary System	
Acute nephrosis (toxicosis)	NS
Acute nephritis-pyelonephritis	NS
Urinary calculi: renal	PS, PE
Urinary calculi: ureteral	PS, PE
Urinary calculi: cystic	PS, PE
Urinary calculi: urethral	PS, PE
Trauma-avulsion-rupture (renal, ureteral, cystic, urethral)	DS, PE
Obstruction (neoplasia, stricture): ureter	DS, PE
Obstruction (neoplasia, stricture): urethra	DS, PE
Renal artery thrombosis	PS, PE
Renal neoplasia	PS, PE
Reproductive System	
Female	
Acute metritis	PS, PE
Pyometra	DS, DE
Uterine torsion	DS, DE
Dystocia	PS, PE
Ovarian cyst	PS, PE
Ovarian neoplasia	DS, PE
Male	
Acute prostatitis	NS
Prostatic abscess	DS, PE
Prostatic cysts	DS, PE
Prostatic neoplasia	DS, PE
Testicular torsion	DS, DE
Hematopoietic System: Spleen	

Body System: Cause of Acute Abdomen	**Treatment**
Splenic mass (hematoma, extramedullary hema- topoiesis, neoplasia, nodular hyperplasia, abscess)	DS, PE
Splenic rupture (mass)	DS, DE
Splenic rupture (trauma)	PS, PE
Splenic torsion	DS, DE
Peritoneum and Mesentery	
Peritonitis: septic	DS, DE
Peritonitis: chemical (bile, urine, enzymes)	PS, PE
Parietal peritoneal trauma: blunt	NS
Parietal peritoneal trauma: penetrating	DS, DE
Mesenteric traction: large masses	DS, PE
Mesenteric lymphadenopathy	PS, PE
Mesenteric lymphadenitis	NS
Mesenteric volvulus	DS, DE
Mesenteric avulsion	DS, DE
Mesenteric artery thrombosis	DS, DE
Adhesions with organ entrapment: internal hernias	DS, PE
Abdominal Wall	
Trauma	PS, PE
Abscess	DS, PE
Hematoma	PS, PE
Strangulated hernias	DS, DE
Extraabdominal	
Intervertebral disk disease	PS, PE
Diskospondylitis	PS, PE
Intoxications (heavy metal)	NS
Thoracic wall disease	PS, PE
Steatitis	NS
Myositis	NS
Hypoadrenocorticism	NS

Acidosis, Respiratory

Causes

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, ed 3, St Louis, 2006, Saunders.

Airway Obstruction

- Aspiration (e.g., foreign body, vomitus)

Respiratory Center Depression

- Neurologic disease (e.g., brainstem, high cervical spinal cord lesion)
- Drugs (e.g., narcotics, sedatives, barbiturates, inhalation anesthetics)

Cardiopulmonary Arrest

Neuromuscular Defects

- **Myasthenia gravis**
- **Tetanus**
- **Botulism**
- **Polyradiculoneuritis**
- **Polymyositis**
- **Tick paralysis**
- **Hypokalemic myopathy in cats**
- **Hypokalemic periodic paralysis in Burmese cats**
- **Drug-induced (succinylcholine, pancuronium, aminoglycosides with anesthetics, organophosphates)**

Restrictive Defects

- **Diaphragmatic hernia**
- **Pneumothorax**
- **Pleural effusion**
- **Hemothorax**
- **Chest wall trauma**
- **Pulmonary fibrosis**
- **Pyothorax**

Pulmonary Disease

- **Acute respiratory distress syndrome**
- **Pneumonia**
- **Severe pulmonary edema**
- **Diffuse metastatic disease**
- **Smoke inhalation**
- **Pulmonary thromboembolism**
- **Chronic sterile bronchitis**
- **Pulmonary fibrosis**

Inadequate Mechanical Ventilation

Acidosis, Metabolic

Causes

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, ed 3, St Louis, 2006, Saunders.

- **Increased Anion Gap (Normochloremic)**
- Ethylene glycol intoxication
- Salicylate intoxication
- Other rare intoxications (e.g., paraldehyde, methanol)
- Diabetic ketoacidosis*
- Uremic acidosis†
- Lactic acidosis
- **Normal Anion Gap (Hyperchloremic)**
- Diarrhea
- Renal tubular acidosis
- Carbonic anhydrase inhibitors (e.g., acetazolamide)
- Ammonium chloride
- Cationic amino acids (e.g., lysine, arginine, histidine)
- Posthypocapnic metabolic acidosis
- Dilutional acidosis (e.g., rapid administration of 0.9% saline)
- Hypoadrenocorticism‡

Acidosis, Lactic

Causes*

*d-lactic acidosis occurs with short bowel syndrome in human beings and has been observed in cats fed propylene glycol.

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, ed 3, St Louis, 2006, Saunders.

Type A: Hypoxic

- Increased oxygen demand
  - Severe exercise
  - Convulsions
- Decreased oxygen availability
  - Reduced tissue perfusion
    - Cardiac arrest, cardiopulmonary resuscitation
    - Shock
    - Hypovolemia
    - Left ventricular failure
    - Low cardiac output
    - Acute pulmonary edema
  - Reduced arterial oxygen content
    - Hypoxemia (Po2 30 mm Hg)
    - Extremely severe anemia (packed cell volume [PCV] < 10%)

Type B: Nonhypoxic

- Drugs and toxins
  - Salicylates
  - Ethylene glycol
  - Many others
- Diabetes mellitus
- Liver failure
- Neoplasia (e.g., lymphoma)
- Sepsis
- Renal failure
- Hypoglycemia
- Hereditary defects
  - Mitochondrial myopathies
  - Defects in gluconeogenesis

Abortion, Canine

From Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

AGID, Agar gel immunodiffusion test; *RSAT,* rapid slide agglutination test; *TAT,* tube agglutination test; *TSH,* thyroid-stimulating hormone.

Causes and Methods for Diagnosis of Canine Abortions

Causative Agents	Clinical Findings	Necropsy Findings	Tests
Bacteria			
Brucella canis	Third-trimester abortion	Autolyzed fetuses	Culture (special media): vaginal discharge and blood serologic examination: RSAT, TAT, and AGID
B. abortus, *B. suis*, or *B. melitensis*	History of contact with infected livestock, third-trimester abortion	Autolyzed fetuses	Serologic testing: specific for organism
Salmonella spp.	Systemic disease in bitch, purulent vaginal discharge	Fetal septicemia	Culture: vaginal discharge and fetal tissues
Campylobacter spp.	History of diarrhea in bitch or contact with humans	Placentitis	Culture (special media): vaginal discharge and fetal tissues
Escherichia coli or *Streptococcus* spp.	Purulent vaginal discharge, systemic disease in bitch	Fetal septicemia	Culture: vaginal discharge and fetal tissues
Viruses			
Canine herpesvirus	Third-trimester abortion, bitch asymptomatic, vaginal vesicles, stillbirth, infertility	Fetal septicemia; multifocal petechiae; necrosis in fetal adrenal glands, kidney, liver, and lung	Serology in bitch: paired samples 2 weeks apart, run together
Canine distemper or canine adenovirus	Systemic involvement in bitch	Depends on virus involved	Depends on virus involved
Other Organisms			
Mycoplasmataceae (*Mycoplasma* or *Ureaplasma* spp.)	Asymptomatic bitch housed in overcrowded conditions, vaginal discharge, infertility	Fetal septicemia	Culture: vaginal discharge and fetal tissues
Toxoplasma gondii	Bitch may be asymptomatic or have multisystemic involvement	Placentitis, multiorgan involvement in fetus	Serology: paired samples 2 weeks apart, run together (fourfold increase significant)
Endocrine Causes			
Progesterone deficiency	Infectious causes ruled out	None	Serial progesterone assays during luteal phase
Hypothyroidism	Obesity, lethargy, symmetric hair loss	None	TSH stimulation test

Bronchial Disease, Chronic

Possible Causes of Chronic Bronchitis in Dogs

Modified with permission from Kuehn NF: Chronic bronchitis in dogs. In King L: In Textbook of respiratory disease in dogs and cats, 2004, Saunders, p 381.

- **Atmospheric pollution**
- **Passive smoking**
  - Chronic exposure to smoke in poorly ventilated confined spaces
- **Respiratory tract infections**
  - Chronic fungal infection
  - Chronic bacterial infection: *Bordetella bronchiseptica, Mycoplasma* spp.
  - Viral infection: canine distemper virus, adenovirus (types 1 and 2), herpesvirus
  - Parasites: *Filaroides milksi, F. hirthi, Crenosoma vulpis, Capillaria aerophila, Dirofilaria immitis*
- **Genetic or acquired defects**
  - α1-Antitrypsin deficiency
  - Mucociliary defects
  - Immunodeficiency
- **Hypersensitivity (allergic) lung disease**

Bradycardia

Causes of Bradycardia in Dogs and Cats

- **Arrhythmias**
  - Second-degree AV block
  - Third-degree AV block
  - SSS/sinus node dysfunction
  - Atrial standstill (hyperkalemia, atrial myopathy)
- **Hypothermia**
- **Hypothyroidism**
- **Organophosphate toxicosis**
- **Pharmacologic** (e.g., due to β-blockers, calcium channel blockers, digitalis, opiates, α2 blocking drugs)
- **Vagai tone high: normal**
  - Brachycephalic breed
  - Athletic animal at rest
  - Sleep
- **Vagai tone high: abnormal**
  - GI disturbances
  - Upper respiratory obstruction (e.g., foreign body, laryngeal paralysis, elongated soft palate, mass, anesthetic circuit problem)
  - Neurologic lesions (central and severe: usually coma)

AV, Atrioventricular; *GI,* gastrointestinal; *SSS,* sick sinus syndrome.

Notes: First-degree AV block does not affect the heart rate.

In critically ill or anesthetized animals, an acute transition from tachycardia to bradycardia may indicate an upcoming cardiac arrest.

Definition of bradycardia in the clinical setting: heart rate < 60 bpm (large-breed dogs), <70 bpm (medium-breed dogs), <90 bpm (small-breed dogs), <130 bpm (cats).

Bone Neoplasia

From Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

Comparison of Primary Bone Tumors of the Appendicular Skeleton in Dogs

	Osteosarcoma	Chondrosarcoma	Fibrosarcoma	Hemangiosarcoma
Incidence of overall bone tumors	80%-85%	10%	<5%	<5%
Prevalence in appendicular versus axial skeleton	75%	11%	<40%	<50%
Age	Median 7-8 years	5-9 years	Mean 8.4 years	Young to middle-aged
Sex predilection	None (historically, male)	None	None	None
Breed predilection	Large and giant breeds	Medium to large breeds (golden retrievers)	Medium to large breeds	Medium to large breeds (German shepherds, boxers, Great Danes)
Radiographic findings	Osteolytic and osteoproductive	Osteolytic with periosteal reaction	Primarily lytic	Primarily lytic with considerable intramedullary extension
Histopathologic findings	Malignant spindle cells producing osteoid	Malignant spindle cells producing neoplastic chondroid in a fibrillar matrix	Malignant tumor of fibrous connective tissue	Malignant tumor of vascular endothelium
Sites	Metaphyseal; forelimb > hindlimb; distal radius primary	Primarily metaphyseal; hindlimb > forelimb	Metaphyseal and diaphyseal	Proximal and distal third of long bones; proximal humerus primary
Metastatic rate without treatment	90% before 1 year	20% (very slow)-100%	6%	Very high, at least 88%
Metastatic sites	Lungs > bone	Lung primary	Multiple	Multiple
Prognosis improved with tumor removal	Yes	Yes	Yes	Unknown
Prognosis improved with adjuvant chemotherapy	Yes	Unknown	Unknown	Unknown (possibly with doxorubicin)
Median survival without treatment	3-5 months	<2 months	Unknown	<3 months
Median survival with treatment	12 months	19 months	47% survival at 1 year	<5 months; <10% 1-year survival rate with amputation
Prognostic factors	Age, tumor size, percentage of tumor necrosis, tumor microvessel density, histologic grade, serum alkaline phosphatase	Histologic grade, location (i.e., if not resectable)	Degree of histologic differentiation	Unknown; all histologic grades carry a grave prognosis

	Osteosarcoma	Chondrosarcoma	Fibrosarcoma	Hemangiosarcoma

Bone Marrow Disorders

From Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

FeLV, Feline leukemia virus; *FIV,* feline immunodeficiency virus; *IHA,* immune-mediated hemolytic anemia.

Causes Based on Blood and Bone Marrow Examination

PERIPHERAL BLOOD EXAMINATION			
Cytopenia	**Hematocytosis**	**Dysplastic Cells**	**Blast Cells**
BONE MARROW EVALUATION			
Aplasia or Hypoplasia	**Hyperplasia**	**Myelodysplasia**	**Neoplasia**
Infections:	Infections:	Myelodysplastic syndrome	Acute lymphoblastic leukemia
Viral	Bacterial	Drug-induced dysplasia	Acute myelogenous leukemia
Rickettsial	Mycoplasmal	Lead toxicosis	Metastatic neoplasm
Protozoal	Rickettsial	Infections:	
Fungal	Protozoal	FeLV	
Drugs or chemicals	FIV (early)	FIV	
Estrogen (neoplasm or iatrogenic)	Parasitic	Nutritional deficiencies	
Organ failure	Viral (recovery)	Pelger-Huët anomaly	
Chronic disease or inflammation	Immune-mediated damage	Macrocytosis (poodles)	
Endocrine disorders	Iron deficiency	Myeloid leukemia	
Irradiation	Oxidative injury	IHA	
Hereditary cytopenia	Zinc toxicosis	Lymphoma	
Nutritional deficiencies	Hereditary enzyme deficiency		
Myelophthisis	Allergic reactions		
Myelofibrosis	Inflammation or hypersensitivity		
Marrow necrosis	Chronic leukemias		
Immune-mediated damage	Paraneoplastic syndrome		

Bone Diseases, Congenital

Congenital Skeletal Disorders of Small Animals

Adapted from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders, p 1970.

Generalized Bone Malformations

- Osteopetrosis—dense bones
- Osteogenesis imperfecta—osteopenia and bone fragility
- Mucopolysaccharidosis—lysosomal enzyme defects
- Dwarfism—osteochondrodysplasias (Scottish fold) and pituitary
- Congenital hypothyroidism
- Retained cartilage cores
- Craniomandibular osteopathy
- Multiple cartilaginous exostoses
- Avascular necrosis of the femoral head

Malformations of Individual Bones

- Hemimelia—radial or tibial agenesis
- Congenital amputation—absence of distal limb portion
- Phocomelia—missing segment of limb
- Amelia—absence of complete limb

Malformations of Bone Combinations

- Syndactyly—fused digits
- Polydactyly—extra digits
- Ectrodactyly—split or lobster claw deformity

Blood Type Frequencies, Dogs

From limited surveys in Giger U, Gelens J, Callan MB, et al: An acute hemolytic transfusion reaction caused by dog erythrocyte antigen 1.1 incompatibility in a previously sensitized dog. J Am Vet Med Assoc 206:9, 1995.

DEA, Dog erythrocyte antigen.*DEA 1.1 and 1.2 negative dogs.

	PERCENTAGE (%)	
Blood Type	**Positive**	**Negative**
DEA 1.1*		
1.1 (A1)	33–45	55–67
1.2 (A2)	7–20	35–60*
DEA 3 (B)	5–10	90–95
DEA 4 (C)	87–98	2–13
DEA 5 (D)	12–22	78–88
DEA 7 (Tr)	8–45	55–92

Blood Type Frequencies, Cats

With permission from Oxford University Press, adapted from Giger U, Bucheler J, Patterson DF: Frequency and inheritance of A and B blood types in feline breeds of the United States. J Hered 82:15, 1991. Also with permission, adapted from Giger U, Griot-Wenk M, Bucheler J, et al: Geographical variation of the feline blood type frequencies in the United States. Feline Pract 19:5, 1991.

*Breeds with isolated type AB cats.

Blindness

From Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

Acute Blindness

Location	Diagnosis	Potential Causes
Cornea	Edema	Loss of endothelial function (glaucoma, trauma, uveitis)
Anterior chamber	Uveitis	Hyphema
		Hypopyon
		Lipemic flare
Lens	Cataract	Diabetes mellitus
Vitreous		Hemorrhage
Retina	Retinal detachment	Hypertension, hyperviscosity
		Trauma
		Uveodermatologic syndrome
		Other immune-mediated disease
		Collie eye anomaly
		Vitreoretinal dysplasia
		Infectious:
		Mycotic
		Ehrlichiosis
		Rocky Mountain spotted fever
		Protothecosis
		Toxoplasmosis
		Feline immunodeficiency virus
		Feline leukemia virus
		Other
		Rhegmatogenous (shih tzu)
		Neoplasia (primary versus secondary)
	Retinal degeneration	Sudden acquired retinal degeneration
		Glaucoma
		Toxic: enrofloxacin, ivermectin, others
		Glaucoma
Optic nerve, optic chiasm, optic tract		Optic neuritis (infectious and noninfectious)
		Reticulosis
		Neoplasia (primary versus secondary)
		Trauma
Lateral geniculate body, optic radiation, visual cortex		Inflammatory (infectious and noninfectious)
		Postanesthesia
		Elevated intracranial pressure
		Neoplasia

Location	Diagnosis	Potential Causes
		Postictal
		Reticulosis

Bleeding Disorders: Primary Versus Secondary

With permission from Bonagura J: Kirk's current veterinary therapy XII: small animal practice, St Louis, 1995, Saunders, p 459.

Clinical Manifestations of Primary and Secondary Hemostatic Defects

Primary Hemostatic Defect	Secondary Hemostatic Defect
Petechiae common	Petechiae rare
Hematomas rare	Hematomas common
Bleeding at mucosal membranes, bleeding from multiple sites	Bleeding into muscles, joints, and body cavities
Bleeding immediately after venipuncture	Delayed bleeding after venipuncture
Examples: immune-mediated thrombocytopenia, aspirin therapy, von Willebrand disease	Examples: anticoagulant rodenticide intoxication, coagulopathy of hepatic insufficiency, hemophilias

Bleeding Disorders

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

APTT, Activated partial thromboplastin time; *BMBT,* buccal mucosal bleeding time; *D,* decreased; *DIC,* disseminated intravascular coagulation; *FDP,* fibrin degradation products; *I,* increased; *N,* normal; *PT,* prothrombin time; *vWD,* von Willebrand disease. DIC can have widely variable results.*Initially stops in normal time period but may start bleeding again.†Mild thrombocytopenia may occur if patient is concurrently hypothyroid.‡Usually normal but may be increased.

Expected Hemostatic Test Results in Selected Diseases

	HEMOSTATIC PROFILE				
Disease	**BMBT**	**Platelet Count**	**APTT**	**PT**	**FDP**
Thrombocytopenia (e.g., ehrlichiosis)	I	D	N	N	N
Platelet dysfunction (e.g., aspirin treatment, vWD)	I	N	N	N	N
Intrinsic pathway defect (e.g., hemophilia A or B)	N*	N	I	N	N
Factor VII deficiency	N	N	N	I	N
Multiple factor defects (e.g., vitamin K antagonism)	N*	N	I	I	N
Common pathway defect (e.g., factor X deficiency)	N*	N	I	I	N
DIC	I	D	I	I	I
von Willebrand disease	I	N†	N‡	N	N

Behavioral Change: Primary Behavioral Versus Neurologic

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 4, St Louis, 1994, Saunders.

Behavioral Signs Usually Caused by a Primary Behavioral Problem

- Aggression: dominance, competition, internal, fear, pain, learned, idiopathic
- Fear: fearful reactions to thunderstorms, gunshots, fireworks, separation anxiety, other animals, specific people
- Barking/hyperactivity: not true hyperkinesis
- Destruction: scratching, chewing, digging
- Roaming
- Inappropriate elimination: marking territory, urine spraying in cats, submissive
- Sexual: inappropriate mounting, lack of interest
- Maternal: cannibalism, anxiety, pseudopregnancy, indifference
- Predation feeding: aversions, coprophagy, pica, anorexia, wood chewing, grass and plant eating
- Attention-getting: self-mutilation; biting or chewing own feet, tail, or objects; barking; chasing shadows
- Stress response: self-mutilation, flank-sucking, head-bobbing or weaving, fly snapping, flank-staring, circling, face-rubbing, excessive grooming, tail and back twitching

Behavioral Signs Usually Caused by Neurologic Disease

- Persistent circling
- Aimless pacing
- Head pressing/getting stuck in corners
- Disorientation
- Nonrecognition of owners and familiar objects
- Dullness, depression, lethargy
- Hiding
- Seizures (episodic, untriggered behavioral abnormalities)
- Sudden idiopathic increase or loss of appetite
- Idiopathic polydipsia, sudden onset of frequent urination, unknowing dropping of fecal material in house, unexplained tremors, deafness, no response to sounds, bumping into objects

Bacteria Isolated from Sites of Infection

Data compiled from Greene CE, editor: Clinical microbiology and infectious diseases of the dog and cat, Philadelphia, 1998, Saunders.

Integument

- ***Pyoderma***
  - *Staphylococcus aureus/pseudintermedius*
  - *Proteus* spp.
  - *Pseudomonas* spp.
  - *Escherichia coli* (usually secondary to staphylococci)
- ***Ear***
  - *Pseudomonas* spp.
  - *S. aureus/intermedius*
  - *Proteus* spp.

Respiratory System

- ***Pneumonia***
  - *Pseudomonas* spp.
  - *E. coli*
  - *Klebsiella* spp.
  - *Pasteurella* spp.
  - *Bordetella* spp.
  - *Staphylococcus* spp.
  - *Streptococcus* spp.
  - *Mycoplasma* spp.
- ***Pleural Cavity***
  - *Nocardia* spp.
  - *Actinomyces* spp.
  - *Pasteurella* spp.
  - Anaerobes

Gastrointestinal Tract

- ***Intestine***
  - *Salmonella* spp.
  - *Campylobacter* spp.
  - *Clostridium perfringens*
  - *E. coli*

Genitourinary Tract

- *E. coli*
- *Proteus* spp.
- *Klebsiella* spp.
- *S. aureus/intermedius*

Eye (Conjunctiva and Cornea)

- *S. aureus* (coagulase positive and negative)
- *Streptococcus* spp.
- *S. epidermidis*
- *E. coli*
- *Proteus* spp.
- *Bacillus* spp.

Cardiovascular System

- ***Aerobes***
  - *S. aureus*
  - β-hemolytic streptococci
  - *E. coli*
  - *Klebsiella* spp.
  - *Pseudomonas* spp.
  - *Proteus* spp.
  - *Salmonella* spp.
- ***Anaerobes***
  - *Bacteroides* spp.
  - *Fusobacterium* spp.
  - *Clostridium* spp.

Cyanosis: Differentiation

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 5, St Louis, 2000, Saunders.

↓, Decreased; ↓↓, markedly decreased; ↑, increased; ↑↑, markedly increased.*Normal SaO2 (room air) = ~97%; normal PaO2 (room air) = ~100 mm Hg; normal PaCO2 (room air) = ~40 mm Hg; (−), no response.†Unless drawn from affected area.

Blood Gas Measurements, Oxygen Saturations, and Response to Oxygen Supplementation in Various Cyanotic Disorders

	Sao2	Pao2		Pao2
Problem	**Room Air***	**Room Air***	**PaCO2***	**Response to 100% O2**
Peripheral cyanosis	Normal†	Normal†	Normal	(−)
Right-to-left intracardiac shunt	↓↓	↓↓	Normal	(−)
Pulmonary parenchymal disease	↓↓	↓↓	↑	↑
Hypoventilation	↓	↓	↑↑	↑
Systemic hypoperfusion	↓	↓	Normal/↑	↑
Ventilation/perfusion mismatch	↓	↓	Normal/↓	↑
Methemoglobinemia	↓	Normal	Normal	(−)

Cyanosis

Causes of Central and Peripheral Cyanosis

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

CENTRAL CYANOSIS

Cardiac (Right-to-Left Shunting)

Intracardiac:

- Tetralogy of Fallot
- Atrial or ventricular septal defect with pulmonic stenosis or pulmonary hypertension

Extracardiac:

- Reversed patent ductus arteriosus (PDA) (differential cyanosis)
- Pulmonary arteriovenous fistulas with pulmonary hypertension

Pulmonary

Hypoventilation:

- Pleural effusion, pneumothorax
- Respiratory muscle failure (e.g., fatigue, myopathy, or neuromuscular disease)
- Toxicity (e.g., sedative or anesthetic overdose)
- Primary neurologic disease (e.g., neoplasia, inflammatory)

Obstruction:

- Laryngeal paralysis
- Foreign body (e.g., laryngeal, tracheal)
- Mass lesion of large airways (e.g., neoplasia, parasitic, inflammatory)
- Inadequate oxygen concentration of inspired gas (e.g., high-altitude, anesthetic complication)

Ventilation-Perfusion Mismatch

- Pulmonary thromboembolism
- Pulmonary infiltration
- Edema
- Inflammation
- Neoplasia
- Acute respiratory distress syndrome (ARDS)
- Chronic obstructive pulmonary disease or pulmonary fibrosis

Non–Oxygen-Carrying Hemoglobin (e.g., methemoglobinemia)

PERIPHERAL CYANOSIS

- Central cyanosis (e.g., congestive heart failure)
- Decreased arterial supply (e.g., surgical ligation of artery)
- Peripheral vasoconstriction (e.g., hypothermia, shock)
- Arterial thromboembolism
- Low cardiac output
- Obstruction of venous drainage: tourniquet or foreign object (i.e., rubber band), venous thrombosis, right-sided heart failure

Cutaneous Neoplastic and Nonneoplastic Masses

Classification

Epithelial Neoplastic and Nonneoplastic Skin MassesEpidermal Origin

- Viral papilloma
- Squamous cell carcinoma
- Basal cell carcinoma
- Dermoid cyst (Rhodesian ridgeback)

Follicular Origin

- Follicular cyst (infundibular cyst)
- Follicular hamartoma
- Trichoblastoma
- Trichoepithelioma
- Trichofolliculoma
- Infundibular keratinizing acanthoma (intracutaneous cornifying epithelioma, keratoacanthoma)
- Pilomatricoma

Melanocytic Origin

- Melanocytoma
- Melanoma

Sebaceous Origin

- Sebaceous hamartoma/nevus
- Sebaceous gland hyperplasia/adenoma
- Sebaceous epithelioma
- Sebaceous carcinoma
- Perianal (hepatoid) gland hyperplasia and adenoma
- Perianal gland epithelioma
- Perianal gland carcinoma

Sweat Gland Origin

- Apocrine cyst
- Apocrine adenoma
- Apocrine adenocarcinoma
- Eccrine carcinoma

Mesenchymal Neoplastic and Nonneo-plastic Skin MassesFibrous Origin

- Collagenous hamartoma/nevus
- Canine nodular dermatofibrosis (German shepherd)
- Acrochordon (skin tag)
- Fibroma
- Fibrosarcoma

Vascular and Perivascular Origin

- Hemangioma
- Hemangiosarcoma
- Lymphangiosarcoma
- Hemangiopericytoma

Lipocytic Origin

- Lipoma
- Liposarcoma

Muscular Origin

- Leiomyoma
- Leiomyosarcoma

Neural and Perineural Origin

Merkel cell tumor

Lymphohistiocytic Skin MassesHistiocytic Origin

- Canine cutaneous histiocytoma
- Canine reactive histiocytosis (cutane-ous, systemic)
- Histiocytic sarcoma

Lymphocytic Origin

- Plasmacytoma
- Epitheliotropic lymphoma
- Nonepitheliotropic lymphoma
- Cutaneous lymphomatosis

Miscellaneous Origins

- Mast cell tumor
- Transmissible venereal tumor
- Cutaneous metastases

* For noninflammatory and infectious processes, see algorithm of Nodular Dermatitis, .

AUTHOR: MANON PARADIS

Cranial Nerve Deficits

With permission from Braund KG: Clinical syndromes in veterinary neurology, St Louis, 1994, Mosby.

Cranial Nerve Dysfunction

Nerve	Clinical Signs	Clinical Tests	Normal Response	Abnormal Response
I. Olfactory	Hyposmia or anosmia	Smell of food or nonirritating, volatile substance	Interest in food; sniff, recoil, or nose lick with volatile substance	No response
II. Optic	Visual impairment and hesitancy in moving	• Obstacle test • Visual placing reaction • Menace reaction • Following movement test	• Avoidance of obstacle • Visual placement of limbs • Eye blink • Eyes following objects	• Bumping objects • No response
III. Oculomotor	Ventrolateral strabismus	1. Ocular movement in horizontal and vertical planes	1. Normal ocular excursion	1. Impaired movements of affected eye
	Paralysis of upper eyelid (ptosis), mydriasis	2. Point source of light in each eye	2. Direct and consensual pupillary light reflexes	2. On affected side, direct pupillary reflex absent, consensual reflex present; on normal side, direct pupillary reflex present, consensual reflex absent
Sympathetic control of pupillary function	Constricted pupil (miosis), enophthalmos, prolapse of third eyelid, ptosis of upper lid			
IV. Trochlear	Usually not noted			
V. Trigeminal (motor and sensory)	• Atrophy of masticatory muscles • Inability to close mouth	• Jaw tone • Palpate and observe masticatory muscles • Palpebral reflex • Corneal reflex • Probe nasal mucosa • Touch face	• Resistance to opening jaws • Normal muscle contour and resilience • Eye blink • Eye blink and globe retraction • Recoil • No reaction	• Lack of resistance • Atrophy, hypotonia • No response • Intense discomfort
VI. Abducent	Medial strabismus	Ocular movements in horizontal plane	Normal ocular excursion	Impaired lateral movement of affected eye
VII. Facial	• Asymmetry of facial expression • Inability to close eyelids • Lip commissure paralysis • Ear paralysis	• Palpebral reflex • Corneal reflex • Menace reaction • Tickle ear	1-3. Eye blink • Ear flick	1-4. No response
VIII. Vestibulocochlear				

Nerve	Clinical Signs	Clinical Tests	Normal Response	Abnormal Response
Vestibular	• Nystagmus, head tilt, circling • Falling and rolling	• Ocular movements in horizontal and vertical planes • Caloric and rotatory test • Righting reactions	1-2. Normal physiologic nystagmus • Normal righting	1-3. No response, ventrolateral strabismus on dorsal extension of head
Cochlear	Deafness	Hand clap	Startle reaction, blink ear contraction	No response
IX. Glossopharyngeal	Dysphagia	Gag reflex	Swallowing response	No response
X. Vagus	• Dysphagia • Abnormal vocalizing • Inspiratory dyspnea • Megaesophagus	• Gag reflex • Laryngeal reflex • Oculocardiac reflex	• Swallow • Cough • Bradycardia	1-3. No response
XI. Spinal accessory	Usually not noted			
XII. Hypoglossal	Deviation of tongue	• Tongue stretch • Nose rub	• Retraction • Lick response	1-2. No response

Coughing

Modified with permission from King L: In Textbook of respiratory disease in dogs and cats, Philadelphia, 2004, Saunders, p 44.

COPD, Chronic obstructive pulmonary disease; *PIE,* pulmonary infiltrates with eosinophils.

Causes of Cough in Small Animals

Allergic Inflammatory

- Feline asthma
- Chronic bronchitis/COPD
- Eosinophilic bronchopneumopathy/PIE
- Eosinophilic pneumonitis

Cardiovascular

- Pulmonary edema
- Left atrial enlargement
- Pulmonary thromboembolism

Infectious

- Tracheobronchitis
- Pneumonia
- Bacterial
- Viral
- Fungal
- Protozoal

Neoplastic

- Primary
- Lung
- Trachea
- Larynx
- Metastatic
- Heart-base tumor
- Compression due to enlarged lymph nodes

Parasites

- *Filaroides*
- *Aelurostrongylus*
- *Paragonimus*
- *Capillaria*
- *Dirofilaria*, especially post adulticide treatment
- Larval migration (*Toxocara* spp., *Ancylostoma caninum*, *Strongyloides stercoralis*)
- Other

Trauma and Physical Abnormalities

- Foreign body
- Collapsing trachea
- Tracheal hypoplasia
- Tracheal stenosis
- Smoke inhalation
- Pulmonary hemorrhage

Corneal Ulcer

Underlying Causes of Corneal Ulceration in Dogs and Cats

Modified with permission from Kirk R: Kirk's current veterinary therapy XI: small animal practice, ed 11, Philadelphia, 1993, Saunders, p 1103.

- Entropion
- Other lid defects
- Distichiasis
- Ectopie cilia
- Lagophthalmos
- Exophthalmos
- Foreign body
- KCS
- Ocular trauma
- Qualitative tear film deficiencies (mucin and/or lipid)
- Severe debilitation
- Cranial nerve deficits; CN V and/or VII

CN, Cranial nerve; *KCS,* keratoconjunctivitis sicca.

Constipation

Differential Diagnosis of Constipation in the Cat

Adapted from Washabau RJ, Hasler AH: Constipation, obstipation, and megacolon In August JR, editor: Consultations in feline internal medicine, ed 3, Philadelphia, 1997, Saunders, p 106.

Neuromuscular Dysfunction

- Colonie smooth muscle: idiopathic megacolon, aging
- Spinal cord disease: lumbosacral disease, cauda equina syndrome, sacral spinal cord deformity (Manx cat)
- Hypogastric or pelvic nerve disorders: traumatic injury, malignant disease, dysautonomia
- Submucosal or myenteric plexus neuropathy: dysautonomia, aging

Mechanical Obstruction

- Intraluminal: foreign material (bones, plant material, hair), neoplasia, rectal diverticulum, permeai hernia, anorectal stricture
- Intramural: neoplasia
- Extraluminal: pelvic fracture, neoplasia, prostatic disease

Inflammation

- Perianal fistula, proctitis, anal sac abscess, anorectal foreign body, perianal bite wound

Metabolic and Endocrine

- Metabolic: dehydration, hypokalemia, hypocalcemia, hypercalcemia
- Endocrine: hypothyroidism (e.g., post-thyroidectomy), obesity, nutritional secondary hyperparathyroidism

Pharmacologic

- Opioid agonists, cholinergic antagonists, diuretics, barium sulfate, phenothiazines

Environmental and Behavioral

- Soiled litter box, inactivity, hospitalizaron, change in environment

Conjunctivitis, Feline

Modified from Kirk RW: Current veterinary therapy VI, ed 6, Philadelphia, 1971, Saunders, p 1284; Modified with permission from Panel report, colloquium on feline diseases. J Am Vet Med Assoc 158:838-839.

CF test, complement-fixing test; *CNS,* central nervous system; *FA test,* Fluorescent antibody test; *HA test,* hemagglutinating antibody test; *H&E,* hematoxylin and eosin stain; *MLV,* modified live vaccine; *SN test,* serum-neutralizing test.

Differential Diagnosis of Feline Conjunctivitis and Respiratory Disease Complex

	Rhinotracheitis	**Caliciviral Disease (FCV)**	**Reovirus Infection (FRI)**	**Chlamydiosis**	**Mycoplasma and Other Infections**
Agent	Feline herpesvirus	Feline caliciviruses (picornaviruses, numerous strains)	Reovirus	*Chlamydophila felis* (formerly *Chlamydia psittaci*)	*Mycoplasma* spp., *Staphylococcus pyogenes*, *Pasteurella multocida*, *Bordetella bronchiseptica*, and others
Signs:					
Severity	Regularly more severe	Mild to moderate, subclinical infections common	Mild	Mild	Subclinical infections common
Ocular	Lacrimation, conjunctivitis, chemosis, occasionally keratitis	Lacrimation, sometimes conjunctivitis	Lacrimation	Conjunctivitis (can be follicular)	Conjunctivitis
Nasal	Serous or mucopurulent discharge, sneezing	Serous discharge, occasional sneezing, ulceration of external nares	Nasal discharge rare	Nasal discharge rare	None or purulent
Oral	Occasional small vesicles and ulcers in buccal epithelium	Frequent ulceration on anterior dorsal margin of tongue and hard palate, gingivitis	None	None	None
Other	Coughing, abortion, skin ulcers, CNS signs	Paw erosions	None	None	None
Course	2-4 weeks	7-10 days	1-26 days	Often chronic or recurrent	May be chronic
Incubation (natural infection)	2-10 days	1-9 days	4-19 days	6-15 days	Usually secondary
Immunity	Initially low and transient, can be boosted and become persistent	Some strains produce broad cross-protection clinically but allow reduced viral multiplication	Unknown	Weak, transient	Weak, transient

	Rhinotracheitis	Caliciviral Disease (FCV)	Reovirus Infection (FRI)	Chlamydiosis	Mycoplasma and Other Infections
Diagnosis	Demonstration of intranuclear inclusions in H&E-stained biopsy specimens, tissue culture isolation, FA test	Tissue culture isolation, FA test	Tissue culture isolation, SN test, HA test	Conjunctival smears Giemsa-stained to show elementary bodies, CF tests	Culture
Inclusions	Intranuclear inclusions in respiratory epithelial cells, conjunctiva, and other such areas	None	Paranuclear cytoplasmic	Intracytoplasmic elementary bodies in conjunctival epithelial cells	None
Carrier state	Latent phase with periodic excretion after stress	Continuous shedding until self-clearance	Probable	Yes	Yes
Morbidity	High	High	50%	Variable	Variable
Mortality	High in kittens, aged, or immunocompromised	Variable; may be moderate in young kittens	Very low	Very low	Very low
Maternal antibody	<9 weeks	<11 weeks	Unknown	Unknown	Unknown
Prophylaxis	MLV	MLV	None	MLV	None
Treatment	Symptomatic, supportive with antibiotics; oral L-lysine as needed	Symptomatic, supportive with antibiotics	Symptomatic	Tetracyclines locally and systemically	Antibiotics

Congestive Heart Failure: Classification

Functional Classification of CHF

New York Heart Association Classification*

I. Normal activity does not produce undue fatigue, dyspnea, or coughing.
II. The dog or cat is comfortable at rest, but ordinary physical activity causes fatigue, dyspnea, or coughing.
III. The dog or cat is comfortable at rest, but minimal exercise may produce fatigue, dyspnea, or coughing. Signs may also develop while the animal is in a recumbent position (orthopnea).
IV. CHF, dyspnea, and coughing are present even when the dog or cat is at rest. Signs are exaggerated by any physical activity.

International Small Animal Cardiac Health Council†

I. Asymptomatic patient
    - Signs of heart disease but no cardiomegaly
    - Signs of heart disease and evidence of compensation (cardiomegaly)
II. Mild to moderate CHF
    - Clinical signs of CHF are evident at rest or with mild exercise and adversely affect the quality of life
III. Advanced CHF
    - Clinical signs of CHF are immediately obvious.
        - Home care is possible.
        - Hospitalization is recommended (cardiogenic shock, life-threatening edema, large pleural effusion, refractory ascites).

Consensus Panel of the Specialty of Cardiology, American College of Veterinary Internal Medicine, 2009‡

Stage A. Propensity to develop structural heart disease with or without overt clinical signs (phenotype) but no detectable abnormality on physical examination or clinical diagnostic testing.

- Example: Cavalier King Charles spaniel dog destined to develop myxomatous mitral valve disease, examined months/years before developing a heart murmur. Normal physical examination and echocardiogram.

Stage B. Physical exam abnormality consistent with cardiovascular disease but no overt clinical signs.

- Stage B1. No secondary changes on diagnostic investigation
    - Example: Cavalier King Charles spaniel dog with incidentally discovered heart murmur due to myxomatous mitral valve disease. No overt clinical signs. No left atrial enlargement on echocardiogram.
- Stage B2. Evidence of secondary changes on diagnostic tests.
    - Example: Cavalier King Charles spaniel dog with incidentally discovered heart murmur due to myxomatous mitral valve disease. No overt clinical signs. Moderate left atrial enlargement on echocardiogram.

Stage C. Decompensation of the underlying cardiovascular lesion, causing overt clinical signs

- Stage C1. Acute congestive heart failure. Overt clinical signs are present.
    - Example: Cavalier King Charles spaniel dog with dyspnea, cough, and orthopnea due to cardiogenic pulmonary edema
- Stage C2. Chronic controlled congestive heart failure. Overt clinical signs are absent while appropriate treatment is being administered, typically at home.
    - Example: Cavalier King Charles spaniel dog with a history of cardiogenic pulmonary edema, now home and feeling well with daily medications.

Stage D. Refractory congestive heart failure. Despite increases in oral medications, signs of decompensation persist.

- Stage D1. Acute, refractory congestive heart failure. In-hospital treatment.
    - Example: Cavalier King Charles spaniel dog reevaluated because of severe dyspnea due to recurrent pulmonary edema.
- Stage D2. Chronic, persistently overt congestive heart failure.
    - Example: Cavalier King Charles spaniel dog previously in stage D1, with improved but not fully resolved overt clinical

signs, discharged to home/palliative care.

CHF, Congestive heart failure.

Congestive Heart Failure: Physical Signs

Physical Signs Associated With CHF

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 4, St Louis, 1994, Saunders.

Pulmonary Signs (Left-Sided CHF)

- Rales/crackles on auscultation (alveolar edema)
- Frothy, pink sputum
- Shortness of breath, tachypnea
- Dyspnea and discomfort during recumbency (orthopnea)
- Cough

Signs Attributable to Either Left or Right CHF

- Weakness and fatigue (general exercise intolerance)
- Exertional dyspnea
- Gallop sound/"gallop rhythm" (accentuated third heart sound)
- Poor peripheral perfusion: pale mucous membranes, slow capillary refill time, mild cyanosis, cool extremities
- Tachycardia
- Weight loss (cachexia)

Systemic Signs (Right-Sided CHF)

- Generalized venous engorgement
- Hepatomegaly
- Body cavity effusions (modified transudate): ascites, pleural effusion, pericardial effusion
- Dependent peripheral edema
- Weight gain (retained fluid)

CHF, Congestive heart failure.

Congestive Heart Failure: Causes

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2000, Saunders.

Causes

Valvular Heart Disease

- Congenital malformations: aortic or subaortic stenosis, mitral valve malformation, pulmonic stenosis, tricuspid valve malformation
- Acquired diseases: myxomatous atrioventricular valvular disease, ruptured chordae tendineae, bacterial endocarditis

Myocardial Diseases

- Malformations: defects of the atrial and ventricular septum
- Dilated cardiomyopathy
- Hypertrophic cardiomyopathy
- Restrictive cardiomyopathy (endomyocardial. brosis)
- Unclassified feline cardiomyopathies
- Atrial muscle degeneration
- Right ventricular cardiomyopathy
- Myocarditis
- Secondary myocardial diseases: hyperthyroidism, acromegaly, hypertension

Pericardial Diseases

- Idiopathic pericardial hemorrhage/pericarditis
- Cardiac neoplasia leading to pericardial effusion
- Infectious

Vascular Diseases

- Malformation: patent ductus arteriosus, arteriovenous. stula
- Heartworm disease

High-Output States

- Anemia
- Thyrotoxicosis

Cardiac Arrhythmia

- Chronic bradyarrhythmia
- Chronic tachyarrhythmia

Congenital Heart Disease: Breed Predilections

With permission from Kirk R, Bonagura J, editors: Kirk's current veterinary therapy XI: small animal practice, St Louis, 1993, Saunders, p 650. Data from Veterinary Medical Data Base (VMDB) at Purdue University, 1987-1989: 1320 dogs with congenital heart disease (CHD) out of 154,233 dogs. Numbers 1, 2, and 3 identify predisposed breeds represented by four or more affected dogs in which relative risk for the indicated abnormality was significantly elevated in this series (P 0.05 to P 0.0001):

- 1: Mildly increased risk (odds ratio 1.5-2.9 times all other dogs)
- 2: Moderate risk (odds ratio 3-4.9 times others)
- 3: Marked risk (odds ratio 5 times others)

*Breed-associated diseases were not confirmed in this study but suggested or confirmed by others.Sex predominance: PDA (females 3:1), PS in English bulldogs (males 4:1), mitral and tricuspid dysplasia (males 2:1).

Breed Predilections in Dogs With CHD

Breed	Condition
Airedale terrier	Pulmonic stenosis (PS)-2
Beagle	PS*
Bichon frise	Patent ductus arteriosus (PDA)-2
Boxer	Aortic stenosis (AS)-3
Boykin spaniel	PS*
Bull terrier	Mitral dysplasia (MD)*
Chihuahua	PS,* PDA*
Cocker spaniel	PDA-1, PS-1
Collie	PDA-1
Doberman pinscher	Atrial septal defect (ASD)*
English bulldog	PS-3, ventricular septal defect (VSD)-3, AS-1, tetralogy of Fallot (TF)*
English springer spaniel	PDA-2
German shepherd	Tricuspid dysplasia (TD)-3, AS-1, persistent right aortic arch (PRAA)-2, MD,* PDA*
German shorthaired pointer	AS*
Golden retriever	AS-3, TD*
Great Dane	AS-1, PRAA-3, MD,* TD*
Irish setter	PRAA*
Keeshond	PDA-2, TF*
Kerry blue terrier	PDA-3
Labrador retriever	TD-3
Maltese	PDA-3
Mastiff	PS-3
Miniature schnauzer	PS-2
Newfoundland	AS-3
Pomeranian	PDA-3

Breed	Condition
Poodles	PDA-2
Rottweiler	AS-3
Samoyed	PS-3, AS-1, ASD*
Scottish terrier	PS-2
Shetland sheepdog	PDA-3
West Highland white terrier	PS-3
Weimaraner	TD,* peritoneopericardial hernia*
Yorkshire terrier	PDA-1

Coma, Stupor

Causes of Stupor and Coma

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 5, St Louis, 2000, Saunders.

Congenital or Familial Disorders

- Hydrocephalus
- Lysosomal storage disorders
- Lissencephaly

Metabolic Disorders

- Hepatic encephalopathy
- Hypoadrenocorticism
- Diabetes mellitus
- Hypoglycemia
- Hypothyroidism
- Uremia
- Hypoxemia
- Acid-base imbalance
- Osmolality imbalance
- Heatstroke
- Hyperlipidemia

Nutritional Disorders

- Thiamine deficiency (end-stage)

Neoplasia

- Primary lesions
- Metastatic lesions

Inflammation

- Canine distemper
- Rabies
- Rocky Mountain spotted fever
- *Ehrlichia* infection
- Feline infectious peritonitis
- Fungal, protozoal, and bacterial infections
- Granulomatous meningoencephalitis

Toxins/Drugs

- Ethylene glycol
- Lead
- Barbiturates
- Mushroom poisoning
- Alcohol
- Cannabinoids
- Hallucinogens

Trauma

- Cranial trauma

Vascular

- Coagulopathies
- Hypertension
- Cardiomyopathy
- Bacterial emboli
- Feline ischemic encephalopathy
- Ischemia

Other

- Status epilepticus

Chronic Kidney Disease: Complications

Complications and Comorbid Conditions in Animals With Chronic Kidney Disease

Adapted from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Complications of Chronic Kidney Disease

- Anemia
- Systemic hypertension
- Dehydration
- Hyperparathyroidism
- Hypermagnesemia
- Hyperphosphatemia
- Hypocalcemia and hypercalcemia
- Hypokalemia
- Malnutrition
- Metabolic acidosis
- Uremic encephalopathy
- Uremic gastritis
- Uremic pneumonitis
- Uremic stomatitis

Comorbid Conditions: Common

- Cardiac disease
- Degenerative joint disease
- Dental and oral diseases
- Hyperthyroidism (cats)
- Nephroliths and ureteroliths
- Urinary tract infections

Chronic Kidney Disease: Stages

From Ettinger SJ, Feldman, EC: Textbook of veterinary internal medicine, ed 7, St Louis, 2010, Saunders.

Stages of Chronic Kidney Disease in Dogs and Cats

SERUM CREATININE VALUES (mg/dL/µmol/L)		
Stage	**Dogs**	**Cats**
Stage 1	<1.4 / <125	<1.6 / <140
Stage 2	1.4-2.0 / 125-179	1.6-2.8 / 140-249
Stage 3	2.1-5.0 / 180-439	2.9-5.0 / 250-439
Stage 4	>5.0 / >440	>5.0 / >440

Cerebrospinal Fluid Abnormalities

Modified from de Lahunta A: Veterinary neuroanatomy and clinical neurology, St Louis, 1983, Saunders.

cmm, Cubic millimeter; *CSF*, cerebrospinal fluid; *WBC*, white blood cell.

CSF Determinations and Diseases of the Nervous System

	DISEASE	
Determination	**Meningitis**	**Parenchymal Disease**
	Bacterial disease: suppurative inflammation	Tissue necrosis: neoplasia, degenerations Viral disease: nonsuppurative inflammation
Physical	Turbid, clot	Clear, colorless
Cytologic (WBC)		
Quantitative	Large increase: >100/cmm	Small increase: <100/cmm
Differential	Mostly neutrophils	Mostly mononuclear cells
Chemical		
Protein, Quantitative (total)	Large increase: >100 mg/dL	Small increase: <100 mg/dL
Glucose: normally about 80% of blood level	Normal or decreased to below 50% of blood level	Normal

Central Nervous System Disorders, Multifocal

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

CNS, Central nervous system; *FIP,* feline infectious peritonitis virus; *FIV,* feline immunodeficiency virus; *GME,* granulomatous meningoencephalitis; *RMSF,* Rocky Mountain spotted fever.

Diseases That Typically Result in Multifocal or Diffuse CNS Signs

Degenerative

- Storage disease
- Multineuronal degeneration

Anomalous

- Hydrocephalus/syringomyelia/hydromyelia complex

Metabolic

- Hepatic
- Renal
- Hypoglycemia
- Hyperthyroidism
- Hypothyroidism
- Hyperadrenocorticism
- Hyperosmolar syndromes
    - Adipsia

Neoplastic

- Lymphoma
- Leukemias
- Metastatic tumors

Nutritional

- Thiamine

Inflammatory

- ***Infectious***
- Viral
    - Distemper
    - Herpes
    - Parvovirus
    - Parainfluenza
    - FIP
    - FIV
- Bacterial
    - Bacterial encephalitis
    - Tetanus
- Fungal
    - Cryptococcosis
    - Blastomycosis
    - Coccidioidomycosis
    - Candidiasis
    - Aspergillosis
- Protozoal
    - Toxoplasmosis
    - Neosporosis
- Parasitic
    - *Toxocara*
    - *Cuterebra*
- Rickettsial
    - RMSF
    - *Ehrlichia*
- Unclassified
    - Protothecosis

Noninfectious

- GME
- Breed-associated CNS inflammation (necrotizing encephalitis): pug, Maltese, Yorkshire terrier
- Spinal cord vasculitis
- Nonclassified
    - Steroid-responsive meningoencephalitis

Idiopathic

- Dysautonomia

Toxins

Vascular disease

- Intracranial hemorrhage
- Thromboembolism
- Hypertension
- Spinal hemorrhage

Dystocia: Causes

From Feldman EC, Nelson RW: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

Causes in Bitches and Queens

Cause	Bitch (%)	Queen (%)
Maternal	**75.3**	**67.1**
Primary complete inertia	48.9	36.8
Primary partial inertia	23.1	22.6
Birth canal too narrow	1.1	5.2
Uterine torsion	1.1	—
Uterine prolapse	—	0.6
Uterine strangulation	—	0.6
Hydrallantois	0.5	—
Vaginal septum formation	0.5	—
Fetal	**24.7**	**29.7**
Malpresentations	15.4	15.5
Malformations	1.6	7.7
Fetal oversize	6.6	1.9
Fetal death	1.1	1.1

Dystocia Versus Other Periparturient Phenomena

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Reasons for Seeking Veterinary Assistance for Reproductive Disorders

Presenting Complaint	Disorder(s)
No signs of labor >24 hours after temperature decrease to <37.8°C	Normal or dystocia
More than 1 week overdue	
Fetal membranes in vulva >15 minutes	
Strong contractions >30 minutes without delivery	
No fetus produced after 4-6 hours of onset of stage II labor	Dystocia
More than 3 hours between fetal delivery	Dystocia in canine
Vaginal discharge	Dystocia, metritis, pyometra
Temperature >39.7°C in the bitch	Dystocia, metritis, pyometra, uterine torsion, mastitis
Profuse vomiting, diarrhea, and toxemia in the bitch	
Incessant crying of offspring	
Anorexia, lethargy, depression >24 hours postpartum	Metritis, mastitis
Hot, painful, swollen mammary glands	Mastitis
Extreme restlessness, panting, tremors, and stiff gait	Eclampsia

Dyspnea

Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 5, St Louis, 2000, Saunders.

Upper Airway Disorders

- Nasal cavity*
  - Stenotic nares
  - Obstruction (infection, inflammation, neoplasia, trauma, bleeding disorders)
- Pharynx, larynx
  - Elongated or edematous soft palate
  - Pharyngeal polyp (cat)
  - Laryngeal edema, collapse, foreign body, inflammation, trauma, paralysis, spasm, neoplasia, vocal-fold webbing
  - Everted laryngeal saccules
- Cervical trachea
  - Collapse, stenosis
  - Trauma, foreign body
  - Neoplasia, osteochondral dysplasia
  - Parasites (*Oslerus osleri*)

Lower Airway Disorders

- Thoracic trachea (see Cervical Trachea, above)
  - Extraluminal compression (lymphadenopathy, heart-based tumors, enlarged left atrium)
- Bronchial disease (allergic, infectious, parasitic, chronic obstructive pulmonary disease)

Pulmonary Parenchymal Disorders

- Edema (cardiogenic, noncardiogenic)
- Pneumonia (infectious, parasitic, inhalation)
- Neoplasia
- Allergy (allergic pneumonitis, including heartworm; eosinophilic granuloma; eosinophilic bronchopneumopathy)
- Embolism (dirofilariasis, hyperadrenocorticism, disseminated intravascular coagulation)
- Trauma, bleeding disorders

Pleural/Body Wall Disorders

- Pneumothorax
- Pleural effusion
- Congenital body wall disorders (pectus excavatum)
- Thoracic wall trauma
- Thoracic wall neoplasia
- Thoracic wall paralysis
- Diaphragmatic hernia (congenital, acquired)

Mediastinal Disorders

- Infection
- Trauma, including pneumomediastinum
- Neoplasia

Peritoneal Cavity Disorders

- Organomegaly, obesity
- Effusion
- Gastric torsion, dilatation/volvulus

Hemoglobin Disorders

- Anemia
- Methemoglobinemia
- Cyanosis

Miscellaneous

- Central nervous system (brain, spinal cord)
- Peripheral nerve, neuromuscular, muscular
- Metabolic (acidemia; severe hypokalemia in cats)
- Anxiety
    - Fear
    - Pain

Dysphagia

Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Anatomic or Mechanical Lesions

- Pharyngeal inflammation (e.g., abscess, inflammatory polyp, oral eosinophilic granuloma)
- Foreign-body obstruction (oral, pharyngeal, nasopharyngeal, proximal esophagu)
- Neoplasia
- Retropharyngeal lymphadenomegaly
- Sialocele
- Mandibular fracture
- Lingual frenulum disorder
- Cricopharyngeal achalasia or asynchrony
- TMJ disorder (e.g., luxation, fracture)
- Cleft palate
- Pharyngeal trauma

Pain

- Stomatitis/glossitis/pharyngitis (FIV, FeLV, immune-mediated disease, uremic glossitis, ingestion of a caustic substance)
- Tooth-related problems (tooth root abscess, fracture, periodontitis)
- Trauma
- Electric cord burns
- Retrobulbar abscess

Neuromuscular Disorders

- Myasthenia gravis (focalized or generalized)
- Acute polyradiculoneuritis
- Masticatory myositis
- Tick paralysis
- Botulism
- Polymyositis
- TMJ disease

Neurologic Disorders

- Rabies
- Trigeminal paralysis or neuritis
- Neuropathies of CN VII, IX, X, or XII
- CNS disease (brainstem lesion)

CN, Cranial nerve; *CNS,* central nervous system; *FeLV,* feline leukemia virus; *FIV,* feline immunodeficiency virus; *TMJ,* temporomandibular joint.

Disseminated Intravascular Coagulation (DIC)

Associated Conditions

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Intravascular Hemolysis

- Hemolytic transfusion reaction
- Hemolytic anemia

Septicemia

- Gram-negative bacteria (endotoxin)
- Gram-positive bacteria (bacterial coat mucopolysaccharide)

Viremia

Parasitic Infections

- Protozoal infection
- Metazoal infection

Obstetric Complications

Miscellaneous

- Gastric dilatation/volvulus
- Diabetes mellitus

Neoplasia

Massive Tissue Injury

- Burns
- Trauma
- Surgical procedures
- Heatstroke

Venoms and Toxins

- Snakebites
- Insect stings
- Aflatoxin

Hepatic Disease

Pancreatitis

While a cause-and-effect relationship has not been established for most cases of DIC in dogs and cats, the conditions listed here are suspected to contribute to the onset, perpetuation, or both, of DIC.

Diskospondylitis: Microorganisms

Infectious Agents Associated With Diskospondylitis in Dogs and Cats

Modified from Greene C: Infectious diseases of the dog and cat, ed 2, St Louis, 1999, Saunders.

Dogs

- Bacterial
  - *Staphylococcus pseudintermedius*
  - *Bruceila canis*
  - *Nocardia*
  - *Actinomyces*
  - *Streptococcus canis*
  - *Escherichia coli*
  - *Alcaligenes*
  - *Micrococcus*
  - *Proteus*
  - *Mycobacterium*
  - *Corynebacterium*
- Fungal
  - *Aspergillus terreus*
  - *Paecilomyces varioti*
  - *Fusarium*
  - *Mucor*

Cats

- *S. canis*
- *Actinomyces*
- *E. coli*

Discolored Urine

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

RBCs, Red blood cells.

Potential Causes in Dogs and Cats

Urine Color	Causes
Dark yellow	Concentrated urine
Pale yellow	Normal urochromes, urobilin
Yellow-brown	Bile pigments
Yellow-orange	Bilirubin
	Fluorescein
	Concentrated urine
	Phenazopyridine
Red	Hemoglobin
	RBCs
	Myoglobin
	Dyes
	Phenazopyridine
	Phenolsulfonphthalein
Green-blue	Methylene blue
	Dithiazanine
	Biliverdin
Brown-black	Bile pigments
	Myoglobin
	Methemoglobin
Milky	Pyuria
	Lipiduria
	Phosphate crystals
Colorless	Dilute

Dilated Cardiomyopathy Differential Diagnosis: Myocardial Failure

Modified with permission from Kittleson M: Small animal cardiovascular medicine, St Louis, 1998, Mosby, p 320.

†These causes constitute less than 10% of the clinical cases of severe myocardial failure seen clinically. The remainder are idiopathic.

*Clinically documented causes of myocardial failure in veterinary medicine.

Potential Causes of Ventricular Dilation and Poor Contractility (Myocardial Failure)

Viral

- Parvovirus*
- Distemper virus
- Canine herpesvirus

Fungal

Rickettsial

- *Ehrlichia canis*
- *Rickettsia rickettsii*
- *Bartonella elizabethae*

Spirochetal

- *Borrelia burgdorferi**

Parasitic

- *Trypanosoma cruzi**
- *Toxoplasma gondii*
- *Toxocara canis*

Endocrinologic

- Severe hypothyroidism
- Hyperthyroidism*
- Pheochromocytoma

Drugs and Toxins

- Adriamycin*
- Cobalt
- Gossypol

Physical Injury

- Electric shock
- Trauma
- Heatstroke

Nutritional Deficiencies

- Taurine*
- Carnitine*

Ischemia/Infarction

- Septic coronary artery embolus*
- Atherosclerosis*

Muscular Dystrophy

Diet: Assessment

Relevant Considerations

- Inquire about specific varieties and amounts of what the patient is typically fed and what it is currently being fed, including:
  - Commercial pet foods
  - Home-prepared diets
  - Table foods or scraps
  - Treats
  - Dietary supplements
  - Foods used to deliver medications or supplements
- Establish who lives in the household and whether there have been any recent changes, including:
  - People and other pets
- Inquire about how the patient is fed and whether there have been any recent changes, including:
  - Who feeds the pet
  - Timing of meals
  - Free choice versus meal feeding
- Ask about the patient's feeding behavior.

AUTHOR: KATHRYN MICHEL

Diarrhea

Major Categories and Causes for Acute Diarrhea in Dogs and Cats

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Intestinal Parasites

- Hookworms
- Roundworms
- Whipworms
- Coccidia
- *Giardia intestinalis* (sometimes difficult to diagnose)
- Strongyloides
- Trichomoniasis

Dietary Problems

- Poor-quality food or food poisoning
- Sudden dietary change (especially in young animals)
- Food intolerance or allergy

Acute Viral or Bacterial Enteritis

- Parvovirus (canine and feline)
- Coronavirus (canine and feline)
- *Clostridium perfringens*–associated enteritis
- Campylobacteriosis
- Salmonellosis
- *Escherichia coli*–associated enteritis (verotoxin-producing strains)

Intussusception

Intoxication

- Garbage
- Food poisoning
- Heavy metal
- Organophosphate

Hemorrhagic Gastroenteritis

Diarrhea, Small Versus Large Intestine

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Differentiation of Chronic Small-Intestinal from Chronic Large-Intestinal Diarrhea

	Small-Intestinal Diarrhea	Large-Intestinal Diarrhea
Weight loss (most important criterion)	Expected	Uncommon except with histoplasmosis, pythiosis, or cancer
Polyphagia	Often present	Uncommon
Vomiting	Common	Occurs in 10%-20% of animals
Volume of feces	May be normal or larger than normal	May be normal or smaller than normal
Frequency of defecation	Normal to slightly increased	Normal to markedly increased; may have many small defecations per bowel movement
Slate-gray feces (steatorrhea)	Occasionally	No
Hematochezia	No	Sometimes present
Melena	Sometimes	No
Mucoid stools	Rare (unless ileum is diseased)	Often present
Tenesmus/dyschezia	Rarely present	Sometimes present

Diarrhea, Neonatal

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

FeLV, Feline leukemia virus; *FIP,* feline infectious peritonitis; *FIV,* feline immunodeficiency virus.

Causes of Neonatal Diarrhea in Puppies and Kittens

Dietary

- Abrupt change in diet
- Overfeeding
- Indiscretion: garbage ingestion
- Ingestion of abrasive or indigestible material
- Food intolerance
- Intolerance of lactose ingested as milk

Endoparasitic

- Helminths: ascarids, hookworms, whipworms, *Strongyloides*
- Others: cestodes, trematodes, *Trichinella*
- Protozoa: coccidia (*Cystoisospora*), *Cryptosporidium*, *Giardia lamblia*
- Others: *Pentatrichomonas*, *Entamoeba*, *Balantidium*, rickettsial organisms
- Salmon poisoning disease

Obstructive

- Intestinal foreign body
- Intussusception
- Intestinal volvulus

Idiopathic Chronic Diarrhea in Young Cats

Drug- and Toxin-Induced

- Antiinflammatory drugs
- Antimicrobials
- Anthelmintics
- Heavy metals: lead, arsenic, thallium
- Insecticides: organophosphates
- Plants

Infectious

- Viral: parvoviruses, coronaviruses, rotaviruses, canine distemper, FeLV, FIV, FIP
- Bacterial: *Salmonella* spp., *Campylobacter* spp., *Yersinia enterocolitica*, *Bacillus piliformis*, *Escherichia coli*, *Clostridium* spp.

Extraintestinal

- Renal failure
- Hepatic disease
- Hypoadrenocorticism
- Acute pancreatitis
- Diabetes mellitus

Diarrhea, Chronic Large Intestinal: Causes

From Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Diagnosis in 74 Cases of Chronic Large-Bowel Diarrhea

Diagnosis	Number of Cases
Idiopathic	19
Plasmacytic lymphocytic colitis	15
Clostridium perfringens enterotoxicosis	10
Malignant neoplasia	10
Pyogranulomatous colitis	6
Histiocytic ulcerative colitis	3
Eosinophilic granulomatous colitis	2
Trichuris vulpis	1
Histoplasmosis	1
Miscellaneous	7

Diabetes, Ketoacidosis

Triggers and Predisposing Conditions

- Acromegaly
- Chronic kidney disease
- Congestive heart failure
- Epinephrine release
- Glucagonoma
- Glucocorticoid treatment
- Hepatitis/cholangiohepatitis
- Hyperadrenocorticism
- Infection
    - Abscess (subcutaneous, other)
    - Periodontal/oral
    - Pneumonia
    - Pyoderma
    - Pyometra
    - Urinary tract infection
- Pancreatitis
- Progesterone (diestrus; progestagen treatment)

Diabetes Mellitus

Complications in Dogs and Cats

Modified from Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

Common

- Iatrogenic hypoglycemia
- Persistent polyuria and polydipsia (PU/PD)
- Weight loss
- Cataracts (dogs)
- Bacterial infections, especially in the urinary tract
- Pancreatitis
- Ketoacidosis
- Hepatic lipidosis
- Peripheral neuropathy (cat)

Uncommon

- Peripheral neuropathy (dog)
- Glomerulonephropathy, glomerulosclerosis
- Retinopathy
- Systemic hypertension
- Exocrine pancreatic insufficiency
- Gastric paresis
- Diabetic diarrhea
- Diabetic dermatopathy (dog) (i.e., superficial necrolytic dermatitis/hepatocutaneous syndrome)

Diabetes Insipidus, Nephrogenic

Causes

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2000, Saunders.

Congenital (Primary)

Acquired (Secondary)Functional

- Drugs
  - Glucocorticoids
  - Lithium
  - Demeclocycline
  - Methoxyflurane
  - *Escherichia coli* endotoxin (e.g., pyelonephritis, pyometra)
  - Diuretics
- Electrolyte/mineral disturbances
  - Hypokalemia
  - Hypercalcemia
- Altered medullary hypertonicity
  - Hypoadrenocorticism
- Multifactorial or unknown mechanism
  - Hepatic insufficiency
  - Hyperthyroidism
  - Hyperadrenocorticism
  - Postobstructive diuresis
  - Acromegaly

Structural

- Medullary interstitial amyloidosis (e.g., in cats, shar-pei dogs)
- Polycystic kidney disease
- Chronic pyelonephritis
- Chronic interstitial nephritis

Dermatosis, Periocular

Dogs

- Parasitic:
  - Demodicosis
  - Sarcoptic acariasis
  - Trombiculiasis
- Fungal:
  - Dermatophytosis
  - *Malassezia* dermatitis
- Bacterial:
  - Staphylococcal folliculitis
  - Mucocutaneous pyoderma
- Protozoal:
  - Leishmaniasis
- Allergic:
  - Atopic dermatitis
  - Food allergy
  - Contact allergic dermatitis
  - Angioedema
- Autoimmune/immune-mediated:
  - Pemphigus (foliaceus, erythematosus, vulgaris)
  - Lupus erythematosus (cutaneous, systemic)
  - Bullus pemphigoid
  - Canine familial dermatomyositis
  - Erythema multiforme
  - Uveodermatologic syndrome
  - Vitiligo
- Neoplastic:
  - Epitheliotropic lymphoma
- Miscellaneous:
  - Juvenile cellulitis
  - Superficial necrolytic dermatitis (hepatocutaneous syndrome)
  - Zinc-responsive dermatosis
  - Actinic dermatitis

Cats

- Parasitic:
  - Notoedric acariasis
  - Demodicosis
  - Trombiculiasis
- Fungal:
  - Dermatophytosis
- Bacterial:
  - Staphylococcal folliculitis
- Allergic:
  - Atopic dermatitis
  - Food allergy
  - Contact allergic dermatitis
- Autoimmune/immune-mediated:
  - Pemphigus (foliaceus, erythematosus, vulgaris)
  - Cutaneous lupus erythematosus
  - Systemic lupus erythematosus
  - Erythema multiforme
  - Periocular leukotrichia (Siamese)
- Miscellaneous:
  - Actinic dermatitis
  - Idiopathic facial dermatitis (Persian, Himalayan, exotic short hair)

Dermatoses, Scaling and Crusting

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

BC, Bacterial culture; *Bx,* skin biopsy; *C,* common; *CS,* clinical signs; *Cyt,* cytology; *DTM,* dermatophyte test medium fungal culture; *Hx,* history; *IDST,* intradermal skin test; *IgE,* allergen-specific serum IgE assay; *MDB,* minimum database; *NSF,* no significant findings; *R,* rare; *SS,* skin scraping; *U,* uncommon; +, positive; −, negative.

Scaling and Crusting Dermatoses of Dogs and Cats

Disease	Lesions	Species	Signalment	Lesion Distribution	Frequency	Pruritus	Diagnosis
Bacterial							
Superficial folliculitis	Crusts, scales, collarettes, pustules	Dog > cat	Varies	Trunk	C	− to + +	CS, Cyt, BC, Bx
Deep pyoderma	Crusts, ulcers	Dog > cat	Varies	Trunk, feet	C	+	CS, Cyt, BC, Bx
Mucocutaneous pyoderma	Crusts, ulcers	Dog	German shepherd or others	Lips, peribuccal	U	+ (painful)	CS, Bx
Acute moist dermatitis	Moist crust, exudation, erythema	Dog	Any (often flea related)	Face, neck, caudal trunk	C	+ + +	CS
Fungal							
Dermatophytosis	Crusts, scales, alopecia, erythema	Cat > dog	Young most frequently	Head, extremities, trunk	C	− to + +	DTM, Wood's light
Malassezia dermatitis	Crusts, scales, erythema, lichenification	Dog > cat	Adult most frequently	Axillary, groin, interdigital, facial	C	+ + +	Cyt
Parasitic							
Ctenocephalides felis (flea)	Scales, erythema	Dog > cat	Any	Lumbosacral, neck	C	+	CS, parasite exam
Sarcoptes scabiei	Crusts, scales, excoriations, alopecia, erythema	Dog	Any	Pinnal margins, lateral elbows, ventrum	C	+ + +	SS, response to therapy
Demodex canis	Crusts, scales, exudation, alopecia, erythema	Dog	Young or immunocompromised adults	From single lesions on the head to generalized	C	− to +	SS
Cheyletiella spp.	Scales	Dog, cat	Young, most frequently	Dorsal trunk to generalized	U	− to + + +	SS, tape impression
Notoedres cati	Crusts, scales	Cat	Any	Head, feet, generalized	U	− to + + +	SS
Viral							
Feline leukemia virus (FeLV)	Crusts, scales, erosions	Cat	Any	Face, pinnae, perioral, feet, trunk	U	++	Serology, Bx
Allergic Reaction							

Disease	Lesions	Species	Signalment	Lesion Distribution	Frequency	Pruritus	Diagnosis
Atopic dermatitis	Erythema, alopecia, crusts (excoriation), scales, and others	Dog > cat	All, dogs often 1-5 years old	Face, ears, feet, ventrum	C	+ to + + +	CS, IDST, IgE
Food hypersensitivity	Erythema, crusts (excoriation), and others	Dog, cat	All, any age	Any	C	+ to + + +	Food trial
Flea bite hypersensitivity	Erythema, crusts (excoriation), and others	Dog, cat	All	Caudal dorsum, ventrum, thighs	C	+ + to + + +	Response to flea control
Miliary dermatitis	Small hemorrhagic crusts	Cat	All (often associated with fleas)	Dorsum	C	+ +	CS
Endocrine and Metabolic							
Hyperadrenocorticism	Alopecia, cutaneous atrophy, calcinosis cutis, crusts (pyoderma)	Dog > cat	Middle-aged, older animals	Trunk	C	− (occ. +)	MDB, hormone assays, imaging, Bx
Hypothyroidism	Scaling, dry skin, pyoderma, ± alopecia	Dog	Middle-aged, often large breeds	Generalized	C	−	MDB, thyroid assay
Superficial necrolytic dermatitis (hepatocutaneous syndrome)	Severe adherent crusting	Dog (cat)	Old	Muzzle, footpads, pressure points	R	+ to ++ (painful)	Bx, MDB, liver assays, imaging
Immune-Mediated Disease							
Pemphigus foliaceus	Crusts, pustules	Dog, cat	Any age and sex; Akita, chow chow, and others	Nasal planum, muzzle, pinnae, footpads, trunk	U	− to +	Bx
Discoid lupus erythematosus (DLE)	Crusts, depigmentation, erosions, ulcers	Dog, cat	Collies, Shetland sheepdog, and others	Nasal planum, muzzle	U	−	Bx
Exfoliative cutaneous lupus erythematosus	Excessive scaling	Dog	German short-haired pointer	Generalized	U		Bx
Erythema multiforme	Crusts, vesicles erythema, target lesions, erosions, ulcers	Dog, cat	Any	Axillae, groin, mucocutaneous junctions	U	−	Bx
Congenital and Hereditary							
Primary seborrhea	Excessive scaling or greasy skin	Dog (cat)	Onset before 6 months of age; American cocker spaniel and others	Generalized	U	− to + +, especially with secondary infections	Bx

Disease	Lesions	Species	Signalment	Lesion Distribution	Frequency	Pruritus	Diagnosis
Ichthyosis	Excessive scaling	Dog	Golden retriever, Norfolk terrier, American Bulldog and others	Generalized	U		Bx
Schnauzer comedo syndrome	Comedones that may become crusted	Dog	Miniature schnauzer	Dorsum	C	−	CS, Bx
Familial canine dermatomyositis	Alopecia, scaling, depigmentation	Dog	Onset before 6 months of age, collie, Shetland sheep dog, and others	Face, pressure points	U	−	Cx, Bx
Cornification Defects							
Secondary seborrhea	Excessive scaling or greasy skin	Dog, cat	Any age	Depends on primary cause	C	− to + + + depending on cause	CS, any appropriate tests for primary disease
Vitamin A–responsive dermatosis	Marked follicular plugging, hyperkeratotic plaques	Dog	Cocker spaniel and others; Adult onset	Generalized, more pronounced on ventrum	U	− to + +	CS, Bx
Ear margin dermatosis	Follicular casts and scaling	Dog	Dachshund and others	Ear margins, lateral and medial	U	− may become painful	CS, Bx
Environmental							
Solar dermatitis	Erythema, scaling, may progress to exudation and crusting	Dog > cat	Light-haired animals, outdoor exposure	Pinnae, nasal planum (cat), bridge of nose, ventrum (dog)	C	− to +	CS, Bx
Nutritional							
Zinc-responsive dermatosis	Crusts, scales, erythema, alopecia	Dog	Siberian husky, Alaskan malamute; young adults	Periocular, perioral mucocutaneous junctions, pressure points	U	− to +	Bx
Fatty acid deficiency	Scales	Dog, cat	Any	Generalized	U	− to + +	Dietary hx
Others							
Cutaneous lymphoma	Lesions highly variable but may include severe scaling	Dog > cat	Older animals	Generalized or localized	U	− to + + +	Bx
Granulomatous sebaceous adenitis	Hyperkeratosis, alopecia, follicular casts, may be erythematous	Dog (cat)	Young to middle-aged, standard poodle, Akita, vizsla, and others	Face, trunk, pinnae, become generalized	C	− to + +	CS, Bx

Disease	Lesions	Species	Signalment	Lesion Distribution	Frequency	Pruritus	Diagnosis
Otitis externa	Scale, erythema otic exudate	Dog > cat	Any	Pinnae, ear canal	C	+ +	Otoscopic examination, Cyt, BC

Eosinophilia

Potential Causes of Eosinophilia in Dogs and Cats

From Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders, 2004.

- Parasitism
  - Heartworm disease
  - GI
  - Dermatologic
  - Other
- Asthma
- Nonparasitic dermatologie disease
- Mast cell tumor
- Hypoadrenocorticism (Addison's disease)
- Uterine disease
- Eosinophilic myositis
- Eosinophilic pneumonitis/rhinitis/conjunctivitis
- Eosinophilic enterocolitis (allergic colitis)
- Eosinophilic leukemia
- Eosinophilic granuloma complex
- Eosinophilic vasculitis
- Drug reaction

GI, Gastrointestinal.

Enteropathies: Breed-Related

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Suspected and Confirmed Breed Susceptibilities for Small-Intestinal Disease in Dogs and Cats

Breed	Condition
Basenji	Lymphocytic-plasmacytic enteritis (also called immunoproliferative disease)
Beagle	Cobalamin deficiency
Border collie	Cobalamin deficiency
Boxer	Histiocytic ulcerative colitis
German shepherd	Idiopathic antibiotic-responsive, inflammatory bowel disease (lymphoplasmacytic, eosinophilic)
Giant schnauzer	Defective cobalamin absorption
Irish setter	Gluten-sensitive enteropathy
Lundehund	Lymphangiectasia
Retrievers	Dietary allergy
Rottweiler	Susceptibility to parvovirus
Soft-coated wheaten terrier	Protein-losing enteropathy/nephropathy
Shar-pei	Lymphocytic-plasmacytic enteritis, cobalamin deficiency
Toy breeds	Hemorrhagic gastroenteritis
Yorkshire terrier	Lymphangiectasia

Endocarditis

Modified with permission from Greene C: Infectious diseases of the dog and cat, ed 2, St Louis, 1999, Saunders, p 568.

Frequency of Isolation of Bacteria from Positive Blood Culture

Bacteria	Canine Endocarditis (% of Cases)
Gram Positive	
Staphylococcus intermedius	6–33
Streptococcus spp.	12–26
Gram Negative	
Escherichia coli	6–30
Anaerobic	
Propionibacterium acnes	6
Erysipelothrix rhusiopathiae	19
Corynebacterium spp.	19
Other	
Bartonella spp.	28

Electrocardiogram (ECG) Abnormalities

Common Associations

Baseline

- Sawtooth: atrial flutter versus artifact (panting, purring, electrical interference).

P waves

- Tall (>0.4 mV [dog], >0.2 mV [cat]): P pulmonale. Rule out right atrial enlargement. Tall P waves are normal if R-R interval is short (i.e., normal during sinus tachycardia), but P wave height should normalize when heart rate slows.
- Wide (>0.05 sec [dog], >0.04 sec [cat]): P mitrale. Rule out left atrial enlargement.
- Cyclical increase and decrease in P-wave amplitude: wandering pacemaker.
- Absent: isoelectric to that lead (P waves are present but visible only in other leads), atrial standstill due to hyperkalemia, atrial standstill due to atrial myocardial disorder (rare), atrial fibrillation (fine, wavy baseline and irregularly irregular R-R interval must be present also).

PR Association

- Long PR interval (>0.13 sec [dog], >0.09 sec [cat]): first-degree atrioventricular (AV) block.
- Progressive lengthening of PR interval until longest one is followed by P wave without QRS complex: second-degree AV block, Mobitz type I.
- Two or more consecutive P waves without QRS complexes, then a P wave triggers a QRS complex: second-degree AV block, Mobitz type II.
- P waves and QRS complexes occur independently: third-degree AV block (normal or high atrial [P wave] rate, ventricular escape rhythm [wide, bizarre QRS complexes] slower than atrial rate) or ventricular tachycardia (wide, bizarre QRS complexes occur at a faster rate than P waves, which are often buried within the QRS complexes).
- Short PR interval (<0.06 sec [dog], <0.05 sec [cat]): preexcitation/Wolff-Parkinson-White syndrome (PR interval is short at any heart rate) or sinus tachycardia (PR interval normally shortens as heart rate increases).

QRS Complexes

- Wide (>0.06 sec [dogs], >0.04 sec [cats]): diagnostic of left bundle branch block. Strongly suggests left ventricular enlargement; also occurs with severe hyperkalemia, quinidine toxicity.
- Small (low amplitude): rule out hypothyroidism, pericardial effusion, pleural effusion, ascites, obesity, pneumothorax, intrathoracic mass, hypothermia (dogs); rule out normal (cats).

Q Waves (Lead II)

- Deep: generally normal, especially in young, large-breed dogs; has been loosely associated with interventricular septal hypertrophy in dogs.

R Waves (Lead II)

- Tall (>2.5 mV [dogs that are small or medium breeds], >3.0 mV [dogs that are large breeds], >0.9 mV [cats]): left ventricular enlargement.

S Waves (Lead II)

- Deep: rule out right ventricular enlargement.
- S1S2S3 (S wave present in leads I, II, and III): strongly suggests right ventricular enlargement.

ST Segment

- Elevation (>0.15 mV [dog], any [cat]) or depression (>0.2 mV [dog], any [cat]): myocardial hypoxia, electrolyte disturbances.
- Slurring/coving: myocardial hypoxia.

T Waves

- Tall (>1 mV or >¼ of height of R wave [dog]; >0.3 mV [cats]): commonly normal. If onset of tall T waves is noted during ECG monitoring over time: rule out hyperkalemia, myocardial hypoxia, movement artifact (change in limb position).
- Different from rest of T waves: indicates abnormal repolarization, which in turn suggests abnormal ventricular depolarization of that heartbeat (e.g., premature ventricular complex).

Widespread availability of echocardiography has demonstrated that ECG is of limited accuracy for inferring cardiac structure. Indications of abnormal cardiac chamber size based on ECG features should be considered tentative and are best confirmed or ruled out using echocardiography.

Effusions

Modified with permission from Kittleson MD, Kienle RD, editors: Pericardial disease and cardiac neoplasia. In Small animal cardiovascular medicine, St Louis, 1998, Mosby, p 420.

FIP, Feline infectious peritonitis; *GI,* gastrointestinal.

Characteristics of Effusions

Parameter	Transudate	Modified Transudate	Exudate	Hemorrhage
Specific gravity	<1.018	1.018-1.025	>1.025	>1.025
Protein (g/dL)	<2.5	2.5-6.0	>2.5	>2.5
Appearance	Clear and watery	Clear to serosanguineous	Turbid, serosanguineous, serofibrinous	Serosanguineous, sanguineous
Cellularity (cells/mm^3)	<1000	>2500	>5000	>5000
Cytologic examination	Macrophages, mesothelial cells, and occasional neutrophils	Macrophages, mesothelial cells, and occasional neutrophils and erythrocytes	Variable	Primarily erythrocytes
Examples	Hypoalbuminemia (renal loss, GI loss, hepatic synthetic failure, massive skin wound/burn loss), prehepatic congestion/obstruction (e.g., portal vein thrombosis)	Heart failure, posthepatic vascular obstruction (e.g., caudal vena caval thrombosis), neoplasia, chyle	Septic (bacterial infection [aerobic, anaerobic]), nonseptic (e.g., FIP)	Anticoagulant rodenticide toxicosis, ruptured neoplasm, trauma

Effusions, Bicavitary*

Conditions Associated With Bicavitary Effusions

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

- Cardiovascular conditions
  - Pericardial effusion of any cause (neoplastic, idiopathic, toxic [anticoagulant], other) causing cardiac tamponade
  - Constrictive pericardial disease
  - Right-sided congestive failure: dilated cardiomyopathy, tricuspid regurgitation of any cause (tricuspid dysplasia, myxomatous tricuspid valve disease/endocardiosis, other), severe pulmonic stenosis, cor pulmonale of any cause (heartworm disease/caval syndrome, idiopathic pulmonary hypertension, other), tricuspid valve stenosis
  - Caudal vena cava thromboembolism
- Congenital obstruction: caudal vena cava
- Hypoalbuminemia: protein-losing nephropathy, protein-losing enteropathy, advanced hepatic disease, pancreatitis, extensive burns
- Bile peritonitis
- Vasculitis (e.g., FIP)
- Neoplastic conditions
  - Right atrial fibroma
  - Metastatic adenocarcinoma
  - Lymphoma
  - Hemangiosarcoma
  - Mesothelioma
  - Cholangiocellular carcinoma
  - Chemodectoma
  - Prostatic adenocarcinoma
  - Diffuse carcinomatosis

FIP, Feline infectious peritonitis.

Edema

Modified from Mitchell RN, Cotran RS: Hemodynamic disorders, thrombosis, and shock. In Cotran RS, et al, editors: Robbins pathologic basis of disease, ed 6, Philadelphia, 1999, Saunders.

Cause	Contributing Factor	Specific Clinical Syndromes
Increased hydrostatic pressure	Impaired venous return	Congestive heart failure (CHF)
		Pericardial disease (pericardial effusion, constrictive pericarditis, pericardial cyst or neoplasm)
		Portal hypertension
		Venous obstruction or compression (thrombosis, external pressure, extremity inactivity)
	Small-caliber arteriolar dilation	Heat
		Neurohumoral dysregulation
Reduced plasma oncotic pressure	Hypoproteinemia	Protein losing nephropathy (amyloidosis, glomerulonephritis)
		Synthetic failure (chronic liver disease)
		Malnutrition
		Protein-losing gastroenteropathy
Lymphatic obstruction	Decreased lymphatic drainage of interstitium	Various inflammatory conditions
		Congenital (lymphedema)
		Neoplastic
		Postsurgical
		Postirradiation
Sodium retention	Excess dietary intake with renal insufficiency	
	Increased tubular sodium resorption	Renal hypoperfusion
		Increased renin-angiotensin-aldosterone secretion
Inflammation	Acute inflammation	
	Chronic inflammation	
	Angiogenesis	

Fever of Unknown Origin

Associated Conditions

Modified with permission from Greene C: Table 96-3: Conditions associated with fevers of unknown origin. In Greene C, editor: Infectious diseases of the dog and cat, ed 2, St Louis, 1999, Saunders, p 696.

Systemic Infections

Dogs

- Bacterial endocarditis, bacteremias from an inapparent focus (e.g., secondary to persistent neutropenia or a congenital/acquired immunodeficiency syndrome); Lyme borreliosis (acute); leptospirosis; brucellosis; mycobacterial infections; rickettsial disease (e.g., ehrlichiosis, RMSF); protozoal infections (e.g., babesiosis, leishmaniasis, disseminated toxoplasmosis, neosporosis); disseminated mycotic infections (e.g., histoplasmosis, blastomycosis, cryptococcosis, coccidioidomycosis, aspergillosis)

Cats

- FIV infection; FeLV infection; feline hemotropic mycoplasma infection; feline infectious peritonitis; bacteremias from an inapparent focus; systemic mycoses (e.g., histoplasmosis, cryptococcosis); mycobacterial infections (often atypical); atypical calicivirus infection

Localized Infections

Dogs

- Bacterial endocarditis; urogenital infections (e.g., pyelonephritis, chronic prostatitis/prostatic abscess, stump pyometra); pyothorax and lung infections (e.g., inhaled pulmonary foreign bodies/pulmonary abscess, bronchopneumonia); occult hepatic abscess or cholangitis; localized peritonitis; diskospondylitis; juvenile metaphyseal osteomyelitis; retrobulbar or tooth root abscess; oropharyngeal stick injuries, septic thrombi

Cats

- Pyothorax and lung infections (e.g., pulmonary abscess, bronchopneumonia), upper respiratory infections; occult hepatic abscess or cholangiohepatitis; urogenital infections (e.g., pyelonephritis); localized peritonitis; osteomyelitis; cat bite abscess/cellulitis

Immune-Mediated Diseases

Dogs

- SLE; immune-mediated polyarthropathies: rheumatoid arthritis (erosive); nonerosive, nonseptic polyarthritis; idiopathic diseases; polyarthritis-meningitis complex (weimaraner, Newfoundland, German shorthaired pointer, boxer, beagle); polyarthritis-polymyositis complex (spaniel breeds); polyarthritis of Akitas; polyarthritis and amyloidosis of the Chinese shar-pei (shar-pei hock/fever); polyarteritis nodosa; autoimmune hemolytic anemia and immune-mediated thrombocytopenia; steroid-responsive meningitis; immunodeficiency syndromes

Cats

- SLE (rare in cats); chronic progressive polyarthropathy, including the ankylosing (periosteal proliferative) and luxating (erosive) forms; autoimmune hemolytic anemia (uncommon; may be FeLV associated); immune-mediated thrombocytopenia (rare; may be FeLV associated)

Neoplasia

Dogs

- Solid neoplasms (especially those that are necrotic, elicit an inflammatory response or have widespread metastases); lymphoproliferative or myeloproliferative disease

Cats

- FeLV-related lymphoproliferative and myeloproliferative disorders

Miscellaneous

Dogs

- Metaphyseal osteopathy, panosteitis; inflammatory-granulomatous bowel disease; liver disease (e.g., hepatic necrosis, cirrhosis, portosystemic shunts); pulmonary emboli; nodular panniculitis; drug reactions (tetracyclines, penicillin, sulfonamides, amphotericin B, quinidine)

Cats

- Pansteatitis (cats on fish-rich diets); hypervitaminosis A; drug reactions (e.g., tetracycline, levamisole)

FeLV, Feline leukemia virus; *FIV,* feline immunodeficiency virus; *RMSF,* Rocky Mountain spotted fever; *SLE,* systemic lupus erythematosus.

Feline Leukemia Virus and Feline Immunodeficiency Virus: Associated Disorders

Associated Diseases

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 5, St Louis, 2000, Saunders.

- Immunosuppression with opportunistic infections
- Gingivitis/stomatitis (FIV > FeLV)
- Myeloproliferative disease/erythroleukemia (FeLV ≫ FIV)
- Lymphosarcoma/lymphoid leukemias (FeLV ≫ FIV)
- Diarrhea/panleukopenia-like syndrome
- Weight loss/cachexia
- Chronic fever
- Glomerulonephritis
- Anterior uveitis/pars planitis/glaucoma (FIV ≫ FeLV)
- Behavioral changes/dementia/peripheral neuropathies
- Hypergammaglobulinemia (FIV > FeLV)
- Hemolytic anemias/aplastic anemias (FeLV ≫ FIV)
- Lymphopenia/neutropenia
- Thrombocytopenia (FeLV ≫ FIV)
- Abortion/fetal resorption/thymic atrophy (FeLV ≫ FIV)
- Chronic progressive polyarthritis
- *FeLV,* Feline leukemia virus; *FIV,* feline immunodeficiency virus.

Glucosuria

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Causes in Dogs and Cats	
Blood glucose concentration exceeding renal threshold (common)	• Diabetes mellitus • Stress (especially in cats) • Infusion of dextrose-containing fluids • Hyperadrenocorticism (rarely causes glucose >180 mg/dL) • Pheochromocytoma (rare)
Abnormal proximal renal tubular function	• Aminoglycoside toxicity • Acute renal failure • Fanconi syndrome • Primary renal glucosuria
Contamination	• Urinary hemorrhage in an animal with mild hyperglycemia

Glomerular Diseases, Dogs

Associated Diseases Reported in Dogs

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Infectious

- Bacterial
  - Bartonellosis (G)
  - Borreliosis (G)
  - Brucellosis (G)
  - Endocarditis (G)
  - Pyometra (A, G)
  - Pyoderma (A, G)
  - Other chronic bacterial infections (A, G)
- Protozoal
  - Babesiosis (MPGN)
  - Hepatozoonosis (G)
  - Leishmaniasis (A, MN, P-E, and P-M)
  - Trypanosomiasis (G)
- Rickettsial
  - Ehrlichiosis (G)
- Viral
  - Canine adenovirus type 1 (P-M)
- Parasitic
  - Dirofilariasis (A, MN)
- Fungal
  - Coccidioidomycosis (A, G)
  - Blastomycosis (G)

Inflammatory

- Chronic dermatitis (A, G)
- Inflammatory bowel disease (G)
- Pancreatitis (A, G)
- Periodontal disease (A, G)
- Polyarthritis (A, G)
- SLE (A, MN, P-E, and P-M)
- Other immune-mediated diseases (G)

Neoplastic

- Leukemia (G)
- Lymphosarcoma (A, G)
- Mastocytosis (G)
- Primary erythrocytosis (MCD?)
- Systemic histiocytosis (G)
- Other neoplasms (A, G, MN)

Miscellaneous

- Corticosteroid excess (G)
- Trimethoprim-sulfa therapy (G)
- Hyperlipidemia (?)
- Congenital C3 deficiency

Familial

Idiopathic (A, G, MN, MCD, P-E, or M)

A, Amyloidosis; G, glomerulonephritis, uncharacterized; *MCD,* minimal change disease; *MN,* membranous nephropathy; *MPGN,* membranoproliferative (mesangiocapillary) glomerulonephritis; *P*, proliferative (*E*, endocapillary; *M,* mesangial); *SLE,* systemic lupus erythematosus; *?*, association uncertain.

Glomerular Diseases, Cats

Associated Diseases Reported in Cats

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Systemic Disease (Glomerular Disease)

Infectious

- Bacterial
  - Chronic bacterial infections (G)
  - Mycoplasmal polyarthritis (G)
- Viral
  - FIV (G)
  - FIP (MN)
  - FeLV (G, MN)

Inflammatory

- Pancreatitis (G)
- Cholangiohepatitis (G)
- Chronic progressive polyarthritis (G)
- SLE (MN)
- Other immune-mediated diseases (G)

Neoplastic

- Leukemia (MN)
- Lymphosarcoma (MN)
- Mastocytosis (G)
- Other neoplasms (G)

Miscellaneous

- Acromegaly (?)
- Mercury toxicity (MN)

Familial (MN)

Idiopathic (MN)

FeLV, Feline leukemia virus; *FIP,* feline infectious peritonitis; *FIV,* feline immunodeficiency virus; *G*, glomerulonephritis, uncharacterized; *MN,* membranous nephropathy; *SLE,* systemic lupus erythematosus; γ, uncertain association.

Gastrointestinal Ulceration

Conditions and Drugs Associated With GI Ulceration in Small Animals

From Bonagura J: Kirk's current veterinary therapy XII: small animal practice, St Louis, 1995, Saunders.

Impaired Mucosal Defense

- Drugs
  - NSAIDs*
  - Corticosteroids
- Stress
  - Shock
  - Sepsis
  - Trauma
  - Major surgery
- Neurologic disease
  - Head trauma
  - Intervertebral disk disease†
- Metabolic disorders
  - Liver disease
  - Renal disease
  - Pancreatitis
- Inflammatory bowel disease
- GI neoplasia
- Mastocytosis
- Gastric motility disorders

Hyperacidity

- Gastrinoma
- Mastocytosis

GI, Gastrointestinal; *NSAIDs,* nonsteroidal antiinflammatory drugs.

* NSAIDs that have been associated with GI ulcers in small animals include aspirin, indomethacin, phenylbutazone, flunixin, ibuprofen, deracoxib, meloxicam, naproxen, and piroxicam.

† Treated with corticosteroids.

Gastrointestinal Endocrine Diseases

Disease	Main Clinical Abnormality
Glucagonoma	Persistent hyperglycemia; hepatocutaneous syndrome possible
Gastrinoma	Gastric ulceration
Carcinoma	Liver; lethargy, anorexia; metastasis; no vasoactive amine signs
Pancreatic polypeptidoma	Chronic vomiting

Gastric Outflow Obstruction

From Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

AAPH, Acquired antral pyloric hypertrophy; *CHPG,* chronic hypertrophic pyloric gastropathy.*Condition is secondary to CHPG/AAPH, gastric motility disorders, chronic gastritis, gastric or duodenal ulcers, gastric neoplasia, or extragastric causes.

History, Physical Findings, and Laboratory Findings in Animals With Gastric Retention or Outflow Obstruction*

	CHPG/AAPH	Motility Disorder	Chronic Gastritis Related	Ulcer Related or Gastric Neoplasia	Extragastric
History	Vomiting present: variable chronicity	Vomiting present: variable chronicity	Vomiting present: variable chronicity; intermittent occurrence	Vomiting present: progressive increase in frequency	Vomiting present
	Partially digested food	Partially digested food	Partially digested food or bile-stained fluid	Partially digested food or bile-stained fluid	
	Occurs anytime after eating	Occurs anytime after eating	Exacerbated by eating or drinking	Hematemesis common	
			Hematemesis may be present		
	Dietary modifications affect frequency				
	Abdominal distention present	Abdominal distention present	Abdominal distention present	Abdominal distention present	Abdominal distention present
	Appetite good	Appetite good	Appetite variable to poor	Appetite variable to poor	Appetite variable to poor
	Body weight variable	Body weight variable	Weight loss, unthrifty	Weight loss, unthrifty	Body weight variable
		May have history of acute or gastric dilatation with volvulus or other gastric disease or surgery	Melena may be present	Melena common; abdominal pain present	History compatible with specific extragastric disease
				Appetite variable to poor	
Physical Examination	Normal to decreased body condition	Normal to decreased body condition	Slight to significant decreased body condition	Slight to significant decreased body condition	Signs consistent with extragastric disease
	Bright, responsive	Bright, responsive	Normal to depressed	Normal to depressed	
	No abdominal pain	No abdominal pain	Variable cranial abdominal pain	Variable cranial abdominal pain	
	Cranial abdominal distention	Cranial abdominal distention	Cranial abdominal distention	Cranial abdominal distention	Cranial abdominal distention

	CHPG/AAPH	Motility Disorder	Chronic Gastritis Related	Ulcer Related or Gastric Neoplasia	Extragastric
Laboratory Findings	No abnormalities unless severe vomiting	No abnormalities unless severe vomiting	Variable acid-base status	Variable acid-base status	Variable acid-base status
	Alkalosis	Alkalosis	Hypokalemia	Hypokalemia	Laboratory findings consistent with extragastric disease
	Hypokalemia	Hypokalemia	Anemia (chronic disease, blood loss, or iron deficiency)	Anemia (chronic disease, blood loss, or iron deficiency)	
	Hypochloremia	Hypochloremia	Hypoproteinemia	Hypoproteinemia	
	Hemoconcentration	Hemoconcentration			

Hypoxemia

Causes

Hypoventilation*

- Acute barbiturate toxicosis, CNS lesion, neuromuscular disease (e.g., botulism, polyradiculoneuritis), pneumothorax, flail chest, pleural effusion, upper airway obstruction (e.g., laryngeal paralysis, foreign body, large airway trauma, large airway mass), anesthetic circuit problems

Diffusion/Gas Exchange Disorder*

- Pneumonia, pulmonary edema, pulmonary hemorrhage

Ventilation/Perfusion Mismatch*

- Pulmonary thromboembolism, prolonged recumbency

Right-to-Left Cardiovascular Shunt

- Tetralogy of Fallot, right-to-left shunting patent ductus arteriosus, other forms of Eisenmenger's physiology

CNS, Central nervous system.

Hypothyroidism

Neurologic Associations (Confirmed or Suspected)

- Neuromuscular weakness (slowly progressive)
- Muscle atrophy (scapular, masticatory)
- Facial nerve paralysis
- Vestibular signs (peripheral)
- Laryngeal paralysis
- Megaesophagus

Hypothermia

Causes

Modified with permission from Bonagura J: Kirk's current veterinary therapy XII small animal practice, St Louis, 1995, Saunders, p 159.

Iatrogenic

- Surgery
- Anesthesia
- Overzealous treatment of hyperthermia

Systemic Disease

- Cardiac
- Hypothyroidism
- Sepsis
- Chronic kidney disease
- Hypoadrenocorticism
- Malnutrition
- Hypoglycemia
- Neurologic:
    - Head trauma
    - Neoplasia
    - Cerebrovascular accident

Environmental

- Exposure
- Trauma

Hypotension, Systemic

Causes

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Decreased PreloadHypovolemia

- Hemorrhage
- Trauma
- Gastrointestinal losses
- Polyuria
- Hypoadrenocorticism
- Effusions or other third spacing of fluid
- Burns
- Heatstroke
- Pulmonary arterial hypertension (severe)

Decreased Venous Return

- Pericardial effusion/cardiac tamponade
- Constrictive pericarditis
- Severe pneumothorax
- Positive-pressure ventilation
- Gastric dilatation/volvulus
- Heartworm disease (cavai syndrome)

Decreased Cardiac Function

- Cardiomyopathy
- Valvular disease
- Bradyarrhythmias
- Tachyarrhythmias
- Electrolyte abnormalities
- Acid-base disturbances
- Severe hypoxemia

Decreased Vascular Tone

- SIRS
- Anaphylaxis
- Neurogenico
- Drug-induced (anesthetic agents, vasodilators, β-blockers, calcium channel blockers)
- Electrolyte abnormalities
- Acid-base disturbances
- Severe hypoxemia

SIRS, Sepsis/systemic inflammatory response syndrome.

Hypophosphatemia

Causes

Modified from DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2000, Saunders.

Maldistribution (Translocation)

- Treatment of diabetic ketoacidosis
- Carbohydrate load or insulin administration
- Respiratory alkalosis or hyperventilation
- Parenteral nutrition or nutritional recovery
- Hypothermia

Increased Loss (Reduced Renal Resorption)

- Primary hyperparathyroidism
- Renal tubular disorders (e.g., Fanconi syndrome)
- Proximally acting diuretics (e.g., carbonic anhydrase inhibitors) *(?)
- Eclampsia
- Hyperadrenocorticism (?)

Decreased Intake (Reduced Intestinal Absorption)

- Dietary deficiency (?)
- Vomiting (?)
- Malabsorption (?)
- Phosphate binders
- Vitamin D deficiency

Laboratory Error

- Example: mannitol administration

Hyponatremia

Causes

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2000, Saunders.

With Normal Plasma Osmolality

- Hyperlipidemia
- Hyperproteinemia

With High Plasma Osmolality

- Hyperglycemia
- Mannitol infusion

With Low Plasma Osmolality

- Including Hypervolemia
  - Severe liver disease
  - Congestive heart failure
  - Nephrotic syndrome
  - Advanced renal failure
- Including Normovolemia
  - Psychogenic polydipsia
  - Syndrome of inappropriate antidiuretic hormone secretion
  - Antidiuretic drugs
  - Myxedema coma of hypothyroidism
  - Hypotonie fluid infusion
- Including Hypovolemia
  - Gastrointestinal loss:
    - Vomiting
    - Diarrhea
  - Third-space loss:
    - Pancreatitis
    - Peritonitis
    - Uroabdomen
    - Pleural effusion (e.g., chylothorax)
    - Peritoneal effusion
  - Cutaneous loss:
    - Burns
  - Hypoadrenocorticism
  - Diuretic administration

Hypomagnesemia

Causes of Magnesium Depletion in Humans

Modified from DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2000, Saunders.

Inadequate Dietary Intake

- Protein-calorie malnutrition
- Magnesium-free fluids and total parenteral nutrition

Gastrointestinal Disorders

- Prolonged nasogastric suction
- Chronic diarrhea
- Malabsorption syndromes
- Extensive bowel resection
- Intestinal and biliary fistulas
- Primary infantile hypomagnesemia

Renal Loss

- Chronic parenteral fluid therapy with magnesium-free fluids
- Intrinsic tubular disorders:
    - Chronic interstitial nephritis, pyelonephritis, glomerulonephritis
    - Acute tubular necrosis (diuretic phase)
    - Postobstructive diuresis
    - Renal tubular acidosis
    - Congenital magnesium wasting
    - Drug injury:
        - Aminoglycosides
        - Amphotericin B
        - Cisplatin
        - Cyclosporine
    - Loop diuretics
    - Osmotic diuretics: glucose, mannitol, urea
    - Hypercalcemia
    - Hypokalemia
    - Alcohol

Metabolic

- Hypercalcemia
- Hypophosphatemia

Endocrine

- Diabetes mellitus
- Hyperthyroidism
- Primary hyperparathyroidism
- Hyperadrenocorticism
- Syndrome of inappropriate antidiuretic hormone secretion

Redistribution

- Pancreatitis
- Hyperadrenergic states
- Massive blood transfusion
- Insulin therapy
- Refeeding syndrome

- Hypothermia
- Acute respiratory alkalosis
- Sepsis
- Cardiopulmonary bypass

Miscellaneous

- Severe burns
- Excessive lactation
- Excessive sweating

Hypokalemia: Associated Disorders (Cats)

Conditions Associated With Hypokalemia in Cats

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

- Thyrotoxicosis
- Chronic kidney disease
- Metabolic acidosis
- Dietary
  - Potassium deficient
  - Acidified diets
- Insulin overdose
- Diuretic therapy (furosemide)
- Metabolic alkalosis
- Chronic vomiting/diarrhea
- Fluid administration (plasma dilution and volume-induced diuresis)
- Idiopathic (Burmese breed)
- Systemic diseases
  - Hepatic disease
  - Infectious disease
- Hyperaldosteronism (adrenocortical tumor)
- Renal tubular acidosis

Hypokalemia: Causes

Causes

Modified from DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2000, Saunders.

Decreased Intake

- Alone, unlikely to cause hypokalemia unless diet is aberrant
- Administration of potassium-free fluids (e.g., 0.9% NaCl, 5% dextrose in water)

Translocation (ECF to ICF)

- Alkalemia
- Insulin/glucose-containing fluids
- Catecholamines
- Hypothermia (?)
- Hypokalemic periodic paralysis (Burmese cats)

Increased LossGI (FEk < 4%-6%)

- Vomiting of stomach contents
- Diarrhea

Urinary (FEk > 4%-6%)

- Chronic kidney disease in cats
- Diet-induced hypokalemic nephropathy in cats
- Distal (type I) RTA
- Proximal (type II) RTA after NaHco3 treatment
- Postobstructive diuresis
- Dialysis
- Mineralocorticoid excess:
    - Hyperadrenocorticism
    - Primary hyperaldosteronism (adenoma, hyperplasia)

Drugs

- Loop diuretics (e.g., furosemide, ethacrynic acid)
- Thiazide diuretics (e.g., chlorothiazide, hydrochlorothiazide)
- Amphotericin B
- Penicillins
- Albuterol overdosage

ECF, Extracellular fluid; *FEk,* urinary fractional excretion of potassium; *GI,* gastrointestinal; *ICF,* intracellular fluid; *RTA,* renal tubular acidosis.

Hypoglycemia

Causes

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

- Beta-cell tumor (insulinoma)*
- Extrapancreatic neoplasia
  - Hepatocellular carcinoma, hepatoma
  - Leiomyosarcoma, leiomyoma
  - Hemangiosarcoma (rarely)
- Hepatic insufficiency*
  - Portocaval shunts*
  - Chronic fibrosis, cirrhosis
- Sepsis*
- Hypoadrenocorticism
- Hypopituitarism
- Idiopathic hypoglycemia*
  - Neonatal hypoglycemia
  - Juvenile hypoglycemia (esp. toy breeds)
  - Hunting dog hypoglycemia
- Renal failure (rarely)
- Exocrine pancreatic neoplasia
- Hepatic enzyme deficiencies
  - von Gierke's disease (type 1 glycogen storage disease)
  - Cori's disease (type 3 glycogen storage disease)
- Severe polycythemia
- Prolonged starvation
- Prolonged sample storage*
- Iatrogenic*
  - Insulin therapy
  - Sulfonylurea therapy
  - Ethanol
  - Ethylene glycol
- Artifact
  - Glucometers
  - Laboratory error

Hypochloremia

Causes

Adapted from de Morais: Chloride ion in small animal practice: the forgotten ion. J Vet Emerg Crit Care 2:11-24, 1992.

- Pseudohypochloremia
  - Lipemic samples (titrimetric methods)
- Excessive loss of chloride relative to sodium
  - Vomiting of stomach contents*
  - Therapy with thiazides or loop diuretics*
  - Chronic respiratory acidosis
  - Hyperadrenocorticism
  - Exercise
- Therapy with solutions containing high sodium concentration relative to chloride
- Sodium bicarbonate
- Sodium penicillin (extremely high doses)

Hypocapnia

Causes

Modified with permission from King L: Textbook of respiratory disease in dogs and cats, St Louis, 2004, Saunders, 183.

- Hypotension
- Fever
- Sepsis
- Excitement
- Exercise
- Pain
- Pulmonary thromboembolism
- Early pulmonary parenchymal disease
- Cytokine release in the systemic inflammatory response syndrome
- Inappropriate ventilator settings
- Compensation for metabolic acidosis

Definition of hypocapnia: abnormally decreased arterial carbon dioxide tension (e.g., in dogs: Pco2 <33 mm Hg [venous], <36 mm Hg [arterial]; in cats: Pco2 <33 mm Hg [venous], <28 mm Hg [arterial]).

Hypocalcemia

Conditions Associated With Hypocalcemia

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2000, Saunders.

Common

- Hypoalbuminemia
- Chronic kidney disease
- Puerperal tetany (eclampsia)
- Acute kidney disease
- Acute pancreatitis
- Undefined cause (mild hypocalcemia)

Occasional

- Soft-tissue trauma or rhabdomyolysis
- Hypoparathyroidism:
    - Primary:
        - Idiopathic or spontaneous
        - Postoperative bilateral thyroidectomy
    - After sudden reversal of chronic hypercalcemia
- Ethylene glycol intoxication
- Phosphate enema
- After NaHco3 administration

Uncommon

- Laboratory error
- Improper sample anticoagulant (EDTA)
- Infarction of parathyroid gland adenoma
- Rapid IV infusion of phosphates
- Acute calcium-free IV infusion (dilutional)
- Intestinal malabsorption or severe starvation
- Hypovitaminosis D
- Blood transfusion (citrated anticoagulant)
- Hypomagnesemia
- Nutritional secondary hyperparathyroidism
- Acute tumor lysis syndrome

Human

- Pseudohypoparathyroidism
- Drug-induced
- Hypercalcitoninism
- Osteoblastic bone neoplasia (prostate cancer)

EDTA, Ethylenediamine tetraacetic acid.

Hypoalbuminemia

Causes

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Decreased Production or Uptake

- Chronic hepatic insufficiency*
- Inadequate protein intake†‡
- Maldigestion†
- Malabsorption†

Hypergammaglobulinemia

Sequestration

- Body cavity effusion
- Vasculopathy

Increased Loss

- PLN due to glomerular disease*
- GI: PLE*
- Cutaneous
- Whole blood loss

Dilution

GI, Gastrointestinal; *PLE,* protein-losing enteropathy; *PLN,* protein-losing nephropathy.

Hyperthyroid Therapy

From Bonagura J: Kirk's Current veterinary therapy XIII, St Louis, 2000, Saunders.

Adverse Reactions Associated With Drugs Used Therapeutically in Feline Hyperthyroidism

Drug	Reaction	Approximate Percentage of Cats Affected	Time of Occurrence	Treatment Required
Methimazole	Vomiting, anorexia, depression	15	<4 weeks	Usually transient
	Eosinophilia, leukopenia, lymphocytosis	15	<8 weeks	Usually transient
	Self-induced excoriations	2	<4 weeks	Withdrawal and glucocorticoid therapy
	Agranulocytosis, thrombocytopenia	<5	<3 months	Withdrawal and supportive therapy
	Hepatopathy (anorexia, alanine aminotransferase, alkaline phosphatase elevations)	<2	<2 months	Withdrawal and supportive therapy
	Positive antinuclear antibody (ANA)	>50	>6 months	Decrease daily dosage
	Acquired myasthenia gravis	Rare	<16 weeks	Withdrawal or glucocorticoid therapy
Carbimazole	Vomiting, anorexia, depression	10	<3 weeks	Usually transient
	Eosinophilia, leukopenia	5	<2 weeks	Usually transient lymphocytosis
	Self-induced excoriations	Rare	<4 weeks	Withdrawal and glucocorticoid therapy
Stable iodine	Salivation and anorexia	Occasional	Immediate	Change formulation

Hyperthermia: Nonfebrile

Causes of Increased Body Temperature Excluding Fever

Modified with permission from Greene C: Infectious diseases of the dog and cat, ed 2, St Louis, 1999, Saunders, p 694.

Impaired Heat Loss

- Exposure to high ambient temperatures in a closed, poorly ventilated environment (heatstroke)
- Strenuous exercise, especially if concurrent respiratory embarrassment (e.g., if animal is brachycephalic or has laryngeal paralysis)

Hypermetabolic Disorders

- Malignant hyperthermia
- Hyperthyroidism
- Pheochromocytoma

Increased Muscle Activity

- Tetanus
- Seizure activity
- Metaldehyde intoxication
- Hypocalcemia

Miscellaneous Causes

- Hypothalamic tumor
- Certain drugs (phenothiazines, cholinergics)

Hypertension, Systemic

Diseases/Clinical Findings Commonly Associated With Systemic Hypertension

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Dogs

- Ocular findings consistent with hypertensive choroidopathy, hypertensive retinopathy, or intraocular hemorrhage
- Chronic or acute renal failure
- Hyperadrenocorticism
- Diabetes mellitus
- Neurologic signs unexplained by other causes
- Pheochromocytoma
- Unexplained left ventricular hypertrophy (uniform/symmetrical)

Cats

- Ocular findings consistent with hypertensive choroidopathy, hypertensive retinopathy, or intraocular hemorrhage
- Chronic or acute renal failure
- Hyperthyroidism
- Diabetes mellitus
- Any neurologic signs
- Age >10 years
- Heart murmur caused by uniform/symmetrical left ventricular hypertrophy (reversible with long-term control of hypertension)

A complete funduscopic examination and BP measurement are indicated in animals known to have or suspected of having these disease conditions. Conditions that are rare in the species (e.g., hyperthyroidism in dogs) are not included. BP measurement is often included in routine cardiac evaluations. Idiopathic hypertrophic cardiomyopathy cannot be diagnosed without excluding hypertension.

Hypersensitivity

Types and Examples

Features: Type and Mechanism	Examples	Pathophysiology	Signs
Type I Immediate (anaphylactic)	• Food allergy • Atopy • Insect bite hypersensitivity • Adverse vaccine reaction • Adverse drug reaction	Acute, systemic inflammation is triggered by IgE-mediated degranulation of mast cells and basophils; degranulation releases histamine, leukotrienes, interleukins, and other vasodilatory and inflammatory substances.	• Urticaria (plaques of skin swelling) • Angioedema (regional or diffuse cutaneous or visceral swelling) • Pruritus • If severe: hypotension and shock (dogs) or dyspnea (cats)
Type II Cytotoxic	• Immune-mediated hemolytic anemia • Immune-mediated thrombocytopenia • Hypothyroidism (lymphocytic thyroiditis) • Hemolytic reaction (incompatible transfusion donor-recipient match; neonatal isoerythrolysis) • Pemphigus • Adverse drug reaction	• Antibody (IgM or IgG) binds to surface molecules (rightly or wrongly perceived as antigenic) on cells of body tissues. • The antibody-tagged cells are destroyed by the mononuclear-phagocytic (reticuloendothelial) system.	• Signs depend on body tissue cells involved. • Examples include hemolysis and cutaneous lesions.
Type III Immune complex–mediated	• Systemic lupus erythematosus • Rheumatoid arthritis • Feline infectious peritonitis	• Complexing of antibody with soluble antigen (slight excess of antigen causes the most intense reactions). Deposition of antigen-antibody complexes in tissues elicits neutrophil release of enzymes and free radicals, causing tissue damage. • Common sites of tissue damage include glomeruli, synovium, and vascular endothelium.	Signs of protein-losing nephropathy, polyarthritis, polyarteritis
Type IV Delayed cell-mediated	• Contact hypersensitivity • Transplanted organ rejection	• T lymphocyte–mediated (rather than primarily antibody-mediated) interaction with antigen. • “Delay” refers to late onset of reaction (>12 hours after beginning of exposure) due to mobilization and infiltration of T lymphocytes, usually “memory T cells” from prior or ongoing exposure to antigen. These T lymphocytes secrete inflammatory substances and attract macrophages and more lymphocytes, leading to tissue destruction.	Signs depend on body tissue involved. Examples include cutaneous lesions (contact hypersensitivity) and organ dysfunction (transplant rejection).

Hyperphosphatemia

Causes

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2000, Saunders.

Maldistribution (Translocation)

- Tumor cell lysis
- Tissue trauma or rhabdomyolysis
- Hemolysis
- Metabolic acidosis

Increased Intake

- Gastrointestinal
  - Phosphate enemas
  - Vitamin D intoxication
- Parenteral
  - IV phosphate

Decreased Loss

- Acute or chronic kidney disease
- Uroabdomen or urethral obstruction
- Hypoparathyroidism
- Acromegaly(?)*
- Hyperthyroidism

Physiologic: young growing animal

Laboratory Error (e.g., lipemia, hyperproteinemia, depending on methodology)

Hypernatremia

Causes

From DiBartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2000, Saunders.

Pure Water Deficit

- Primary hypodipsia (e.g., in miniature schnauzers)
- Diabetes insipidus:
  - Central
  - Nephrogenic
- High environmental temperature
- Fever
- Inadequate access to water

Impermeable Solute Gain

- Salt poisoning
- Hypertonic fluid administration
  - Hypertonic saline
  - Sodium bicarbonate
  - Parenteral nutrition
  - Sodium phosphate enema
- Hyperaldosteronism
- Hyperadrenocorticism

Hypotonic Fluid LossExtrarenal

- Gastrointestinal
  - Vomiting
  - Diarrhea
  - Small-intestinal obstruction
- Third-space loss
  - Peritonitis
  - Pancreatitis
- Cutaneous
  - Burns

Renal

- Osmotic diuresis
  - Diabetes mellitus
  - Mannitol infusion
- Chemical diuretics
- Chronic renal failure
- Nonoliguric acute renal failure
- Postobstructive diuresis

Hyperlipidemia

Diseases and Conditions That Cause Hypertriglyceridemia and Hypercholesterolemia

Data from Stockham FL, Scott MA: Lipids. In: Fundamentals of veterinary clinical pathology, Ames, Iowa, 2002, Iowa State Press, pp 521–537.

Causes of HypertriglyceridemiaIncreased Triglyceride Production

- By hepatocytes
- By enterocytes:
    - Postprandial hyperlipidemia

Decreased Lipolysis or Intravascular Processing of Lipoproteins

- Hypothyroidism
- Nephrotic syndrome
- Lipoprotein lipase deficiency (rare in cats, very rare in dogs)

Other, Unknown, or Multiple Mechanisms

- Acute pancreatitis
- Diabetes mellitus
- High-lipid diet
- Hyperadrenocorticism or excess glucocorticoids
- Hyperlipidemia in a Brittany spaniel
- Idiopathic hyperlipidemia of miniature schnauzers

Causes of HypercholesterolemiaIncreased Cholesterol Production

- By hepatocytes:
    - Nephrotic syndrome or protein-losing nephropathy
- By enterocytes:
    - Postprandial hyperlipidemia

Decreased Lipolysis or Intravascular Processing of Lipoproteins

- Hypothyroidism
- Nephrotic syndrome or protein-losing nephropathy
- Lipoprotein lipase deficiency (very rare in dogs)

Other, Unknown, or Multiple Mechanisms

- Acute pancreatitis
- Cholestasis (obstructive)
- Diabetes mellitus
- Hyperadrenocorticism
- Hypercholesterolemia in briards
- Idiopathic hyperlipidemia of miniature schnauzers

Hyperkalemia

Causes

Modified from DiBartola S: Fluid, Electrolyte and acid-base disorders in small animal practice, St Louis, 2006, Saunders.

Pseudohyperkalemia

- Platelet activation (blood clotting in vitro)
- Thrombocytosis
- Hemolysis in susceptible breeds (Akita, Shiba Inu, Tosa Inu)

Increased Intake

- Unlikely to cause hyperkalemia in presence of normal renal function unless iatrogenic (e.g., continuous infusion of excessive amounts of potassium)

Translocation (ICF to ECF)

- Acute mineral acidosis (e.g., HCl, NH_4Cl)
- Insulin deficiency (e.g., diabetic ketoacidosis)
- Acute tumor lysis syndrome
- Reperfusion of extremities after aortic thromboembolism in cats with cardiomyopathy
- Hyperkalemic periodic paralysis (one case report in a pit bull)
- Drugs: nonspecific beta-blockers (e.g., propranolol)*

Decreased Urinary Excretion

- Urethral obstruction
- Ruptured bladder
- Anuric or oliguric renal failure
- Hypoadrenocorticism
- Selected GI disease (e.g., trichuriasis, salmonellosis, perforated duodenal ulcer)
- Chylothorax with repeated pleural fluid drainage
- Hyporeninemic hypoaldosteronism

Drugs

- Angiotensin-converting enzyme inhibitors (e.g., captopril, enalapril, benazepril, ramipril, lisinopril)*
- Potassium-sparing diuretics (e.g., spironolactone, amiloride, triamterene)*
- Prostaglandin inhibitors (e.g., indomethacin)*
- Heparin*

ECF, Extracellular fluid; *GI,* gastrointestinal; *ICF,* intracellular fluid.

Hyperglycemia

Causes of Altered Blood Glucose in Dogs and Cats

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

- Diabetes mellitus*
- "Stress" (cat)*
- Postprandial
- Hyperadrenocorticism*
- Acromegaly (cat)
- Diestrus (bitch)
- Pheochromocytoma (dog)
- Pancreatitis
- Exocrine pancreatic neoplasia
- Renal insufficiency
- Drug therapy*
    - Glucocorticoids
    - Progestogens
    - Megestrol acetate
    - Thiazide diuretics
    - Parenteral nutrition

Hyperglobulinemia

Causes

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Polyclonal

Infections

- Bacterial[*†]
  - Brucellosis
  - Pyoderma
  - Bacterial endocarditis
- Viral
  - FIP[‡]
  - FIV
  - FeLV
- Fungal[*†]
  - Systemic fungal infections (e.g., blastomycosis, histoplasmosis, coccidioidomycosis)
- Rickettsial[†‡]
  - Ehrlichiosis
- Parasitic
  - Dirofilariasis[*†]
  - Demodicosis
  - Scabies

Immune-Mediated Disease

- Infections (immune complex)
  - Dirofilariasis[*†]
  - Feline cholangitis/cholangiohepatitis
  - Pyometra
- SLE, including glomerulonephritis, IMHA, IMT, and polyarthritis[*]
- IMHA, IMT (not because of SLE)[*]
- Pemphigus complex, bullous pemphigoid[*]
- Rheumatoid arthritis[*]

Neoplasia[†‡]

Monoclonal

Infection

- Ehrlichiosis[†‡]
- Leishmaniasis[†‡]
- FIP (rare)

Idiopathic[†‡]

- Benign monoclonal gammopathy

Neoplasia[†‡]

- Multiple myeloma[‡]
- Macroglobulinemia

- Lymphoma
- Chronic lymphocytic leukemia
- Extramedullary plasmacytoma (rare)

Miscellaneous

- Cutaneous amyloidosis
- Plasmacytic gastroenterocolitis*

Effect of age should be considered when assessing globulin value.

FeLV, Feline leukemia virus; *FIP,* feline infectious peritonitis; *FIV,* feline immunodeficiency virus; *IMHA,* immune-mediated hemolytic anemia; *IMT,* immune-mediated thrombocytopenia; *SLE,* systemic lupus erythematosus.

*Mild (4−5 g/dL).

†Moderate (5−6 g/dL).

‡Severe (>6 g/dL).

Hyperchloremia

Adapted from de Morais: Chloride ion in small animal practice: the forgotten ion. J Vet Emerg Crit Care 2:11–24, 1992.

*May be associated with corrected hypochloremia in cats.

Causes of Corrected Hyperchloremia

Pseudohyperchloremia

- Lipemic samples (colorimetric methods)
- Potassium bromide therapy

Excessive Loss of Sodium Relative to Chloride

- Diarrhea

Excessive Gain of Chloride Relative to Sodium

- Therapy with chloride salts (NH_4Cl, KCl)
- Total parenteral nutrition
- Fluid therapy (e.g., 0.9% NaCl, hypertonic saline, KCl-supplemented fluids)
- Salt poisoning

Renal Chloride Retention

- Renal failure
- Renal tubular acidosis
- Hypoadrenocorticism*
- Diabetes mellitus*
- Chronic respiratory alkalosis
- Drug-induced: acetazolamide, spironolactone

Hypercapnia

Causes

Hypoventilation

Neuromuscular disorder

Medullary dysfunction (excessive depth of anesthesia, intracranial disease)

Cervical disease or neuromuscular disease

Airway Obstruction

Large-airway obstruction (laryngeal paralysis, tracheal collapse)

Small-airway obstruction (chronic airway disease, bronchoconstriction)

Thoracic Wall Problems

Open pneumothorax

Flail chest

Anterior displacement of the diaphragm by abdominal space filling disorders

Pleural space filling disorder (air, fluid, diaphragmatic hernia)

Pleural fibrosis

Pulmonary Parenchymal Disease (Late)

Inappropriate Ventilator Settings

Dead-Space Rebreathing

Recent Bicarbonate Therapy (in Ventilatory Compromised Animals)

Compensation for Metabolic Acidosis

Malignant Hyperthermia

With permission from King L: Textbook of respiratory disease in dogs and cats. St Louis, 2004, Saunders, 184.

Definition of hypercapnia (synonym: hypercarbia): abnormally increased arterial carbon dioxide tension (e.g., in dogs: Pco2 >50 mm Hg [venous], >44 mm Hg [arterial]; in cats: PCO2 >45 mm Hg [venous], >32 mm Hg [arterial]).

Hypercalcemia: Lab

Modified from Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

BUN, Blood urea nitrogen; *N,* normal blood concentration; *PTH,* parathyroid hormone; *PTHrP,* PTH-related protein; (−), below normal blood concentration; (+), greater than normal blood concentration.

Relative Values of Selected Hematologic Parameters in Dogs and Cats With Hypercalcemia-Associated Diseases

	PTH	PTHrP	Ionized Calcium	Phosphorus	Vitamin D	BUN
Parathyroid adenoma	N to +++	−	+++	−	N/++	N/+
Hypercalcemia of malignancy	−	++	++	−	N	N/+
Hypoadrenocorticism	N	N	+	N/+	N	N
Vitamin D toxicosis	−	−	+++	++	+++	N/+
Renal secondary hyperparathyroidism	++	N/++	+	++	N	+++
Inflammatory disease	−/N	?	+	N	N/+	N
Parathyroid hyperplasia	N to +++	−	+++	−	N/++	N/+

Hypercalcemia: Causes

Causes

Adapted from Dibartola S: Fluid, electrolyte, and acid-base disorders in small animal practice, St Louis, 2006, Saunders.

Nonpathologic

- Nonfasting (minimal increase)
- Physiologic growth of young
- Laboratory error
- Spurious:
  - Lipemia
  - Detergent contamination of sample or tube

Transient or Inconsequential

- Hemoconcentration
- Hyperproteinemia
- Hypoadrenocorticism
- Severe environmental hypothermia

Pathologic or Consequential—Persistent

- Associated with malignancy:
  - Humoral hypercalcemia of malignancy:
    - Lymphoma (common)
    - Anal sac apocrine gland adenocarcinoma (common)
    - Carcinoma (sporadic): squamous cell (cats; common), lung, pancreas, skin, nasal cavity, thyroid, mammary gland, adrenal medulla
    - Thymoma (rare)
  - Hematologic malignancies (bone marrow osteolysis):
    - Lymphoma
    - Multiple myeloma
    - Myeloproliterative disease (rare)
    - Leukemia (rare)
  - Metastatic or primary bone neoplasia (very uncommon)
- Chronic kidney disease
- Hypervitaminosis D:
  - Iatrogenic
  - Plants (calcitriol glycosides)
  - Vitamin D3 ointments
  - Rodenticide
- Granulomatous disease:
  - Blastomycosis
  - Cryptococcosis (cats)
  - Schist osomiasis
  - Dermatitis
- Primary hyperparathyroidism:
  - Adenoma (common)
  - Adenocarcinoma (rare)
  - Hyperplasia (uncommon)
- Acute renal failure
- Skeletal lesions (nonmalignant, uncommon):
  - Osteomyelitis (bacterial or mycotic)
  - Hypertrophie osteodystrophy
  - Disuse osteoporosis (immobilization)
- Excessive calcium-containing intestinal phosphate binders
- Excessive calcium supplementation (calcium carbonate)
- Hypervitaminosis A
- Hypercalcemic conditions in human medicine:

    - Milk-alkali syndrome (rare in dogs)
    - Thiazide diuretics
    - Acromegaly
    - Thyrotoxicosis
    - Postrenal transplantation
- Aluminum exposure (dogs?)
- Idiopathic (cats)

Horner's Syndrome

Modified from Delahunta A: Veterinary neuroanatomy and clinical neurology, St Louis, 1983, Saunders.

Summary of Lesions

Location	Example of Lesion	Associated Neurologic Deficit
Cervical spinal cord	• External injury • Focal leukomyelomalacia, embolic infarct, disk compression	• Tetraplegia-spastic; dyspnea • Hemiplegia-ipsilateral, spastic
T1–T3 spinal cord	• External injury • Neoplasm • Focal poliomyelomalacia (embolic infarct) • Diffuse myelomalacia (ascending and pelvic limbs, descending)	• Pelvic and thoracic limb or paresis or paralysis with lower motor neuron deficit in thoracic limbs and upper motor neuron deficit in pelvic limbs • Lower motor neuron deficit; analgesia of tail, anus, abdomen, and thorax with paretic thoracic limbs
T1–T3 ventral roots	Avulsion of roots of brachial plexus	Lower motor neuron paresis or paralysis of the thoracic limb on the same side
Proximal spinal nerves	Lymphoma	None if confined to the trunk
Cranial thoracic sympathetic trunk	Neurofibroma	None if confined to the trunk
Cervical sympathetic trunk	Injury from surgical intervention in the area or from dog bites	None if unilateral; bilateral lesions interfere with laryngeal and esophageal function because of vagal involvement
Middle ear cavity (small animals)	• Otitis media • Neoplasia	Signs of peripheral vestibular disturbance; ipsilateral ataxia, head tilt, nystagmus, and sometimes facial palsy or hemifacial spasm
Retrobulbar	• Contusion • Neoplasia	Varies with degree of contusion to the optic and oculomotor nerves, which also influence pupillary size and vision

Hepatotoxic Agents

Adapted from Khan SA: Intoxication versus acute nontoxicologic illness: differentiating the two. In Ettinger SJ, Feldman EC, editors: Textbook of veterinary internal medicine, St Louis, 2010, Saunders, pp 549–554.

GI, Gastrointestinal; *NSAID,* nonsteroidal antiinflammatory drug.

Agent	Comments/Notes
Anticonvulsants (primidone; phenytoin; phenobarbital)	Dogs; occurs after repeated use for weeks, months
Diazepam	Cats; idiosyncratic reaction after repeated use for 5-11 days or more
NSAID-induced hepatopathy	Dogs; reported from carprofen; can occur from any NSAID following repeated use (days to weeks)
Corticosteroids (steroid hepatopathy)	Occurs from long-term use
Mushroom (*Amanita* type)	Mostly dogs; delayed onset of GI signs (12 hours); acute hepatic damage within 1-3 days
Acetaminophen	Cats more prone to methemoglobinemia within a few hours of exposure; dogs can have both hepatic damage and methemoglobinemia; hepatic damage in 1-3 days
Iron (multivitamin ingestion)	Dogs; prenatal multivitamins have more elemental iron; initial GI signs followed by shock and liver damage in 1-2 days
Sago palm or cycad palm toxins	Dogs; all parts toxic; seeds contain more toxin; GI signs, liver damage, seizures; mortality 33%
Blue-green algae toxins	Dogs; shock and acute hepatic damage
Aflatoxins (contaminated commercial dog food)	Dogs very sensitive; several outbreaks reported in the United States; can occur with acute exposure (large dose) or with repeated exposure (low doses)
Copper storage disease	Dogs; certain breeds can accumulate copper in the liver over a period of time
Xylitol (sugar alcohol present in gums, bakery products, confectionery)	Dogs; hypoglycemia within 12 hours; hepatic damage and coagulopathy in 1-3 days
Zinc metal	Dogs; zinc-containing objects (pennies, nuts); affects multiple organs; hemoglobinuria, anemia, increased liver enzymes, azotemia, pancreatitis
Castor beans (ricinus)	All parts toxic; seeds more toxic; affects multiple organs such as GI, kidney, and liver
Joint chews (containing glucosamine, chondroitin sulfate, dimethylsulfone, and other ingredients)	Dogs; recently reported with accidental overdose; elderly dogs appear at higher risk

Hepatopathy, Vacuolar

Differential Diagnoses for Canine Vacuolar Hepatopathy

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Hyperadrenocorticism

- Spontaneous disease
- Pituitary or adrenal origin

Iatrogenic, Glucocorticoid Therapy:

- **PO, IM, SQ, topical (skin, eye, ear)**

Adrenal Hyperplasia Syndrome

- Abnormal sex hormone production (aberrant adrenocortical disease)

Superficial Necrolytic Dermatitis (Hepatocutaneous Syndrome)

Chronic Stress

- Illness > 4 weeks

Severe Dental Disease

- Infection

Chronic Infections or Inflammation

- Pyelonephritis, chronic dermatitis (examples)

Inflammatory Bowel Disease (IBD)

- Lymphoplasmacytic
- Eosinophilic

Neoplasia

- Lymphoma, other

Disorders Influencing Lipid Metabolism

- Diabetes mellitus
- Idiopathic hyperlipidemia (e.g., schnauzer, Shetiland sheepdog, other)

Pancreatitis, Chronic

Hypothyroidism, Severe

Congestive Heart Failure (CHF)

Hepatic Neoplasia

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Dogs

- **Primary Hepatic Tumors (26%)*
  - Hepatocellular carcinoma
  - Hepatocellular adenoma
  - Hepatic hemangiosarcoma
  - Biliary carcinoma
- *Other*
  - Leiomyosarcoma
  - Liposarcoma
  - Myxosarcoma
  - Fibrosarcoma
  - Biliary adenoma
  - Hepatic carcinoid
- *Hemolymphatic Neoplasia (28%)*
  - Lymphoma
  - MCT
  - Plasma cell tumor
- *Metastatic Neoplasia (46%)*

Cats

- **Primary Hepatic Tumors (20%)*
  - Biliary carcinoma
  - Hepatocellular carcinoma
  - Hepatic hemangiosarcoma
- *Other*
  - Biliary cystadenoma
  - Myelolipoma
  - Hepatic carcinoid
- *Hemolymphatic Neoplasia (60%)*
  - Lymphoma
  - MCT
  - Plasma cell tumor
- *Metastatic Neoplasia (20%)*

MCT, Mast cell tumor

Primary tumors: in order of prevalence.

Hepatic Infections and Abscesses

Bacteria Isolated from Hepatobiliary Suppurative Inflammation and Abscesses

Modified with permission from Greene C: Infectious diseases of the dog and cat, ed 2, St Louis, 1999, Saunders, p 616.

Aerobic Cultures (Positive Cultures: n = 54)

- n ≥ 3 each
  - *Escherichia coli*
  - *Staphylococcus pseudintermedius*
  - *S. aureus*
  - *S. epidermidis*
  - *Streptococcus* group D enterococci
  - *Streptococcus* β-hemolytic
  - *Enterococcus*
  - *Enterobacter aerogenes*
  - *E. agglomerans*
  - *Pseudomonas aeruginosa*
- n = 1 each
  - *Pseudomonas fluorescens*
  - *Klebsiella pneumoniae*
  - *Bacillus spp.*
  - *Acinetobacter calcoaceticus*
  - *Citrobacter freundii*
  - *Moraxella phenylpyruvica*
  - *Pasteurella multocida*
  - *Bordetella bronchiseptica*
  - *Nocardia*
  - *Salmonella*
  - *Campylobacter jejuni*

Anaerobic Cultures (Positive Cultures: n = 26)

- *Propionibacterium acnes*
- *Clostridium perfringens*
- *Clostridium*
- *Bacteroides melaninogenicus*
- *Corynebacterium* spp.
- *Actinomyces*
- *Peptostreptococcus*
- *Fusobacterium*
- Anaerobic streptococci

Additional Microbes Reported Elsewhere

- *Bacillus piliformis*
- *Corynebacterium* spp.
- *Proteus* spp.
- *Francisella tularensis*
- *Listeria monocytogenes*
- Eugenic fermenter-4 bacilli

In order from most to least common. Data acquired from case records, Companion Animal Hospital, College of Veterinary Medicine, Cornell University, Ithaca, NY, 1985–1996.

Hepatic Fibrosis

Causes in Dogs

From Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

- Chronic hepatitis
  - Hepatic copper accumulation
    - Primary (Bedlington terriers, West Highland white terriers)
    - Secondary (Doberman pinschers, Skye terriers)
  - Infectious
  - Drug-induced Primidone
  - Metabolic
    - α1-Antitrypsin deficiency
  - Others
    - Lobular dissecting hepatitis
    - Idiopathic chronic hepatitis
- Toxins, chemicals
  - Pyrrolizidine alkaloids, CCl_4
- Postnecrotic fibrosis
- Chronic congestive heart failure
- Chronic cholangiohepatitis
- Chronic biliary obstruction
- Idiopathic hepatic fibrosis
  - Perivenous
  - Diffuse pericellular
  - Periportal

Hepatic Failure, Acute

Clinically Relevant Causes

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 4, St Louis, 1994, Saunders.

Category of Injury	Examples
Trauma	• Automobile accident • High-rise syndrome

Toxin	• Environmental agents:
	  ○ Aflatoxin
	  ○ *Amanita pantherina*, *Amanita phalloides*
	  ○ Cycadaceae
	  ○ Heavy metals
	• Drugs:
	  ○ Thiacetarsemide
	  ○ Mebendazole
	  ○ Diethylcarbamazine-oxibendazole
	  ○ Acetaminophen
	  ○ Methoxyflurane, halothane
	  ○ Diethylcarbamazine
	  ○ Tetracycline
	  ○ Trimethoprim-sulfadiazine
	  ○ Griseofulvin
	  ○ Diazepam (cats)

Infectious agents	• Infectious canine hepatitis • Leptospirosis • Toxoplasmosis • Heartworm caval syndrome • Bacterial sepsis
Thermal	Heatstroke
Extension of abdominal inflammation	• Pancreatis • Peritonitis • Inflammatory bowel disease
Metabolic disorder	Lipidosis (cats)

Hemothorax

Causes of Hemothorax and Sanguineous Pleural Effusion

Modified with permission from King L: Textbook of respiratory disease in dogs and cats. St Louis, 2004, Saunders, p 611.

- Trauma
- Malignancy
- Coagulopathy
- Diaphragmatic hernia
- Lung lobe torsion
- Pulmonary infarction
- Pulmonary abscessation
- Recent surgery
- Aortic aneurysm
- Swan-Ganz catheter placement*
- Tube thoracostomy*
- Hemopneumothorax*
- Costal exostosis*
- Endometriosis*
- Foreign body
- Heartworm disease
- Central venous catheter placement

* Reported only in human literature.

Hemoptysis

Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Pulmonary

- Pulmonary thromboembolism: secondary to neoplastic, endocrine, cardiac, metabolic disease
- Pulmonary hypertension: secondary to heartworm disease; congenital or acquired cardiac defects that result in shunting of blood
- Chronic bronchitis/bronchiectasis
- Bacterial pneumonia
- Nocardiosis
- Pulmonary abscess
- Kennel cough (rarely causes hemoptysis)
- Fungal pneumonia: blastomycosis, histoplasmosis, coccidioidomycosis
- Parasites: *Paragonimus kellicotti, Capillaria aerophila*, *Aelurostrongylus abstrusus*
- Eosinophilic bronchopneumopathy
- Neoplasia, lung: primary adenocarcinoma, undifferentiated carcinoma, SCC, chondrosarcoma; metastatic; primary tracheal tumors
- Lung lobe torsion

Cardiovascular

- Heartworm disease
- Cardiogenic pulmonary edema
- Arteriovenous fistula
- Bacterial endocarditis

Systemic

- Bleeding disorder: primary (quantitative or qualitative platelet defects) or secondary hemostatic (factor deficiencies, anticoagulant rodenticide toxicity, DIC) abnormalities
- Trauma: pulmonary contusion, tracheal rupture, FB
- Iatrogenic: endotracheal intubation; complication of lung biopsy/aspirate, transtracheal wash, or bronchoscopy

DIC, Disseminated intravascular coagulopathy; *FB,* foreign body; *SCC,* squamous cell carcinoma.

Hematuria

Causes

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Urinary Tract Origin (Kidneys, Ureters, Bladder, Urethra)

- Trauma
  - Traumatic collection (e.g., catheter, cystocentesis)
  - Renal biopsy
  - Blunt trauma (e.g., automobile accident)
- Urolithiasis
- Neoplasia
- Inflammatory disease
- Urinary tract infection
- Feline lower urinary tract signs/disease/interstitial cystitis
- Chemically-induced inflammation (e.g., cyclophosphamide-induced cystitis)
- Parasites
  - *Dioctophyma renale*
  - *Capillaria plica*
- Bleeding disorder
  - Warfarin intoxication
  - Disseminated intravascular coagulation
  - Hemophilia
  - Thrombocytopenia
- Renal infarction
- Renal pelvic hematoma
- Vascular malformation
  - Renal telangiectasia (Welsh corgi)
  - Idiopathic renal hematuria

Genital Tract Contamination (Prostate, Prepuce, Vagina)

- Estrus
- Inflammatory, neoplastic, and traumatic lesions of the genital tract

Hematochezia

Causes

Modified from Tams TR: Gastrointestinal symptoms. In: Handbook of small animal gastroenterology, Philadelphia, 1996, Saunders.

Anal Disease

- Perianal fistulas
- Anal sacculitis or abscess
- Stricture
- Neoplasia (e.g., anal sac tumor)
- Trauma (e.g., bite wound)
- Perianal hernia
- Foreign body

Rectum and Colon

- Proctitis (inflammation of the rectal mucosa)
- Colitis
    - Idiopathic
    - Inflammatory bowel disease
    - Stress
    - Infectious
        - *Campylobacter spp.*
        - *Clostridium perfringens*
- Parvovirus
- Parasitism
    - Hookworms
    - Whipworms
    - Coccidia
    - Roundworms
- Neoplasia
    - Rectal polyp
    - Adenocarcinoma
    - Lymphoma
- Rectal prolapse
- Mucosal trauma
    - Movement of foreign material (e.g., hairballs)
    - Iatrogenic (e.g., thermometers, enemas, fecal loops)
- Automobile trauma
- Ileocecocolic area: intussusception
- Bleeding disorder

Constipation often can cause excessive straining which can result in formed stools with blood on the surface.

Hematemesis

Causes

Modified with permission from Kirk RW, Bonagura JD, editors: Kirk's current veterinary therapy XI: small animal practice, St Louis, 1992, Saunders, p 133.

Bleeding Disorders

- Disseminated intravascular coagulation
- Anticoagulant rodenticide toxicity
- Thrombocytopenia
- Congenital or acquired coagulation factor deficiencies/defects

Heavy Metal Toxicity

- Arsenic
- Lead
- Zinc

Infectious Disorders

- GI parasitism
- Viral gastroenteritis
- Bacterial gastroenteritis

Perioperative Hemorrhage

- Gastric dilatation/volvulus
- Gastrectomy
- Gastrostomy

Gastric/Duodenal Erosions/UlcerationsInfiltrative Disease

- Neoplasia
- Inflammatory bowel disease
- Phycomycosis

Metabolic Disorders

- Renal disease
- Liver disease
- Hypoadrenocorticism

Stress Erosions/Ulcerations

- Burns (Curling's ulcer)
- Neurologic disorders
    - Head trauma (Cushing's ulcer)
    - Spinal cord disorders
- Sepsis/septic shock
- Hypovolemic shock
- Multiple trauma

Drug AdministrationGlucocorticoids

NSAIDs

- Aspirin
- Indomethacin
- Phenylbutazone
- Naproxen
- Sulindac
- Deracoxib
- Ibuprofen
- Flunixin meglumine
- Meclofenamic acid
- Piroxicam

Gastric/Duodenal Foreign Bodies

Neoplasia

- Mast cell tumor
- Gastrinoma (Zollinger-Ellison syndrome)
- Pancreatic polypeptide–secreting tumor
- Basophilic leukemia

Hemorrhagic Gastroenteritis

Esophageal Disorders

- Esophagitis
- Esophageal neoplasia
- Esophageal foreign bodies

GI, Gastrointestinal: *NSAIDs,* nonsteroidal antiinflammatory drugs.

Heartworm: Clinical Severity

With permission from Fox P: Textbook of canine and feline cardiology: principles and practice, St Louis, 2000, Saunders, p 707.

Classification of Heartworm Disease Severity Based on Signs, Physical Examination, and Radiographic Findings

Class	Clinical Signs	Examination Findings	Radiographic Findings
1	None to occasional cough	Normal examination	No lesions
2	Occasional cough and mild-to-moderate exercise intolerance	Increased lung sounds	Slight pulmonary arterial enlargement
		Fair general condition	Circumscribed perivascular density plus mixed alveolar- interstitial lesions
3	Persistent cough, moderate to severe exercise intolerance	Increased lung sounds	Moderate-to-severe pulmonary arterial enlargement
Caval syndrome	Weight loss, cachexia	Accentuated or split S2	RV enlargement
	Respiratory distress	Right apical gallop	Diffuse and severe pulmonary infiltrates
	Overt right heart failure	Tachypnea, dyspnea	
	General loss of condition		

Heartworm Disease: Complications

Complications

Untreated

- Eosinophilic granulomatosis
- Eosinophilic pneumonitis
- Right-sided congestive heart failure*
- Hemoglobinuria, "pigment nephropathy"*
- Hemolytic anemia*
- Pulmonary thromboembolism

During or Shortly After Treatment Period

- Acute (Surgical Removal)
  - Anaphylaxis
  - Hypotension
  - Cardiac arrest
- Subacute (Medical Treatment)
  - Eosinophilic pneumonitis
  - Pain at injection site (melarsomine)
  - Pulmonary thromboembolism (possibly massive, especially if inadequate exercise restriction)
  - Sudden death (especially if inadequate exercise restriction)

* Together, comprise the "caval syndrome" of heartworm disease

Heartworm *Dirofilaria* Versus *Acanthocheilonema*

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Differentiating Characteristics of *Acanthocheilonema* (formerly *Dipetalonema*) *reconditum* and *Dirofilaria immitis*

	Number in Blood	Motion	Shape	Length (Modified Knott Test)
Acanthocheilonema reconditum	Usually few	Progressive	Curved body Blunt head Curved or “buttonhook” tail	263 µm (250-288 µm)
Dirofilaria immitis	Usually many	Stationary	Straight body and tail Tapered head	308 µm (295-325 µm)

Heart Murmurs: Congenital Heart Defect-Associated

Modified with permission from Kittleson M: Small animal cardiovascular medicine, St Louis, 1998, Mosby, p 197.

PDA, Patent ductus arteriosus; *VSD,* ventricular septal defect.

Auscultatory Abnormalities in Dogs With Congenital Cardiac Disease

Abnormality	Timing of Murmur	Quality of Murmur	Point of Maximal Intensity	Comments
Aortic regurgitation	Diastolic	Decrescendo; usually soft	Left base	May occur in association with a VSD
Atrial septal defect	Systolic	Soft	Left base	Result of relative pulmonic stenosis
Eisenmenger's syndrome (right-to-left shunting PDA or VSD)	Absent (a systolic murmur may still be present in a PDA with bidirectional shunting)	—	Left axillary region for a bidirectional PDA	Split second heart sound may be present
Mitral dysplasia	Systolic	Holosystolic or pansystolic; plateau	Left apex	May radiate widely
Left-to-right shunting PDA	Continuous	Wind tunnel	Cranial to the left base	Peaks in intensity at S2
Pulmonic stenosis	Systolic	Crescendo-decrescendo	Left base	Possible ejection sound
Subaortic stenosis	Systolic	Crescendo-decrescendo	Left-base (occasionally right base and occasionally apex)	May radiate up into carotid arteries
Tetralogy of Fallot	Systolic	Crescendo-decrescendo	Left base	Murmur may rarely be absent
Tricuspid dysplasia	Systolic	Holosystolic or pansystolic; plateau	Right apex	May be soft or absent in cats with severe disease
VSD	Systolic	Holosystolic or pansystolic; plateau	Cranial to or at right apex; left base	Second heart sound may be split
VSD and aortic regurgitation	Systolic and diastolic (to-and- fro murmur)	Pansystolic murmur followed by a diastolic decrescendo murmur	Left base or cranial to right apex	May sound as if it is continuous and may be confused with a PDA murmur

Heart Murmurs

Characteristics and Clinical Signs Associated With "Innocent" Murmurs Versus Murmurs Associated With CHD

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Innocent Murmur

- Grade usually <III/VI
- Systolic
- PMI: usually left base
- Murmur characteristics may change with animal position
- Murmur intensity may increase or decrease with increasing heart rate
- Decreased intensity with age
- Generally inaudible after ~16 weeks of age
- Animal clinically normal

Congenital Heart Disease

- Any grade
- Any timing possible
- PMI: any possible
- Similar murmur characteristics in all body positions
- Murmur intensity increases with increase in heart rate
- Same or increasing intensity up to and beyond 16 weeks of age
- Persists after ~16 weeks of age
- Stunting, unthriftiness, cyanosis, or signs of heart failure may be present.

CHD, Congenital heart disease; *PMI,* point of maximal murmur intensity.

Halitosis

Causes

Oral Diseases

- Periodontal disease (gingivitis, periodontitis, abscessation)
- Neoplasia (melanoma, fibrosarcoma, SCC)
- Foreign body or trauma (fractures, electrical cord injury)
- Pharyngitis
- Stomatitis, lymphocytic-plasmacytic feline stomatitis

Respiratory Diseases

- Rhinitis and/or sinusitis
- Neoplasia
- Pneumonia or pulmonary abscess

Dermatologic Diseases

- Lip fold pyoderma
- Ulcerative mucocutaneous pyoderma
- Feline or canine eosinophilic granulomas
- Pemphigus complex, bullous pemphigoid, systemic lupus erythematosus
- Drug eruptions
- Cutaneous lymphoma
- Exposure to DMSO

Metabolic Diseases

- Renal failure/uremia
- Diabetic ketoacidosis

Gastrointestinal Diseases

- Megaesophagus
- Inflammatory bowel disease
- Exocrine pancreatic insufficiency
- Neoplasia
- Constipation

Dietary

- Aromatic foods (onions, garlic)
- Fetid foodstuffs (e.g., ingestion of carrion)
- Coprophagy

Grooming Behavior

- Anal sacculitis
- Vaginitis/balanoposthitis
- Lower UTI

Adapted from Veterinary clinical guide to odor and disease: the oral cavity and dermatology, Yardley, Penna., 1997

DMSO, Dimethyl sulfoxide; SCC, squamous cell carcinoma; *UTI,* urinary tract infection.

Iron Abnormalities

N, Normal; *TIBC,* total iron-binding capacity (equivalent to saturated transferrin concentration).*Concurrent inflammation or other disorders may raise ferritin level into normal range.

	Serum [Iron]	TIBC	Ferritin
Normal	N	N	N
Hemolytic anemia	↑	↑	↑
Anemia of chronic disease	N or ↓	N or ↓	N or ↑
Iron deficiency (= chronic blood loss)	↓	N or ↑	↓*
Inflammation	↓	↓	↑
Glucocorticoid treatment/excess	↑	N	—
Iron overload/toxicosis	↑	↓	↑
Artifact (sample contamination)	↑ (serum Fe > TIBC)	↓ or N	—

Insulin Resistance

Recognized Causes of Insulin Ineffectiveness or Insulin Resistance in Diabetic Dogs and Cats

From Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

Caused by Insulin Therapy

- Inactive insulin
- Diluted insulin
- Improper administration technique
- Inadequate dose
- Somogyi effect
- Inadequate frequency of insulin administration
- Impaired insulin absorption, especially Ultralente insulin
- Antiinsulin antibody excess

Caused by Concurrent Disorder

- Diabetogenic drugs
- Hyperadrenocorticism
- Diestrus (bitch)
- Acromegaly (cat)
- Infection, especially of oral cavity and urinary tract
- Hypothyroidism (dog)
- Hyperthyroidism (cat)
- Renal insufficiency
- Liver insufficiency
- Cardiac insufficiency
- Glucagonoma (dog)
- Pheochromocytoma
- Chronic inflammation, especially pancreatitis
- Pancreatic exocrine insufficiency
- Severe obesity
- Hyperlipidemia
- Neoplasia

Inflammatory Bowel Diseases

Causes of Chronic Small Bowel Inflammation

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Chronic Infection

- *Giardia* sp.
- *Histoplasma* sp.
- *Toxoplasma* sp.
- *Mycobacteria* sp.
- Protothecosis
- Pythiosis
- Pathogenic bacteria (*Campylobacter, Salmonella* spp., pathogenic *Escherichia coli*)

Food Allergy

Small Bowel Inflammation Associated With Other Primary Gastrointestinal Diseases

- Lymphoma
- Lymphangiectasia

Idiopathic Causes

- Lymphocytic-plasmacytic enteritis (LPE)
- Eosinophilic gastroenterocolitis (EGE)
- Granulomatous enteritis (same as regional enteritis?)

Infertility, Male

Based on Inability to Sire a Litter

Modified from Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

Congenital InfertilityHormonal

- Hypopituitarism
- Hypothyroidism

Chromosomal aberration

Developmental

- Cryptorchidism
- Penis, prepuce, os penis anomaly
- Testicular hypoplasia
- Duct aplasia

Motility defect

- Kartagener's syndrome
- Retrograde ejaculation

Acquired InfertilityHormonal

- Hypopituitarism
- Hypothyroidism
- Hyperadrenocorticism

Metabolic

- Uremia
- Hepatic

Neoplasia

- Compression
- Hormonal secretion

Stress

Infection

Fever

Duct obstruction

Immune-mediated orchitis

Drugs, exogenous hormone therapy

Retrograde ejaculation

Idiopathic testicular degeneration

Sexual overuse?

Psychological?

Infertility With Preserved Libido

Drugs and Exogenous Hormones That Affect Fertility in Humans and Possibly Dogs

From Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

Chemotherapeutic Drugs

- Busulfan
- Chlorambucil
- Cisplatin
- Cyclophosphamide
- Methotrexate
- Vinblastine
- Vincristine

Miscellaneous Drugs

- Amphotericin B*
- Alloxan
- Cimetidine*
- Clomipramine
- Ketoconazole*
- Spironolactone
- Sulfasalazine

HormonesAnabolic Steroids

- Methyltestosterone*
- Testosterone esters*

Estrogens

- Estradiol 17B*
- Diethylstilbestrol*
- KABI 1774*

Progestogens

- Medroxyprogesterone acetate*
- Megestrol acetate*
- Delmadinone acetate*

Others

- Glucocorticoids*
- Tamoxifen citrate*
- Gossypol*
- GnRH antagonists*
- GnRH agonists*

Incontinence, Urinary

Causes

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

- Urethral sphincter mechanism incompetence
- Ectopie ureters
- Neurologic disorders
- Urge incontinence (secondary to urinary tract infection [UTI] or uroliths)
- Idiopathic detrusor instability
- Paradoxic (overflow) incontinence
- Ureterocele
- Pelvic bladder
- Ureterovaginal or urethrorectal fistula
- Patent urachus

Incontinence, Fecal

Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Neurologic DiseaseSacral Spinal Cord

- Congenital vertebral malformation
- Meningomyelocele
- Sacrococcygeal hypoplasia of Manx cats
- Sacral fracture
- Sacrococcygeal subluxation
- Lumbosacral instability
- Viral meningomyelitis
- Diskospondylitis
- Degenerative myelopathy
- Neoplasia

Peripheral Neuropathy

- Trauma
- Repair of perineal hernia
- Perineal urethrostomy
- Penetrating wounds
- Dysautonomia
- Hypothyroidism
- Diabetes mellitus

Nonneurologic DiseaseColorectal Causes

- Inflammatory bowel disease
- Neoplasia
- Constipation

Anorectal Causes

- Trauma
- Surgery (anal sac, perineal hernia, rectal resection)
- Perianal fistula
- Neoplasia

Miscellaneous Causes

- Severe diarrhea
- Irritable bowel syndrome
- Decreased mentation
- Old age/cognitive disfunction

Immunodeficiency-Related Complications

Organisms and Medical Problems Commonly Implicated in Immunocompromised Hosts

Modified with permission from Greene C: Infectious diseases of the dog and cat, ed 2, St Louis, 1999, Saunders, p 684.

Opportunistic Organisms

- Viruses: feline herpesvirus, feline infectious peritonitis, feline calicivirus, canine papillomavirus, canine herpesvirus
- Rickettsia: *Haemobartonella*
- Bacteria: Citrobacter sp., *Escherichia coli, Enterobacter, Klebsiella pneumoniae, Mycobacterium* spp., *Nocardia asteroides, Proteus, Pseudomonas aeruginosa, Serratia marcescens, Staphylococcus pseudintermedius*
- Fungi: *Aspergillus* sp., *Candida* sp., *Cryptococcus, Histoplasma, Mucor*
- Protozoa: *Pneumocystis carinii, Toxoplasma gondii, Cryptosporidium*
- Metazoa: *Demodex canis, Otodectes, Notoedres, Sarcoptes scabiei*

Medical Problems

- Recurrent skin infections
- Recurrent mucosal infections
- Neonatal sepsis and mortality
- Reactive amyloidosis
- Vasculitis, arteritis, polyarthritis
- Recurrent bacteremia
- Granulomatous infections
- Chronic hypersensitivity reactions
- Autoimmune diseases
- Persistent intracellular rickettsial or bacterial infections
- Disproportional leukocytosis
- Persistent lymphopenia

Immunodeficiency Syndromes: Congenital

With permission from Greene C: Infectious diseases of the dog and cat, ed 3, St Louis, 2006, Saunders, p 1015–1016. In addition to the listed syndromes, bone marrow dyscrasia has been described in miniature and toy poodles and transient hypogammaglobulinemia in Samoyeds, but less is known of these disorders.

AD, autosomal dominant; *AR,* autosomal recessive; *GI,* gastrointestinal; *HOD,* hypertrophic osteodystrophy; *Ig,* immunoglobulin; *IL,* interleukin; *RAMP,* resistance against mycobacterial protein; *U,* unknown; *XR,* X-linked recessive; γ, suspected.*(E.g., springer spaniel, Old English sheepdog, English setter, West Highland white terriers, pointers.)

Primary or Hereditary Immunodeficiencies

Disease (Synonyms)	Inheritance	Breeds	Defect	Characterization
Dog				
Ciliary dyskinesia (immotile cilia syndrome)	AR	Many breeds*	Functional/morphologic cilia abnormalities	Rhinosinusitis, bronchopneumonia with bronchiectasis, situs inversus
Respiratory infections	U	Irish wolfhound	Unknown, IgA defect?	Rhinitis, pneumonia
Bactericidal neutrophil defect	U	Doberman pinscher	Unknown	Upper respiratory tract infections, reduced bactericidal activity, ciliary dyskinesia not excluded
Cyclic hematopoiesis (cyclic neutropenia)	AR	Gray collie	Hematopoietic growth factors	Severe neutropenia every 12-14 days, reactive amyloidosis
Leukocyte adhesion deficiency (canine granulocytopathy)	AR	Irish setter	CD11/18 deficiency, B-chain (CD18) deficiency	Severe leukocytosis, limited pus formation, lack of neutrophil adhesion
Complement component 3 (C3) deficiency	AR	Brittany spaniel	C3 deficiency	Pyogenic infections, lack of C-mediated phagocytosis in colony of dogs with neuromuscular disease
Selective cobalamin malabsorption	AR	Giant schnauzerBorder collie	Ileal cobalamin receptor defect	Weight loss, inappetence, leukopenia with hypersegmentation, megaloblastic bone marrowMethylmalonic aciduria
Increased susceptibility to avian mycobacteriosis	U	Basset hound	RAMP deficiency?	
Increased susceptibility to	XR	Dachshund	Unknown	
Pneumocystis carinii pneumonia				
Pelger-Huët anomaly	AD	Australian shepherd, foxhound, others	Unknown	No immunodeficiency, hyposegmented granulocytes
Susceptibility to fungal and rickettsial infections, pyoderma	U	German shepherd	Macrophage? T cell?	

Disease (Synonyms)	Inheritance	Breeds	Defect	Characterization
Severe combined immunodeficiency	XR	Basset hound, Cardigan, Welsh corgi	Common gamma chain of IL-2 and other cytokines	Severe bacterial/viral infections, no IgG and IgA, deficient lymphocyte blastogenesis
Selective IgA deficiency	U	Beagle, shar-pei, German shepherd	IgA deficiency	Respiratory and GI infections
Thymic abnormalities and dwarfism	U	Weimaraner	Unknown	Reduced growth (thymosin responsive)
Recurrent infections	U	Weimaraner	Reduced IgG	Pyoderma, severe abscess formation, bleeding tendency (HOD)
Combined immunodeficiency	U	Shar-pei	T cell, B cell, low IL-6 and IL-2	Skin, respiratory, and GI infections
Amyloidosis	U	Shar-pei	Elevated IL-6	Arthritis, amyloidosis, renal failure, hepatic rupture, hypoproteinemia
Lethal acrodermatitis	AR	Bull terrier	Zinc metabolism defect	Zinc deficiency, hyperkeratosis
Increased susceptibility to parvoviral infection	U	Rottweiler, Doberman	Unknown	
Vaccine-exacerbated immunity	U	Akita	Unknown	Variable meningitis, polyarthritis
Cat				
Hypotrichosis, congenital and thymic aplasia	AR	Birman	Unknown	Nude kittens, neonatal death, no thymus
Thymic and lymphoid atrophy	U	Ragdoll	Unknown	Neonatal death or fatal infections at weaning, lack of lymph nodes and thymus
Leukocyte granulation	U	Birman	Unknown	No immunodeficiency, acidophilic granules
Pelger-Huët anomaly	AD	Domestic shorthair	Unknown	No immunodeficiency, hyposegmented granulocytes
Chédiak-Higashi syndrome	AR	Persian	Unknown	No immunodeficiency, large granules in phagocytes, bleeding tendency
Reactive AA amyloidosis	U	Abyssinian, Siamese, Oriental shorthair	Unknown	Reactive AA amyloidosis, renal or hepatic failure

Immunodeficiency Syndromes: Acquired

Common Acquired Causes of Compromised Immune System Function

From Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Drugs

- Antineoplastics
- Corticosteroids
- Other immunosuppressive agents (e.g., azathioprine, gold salts)

Malnutrition

- Intestinal parasitism
- Inflammatory bowel disease
- Protein-calorie deficiency
- Obesity

Infections

- Viral infection (FeLV, FIV, FIP, CDV, parvovirus)
- *Ehrlichia canis*

Endocrine Disease

- Hyperadrenocorticism
- Diabetes mellitus

Neoplasia

Miscellaneous

- Neonatal colostrum deprivation

CDV, Canine distemper virus; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *FIV,* feline immunodeficiency virus.

Ileus

Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Physical

- Intestinal obstruction
- Overdistention by aerophagia

Neuromuscular

- Anticholinergic drugs
- Dysautonomia
- Spinal cord injury
- Visceral myopathies

Metabolic

- Hypokalemia
- Uremia
- Endotoxemia

Functional

- Abdominal surgery
- Ischemia
- Inflammatory causes
- Peritonitis
- Pancreatitis
- Parvovirus

Icterus

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 4, St Louis, 1994, Saunders.

DIC, Disseminated intravascular coagulation; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *ICH,* infectious canine hepatitis; *SLE,* systemic lupus erythematosus.

Differential Diagnosis of Icterus

Prehepatic or Hemolytic Icterus	**Extrahepatic Icterus**	**Hepatic Icterus**	
Hemolytic Anemias	**Bile Duct Occlusion**	**Miscellaneous Disorders**	Hemolytic disease → cholestasis
Erythrocyte parasitemia:	Cholecystitis	Endotoxemia/sepsis	
Babesia	Cholangitis	Shock	Anoxia → cholestasis
Mycoplasma haemofelis	Secondary peribiliary disease	Chronic passive congestion	DIC
Incompatible blood transfusion	Congenital malformations	Hyperthyroidism (cat, rare)	
Neonatal isoerythrolysis	Choledochal cysts		
Microangiopathic hemolytic anemia	Multiple biliary cysts (cat)	**Intrahepatic Cholestasis**	
DIC	Intraluminal bile duct occlusion	Infectious	
Vasculitis	Inspissated bile syndrome (cat)	Neoplasia:	
Dirofilariasis	Cholelithiasis	Mechanical infiltrative-sinusoids, peribiliary	
Vascular neoplasia (hemangiosarcoma)	Trauma → blood clots		
Congenital erythrocyte defects	Neoplasia:	Paraneoplastic effects	
Pyruvate kinase deficiency (basenji dog)	Primary and secondary biliary involvement	Viral (FIP, ICH, parvovirus)	
Phosphofructokinase deficiency		Bacterial (leptospirosis, septicemia)	
Hereditary stomatocytosis (malamute)	Pancreatic disease	Mycotic	
Immune-mediated hemolytic anemia	Parasitic infection (flukes)	Drug associated:	Diltiazem (sustained-release formulation)
SLE	Ruptured biliary tract (bile duct or gallbladder)	Methyltestosterone	
Infectious disease associated		Impeded androgens (danazol)	Carprofen
Idiopathic	Trauma	Sulfa antibiotics	Mebendazole
Drug associated	Cholelithiasis	Anticonvulsants (phenytoin, primidone, phenobarbital)	Thiacetarsemide
Infectious:	Cholangitis/cholecystitis		
FeLV	Iatrogenic: hepatic biopsy	Acetaminophen	

Prehepatic or Hemolytic Icterus	**Extrahepatic Icterus**	**Hepatic Icterus**	
Ehrlichia		Specific hepatic disorders:	
Dirofilariasis		Cholangitis	Cholangiohepatitis syndrome (cat)
Leptospirosis		Cirrhosis	
Septicemia		Chronic idiopathic hepatitis of dogs	Lobular dissecting hepatitis
Heinz body anemia			
Onion toxicity, zinc toxicity		Hepatic lipidosis (cat)	Breed-specific disorder:
Benzocaine (cat), methionine		Idiopathic lipidosis secondary to other disorders	Bedlington terrier
Cetacaine (cat), methylene blue			
Vitamin K1, acetaminophen		Diabetes mellitus	Doberman pinscher
Phenazopyridine		Hepatic necrosis: many causes	West Highland white terriers
Propylene glycol		Infiltrative disease (neoplasia, amyloid, infectious agents)	
Increased Hemoprotein Liberation			Cocker spaniels
Body cavity hemorrhage			Severe steroid hepatopathy (dogs only)
Large hematoma formation and absorption			
Ineffective erythropoiesis			
Congenital porphyria (cat, rare)			

Joint Effusion

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders. *LE,* Lupus erythematosus; *RBC,* red blood cell; *WBC,* white blood cell.

Analysis of Joint Effusions

	NONINFLAMMATORY JOINT DISEASE	**INFLAMMATORY JOINT DISEASE**				
	Degenerative Joint Disease	**Neoplastic Joint Involvement**	**Hemarthrosis**	**Infectious Inflammation**	**Noninfectious Inflammation**	**NORMAL**
Color	Light yellow	Light yellow, blood-tinged	Bloody, xanthochromic	Variable: yellow, blood-tinged, bloody	Variable: yellow, blood-tinged	Straw-colored
Turbidity	Clear, slightly turbid	Mild to moderate turbidity	Turbid	Turbid to purulent	Variable: slight to moderate turbidity	Clear
Viscosity	Normal	Normal to reduced	Reduced	Reduced	Reduced	Viscous
Mucin clot test	Normal firm	Normal firm	Normal to slightly friable	Friable	Friable	Firm
Cytologic Analysis						
RBC	Few	Few to many	Many, erythrophagocytosis	Moderate	Few to moderate	Rare
WBC/µL	<3000	Variable	Variable	40,000-250,000	Many but variable	0-2900
Neutrophils	Few (<20%)	Moderate	Moderate	Many (usually >90%)	Many but variable	0%-10%
Degenerative WBC changes	Absent	Absent	Absent	May be present	None to mild	None
Lymphocytes	Few to moderate	Few to moderate	Rare	Few	Few to moderate	Few
Synoviocytes	Common	Few	Rare	Few to moderate	Few to moderate	Few
Macrophages	Few to moderate	Few to moderate	Moderate if chronic	Few to moderate	Few to moderate	Rare
Microorganisms	None	None	None	May be present	None	None
Neoplastic cells	None	Variable	None	None	None	None
Others					May see LE cells	

Ketonuria

Causes

- Diabetes mellitus/diabetic ketoacidosis
- Starvation
- Lactation
- Pregnancy
- Fever
- Renal glucosuria
- Severely carbohydrate-restricted diet
- Glycogen storage disease

Keratoconjunctivitis Sicca (KCS)

Causes

Modified with permission from Bonagura J: Kirk's current veterinary therapy XII: small animal practice, Philadelphia, 1995 WB Saunders, p 1232.

- Imune-mediated adenitis: most common (dogs)
- Breed predisposition
- Congenital anomaly
- Drug induced (transient KCS): general anesthesia, topical anesthesia, atropine
- Drug toxicosis (transient or permanent KCS): sulfa drugs, phenazopyridine, aminosalicylic acid, etodolac
- Iatrogenic:
    - Removal of the gland of the third eyelid
- Idiopathic
- Infectious agents:
    - Canine distemper virus
    - Feline herpesvirus
- Metabolic disease (hypothyroidism, hyperadrenocorticism, diabetes mellitus)
- Chronic blepharoconjunctivitis (chemosis/ascending infection from lacrimal gland, causing lacrimal ductile obstruction)
- Neurogenic
- Radiation therapy for nasal or intracranial neoplasms
- Trauma to orbit or eye

Lymphoma Staging Classification

The World Health Organization (WHO) Clinical Staging System for Lymphoma

Modified from Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

- Stage I Single lymph node involved
- Stage II Multiple lymph nodes involved on one side of the diaphragm
- Stage III Generalized peripheral lymph node involvement
- Stage IV Liver and/or splenic involvement with or without stages I-III
- Stage V Blood and/or bone marrow involvement and/or extranodal involvement; with or without stages I-IV
- Substage A: no signs of systemic illness
- Substage B: signs of systemic illness, hypercalcemia, uveitis, fever
- Substage E: designation used for extranodal tumors

Lymphoma and Lymphoid Neoplasia

Modified from Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders. *FeLV,* Feline leukemia virus; *FIV,* feline immunodeficiency virus; *GI,* gastrointestinal.

Anatomical Classification of Lymphoid Neoplasms

Name	Incidence in Dogs	Incidence in Cats (FeLV status)	Selected Clinicopathologic Characteristics
Lymphoma			
Multicentric	80%-85%	20%-40% (commonly FeLV+)	In cats, spleen and liver are virtually always affected; feline lymphoid hyperplasia is a common cause of generalized lymphadenopathy; in dogs, diffuse pulmonary infiltrates are in 25%-35% of cases.
Alimentary	<7%	15%-45% (uncommonly FeLV+)	Regional lymph nodes are commonly affected; late-stage disease affects kidneys; in some cats, the condition may be associated with FIV.
Mediastinal (thymic)	<5%	20%-50% (commonly FeLV+)	Sternal lymph nodes are affected in dogs, and nodes and thymus are affected in cats; pleural effusion and hypercalcemia are common (40%).
Extranodal sites	7%	5%-10%	B-cell tumors are termed *cutaneous lymphoma*; T-cell tumors are termed *mycosis fungoides*.
Nervous system		(commonly FeLV+)	This is the most common cause of posterior paresis in cats; the bone marrow is often affected; in dogs, the condition usually reflects late-stage multicentric disease. Late-stage disease affects CNS; patients are often presented in renal failure.
Renal			
Plasma Cell Tumors			
Multiple myeloma	Uncommon	Rare (no association with FeLV)	75% of dogs have immunoglobulin or monoclonal gammopathy, and 10% have circulating plasmacytes; immunoglobulin M-producing tumor termed *macroglobulinemia* (Waldenstrom's).
Cutaneous	Infrequent	Extremely rare	Rarely metastasize (<5%)
GI	Infrequent	Unreported	Uncommonly metastasize
Osseous	Rare	Unreported	Often progress to systemic myeloma within 6 months

Lymphatic Drainage

From Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

Normally Palpable Lymph Nodes and Body Regions That Nodes Drain

Lymph Node	Area Drained
Mandibular	All parts of the head not drained by parotid node (parotid node drains cutaneous area of caudal half of dorsum of muzzle and lateral cranium, parotid gland, and muscles of mastication)
Superficial cervical (prescapular)	Skin on caudal part of head, including pharynx, part of pinna, lateral surface of neck and thoracic limb except shoulder, and medial side of brachium and antebrachium
Axillary and accessory axillary	Mammary glands, thoracic wall, and deep structures of thoracic limb
Superficial inguinal	Ventral half of abdominal wall, including abdominal and inguinal mammary glands as well as efferent vessels from popliteal lymph nodes, penis, prepuce, and scrotum in the male
Popliteal	All parts of pelvic limb distal to node

Lymphatic Disorders

Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Lymphangitis, Lymphedema, Lymphadenitis, Lymphadenopathy

- Infection
- Neoplasia
- Reactive hyperplasia
- Granuloma

LymphedemaPrimary Developmental Abnormality of Lymphatics

- Hypoplasia
- Aplasia
- Lymphangiectasia
- Hyperplasia

Secondary Acquired Abnormality of Lymphatics

- Surgical excision of lymphatics or lymph nodes
- Posttraumatic lymphangiopathy
- Neoplastic invasion
- Extrinsic compression of lymph vessels or tissue
- Acute obstructive lymphadenitis
- Chronic sclerosing lymphadenitis/lymphangitis
- Lymphatic atrophy with interstitial fibrosis
- Radiation therapy

Lymphocysts

- Cystic hygroma, lymphoceles, pseudocyst

Lymphangiomas

Liver Enzyme Elevations

Conditions That Cause Liver Enzyme Elevations in the Absence of Primary Liver Disease

ALP, Alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase; GGT, gamma-glutamyl transpeptidase.

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 5, St Louis, 2000, Saunders.

Drug Induction

Corticosteroids (dogs):↑↑↑ALP,↑↑GGT,↑ALT,↑AST

Anticonvulsants (phenobarbital, phenytoin, primidone):↑ALT,↑ALP,↑AST,↑GGT

Endocrinopathies

Hyperthyroidism (cats):↑ALP,↑ALT

Hypothyroidism (dogs):↑ALP

Diabetes mellitus:↑ALP

Hyperadrenocorticism (dogs):↑↑↑ALP,↑ALT,↑GGT,↑AST

Hypoxemia/Hypotension: ↑↑↑ ALT, ↑ ALP, ↑ GGT, ↑ AST

Congestive heart failure

Severe acute blood loss

Status epilepticus

Hypotensive crisis

Surgery

Septic shock

Hypoadrenocorticism

Hypovolemic shock

Muscle Injury: ↑ AST

Acute muscle necrosis/trauma

Malignant hyperthermia

Myopathies

Neoplasia

Adenocarcinomas: pancreatic, intestinal, adrenocortical, mammary

Sarcomas: hemangiosarcoma, leiomyosarcoma

Hepatic metastasis: ↑ AST,↑ALT,↑ ALP

Unique enzyme induction: ↑↑ ALP, ↑↑ GGT

Miscellaneous

Systemic infections

Pregnancy (cats): ↑ placental ALP

Colostrum-fed neonates (dogs): ↑ GGT

Bone Disorders: ↑ ALP

Young animals (up to 7 months)

Osteosarcoma

Osteomyelitis

Laryngeal Neoplasia

Malignant Tumors of the Canine and Feline Larynx

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

- Lymphoma
- Squamous cell carcinoma
- Mast cell tumor
- Osteosarcoma
- Melanoma
- Oncocytoma
- Rhabdomyosarcoma
- Plasmacytoma
- Adenocarcinoma
- Chondrosarcoma
- Granular cell myoblastoma
- Fibrosarcoma
- Anaplastic carcinoma
- Leiomyoma

Lactate: Elevated Serum Levels

Major Causes

From Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Type A: Clinical Evidence of Absolute or Relative Tissue HypoxiaShock (Systemic Hypoperfusion)

- Hypovolemic
- Cardiogenic
- Septic

Local Hypoperfusion

- Gastric necrosis and other causes of splanchnic ischemia
- Aortic thromboembolism

Severe Hypoxemia (Pao2 < 30-40 mm Hg)

- Severe anemia (packed cell volume < 15%)
- Carbon monoxide toxicity
- Excessive muscular activity:
  - Exercise
  - Trembling
  - Seizures

Type B: No Clinical Evidence of Tissue HypoxiaType B1 (In Association With Underlying Disease)

- Diabetes mellitus
- Severe liver disease
- Malignancy
- Sepsis
- Pheochromocytoma
- Thiamine deficiency

Type B2 (Due to Drugs and Toxins)

- Acetaminophen
- Cyanide
- Epinephrine
- Ethanol
- Ethylene glycol
- Insulin
- Methanol
- Morphine
- Nitroprusside
- Propylene glycol
- Salicylates
- Terbutaline

Type B3 (Due to Inborn Metabolic Defects)

- Mitochondrial myopathy

Miscellaneous

- Alkalosis: hyperventilation
- Hypoglycemia

Lacrimation/Epiphora, Chronic

CAT

- Chronic conjunctivitis due to feline herpesvirus
- Lacrimal punctal atresia
- Feline corneal sequestration
- Entropion
- Painful corneal lesion (e.g., corneal ulcer)
- Punctal scarring after conjunctivitis
- Dacryocystitis
- Feline proliferative (eosinophilic) keratoconjunctivitis

DOG

- Entropion
- Painful corneal lesion (e.g., corneal ulcer)
- Dacryocystitis
- Lacrimal punctal atresia
- Distichiasis
- Ectopic cilia
- Tear-staining syndrome (e.g., medioventral entropion and caruncular trichiaisis in brachycephalic breeds of dogs)
- Allergic inhalant dermatitis (atopy)
- Uveitis
- Chronic conjunctivitis as a result of concurrent tear film deficiency (e.g., KCS; mucin and/or lipid deficiency), ectropion or allergic inhalant dermatitis (atopy)

Modified from Slatter D: Fundamentals of veterinary ophthalmology, St Louis, 2001, Saunders.

Myositis

Microorganisms Associated With Musculoskeletal Infections

Modified with permission from Greene C: Infectious diseases of the dog and cat, ed 2, St Louis, 1999, Saunders, p 555; and Morgan R: Handbook of small animal practice, ed 5, St Louis, 2008, Saunders, p 800.

Causes of Myositis Infection

- *Hepatozoon*
- *Toxoplasma gondii*
- *Neospora caninum*
- *Leptospira*
- *Borrelia*
- Numerous bacteria (e.g., *Staphylococci* [dogs], *Pasteurella multocida* [cats])
- Toxigenic *Streptococcus canis*

Myopathies

Classification

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders; and Shelton D: What's new in muscle and peripheral nerve disease. Vet Comp Orthop Traumatol 20:249-255, 2007.

Inflammatory

- Infectious
  - Bacterial: leptospirosis
  - Protozoal: toxoplasmosis/neosporosis
  - Parasitic: *Toxocara*, others
- Immune-mediated
  - Masticatory myositis
  - Polymyositis
  - Dermatomyositis
- Degenerative
  - Acquired
    - Endocrine:
      - Hyperadrenocorticism
      - Hypothyroidism
      - Hypokalemic polymyopathy (cats)
    - Fibrotic/ossifying myopathies
    - Ischemic
    - Nutritional
    - Neoplastic
    - Toxic
  - Inherited
    - Muscular dystrophy:
      - Exercise-induced collapse in Labrador retrievers
      - X-linked muscular dystrophy (dystrophin deficient)
      - Other muscular dystrophies (dystrophin positive)
    - Myotonia
    - Metabolic:
      - Pyruvate dehydrogenase phosphatase 1 deficiency in Clumber and Sussex spaniels
      - Glycogen storage disease
        - Mitochondrial myopathy
        - Lipidic myopathy
        - Malignant hyperthermia
    - Centronuclear myopathy (Labrador retriever)
    - Hypertonicity in Cavalier King Charles spaniels
    - Inherited myopathy of Great Danes

Myopathies, Feline Congenital

From Gaschen F, Jaggy A, Jones B: Congenital diseases of feline muscle and neuromuscular junction. J Feline Med Surg 6:355–366, 2004.

ACH, Acetylcholine; *AUS,* Australia; *CH,* Switzerland; *DSH,* domestic shorthair; *GB,* Great Britain; *GBE,* glycogen branching enzyme; *MG,* myasthenia gravis; *NL,* Netherlands; *NZ,* New Zealand; *US,* United States.

Characteristics

Disease	Affected Breeds and Geographical Provenance	Mode of Inheritance	Underlying Defect	Clinical Signs	Prognosis
Congenital myotonia	DSH (NZ, US)	Autosomal recessive	Probable defect in chloride channels	Stiff gait, hyperactivity of selected muscle groups when startled, percussion dimple	Fair to good (nonprogressive condition, cats enjoy a normal quality of life)
Devon rex myopathy	Devon rex (AUS, GB)	Autosomal recessive	Unknown	Cervical ventroflexion; generalized muscle weakness; abnormal gait; megaesophagus	Poor (many cats die of asphyxiation)
Dystrophin-deficient myopathy	DSH (US, NL, CH)	X-linked recessive	Dystrophin deficiency	Skeletal muscle hypertrophy with possible complications, sensitivity to stress, stiff gait	Guarded to fair (cats can have an almost normal quality of life but may require more frequent veterinary visits)
Glycogen storage disease type IV	Norwegian forest cats (US, Europe)	Autosomal recessive	GBE deficiency	Stillbirth, muscle tremor, muscle atrophy; cardiomyopathy	Poor (all cats eventually die from the condition)
Hypokalemic myopathy	Burmese (AUS, NZ, GB, NL)	Probably autosomal recessive	Unknown	Transient, paroxysmal clinical signs with generalized muscle weakness, cervical ventroflexion	Good response to potassium supplementation
Malignant hyperthermia	DSH	Unknown	Unknown	Severe hyperthermia during anesthesia (halothane)	Poor (two reported cases in which cats died)
Merosin-deficient myopathy	DSH, Siamese (US)	Unknown	Merosin (laminin-2) deficiency	Hind limb weakness from 6 months old, worsening to muscle atrophy and contractures at 1 year old	Poor (both cats in the two reported cases were euthanized before 2 years of age)
MG	DSH	Unknown	Lack of ACH receptors	Generalized muscle weakness	Fair, generally good response to therapy
Nemaline myopathy	DSH (US)	Possibly autosomal recessive	Unknown	Progressive weakness (6–18 months); rapid, choppy, hypermetric gait; tremor, exercise intolerance	Poor (five reported cats died or were euthanized)

Myocarditis

Causes

Modified with permission from Greene C: Infectious disease of the dog and cat, ed 2, St Louis, 1999, Saunders, p 580.

Viral

- Canine distemper virus (neonate)
- Canine parvovirus (prenatal, neonate)

Rickettsial

- *Rickettsia rickettsii*

Bacterial

- Numerous genera
- *Borrelia burgdorferi*

Algal

- *Prototheca* spp.

Fungal

- *Cryptococcus neoformans*
- *Coccidioides immitis*
- *Aspergillus terreus*
- *Paecilomyces variotii*

Protozoal

- *Trypanosoma cruzi*
- *Toxoplasma gondii*
- *Hepatozoon canis*
- *Neospora caninum*

Traumatic

- Automobile trauma
- Injury from falling
- Penetrating trauma
- Cardiac catheterization

Immune-Mediated Conditions

- Rarely reported in veterinary medicine

Unknown

- Transmissible myocarditis-diaphragmitis of cats

Myocardial Diseases, Feline

Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 5, St Louis, 2000, Saunders.

Idiopathic

- Hypertrophic cardiomyopathy
- Restrictive cardiomyopathy
- Dilated cardiomyopathy
- Arrhythmogenic right ventricular cardiomyopathy

Secondary (Including Specific Cardiomyopathies)

- Inflammatory
  - Viral (panleukopenia?)
  - Bacterial
  - Protozoal
  - Fungal
  - Algal
  - Parasitic
- Metabolic
  - Nutritional:
    - Taurine deficiency
  - Endocrine:
    - Thyrotoxicosis
    - Acromegaly
    - Diabetes mellitus
  - Toxic:
    - Anthracyclines (doxorubicin)
- Vascular
  - Systemic hypertension
- Infiltrative
  - Neoplastic
  - Glycogen storage disorders
  - Mucopolysaccharidosis
- Fibroplastic
  - Endomyocardial fibrosis
  - Endocardial fibroelastosis
- Genetic
  - Hypertrophic cardiomyopathy
- Physical Agents
  - Heatstroke
- Unclassified Cardiomyopathies
  - Idiopathic unclassified cardiomyopathy
  - Persistent atrial standstill
- Miscellaneous
  - Ischemia
  - Excessive left ventricular moderator bands

Monoclonal Gammopathy

Associated Conditions

With permission from Bonagura J: Kirk's current veterinary therapy XII: small animal practice, St Louis, 1995, Saunders, p 525.

- Multiple myeloma
- Waldenstrom's macroglobulinemia
- Plasma cell leukemia
- Nonsecretory myeloma
- Extramedullary plasmacytoma
- Monoclonal gammopathy of undetermined significance
- Chronic lymphocytic leukemia
- Lymphoma
- Feline infectious peritonitis
- Ehrlichiosis
- Amyloidosis
- Lymphocytic enteritis

Melena

Causes

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Ingested Blood

- Oral lesions
- Nasopharyngeal lesions
- Pulmonary lesions
- Diet

Parasitism

- Hookworms

Neoplasia

- Adenocarcinoma
- Lymphoma
- Leiomyoma or leiomyosarcoma
- Mast cell tumor
- Gastrinoma

Coagulopathies

- DIC
- Rodenticide intoxication

Drug Administration

- NSAIDs
- Glucocorticoids

Miscellaneous

- Liver failure
- Pancreatitis
- Renal failure
- Inflammation (e.g., foreign body, acute gastritis, hemorrhagic gastroenteritis, inflammatory bowel disease)
- Hypoadrenocorticism
- GI ischemia (e.g., shock, volvulus, intussusception)
- Foreign bodies
- GI blood vessel malformations (e.g., arteriovenous fistula)
- Polyps

DIC, Disseminated intravascular coagulation; *GI*, gastrointestinal; *NSAIDs*, nonsteroidal antiinflammatory drugs.

Note: Melena occurs as a result of oxidization of heme in blood in the GI tract, a time-dependent process. Since transit time is longer from the small intestine than from the large intestine, melena is considered a sign of small-intestinal disease. However, melena may occur with large-intestinal bleeding if there is a delay or stoppage of colonic motility, allowing heme oxidation.

Megaesophagus

Associated Diseases and Causes in Dogs

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders., γ, Cause-and-effect relationship not established.

Central Nervous System

- Canine distemper
- Cervical spondylomyelopathy with leukomalacia
- Brainstem lesions
- Neoplasia
- Trauma

Peripheral Neuropathies

- Polyneuritis
- Polyradiculoneuritis
- Ganglioradiculitis
- Dysautonomia
- Giant cell axonal neuropathy
- Spinal muscular atrophy
- Intoxication:
  - Lead
  - Thallium
  - Acrylamide
- Bilateral vagal damage

Neuromuscular Junction

- Myasthenia gravis
- Botulism
- Tetanus
- Anticholinesterase toxicity

Esophageal Musculature

- Esophagitis
- Systemic lupus erythematosus
- Glycogen storage disease
- Polymyositis
- Dermatomyositis
- Cachexia
- Trypanosomiasis
- Hypoadrenocorticism
- Hypothyroidism?

Miscellaneous

- Pyloric stenosis
- Gastric dilatation/volvulus
- Pituitary dwarfism
- Thymoma
- Mediastinitis

Mediastinal Enlargement

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Differential Diagnoses for Lesions Associated With Focal Mediastinal Enlargement

Region	Diseases
Cranioventral	Lymphadenopathy; abscess; thymic mass; ectopic thyroid; hematoma; granuloma; obesity; vascular mass (aorta, cranial vena cava); esophageal mass, foreign body, or dilatation; tracheal mass
Craniodorsal	Esophageal mass, foreign body, or dilatation; heart base mass; neurogenic tumor; paraspinal or spinal mass; hematoma; lymphadenopathy; aortic stenosis; patent ductus arteriosus; abscess; tracheal mass
Perihilar	Lymphadenopathy; left atrial enlargement; esophageal mass, foreign body, or dilatation; main pulmonary artery mass (poststenotic dilatation); heart base or right atrial mass; spinal or paraspinal mass
Caudodorsal	Esophageal mass, foreign body, or dilatation; hiatal hernia; diaphragmatic hernia or mass; spirocercosis; spinal or paraspinal mass; aortic aneurysm; gastroesophageal intussusception
Caudoventral	Diaphragmatic hernia; peritoneopericardial diaphragmatic hernia; abscess; granuloma; hematoma

Neutrophil Dysfunction

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

FeLV, Feline leukemia virus; FIP, feline infectious peritonitis.*Neutrophil chemotaxis was tested in only one of four English-American (Walker) foxhounds with Pelger-Huët anomaly; defective chemotaxis has not been found in other dogs, including foxhounds, with the anomaly.

Causes of Congenital and Acquired Neutrophil Dysfunction

Dysfunction	Species
Chemotactic Factor Generation	
Congenital	
C3 deficiency (Brittany spaniel)	Dog
Adherence	
Congenital	
CD11–CD18 adhesion protein deficiency (Irish setter)	Dog
Acquired	
Diabetes mellitus (poorly regulated)	Dog
Chemotaxis	
Congenital	
C3 deficiency (Brittany spaniel)	Dog
CD11–CD18 adhesion protein deficiency (Irish setter)	Dog
Chédiak-Higashi syndrome (Persian)	Cat
Pelger-Huët anomaly? (foxhound)	Dog*
Primary ciliary dyskinesia (pointer)	Dog
Recurrent infections (weimaraner)	Dog
Acquired	
Bacterial pyoderma	Dog
Demodicosis (serum inhibitor?)	Dog
FeLV infection	Cat
FIP	Cat
Hyperalimentation-induced hypophosphatemia	Dog
Protothecosis (serum inhibitor?)	Dog
Phagocytosis	
Congenital	
C3 deficiency (Brittany spaniel)	Dog
CD11–CD18 adhesion protein deficiency (Irish setter)	Dog
Recurrent and persistent infections (weimaraner)	Dog
Acquired	

Dysfunction	Species
Continuous-flow centrifugation and filtration-leukapheresis	
Collected neutrophils (few hours after pheresis)	Dog
Hyperalimentation-induced hypophosphatemia	Dog
Bacterial Killing	
Congenital	
CD11–CD18 adhesion protein deficiency (Irish setter)	Dog
Cyclic neutropenia (Gray collies)	Dog
Recurrent and persistent infections (weimaraner)	Dog
Rhinitis-pneumonia syndrome (Doberman pinscher)	Dog
Acquired	
FeLV infection	Cat
Hyperalimentation-induced hypophosphatemia	Dog
Lead toxicosis	Dog
Turpentine-induced inflammation	Dog

Neutropenia

Courtesy M.D. Willard from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

FeLV, Feline leukemia virus; *FIV,* feline immunodeficiency virus.*Incomplete list of other drugs is in text.

Consumption of Neutrophils	**Affected Animals**
Overwhelming sepsis/endotoxemia (important)	Dogs/Cats
Parvovirus enteritis (important)	Dogs/Cats
Salmonellosis	Dogs/Cats
Immune-mediated destruction (rare)	Dogs
Bone Marrow Suppression	**Affected Animals**
FeLV (important)	Cats
FIV	Cats
Parvovirus (important)	Dogs/Cats
Ehrlichiosis	Dogs
Bone marrow toxicosis	Dogs/Cats
Estrogen (endogenous/exogenous)	Dogs
Phenylbutazone*	Dogs/Cats
Cancer chemotherapy	Dogs/Cats
Irradiation	Dogs/Cats
Leukemia (important)	Dogs/Cats
Myelophthisis/myelonecrosis	Dogs/Cats
Immune-mediated destruction of neutrophil precursors (rare)	Dogs/Cats

Neuromuscular Diseases

From de Lahunta A: Veterinary neuroanatomy and clinical neurology, St Louis, 1983, Saunders.

Diseases of the Lower Motor NeuronNeuromuscular Junction

- Botulism
- Tick paralysis
- Myasthenia gravis
- Organophosphate intoxication

Peripheral Nerve

- Trauma
- Neoplasia
- Ischemia—caudal aortic thrombosis-embolism

Spinal Roots and Nerves

- Trauma—root avulsion
- Lumbosacral stenosis—cauda equina syndrome
- Neoplasia—neurofibroma
- Inflammation

Spinal Roots and/or Nerves and Peripheral Nerves

- Inflammation:
  - Acute polyneuritis/polyneuropathy:
    - Dog: idiopathic polyradiculoneuritis/coonhound paralysis
    - Acute idiopathic polyneuropathy
    - Postrabies vaccination
    - Distal denervating disease
    - Brachial plexus neuritis
  - Chronic polyneuritis/polyneuropathy:
    - Dog: chronic polyneuritis
    - Inherited hypertrophic neuropathy
    - Giant axonal neuropathy
    - Distal symmetric polyneuropathy
    - Metabolic neuropathy

Spinal Cord

- Focal myelopathy from compression
- Acute ischemic myelopathy: fibrocartilaginous emboli
- Diffuse myelomalacia
- Inflammations: viral, protozoal
- Hereditary neuronal abiotrophy in Swedish Lapland dogs
- Hereditary spinal muscular atrophy in Brittany spaniels
- Stockard's paralysis

Muscle Disease

- Myositis:
  - Infectious
  - Idiopathic—immune mediated:
    - Masticatory
    - Polymyositis
- Myotonia:
  - Hereditary myopathic myotonia of young animals
  - Acquired myopathic myotonia of old dogs

- Other myopathies

Neurologic Signs and Underlying Causes

From de Lahunta A: Veterinary neuroanatomy and clinical neurology, St Louis, 1983, Saunders.

CN, Cranial nerve; *CNS,* central nervous system; *LMN,* lower motor neuron; *UMN,* upper motor neuron; γ, may occur with lesion in this location.

Relationship of Clinical Signs to Anatomic Site of Lesion

Clinical Signs	Functional System	Anatomic Location
Inability to prehend	Masticatory and tongue muscles	CN V, XII, pons-medulla
Dysphagia	Tongue, palatal, pharyngeal, and esophageal muscles	CN IX, X, XI, XII, medulla
Drooling	Facial paralysis, dysphagia	• CN VII, middle ear, medulla • CN IX, X, medulla
Head tilt, nystagmus, loss of balance, rolling	Vestibular system	CN VIII: inner ear, medulla, cerebellum
Strabismus	CN to extraocular muscles, vestibular system	• CN III, IV, VI, midbrain-medulla • Inner ear-medulla-cerebellum
Circling		
With loss of balance	Vestibular system	Inner ear, medulla, cerebellum
Without loss of balance	Limbic system (?)	Frontal lobe, rostral thalamus
Head and eye deviation-turning to one side	Limbic system (?)	Frontal lobe, rostral thalamus
Pacing, head pressing	Limbic system	Frontal lobe, rostral thalamus
Opisthotonos	Upper motor neuron	Rostral cerebellum, midbrain
Blindness	Visual system	
	Dilated unresponsive pupils	Eyeball, optic nerves
	Normal pupils	Visual cortex-cerebrum, (midbrain)
Depression, semicoma, coma	Ascending reticular activating system	Pons to thalamus-cerebral cortex
Seizures	Cerebrum, thalamus-hypothalamus	
Hyperesthesia, hyperactivity to external stimuli	Ascending reticular activating system	Thalamus, cerebrum
Aggressive behavior, mania-hysteria, odontoprisis	Limbic system	Thalamus, cerebrum
Tremor		
Associated with movements, head, and neck	Cerebellar system	Cerebellum
Associated with movements, head, trunk, limbs	Multiple systems	Diffuse CNS

Clinical Signs	Functional System	Anatomic Location
Episodic, not associated with movements, head, trunk, limbs		Thalamus, cerebrum
Bradycardia, hypothermia, hyperthermia	UMN for general visceral efferent system	Hypothalamus
Irregular-ataxic respirations	UMN for respiratory muscle LMN	Pons-medulla

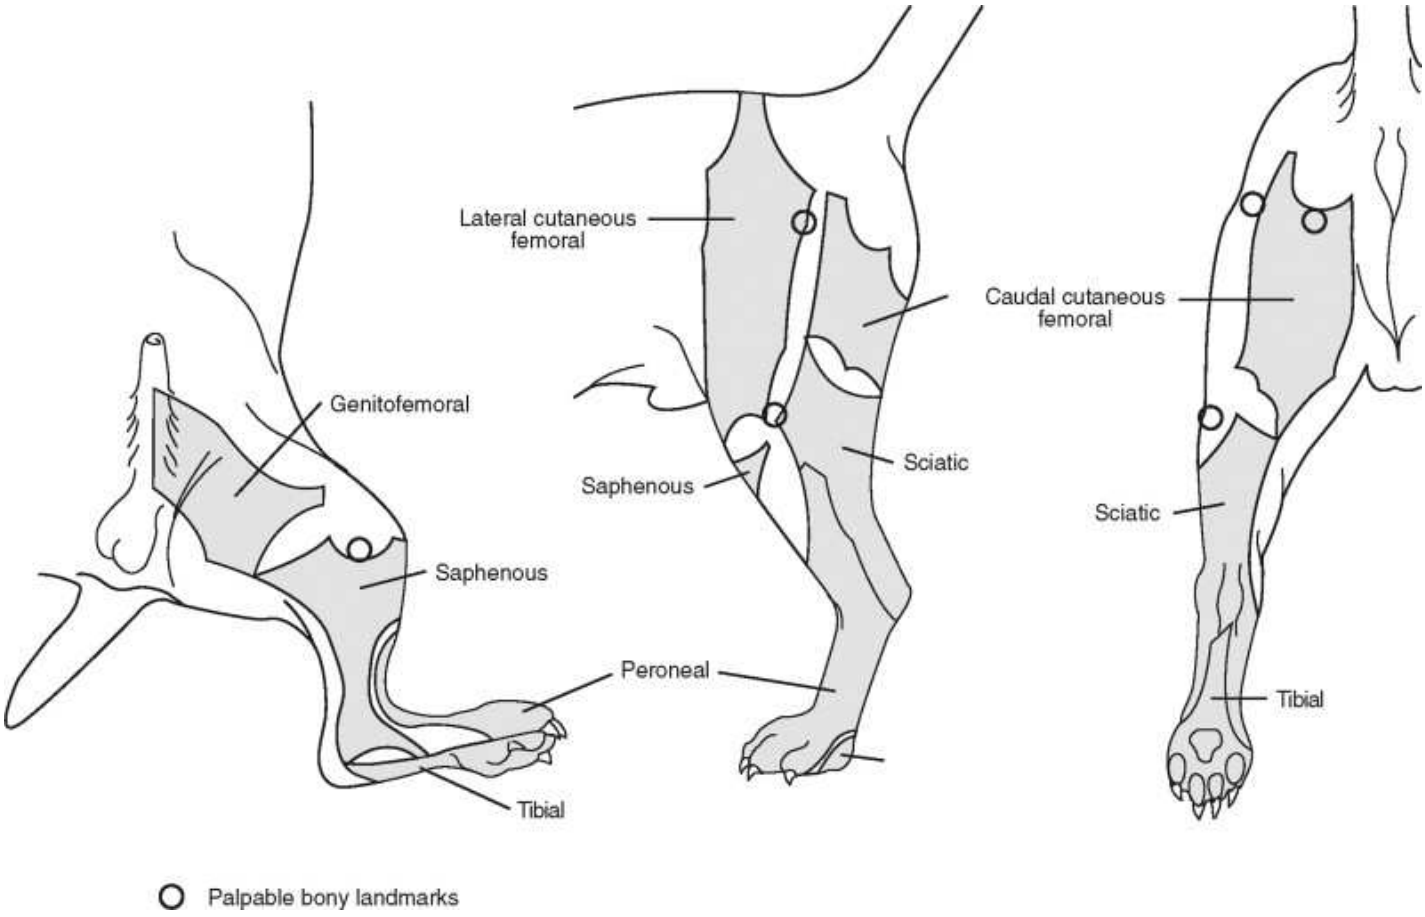
Nerves of the Hind Limb: Localization of Contributing Spinal Cord Segments

Nerves of the Hind Limb

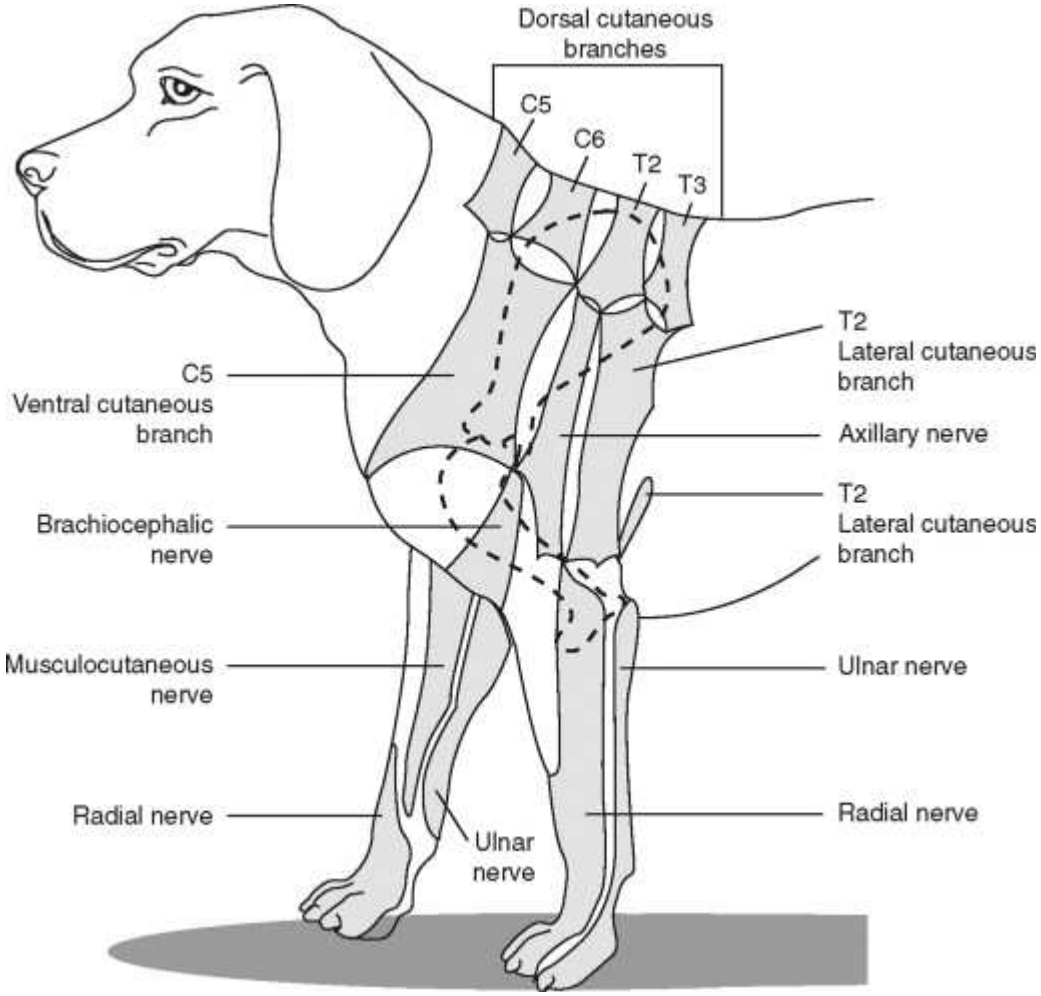
From Evans H, de Lahunta A: Guide to the dissection of the dog, ed 6, St Louis, 2004, Saunders.

Nerve	Spinal Cord Segments
Femoral	L4, 5, 6
Obturator	L(4), 5, 6
Cranial gluteal	L6, 7, S1
Caudal gluteal	L7, S1, 2
Sciatic	L6, 7, S1, 2
Pudendal	S1, 2, 3

Nerves of the Hind Limb: Cutaneous Distribution



Nerves of the Forelimb: Cutaneous Distribution



Nerves of the Forelimb: Localization of Contributing Spinal Cord Segments

Nerves of the Forelimb

From Evans H, de Lahunta A: Guide to the dissection of the dog, ed 6, St Louis, 2004, Saunders.

Nerve	Spinal Cord Segments
Phrenic	C5, 6, 7
Cranial pectoral	C6, 7, 8
Suprascapular	C6, 7
Subscapular	C6, 7
Musculocutaneous	C6, 7, 8
Axillary	C7, 8
Thoracodorsal	C8
Lateral thoracic	C8, T1
Radial	C7, 8, T1, 2
Median and ulnar	C8, T1, 2
Caudal pectoral	C8, T1, 2
Sympathetics (Horner's)	T1, 2, 3

Nephrotoxic Agents in Dogs and Cats

Adapted from Khan SA: Intoxication versus acute nontoxicologic illness: differentiating the two. In Ettinger SJ, Feldman EC, editors: Textbook of veterinary internal medicine, St Louis, 2010, Saunders, pp 549–554.

CNS, Central nervous system; *CV,* cardiovascular; *GI,* gastrointestinal; *NSAIDs,* nonsteroidal antiinflammatory drugs.

Agent	Comments/Notes
Aminoglycoside antibiotics like neomycin, kanamycin, gentamicin, amikacin, and tobramycin	Dogs, cats; not common anymore; mostly seen with parenteral use with repeated dosing, especially if dehydration has not been corrected first
Tetracyclines	Dogs; reported with intravenous use; rare
Sulfonamides	Crystalluria leading to nephrotoxicity; used less commonly such that toxicity not common anymore
NSAIDs such as carprofen, deracoxib, naproxen, ibuprofen, nabumetone, ketoprofen, oxaprozin, etodolac, piroxicam, flurbiprofen, sulindac, diclofenac, meloxicam, tepoxalin	Cats generally more sensitive than dogs; renal toxicosis can occur with acute single large overdose or with repeated use; adverse GI effects more common
Ethylene glycol (antifreeze)	Cats more sensitive than dogs (require less amount to be toxic), but more cases seen in dogs
Melamine and cyanuric acid (contamination)	Cats, dogs; outbreak in United States from contaminated dog and cat food in 2007; crystalluria, azotemia, GI signs
Grapes and raisins ingestion	Dogs only; initial GI signs followed by evidence of renal damage/failure, azotemia > 24 hours
Plants: Easter lily (*Lilium longiflorum*), tiger lily (*Lilium tigrinum*), day lily (*Hemerocallis* spp.), rubrum or Japanese show lilies (*Lilium speciosum*)	Cats only; initially vomiting, anorexia, and lethargy followed by evidence of renal damage within 24–72 hours
Cholecalciferol and other vitamin D3 analogs such as calcipotriene and calcitriol	Dogs and cats; mostly reported in dogs; initial GI signs followed by hyperphosphatemia, hypercalcemia, azotemia, CV and CNS effects
Zinc (pennies, zinc-plated nuts, wires)	Dogs; affects multiple organs; hemoglobinuria, anemia, azotemia, increased liver enzymes, pancreatitis
Heavy metals such as lead, mercury, arsenic	These affect multiple organs; GI signs, CNS effects, increased liver enzymes, azotemia; profuse diarrhea and shock from arsenic

Nasal Obstruction/Discharge in Cats, Chronic

Causes

- Viral rhinitis with or without secondary bacterial infection
  - Herpesvirus (feline viral rhinotracheitis)
  - Calicivirus
- Nasopharyngeal stenosis
- Esophageal motility dysfunction
- Foreign body (typically blade of grass)
- Allergic rhinitis
- Nasopharyngeal polyp
- Neoplasia (nasal lymphoma, other)
- Cryptococcal rhinitis
- Cleft palate (congenital) (uncommon)

Nasal Neoplasia

Malignant Tumors of the Canine and Feline Nasal and Paranasal Sinuses

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Canine

- Adenocarcinoma
  - Differentiated
  - Undifferentiated
- Squamous cell carcinoma
- Chondrosarcoma
- Fibrosarcoma
- Lymphosarcoma

Feline

- Adenocarcinoma
- Lymphoma

Infrequently Reported

- Osteosarcoma
- Hemangiosarcoma
- Rhabdomyosarcoma
- Leiomyosarcoma
- Nerve sheath tumors
- Neuroblastoma

Nasal Discharge and Sneezing

Causes of Concurrent Nasal Discharge and Sneezing

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Structural Anomalies

- Cleft palate
- Oronasal fistula
- Cricopharyngeal achalasia
- Megaesophagus

Allergic/Immunologic

- Allergic rhinitis
- Lymphoplasmacytic rhinitis

Bleeding Disorder

- Factor deficiency (congenital and acquired)
- Thrombocytopenia (infectious and immune mediated)
- Vessel wall (trauma and vasculitis)
- Foreign bodies/trauma

Infections

- Viral: distemper, parainfluenza, adenovirus type 2 (dogs); her-pesvirus, calicivirus (cats)
- Bacterial: including dental disease, chronic feline rhinosinusitis
- Fungal: *Aspergillus* spp., *Penicillium* spp., *Cryptococcus neoformans, Rhinosporidium seeberi*; other opportunistic fungi are rare (e.g., *Trichosporon*)
- Rickettsial (*Ehrlichia canis*, Rocky Mountain spotted fever)
- Parasitic (*Pneumonyssoides caninum, Linguatula serrata, Capil-laria aerophila, Syngamus ierei, Cuterebra* spp.)
- Other (*Chlamydia* spp.)

Neoplasia/Polyps

- Carcinomas, sarcomas, transmissible venereal tumor
- Polyp (nasopharyngeal in cats)

Ototoxic Agents

Agents With Potential to Cause Cochlear or Vestibular Damage

Ototoxic Agents	Comments
Aminoglycoside antibiotics (streptomycin, neomycin, kanamycin, amikacin, gentamicin, tobramycin)	Affects cochlear or vestibular apparatus; can be unilateral or bilateral; ototoxicity occurs mostly with repeated use; affects higher-frequency range first, followed by lower-frequency range
Other antibiotics (erythromycin; chloramphenicol; polymyxin B; minocycline; vancomycin, hygromycin B)	IV or large oral doses of erythromycin reversible; minocycline reversible; topical administration of polymyxin or some aminoglycosides in patients with perforated tympanic membrane; hygromycin B fed to 3 collies for 10 months
Tea tree oil	Possible if concentrated oil administered in the ear for treating otitis externa; high risk in patients with perforated tympanic membrane
Chemotherapeutic agents such as cisplatin or carboplatin	Likely with repeated doses or high acute administration
Salicylate analgesics	Possible with large acute ingestion; reversible
Diuretics (furosemide, ethacrynic acid)	Can affect stria vascularis in cochlea; possible with rapid IV use, especially in human renal failure patients; toxicosis not reported in small animals
Antiseptics (quaternary ammonium compounds such as benzethonium chloride, benzalkonium chloride, and cetrimide; ethanol, iodine or iodophors in 70% alcohol; chlorhexidine)	Possible with topical use; higher risk in patients with perforated tympanic membrane
Heavy metals (lead, mercury, arsenic)	Directly toxic to neural tissues; may affect hearing; ototoxicity not well documented in small animals
Quinine (antimalarial)	Likely not an issue in small animals
Propylene glycol	Possible with 100% solution used topically

Osteomyelitis

Causes in Dogs

Bacterial Aerobes

- *Escherichia coli*
- *Klebsiella* spp.
- *Pasteurella* spp.
- *Proteus* spp.
- *Pseudomonas* spp.
- *Staphylococcus* spp. (most common of the bacteria that cause osteomyelitis)
    - *S. pseudintermedius*
- *Streptococcus* spp.

Anaerobes

- *Actinomyces* spp.
- *Bacteroides* spp.
- *Clostridium* spp.
- *Fusobacterium* spp.
- *Nocardia* spp.
- *Peptostreptococcus* spp.

Viral

- Canine distemper virus

Fungal

- *Aspergillus* spp.
- *Blastomyces dermatitidis Candida* spp.
- *Coccidioides immitis*
- *Cryptococcus neoformans*
- *Histoplasma capsulatum*

Orbital Disorders

From Maggs DJ, Miller PE, Ofri R: Slatter's fundamentals of veterinary ophthalmology, ed 4, St Louis, 2008, Saunders, p 362.

Type of Disorder	Condition	Clinical Signs
Developmental abnormalities	Shallow orbit (brachycephalic breeds)	Exophthalmos, exposure keratitis, corneal ulceration, pigmentation
	Microphthalmos, anophthalmia	Small or absent globe, narrow palpebral fissure, prominent third eyelid, epiphora, blindness
	Hydrocephalus with orbital malformation	Exotropia, hypotropia, poor vision
	Euryblepharon	Long palpebral fissure resulting in apparent exophthalmos
	Orbital arteriovenous malformation or venous varices	Exophthalmos may be pulsatile, sometimes varies with position of varices; fremitus, pulse detectable; arteriovenous malformation has audible bruit
Trauma	Hemorrhages	Subconjunctival and episcleral hemorrhages; retrobulbar hemorrhage with exophthalmos or proptosis
	Penetrating foreign bodies (e.g., grass awns, needles, from mouth)	Discharging sinus fluid through the conjunctiva, periocular skin, buccal mucosa; exophthalmos, periorbital swelling, pain on opening of mouth
	Orbital fractures	Pain, crepitus; skin abrasions, displacement of globe
	Acquired vascular shunts	Pulsatile exophthalmos, may vary with position; audible bruit, fremitus
Infections	Bacterial, fungal	Ocular discharge usually secondary to penetrating foreign bodies from conjunctiva or oral cavity; sinusitis, rhinitis, or infections of roots of teeth
	Parasites (*Dirofilaria immitis*; *Pneumonyssoides caninum*)	Granulomatous lesions due to wandering larvae (*Dirofilaria* [rare]) or extension of infection from nasal cavity (*Pneumonyssoides*)
Neoplasia	Primary orbital neoplasms and neoplasia extending from adjacent area: sarcoma, meningioma, adenocarcinoma from orbital glands or nasal cavity, lymphosarcoma in cats	Exophthalmos, exposure keratitis, strabismus, displacement of globe, usually not painful; possible nasal or neurologic signs
	Metastatic: includes lymphosarcoma	Localized signs as already listed; possible systemic signs
Miscellaneous conditions	Zygomatic mucocele/sialocele	Exophthalmos, strabismus, swelling in any part of orbit or behind upper last molar tooth
	Infections of roots of teeth (especially carnassial)	Discharging fistula beneath eye in dogs
	Dehydration	Enophthalmos, protrusion of third eyelid

Type of Disorder	Condition	Clinical Signs
	Masticatory myositis	Exophthalmos, pain with dysphagia in acute stage; enophthalmos potentiated by opening of mouth in chronic stage when temporal muscles have atrophied
	Extraocular polymyositis	Exophthalmos, often bilateral, may be accentuated with exercise and stress
	Horner's syndrome	Enophthalmos, miosis, ptosis, protrusion of nictitating membrane, dermal vasodilation, local hypothermia

Oral Ulcers

Modified with permission from Greene C: Infectious diseases of the dog and cat, ed 3, St Louis, 2006, Saunders, p 888.

B, Both cat and dog; *C,* cats; *D,* dogs; *FeLV,* feline leukemia virus; *FIV,* feline immunodeficiency virus; *RMSF,* Rocky Mountain spotted fever.

Comparison of Ulcerative Lesions in Oral Cavities of Dogs and Cats

Cause	Species	Lesion Location
Excessive licking (eosinophilic ulcer)	C	Upper incisor or carnassial area of lip, near philtrum, roof of mouth (hard palate)
Autoimmune diseases, bullous pemphigoid	D	Roof of mouth, lips, cheeks, often symmetric; other mucocutaneous regions, footpads
Irritants, uremia	B	Tip of tongue
Viral (parvoviral), rickettsial (RMSF)	D	Multifocal lingual
Maltese terrier stomatitis	D	Ulcerative lesions, lateral tongue, and buccal mucosa
Dental tartar, periodontal disease	B	Periodontal regions (gingival margins)
Herpesvirus	C	Tongue, palate, multifocal
Calicivirus	C	Acute: tongue, palate, multifocal
		Chronic: fauces (glossopharyngeal reflection, upper last molar region), occasionally extends rostrally, occasionally roof of mouth (hard palate)
Immunosuppression; hyperadrenocorticism, leukopenia, FeLV, FIV, Abyssinian, Persian	B	Periodontal region, may spread to gums and cheeks
Electrocution	C	Tongue, often in linear pattern (electrical cord bite)

Optic Nerve Disorders

From Slatter D: Fundamentals of veterinary ophthalmology, St Louis, 2001, Saunders.

Feature	Optic Neuritis	Papilledema	Myelination of the Nerve Fiber Layer
Age	Middle-aged dogs	No specific age group unless associated with cerebral neoplasia, which is more common in older dogs	Present from birth, nonprogressive, and not pathologic
Vision	Severely affected or absent	No effect	No effect
Direct pupillary light reflex	Depressed or absent	Present	Present
Disc hemorrhages	Usually present	Rarely present	Absent
Peripapillary chorioretinitis	Often present	Absent (edema may be present)	Absent
“Kink” in vessels at disc margin	Often present	Often present	Absent
Vitreous haze	Often present	Absent	Absent

Obesity, Causes of/Contributors to

- Excess caloric intake
- Insufficient physical activity
- Neutering
- Hypothyroidism
- Hyperadrenocorticism
- Hypothalamic disorders
- Chronic steroid or antiepileptic drug use
- Orthopedic disease

AUTHOR: DR. KATHRYN MICHEL

Pyoderma

Differential Diagnosis of Canine Pyoderma

Surface Pyoderma

Pyotraumatic dermatitis (acute moist dermatitis, hot spots):

- Pyotraumatic folliculitis and furunculosis, demodicosis, dermatophytosis, neoplasia, cutaneous metastasis, fixed drug eruption, early necrotizing form of idiopathic nodular panniculitis, early localized vasculitis

Intertrigo (skinfold pyoderma):

- Localized demodicosis, mucocutaneous pyoderma, dermatophytosis, *Malassezia* dermatitis, candidiasis, superficial necrolytic dermatitis, zinc-responsive dermatosis

Bacterial overgrowth:

- *Malassezia* dermatitis, atopic dermatitis, food allergy

Superficial Pyoderma

Impetigo (puppy pyoderma):

- Superficial bacterial folliculitis, demodicosis, dermatophytosis, early scabies

Superficial bacterial folliculitis:

- Impetigo, superficial spreading pyoderma, dermatophytosis, demodicosis, sarcoptic acariasis, flea allergy dermatitis, pemphigus foliaceus, urticaria, drug eruption, erythema multiforme, sterile eosinophilic pustulosis, leishmaniasis

Superficial spreading pyoderma:

- Superficial bacterial folliculitis, dermatophytosis, demodicosis, pemphigus foliaceus

Mucocutaneous pyoderma:

- Intertrigo, *Malassezia* dermatitis, localized demodicosis, early discoid lupus erythematosus, zinc-responsive dermatosis, autoimmune skin diseases (DLE, SLE, PV, BP), epitheliotropic lymphoma (mycosis fungoides)

Deep Pyoderma

Pyotraumatic folliculitis:

- Pyotraumatic dermatitis/acute moist dermatitis (hot spot), demodicosis, neoplasia, cutaneous metastasis, fixed drug eruption, idiopathic nodular panniculitis, localized vasculitis

Muzzle folliculitis and furunculosis (canine acne):

- Localized demodicosis, dermatophytosis, early juvenile cellulitis, eosinophilic furunculosis, contact dermatitis

Pedal folliculitis and furunculosis:

- Pelodera dermatitis, dermatophytosis, subcutaneous and systemic mycoses, opportunistic fungal diseases, mycobacterial diseases, interdigital pyogranulomas, neoplasia
- Callus/pressure-point pyoderma: acral lick dermatitis, focal actinic comedones, sarcoptic acariasis

German shepherd dog pyoderma:

- Demodicosis with secondary deep pyoderma, subcutaneous and deep mycoses, opportunistic fungal infection, idiopathic

nodular panniculitis, vasculitis

DLE, Discoid lupus erythematosus; *SLE,* systemic lupus erythematosus; *PV,* pemphigus vulgaris; *BP,* bullous pemphigoid.

AUTHOR: MANON PARADIS DMV, MSc, DACVD

Pulmonary Markings

Differential Diagnoses for the Various Lung Patterns on Thoracic Radiographs

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Bronchial Pattern

- Chronic bronchitis (irritant, allergic, parasitic)
- Calcification
- Peribronchial cuffing (edema, bronchopneumonia, eosinophiliic bronchopneumopathy)

Interstitial Pattern Nodular

- Neoplasia
- Granuloma (eosinophilic, fungal, parasitic- or heartworm-associated, foreign body)
- Bulla with fluid
- Hematoma, abscess, cyst
- Mucus-filled bronchus
- Bronchiectasis

Hazy and Unstructured, Diffuse

- Artifact (underexposure, obesity, end-expiratory film)
- Degenerative changes (“old dog lung”)
- Neoplasia (lymphoma, metastasis)
- Pneumonitis (toxic, inhalant, metabolic, viral, parasitic)
- ARDS
    - Transitional stages of disease, such as edema, hemorrhage, bronchopneumonia

Hazy and Unstructured, Localized

- Hemorrhage
- PTE
- Foreign body
- Partial atelectasis
- Transitional stages of disease, such as edema, bronchopneumonia, hemorrhage, or parasites

Alveolar PatternDiffuse

- Edema (cardiogenic or noncardiogenic)
- Bronchopneumonia
- Hemorrhage
- Smoke inhalation
- Near-drowning incident
- Acute respiratory distress syndrome

Localized

- Edema
- Bronchopneumonia
- Hemorrhage
- Primary lung tumor or metastasis
- Lobar collapse or atelectasis
- Heartworm disease
- Infarct

ARDS, Acute respiratory distress syndrome; *PTE,* pulmonary embolism.

Pulmonary Hypertension

Causes

- Airway or pulmonary parenchymal disease (chronic)
- Branch pulmonary artery stenosis (congenital)
- Congestive heart failure (chronic left-sided)
- Heartworm disease
- Hypoxia (chronic): high altitude, chronic airway obstruction
- Idiopathic/"primary"
- Left-to-right shunting congenital malformations
- Persistently underdeveloped/"fetal" pulmonary circulation
- Pulmonary thromboembolism

Pruritic Feline Dermatoses

Modified by Manon Paradis from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

C, Common; *L,* less common; *R,* regional; *S,* seasonal; *U,* uncommon.

Disease	Site	Lesions
Flea allergy dermatitis C, R, S	Neck, dorsum, lumbosacral, caudal and medial thighs, groin, ears	"Miliary dermatitis," erythema, alopecia, eosinophilic plaques
Eosinophilic plaque C, R, S	Ventral abdomen, medial thighs, anywhere	Raised, ulcerated, erythematous alopecic plaques secondary to allergy (primarily flea allergy dermatitis)
Otodectic acariosis (ear mites) C	Ears, head, neck, rarely generalized	Otitis externa, excoriations, "miliary dermatitis"
Food allergy C	Head, neck, ears, generalized	Erythema, excoriations, alopecia, lack of primary lesions, "miliary dermatitis," eosinophilic plaque
Self-induced pruritic hair loss (atopic dermatitis, food allergy, flea allergy) L	Bilaterally symmetric, caudal and lateral thighs, ventral abdomen, perineum	Alopecia, hair stubble, erythema, papules, underlying skin may be normal
Atopic dermatitis L, S	Head, neck, ears, generalized	"Miliary dermatitis," erythema, excoriations, alopecia, eosinophilic plaque
Self-induced psychogenic hair loss L	Bilaterally symmetric, stripe(s) on dorsal thorax, caudal and lateral thighs, ventral abdomen, perineum, forelegs	Alopecia, hair stubble, normal underlying skin
Cheyletiellosis L, R	Dorsum of thorax, generalized	Large scales, crusts, seborrhea, "miliary dermatitis"
Demodicosis L, R	Trunk, ventral, generalized	Alopecia, scaling
Mosquito-bite hypersensitivity U, R, S	Bilaterally symmetric, dorsal muzzle, planum nasale	Papules, crusts, alopecia, erosion, exudation, periorbital, pinnae, paw pad margins fistulation
Pediculosis U, R, S	Dorsum, generalized	Scales, crusts, alopecia
Notoedric acariosis (feline scabies) U, R	Head, ears, neck, generalized	Erythema, papules, crusts, excoriations, partially bilaterally symmetric alopecia
Harvest mites (chiggers, trombiculiasis) U, R, S	Ventrum, legs, anywhere	Erythema, scales, crusts, papules, alopecia
Pruritic dermatophytosis U	Head, neck, ears, generalized	Erythema, alopecia, hair stubble, "miliary dermatitis," hyperpigmentation
Drug eruptions U	Anywhere, localized or generalized, pinnae, face	Pleomorphic, erythema, papules, coalescing target lesions
Pemphigus foliaceus U	Bilaterally symmetric, face, planum nasale, ears, interdigital webs, nipples, generalized	Pustules, epidermal collarettes, crusts, alopecia

Pruritic Canine Dermatoses

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

C, Common; *L,* less common; *R,* regional (geographically variable); *S,* seasonal; *U,* uncommon.

Disease	Site	Lesions
Flea allergy dermatitis C, R, S	Bilaterally symmetric, dorsal lumbosacral, caudal thighs, groin, axilla, caudal half of body	Papules, macules, alopecia, erythema, lichenification, hyperpigmentation, excoriations, fibropruritic nodules
Canine scabies C	Ventrum, pinnae margins, face, elbows, partially bilaterally symmetric	Macules, papules, erythema, alopecia, crusts, excoriations
Demodicosis C	Periorbital, commissures of mouth, forelegs, generalized	Alopecia, erythema, crusts, follicular plugging, hyperpigmentation, secondary pyoderma
Pyoderma C	Groin, axilla, ventrum, interdigital webs, generalized, pressure points	Pustules, crusted papules, erythema, alopecia, target lesions, coalescing collarettes, hyperpigmentation
Atopic dermatitis C, S	Face, periorbital, ears, caudal carpi and tarsi, feet (dorsum), otitis externa, axillae, generalized	Erythema, alopecia, excoriations, lack of primary lesions, lichenification, hyperpigmentation
Malassezia dermatitis C, R, S	Ventral neck, groin, skin folds, face, feet, ventrum	Erythema, exudative or dry, alopecia, hyperpigmentation, lichenification
Otodectic acariosis (ear mites) C	Ear canal, pinnae	Erythema, brown otic discharge, excoriation, alopecia
Food allergy L	Face, feet, ears, generalized	Erythema, alopecia, excoriations, lack of primary lesions
Cheyletiellosis L, R	Dorsum of thorax, generalized	Large scales, crusts, alopecia, erythema
Cornification defects L	Generalized, ears, preen body	Scales, crusts, alopecia, erythematous plaques
Acral lick dermatitis L	Anterior carpal, metacarpal, radial, metatarsal, tibial regions	Firm alopecic plaque, central irregular ulcer, hyperpigmented halo
Contact dermatitis U	Hairless areas, feet (ventrum), genitals, groin, axilla, generalized	Erythema, exudation, lichenification, hyperpigmentation, papules
Drug eruptions U	Anywhere, localized or generalized, face ears, scrotum	Pleomorphic, erythema, papules, coalescing target lesions
Pediculosis U, R, S	Dorsum, generalized	Scales, crusts, alopecia, papules
Harvest mites (chiggers, trombiculiasis) U, R, S	Ventrum, legs, anywhere	Erythema, scales, crusts, papules, alopecia
Endoparasitic migration in puppies U	Face, feet, generalized	Erythema, alopecia, excoriations, lack of primary lesions
Pelodera dermatitis U, R, S	Ventrum, legs, groin	Erythema, papules, alopecia, crusts
Superficial necrolytic dermatitis (hepatocutaneous syndrome) U	Footpads, face, mucocutaneous junctions, genitals, groin	Adherent crusts, ulcers, erythema, excoriations, fissured pads
Epitheliotropic lymphoma U	Mucocutaneous, generalized	Erythema, alopecia, scaling, ulcers, nodules

Disease	Site	Lesions
Calcinosis cutis U	Dorsal neck, anywhere	Papules, plaques, erythema, crusting
Tail-dock neuroma U	Previously docked tail	Erythema, excoriations, alopecia

Proteinuria

Modified with permission from Bonagura J: Kirk's current veterinary therapy XII: small animal practice, St Louis, 1995, Saunders, p 938.

PreglomerularPhysiologic

- Stress
- Extreme temperatures
- Strenuous exercise
- Renal venous congestion

Overload

- Hyperproteinemia (total protein > 9 g/dL)
- Hemoglobinemia
- Myoglobinemia
- Paraproteinemia

GlomerularGlomerulonephritis

- Infectious:
  - Dirofilariasis
  - *Ehrlichia canis* infection
  - Chronic bacterial infections
  - Bacterial endocarditis
  - Brucellosis
  - Leishmaniasis
  - Borreliosis
  - Septicemia
- Inflammatory:
  - SLE
- Neoplastic
- Familial
- Idiopathic

Amyloidosis

- Familial
- Inflammatory:
  - SLE
- Neoplastic
- Idiopathic

Glomerulosclerosis

- Diabetes mellitus
- Hyperadrenocorticism
- Hyperfiltration
- Hypertension

PostglomerularTubular Dysfunction

- Fanconi syndrome
- Acute tubular necrosis
- Genitourinary inflammation

Hemorrhage

UTI

Urolithiasis

Trauma

Neoplasia

SLE, Systemic lupus erythematosus; *UTI,* urinary tract infection.

Protein-Losing Enteropathies

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

HGE, Hemorrhagic gastroenteritis.

Causes	Examples
Lymphangiectasia	Primary lymphatic disorder, venous hypertension (e.g., right heart failure, hepatic cirrhosis)
Infectious	Parvovirus, salmonellosis, histoplasmosis, phycomycosis
Structural	Intussusception
Neoplasia	Lymphoma
Inflammation	Lymphocytic-plasmacytic, eosinophilic, granulomatous
Endoparasites	*Giardia*, *Ancylostoma* spp.
Gastrointestinal hemorrhage	HGE, neoplasia, ulceration

Prostatomegaly

- Abscess (asymmetric, often painful)
- Benign prostatic hyperplasia (symmetric, nonpainful; uncommon in castrated dogs)
- Cyst (prostatic, paraprostatic; asymmetric, nonpainful)
- Neoplasia (adenocarcinoma, others; asymmetric, usually nonpainful)
- Prostatitis (asymmetric; painful [acute prostatitis] or nonpainful [chronic])

Preputial Discharge

Urine

- PU/PD
- Ectopie ureters
- Urethral sphincter dysfunction
- UTI
- Urolithiasis

Hemorrhagic

- Bleeding disorder (thrombocytopenia, coagulopathy)
- Neoplasia (bladder, urethra, prostate, testicle)
- Inflammation/infection (bladder, urethra, prostate, testicle, penis/prepuce [balanoposthitis])
- Foreign body (bladder, urethra, prepuce)
- Trauma
- Urolithiasis

Mucopurulent

- Penile and preputial inflammation/infection (balanoposthitis)
- Neoplasia
- Foreign body (preputial, urethral)
- Phimosis

PU/PD, Polyuria/polydipsia; *UTI,* urinary tract infection.

Portosystemic Shunts

Breeds

- More commonly single, intrahepatic in large-breed dogs
- More commonly single, extrahepatic in small-breed dogs and cats

Multiple Shunts

- Multiple shunts are extrahepatic and are most commonly acquired rather than congenital. They occur secondary to portal hypertension induced by chronic hepatopathies or surgical intervention in an animal with hepatic microvascular dysplasia.

Location on Portogram

- If shunt is cranial to T13, more likely intrahepatic
- If any part of the shunt is caudal to T13, more likely extrahepatic

Polyuria and Polydipsia: Drug-Induced

Modified from Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

PU/PD, Polyuria and polydipsia; *WBC/HPF,* white blood cells counted per high-power field.

Urinalysis Results in Dogs With Selected Disorders Causing PU/PD

URINE SPECIFIC GRAVITY					
Disorder	**Number of Dogs**	**Mean**	**Range**	**Proteinuria**	**WBC (>5/HPF)**
Central diabetes insipidus	20	1.005	1.001-1.012	5%	0%
Psychogenic polydipsia	18	1.011	1.003-1.023	0%	0%
Hyperadrenocorticism	20	1.012	1.001-1.027	48%	0%
Chronic kidney disease	20	1.011	1.008-1.016	90%	25%
Pyelonephritis	20	1.019	1.007-1.045	70%	75%

Polyuria and Polydipsia: Differential Diagnosis

From Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

ACTH, Adrenocorticotropic hormone; *BP,* blood pressure; *BUN,* blood urea nitrogen; *CBC,* complete blood count; *PD,* polydipsia; *PU/PD,* polyuria and polydipsia.

Differential Diagnosis for PU/PD and Useful Diagnostic Tests

Disorder	Diagnostic Aids
Diabetes mellitus	Fasting blood glucose, urinalysis
Renal glycosuria	Fasting blood glucose, urinalysis
Chronic kidney disease	BUN, creatinine, Ca:P, urinalysis
Postobstructive diuresis	History, monitoring urine output
Pyometra	History, CBC, abdominal radiography, abdominal ultrasonography
Escherichia coli septicemia	Blood, urine, or other bacterial cultures
Hypercalcemia	Serum calcium
Hepatic insufficiency	Biochemistry panel, bile acids, ammonia tolerance test, abdominal radiography and ultrasonography
Hyperadrenocorticism	History, ACTH stimulation test, dexamethasone suppression test, urine cortisol/creatinine ratio
Primary hyperaldosteronism	Serum sodium and potassium, BP, abdominal ultrasonography, ACTH stimulation test (aldosterone)
Bacterial pyelonephritis	Urine culture, abdominal ultrasonography, excretory urography
Hypokalemia	Serum potassium
Hyponatremia	Serum sodium
Hypoadrenocorticism	Na:K, ACTH stimulation test
Hyperthyroidism	Serum thyroxine
Diabetes insipidus	Modified water deprivation test
Psychogenic PD	Modified water deprivation test
Polycythemia	CBC
Acromegaly	Serum GH and IGF-I, CT scan
Paraneoplastic disorders:	
Intestinal leiomyosarcoma	Abdominal ultrasonography, biopsy
Iatrogenic disorders	History
Very low-protein diet	History

Polyphagia

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Primary PolyphagiaDestruction of Satiety Center

- Trauma
- Mass lesion (e.g., neoplasia)
- Infection

Psychogenic Causes

- Stress
- Introduction of a more palatable diet
- Gluttony

Drug-Induced Polyphagia

- Glucocorticoids
- Anticonvulsants
- Antihistamines
- Progestins
- Benzodiazepines
- Amitraz
- Cyproheptadine

Reported Specific Disorders

Associated With Polyphagia

- FIP
- Lymphocytic cholangitis (feline)
- Spongiform encephalopathy (feline)
- Foreign body encephalitis (feline)

Secondary PolyphagiaPhysiologic Increase in Metabolic Rate

- Cold temperature
- Lactation
- Pregnancy
- Growth
- Increased exercise

Pathologic Increase in Metabolic Rate

- Hyperthyroidism
- Acromegaly

Decreased Energy Supply

- Diabetes mellitus
- Malassimilation syndromes:
    - Pancreatic exocrine insufficiency
    - Infiltrative bowel disease
    - Parasites
    - Lymphangiectasia

Decreased Intake

- Megaesophagus (congenital)
- Low-calorie diet
- Hypoglycemia

Unknown

- Hyperadrenocorticism
- Portosystemic shunt/hepatoencephalopathy
- SARDS

FIP, Feline infectious peritonitis; *SARDS,* sudden acquired retinal degeneration.

Polycythemia

Relative

- Dehydration
- Splenic contraction

Absolute

- Hypoxemia (respiratory disease, obesity, high altitude)
- Renal neoplasm
- Pyelonephritis
- Renal cyst
- Hydronephrosis
- Hepatoma
- Right-to-left shunting cardiovascular malformation (Eisenmenger's physiology)
    - Tetralogy of Fallot
    - Right-to-left patent ductus arteriosus
    - Septal defect with concurrent severe pulmonic stenosis or pulmonary hypertension
    - Double outlet right ventricle
    - Transposition of the great arteries
- Polycythemia vera

NOTE: Strictly speaking, the correct term is *erythrocytosis* (an increase in number of red blood cells). However, the term *polycythemia* (increase in numbers of all blood cell lines) is used interchangeably and in this table, refers to erythrocytosis specifically.

Polyarthritis

Classification of Immune-Based Arthritis

Modified with permission from Bonagura J: Kirk's current veterinary therapy XII: small animal practice, St Louis, 1995, Saunders, p 1189.

Erosive

- Rheumatoid arthritis
- Periosteal proliferative polyarthritis
- Polyarthritis of greyhounds

Nonerosive

- Systemic lupus erythematosus
- Polyarthritis/polymyositis
- Polyarthritis/meningitis
- Calicivirus-associated (cats)
- Arthritis of Akita dogs
- Amyloidosis of shar-pei
- Polyarteritis nodosa
- Idiopathic
    - Type I (uncomplicated)
    - Type II (reactive)
    - Type III (enteropathic)
    - Type IV (malignancy)

Miscellaneous

- Vaccination “reactions”
- Plasmacytic/lymphocytic synovitis
- Drug induced

Pneumonia, Bacteria Isolated in Tracheal Aspirates from Dogs

From pharyngeal isolates, *Mycoplasma* are isolated 85.7%-100% of the time, representing normal microflora; from transtracheal washings, 34%-69%; from bronchiolar washings, 7.1%-26.9% (Jameson et al., 1995; Randolph et al., 1993). A range is not listed for anaerobes because data are from one study of 203 dogs (Angus et al., 1997); Data taken from

- Creighton SR, Wilkins RJ: Bacteriologic and cytologic evaluation of animals with lower respiratory tract disease using transtracheal aspiration biopsy.
- J Am Anim Hosp Assoc 10:227–232, 1974 (30 dogs); Harpster NK: The effectiveness of the cephalosporins in the treatment of bacterial pneumonias in the dog.
- J Am Anim Hosp Assoc 17:766–772, 1981 (30 dogs); Thayer GW, Robinson SK: Bacterial bronchopneumonia in the dog: a review of 42 cases.
- J Am Anim Hosp Assoc 20:731–735, 1984 (42 dogs); Hirsh DC: Bacteriology of the lower respiratory tract. In Kirk RW (ed), Current veterinary therapy IX. Philadelphia, 1986, WB Saunders, pp 247–250 (105 dogs); Jameson PH, King LA, Lappin MR, et al: Comparison of clinical signs, diagnostic findings, organisms isolated, and clinical outcome in dogs with bacterial pneumonia: 93 cases (1986-1991).
- J Am Vet Med Assoc 206:206–209, 1995 (48 dogs); Angus JC, Jang SS, Hirsh DC: Microbiological study of trans-tracheal aspirates from dogs with suspected lower respiratory tract disease: 264 cases (1989-1995).
- J Am Vet Med Assoc 218:55–58, 1997 (203 dogs); With permission from Greene C: Infectious diseases of the dog and cat, ed 3, St Louis, 2006, Saunders, p 870.

Bacteria	Range Percentage (%)
Gram Negative	
Escherichia coli	17–43
Klebsiella	3.9–23
Bordetella	3–23
Pseudomonas	4.9–33
Pasteurella	0–45
Enterobacter	0–5
Acinetobacter	0–7
Moraxella	2–26
Other gram-negative rods	4.4–12
Gram Positive	
Staphylococcus	5.4–27
Streptococcus	13.8–47
Nonhemolytic	0–13
α-Hemolytic	3–30
β-Hemolytic	0–16
Corynebacterium	0–5
Mycoplasma	2.9–100
Anaerobes	
Total	18.7
Bacteroides	23.7
Clostridium perfringens	5.3

Bacteria	Range Percentage (%)
Eubacterium	2.6
Fusobacterium	15.8
Peptostreptococcus	23.7
Prevotella	5.3
Porphyromonas	15.8
Propionibacterium	2.6

Pneumonia, Aspiration

Conditions Predisposing an Animal to Aspiration of Stomach Contents

With permission from King L: Textbook of respiratory disease in dogs and cats, St Louis, 2004, Saunders, p 423.

Impairment of Protective Airway Reflexes

- Coma
- Head trauma
- Metabolic derangements
- Central depressant medications (sedation, general anesthesia)
- Muscle relaxants
- Seizures
- Airway trauma
- Laryngeal/pharyngeal dysfunction

Large Volumes of Intragastric Food/Fluid

- Delayed gastric emptying:
  - Ileus
  - Bowel obstruction
  - Pain
  - Anxiety
  - Opioid medication
  - Peristaltic abnormalities
  - Pregnancy
  - Obesity
- Overfeeding by enteral tube
- Recent meal (before emergency anesthesia/surgery)

Impaired Function of Gastroesophageal Sphincter

- Presence of a nasogastric feeding tube
- Achalasia
- Esophageal obstruction
- Abnormalities of esophageal function:
  - Megaesophagus
  - Reflux esophagitis
  - Myasthenia gravis

Pleural Effusion

Modified with permission from King L: Textbook of respiratory disease in dogs and cats, St Louis, 2004, Saunders, p 16.

C&S, Culture and sensitivity; *FIP,* feline infectious peritonitis; *PCR,* polymerase chain reaction; *RBCs,* red blood cells.*Occasionally translucent; definitive diagnosis via triglyceride concentration, which is higher in chylous effusions than in blood.

Cause, Appearance, Total Protein, and Cytologic Examination Findings of Pleural Effusions

Cause	Appearance	Total Protein	Cytologic Examination	Other Tests
Pyothorax *(septic exudate)*	Cloudy, tomato soup, malodor	>4 g/dL	Degenerative neutrophils, intracellular and extracellular bacteria, macrophages, RBCs	Aerobic and anaerobic C&S
Idiopathic chylothorax *(modified transudate)*	Milky white*	3 g/dL	Mature lymphocytes, few RBCs, few macrophages, few neutrophils	Effusion and serum triglyceride levels
Right-sided (±left-sided in cats) heart failure *(modified transudate)*	Clear	2 g/dL	Very few cells: RBCs, lymphocytes	Echocardiogram
Lymphoma *(modified transudate or nonseptic exudate)*	Clear, milky, serosanguineous	2-4 g/dL	Immature lymphoblasts, few mature lymphocytes, few RBCs	Thoracic radiographs, thoracic ultrasound, aspirate/cytologic examination of mass
Thymoma *(modified transudate or nonseptic exudate)*	Clear, milky, serosanguineous	2-4 g/dL	Mesothelial cells, mature lymphocytes, few RBCs, few macrophages	Thoracic radiographs, thoracic ultrasound, aspirate/cytologic examination of mass
Other neoplasia (e.g., carcinoma) *(modified transudate or nonseptic exudate)*	Clear, cloudy, serosanguineous, bloody	2-4 g/dL	Clumps of neoplastic cells	Thoracic radiographs, thoracic ultrasound
Hypoalbuminemia *(pure transudate)*	Clear, watery	<2.5 g/dL	Mononuclear cells (mesothelial cells, lymphocytes, macrophages)	Serum albumin, urine protein/creatinine ratio, bile acids
FIP (cats) *(nonseptic exudate)*	Straw-colored, cloudy	>4 g/dL	Macrophages, lymphocytes, RBCs, fibrin	FIP PCR on fluid, serum FIP titer

Petechiae, Ecchymosis

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 5, St Louis, 2000, Saunders.

Thrombocytopenia

- ***Decreased Platelet Production***
- Drug:
  - Albendazole (D)
  - Azathioprine (D,C)
  - Chemotherapeutic agents (D,C)
  - Chloramphenicol (D,C)
  - Estrogen (D)
  - Griseofulvin (C)
  - Meclofenamic acid (D)
  - Phenobarbital (D)
  - Phenylbutazone (D)
  - Trimethoprim-sulfadiazine (D)
- Infection:
  - *Ehrlichia* spp.
  - FeLV
  - FIV
  - Disseminated histoplasmosis
- Myelophthisis
- Myelofibrosis
- Immune-mediated disorder (antimegakaryocytic)
- ***Increased Platelet Destruction***
- Primary IMT:
  - ITP
  - SLE
- Secondary IMT:
  - Infection
  - Neoplasia
  - Vaccine
  - Drug:
    - Sulfonamides (D)
    - Cephalosporins (D)
    - Gold salts (D)
    - Methimazole (C)
    - Propylthiouracil (C)
    - Dextrans (D)
- *Ehrlichia* spp. infection
- ***Increased Platelet Consumption***
- Disseminated intravascular coagulation
- Vasculitis:
  - Sepsis
  - *Rickettsia rickettsii*
  - *Leptospira* spp.
  - *Ehrlichia* spp.
  - FIP
- Neoplasia
- Inflammation
- Immune-mediated disorder
- Drug reaction

Thrombopathia

- ***Inherited***
- Chédiak-Higashi syndrome of Persian cats
- Thrombasthenia of otterhounds
- Delta storage–pool disease of American cocker spaniel

- Other thrombopathias:
  - Basset hound
  - Spitz
  - Grey collies with cyclic hematopoiesis
  - Domestic shorthair
- ***Acquired***
- Drug:
  - Aspirin
  - Cephalothin
  - Acepromazine
- Systemic disease:
  - Uremia
  - Liver disease
- Hematologic disorders:
  - IMT
  - Myelo-/lymphoproliferative disorders
  - Dysproteinemia (e.g., multiple myeloma)

Vascular Disorders

- Vasculitis (see Increased Platelet Consumption)
- Hyperadrenocorticism
- Dysproteinemia

C, Cats; *D,* dogs; *IMT,* immune-mediated thrombocytopenia; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *FIV,* feline immunodeficiency virus; *ITP,* idiopathic thrombocytopenic purpura; *SLE,* systemic lupus erythematosus.

Peritonitis

Causes of Peritonitis

From Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

Aseptic Peritonitis

- Chemical peritonitis:
  - Bile peritonitis
  - Uroperitoneum
- Peritoneal foreign body
- Starch granulomatous peritonitis
- Sclerosing encapsulating peritonitis
- Mechanical peritonitis

Septic Peritonitis

- Leakage of gastrointestinal contents:
  - Perforating intestinal foreign body
  - Gastric rupture in gastric dilation/volvulus
  - Perforating gastric or intestinal ulcers
  - Colonic perforation (steroidal or nonsteroidal antiinflammatory drug induced)
  - Dehiscence of intestinal surgical wound
- Iatrogenic perforation:
  - Intraperitoneal alimentation
- Penetrating abdominal wounds
- Blunt abdominal trauma
- Ischemic intestinal injury
- Pancreatitis
- Ruptured pyometra
- Uterine torsion
- Ruptured prostatic abscess
- Liver abscess or hepatitis
- Splenic abscess or splenitis
- Splenic torsion
- Mesenteric lymph node abscess
- Ruptured gallbladder or bile duct with bacterobilia
- Ruptured bladder with cystitis
- Umbilical abscess
- Surgical peritoneal contamination
- Peritoneal dialysis

Pericardial Effusion in the Dog

BUN, Blood urea nitrogen; *C&S,* culture and sensitivity; *FIP,* feline infectious peritonitis; *PT,* prothrombin time.

	Gross Appearance of Effusion	Echocardiographic Appearance	Next Test
Hemangiosarcoma	Hemorrhagic; "port wine" color; usually does not clot (rarely, may clot if brisk hemorrhage); cytologic examination unhelpful	Small, medium, or large amount of anechoic effusion; right atrial/right atrioventricular epicardial mass may or may not be seen; diastolic right atrial and/or right ventricular collapse may be seen.	Serum troponin Central venous pressure elevated
Idiopathic benign pericarditis	Hemorrhagic; "port wine" color; does not clot; cytologic examination unhelpful	Small, medium, or large amount of anechoic effusion; diastolic right atrial and/or right ventricular collapse may be seen.	Serum troponin Central venous pressure elevated
Mesothelioma	Generally hemorrhagic; does not clot; cytologic examination unhelpful	Small, medium, or large amount of anechoic effusion; diastolic right atrial and/or right ventricular collapse may be seen; rarely, pericardium is noted to be thickened; rarely, forms a heart base mass.	Pericardial biopsy/pericardiectomy Central venous pressure elevated
Heart base tumor (chemodectoma; rarely ectopic thyroid carcinoma, mesothelioma, or other)	Generally hemorrhagic; does not clot	Small, medium, or large amount of anechoic effusion; mass generally seen between aortic root and either atrium; diastolic right atrial and/or right ventricular collapse may be seen.	Central venous pressure elevated
Hemorrhage/hemopericardium (coagulopathy, left atrial rupture)	Frank blood; erroneous centesis from the ventricle(s) produces a similar appearance.	Typically small to medium volume of effusion; spontaneous contrast (particulate specks or swirling waves of echogenic material) may be present, representing small clots; diastolic atrial and/or right ventricular collapse may be seen with left atrial rupture or with anticoagulant rodenticide toxicosis; marked atrial enlargement is always present if atrial rupture is the cause.	Platelet count, PT
Inflammatory (e.g., FIP, bacterial pericarditis)	Serosanguineous, rarely grossly purulent (exudate); because of small volume of effusion, pericardiocentesis is often challenging or dangerous and should not	Generally small volume of effusion; echogenic particles may be seen in the effusion, representing small clumps of inflammatory cells, bacteria, and fibrin (bacterial infection) or clumps of proteins/globulin	C&S, aerobic and anaerobic, of pericardial effusion

	Gross Appearance of Effusion	Echocardiographic Appearance	Next Test
	be performed unless clinical (right heart failure signs) and echocardiographic (atrial collapse) signs of tamponade are present.	(such as in FIP).	Surgical exploration if effusion is septic
Hypoalbuminemia	Serosanguineous and watery (pure transudate); because of small volume and low pressure of effusion, pericardiocentesis is challenging or dangerous, is of little additional diagnostic value, and generally is contraindicated.	Generally very small volume of effusion; anechoic	Serum albumin level Central venous pressure normal
Uremia	Serosanguineous and watery (pure transudate); because of small volume and low pressure of effusion, pericardiocentesis is challenging or dangerous, is of little additional diagnostic value, and generally is contraindicated.	Generally very small volume of effusion; anechoic	Serum/blood BUN, creatinine urinalysis Central venous pressure normal
Lymphoma	Serosanguineous or hemorrhagic	Small to medium volume of effusion	Pericardial biopsy rarely indicated
Pericardial cyst	Hemorrhagic	Small, medium, or large volume of effusion Intrapericardial mass distinctly attached to apical aspect of pericardium (not attached to heart)	Thoracotomy and biopsy
Right heart failure	Serosanguineous (modified transudate)	Right heart abnormality (tricuspid valve insufficiency causing marked right atrial enlargement, pulmonic stenosis, right ventricular hypertrophy, etc.); no diastolic collapse of right atrium or ventricle (unless [rarely] right atrial rupture is present)	Thoracic radiographs Abdominal ultrasound should identify enlarged hepatic veins.

Pericardial Diseases

With permission from Kittleson M, Kienle R: Small animal cardiovascular medicine, St Louis, 1998, Mosby, p 417.

Congenital Disorders Pericardial Defects

- Peritoneopericardial diaphragmatic hernia
- Pericardial cyst

Acquired Disorders Pericardial Effusion

- Hydropericardium (transudate)*
  - Congestive heart failure
  - Hypoalbuminemia
  - Peritoneopericardial diaphragmatic hernia
- Pericarditis (exudates)
  - Infectious (bacterial, fungal)
  - Sterile (idiopathic, metabolic, viral)
- Hemopericardium (hemorrhage)
  - Neoplastic
  - Traumatic
  - Cardiac rupture (especially left atrial)
  - Idiopathic

Pericardial Mass Lesions *(± Effusion)*

- Neoplastic
- Granulomatous (actinomycosis, coccidioidomycosis)
- Pericardial abscess

Constrictive Pericardial Disease

- Idiopathic
- Infectious
- Pericardial foreign body
- Neoplastic

Paraneoplastic Syndromes

With permission from Bonagura J: Kirk's current veterinary therapy XII: small animal practice, St Louis, 1995, Saunders, p 531.

Paraneoplastic Disorder	Clinical Features	Associated Neoplasms in Companion Animals
Malignancy-associated hypercalcemia	Dehydration, depression, muscular weakness, anorexia, polyuria and polydipsia, vomiting, arrhythmias	Lymphoma (thymic, multicentric, extranodal leukemia), carcinomas (nasal, pulmonary, mammary, squamous cell, thyroid, apocrine gland of anal sac, gastric, pancreatic, testicular, parathyroid gland), thymomas, multiple myeloma, epidermoid carcinoma of the lung
Extrapancreatic hypoglycemia	Weakness, seizures	Hepatocellular carcinoma, hepatoma, hemangiosarcoma, leiomyosarcoma, splenic hemangiosarcoma, salivary gland adenocarcinoma, metastatic oral melanoma, mammary carcinoma, pulmonary carcinoma, plasma cell tumor, lymphocytic leukemia, renal carcinoma
Hyperhistaminemia, mast cell degranulation	Gastrointestinal ulceration with melena and hematemesis, urticaria, erythema, pruritus, poor wound healing, anaphylactoid reaction, hypotension/arrhythmias, altered coagulation	Mast cell tumor
Cancer anorexia/cachexia syndrome	Weight loss >5%-10% body weight, anorexia >2-3 days' duration, early satiety	Any tumors
Syndrome of inappropriate antidiuretic hormone secretion	Hyponatremia, polyuria and polydipsia, edema	Pulmonary carcinoma (dog)
Fever	Persistent pyrexia >39.7°C (103°F) without infection	Lymphoproliferative and myeloproliferative neoplasms; mast cell, hepatic, and brain tumors
Polycythemia	Exercise intolerance, seizures, red mucous membranes, packed cell volume >60	Renal tumors, lymphoma, polycythemia vera, hepatic tumors
Hypertrophic osteopathy	Painful, hard, swollen distal limbs, reluctance to walk	Primary lung tumors, rhabdomyosarcoma (bladder), esophageal sarcomas, pulmonary metastasis, carcinoma, renal carcinomas, hepatic adenocarcinoma, renal papillary adenoma (cat), Sertoli cell tumor, transitional cell carcinoma of bladder, adrenocortical carcinoma
Dermatologic disorders	Nodular dermatofibrosis, erythema, flushing, necrolytic migratory erythema	Renal cystadenocarcinoma, mast cell tumor, pheochromocytoma, pancreatic adenocarcinoma
Renal disorders	Amyloid deposition, glomerulonephritis, concentrating defects, proteinuria, nephrotic syndrome	Many tumors, including lymphoma, plasma cell tumors, mast cell tumors

Paraneoplastic Disorder	Clinical Features	Associated Neoplasms in Companion Animals
Central nervous system dysfunction	Tissue hypoxia with or without thromboembolism, due to hyperviscosity syndrome (seizures, dementia)	Lymphoma, plasma cell tumors
Peripheral nervous system disorders:		
Neuromuscular junction	Myasthenia gravis (weakness with exercise that improves with rest)	Thymoma, hepatocellular carcinoma, osteosarcoma, mammary adenocarcinoma, pheochromocytoma, pulmonary adenocarcinoma
Neuropathy	Weakness, cranial nerve abnormalities	Lymphoma, bronchogenic carcinoma, insulinoma, leiomyosarcoma, hemangiosarcoma, and undifferentiated sarcomas
Neuromyopathy	Weakness, muscle pain, proprioception deficits	Pulmonary carcinoma
Myopathy	Myositis	Thymoma

Panting

Causes

Modified with permission from King L: Textbook of respiratory disease in dogs and cats, St Louis, 2004, Saunders, p 47.

- Elevated ambient temperature
- Overweight/obesity
- Fever, hyperthermia
- Anxiety, nervousness
- Pain
- Hyperadrenocorticism
- Glucocorticosteroid therapy
- Pheochromocytoma
- Hyperthyroidism
- Hypocalcemia
- Narcotic administration
- Cardiac disease/tachyarrhythmias
- Brain disease

Retinopathies

Common Systemic Disorders Affecting the Retina

Modified from Slatter D: Fundamentals of veterinary ophthalmology, St Louis, 2001, Saunders.

Dog

- Blastomycosis
- Coccidioidomycosis
- Cryptococcosis
- Distemper
- Ehrlichiosis
- Rocky Mountain spotted fever
- Histoplasmosis
- Systemic hypertension
- Larva migrans *(Toxocara* spp.)
- Leishmaniasis
- Lymphoma
- Multiple myeloma
- Toxoplasmosis
- Uveodermatologic syndrome

Cat

- Blastomycosis
- Cryptococcosis
- FIP
- Histoplasmosis
- Multiple myeloma
- Systemic hypertension
- Lymphoma (both FeLV positive and negative)
- Toxoplasmosis
- Tuberculosis

FeLV, Feline leukemia virus; *FIP*, feline infectious peritonitis.

Respiratory Parasites

Parasite (Host)	Comment
Aelurostrongylus abstrusus (cats)	Coughing, sneezing, lethargy possible but usually no signs
Capillaria aerophila (dogs, cats)	Chronic cough or no clinical signs
Crenosoma vulpis (wild canids; rarely dogs)	Chronic cough clinically mimicking chronic sterile bronchitis
Eucoleus boehmi (dogs, cats)	Chronic sneezing, nasal discharge, facial rubbing
Filaroides hirthi (dogs only)	Breeding kennels; zinc sulfate flotation is best (not Baermann)
Oslerus osleri (wild canids; rarely dogs)	Nodules in large airway mucosa; treatment difficult
Paragonimus kellicotti (dogs, cats)	Chronic cough ± pneumothorax; rust-colored pharyngeal phlegm
Pneumonyssoides caninum (dogs)	Nasal mite; sensitive to parenteral (and presumably oral) ivermectin

Renal Failure, Acute

Causes of Intrinsic Acute Renal Failure

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Renal Ischemia

- Progression of prerenal azotemia
- Renal vascular disease (avulsion, thrombosis, stenosis)

Nephrotoxicosis

- Exogenous toxins
- Endogenous toxins
- Drugs

Primary Renal Diseases

- Infections: pyelonephritis, leptospirosis, infectious canine hepatitis
- Immune-mediated disease: acute glomerulonephritis, SLE, renal transplant rejection
- Neoplasia: lymphoma
- Miscellaneous: “Alabama rot”

Systemic Diseases With Renal Manifestations

- Infections: FIP, borreliosis, babesiosis, leishmaniasis, bacterial endocarditis
- Pancreatitis
- SIRS, sepsis, multiple organ failure, DIC
- Heart failure
- SLE
- Hepatorenal syndrome
- Malignant hypertension
- Hyperviscosity syndrome: polycythemia, multiple myeloma

DIC, Disseminated intravascular coagulopathy; *FIP*, feline infectious peritonitis; *SIRS*, systemic inflammatory response syndrome; *SLE*, systemic lupus erythematosus.

Renal Failure, Acute Versus Chronic

From Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

ARF, Acute renal failure; *CKD,* chronic kidney disease; *PCV,* packed cell volume; *PU/PD,* polyuria and polydipsia.*The clinician should be aware that there are many caveats to using these aids.

Diagnostic Aids for the Differentiation of Acute Renal Failure and Chronic Kidney Disease*

	Acute Renal Failure	Chronic Renal Failure	Caveats
History	Ischemic episode, toxicant exposure, nephrotoxic drug use, acute illness	Long-standing signs of weight loss, PU/PD, nocturia, vomiting, diarrhea; prior episodes of illness; prior renal disease/insufficiency	Animals with ARF developing secondary to another disease may have long-standing signs; urine output does not differentiate ARF from CKD.
Body condition	Good	Poor	Some animals with ARF have a poor body condition from another disease process; some animals with CKD look fine.
Kidneys	Normal to large, smooth contour, may be painful	Small, irregular contour	Some chronic renal diseases cause renal enlargement.
Osteodystrophy	Absent	Sometimes present	
PCV	Normal to increased	Decreased (nonregenerative)	Animals with ARF may have nonregenerative anemia.
Urine sediment	May be active	Often inactive	Many animals with ARF have inactive urine sediments.
Serum creatinine	Recently within reference range	Previously increased	Previous prerenal and postrenal factors could also have caused increase.
Serum potassium	Normal to increased	Normal to decreased	Urine output is a major determinant of serum potassium concentration.
Metabolic acidosis	More severe	Less severe	
Histopathologic features	Acute tubular necrosis, acute inflammation	Interstitial fibrosis, glomerulosclerosis, chronic inflammation	Chronic renal lesions can be an incidental finding.
Carbamylated hemoglobin	Normal to mild increase	Increased	

Regurgitation

Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders. *AChE*, Acetylcholinesterase; *SLE*, systemic lupus erythematosus.

Esophageal Disease

- Megaesophagus (primary or secondary)
- Esophagitis
- Mechanical obstruction (foreign body, stricture, vascular ring anomaly)

Alimentary Disorders

- Pyloric outflow obstruction
- Gastric dilatation/volvulus
- Hiatal hernia

Neuropathies

- Peripheral (polyradiculitis, giant-cell axonal neuropathy, polyneuritis, lead poisoning)
- Central (distemper, brainstem lesion, neoplasia, trauma)

Neuromuscular Junction Abnormalities

- Myasthenia gravis (focal or generalized)
- Botulism
- Tetanus
- AChE toxicity

Immune-Mediated Causes

- SLE
- Polymyositis
- Dermatomyositis

Endocrine

- Hypothyroidism
- Hypoadrenocorticism

Red Eye: Differential Diagnosis

With permission from Lavignette AM: Differential diagnosis and treatment of anterior uveitis. Vet Clin North Am 3:504, 1973. Modified from Slatter D: Fundamentals of veterinary ophthalmology, St Louis, 2001, Saunders.

Note: These disorders often do not exist in isolation, and features of two or more disorders may be present simultaneously, may negate each other, or may be additive.

Parameter	Anterior Uveitis	Conjunctivitis	Superficial Keratitis	Glaucoma
Conjunctiva	Not thickened, vessels easily seen	Thick, folded, and hyperemic, vessels concealed	Not thickened	Not thickened
Conjunctival vessels	Circumcorneal and straight, not movable with conjunctiva	Superficial, diffuse, and tortuous	Diffuse, vessels form fine network in vicinity of cornea	Diffuse, superficial and prominent
Secretion or discharge	None	Moderate to copious	Serous to purulent	None
Pain	Moderate	Severe	Moderate to severe	Severe to acute
Photophobia	Moderate	None	Severe	Slight
Cornea	Clear to steamy	Clear	Clouded to opaque	Steamy
Pupil size	Small, sluggish, irregular, or fixed	Normal	Normal	Dilated, moderate to complete, and fixed
Pupillary light reflex	Poor	Normal	Normal	Absent
Intraocular pressure	Variable; typically low/diminished acutely	Normal	Normal	Elevated

Systemic Inflammatory Response and Multiple Organ Dysfunction

With permission from Fox P: Textbook of canine and feline cardiology: principles and practice, St Louis, 2000, Saunders, p 275.

MODS, Multiple organ dysfunction syndrome; *SIRS,* systemic inflammatory response syndrome; *Y,* yes, usually present; +, possibly present; +/++/+++, mild, moderate, severe.

Clinical Manifestations of SIRS and MODS

	SIRS	MODS
Historic Abnormalities		
Anorexia	+/++	++/+++
Lethargy	+/++	++/+++
Diarrhea (hemorrhagic)		+
Physical Examination		
Mental depression	+/++	+++
Fever	Y	
Hypothermia		Y
Vasodilation (red mucous membranes, accelerated capillary refill time)	Y	
Vasoconstriction (pale mucous membranes, prolonged capillary refill time)		Y
Heart murmur	Y	+
Arterial pulse quality:		
“Bounding”	Y	
Normal or decreased		Y
Tachycardia, arrhythmias	+	Y
Tachypnea, hyperventilation	Y	Y
Petechiae or bleeding	+	+/Y
Clinical Pathologic Findings		
Hyperglycemia	+/Y	
Hypoglycemia		+/Y
Leukocytosis (possibly following transient leukopenia; left shift, mild toxic changes)	Y	
Leukopenia or rapid decrease in leukocytes, with marked left shift, toxic neutrophils		Y
Coagulation parameters:		
Normal to hyperactive	Y	
Hypoactive		Y
Increased liver enzymes (particularly alkaline phosphatase)		Y
Hyperbilirubinemia		+/Y
Hypoalbuminemia	+/Y	+/Y
Azotemia	+/++	+/++/+++
Acidosis (lactic/metabolic)	+	+/++

	SIRS	MODS
Hemodynamic Changes		
Cardiac output:		
Normal to high	Y	
Low		Y
Arterial blood pressure; central venous pressure:		
Normal	+/++	+
Low	+/++/+++	+/++

Syncope

Differential Diagnoses for Syncope and Episodic Weakness

From Fox P: Textbook of canine and feline cardiology: principles and practice, St Louis, 2000, Saunders, 447.

Primary Cardiac Causes

- Arrhythmias
- Obstruction to cardiac filling
- Obstruction of ventricular ejection

Hypotension

- Inadequate cardiac output (e.g., dilated cardiomyopathy)
- Inadequate vascular tone (e.g., vasodilators, b-blockers)
- Inadequate blood volume:
    - Blood loss:
        - Internal (e.g., splenic hemangiosarcoma, GI blood loss)
        - External (e.g., trauma)
    - Diuresis (e.g., furosemide)
    - Hypoadrenocorticism
    - Fluid loss (e.g., emesis, diarrhea)

Hypoxemia

- Respiratory failure
- Pulmonary thromboembolism

Abnormalities of Blood Constituents

- Hypoglycemia
- Hypokalemia
- Anemia
- Hepatoencephalopathy

Neurologic and Neuromuscular Disorders

- Epilepsy
- Structural CNS disorders:
    - Neoplasia
    - Cerebral arterial disease
    - Thromboembolism
- Narcolepsy
- Myasthenia gravis

Syncope, Disease Associations

With permission from Fox P: Textbook of canine and feline cardiology: principles and practice, St Louis, 2000, Saunders, p 451.

Cardiovascular Causes of Syncope and Breed Predispositions

Causes of Syncope	**Breed Predispositions**
Structural Heart Diseases	
Dilated cardiomyopathy	Doberman pinscher, boxer, cocker spaniel, giant-breed dogs
Chronic valvular disease	Small-breed dogs (middle-aged to geriatric)
Pulmonic stenosis	English bulldog, Samoyed, beagle, Chihuahua, cocker spaniel, others
Subaortic stenosis	Newfoundland, boxer, golden retriever, German shepherd, others
Right-to-left shunting congenital defects	English bulldog
Hypertrophic cardiomyopathy	Cats (Maine coon, Ragdoll, Sphynx, Himalayan)
Pericardial effusion	
Intracardiac mass lesions (neoplasia; thrombus)	German shepherd, golden retriever, others
Cardiac Arrhythmias	
Sick sinus syndrome	Miniature schnauzer, dachshund, West Highland white terrier, cocker spaniel
Advanced AV block	German shepherd, dachshund, pug, Doberman pinscher
Asystole	
Sinus bradycardia	
Supraventricular tachycardia	Labrador retriever
Ventricular tachycardia	German shepherd, boxer, Doberman pinscher, cocker spaniel
Cor Pulmonale	
Pulmonary embolism	
Pulmonary hypertension	
Heartworm disease	
Tussive “Cough Drop” Syncope	Small-breed dogs with combined cardiopulmonary disease
Vasovagal Syncope	Boxer, brachycephalic breeds?

Stunted Growth

Potential Causes of Small Stature in Dogs and Cats

From Feldman E, Nelson R: Canine and feline endocrinology and reproduction, ed 3, St Louis, 2004, Saunders.

Endocrine

- Hyposomatotropism
- Hypothyroidism
- Hyperadrenocorticism
- Hypoadrenocorticism
- Diabetes mellitus

Nonendocrine

- Malnutrition
- Gastrointestinal:
  - Maldigestion
  - Pancreatic exocrine insufficiency
  - Malabsorption
  - Heavy intestinal parasitism
- Hepatic:
  - Portosystemic vascular shunt
  - Glycogen storage disease
- Renal disease
- Cardiovascular disease (especially congenital heart defects)
- Skeletal dysplasia; chondrodystrophy
- Mucopolysaccharidosis
- Hydrocephalus

Storage Disorders

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 5, St Louis, 2000, Saunders.

CNS, Central nervous system; *DSH,* domestic shorthair; *PNS,* peripheral nervous system.

Lysosomal Storage Disorders

Species/Breed	Age of Onset	Duration	Signs/Pathologic Examination
Neuronal Disorders			
GM1 Gangliosidosis (Betagalactosidase Deficiency)			
Feline Siamese, Korat, mixed breeds	4-6 months	6-10 months	Ataxia, tremors, paresis, visual loss, seizures, behavioral changes; corneal and retinal lesions; CNS, liver, pancreatic acinar cells involved
Canine Beagle/mixed	2-4 months	4-6 months	Visual signs, tremors, dysmetria, paresis, behavioral changes; CNS, liver, kidney, spleen, lymph nodes
Canine German shorthaired pointers	6 months	18 months	Behavioral changes, seizures, ataxia, weakness, visual signs, coma; CNS
Feline DSH	4-10 weeks		Tremors, dysmetria, ataxia, paresis; dwarfism, corneal opacity; CNS, liver, endothelium, bone marrow, spleen, kidney
Sphingomyelin Lipidosis (Sphingomyelinase Deficiency)			
Feline Siamese, DSH	3-6 months	3-6 months	Stunted growth, ataxia, dysmetria, tremors; CNS, liver, lung, spleen, lymph nodes, kidney, bone marrow, adrenal gland
Sphingomyelin in Lipidosis (Glucocerebrosidase Deficiency)			
Canine Sidney silkie	7 months	1 month	CNS, liver
Mannosidosis (α-Mannosidase Deficiency)			
Neuronal Ceroid Lipofuscinosis			
Canine English setters	14-18 months	8-12 months	Visual, mental, behavioral changes, cerebellar signs, seizures; CNS, lymph nodes, salivary gland, prostate, kidney
Leukodystrophies: Globoid Cell			
Canine Cairn and West Highland white terriers, beagles, blue tick hound, poodles	11-30 weeks	2-3 months	Tremor, dysmetria, paresis, muscle atrophy, visual changes, mental changes
Feline			CNS, PNS
Metachromatic Leukodystrophy: Cavitating leukodystrophy			
Canine Dalmatians	3-6 months		Decreased vision, ataxia, paresis

Stomatitis

Modified from Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

FeLV, Feline leukemia virus; *FIV,* feline immunodeficiency virus.

Causes of Stomatitis

Conditions associated with immune system depression or dysfunction	• Necrotizing ulcerative gingivostomatitis • Mycotic infections (commonly candidiasis) • Neutrophil dysfunction, gray collie syndrome, drug therapy, viral infection (e.g., FeLV)
Autoimmune disorders	• Vesiculobullous skin diseases (e.g., pemphigus and pemphigoid) • Systemic or discoid lupus erythematosus • Sjögren-like syndrome
Hypersensitivity	• Drug eruptions • Insect stings
Viral infections	• FeLV • FIV • Calicivirus
Miscellaneous conditions	• Eosinophilic granuloma complex • Feline chronic gingivostomatitis

Splenomegaly

Causes of Splenomegaly

Modified from Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Generalized SplenomegalyInflammation

- Infectious
- Granulomatous condition

Neoplasia

- Primary:
  - Lymphoma
  - Mastocytosis
  - Histiocytosis
  - Leukemias (acute, chronic)
- Metastatic

Hyperplasia

- Extramedullary hematopoiesis

Amyloidosis

Congestion

- Pharmacologic:
  - Phenothiazine tranquilizer
  - Barbiturates
- Torsion of splenic pedicle:
  - Isolated
  - With gastric dilatation/ volvulus
- Portal vein/caudal vena cava hypertension:
  - Vascular anomaly
  - Congestive heart failure
  - Hepatic cirrhosis
  - Neoplasia

Localized SplenomegalyNeoplasia

- Hemangiosarcoma
- Hemangioma
- Lymphoma
- Leiomyosarcoma
- Fibrosarcoma
- Osteosarcoma

Other

- Hematoma
- Nodular hyperplasia
- Abscess

Splenic Diseases: Infectious

Infectious Causes of Splenomegaly/Splenitis*

*Infectious disease may affect the spleen directly or indirectly cause splenomegaly by causing chronic anemia, chronic antigen stimulation, or disturbances in blood flow (e.g., endotoxemia).

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Viral Diseases

- FIP (C)
- FeLV (C)
- FIV (C)
- Infectious canine hepatitis (D)

Rickettsial and Mycoplasmal Diseases

- Ehrlichiosis (canine and feline)
- RMSF (*Rickettsia rickettsii*)
- Q fever (*Coxiella burnetii*)
- Hemotropic mycoplasmosis (*Mycoplasma haemofelis*)

Bacterial Infections

- Canine brucellosis
- Mycoplasmosis
- Florida borreliosis
- Plague
- Tularemia
- Streptococcosis
- Staphylococcosis
- Salmonellosis
- *Francisella* infection
- Endotoxemia

Fungal Diseases

- Cryptococcosis
- Histoplasmosis
- Blastomycosis

Protozoal Diseases

- Toxoplasmosis
- Cytauxzoonosis (C)
- Babesiosis (*Babesia canis* and *B. gibsoni*)
- Leishmaniasis (D)

C, Cats; *D*, dogs; *FeLV*, feline leukemia virus; *FIP*, feline infectious peritonitis; *FIV*, feline immunodeficiency virus; *RMSF*, Rocky Mountain spotted fever.

Shock

With permission from Fox P: Textbook of canine and feline cardiology: principles and practice, St Louis, 2000, Saunders, p 273.

Clinical Classification of Shock: Mechanism or Primary Cause

Shock Classification	Primary Mechanism	Examples
Cardiogenic	Poor ventricular contractility	Dilated cardiomyopathy
		Toxins/drugs
		Myocardial infarction
		Pericardial effusion/cardiac tamponade
Distributive	Vasomotor dysfunction	Arteriovenous shunting
		Hypotension (expanded venous capacitance)
		High or normal resistance
		Hypodynamic late septic shock
Hypoxemic	Lack of oxygen	Anemia
		Hypoxemia
Metabolic	Inability to utilize energy substrates	Sepsis
		Cyanide poisoning
		Heatstroke
		Hypoglycemia
Obstructive	Inadequate cardiac preload	Pericardial tamponade
		Restrictive pericarditis
		Intracardiac masses
Hypovolemic	Inadequate circulating blood volume	Dehydration (any cause)
		Hypoproteinemia
		Blood loss
Septic	Bacteremia	Sepsis
	Endotoxemia	

Serotonin Syndrome–Inducing Agents

From Crowell-Davis SL, Poggiagliolmi S: Understanding behavior: serotonin syndrome. Compend Contin Educ Vet 30:490–493, 2008 and Mohammad-Zadeh LF, Moses L, Gwaltney-Brant SM: Serotonin: a review. J Vet Pharmacol Ther 31:187–199, 2008.

Substances That Potentially May Cause Serotonin Syndrome

Agent	General Comments for Each Category of Agent
• *Foods or supplements:* • L-5-HTP, L-tryptophan, *Griffonia* seed extract • Aged cheese, chicken liver	• L-5-HTP is an OTC supplement used in humans for depression, insomnia; serotonin syndrome (SS) reported as a result of accidental ingestion in dogs. • Tyramine present in certain foods can interfere with MAO inhibitors' action and enhance their toxicity.
• *Medications that increase presynaptic release of serotonin:* • Amphetamine • Methylphenidate • Ecstasy (MDMA; 3,4 methylenedioxymethamphetamine) • Bromocriptine • l-dopa	• In addition to CNS excitation from amphetamine, signs of confusion, disorientation, hallucination, and rigidity may be due to SS. • Cyproheptadine, 1.1 mg/kg for dogs and 2-4 mg/cat PO or per rectum q 6-8 h, can be used for treating signs of SS; discontinue after 2-3 treatments if no relief. • Chlorpromazine and other phenothiazines possess some antiserotonin effects.
• *Presynaptic reuptake inhibitors, selective serotonin reuptake inhibitors (SSRIs), and tricyclic antidepressants:* • Fluoxetine • Bupropion • Duloxetine • Fentanyl • Pethidine • Paroxetine • Sertraline • Citalopram • Fluvoxamine • Amitriptyline • Clomipramine (Clomicalm) • Tramadol • Chlorpheniramine • Venlafaxine • Dextromethorphan • Meperidine	• SS is a clinical entity characterized by presence of some GI signs, CNS signs (hyperreflexia, tremors, rigidity, confusion, agitation, excitation, seizures), and mydriasis, tachycardia, hyperthermia. • SS can be seen with acute large overdose or with repeated therapeutic treatment. • Cyproheptadine, 1.1 mg/kg for dogs and 2-4 mg/cat PO or per rectum q 6-8 h, can be used for treating signs of SS; discontinue after 2-3 treatments if no relief. • Chlorpromazine and other phenothiazines possess some antiserotonin effects.
• *Serotonin metabolism inhibitors:* • Selegiline (MAO-B inhibitor; Anipryl) • Amitraz	• Selegiline recommended for use in dogs for cognitive dysfunction • Interaction likely when selegiline used concurrently with tricyclic antidepressants, amitraz, meperidine, and SSRIs
• *Serotonin agonists at postsynaptic membrane:* • Buspirone • Lithium • LSD (lysergic acid diethylamide)	

Seizures: Characteristics and Differentiation

Modified from Ettinger SJ, Feldman EC: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders, p 27.

Convulsive syncope (anoxic or anoxic-epileptic seizures) are syncopal events generally caused by cardiac arrhythmias that produce profound syncope, temporary cerebral hypoxia, and seizures. Therefore, clarification of the type of event observed by the owner (syncope versus seizure) may be difficult and generally rests on the observation of an episode, the presence of heart disease, and the documentation of a severe bradycardia or tachycardia during the event. Videotaping of an episode by the owner and cardiac event monitoring (pager-size portable electrocardiographic [ECG] unit that is triggered by the owner when an event occurs) can be invaluable in clarifying whether an animal is experiencing seizures versus syncope.

Seizures, Differentiation from Other Events

	Seizure (Grand Mal)	Seizure (Partial)	Syncope	Episodic Weakness	Narcolepsy/Cataplexy
Precipitating event	Usually none	Usually none	Exertion, pain, micturition, defecation, cough, stressful event	Exertion or none	Excitement, feeding
Prodrome	Minutes to days; atypical behavior (e.g., anxious, more withdrawn, attention-seeking) ± vomiting		Seconds; acute weakness, staggering, vocalization, autonomic stimulation	None (disorder is neuromuscular)	None
Aura	None	Marks onset of partial seizure	None	None	None
Event features	Chomping, hypersalivation, tonic-clonic limb motion; duration often 1-2 minutes; duration > 5 minutes is consistent with seizure and highly inconsistent with syncope	Localized signs	Motionlessness; flaccid or rigid extension of limbs; opisthotonos possible; no tonic-clonic activity; duration generally transient (<1 minute)	Gradual or sudden loss of muscle tone, causing recumbency; mentation and consciousness remain normal; no tonic-clonic activity	Instantaneous loss of muscle tone; animal is immobile (sleeping) but appears to be aware of its surroundings.
Recovery	Slowness returning to consciousness; disorientation (commonly 10 minutes or longer); blindness, circling, and other signs of central nervous system dysfunction common	Varies	Rapid recovery of normal mentation; often able to walk (and considered back to normal by owner) within minutes	Highly variable; generally reflective of course of onset (gradual onset associated with slow recovery); in some cases, rapid onset disorders may have a protracted course.	Fairly rapid (several seconds to 1 minute), with appearance of waking from sleep

Seizures: Causes Grouped According to Age

Prevalence of Common Seizure Disorders in Relation to Patient's Age at Time of Onset of First Seizure

Modified with permission from Braund KB: Clinical syndromes in veterinary neurology, St Louis, 1994, Mosby, p 242.

Age at Onset: Before 8 Months

Rare: **Idiopathic Epilepsy**
Mainly:

- Developmental disorders (e.g., malformations, hydrocephalus)
- Encephalitis or meningitis
- Trauma
- Extracranial causes:
    - Hepatic encephalopathy (e.g., portocaval shunt)
    - Hypoglycemia
    - Intoxications
    - Intestinal parasitism

Age at Onset: 8 Months to 4 Years

Mainly: **Idiopathic Epilepsy**
Seldom:

- Developmental disorders (e.g., malformations, hydrocephalus)
- Trauma
- Encephalitis or meningitis
- Acquired hydrocephalus
- Neoplasia
- Extracranial causes:
    - Hepatic encephalopathy (e.g., portacaval shunt, liver disease)
    - Hypocalcemia
    - Electrolyte disturbances
    - Hypothyroidism
    - Intoxications

Age at Onset: More Than 4 Years

Seldom:

- Idiopathic epilepsy
- Trauma
- Encephalitis or meningitis
- Acquired hydrocephalus
- Extracranial causes:
    - Hepatic encephalopathy (e.g., serious liver disease)
    - Hypocalcemia
    - Electrolyte disturbances
    - Hypothyroidism

Increasing:

- Neoplasia
- Degenerative disorders
- Vascular disorders
- Extracranial causes:
    - Hypoxia
    - Hypoglycemia

Seizures

Causes

Modified from de Lahunta A: Veterinary neuroanatomy and clinical neurology, St Louis, 1983, Saunders.

Extracranial

- Hypoglycemia:
  - Glycogen storage diseases
  - Beta-cell neoplasm of pancreas/insulinoma
  - Youth and malnutrition (especially small or toy breeds)
  - Youth and GI disease (especially small or toy breeds)
  - Insulin excess during treatment for diabetes mellitus
  - Intestinal leiomyosarcoma
- Hypoxemia:
  - Cardiorespiratory disease (e.g., severe bradycardia or severe tachycardia, disorders producing polycythemia)
- Hepatoencephalopathy
- Renal disease, especially nephrotic syndrome (embolism)
- Hypocalcemia
- Hyperkalemia
- Hyperlipoproteinemia
- GI disease:
  - Parasitism
  - “Garbage intoxication”
- Polycythemia:
  - Right-to-left shunt (e.g., reversed patent ductus arteriosus, tetralogy of Fallot, atrial or ventricular septal defect with concurrent pulmonic stenosis or pulmonary hypertension)
  - Renal neoplasm (erythropoietin-producing)
  - Chronic lung disease
  - Polycythemia vera

Intracranial

- Inflammation:
  - Canine distemper encephalitis, toxoplasmosis, cryptococcosis, neosporosis
  - Other viral encephalitides: rabies FIP meningoencephalitis in cats
- Neoplasia:
  - Primary or metastatic
- Malformation:
  - Hydrocephalus, lissencephaly-pachygyria
- Injury
- Degeneration:
  - Thiamine deficiency in cats
  - Cerebral infarction in cats
  - Intoxications: lead, mercury, arsenic, chlorinated hydrocarbons, organophosphates, hexachlorophene, ethylene glycol, radiopaque media for myelography, metaldehyde, tremorgenic mycotoxins (penitrem A, roquefortine), blue-green algae, chocolate, marijuana, ethanol/ methanol/fermented materials (e.g., bread dough), prescription human medications

Idiopathic Epilepsy

FIP, Feline infectious peritonitis; *GI*, gastrointestinal.

Seizures, Refractory or Poorly Controlled

Factors Responsible for Inadequate Control of Seizures

Modified with permission from Kirk RW, Bonagura JD, editors: Kirk's current veterinary therapy XI: small animal practice, St Louis, 1993, Saunders, p 986.

Medication and Dosage

- Improper choice of drug
- Insufficient drug dosage
- Delayed increase in dosage
- Inadequate increase in dosage
- Too rapid change of medication
- Too rapid reduction of dosage
- Excessive fluctuations in serum concentrations
- Inappropriately combined drugs
- Failure to monitor serum levels
- Noncompliance
- Drug-drug interactions

Other Precipitating Factors

- Additional medications
- Additional diseases
- Physical or psychological stress

Diagnostic Failures

- Extracerebral causes of seizures
- Progressive brain lesions
- Misidentification of episodes
- Syncope
- Myasthenia gravis
- Narcolepsy/cataplexy

Salter-Harris Fracture Classification

Modified from Piermattei D, Flo G: Brinker, Piermattei, and Flo's handbook of small animal orthopedics and fracture repair, ed 3, St Louis, 1997, Saunders.

Salter-Harris Classification of Separations or Fracture-Separations Involving a Growth Plate and the Adjacent Metaphysis and Epiphysis

Type of Fracture	Radiographic Findings	Principal Anatomic Region Involved
Type 1	Physeal separation, displacement of the epiphysis from the metaphysis at the growth plate	Proximal humerus and femur, distal femur
Type 2	Small corner of the metaphyseal bone fractured, with displacement of the epiphysis from the metaphysis at the growth plate	Distal femur and humerus, proximal humerus, proximal tibia
Type 3	Fracture through the epiphysis and part of the growth plate, with the metaphysis unaffected	Distal humerus
Type 4	Fracture through the epiphysis, growth plate, and metaphysis; several fracture lines possible	Distal femur, distal humerus
Type 5	Compression of the growth plate. Soft-tissue swelling but no bony abnormalities seen following the injury.	Distal ulna, distal radius, distal femur

Tracheal Neoplasia

Malignant Tumors of the Canine and Feline Trachea

Modified from Bonagura JD: Kirk's current veterinary therapy XIII, ed 13, 1999, Saunders, p 503.

- Lymphoma
- Squamous cell carcinoma
- Mast cell tumor
- Chondrosarcoma
- Adenocarcinoma
- Osteosarcoma
- Anaplastic carcinoma
- Leiomyoma

Toxicants, Radiopaque

Differential Diagnosis for Radiopaque Objects in the Gastrointestinal Tract

Name of Substance/Toxicant	Comments
Zinc	Pennies minted after 1987; zinc-coated wires, nuts, bolts, screws
Lead	Fishing sinkers, some curtain weights, slug shots, pet toys (some)
Cadmium	Batteries (metal poisoning unlikely)
Mercury	Uncommon occurrence; difficult to see, since mercury from a broken thermometer can evaporate
Iron	Multivitamin pills containing iron; helpful for determining if exposure has occurred or not
Bismuth subsalicylates and other bismuth salts	Pills containing bismuth salts; pills may resemble pennies on radiograph.
Copper	Pennies (outer coating); copper-containing metallic objects (systemic copper poisoning from copper objects not likely; could see gastrointestinal (GI) signs)
Enteric-coated pills (e.g., aspirin)	May help confirm exposure on plain radiograph
Paradichlorobenzene-type moth balls	Naphthalene types are not radiopaque.
Barium sulfate or other barium salts	Used for contrast radiography
Iodine crystals	Sometimes used for contrast studies
Some sustained-release or extended-release medications (e.g., tricyclic antidepressants, phenothiazines)	Ingestion of large amounts can be seen on the plain radiograph early on; this can help determine exposure.
Chloral hydrate	Crystals; no longer commonly used or available
Expandable polyurethane glue	Glues containing cyanates or isocyanates as active ingredients; glue can expand and cover entire stomach; glue not radiopaque but will be visible as a foreign-body object
Aluminum	Could see GI signs; systemic aluminum toxicosis from aluminum-containing products not likely
Nickel	U.S. coins (nickel, dime, quarter); could see GI signs; systemic nickel poisoning not expected
Calcium, magnesium, or aluminum-containing salts (antacids)	Antacid pills containing calcium carbonate, aluminum hydroxide, or magnesium hydroxide may be visible on radiograph early on.

Total Protein Elevation, Serum

Modified from Cowell R: Veterinary clinical pathology secrets, St Louis, 2004, Mosby, 56.

Inflammation

-

Infectious

- Bacterial (e.g., deep pyoderma)
- Viral (e.g., feline infectious peritonitis)
- Protozoal (e.g., leishmaniasis)
- Fungal (e.g., blastomycosis)
- Rickettsial (e.g., ehrlichiosis)

Noninfectious

- Neoplasia (especially if necrotic areas are present)
- Foreign-body granuloma
- Antigenic response (e.g., inflammatory bowel disease)

Paraneoplastic Protein Synthesis

- Multiple myeloma
- Lymphoma

Dehydration

- Hemoconcentration can elevate both albumin and globulin fractions.
- Dehydration/hemoconcentration is the only differential diagnosis to explain hyperalbuminemia.

Thyroid Hormone Alterations

From Nelson RW, Couto GC: Small animal internal medicine, ed 3, St Louis, 2003, Mosby.

T3, Triiodothyronine; *T4,* thyroxine; *TSH,* thyroid-stimulating hormone.*There is a direct correlation between the severity and systemic nature of illness and suppression of serum T4 and free T4 concentrations.

Variables That May Affect Baseline Serum Thyroid Hormone Function Test Results in Dogs

Age	Inversely proportional effect
Neonate (<3 months)	Increased T4
Aged (>6 years)	Decreased T4
Body size	Inversely proportional effect
Small (<10 kg)	Increased T4
Large (>30 kg)	Decreased T4
Breed:	
Sight hounds (e.g., greyhound)	T4 and free T4 lower than normal range established for dogs; no difference for TSH
Gender	No effect
Time of day	No effect
Weight gain/obesity	Increased
Weight loss/fasting	Decreased T4, no effect on free T4
Strenuous exercise	Increased T4, decreased TSH, no effect on free T4
Estrus (estrogen)	No effect on T4
Pregnancy (progesterone)	Increased T4
Surgery/anesthesia	Decreased T4
Concurrent illness*	Decreased T4 and free T4; depending on illness, TSH may increase, decrease, or not change
Drugs:	
Carprofen	Decreased T4, free T4, and TSH
Etodolac	No effect on T4, free T4, or TSH
Glucocorticoids	Decreased T4 and free T4; decreased or no effect on TSH
Furosemide	Decreased T4
Methimazole	Decreased T4 and free T4; increased TSH
Phenobarbital	Decreased T4 and free T4; delayed increase in TSH
Phenylbutazone	Decreased T4
Potassium bromide	No effect on T4, free T4, or TSH
Progestogens	Decreased T4
Propylthiouracil	Decreased T4 and free T4; increased TSH
Sulfonamides	Decreased T4 and free T4; increased TSH
Ipodate	Increased T4, decreased T3

Dietary iodine intake	If excessive, decreased T4, and free T4; increased TSH
Thyroid hormone autoantibodies	Increased or decreased T4; no effect on free T4 or TSH

Thromboembolism

Causes and Predisposing Factors of Thrombosis and Thromboembolism

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Vascular Endothelial Damage	Hypercoagulability	Abnormal Blood Flow
• Arteriosclerosis • Atherosclerosis • Vasculitis • Heartworm disease • Catheterization • Injection of irritating substances • Neoplasia • Vascular incarceration/compression • Hyperhomocysteinemia • FIE • Fibrocartilaginous embolism	• Infection/sepsis/abscess • Neoplasia • Hyperadrenocorticism • PLN • PLE • DIC • Thrombocytosis • Platelet hyperreactivity • IHA • Parvovirus infection	• Neoplasia • Cardiomyopathy • CHF • Endocarditis • Hypovolemia • Shock • Anemia • Polycythemia • Dehydration • Hyperviscosity

CHF, Congestive heart failure; *DIC*, disseminated intravascular coagulation; *FIE*, feline ischemic encephalopathy; *IHA*, immune-mediated hemolytic anemia; *PLE*, protein-losing enteropathy; *PLN*, protein-losing nephropathy.

Third Eyelid (Nictitating Membrane) Abnormalities

Differential Diagnosis of Prominent Third Eyelid/Third Eyelid Protrusion, and Treatment Approaches

From Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

Prominent Third Eyelid With Focal Abnormality

- Curled or scrolled leading edge: excise abnormal cartilage
- Pink, fleshy mass protruding between globe and third eyelid in a young dog (“cherry eye”): surgically reposition the gland
- Pink, fleshy mass protruding between globe and third eyelid in an old dog: possible neoplasia; biopsy or complete excision of third eyelid
- Mass within or on anterior surface of third eyelid: biopsy or local excision with or without adjunctive therapy; larger masses may require complete excision of third eyelid.

Generalized Enlargement of Third Eyelid

- Thickened and depigmented; may have corneal involvement (chronic superficial keratoconjunctivitis; “pannus”): conjunctival scraping or biopsy; treat with topical corticosteroids, cyclosporine.
- Thickened and inflamed with firm, fibrous nodules; cornea, episclera, and bulbar conjunctiva are also often involved: biopsy; treat on basis of breed and biopsy results (collie: nodular granulomatous episclerokeratitis; other breeds: ocular nodular fasciitis)
- Diffuse, generalized enlargement of third eyelid or gland of the third eyelid: aspiration or biopsy; lymphoma or other systemic neoplasia

Prominent Third Eyelid Only

- Nonpigmented leading edge: appears prominent but needs no therapy
- Secondary to pain: check for corneal ulcer, foreign body, or other source of ocular or intraocular pain.
- Horner's syndrome: look for other signs of miosis, ptosis, and enophthalmos; attempt to localize lesion and treat if needed.
- Secondary to orbital disease: enophthalmos may lead to passive protrusion or orbital mass; cellulitis or myositis may displace third eyelid, causing protrusion.
- Systemic disease, such as tetanus Nonpigmented leading edge/margin (seen congenitally as a normal variant): appears prominent but needs no therapy

Testicular Dimension Abnormalities

Diseases That Cause Change in Testicular Size

From Bonagura J: Kirk's current veterinary therapy XIII, St Louis, 2000, Saunders.

Large Testes	Small Testes
Neoplasia	Hypoplasia
Acute infection	Chronic inflammation
Testicular torsion	Cryptorchidism
Inguinoscrotal hernia	Degeneration
Sperm granuloma	Intersex

Tenesmus/Dyschezia

Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Colorectal Disease

- Constipation
- Colitis-proctitis:
  - Inflammatory bowel disease
  - *Histoplasma capsulatum* (histoplasmosis)
  - *Clostridium perfringens* (enterotoxicosis)
  - *Prototheca zopfii* (protothecosis)
- Rectal stricture
- Neoplasia: polyps
- Foreign material
- Irritable bowel syndrome

Perineal-Perianal Disease

- Anal sacculitis, impaction, or abscess
- Anal sac neoplasia
- Perianal fistula
- Perineal hernia

Urogenital Disease

- Cystitis-urethritis-vaginitis
- Obstructive material—urethral calculi, foreign body
- Prostatitis-prostatic abscess
- Parturition
- Neoplasia of the urethra, bladder, prostate, or vagina

Miscellaneous Causes

- Caudal abdominal cavity mass
- Pelvic fracture: neoplasia

Tachycardia

Differential Diagnosis for a Rapid Heart Rate

- Sinus tachycardia:
  - Excitement
  - Pain
  - Toxicosis (e.g., chocolate; digitalis; aminophylline/theophylline; pseudoephedrine, phenylpropanolamine, and related compounds)
  - Sepsis
  - Hypotension
  - Congestive heart failure
  - Systemic illness (e.g., hyperthyroidism, fever, anemia)
- Atrial flutter
- Atrial fibrillation
- Atrial/junctional tachycardias
- Preexcitation (Wolff-Parkinson-White syndrome, others)
- Ventricular tachycardia
- Ventricular flutter
- Torsade de pointes

Uveitis

Causes of Anterior Uveitis in Cats and Dogs

From Bonagura JD, Twedt DC, editors: Current veterinary therapy XIV, St Louis, 2009, Saunders. *C*, Cat; *D*, dog.

Systemic InfectionBacterial

- Bacteremia or septicemia (e.g., pyometra, abscess) (D, C)
- Brucellosis (D)
- Bartonellosis (D, C)
- Leptospirosis (D)
- Borreliosis (Lyme disease) (D)

Rickettsial

- Ehrlichiosis (D, C)
- Rocky Mountain spotted fever (D)

Viral

- Canine adenovirus 1 (D)
- Feline leukemia virus (C)
- Feline immunodeficiency virus (C)
- Feline infectious peritonitis (C)

Mycotic

- Blastomycosis (D, C)
- Histoplasmosis (D, C)
- Coccidiomycosis (D, C)
- Cryptomycosis (D, C)
- Aspergillosis (D)

Algal

- Protothecosis (D)

Parasitic

- Aberrant nematode larval migration
- *Toxocara* (ocular larval migrans) (D, C)
- *Dirofilaria* larvae (D)
- Others

Protozoan

- Toxoplasmosis (D, C)—primarily cats
- Leishmaniasis (D, C)

Immune Mediated

- Lens-induced uveitis (D, C)
- Canine adenovirus vaccine (CAV-1 or CAV-2) reaction (D)
- Uveodermatologic syndrome (D)—primarily Akita and Arctic breeds of dogs
- Pigmentary uveitis (D) primarily golden retrievers
- Idiopathic anterior uveitis (D, C)

Neoplasia

- Primary (D, C)
- Metastatic—lymphoma most common (D, C)

Metabolic

- Diabetes mellitus—primarily through cataract and lens-induced uveitis (D)
- Hyperlipidemia (D)

Trauma

- Blunt or sharp trauma to the globe

Miscellaneous Causes of Blood-Eye Barrier Disruption

- Hyperviscosity syndrome (D, C)
- Hypertension (D, C)
- Scleritis (D)
- Ulcerative keratitis (D, C)

Uroliths

From Slatter D: Textbook of small animal surgery, ed 3, Philadelphia, 2003, Saunders.

*Not observed as a primary mineral in cats.

Radiographic Characteristics of Common Uroliths

Mineral Type	Degree of Radiopacity	Shape
Cystine	+ to ++	Smooth, usually small, round to oval
Calcium oxalate dihydrate	++++	Often rough, round to oval (occasionally jackstone)
Calcium oxalate monohydrate	+++	Often smooth, round (occasionally jackstone)
Struvite	+ to ++++	Smooth, round or faceted; sometimes assumes shape of renal pelvis, ureter, bladder, or urethra; sometimes laminated
Calcium phosphate	++++	Smooth, round or faceted
Ammonium urate and uric acid	0 to ++	Smooth but occasionally irregular; round or oval
Silica*	++ to ++++	Typically jackstone
Mixed and compound	+ to ++++	Varies with composition; may have detectable nucleus and shell
Matrix	0 to +	Usually round but may be influenced by location

Urinary Tract Infections, Recurrent and Persistent

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

C&S, Culture and sensitivity; *PU/PD,* polyuria and polydipsia; *UTI,* urinary tract infection; *WBC,* white blood cell.

Underlying Causes of a Recurrent or Persistent Urinary Tract Infection

Cause	Means of Diagnosis
Lack of owner compliance in drug administration	History (count remaining doses of medication)
Upper UTI	Abdominal ultrasound showing dilated renal pelvis, culture urine from renal pelvis, urinalysis demonstrating WBC casts
Calculi	Survey and/or contrast radiographs, ultrasonography, cystoscopy
Prostatitis	Rectal palpation, ejaculate cytologic examination and culture, prostatic aspirate, prostatic biopsy, ultrasonography
Neoplasm	Rectal palpation, vaginal palpation, cytologic examination of urine sediment, contrast radiographs, biopsy, ultrasonography, urethrocystoscopy
Diverticulum	Positive-contrast radiographs
Granuloma	Contrast radiographs, urethrocystoscopy, biopsy
Urinary incontinence or urine retention due to any cause	History, physical examination, determination of residual urine volume
Decreased resistance to infection	History, physical exam, medical evaluation to detect hyperadrenocorticism, diabetes mellitus, retroviral infection in cats, or other causes of immune compromise
Incorrect antibiotic selection	Urine C&S
Urinary catheterization	History, physical examination
Antibiotic resistance	Urine C&S
Foreign body	Ultrasound, cystoscopy
PU/PD (severe): antibiotic fails to attain adequate concentration in urine	Measure water intake; urinalysis
Vaginal or preputial conformational abnormalities (common, and commonly overlooked)	Physical exam

Urinary Crystals

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Note: See for composite diagram of crystals found in urinary sediment.

Name	Description	Significance
Struvite (magnesium ammonium phosphate)	Colorless prisms with three to six sides (coffin lid)	Common in mildly acidic to alkaline urine in normal dogs and cats; may be associated with struvite calculi and infection with urease-producing bacteria
Calcium oxalate (monohydrate)	Dumbbells or small spindles	May be normal (especially if delay in analysis after urine collection) or due to ethylene glycol intoxication; may be associated with oxalate calculi
Calcium oxalate (dihydrate)	Colorless envelopes or small stars	May be normal (especially if delay in analysis after urine collection) or due to ethylene glycol intoxication; may be associated with oxalate calculi
Calcium phosphate	Prisms (long) or amorphous	May be normal or associated with calculi
Ammonium urate	Yellow-brown “thorn apples”	Normal in dalmatians and English bulldogs; associated with hepatic insufficiency and portosystemic shunts; may be associated with urate calculi
Uric acid	Yellow to yellow-brown prisms, diamonds, or rosettes	Same as ammonium urate
Bilirubin	Golden yellow to brown needles or granules	May be present in normal dogs with concentrated urine or may be due to bilirubinuria
Cystine	Colorless, flat hexagonal plates	Due to cystinuria; may be associated with calculi
Cholesterol	Colorless flat, notched plates	May be found in normal dogs and cats
Hippuric acid	Prisms (four to six sides with rounded corners)	Uncertain; have been confused with calcium oxalate monohydrate crystals
Sulfonamide	Clear to brown eccentrically bound needles in sheaves	Associated with sulfonamide administration

Upper Respiratory Infection, Feline

Adapted from Gaskell RM, Bennett M: Feline and canine infectious diseases. Oxford, 1996, Blackwell Science, p 8.

Blackwell Science *Bb, Bordetella bronchiseptica* infection; *FCh, Chlamydophila felis* (formerly *Chlamydia psittaci*) infection; *FCV,* feline calicivirus infection; *FVR,* feline viral rhinotracheitis (feline herpesvirus infection; (+), uncommon but may occur; ±, lesions may be present but are not usually seen clinically.*Strain variation.†Often persistent.‡Slight wetness may be seen around the mouth if ulcers present.

Essential Clinical Features of Respiratory Disease Related to Pathogen Involved

Feature	FVR	FCV*	FCh	Bb
Lethargy	+++	+	+	+
Sneezing	+++	+	+	++
Conjunctivitis	++	++	+++†	–
Hypersalivation	++	–‡	–	–
Ocular discharge	+++	++	+++	(+)
Nasal discharge	+++	++	+	++
Oral ulceration	+	+++	–	–
Keratitis	+	–	–	–
Coughing	(+)	–	–	++
Pneumonia	(+)	+	±	+
Lameness	–	++	–	–

Ulcers and Erosions (Cutaneous), Distribution

Distribution of Ulcers and Erosions as a Diagnostic Clue

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Axillary/Inguinal

- Fungal (*Malassezia pachydermatis*, *Candida* spp.) (D)
- Vesicular cutaneous lupus erythematosus (D)
- Intertrigo (D)
- Urine scald (D)

Focal/Multifocal

- Calcinosis cutis (D)
- Demodicosis (D)
- Eosinophilic plaque (C)
- Indolent ulcer (C)
- Intertrigo (D)
- Neoplasia (D, C)
- Pyoderma (principally pyotraumatic dermatitis or folliculitis) (D)
- Systemic/subcutaneous mycosis (D, C)

Facial

- Arthropod bites (D, C)
- Bullous pemphigoid (D, C)
- Deep pyoderma (D)
- Demodicosis (D)
- Dermatomyositis (D)
- Discoid lupus erythematosus (D)
- Linear immunoglobulin A (IgA) bullous disease (D)
- Pemphigus foliaceus/erythematosus (D, C)
- Solar injury (D, C)
- Squamous cell carcinoma (C)
- Systemic/subcutaneous mycosis (D, C)
- Uveodermatologic syndrome (D)

Mucocutaneous

- Bacteria (aerobic/anaerobic) (D, C)
- Bullous pemphigoid (D, C)
- Bullous systemic lupus type 1
- Epidermolysis bullosa acquisita (D)
- Epitheliotropic lymphoma (D)
- Fungal (*M. pachydermatis*, *Candida* spp.) (D)
- Mucocutaneous pyoderma (D)
- Mucocutaneous pemphigoid (D)
- Pemphigus vulgaris (D)
- Toxic epidermal necrosis/erythema multiforme (D, C)
- Uremia (D, C)
- Viral infection (calicivirus/herpesvirus) (C)

Generalized/Extensive

- Bullous pemphigoid (D)
- Deep pyoderma (D)
- Demodicosis (D)
- Drug reaction (D, C)

- Epitheliotropic lymphoma (D)
- *Malassezia* dermatitis (D)
- Pemphigus group (D, C)
- Thermal injury (D, C)
- Toxic epidermal necrolysis/erythema multiforme (D, C)

C, Cat; *D,* dog.

Ulcerative/Erosive Skin Lesions

Differential Diagnosis of Ulcers and Erosions Affecting Skin and Mucous Membranes

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Canine Diseases

Infectious

Bacterial pyoderma:

- Surface:
  - Acute moist dermatitis (pyotraumatic dermatitis)
  - Intertrigo
- Deep:
  - Folliculitis/furunculosis (including pyotraumatic folliculitis)
  - Oral bacterial infections (aerobic/anaerobic)
- Fungal:
  - Yeast infections (*Malassezia pachydermatis*, *Candida* spp.)
  - Systemic/subcutaneous
- Parasitic:
  - Demodicosis

Metabolic

Calcinosis cutis (hyperadrenocorticism)

Uremia/renal failure

Necrolytic migratory erythema/metabolic epidermal necrosis/hepatocutaneous syndrome

Neoplastic

Epitheliotropic lymphoma

Squamous cell carcinoma

Physical, Chemical

Drug reactions

Solar injury

Thermal injury (freeze or burn)

Urine scald

Immune Mediated/Autoimmune

Discoid lupus erythematosus

Vesicular cutaneous lupus erythematosus

Pemphigus group

Uveodermatologic syndrome

Miscellaneous autoimmune subepidermal vesiculobullous diseases:

- Bullous pemphigoid
- Epidermolysis bullosa acquisita

- Linear immunoglobulin A (IgA) bullous disease
- Mucocutaneous pemphigoid
- Bullous systemic lupus type 1

Miscellaneous

Arthropod bites

Dermatomyositis

Dystrophic epidermolysis bullosa

Junctional epidermolysis bullosa

Toxic epidermal necrolysis/erythema multiforme

Acral mutilation syndrome (French spaniel, German and English pointers)

Cutaneous asthenia (Ehlers-Danlos syndrome)

Feline Diseases

Infectious

Viral:

- Calicivirus and herpesvirus

Bacterial:

- Atypical mycobacteriosis

Fungal:

- Subcutaneous mycoses (e.g., sporotrichosis)
- Systemic mycoses (e.g., cryptococcosis)

Metabolic

Uremia/renal disease

Neoplastic

Fibrosarcoma

Lymphoma

Squamous cell carcinoma

Physical/Chemical

Drug reactions

Thermal injury (burn or frostbite)

Immune Mediated/Autoimmune

Bullous pemphigoid

Pemphigus foliaceus

Toxic epidermal necrolysis/erythema multiforme

Miscellaneous/Idiopathic

Arthropod bites

Dystrophic epidermolysis bullosa

Eosinophilic plaque

Idiopathic ulceration of dorsal neck

Indolent ulcer

Junctional epidermolysis bullosa

Skin fragility syndrome

Cutaneous asthenia (Ehlers-Danlos syndrome)

Vulvar Discharge

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Hemorrhagic

- ***With Mainly Superficial (Mature)***
- ***Epithelial Cells***
- Normal proestrus, estrus, or early diestrus
- Ovarian remnant
- Ovarian pathologic condition (i.e., cystic follicles, functional ovarian tumor)
- Exogenous estrogen

Without Superficial (Mature)

- ***Epithelial Cells***
- Normal lochia
- Subinvoluted placental sites
- Vaginal laceration
- Neoplasia of vagina or uterus
- Uterine torsion
- Bleeding disorder

Mucoid

- Normal:
  - Lochia
  - Late pregnancy
  - Luteal phase (diestrus)
- Androgenic stimulation:
  - Endogenous (intersex)
  - Exogenous (mibolerone, testosterone)
- Cervicitis
- Mucometra
- Idiopathic (?)

Vomiting

Common Causes

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders. *NSAIDs*, Nonsteroidal antiinflammatory drugs.

Metabolic/Endocrine Disorders

- Uremia
- Hypoadrenocorticism
- Diabetes mellitus
- Hyperthyroidism
- Hepatic disease
- Endotoxemia/septicemia
- Electrolyte disorders
- Acid-base disorders

Intoxicants

- Lead
- Ethylene glycol
- Zinc
- Strychnine

Drugs

- Cardiac glycosides
- Erythromycin
- Chemotherapy agents
- Apomorphine
- Xylazine
- Medetomidine
- Penicillamine
- Tetracycline
- NSAIDs

Abdominal Disorders

- Pancreatitis
- Peritonitis
- Neoplasia

Dietary Causes

- Indiscretions
- Intolerances
- Allergy

Gastric Disorders

- Gastritis
- *Helicobacter* infection
- Parasites
- Ulceration
- Neoplasia
- Foreign bodies
- Dilatation/volvulus
- Hiatal hernia
- Obstruction

- Motility disorders

Disorders of the Small Intestine

- Inflammatory bowel disease
- Neoplasia
- Foreign body
- Intussusception
- Parasites
- Parvovirus
- Bacterial overgrowth

Disorders of the Large Intestine

- Colitis
- Obstipation
- Parasites

Vomiting, Chronic

Major Causes

Modified from Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Obstructive Disease

- Foreign objects (especially common)
- Intussusception
- Neoplasia (gastric or intestinal)
- Pyloric stenosis
- Gastric antral mucosal hyperplasia
- Inflammatory infiltrates (gastric or intestinal)
- Chronic partial gastric volvulus
- Idiopathic hypomotility of stomach/intestines (physiologic obstruction; rare)
- Congenital structural abnormalities (rare)

Inflammatory Disease

- Inflammatory bowel disease (common)
- Pancreatitis (common)
- Chronic gastritis
- GI ulceration/erosion
- Peritonitis (sterile or septic)
- Pharyngitis (caused by upper respiratory virus in cats)
- Parasites (e.g., *Physaloptera*)

Systemic*

- Hepatic disease/insufficiency
- Hypoadrenocorticism
- Diabetic ketoacidosis
- Uremia
- Hypercalcemia
- Cholecystitis
- Pyometra

Miscellaneous Causes

- Feline hyperthyroidism (common)
- Feline heartworm disease (variable)
- CNS disease (e.g., limbic epilepsy, tumor, encephalitis, or increased intracranial pressure; rare)
- Psychotic or behavioral changes (rare)
- Early CHF (questionable)
- *CHF,* Congestive heart failure; *CNS,* central nervous system; *GI,* gastrointestinal.

Vomiting, Acute

Major Causes

From Willard M, Tvedten H: Small animal clinical diagnosis by laboratory methods, ed 4, St Louis, 2004, Saunders.

Common

- Eating inappropriate or spoiled foods
- Motion sickness
- Postoperative nausea
- Acute gastritis-enteritis (various viral or bacterial agents or toxins):
    - Parvoviral enteritis (dogs and cats)
    - Hemorrhagic gastroenteritis
    - Parasites

GI Obstruction

- Obstructing foreign body
- Linear foreign body
- Intussusception

Dietary Indiscretion

- Overeating
- Eating inappropriate or spoiled foods

Acute Pancreatitis

-

Drug Administration

- Adriamycin
- Chloramphenicol
- Cisplatin
- Cyclophosphamide
- Digitalis
- Erythromycin
- Narcotics
- Nitrofurantoin
- Tetracycline
- Theophylline
- Xylazine

Intoxications

- Ethylene glycol
- Herbicides
- Organophosphates
- Strychnine
- *GI,* Gastrointestinal.

Vestibular Disease: Central Versus Peripheral

Modified with permission from Braund KG: Clinical syndromes in veterinary neurology, St Louis, 1994, Mosby, p 65.

	Central Vestibular Disease	Peripheral Vestibular Disease
Loss of balance	Yes	Yes
Head tilt	Yes	Yes
Falling/rolling	Yes (greater tendency to roll)	Yes
Nystagmus	Yes	Yes
Horizontal	Yes	Yes
Rotatory	Yes	Yes
Vertical	Yes	No
Positional	Yes	No
Strabismus (ventrolateral)	Yes	Yes
Cranial nerve deficits	Possible I-XII, especially V, VI, VII	Possible VII
Horner's syndrome	No	Possible
Cerebellar signs	Possible	No
Mental depression	Possible	No
Hemiparesis with ipsilateral postural reaction deficits	Possible	No

Vascular Disorders

Peripheral Vascular Diseases

From Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Diseases of Arteries and ArteriolesOcclusive Diseases

- Arterial embolism
- Arterial thrombosis
- Angiitis, vasculitis
- Vasospasm, traumatic, toxic
- Diabetic arteriopathy

Nonocclusive Diseases

- Arteriovenous (AV) fistula
- Arterial aneurysm
- Arterial calcification
- Arteriosclerosis, hyalinosis, amyloidosis
- Atherosclerosis
- Vasculitis

Diseases of Veins

- Phlebectasia
- Varicosis
- Phlebitis and thrombophlebitis
- Venous thrombosis
- Venous malformations

Diseases of Lymphatics

- Lymphangitis
- Lymphedema
- Lymphangiectasia
- Lymphatic hypoplasia, aplasia, hyperplasia
- Lymphangioma, lymphocysts
- Lymphangiosarcoma

Tumors of Peripheral Blood Vessels

- Angioma, hemangioma, hemangiosarcoma

Vaccine Failure

Causes

From Greene C: Infectious diseases of the dog and cat, ed 2, St Louis, 1999, Saunders. γ, Uncertain.

Host Factors	Vaccine Factors	Human Error
• Primary immunodeficiencies • Maternal antibody interference • Age: very young or very old • Pregnancy • Stress, concurrent illness • Pyrexia, hypothermia • Incubating disease at time of vaccination • Drugs: cytotoxic, glucocorticoids • Anesthesia? • Hormonal fluctuations • General debilitation, malnutrition	• Rendered noninfectious during handling • Improper storage • Vaccines not protecting 100% of population (biological variation) • Disinfectant used on needles and syringes • Wrong strain • Excessive attenuation • Overwhelming exposure	• Improper mixing of products • Exposed at time of vaccination • Concurrent use of antimicrobials or immunosuppressive drugs • Simultaneous use of antisera • Too frequent administration (<2-week interval) • Disinfection of skin? • Wrong route of administration • Delay between vaccines in initial series • Omission of booster vaccination

Weight Loss

Diagnostic Considerations for Animals With Marked, Unintended Weight Loss

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders.

Dietary History: Inadequate Diet

- Starvation
- Underfeeding
- Poor-quality food

Dietary History: Adequate Diet

- Environmental/housing factors:
  - Competition for food from other pets
  - Limited access to food
- Oral and dental disease
- Impaired use of nutrients:
  - Specific nutrient deficiency
  - Maldigestion of any cause
  - Malabsorption of any cause
  - Diabetes mellitus
  - Protein-losing disease:
    - Nephropathy
    - Gastroenteropathy
  - Cardiac disease*
- Elevated metabolism:
  - Hyperthyroidism
  - Chronic fever of any cause*
- End-stage chronic kidney disease*
- Neoplasia*
- Chronic infection*
- Chronic inflammation of any cause (e.g., immunologic disease*)

Weakness

Major Causes

Modified from Ettinger S, Feldman E: Textbook of veterinary internal medicine, ed 5, St Louis, 2000, Saunders.

- Anemia
- Abdominal effusion
- Cardiovascular
- Chronic inflammation/infections
- Chronic wasting diseases
- Drug related
- Electrolyte disorders
- Endocrine disorders
- Fever
- Metabolic dysfunction states
- Neoplasia
- Neurologic disorders
- Neuromuscular/polyneuropathies
- Nutritional disorders
- Overactivity
- Psychological disorders
- Pulmonary diseases
- Skeletal diseases

Zoonotic Diseases

Zoonoses: Diseases for Which Immunocompromised People Are at Increased Risk, and Routes of Disease Transmission

With permission from Greene C: Infectious diseases of the dog and cat, ed 2, St Louis, 1999, Saunders, p 711.

Direct Zoonoses from Pets*

- Bite, saliva: rabies, pasteurellosis, capnocytophagiosis, helicobacteriosis
- Scratch, contact: dermatophytosis, bartonellosis
- Inhaled, aerosols: plague (cat), tularemia, bordetellosis
- Feces: toxoplasmosis, cryptosporidiosis, campylobacteriosis, helicobacteriosis, salmonellosis, giardiasis, ancylostomiasis, toxocariasis
- Urine: brucellosis (dog), leptospirosis (dog)
- Transport of insect vector: bartonellosis, tularemia, plague, RMSF, dipylidiasis
- Other animal hosts: *Rhodococcus equi* infection (horse), *Mycobacterium marinum* infection (fish), psittacosis (birds), salmonellosis (reptiles and amphibians)

Environmentally Acquired Zoonoses

- Saprophytic: pneumocystosis, microsporidiosis, *Mycobacterium avium*–complex infection, cryptococcosis, coccidioidomycosis, histoplasmosis, blastomycosis, aspergillosis
- Vector acquired: ehrlichiosis, borreliosis, babesiosis, plague, RMSF, tularemia, bartonellosis

RMSF, Rocky Mountain spotted fever.

Zoonotic Diseases

- Vector acquired: ehrlichiosis, borreliosis, babesiosis, plague, RMSF, tularemia, bartonellosis

RMSF, Rocky Mountain spotted fever.

Aspergillus spp. Serology

DEFINITION

Specific tests may detect either antibodies to *Aspergillus* spp. (by ELISA, agarose gel immunodiffusion [AGID], or counterimmunoelectrophoresis) or the presence of *Aspergillus* antigen (ELISA) in the serum.

PHYSIOLOGY

Aspergillus spp. are common environmental fungi (saprophytes) and opportunistic pathogens. Nasal aspergillosis characterized by nasal discharge, ulceration of nares, and facial pain is the most common manifestation of disease. Infection is more common in dogs than cats. Disseminated aspergillosis also occurs in dogs (most commonly German shepherd dogs, see pp. 96 and 1335).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS:

- Antibody tests: presence of antibodies indicates exposure, but not necessarily active infection.
- Antigen: presence of serum antigen indicates systemic infection or, at the very least, colonization of skin or mucosal surfaces.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: False-positive and false-negative test results can occur with all tests for aspergillosis (including culture, Cytologie analysis, and histopathologic analysis). No single test is diagnostic. Nasal radiography or CT showing turbinate destruction and increased areas of radiolucency, and rhinoscopy for direct visualization and to obtain specimens for analysis (Cytologie, histopathologic, or microbiological) are the most informative tests.

SPECIMEN AND PROCESSING CONSIDERATIONS

IMPORTANT INTERSPECIES DIFFERENCES: Serologie tests often use species-specific antibodies. Confirm with the lab that the specific test being used is valid for the animal species in question.

SPECIMEN: Serum (red-top tube), refrigerated

RELATIVE COST: Fungal serology, $$$; fungal culture, $$; biopsy or cytology (one site), $$

PEARLS

- *Penicillium* spp. is another genus of fungus that can cause nasal disease in dogs. The organisms appear similar and can only be differentiated via culture or serologic testing, not Cytologie appearance. Serologic tests that detect antibody to either antigen are preferred.
- Both *Penicillium* spp. and *Aspergillus* spp. are ubiquitous in the environment. Positive culture results of blindly obtained specimens or nasal discharge, without cytologic/histologic evidence of inflammation and tissue invasion, may represent only contamination. Conversely, the fungal plaques are localized and blind biopsy/cytology collection often shows only nonspecific inflammation if the fungal plaques are missed. Rhinoscopy-guided collection of tissue samples is most likely to yield a positive diagnosis.

$$$: $76-150
$$$$: >$150

Antithrombin III (ATIII)

DEFINITION

Endogenous anticoagulant. Major plasma inhibitor of serine protease factors of the coagulation cascade (factors XII, XI, X, and IX; thrombin and plasmin).

SYNONYMS

Antithrombin, heparin cofactor

TYPICAL NORMAL RANGE

Dogs: 75%-120%. Cats: 75%-110%. Measured as a percentage of species-specific pooled samples.

PHYSIOLOGY

Synthesized in liver and endothelial cells; ATIII (with the help of heparin) binds to thrombin, preventing conversion of fibrinogen to fibrin; ATIII forms a 1:1 complex with thrombin (and other serine proteases). Heparin functions as an anticoagulant by accelerating the reaction that alters the configuration of ATIII (potentiates ATIII), increasing the rate of complex formation. Complex is cleared by hepatocytes.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Exogenous cortisol administration, inflammation (as part of positive acute-phase response)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Increased ATIII is not clinically significant.

CAUSES OF ABNORMALLY LOW LEVELS: Decreased production (hepatopathy, portosystemic shunts), increased loss (protein-losing nephropathy, glomerulonephritis, renal amyloidosis, protein-losing enteropathy), increased hepatic clearance of ATIII enzyme complexes (disseminated intravascular coagulation [DIC])

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Assess other aspects of the coagulation cascade (activated partial thromboplastin time and prothrombin time), platelet count, fibrinogen level, d-dimers, and fibrin degradation products. A procoagulant state may exist because of low ATIII levels alone or in conjunction with other disorders (e.g., DIC).

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Exogenous cortisol administration has been associated with mild to moderate increases in ATIII in dogs (dogs with hyperadrenocorticism have decreased levels, perhaps secondary to the associated changes in the liver, which may explain the association of hyperadrenocorticism with thromboembolic disease).

LAB ARTIFACTS THAT MAY INTERFERE: Age: Lower levels of ATIII have been reported in young animals. Assay differences: ATIII may be overestimated in certain thrombin chromogenic assays (heparin cofactor II activity in addition to ATIII is detected).

SPECIMEN: Citrate (blue-top tube), separate plasma and transfer to plastic tube; freeze (store at 0°C-4°C).

RELATIVE COST: $$

PEARLS

Patients with DIC, thrombosis, or nephrotic syndrome will commonly have decreased levels. If the ATIII activity is <70% of the control, the animal likely will be unresponsive to heparin treatment; ATIII replacement therapy is required for heparin to be effective in such cases.

AUTHOR: DEBORAH G. DAVIS

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Antinuclear Antibody (ANA)

DEFINITION

Indirect immunofluorescent antibody (IFA) test to detect antibodies specific for DNA, RNA, and nucleoprotein

TYPICAL NORMAL RANGE

Reported as negative or positive; positive results will have a titer and pattern associated with it (homogeneous nuclear, speckled nuclear, nuclear rim, or nucleolar).

PHYSIOLOGY

Antinuclear antibodies are associated with autoimmune disorders, most prominently systemic lupus erythematosus (SLE).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: SLE, some bacterial and protozoal infections

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess for other systemic signs consistent with SLE, rule out other infections.

SPECIMEN AND PROCESSING CONSIDERATIONS

IMPORTANT INTERSPECIES DIFFERENCES: Requires use of species-specific fluorescent antibody

DRUG EFFECTS ON LEVELS:

- Decreased or false-negative titers: cytotoxic drugs, high doses of corticosteroids
- False-positive tests: sulfonamides, tetracycline, hydralazine, procainamide, griseofulvin. False positive tests are also reported in cats treated with propylthiouracil, methimazole.

SPECIMEN: Serum (red-top tube). Store at 2°C-8°C (refrigeration).

RELATIVE COST: $$

PEARLS

- Significance of pattern in domestic animals is unclear.
- Positive ANA titers support a clinical diagnosis of SLE in dogs but are not specific.
- Low positive titers can be seen with various diseases and in older animals.
- ANA titer is much more sensitive (better screening test) for SLE than the LE prep.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Anion Gap

DEFINITION

Calculated value using the formula [(Na^+ + K^+) − (Cl^- + HCO^-3)]. Represents the negatively charged atoms and molecules in the bloodstream that are not measured by the analysis of these four ions.

TYPICAL NORMAL RANGE

Dogs and cats: approximately 5-15 mEq/L (mEq/L = mmol/L)

PHYSIOLOGY

The total of positive and negative charges in the blood must be equal. Routine serum biochemistry profile measures only some cations and anions. “Unmeasured anions” (e.g., lactate, charges on proteins) and “unmeasured cations” (e.g., magnesium, calcium) exist. *Unmeasured* refers to anything other than the four ions included in the anion-gap formula. Measured cations (Na^+, K^+) normally exceed measured anions (Cl^-, $HCO3^-$) by about 5-15 mEq/L. Because total positive and negative charges must be equal, unmeasured anions must outnumber unmeasured cations by that same amount. In health, excess unmeasured anions are mostly charges on proteins. An increased anion gap indicates an increase in unmeasured anions, usually resulting from organic acid (e.g., lactic acid) accumulation.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Conditions usually causing metabolic acidosis, most commonly lactic acidosis, uremia, ketoacidosis, ethylene glycol toxicosis

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Review history for ethylene glycol exposure. Evaluate serum biochemistry profile for azotemia, diabetes mellitus. Collect urine for specific gravity, ketone measurement, examination for calcium oxalate monohydrate crystals.

CAUSES OF ABNORMALLY LOW LEVELS: Decreases not usually associated with specific conditions and are not clinically relevant. May occur with hypoalbuminemia.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Potassium bromide may falsely increase serum chloride measurement, decreasing the anion gap and often producing a negative number.

LAB ARTIFACTS THAT MAY INTERFERE: Anything interfering with the measurement of the ions included in the anion-gap calculation will alter the anion-gap value (e.g., lipemia, hemolysis).

SPECIMEN: Serum (red-top tube) for routine chemistry/electrolyte profile

RELATIVE COST: $$

PEARLS

- The anion gap is commonly used for differentiating between bicarbonate loss (normal anion gap) and organic acid accumulation (high anion gap) in patients with metabolic acidosis.
- In mixed acid-base disorders, an animal may have metabolic acidosis, but the pH may be in the normal or alkaline range because of competing factors. In this situation, a high anion gap helps identify “occult” acidosis.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: JAMES H. MEINKOTH

Pricing Information

$: <$20

$$: $21-75
$$$: $76-150
$$$$: >$150

Anemia, Regenerative

DEFINITION

Anemia characterized by polychromasia or reticulocytosis; may be accompanied by basophilic stippling, Howell-Jolly bodies, and nucleated red blood cells (normoblastemia)

SYNONYM

Responsive anemia

TYPICAL NORMAL RANGE

Anemias with absolute reticulocyte count (percent reticulocyte x red blood cell count/µL) of >50,000/µL (cats) and >60,000/µL (dogs) indicate regeneration

PHYSIOLOGY

Hypoxemia induced by decreased red cell mass stimulates erythropoietin production and subsequently erythropoiesis.

CLINICAL APPLICATIONS

CAUSES: Blood loss and/or hemolysis

NEXT DIAGNOSTIC STEP TO CONSIDER IF PRESENT: Blood smear evaluation of red cell morphology for evidence of size, color, and shape changes, agglutination, and parasitic inclusions; physical examination for evidence of blood loss via gastrointestinal tract or elsewhere, ectoparasites, neoplasia; biochemical profile; fecal analysis, urinalysis; serologic testing for infectious agents, Coombs' test IMPORTANT INTERSPECIES DIFFERENCES: Dogs can mount a greater regenerative response than cats. Both aggregate and punctate reticulocytes are enumerated in cats to assess reticulocyte response.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Presence of *Mycoplasma haemofelis* (formerly *Haemobartonella felis)* inclusions may falsely increase flow cytometric reticulocyte counts.

SPECIMEN: EDTA-anticoagulated blood (lavender-top tube) for CBC and reticulocyte count; fresh direct blood smear for morphologic evaluation of red cells

RELATIVE COST: $ (reticulocyte count); $$ (CBC; included in some CBC panels)

PEARLS

An absolute reticulocyte count is the most reliable means of assessing red cell regeneration. The mere presence of polychromasia on peripheral blood smears does not necessarily reflect adequacy of regenerative response. Presence of nucleated red blood cells, Howell-Jolly bodies, and basophilic stippling without polychromasia may indicate bone marrow injury, disease, or toxicosis (such as lead poisoning) interfering with red blood cell maturation.

Anemia, Nonregenerative

DEFINITION

Anemia characterized by inadequate polychromasia or reticulocytosis

SYNONYM

Nonresponsive anemia

PHYSIOLOGY

Primary cause is decreased erythrocyte (red blood cell [RBC]) production. If decreased production is the sole cause, it may take weeks to months for anemia to be clinically evident, depending on the RBC lifespan. In anemia of chronic disease, inflammatory cytokines may decrease erythrocyte lifespan; they decrease release of erythropoietin from the kidney, resulting in decreased erythrocyte production.

CLINICAL APPLICATIONS

CAUSES: Chronic disease (renal disease, endocrinopathies, neoplasia, many others) or inflammation, primary bone marrow disease, therapeutic agents (hydroxyurea, phenylbutazone, sulfa-containing antibiotics, estrogen), long-term treatment with erythropoietin, nutritional deficiency (iron, copper, folate, or vitamin B12)

NEXT DIAGNOSTIC STEP TO CONSIDER IF PRESENT: Identification of underlying cause: serum biochemistry profile, urinalysis, diagnostic imaging if systemic illness is present and anemia of chronic disease is suspected. Advanced diagnostic testing may then include bone marrow evaluation, serologic tests for infectious disease (e.g., feline leukemia virus, ehrlichiosis), thyroid function tests, serum ferritin.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA-anticoagulated blood (lavender-top tube) for CBC and reticulocyte count; freshly made direct blood smear for morphologic evaluation

RELATIVE COST: $$ (CBC)

PEARLS

Anemia due to early or acute hemolysis and blood loss may initially appear nonregenerative when the bone marrow has not had time to respond. It takes about 2-3 days after acute hemolysis or blood loss for reticulocytosis to be evident, and 7 days for optimum response. Thus, in cases of nonregenerative anemia where a very recent onset of the anemia is possible, serial CBC, blood smear evaluation, and reticulocyte counts are recommended to assess eventual bone marrow response. Once lack of regeneration has been determined, bone marrow assessment may be considered to help determine cause. Immune-mediated destruction of erythroid precursors could also cause a severe nonregenerative anemia.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Amylase

DEFINITION

Enzyme principally involved in hydrolysis of complex carbohydrates (starches); concentrations measured in serum. Spectrophotometric methods are most often used; “dry reagents” are used less frequently.

TYPICAL NORMAL RANGE

Dogs: 371-1503 U/L. Cats: 530-1660 U/L.

PHYSIOLOGY

Amylase is a cytoplasmic enzyme found in high concentration in the pancreas, intestine, and liver. It is a digestive enzyme that catabolizes complex starches. Ca^{2+} is a required cofactor. Amylase is metabolized by the liver and may also be eliminated via the urinary tract. Amylase has a very short serum half-life.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Pancreatitis (may be normal to markedly increased) in dogs; vomiting; decreased glomerular filtration (increase is usually less than three times upper reference range value); gastrointestinal disease; hepatic disease; neoplasia.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Correlate with history, physical examination, CBC, and remainder of serum chemistry panel. If consistent with pancreatitis, consider abdominal ultrasonography and/or pancreas-specific lipase immunoreactivity to assess further.

IMPORTANT INTERSPECIES DIFFERENCES: Amylase is not useful for the diagnosis of pancreatitis in cats insofar as serum concentrations are usually not increased in pancreatitis in this species.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Serum (red-top tube), allow to clot, centrifuge, separate serum, refrigerate, and ship on ice. Amylase is fairly stable compared to other analytes measured in routine chemistry panels.

RELATIVE COST: $

PEARLS

- One-time measurement of amylase level in a dog is of very little significance with respect to pancreatitis (neither normal nor elevated levels rule out or rule in pancreatitis), likely owing to its short half-life. Trends in amylase levels over time (e.g., daily) may be more informative in terms of disease progression in patients with acute pancreatitis.
- Intestinal amylase comprises a small proportion of the total amylase in serum, but intestinal injury does not cause an increase in serum amylase concentration.
- Measurement of isoenzymes is of limited clinical value.

AUTHOR: BRUCE LEROY

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Ammonia

DEFINITION

Measurement of ammonium ($NH4^+$) concentration in plasma. $NH4^+$ is the predominant form of the analyte in blood. Routine assays require plasma, not whole blood.

SYNONYMS

Ammonia: NH3. Ammonium: $NH4^+$

TYPICAL NORMAL RANGE

Dogs: 45-120 µg/dL; cats: 30-100 µg/dL. To convert from µg/dL to µmol/L multiply by 0.5872.

PHYSIOLOGY

Ammonium is produced in the gastrointestinal tract by enteric bacterial metabolism and carried via the portal circulation to the liver. Hepatic transformation of two ammonium molecules into one urea molecule requires adequate hepatic function. Circulating ammonium concentrations are useful for assessing hepatic function. Ammonia is converted to urea in the liver, reenters the systemic circulation, and is eliminated in the urine. In patients with decreased hepatic blood flow (congenital or acquired portosystemic shunts), ammonia bypasses the liver, remains in the circulation, and results in hyperammonemia.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Decreased clearance from blood: decreased functional liver mass, decreased portal blood flow, urea cycle abnormalities, cobalamin deficiency. Increased production: postprandial, post-exertion (greyhounds, other racing dogs).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Review history, examination, CBC, serum biochemistry panel, and abdominal imaging results to assess for signs of hepatobiliary disease and portal circulation abnormalities.

DRUG EFFECTS ON LEVELS: Decrease: antibiotics that affect gastrointestinal flora (aminoglycosides), lactulose, *Lactobacillus acidophilus* culture, enema. Increase: asparaginase, narcotics, diuretics causing hypokalemia, high protein diet.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Increase: delay in harvesting plasma, specimen processing; hemolysis (if spectrophotometric assay used); prolonged tourniquet use SPECIMEN: Twelve-hour fasting specimen preferred. Collect heparinized whole blood (green-top tube), separate plasma from cells immediately, store on ice, and test within 4 hours; or freeze (—20°C) and test within 48 hours. Arterial samples are preferred but not essential.

RELATIVE COST: $$

PEARLS

Because of difficulty in proper specimen handling, measurement of preprandial and postprandial serum bile acids and urinary bile acid/creatinine ratio has replaced ammonium measurement. However, ammonia may have superior sensitivity and specificity for diagnosing portosystemic shunts. Ammonia is also superior to bile acids for assessing hepatic function if cholestasis is present.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Alkaline Phosphatase

DEFINITION

Alkaline phosphatase (ALP) is a membrane-associated enzyme found in liver, bone, colostrum, and many other tissues. Its physiologic function is not known.

SYNONYMS

Alk phos, ALP, sALP

TYPICAL NORMAL RANGE

Dogs: 0 to 90 U/L; cats 4 to 80 U/L

PHYSIOLOGY

Domestic mammals have two genes responsible for ALP production. I-ALP (intestinal-associated isoenzyme) is not associated with measured serum increases. Tissue nonspecific ALP is modified to two isoforms, L-ALP (liver associated) and B-ALP (bone associated). Another isoform, C-ALP, appears to be unique to dogs. Increased C-ALP is stimulated by endogenous and exogenous corticosteroids. Most routine assays measure total serum ALP, but there are tests that measure the liver and corticosteroid isoenzymes.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Cholestasis, hormone (corticosteroids) or drug (prednisone, phenobarbital) induction, osteoblast activity (normal growth in young dogs, fracture repair, osteosarcoma)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Disregard in young animals (if no other abnormalities found); evaluate hepatobiliary structure and function; review medication history; assess for hyperadrenocorticism only if consistent history and physical examination.

IMPORTANT INTERSPECIES DIFFERENCES:

- Dogs: corticosteroid induction seems unique to dogs; laboratories can specifically measure for this form. Analysis does not differentiate source of corticosteroid, however (e.g., endogenous—stress, adrenal hyperplasia, hyperadrenocorticism —versus exogenous/iatrogenic all are measured as corticosteroid isoenzyme).
- Cats: ALP has poor sensitivity for cholestasis, except in hepatic lipidosis. Short serum half-life (8 hours in cats versus 24 hours in dogs) makes even low-magnitude ALP elevations generally more clinically significant than in the dog.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Increase: corticosteroid, phenobarbital, primidone, prednisone, thyroxine

LAB ARTIFACTS THAT MAY INTERFERE: Increase: marked hemolysis

SPECIMEN: Serum (red-top tube); allow to clot, centrifuge, collect serum, refrigerate, and ship on ice.

RELATIVE COST: $ (total serum concentration); $$ (corticosteroid isoenzyme)

PEARLS

The vast majority of dogs with increased ALP do not have hyperadrenocorticism (Cushing's disease). Therefore, an elevated serum alkaline phosphatase level warrants a detailed review of history and physical examination before determining whether testing for hyperadrenocorticism is warranted.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Aldosterone, Endogenous

DEFINITION

Mineralocorticoid steroid hormone secreted by adrenal cortex. Endogenous aldosterone measurement determines circulating aldosterone concentration.

TYPICAL NORMAL RANGE

Dog: 2-96 pg/mL. To convert pg/mL to ng/dL, divide pg/mL result by 10. To convert pg/mL to pmol/L, multiply pg/mL result by 2.775.

PHYSIOLOGY

Synthesized by adrenal cortex in response to angiotensin II. Acts on receptors throughout the body, but primarily in distal renal tubules, to enhance retention of sodium and water and promote excretion of potassium, effectively maintaining or increasing blood pressure.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Adrenal neoplasia or hyperplasia, low sodium intake, wide variety of nonadrenal diseases leading to hypovolemia

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate for decreased blood volume. If patient is euvolemic or hypertensive and there is hypokalemia/hyperkaluria, hypernatremia with decreased urine excretion, and/or hypertension, evaluate for adrenal hyperplasia/neoplasia.

CAUSES OF ABNORMALLY LOW LEVELS: Hypoadrenocorticism/adrenal atrophy (idiopathic, secondary to medication, pituitary disease), high sodium intake

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Review treatment/medication history; ACTH stimulation test to evaluate hypothalamic, pituitary, adrenal axis.

DRUG EFFECTS ON LEVELS:

- Decrease: angiotensin converting enzyme inhibitors, nonsteroidal antiinflammatory drugs, propranolol
- Increase: lithium, spironolactone

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Artifactual decrease: storage at 22○C for =3 days or at 37○C for 1 day SPECIMEN: Plasma collected in EDTA (lavender-top tube) or heparin (green-top tube). Centrifuge, collect plasma as soon as possible. Freeze, ship on ice.

RELATIVE COST: $$

PEARLS

Test is rarely indicated. A working diagnosis of hyperaldosteronism may be obtained by simpler means (e.g., adrenal mass in persistently severely hypokalemic patient). Evaluating aldosterone concentration in light of the plasma renin concentration (aldosterone/renin ratios) may aid determination of an appropriate or inappropriate response.

AUTHOR: BRUCE LEROY

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Albuminuria and Proteinuria

DEFINITION

The presence of excess protein, and/or albumin specifically, in urine

TYPICAL NORMAL RANGE

Wet chemistry instrument methods: 4-95 mg/dL protein. Urine dipstick: negative, trace, +1 (with no evidence of urinary tract disease). Urine concentration (specific gravity) should be taken into consideration; urine that is more concentrated may have greater protein concentrations (e.g., +1 rather than negative or trace) irrespective of health or disease.

PHYSIOLOGY

- Proteins <68,000 daltons readily pass the glomerular filter, but most are resorbed in the proximal tubules. Although it is a relatively small protein, albumin is too large to filter through the normal glomerulus and thus stays in the circulation of healthy animals.
- Tamm-Horsfall protein—a mucoprotein secreted by tubular and collecting duct cells—and albumin make up most of the protein found in the urine of healthy animals.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS:

- Overflow proteinuria: caused by increased plasma levels of protein (e.g., hemoglobinuria, hyperglobulinemia, myoglobinuria)
- Tubular proteinuria: caused by decreased protein resorption
- Glomerular proteinuria: caused by increased glomerular permeability
- Hemorrhage in urinary system
- Inflammation in urinary system, causing increased vascular permeability

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH:

- Examine urine sediment for evidence of inflammation or hemorrhage.
- Examine serum for evidence of hemolysis.
- Measure serum protein (hyperproteinemia, hyperglobulinemia, or hypoalbuminemia).
- Urine protein/creatinine ratio

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE:

- False increase (with dipstick method): prolonged contact with alkaline urine
- False decrease (with dipstick method): if protein is other than albumin (e.g., Bence Jones proteinuria does not react with dipstick reagent)
- False decrease (acid precipitation method): if urine is highly alkaline
- False increase (sulfosalicylic acid method): after administration of iodine-based contrast media, sulfisoxazole, very large doses of penicillin, and precipitation of crystals due to low pH

SPECIMEN: Urine in clean container

RELATIVE COST: $ (reported as part of urinalysis)

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150

$$$$: >$150

Albumin

DEFINITION

Albumin is the predominant protein in peripheral blood. Serum albumin concentration is measured, but different dye binding assays may also include some nonalbumin proteins.

TYPICAL NORMAL RANGE

Dogs and cats: 2.5-4.0 g/dL (25 to 40 mg/mL); neonates and young animals often have slightly lower concentrations.

PHYSIOLOGY

Albumin is synthesized by the liver. It is the major contributor to plasma oncotic pressure and also functions as a transport protein for ions, bilirubin, thyroxine, numerous drugs, and other compounds. Spectrophotometric method is usually used for measuring serum albumin.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Dehydration, laboratory error. Glucocorticoid administration may cause mild increases in albumin concentration. In dogs, hyperalbuminemia has been associated with hepatocellular carcinoma. NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess hydration status; if normal, recheck results.

Review history/medical record for glucocorticoid usage.

CAUSES OF ABNORMALLY LOW LEVELS:

- Loss: nephropathy/glomerular disease; enteropathy, severe exudative skin lesions/burns, massive hemorrhage (total protein and globulin are also low).
- Decreased production: severe chronic liver disease; acute inflammation (negative acute-phase protein); protein malnutrition secondary to starvation or severe gastrointestinal diseases
- Dilutional effects: IV fluid overload, fluid accumulation disorders (e.g., congestive heart failure, syndrome of inappropriate antidiuretic hormone secretion; total protein and albumin are also low)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Review history and physical exam with respect to intestinal, renal, and liver function. Assess in conjunction with hematocrit, total protein, serum globulin, liver enzymes, and renal function. Calculation of the albumin/globulin (A:G) ratio may allow detection of subtle protein abnormalities. If a cause is not determined, additional testing to be considered includes preprandial and postprandial bile acids, serum protein electrophoresis, urine protein/creatinine ratio, fecal flotation, fecal occult blood, and fecal alpha-1-protease inhibitor. Additional tests (radiographs, ultrasound, biopsy) should be dictated by history, physical examination, and previous test results.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Long-term therapy with hepatotoxic drugs (e.g., anticonvulsants) may cause low levels secondary to liver injury. LAB ARTIFACTS THAT MAY INTERFERE:

- Decrease: use of reagents for human testing (bromocresol purple dye binding reaction)
- Increase: bromocresol green dye may bind to globulin.

SPECIMEN: Serum (red-top tube); allow specimen to clot, then centrifuge, collect serum, refrigerate, and ship on ice.

RELATIVE COST: $

PEARLS

Concentration may be slightly lower in very young and very old patients.

AUTHOR: BRUCE LEROY

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Alanine Aminotransferase (ALT)

DEFINITION

Enzyme located in hepatocyte cytoplasm

SYNONYM(S)

Serum glutamic pyruvate transaminase (SGPT)

TYPICAL NORMAL RANGE

Dogs: 0 to 30 U/L; cats: 10 to 25 U/L

PHYSIOLOGY

ALT is released from the cytoplasm following injury to the hepatocyte cell membrane. Low concentrations in erythrocytes or skeletal muscle may cause minor (usually clinically insignificant) increases in hemolytic diseases or with muscle injury, respectively.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hepatocellular injury from any cause. Liver injury may be primary (e.g., hepatitis, neoplasia, blunt trauma) or secondary (e.g., translocation of enteric bacteria due to intestinal disease). Dystrophin-deficient muscular dystrophy causes slight to moderate increases in dogs and slight to marked increases in cats.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: If elevations >2 times the upper limit of reference range persist, assess history for exposure to hepatotoxins (including medications). If none, assess hepatic structure (e.g., abdominal radiographs, ultrasound) and function (preprandial and postprandial serum bile acids; alkaline phosphatase, bilirubin). Consider biopsy if values remain elevated or increase or if aforementioned tests reveal abnormalities.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Many drugs induce hepatocellular injury. Drugs commonly implicated include glucocorticoids and phenobarbital.

LAB ARTIFACTS THAT MAY INTERFERE: Increase: lipemia, hemolysis (in vivo or artifactual)

SPECIMEN: Serum (red-top tube); allow to clot, centrifuge, separate serum from clot. RELATIVE COST: $

PEARLS

ALT elevation indicates hepatocyte damage but is not a test of hepatic function. ALT does not provide information on the reversibility of hepatic injury. Mild elevations in ALT may indicate serious disease processes or relatively benign conditions; correlating the finding to the remainder of the case and monitoring trends if necessary are essential for properly interpreting high ALT values.

AUTHOR: BRUCE LEROY

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Activated Partial Thromboplastin Time (APTT)

DEFINITION

Screening test for disorders of the intrinsic and common coagulation pathways

SYNONYM

Partial thromboplastin time (PTT)

TYPICAL NORMAL RANGE

Reported in seconds. Approximate ranges for normal animals are 8.6-12.9 seconds (canine) and 13.7-30.2 seconds (feline), but laboratory-, instrument-, and species-specific reference ranges must be used. Prolonged when at least one coagulation factor is <70% of normal.

PHYSIOLOGY

Citrated plasma is incubated at 37°C with excess procoagulant phospholipid. Contact activator is added to activate the intrinsic pathway via factors XII and XI. Citrate in the specimen chelates Ca^{2+}, limiting activation beyond factor Xla. After additional incubation, CaCl2 is added to saturate the citrate and allow the reaction to continue to clot formation. The APTT is the time from addition of CaCl2 to clot formation.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Liver disease (decreased factor production), vitamin K inactivation (anticoagulant rodenticides, coumarin therapy), decreased vitamin K absorption (biliary obstruction), increased factor inactivation or consumption (disseminated intravascular coagulation [DIC]), factor dilution (massive blood loss, with colloid or crystalloid fluid replacement), hereditary factor defects, heparin therapy NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess history for exposure to toxic substances or treatment. Measurement of individual factors if hereditary disease is suspected.

IMPORTANT INTERSPECIES DIFFERENCES: Prolonged APTT is reported in cats without evidence of clinical hemostatic disease, leading to increased false-positive results in this species.

DRUG EFFECTS ON LEVELS: Increased: heparin, aspirin. Polymerized bovine hemoglobin (Oxyglobin) administration interferes with ability to detect clot.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE:

- Decrease: contamination with tissue factor when specimen obtained; overfilling citrate tube
- Increase: underfilling of citrate tube; old/improperly stored samples

SPECIMEN:

- Citrated whole blood (blue-top tube). Fill completely. Refrigerate and submit to reference lab. If time interval between sampling and testing is >6 hours, mix thoroughly, centrifuge, collect plasma, freeze. Samples stored at −20°C may show significant false increases in APTT.
- Minimally traumatic phlebotomy is required to prevent tissue factor from falsely shortening the result. Ideally, collect a sufficient volume of blood to place first aliquot in red-top tube and discard (or use for serologic tests). Acceptable samples for APTT may be collected from an indwelling venous catheter.

RELATIVE COST: $$

PEARLS

APTT values generally increase before PT values with heparin therapy, but not with warfarin/anticoagulant rodenticide toxicosis or

coagulopathy of liver disease.

AUTHOR: BRUCE LEROY

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Activated Coagulation Time (ACT)

DEFINITION

The time interval from contact of blood with diatomaceous earth pellets to formation of a visible clot. ACT evaluates the intrinsic and common pathways but is less sensitive than activated partial thromboplastin time (APTT).

TYPICAL NORMAL RANGE

Dogs: <120 seconds. Cats: <165 seconds.

PHYSIOLOGY

Contact activation occurs when whole blood is drawn into a warmed (37°C) tube containing diatomaceous earth pellets. After multiple inversions for mixing, the tube is kept in a heating block or tucked in the clinician's axilla and checked for clot formation every 5-10 seconds.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Decreased concentration of any of coagulation factors of the intrinsic or common coagulation pathways (all factors except VII) to less than 5% of normal; severe thrombocytopenia (< 10,000 platelets/μL); uremia. In the absence of coagulopathy, critically ill dogs may have prolongation of ACT due to inflammatory disease.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Confirm with tests that are more sensitive (activated partial thromboplastin time); platelet count.

DRUG EFFECTS ON LEVELS: Prolonged by heparin or aspirin therapy, some antibiotics (newer lipoglycopeptide antibiotics may interfere with factor Xa), and barbiturates (contribute to splenic sequestration of platelets).

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Considered an in-office test. Any variation in test protocol may alter results. Endpoint (visual clot detection) is subject to observer variability. Difficult venipuncture causing platelet activation may falsely shorten ACT.

SPECIMEN: Whole blood into siliceous (gray top, with large granules) tube, prewarmed to 37°C. Mix by inversion, incubate at 37°C (purpose-made heating block, water bath, or human axilla), and check for clot formation every 5-10 seconds. Do not incubate in a closed palm, as it does not provide a consistent 37°C environment.

PEARLS

Considered an insensitive test but may be useful for suspected warfarin-intoxicated dogs if APTT unavailable. Carriers of hemophilia (coagulation factors are 40%-60% of normal) and beagles with hereditary factor VII deficiency will not be detected by the ACT.

AUTHOR: BRUCE LEROY

ACTH (Adrenocorticotropic Hormone), Endogenous/Baseline

DEFINITION

Peptide hormone secreted by anterior pituitary in response to corticotrophin releasing hormone (CRH) secreted by hypothalamus

SYNONYM

Corticotropin

TYPICAL NORMAL RANGE

Dogs: 10 to 110 pg/mL; cats: 0 to 110 pg/ml. To convert pg/mL to pmol/L, multiply pg/mL by 0.22.

PHYSIOLOGY

Stress causes hypothalamic release of CRH. CRH stimulates anterior pituitary release of a large precursor hormone, proopiomelanocortin (POMC), which undergoes proteolytic cleavage to yield ACTH, β-endorphin, melanocyte-stimulating hormone, and other hormones. ACTH stimulates cortisol and aldosterone release from the adrenal cortex. High circulating levels of cortisol inhibit release of CRH (feedback inhibition). High baseline ACTH concentrations help differentiate pituitary-dependent hyperadrenocorticism from functional adrenal cortical tumors, in which serum ACTH is subnormal.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hypocortisolism, either natural (primary Addison's disease) or iatrogenic (after sudden cessation of chronic glucocorticoid administration); pituitary-dependent hyperadrenocorticism due to pituitary neoplasia. Additionally, there are rare instances of nonendocrine neoplasms producing high concentrations of ACTH (ectopic ACTH syndrome).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH:

- Determine treatment (glucocorticoid, including topical medications) history.
- ACTH stimulation test if no history of glucocorticoid administration
- Evaluation for occult nonendocrine neoplasm (rare)

CAUSES OF ABNORMALLY LOW LEVELS: High endogenous cortisol levels, either spontaneously (hyperadrenocorticism/Cushing's disease) or iatrogenic (during administration of glucocorticoids); panhypopituitarism

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Rule out sampling error (see below). Evaluate for hyperadrenocorticism. If history, physical examination, and diagnostic tests support hyperadrenocorticism, and ACTH level is below the normal range, a diagnosis of adrenal cortical neoplasia is suspected, and further testing (e.g., abdominal ultrasonography) is warranted.

IMPORTANT INTERSPECIES DIFFERENCES: Adrenal disease is uncommon in cats; test is infrequently done in this species.

DRUG EFFECTS ON LEVELS:

- Increase: insulin
- Decrease: glucocorticoid administration

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Decrease: thawing of specimen; collection or storage in glass tubes SPECIMEN: Morning sample preferred. Collect in cold, heparinized plastic syringe; centrifuge; collect plasma immediately; freeze in plastic tubes. Samples must be shipped frozen and remain frozen until analysis to avoid degradation of ACTH. Aprotinin-containing tubes may help prevent degradation in unfrozen samples.

RELATIVE COST: $$

PEARLS

Useful for differentiating pituitary-dependent Cushing's disease from adrenal cortical tumor. The hormone is very labile, however; inappropriate specimen handling yields false-negative results.

AUTHOR: BRUCE LEROY

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Acetylcholinesterase Level

DEFINITION

Blood level of the enzyme that catabolizes acetylcholine

SYNONYM

Cholinesterase level

TYPICAL NORMAL RANGE

500 to 1500 U/L for dogs. A positive diagnosis of low level means the patient's level is at least 25% less than the lower limit of normal range.

PHYSIOLOGY

Acetylcholine is the main neurotransmitter at the neuromuscular junction, and the enzyme responsible for catabolism of acetylcholine is acetylcholinesterase. When acetylcholinesterase levels are low, there is decreased catabolism of acetylcholine, resulting in poorly controlled or uncontrolled neuromuscular activation. Muscle tremors and smooth-muscle activation (gastrointestinal and other autonomic signs) occur. Organophosphates antagonize acetylcholinesterase, leading to these clinical signs. Organophosphate intoxication is the most common cause of low blood levels of this enzyme. Measurement of red blood cell acetylcholinesterase concentration helps diagnose intoxication with organophosphate-containing insecticides.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY LOW LEVELS: Organophosphate intoxication, carbamate intoxication

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Response to treatment

IMPORTANT INTERSPECIES DIFFERENCES: Cats naturally have lower cholinesterase levels, making the test less reliable in this species (false-positive results).

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Whole blood in EDTA (lavender-top tube) or heparin (green top); 20 grams of brain tissue may be used for postmortem diagnosis.

RELATIVE COST: $$

PEARLS

Turnaround time is usually longer than clinical condition allows, so the test is often confirmatory (retrospective). Treatment decisions must be based on physical exam findings +/− known history of intoxication before results are available. See Organophosphate Intoxication, p. 792.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Acetylcholine Receptor Antibody Test

DEFINITION

Test for detection of antiacetylcholinereceptor (AChR) antibodies, which cause acquired myasthenia gravis

SYNONYMS

ARAT, myasthenia gravis titer

TYPICAL NORMAL RANGE

0 to 0.6 nmol/L (dogs), 0 to 0.3 nmol/L (cats)

PHYSIOLOGY

Acetylcholine is released from a neuron's presynaptic membrane at the neuromuscular junction. In myasthenia gravis patients, the acetylcholine fails to adequately bind to muscle-based receptors in the postsynaptic membrane (sarcolemma) because the receptors are inactivated by autoantibodies. This test detects the autoantibodies in the serum.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Myasthenia gravis

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: The ARAT is the confirmatory diagnostic test for myasthenia gravis; assessment of the response to immunosuppressive and/or oral pyridostigmine treatment may further support the diagnosis but is variable (some cases may be refractory to treatment). Intravenous edrophonium (Tensilon) is occasionally used for immediate relief of signs, but response rate is low even in confirmed cases.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: False negative: corticosteroid or other immunosuppressive therapy. If clinically feasible, treatment should be stopped at least 4 weeks prior to testing.

LAB ARTIFACTS THAT MAY INTERFERE: False negative: failure to keep specimen chilled

SPECIMEN: Serum (red-top tube), 2 mL minimum; separate from clot as soon as possible. Should be frozen and sent on dry ice (preferable) or cold pack to reference lab immediately (courier/overnight express delivery). RELATIVE COST: $$$

PEARLS

Some dogs with myasthenia gravis are negative for AChR antibodies but have immune complexes associated with other antigens at the neuromuscular junction that interfere with neurotransmission. Nerve stimulation studies may be needed in these patients (see p. 1255).

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Acanthocyte

DEFINITION

Erythrocyte morphologic abnormality characterized by irregular, usually blunt projections from the normally smooth round cell membrane (from the Greek *akantha,* meaning “thorn”).

SYNONYMS

Burr cell, spur cell, echinoacanthocyte

TYPICAL NORMAL RANGE

Not reported unless seen on blood film. Healthy dogs and cats should not have appreciable numbers of circulating acanthocytes on properly prepared, fresh blood films.

PHYSIOLOGY

Mechanism for membrane shape abnormality is not known. Associated with abnormalities in red blood cell membrane lipids.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hemangiosarcoma; liver, splenic or renal disease; artifact of blood film preparation

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Repeat CBC to confirm; if consistent finding, evaluate for liver, splenic, or renal disease and metabolic abnormalities as suggested by clinical signs.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Specimen age artifact (delay in preparing blood film, sample not refrigerated); artifact of blood film preparation SPECIMEN: Whole blood in EDTA (lavender-top tube) or heparin (green-top tube); include a blood film prepared when specimen was collected to help rule out specimen age artifact.

RELATIVE COST: Reported if present on blood film; $/$$ (depending on reflex testing included in CBC panel)

PEARLS

Considered nonspecific and a common artifact; should be evaluated in a second, fresh specimen prior to drawing diagnostic conclusions

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Buffy Coat

DEFINITION

The thin white layer of packed leukocytes and platelets found atop the packed erythrocytes following high-speed centrifugation of anticoagulated blood

TYPICAL NORMAL RANGE

Typically not measured. The height of this layer in a spun blood specimen was previously used as a crude index of the total leukocyte count.

PHYSIOLOGY

Leukocytes and platelets are less dense than erythrocytes, so they deposit above the packed erythrocytes following centrifugation. A specific hematology analyzer (IDEXX VetAutoread) can expand and differentiate the layers of buffy coat to generate hemograms.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Any condition causing leukocytosis or thrombocytosis will increase thickness of buffy coat layer.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: CBC with blood smear examination CAUSES OF ABNORMALLY LOW LEVELS: Leukopenia

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: CBC with blood smear examination

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA whole blood (lavender-top tube)

RELATIVE COST: $$

PEARLS

- Smears of buffy coat cells can be an important tool for concentrating abnormal leukocytes that occur in very low number. Examples: detection of mastocytemia as a staging tool in dogs with mast cell neoplasm, detection of infectious agents in neutrophils or monocytes (e.g., *Histoplasma* in cats, *Hepatozoon* in dogs).
- Low numbers of circulating mast cells occur more often as an incidental finding in dogs (and rarely in cats) with various inflammatory diseases, compared to dogs with systemic mast cell neoplasms. Therefore, buffy coat detection of mast cells is more helpful as a staging tool for dogs and cats with confirmed mast cell neoplasms, rather than a means to screen for mast cell neoplasms.

Bruceila Slide Agglutination

DEFINITION

ELISA test for detection of *Brucella canis* antibody in serum

SYNONYM

Rapid slide agglutination test (RSAT)

TYPICAL NORMAL RANGE

Agglutination indicates positive test; serum from noninfected dogs fails to agglutinate.

PHYSIOLOGY

Highly sensitive screening test used for detecting active *B. canis* infection. Patient serum is mixed with heat-killed *B. ovis* on slide. Specimens from patients with antibodies to *B. canis* have positive agglutination.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: *B. canis* infection; false-positive test may occur in patients with antibodies to *Bordetella bronchiseptica, Pseudomonas* spp., *Moraxella* spp., or other gram-negative bacteria. Overall, approximately 40% of positive tests are associated with true *B. canis* infection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Confirm positive test results with 2-mercaptoethanol tube agglutination, agar gel immunodiffusion (AGID), or culture. Appropriate culture samples (vaginal exudate, aborted pups, semen) depend on clinical signs and associated available tissues or specimens.

CAUSES OF ABNORMALLY LOW LEVELS: For the first 3-4 weeks after infection, serologic tests may be negative even if bacteremia is present.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Retesting after 30 days is suggested before admission to breeding kennels. Low or intermediate titers may indicate previous disease or recent exposure. Follow-up blood culture may be helpful in these animals.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Serum (red-top tube); separate serum from clot, refrigerate sample.

RELATIVE COST: **$$**

PEARLS

- Humans are susceptible (zoonosis), but infections are rare.
- Post-bacteremia, organisms may concentrate in prostate and epididymis. Agglutination titers decline.
- Chronically infected female dogs typically have recurrent bacteremia and highest titers during proestrus, estrus, pregnancy, or abortion. Testing is suggested at these times.
- The test has a high sensitivity and thus is a reasonable screening test.

$$: $21-75
$$$: $76-150
$$$$: >$150

Bromide

DEFINITION

Active ingredient in potassium (KBr) or sodium bromide (NaBr), drugs used for treating seizure disorders

TYPICAL NORMAL RANGE

Serum level target therapeutic range: 0.5-2.3 mg/mL

PHYSIOLOGY

- As a seizure-controlling drug, bromide competes with chloride transport across cell membranes, resulting in neuronal hyperpolarization and increased seizure threshold. Neuron excitability is depressed.
- The standard method for measuring serum concentration is spectrophotometrically using the gold chloride method. Measurement by ion-selective electrode is considered inaccurate.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Excessive therapeutic dose NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Lower dose IMPORTANT INTERSPECIES DIFFERENCES: Used primarily in dogs; cats are more prone to exhibiting toxic side effects (lethargy, vomiting, polydipsia, polyuria, constipation, pancreatitis).

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: High-chloride diets and diuretics enhance bromide elimination, increasing the bromide dose required for therapeutic effect. Conversely, low-chloride diets and concurrent use of central nervous system depressants can enhance bromide effects/toxicity.

LAB ARTIFACTS THAT MAY INTERFERE: Increase: ion-selective electrode method of measurement (chloride interference)

SPECIMEN: Serum (red-top tube), refrigerate. First sample should be submitted within 1 week of loading dose; second specimen at 1 month; monitor every 3-6 months. RELATIVE COST: $$

PEARLS

- Higher incidence of adverse reactions in older patients and patients with renal dysfunction.
- Bromides are not approved by the U.S. Food and Drug Administration for use in animals.
- Serum bromide concentration at which toxic signs manifest is known to be variable in humans; variability in sensitivity to toxicity is likely in animal species as well.

$$: $21-75
$$$: $76-150
$$$$: >$150

Borreliosis (Lyme Disease) Serology

DEFINITION

Lyme borreliosis is a tickborne disease of dogs, cats, and humans that is caused by the spirochete *Borrelia burgdorferi*

TYPICAL NORMAL RANGE

- In-house SNAP qualitative ELISA for antibody to the C6 peptide of *B. burgdorferi* antigen: positive or negative result
- Quantitative C6 antibody test negative result (reference laboratory): <30 units/mL
- Immunofluorescent antibody (IFA; reference laboratory) negative result: <1:64
- Consult laboratory conducting the test for exact reference values for C6 antibody and IFA tests.

PHYSIOLOGY

Borrelia spp. organisms are inoculated into the skin via an *Ixodes* tick bite, where they proliferate and spread to many tissues, including joints and the central nervous system. Persistent infections are common; they may produce no clinical signs or may result in chronic debilitating disease such as arthritis, meningitis, or protein-losing nephropathy. Host's own inflammatory response likely plays a role in development of disease.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: In-house SNAP qualitative or quantitative C6 ELISA assay: positive test indicates natural exposure to *B. burgdorferi.* Whole-cell ELISA or IFA: seropositivity indicates natural exposure to pathogenic or nonpathogenic *Borrelia* organisms or vaccination with borreliosis vaccine.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: If the in-house SNAP qualitative C6 ELISA test is positive, consider the quantitative C6 antibody test to establish a baseline titer for monitoring effect of treatment in dogs. If IFA is positive, consider Western blot, ELISA testing for specific outer surface proteins, or C6 ELISA assay. PCR and blood culture have been used for confirming a diagnosis, but these tests have low sensitivity (difficult to detect organisms).

CAUSES OF NEGATIVE TEST/TITER: Early infection or noninfected

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Consider repeating C6 antibody test or IFA in 3-5 weeks if clinically appropriate (if early infection caused undetectable titer initially).

IMPORTANT INTERSPECIES DIFFERENCES: Despite evidence of seropositivity for *Borrelia* in cats, natural disease has not been described as a distinct clinical entity in this species. Cats may be more resistant than dogs to developing clinical signs of Lyme borreliosis. Polyarthritis and meningitis have been observed in some experimentally infected cats. The C6 ELISA assay may be used in cats.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: C6 titer may decrease within 4-5 months following successful treatment with doxycycline or amoxicillin.

SPECIMEN: The in-house SNAP C6 qualitative ELISA test requires 1 mL of serum or plasma (red-top or lavender-top tube). IFA and Western blot: 1 mL of serum (red-top tube). Samples are stable for up to 4 days at refrigerator temperature.

RELATIVE COST: $$ (Quantitative C6, ELISA); $$$ (Western blot)

PEARLS

A large proportion of dogs exposed to *Borrelia* (and therefore, having a positive test result) do not develop clinical signs of Lyme disease; the decision to treat should always be based on clinical characteristics in addition to serologic test results.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Bone Marrow Cytology

DEFINITION

Cytologic evaluation allowing assessment of blood precursor cell production and morphology

TYPICAL NORMAL RANGE

Marrow particles should contain 25%-75% hematopoietic cells, with all cell lines exhibiting orderly, complete maturation and normal shape, size, and features (morphology). The normal myeloid/erythroid (M:E) ratio is approximately 1:1, but can range from 0.6:1 to 4:1.

PHYSIOLOGY

Bone marrow contains trabecular bone with marrow spaces containing capillaries, hematopoietic cells, and adipocytes. Hematopoietic activity occurs in response to peripheral demand. Bone marrow aspiration is indicated when there are unexplained cytopenias (nonregenerative anemia, neutropenia, and/or thrombocytopenia), hyperglobulinemia, suspicion of neoplasia, or as part of staging of confirmed lymphoma and systemic mastocytosis cases.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hyperplasia of one or more cell lines may occur secondary to increased peripheral demand for cells due to cell destruction, increased utilization, or loss. Neoplasia such as acute or chronic leukemia (with or without maturation and morphologic abnormalities) results in high marrow cellularity and effacement of normal marrow tissue. Lymphocytes and plasma cells may be increased in marrow because of antigenic stimulation or neoplasia. Iron stores may be increased with anemia of chronic disease and hemolytic anemia. Inflammation, infiltrating neoplasia, or hemophagocytic disease also results in increased cellularity of the marrow.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Dependent on differential diagnosis based on history, physical exam findings, and results of CBC, serum biochemistry profile, and other diagnostic tests.

CAUSES OF ABNORMALLY LOW LEVELS

- Marrow hypoplasia indicates decreased cell production. Causes include anemia of chronic disease, chronic kidney disease, ehrlichiosis (dogs), drug-induced or immune-mediated destruction of precursor cells in the marrow, toxic insult (e.g., sulfa antibiotics, albendazole, phenylbutazone), viral infection (i.e., feline leukemia virus, parvovirus, canine distemper), myelofibrosis.
- Maturation arrest and dysplastic changes of red blood cells occur with viral infection, iron deficiency, myelodysplastic syndrome, or toxic insult.
- Iron stores are decreased with blood loss and iron deficiency.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Dependent on differential diagnosis based on history, physical exam findings, and results of CBC, serum biochemistry profile, and other diagnostic tests. Bone marrow aspiration often is the final diagnostic step for confirming hematopoietic disorders.

IMPORTANT INTERSPECIES DIFFERENCES: Iron stores are not usually visible in cat bone marrow and cannot be evaluated cytologically.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Aspirated marrow should immediately be made into fresh smears and also placed in an EDTA (lavender-top) tube. Proper collection and preparation of slides are essential for accurate interpretation. Hematopoietic cells degenerate rapidly after collection. Slides must be prepared immediately (before a clot forms) or within 30 minutes after collection if anticoagulant is used. A good bone marrow aspirate has several marrow particles for evaluation, with spreading of the cells in a monolayer for evaluation of morphology.

RELATIVE COST: $$, plus cost of aspiration procedure

PEARLS

- Bone marrow aspirates must be interpreted concurrently with CBC results.
- An accompanying bone marrow core biopsy may help in the interpretation of overall cellularity of the bone marrow, which complements the evaluation of morphology and maturation sequence from the marrow aspirate.
- A fresh smear of the marrow aspirate should be stained and examined for the presence of marrow spicules/cells while the animal is still sedated/anesthetized; if spicules are not adequate, the procedure may be repeated immediately.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Blood Urea Nitrogen (BUN)

DEFINITION

Concentration of urea in serum, plasma, or whole blood (usually measured in serum)

SYNONYM

Serum urea nitrogen (SUN)

TYPICAL NORMAL RANGE

- Dogs: 10-25 mg/dL
- Cats: 5-30 mg/dL
- Conversion: mg/dL × 0.36 = mmol

PHYSIOLOGY

Most of serum urea is synthesized via hepatic urea cycle, which converts ammonium derived from bacterial metabolism of dietary protein to urea. A small amount of ammonium is derived from deamination of amino acids. The kidneys excrete urea. Urea is freely filtered by glomeruli: some is resorbed by tubular epithelial cells to establish (with sodium) the medullary concentration gradient. Serum urea concentration often parallels creatinine concentration.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Mild to moderate increases can result from prerenal causes such as dehydration, decreased cardiac output, or shock (increased concentration of BUN often exceeds creatinine).
- Renal disease with decreased GFR (glomerular filtration rate) of virtually any etiology (inflammatory, degenerative, neoplastic, congenital, toxic, or other) can cause azotemia (concentrations of BUN and creatinine often parallel).
- Urinary outflow obstruction results in postrenal azotemia (increased BUN and creatinine).
- Gastrointestinal hemorrhage results in increased urea production (less effect on creatinine concentration).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Urine specific gravity, measurement of volume of urine production, evaluation of any disorder that may cause renal tubular cells to have decreased response to actions of ADH and therefore have lower than expected urine concentrating ability.

CAUSES OF ABNORMALLY LOW LEVELS

- Lack of hepatic urea production owing to decreased dietary protein (low-protein diet, anorexia), hepatic failure, decreased functional hepatic mass, portosystemic shunt, congenital deficiency of urea cycle enzymes (rare).
- Increased urea excretion is due to crystalloid or osmotic diuresis or marked polydipsia/polyuria, such as iatrogenic water drinkers (rare) or nephrogenic or central diabetes insipidus.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Assess urine specific gravity, urine output, water intake, serum concentrations of electrolytes and calcium.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Serum (red-top tube) preferred. Heparinized plasma (green-top tube) acceptable. Some methods can use EDTA plasma (lavender-top tube) or whole blood.

RELATIVE COST: $$ (part of most serum biochemistry profiles); $ (as a single test)

PEARLS

- High doses of gastroduodenal ulcerogenic drugs (corticosteroids, nonsteroidal antiinflammatories) may cause intestinal

hemorrhage, increasing BUN, but with little effect on creatinine

- Elevated BUN with concurrent isosthenuria (urine specific gravity approximating 1.008-1.012) signifies compromised renal function, with three exceptions: hypoadrenocorticism, diabetes insipidus, and diuretics may cause these laboratory changes without necessarily indicating that renal function is decreased.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Blood Typing

DEFINITION

Identification of specific inherited characteristic cell surface antigens on erythrocyte membrane

TYPICAL NORMAL RANGE

- Canine: dog erythrocyte antigen (DEA) 1.1, 1.2, 1.3 (the “A” system). Other classification systems exist, but the “A” system is most important for transfusion purposes. Any DEA can elicit an antibody response in dogs that lack it.
- Feline: type A (most common), type B (less common), type AB (rare)

PHYSIOLOGY

- Canine: The recognized canine antigens are DEA 1.1, 1.2, 1.3, 3, 4, 5, 6, and 7. DEA 1.1 antigen in particular can induce acute hemolytic reactions in sensitized dogs; identified by monoclonal antibodies on blood typing cards (see p. 1234).
- Feline: type A (>95%), type B (<5%); defined by preexisting, naturally occurring isoantibodies against the antigen they lack; type AB lacks antibodies: isoantibodies responsible for transfusion reactions and neonatal isoerythrolysis (see p. 1234).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Reported result is individual animal's blood type.

IMPORTANT INTERSPECIES DIFFERENCES

- Dogs do not have naturally occurring antierythrocyte surface antigen antibodies; a first transfusion will not cause hemolytic reaction (cross-matching is unnecessary for first transfusion, but typing is still recommended to provide transfused blood of a type that is least likely to elicit a long-term antibody response).
- All type B cats >3 months of age have high titers of naturally occurring type A antibodies that act as strong hemagglutinins and hemolysins. Type A or AB kittens born to type B queens are at risk of developing neonatal isoerythrolysis. Generally higher incidence of type B blood: British shorthair, Devon Rex, Cornish Rex breeds, DSH and DLH on U.S. west coast, Europe, Japan, and Australia (see p. 1379).

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN

- EDTA whole blood (lavender-top tube)
- Typing cards are species specific. Dog blood typing cards can be used for determining DEA 1.1 antigen status, and cards for cats can be used for determining type A, B, or AB.
- Marked anemia, marked hemolysis, or autoagglutination can interfere with results.

RELATIVE COST: $$$

PEARLS

- Dogs: blood groups that have the most clinical relevance are DEA 1.1 and DEA 1.2, also called *A1* and *A2*. Because DEA 1.1 is the most antigenic, DEA 1.1-negative dogs are recommended as donors for patients with unknown blood types.
- Cats: because of the widespread prevalence of naturally occurring erythrocyte antigens, blood from blood donor cats and the recipient cat should be typed, and a cross-match performed (see p. 1234) prior to any blood transfusion. Blood types should be compatible (acceptable: A into A; B into B; A, B, or AB into AB) and the cross-match should not show incompatibility.

AUTHOR: DEBORAH G. DAVIS

Pricing Information

$: <$20

$$: $21-75
$$$: $76-150
$$$$: >$150

Blood pH

DEFINITION

Measure of the hydrogen ion (H^+) concentration (acidity) of the blood

TYPICAL NORMAL RANGE

Dogs, 7.31-7.42; cats, 7.24-7.40

PHYSIOLOGY

Blood pH is inversely related to H^+ concentration; increased [H^+] = decreased pH. Hydrogen ions are continuously produced by metabolic processes and excreted via the kidneys or bound to buffers.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Increased pH indicates alkalosis, either respiratory (decreased Pco2) or metabolic (increased bicarbonate). Metabolic causes: vomiting, diuretics, overadministration of bicarbonate. Respiratory alkalosis is caused by hyperventilation due to pulmonary disease, direct stimulation of central nervous system (pain, anxiety), septicemia.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Respiratory: thoracic radiography/ultrasound, evaluate mentation and respiratory rate and depth, blood cultures. Metabolic: evaluate for vomiting, review treatment history.

CAUSES OF ABNORMALLY LOW LEVELS: Decreased pH indicates acidosis, either metabolic (low bicarbonate) or respiratory (increased Pco2). Metabolic causes: bicarbonate loss (and/or production of endogenous acids) due to diarrhea, lactic acidosis, ketoacidosis, uremia, ingestion of exogenous toxins (ethylene glycol). Respiratory causes: pulmonary parenchymal disease, pulmonary restrictive disease (pleural effusion, pneumothorax, diaphragmatic hernia), central nervous system depression (anesthesia, narcotics, brainstem disease), airway obstruction.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Consider serial blood lactate measurements to monitor progression if clinically indicated. Metabolic: calculate anion gap to determine if due to loss of bicarbonate (anion gap normal) or accumulation of organic acid (high anion gap). Evaluate serum biochemistry profile and urinalysis for renal disease, diabetes mellitus, and other systemic causes. Respiratory: ensure patent airway, thoracic radiography/ultrasound, evaluate mentation.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Decrease: sedative, narcotic, general anesthetics causing respiratory depression. Increase: bicarbonate or diuretic administration.

LAB ARTIFACTS THAT MAY INTERFERE: Decrease: delayed analysis of sample, excessive heparin in syringe. Increase: sample exposure to room air.

SPECIMEN: Whole blood collected and maintained in heparinized syringe, 0.05-0.1 mL of heparin/mL blood. Cap syringe end to limit exposure to room air. Specimens analyzed within 15 minutes of collections are preferred. Storage in a capped syringe on ice at 4°C for up to 2 hours is acceptable.

RELATIVE COST: $$ (reported as part of blood gas analysis)

PEARLS

Disturbances of pH can be life threatening. Periodic monitoring during prolonged anesthesia and in patients with severe metabolic illness (vomiting, diarrhea, shock) is critical.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: JAMES H. MEINKOTH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Blood Gas Analysis

DEFINITION

Evaluation of blood pH, Pco2, Po2, and bicarbonate. Other calculated parameters may be included. A blood pH lower than normal indicates acidosis, whereas a blood pH higher than normal indicates alkalosis. The acidosis is considered metabolic if a low $Hco^{-}3$ is a predominant coabnormality; conversely, is considered respiratory if high Pco2 is a predominant coabnormality.

SYNONYM

Acid-base analysis

TYPICAL NORMAL RANGE

- Arterial pH: dog, 7.35-7.45; cat, 7.30-7.42
- Pco2 (mm Hg): dog, 31-42; cat, 25-37
- Po2 (arterial, breathing room air; mm Hg): dog, 90-100; cat, 90-100
- $Hco^{-}3$ (mEq/L): dog, 19-26; cat, 14-21

PHYSIOLOGY

- Blood pH is maintained within narrow limits by a variety of buffers acting in concert. Pco2 and bicarbonate (Hco3) are the main parameters used for detecting respiratory and metabolic derangements (respectively) altering pH. Arterial Po2 is used for evaluating pulmonary function. Normal respiration maintains high Po2 and relatively low Pco2 concentration.
- General interpretive steps are to determine whether the pH has changed significantly and then evaluate the $Hco^{-}3$ and Pco2 to determine whether the change is due to metabolic or respiratory abnormalities, respectively.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: See individual tests, particularly pH.

CAUSES OF ABNORMALLY LOW LEVELS: See individual tests, particularly pH.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Diuretics such as furosemide can cause metabolic alkalosis.

LAB ARTIFACTS THAT MAY INTERFERE: Exposure to room air will result in falsely increased Po2 and decreased Pco2. Failure to analyze samples promptly can result in decreases in pH and Po2.

SPECIMEN: Whole blood collected and maintained in heparinized syringe (0.05-0.1 mL of heparin [1000 units/mL] per mL blood). Cap end of syringe to limit exposure to room air. Specimens analyzed within 15 minutes of collection are preferred. Storage in a capped syringe on ice at 4○C for up to 2 hours is acceptable.

RELATIVE COST: $$

PEARLS

- Alterations in pH can be life threatening. Handheld point-of-care analyzers are available for use in clinics.
- Venous blood samples are sufficient for routine evaluation of pH, Pco2, and $Hco^{-}3$. Arterial samples are more difficult to obtain but are needed for meaningful interpretation of Po2 levels.
- Submission of specimens to a reference lab may not be practical because of specimen sensitivity to environmental influence.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: JAMES H. MEINKOTH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Blastomyces Testing

DEFINITION

Blastomycosis is a systemic fungal infection caused by the dimorphic fungus *Blastomyces dermatitidis.*

SYNONYMS

Agar-gel irnmunodiffusion (AGID) test for antibody, enzyme immunoassay (EIA) test for antigen

PHYSIOLOGY

Following inhalation of *Blastomyces* spores, a primary lung infection develops, with subsequent dissemination via blood and lymphatics to multiple tissues, most notably skin, eye, bone, lymph nodes, and brain.

TYPICAL NORMAL RANGE

- Consult the laboratory conducting the test for information regarding reference range for AGID.
- Reference range for EIA antigen test is <0.1 EIA units (EU); 1-2 EU is considered a weak positive and should be verified by repeat testing (sensitivity and specificity reported as 90% and 80%-93%, respectively).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: A positive AGID test indicates exposure to *Blastomyces.* A positive EIA indicates possible *Blastomyces* infection. NEXT DIAGNOSTIC STEP TO CONSIDER IF TEST IS POSITIVE: If EIA positive, consider AGID, culture (only in laboratory with special handling capabilities), and cytology or biopsy. Correlate serology results with clinical signs and radiographic findings. Demonstration of the organism in Cytologie or tissue biopsy samples is required for definitive diagnosis. DNA probe testing is also available.

CAUSES OF NEGATIVE RESULT: Negative test result indicates lack of exposure, or early infection, or inadequate immune response to exposure.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If high clinical suspicion of *Blastomyces* spp. exists, but antibody and antigen tests are negative, consider collection of relevant Cytologie samples or biopsy samples to demonstrate organisms. PCR testing may detect early infections.

IMPORTANT INTERSPECIES DIFFERENCES: Blastomycosis is more common in dogs than cats.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Effective antifungal treatment may decrease antigen levels in the EIA test. LAB ARTIFACTS THAT MAY INTERFERE: Interfering substances for the EIA test include sputolysin, sodium hydroxide, EDTA, rheumatoid factor, and heterophile antibodies.

SPECIMEN: Submit 1 mL of serum (red-top tube) for AGID serology test. Submit 2 mL of urine (preferred sample), heparinized plasma (green-top tube), BAL, CSF, or sterile body cavity fluid for EIA test. Sample for EIA is stable for 1 week at room temperature, for 1 month with refrigeration, and indefinitely if frozen.

RELATIVE COST: $$ (AGID); $$$ (EIA)

PEARLS

EIA antigen test has higher sensitivity than AGID for diagnosing canine blastomycosis. Specificity of EIA may be lower because of possible cross-reactions with histoplasmosis and other endemic mycoses. EIA antigen test may be used for monitoring response to therapy and for early detection of relapse.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Bilirubinuria

DEFINITION

The presence of bilirubin in urine. Most common is conjugated bilirubin, which is water soluble; some unconjugated bilirubin is bound to albumin if albuminuria or proteinuria present.

TYPICAL NORMAL RANGE

- Negative in healthy cats; rarely trace or +1 in normal cats with extremely concentrated urine (>1.055 specific gravity).
- Negative in healthy dogs, trace or +1 in normal dogs with moderately or highly concentrated urine.

PHYSIOLOGY

Bilirubin is a byproduct of erythrocyte hemoglobin metabolism. Increased bilirubin production/release is caused by hemolytic states and abnormalities in hepatobiliary excretion of bilirubin. Water-soluble conjugated bilirubin is readily filtered through the glomerulus; dogs have especially low renal thresholds, with minimal tubular resorption of bilirubin such that bilirubinuria precedes hyperbilirubinemia (icterus). Also, canine renal tubular epithelial cells are capable of bilirubin production from hemoglobin resorbed from urine. Cats have higher thresholds and greater tubular resorption of conjugated bilirubin; therefore, bilirubinuria is more clinically significant than in dogs and usually indicates hepatobiliary disease. Albumin-bound unconjugated bilirubin does not pass the glomerulus readily, but animals with albuminuria/proteinuria may have enough albumin/protein in urine to get measurable amounts of unconjugated bilirubin in urine.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hemolytic diseases and decreased hepatobiliary excretion of bilirubin

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess urine specific gravity, hematocrit (if very low, likely bilirubinuria secondary to hemolytic crisis), liver enzymes (alanine aminotransferase, alkaline phosphatase, ± γ-glutamyl transferase; if significantly increased, bilirubinuria likely caused by decreased hepatobiliary excretion), and serum total bilirubin concentration.

IMPORTANT INTERSPECIES DIFFERENCES: In health, only dogs are expected to have bilirubinuria; however, cats with extremely concentrated urine may have trace or +1 reaction on dipstick.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Indican (a substance that may occur in the urine of normal animals) and etodolac metabolites may cause spurious increase.
- Ascorbic acid may cause spurious decrease.

LAB ARTIFACTS THAT MAY INTERFERE: Ultraviolet light causes bilirubin degradation. It is best if the urine sample has less than 30 minutes of direct ultraviolet light exposure prior to analysis.

SPECIMEN: Urine (minimum 5 mL) in clean/sterile container collected by free catch, catheterization, or cystocentesis

RELATIVE COST: $ (reported as part of urinalysis)

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Bilirubin

DEFINITION

A pigment produced by the degradation of the heme portion of hemoglobin (and to a lesser extent, other porphyrin-containing compounds)

TYPICAL NORMAL RANGE

- Dogs: approximately 0-0.3 mg/dL
- Cats: approximately 0-0.1 mg/dL.
- Specific values vary among laboratories.
- For mmol/L, multiply mg/dL × 17.1.

PHYSIOLOGY

During the breakdown of red blood cells (either senescent or pathologic hemolysis), heme is split to iron and protoporphyrin; protoporphyrin is converted to biliverdin then to unconjugated bilirubin predominately in macrophages of the spleen, bone marrow, and liver. Unconjugated bilirubin is released into the circulation, where it is bound to carrier proteins (albumin, globulins) and transported to the liver for uptake, conjugation, and secretion into bile. Conjugation renders bilirubin water soluble. Laboratory assays include total serum bilirubin, direct (conjugated) bilirubin, and indirect (unconjugated) bilirubin, which is a calculated value.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hemolysis, decreased hepatic uptake, decreased functional liver mass, decreased bile excretion (intrahepatic or extrahepatic)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess for hemolytic disease (CBC, saline prep for autoagglutination, Coombs' test), bile obstruction (alkaline phosphatase [ALP], imaging), hepatic disease (alanine aminotransferase, ALP, liver biopsy).

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE

- Hemolysis interferes with (either increases or decreases, depending on the method) measurement.
- Lipemia falsely increases bilirubin.
- Light degrades bilirubin (up to 50% in 1 hour in direct sunlight or fluorescent light).

SPECIMEN: Nonhemolyzed serum (red top tube). Separate serum from red blood cells as soon as possible. Store at 2°C-8°C (refrigeration). Protect from light.

RELATIVE COST: $$ (Typically part of chemistry profile); $ (as an individual test)

PEARLS

Determination of conjugated and unconjugated forms of bilirubin is not usually useful in differentiating hemolytic from hepatic/biliary causes of icterus in dogs and cats.

Bile Acids (Blood, Urinary)

DEFINITION

Family of detergent-like compounds (predominately cholic acid and chenodeoxycholic acid) synthesized in the liver from cholesterol and secreted in bile to aid in digestion and absorption of fat and fat-soluble vitamins.

TYPICAL NORMAL RANGE

- Fasting bile acids normally <5 mmol/L
- Fasting bile acids >20 mmol/L, postprandial samples >25 mmol/L, and/or urine bile acid/creatinine ratio >7.1 indicate liver disease.
- Urine: urine sulfated bile acids (USBA)/creatinine (crt) and total BA: crt are considered diagnostically useful.
- Dogs: USBA:crt > 1.0 and total BA:crt > 7 suggest liver disease
- Cats: USBA: crt > 2.0 and total BA:crt > 4 suggest liver disease

PHYSIOLOGY

Bile acids are stored in the gallbladder; released as a bolus into the small intestines upon feeding. In health, an efficient enterohepatic circulation exists, and up to 95% of bile acids are recycled via this cycle. Serum bile acids are evaluated in paired samples (fasting, postprandial). When portal blood clearance or biliary excretion is impaired, urinary excretion of BA increases. Urinary bile acid/creatinine ratios reflect an average serum bile acid concentration. Only a single urine sample is required.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Decreased clearance from blood (decreased functional liver mass, compromised portal circulation [congenital or acquired portosystemic shunt]). Cholestasis due to obstruction, cirrhosis, inflammation. Specific causes are many.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess for cholestasis (bilirubin, alkaline phosphatase), portosystemic shunt (imaging), other liver diseases (alanine aminotransferase, imaging, liver biopsy).

CAUSES OF ABNORMALLY LOW LEVELS: Low bile acid values are not clinically significant.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE

- Decrease: hemolysis, lipemia (spectrophotometric method), no effect on radioimmunoassay
- Increase: hypertriglyceridemia (spectrophotometric method), no effect on radioimmunoassay

SPECIMEN

- Serum (red-top tube): 12-hour fasting sample and 2-hour postprandial sample recommended separate serum from red blood cells as soon as possible. Store at 2°C-8°C (refrigeration).
- Urine: fresh urine, avoid blood contamination.

RELATIVE COST: Serum (single), $$ serum (paired), $$; urine bile acid/crt, $$

PEARLS

- If cholestasis is present (e.g., patient is icteric without evidence of hemolysis), bile acids do not provide any additional information on hepatic function. Bile acids are a good indicator of hepatobiliary function but are not specific for the type of underlying disease.
- Extrahepatic disorders (e.g., gastrointestinal disease) can elevate bile acid concentrations.
- Urine bile acids are more specific for canine liver dysfunction than serum bile acids.
- Occasional preprandial values that exceed postprandial values are attributed to spontaneous gallbladder contraction.
- Urine test has low diagnostic sensitivity (false negatives common) but good specificity (few false positives).

Bicarbonate

DEFINITION

An anion that is the major extracellular buffer in blood

TYPICAL NORMAL RANGE

Dogs and cats: 17-24 mEq/L (mEq/L = mmol/L).

PHYSIOLOGY

Bicarbonate is formed from the conversion of carbon dioxide and water to carbonic acid by carbonic anhydrase. Carbonic acid dissociates into bicarbonate and hydrogen ion. During metabolic acidosis, bicarbonate minimizes pH changes by binding to excess H^+. Binding excess H^+ decreases measurable Hco^-3.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Metabolic alkalosis (causes: vomiting, diuretics, overadministration of bicarbonate) or respiratory acidosis (causes: pulmonary parenchymal disease [pneumonia, pulmonary edema], pulmonary restrictive disease [pleural effusion, pneumothorax, diaphragmatic hernia], hypoventilation/central nervous system depression [anesthesia, narcotics, brain stem disease], airway obstruction)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate arterial blood gas profile (particularly pH and Pco2) to differentiate between metabolic alkalosis (high pH, high Hco^-3, high Pco2) and metabolic compensation for respiratory acidosis (low pH, high Pco2, high Hco^-3). Evaluate for underlying causes listed above.

CAUSES OF ABNORMALLY LOW LEVELS: Metabolic acidosis (causes: bicarbonate loss due to diarrhea, lactic acidosis, ketoacidosis, uremia, and ingestion of ethylene glycol) or compensation for respiratory alkalosis (causes: pulmonary disease [pneumonia, pulmonary edema], direct stimulation of central nervous system [pain, anxiety], septicemia)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate arterial blood gas profile to differentiate between metabolic acidosis (low pH, low Hco^-3, low Pco2) and metabolic compensation for respiratory alkalosis (high pH, low Pco2, low Hco^-3). Evaluate for underlying causes listed above.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Decrease: processing delay. Specimens analyzed within 15 minutes of collections are preferred. Storage in a capped syringe on ice at 4°C for up to 2 hours is acceptable.

SPECIMEN: Bicarbonate is a calculated value provided as part of a blood gas analysis. Whole blood in a heparinized syringe, avoiding exposure to room air, is used as described for blood gas analysis.

RELATIVE COST: $$ (part of blood gas analysis, not available as a separate test)

PEARLS

- Total carbon dioxide (Tco2) estimates plasma bicarbonate, which is part of most serum biochemistry profiles. Tco2 is the total amount of co2 gas that can be released from serum.
- At physiologic pH (7.4), about 95% of the potential gas is co2 and 5% is Hco^-3. Therefore, although Tco2 is usually slightly higher (1-2 mEq/L) than bicarbonate on a blood gas profile, it is considered a clinically accurate assessment of bicarbonate.
- May not be practical to submit to a reference laboratory, owing to sensitivity of specimen to environmental influences and time constraints for accurate test results

Bence Jones Urinary Proteins

DEFINITION

Unassociated immunoglobulin light chains produced in excess by abnormal plasma cells, typically with malignant plasma cell neoplasia (multiple myeloma).

SYNONYMS

Free immunoglobulin light chains, M-proteins, myeloma proteins, paraproteinuria

TYPICAL NORMAL RANGE

Reported as negative or positive

PHYSIOLOGY

Light chains are a component of immunoglobulins. Increased production occurs with increased immunoglobulin production or catabolism, as with multiple myeloma or (rarely) plasma cell tumors, the benign counterpart. Bence Jones proteins precipitate when heated, followed by redissolving when boiled and precipitation again when cooled.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Multiple myeloma; less often associated with extramedullary plasmacytoma or chronic lymphocytic leukemia; rarely associated with chronic infectious diseases

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Confirm monoclonal gammopathy with plasma immunoelectrophoresis. Assess for osteolytic bone lesions (radiographs); bone marrow plasmacytosis or plasma cell neoplasia (cytologic analysis of aspirate, or biopsy); urine protein electrophoresis (monoclonal spike in β or d regions).

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: False positives can occur with marked proteinuria.

SPECIMEN: Urine: Store at 2°C-8°C (refrigeration).

RELATIVE COST: $$

PEARLS

Heat precipitation method is not highly sensitive. Urine protein dipstick tests do not detect Bence Jones protein. The presence of Bence Jones proteins in the urine does not indicate glomerular disease (the molecules are sufficiently small to pass through normal glomerular fenestrations).

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: FONZIE QUANCE-FITCH

Pricing Information

$$: $21-75
$$$: $76-150
$$$$: >$150

Basophils

DEFINITION

White blood cell (granulocytic leukocyte) that has a segmented nucleus and metachromatic (purple) granules in cytoplasm. Basophils are rarely encountered in the blood of healthy animals.

TYPICAL NORMAL RANGE

Dogs and cats: 0-0.1 × 10^3 basophils/µL.

PHYSIOLOGY

Basophilic precursors undergo differentiation in the bone marrow, enter peripheral blood circulation for a few hours, and then enter tissue. Basophils produce leukotrienes and release histamine, heparin, and other mediators from their granules. Basophils participate in immunoglobulin E-mediated hypersensitivity reactions. They are similar in morphology to mast cells, but mast cells have a nonsegmented nucleus and primarily reside in tissue.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Allergic reactions (e.g., food, insect sting); parasitism (e.g., dirofilariasis/heartworm disease, flea infestation): mast-cell neoplasm; basophilic leukemia; myeloproliferative neoplasms (e.g., essential thrombocythemia, polycythemia vera)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Additional tests directed by history, physical exam findings, and results of ancillary diagnostic tests to rule out causes of high values listed above

IMPORTANT INTERSPECIES DIFFERENCES: The granules in feline basophils stain lavender or light violet. The metachromatic staining of granules in feline basophilic myelocytes diminishes as the basophilic precursors undergo maturation in the marrow. Because canine basophils have comparatively low numbers of metachromatic granules, a grey basophilic cytoplasm, and are large, they can be misidentifled as monocytes on blood smear.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA whole blood (lavender-top tube) and freshly prepared blood smear

RELATIVE COST: $$ (reported as part of CBC)

PEARLS

Basophilia often accompanies eosinophilia, a further indication of allergic or parasitic disease. Careful examination is necessary to identify basophils; when stained with the rapid Romanowsky stains (e.g., Diff-Quik), the cytoplasmic granules of canine basophils may be even less apparent.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Bartonellosis Testing

DEFINITION

Bartonella spp. are a group of vector-transmitted, intraerythrocytic bacterial organisms that can induce persistent infections in dogs, cats, and humans.

TYPICAL NORMAL RANGE

Consult laboratory for information regarding reference ranges. Some general guidelines include:

- Immunofluorescence antibody (IFA) test for *B. vinsonii* and *B. henselae*. Negative titer is <1:64.
- Western immunoblot (FeBart) for multiple *Bartonella* spp. in dogs and cats. Results available as negative or +1 to +4, with +3 and +4 considered positive and +2 considered to be possibly affected.

PHYSIOLOGY

Following vector transmission, chronic intravascular infections may produce no clinical signs or cause acute, life-threatening disease or chronic debilitating illness. Cats may exhibit fever, lymphadenopathy, or central nervous system (CNS) signs. Seropositive dogs may exhibit polyarthritis, endocarditis, myocarditis, CNS signs, idiopathic pleural effusion, granulomatous disease, cutaneous vasculitis, uveitis, immune-mediated hemolytic anemia, or immune-mediated thrombocytopenia.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Seropositivity indicates exposure to *Bartonella* spp.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: If seropositive, consider: (1) submitting whole blood for preenrichment culture (with BAPGM) followed by PCR and subculture onto agar plates; (2) tissue biopsy for histopathologic analysis, Warthin-Starry stain; or (3) submit whole blood or 25-50 mg of fresh or frozen tissue for PCR. Speciation for *B. henselae, B. clarridgeiae, B. quintana,* and *B. vinsonii* is possible with PCR testing. Diagnosis may be difficult to confirm.

IMPORTANT INTERSPECIES DIFFERENCES: Culture may be a less sensitive method for diagnosis in dogs than in cats, but the newly introduced preenrichment culture method has greatly improved sensitivity.

CAUSES OF ABNORMALLY LOW LEVELS: In both species, cyclic bacteremia can result in false negatives for both blood culture and PCR.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Pursue additional testing techniques, repeat testing, or empirical treatment.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Effective antibiotic treatment may decrease serology titers. Use of effective antibiotics prior to sample collection may result in a false-negative culture or PCR test.

LAB ARTIFACTS THAT MAY INTERFERE: PCR: false-positive results via contamination of samples; false-negative results due to degradation of nucleic acids via improper sample handling and storage. SPECIMEN: Contact laboratory for specific instructions. IFA: submit 1 mL serum (red-top tube). Western immunoblot (FeBart): submit whole blood, serum (red-top tube), or plasma (green-top or lavender-top tube). PCR: submit whole blood collected in EDTA (lavender-top tube). Preenrichment culture with PCR: submit 2 mL whole blood collected in EDTA (lavender-top tube).

RELATIVE COST: $$ (IFA, Western blot, PCR)

$$: $21-75
$$$: $76-150

$$$$: >$150

Baermann Fecal Examination

DEFINITION

A method used for microscopic evaluation of fecal specimens for parasite larvae. Rather than being drawn to the surface, as with a fecal flotation, parasites are detected after being drawn to the bottom of the Baermann apparatus. The Baermann apparatus is a funnel with a rubber tube attached to the stem, usually supported by a ring stand. Feces are put on cheesecloth in a strainer, which is placed in the funnel. Water is added to cover the specimen, which is then macerated. An aliquot of fluid collected after a few hours is examined microscopically for parasitic larvae.

TYPICAL NORMAL RANGE

Reported as negative or positive with species identification

PHYSIOLOGY

The Baermann apparatus uses the larvae's tendency to migrate from fecal matter to warm water.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Filarid parasite *(Filaroides osleri, F. milksi, F. hirthi, Crenosoma vulpis,* and *Aelurostrongylus abstrusus)* infections are most likely to be detected by this method of fecal examination.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Positive fecal with parasite identification is considered diagnostic.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Anthelmintics may decrease larval shedding. LAB ARTIFACTS THAT MAY INTERFERE: Test is not sensitive. A negative test does not rule out infection because fecal shedding of larvae is intermittent.

SPECIMEN: Fresh (less than 24 hours old) fecal specimen submitted in dry container.

RELATIVE COST: $$

PEARLS

Bronchoscopy is preferred for detection of *F. osleri,* but the procedure is time consuming, more costly, and requires general anesthesia. Baermann fecal flotation is considered to have a slight advantage over usual fecal flotation for detection of larvae in feces; no advantage for detection of ova.

$$$: $76-150
$$$$: >$150

Cyclosporine Serum Levels

DEFINITION

Cyclosporine is an immunosuppressant drug that has a selective inhibitory effect on T lymphocytes, suppressing the early cellular response to antigenic and regulatory stimuli.

TYPICAL NORMAL RANGE

400-600 ng/mL (FPIA Assay) at 6-8 hours post administration

PHYSIOLOGY

Peak plasma levels usually occur 1.3-4 hours after oral administration. Ingestion of a fatty meal significantly delays absorption of cyclosporine in the gelatin capsule formulation (Sandimmune) but not in the more commonly used microemulsion formulation (Neoral, Atopica). In whole blood, 50%-60% of cyclosporine accumulates within erythrocytes, 10%-20% accumulates within leukocytes, and the remainder of the drug in circulation is associated with plasma lipoproteins. Half-life is approximately 6 hours. Extensive metabolism in the liver to >30 metabolites. Elimination primarily via bile. In the presence of hepatic dysfunction, dosage adjustments may be necessary. Major toxic effect is renal, but other potential toxicities include systemic hypertension, hepatotoxicity, neurotoxicity, gingival hyperplasia, gastrointestinal toxicity.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Overdosage, hepatic impairment, interaction with drugs (see below) CAUSES OF ABNORMALLY LOW LEVELS: Interaction with drugs (see below), insufficient dosage

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Interacts with a variety of commonly used drugs. Clearance is accelerated with coadministration of phenobarbital, phenytoin, trimethoprim-sulfamethoxazole, and rifampin (induction of hepatic P450). Clearance is decreased when coadministered with amphotericin B, erythromycin, or ketoconazole.

SPECIMEN: A blood cyclosporine level is typically checked 1-2 days after initiating therapy and then at 2- to 4-week intervals. Trough levels (24-hour): either whole blood or plasma is satisfactory but because of binding to red/white blood cells, values will vary depending upon sample submitted; check with laboratory prior to submission.

RELATIVE COST: $$$$ (peak and trough)

PEARLS

The decrease in cyclosporine excretion caused by ketoconazole can be used advantageously. Cyclosporine is a costly medication, whereas ketoconazole is inexpensive. Therefore ketoconazole, 5 mg/kg PO q 24 h may be coadministered with cyclosporine microemulsion (e.g., Neoral), 5 mg/kg PO q 24 h, which halves the required cyclosporine dose (from q 12 h to q 24 h) while maintaining the same serum cyclosporine concentration. To ensure avoidance of potentially toxic levels, monitoring plasma/blood levels is recommended. Metabolites may be active, so monitor response to therapy, not only blood levels of parent compound, to reduce risk of toxicosis.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Culture and Sensitivity, Bacterial

DEFINITION

Submission of infected tissue or fluid for enhanced growth and isolation of bacteria and evaluation of the antibiotics (antibacterials) that could kill or inactivate them

TYPICAL NORMAL RANGE

- Bacterial isolates are reported by genus and species.
- Antibiotic sensitivity, which is determined either by disk diffusion method

(Kirby-Bauer) or determination of minimum inhibitory concentration (MIC) method, is reported as sensitive, intermediate (or indeterminate), or resistant.

PHYSIOLOGY

Small quantities of suspect tissues are aseptically plated on media that enhance the growth of bacteria. Individual colonies are isolated and identified by morphologic features (texture, color) and specific chemical reactions. Isolated colonies are exposed to known concentrations of antibiotics and evaluated for growth inhibition.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Bacterial infection or contamination

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Select an appropriate antibiotic based on sensitivity, appropriate method of delivery (e.g., injection, oral, topical), and site of infection.

IMPORTANT INTERSPECIES DIFFERENCES

- Some organisms are normal flora in some species but pathogens in others.
- Some antibiotics are appropriate for one species of patient but toxic in another.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Previous or concurrent antibiotic therapy, even if not the drug of choice, may inhibit culture growth.

LAB ARTIFACTS THAT MAY INTERFERE

- Contamination (during collection by use of nonsterile containers, prolonged storage at room temperature, or delays in shipment) may result in overgrowth.
- Contaminant organisms may inhibit growth of more fastidious organisms.

SPECIMEN: Fresh tissue or fluid in sterile container; culture swab is acceptable for both aerobic and anaerobic culture. Blood specimens should be collected in blood specimen vials. Serum (red-top tubes) with serum-separator plug should not be used for blood culture specimen.

RELATIVE COST: $$

PEARLS

Monitor potential antibiotic toxicosis by appropriate clinical monitoring and laboratory tests. MIC is the lowest concentration (greatest dilution) of an antibiotic that inhibits bacterial growth in culture media. Serial dilutions of antibiotic are made, and the highest effective dilution is reported as the MIC. Therefore, the higher the reported MIC, the more effective an antibiotic is for inhibiting the growth of a particular organism; an MIC result of 1:256 indicates an antibiotic that inhibits bacterial growth much more effectively than an antibiotic with MIC of 1:8, for example.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$$$: $76-150
$$$$: >$150

Crystals in Urine Sediment

DEFINITION

Precipitation of salts of metabolic products, forming crystals observed in urine sediment

SYNONYM

Crystalluria

TYPICAL NORMAL RANGE

- Reported as negative or number of crystals per microscopic high-power field, with specific identification
- Normal dogs and cats may have low numbers of crystals.

PHYSIOLOGY

Metabolic products that are normal, abnormal, or related to medication may precipitate, forming crystals that may be seen in urine sediment. Crystal formation depends on urine pH, temperature, and compound concentration.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Abnormal or increased metabolic products, changes in urine pH, enhancing formation of specific crystals NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Assess diet, medication history, or evaluate for metabolic abnormalities suggested by specific crystals.
- Urine culture and sensitivity in all dogs with struvite crystalluria, because infection with urease-producing bacteria is the most common cause.

IMPORTANT INTERSPECIES DIFFERENCES: Dalmatian dogs normally can have ammonium urate crystals; in other breeds, this may indicate hepatic dysfunction.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Sulfonamides, radiopaque injectable contrast are associated with crystalluria.

LAB ARTIFACTS THAT MAY INTERFERE: Crystals may dissolve over time as urine pH changes following voiding. Conversely, refrigeration of specimens may result in in vitro formation of both struvite (ammonium magnesium phosphate, triple phosphate) and oxalate crystals over time, which remain when specimens are returned to room temperature. Therefore, immediate processing is recommended, and retesting of fresh specimens is suggested if numbers of crystals are high and the possibility of clinical significance exists.

SPECIMEN: Fresh urine in sterile container for urinalysis; at least 5 mL; 10 mL is preferred by most laboratories.

RELATIVE COST: $ (reported as part of urinalysis)

PEARLS

Crystalluria may be indicative of urolithiasis. Absence of crystals does not rule out disease. If clinically significant (calcium oxalate) crystalluria is suspected, a fresh specimen should be analyzed.

AUTHOR: LOIS ROTH-JOHNSON

Cell Name	Appearance	Clinical Relevance
Ammonium magnesium phosphate (triple phosphate, struvite)		Common in dogs (infection) and cats (nutrition), especially with alkaline urine or as artifact
Ammonium biurate		Infrequent in healthy patients except Dalmatians and English bulldogs; if numerous, suggests liver dysfunction or shunt in dogs and cats
Bilirubin		Associated with bilirubinuria
Calcium oxalate monohydrate		Suggests ethylene glycol toxicity
Calcium oxalate dihydrate		Seen in healthy patients; suggests ethylene glycol toxicity
Calcium phosphate		Seen in healthy dogs
Cyst(e)ine		Rare; suggests liver disease or primary cyst(e)inuria (e.g., breed-related)
Cholesterol		Uncommon in healthy dogs; may occur with hypercholesterolemia or renal disease
Drug crystals		Sulfa, contrast media; renal elimination of material
Hippuric acid		Rare; should be distinguished from calcium oxalate monohydrate (history, physical exam)

CRYSTALS IN URINE SEDIMENT

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Cryptococcus Antigen Test

DEFINITION

Cryptococcus is a saprophytic dimorphic fungus with a worldwide distribution. *C. neoformans* is the most common species to cause disease in animals. *C. gattii* is an emerging pathogen in the Pacific Northwest, affecting immunocompetent animals and people. The antigen test detects capsular antigen (for both *C. neoformans* and *C. gatti)* present in the patient's serum.

PHYSIOLOGY

- Pigeon droppings are considered the main reservoir for *C. neoformans.* Inhalation is the presumed mode of infection. Nasal or pulmonary infection occurs; potential dissemination to central nervous system, eyes, skin, bones, lymph nodes.
- Colonization of nasal passages can occur without producing overt clinical signs.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Methods include latex agglutination and ELISA. Positive titer confirms active infection. Ability to detect antigen is high (sensitivity ~97%), but false-negative results do occur, possibly due to localized disease or a prozone effect (excessively high concentrations that paradoxically inhibit reaction). False-positive results are very uncommon (specificity approaches 100%). Higher titers are seen with disseminated disease. Monitoring titers is useful to evaluate therapeutic success; declining titers are considered a good prognostic sign.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Cytologie evaluation, histopathologic evaluation, and culture of specimens may be useful to confirm but generally are unnecessary when a positive antigen test result occurs in a patient with compatible clinical signs.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN

- Serum (most common), urine, or cerebrospinal fluid (CSF); check with individual laboratory
- CSF is preferred if central nervous system signs are present; may be more sensitive.

RELATIVE COST: $$

PEARLS

Titers from different laboratories using different methods can vary considerably; use the same method if performing repeated titers to monitor treatment.

AUTHOR: ROBIN W. ALLISON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Cross-Matching

DEFINITION

Laboratory procedure to detect antibodies between an animal and potential blood donor. Major cross-match involves patient's serum and donor blood cells; the minor uses donor serum and patient's blood cells.

TYPICAL NORMAL RANGE

Lack of agglutination

PHYSIOLOGY

Major cross-match determines if there are agglutinating and/or hemolytic antibodies against the donor antigens in the patient. Incompatible reactions occur when blood is transfused to a patient having antibodies (whether naturally occurring antibodies, as occurs in all cats, or antibodies induced by a previous mismatched transfusion, which can occur in any species) or isosensitization from transplacental immunization. The placenta is impermeable to immunoglobulins such that a developing fetus's blood type may be different from its dam's, even if the dam has circulating antibodies against the fetal erythrocytes; ingestion of immunoglobulin rich colostrum by the neonate in the first day postpartum allows maternal antibodies to lyse neonatal erythrocytes because of neonatal gastrointestinal permeability (see p. 757). Incompatible minor cross-match is not associated with severe transfusion reactions.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Agglutination (either macroscopic or microscopic) or significant hemolysis in the cross-match tubes but not in control indicates an incompatible donor.

IMPORTANT INTERSPECIES DIFFERENCES: Cross-matching should always be performed prior to transfusion in cats, regardless of previous transfusion history, owing to the presence of naturally occurring antibodies. Transfusion of type A blood into type B cats causes rapid hemolysis (in minutes to 2 days instead of the typical 29- to 39-day transfused erythrocyte lifespan in cats) and severe anaphylaxis.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Glucocorticoids and other immunosuppressants may reduce the incidence of incompatibility (reduce negative cross-matches).

LAB ARTIFACTS THAT MAY INTERFERE: Agglutination in the control tubes (patient serum added to patient red blood cells [RBCs] or donor serum added to donor RBCs) indicates reagent contamination or autoagglutination. SPECIMEN: Two tubes are preferred, one EDTA (lavender-top tube) and one tube without anticoagulant (red-top tube or serum-separator tube).

RELATIVE COST: $$

PEARLS

A compatible cross-match does not indicate that the animal and the donor have the same blood type; it merely means that erythrocyte antibodies were not detected. Therefore blood typing remains essential in all donors and recipients.

AUTHOR: DEBORAH G. DAVIS

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Creatinine

DEFINITION

Creatinine is a waste product that results from degradation of muscle creatine or creatine phosphate.

TYPICAL NORMAL RANGE

Dogs and cats: approximately 0-1.5 mg/dL (0-133 µmol/L)

PHYSIOLOGY

Creatinine is continuously produced from slow, daily degradation of muscle creatine and is excreted in urine. It is freely filtered by the glomerulus and is not resorbed by renal tubular epithelial cells.

CAUSES OF ABNORMALLY HIGH LEVELS

- Decreased glomerular filtration rate (GFR) causes increased creatinine concentration.
- Animals with greater muscle mass, such as greyhounds, have higher creatinine concentrations than less well-muscled animals. Healthy greyhounds often have a creatinine concentration of 1.5-2.5 mg/dL.

CLINICAL APPLICATIONS

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Check serum urea (BUN) concentration and urine specific gravity. Urea and creatinine concentrations increase in parallel in many urinary tract disorders of dogs and cats.

CAUSES OF ABNORMALLY LOW LEVELS: Thin body condition/muscle loss may result in low creatinine concentration.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate for causes of muscle loss/pathologic weight loss if present on physical exam.

SPECIMEN: Serum (red-top tube) or heparinized plasma (green-top tube)

RELATIVE COST: $$ (part of most serum biochemistry profiles); $ (as a single test)

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Creatine Kinase (CK)

DEFINITION

Cytosolic enzyme that has the highest activity in skeletal muscle, cardiac muscle, smooth muscle, brain, and nerves. Skeletal muscle injury is responsible for clinically significant elevations in dogs and cats.

SYNONYM

Creatine phosphokinase (CPK)

TYPICAL NORMAL RANGE

Dogs: 10-200 U/L. Cats: 64-440 U/L.

PHYSIOLOGY

- CK is critical for energy production to cause muscle contraction.
- CK catalyzes the formation of adenosine triphosphate (ATP) by transfer of high-energy phosphate from creatine phosphate to adenosine diphosphate (ADP). It also catalyses the reverse reaction when muscles are at rest.
- Serum CK activity is primarily of muscle origin. It is a sensitive indicator of skeletal muscle damage.
- CK is released into the interstitium when muscle membrane becomes permeable or is damaged. The plasma concentration increases 4-6 hours after injury and peaks at approximately 12 hours. Values return to normal within 24-48 hours.
- The half-life in blood is approximately 2-4 hours. Persisting elevation of CK indicates ongoing muscle damage.
- CK isoenzymes may be measured to more specifically localize muscle damage to cardiac or skeletal muscle. CK isoenzyme measurements are not routinely used in veterinary medicine. In human cardiology, other biomarkers have superseded CK (see p. 1505).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Trauma, exertion, seizures, malignant hyperthermia, intramuscular injections, degenerative muscle disease, infectious and noninfectious myopathies, ischemia, necrosis, metabolic myopathies, toxic, drug-induced and nutritional myopathies, arterial thromboembolism, anorexia in cats resulting in muscle catabolism

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate for muscle disease or injury or muscle catabolism. In dogs, as in people, serum cardiac troponin-I levels are probably more sensitive and specific for myocardial damage than CK myocardial isoenzyme.

IMPORTANT INTERSPECIES DIFFERENCES: CK elevation commonly occurs in anorexic cats.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE

- Increase: hemolysis, lipemia, hyperbilirubinemia, contamination of blood with muscle fluid during difficult venipuncture; dilution of samples (attributed to dilution of CK inhibitors in serum)
- Decrease: collection in citrate (blue-top tube) or sodium fluoride (grey-top tubes)

SPECIMEN: Serum (red-top tube), heparinized plasma (green-top tube), or EDTA plasma (lavender-top tube). Refrigerated samples are stable for 8-12 hours; samples stored at −20°C are stable for 2-3 days.

RELATIVE COST: $

PEARLS

Persistent exceedingly high CK levels (e.g., >200,000 U/L) are strongly suggestive of muscular dystrophy.

Cortisol

DEFINITION

Cortisol is a glucocorticoid hormone produced by the adrenal gland cortex. It initiates synthesis of proteins and receptors for hormones and cytokines involved in gluconeogenesis, protein catabolism, lipolysis, immune responses, and water balance.

TYPICAL NORMAL RANGE

Baseline cortisol concentration in health is 0.4-6 µg/dL or 10-160 nmol/L in dogs and 0.4-4 µg/dL or 10-110 nmol/L in cats.

PHYSIOLOGY

Identification of a naturally occurring, abnormally high concentration of cortisol is helpful towards making a diagnosis, because concentrations fluctuate numerous times daily. Increased concentrations may need to be provoked or suppressed for diagnostic purposes.

ACTH released from pituitary adenomas/adenocarcinomas stimulates adrenal cortical release of cortisol. Adrenocortical adenoma/adenocarcinoma in dogs and most cats overproduce cortisol. In ferrets and some cats, adrenocortical tumors produce other steroid hormones such as estrogen or progesterone and may result in clinical signs of hyperadrenocorticism. Ovarian/Sertoli cell tumors in dogs can produce cortisol-like compounds. Stress of systemic disease causes increased release of ACTH from the pituitary gland, with subsequent increased release of cortisol from adrenal glands. Administration of exogenous ACTH for use in the diagnosis of hyperadrenocorticism causes increased adrenal gland production and release of cortisol. Administration of exogenous corticosteroids (specifically dexamethasone) is used for suppressing production/release of ACTH, with subsequent decrease in adrenal release of cortisol. Dexamethasone is used for this test because it cross-reacts with cortisol minimally [<0.1%], which is considerably less than most other available corticosteroids.

With lack of appropriate ACTH secretion from pituitary gland or atrophy or destruction/necrosis of adrenal cortex, cortisol concentration can be low: hypoadrenocorticism (Addison's disease). Sudden withdrawal of administration of exogenous glucocorticoids that had caused adrenal gland atrophy can precipitate iatrogenic hypoadrenocorticism.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Pituitary tumor production of excess ACTH: pituitary-dependent hyperadrenocorticism (Cushing's disease)
- Adrenal tumor production of excess cortisol: functional adrenal adenoma or adenocarcinoma
- Stress of systemic disease (endogenous production of increased ACTH)
- Ovarian/Sertoli tumor production of cortisol-like compounds
- Administration of exogenous **ACTH NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH:** Low-dose dexamethasone suppression test, imaging of adrenal glands, ACTH stimulation test **CAUSES OF ABNORMALLY LOW LEVELS**
- Primary hypoadrenocorticism (Addison's disease) caused by immune-mediated atrophy or destruction of the adrenal cortex can result in low concentrations of cortisol, cortisol and aldosterone, or only aldosterone.
- Secondary hypoadrenocorticism (ACTH deficiency) is caused by destruction, necrosis, or removal of the pituitary gland.
- Iatrogenic hypoadrenocorticism occurs secondary to sudden withdrawal of exogenously administered corticosteroids that have caused adrenal gland atrophy.
- Ketoconazole inhibits steroid biosynthesis, which can cause low concentrations of cortisol.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: ACTH stimulation test

IMPORTANT INTERSPECIES DIFFERENCES

- Cat adrenal tumors may produce hormones (progesterone) other than cortisol.
- Ferret adrenal tumors usually produce hormones (estrogen and progesterone) other than cortisol.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Immunoassays for cortisol measurement have significant cross-reactivity with other glucocorticoids:

cortisol (100%), prednisolone (69%), prednisone (6.4%), 11-deoxycortisol (7.5%), cortisone (4.2%), corticosterone (3.5%), spironolactone (<0.2%), and dexamethasone (<0.1%).

SPECIMEN

- Serum (red-top tube) or EDTA plasma (lavender-top tube)
- Cortisol in EDTA plasma is more stable than in serum and more stable in cooled samples compared with warm samples.
- Cortisol is equally distributed between red cells and plasma; therefore, rapid separation of plasma from cells (previously reported) is of no added benefit.
- EDTA interferes with some methods of testing; check with reference laboratory if submitting EDTA plasma.

AUTHOR: ELIZABETH G. WELLES

Coombs' Test

DEFINITION

Demonstrates the presence of immunoglobulin (Ig) or complement bound to the surfaces of erythrocytes

SYNONYM

Direct antiglobulin test (DAT)

TYPICAL NORMAL RANGE

Reported as negative or positive

PHYSIOLOGY

Coombs' reagent (polyvalent, species-specific anti-IgG, anti-IgM, and anti-complement antibodies) is added to patient's washed red blood cells. If Ig or complement is present on the patient's red blood cells, cross-linking will occur, resulting in agglutination (positive result).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Immune-mediated hemolytic anemia (IMHA)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Examine blood smear for spherocytes, assess for anemia, rule out infectious or neoplastic conditions that may cause positive test.

IMPORTANT INTERSPECIES DIFFERENCES: Species-specific Coombs' reagent is required.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Treatment with glucocorticoids may cause false-negative results.

LAB ARTIFACTS THAT MAY INTERFERE

- Positive result not associated with IMHA may be seen if: post transfusion (>3 to 7 days after transfusion) with nonspecific coating of erythrocytes, or with in vitro complement binding during storage.
- False-negative result may be seen if: antibody is present in too low a titer to be detected by test, weakly bound antibody elutes during washing, or antibody or complement detaches from RBCs due to sample aging.

SPECIMEN: Whole blood collected in EDTA (lavender-top tube), store at 8°C; test as soon as possible.

RELATIVE COST: $$

PEARLS

- Test is supportive of but not specific for IMHA. Positive results can occur in patients with infectious or neoplastic disease. Coombs' test is unnecessary (already "positive") in patients with spontaneous autoagglutination.
- A Coombs' test is neither sensitive nor specific. Physical exam, erythrocyte indices, and examination of a blood smear may be sufficient for determining the diagnosis of IMHA.

Complete Blood Count

DEFINITION

A group of routine hematologic tests for measuring several parameters of erythrocytes, leukocytes, and platelets. Tests include blood cell concentrations, measurement of cell sizes and hemoglobin concentration, differential leukocyte count, and evaluation of morphology of blood cells on a stained blood smear. A refractometric plasma protein concentration is also included by many labs.

SYNONYMS

CBC, hemogram

TYPICAL NORMAL RANGE

See Hematocrit, Leukocytes, and other Section-IV entries for specific information, including reference intervals.

PHYSIOLOGY

See Hematocrit, Leukocytes, and other Section-IV entries for specific information.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA (lavender-top tube) blood sample and freshly prepared blood smear for lab to stain

RELATIVE COST: $$

PEARLS

Although automated hematology analyzers provide 3- or 5-part differential leukocyte counts as part of a CBC, the differential counts obtained from stained blood smears remain the most accurate method for differentiating leukocytes and detecting left shifts in dogs and cats.

AUTHOR: STEPHEN D. GAUNT

Cell Name	Appearance	Clinical Relevance
Acanthocyte (burr cell)		Associated with vascular, liver, or renal disease
Codocyte (target cell)		Regenerative anemia; liver or renal disease; abnormal lipid metabolism
Eccentrocyte (burr cell)		Oxidative injury
Keratocyte		Vascular disease, including hemangiosarcoma and disseminated intravascular coagulation
Heinz body		Oxidative injury
Leptocyte		Iron deficiency
Schistocyte		Vascular disease including hemangiosarcoma, disseminated intravascular coagulation
Spherocyte		Immune-mediated hemolysis or partial phagocytosis. Unlike small red blood cells (microcytosis), spherocytes have no central pallor

COMPLETE BLOOD COUNT Red cell abnormalities. See also for discussion of various red blood cell morphologic abnormalities (i.e., poikilocytosis).

Colloid Osmotic Pressure

DEFINITION

The portion of serum osmotic pressure generated by colloids (typically proteins) and other molecules too large to freely cross the vascular endothelium

SYNONYM

Oncotic pressure

TYPICAL NORMAL RANGE

- Dogs: 14-27 mm Hg
- Cats: 21-34 mm Hg

PHYSIOLOGY

Colloid osmotic pressure (COP) and hydrostatic pressure control fluid movement between the intravascular and interstitial spaces. In health, COP is generated largely by albumin (~80%), with the remainder being mostly fibrinogen and globulins. Therapeutic administration of colloidal solutions (plasma, polymerized bovine hemoglobin [Oxyglobin], hetastarch) can be used for compensating for pathologic decreases in COP.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Marked hyperglobulinemia (e.g., plasma cell myeloma, feline infectious peritonitis), overadministration of therapeutic colloids (i.e., Oxyglobin)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate serum proteins; protein electrophoresis; review drug history for administration of colloids.

CAUSES OF ABNORMALLY LOW LEVELS: As for hypoalbuminemia (hemorrhage, gastrointestinal or renal protein loss, hepatic failure). Acidosis lowers COP independently of protein concentration. NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate serum proteins, screen for blood/plasma loss, urine protein, liver function.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Increase: therapeutic administration of colloids (intended effect)

LAB ARTIFACTS THAT MAY INTERFERE: Marked hemolysis may increase COP.

SPECIMEN: Plasma collected in heparin (green-top tube) or EDTA (lavender-top tube), spun, and separated from cells. A specific instrument (colloid osmometer) is required for measurement; COP is not reported routinely on small-animal blood profiles.

RELATIVE COST: NA; not offered by most reference laboratories

PEARLS

- COP is superior to albumin measurement (and therefore is most useful) when evaluating and monitoring the oncotic pressure of an animal receiving treatment with nonalbumin-type colloids such as synthetic colloids (hetastarch, pentastarch).
- COP must be interpreted in context of clinical situation.
- Decreased COP due to acute changes in protein concentration (hemorrhage) is more likely to result in clinical abnormalities than the same low COP due to chronic hypoalbuminemia.
- Trends in COP change may be more significant than a single value.
- COP may be useful in differentiating causes of edema (decreased COP versus increased hydrostatic pressure versus vasculitis [COP normal for the latter two]).
- Equations to estimate COP using serum/plasma protein concentration are unreliable in critically ill animals. Direct measurement using a colloid osmometer is needed.
- For clinical use, the terms *colloid osmotic* and *oncotic* pressure can be used interchangeably.

Coccidioides immitis Serology

DEFINITION

Coccidioides immitis is a soil-borne dimorphic fungus restricted to certain geographic regions, specifically the Lower Sonoran life zone within the southwestern United States, Mexico, and Central and South America. Serologie testing measures the anti-*Coccidioides* antibodies that may be present in serum by one of several methods.

PHYSIOLOGY

Infection is typically acquired by inhalation, initially causing pulmonary infection that may disseminate to lymph nodes, bones, eyes, heart, testicles, brain, spinal cord, and other visceral organs.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Interpretation of positive titers varies substantially depending upon the type of test performed. Consult with individual laboratory.

- Tube precipitin (TP) antibody: detects immunoglobulin (Ig)M; positive early in infection only
- Complement fixation (CF) antibody: detects IgG; positive with past exposure or active infection; titers =1:64 usually indicate severe or disseminated disease
- Latex agglutination: detects IgM; positive early; some false-positive results in dogs
- Agar gel immunodiffusion (AGID) with TP antigen: more sensitive than TP antibody in early infection
- AGID with CF antigen: detects IgG; more sensitive than CF antibody
- ELISA for IgM: ~15% false positives; may cross react with blastomycosis
- ELISA for IgG: similar to CF and AGID/CF; may cross-react with blastomycosis

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Confirm diagnosis with Cytologie or histopathologic analysis of specimens if appropriate samples can be obtained.

IMPORTANT INTERSPECIES DIFFERENCES: Both CF and TP antibodies may persist in cats for long periods of time (years), even with therapy.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE

- False-negative CF antibody test in dogs may be due to interference from anti-complement factors in 15%-25% of normal dog sera.
- Cross-reactivity with blastomycosis possible in ELISA tests

SPECIMEN: Serum, single sample or paired samples obtained 4-6 weeks apart. Refrigerate.

RELATIVE COST: $$

PEARLS

Specimens from patients thought to have coccidioidomycosis should not be cultured without biosafety precautions; mycelial phase is highly infectious to humans by inhalation.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Cobalamin

DEFINITION

Water-soluble vitamin with a porphyrin ring; side chains bound to cobalt

SYNONYMS

Cyanocobalamin, vitamin B^{12}

TYPICAL NORMAL RANGE

- Dog serum: 238-733 ng/L
- Cat serum: 290-1500 ng/L
- Conversion: 1 pg/mL = 0.1 ng/dL; 1 pg/mL × 0.7378 = pmol/L

PHYSIOLOGY

Source is dietary. Released from food during gastric digestion and bound to R-proteins (nonspecific binding proteins) found in salivary and gastric secretions. Transferred to intrinsic factor (IF) in alkaline intestinal pH. IF enhances ileal cobalamin absorption. Cobalamin is stored in the liver. It is a required cofactor in metabolic pathways involving folate and formation of neuronal lipids.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Uncommon; dietary supplementation and hepatocellular necrosis (theoretical)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Review oral or parenteral supplements, sampling and testing protocol.

CAUSES OF ABNORMALLY LOW LEVELS: Decreased ileal absorption due to inflammation, villous atrophy or other mucosal disease; decreased IF production due to gastric disease in dogs and exocrine pancreatic insufficiency in dogs and cats; congenital insufficiency of IF in giant Schnauzers, border collies; malabsorption; bacterial overgrowth in proximal small intestine (enteric bacteria bind cobalamin).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Assess for inflammatory bowel disease (IBD): history, physical exam, serial fecal flotations, and possibly empirical parasiticide treatment and/or abdominal ultrasonography to rule out other causes; biopsy of small intestine ultimately needed for histologic demonstration of IBD). Assess for pancreatic exocrine insufficiency (serum trypsin like immunoreactivity).

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Oral or parenteral supplements increase concentration.

LAB ARTIFACTS THAT MAY INTERFERE

- Falsely increased by hemolysis or heparin
- Falsely decreased by excessive light exposure

SPECIMEN: Serum; separate from clot as soon as possible; store at 8°C.

RELATIVE COST: $$

PEARLS

- Assays for human specimens are unreliable in dogs and cats because of species-specific carrier.
- Assessment of cobalamin (and folate) levels is no longer considered reliable for the diagnosis of antibiotic-responsive enteritis/small-intestinal bacterial overgrowth.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$$: $21-75
$$$: $76-150
$$$$: >$150

Coagulation Profile

DEFINITION

Series of tests designed to assess the coagulation pathway and localize specific hemostatic defects causing coagulopathies. Consists of partial thromboplastin time (PT), activated partial thromboplastin time (APTT), and activated clotting time (ACT).

TYPICAL NORMAL RANGE

- ACT: 60-100 seconds (dogs) and <65 seconds (cats)
- APTT: 8.6-12.9 seconds (dogs) and 13.7-30.2 seconds (cats)
- PT: 5.1-7.9 seconds (dogs) and 8.4-10.8 seconds (cats)
- Reference values are laboratory-and instrument-specific; the ranges listed above are approximate.
- Neonates (<24 hours old) may normally have greater values than adults.

PHYSIOLOGY

Coagulation factors are a cascade of enzymes that require sequential activation. They stabilize the platelet plug through the conversion of fibrinogen to fibrin, forming a fibrin platelet plug that resists plasmin degradation. The coagulation cascade is divided into intrinsic, extrinsic, and common pathways. Pathways of activation are through tissue thromboplastin (extrinsic; released from cell surface membranes of injured tissues) and by contact activation of basement membranes and negatively charged surfaces of collagen or platelets (intrinsic; e.g., contact with a vessel denuded of endothelium). The division is imperfect because the tissue factor/factor Vlla complex is a potent activator of both factors IX and X.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Prolonged PT: extrinsic (factor Vll) or common coagulation (X, V, ll, thrombin, and fibrinogen) pathway defect; most sensitive test of warfarin-type toxicity; increased with a decrease/absence of factors of extrinsic or common pathway, disseminated intravascular coagulation (DIC), FDPs, antiphospholipid antibodies, antibodies to coagulation factors, acquired vitamin K deficiency, biliary obstruction, liver failure
- Prolonged APTT: defects in intrinsic pathway (factors Xll, Xl, IX, Vlll); hemophilia, von Willebrand disease, DIC, vitamin K antagonism or absence, bile insufficiency or liver failure
- Prolonged ACT: any disorder that sufficiently increases PT, aPTT, or both (common pathway) can increase ACT.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Platelet count, buccal mucosal bleeding time, fibrin degradation products, specific factor analysis

CAUSES OF ABNORMALLY LOW LEVELS: Coagulation times shorter than reference range are uncommon and unlikely associated with clinical disease.

DRUG EFFECTS ON LEVELS: Increased: warfarin, heparin therapy

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Increase: inadequately filled tubes, causing specimen dilution by anticoagulant

SPECIMEN: Citrated plasma (blue-top tube) for most tests. Diatomaceous earth (gray-top tube) for ACT. Fill tubes completely. Refrigerate, send to lab on ice.

RELATIVE COST: $$

PEARLS

- ACT is insensitive except in cases of severe coagulopathy (e.g., severe warfarin intoxication); it is an immediate point-of-care test that should always be followed up with PT and APTT assessments.
- Low PT, APTT, ACT values do not indicate a procoagulant or thrombogenic state.

Cholesterol

DEFINITION

A lipid that is found only in animal tissues. The test measures circulating blood (serum) levels.

Hyperlipidemia is a term that groups hypercholesterolemia and hypertriglyceridemia.

TYPICAL NORMAL RANGE

Dogs: 112-328 mg/dL. Cats: 82-218 mg/dL.

PHYSIOLOGY

Synthesized by the liver or absorbed in intestines from dietary sources. Cholesterol is essential to life as a major component of cell membranes and precursor for synthesis of steroid hormones and bile acids. The liver is the major site of cholesterol synthesis, excretion, and catabolism. Cholesterol and other lipids are insoluble in water. They are transported in the blood attached to apoproteins. Lipid-apoprotein complexes are called *lipoproteins.* They contain variable proportions of triglycerides, cholesterol, cholesterol esters, and phospholipid. In laboratory analysis, lipoproteins can be separated by ultracentrifugation into chylomicra, high-density lipoproteins (HDL), intermediate-density lipoproteins, low-density lipoproteins (LDL), and very low-density lipoproteins (VLDL), but the clinical importance of lipoprotein profiling in small-animal medicine is minimal compared to human medicine.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Primary hyperlipidemia: idiopathic in schnauzer dogs and rarely in other breeds; hypercholesterolemia of Briard dogs, Doberman pinschers, and rottweilers; familial hyperchylomicronemia of cats
- Secondary hyperlipidemia: postprandial (most common), hypothyroidism, diabetes mellitus, liver disease, hyperadrenocorticism, pancreatitis in dogs and cats, nephrotic syndrome, high fat diet

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Ensure that blood sample was drawn after >= 12-hour fast.
- Assess for causes of secondary hyperlipidemia (endocrine or metabolic disease). If no cause is identified, consider primary hyperlipidemia.

CAUSES OF ABNORMALLY LOW LEVELS: Chronic liver disease, starvation NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate for chronic liver disease. Rule out starvation. IMPORTANT INTERSPECIES DIFFERENCES: Dogs and cats are resistant to atherosclerosis, partly owing to the low concentration of very low-density lipoproteins in these species. High-density lipoproteins are the major lipoproteins in dogs and cats.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Increase: exogenous corticosteroids, phenytoin, methimazole
- Decrease: lipid-lowering diets, bile acid sequestrants, hepatic hydroxymethylglutaryl coenzyme A reductase inhibitors (statins), and dirlotapide lower cholesterol levels.

LAB ARTIFACTS THAT MAY INTERFERE: Increase: hemolysis

SPECIMEN

- A 10- to 12-hour fast is required. Postprandial hypercholesterolemia is mild, (usually associated with less than a twofold elevation).
- Serum (red-top tube), heparinized plasma (green-top tube), or EDTA plasma (lavender-top tube). Stable for 1 week at 2°C-8°C and 4 weeks at −20°C.

RELATIVE COST: $

PEARLS

The most common cause for hypercholesterolemia and no other CBC/serum biochemistry abnormalities in an adult fasted dog is hypothyroidism.

AUTHOR: RUANNA GOSSETT

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Chloride

DEFINITION

Major extracellular fluid (ECF) anion. Serum [Cl^-] essentially equals ECF [Cl^-]. Na^+, Hco^-3 influence CT concentrations.

TYPICAL NORMAL RANGE

Dogs: 105-115 mEq/L. Cats: 115-125 mEq/L; mEq/L = mmol/L.

PHYSIOLOGY

Major component of gastric juices; intestinal resorption coupled to Na^+ resorption, Hco^-3 secretion. Kidneys play major regulatory role: filtered by glomeruli, reabsorbed in renal tubules following Na^+ and water. Acid-base balance helps regulate serum levels: inverse relationship between serum [CT] and [Hco^-3]. Serum [Na^+] and [Cl^-] usually change proportionally, but if [Na^+] remains the same, increased [Cl^-] causes hyperchloremic acidosis; decrease causes hypochloremic alkalosis.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- With proportional [Na^+] increase: same as hypernatremia (see pp. 1517 and 559)
- Without proportional increase in [Na^+]: hyperchloremic acidosis caused by gastrointestinal (GI) or renal loss of Hco^-3, compensation for chronic respiratory alkalosis

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Evaluate in relation to serum [Na^+], acid-base balance.
- Calculate corrected serum [Cl^-] to determine if proportional change relative to [Na^+]: [Cl^-] (corrected) = [Cl^-] (measured) × ([Na^+] (mean normal)/[Na^+] (measured). Reference interval for conected [Cl^-] is the same as for [Cl^-].

CAUSES OF ABNORMALLY LOW LEVELS

- With proportional decrease in serum [Na^+]: same as hyponatremia (see pp. 1517 and 559)
- Without proportional decrease in [Na^+]: hypochloremic alkalosis caused by loss/sequestration of HC1 (gastric vomiting, upper GI obstruction), compensation for chronic respiratory acidosis

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW

- Evaluate in relation to [Na^+], acid-base balance.
- Calculate corrected serum [Cl^-] to determine if proportional change.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Decreased: thiazide or loop diuretics, $NaHco^-3$, Na penicillin (high doses)
- Increased: NH4Cl, KCl, parenteral saline administration, acetazolamide, spironolactone

LAB ARTIFACTS THAT MAY INTERFERE

- Marked hyperlipidemia/hypercholesterolemia or hyperproteinemia may decrease measured [Cl^-] by electrolyte exclusion effect (method dependent). Serum osmolality is normal.

- False increase: halides (bromide, iodide) are measured as Cl^-.

SPECIMEN: Serum (red-top tube) preferred; heparinized plasma (green-top tube) may be used.

RELATIVE COST: **$**

PEARLS

Changes independent of [Na^+] should be interpreted in conjunction with the anion gap. Mixed acid-base disorder is suggested by selective hypochloremia with high anion gap. Most reference laboratory methods are subject to electrolyte exclusion effect artifacts.

AUTHOR: ROBIN W. ALLISON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Cerebrospinal Fluid (CSF) Analysis

DEFINITION

Cerebrospinal fluid (CSF) is the aqueous fluid that surrounds the brain and spinal cord. *Pleocytosis* refers to an increased cellularity of the CSF sample. *Xanthochromia* refers to a yellow discoloration of the sample, typically from blood that has been present in the CSF for days or longer. *Albuminocytologic dissociation* refers to a disproportionate elevation of CSF protein compared to minimally elevated or normal CSF cell count.

TYPICAL NORMAL RANGE

Dogs: red blood cell (RBC), <30/µL; white blood cell (WBC), 0-4/µL; protein, <35 mg/dL. Cats: RBC, <30/µL; WBC, 0-4/µL; protein, <36 mg/dL.

PHYSIOLOGY

CSF provides support and protection for neural structures, serves as a transport medium for metabolic products to and from the brain, and provides a barrier to control the microenvironment of the nervous system. It is normally colorless, clear, and almost acellular. Cytocentrifugation is required for cytologic evaluation of cells to assess for inflammation, hemonhage, and infectious agents. Protein (primarily albumin) concentration is normally very low and requires microprotein assays for accurate assessment.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Increased protein: hemorrhage, increased permeability of the blood-CSF barrier, or localized production of immunoglobulins
- Increased protein with normal cellularity: trauma, degenerative disease, intervertebral disc disease, fibrocartilaginous embolism, cervical spondylomyelopathy, neoplasia, and viral infections
- Increased protein and cell counts: inflammation, infection (viral, fungal, protozoal, bacterial, rickettsial, parasitic), granulomatous meningoencephalitis, steroid responsive meningitis, neoplasia, immune mediated disease, vasculitis, and necrotizing meningoencephalitis. Neoplastic cells are rare in CSF; lymphoma is the most commonly identified neoplasm.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Correlate CSF findings with history, general physical, neurologic, and radiographic findings.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Glucocorticoids may reduce inflammatory cell counts after 24 hours of initiation of treatment, but glucocorticoid treatment may be initiated for patient stabilization if a high degree of steroid-responsive disease exists. Provided CSF tap occurs within 24 hours, accurate CSF cell counts are expected.

SAMPLE FOR COLLECTION AND ANY SPECIAL SPECIMEN HANDLING NOTES: Fluid in EDTA (lavender-top tube) or plain red-top tube; refrigerate. Analysis should be performed as soon as possible; cells deteriorate and lyse rapidly because of the low protein concentration. Addition of autologous serum to CSF (1:1) helps preserve cells for cytologic evaluation. However, a separate aliquot of CSF must be submitted for protein determination and cell counts.

RELATIVE COST: $$

Casts in Urine Sediment

DEFINITION

Coagulum of protein, cells, and/or cell debris forming in renal tubules and observed during microscopic examination of urine sediment

SYNONYM

Cylindruria

TYPICAL NORMAL RANGE

- Reported as negative or average number of casts per low-power microscope field with cast identification
- Up to two hyaline casts in moderately concentrated urine (e.g., specific gravity >1.020) is considered normal.

PHYSIOLOGY

Tamm Horsfall mucoprotein, secreted by renal tubular epithelium, combines with cells in renal tubules, forming cylindrical structures (casts) that are passed in urine. This type of cast is occasionally referred to as a *hyaline cast.* Some casts (granular, cellular, fatty) are composed of renal tubular epithelial cells or material that reflects their degeneration. Waxy casts are uncommon and indicative of chronic kidney disease. They form from granular casts that have degenerated. Others are composed of leukocytes or red blood cells, indicating inflammation or hemorrhage, respectively.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Toxic renal tubular injury, pyelonephritis

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate history for exposure to renal toxins; kidney biopsy if otherwise clinically indicated.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Gentamicin, amikacin, or other renal tubular toxins may cause granular, cellular, or fatty casts.

LAB ARTIFACTS THAT MAY INTERFERE: Delay in examination, excessive specimen mixing, and alkaline urine promote disintegration of casts and false-negative results.

SPECIMEN: Fresh urine (at least 10 ml) in clean, sterile container for urinalysis

RELATIVE COST: $ (reported as part of urinalysis)

PEARLS

Failure to see casts does not rule out renal tubular disease.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

Canine Parvovirus Tests

DEFINITION

Canine parvoviral enteritis is a highly infectious, often fatal disease of Canidae caused by a small, nonenveloped DNA virus, CPV-2, that requires rapidly dividing cells for replication.

SYNONYM

Parvo

TYPICAL NORMAL RANGE

Negative or positive with titer. Available tests: serum immunoglobulin (Ig)M and IgG immunofluorescent antibody (IFA), serum antibody by hemagglutination inhibition (HI), fecal antigen ELISA, and electron microscopy for identification of parvovirus particles.

PHYSIOLOGY

Following oronasal exposure to contaminated feces, CPV-2 replicates in oropharyngeal lymphoid tissue, mesenteric lymph nodes, and thymus. Viremia develops 1-5 days post exposure, without enteric shedding. Virus infects intestinal crypt epithelium, causing necrosis and clinical signs that may include lethargy, anorexia, vomiting, and bloody diarrhea. Virus spreads to lymphoid tissue and bone marrow, causing necrosis, subsequent leukopenia, and immunosuppression. Without treatment, secondary infection, gram-negative sepsis, and death may ensue.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS:

- Positive fecal ELISA test indicates viral antigen shedding due to natural infection or recent (5-12 days) vaccination with modified live vaccine.
- Positive serum IgM by IFA indicates recent exposure (natural or vaccination); usually positive by the time clinical signs are present.
- Positive IgG titer by IFA indicates exposure (natural or vaccination); can demonstrate rising titer in acute and 10- to 14-day convalescent serum samples, although urgency of initial diagnosis and treatment usually minimizes utility of this approach.
- Serum antibody titer by HI of >=1:64 indicates previous exposure (natural or vaccination) and protective antibody.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Positive fecal ELISA with appropriate clinical signs is generally diagnostic.

CAUSES OF ABNORMALLY LOW LEVELS

- Negative fecal ELISA indicates uninfected, very early postexposure, or end of viral shedding (virus seldom detectable 10-12 days after natural infection; 5-7 days of clinical signs).
- False-negative fecal ELISA may occur if the sample is obtained ex vivo (e.g., defecated stool) rather than being swabbed from the rectum.
- Negative serologic result indicates lack of exposure to virus and inadequate vaccine protection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If clinical signs and laboratory findings are consistent, but ELISA and IFA are negative, electron microscopic exam of feces can be performed. Additional tests—such as histopathologic evaluation of necropsy or biopsy tissue, or tissue culture—are possible but are invasive and potentially hazardous to the patient.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Severe hemolysis and lipemia interferes with IFA.

SPECIMEN: ELISA: fresh fecal swab stored for =48 hours (2°C-8°C). HI, IFA: serum (red-top tube), can be stored at 2°C-8°C up to 4 days.

RELATIVE COST: $$ (ELISA, IFA)

PEARLS

Some (but not all) ELISA tests for canine parvovirus will also detect feline parvovirus (panleukopenia) in the feces of cats that are shedding virus. False-negative results occur in early stages (prior to fecal shedding) or late stages (virus has become bound to specific antibody). Positive results due to vaccination may occur in cats for up to 2 weeks post inoculation.

AUTHOR: PATTY J. EWING

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Canine Distemper Testing

DEFINITION

Canine distemper is a multisystemic disease caused by canine distemper virus (CDV), a *Morbillivirus.*

TYPICAL NORMAL RANGE

Refer to laboratory conducting the tests. Available tests include serum immunofluorescent antibody test (IFA) titer, direct IFA, and viral neutralization assay.

PHYSIOLOGY

Distemper is spread via inhalation. Virus attaches to upper respiratory tract epithelium and replicates in macrophages. It spreads to regional lymph nodes and subsequently to bone marrow, thymus, spleen, mesenteric lymph nodes, and gastrointestinal tract. Then 8-14 days later, it spreads to epithelial tissue and the central nervous system, at which time it becomes most easily detected with clinical diagnostic tests. Young dogs may develop fever, leukopenia, respiratory signs, and demyelinating encephalomyelitis. Viral persistence is associated with chronic encephalitis.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS:

- Positive IFA immunoglobulin (Ig) M titer indicates recent exposure to vaccine or acute natural infection. IgM is detectable from 1-4 weeks post exposure. Positive IFA IgG titer indicates exposure to vaccine, presence of maternal antibody, or chronic natural infection. Serum viral neutralization assay is preferred for determining protective antibody response to vaccination.
- Positive direct IFA on Cytologie or histopathologic sample is diagnostic of infection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Direct immunofluorescence is used for detecting antigen in Cytologie smears of conjunctival, tonsillar, genital, or urinary bladder epithelium, or in white blood cells (buffy coat or bone marrow). Cerebrospinal fluid (CSF): increased protein and lymphocytic pleocytosis are common. Increased anti-CDV antibody in CSF not contaminated with serum is a sensitive and specific indicator of distemper encephalitis. PCR testing can be performed on CSF, ocular or nasal swab, whole blood, or tissue. Routine Cytologie evaluation of conjunctival smears for inclusions (routine staining, with or without IFA) is generally unrewarding.

CAUSES OF ABNORMALLY LOW LEVELS: Lack of protective vaccine antibody titer. Early infection with natural exposure.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If clinically indicated, evaluate IgM titer or repeat IgG titer in 2-3 weeks (expect increase if original low/absent level was due to early infection).

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Serologie test: 1 mL of serum (red-top tube). May store 4 days refrigerated or up to months frozen. IFA: conjunctival, urinary sediment, buffy coat smears air dried and preferably fixed in acetone for 5 minutes. Whole blood in EDTA (lavender-top tube) stored for no more than 48 hours refrigerated may be used in place of buffy coat smear. PCR: Minimum 0.5 mL of CSF or whole blood in EDTA (lavender-top tube).

RELATIVE COST: $$ (IFA, PCR)

PEARLS

- Serologie testing is the most sensitive and specific test in the live patient: IgM titers rise early in infection and, barring a recent history of vaccination, are specific to infection.
- Although studies suggest that currently available commercial vaccinations offer protection from disease for 3 years, determination of protective serum titer values has not been done. Immunologically competent dogs that have been vaccinated should be able to mount an anamnestic response that would prevent viral exposure leading to disease.

Calcium, Serum

DEFINITION

Essential mineral with important regulatory functions (cell signaling). Serum total calcium includes protein-bound (35%), anioncomplexed (10%), and ionized (55%) fractions.

TYPICAL NORMAL RANGE

- Total Ca^{2+}: 8-11.5 mg/dL (2-3.8 mmol/L)
- Ionized Ca^{2+}: 4.5-6 mg/dL (1.1-1.5 mmol/L)
- Unit conversion: mg/dL × 0.2495 = mmol/L; mEq/L × 0.5 = mmol/L

PHYSIOLOGY

Serum levels are regulated by parathyroid hormone (PTH) and calcitriol (vitamin D metabolite) affecting intestine, kidney, and bone. Dietary absorption depends on calcitriol. Glomeruli filter nonproteinbound Ca^{2+}; 98% reabsorbed by tubules. Low ionized Ca^{2+} stimulates PTH production, mobilizing Ca^{2+} from bone, increasing renal tubular resorption, stimulating calcitriol synthesis.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hypercalcemia of malignancy, hypoadrenocorticism, primary hyperparathyroidism, osteolysis, granulomatous conditions, hypervitaminosis D, renal failure, excess supplementation (rare from oral supplementation alone) NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Measure ionized Ca^{2+}. If ionized hypercalcemia, evaluate for neoplasia (including rectal palpation for anal sac neoplasm in adult dogs), exposure to oral vitamin D (rodenticides, supplements, ointments). Measure serum phosphorus, parathormonerelated peptide, PTH.

CAUSES OF ABNORMALLY LOW LEVELS: Hypoalbuminemia, renal failure, pancreatitis, puerperal tetany, hypoparathyroidism, severe tissue trauma, ethylene glycol intoxication, exocrine pancreatic insufficiency, malabsorption syndromes, hypomagnesemia, phosphate enema, acute tumor lysis syndrome

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Measure ionized Ca^{2+}, serum albumin levels. Evaluate for renal failure, gastrointestinal diseases. Measure serum PTH, magnesium levels.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Increase: thiazide diuretics, supplements containing vitamin D, rodenticides, excess oral phosphate binders
- Decrease: furosemide, glucocorticoids, phosphate enemas, Ca^{2+}-binding anticoagulants

LAB ARTIFACTS THAT MAY INTERFERE

- Decreased: Ca^{2+}-binding anticoagulants (EDTA, citrate, oxalate; artifactual/in vitro decrease)
- Increased: lipemia, hemolysis
- Decreased ionized Ca^{2+}: aerobic sample handling, overheparinization. Increased ionized Ca^{2+}: prolonged exposure to erythrocytes, serum separator tubes.

SPECIMEN

- Serum (red-top tube) preferred; heparinized plasma (green-top tube) may be used.
- Ionized Ca^{2+}: anaerobic handling necessary. Harvest serum or plasma within 1 hour. Stable in heparinized blood for 9 hours (4○C), serum or plasma for 1 week (4○C). Do not use serum separator tubes. Heparin concentration should not exceed 15 U/mL of blood.

RELATIVE COST: $ (serum calcium, single test); $$ (as part of serum electrolyte profile); $$ (ionized calcium)

PEARLS

- Use of correction formula in hypoalbuminemic dogs no longer recommended because of inaccuracy; measure ionized Ca^{2+} instead.
- Acidosis increases ionized serum Ca^{2+} concentration; alkalosis decreases it. Acid-base status affects signs associated with hypocalcemia.

Digoxin, Serum Level

DEFINITION

Digoxin, a drug in the cardiac glycoside class, has complex cardiovascular actions. It is used in the management of supra-ventricular arrhythmias (e.g., atrial fibrillation) and certain cases of congestive heart failure.

SYNONYM

Digitalis

TYPICAL RANGE

In humans, serum level >2 ng/mL is suggestive of toxicosis; therapeutic levels range from 0.5-1.5 ng/dL or 0.8-2 ng/mL (see below). In veterinary medicine, the same values are used, but no clinical trial has ever proven that “therapeutic levels” are beneficial over empirical dosing.

PHYSIOLOGY

Digoxin is rapidly absorbed as an oral elixir (serum levels detectable in 45 minutes; bioavailability 100%) and slightly less so in tablet form (hours; bioavailability 80%). Intravenous administration is no longer recommended. Regardless of administration route, excretion is renal. The linear dose/response curve of digoxin suggests that serum levels previously considered “subtherapeutic,” which are associated with fewer side effects, may provide beneficial effects. Revised therapeutic serum levels of 0.5-1.5 ng/mL have been suggested in human cardiology. The primary mechanism of action of cardiac glycosides is interference with Na/K-ATPase, with resultant increase in intracellular calcium. Adverse effects, including severe lethargy, anorexia, and arrhythmias such as atrioventricular block due to progressive interference with electrical conduction and increase in vagal tone, may occur.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Large body size, obesity (digoxin is not distributed in fat), and renal failure warrant lowering digoxin dose; otherwise, high serum levels and toxicity may occur. Dosing based on body surface area has been recommended. The half-life of cardiac glycosides is highly variable among patients.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Adjust dose, depending on suspected cause.

CAUSES OF ABNORMALLY LOW LEVELS: A rninimum serum concentration for clinical effect has not been established for dogs and cats. Hypokalemia potentiates digitalis-induced anhythmias. If toxicosis is evident but the serum concentration is not excessive, serum potassium should be evaluated.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Measure serum potassium.

IMPORTANT INTERSPECIES DIFFERENCES: Enterohepatic recycling of cardiac glycosides is very important in humans, less so in dogs.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVEL: Drugs inducing hepatic metabolism (e.g., phenytoin, rifampin) accelerate digitoxin metabolism, resulting in higher than expected digoxin serum levels. Quinidine elevates serum concentrations by decreasing clearance and volume of distribution. Other drugs that may increase serum digoxin concentrations include verapamil, diltiazem, amiodarone, flecainide, and spironolactone.

SAMPLE FOR COLLECTION AND ANY SPECIAL SPECIMEN HANDLING NOTES: Serum (red-top tube); store at 2°C-8°C.

RELATIVE COST: $$

PEARLS

Serum digoxin levels may be used for confirming ingestion of plants (milkweed, foxglove, oleander, dogbane) that contain cardiac glycosides.

AUTHOR: SHERRY J. MORGAN

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150

D-Dimer

DEFINITION

Protein fragments that are formed from the degradation of cross-linked fibrin. They are specific for fibrin degradation products (fibrinolysis). This is a specific method of detecting active coagulation and fibrinolysis.

TYPICAL NORMAL RANGE

0.02-0.28 mg/mL

PHYSIOLOGY

D-dimers form when plasmin digests cross-linked fibrin; the test is more specific than fibrinogen degradation products (FDPs) and indicates both thrombin and plasmin generation.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Increased fibrinolysis or decreased clearance of fibrin degradation products by the liver or mononuclear phagocytic system; specific causes include local and disseminated intravascular coagulation, internal hemorrhage, liver disease, chronic renal failure.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluation of the coagulation system: platelet count, antithrombin III, activated coagulation time (ACT) or activated partial thromboplastin time (APTT), prothrombin time (PT), thrombin time (TT), fibrinogen. If clinical suspicion of pulmonary thromboembolism exists, further evaluation (ultrasound, thoracic radiography and arterial blood gas measurement; possibly angiography) may be indicated.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Citrate (blue top) tubes are used; it is important that traumatic venipuncture be avoided to prevent activation of platelets and the coagulation systems; blood and anticoagulant should be mixed thoroughly immediately after collection. Tubes should be completely filled.

RELATIVE COST: $$

PEARLS

Assays for D-dimers are still being evaluated for their usefulness in veterinary medicine. Quantitive assays are replacing semiquantitative assays, allowing precise monitoring and early detection of thrombosis.

Ethylene Glycol Bench Test

DEFINITION

Test kit for diagnosing ethylene glycol (antifreeze) poisoning

SYNONYM

EGT kit (manufactured by PRN Pharmacal)

TYPICAL NORMAL RANGE

Qualitative test reported as positive or negative

PHYSIOLOGY

Intoxication occurs from consumption of antifreeze or “snow globe” liquid. Following ingestion, ethylene glycol is metabolized to toxic metabolites via the action of alcohol dehydrogenase. The glycolic acid metabolite causes severe high-anion-gap metabolic acidosis. The oxalic acid metabolite combines with serum calcium, forming calcium oxalate crystals that deposit in renal tubules. Severe renal tubular damage can lead to anuric or oliguric renal failure. The test kit detects only ethylene glycol, not the metabolites.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Positive result indicates recent consumption (usually within 12 hours) of ethylene glycol.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Determination of anion and osmolal gap (increased in ethylene glycol poisoning). Electrolyte panel and blood gas determination to evaluate for metabolic acidosis and electrolyte abnormalities (hypochloremia/hyperkalemia). Renal profile and urinalysis to evaluate for renal failure and presence of calcium oxalate monohydrate crystals. When crystalluria and/or systemic abnormalities (azotemia, hyperkalemia) is/are present, extensive and irreversible renal damage has usually occurred. Therefore, a positive EGT test result with normal urinalysis and serum biochemistry panel are the most promising for successful treatment and prognosis.

CAUSES OF ABNORMALLY LOW LEVELS: Ethylene glycol is rapidly metabolized and excreted. Test results are negative if >12-18 hours since consumption.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If historic evidence suggests toxicosis is suspected, evaluate renal function, electrolyte status. Determine serum levels of metabolite (glycolic acid).

IMPORTANT INTERSPECIES DIFFERENCES: The bench test is approved for use in dogs only.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Positive: propylene glycol or glycerol

SPECIMEN: 1 mL EDTA-anticoagulated whole blood (lavender-top tube). Sample is stable for 48 hours at 0○C-4○C, but it should be brought to laboratory and run as a stat test because of clinical urgency.

RELATIVE COST: $$$

PEARLS

- If antifreeze toxicity is suspected but it has been >48 hours since ingestion, blood urea nitrogen and creatinine are increased, and patients are acidotic with an increased anion gap.
- Local human hospitals may also be able to perform the test. Because the test evaluates only the concentration of ethylene glycol, a human assay can be used for animals.

AUTHOR: SHERRY J. MORGAN

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Estradiol/Estrogen, Serum Levels

DEFINITION

Hormone synthesized and secreted by developing ovarian follicles

TYPICAL NORMAL RANGE

Baseline estradiol/estrogen in canine anestrus is 5-15 pg/mL.

PHYSIOLOGY

- Dogs: Proestrus is under the influence of progressively increasing circulating concentrations of estradiol, which is produced by the developing ovarian follicles. A rising estradiol level correlates with development of marked changes in the vaginal mucosa, vulva, and uterus. Serum estradiol concentrations start to increase just before proestrus becomes clinically detectable. Estradiol concentrations above 25 pg/mL are typical of early proestrus, and concentrations greater than 60-70 pg/dL are typical of late proestrus. Peak estradiol serum concentrations are reached 24-48 hours prior to the end of proestrus before standing heat (estrus). Male dogs with Sertoli cell tumors and male feminization syndrome have increased production of estrogens by testicular tumor cells, or increased androgenous hormone conversion to estrogens by metabolic tissues (liver, neural tissue, etc.) or testicular cells, or normal estrogen levels are concurrent with decreased androgen levels. In male dogs with Sertoli cell tumors, estrogens are typically not measured. Typically, the feminizing syndrome is recognized through overt clinical signs, and the underlying tumor is surgically removed without serologic testing. • Cats: Anestrus and interestrus periods typically are associated with estradiol serum concentrations <12-15 pg/mL. Estradiol concentrations >20 pg/mL typically accompany follicular activity (follicular phase of the feline cycle averages 7.0-7.7 days, depending on whether coitus is experienced and whether ovulation is induced). Day 1 of the follicular phase of estrus typically is associated with an estradiol concentration ≈25 pg/mL; at day 3 it is ≈45 pg/mL, at day 5 it is ≈50 pg/mL or above, at day 7 it is ≈20-25 pg/mL, and by day 8 it has returned to ≈10 pg/mL.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: In intact female dogs, high levels indicate mid- to late proestrus. In intact female cats, high levels indicate the mid-follicular phase of the cycle. In ovariectomized female cats, high levels (above baseline) suggest incomplete excision of ovarian tissue.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: In ovariectomized cats: administer hCG to cause luteolysis of follicles, check for increasing progesterone. If progesterone increases above 2.5 ng/mL 5-7 days later, exploratory surgery is recommended (persistent ovarian tissue). This test is not used in dogs.

CAUSES OF ABNORMALLY LOW LEVELS

- Ovariectomy
- Basal (low) concentrations of estradiol occur in anestrus and diestrus.
- Important interspecies differences: cats are induced ovulators and are seasonally polyestrous; dogs are spontaneous ovulators and have a typical interestrus interval of 7-12 months.

SPECIMEN

LAB ARTIFACTS THAT MAY INTERFERE: Increased: hemolyzed or lipemic specimens

SAMPLE FOR COLLECTION AND SPECIAL SPECIMEN HANDLING NOTES: Serum (red-top tube), 2 mL minimum. Do not use serum-separator tubes.

RELATIVE COST: $$

PEARLS

Measurement of luteinizing hormone is the preferred test for assessing for ovarian remnants and evaluating spay status.

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Erythropoietin

DEFINITION

Renal hormone that stimulates erythropoiesis in the bone marrow in response to tissue hypoxia

SYNONYM

EPO

TYPICAL NORMAL RANGE

Radioimmunoassay method: dogs, 8.4-28 mU/mL; cats, 10-30 mU/mL

PHYSIOLOGY

EPO is produced primarily by the kidney (sole source in dogs), with small amounts produced by the liver in some species. Tissue hypoxia stimulates EPO production. EPO induces differentiation of erythroid progenitor cells to rubriblasts, stimulates mitosis of erythroid cells, reduces maturation time, and accelerates release of reticulocytes from the bone marrow into circulation.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: hypoxemia-inducing cardiovascular or pulmonary disease; hypoxemia due to high altitude; inappropriate EPO production due to EPO-producing neoplasia, renal cyst, pyelonephritis, or hydronephrosis; hyperthyroidism; EPO therapy. Regardless of cause, secondary polycythemia is the result.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Confirm polycythemia. If polycythemia is absent, EPO result may be spurious or represent early disease. Serial monitoring of hematocrit is warranted in these cases.
- Identify cause of any hypoxemia-inducing condition: thoracic radiographs, arterial blood gas measurement, possibly echocardiography.
- Evaluate for neoplasia, renal disease, and endocrinopathy.

CAUSES OF ABNORMALLY LOW LEVELS: Decreased EPO in the presence of polycythemia and normal Po2 suggests polycythemia vera; chronic renal failure (anemia concurrent).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Assess renal structure and function.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Increased: hemolyzed or lipemic specimens

SPECIMEN: Serum (red-top tube) or heparinized plasma (green-top tube); separate serum or plasma from erythrocytes, freeze, and transport frozen. Do not use serum-separator tubes.

RELATIVE COST: $$$

PEARLS

Measurement of serum EPO levels is an appropriate test in patients with repeat-able absolute polycythemia without hypoxemia.

AUTHOR: FIDELIA R. FERNANDEZ

Pricing Information

$: <$20
$$: $21-75

$$$: $76-150
$$$$: >$150

Eosinophils

DEFINITION

Granulocytic leukocyte with eosinophilic granules in cytoplasm and a segmented nucleus

TYPICAL NORMAL RANGE

Dogs: 0.1-1.3 × 10^3 eosinophils/µL. Cats: 0-1.5 × 10^3 eosinophils/µL.

PHYSIOLOGY

Eosinophilic precursors develop in the marrow under influence of interleukin 5 (IL-5). Mature eosinophils are released into blood to circulate for a few hours and then enter tissue. Eosinophils contain major basic protein, which is important in attacking helminthic parasites. Eosinophils can both promote and inhibit hypersensitivity reactions. Eosinophilic inflammation occurs more often in cutaneous, respiratory, and intestinal tissues.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Parasitism (e.g., dirofilariasis, larval migration in tissues); allergic reactions (e.g., flea bite hypersensitivity); idiopathic eosinophilic inflammation (e.g., hypereosinophilic syndrome in cats, eosinophilic bronchopneumopathy in dogs); hypoadrenocorticism ("relaxed" leukogram, which is the unexpected absence of stress leukogram with eosinopenia in an ill patient); mast cell neoplasm; eosinophilic leukemia (rare)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Use history and physical exam findings to assess for causes listed.

CAUSES OF ABNORMALLY LOW LEVELS: Stress leukogram, from endogenous or exogenous glucocorticoids; acute inflammation

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Low values are rarely of clinical significance.

IMPORTANT INTERSPECIES DIFFERENCES

- In canine eosinophils, the granules are round and can vary considerably in size and number. In some dogs (especially greyhounds), clear vacuoles appear instead of eosinophilic granules.
- Feline eosinophils have distinctive rod-shaped granules.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Glucocorticoids cause increased sequestration of eosinophils in tissues, with development of eosinopenia.

SPECIMEN: EDTA whole blood (lavender-top tube) and freshly prepared blood smear for lab to stain

RELATIVE COST: $$ (reported as part of CBC)

AUTHOR: STEPHEN D. GAUNT

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Ehrlichia Serology

DEFINITION

Detection of serum antibodies directed against *Ehrlichia* spp. (most commonly *E. canis)*

TYPICAL NORMAL RANGE

Reporting differs among reference laboratories. Consult with laboratories for proper interpretation of values.

PHYSIOLOGY

Ehrlichia spp. are rickettsial agents that infect a wide range of host species. Numerous species of *Ehrlichia* have been shown to infect dogs. *E. canis* produces an acute disease (canine monocytic ehrlichiosis) from which animals recover, but which typically remains subclinical and may later produce more severe disease. Early (7 days post infection) titers are due to immunoglobulin (Ig)A and IgM; 3 weeks postinfection titers are mostly due to IgG. Most laboratories measure IgG.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- The presence of antibodies directed against *E. canis* indicates exposure to *E. canis* or related organisms. Some antigens of *E. canis, E. ewingii,* and *E. chaffeensis* are cross-reactive, whereas others are not.
- A positive titer indicates only exposure and does not prove that current clinical signs are due to active infection.
- *E. canis* can cause a persistent subclinical infection, so a dog with a positive titer is likely to still be infected unless treated with appropriate antimicrobial therapy.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate whether the patient's current signs are consistent with ehrlichiosis, and consider treatment with appropriate antimicrobial therapy. A positive test for ehrlichial DNA via PCR supports active infection and can determine the specific species of *Ehrlichia* involved.

CAUSES OF ABNORMALLY LOW LEVELS: Infection with different *Ehrlichia* spp.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If a clinical suspicion for ehrlichiosis persists despite a negative titer to *E. canis,* titers to other ehrlichial species (e.g., *Anaplasma phagocytophilum,* formerly *E. equi)* should be performed, because cross-reactivity does not occur reliably.

SPECIMEN AND PROCESSING CONSIDERATIONS

IMPORTANT INTERSPECIES DIFFERENCES: Serologic tests often use species-specific reagents, and *Ehrlichia* serologic testing is most often performed on dogs. Check with lab as to appropriateness if testing cats.

SPECIMEN: Serum (red-top)

RELATIVE COST: $$

PEARLS

- Some dogs maintain persistent titers for years despite appropriate therapy and apparent resolution of disease.
- An in-clinic, ELISA-based serology test (SNAP4Dx, IDEXX Labs) for detecting *E. canis* antibody appears to have high specificity when compared with immunofluorescent assay, but it may not detect low titers.
- Dogs may have negative titers if early in infection or if infected with other ehrlichial species other than those being evaluated.
- *Ehrlichia* serologic testing is much more sensitive (i.e., better screening test) than evaluating a blood smear for the presence of ehrlichial inclusions in leukocytes.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: JAMES H. MEINKOTH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Eccentrocyte

DEFINITION

Erythrocyte damaged by oxidants. Characterized by focal area of fused membranes with eccentric displacement of hemoglobinized cytosol and loss of any central pallor. The collapsed area with fused membranes appears as a clear area at periphery of erythrocyte which is outlined by a barely visible cell membrane.

SYNONYMS

Bite cell, hemighost

TYPICAL NORMAL RANGE

Absent in health

PHYSIOLOGY

During oxidative damage, hemichromes (oxidized forms of hemoglobin) bind to the band 3 protein of the membrane cytoskeleton. This creates cross-linking and fusion of the erythrocyte cytoskeleton and alters the membrane, with externalizing of antigenic proteins and attachment of autoantibodies. Hemichromes can also precipitate to form Heinz bodies.

CLINICAL APPLICATION

CAUSES OF ABNORMALLY HIGH LEVELS

- Oxidative damage to erythrocyte from toxins such as acetaminophen, onions, and benzocaine in dogs and cats, zinc and garlic in dogs. Heinz bodies may also be seen in conjunction with eccentrocytes.
- Also reported in dogs with vitamin K antagonist intoxication, T-cell lymphoma, and diabetic ketoacidosis
- Decreased antioxidant activity of erythrocytes (rare): congenital deficiency of glucose-6-phosphate dehydrogenase, with decreased production of reduced nicotinamide adenine dinucleotide phosphate (NADPH) in erythrocytes NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate history for source of oxidative damage to erythrocytes.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS: Associated with propofol anesthesia in dogs

SPECIMEN: EDTA whole blood and freshly prepared blood smear for lab to stain

RELATIVE COST: $$ (reported as part of CBC)

AUTHOR: STEPHEN D. GAUNT

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Fungal Culture

DEFINITION

Analysis of tissue or exudate for fungal organisms

TYPICAL NORMAL RANGE

Reported as negative or degree (slight, moderate, heavy) of growth of specific pathogens

PHYSIOLOGY

Laboratory conditions enhance growth of pathogens and allow isolation of fungal colonies and their identification by morphologic features and chemical tests.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Fungal infection. Common fungal infections include dermatophytosis, aspergillosis, cryptococcosis, blastomycosis, histoplasmosis, and coccidioidomycosis. Saprophytes may cause skin lesions or systemic disease in immunocompromised patients.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Culture is definitive. Used as a confirmatory test for dermatophytes. *Aspergillus* spp. may be cultured for specific identification if organisms are seen in cytologic or histologic specimens. Dimorphic fungi are typically not cultured owing to health risk for laboratory personnel; instead, serologic tests and/or cytologic demonstration of organisms are confirmatory.

IMPORTANT INTERSPECIES DIFFERENCES: Dermatophytes may cause pseudomycetoma (deep granulomatous or pyogranulomatous lesions) in cats, especially Persian cats.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Corticosteroids and other immunosuppressive therapies may decrease patient resistance, enhancing organism growth.

LAB ARTIFACTS THAT MAY INTERFERE: False negative: improper media or growth conditions

SPECIMEN

- Dermatophytes: hair plucked from affected areas should be submitted in dermatophyte test media or sterile dry containers.
- Tissue or exudate: sterile, dry container

RELATIVE COST: $$

PEARLS

Do not submit specimens for culture if cryptococcosis, blastomycosis, histoplasmosis, or coccidiomycosis is suspected. In culture, these organisms are health hazards to laboratory personnel (zoonosis via inhalation or accidental inoculation), and serologic tests coupled with cytologic or histologic lesions are appropriate for diagnosis instead.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Fructosamine

DEFINITION

Fructosamine is an amino sugar formed by the reduction of osazone glucosamine. It is dependent on the concentration of glucose-bound serum proteins. The test is used for assessing the average serum glucose concentration over the preceding 2-3 weeks.

TYPICAL NORMAL RANGE

Range varies with instrument. Heska SpotChem: roughly <200 mmol/L in healthy dogs and cats.

PHYSIOLOGY

Persistent hyperglycemia results in irreversible binding of glucose to reactive molecules such as serum proteins, erythrocyte membranes, and other cell membranes. Transient hyperglycemia may result in noncovalent reversible binding of glucose to reactive molecules. Therefore, this test may help differentiate transient stress-induced hyperglycemia from diabetes mellitus in cats.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Persistent hyperglycemia.

- With Heska SpotChem: Values of 200-450 mmol/L in diabetic dogs and 165-350 mmol/L in diabetic cats are considered indicators of reasonably good glycemic control. If patients are near the upper end of these intervals or have signs of poor regulation (polyuria, glucosuria, polyphagia, weight loss), management should be reevaluated.
- Patients with values >450 mmol/L (dogs) and >350 (cats) have suboptimal to poor glycemic control.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Review history and physical exam for findings indicative of diabetes mellitus. Check serum glucose level and urine for the presence of glucose +/− ketones.

CAUSES OF ABNORMALLY LOW LEVELS

- Animals with hypoproteinemia and hypoalbuminemia may have lowered fructosamine. If hypoalbuminemia is concurrent with diabetes mellitus, the fructosamine level may appear falsely low.
- Hyperthyroid cats have lower fructosamine than healthy cats because of accelerated protein (albumin) turnover.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Check serum albumin and globulin concentrations.

In cats >6 years old, test for hyperthyroidism.

IMPORTANT INTERSPECIES DIFFERENCES: Glucose has a higher affinity for albumin in dogs and globulins in cats, and conection methods are used by reference laboratories.

SPECIMEN AND PROCESSING CONSIDERATIONS SPECIMEN: Serum (red-top tube) or heparinized plasma (green-top tube)

RELATIVE COST: $$

PEARLS

Fructosamine is not typically used for assessing persistent hypoglycemia, as would occur in patients with insulinoma.

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Folate

DEFINITION

The anionic form of folic acid. Part of B-vitamin complex.

SYNONYM

Folic acid

TYPICAL NORMAL RANGE

Dogs: 6.5-11.5 mg/L. Cats: 9.7-21.6 mg/L.

PHYSIOLOGY

Primary source is diet; also produced by enteric bacteria. Ingested folate is released from food and hydrolyzed in proximal small intestine. Dietary and bacterial-origin folate is taken up by intestinal epithelium, metabolized, and systemically absorbed (blood).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Intestinal bacterial overgrowth, exocrine pancreatic insufficiency (EPI), excessive gastric acid production, over-supplementation

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Test for bacterial overgrowth, EPI. Evaluate diet.

CAUSES OF ABNORMALLY LOW LEVELS: Small-intestinal mucosal disease, dietary deficiency, medication (sulfasalazine, phenytoin, antibiotics that deplete gastrointestinal flora, causing decreased folate production), extensive intestinal neoplasia

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate diet, medication history. Assess for intestinal mucosal disease (endoscopy or surgery). IMPORTANT INTERSPECIES DIFFERENCES: Different reference ranges for dogs and cats. High serum concentration in cats is of no known clinical significance. Cobalamin deficiency has been associated with decreased folate utilization and resultant increased folate values in cats. Increased serum folate (due to bacterial overgrowth) associated with low immunoglobulin A in German shepherd dogs.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Decrease: associated with sulfasalazine, phenytoin, and antibiotics that disturb intestinal flora.

LAB ARTIFACTS THAT MAY INTERFERE: False increase: hemolyzed specimens (released from red blood cells). SPECIMEN: Nonhemolyzed serum (red-top tube; separate serum from clot immediately, and place in fresh red-top tube for submission). Stable at 4°C for 1 day, −20°C for 6-8 weeks. Avoid repeated freezing, thawing.

RELATIVE COST: $$

PEARLS

- Folate should be evaluated in conjunction with cobalamin and trypsinlike immunoreactivity for best interpretation. Low cobalamin concentration may result in a functional folate deficiency, with measured folate concentration within the reference interval.
- Maternal folate deficiency is associated with congenital malformations (neural tube and conotruncal cardiac defects) in humans, but there is no evidence of a similar problem in dogs and cats.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20

$$: $21-75
$$$: $76-150
$$$$: >$150

Fluid Analysis

DEFINITION

Biochemical and Cytologie analysis of fluid aspirated from body cavities (abdominal, pleural, pericardial) or joints (see p. 1519). Typically includes assessment of color, turbidity, viscosity, protein concentration, total cell counts (may include differential), and Cytologie description.

TYPICAL NORMAL RANGE

Body cavity effusions are classified as: *Conversion: for mg/mL, multiply g/dL by 10.

	Protein (g/dL)*	Cell Count (Cells/µL)
Transudate	<2.5	<1500
Modified transudate	2.5-7.5	1000-7000
Exudate	>7.5	>7000

PHYSIOLOGY

- Transudates: decreased plasma osmotic pressure, usually due to hypoalbuminemia, results in fluid movement from vasculature to body cavities. Causes include protein-losing enteropathy and nephropathy, severe chronic liver disease with decreased protein production.
- Modified transudate: results from increased hydrostatic pressure or increased vascular permeability; causes are numerous, including congestive heart failure, inflammation, and neoplasia.
- Exudate: due to inflammation with increased vascular permeability

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Altered plasma protein osmotic pressure, hypoproteinemia, vascular obstruction, inflammation, neoplasia

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assessment of history and physical examination findings in combination with serum biochemical changes and Cytologie appearance of fluid help determine if fluid accumulation is the result of metabolic, inflammatory, orneoplastic disease.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Peritoneal lavage, IV or subcutaneous fluid administration may alter protein concentration and cell counts. Corticosteroid administration may have adverse affect on cell morphology.

SPECIMEN

- Obtain specimens using sterile technique. Fill EDTA (lavender-top) tube to prevent clotting. A sterile tube (red top) or other container should be used for specimens to be cultured.
- Submission of direct or sediment smears prepared when the specimen is obtained is suggested to allow evaluation of cells before autolytic changes occur.

RELATIVE COST: $$

PEARLS

- Clear, colorless fluids are usually transudates; increasing turbidity is associated with increased protein concentration and/or cell counts and classified as modified transudates or exudates.
- Sediment smears should be prepared if low cellularity is suspected.
- Fluid analysis from cysts or abscesses is not diagnostically useful. Fluid from these sources should be submitted only for Cytologie analysis.

Fibrinogen

DEFINITION

A glycoprotein important in hemostasis; a positive acute-phase protein that increases due to inflammation or tissue injury; important in tissue repair

TYPICAL NORMAL RANGE

Dogs: 150-300 mg/dL; cats: 150-300 mg/dL

PHYSIOLOGY

Made in the liver; production is upregulated with inflammation or tissue damage (due to cytokines interleukin [IL]-1, IL-6, and tumor necrosis factor [TNF]). It is a nonenzymatic coagulation factor (factor I), cleaved (activated) by thrombin to form fibrin and promote stable clot formation.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Two major causes include dehydration (hemoconcentration) and increased production by the liver (positive acute-phase protein) in response to cytokines IL-1, IL-6, and TNF due to inflammation or tissue damage. Can also increase with physiologic stress (pregnancy).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Look for source of inflammation/tissue injury: review history and physical exam; CBC (determine if inflammatory leukogram is present), serum biochemistry profile; if hyperglobulinemia, serum protein electrophoresis is warranted to document a polyclonal gammopathy supportive of an inflammatory process.

CAUSES OF ABNORMALLY LOW LEVELS: Increased consumption in disseminated intravascular coagulation or increased fibrinogenolysis, decreased hepatic fibrinogen synthesis, inherited/congenital disorders (documented in bichon frise, Bernese mountain dogs, Lhasa apso, vizsla, and collie).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Full coagulation profile (activated partial thromboplastin time, prothrombin time, thrombin time, platelet count, and fibrinogen degradation products) to assess for disseminated intravascular coagulation. Serum biochemistry profile to evaluate hepatic parameters. Serum bile acids to evaluate hepatobiliary function.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Citrated plasma (blue-top tube). Centrifuge and remove plasma within 1 hour of collection and transfer to plain red-top tube. Label as plasma. Test as soon as possible. Stable at 2-8°C for 24 hours; freeze if there is a longer time interval before testing.

RELATIVE COST: $$

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Fibrin or Fibrinogen Degradation Products

DEFINITION

Fibrin or fibrinogen degradation products (FDPs) are protein fragments of fibrin or fibrinogen that have been cleaved by plasmin as part of fibrinolysis. Assays to detect FDPs are used for identifying increased fibrin or fibrinogen breakdown that is seen with excessive coagulation (disseminated intravascular coagulation [DIC]). Plasmin can act on both fibrinogen and fibrin, and assays for FDPs do not differentiate between fibrinolysis and fibrinogenolysis.

TYPICAL NORMAL RANGE

Semiquantitative normal values: dogs, 0-10 mg/mL; cats, 0-8 mg/mL. Abnormal values are reported as moderately increased or markedly increased. Exact values are laboratory dependent.

PHYSIOLOGY

- Formed by plasmin breakdown of non-cross-linked fibrin and fibrinogen. FDPs are potent inhibitors of coagulation; they compete with fibrinogen for the active sites on thrombin and interfere with the conversion of fibrinogen to fibrin.
- Interfere with platelet aggregation; they bind to the fibrinogen-binding site on platelets.
- Eliminated by the liver and kidney, so patients with hepatic or renal disease can have elevated FDPs in the absence of significantly elevated levels of fibrin(ogen) breakdown.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Increased fibrinolysis: internal hemorrhage, local or disseminated intravascular coagulation, sepsis or other severe inflammation
- Decreased FDP clearance: hepatic disease, renal failure

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- CBC with platelet count/serum chemistry profile/urinalysis
- Coagulation profile: activated partial thromboplastin time, prothrombin time, thrombin time, angiotensin lll and D-dimer levels

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: False increases can occur when FDP generation occurs during collection (traumatic venipuncture).

SPECIMEN: Serum assay: use tubes filled with thrombin, or reptilase (snake venom) with soybean trypsin inhibitor or aprotinin (light blue-top tubes with yellow label). Plasma assays: citrated (light blue top-tube). Tubes should be completely filled.

RELATIVE COST: $$

PEARLS

- Serum (plain red-top tube) specimens cannot be used because clot formation consumes FDPs, lowering measurement. A clot in the citrate tube will interfere with accuracy of the plasma assay.
- D-dimer assays continue to be evaluated in small-animal medicine and may prove to be more sensitive and/or specific than FDP assays for detecting coagulation and clot lysis.

$$$$: >$150

Feline Leukemia Virus Immunofluorescent Antibody (IFA)

DEFINITION

Feline leukemia virus (FeLV) is a retrovirus of cats that causes hematopoietic neoplasia, immunosuppression, and/or anemia.

TYPICAL NORMAL RANGE

Reported as positive or negative

PHYSIOLOGY

Following exposure to FeLV via the oronasal route, the virus replicates in oropharyngeal lymphoid tissue. The virus may be cleared with an effective immune response. An ineffective immune response results in viremia and replication in bone marrow and lymphoid cells. Affected cats may be transiently viremic with latent virus residing in the marrow, may become persistently viremic, or may be overtly healthy carriers. Persistent viremia may result in immunosuppression, myelosuppression, hematopoietic neoplasia, immune complex diseases, or reproductive disorders.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: IFA detects the cell-associated FeLV core antigen, p27, in cells; therefore, a positive IFA indicates infection with FeLV and probable bone marrow infection. A positive IFA with a negative ELISA is always a false result, and both tests should be repeated.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Correlate with history, clinical findings, and laboratory data.

CAUSES OF ABNORMALLY LOW LEVELS: A negative IFA with a positive ELISA indicates either uninfected (false-positive ELISA) or early infection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If positive ELISA and negative IFA, repeat both tests in 6-8 weeks to determine effective clearance of virus versus persistent infection.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Marked thrombocytopenia, marked leukopenia, eosinophilia, or poor-quality buffy coat or bone marrow smear may cause false-negative or false-positive results.

SPECIMEN

- 1 mL EDTA-anticoagulated whole blood (lavender-top tube); stable at 4°C for 4 days.
- Air-dried buffy coat smears or bone marrow smears: store at room temperature.

RELATIVE COST: $$

PEARLS

- Vaccination for FeLV involves a different component of the virus (gp70 protein) than the one detected by IFA. Therefore, prior vaccination does not affect test results.
- The FeLV IFA test is less sensitive (does not catch all FeLV-positive cases) but more specific (positive result is reliably positive) compared to the FeLV ELISA. Therefore, FeLV IFA is not a good initial screening test but is an excellent confirmatory test.

AUTHOR: PATTY J. EWING

Pricing Information

$: <$20
$$: $21-75

$$$: $76-150
$$$$: >$150

Feline Leukemia Virus (ELISA)

DEFINITION

Feline leukemia virus (FeLV) is a retrovirus of cats that causes hematopoietic neoplasia, immunosuppression, and/or anemia.

SYNONYMS

FeLV enzyme-linked immunosorbent assay

TYPICAL NORMAL RANGE

Reported as positive or negative

PHYSIOLOGY

Following exposure to FeLV via the oronasal route, the virus replicates in oropharyngeal lymphoid tissue. The virus may be cleared with an effective immune response. An ineffective immune response results in viremia and replication in marrow and lymphoid cells. Affected cats may be transiently viremic with latent virus residing in the marrow, may become persistently viremic, or may be overtly healthy carriers. Persistent viremia may result in immunosuppression, myelosuppression, hematopoietic neoplasia, immune complex diseases, or reproductive disorders.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: ELISA detects the free soluble FeLV core antigen, p27; therefore, a positive ELISA indicates that the cat is viremic (infected with FeLV). False-positive results due to technical error can occur, but this occurs infrequently (sensitivity and specificity are reported to be 99.9%).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Confirm with FeLV IFA test.

CAUSES OF ABNORMALLY LOW LEVELS: A negative ELISA indicates that either the cat is not infected or has an early infection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If the cat was recently exposed to an FeLV positive cat but the ELISA is negative, early infection is possible and retesting in 30-90 days is recommended.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Hemolysis may cause a false-positive or false-negative result.

SPECIMEN: 1 mL serum (red-top tube) or EDTA plasma (lavender-top tube)

RELATIVE COST: $

PEARLS

- Vaccination for FeLV involves a different component of the virus (gp70 protein) than the one detected by ELISA. Therefore, prior vaccination does not affect test results.
- The FeLV ELISA test is more sensitive (more likely to catch all FeLV-positive cases) but less specific (may also erroneously identify a few FeLV-negative cases as positive) compared to the FeLV IFA. Therefore, FeLV ELISA is a good initial screening test, but positive results may or may not be true positives and need to be confirmed with IFA.

Feline Immunodeficiency Virus Testing

DEFINITION

Feline immunodeficiency virus (FIV) is a retrovirus (lentivirus) that attacks the immune system of cats and results in progressive immunosuppressive disease.

TYPICAL NORMAL RANGE

Reported as positive or negative

PHYSIOLOGY

FIV is inoculated via saliva or blood from bite wounds. There are three stages of infection. *Acute phase:* FIV initially infects T lymphocytes and salivary glands, with subsequent spread to other mononuclear cells; cats may have fever, leukopenia, and lymphadenopathy. *Subclinical phase:* cats may be without clinical signs for years. *Chronic phase:* progressive immunosuppression with development of a wide variety of clinical disorders, including stomatitis/gingivitis, anemia and leukopenia, neurologic signs, enteritis, weight loss, and opportunistic infections. A cat may have no clinical signs for years, owing to a prolonged subclinical phase that follows acute infection. Available tests measure circulating FIV antibody levels, not viral antigen. The extended natural course of lentivirus infections makes the presence of antibody essentially equivalent to infection (exceptions: maternal antibody, vaccination).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Screening test: ELISA (SNAP) or rapid immunomigration assay—positive indicates possible exposure to FIV or FIV vaccine; positive or equivocal result requires confirmatory testing. Due to maternally transferred antibody, FIV testing of kittens <6 months of age is unreliable (false positives) and is not recommended.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Confirmatory tests: Western blot or IFA. Positive Western blot or IFA indicates maternal antibody (kittens <6 months old) or exposure to FIV or the vaccine. PCR test may be a useful test in the future for differentiating vaccine exposure from true infection; however, currently available tests vary markedly in their diagnostic accuracy and should be interpreted with caution.

CAUSES OF ABNORMALLY LOW LEVELS: Negative ELISA indicates lack of exposure or acute infection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If clinical signs suggest FIV infection, retest in 4-12 weeks.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: PCR: false-positive results due to contamination of samples; false-negative results due to degradation of nucleic acids via improper sample handling and storage. Up to 50% false-negative results due in part to insufficient primer and probe sequences (many strain variations of FIV present). SPECIMEN

- ELISA: 1 mL serum (red-top tube) or plasma (lavender- or green-top tube)
- Western blot or IFA: 1 mL of serum (red-top tube)

RELATIVE COST: $$ (IFA, ELISA); $$$ (Western blot)

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Feline Coronavirus Testing

DEFINITION

Feline coronavirus (FCV) infection refers to two distinct entities: feline infectious peritonitis (FIP) and feline enteric corona-viral (FECV) enteritis. FIP is a systemic viral disease of high mortality characterized by insidious onset, fever, disseminated pyogranulomatous inflammation, and in some cases, proteinaceous exudative effusions in body cavities ("wet form"). FECV causes mild transient diarrhea and/or vomiting and, less commonly, chronic or severe diarrhea. A positive titer does not distinguish between these two entities.

TYPICAL NORMAL RANGE

Consult with laboratory conducting the test.

PHYSIOLOGY

In FIP FCV is ingested and then replicates in intestinal epithelial cells and probably tonsils and oropharynx. The virus infects macrophages, with subsequent extension to multiple tissues. Antiviral antibodies are produced such that immune complexes form and are deposited in blood vessels of serosal surfaces, uvea, kidney, liver, and other tissues. A pyogranulomatous response ensues. Proteinaceous abdominal or thoracic effusion results from increased vascular permeability. FIP-type coronavirus is thought to represent a spontaneous mutation of FCV that occurs in vivo in certain individual cats.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Positive FCV titer indicates nonspecific exposure to any of the following: FIP coronavirus, feline enteric coronavirus, other coronaviruses, or FIP vaccine. Serology is therefore nonspecific.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Correlate with history, physical exam findings, and other laboratory data. Consider cytologic evaluation, A: G ratio, PCR, or IFA on effusion fluid, all of which are supportive but not definitive (none of these tests differentiates between FIP coronavirus and enteric coronavirus). Quantitative mRNA PCR Multi-Test on blood, feces, and effusion or tissue aspirate may differentiate FIP-coronavirus from enteric coronavirus. Histopathologic analysis of biopsy or necropsy tissue is generally required for definitive diagnosis.

CAUSES OF ABNORMALLY LOW LEVELS: False-negative serologic test results may arise from peracute infection, low antibody level, lack of antibody production, or antibody bound within immune complexes.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If FIP is still suspected, consider same diagnostic steps as if test is positive.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: PCR: false-positive results due to specimen contamination; false-negative results due to degradation of nucleic acids via improper sample handling and storage

SPECIMEN: One mL serum (red-top tube) for serology. Samples for serologic analysis can be stored up to 4 days at refrigerator temperature or for longer periods at −20°C without loss of antibody. For mRNA PCR Multi-Test, submit (at room temperature) up to 700 µL of EDTA blood (lavender-top tube) and/or sample fluid (body cavity fluid, CSF, joint fluid), tissue or fecal swab, or piece of tissue not larger than 5 mm in diameter in special sample buffer (obtained from Auburn University, http://www.vetmed.auburn.edu/molecular-diagnostics/faq).

RELATIVE COST: $$ (IFA serum antibody, PCR), $$$ (IFA tissue)

PEARLS

A negative titer alone does not rule out FIP, nor does a positive titer alone indicate FIP. Multiple sampling and evaluation via the FIP mRNA PCR test increases sensitivity over single sampling, and detection of FIP mRNA via PCR in any extraintestinal sample confirms FIP with nearly 100% specificity.

AUTHOR: PATTY J. EWING

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Fecal Flotation

DEFINITION

Screening test for detection of parasitic ova and larvae in feces

TYPICAL NORMAL RANGE

Reported as negative or positive with species identification

PHYSIOLOGY

Flotation of parasitic ova and cysts is promoted in solutions with a greater osmolarity than water. Fecal specimens are mixed with saturated sugar or zinc sulfate solution in a small cylinder topped with a coverslip. After allowing time for ova or cysts to rise to the surface, the coverslip is examined microscopically.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Gastrointestinal or, less commonly, respiratory parasitic infection. Ova of ascarids, hookworms, and flukes. Coccidia, tapeworm segments, and protozoa may be identified.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Positive test result is definitive.

CAUSES OF ABNORMALLY LOW LEVELS: Intermittent shedding of ova

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Serial fecal analyses, empirical anthelmintic treatment, further diagnostic testing of gastrointestinal or respiratory system

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Anthelmintic treatment may decrease parasite burden.

LAB ARTIFACTS THAT MAY INTERFERE: Freezing or delayed specimen processing distorts or destroys ova. decreasing detection.

SPECIMEN: Fresh feces (<24 hours, room temperature or refrigerated) in dry container. If a delay in processing is anticipated, a solution of feces (one part) and sodium acetate/acetic acid formalin (three parts) may be submitted. To prepare solution, combine 1.5 g sodium acetate, 2 mL glacial acetic acid, 4 mL 40% formaldehyde, and 92.5 mL water. Indicate that specimen has been diluted.
RELATIVE COST: $

PEARLS

- Diarrhea may decrease ova concentration.
- Ova shedding is intermittent, so a single negative test does not rule out infection. Serial testing (at least three) should be done if parasitic disease is suspected.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Fecal Culture

DEFINITION

Analysis of feces for enteric bacterial pathogens

TYPICAL NORMAL RANGE

Reported as negative or degree (slight, moderate, heavy) of growth of specific pathogens

PHYSIOLOGY

Chronic diarrhea, especially in patients with signs of systemic disease (intermittent or persistent fever, leukocytosis or leukopenia) or melena, may be due to enteric bacterial infection. Laboratory conditions enhance growth of pathogens, allowing isolation of bacterial colonies and their identification by morphologic features and chemical tests.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Enteric infection. Common enteric pathogens include *Salmonella* spp., *Clostridium* spp., *Shigella* spp., *Yersinia* spp., *Escherichia coli,* and *Campylobacter* spp. Culture results that include only normal enteric organisms are not helpful in identifying enteric diseases resulting from their overgrowth. In such cases, underlying causes for clinical disease including immune deficiencies, and primary viral infections should be considered.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Request specific antibiotic sensitivity.

IMPORTANT INTERSPECIES DIFFERENCES: Bacterial enteritis is an uncommon but serious disease in dogs and very rare in cats.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Low-level antibiotic therapy may inhibit culture growth.

LAB ARTIFACTS THAT MAY INTERFERE: False-negative results: delay in setting up culture, contamination or overgrowth of normal flora, failure to notify lab of suspected fastidious pathogens requiring special handling, exposure of anaerobes to oxygen

SPECIMEN: Fresh feces in sterile container. If shigellosis, campylobacteriosis, or clostridial infection is suspected, special transport media may be needed, depending on transport time to reference laboratory. Contact laboratory to obtain appropriate transport media.

RELATIVE COST: $$

PEARLS

- Most enteric pathogens cause disease in humans; specimen-handling precautions are necessary to reduce risk of zoonosis.
- Much overlap exists between bacterial flora of dogs with enteritis and normal dogs. Identification of certain fecal bacteria does not necessarily indicate a cause-and-effect relationship.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Glycated Hemoglobin

DEFINITION

The concentration of glucose bound to hemoglobin. The test is used for assessing the average serum glucose concentration over the preceding 2-3 months.

SYNONYMS

Glycosylated hemoglobin, hemoglobin

TYPICAL NORMAL RANGE

Reference interval is laboratory-specific.

PHYSIOLOGY

Persistent hyperglycemia results in irreversible binding of glucose to reactive molecules such as hemoglobin. The time frame over which glycated hemoglobin indicates glucose levels (2-3 months) is a reflection of the average blood glucose concentration and red blood cell lifespan.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Persistent hyperglycemia, typically due to uncontrolled or poorly controlled diabetes mellitus

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Review history and physical exam for findings indicative of diabetes mellitus. Assess for hyperglycemia and the presence of urine glucose and ketones. If the patient is diabetic and being treated with insulin, check insulin expiration date and owner's technique for storing, preparing, and administering the insulin; reassess the dosage (may be too low or too high [Somogyi]); and investigate insulin-antagonistic disorders (e.g., hyperadrenocorticism or hyperprogesteronism) if relevant.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Anticoagulated whole blood (EDTA [lavender-top tube] or heparin [green-top tube]); keep refrigerated, submit on ice.

RELATIVE COST: $$$

PEARLS

Glycated hemoglobin is used less often than fructosamine values to assess hyper-glycemic conditions. Increased glycated hemoglobin values take longer to develop and are dependent on hematocrit and red blood cell life span.

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Glucosuria

DEFINITION

Glucose in urine

SYNONYM

Glycosuria

TYPICAL NORMAL RANGE

Negative in healthy dogs and cats, rarely positive in healthy cats with “stress hyperglycemia”

PHYSIOLOGY

Glucose is a small molecule that is freely filtered by glomeruli. Renal tubular epithelium normally resorbs all glucose. Serum glucose concentrations above which tubular cells are unable to fully resorb glucose from urine filtrate (renal threshold) are 180-220 mg/dL (10-12.2 mmol/L) in dogs and 250-300 mg/dL (13.9-16.7 mmol/L) in cats.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Persistent (several hours to days) hyperglycemia caused by diabetes mellitus or administration of glucose-containing fluids
- Transient hyperglycemia if the renal threshold is exceeded for a sufficient time and bladder has minimal glucose-free urine for dilution (e.g., stress hyperglycemia in cats)
- Defective renal tubular resorption due to acute tubular disease, acute renal failure, or Fanconi syndrome

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Measure serum glucose concentration. May need to measure serum fructosamine to differentiate diabetes mellitus from transient stress-induced hyperglycemia, especially in cats.

IMPORTANT INTERSPECIES DIFFERENCES: Compared with dogs, cats have a higher renal threshold for hyperglycemia before glucosuria occurs but are also prone to much greater levels of hyperglycemia caused by stress.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: With most urine dipsticks (glucose oxidase method), vitamin C/ascorbic acid causes a falsely decreased reaction. With the Clinitest (copper reduction method), ascorbic acid and cephalosporin antibiotics can cause false-positive reactions.

LAB ARTIFACTS THAT MAY INTERFERE: False-positive/increase: hydrogen peroxide and sodium hypochlorite (bleach). False-negative/decrease: ketones, very concentrated samples, and cold urine.

SPECIMEN: Clean urine collected as free catch, catheterization, or cystocentesis and of sufficient quantity into which to dip the urine dipstick. Alternatively, a large drop can be placed on the specific reagent pad on the dipstick.

RELATIVE COST: $ (reported as part of urinalysis)

PEARLS

Urine should be at least room temperature or warmer (>20°C or 70°F) for enzymes in reagent pad of dipstick to have appropriate activity. Dipstick +1 and +2 readings lack accuracy; repeated analysis at later date or measurement of urine glucose by clinical chemistry analyzer may provide a more accurate assessment.

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Glucose, Blood

DEFINITION

Blood concentration of the sugar utilized for energy production

SYNONYM

Blood sugar

TYPICAL NORMAL RANGE

Dogs: 60-125 mg/dL (33-6.9 mmol/L). Cats: 70-150 mg/dL (3.9-8.3 mmol/L).

PHYSIOLOGY

Carbohydrates in the diet are catabolized to glucose for absorption and transport to the liver and other tissues. The liver produces glucose via gluconeogenesis and glycogenolysis, and stores glucose in the form of glycogen or converts glucose to amino acids and lipids. Blood glucose levels are regulated by dietary intake and such hormones as insulin and glucagon that regulate its hepatic storage and release and tissue utilization. Glucose metabolism and blood glucose concentration are affected by many disorders.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Diabetes mellitus, glucose-containing fluids, hyperadrenocorticism, stress, hyperthyroidism, acromegaly/hyperpituitarism, acute pancreatitis, excitement-induced epinephrine release (primarily cats), postprandial (minor elevations)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess for persistent hyperglycemia, glucosuria and ketonuria, serum fructosamine.

CAUSES OF ABNORMALLY LOW LEVELS: Paraneoplastic (insulinoma, leiomyosarcoma, other tumors), insulin overdose, neonatal or juvenile hypoglycemia (infrequent feedings, parasitism, other), advanced chronic liver disease, congenital portosystemic shunt, extreme exertion, sepsis, hypoadrenocorticism, hypopituitarism, long-term starvation (rare cause of hypoglycemia in adults) or malabsorption, glycogen storage diseases, artifact (delay in processing, or centrifuging and separating red blood cells from whole blood sample)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Resample to verify persistent hypoglycemia. Correlate with other clinical and laboratory findings. Serum insulin levels to assess for hyperinsulinism due to insulinoma.

IMPORTANT INTERSPECIES DIFFERENCES: Hyperglycemia due to excitement-induced epinephrine release is common in cats.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Increase: glucocorticoids; adrenocorticotropic hormone; intravenous fluids containing dextrose, growth hormone, megestrol acetate, thiazide diuretics, xylazine, ketamine in cats, morphine, and phenothiazine tranquilizers
- Decrease: insulin injection, ethanol, salicylates, sulfonylurea, and o, p'-DDD

LAB ARTIFACTS THAT MAY INTERFERE

- Decrease: delayed separation of serum or plasma from red blood cells results in artificial depression due to utilization of glucose by blood cells.
- Increase: lipemia

SPECIMEN: Serum (red-top tube) or heparinized plasma (green-top tube). Separate from cells within 30 minutes after sample collection. Use fluoride oxalate anticoagulant (grey-top tube) if plasma separation is not possible: stable at 2°C-8°C for 4 days.

RELATIVE COST: $

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Globulins

DEFINITION

In routine serum chemistry profiles, globulin concentration is calculated from subtraction of measured albumin from measured total serum protein. Globulins can be classified as α, β, or γ via protein electrophoresis (see p. 1511).

TYPICAL NORMAL RANGE

Dogs: 2-4 g/dL. Cats: 2.5-5 g/dL. Conversion: g/dL × 10 = g/L.

PHYSIOLOGY

Globulins are a heterogeneous group of large serum proteins including immunoglobulins, coagulation factors, complement, and many acute-phase proteins and lipoproteins, with a wide variety of physiologic functions.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Polyclonal gammopathy: chronic inflammation, hepatic disease, feline infectious peritonitis, immune-mediated disease, rarely neoplasia
- Monoclonal gammopathy: multiple myeloma, lymphosarcoma, canine ehrlichiosis, leishmaniasis
- If concurrent hyperalbuminemia: dehydration

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Evaluate albumin/globulin (A: G) ratio. Decreased A: G ratio when albumin within reference interval and globulin level is high indicates increased globulin production. If the A:G ratio ≈1, consider dehydration as a cause for a relative increase in globulin.
- Protein electrophoresis and/or immunoelectrophoresis to identify mono-versus polyclonal.

CAUSES OF ABNORMALLY LOW LEVELS

- If concurrent with normal albumin level: failure of passive transfer (neonates), immunodeficiencies, hepatic insufficiency
- If concurrent with hypoalbuminemia: hemorrhage, gastrointestinal (rarely renal) protein loss, severely inadequate nutrient intake/maldigestion/malabsorption, hepatic insufficiency

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW

- Evaluate A: G ratio.
- Evaluate for possible hemorrhage.
- Assess for gastrointestinal protein loss, hepatic failure, poor dietary history, maldigestion, or malabsorption.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: As a calculated value, anything affecting accuracy of total protein or albumin measurements will be reflected in globulin concentration.

SPECIMEN: serum in red-top tube

RELATIVE COST: $$ (part of serum biochemistry profile; serum protein electrophoresis)

PEARLS

Magnitude of increase of a and β globulins are usually insufficient to cause an increase in globulin values. An electrophoresis is needed to identify increased peaks (see p. 1511).

Giardiasis Testing

DEFINITION

Giardia lamblia is a protozoan causing chronic severe diarrhea in pets and humans. Contaminated water is the usual source of infection. Fecal flotation using zinc sulfate detects trophozoites. Fecal ELISA detects antigen. Real-time PCR detects organism DNA.

SYNONYMS

Lamblia intestinalis, “beaver fever”

TYPICAL NORMAL RANGE

Reported as negative or positive for trophozoites (fecal flotation), fecal antigen (ELISA), or DNA (real time PCR).

PHYSIOLOGY

- Zinc sulfate fecal flotation depends on accurate identification of trophozoites in fecal specimens combined with zinc sulfate solution. Trophozoites float to the surface, and an aliquot of fluid is examined microscopically.
- ELISA test detects specific antigens in feces.
- Real-time PCR detects *Giardia* sp. DNA by amplification of specific genetic material.
- A true positive result with any of these tests indicates shedding, which is likely—but not certain—to indicate causality in a patient with diarrhea.

For example, a prevalence of *Giardia* infection of up to 40% in puppies has been documented, mostly as subclinical infections.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Intestinal infection

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Identification of organisms or positive detection of antigen or DNA is considered diagnostic of organism shedding, and most clinicians advocate anti-*Giardia* treatment based on a positive result.

CAUSES OF ABNORMALLY LOW LEVELS: Intermittent shedding, previous antiprotozoal therapy

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Repeat testing as clinically indicated.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Anthelmintic drug treatment may lower fecal shedding of organisms.

LAB ARTIFACTS THAT MAY INTERFERE: Feces for flotation must be fresh (analyzed =24 hours since passed). Even with skilled microscopists and optimal technique, fecal flotation has low sensitivity (50%) and specificity (76%). Specimens should be examined within 15 minutes of flotation setup to minimize cyst rupture or distortion. At least three negative results should be obtained before giardiasis is ruled out. ELISA test is more sensitive (92%) and specific (99%). In-office testing devices are available. Real-time PCR is highly specific. Single tests may not detect low levels of DNA.

SPECIMEN: Fresh (=24 hours) fecal specimen in clean dry container, store at 2°C-8°C. Freeze or preserve in formalin for longer storage. ELISA test kits are available for in-office testing.

RELATIVE COST: $$ (ELISA, PCR)

PEARLS

- Affects humans, though recent work indicates a less severe risk of zoonosis than previously suspected (more common-source infections). The disease is especially severe in immunocompromised humans, dogs, and cats, and thorough washing of hands with soap remains important following cleaning up pet waste. Babies should be kept away from pets with diarrhea.
- Animals that test positive may be asymptomatic but be a source of environmental contamination and zoonotic infection.

$$$: $76-150
$$$$: >$150

Gastrin

DEFINITION

Group of peptide hormones secreted by G cells of gastric antrum and duodenum in response to protein meal. Functions to stimulate parietal-cell secretion of gastric acid and histamine release by enterochromaffin cells. Also stimulates pancreatic acinar cells when bound to cholecystokinin.

SYNONYM(S)

G-34 (big gastrin), G-17, g-14 (mini gastrin)

TYPICAL NORMAL RANGE

0-27.8 ng/L (most normal dogs have undetectable levels)

PHYSIOLOGY

Ingestion of protein meal stimulates release. Binds to receptors (parietal, enterochromaffin cells), regulating gastric acid release for protein digestion. Enhances digestion by stimulating gastric blood flow, antral motility, and pancreatic secretion. Stimulates DNA, RNA production, and proliferation of parietal cells and gastric mucosa.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Excess secretion (gastrinoma/Zollinger-Ellison syndrome) associated with gastric mucosa hypertrophy, gastric and duodenal ulceration. The underlying cause is typically a neoplasm of pancreatic islet d cells (gastrinoma); when these cells undergo neoplastic transformation, they regain the ability to produce gastrin (normally only occurs in the fetus).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate gastric mucosa (endoscopy) for hypertrophy, ulceration; assess for pancreatic islet (8-cell) tumor (abdominal ultrasound and, if a pancreatic mass or liver lesions suggestive of metastases, laparotomy).

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Frozen serum (red-top tube); fasting specimen suggested

RELATIVE COST: $$

PEARLS

- Send out test to specialized gastrointestinal laboratories for most commercial reference labs.
- Recommended cutoff value for diagnosis of gastrinoma is 10 times upper limit of reference interval (278 ng/L).

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Gamma-Glutamyltransferase

DEFINITION

Serum enzyme used as marker for liver disease associated with cholestasis

SYNONYMS

GGT, γ-glutamyltransferase

TYPICAL NORMAL RANGE

Dogs: −0-6 U/L. Cats: −0-4 U/L.

PHYSIOLOGY

Membrane-bound enzyme present in many cells, with biliary epithelium, renal tubular epithelial cells, pancreatic cells, and mammary epithelial cells (especially during lactation) having the greatest activity. Significant increases in serum activity associated primarily with liver disease. Renal urinary GGT may be measured as evidence for renal tubular damage. Colostrum of some species contains high levels of GGT.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Cholestasis, biliary hyperplasia, ingestion of colostrum in neonates; may be induced by corticosteroid administration in dogs

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Evaluate recent drug administration.
- Measure alkaline phosphatase (ALP), bilirubin, bile acids; liver biopsy.

CAUSES OF ABNORMALLY LOW LEVELS: Low end of reference intervals are usually very low, and low serum levels are not clinically significant.

IMPORTANT INTERSPECIES DIFFERENCES: Colostrum in most species contains high GGT concentrations. Increase in serum GGT occurs within 24 hours of suckling: sensitive indicator of passive transfer. In pups, levels fall to within reference intervals by 10 days of age.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Increases secondary to therapeutic drugs causing cholestasis. Increases also seen with anticonvulsant and corticosteroid therapy.

LAB ARTIFACTS THAT MAY INTERFERE: Increase: heparin (therapy or use as anticoagulant for collection) in samples measured by transmission photometry.

SPECIMEN: Serum; separate as soon as possible, store at 8°C.

RELATIVE COST: $ (as individual test); may be included in some chemistry/hepatic chemistry profiles

PEARLS

GGT is more sensitive but less specific than ALP in the cat (for all diseases except hepatic lipidosis) and more specific but less sensitive in the dog.

AUTHOR: LOIS ROTH-JOHNSON

$$$$: >$150

Howell-Jolly Bodies

DEFINITION

Retained nuclear fragments. They are spherical, 0.5- to l-µm diameter, magenta structures in the cytoplasm of red blood cells.

TYPICAL NORMAL RANGE

Howell-Jolly bodies are occasionally found in the erythrocytes of clinically normal animals. Up to 1% of normal feline red blood cells may contain Howell-Jolly bodies. They are only reported as part of the CBC if they are excessive.

PHYSIOLOGY

During development in the bone marrow, mammalian erythroid progenitor cells contain nuclei. Howell-Jolly bodies are composed of nucleic acids and represent tiny nuclear fragments that have separated from the nucleus of the developing erythrocyte. They are removed from erythrocytes by the splenic mononuclear phagocyte system. In health, red cells usually do not contain more than a single Howell-Jolly body.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Increased numbers of Howell-Jolly bodies have been associated with hyposplenism or splenectomized animals, regenerative anemias, macrocytosis of poodles, and megaloblastic anemias.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Review history for prior splenectomy. If patient is a toy or miniature poodle, consider macrocytosis of poodles (MCV may range from 90-100). If a strongly regenerative anemia is present, no further investigation of the Howell-Jolly bodies is necessary. Mega-loblastic anemias are rare in veterinary medicine but have been associated with anticonvulsant therapy.

IMPORTANT INTERSPECIES DIFFERENCES: As above for cats

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Anticoagulated blood sample collected in EDTA (lavender-top tube), citrate (blue-top tube), or heparin (green-top tube)

RELATIVE COST: $$ (reported as part of CBC, and only if excessive)

PEARLS

If numerous inclusions suspected to be Howell-Jolly bodies are found, the smear should be reviewed by a clinical pathologist for confirmation.

High-Dose Dexamethasone Suppression Test

DEFINITION

Administration of dexamethasone suppresses production/release of hypothalamic corticosteroid releasing hormone (CRH) and pituitary adrenocorticotrophic hormone (ACTH), with subsequent reduction in production/release of cortisol from adrenal glands.

SYNONYMS

HDDST, high-dose dex

TYPICAL NORMAL RANGE

Baseline cortisol: 0.4-6 µg/dL (10-160 nmol/L) in dogs; 0.4-4 µg/dL (10-110 nmol/L) in cats. Postdexamethasone cortisol concentration at 4 or 8 hours: <1 or <1.4 mg/dL (<30 or 40 nmol/L) in dogs; variable lab reference intervals. In cats: <1.4 µg/dL (<35 nmol/L). A 50% reduction in cortisol concentration from baseline to either 4 or 8 hours post dexamethasone administration (or both) is also interpreted as adequate suppression.

PHYSIOLOGY

- The HDDST is used for helping to differentiate pituitary-dependent hyperadrenocorticism from functional adrenal adenoma/adenocarcinoma. Dexamethasone sodium phosphate is administered IV at 0.1 mg/kg in dogs and 1 mg/kg in cats. Serum cortisol level is measured predexamethasone administration and at 4 and 8 hours postadministration.
- HDDST results in adequately decreased cortisol concentration in 75% of cases of hyperadrenocorticism caused by pituitary tumors, whereas hyperadrenocorticism caused by adrenal tumors does not result in adequately decreased cortisol concentration with HDDST. Dogs with nonadrenal illness and healthy dogs should have adequately decreased cortisol concentration (same response as dogs with pituitary dependent hyperadrenocorticism).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Adrenal neoplasia and 25% of patients with pituitary dependent hyperadrenocorticism

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Imaging for assessment of adrenal size: abdominal ultrasound most commonly, or by more sophisticated modalities such as nuclear scan, MRI, or CT.

CAUSES OF ABNORMALLY LOW LEVELS: If cortisol concentration is adequately decreased after HDDST, a glucocorticoid-producing adrenal neoplasm is very unlikely to be present.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: As clinically indicated, consider evaluating for nonadrenal disease and/or performing an MRI scan of brain to assess for pituitary lesion.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Immunoassays for cortisol measurement have significant cross-reactivity with other glucocorticoids: prednisolone (69%), prednisone (6.4%), 11-deoxycortisol (7.5%), cortisone (4.2%), corticosterone (3.5%), spironolactone (<0.2%), and dexamethasone (<0.1%).
- Ketoconazole inhibits steroid biosynthesis, causing low cortisol concentration.

SPECIMEN

- Serum (red-top tube) or EDTA plasma (lavender-top tube)
- Cortisol in EDTA plasma is more stable than in serum and more stable in cooled samples compared with warm samples. Cortisol is equally distributed between red cells and plasma; therefore, rapid separation of plasma from cells (previously reported) is of no added benefit.

RELATIVE COST: $$ (equilibrium dialysis method); $$$ (radioimmunoassay)

PEARLS

- Careful measurement of dexamethasone dose is important for accuracy. For small dogs, an insulin syringe may be used (no dead space in hub of needle and syringe); if dilution is needed for accuracy, dexamethasone should be added to diluent and not vice versa.
- When a highly skilled ultrasonographer and high-resolution ultrasound machine are available, imaging often supersedes HDDST testing.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Hemolysis

DEFINITION

Hemolysis is rupture of erythrocytes, releasing hemoglobin. It results in red discoloration of serum or plasma.

PHYSIOLOGY

Hemolysis is most commonly an in vitro artifact from traumatic venipuncture or improper sample handling. It may also occur in vivo secondary to pathologic intravascular or extra vascular hemolysis. Hemolysis may interfere with certain laboratory assays by discoloration of sample, altering spectrophotometric assay results; dilution of normal substances in serum; or leakage of analytes from red blood cells (RBCs), resulting in false increase in these substances in the serum or plasma. The degree of hemolysis of a sample may affect some analytes more than others (see individual test entries in this section of the textbook). The analytes affected and degree of interference depend on the method and type of analyzer. Many laboratories report the presence and degree of hemolysis as well as the expected severity of interference and analytes affected.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: As listed above

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE

- Hemolysis causes artifactual increase in hemoglobin, mean corpuscular hemoglobin concentration, calcium, potassium, alanine aminotransferase, aspartate aminotransferase, creatine kinase, lactate dehydrogenase, triglycerides, and total protein.
- Hemolysis causes artifactual decrease in RBC count, hematocrit, glucose, creatinine, total bilirubin, bile acids, alkaline phosphatase, gammaglutamyltransferase, amylase, and lipase.
- Ways to prevent in vitro hemolysis include: avoid traumatic venipuncture, avoid using a needle with an inappropriately small diameter, avoid excess negative pressure when drawing blood into syringe and excessive agitation of the sample in the tube, ensure prompt separation of serum from the clot and proper storage of sample (refrigeration; avoid freezing), and avoid delay in sample analysis or delayed transport of samples to the laboratory for analysis.

AUTHOR: RUANNA GOSSETT

Hemoglobinuria and Hematuria

DEFINITION

Hemoglobinuria is the presence of hemoglobin in urine and is associated with red to brown urine that persists in the specimen even with centrifugation. Hematuria is the presence of red cells in urine and is associated with red, cloudy urine that clears with centrifugation. Either one may cause a positive reaction on the blood reagent square of a urine dipstick.

TYPICAL NORMAL RANGE

Hemoglobin is not found in normal urine. Finding fewer than 5 red blood cells (RBCs) per high-power microscope field is considered normal in urine sediment.

PHYSIOLOGY

Free hemoglobin in the plasma binds haptoglobin. Complex is cleared in the liver. When haptoglobin becomes saturated, the free hemoglobin splits into dimers which are excreted by the kidneys. Hemoglobin in glomerular filtrate is absorbed by proximal tubules and metabolized to bilirubin, iron, and globin. Unabsorbed hemoglobin appears in urine (hemoglobinuria).

Erythrocytes may appear in the urine from upper urinary (renal, rarely ureteral), lower urinary (bladder, urethra), urogenital (prostate, testes, prepuce, uterus, vagina, vulva), or artifactual (traumatic sampling) sources.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Hemoglobinuria: severe intravascular hemolysis. Free hemoglobin may appear in urine in cases of hematuria where large numbers of red cells lyse in very dilute (specific gravity =1.008) or alkaline urine.
- Hematuria may be associated with hemorrhage, trauma, inflammation, necrosis, or neoplasia in the urinary tract.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Hemoglobinuria: identify cause of hemolysis by blood smear evaluation for hemic parasites, Heinz bodies, spherocytes, and RBC membrane defect. Systemic evaluation (CBC, serum biochemistry profile, abdominal and thoracic imaging) may be indicated for identifying triggers of hemolytic anemia.
- Hematuria: determine when hematuria occurs during micturition. Hematuria at the beginning of urination suggests lower urinary or genital origin; at the end of urination, bladder origin (calculi, polyps); throughout urination, renal disease, diffuse bladder disease, prostatic disease. Radiographic and ultrasonographic evaluations are helpful in localizing the lesion.

DRUG EFFECTS ON LEVELS: Drugs causing intravascular hemolysis can also result in hemoglobinuria.

PEARLS

Cystocentesis and catheterization are frequently associated with microscopic hematuria. These collection methods are not recommended for monitoring remission or progression of hematuria. Free-catch urine from bitches in heat (proestrus) may also be contaminated with blood. A urine reagent strip that is positive for blood in the absence of red cells on urine sediment warrants evaluation for hemoglobinuria or myoglobinuria.

AUTHOR: FIDELIA R. FERNANDEZ

Hematocrit

DEFINITION

The percentage of blood composed of red cells. Electronic cell counters calculate hematocrit using the formula: (MCV × RBC/10 = HCT, where HCT is hematocrit, MCV is mean corpuscular volume (in femtoliters [fL]), and RBC is erythrocyte count ($\times 10^6$/fL). Provided Hb (hemoglobin) reading is accurate (i.e., no interference from hemolysis, lipemia, Heinz bodies, etc), HCT = Hb × 3.

SYNONYMS

Centrifugal microhematocrit, HCT, packed cell volume, PCV

TYPICAL NORMAL RANGE

Dogs: 36%-60%. Cats: 29%-48%.

PHYSIOLOGY

HCT values are slightly less than packed cell volume (PCV) because there is no trapped plasma in an automated hematocrit calculation, as can occur with spun packed cell volumes. Sources of variation:

- Due to the variable MCV of domestic animals, values for HCT may be erroneous if the instrument is not calibrated for specific species.
- Abnormal plasma osmolality and electrolyte balance may also result in a difference between HCT and PCV that is generally not clinically significant.
- Although PCV measures change in red cell volume as they occur in vivo, dilution of red cells with normal saline and standing in hematology instruments may cause red cells to return to their normal volume.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Polycythemia due to breed (sight hounds), dehydration, or splenic contraction ("relative polycythemia"), or due to hypoxemia, independent erythropoietin production (renal lesions), or polycythemia vera (myeloproliferative disease of erythrocytes or primary absolute polycythemia)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess hydration status, review clinical history, evaluate for causes of polycythemia.

CAUSES OF ABNORMALLY LOW LEVELS: Anemia, overhydration

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Blood smear evaluation for type of anemia and evidence of regeneration (e.g., polychromasia), absolute reticulocyte count, then further testing as indicated.

IMPORTANT INTERSPECIES DIFFERENCES: Greyhounds and whippets have slightly higher normal values (up to 65% is considered normal, with some individuals exceeding even this level).

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Erythropoietin injections increase HCT; drugs toxic to bone marrow (hydroxyurea, methimazole, many others) and drugs that cause hemolysis (e.g., zinc, methylene blue, benzocaine) can decrease HCT.

LAB ARTIFACTS THAT MAY INTERFERE

- Hemolysis, lipemia, and specimen clotting prevent accurate reading.
- Decrease: insufficient filling of EDTA (lavender-top) tube dilutes specimen; tubes should be filled to capacity for accurate results.

SPECIMEN: EDTA anticoagulated blood (lavender-top tube); two capillary tubes for PCV; Vacutainer tubes must be completely filled. Transport at room temperature or refrigerate.

RELATIVE COST: $

PEARLS

The differences between HCT and PCV values are not clinically significant except at very high values (PCV/HCT > 65%), where plasma trapping becomes substantial.

AUTHOR: FIDELIA R. FERNANDEZ

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Heinz Bodies

DEFINITION

Single or multiple precipitated denatured hemoglobin particles on the red cell (erythrocyte) membrane, often associated with oxidative damage

SYNONYMS

Erythrocyte refractile body or ER body, HB, Schmauch body

TYPICAL NORMAL RANGE

Low proportion seen in red blood cells (RBCs) of normal cats (see below)

PHYSIOLOGY

Oxidants may cause irreversible denaturation of hemoglobin molecule, causing Heinz body (HB) formation. HBs have affinity for membrane protein band 3, forming a complex with it, resulting in clustering of membrane protein band 3 on both the internal and external RBC membrane. External clustering of protein band 3 creates a recognition site for autoantibodies. HBs also make RBCs rigid and less deformable (via cross-linking of spectrin and hemoglobin). These mechanisms make affected RBCs prone to lysis (intravascular hemolysis) or phagocytosis by macrophages in the spleen (extravascular hemolysis).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Drugs (see drug effects) and chemicals from food (onions, garlic, chives) or other substances (zinc); deficiency of enzymes that protect against oxidants

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH:

- Review patient history (diet, drug or toxin exposure).
- Check CBC, urinalysis, chemistry profile for anemia, hemolysis.

IMPORTANT INTERSPECIES DIFFERENCES: Normal in feline RBCs (5%-96% may have HBs) because of innately unstable hemoglobin structure, predisposition to form methemoglobin (low methemoglobin reductase activity), and inefficient removal by spleen. Normally occurring HBs are not associated with anemia or hemolysis. Increased HB formation may also occur without significant anemia in diabetes mellitus, hyperthyroidism, and lymphoma. In other species, increased numbers of HBs may be seen post splenectomy.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Acetaminophen, benzocaine-containing products, dl-methionine, methylene blue, phenacetin, phenazopyridine, phenothiazine, and vitamin K^3 cause HB formation and hemolytic anemia.

SPECIMEN: EDTA whole blood (lavender-top tube) for CBC and new methylene blue stained smears

RELATIVE COST: $$ (reported as part of CBC)

PEARLS

Free HBs may falsely increase instrument platelet counts and hemoglobin measurement. HBs may occur concurrently with eccentrocytes (also a result of oxidative injury) and spherocytes (due to removal of HBs from cell membranes in the spleen).

AUTHOR: FIDELIA R. FERNANDEZ

Pricing Information

$$: $21-75
$$$: $76-150
$$$$: >$150

Heartworm Filter Test

DEFINITION

Concentration method for the detection of circulating microfilariae of *Dirofilaria immitis.*

SYNONYMS

Difil test, filaria filter test, Knott's test

TYPICAL NORMAL RANGE

Reported as negative or positive

PHYSIOLOGY

Circulating microfilariae are the larval (L1) stage of adult heartworms *(D. immitis).* Must be distinguished from circulating larval form of Acanthocheilonema (formerly *Dipetalonema) reconditum.*

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Circulating microfilariae of *D. immitis* or *A. reconditum*

NEXT STEP TO CONSIDER IF LEVELS HIGH: Rule out *A. reconditum* larva is larger than a red blood cell; (diameter of *D. immitis* is smaller than a red blood cell); confirm with heartworm antigen test; thoracic radiographs (+/− CBC, serum biochemistry profile, urinalysis, echocardiography) may be useful to stage the disease.

CAUSES OF ABNORMALLY LOW LEVELS: Occult infections (adult heartworms are present but circulating microfilariae are absent) may be present due to single-sex infection, immature worms, immune-mediated destruction of microfilariae, prophylactic administration without initial testing.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Heartworm antigen test to rule out occult infection

IMPORTANT INTERSPECIES DIFFERENCES: Cats with heartworm disease are frequently microfilaria negative.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Animals receiving monthly heartworm prophylaxis may be microfilaremia negative despite having heartworm disease.

SPECIMEN: Anticoagulated whole blood in EDTA (lavender-top tube), citrate (blue-top tube) or heparin (green-top tube)

RELATIVE COST: $

PEARLS

As a screening test, the heartworm microfilaria test is less sensitive than the heartworm antigen test. It has been replaced almost entirely by antigen testing, except in large colony environments where the lower material cost of microfilaria testing makes it the only feasible choice (e.g., certain shelter contexts).

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: FONZIE QUANCE-FITCH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150

$$$$: >$150

Heartworm Antigen and Antibody Tests

DEFINITION

Antigen test kits detect adult heartworm *(Dirofilaria immitis)* antigen. Antibody tests detect circulating antibody to either microfilarial cuticular antigen or to adult heartworm antigen.

SYNONYM

Occult heartworm test

TYPICAL NORMAL RANGE

Results are reported as negative or positive. Some tests are semiquantitative, reported as weakly positive. This is not necessarily indicative of worm burden (see causes of abnormally low levels).

PHYSIOLOGY

- Antigen tests detect an antigen primarily derived from adult female heartworm reproductive tract in the circulating blood of the host.
- Antibody tests detect host species-specific circulating antibodies against either adult heartworms or larvae.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Antigen: infection with adult heartworms
- Antibody: indicates exposure to *D. immitis,* but not all infected animals will develop adult heartworms or heartworm disease.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Thoracic radiographs, CBC, serum biochemistry panel, urinalysis, +/–echocardiogram (if significant changes in aforementioned tests)

CAUSES OF ABNORMALLY LOW LEVELS

- Antigen test: falsely low levels may be seen with very low worm burden (one or two female worms), single-sex (male) infection, immature worms (<5 months old).
- Antibody test: false negatives may occur <30 days postinfection or if animal fails to produce detectable antibodies.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Retest in 1-2 months, assess for clinical signs of heartworm disease.

IMPORTANT INTERSPECIES DIFFERENCES: Antigen tests are less sensitive in the cat (low worm burden, single-sex infections). Antibody tests can be useful in cats with clinical signs, but even these may only become positive 2-3 months postinfection and return to negative within 3 months thereafter. Therefore, a combination of an antigen and antibody test, and possibly echocardiography, may improve overall sensitivity in cats compared to the use of individual antibody tests alone.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Antigen test may remain positive up to 16 weeks post adulticide treatment.

LAB ARTIFACTS THAT MAY INTERFERE: Severe hemolysis or lipemia may interfere with test (false positives, some false negatives). Antigen may degrade if sample not properly handled or stored.

SPECIMEN: Serum (red-top tube). Store at 2°C-8°C. Some assays may also allow whole blood or plasma.

RELATIVE COST: $

PEARLS

Echocardiography (cardiac ultrasound) rivals or surpasses the heartworm antibody test for sensitivity of detection of adult heartworms in cats.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: FONZIE QUANCE-FITCH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Iron Profile

DEFINITION

A group of tests that typically includes serum iron, total iron-binding capacity (TIBC), and serum ferritin. Some profiles include unbound iron-binding capacity (UIBC) and percent transferring saturation, values calculated from other parameters in the profile.

SYNONYMS

Iron panel, Fe profile or panel. Individual tests: serum Fe, SI, TIBC, UIBC, % transferring saturation.

TYPICAL NORMAL RANGE

Dog: serum iron 125-225 µg/dL; TIBC 225-325 µg/dL; ferritin 525-1100 µg/L

PHYSIOLOGY

Body stores of iron are regulated by absorption. Iron is absorbed from the gut lumen into enterocytes where it is bound to the protein ceruloplasmin. Ceruloplasmin is needed to transfer iron from intestinal epithelium to transferrin, an iron-binding molecule in serum. Iron is stored in macrophages bound to ferritin or as hemosiderin. It is incorporated into erythrocytes during heme synthesis.

- Profile is helpful in evaluating patients with nonregenerative anemia due to iron deficiency or chronic disease, and patients with iron overload.
- In serum, iron is bound to the protein transferrin. Measurement of serum iron by itself is not a good assessment of total body stores.
- TIBC is a measurement of the maximum amount of iron plasma proteins (primarily transferrin) will carry.
- Ferritin is the protein responsible for binding iron within cells. In the bound state, iron is kept soluble and non-toxic. Assays for ferritin are species specific.
- UIBC is the difference between TIBC and serum iron.
- % transferrin saturation equals (serum Fe concentration × 100) divided by TIBC.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Serum iron: excess intake via dietary supplements or injection, release from damaged tissues, excess endogenous or exogenous glucocorticoids in dogs
- TIBC: increased production during iron deficiency
- Ferritin: increased serum iron, inflammation, release from damaged tissue

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate history for supplementation or accidental ingestion. Assess liver function.

CAUSES OF ABNORMALLY LOW LEVELS:

- Serum iron: chronic blood loss, decreased intake, inflammation (acute and chronic)
- TIBC: inflammation, liver disease (decreased production of transferrin), protein-losing disorders (enteritis or renal disease)
- Ferritin: decreased iron stores

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate for blood loss, including parasitism (fleas, hookworms, ticks); assess for chronic inflammatory disease, enteric disease, liver dysfunction, or protein-losing nephropathy or enteropathy. Bone marrow evaluation may be useful for assessing iron stores.

IMPORTANT INTERSPECIES DIFFERENCES: Cats: bone marrow iron does not stain in cytologic or histologic specimens.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Glucocorticoids increase serum iron levels in dogs (unknown mechanism).

LAB ARTIFACTS THAT MAY INTERFERE: Hemolysis falsely increases serum iron

SPECIMEN: Fast patient overnight. Collect in serum (red-top) tube; spin and separate cells from serum within 2 hours; transfer serum to plastic tube. Freeze and ship to lab on ice. Specimen must be free of hemolysis.

RELATIVE COST: $$$

PEARLS

- Kittens (especially) and puppies often have low serum iron, TIBC, and ferritin.
- Patients with iron deficiency typically have low serum iron and ferritin and normal to high TIBC.
- Patients with anemia of chronic disease typically have normal to low serum iron, TIBC, and normal to high serum ferritin.
- Ferritin is a good indicator of total body stores of iron in cats and dogs.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Insulin and Insulin/Glucose Ratio

DEFINITION

Insulin is a hormone produced and secreted by the β cells of the pancreatic islets of Langerhans. It promotes cellular uptake of glucose, notably by fat, skeletal muscle, and liver, but not neurons, red blood cells (RBCs), renal tubular epithelial cells, enterocytes, or ocular lens. It promotes anabolic metabolism of carbohydrates, proteins, lipids, and nucleic acids.

The amended insulin/glucose ratio is calculated according to the following formula: serum insulin (μU/mL) × 100/ serum glucose (mg/dL) − 30; if the denominator is negative, substitute 1.

This formula compares the insulin concentration in relationship with serum glucose concentration; however, it is generally considered inaccurate and should not be used. Rather, the absolute serum insulin concentration during hypoglycemic episodes should be evaluated along with history, physical examination findings, and laboratory test results.

TYPICAL NORMAL RANGE

Serum insulin reference interval varies with laboratory and should be established for each laboratory. Insulin/glucose ratio <30 is considered normal, ratio >30 is suggestive of hyperinsulinism but is nonspecific for neoplasia (other causes of hypoglycemia also elevate this ratio in dogs).

PHYSIOLOGY

Under normal conditions, high blood glucose levels trigger insulin release, and high insulin levels decrease blood glucose levels. This feedback mechanism ensures glucose homeostasis and is the reason the insulin/glucose ratio is low (<30) in health. Persistent and/or excessive (e.g., paraneoplastic) hyperinsulinism may cause rapid, excessive cellular uptake of glucose, which results in hypoglycemia and associated clinical signs. Decreased concentrations of insulin are absolute with type I diabetes mellitus and often relative with type II and type III diabetes mellitus.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Pancreatic β-cell neoplasia (insulinoma), leiomyosarcoma, insulin therapy, artifact (see below)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Measure serum glucose concentration simultaneously. Assess pancreas and small intestine by ultrasonographic examination.

CAUSES OF ABNORMALLY LOW LEVELS: Diabetes mellitus, although serum insulin levels are not usually measured as part of diagnosis or management of diabetic patients

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Check serum glucose concentration, urine glucose, and urine ketones. In diabetes mellitus, the serum glucose is increased; if untreated, there is often glucosuria ± ketonuria.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Antiinsulin antibodies (contributors to diabetes mellitus) interfere with insulin assays and cause false, markedly increased insulin concentration results.

SPECIMEN: Serum (red-top tube)

RELATIVE COST: $$

PEARLS

- Insulin should always be assessed concurrently with serum glucose.
- Insulin levels are almost always measured when investigating hypoglycemia and are virtually never indicated for assessment of hyperglycemia.
- Several noninsulinoma diseases may cause ratio results >30; this ratio is often inaccurate and should not be used as the sole test to diagnose insulinoma. Absolute insulin concentration in hypoglycemic patients, together with signalment, history, physical examination findings, and other laboratory results, should be evaluated.

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Ketonuria

DEFINITION

Ketones (acetoacetate, β-hydroxybutyrate, acetone) in urine

TYPICAL NORMAL RANGE

Reported as negative or slight (1+), moderate (2+), marked (+3)

PHYSIOLOGY

Urine is normally negative for ketones. Their presence in urine is the result of increased fat/lipid metabolism and decreased utilization of carbohydrates as an energy source. The standard laboratory (dipstick) test only detects acetoacetate and acetone.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Diabetes mellitus, hypoglycemia, starvation

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess nutritional condition, evaluate for diabetes mellitus (serum glucose, ± fructosamine concentration), evaluate for disorders of glucose metabolism (especially in young patients).

DRUG EFFECTS ON LEVELS: False increases: streptozotocin, aspirin

LAB ARTIFACTS THAT MAY INTERFERE: Standard test does not detect β-hydroxybutyrate, considered the ketone excreted in the earliest stages of diabetes mellitus. Acetate tablet method (Bayer) is considered a more sensitive method and is recommended if ketonuria is suspected.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Fresh urine specimen in sterile container for standard urinalysis

RELATIVE COST: $ (reported as part of urinalysis)

PEARLS

If ketonuria coexists with glucosuria and hyperglycemia, diabetes mellitus ± diabetic ketoacidosis is likely. Serum Na, K, P, and blood gas determinations are recommended. Ketonuria without glucosuria is suggestive of starvation, fasting.

Lymphocytes (Lymphocytosis, Lymphopenia)

DEFINITION

The mononuclear leukocytes that mediate immune responses. Most lymphocytes are small with scant basophilic cytoplasm, although very low numbers have fine magenta granules clustered near nucleus (granular lymphocytes).

TYPICAL NORMAL RANGE

Dogs: 1.0-5.0 × 10^3 lymphocytes/µL. Cats: 1.5-7.0 × 10^3 lymphocytes/µL.

PHYSIOLOGY

Most lymphocytes are produced in lymphoid tissues such as lymph nodes, spleen, and thymus. Lymphocytes are long-lived cells. They emigrate from blood into lymphoid tissues but then circulate in the lymphatic system to reenter venous circulation via the thoracic duct. Using surface receptors as markers, lymphocytes can be classified as T lymphocytes (e.g., CD3 positive) that mediate cell-mediated responses, B lymphocytes (e.g., CD79a positive) that mediate humoral responses, or null cells that mediate cytotoxicity. Most of the circulating lymphocytes in blood are T lymphocytes.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Inflammatory diseases (especially infectious causes) with antigenic stimulation
- Excitement with epinephrine release (especially young cats)
- Lymphoid neoplasms (e.g., leukemia, lymphoma)
- Hypoadrenocorticism (“relaxed” leukogram: lymphocytosis without neutrophilia in an obviously stressed animal; conspicuous absence of a stress leukogram)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate for causes listed, depending on clinical signs.

CAUSES OF ABNORMALLY LOW LEVELS

- Endogenous or exogenous glucocorticoids (stress leukogram)
- Acute inflammation (especially viral infections)
- Disruption of lymphatic flow (e.g., chylothorax, lymphadenopathy, lymphangiectasia)
- Immunodeficiency (e.g., severe combined immunodeficiency)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate for causes listed, depending on clinical signs.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Glucocorticoids cause lymphopenia by causing sequestration of lymphocytes in lymphoid tissue and lympholysis.

SPECIMEN: EDTA whole blood (lavender-top tube) and freshly prepared blood smear for laboratory to stain

RELATIVE COST: $$ (reported as part of CBC)

PEARLS

In evaluating lymphocytosis, cell morphology is important. Markedly increased numbers of large or atypical lymphocytes indicate lymphoblastic leukemia, whereas a marked increase in small, well-differentiated lymphocytes occurs with chronic lymphocytic leukemia.

$$$: $76-150
$$$$: >$150

Luteinizing Hormone (LH)

DEFINITION

A glycoprotein gonadotrophin produced by the anterior pituitary

TYPICAL NORMAL RANGE

2-29 ng/mL; considerable variability during anestrus

PHYSIOLOGY

LH synergizes with follicle-stimulating hormone (FSH) to initiate ovulation as well as secretion of progesterone. LH is essential for corpus luteum formation. In males, LH is important for normal growth and function of testicular interstitial (Leydig) cells, which secrete testosterone.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Preovulation, cystic ovary disease

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: A marked increase in LH concentration occurs approximately 48 hours prior to ovulation. Monitor progesterone concentrations subsequently to determine if pregnancy has occurred. Evaluation for cystic ovaries with abdominal ultrasound.

CAUSES OF ABNORMALLY LOW LEVELS: Low values are associated with anestrus.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate for anestrus.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Hemolyzed samples should not be used for LH ELISA. Hemolysis does not interfere with radioimmunoassay.

SPECIMEN: Serum should be used for LH ELISA. Collect blood in red-top tube, spin, and collect serum. Sample should be free of hemolysis and lipemia. Ship frozen or on ice.

RELATIVE COST: $$

PEARLS

To facilitate ovulation timing, once visible signs of estrus have begun and vaginal cytology reveals >70% cornified cells, serum LH levels should be measured daily to ensure detection of the preovulatory LH surge and optimal timing of breeding/insemination.

AUTHOR: BRUCE LEROY

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Lupus Erythematosus Preparation (LE Prep)

DEFINITION

Preparation of incubated clotted blood crushed through a wire sieve. Fluid is collected and centrifuged; buffy coat is mixed with equal amounts of serum, smeared, and stained with Wright stain or new methylene blue. Preparations positive for lupus erythematosus (LE) show rosetting of neutrophils around nuclear material and LE cells (neutrophils with phagocytized smooth, homogeneous nuclear material).

SYNONYMS

LE clot test, LE preparation/prep

TYPICAL NORMAL RANGE

Reported as negative or positive. Positive test indicates active disease (systemic lupus erythematosus [SLE]).

PHYSIOLOGY

LE cell formation occurs in the presence of sufficient immunoglobulin G antibody to deoxyribonucleoprotein along with complement. This antinuclear antibody binds the nuclei of traumatized or nonviable leukocytes. Viable neutrophils then phagocytize the opsonized nuclear material, forming the LE cell.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Active systemic lupus erythematosus

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess presence of antinuclear antibodies by indirect immunofluorescence (ANA test).

LAB ARTIFACTS THAT MAY INTERFERE: Mere phagocytosis of nuclear material with intact chromatin pattern (tart cell) does not constitute an LE cell.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: 5-10 mL of blood in a glass test tube. Heparinized blood (green-top tube) may also be used.

RELATIVE COST: $$

PEARLS

- LE cells may occur in skin lesions and joint fluid of patients with active SLE.
- Absence of LE cells does not rule out SLE: the test is specific (positive is true positive) but is a very poor screening test (low sensitivity; positives are seen very uncommonly in patients with SLE).
- ANA testing and correlation with clinical signs are needed for diagnosis of SLE.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Low-Dose Dexamethasone Suppression Test

DEFINITION

Administration of dexamethasone to suppress production/release of hypothalamic corticosteroid releasing hormone (CRH) and pituitary adrenocorticotrophic hormone (ACTH), with subsequent reduction in production/release of cortisol from adrenal glands. It is most often used as a "screening" test for hyperadrenocorticism in dogs and cats (8-hour sample result), but can be used as a "discriminating" test between pituitary-dependent hyperadrenocorticism and adrenal tumor hyperadrenocorticism (4-hour sample result) in dogs (not cats).

SYNONYMS

LDDST, Low-dose dex

TYPICAL NORMAL RANGE

Baseline cortisol: 0.4-6 µg/dL or 10-160 nmol/L (dogs); 0.4-4 µg/dL or 10-110 nmol/L (cats). After dexamethasone administration: expect cortisol concentration <30 or 40 nmol/L or <1-1.4 µg/dL (depends on lab reference intervals, healthy dogs); <1.4 µg/dL or <35 nmol/L (healthy cats). Reduction in cortisol concentration of 50% or more from baseline (at 4 or 8 hours post dexamethasone injection) can also be interpreted as adequate suppression. Failure to suppress is strongly suggestive of hyperadrenocorticism (either pituitary based or primary adrenal based).

PHYSIOLOGY

LDDST is a screening test for hyperadrenocorticism. Serum or plasma cortisol concentration is determined before administration (0.01 mg/kg IV in dogs, 0.1 mg/kg IV in cats) of dexamethasone. In health, hypothalamic CRH and pituitary ACTH production/release are suppressed for several hours (up to 24-48 hours in dogs), with subsequent reduction in adrenal cortisol production/release. Cortisol half-life is 2 hours; at 4 and 8 hours post dexamethasone administration, cortisol concentration in healthy dogs and cats should be markedly decreased. LDDST can cause adequately decreased cortisol in dogs with pituitary-dependent hyperadrenocorticism (up to 80% of patients in some studies) but almost never in adrenal tumor-dependent cases of hyperadrenocorticism. However, nonadrenal illness also may cause failure of LDDST to suppress cortisol levels (false positive). To use LDDST as a discriminating test able to distinguish pituitary-dependent hyperadrenocorticism from adrenal tumor-dependent hyperadrenocorticism, one or more of three criteria must be met: (1) 4-h plasma cortisol <1.4 µg/dL, (2) 4-h plasma cortisol <50% of basal concentration, or (3) 8-h plasma cortisol <50% of basal concentration. If cortisol adequately suppresses, then pituitary-dependent hyperadrenocorticism is likely.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS (FAILURE TO SUPPRESS)

- Hyperadrenocorticism: pituitary dependent or adrenal neoplasia
- Nonadrenal illness. If the patient is ill (owing to adrenal or nonadrenal disease), LDDST should not be performed. Stabilize the patient prior to testing.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Imaging of abdomen by ultrasound, MRI, or CT to evaluate size (enlargement) of adrenal glands
- Review history, physical examination findings, and laboratory data.
- Repeat LDDST when other (nonadrenal) problems are controlled.

CAUSES OF ABNORMALLY LOW LEVELS (ADEQUATE SUPPRESSION): Patients with adequate cortisol suppression are either healthy (vast majority) or have pituitary-dependent hyperadrenocorticism (some dogs, not in cats).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Reassess history, physical exam, CBC, serum chemistry profile, urinalysis, blood pressure measurement, and diagnostic imaging results for other causes of clinical signs. If hyperadrenocorticism remains a possible differential diagnosis, LDDST may be repeated 1-3 months later, or abdominal imaging can define adrenal size by a more sophisticated modality such as nuclear scan, MRI, or CT.

IMPORTANT INTERSPECIES DIFFERENCES: Hyperadrenocorticism is rare in cats. Cats require administration of 0.1 mg/kg

dexamethasone IV because 15%-20% of healthy cats fail to suppress with 0.01 mg/kg dose (dose used in dogs).

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Immunoassays for cortisol measurement have significant cross reactivity with other glucocorticoids and drugs: prednisolone (69%), prednisone (6.4%), 11-deoxycortisol (7.5%), cortisone (4.2%), corticosterone (3.5%), spironolactone (<0.2%), and dexamethasone (<0.1%).
- Ketoconazole inhibits steroid biosynthesis, causing low cortisol concentration.

SPECIMEN

- Serum (red-top tube) or EDTA plasma (lavender-top tube)
- Cortisol in EDTA plasma is more stable than in serum. Cool specimens are more stable than warm samples. Cortisol is equally distributed between red cells and plasma; therefore, rapid separation of plasma from cells (previously reported) is of no benefit.

RELATIVE COST: $$ (equilibrium dialysis method); $$$ (radioimmunoassay)

PEARLS

Very small volumes of dexamethasone are used (0.01 mg/kg using dexamethasone 4 mg/mL equals 0.01 mL for a 4-kg [9-lb] dog, for example). Therefore, dead space in a regular syringe and needle hub should be considered. Either dilution (add dexamethasone to diluent, not the other way around) or use of an insulin syringe (no dead space in hub) should be considered.

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Lipemia

DEFINITION

Lipemia is the increased concentration of triglyceride-rich lipoproteins (chylomicra and very low density lipoproteins) in blood, resulting in the cloudy/turbid appearance of serum or plasma.

TYPICAL NORMAL RANGE

Normally absent from a fasting blood sample

PHYSIOLOGY

Lipemia may interfere with certain laboratory assays by causing dilution of substances in serum, or turbidity of the sample which affects the results of spectrophotometric assays. Lipemia causes hemolysis that further contributes to interference with laboratory assays.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Postprandial specimens, primary hyperlipidemia, secondary hyperlipidemia

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Determine whether specimen is postprandial. Normally, lipemia may be avoided by fasting for 12-24 hours prior to sample collection. Ultracentrifugation may clear lipemic serum. If lipemia in dogs persists with fasting, it may be cleared (for purposes of eliminating lipemia related artifacts) by injection of 100 U/kg of sodium heparin intravenously and collection of the blood sample 15 minutes later. Triglycerides should be measured in an aliquot of the fasting lipemia serum prior to clearing.
- Evaluation for causes of secondary hyperlipidemia (hypothyroidism, diabetes mellitus, acute pancreatitis, hyperadrenocorticism, nephrotic syndrome, and high-fat diet) is indicated if lipemia is present in a fasted blood sample. If no evidence of these conditions is found, consider primary hyperlipidemia.

PEARLS

- Examples of analytes that can be artifactually increased by lipemia include hemoglobin, mean corpuscular hemoglobin concentration, triglycerides, plasma protein measured by refractometer, and spectrophotometric assays for glucose, calcium, phosphorus, alanine aminotransferase (ALT), creatine kinase (CK) and total bilirubin.
- Examples of analytes that can be artifactually decreased by lipemia include lipase, amylase, bile acids and albumin.
- Hypercholesterolemia does not cause lipemia.

AUTHOR: RUANNA GOSSETT

Lipase

DEFINITION

Enzyme that hydrolyzes triglycerides to fatty acids and glycerol

TYPICAL NORMAL RANGE

Serum lipase activity based on enzymatic activity:

- Dogs: 100-750 IU/L
- Cats: 10-195 IU/L

Pancreas-specific lipase immunoreactivity (spec cPLI for canine and fPLI for feline: species-specific immunoassay utilizing antipancreatic lipase antibodies):

- Dogs: normal ≤200 µg/L (pancreatitis is unlikely); questionable range is 201-399 µg/L (evaluate other possible diagnoses; recheck cPLI in 2-3 weeks); >400 µg/L is consistent with pancreatitis.
- Cats: normal ≤3.5 µg/L (pancreatitis is unlikely); questionable range is 3.6-5.3 µg/L (evaluate other possible diagnoses; recheck fPLI in 2-3 weeks); =5.4 µg/L is consistent with pancreatitis.

PHYSIOLOGY

Lipase is present in pancreas, adipose tissue, gastric mucosa, and duodenal mucosa. Pancreatic lipase catabolizes triglycerides into fatty acids and glycerol, monoglycerides, and diglycerides in the proximal small intestine. Bile salts and colipase enhance the efficiency of lipase activity. The pancreas is considered the primary source of serum lipase concentration, although other tissues may contribute. Pancreas-specific lipase immunoreactivity is a sensitive and specific test for pancreatic lipase levels in the serum of dogs and cats.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Pancreatitis, renal failure, azotemia, hepatic disease, gastrointestinal disease (gastroenteritis, duodenal obstruction, peritonitis, inflammatory bowel disease), neoplasia

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: If clinical signs consistent with pancreatitis (dogs and cats), with or without increase in serum amylase (dogs only), assess pancreatic lipase immunoreactivity (spec cPLI, fPLI) and/or abdominal ultrasound. Evaluate for concurrent disease such as IBD, gastroenteritis, proximal intestinal foreign body, hepatic disease, neoplasia, and especially in cats, cholangiohepatitis and hepatic lipidosis.

CAUSES OF ABNORMALLY LOW LEVELS: Exocrine pancreatic insufficiency

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Serum trypsinlike immunoreactivity, cobalamin, folate

IMPORTANT INTERSPECIES DIFFERENCES: Total serum lipase levels are not a reliable indicator of pancreatitis in cats. Pancreatic-specific lipase immunoreactivity is a much more sensitive and specific test for diagnosis of pancreatitis in both dogs and cats.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Dexamethasone and prednisone therapy increase lipase activity, without concurrent increase in amylase.

LAB ARTIFACTS THAT MAY INTERFERE: Decrease: lipemia, hemolysis, icterus

SPECIMEN: Serum (red-top tube) or serum separator tube (red-top SST). Fasted sample preferred. Stable at 2°C-8°C for 3 weeks. Avoid freeze/thaw.

RELATIVE COST: $ (serum lipase); $$ (spec cPL, spec fPL)

PEARLS:

- Degree of elevation of lipase in serum does not correlate with severity of pancreatitis. Rather than using individual values, continued elevations, decreases, or plateau of levels are likely to provide more diagnostic information.
- Pancreas-specific lipase may be measured serially in a confirmed pancreatitis patient (dog or cat) to assess disease progression.

$$: $21-75
$$$: $76-150
$$$$: >$150

Leukocytes (Leukocytosis/Leukopenia)

DEFINITION

Leukocyte is the term for blood cells that can be categorized as either granulocytic (neutrophils, eosinophils, and basophils) or mononuclear (lymphocytes and monocytes). *Leukocytosis* indicates an increase above the normal range; *leukopenia* indicates a decrease below the normal range.

SYNONYM

White blood cells (WBCs)

TYPICAL NORMAL RANGE

Dogs: 6-17 × 10^3 leukocytes/µL. Cats: 6-19 × 10^3 leukocytes/µL.

PHYSIOLOGY

Encompasses several different types of cells with different functions and kinetics. More specific analysis of neutrophils, lymphocytes, monocytes, eosinophils, and basophils is indicated (see respective topics). Changes in the number and morphology of each different leukocyte should be investigated.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Increased numbers of neutrophils (neutrophilia) and lymphocytes (lymphocytosis) are the most common contributors to leukocytosis. Leukocytosis does not automatically equal inflammation. A variety of disorders can induce leukocytosis, and stress leukograms (due to epinephrine release) are common in dogs and less so in cats. Leukocytosis caused by inflammation can be accompanied by band neutrophils/left shift, toxic neutrophilic changes, or both. Leukocytosis should be interpreted with physical exam findings and other laboratory test results.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate the absolute concentrations of each leukocyte type to determine the specific cause of leukocytosis.

CAUSES OF ABNORMALLY LOW LEVELS: Leukopenia is most often attributed to neutropenia or lymphopenia.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW:

- Evaluate the absolute concentration of each leukocyte type to determine the specific cause of leukopenia.
- The most common next diagnostic step indicated in patients with persistent leukopenia attributed to neutropenia without an identifiable systemic cause is bone marrow aspiration for cytology, although in cats, retroviral testing (feline leukemia virus, feline immunodeficiency virus) should be performed first.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Nucleated erythrocytes (NRBCs) cannot be accurately differentiated from leukocytes by leukocyte counting instruments, so any NRBC present would add to the total leukocyte concentration. A correction formula is used for calculating the concentration of total leukocytes when RBCs are present: correct WBC/µL = counted WBC/µL × 100/100 + number of NRBCs. Be aware that not all laboratories necessarily make this correction on the final CBC report, and “leukocytosis” in the presence of NRBC should prompt investigation of this possible artifact.

SPECIMEN: EDTA whole blood (lavender-top tube) and freshly prepared blood smear for laboratory to stain

RELATIVE COST: $$ (reported as part of CBC)

PEARLS

- Rather than total leukocyte count (especially if it is within the reference interval), the absolute concentrations of individual leukocytes should be evaluated: neutrophil, lymphocyte, monocyte, eosinophil, and basophil.
- Severe leukocytosis (>50,000), regardless of cause, is generally associated with a guarded to poor prognosis.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Leukocyte Function Tests

DEFINITION

Tests of the in vitro ability of leukocytes to perform specific functions unique to that cell type (e.g., neutrophils, lymphocytes). These tests are not routine; the specific leukocyte may have to be isolated from blood, and tests are only available at research laboratories.

PHYSIOLOGY

Neutrophil function tests include measuring response to chemotactic stimuli, respiratory burst and release of oxidative metabolites, phagocytosis and killing of bacteria, and expression of activation cell markers (e.g., CD18). Monocytes are tested for ability to phagocytose particles. Lymphocyte tests include proliferative response to specific mitogens (e.g., concanavalin A, pokeweed mitogen), expression of Band T-cell receptors and other markers, using flow cytometry or PCR and immunoelectrophoresis and quantitation of serum antibodies.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY LOW LEVELS: Abnormal function of neutrophils: congenital disorders such as canine leukocyte adhesion defect, cyclic hematopoiesis of grey collies. Abnormal function of lymphocytes: congenital disorders such as severe combined immunodeficiency.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Tests are diagnostic of cell function abnormalities.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: The laboratory performing tests should be contacted for specific sample collection and shipment handling, although heparinized blood (green-top tube) is typically used for leukocyte isolation and function testing.

AUTHOR: STEPHEN D. GAUNT

Leptospira Serology, Canine

DEFINITION

Leptospirosis is a zoonotic disease caused by pathogenic serovars of *Leptospira interrogans,* a motile, spiral-shaped bacterium (spirochete). Serovars of importance include canicola, icterohaemorrhagiae, grippotyphosa, pomona, hardjo, bratislava, and autumnalis.

TYPICAL NORMAL RANGE

Reported as titer values; panel of serovars varies among laboratories.

PHYSIOLOGY

Organisms penetrate abraded skin and/or mucous membranes, replicate within bloodstream; rapid dissemination to multiple organs, most importantly liver and kidney (allows shedding in urine). Organisms replicate in the renal tubular epithelium, causing chronic tubulointerstitial nephritis and persistent carrier state if untreated.

Vaccines elicit immunity against canicola and icterohaemorrhagiae serovars; newer vaccine (Fort Dodge Duramune) elicits immunity against these plus grippotyphosa and pomona.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Microscopic agglutination test (MAT): a titer of =1:800 or fourfold rise in titer (paired serum 3 weeks apart) to a serovar against which the dog has not previously been vaccinated suggests active disease. Vaccine-induced titers are generally low (<1:800) but may be as high as 1:3200; these higher titers generally do not persist longer than 3 months.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: PCR using urine, blood, cerebrospinal fluid, aqueous humor, or tissue is possible, as is direct fluorescent antibody testing on tissue (kidney, liver). Darkfield microscopy or culture (blood, urine) prior to antibiotic therapy can be performed but is technically difficult and not widely available.

CAUSES OF ABNORMALLY LOW LEVELS: Early infection, antibiotic treatment

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: ELISA for immunoglobulin (Ig) G and IgM antileptospiral antibodies. IgM may be detected 1 week after infection. May be useful in detecting acute leptospirosis prior to IgG increase.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Antibiotic therapy may cause a decreased MAT titer, prevent a rising titer in paired sample, and cause negative PCR results and negative culture results.

SPECIMEN: Collect 2 mL of serum (red-top tube). Stable for 4 days at 4°C or longer at 0°C.

RELATIVE COST: $$

PEARLS

The diagnosis can be missed if relevant serovars are excluded from serologic testing, because there is no consistent serologic cross-reactivity from one serovar to another. Serovars currently recommended for testing: canicola, pomona, grippotyphosa, bratislava, icterohaemorrhagiae, hardjo, and autumnalis. It may be useful to evaluate urine PCR and serology concurrently.

AUTHOR: PATTY J. EWING

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150

$$$$: >$150

Left Shift

DEFINITION

The presence of band neutrophils (or earlier neutrophilic precursors such as metamyelocytes or myelocytes) in peripheral blood. This finding nearly always indicates active inflammation. It is clinically useful to define the type of left shift present in leukograms. When segmented neutrophils are also increased, the left shift can be described as "regenerative," suggesting appropriate marrow response to increased tissue demands for neutrophils. Alternately, when the segmented neutrophil count is unchanged or decreased, the left shift is described as "degenerative," suggesting the granulopoietic response of marrow is outweighed by tissue demand.

TYPICAL NORMAL RANGE

Dogs: 0-0.3 × 10^3 band neutrophils/µL. Cats: 0-0.2 × 10^3 band neutrophils/µL.

PHYSIOLOGY

Band neutrophils, metamyelocytes, and myelocytes are late neutrophilic precursors that normally remain in the marrow storage pool to differentiate into segmented neutrophils. If intense tissue demand for neutrophils during inflammation depletes the segmented neutrophils from the marrow storage pool, band neutrophils (and earlier precursors) can be prematurely released from the marrow into blood.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Acute inflammation, granulocytic leukemia

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Identify source of inflammation; if none is found despite comprehensive evaluation and repeated assessments, a bone marrow aspirate and core biopsy could be indicated to assess for granulocytic leukemia (rare).

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA whole blood (lavender-top tube) and freshly prepared blood smear for laboratory to stain

PEARLS

- Always examine a stained blood smear for band neutrophils, because the neutrophil counts generated by automated hematology analyzers do not distinguish between segmented and band neutrophils. The presence of toxic changes in neutrophils is another indicator of intense inflammation.
- The hyposegmentation of neutrophils in Pelger Huët syndrome is not considered a left shift.

AUTHOR: STEPHEN D. GAUNT

Lead, Blood Level

DEFINITION

Lead intoxication is relatively common, and whole-blood lead levels are the diagnostic test of choice. Exposure is usually by ingestion. Inhalation, dermal, subcutaneous/intramuscular exposure occur uncommonly.

TYPICAL TOXIC RANGE

- 0.6 ppm or greater is diagnostic of lead toxicosis.
- 0.35 ppm or greater with signs and confirmatory tests (d-aminolevulinic acid [ALA] or fecal lead) is also diagnostic.

PHYSIOLOGY

Although lead is poorly absorbed from the digestive tract, once absorbed it is retained by tissues (kidney, bone). Blood levels decline slowly; they may be elevated for 1-2 months after a single exposure. Blood concentration indicates exposure but does not reflect exposure duration or total body concentration. Lead crosses the placental barrier and is also excreted in milk. Young animals are more susceptible to toxicosis.

Lead exposure results in increased urinary excretion of ALA and inhibits conversion of coproporphyrinogen III to protoporphyrin and heme synthetase. Interference with hemoglobin synthesis, hemogram abnormalities such as basophilic stippling, and increased number of nucleated red blood cells in nonanemic patients are suggestive but not diagnostic of lead toxicosis.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Exposure to lead

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Serum ALA dehydratase inhibition and erythrocyte protoporphyrin assays are highly sensitive tests for exposure and an indication of possible effect of lead. They are not a substitute for blood lead assay, which confirms the presence of lead. Fecal lead analysis may be of benefit; a value of =35 ppm is suspect.

IMPORTANT INTERSPECIES DIFFERENCES: Lead toxicosis is less common in cats than dogs.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Heparinized (green-top tube) or EDTA (lavender-top tube) whole blood. Because 90% of circulating lead is bound to erythrocytes, serum lead is not routinely used and not readily interpretable.

RELATIVE COST: $$

PEARLS

- Kidney and liver tissue may be submitted if blood is not available. Kidney is considered preferable (=10 ppm is diagnostic). Formalin-fixed samples may be used for retrospective analyses.
- Chronic exposure is more common than acute exposure.
- Blood levels and clinical signs do not always correlate. Blood levels are the best indicator of lead exposure but may not indicate duration or dose of exposure.
- Ingested items containing lead may be seen radiographically.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Lactate

DEFINITION

Metabolic end product of anaerobic glycolysis

SYNONYM

Lactic acid

TYPICAL NORMAL RANGE

Range: 1.8-22.5 mg/dL; <2 mEq/L (experimental studies, primarily in dogs at rest). Unit conversion: mg/dL × 0.112 = mEq/L; 1 mmol/L = 1 mEq/L.

PHYSIOLOGY

Normally produced in small quantities in skin, erythrocytes, brain, skeletal muscle, GI tract. Increased production occurs when tissues (primarily skeletal muscle and GI tract) must maintain energy production under anaerobic conditions (tissue hypoxia). Abnormal carbohydrate metabolism associated with some diseases may also increase production. Liver and kidney are the primary consumers of lactate. Lactic acidosis occurs when production exceeds utilization.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Hypoxemic: strenuous exercise, seizures, any cause of decreased oxygen availability (shock, hypovolemia, cardiac disease, pulmonary edema)
- Nonhypoxemic: gastric dilatation/volvulus, diabetes mellitus, liver failure, neoplasia, sepsis, renal failure, hypoglycemia, babesiosis, rare hereditary defects (mitochondrial myopathy, pyruvate dehydrogenase deficiency)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Not measured as part of routine biochemical profile, but cageside use is increasingly common in emergency/critical care setting.
- Lactic acidosis should be suspected when there is an unexplained increase in the anion gap. Evaluate patient for underlying causes.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Increases associated with salicylates, ethylene glycol, epinephrine, and phenobarbital

LAB ARTIFACTS THAT MAY INTERFERE: Increased: delayed plasma harvest, venous stasis (prolonged holding off of the vein), struggling during venipuncture. Decreased: free hemoglobin, bromide (method dependent).

SPECIMEN: Plasma collected in lithium heparin (green-top tube) or sodium fluoride (grey-top tube); must be centrifuged immediately and plasma removed from erythrocytes. Refrigerate immediately or freeze. Some blood gas analyzers use whole blood.

RELATIVE COST: $$$ (at reference laboratory)

PEARLS

Markedly elevated lactate concentrations have been associated with a poor prognosis in critical care settings. For example, dogs with gastric dilatation/volvulus have a 99% survival rate if plasma lactate <6 mmol/L but a 58% survival rate if plasma lactate >6 mmol/L.

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Lactate Dehydrogenase

DEFINITION

Cytosolic enzyme found in most cells in the body

TYPICAL NORMAL RANGE

Dogs: 50-380 U/L. Cats: 46-350 U/L.

PHYSIOLOGY

Lactate dehydrogenase (LDH) catalyzes the oxidation of L-lactate to pyruvate and the reverse reaction. LDH is nonspecific because it is present in many tissues. It is concentrated in heart, skeletal muscle, liver, kidney, and erythrocytes. Leakage of this enzyme into the blood and extracellular space occurs with injury to most tissues. It also increases with only slight sample hemolysis. There are five LDH isoenzymes that can be separated electrophoretically. These isoenzymes are present in certain tissues and are therefore more specific: one primarily in myocardium, another primarily in skeletal muscle, and the remaining isoenzymes are present in several different tissues. Therefore LDH isoenzyme determination may be used to identify cardiac or skeletal muscle injury. Yet LDH isoenzyme measurement is usually restricted to research applications in veterinary medicine. LDH isoenzyme determination is not practical, readily available, or cost effective in the clinical setting, since there are other more sensitive and specific markers of muscle and hepatic injury.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Cardiac disease, skeletal muscle disease, renal injury, liver disease, and hemolysis

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate for muscle injury, hepatic disease, or hemolytic anemia.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Hemolysis results in false elevation, because red blood cells contain LDH.

SPECIMEN: Serum (red-top tube). Store at 4°C.

RELATIVE COST: $

$$: $21-75
$$$: $76-150
$$$$: >$150

Myoglobinemia, Myoglobinuria

DEFINITION

Myoglobin is a low-molecular-weight heme protein found in muscle tissue.

TYPICAL NORMAL RANGE

Serum myoglobin in dogs: <10.0-13.6 ng/mL. Cats: <10.0-13.8 ng/mL. Not present in urine of healthy animals.

PHYSIOLOGY

Myoglobin stores and transports oxygen in muscle fibers. It is released from muscle when there is severe disruption of the muscle membrane or necrosis. Myoglobin is detected in the serum within 2-4 hours after injury. Myoglobin does not significantly bind serum proteins. It passes quickly through the glomerulus and is excreted in urine. Red to brown urine discoloration due to myoglobinuria occurs before the plasma appears discolored. Myoglobin causes a positive occult blood test on urine dipstick.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Trauma, ischemia, toxic injury, or necrosis of muscle tissue

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate for muscle injury or necrosis (e.g., serum creatine kinase level) versus laboratory evidence of hemolysis.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Must distinguish myoglobinuria from other causes of positive reaction for blood on urine dipstick such as hematuria, hemoglobinuria, and substances that cause a false-positive reaction (high bilirubin concentration, contamination of urine with oxidizing agents in disinfectants, leukocytes, bacteria, peroxidase, or iodine)

SPECIMEN

- Myoglobinemia: serum (red-top tube), heparinized plasma (green-top tube), or EDTA plasma (lavender-top tube). Refrigerate at 2°C-8°C.
- Myoglobinuria: 1 mL urine (clean container without additives)

RELATIVE COST: $$$

PEARLS

Myoglobinuria may be distinguished from hemoglobinuria and hematuria by checking the urine sediment for the presence (hematuria) or absence of red blood cells and evaluating the color of the plasma or serum for a pink discoloration (hemoglobinemia). Hemoglobin in plasma binds haptoglobin and is not readily cleared by the glomerulus. Pink discoloration of the serum indicates hemolysis and suggests hemoglobinuria as cause for positive urine blood result. Myoglobin is readily excreted in the urine, so the serum is usually clear to yellow. If there is no hematuria in urine sediment and no evidence of hemoglobinemia, positive blood result on urine dipstick suggests myoglobinuria by process of elimination. Myoglobinuria may be confirmed with an ammonium sulfate precipitation test on urine as well as checking for other clinical and laboratory evidence of muscle damage such as elevation of serum creatine kinase. Addition of ammonium sulfate to urine to 80% concentration will cause hemoglobin to precipitate. Myoglobin does not precipitate and will continue to give a positive occult blood result on urine dipstick.

$$$$: >$150

Mycoplasma spp. Culture

DEFINITION

Laboratory growth of infectious *Mycoplasma* spp. agents to allow isolation and identification

TYPICAL NORMAL RANGE

Reported as no growth or growth with identification of pathogens

PHYSIOLOGY

Mycoplasma spp. are the smallest, simplest self-replicating bacteria. Hemotropic *Mycoplasma* spp. (previously called *Haemobartonella* spp.) are associated with hemolytic anemia. This type of organism is fastidious and grows slowly in culture.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Infection is associated with arthritis, respiratory disease, hemolytic disease, and conjunctivitis.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess immune function; clinical disease is more likely in immunocompromised patients.

IMPORTANT INTERSPECIES DIFFERENCES: Diseases caused solely by *Mycoplasma* spp. other than hemotropic *Mycoplasma* are uncommon in cats and dogs. Coinfection with *Mycoplasma* and other species of bacteria may occur in more than 60% of dogs with pneumonia, however. Mycoplasmal conjunctivitis and respiratory disease are more likely to occur in cats; arthritis is more likely to occur in dogs. Hemotropic *Mycoplasma*most often infects male cats allowed outdoors.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Glucocorticoid or other immunosuppressive therapies may enhance growth.

LAB ARTIFACTS THAT MAY INTERFERE: Contamination with commensals may mask growth. Organism takes a long time to grow in culture, and cultures may be discarded inadvertently if laboratory personnel are not informed that *Mycoplasma* spp. infection is suspected.

SPECIMEN: Swabs, exudate, or tissue should be submitted in specific transport media to enhance growth. Laboratory should be contacted to obtain media for sample submission.

RELATIVE COST: $$

PEARLS

Growth in culture may take up to 2 weeks: serologic tests or PCR should be used for confirming infection.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Mycobacterial Culture

DEFINITION

Laboratory growth, isolation, and identification of *Mycobacterium* spp.

TYPICAL NORMAL RANGE

Reported as growth or no growth, with identification of organisms

PHYSIOLOGY

When an infection is present, organisms may be shed intermittently in respiratory specimens (tracheal exudate) but should be present constantly in solid tissue specimens (skin, lymph node). The organism must be isolated from other flora and grown in media specific for *Mycobacterium* spp. Growth and identification of these fastidious organisms may take 2-4 months.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Infection with *Mycobacterium* spp. Common sites of infection include skin and respiratory tract. Infections may become systemic, involving lymphatics system and bone marrow.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH:

Determine appropriate antibiotic for treatment.

IMPORTANT INTERSPECIES DIFFERENCES

- Feline leprosy *(M. lepraemurium)* and atypical mycobacteriosis *(M. avium. M. fortuitum, M. thermoresistibile, M. xenopi, M. phlei,* and *M. smegmatis)* are considered unique to the cat.
- Dogs, especially basset hounds, are susceptible to systemic disease caused by *M. avium.*
- Humans can transmit *M. bovis* to dogs.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Concurrent or recent antibiotic therapy may inhibit growth.

LAB ARTIFACTS THAT MAY INTERFERE: Contamination or overgrowth by commensal organisms may mask growth.

SPECIMEN: Tissue or exudate from lesion in a sterile container. If zoonotic *Mycobacterium* spp. are suspected, the container should have a screw top and a double outer container should be used; label as biohazard. Submit to laboratory as soon as possible.

RELATIVE COST: $$

PEARLS

- Cutaneous or localized infections are more likely to become systemic in immunocompromised hosts. Immunocompromised owners may be more susceptible to zoonotic infection.
- Fine-needle aspirates of solid tissue lesions are characterized by macrophages containing rod-shaped organisms that appear as negative images with Wright-Giemsa or Diff-Quik stains.
- Organisms will stain with acid-fast stains.
- PCR testing for detection of DNA is available for some of the zoonotic strains of *Mycobacterium* spp.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150

$$$$: >$150

Monocytes (Monocytosis, Monocytopenia)

DEFINITION

Largest leukocyte on blood smear. It has an oval to lobulated nucleus and gray basophilic cytoplasm with fine azurophilic granules and occasionally clear vacuoles. Monocytes become macrophages upon entering tissues and fluids.

TYPICAL NORMAL RANGE

Dogs: 0.1-1.5 × 10^3 monocytes/µL. Cats: 0-1 × 10^3 monocytes/µL.

PHYSIOLOGY

Monocytes are produced in the marrow, with a short transit time from monoblast to monocyte, which quickly enters blood. Monocytes and macrophages are involved in several different functions that include killing bacteria and fungi, presenting antigens to lymphocytes, removal of necrotic and apoptotic cell debris, and destruction of senescent or abnormal erythrocytes.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Inflammation, acute or chronic
- Stress leukogram, from endogenous or exogenous glucocorticoids
- Monocytic leukemia, myelomonocytic leukemia

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate for given causes, depending on history and physical exam.

CAUSES OF ABNORMALLY LOW LEVELS: Monocytopenia is not considered a clinically significant abnormality, because monocytes often occur in very low numbers naturally.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA whole blood (lavender-top tube) and freshly prepared blood smear for laboratory to stain

RELATIVE COST: $$ (reported as part of CBC)

PEARLS

After acute onset of neutropenia caused by transient suppression of hematopoiesis (e.g., chemotherapy), monocytes return to high levels in blood sooner than neutrophils. Therefore, in neutropenic patients, monocytosis can signal hematopoietic recovery and impending resolution of neutropenia.

AUTHOR: STEPHEN D. GAUNT

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Methemoglobinemia, Methemoglobinuria

DEFINITION

Methemoglobinemia: accumulation of methemoglobin in blood. Methemoglobinuria: presence of methemoglobin in urine. Methemoglobin has an iron moiety that has been oxidized to the ferric (Fe^{3+}) state from the normal ferrous (Fe^{2+}) state in hemoglobin.

SYNONYM

MetHb

TYPICAL NORMAL RANGE

- Methemoglobin spot test: drop of venous blood on a white paper towel normally is bright red; if methemoglobin concentration is >10%, spot remains dark with a brown tinge.
- Blood/urine levels: methemoglobin normally represents <1% of total hemoglobin.

PHYSIOLOGY

Increased production of methemoglobin results from exposure to oxidant chemicals, drugs, plants, or decreased reduction of methemoglobin due to a hereditary deficiency of erythrocyte methemoglobin reductase. Methemoglobin cannot bind and carry oxygen to tissue. If sufficient amounts of methemoglobin are present, low blood oxygen tension (hypoxemia) results.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hereditary deficiency of methemoglobin reductase or exposure to oxidant chemicals (nitrite, copper), drugs (e.g., acetaminophen, benzocaine, phenazopyridine, zinc), or plants

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- If spot test is positive, consider arterial blood gas, pulse oximetry, and if available, cooximetry analysis. Cooximetry measures concentrations of methemoglobin as a percentage of the total hemoglobin concentration in the blood sample.
- CBC to determine if hemolytic anemia is present, because it is a common sequela to oxidant injury of erythrocytes
- Evaluation of red blood cell morphology for Heinz bodies and eccentrocytes (hallmarks of oxidant injury)
- Methemoglobin reductase level determination if hereditary deficiency is suspected

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN

- Anticoagulated whole blood collected in EDTA (lavender-top tube) for spot test; 0.5 mL minimum
- Methemoglobin reductase level determination: prior arrangements must be made with a laboratory before submitting samples. Whole blood (1 mL in EDTA [lavender-top tube]) should be refrigerated and sent chilled (not frozen) to a laboratory allowing assay to be done the same day the specimen is collected. One or more samples collected from normal animals should be submitted with the patient samples for use as controls. Not offered by most veterinary reference labs; may be run in human lab if erythrocyte lysing agent does not cause methemoglobin formation.

PEARLS

- Severe methemoglobinemia produces chocolate brown discoloration of the blood.
- Most chemicals producing methemoglobinemia also produce Heinz body hemolytic anemia.
- Spot testing (see above) is rapid, inexpensive, and may be done in-house.

AUTHOR: SHERRY J. MORGAN

Magnesium

DEFINITION

Essential nutrient and major divalent cation. Serum total magnesium includes protein-bound (30%), anioncomplexed (15%), and ionized (55%) fractions.

SYNONYMS

Mg, Mg^{2+}

TYPICAL NORMAL RANGE

Range: 1.5-2.7 mg/dL. Unit conversion: mg/dL × 0.4114 = mmol/L; mEq/L × 0.5 = mmol/L.

PHYSIOLOGY

Sources: dietary; commercial foods are fortified. Absorbed in small intestine; vitamin D may enhance absorption. Excreted in urine, feces, milk. Extracellular fluids contain <2% of total, bone contains 50%-60%, remainder is intracellular. Shifts from extracellular to intracellular compartments. Ionized Mg^{2+} is the biologically active form.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Decreased urinary excretion (decreased glomerular filtration rate, renal failure). Uncommon: excess oral administration (antacids, laxatives), intravenous Mg.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate renal function, review oral and parenteral supplements.

CAUSES OF ABNORMALLY LOW LEVELS

- Hypoproteinemia: decreases protein-bound Mg; no effect on ionized Mg
- Excess urinary excretion: fluid diuresis; diuretic drugs; renal tubular disease
- Inadequate gastrointestinal absorption: chronic diarrhea, malabsorption syndromes, binding to other nutrients (excess fatty acids, oxalate, phosphate, fiber)
- Shifts from extracellular to intracellular compartments: treatment for diabetic ketoacidosis (insulin, bicarbonate infusions)
- Diabetes mellitus, hyperparathyroidism, hyperthyroidism, pancreatitis, trauma, sepsis may predispose

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW

- Measure serum albumin; measure serum ionized magnesium.
- Evaluate for renal, gastrointestinal disease as a primary or contributing cause.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Renal excretion increased by loop and osmotic diuretics, and drug-induced renal tubular injury (e.g., aminoglycosides, cisplatin, amphotericin B)
- Insulin, glucose, or bicarbonate infusions promote intracellular shifting, decreasing serum Mg.
- Administration of Mg-containing laxatives, antacids causes increases.

LAB ARTIFACTS THAT MAY INTERFERE

- Falsely increased by hemolysis or delayed removal of serum from clot
- Falsely decreased if anticoagulants that bind Mg are used (EDTA [lavender-top tube], citrate [blue-top tube], oxalate)

SPECIMEN: Serum preferred (red-top tube); heparinized plasma (green-top tube) may be used. Remove serum from erythrocytes

promptly after centrifugation.

RELATIVE COST: $

PEARLS

Concurrent hypocalcemia, hypokalemia may be refractory to therapy until hypo-magnesemia is corrected.

AUTHOR: ROBIN W. ALLISON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

N-Terminal Pro-B-Type Natriuretic Peptide (NT-proBNP)

DEFINITION

Circulating biomarker for cardiac disease in dogs and cats

TYPICAL NORMAL RANGE

Dog:

- <900 pmol/L within reference interval
- 900-1800 pmol/L slight increase; cardiac workup suggested if clinical signs present
- >1800 pmol/L consistent with heart disease

Cat:

- <100 pmol/L within reference interval
- 100-270 pmol/L slight increase; cardiac workup suggested if clinical signs present
- >270 pmol/L consistent with heart disease

PHYSIOLOGY

When intracardiac hydrostatic pressure is increased, BNP is released from cardio-myocytes. In circulation it is enzymatically separated into two products. Serum increases of the biologically active moiety, C-terminal BNP, reflect acute changes in cardiac volume but are diagnostically limited because of its short half-life (minutes). NT-proBNP has a longer half-life, and elevations in serum levels can be interpreted as indicative of cardiac lesions of longer duration. Daily variations in concentrations are reported.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Increased intracardiac hydrostatic pressure. Azotemia (renal, prerenal) and dehydration may cause mild elevations. Lung disease has been reported to cause elevations, presumably by causing cor pulmonale and not from the lungs directly. Serum NT-proBNP levels accurately differentiate between dyspneic patients with cardiogenic pulmonary edema (high NT-proBNP) and dyspneic patients with noncardiac disease (normal NT-proBNP) in both dogs and cats.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Cardiac workup including ultrasound

IMPORTANT INTERSPECIES DIFFERENCES: The test is a species-specific ELISA test, because the NT-proBNP molecule is different between species.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Drugs used for treating cardiac disease (diuretics, angiotensin-converting enzyme inhibitors, β-adrenergic receptor Mockers, vasodilators, antiarrhythmics) may decrease values.

LAB ARTIFACTS THAT MAY INTERFERE: Prolonged contact with glass, delayed separation of cells from plasma, and improper or prolonged storage will decrease values.

SPECIMEN

- Collect blood in EDTA (lavender-top) tube, spin, and separate immediately, transferring to special transport tube. 1 mL plasma minimum. May be stored 2°C-8°C in transport tube for up to 48 hours. Freeze at 0°C if there will be a longer testing interval.
- Call testing laboratory to obtain transport tubes prior to obtaining specimen.

RELATIVE COST: $$

PEARLS

- Patients with pulmonary hypertension or renal disease may have elevated NT-proBNP values.
- Daily variation may occur secondary to physical exertion, fluid intake, and suspected circadian rhythm.

- NT-proBNP does not consistently distinguish between normal patients and patients with compensated (“asymptomatic”) heart disease, so this test cannot be used as a screening test for heart disease in patients with no clinical signs.

$$: $21-75
$$$: $76-150
$$$$: >$150

Neutrophils (Neutrophilia, Neutropenia)

DEFINITION

Blood leukocyte with segmented nucleus and inconspicuous cytoplasmic granules. Its primary functions during inflammation are phagocytosis and killing bacteria.

SYNONYMS

Polymorphonuclear neutrophil (PMN), segmented neutrophil

TYPICAL NORMAL RANGE

Dogs: 3-11.5 × 10^3 neutrophils/µL. Cats: 2.5-12.5 × 10^3 neutrophils/µL.

PHYSIOLOGY

Precursors in bone marrow respond to colony-stimulating factors produced during inflammatory and immune responses. Mature neutrophils are initially retained in marrow as part of storage pool. In blood, neutrophils occur either in the circulating pool or are associated with endothelial cells as marginal pool and then migrate into tissue. Neutrophils circulate for only a few hours. In blood samples collected for CBC, only neutrophils in the circulating pool are counted.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS (NEUTROPHILIA)

- Inflammation, whether acute or chronic, infectious or noninfectious. If acute inflammation, left shift and/or toxic changes may be present.
- Stress leukogram (glucocorticoids shift neutrophils from marrow storage pool and from marginal pool into circulating pool).
- Excitement leukocytosis (increased blood flow shifts neutrophils from marginal to circulating pool).
- Paraneoplastic production of colony-stimulating factor
- Granulocytic leukemia
- Canine leukocyte adhesion deficiency

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Assess for cause depending on clinical signs.

CAUSES OF ABNORMALLY LOW LEVELS (NEUTROPENIA)

- Intense inflammation, especially if bacterial cause (increased tissue demand)
- Endotoxemia (shift from circulating to marginal pool)
- Acute parvoviral infection (decreased marrow production and endotoxemia)
- Decreased granulopoiesis (e.g., feline leukemia virus [FeLV] infection, feline immunodeficiency virus [FIV] infection, drugs [see below], myelophthisis)
- Destruction of mature neutrophils (e.g., immune-mediated neutropenia)
- Previous use of recombinant human colony-stimulating factor

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Bone marrow aspirate or core biopsy

IMPORTANT INTERSPECIES DIFFERENCES

- Neutrophilia from excitement is more likely in young cats, whereas neutrophilia from glucocorticoids (stress leukogram) is more likely in dogs.
- Dogs typically have higher degrees of neutrophilia than cats.
- Cats may have benign idiopathic neutropenia (diagnosis of exclusion).

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Increase: glucocorticoids
- Decrease: albendazole, methimazole, trimethoprim-sulfa, many chemotherapeutic anticancer agents, many others

SPECIMEN: EDTA whole blood (lavender-top tube) and freshly prepared blood smear for laboratory to stain

RELATIVE COST: $$ (reported as part of CBC)

PEARLS

Inflammation is not the only cause of neutrophilia; other causes are stress leukogram and excitement leukocytosis. Extreme neutrophilia (>50,000 neutrophils/µL) is more often reported in dogs with pyometra, hepatozoonosis, immunemediated hemolytic anemias, paraneoplastic production of colony-stimulating factor, or chronic granulocytic leukemia.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Neospora caninum Serology

DEFINITION

Detection of serum antibody to *Neospora caninum* by IFA or ELISA

PHYSIOLOGY

N. caninum is a coccidian parasite whose morphology is identical to *Toxoplasma gondii* under light microscopy. Clinical manifestations of *N. caninum* in dogs are primarily neurologic and musculoskeletal. Transplacental transmission occurs.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Infection with or prior exposure to *N. caninum.* Rising titer (>fourfold) confirms active infection. Positive cerebrospinal fluid titers are considered suggestive of disease.
- IFA tests have little cross-reactivity with other parasites, including *T. gondii*. However, cross-reactivity depends on the antigen source used for the assay (among other laboratory-based factors) and may vary.
- Most dogs with confirmed neosporosis have titers =1:200. High titers have been found in clinically normal dogs, suggesting subclinical disease.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Treatment for neosporosis if clinical signs are compatible with this disease.

IMPORTANT INTERSPECIES DIFFERENCES: Serologic tests use species-specific reagents and must be adapted for the species of interest. Cats have been experimentally infected, but clinically, neosporosis in cats is unknown; natural disease in small animals is mainly seen in dogs. *N. caninum* is an important cause of abortion in ruminants.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Serum (red-top tube), refrigerated

RELATIVE COST: $$$

PEARLS

- Diagnosis is sometimes made via observation of tachyzoites of *N. caninum* in biopsy/necropsy tissue or in Cytologic preparations. The morphology of the tachyzoites of *N. caninum* and *T. gondii* is identical, but differentiation can be made via direct fluorescent antibody or immunohistochemistry of tissue samples using species specific antibodies. Alternatively, molecular techniques (PCR) have been used for differentiating the two organisms.
- Almost all commercially available laboratory tests for antibody are for immunoglobulin G.
- Transplacental transmission may occur in dogs.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: JAMES H. MEINKOTH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Pyuria

DEFINITION

The presence of increased numbers of leukocytes in urine sediment

TYPICAL NORMAL RANGE

Fewer than 5 leukocytes/high power field (HPF = 40x objective)

PHYSIOLOGY

In health, a few leukocytes from the kidneys, urinary bladder, reproductive tract, or urethra enter the urine (free catch or catheterization).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Inflammation of genital or urinary tract

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Assess method of urine collection: free catch, catheterization, cystocentesis.
- If free catch, obtain fresh sample (for further evaluation) via cystocentesis if possible or via urethral catheter or midstream catch if not possible.
- Similarly, if catheter sample, obtain fresh sample by cystocentesis if possible.
- Assess other findings in urinalysis, such as pH, numbers of red cells, and presence of bacteria.
- Bacterial culture and antibiotic susceptibility testing of urine.

CAUSES OF ABNORMALLY LOW LEVELS

- Diseases that hamper neutrophil function (e.g., diabetes mellitus, hyperadrenocorticism) may falsely reduce the number of leukocytes observed in a patient with urinary tract infection.
- Diseases that cause urine to be dilute (endocrinopathies, liver disease, renal failure, others) may give the misleading appearance of a low concentration of leukocytes (or their absence) in the urine of patients with urinary tract infections.
- Samples that are not analyzed in a timely fashion, dilute urine, or alkaline urine may have decreased numbers of leukocytes due to lysis of cells.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Urine in clean/sterile container. Sediment examination of urine should be done within a few of hours of collection, because leukocytes deteriorate, falsely decreasing their numbers.

RELATIVE COST: $ (reported as part of urinalysis)

PEARLS

- Should be detected during sediment examination, a part of urinalysis
- For negative bacterial urine culture with concurrent pyuria, consider antibiotic effect, fungal or algal urinary tract infection.
- A urine culture with antibiotic susceptibility testing is indicated even when pyuria is absent if the differential diagnosis includes diseases that reduce neutrophil function and/or cause dilute urine.
- Patients with chronic kidney disease, in particular, may not show pyuria despite having low-grade pyelonephritis. Identifying such an infection through culture and susceptibility is important because it offers the possibility of reversing renal tubular damage with appropriate antibiotic treatment.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Prothrombin Time

DEFINITION

Screening coagulation test of the extrinsic and common coagulation pathways

SYNONYMS

One-stage prothrombin time (OSPT); PT

TYPICAL NORMAL RANGE

Values are approximate (normals are laboratory and instrument specific). Dogs: 7-11 seconds. Cats: 5-8 seconds.

PHYSIOLOGY

Plasma to be tested and the reagent (Ca^{2+}-thromboplastin reagent) are warmed and mixed together to allow tissue factor in the reagent to activate factor VII in the plasma, initiating the extrinsic pathway and then the common pathway. A fibrin clot is formed that is detected by the instrument. The prothrombin time (PT) is the time from the plasma and reagent mixing to the formation of the clot.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Prolonged PT: hepatic disease, vitamin K deficiency, disseminated intravascular coagulation (DIC), anticoagulant intoxication, hereditary defects in extrinsic or common pathway (factors VII, X, V, II, and I), heparin, presence of fibrin degradation products (FDPs), antibodies to phospholipids or coagulation factors.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Rule out acquired causes and DIC; specific coagulation factor assays (rare).

CAUSES OF ABNORMALLY LOW LEVELS: Shortened PT is not a reliable measure of hypercoagulability.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG **EFFECTS ON** LEVELS: Warfarin can cause a prolonged PT. PT is often the first coagulation test affected by warfarin administration.

LAB ARTIFACTS THAT MAY INTERFERE: Different thromboplastin reagents can produce different results; improper blood/citrate ratios falsify results (too little blood can prolong results, and too much blood can shorten coagulation times).

SPECIMEN: Citrated plasma (blue-top tube). Care should be taken to avoid traumatic venipuncture, which can cause in vitro activation of tissue factor, artifactually shortening the PT. Immediately mix the blood and anticoagulant.

RELATIVE COST: $

PEARLS:

- Antagonism or absence of vitamin K-dependent coagulation factors, as occurs in anticoagulant rodenticide intoxication or liver disease, tends to increase PT before activated partial thromboplastin time (APTT). This is due to the short half-life of factor VII.
- Citrate (blue-top) tube must be filled to capacity generated by its vacuum to avoid artifactual alteration of result.
- A patient with overt clinical signs of hemorrhage due to anticoagulant rodenticide intoxication will invariably have an elevated PT (usually markedly elevated).
- Decreased PT does not indicate hypercoagulability; rather, it is usually a result of suboptimal phlebotomy (sample collection artifact).

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Proteins Induced by Vitamin K Absence or Antagonism (PIVKA)

DEFINITION

Proteins induced by vitamin K absence or antagonism (PIVKA) are inactive precursor coagulation proteins that accumulate in the peripheral blood when vitamin K is absent or inhibited.

SYNONYMS

PIVKA, Thrombotest

TYPICAL NORMAL RANGE

Dogs: 12-20 seconds. Cats: 20-30 seconds.

PHYSIOLOGY

Factors II, VII, IX, and X, factor C, and factor S are all vitamin K-dependent proteins involved in coagulation homeostasis. They are synthesized in inactive precursor form in the liver and require carboxylation of their glutamyl residues by vitamin K for activation. The enzyme, vitamin K epoxide reductase, is critical for this carboxylation. In the absence of vitamin K or if vitamin K epoxide reductase is inhibited (e.g., by anticoagulant rodenticides), a bottleneck phenomenon occurs whereby the inactive coagulation precursors (PIVKAs) and vitamin K epoxide accumulate in the blood, where they can be measured. Thus, the PIVKA test is a sensitive indicator of anticoagulant intoxication.

CLINCIAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Decreased vitamin K: neonate born to malnourished mother, sterilization of gastrointestinal tract (due to antibiotic therapy), prolonged anorexia/abnormal diet, malabsorption of vitamin K (cholestasis, exocrine pancreatic in-sufficiency, infiltrative bowel disease). Vitamin K antagonism: anticoagulant rodenticides, cephalosporins, and sulfonamides.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: CBC/profile, urinalysis, coagulation profile, determine if recent exposure to drugs or anticoagulant rodenticides. Urinalysis should not be obtained by cystocentesis, and blood sampling should be drawn from a compressible vein (e.g., limb, not jugular) in patients with elevated PIVKA concentrations and therefore with a bleeding tendency.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Numerous drugs can worsen the effects of anticoagulant rodenticide toxicity through platelet inhibition (nonsteroidal antiinflammatory drugs, corticosteroids), decreased protein binding (phenylbutazone, corticosteroids, sulfonamides), and increased hepatic metabolism (antibiotics including rifampin, chloramphenicol; barbiturates).

SPECIMEN: Plasma collected in citrate (blue-top tube). Tube must be filled to capacity generated by its vacuum to avoid artifactual alteration of result. Spin and separate plasma. Refrigerate specimens that will be analyzed within 3 hours; freeze >3 hours.

RELATIVE COST: $$

PEARLS

Although helpful in confirming a diagnosis of rodenticide toxicity, in most cases treatment decisions must be made before test results are available.

AUTHOR: DEBORAH G. DAVIS

Pricing Information

Protein Electrophoresis

DEFINITION

Qualitative and quantitative determination of proteins, typically measured in serum but may also be performed on cerebrospinal fluid and urine. Proteins separate into groups (fractions) based on their rate of migration in an electric field. Protein charge and size determine migration rate.

TYPICAL NORMAL RANGE

Conversion: for mg/mL: multiply g/dL by 10.

	Dogs	Cats
α1	0.2-0.5 g/dL	0.2-1.1 g/dL
α2	0.3-1.1 g/dL	0.4-0.9 g/dL
β1	0.6-1.2 g/dL	0.3-0.9 g/dL
β2	0.6-1.4 g/dL	0.6-1.0 g/dL
γ1	0.5-1.3 g/dL	0.6-1.0 g/dL
γ2	0.4-0.9 g/dL	1.4-1.9 g/dL

PHYSIOLOGY

The five major fractions of soluble body proteins are albumin and the four globulin fractions: a1, a2, β, and γ; β and γ globulins each has two fractions. Albumin is the largest fraction in healthy animals. The a1 globulin fraction primarily contains acute-phase proteins. The a2 globulin and β globulin fractions contain acute phase proteins, lipoproteins, and some immunoglobulins. The γ globulin fraction contains immunoglobulin (Ig) A, IgG, and IgM. Elevation of γ globulins may be seen on the electrophoresis tracing as a broad-based peak (polyclonal) or a single narrow peak (monoclonal).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Increased a globulin: acute inflammation, nephrotic syndrome, corticosteroid administration
- Increased β globulin: acute inflammation, nephrotic syndrome, liver disease, immune responses, neoplasia
- Increased γ globulins: immune stimulation, neoplasia

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Polyclonal gammopathy: assess for inflammation, infection, immune-mediated disease, liver disease, neoplasia (neoplasia less commonly polyclonal).
- Monoclonal gammopathy: assess for plasma cell myeloma, B-cell lymphoma, lymphocytic leukemia; inflammatory or infectious disease (ehrlichiosis, feline infectious peritonitis, leishmaniasis, plasmacytic stomatitis, lymphoplasmacytic enterocolitis [infection less commonly monoclonal]).

CAUSES OF ABNORMALLY LOW LEVELS

- Albumin: acute phase response, glomerular disease, liver disease, starvation, cachexia
- Albumin and globulins: gastrointestinal disease (protein losing enteropathy), blood loss, sequestration in body cavity effusion, severe exudative skin disease, excess fluid therapy or water intake
- Globulins: failure of passive transfer (FPT), inherited or acquired immunodeficiency

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Based on which fraction(s) is/are low, investigate for albumin loss or decreased albumin synthesis, globulin loss, FPT, acquired or inherited immunodeficiency

SPECIMEN AND PROCESSING CONSIDERATIONS

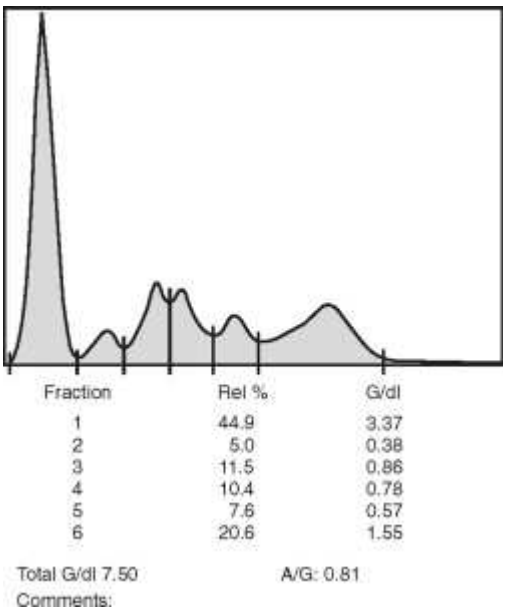
LAB ARTIFACTS THAT MAY INTERFERE: Hemolysis artificially elevates β globulins, because hemoglobin migrates in this region on electrophoresis; lipemia promotes hemolysis.

SPECIMEN: Serum (red-top tube), refrigerate. Heparinized plasma (green-top tube) is acceptable.

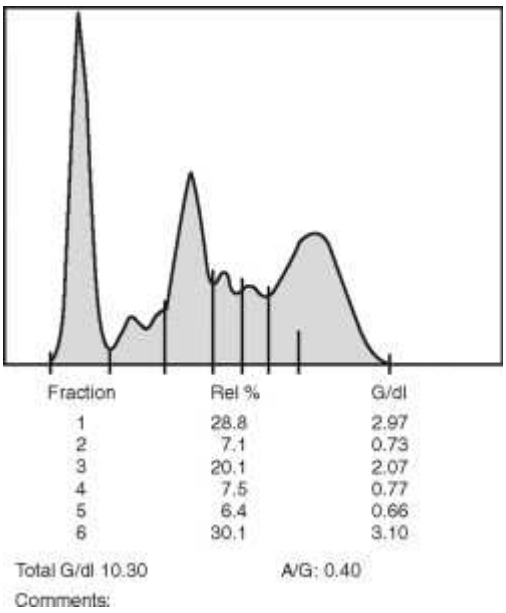
RELATIVE COST: $$

PEARLS

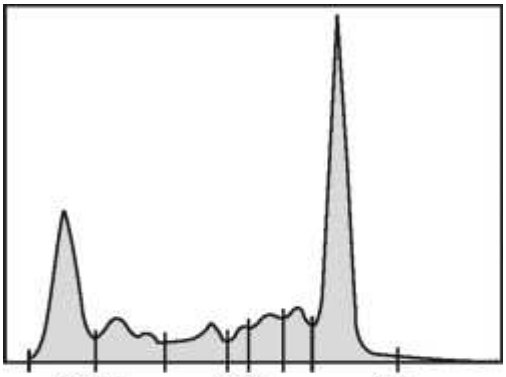
The numerical values obtained from protein electrophoresis must be assessed in conjunction with the tracing. The values alone do not differentiate between monoclonal and polyclonal gammopathies.



PROTEIN ELECTROPHORESIS, NORMAL Serum protein electrophoresis tracing demonstrating a normal distribution of serum proteins.



PROTEIN ELECTROPHORESIS, POLYCLONAL Serum protein electrophoresis tracing demonstrating hyperglobulinemia that is polyclonal in distribution, as is typical of inflammation.



Fraction	Rel %	G/dl
1	23.4	2.41

Progesterone

DEFINITION

Steroid hormone secreted by corpora lutea of the ovaries and by the placenta

TYPICAL NORMAL RANGE

Depends on stage of estrous cycle; concentrations exceeding 2 ng/mL indicate luteal function.

PHYSIOLOGY

Progesterone is secreted by the cells of developing corpus luteum, the presence of which indicates pregnancy, diestrus, or an ovarian lesion (e.g., cyst or neoplasm). Concentrations greater than those of anestrus (i.e., >2 ng/mL) are used for predicting time of ovulation in bitches. Proestrus is characterized by increased estrogen concentration, vulvar swelling, and vaginal discharge. Decreasing estrogen concentration and increasing progesterone concentration, resulting from increased luteinizing hormone (LH), indicates estrus. Behavioral changes (receptivity to breeding) are also important features to be observed. Ovulation occurs approximately 48 hours after the LH surge. Progesterone is needed to maintain pregnancy and is secreted by the placenta. Decreasing progesterone concentrations (<2 ng/mL) indicate the onset of parturition within 24 hours in most bitches.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Developing corpora lutea followed by pregnancy; residual ovarian tissue in a patient thought to have been spayed; luteal cysts; granulosa cell tumor

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Confirm the presence of ovarian abnormalities (e.g., with abdominal ultrasound) if not evaluating a breeding bitch.

CAUSES OF ABNORMALLY LOW LEVELS: Depends on stage of cycle; may indicate normal anestrus or failure to ovulate, become pregnant, or maintain pregnancy; parturition

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate for infertility if repeated failure to maintain pregnancy.

IMPORTANT INTERSPECIES DIFFERENCES: Test used primarily in dogs; not used in cats because they are induced ovulators.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Minimal interference by deoxycortisol, deoxycortisone, and dihydroprogesterone

LAB ARTIFACTS THAT MAY INTERFERE: Falsely decreased with storage at room temperature or delay in separation of serum or plasma from red blood cells (separation should be performed immediately); lipemia interference if measured by chemiluminescence; use of serum separator tubes falsely decreases values.

SPECIMEN: Depends on the laboratory; serum (red-top tube) or heparinized (green-top tube) or EDTA plasma (lavender-top tube) may be used. Do not use serum separator tubes. Separate serum or plasma from red blood cells as soon as possible. Store at 2°C-8°C.

RELATIVE COST: $$

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Potassium

DEFINITION

Major intracellular cation continually pumped into cell by energy-dependent sodium/potassium-ATPase pump at cell membrane; important in cardiac and neuromuscular membrane potentials/excitability

SYNONYM

K^+

TYPICAL NORMAL RANGE

Typically 3.5-5.5 mEq/L (= mmol/L)

PHYSIOLOGY

Influenced by acid-base status. Metabolic acidosis (e.g., with renal failure) causes extracellular shift and hyperkalemia. Under normal conditions, excess plasma K^+ is excreted in the urine. Hyperkalemia is uncommon if renal function is normal (exceptions: postrenal lesions, hypoadrenocorticism, iatrogenic). Potassium is released during normal platelet coagulation, potentially causing artifactual hyperkalemia.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Decreased renal excretion (oliguric/anuric renal failure, urinary tract obstruction or rupture), hypoadrenocorticism, artifact (due to normal platelet clumping or in Asian dog breeds [e.g., Akita]), gastrointestinal disease (salmonellosis, trichuriasis), chylothorax with repeated drainage, diabetic ketoacidosis, metabolic acidosis (due to inorganic acids), rhabdomyolysis (see p. 556)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Repeat measurement using green-top tube (heparin) to collect blood sample if sample was collected in a red-top tube; CBC, serum biochemistry profile, and urinalysis; evaluate for drugs that can cause hyperkalemia; abdominal ultrasound/radiographs (check integrity of urinary tract), ACTH stimulation test to rule out hypoadrenocorticism if clinically compatible; blood gas determination to assess acid-base status.

CAUSES OF ABNORMALLY LOW LEVELS: Increased loss (vomiting, diarrhea), chronic kidney disease (cats), postobstructive diuresis, inappropriate fluid therapy (dilutional hypokalemia), diuresis associated with diabetes mellitus, ketoacidosis, hyperaldosteronism, alkalemia, and hypokalemic periodic paralysis of Burmese cats (see p. 556)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: CBC/serum biochemistry profile/urinalysis/blood gas

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Hyperkalemia: angiotensin-converting enzyme inhibitors, potassium-sparing diuretics (e.g., spironolactone), K^+ penicillin G, oversupplementation of fluids with K^+, o,p'-DDD (iatrogenic hypoadrenocorticism)
- Hypokalemia: loop diuretics (furosemide), thiazide diuretics, amphotericin B, penicillin, administration of K^+-free fluids

LAB ARTIFACTS THAT MAY INTERFERE: Serum K^+ is higher than plasma K^+, especially if thrombocytosis is present; marked hemolysis in dogs (Akitas, English springer spaniels) with high K^+ red blood cell concentration, marked leukocytosis. Avoid by prompt separation of plasma from cells. Drawing blood through an intravenous catheter may dilute sample, resulting in false decrease.

SPECIMEN: Serum (red-top tube); K^+ will remain stable for extended periods of time, but platelet activation-induced K^+ release makes sampling into heparin (green-top) tubes and separation of plasma from red cells preferable. K^+ EDTA (lavender-top tube) should not be used as an anticoagulant.

RELATIVE COST: $

PEARLS

- It is important to measure the acid-base status of hypokalemic/hyperkalemic animals.
- Normal K^+ levels in the presence of metabolic acidemia suggest low K^+ stores. Normal K^+ in an alkalotic animal suggests the total body K^+ is high.
- Hemolysis alone rarely causes artifactual hyperkalemia, and when it does, the patient is generally of a breed that has unusually high intra-RBC K^+ stores [e.g., Asian dog breeds].

Polycythemia

DEFINITION

Increased circulating erythrocyte mass, with increased hematocrit (or packed cell volume [PCV]), hemoglobin concentration, and/or erythrocyte count of blood. Occurs from increase in the circulating erythrocytes only (relative polycythemia) or an increase in both circulating erythrocytes and erythropoietic cells (absolute polycythemia).

SYNONYM

Erythrocytosis; some consider this to be the accurate term and reserve *polycythemia* for states in which all circulating blood cell lines are elevated.

PHYSIOLOGY

Relative polycythemia occurs most commonly, with the increase in circulating erythrocytes from decreased plasma volume (e.g., dehydration) or the release of sequestered erythrocytes following epinephrine-induced splenic contraction. Absolute polycythemia indicates an increase in circulating and erythropoietic cells, the result of increased erythropoietin concentration or heightened response to erythropoietin. Appropriate increase in erythropoietin occurs secondary to hypoxemia. Inappropriate production of erythropoietin occurs uncommonly from hypoxia restricted to kidneys (e.g., right-to-left shunting patent ductus arteriosus [PDA]) or paraneoplastic expression of erythropoietin from neoplasm (usually renal). Polycythemia vera is a myeloproliferative disease resulting from clonal proliferation of well-differentiated erythrocytes without any increase in basal levels of erythropoietin. The resultant erythrocytosis, especially in cases of absolute polycythemia, can cause increased viscosity of blood, sludging of blood flow, and resultant tissue hypoxia and thrombosis. See .

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Dehydration (relative polycythemia); splenic contraction (relative polycythemia); high altitude, most right-to-left cardiac shunts, or chronic pulmonary diseases (appropriate absolute polycythemia); renal hypoxia (due to right-to-left shunting PDA), renal carcinoma with erythropoietin secretion (inappropriate absolute polycythemia); polycythemia vera.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Verify instrument PCV with manual test (spun hematocrit). After ruling out the more common causes of relative polycythemia (e.g., physical exam and evaluation of serum albumin concentration for dehydration), urinalysis and abdominal ultrasound (evaluate kidneys), chest radiographs, echocardiography, arterial Po2 measurement, +/– erythropoietin assay should be considered.

IMPORTANT INTERSPECIES DIFFERENCES

- Polycythemia caused by epinephrine-induced splenic contraction is more likely in cats, although it may be appreciated in breeds of dogs (e.g., dachshunds, greyhounds) with normally higher hematocrits.
- Sight hounds (e.g., greyhounds, deer-hounds, wolfhounds, Afghan hounds) have a higher normal hematocrit/PCV (may exceed 65%).

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA whole blood (lavender-top tube)

PEARLS

Hypovolemia/dehydration is the most common cause of polycythemia in dogs and cats.

AUTHOR: STEPHEN D. GAUNT

Poikilocytes

DEFINITION

General term for presence of abnormally shaped mature erythrocytes in blood. This shape change can be artifactual (e.g., crenation) or pathologic (e.g., spherocytes, schistocytes).

TYPICAL NORMAL RANGE

Only low numbers of artifactually induced poikilocytes (e.g., crenation) should be observed in the blood of healthy animals.

PHYSIOLOGY

Normal shape of mature erythrocyte is discocyte (biconcave disk). With damage to cell membrane (e.g., antibodies, toxins, or lipid accumulation) or damage to hemoglobin (e.g., oxidation), the plasma membrane and/or protein cytoskeleton of the erythrocyte is/are altered and an abnormal erythrocyte shape results.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Immune-mediated hemolytic anemias (spherocytes), erythrocyte fragmentation (schistocytes, acanthocytes), oxidative damage (Heinz bodies, eccentrocytes), hepatic diseases (acanthocytes), venomous snake bite (echinocytes, spherocytes), bee sting (spherocytes), congenital defect in erythrocyte membrane proteins (elliptocytes, spherocytes).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Repeat blood smear for definitive determination of the specific type of poikilocytes present.

IMPORTANT INTERSPECIES DIFFERENCES: Crenation (artifact) occurs more commonly in feline erythrocytes. Spherocytosis is more easily detected in the erythrocytes of dogs, because normal canine erythrocytes have a prominent central pallor which is lacking in spherocytes.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE

- Poorly prepared blood smears will distort canine erythrocytes so that central pallor is lost and cells may resemble spherocytes.
- Erythrocytes on blood smears allowed to slowly air dry during preparation could have refractile markings and distortion; best to rapidly dry smears by waving or use heat block.
- Lipemia will cause lysis and distortion of erythrocyte morphology.
- Crenation often occurs from effects of smear preparation on erythrocytes.

SPECIMEN: EDTA whole blood (lavender-top tube) and freshly prepared blood smear for laboratory to stain.

PEARLS

See for a differential diagnosis diagram of various poikilocytes.

AUTHOR: STEPHEN D. GAUNT

Platelets

DEFINITION

- Thrombocytopenia: decreased platelet count
- Thrombocytosis: increased platelet count
- Thrombopathia: abnormal platelet function

TYPICAL NORMAL RANGE

- Dogs: 150,000-500,000/mcL
- Cats: 150,000-400,000/mcL
- 7-15 platelets per 100× field (blood film) associated with adequate platelet numbers

PHYSIOLOGY

Platelets form from megakaryocytes in bone marrow, spleen, and lung. Platelets are discoid, anucleate, 5- to 7-mcm cytoplasmic fragments important in primary hemostasis. They adhere to subendothelium by the binding of von Willebrand factor (vWF) to platelet glycoprotein Ib (GPIb). Aggregation occurs through binding of platelet membrane $a^{IIb}\beta^{3}$ with fibrinogen or vWF. Activated platelets release granule contents (fibrinogen, factor V, ADP, ATP, plasminogen), thromboxane A2, and arachidonic acid. Mediator release and reactions with leukocytes are important in inflammation and wound healing.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Redistribution (exercise, epinephrine release), neoplasia (essential thrombocythemia, acute megakaryocytic leukemia), increased production (inflammation, iron deficiency, rebound from thrombocytopenia). Associated with hyperadrenocorticism and administration of glucocorticoid, although the mechanism is not known.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Examine blood film to confirm increase; serum iron profile, CBC/serum biochemistry profile for evidence of inflammation (neutrophilia with left shift, elevated globulins); bone marrow aspirate.

CAUSES OF ABNORMALLY LOW LEVELS: Thrombocytopenia: acute, severe blood loss; drugs (myelotoxic); immune-mediated destruction; bone marrow replacement (myelofibrosis, neoplasia); megakaryocytic neoplasia; localized or disseminated intravascular coagulation (DIC); infectious diseases (canine distemper, canine parvovirus, cytauxzoonosis, endotoxemia, feline leukemia virus [FeLV], feline infectious peritonitis [FIP], ehrlichiosis, babesiosis, histoplasmosis, leptospirosis, Rocky Mountain spotted fever, leishmaniasis).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Review history and physical exam for signs of underlying disorder/trigger; evaluation of blood film for hemotropic infectious agents, clumping; coagulation profile to rule out bleeding, DIC; bone marrow aspirate; serologic titers for infectious diseases.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Thrombocytosis: vincristine, vinblastine, exogenous corticosteroids
- Thrombocytopenia: chemotherapeutic agents, estrogens, phenylbutazone, certain diuretics, certain antibiotics/antimicrobials

LAB ARTIFACTS THAT MAY INTERFERE: Clumping, large platelets (macroplatelets) falsely decrease analyzer count. Heparinized samples often have excessive platelet clumping; macroplatelets (and resultant undercounting by automated analyzers [pseudothrombocytopenia]) are an incidental finding in Cavalier King Charles spaniels.

SPECIMEN: EDTA whole blood (lavender-top tube) preferred; citrated whole blood (blue-top tube) can be used.

RELATIVE COST: $ (manual platelet count); automated platelet counts and estimates are reported with CBC ($$)

PEARLS

In a patient with a bleeding disorder, suspect thrombopathia if platelet count, hematocrit, coagulation parameters (prothrombin time,

activated partial thromboplastin time), and vWF are normal but buccal mucosal bleeding time is prolonged. Causes include hereditary, drug associated (barbiturate anesthetics, nonsteroidal antiinflammatory drugs, antihistamines, penicillin), fibrin degradation products, hepatic disease, hyperglobulinemia (with multiple myeloma, ehrlichiosis), FeLV, uremia. Document with specific platelet function tests.

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Phosphorus

DEFINITION

Inorganic form of phosphate; the major intracellular anion; primarily located in bone (as hydroxyapatite), with the remainder in soft tissues and in circulation

SYNONYMS

Phosphate, $Po4^{2-}$

TYPICAL NORMAL RANGE

Dogs: 3.2-8.1 mg/dL (1.03-2.61 mmol/L). Cats: 3.2-6.5 mg/dL (1.03-2.09 mmol/L).

PHYSIOLOGY

Clinical assays measure only the total inorganic phosphorus, although both organic and inorganic phosphorus are present (depending on pH). Blood levels are affected by intestinal absorption, shifting between intracellular and extracellular compartments, renal clearance, and animal age. Parathyroid hormone (PTH) triggers phosphaturia.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Decreased glomerular filtration rate (decreased renal excretion due to renal failure, prerenal or postrenal azotemia), hypoparathyroidism, acromegaly, increased intestinal absorption (phosphate enema, increased vitamin D, ischemic intestinal lesions), myopathies, hyperthyroidism in cats, osteolytic bone lesions, normal bone growth.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Rule out artifact (repeat test).
- Evaluate kidney function, rule out urinary obstruction or rupture; determine PTH levels, thyroid hormone level (cats), ionized calcium; survey skeletal radiographs.

CAUSES OF ABNORMALLY LOW LEVELS: Increased renal excretion (Fanconi syndrome in dogs, prolonged fluid diuresis), prolonged anorexia, intestinal malabsorption, hypovitaminosis D, humoral hypercalcemia of malignancy, primary hyperparathyroidism, hyperinsulinism (endogenous or treatment for diabetic ketoacidosis)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: CBC/chemistry profile/urinalysis; repeat to rule out artifact, ionized calcium.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Decrease: phosphate-binding antacids, anesthetics, diuretics, insulin, anticonvulsants, bicarbonate, mithramycin, salicylates
- Increase: phosphate enemas, intravenous supplementation, furosemide, vitamin D, hydrochlorothiazide, minocycline

LAB ARTIFACTS THAT MAY INTERFERE

- Increase: hemolysis (in vivo or in vitro), delayed separation of serum from clot, hyperlipidemia, hyperproteinemia, thrombocytosis
- Decrease: postprandial carbohydrates (mild), hyperbilirubinemia (with certain assays)

SPECIMEN: Serum (red-top tube) preferred; can also be measured in heparinized plasma (green-top tube) and urine.

RELATIVE COST: $

PEARLS

- Healthy animals <1 year of age may normally have elevated serum phosphorus levels.
- Acute hypophosphatemia (e.g., during initial management of diabetic ketoacidosis) carries the risk of causing severe hemolytic anemia.

AUTHOR: DEBORAH G. DAVIS

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Phenobarbital Serum Level

DEFINITION

Used for monitoring patients receiving phenobarbital for treating seizures and for determining whether therapeutic or potentially toxic levels have been reached

SYNONYMS

PB, PhB, Pheno

TYPICAL NORMAL RANGE

Therapeutic range: 15-40 mg/mL

PHYSIOLOGY

The elimination half-life of orally administered phenobarbital in dogs ranges widely, from 12-125 hours (average approximately 48 hours). Peak levels occur 4-8 hours after administration. Pharmacokinetics can be altered by chronic administration, concurrent disease (especially liver disease), age, and concurrent administration of other drugs. For this reason, monitoring of serum drug levels at steady state (14-16 days after starting treatment) is recommended. Peak and trough levels, which were previously recommended, are not considered necessary for making therapeutic decisions.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: >45 mg/mL considered toxic

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Correlate levels with clinical signs (i.e., presence or absence of seizures). Consider effect of concurrently administered drugs or concurrent disease on pharmacokinetics. Evaluate a liver profile. Whether liver disease, other disease, or drugs are present, high levels should prompt the consideration of dose reduction, with institution of a second antiseizure drug if needed.

CAUSES OF ABNORMALLY LOW LEVELS: Serum levels <10 mg/mL are subtherapeutic.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Correlate drug levels with clinical signs (seizures) to decide whether to increase dose, replace with other antiseizure drug, or discontinue.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Concurrent administration of many other drugs, such as certain antibiotics (e.g., doxycycline, chloramphenicol, metronidazole), anticoagulants (warfarin), cardiopulmonary drugs (e.g., aminophylline/theophylline, certain β-blockers, quinidine), glucocorticoids (prednisone, others) and many others, may increase or decrease levels of phenobarbital. Consult a pharmacology textbook or pharmacist for information regarding specific drug interactions.

LAB ARTIFACTS THAT MAY INTERFERE: Collection of blood in a serum separator tube can falsely decrease levels. Moderate to marked lipemia or icterus may artifactually increase reported drug levels.

SPECIMEN: 1 mL of serum (red-top tube; do not use serum separator tube)

RELATIVE COST: $$

PEARLS

Phenobarbital is involved in many drug interactions; consult a pharmacology textbook or pharmacist if multiple medications.

AUTHOR: SHERRY J. MORGAN

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Pelger Huët

DEFINITION

A congenital defect in nuclear lobulation of leukocytes that is rarely reported in dogs and cats. The characteristic appearance of a hyposegmented nucleus is most evident in neutrophils but also occurs in eosinophils, basophils, monocytes, and megakaryocytes. The nuclear shape of affected neutrophils can be bilobed ("pince nez" cell), band, round, or oval, similar to neutrophilic precursors, but the nuclear chromatin of affected neutrophils is coarsely condensed, similar to mature neutrophils.

SYNONYMS

Pelger Huët anomaly or syndrome, pseudo-Pelger Huët

PHYSIOLOGY

Segmented neutrophils in dogs and cats typically have 3-5 nuclear lobes. In the congenital form of Pelger-Huët, hetero-zygotes are most common, and they exhibit hyposegmented neutrophils, many of which resemble band neutrophils. The heterozygous condition is considered benign because affected animals have no ill effects, and neutrophil function tests are not significantly altered. The low incidence of homozygotes is attributed to embryonic death. Rarely, during the course of severe inflammatory disease in unaffected animals, hyposegmentation of neutrophils will occur as a transient reversible condition ("pseudo" Pelger Huët).

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA whole blood (lavender-top tube) and freshly prepared blood smear for laboratory to stain

PEARLS

- When an otherwise unremarkable CBC report has a substantial left shift in an apparently healthy dog or cat, consider the likelihood of Pelger Huët anomaly.
- Pelger Huët is essentially an incidental finding in dogs, with no clinical adverse effect.

AUTHOR: STEPHEN D. GAUNT

Parathyroid Hormone-Related Protein

DEFINITION

Humoral factor with a molecular structure similar to parathyroid hormone (PTH); can bind to PTH receptors. It plays an important role in humoral hypercalcemia of malignancy.

SYNONYM

PTHrP

TYPICAL NORMAL RANGE

Not normally found circulating in the blood. Dogs: <2 pmol/L.

PHYSIOLOGY

Important endocrine and paracrine hormone in the fetus. Produced in minimal amounts in tissues of normal adults and functions in a paracrine manner. In humoral hypercalcemia of malignancy, neoplastic cells secrete excess amounts of PTHrP and other cytokines. PTHrP binds to the PTH receptors in bone and kidney and mimics the effects of PTH. It results in osteoclastic bone resorption, increased renal resorption of calcium, and decreased renal resorption of phosphate. Malignancies associated with increased levels of PTHrP are T-cell lymphoma, thymoma, and apocrine gland adenocarcinoma of the anal sac. Sporadic cases of humoral hypercalcemia of malignancy have been seen with other carcinomas as well.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Humoral hypercalcemia of malignancy.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Review physical exam, including rectal palpation in all dogs (apocrine gland adenocarcinoma, sublumbar lymphadenopathy). Measure serum ionized calcium, serum phosphorus, serum PTH. Humoral hypercalcemia of malignancy usually causes elevated ionized calcium level, low-normal or low PTH level, and low phosphorus level. CBC, serum biochemistry profile, urinalysis, and diagnostic imaging to identify and define extent of neoplastic disease.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Repeated thawing causes degradation of the protein and interferes with validity of results (either falsely increasing or decreasing). Proteases in serum can degrade PTHrP and cause false-negative results.

SPECIMEN: Contact laboratory for specifics. If serum is sent, immediately spin the sample after it clots, separate serum, transfer to plastic tube, and freeze. Ship frozen. If plasma is used, EDTA (lavender-top tube) with a protease inhibitor (apoprotinin or leupeptin) should be added. Plasma should be separated from the erythrocytes, transferred to a plastic tube, and shipped frozen.

RELATIVE COST: $$$

PEARLS

Three mechanisms can cause cancer-associated hypercalcemia: humoral hypercalcemia of malignancy, local bone resorption induced by hematologic neoplasms growing into the bone marrow (e.g., multiple myeloma), and local bone resorption induced by metastatic bone lesions.

AUTHOR: DEBORAH G. DAVIS

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Parathyroid Hormone

DEFINITION

Hormone produced by parathyroid glands in response to low blood calcium levels; important in the rapid and precise regulation of calcium

SYNONYMS

Parathormone, PTH

TYPICAL NORMAL RANGE

Dogs and cats: 2-13 pmol/L. Results may vary among laboratories; established reference ranges for the laboratory should be used for exact interpretation of results.

PHYSIOLOGY

Parathyroid hormone (PTH) acts directly on bone and kidney and indirectly on the gastrointestinal (GI) tract to increase serum calcium levels. PTH acts on the kidney to increase renal excretion of phosphate, increase tubular resorption of calcium, and convert vitamin D precursors to active vitamin D (which along with PTH increases calcium absorption from the GI tract). PTH acts on bone to mobilize calcium and phosphate. Ultimately, these actions result in elevation of blood calcium and hypophosphatemia.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hyperparathyroidism: primary hyperparathyroidism (parathyroid adenoma/hyperplasia), multiple endocrine neoplasia, chronic kidney disease (renal secondary hyperparathyroidism), pseudohyperparathyroidism (decreased PTH-receptor receptiveness). Rare: nutritional secondary hyperparathyroidism.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Serum ionized calcium, CBC, serum chemistry profile, urinalysis, high-resolution cervical ultrasound (radiologist), thoracic and abdominal imaging of other endocrine organs

CAUSES OF ABNORMALLY LOW LEVELS: Parathyroid inflammation and degeneration (lymphocytic parathyroiditis), inadvertent surgical removal of parathyroid (thyroidectomy in cats), decreased PTH production due to inhibition (hypervitaminosis D, hypercalcemic disorders except primary hyperparathyroidism)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Same as for elevated PTH

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Prolonged storage (>2 months) or thawing of sample may cause artificial results, either increased or decreased. Lipemia and hemolysis falsely decrease measurement. EDTA plasma samples have higher values.

SPECIMEN: Serum (red-top tube without additive; do not use serum separator tube) is used for the assay. Samples should be centrifuged immediately after clotting, frozen, and shipped frozen for analysis as soon as possible.

RELATIVE COST: $$

PEARLS:

- It is important to know both serum ionized calcium and PTH levels to correctly correlate laboratory results. Ionized hypercalcemia should cause PTH levels to be low or undetectable.
- Renal disease and secondary hyperparathyroidism will typically produce increased ionized calcium and normal to decreased PTH.
- PTH levels in the mid- or high-normal range (or higher) with concurrently elevated ionized calcium suggest primary hyperparathyroidism. With normal parathyroid gland function, ionized hypercalcemia should cause feedback inhibition and very low PTH levels.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Rocky Mountain Spotted Fever Serology

DEFINITION

Rocky Mountain spotted fever (RMSF) is a tickborne acute systemic disease caused by *Rickettsia rickettsii*. It is characterized by fever, anorexia, thrombocytopenia, uveitis, and necrotizing vasculitis in dogs.

TYPICAL NORMAL RANGE

Consult the laboratory conducting the test for information regarding reference ranges. General guideline: IFA-negative titer is <1:64.

PHYSIOLOGY

R. rickettsii is inoculated via a tick bite *(Dermacentor* spp.; possibly *Amblyomma* sp. or *Rhipicephalus* sp.), enters the circulatory system, and infects and replicates within endothelial cells of small blood vessels, where it induces vasculitis. Vasculitis leads to increased vascular permeability, microvascular hemorrhage, thrombocytopenia, disseminated intravascular coagulation (DIC), edema, and ultimately hypotensive shock with multiple-organ damage.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: A positive titer indicates exposure to the RMSF organism. A very high single immunoglobulin (Ig) G titer (≥1: 1024), fourfold increase in paired IgG titers (2-4 weeks apart), or a positive IgM titer with characteristic signs is consistent with active infection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: A PCR test, direct FA staining of infected tissues, and tissue culture are available but may not be necessary if clinical signs are compatible with RMSF and the titer(s) are positive.

CAUSES OF ABNORMALLY LOW LEVELS: A negative titer indicates lack of exposure or early/acute infection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If clinical signs of RMSF are present and initial titer is negative, submit a convalescent titer in 2-4 weeks.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Effective antibiotic treatment may decrease serologic titers. Use of effective antibiotics prior to sample collection may result in a false-negative culture or PCR test.

SPECIMEN: Serum (red-top tube), 1 mL minimum. Can store for 4 days at 4°C or at 0°C for several weeks. Paired IgG titers should be submitted to the same laboratory for testing at the same time.

RELATIVE COST: $$

PEARLS

Because of the rapid progression of clinical RMSF, the diagnosis often is made on suggestive physical and general clinicopathologic findings in order to institute treatment rapidly. The turnaround time of RMSF serology may make the result confirmatory in retrospect (i.e., the decision to treat cannot always wait for the test result).

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Rheumatoid Factor

DEFINITION

Autoantibodies to the Fc portion of autologous immunoglobulin (Ig) G

TYPICAL NORMAL RANGE

Reported as negative or positive; positive results will have an associated titer with interpretation specific for each reference laboratory.

PHYSIOLOGY

Predominantly IgM antibodies form immune complexes in sera, synovial fluid, and synovial membranes. Immune complexes localized within inflamed cartilage activate complement and contribute to synovial inflammation.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Rheumatoid arthritis. False-positive results are common and seen in healthy dogs or animals with other causes of polyarthritis, heartworm disease, pyometra, leishmaniasis, and systemic lupus erythematosus.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Synovial fluid analysis, synovial biopsy, serologic testing for infectious diseases (fungal, rickettsial, parasitic [heartworm] diseases; borreliosis), radiography of affected joint(s)

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE

- Decrease/false negative: freezing of specimen destroys antibodies.
- Increase/false positive: animals with antibodies to sheep red blood cells

SPECIMEN: Serum (red-top tube)

RELATIVE COST: $$

PEARLS

Not a reliable test in dogs; neither sensitive nor specific for routine diagnostic use. Rheumatoid factors are only present in about one-fourth of dogs with rheumatoid arthritis. Also can be present in animals with polyarthritis due to other etiologies (e.g., heartworm disease, pyometra, leishmaniasis, systemic lupus erythematosus).

Reticulocytes

DEFINITION

Erythroid precursors that have expelled their nuclei and have larger volume, more ribosomes and RNA, and less hemoglobin than mature erythrocytes. Name derived from reticulum that forms after RNA is precipitated by supravital dyes (e.g., new methylene blue).

SYNONYM

Polychromatophilic erythrocyte

TYPICAL NORMAL RANGE

Dogs: (nonanemic): <80 × 10^3 reticulocytes/µL (or × 10^9/L). Cats: (nonanemic): <60 × 10^3 reticulocytes/µL (or × 10^9/L).

PHYSIOLOGY

With increased erythropoietin and proliferation of erythroid precursors, increased numbers of reticulocytes are released into blood. Two forms of maturating reticulocytes are identified in cats. Aggregate reticulocytes have increased RNA that forms a prominent reticulum with supravital staining and appear as polychromatophilic erythrocytes on Romanowsky-stained smears. Punctate reticulocytes have less RNA that forms pinpoint inclusions on supravital stain. They are not apparent on Romanowsky-stained smears. This distinction has species-related implications (see below).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Regenerative anemias from blood loss or hemolysis (e.g., immune-mediated hemolytic anemia, mycoplasmosis, oxidative anemias, fragmentation anemia)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Determine specific cause of blood loss or hemolysis.

CAUSES OF ABNORMALLY LOW LEVELS: Decreased erythropoietin (e.g., chronic renal failure), inflammation-induced suppression of erythropoiesis, iron deficiency, decreased erythroid precursors in marrow (e.g., immune-mediated attack on erythroid precursors, feline leukemia virus or feline immunodeficiency virus infection, myelophthisis)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Bone marrow aspirate or core biopsy

IMPORTANT INTERSPECIES DIFFERENCES

- In cats, punctate reticulocytes circulate for 10-14 days, so they occur after erythropoietic response and increase in aggregate reticulocytes have abated. Only aggregate reticulocytes should be counted in cats.
- In dogs, punctate reticulocytes do not persist significantly longer than aggregate reticulocytes.
- Dogs mount a higher reticulocyte response than cats during regenerative anemias.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Autoagglutination decreases the number of detectable reticulocytes. Presence of intraerythrocytic inclusions (e.g., basophilic stippling, Pappenheimer bodies, Heinz bodies) could falsely increase the reticulocyte concentration.

SPECIMEN: EDTA whole blood (lavender-top tube) for flow-cytometric counting by analyzers (preferred) or manual counting of supravital stained smears.

RELATIVE COST: $ (reflex reticulocyte counts part of some CBC profiles)

PEARLS

- An increase in absolute concentration (rather than percentage) of reticulocytes is the gold standard for determining whether anemia is regenerative or nonregenerative.

- Reticulocyte counts may not be included in routine CBC; be sure it is included for anemic patients.
- Following acute blood loss or hemolysis of significant degree, increased numbers of reticulocytes are not expected to occur in peripheral blood until at least 3 days afterward.

$$$$: >$150

Relaxin

DEFINITION

Peptide hormone produced by the reproductive tract of many species during pregnancy

TYPICAL NORMAL RANGE

Relaxin is measured by a commercially available assay (Witness Relaxin, Synbiotics). Positive/negative result; negative (undetectable) in nonpregnant (diestral) bitches.

PHYSIOLOGY

The tissue source of relaxin varies with species and stage of the reproductive cycle. It may be produced by the corpus luteum (CL), placenta, or uterus. In pregnant dogs, relaxin is initially produced by the CL, followed by the placenta. The primary effects of relaxin occur during implantation and later during parturition. Relaxin promotes uterine, cervical, and vaginal growth during pregnancy. It may also play an important role in mammary development in some species. Additionally, relaxin is involved in nonreproductive processes such as fibrosis, wound healing, and protection against myocardial ischemia.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Pregnancy. High concentration may persist following abortion. Nonpregnant cats with ovarian cysts have been reported to have high serum concentrations of relaxin.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate for pregnancy (abdominal radiographs, ultrasound).

IMPORTANT INTERSPECIES DIFFERENCES: Relaxin is of value for diagnosing pregnancy in both wild and domestic canids. Small studies have shown it to accurately detect pregnancy in cats.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Hemolysis must be avoided; hemolyzed samples should not be used, as they may cause a false negative.

SPECIMEN: Plasma or serum. Collect blood in EDTA (lavender-top tube), citrate (blue-top tube), or heparin (green-top tube) or serum (red-top tube). Spin down, collect plasma or serum, and transfer to a clean tube without additives.

Do not use whole blood or hemolyzed samples.

RELATIVE COST: $$$

PEARLS

Relaxin is the only protein found to be associated specifically with pregnancy in dogs. It is also useful for ruling out pseudopregnancy, as these dogs do not have detectable relaxin concentrations.

Rabies Diagnostic Testing

DEFINITION

Evaluation of presence or absence of rabies virus infection

TYPICAL NORMAL RANGE

Results are reported as positive or negative.

PHYSIOLOGY

Rabies is an acute encephalitis caused by an RNA virus of the rhabdovirus family. Virus localizes to central nervous system. Direct IFA testing of brain tissue is the method used for definitive diagnosis. Submission of appropriate specimens requires necropsy examination. The test detects viral antigen in the neural tissue of infected animals.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Viral infection

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Exposed personnel should consult their physicians immediately. Exposed animals should be quarantined and observed for development of clinical signs (see p. 961).

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Fresh brain tissue. Note: Aerosolization of rabies virus is possible during craniotomy portion of necropsy or during removal of head (exposure of spinal cord). Therefore, removal of head or brain should be reserved for qualified personnel (e.g., pathologist or state veterinarian). Body of rabies suspect should be chilled (refrigerated), not frozen. Cut brain in sagittal (longitudinal) section. Submit half in clean, dry double bag for IFA test. Clearly label as rabies suspect.

RELATIVE COST: $$—$$$$ (charges vary widely among state labs)

PEARLS

- Most testing is done at state diagnostic laboratories.
- Half the brain should be submitted in formalin to assess for other diseases if rabies testing is negative.
- Brain tissue is the only suitable specimen; other tissue such as whiskers or peripheral nerve are not.
- Dogs and cats that have an implanted microchip, are currently vaccinated for rabies, and have a protective titer certified by the FVNA Laboratory at Kansas State University or the Veterinary Command Food and Diagnostic Laboratory, Fort Sam Houston, Texas may avoid quarantine when traveling from the continental United States to Hawaii or the United Kingdom if they meet other criteria. For more details regarding pet travel, refer to http://www.aphis.usda.gov/animal_welfare/pet_travel/pet_travel.shtml.

$$$$: >$150

Synovial Fluid Analysis

DEFINITION

Analysis of the viscous fluid secreted by synoviocytes that lubricates joints and transports nutrients to articular cartilage.

SYNONYM

Joint fluid analysis.

TYPICAL NORMAL RANGE

Normal synovial fluid is colorless to pale yellow, viscous, has high mucin (hyaluronic acid) content, and does not clot. Red blood cells are absent. Nucleated cell counts vary among species and the joint sampled but are usually 500/µL (up to 3000 cells/µL occasionally reported in normal joints). Synoviocytes and macrophages predominate. Protein concentration ranges from 1.8-4.8 g/dL (refractometer).

PHYSIOLOGY

Analysis includes assessment of viscosity, mucin clot test, cell counts, protein concentration, and Cytologic evaluation. Microscopic examination assesses cell population distribution and may detect infectious agents.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Increased erythrocytes indicate iatrogenic blood contamination or hemarthrosis.
- Increased nucleated cells occur with degenerative and inflammatory arthropathies, and may also occur with neoplasia.
- Mononuclear cells predominate in degenerative arthropathy or joint instability. Causes include trauma, osteoarthrosis, osteochondritis dissecans, or aseptic necrosis of the femoral head.
- Neutrophils predominate in inflammatory arthropathies (infectious, non-infectious such as crystal-induced, immune-mediated). Bacterial infection is usually monoarticular and due to penetrating trauma. Polyarticular infection may be due to systemic bacterial infection, tickborne disease, fungal infection, and (rarely) mycoplasma infection. Noninfectious inflammatory arthropathies are polyarticular or have shifting leg lameness (immune-mediated diseases; chronic progressive polyarthritis in cats).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- Hemorrhage: distinguish iatrogenic versus pathologic. Erythrophagocytosis suggests hemarthrosis. If hemarthrosis, evaluate for trauma versus bleeding disorder.
- Degenerative arthropathy: joint radiographs, assess for joint instability or ligament tear.
- Inflammatory arthropathy: culture synovial fluid, *Borrelia* spp. and *Ehrlichia* spp. serology, serum antinuclear antibody test, assess for systemic disease, and joint radiographs to assess for erosive lesions.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Fluid in EDTA (lavender-top tube) for cell counts, Cytologic evaluation; red-top tube (culture); refrigerate. Include clinical history.

RELATIVE COST: $$ (Most labs apply lower prices for specimens from multiple joints submitted at the same time.)

PEARLS

Some samples are very viscous, and the addition of a drop of crystalline hyaluronidase allows for a more accurate assessment of cell counts. Addition of hyaluronidase should be done at the reference laboratory after viscosity and protein concentration are measured and after the mucin clot test is done and slides for Cytologic evaluation are prepared.

AUTHOR: RUANNA GOSSETT

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Spherocytes

DEFINITION

Small, dense-staining red blood cells with no central pallor, considered the hallmark of immune-mediated hemolytic anemia (IMHA) or a normal finding post blood transfusion.

PHYSIOLOGY

Partial phagocytosis of antibody-coated red cells by macrophages results in loss of surface membrane without loss of volume, resulting in spherocyte formation. Pitting (excision) of Heinz bodies in the spleen also leads to spherocyte formation. May also be seen in cases of canine babesiosis and hemotropic mycoplasmosis (previously hemobartonellosis) in cats and dogs.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Immune-mediated hemolysis or erythrocyte fragmentation associated with snake bite, bee sting, hemoparasitism, zinc toxicosis, neoplasia, or idiopathic; normal phenomenon beginning 2-3 days after transfusion of red cells (even if properly cross-matched).

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate history for causes of anemia; Coombs' test and slide autoagglutination test if IMHA suspected.

IMPORTANT INTERSPECIES DIFFERENCES: Spherocytes are easily detected in dogs because of normally prominent central pallor; difficult to identify in other domestic animals (cats) that normally have no central pallor in their red cells. Some breeds of dogs (Shiba Inu and Akita) normally have microcytic red cells that should not be confused with spherocytes.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA whole blood (lavender-top tube) for evaluation of gross agglutination and CBC, blood smear for evaluation

RELATIVE COST: $$ (reported as part of CBC)

PEARLS

- Microcytic red blood cells of severe iron-deficiency anemia differ from spherocytes in that microcytic red cells are hypochromic and truly microcytic (their mean corpuscular volume is decreased); spherocytes have normal red cell volume and appear hyper-chromic.
- In anemic patients, a CBC and/or fresh blood smears to screen for spherocytes (suggesting IMHA) should always be obtained before transfusion. Spherocytosis after transfusion does not discriminate between IMHA and normal post-transfusion phenomenon.
- Spherocytic anemia or IMHA may not always be accompanied by a positive Coombs' test (false-negative tests in some cases).
- Lack of spherocytes does not rule out IMHA.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Sodium

DEFINITION

Electrolyte and the major extracellular cation. Concentration is relative to hydration status and extracellular fluid (ECF) volume but does not indicate total body Na content. Serum Na concentration essentially equals ECF Na concentration.

SYNONYMS

Na, Na^+

TYPICAL NORMAL RANGE

Dogs: 140-150 mEq/L. Cats: 150-160 mEq/L. Conversion: mEq/L = mmol/L.

PHYSIOLOGY

Serum concentration is net balance of oral intake, excretion, and water shifts between ECF and ICF (intracellular fluid). Na (and water) lost via kidneys, intestine, skin, respiratory tract. Concentration is regulated via balance of blood volume and plasma osmolality by glomerular filtration and renal tubular resorption. With hypovolemia, aldosterone promotes Na resorption, antidiuretic hormone (ADH, vasopressin) promotes water resorption. Hypoosmolality causes decreased water intake, increased urinary water excretion. Hypervolemia reduces Na resorption. Hyperosmolality promotes water intake, ADH-mediated water resorption. Water shifting from ICF to ECF dilutes serum Na.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Hypovolemia; hypotonic fluid loss: vomiting, diarrhea, pancreatitis, peritonitis, osmotic diuresis, renal failure, postobstructive diuresis
- Normovolemia; pure water loss: diabetes insipidus, water deprivation, high temperature, brainstem disease
- Hypervolemia; Na gain (uncommon): salt poisoning, hypertonic fluid administration, hyperaldosteronism

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate hydration status; test for listed diseases.

CAUSES OF ABNORMALLY LOW LEVELS

- High measured osmolality: hyperglycemia, mannitol administration
- Low measured osmolality:
  - Hypovolemia: vomiting, diarrhea, pancreatitis, peritonitis, pleural effusion, uroabdomen, hypoadrenocorticism, prolonged diuretic administration, ketonuria, Na-wasting nephropathy
  - Hypervolemia: heart failure, severe hepatopathy, nephrotic syndrome, advanced renal disease (oliguric/anuric)
  - Normovolemia: hypotonic fluid therapy, psychogenic polydipsia, syndrome of inappropriate antidiuretic hormone secretion (SIADH; rare)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Evaluate hydration status, test for listed diseases, measure plasma osmolality, measure urinary fractional Na excretion.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Increase: osmotic diuretics, phosphate enema, furosemide, corticosteroids
- Decrease: furosemide, prolonged diuresis (osmotic, thiazides)

LAB ARTIFACTS THAT MAY INTERFERE: Marked hyperlipidemia/hypercholesterolemia or hyperproteinemia may decrease measured Na by electrolyte exclusion effect (method dependent). Serum osmolality is normal.

SPECIMEN: Serum (red-top tube) preferred. Heparinized plasma may be used (lithium or ammonium heparin, green-top tube).

RELATIVE COST: $

PEARLS:

- Sampling from an improperly cleared intravenous catheter commonly causes inaccurate values.
- Most reference laboratory methods are subject to electrolyte exclusion effect artifacts. Proteins and lipids are part of the "solids" component of plasma.

When their concentration in the water phase of plasma is increased (hyperproteinemia, hyperlipidemia), they displace sodium ions, resulting in a falsely low measurement of sodium in the same volume of sample fluid.

- The appearance of hypovolemia as a cause of both hypo- and hypernatremia may seem paradoxical. Loss of sodium and fluid, as may occur with diuretic overdose or vomiting, may initially result in volume depletion and a relative hypernatremia. Subsequent intracellular movement of sodium, when accompanied by volume reexpansion, can cause hyponatremia.

Semen Analysis

DEFINITION

Assessment of male ejaculate for volume, sperm number and morphology, percent of live sperm, presence of other cells, bacteria, and, occasionally, alkaline phosphatase and carnitine concentration; used as part of assessment of male fertility

TYPICAL NORMAL RANGE

Normal total sperm count is 400 × 10^6/ejaculate (varying depending on volume of ejaculate), with 52%-90% classified as live and normal in most dogs. Motility, which is often considered an indicator of viability, should be =80%; motility patterns are random. Sperm should have single heads of uniform shape and size; free heads should be rare; tails are normally straight to slightly curved; hooked, kinked, or multiple tails are considered abnormal. It is common to see few urethral, prostatic, or squamous epithelial cells; low numbers of bacteria are also common. Alkaline phosphatase >10,000 U/L.

PHYSIOLOGY

Ejaculate is divided into three fractions. First and third fractions are mostly prostatic secretion; the second sperm-rich fraction should be used for evaluation.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY LOW LEVELS: Decreased numbers of normal viable sperm suggest testicular injury, neoplasia, or atrophy. Decreased concentration of seminal alkaline phosphatase and/or carnitine indicates obstruction of genital tubular structures.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Examination of testicle and epididymis on physical examination and using ultrasound; measurement of resting plasma testosterone.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Aged sample or exposure to temperature extremes invalidates physical and biochemical analysis

SPECIMEN: Motility must be evaluated immediately; it cannot be assessed in specimens transported to a reference laboratory. Physical analysis (color, morphology, sperm count): 1 mL semen in sterile container. Alkaline phosphatase: 1 mL semen in sterile container. Store at room temperature. Specimens <2 hours old are considered best.

RELATIVE COST: $$ (physical analysis); $ (alkaline phosphate)

PEARLS

History is an important aspect of fertility assessment. Do not rely on a single test.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Schistocytes

DEFINITION

Red cell fragments that are considered to be the hallmark of microangiopathic hemolysis

SYNONYM

Schizocyte

PHYSIOLOGY

Schistocytes result from shredding of red cells as they pass through microvasculature containing fibrin thrombi or altered endothelium. Any traumatic or physical injury to red cells can lead to schistocyte formation.

CAUSES OF ABNORMALLY HIGH LEVELS: Disseminated intravascular coagulation (DIC), vasculitis, hemangiosarcoma, dirofilariasis, intravenous catheters, burns, heart valve disease, myelofibrosis, glomerulonephritis. May be seen in severe iron-deficiency anemia (increased red blood cell fragility causes fragmentation).

CLINICAL APPLICATIONS

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Evaluate patient's clinical history and physical exam, heartworm status, coagulation profile, tick titers.

IMPORTANT INTERSPECIES DIFFERENCES: Schistocytes are not typically seen in cats with DIC, possibly because their smaller red blood cells are less likely to be damaged by fibrin in vascular spaces.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: EDTA whole blood (lavender-top tube) for CBC and blood smear evaluation

RELATIVE COST: $$ (reported as part of CBC)

PEARLS

Even small numbers of schistocytes are significant, indicating underlying microangiopathy; unlikely to be induced artifactually by smear preparation technique.

Absence of schistocytes does not rule out DIC (correlate with coagulation profile). A CBC report of *poikilocytosis* (a broad term that refers to circulating presence of any abnormally shaped RBCs) warrants pathologist review of blood smear to better define the shape change and identify any schistocytes.

AUTHOR: FIDELIA R. FERNANDEZ

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Trypsinlike Immunoreactivity

DEFINITION

Immunologic assay that detects trypsinogen, trypsin, and trypsin bound to protease inhibitors. Most detected activity due to trypsinogen.

SYNONYM

TLI

TYPICAL NORMAL RANGE

Dogs: 5-35 mg/L. Cats: 12-82 mg/L.

PHYSIOLOGY

Trypsinogen, the inactive (zymogen) form of trypsin, is produced by pancreatic acinar epithelial cells and is present in low concentration in the blood of normal patients. The assay also detects the active enzyme, trypsin, which may be increased in concentration in the blood of patients with pancreatitis.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Pancreatitis

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Not usually used for diagnosis of pancreatitis; canine -or feline-specific lipase is the preferred test and considered diagnostic. In some cases, clinical signs, diagnostic imaging results, and possibly increased serum amylase and lipase adequate for the diagnosis of pancreatitis. TLI > 50 mg/L (dogs) or >100 mg/L (cats) is consistent with pancreatitis.

CAUSES OF ABNORMALLY LOW LEVELS: Exocrine pancreatic insufficiency (EPI); severe, chronic, persistent pancreatitis or lymphocytic pancreatitis associated with parenchymal destruction

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Less than 2.5 mg/L (dogs) and <8 mg/L (cats) are diagnostic for EPI. Values between these and reference range are equivocal and may indicate loss of acinar tissue due to inflammation. Progressive immune-mediated disease (e.g., previous bout of pancreatitis or immune-mediated disease) may result in EPI. If EPI is suspected, repeat test in 4 weeks. Low levels may also indicate chronic, persistent pancreatitis.

IMPORTANT INTERSPECIES DIFFERENCES

- Cats: age-related increases associated with acinar adenomas.
- Dogs: increased values associated with inadequate nutrition/underfeeding.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Serum (red-top tube), non-hemolyzed, fasting (12-18 hours) sample

RELATIVE COST: $$

PEARLS

Assays are species specific. Check with reference laboratory to be sure that species-specific assays are being performed.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: FONZIE QUANCE-FITCH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Troponins, Cardiac

DEFINITION

Troponins are intracellular myofibrillar proteins expressed in cardiac and skeletal muscle. Cardiac troponin I (cTnI) is the most diagnostically relevant.

TYPICAL NORMAL RANGE

Different diagnostic instruments assess different parts of the cTnI molecule such that normal reference ranges are instrument specific. Contact laboratory for reference range information. Sample normal ranges:

- Dogs: 0.03-0.07 ng/mL (cTnI), 0.01-0.15 ng/mL (cardiac troponin T), 0.05-0.21 ng/mL (cardiac troponin C)
- Cats: 0.03-0.16 ng/mL (cTnI), 0.05-0.22 ng/mL (cardiac troponin T)

PHYSIOLOGY

- Troponins regulate the contractility of striated muscle. They mediate the interaction between the sarcomeric proteins actin and myosin. The troponin complex is composed of three proteins: *troponin I* is the inhibitory component that prevents interaction between actin and myosin until intracellular calcium is bound by *troponin C; troponin T* is the tropomyosin-binding element that binds troponin I to the actin filament.
- The cardiac isoforms of troponins I and T are specific markers for myocardial injury because they are antigenically distinct from skeletal muscle troponins. They are found in high concentration only in cardiac myocytes.
- Cardiac troponins are released into the circulation when there is cardiac ischemia and necrosis. They increase in proportion to the degree of myocardial injury, regardless of cause. Troponins increase in the circulation within 4-6 hours after myocyte injury and may persist up to 1 or 2 weeks; renal function affects clearance. They are sensitive and specific markers of myocardial injury.
- Troponin levels may have prognostic value in dilated cardiomyopathy in dogs and correlate with heart size and survival.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Pericardial effusion caused by hemangiosarcoma or idiopathic pericarditis in dogs (serum levels greater with hemangiosarcoma, though substantial overlap), cardiomyopathy, myocardial contusion, gastric dilatation/volvulus, myocarditis, arrhythmias, structural heart disease associated with congestive heart failure in dogs and cats, hyperthyroidism, acute pulmonary thromboembolism, high-dose doxorubicin toxicity in dogs, and canine babesiosis.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Serum (red-top tube), heparinized plasma (green-top tube), or EDTA plasma (lavender-top tube); refrigerate or freeze at −20°C.

RELATIVE COST: $$

PEARLS

Cardiac troponin concentrations are diagnostically superior to other enzyme assessments (e.g., myocardial isoenzyme of creatine kinase) in human beings and appear to be promising, valuable detection and monitoring tools in veterinary cardiology.

AUTHOR: RUANNA GOSSETT

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Triiodothyronine (T3)

DEFINITION

Active form of iodine-containing thyroid hormone. Primary function is to increase rate of cell metabolism.

SYNONYM

3,5,3'-triiodothyroinine

TYPICAL NORMAL RANGE

Dogs: 0.5-1.8 ng/mL. Cats: 0.4-1.6 ng/mL. Conversion: ng/dL × 10 = pg/mL; ng/dL × 0.01536 = nmol/L; pg/dL × 15.4 = nmol/L = SI unit.

PHYSIOLOGY

Approximately 20% of T3 produced in the thyroid gland; the rest is from conversion of T4 to T3 in cells. More biologically active than thyroxine (T4). In circulation, 99% is protein bound. Dissociates to free T3 to enter cells. Binds to receptor proteins in peripheral tissue cells, which induces DNA translation and production of proteins associated with cell growth, oxidative phosphorylation, and membrane transport of electrolytes, resulting in an increase in metabolic rate and growth stimulation.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hyperthyroidism; presence of autoantibodies; exogenous T3, TSH, or TRH; administration of iodine (or compounds containing iodine)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: If hyperthyroidism suspected: other thyroid tests, imaging. If autoantibodies suspected: assess thyroglobulin autoantibody (TgAA) levels. Evaluate diet and supplements for iodine content.

CAUSES OF ABNORMALLY LOW LEVELS: Hypothyroidism, euthyroid sick syndrome

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: T4, free T4 by equilibrium dialysis, evaluate for nonthyroidal diseases.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Decrease: moderate to marked hemolysis

SPECIMEN: Serum (red-top tube) or EDTA plasma (lavender-top tube). Separate serum or plasma from red blood cells as soon as possible. Store at 2°C-8°C (refrigeration).

RELATIVE COST: $$ (Usually run in conjunction with other thyroid tests; a variety of thyroid testing panels is available from most reference laboratories.)

PEARLS

T3 is of little diagnostic value. Broad overlap in T3 serum levels within euthyroid, hypothyroid, and euthyroid sick dogs. Total T3 is relatively insensitive and often nonspecific in assessment of hypothyroidism. Total and free T3 provide little additional information over total and free T4 by equilibrium dialysis. Serum T3 correlates poorly with thyroid disease.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: FONZIE QUANCE-FITCH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150

$$$$: >$150

Triglycerides

DEFINITION

Main storage form of long-chain fatty acids

SYNONYM

Triacylglycerol

TYPICAL NORMAL RANGE

Serum levels, dogs: 20-150 mg/dL; cats: 20-90 mg/dL

PHYSIOLOGY

Three fatty acid molecules are bound (esterified) to a glycerol backbone to form a triglyceride molecule, the main lipid in adipose tissue and primary form of body fat. Primary sites of triglyceride synthesis are liver, small intestine, adipose tissue and mammary gland, but synthesis occurs in most cells. Triglycerides are transported in the blood bound to apoproteins, forming complexes called *lipoproteins.* Circulating triglyceride levels reflect a balance of absorption and synthesis by the small intestine, synthesis and secretion by hepatocytes, and uptake by adipose tissue. These processes are affected by dietary fat intake and hormones (insulin, glucagon).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Primary hyperlipidemia: idiopathic hyperlipidemia (schnauzer, beagles, and rarely in Brittany spaniels, mixed-breed dogs and cats); familial hyperchylomicronemia in cats
- Secondary hyperlipidemia: postprandial, hypothyroidism (dogs), diabetes mellitus, pancreatitis, hepatic disease, nephrotic syndrome, hyperadrenocorticism, high-fat diet, acromegaly (cats)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Measure fasting levels (minimum 12-hour fast) to rule out postprandial hyperlipidemia. If persistent, assess for causes of secondary hyperlipidemia. If secondary hyperlipidemia is ruled out, primary hyperlipidemia is diagnosis of exclusion.

CAUSES OF ABNORMALLY LOW LEVELS: Malabsorption/maldigestion; hepatic synthetic failure (chronic hepatopathies)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Serum trypsinlike immunoreactivity (TLI), cobalamin (vitamin B12) and folate levels, assess for panhypoproteinemia; serum bile acids (pre- and postprandial).

IMPORTANT INTERSPECIES DIFFERENCES: Hyperlipidemia may occur in cholestatic liver disease. Cats with hepatic lipidosis do not have hyperlipidemia.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Increased: doxorubicin therapy, exogenous corticosteroids, megestrol acetate
- Decreased: lipid-lowering diets, supplementation with fish oils, nicotinic acid and fibric acid derivatives such as gemfibrozil

LAB ARTIFACTS THAT MAY INTERFERE: Hemolysis, lipemia, increased fluid viscosity and glycerol artificially elevate triglyceride levels.

SPECIMEN: Ensure sample collected after 12-hour fast. Serum (red-top tube), heparinized plasma (green-top tube), or EDTA plasma (lavender-top tube). Stable at 2°C-8°C for 1 week, 3 months frozen at 20°C.

RELATIVE COST: $$

PEARLS

Triglyceride levels may be measured in suspected chylous effusions. Triglyceride levels in the fluid that are greater than serum triglyceride levels in effusion indicate chylous effusion, even if the effusion is not grossly milky in appearance.

AUTHOR: RUANNA GOSSETT

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Toxoplasma gondii Serology

DEFINITION

Toxoplasmosis is a protozoan disease caused by *Toxoplasma gondii,* an intracellular parasite that infects many tissues of birds and mammals, including humans (see p. 1105).

TYPICAL NORMAL RANGE

Reported as titer values; consult with reference laboratory.

PHYSIOLOGY

Serum titers are first detectable via ELISA 1-2 weeks (immunoglobulin [Ig] M) or ≥2 weeks (IgG) after infection in dogs and cats. A fourfold increase in IgG titer over 2-3 weeks is consistent with infection. An elevated IgM titer at any time, regardless of IgG titer, is consistent with infection, but a low IgM titer does not rule out past exposure. Since infected animals harbor tissue cysts for life, a long-term measurable IgG titer is expected.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: ELISA-positive IgG with negative IgM titer most consistent with chronic exposure to *T. gondii,* although some IgM titers decrease rapidly in acute infections, as seen in 20%-85% of the cat population (geographically variable). Positive IgM with negative IgG titer most consistent with recent exposure or active infection with *T. gondii.* Positive IgG with positive IgM titer consistent with recent exposure or active infection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: If IgG titer is positive, evaluate IgM titer or paired IgG titers (at least 2 weeks apart). Greater than fourfold increase in paired IgG titers indicates recent exposure. PCR test on cerebrospinal fluid, aqueous humor, whole blood, bronchoalveolar lavage or tracheal wash fluid, or fresh tissue to demonstrate presence of *Toxoplasma* DNA. Definitive diagnosis requires demonstration of organisms in tissue via histopathology, immunohistochemistry, and/or PCR, or rarely via animal or cell culture inoculation. Some infectious disease specialists recommend response to treatment (e.g., with clindamycin) as a diagnostic test in patients with compatible clinical signs and a positive IgM or rising IgG titer.

CAUSES OF ABNORMALLY LOW LEVELS: Negative IgG and IgM titers indicate absence of exposure or peracute infection.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: If clinical signs are suggestive of acute toxoplasmosis, reevaluate IgM and IgG titers in 3 weeks.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Lipemia and hemolysis interfere with the ELISA and may cause a false-positive result.

SPECIMEN: Serum (red-top tube), 1 mL. Stable for 4 days at 4°C or for several weeks at 0°C.

RELATIVE COST: $$ (ELISA, PCR, IFA)

PEARLS

Value of a single IgG measurement in cats is highly limited because a large proportion of healthy cats (20%-85% of the population) has a positive result.

AUTHOR: PATTY J. EWING

Pricing Information

$: <$20

Total Protein (Serum)

DEFINITION

Serum proteins consist of albumin, antibodies, complement, enzymes, coagulation factors, and transport proteins. Albumin and globulin make up the majority of serum total proteins. Fibrinogen, factor V, and factor VIII are present in plasma but not in serum, because they are utilized in clot formation.

SYNONYM

Total solids

TYPICAL NORMAL RANGE

Dogs: 5.1-7.8 g/dL (g/dL × 10 = mg/mL). Cats: 5.9-8.5 g/dL (g/dL × 10 = mg/mL).

PHYSIOLOGY

The proteins in serum are important for maintaining colloid osmotic pressure (primarily albumin), buffering to maintain blood pH, hemostasis, transport of molecules (hormones, drugs, calcium, bilirubin, hemoglobin, other proteins, lipids, and metal ions), acute-phase response to inflammation, and immune response. Most of these proteins are synthesized in the liver and immune system.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Increased globulin: acute and chronic inflammation or infection (rickettsial, bacterial, viral, fungal, protozoal, parasitic), immune-mediated disease, chronic hepatic disease, nephrotic syndrome, and neoplasia (myeloma, lymphoma, lymphocytic leukemia, and rarely solitary plasma cell tumors). Increased albumin occurs with dehydration and is “relative;” increased production does not occur.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Measure serum albumin and globulin levels, assess hydration status, serum protein electrophoresis if hyperglobulinemia is absolute (normal albumin level) and repeatable.

CAUSES OF ABNORMALLY LOW LEVELS: Low albumin without a decrease in globulins occurs with protein-losing nephropathy and chronic hepatopathies. Both hypoalbuminemia and hypoglobulinemia occur with protein-losing enteropathy, whole blood loss (gastrointestinal, lacerations/trauma, other hemorrhage), exudative skin disease, massive burns, and effusive disease. Hypoglobulinemia with normal albumin occurs with decreased immunoglobulin concentration due to failure of passive transfer or inherited or acquired immune deficiency.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Measure serum albumin and globulin levels. As indicated clinically, evaluate for gastrointestinal, hepatic, renal disease.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS

- Total protein levels increased by testosterone, estrogens, growth hormone
- Total protein levels decreased by thyroxine, cortisol

LAB ARTIFACTS THAT MAY INTERFERE: Lipemia, hemolysis, and hyperbilirubinemia may artifactually increase total protein readings (globulin fraction).

SPECIMEN: Serum (red-top tube). Can be evaluated using heparinized plasma (green-top tube) or EDTA plasma (lavender-top tube). Stable for 1 month at 2°C-8°C

RELATIVE COST: $

Thyroxine (Total), Free Thyroxine by Equilibrium Dialysis

DEFINITION

Thyroxine (T4 is the major storage form of iodine-containing thyroid hormone. Its primary function is to increase the rate of cell metabolism. Free T4 (fT4 is the biologically available, non-protein-bound form of the hormone able to enter cells.

SYNONYM

T4: tetraiodothyronine

TYPICAL NORMAL RANGE

- fT4 averages approximately 2 ng/dL
- To convert: mg/dL × 10 = ng/mL; mg/dL × 12.87 = nmol/L; ng/mL × 1.287 = nmol/L (SI unit nearest 1 nmol/L).

PHYSIOLOGY

Thyroxine is highly (up to 99.9%) protein bound in circulation and therefore not biologically active. In cells, thyroxine is deiodinated to the active form of the hormone (T3). Binds to receptor proteins in cells, inducing DNA translation and production of proteins associated with cell growth, oxidative phosphorylation, and membrane transport of electrolytes, resulting in an increase in metabolic rate and growth stimulation.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hyperthyroidism; presence of autoantibodies; exogenous T4, TSH, or TRH; administration of iodine (or compounds containing iodine)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH

- If hyperthyroidism suspected: other thyroid tests, including follow-up testing, imaging
- If autoantibodies suspected: measure serum thyroglobulin autoantibody (TgAA) levels.
- Evaluate diet, supplements for iodine content.

CAUSES OF ABNORMALLY LOW LEVELS: Hypothyroidism, euthyroid sick syndrome.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Measure serum TSH levels, evaluate for nonthyroidal diseases.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Glucocorticoids, sulfonamides, phenobarbital, nonsteroidal antiinflammatory drugs may decrease total T4 concentration, with less (or no) effect on free T4.

LAB ARTIFACTS THAT MAY INTERFERE

- Artifactual increase of free T4 if sample is not kept cold
- Artifactual increase of free and total T4 if stored in glass tubes at 37°C

SPECIMEN: Serum (red-top tube) or EDTA plasma (lavender-top tube). Separate serum or plasma from red blood cells as soon as possible. Store at 2°C-8°C.

RELATIVE COST: $$

PEARLS

- Breed differences occur: T4 and free T4 can be markedly lower in sighthounds: small breeds tend to have higher reference intervals.
- Total T4 is a good screening test because of its sensitivity to disease but a poor confirmatory test because of its lower

specificity.
- Free T4 is not as likely to be affected by nonthyroidal illness or drugs.
- Diurnal fluctuations occur in dogs but are not predictable, up to 20% below normal reference interval.
- Free T4 is also measured by radioimmunoassay, which is cheaper but of no apparent benefit over total T4 and less accurate than free T4 by equilibrium dialysis.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: FONZIE QUANCE-FITCH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Thyroid-Stimulating Hormone

DEFINITION

Pituitary-derived hormone that acts on the thyroid gland to produce and secrete thyroid hormones

SYNONYMS

Canine TSH (cTSH), thyrotropin, TSH

TYPICAL NORMAL RANGE

Dogs: 0.1-0.5 ng/mL (µg/dL × 10 = ng/mL). Be sure test method has been validated for dogs.

PHYSIOLOGY

TSH is released from the pituitary from stimulation by thyrotropin-releasing hormone (TRH), and it acts on the thyroid gland to stimulate synthesis and release of thyroxine (T4) and triiodothyronine (T3). T3 and T4 act as negative feedback to reduce TSH and TRH secretion.

CAUSES OF ABNORMALLY HIGH LEVELS: Hypothyroidism (primary), thyroxine supplementation

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Free T4 by equilibrium dialysis (free T4 ED) and total T4

CAUSES OF ABNORMALLY LOW LEVELS: Sensitivity of the test is not sufficient to differentiate normal from low concentrations.

IMPORTANT INTERSPECIES DIFFERENCES: Species-specific immunoassay required. No valid measurement of feline TSH available; there may be some cross-reactivity with the canine TSH assay. Canine test may detect elevated levels in cats but can not document decreased levels.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Serum (red-top tube) or EDTA plasma (lavender-top tube). Separate serum or plasma from red blood cells as soon as possible. Store at 2°C-8°C (refrigeration).

RELATIVE COST: $$

PEARLS

- Canine patients with low free T4 (ED) and increased cTSH concentrations are extremely likely to have hypothyroidism.
- May increase ability to assess thyroid function when evaluated in conjunction with thyroid hormone concentrations

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: FONZIE QUANCE-FITCH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Thyroglobulin Antibody

DEFINITION

Autoantibodies against thyroglobulin, the major storage form for thyroxine and tri-iodothyronine in the thyroid follicle

SYNONYM

TgAA

TYPICAL NORMAL RANGE

Results reported as negative, positive, or inconclusive.

PHYSIOLOGY

The presence of thyroglobulin antibody (TgAA) is an indicator of immune-mediated thyroiditis and homozygous carrier state for the disease.

CAUSES OF ABNORMALLY HIGH LEVELS: Immune-mediated thyroiditis; low-grade false-positive results may occur with routine vaccinations in the previous 30-40 days.

CLINICAL APPLICATIONS

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Free T4 (equilibrium dialysis). Repeat TgAA test in 2-4 months.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Thyroid supplement associated with false-negative test. Treatment should be discontinued for at least 90 days prior to testing.

SPECIMEN: Serum (red-top tube) or EDTA plasma (lavender-top tube). Separate serum or plasma from red blood cells as soon as possible. Store at 2°C-8°C (refrigeration).

RELATIVE COST: $$

PEARLS

Dogs that test positive are not recommended for breeding, owing to the hereditary nature of immune-mediated thyroiditis and resultant hypothyroidism. Many dogs may develop TgAA prior to clinically evident immune-mediated thyroiditis and hypothyroidism. Carriers (heterozygotes) are negative. Dogs with chronic disease with thyroid destruction may have negative results. Occasionally dogs may have TgAA without having hypothyroidism; TgAA should always be interpreted in conjunction with other thyroid hormone parameters.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: FONZIE QUANCE-FITCH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Testosterone

DEFINITION

Hormone responsible for development of male characteristics

TYPICAL NORMAL RANGE

Usually, serum levels > 1 ng/mL indicate an intact male.

PHYSIOLOGY

Derived from cholesterol, primarily produced by testicular interstitial cells; ovarian theca cells, zona reticularis of the adrenal cortex, and placenta produce lesser amounts. Hematogenous distribution to target tissue; affects bone growth and muscle mass, development of spermatogenic tissue in testes, and behavior. Extratesticular production accounts for sexual behavior in castrated males or animals with ovarian or adrenal tumors.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Cryptorchid or intersex patients may have concentrations consistent with intact male.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Investigate for presence of abdominal testicle(s) or abnormal gonadal tissue.

CAUSES OF ABNORMALLY LOW LEVELS: Infertility

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Resample because cyclically low levels may occur in fertile patients; pulses of testosterone may occur throughout the day. Increased concentration over basal levels following administration of human chorionic gonadotropin (hCG) or gonadotropin-releasing hormone (GnRH) indicates functional testicular tissue.

IMPORTANT INTERSPECIES DIFFERENCES: Male cats have pulsatile secretion of testosterone and may have undetectable levels. Therefore, evaluation should be done following intramuscular injection of either GnRH or hCG as follows:

- 25 µg GnRH IM, then draw sample 1 hour later (reference interval: 17.3-41.6 nmol/L) *or*
- 250 IU hCG IM, then draw sample 1 hour later (reference interval: 10.4-31.2 nmol/L)

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: False increases due to administration of androgenic drugs such as methyltestosterone; administration of radioisotopes falsely increases values measured by radioimmunoassay; chronic administration of androgenic drugs suppresses natural production.

LAB ARTIFACTS THAT MAY INTERFERE: Delayed separation from red blood cells, collection in EDTA (lavender-top tube), and storage at room temperature falsely decrease values.

SPECIMEN: Heparinized (green-top tube) plasma or serum; separate plasma or serum from red blood cells as soon as possible; store specimen at 2°C-8°C.

RELATIVE COST: $$

PEARLS:

- Main indications are assessment of infertile male patients and to help determine whether a male without external testicles is cryptorchid or has been neutered (see p. 268).
- Presence or absence of penile spines in adult male cats helps support or refute testosterone exposure, respectively.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150

Taurine Blood Levels

DEFINITION

Amino acid with important role in retinal and myocardial metabolism

TYPICAL NORMAL RANGE

- Cats: <20 nmol/mL (plasma) is considered diagnostic of cardiomyopathy; cats with <60 nmol/mL should receive supplementation.
- Dogs: <40 nmol/mL (plasma) is considered low and has been associated with dilated cardiomyopathy in the cocker spaniel, golden retriever, and Newfoundland breeds (see p. 1075).
- Whole blood concentrations (and the whole blood reference ranges) are approximately double the plasma concentrations.

PHYSIOLOGY

Low blood levels of taurine have been associated with dilated cardiomyopathy in cats and certain breeds of dogs, such as cocker spaniels, retrievers, and many other breeds. Determination of plasma and/or whole blood levels of taurine may be useful in determining role in dilated cardiomyopathy and need for supplementation. Taurine-deficient cats (but not dogs) may develop degenerative retinal lesions.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY LOW LEVELS: Dietary deficiency, poor dietary bioavailability, excessive loss of metabolic precursors (cysteine), and/or familial predisposition

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Correlate with cardiac and/or ophthalmic evaluation findings.

IMPORTANT INTERSPECIES DIFFERENCES: Fasting may decrease plasma levels of taurine in feline samples; therefore, whole blood is the preferred sample for cats. Ideally, both whole blood and plasma taurine levels should be determined for dogs.

SPECIMENS AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Bacterial contamination may falsely decrease blood taurine levels. Delay in separating and chilling plasma or poor blood collection technique may result in falsely increased levels of plasma taurine, because taurine is released from leukocytes and activated platelets.

SPECIMEN: Collect 2 ml fresh heparinized (green-top tube) whole blood and freeze; freezing heparinized whole blood lyses RBCs and releases taurine (desirable). Alternatively, collect 1 mL of frozen heparinized plasma. Chill sodium heparin collection tube (green-top tube) and separate plasma immediately after collection in a refrigerated centrifuge. After centrifugation, transfer plasma —without disturbing the buffy coat—to red-top tube (without serum separator plug) for submission.

RELATIVE COST: $$$

PEARLS

- Dogs do not need to be eating a taurine-deficient diet to develop taurine-deficient dilated cardiomyopathy; poor bioavailability of nutritional taurine (e.g., binding by rice husks) and excess urinary excretion of taurine precursors (e.g., cystine) have been proposed as mechanisms. Reference intervals in dogs are not well established. They are suspected to be significantly higher than those in cats. Clinically normal dogs have been reported to have 77 + 2.1 (plasma) and 266 + 5.1 (whole blood) nmol/mL taurine.
- Oral taurine supplementation is inexpensive and safe.
- Low taurine levels may be used to confirm a diagnosis of cardiomyopathy but are generally not used as a screening test.

$$: $21-75
$$$: $76-150
$$$$: >$150

Urine Specific Gravity

DEFINITION

Urine specific gravity (USG) is an estimate of urine osmolality. Concentrated urine: USG > 1.030 (dog), >1.035 (cat). Isosthenuria: USG = 1.008-1.012. Hypos-thenuria: USG < 1.008.

TYPICAL NORMAL RANGE

Normally 1.001-1.060, depending on hydration status

PHYSIOLOGY

Assessment of ability to concentrate urine. Depends on hydration status, renal function, and extrarenal influences (diuretics and other drugs, endocrine disorders, etc.).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Increased USG with dehydration may be marked but typically is an appropriate response for preservation of effective circulating volume.
- Proteinuria and glucosuria may cause falsely high estimates of value.
- 1g/dL glucosuria (between 3+ and 4+ on urine dipsticks) increases USG by 0.004-0.005.
- 1 g/dL proteinuria (4+ on urine dipstick) increases USG by 0.003-0.005

CAUSES OF ABNORMALLY LOW LEVELS

- If low USG (1.008-1.012) is concurrent with normal serum urea (BUN) and creatinine concentrations, the most likely explanation is normal formation of dilute urine to preserve euvolemia (e.g., after drinking water). No conclusion can be drawn concerning renal function, except that at least 25% of renal tubules must be functioning for BUN and creatinine levels to be normal.
- If low USG (1.008-1.012) plus azotemia, glucosuria, dehydration, polyuria, or oliguria, then renal tubular concentrating ability is impaired. Underlying causes include:
    - Decreased numbers of functional nephrons (>75% nonfunctioning nephrons); chronic kidney disease
    - Osmotic diuresis (glucosuria, ketonuria, iatrogenic, other)
    - Diabetes insipidus (central, nephrogenic)
    - Diuretics (furosemide, other loop diuretics; thiazides)
    - Aldosterone deficit (hypoadrenocorticism) or resistance (spironolactone)

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Determine hydration status, evaluate serum biochemistry values, especially urea, creatinine, phosphate, glucose, calcium, sodium, and potassium.

IMPORTANT INTERSPECIES DIFFERENCES

- Concentrating abilities vary among species: cat > dog > horse/cow.
- Adults have greater concentrating ability than neonates.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Diuretics cause USG to decrease (sodium and water excretion).

SAMPLE FOR COLLECTION AND ANY SPECIAL SPECIMEN HANDLING

NOTES: Urine, 5 mL minimum, in clean container

RELATIVE COST: $ (reported as part of urinalysis)

PEARLS

- A low USG is meaningless with respect to renal function unless it is accompanied by urea and creatinine concentrations measured on a blood sample drawn at the same time as the urine sample.
- Acute anuric renal failure may be associated with a normal USG (residual urine).
- USG in untreated diabetics is usually 1.025-1.035; isosthenuria suggests concomitant renal disease or hyperadrenocorticism.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Urine Protein/Creatinine Ratio

DEFINITION

Amount of protein excreted in urine compared with (ratio) the concentration of urine, as determined in a single sample collection (spot check)

SYNONYMS

UP:C ratio, UP:UC ratio

TYPICAL NORMAL RANGE

Urine protein/creatinine (UP:C) ratio in healthy individuals is <0.6 (cats) or <0.5 (dogs, 0.5-1 are borderline values).

PHYSIOLOGY

- Absolute amount of protein in a urine sample varies depending on water content (urine concentration), regardless of degree of proteinuria.
- Therefore, increased urinary protein loss can be assessed for significance when compared to the concentration of creatinine in the urine.
- Glomeruli normally allow the passage of only trace amounts of protein (if any) into the urine, with tubular reabsorption of nearly all filtered protein. Glomerular damage, renal tubular damage, or inflammation in the urinary tract can cause proteinuria and an increased UP:C.
- UP:C has traditionally been used in the diagnosis of protein-losing nephropathies (glomerulonephritis, amyloidosis), for which it remains the initial diagnostic test of choice.
- Renal tubular protein loss and associated UP:C increase may also be used as early markers of chronic kidney disease, with important treatment and prognostic implications in dogs and cats.
- Recently it has been shown that most dogs with active urinary sediment (pyuria) do not have detectable proteinuria and have normal UP:C. Those dogs with both pyuria and concurrent hematuria or bacteriuria are more likely to have proteinuria, +/—increased UP:C. Proteinuria may not be present with hematuria until the hematuria is grossly visible and then may not cause increased UP:C.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Urinary tract inflammation (pyuria, hematuria, and bacteriuria) may result in modest UP:C ratio increases (e.g., 1-3), although very high values (e.g., 40) have been reported rarely in patients with bacterial cystitis.
- Tubular loss of protein may result in a UP:C ratio of 1-5.
- Glomerular loss of protein usually results in UP:C >1, usually >3, and renal amyloidosis usually has UP:C ratio >15.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Full urinalysis, serum protein concentration, serum urea and creatinine, urine bacterial culture and susceptibility

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN: Urine, 2 mL minimum, in clean container

RELATIVE COST: $$

PEARLS

- Albumin is a major component of the urinary protein excreted in protein-losing nephropathy. Because it is of a similar molecular size as antithrombin (AT), a markedly increased UP:C may indicate a hypercoagulable state owing to loss of significant AT.
- The presence of an active sediment does not automatically negate the interpretation of an increased UP:C ratio.

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Urine pH Abnormalities

DEFINITION

Urine pH higher or lower than expected based on species and diet; the negative logarithm of hydrogen ion concentration in urine. Aciduria: low urine pH (<7). Alkaluria: high urine pH (>7)

TYPICAL NORMAL RANGE

Dogs and cats: 6.0-7.5

PHYSIOLOGY

Dietary constituents influence urine pH in health.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS

- Alkaluria: expected postprandially in monogastric mammals
- Infections (usually cystitis) in dogs/cats caused by bacteria that contain/produce urease (urea is degraded to ammonia, which is a weak base and removes free hydrogen ion from urine).
- Excess base is excreted or increased acid (free hydrogen ions) is retained (renal proximal and distal tubules) in some cases of metabolic alkalosis and occasionally in cases of chronic respiratory alkalosis.
- Distal renal tubular acidosis (decreased hydrogen ion excretion in distal nephron) may result in alkaline urine or a disproportionately high urine pH (>6) compared with the blood pH (acidemia).
- Proximal renal tubular acidosis (inability to conserve bicarbonate in proximal tubules) may result in high urine pH early in the disorder.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Urine sediment examination (presence of pyuria +/− bacteria) and/or culture for bacteria.

CAUSES OF ABNORMALLY LOW LEVELS

- Aciduria: severe cases of metabolic alkalosis with hypochloridemia + hypokalemia (paradoxical aciduria, see p. 53)
- Hypokalemia (H^+ excretion in exchange for K^+ resorption in intercalated cells of distal tubules)
- Loop diuretic treatment (e.g., furosemide)
- Excretion of excess acid (H^+) in metabolic or respiratory acidosis

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Determine serum electrolyte and acid-base status (Na^+, K^+, Cl^-, HCO^-_3, and anion gap, +/− blood pH).

IMPORTANT INTERSPECIES DIFFERENCES: Dogs and cats typically have urine that is more acidic than that of herbivores.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Potassium-wasting diuretics may result in renal K^+ conservation and excess H^+ excretion (aciduria).

LAB ARTIFACTS THAT MAY INTERFERE

- Marked delay in analysis may result in urine alkalinization (urea converts to ammonia spontaneously or via urease-containing bacteria).
- Prolonged exposure to high-pH (≥9) urine may cause dipstick protein reading to be falsely increased.

SPECIMEN: Urine, minimum of 5 ml, in clean/sterile container collected by free catch, catheterization, or cystocentesis (if culture also needed). Analysis of urine should be completed within 2-3 hours after collection; otherwise, urine pH may increase with age as urea converts to ammonia.

RELATIVE COST: $

AUTHOR: ELIZABETH G. WELLES

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Urine Cortisol/Creatinine Ratio

DEFINITION

Screening test for hyperadrenocorticism that measures the ratio of urinary cortisol to creatinine excretion

TYPICAL NORMAL RANGE

- Ratios < approximately 10×10^{-6} rule out hyperadrenocorticism.
- Ratios > approximately 10×10^{-6} indicate elevated serum cortisol (adrenal or nonadrenal disease).

PHYSIOLOGY

Because urine excretion of creatinine is fairly constant, its ratio to urine cortisol excretion provides a measurement of average serum cortisol levels.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Hyperadrenocorticism, many nonadrenal diseases and physiologic conditions

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Review history and physical exam for signs of hyperadrenocorticism; adrenocorticotropic hormone (ACTH) stimulation, low-dose dexamethasone suppression test (LDDST) if indicated.

IMPORTANT INTERSPECIES DIFFERENCES: Ratio may be abnormally high in cats with hyperthyroidism.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Corticosteroid administration increases levels; ketoconazole therapy decreases levels.

LAB ARTIFACTS THAT MAY INTERFERE: Increase: anticoagulants, bilirubin

SPECIMEN: Fresh urine, 5 mL minimum, morning collection preferred. To minimize stress-associated increases in cortisol, some clinicians advocate that the client obtain the urine sample in a clean plastic container when the dog voids at home immediately prior to traveling to the veterinary hospital.

RELATIVE COST: $$

PEARLS

- Increased ratio is a sensitive but nonspecific test for hyperadrenocorticism. High ratios are associated with stress and nonadrenal disease as well as hyperadrenocorticism.
- Values within reference range strongly indicate patient does not have hyperadrenocorticism.
- Increased urinary cortisol excretion may be physiologic or pathologic.

AUTHOR: LOIS ROTH-JOHNSON

1ST EDITION AUTHOR: FONZIE QUANCE-FITCH

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Urinalysis

DEFINITION

Panel of screening tests done on urine to evaluate for inflammation, degenerative lesions, protein loss, neoplasia in the urinary tract, and systemic disease

TYPICAL NORMAL RANGE

Color: yellow; appearance: clear; pH: 6 to 7.5; specific gravity: 1.001 to >1.030 (dogs), 1.001 to >1.035 (cats); protein, glucose, ketones, bilirubin, blood, bacteria: negative (trace to 1+ bilirubinuria is normal in the dog); red blood cells, leukocytes, epithelial cells: 0 to 5 per high-power field; casts: 0 to 2 per low-power field. Some values depend on collection method.

PHYSIOLOGY

Urine constituents and composition reflect lesions of the urinary tract and may provide an indication of metabolic abnormalities.

SPECIMEN AND PROCESSING CONSIDERATIONS

LAB ARTIFACTS THAT MAY INTERFERE: Delay in specimen processing may decrease some values and increase others. See specific tests. Generally, 10 mL of urine is recommended; reference-range quantitation of urine sediment is usually based on this volume.

SPECIMEN: Fresh urine (10 mL) in sterile container. Indicate method of collection (cystocentesis, catheterization, or free catch).

RELATIVE COST: $

PEARLS

- Collection method may influence interpretation. Blood and epithelial cells in catheterized specimens or bacteria in free catch specimens may not indicate disease.
- Unless contraindicated (e.g., bleeding disorder makes risk of cystocentesis unacceptable), serum biochemistry profiles should always be accompanied by urinalysis to better understand significance of abnormalities of blood glucose, urea, creatinine, albumin, cholesterol, and electrolytes on the profile.

AUTHOR: LOIS ROTH-JOHNSON

Pricing Information

$$: $21-75
$$$: $76-150
$$$$: >$150

von Willebrand Factor Assay

DEFINITION

Assay to detect von Willebrand disease (vWD), which results from decreased functional von Willebrand factor (vWF) and causes prolonged bleeding time and abnormal primary hemostasis

TYPICAL NORMAL RANGE

Dogs: 60%-172% of normal pooled plasma

PHYSIOLOGY

- vWF is produced by endothelial cells and megakaryocytes and circulates with factor VIII, which prolongs its stability. Stored in endothelial cells and platelet α-granules, vWF acts as a bridge between exposed subendothelial collagen and platelets and among platelets. Platelet binding of vWF triggers a cascade of hemostatic and thrombotic events. Low levels of vWF result in lack of platelet activation (see p. 1176).
- Measured by quantitative ELISA with species-specific antibodies to vWF. Multimeric analysis (separates the different vWF multimers) can distinguish between type 1 and 2 vWD. Functional assays exist but are not frequently used in the clinical setting.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Azotemia, liver disease

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: No clinical importance

CAUSES OF ABNORMALLY LOW LEVELS: Types 1, 2, and 3 vWD are the most common hereditary bleeding disorders in dogs. ELISA is typically <35% in vWD. Lack of any detectable vWF indicates type 3 vWD; vWF 30%-70% indicates a carrier.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Genetic tests to identify gene mutations to detect carriers in certain dog breeds. Any dog with factor levels < 70% is considered a carrier and not appropriate for breeding.

IMPORTANT INTERSPECIES DIFFERENCES: Feline platelets contain vWF; canine platelets do not contain significant levels. Thrombocytopenia does not affect vWF values in dogs.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Epinephrine, endotoxin, and 1-deamino-8-d-arginine vasopressin (DDAVP) can increase vWF. DDAVP will increase vWF both in dogs with type 1 vWD and in normal dogs.

LAB ARTIFACTS THAT MAY INTERFERE: Decrease: hemolysis, clotting

SPECIMEN: Collect blood in sodium citrate (blue-top tube) or EDTA (lavender-top tube). After centrifugation, plasma should be promptly collected, frozen, and shipped overnight.

RELATIVE COST: $$

PEARLS

- If the platelet counts and coagulation times are within normal limits, buccal mucosal bleeding time may help diagnose vWD. Affected patients will have prolonged buccal mucosal bleeding times.
- While DNA testing can identify carriers and is specific for the mutation responsible for the disease, it does not necessarily identify whether dogs will be clinically affected. The value obtained from factor assay better predicts the likelihood of clinical signs.

Pricing Information

$: <$20
$$: $21-75
$$$: $76-150
$$$$: >$150

Warfarin

DEFINITION

Commonly used rodenticide; testing is typically for retrospective confirmation (e.g., identification and prevention of future reintoxication or for legal purposes). Note: animals suspected of active hemorrhage due to ingestion of warfarin or other anticoagulant toxicosis should be evaluated with prothrombin time (PT) or assessment of proteins inhibited by vitamin K absence/antagonism (PIVKA), because turnaround time to warfarin assay results is typically long, and it is less widely available.

SYNONYM

- First-generation compounds: warfarin, indanedione-containing rodenticides
- Second-generation compounds: cou-marin-based generics (brodifacoum, difenacoum, bromadiolone) and the indanedione, diphacinone

TYPICAL NORMAL RANGE

Consult laboratory for reference range and for inclusion of both first- and second-generation compounds in test panel.

PHYSIOLOGY

Well- but slowly-absorbed following oral administration. Peak plasma levels in 6-12 hours. Most is plasma protein bound, but high concentrations in liver, spleen, kidney. Metabolism occurs in the liver. Elimination rate depends on compound, amount ingested; may accumulate if small amounts ingested over several days. Warfarin half-life in dog plasma is 14.5 hours; the half-life of diphacinone is suspected to be days. Brodifacoum is assumed to be similar or longer than that of diphacinone. The differences in residual half-lives have important therapeutic implications. Compounds interfere with coagulation by decreasing coagulation factors II, VII, IX, and X (competitive inhibition of vitamin K epoxide-reductase).

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Ingestion of compounds or animals that have consumed compounds. Relay toxicosis (incurred from consumption of prey [e.g., rodents] that have eaten warfarin) rarely occurs with second-generation anticoagulants other than diphacinone.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Remove source; administer vitamin K; whole blood transfusion.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS: Oxyphenbutazone, phenylbutazone, diphenylhydantoin, sulfonamides, and corticosteroids increase toxicity.

SPECIMEN: Chemical detection of specific anticoagulants in vomitus or baits. Liver tissue (frozen) for postmortem diagnosis. Unclotted blood, stomach contents, intestinal content, feces, spleen, and kidney should also be submitted.

RELATIVE COST: $$ (Send-out test for most reference laboratories; additional fees may apply.)

PEARLS

- Conditions enhancing susceptibility are high dietary fat (fatty acids displace the plasma protein-bound anticoagulant), prolonged oral antibiotic therapy, biliary obstruction, liver disease, hypoalbuminemia (warfarin is highly plasma protein bound), renal disease.
- Most veterinary reference laboratories do not do rodenticide testing. When testing is offered, results are usually not available for several days. Testing is typically confirmatory rather than proactively diagnostic.

Zinc, Serum Level

DEFINITION

Zinc is an essential trace mineral that serves as a cofactor for enzymes in many tissues. It is important in regulation of the immune response, modulation of keratogenesis, wound healing, maintenance of normal reproductive function, and acuity of taste and smell.

TYPICAL TOXIC RANGE

Dogs, cats: <2 mg/mL (serum); <30-70 ppm, wet weight (liver). Check with laboratory for values considered diagnostic of toxicity.

PHYSIOLOGY

Source is dietary. Zinc is absorbed via the intestine, metabolized in the liver, and exported to peripheral tissues.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH LEVELS: Ingestion of excessive levels of zinc phosphide (either as powder, bait). Toxicity may also result from relay toxicosis associated with eating tissues of zinc phosphide-poisoned animals or ingestion of U.S. pennies minted after 1983.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH: Vomitus/gastric lavage (phosphine gas) is actually the preferred method of diagnosis in case of toxicity. Caution: phosphine gas (faint garlic or rotten fish odor; gas is liberated in the breath of animals with zinc phosphide intoxication, such as during gastric lavage) is a public health hazard and may cause severe/permanent respiratory injury to veterinary personnel or bystanders.

CAUSES OF ABNORMALLY LOW LEVELS: Malnutrition, malabsorption, animals on total parenteral nutrition

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS LOW: Skin biopsy if zinc-deficient dermatosis is suspected

IMPORTANT INTERSPECIES DIFFERENCES: Zinc-responsive dermatosis occurs in dogs. Familial form (Alaskan malamutes, Siberian huskies) and from affecting puppies fed zinc-deficient or oversupplemented diets. Lethal acrodermatitis is a rare inherited disorder of bull terriers that does not respond to zinc supplementation and is invariably fatal.

SPECIMEN AND PROCESSING CONSIDERATIONS

SPECIMEN

- Serum: because of the use of zinc stearate to coat rubber, serum samples must be drawn in all-glass or all-plastic syringes, and all-glass or all-plastic vials must be used for transport.
- Toxicity: test for toxic metabolite, phosphine gas. Submit frozen vomitus or gastric lavage in airtight containers.

RELATIVE COST: $$$

PEARLS

- In zinc phosphide toxicity, there may be a characteristic acetylene odor to the gastric contents; may be bloody.
- Zinc phosphide causes emesis in dogs and cats, so fatal intoxication is not frequent. Ingestion with a meal enhances toxicity by promoting conversion to zinc phosphine gas.
- Ingested pennies may be detected radiographically.

Introduction to Laboratory Tests

Overview

This section regroups over 150 diagnostic tests that are used widely in small-animal practice. Information is drawn from both basic science and applied clinical medicine to provide a brief summary of each test. The facts and interpretations necessary to understand these tests under most circumstances are included, and additional detail can be found in specific references (see below).

Each topic is organized in a consistent manner. Sections for each entry include:

DEFINITION

a concise explanation of the nature of the test.

SYNONYMS

when applicable, other names by which the test is known.

TYPICAL NORMAL RANGE

a broad reference interval for normal results. Exact ranges are generally laboratory specific and may even be population or test kit specific. The ranges published here should be considered only an approximate guide.

PHYSIOLOGY

a brief description of the natural processes underlying the analyte being measured and specific application of the test.

CLINICAL APPLICATIONS

CAUSES OF ABNORMALLY HIGH/ LOW LEVELS:

the principal differential diagnoses for values falling outside the normal range.

NEXT DIAGNOSTIC STEP TO CONSIDER IF LEVELS HIGH/LOW:

recommended tests or procedures that typically are indicated if the current test is not the definitive test of choice.

IMPORTANT INTERSPECIES DIFFERENCES:

relevant physiologic or test-associated variation.

SPECIMEN AND PROCESSING CONSIDERATIONS

DRUG EFFECTS ON LEVELS:

alterations in test results that may be expected when a patient is receiving certain medications.

LAB ARTIFACTS THAT MAY INTERFERE:

extraneous factors that may produce a false reading and should be considered by the clinician when interpreting test results.

SPECIMEN:

the sample required to perform the test.

RELATIVE COST:

a price scale is included to provide a relative indication of test costs. Necessarily, the exact cost will vary from one laboratory or institution to another and one geographic region to another, and changes over time will alter these values within any laboratory. Nevertheless, by comparing tests to each other according to their costs, the price scale can provide a relative sense of the expense

associated with each test. The scale used is based on costs of tests submitted to a full-service reference laboratory in North America in 2009, as follows:

$: <$20
$$: $21-75
$$$: $76-150
$$$: >$150

PEARLS:

tips, important reminders, or explanations generally acquired through experience. These are clinically important but otherwise often escape publication.

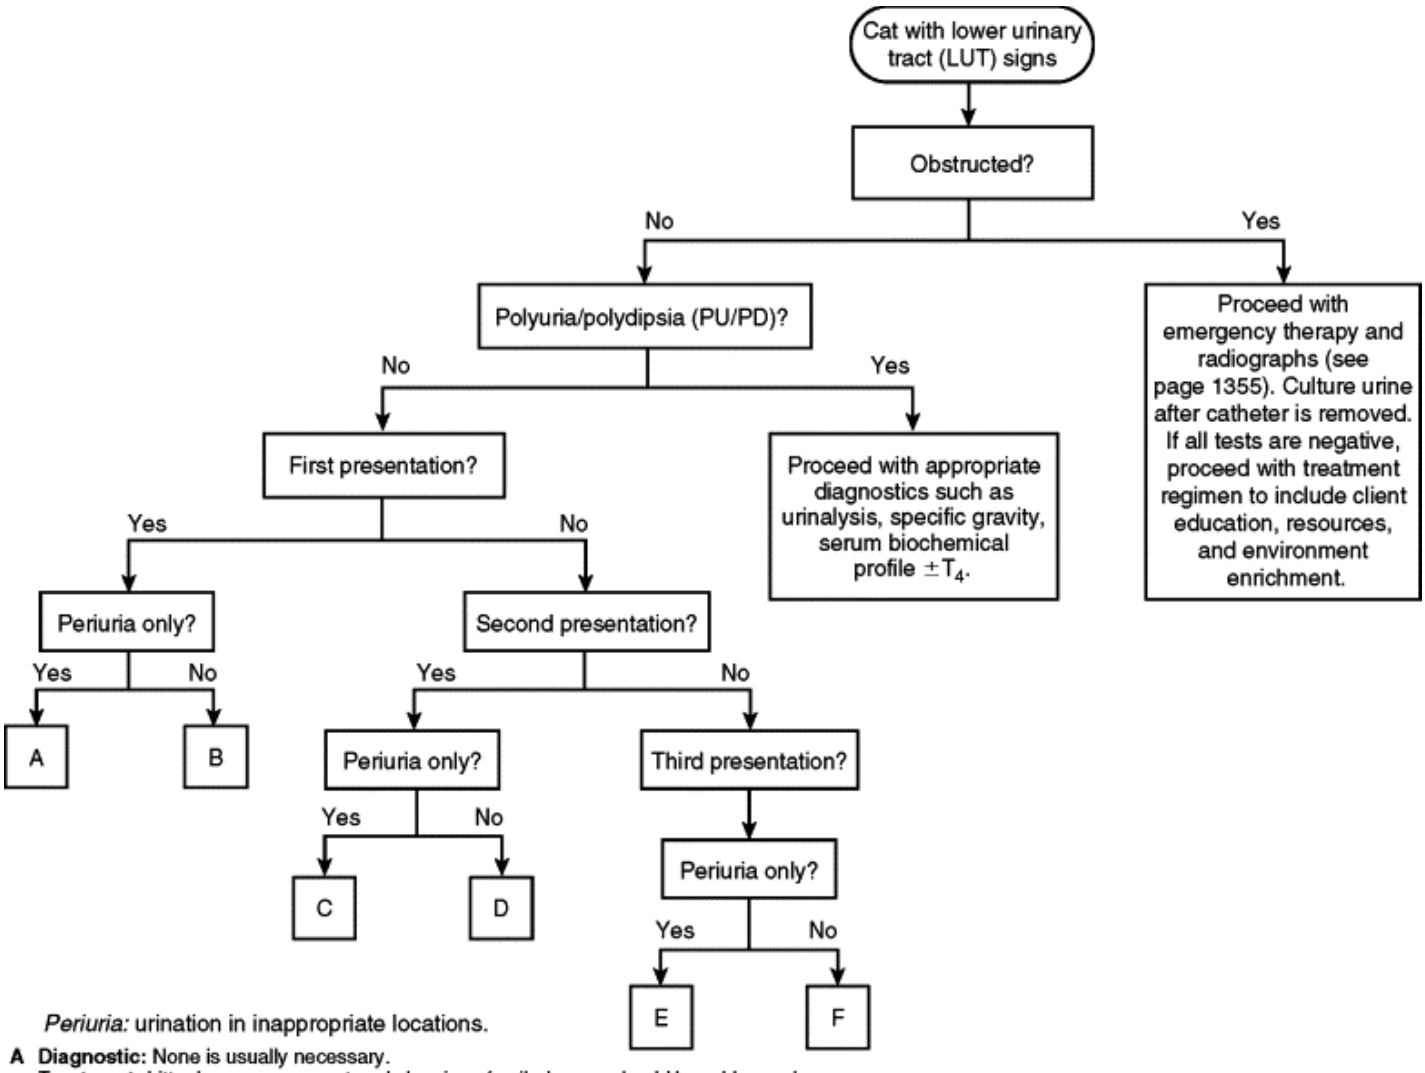
Feline Lower Urinary Tract Signs



Periuria: urination in inappropriate locations.

A **Diagnostic:** None is usually necessary.
Treatment: Litter box management and cleaning of soiled areas should be addressed.
Medications: No medications are recommended.

B **Diagnostic:** A radiograph should be considered, especially if hematuria is present.
Treatment: If the radiograph is negative, therapy should include analgesia for 2 to 3 days during the acute episode. Litter box management and cleaning of soiled areas should be addressed.
Medications: No medications are recommended.

C **Diagnostic:** A urinalysis is recommended. If submaximal urine specific gravity is present, then appropriate diagnostics are needed.
Treatment: If diagnostic tests are negative, then the resource checklist* should be reviewed and additional areas that were not previously addressed should be incorporated.
Medications: Pheromone therapy is recommended.

D **Diagnostic:** A radiograph, urinalysis, and urine culture are recommended.
Treatment: If all tests are negative, analgesia should be provided for 2 to 3 days during acute episode. Canned food is encouraged for the cat in addition to litter box management and cleaning of soiled areas. The cat's urine specity gravity is monitored for 3 to 4 weeks to assess the cat's water intake.
Medications: Pheromone therapy is recommended.

E **Diagnostic:** A urinalysis should be performed if it has not already been done. Radiographs, urine culture, and biochemical profile are also recommended.
Treatment: If all tests are negative, then the resource checklist* is formally reviewed and those areas that have not already been addressed should be incorporated. Further information for cleaning soiled areas should be provided. Additional resources (web sites, books) on how to provide an enhanced indoor environment for cats should be provided to clients. Intercat conflict issues should also be addressed.
Medications: Pheromone therapy should be used in conjunction with behavior-altering medications such as tricyclic antidepressants (TCAs) or buspirone. The medication should be taken for 4 weeks; if no improvement is seen, a referral for further diagnostics and consultation should be considered.

F **Diagnostic:** A radiograph, a urinalysis, and a urine culture should be performed. A complete blood count (CBC) and biochemical profile should also be submitted. If all tests are negative, a contrast study or abdominal ultrasound of the bladder and urethra should be considered to rule out radiolucent calculi and other mass lesions.
Treatment: If all diagnostics are negative, analgesia should be provided for 2 to 3 days during acute episode. In addition to canned food, ensure that water consumption is sufficient. Water should be viewed as a "drug," and the cat's urine specific gravity should be monitored (goal: submaximal concentration, e.g., urine specific gravity < 1.040) to evaluate water intake. The resource checklist* should be formally reviewed, and those areas that have not already been addressed should be incorporated. Additional resources (web sites, books) on how to provide an enhanced indoor environment for cats should be provided to clients. Intercat conflict issues should also be addressed. Follow up and support for clients are essential.
Medications: Phermonotherapy should be used in conjunction with behavior-altering medications such as TCAs or anxiolytics. Medication should be taken for 4 weeks; if no improvement is seen, a referral for further diagnostics such as a cystoscopy should be considered.

Introduction to Drug Formulary

EDITOR

* **Etienne Côté, DVM, DACVIM (Cardiology, Small Animal Internal Medicine)**

* The editor acknowledges and appreciates the work of Stephen J. Ettinger, DVM, DACVIM (Cardiology, Small Animal Internal Medicine), FACC, FAHA and Wayne S. Schwark, DVM, MSc, PhD, who, together with the editor, were redactors of this section in the previous edition. Thanks also to Drs. Justin Allen, Kirstie Barrett, Valerie Case, Crystal Doyle, and Ali Gorgi for providing suggestions and information on new medications.

The drugs listed in this formulary represent a compilation of the more commonly used therapeutic agents in small-animal practice, without implying endorsement (or lack thereof) of specific medications. Not all drugs used in veterinary practice are included, and clinicians may infrequently or never use some of those listed.

Drugs are organized in alphabetical order by generic names, with trade names in parentheses under the generic title, and the drugs also are listed alphabetically by brand name, with a cross-reference. A brief description of the drug's actions or indications is also provided. Canine and feline dosages are given individually. Note that *total dose* is the amount given to an animal in each single dose (in contrast to dose per kilogram body weight) and not the total amount of drug given for the full course of treatment. The fifth column, entitled Comments, describes commonly seen side effects, specific important observations, or other characteristics that are particularly important to the clinician. A sixth column, entitled How the Drug Is Supplied, includes commonly available sizes and formulations. Abbreviations used in the formulary are first defined on this page for the reader's reference.

Entries that are preceded by letters or modifiers are listed according to the principal word in the name of the drug. For example, L-asparaginase is listed under the letter *A,* DL-methionine is listed under the letter *M,* and *S*-adenosyl methionine is also listed under the letter *M.* Entries that are preceded by numbers are listed without the number (e.g., 4-methylpyrazole is listed under M).

While every effort has been made to include clinically useful, important, and accurate information, a comprehensive review of the details of individual drugs is too voluminous to be listed in this format. Therefore, it remains the prescriber's and clinician's responsibility to ensure that the particulars of any drug are appropriate for the intended application. The clinician should recheck drug dosages for accuracy as well as for specific indications, contraindications, and warnings. Drugs are listed not only by their licensed uses but also by commonly practiced uses. Again, the clinician needs to identify the specific and recommended indications for each drug by reviewing relevant information (e.g., product insert, primary sources) before prescribing, recommending, or using a drug.

Drugs, dosages, comments, and side effects are taken from several sources: (1) the clinical experience of the editor and previous redactors of this formulary; (2) drug-related information from the other sections of this textbook; (3) Ettinger SJ, Feldman, EC: Textbook of veterinary internal medicine, ed 6, St Louis, 2005, Saunders; (4) PDR Staff: Physician's desk reference, ed 64, Williston, VT, 2009, PDR Network; (5) Plumb DC: Veterinary drug handbook, ed 6, Ames, Iowa, 2008, Blackwell; (6) Kirk RW, Bonagura JD, editors: Current veterinary therapy IX-XIV, Philadelphia and St Louis, 1986-2008, Saunders; (7) Greene CE, editor: Infectious diseases of the dog and cat, ed 3, St Louis, 2006, Saunders; and (8) websites medlineplus.gov, www.medicinenet.com, www.drugs.com, and www.rxlist.com.

ABBREVIATIONS

AA: amino acid

PT: prothrombin time
PTE: pulmonary thromboembolism
PU/PD: polyuria and polydipsia
q: every
RA: rheumatoid arthritis
RAAS: renin-angiotensin-aldosterone system
RBC: red blood cell
RS: regular strength
S: oral solution
SIBO: small-intestinal bacterial overgrowth/antibiotic-responsive enteritis
SLE: systemic lupus erythematosus
SQ: subcutaneous
SVT: supraventricular tachycardia
T: tablet
$T_{1/2}$: serum half-life
T_3: triiodothyronine
T_4: thyroxine
TCC: transitional cell carcinoma
tbsp: tablespoon ((=15 mL)
tsp: teaspoon ((=5 mL)
TVT: transmissible venereal tumor
Tx: treatment
U: unit(s)
USP: U.S. Pharmacopeia
UTI: urinary tract infection
V/D: vomiting/diarrhea
VM: veterinary medicine
vWF: von Willebrand factor
WBC: white blood cell

TABLE VI-1

Drug Formulary

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
2-PAM	*(see pralidoxime)*				
4-methylpyrazole, 4-MP	*(see fomepizole)*				
5-ASA	*(see mesalamine)*				
5-FU	*(see fluorouracil)*				
Abelcet	*(see amphotericin B, liposomal encapsulated)*				
Acarbose (Precose)	Oral hypoglycemic drug used for treating diabetes mellitus; α-glucosidase inhibitor	12.5-25 mg per dog PO for initial dose; if ineffective, may increase to 50-100 mg per dog if no adverse effects	12.5 mg per cat PO q 12 h	Adverse effects (diarrhea, weight loss) common: 35% of dogs	25, 50, 100 mg T HM
Accolate	*(see zafirlukast)*				
Accutane	*(see isotretinoin)*				
Acepromazine (acetylpromazine, PromAce, AtraVet, “ace”)	Sedation, preanesthetic, central antiemetic	Premedication or as part of sedative protocol; 0.03-0.15 mg/kg SQ, IM, IV; as oral sedative (e.g., prior to travel): 0.5-1 mg/kg PO	Same	Oversedation causes CNS depression; in old or systemically ill animals, use at fraction of low dose (e.g., ¼) or not at all; do not use in animals with seizures or hypotension; breed sensitivities; has no anxiolytic or analgesic properties on its own (travel); hypotensive agent	5, 10, 25 mg T; 10 mg/mL I VM
Acetaminophen (Tylenol, Excedrin, Feverall, Liquiprin, Midol, Pamprin, Panadol, Percogesic, Tempra, Bromo-Seltzer, paracetamol, and most “aspirin-free” preparations)	Antipyretic, analgesic	10-20 mg/kg PO q 12 h	Do not use	Toxic to cats (methemoglobinemia); gastric irritation; hepatotoxicity if overdose; analgesic, not antiinflammatory	Many sizes T OTC
Acetazolamide (Diamox)	Glaucoma, CA inhibitor	2-10 mg/kg PO q 8 h	2-10 mg/kg PO q 8 h	Hypokalemia, panting, acidosis	125, 250 mg T, C HM
Acetylcysteine (Mucomyst)	1. Acetaminophen toxicosis in cats 2. Decrease bronchial secretion viscosity 3. Collagenase-complicated corneal ulcers	1. Same as for cats 2. Nebulize as 2% solution q 12 h 3. One drop 2%-10% solution q 2-4 h in eye	First dose 140 mg/kg PO, then 70 mg/ kg PO q 6 h for 3-7 treatments; may be given as slow bolus IV	Tastes bad, bronchospasm possible, conjunctivitis if prolonged topical use	100, 200 mg/mL, I HM
Acetylsalicylic acid (ASA, aspirin)	Analgesia, antiinflammatory, antipyretic, DIC, antithrombotic via decreased platelet aggregation	10-25 mg/kg PO q 8-24 h; 0.5 mg/kg PO q 12 h as antithrombotic	Per cat: 40.5-81 mg (10-20 mg/kg) PO q 48-72 h; minidose: 5 mg (1 mg/kg) PO q 72 h	Anorexia-nausea, GI irritation, gastric ulcer, bleeding, platelet dysfunction, anemia; doses higher than minidose are *less* anticoagulant in dogs	81, 300, 600 mg, T OTC
Acitretin (Soriatane)	Synthetic retinoid for keratinization disorders in specific breeds (e.g., cocker spaniels)	0.5-1.32 mg/kg PO q 24 h	—	Teratogenic; excreted in milk; adverse effects similar to etretinate	10, 25 mg T HM
ACTH gel (Acthar, corticotropin)	Provocative agent for diagnosis of hyperadrenocorticism or	2 IU/kg IM, obtain blood preinjection and at 2 hours postinjection	Per cat (IM); 10 IU, obtain blood preinjection and	Rare allergic reaction, do not give IV	40, 80 IU/mL I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
	hypoadrenocorticism	for cortisol levels	1 & 2 hours postinjection		
ACTH-like solution, aqueous (tetracosactrin, cosyntropin, Cortrosyn)	Provocative agent for diagnosis of hyperadrenocorticism or hypoadrenocorticism; appears superior to ACTH gel but more costly	Standard dose: 250 mcg/ dog (0.25 mg/dog) once, IV or IM. Low dose: 5 mcg/kg (0.005 mg/kg) IV once; with either protocol, obtain blood preinjection and at 1 hour postinjection for cortisol levels	Per cat: 0.125 mg IM or IV total dose; obtain blood preinjection and at 30 and 60 minutes postinjection	Costly; however, low dose and standard dose are equally effective when used IV; also remains effective if diluted, fractionated, and frozen for use at low dose (dogs) (Peterson ME: J Am Vet Med Assoc 224:198-199, 2004)	250 mcg (0.25 mg) per ampule I HM
Acthar	*(see ACTH gel)*				
Actigall	*(see ursodeoxycholic acid)*				
Actinomycin D (dactinomycin, Cosmegen)	Antineoplastic drug, part of chemotherapy protocols	0.5-1 mg/m^2 slow IV q 3 weeks		Lymphoma reinduction; myelotoxicity and GI adverse effects possible; vesicant (extravasation injury risk)	0.5 mg vial I HM
Activated charcoal (Toxiban, Requa)	GI adsorbent	1 g/5 mL water: give 10 mL of slurry/ kilogram PO; best administered via stomach tube	1 g/5 mL water: give 10 mL of slurry/ kilogram PO; best administered via stomach tube	Do not induce vomiting; inhalation pneumonia may occur; follow with cathartic.	VM HM (various)
Adenosyl methionine, *S*-	*(see methionine, S-adenosyl)*				
Adequan	*(see glycosaminoglycan, polysulfated)*				
Adrenalin	*(see epinephrine)*				
Adriamycin	*(see doxorubicin)*				
Adrucil	*(see fluorouracil)*				
Advantage	*(see imidacloprid)*				
Advil	*(see ibuprofen)*				
Aglepristone (Alizine, RU-534)	Progesterone receptor antagonist	10 mg/kg SQ q 24 h × 2 doses. For progestin-induced acromegaly, continue once weekly × 3 doses.	—	Not licensed or widely used in the United States, abortifacient	30 mg/mL I VM
Albendazole (Valbazen)	*Giardia;* other endoparasites	25-50 mg/kg PO q 12 h for maximum 5 days	15-25 mg/kg PO q 12 h for 5 days	May cause BM suppression at recorded dosages; 4 doses total (2-day course) recommended for giardiasis; up to 10-21 days for *Paragonimus*	300 mg/g (paste) S VM
Albeta	*(see methionine, DL-)*				
Albon	*(see sulfadimethoxine)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Albuterol (Ventolin, Proventil, Volmax, salbutamol)	Immediate but short-acting β_2-adrenergic agonist bronchodilator	0.02-0.05 mg/kg (20-50 mcg/kg) PO q 8-12 h Inhalant: 1 puff PRN, up to q 12 h	1 puff PRN	Beneficial effect lasts <4 hours; restlessness, muscle tremors; use with caution in patients where sympathetic drive could be harmful (e.g., heart disease, hypertension, hyperthyroidism, seizure disorders)	2, 4, 5 mg T, 0.4 mg/mL S, 6.8, 17 g inhalation canisters (0.1 mg [100 mcg] per puff) HM
Aldactazide	*(see hydrochlorothiazide/ spironolactone)*				
Aldactone	*(see spironolactone)*				
Alendronate (Fosamax)	Bisphosphonate Hypercalcemia	0.5-1 mg/kg PO q 24 h		Application for dental resorption in cats investigational	5, 10, 35, 40, 70 T 1 mg/mL S HM
Aleve	*(see naproxen)*				
Alkeran	*(see melphalan)*				
Allopurinol (Zyloprim)	Urate urolithiasis Leishmaniasis	10 mg/kg PO q 8 h, then reduce to 10 mg/kg PO q 24 h after 1 month	None	q 8 h Tx for 30 days then q 24 h	100, 300 mg T HM
Alprazolam (Xanax)	Benzodiazepine Separation anxiety	0.02-0.04 mg/kg PO q 4-6 h PRN	0.0125-0.025 mg/kg PO q 12-24 h	Feline dose range of 0.125-0.25 mg/kg published in other sources represents a 10-fold excess and should not be used	0.25, 0.5, 1, 2 mg T HM
Altace	*(see ramipril)*				
AlternaGEL	*(see aluminum hydroxide)*				
Aluminum hydroxide (Amphojel, AlternaGEL)	Phosphate binder, antacid	Initially, 10-30 mg/kg PO q 8-12 h; titrate based on PO4 to 10-90 mg/kg PO q 6-12 h; 5-10 mL/ dog	Same dose; per cat: approx. 1-3 mL PO q 8-12 h	May cause metabolic alkalosis; Amphojel = 64 mg $Al(OH)_3$/mL; AlternaGEL = 120 mg $Al(OH)_3$/mL; decreases absorption of concurrent drugs (e.g., tetracyclines, ketoconazole)	OTC, S HM
Amantadine (Symmetrel)	NMDA antagonist analgesic drug	3-5 mg/kg PO q 24 h	3-5 mg/kg PO q 24 h	New agent with little published clinical use; safety and efficacy profiles undetermined	100 mg C, 10 mg/ mL S HM
AmBisome	*(see amphotericin B, liposomal encapsulated)*				
Amicar	*(see aminocaproic acid)*				
Amiglyde-V	*(see amikacin)*				
Amikacin (Amikin, Amiglyde-V)	Aminoglycoside, G+ and G− agent	10-20 mg/kg q 24 h or 5-10 mg/kg q 12 h IV, IM, SQ	Same	Nephrotoxic, ototoxic, neuromuscular blockade, poor GI absorption	50 mg/mL I VM
Amikin	*(see amikacin)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Amino acids 3% and glycerin injection with electrolytes (ProcalAmine)	Partial parenteral nutrition; superficial necrolytic dermatitis/ hepatocutaneous syndrome	Maintenance rate	Maintenance rate	Essential and nonessential amino acids, carbohydrates, and electrolytes for IV infusion; see Parenteral Nutrition, p. 1322	IV solution bags, S
Aminocaproic acid (Amicar)	Antiprotease activity for degenerative myelopathy	15 mg/kg PO q 8 h	—	Limited information on side effects or benefits	500, 1000 mg T, 250 mg/mL S, 250 mg/mL I HM
Aminopentamide (Centrine)	Antispasmodic, cholinergic blocking agent, similar to atropine	0.01-0.03 mg/kg PO, IM, SQ q 8-12 h	0.01-0.03 mg/kg PO, IM SQ q 8-12 h	Dryness of the mouth, atropine-like side effects; contraindicated in GI obstruction, GI infection/toxin, glaucoma, heart disease, tachycardia	0.2 mg T, 0.5 mg/ mL I VM
Aminophylline	Bronchodilator, diuretic (very mild)	5-10 mg/kg PO, IV q 8-24 h	2-6 mg/kg PO q 12-24 h	Hyperexcitability, tachycardia, gastric irritation, PU/PD, anorexia; therapeutic serum level = 10-20 mcg/mL, administer IV slowly	100-200 mg T, 25 mg/mL I HM
Aminopropazine (Jenotone)	Used in urethral obstructions, smooth muscle relaxant	2.2-4.4 mg/kg IM q 12-24 h	Per cat: 6.25-12.5 mg IM q 12-24 h for 48 hours	Do not use with cystic atony; contraindicated in hypotension	25 mg T, 25 mg/mL I VM
Amiodarone (Cordarone)	Type III antiarrhythmic agent for serious/life-threatening ventricular tachyarrhythmias	10 mg/kg PO q 12 h for 1 week (loading), then 8 mg/kg PO q 24 h	—	Photosensitivity, liver necrosis, keratopathy, positive Coombs' test; may be proarrhythmic	100, 200, 400 mg T 50 mg/mL I HM
Amitraz (Mitaban)	Demodicosis, mites, ticks	5-10 mL/gallon H_2O, dip dog; air dry; = 0.025 to 0.05% solution; use 3× /wk on feet, with a fresh solution of 0.5 mL in 30 mL propylene glycol or mineral oil	—	CNS depression; wear gloves when applying; requires multiple dips; transient pruritus noted; small breeds more susceptible; use in ventilated areas and in accordance with relevant regulations (e.g., EPA)	19.9% solution for dilution and topical skin application VM
Amitriptyline HCl (Elavil)	Separation anxiety–related disorders, destructive disorders, feline inappropriate elimination; tricyclic antidepressant; long onset to clinical benefit	1.1-4.4 mg/kg PO q 12-24 h	Per cat: 2.5-5 mg total dose (0.5-1 mg/kg) PO q 12-24 h	Sedation, psychosis, anticholinergic side effects; caution if seizure history, glaucoma, dysuria	10, 25, 50, 75, 100, 150 mg T HM
Amlodipine (Norvasc)	Long-acting calcium channel blocking agent for hypertension	0.0625-0.25 mg/kg PO q 24 h	0.125-0.25 mg/kg PO q 24 h	Somnolence, hypotension	2.5, 5, 10 mg T HM
Ammonium chloride (Uroeze)	Urinary acidifier	20-50 mg/kg PO q 12 h	20-40 mg/kg PO q 12 h	Poor palatability, GI signs; contraindicated in liver disease and renal failure; granules = 200 or 400 mg in ¼ tsp	500 mg T, HM; 400 mg T; 200, 400 mg per ¼ tsp P VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Amoxicillin (Amoxitabs, Amoxi-drops, Robamox-V)	Penicillin class antibiotic, G+ (some G−) and anaerobic antibacterial agent	10-20 mg/kg PO, SQ, IM, IV q 8-12 h	Same	Penicillin contraindications	50, 100, 150, 200, 400 mg T, 25, 50 mg/mL S VM, HM
Amoxicillin/clavulanic acid (Clavamox, Augmentin)	*(see amoxicillin);* no penicillinase inactivation	10-20 mg/kg PO q 12 h	Same	Penicillin sensitivity, vomiting in cats; tablets must remain in foil until used	62.5, 125, 250, 375 mg T; 50 mg/mL S VM, HM
Amoxitabs	*(see amoxicillin)*				
Amphojel	*(see aluminum hydroxide)*				
Amphotericin B (Fungizone)	Systemic mycoses	Test dose (monitor for acute febrile reaction) = 0.25 mg/kg IV; if okay, then 0.5 mg/kg in D5W given IV CRI 3 times weekly for 2-4 months; do not exceed 5-10 mg/kg	Test dose (monitor for acute febrile reaction) = 0.1 mg/kg IV; if okay, then 0.1-0.25 mg/kg in 5-20 mL of D5W given slowly IV 3 times weekly for up to 6 weeks	Nephrotoxic; monitor BUN: pretreat with antiemetics; extravasation injury, anaphylaxis possible; may administer at lower dosage SQ in 0.45% saline plus 2.5% dextrose; combination with oral azoles to decrease dose/toxicity	50 mg/vial (or 100 mg/vial [Abelcet]) I HM
Amphotericin B, liposomal encapsulated (AmBisome, Abelcet)	Blastomycosis, histoplasmosis, cryptococcosis, coccidioidomycosis	0.5 mg/kg IV test dose; then 1-2.5 mg/kg IV, q 48 h; recommended cumulative dose = 12 mg/kg	—	Anaphylaxis possible; less nephrotoxic than aqueous amphotericin B (as already described)	50 mg/vial I HM
Ampicillin	Penicillin class antibiotic; routine G+ and anaerobic infections, some G−	10-20 mg/kg PO, SQ, IM, IV q 8 h	Same	Penicillin contraindications, phlebitis; trihydrate (Polyflex) for IM or SQ use only	125, 250, 500 mg C; 125 mg/5 mL S; 1, 3, 6 g vials I VM, HM
Ampicillin + sulbactam (Unasyn)	Beta lactamase–inhibiting-penicillin combination	20-50 mg/kg IM or IV	Same	Broad-spectrum antibacterial typically for in-hospital/ intensive care use. Dosage reflects total dose (e.g., a vial contains 1.5 grams; 1 gram = ampicillin and 0.5 grams = sulbactam, but product is dosed based on 1.5 grams)	1.5, 3 g vials I HM
Amprolium (Corid)	Enteric coccidiostat	Per pup: 100 mg total dose q 24 h in food or water (not both) for 10 days; per adult dog: 300 mg total dose q 24 h in food or water (not both) for 10 days	—	Overdosage causes CNS disturbances; thiamine is antidote	9.6% S VM
Amrinone (Inocor)	Low-output systolic myocardial failure; phosphodiesterase inhibitor	1-3 mg bolus IV, then 0.01-0.1 mg/kg/min (10-100 mcg/kg/min) IV CRI	—	Tachycardia, anxiety; monitor pulse and BP	5 mg/mL I HM
Anafranil	*(see clomipramine)*				
Ancef	*(see cephalosporin antibiotics)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Ancobon	*(see flucytosine)*				
Ancotil	*(see flucytosine)*				
Anipryl	*(see selegiline)*				
Antirobe	*(see clindamycin)*				
Antisedan	*(see atipamezole)*				
Antivert	*(see meclizine)*				
Antizol-Vet	*(see fomepizole)*				
Anzemet	*(see dolasetron)*				
Apomorphine	Induction of vomiting	0.03 mg/kg IV or ¼-½ tablet in conjunctival sac (flush out after onset of emesis)	Same	Do not use if decreased consciousness; do not use in cases of corrosive poisoning; periocular irritation	6 mg T VM, HM
Apresoline	*(see hydralazine)*				
Aqua-Mephyton	*(see vitamin K1)*				
ARA-C	*(see cytosine arabinoside)*				
Aranesp	*(see darbepoetin)*				
Arava	*(see leflunomide)*				
Aredia	*(see pamidronate)*				
Arixtra	*(see fondaparinux)*				
Artificial tears ointment (Adapt, Lacrilube)	Used for insufficient tear production or with decreased blinking	1 drop in affected eye PRN	Same	Hypersensitivity	OTC HM
ASA	*(see acetylsalicylic acid)*				
Asacol	*(see mesalamine)*				
Ascorbic acid (vitamin C)	Acetaminophen-induced methemoglobin toxicity, copper hepatotoxicity	Per dog: 100-500 mg PO, total dose q 8 h	30 mg/kg PO, SQ, IM, IV q 6 h for acetaminophen toxicity	Caution in urolithiasis	500 mg/mL I; 50, 100, 25, 500 mg, 1 g T HM, OTC
Ascriptin	*(see acetylsalicylic acid)*				
l-asparaginase (Elspar)	Induction therapy for lymphoreticular neoplasms, ITP	400 IU/kg IM, IP once or as part of a protocol; or 10,000-20,000 IU/m^2 IM, IP, SQ	Same	Allergic reactions; anaphylaxis; pretreat with antihistamines; pancreatitis; coagulopathies See pp. 671, 677 for body surface area (m^2 to body weight) conversion chart.	10,000 IU/vial I HM
Aspirin	*(see acetylsalicylic acid)*				
Atabrine	*(see quinacrine)*				
Atarax	*(see hydroxyzine)*				
Atenolol (Tenormin)	β1-adrenergic blockage; supraventricular tachyarrhythmias, systemic hypertension, hypertrophic cardiomyopathy	0.25-1 mg/kg PO q 24 h to q 12 h	Per cat: ¼-½ of 25-mg tab PO total dose, q 24 h to q 12 h	Hypotension, depression, β-blockade induced CHF, inappetence, bradycardia; generally start at low dose and	25, 50, 100 mg T HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				titrate up as necessary	
Atipamezole (Antisedan)	Synthetic α2-adrenergic antagonist; used for reversing analgesic-sedative effects of medetomidine or dexmedetomidine	0.025-0.1 mg/kg IV or IM; volume of dose is same as volume of (dex)medetomidine administered; reduce dose if >1 hour since (dex)medetomidine	Same	Return to normal state may not be immediate	5 mg/mL I VM
Ativan	*(see lorazepam)*				
Atopica	*(see cyclosporine)*				
Atovaquone (Mepron)	Antiparasitic drug; part of protocol for babesiosis	13.3 mg/kg PO q 8 h × 10 days		Coadministered with azithromycin 10 mg/kg PO q 24 h. May be cost-prohibitive.	150 mg/mL S HM
Atracurium (Tracrium)	Neuromuscular-blocking paralytic agent	0.2 mg/kg IV, then 4-9 mcg/kg/min IV CRI PRN	Same	Adjust as needed based on respirations (excess) and skeletal muscle movement (inadequate); no analgesia	10 mg/mL I HM
Atravet	*(see acepromazine)*				
Atropine SO4	Parasympatholytic, anticholinergic; preanesthetic agent, organophosphate toxicity; supraventricular bradyarrhythmia; atropine response test	0.02-0.044 mg/kg IM, SQ, IV. Atropine response test: give IV only, and recheck ECG after 2-15 minutes. For organophosphate poisoning, give 0.2-2 mg/kg IV, IM, or SQ (give ¼ dose IV and the remainder IM or SQ)	Same	Tachycardia, mydriasis, ileus, photophobia, dysuria; do not use in CHF unless bradycardia is present	0.54 mg/mL I VM various HM
Atropine sulfate ophthalmic solution or ointment	Used when pupillary dilation is desired (e.g., uveitis)	1 drop in affected eye q 12-24 h	Same: 1 drop in affected eye q 12-24 h	Atropine side effects; contraindicated in the presence of glaucoma; cats may salivate	0.5, 1% OO; 0.5, 1, 2, and 3% OS HM
Augmentin	*(see amoxicillin/clavulanic acid)*				
Auranofin (triethylphosphine gold; Ridaura)	Gold salt used in treatment of autoimmune disease	0.1-0.2 mg/kg PO q 12 h		Veterinary experience with efficacy and side effects is very limited	3 mg C HM
Aurothioglucose (Solganal)	Pemphigus complex, autoimmune diseases, rheumatoid arthritis	Week 1: 0.1 mg/kg IM single dose; week 2: 0.2 mg/kg single dose; then 1 mg/kg once a week IM, decreasing to once a month for maintenance immunosuppression	Per cat, week 1: 1 mg IM; week 2: 2 mg IM; then 1 mg/kg once a week IM, decreasing to once a month	Blood dyscrasias, renal and hepatotoxicity, neuritis-encephalitis, cutaneous toxicity, pain at injection site, many others	50 mg/mL I HM
Avapro	*(see irbesartan)*				
Avlosulfon	*(see dapsone)*				
Axid	*(see nizatidine)*				
Azactam	*(see aztreonam)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Azathioprine (Imuran)	Immunosuppressive agent (SLE, RA, immune-mediated hepatopathies, pemphigus, polymyositis, ITP, IHA, etc.)	1-2 mg/kg PO q 24-48 h	Do not use: toxic	Monitor CBC; BM suppression (leukopenia, thrombocytopenia); rarely hepatotoxic; use chemo precautions when handling or administering	50 mg T HM
Azidothymidine (AZT, zidovudine, Retrovir)	Antiretroviral agent	—	5-15 mg/kg PO q 12 h for 21 days	Monitor for anemia	100 mg C; 300 mg T; 10 mg/mL S HM
Azithromycin (Zithromax)	Broad-spectrum static macrolide antibiotic; refractory respiratory infections, other infections	5-10 mg/kg PO q 24 h for 1-5 days	5 mg/kg PO q 24 h for 1-5 days; pulse therapy or longterm treatment possible (weeks)	Resistant infections, GI effects, perishable (oral solution expires after 1 week despite refrigeration)	250, 600 mg T; 20, 40 mg/mL S HM
Azium	*(see dexamethasone)*				
AZT	*(see azidothymidine)*				
Aztreonam (Azactam)	Beta-lactam antibiotic; IV use in G− sepsis	30 mg/kg IV q 6-8 h		Limited information in clinical veterinary medicine	500 mg, 1g, 2g I HM
Azulfidine	*(see sulfasalazine)*				
Bactrim	*(see trimethoprim/ sulfamethoxazole)*				
Bactrovet	*(see sulfadimethoxine)*				
BAL	*(see dimercaprol)*				
Banamine	*(see flunixin meglumine)*				
Baytril	*(see enrofloxacin)*				
BCNU	*(see carmustine)*				
Benadryl	*(see diphenhydramine)*				
Benazepril (Fortekor, Lotensin)	ACE inhibitor, vasodilator, CHF therapy; glomerulopathy; systemic hypertension (usually in conjunction with other Tx; ineffective as antihypertensive monotherapy)	0.25-0.33 mg/kg PO q 24 h	0.25 mg/kg PO q 24 h	Dual renal-hepatic elimination; sedation, anorexia (both very rare); monitor potassium, renal and liver values; veterinary formulation not available nor approved in the United States	5, 20 mg VM (Canada, Europe, others); 5, 10, 20, 40 mg T HM
Bentyl	*(see dicyclomine)*				
Benzapen	*(see penicillin-benzathine)*				
Benzoyl peroxide (Oxydex, Pyoben)	Acne, cornification disorders/seborrhea, pyoderma, pruritus	Shampoo PRN; leave on skin for 10 minutes and rinse. Gel: apply topically q 8-12 h	Shampoo PRN; leave on skin for 10 minutes and rinse. Gel: apply topically q 8-12 h	Bleaches fabric; may be skin irritant	OTC, VM, HM
Benztropine mesylate (Cogentin)	Priapism	0.015 mg/kg IV		Anticholinergic, antihistaminic drug most proven in horses	1 mg/mL I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				with priapism. Must be given within 6 hours of onset of priapism for efficacy.	
Berenil	*(see diminazene)*				
Betamethasone (Betasone, Celestone)	Injectable or topical long-acting steroid	0.1-0.4 mg/kg IM; apply ointment topically PRN up to q 8 h	Apply ointment topically PRN up to q 8 h	Glucocorticoid adverse effects; 7-10 times the potency of prednisolone	2, 5 mg/mL I, VM; 0.6 mg T; 3 mg/mL I HM
Betapace	*(see sotalol)*				
Betasone	*(see betamethasone)*				
Bethanechol (Urecholine)	Bladder atony (nonobstructive), cholinergic agent	Per dog: 5-25 mg PO total dose q 8 h, or 2.5-15 mg SQ q 8 h	Per cat: 2.5-5 mg PO total dose q 12 h	Do not use with obstruction or areflexic bladder; GI adverse effects possible	5, 10, 25, 50 mg T HM
Biaxin	*(see clarithromycin)*				
BiCNU	*(see carmustine)*				
Biosol	*(see neomycin)*				
Bisacodyl (Dulcolax)	Laxative (stimulant and cathartic)	5-20 mg/dog PO q 24 h	5 mg/cat PO q 24 h	Short-term use only; may cause cramping, diarrhea	5 mg T OTC, HM
Bismuth subsalicylate (Pepto-Bismol)	GI tract protectant, antidiarrheic, *Helicobacter* protocols	1 mL per 4 kg BW PO up to q 6 h	Same with caution due to salicylate composition	Side effect (uncommon): vomiting; causes stool to develop dark grey or black discoloration	17, 35 mg/mL S; 262 mg T OTC, HM
Blenoxane	*(see bleomycin)*				
Bleomycin (Blenoxane)	Antineoplastic agent	10 U/m^2 IV or SQ q 24 h × 3 days, then 10 U/m^2 q 7 days; maximum total = 200 U/m^2 See pp. 671, 677 for body surface area to body weight conversion chart.		Other described uses in dogs include vincristine-resistant transmissible venereal tumor and intralesional use in acanthomatous ameloblastoma. Acute (hyperthermia, vomiting) and delayed (epithelial) toxicoses.	15 U vial I HM
Blood products	From typed donors: 1. Whole fresh; or packed RBCs 2. Fresh frozen plasma. 3. Fresh frozen plasma, initial dose (then PRN) 4. Fresh frozen plasma dose that raises plasma albumin 1 g/dL 5. For coagulation factors 6. Cryoprecipitate for vWF, hemophilia A, fibrinogen deficiencies	1. 5-22 mL/kg slowly IV; rapid if active hemorrhage is present 2. 6-10 mL/kg IV 3. 45 mL/kg IV 4. 6-10 mL/kg IV 5. 1 unit (225 mL)/10 kg BW IV	Same	Precautions are detailed in respective chapters (see Transfusion Reactions, p. 1111; Transfusion Therapy p. 1347)	VM, I
Bonine	*(see meclizine)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Bovine polymerized hemoglobin	*(see hemoglobin glutamer)*				
Brethine	*(see terbutaline)*				
Brevibloc	*(see esmolol)*				
British anti-Lewisite	*(see dimercaprol)*				
Bromide (KBr-generic)	Anticonvulsant	20-35 mg/kg PO q 24 h; divide q 12 h if GI upset; may load initially with 50 mg/ kg PO with food q 6 h × 48 h; lower dosage with concurrent phenobarbital; titrate using serum levels	Do not use; may trigger severe airway disease (asthma-like) in cats	Used with other antiepileptic drugs or alone; may increase sedation, weakness; dietary chloride should be constant to avoid altering rate of elimination; pancreatitis reported sporadically	400 mg/mL S VM
Bromocriptine (Parlodel)	Dopamine agonist prolactin inhibitor; causes luteolysis	Pyometra: 0.03 mg/kg PO q 8 h for 10 days; pregnancy termination: 0.01-0.05 mg/kg PO q 8 h for 3-4 days		Used in conjunction with prostaglandin F2α inhibitor; adverse side effects include nausea, neurologic signs, mainly seen at higher dose; abortifacient	2.5, 5 mg T HM
Bromo-Seltzer	*(see acetaminophen)*				
Budesonide (Entocort)	Glucocorticoid with minimal systemic effects due to topical GI distribution and rapid first-pass hepatic metabolism; inflammatory bowel disease	Per dog: 1-6 mg PO total dose, q 24-48 h; for noninfectious colitis: ½ to 1 enema (based on body size) per rectum q 24 h after defecation		Dosing limited by formulation (one-size unbreakable capsule); capsule dissolution designed for human ileum, unproven in VM	1, 3 mg C; 2 mg enema HM
Bufferin	*(see acetylsalicylic acid)*				
Bunamidine (Scolaban)	*Taenia, Dipylidium, Echinococcus*	25-50 mg/kg PO once; fast 3 hours before and after administration	Same	V/D rarely observed	100, 200, 400 mg T VM
Buprenex	*(see buprenorphine)*				
Buprenorphine HCl (Buprenex)	Opiate agonist: analgesia Sedative for medical procedures	0.01-0.02 mg/kg (10-20 mcg/kg) IV, IM 0.0075-0.01 mg/kg (7.5-10 mcg/kg) IV, IM	0.005-0.01 mg/kg (5-10 mcg/kg) IV, IM	Respiratory depression; use cautiously in aged or debilitated patients; neuroleptanalgesia when used with diazepam or acepromazine	0.324 mg/mL I HM
BuSpar	*(see buspirone)*				
Buspirone (BuSpar)	Anxiolytic agent; urine spraying, aggression, repetitive behaviors	Per dog: 2.5-10 mg PO total dose q 8-12 h	Per cat: 2.5-5 mg PO total dose q 12-24 h	Caution when used with hepatic or renal disease; may induce CNS stimulation or depression	5, 10, 15 mg T HM
Busulfan (Myleran)	Antineoplastic agent; leukemias	3-4 mg/m^2 PO q 24 h See pp. 671, 677 for body surface area to body weight conversion chart.		Uncommonly used, myelosuppression risk	2 mg T HM
Butazolidin	*(see phenylbutazone)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Butorphanol tartrate (Torbutrol, Torbugesic, Stadol)	Cough suppressant, narcotic agonist/ antagonist, analgesia, sedative	Analgesia, sedation: 0.2-1 mg/kg PO, IM, SQ q 12 h to q 6 h; 0.1-0.2 mg/kg IV; antitussive: 0.5-1 mg/kg PO q 6-12 h	Analgesia, sedation: 0.1-0.4 mg/kg, SQ, IM, IV q 6-12 h	Vomiting, sedation; possible overexcitement in cats	1, 5, 10 mg T; 1 mg/mL, 10 mg/ mL I VM, HM
B vitamins	*(see thiamine, cobalamin)*				
Cabergoline (Dostinex)	Dopamine agonist prolactin inhibitor; causes luteolysis	Pyometra: 0.005 mg/kg PO q 24 h for 10 days; pregnancy termination: 0.005 mg/kg PO q 8 h for 3-4 days	—	Abortifacient	0.5 mg T HM
Calan	*(see verapamil)*				
Calcet	*(see calcium gluconate)*				
Calciferol	*(see ergocalciferol)*				
Calcijex	*(see calcitriol)*				
Calcimar	*(see calcitonin)*				
Calcitonin (Calcimar, Miacalcin)	Reduces serum calcium in hypercalcemic states, especially cholecalciferol toxicosis	4-8 IU/kg IV, IM, SQ q 12 h	4-8 IU/kg IV, IM, SQ q 12 h	Injections are irritating; GI upset possible	200 IU/mL I HM
Calcitriol (Rocaltrol, Calcijex)	Vitamin D analog; hypocalcemia	0.02 mcg/kg PO q 24 h (hypoparathyroidism) or 0.002-0.004 mcg/ kg PO q 24 h (adjunct treatment of chronic renal failure/ renal secondary hyperparathyroidism) titrate according to response	Same	Rapid onset of action and shorter duration of activity (days) versus other drugs (e.g., DHT). Caution re. ng/kg versus mcg/ kg dosage; avoid 1000-fold dosing error	0.25-, 0.5 mcg C; 1 mcg/mL S
Calcium carbonate (Titralac, Tums)	Hypocalcemia, adjunct treatment	1-4 g/day PO	Same	Could cause alkalosis	OTC, HM
Calcium chloride (10% solution)	Ventricular asystole	0.1 mL/kg IV slowly, or IC	Same		100 mg/mL I HM
Calcium citrate (Citracal)	Calcium supplementation	20 mg/kg/day, with meals	10-30 mg/kg PO q 8 h with meals		950 mg (contains 200 mg calcium T HM, OTC
Calcium EDTA (Versenate, Edetate, Havidote)	Lead, zinc, and other metal poisoning	25 mg/kg SQ q 6 h for 5 days maximum; dilute in 5% D5W or 0.9% saline	Same	Empty gut of lead prior to use; injection may be painful despite dilution; potentially nephrotoxic	200 mg/mL I HM
Calcium gluconate (Calcet)	Critical hypocalcemia, ventricular asystole	50-200 mg/kg IV slowly over 15-30 minutes, up to q 6 h; 50-150 mg Ca^{++}/kg per day in continuous IV infusion; oral: 150-250 mg/kg PO q 8 h	Same	Arrhythmias; monitor ECG and overt response to treatment during infusion; V/D; dystrophic calcification	100 mg/mL (10% solution) I HM
Caninsulin	*(see insulin)*				
Caparsolate	*(see thiacetarsemide)*				
Capoten	*(see captopril)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Capstar	*(see nitenpyram)*				
Captan powder 50% (Orthocide)	Dermatomycoses	Mix 2 tbsp per gallon of water, and apply topically every 3-7 days; do not rinse after applying	Same	May induce contact sensitization in humans	VM
Captopril (Capoten)	Vasodilator, CHF, hypertension, ACE inhibitor	0.5-1.5 mg/kg PO q 8-12 h	Per cat: 3.125-6.25 mg PO q 12 h total dose	Hypotension-depression, anorexia, V/D; could exacerbate renal failure; less effective and shorter duration of action than most other ACE inhibitors	12.5, 25, 50, 100 mg T HM
Carafate	*(see sucralfate)*				
Carbaryl	Cholinesterase inhibitor for fleas, ticks, cheyletiellic mange	Use as a dip every 7-14 days; do not rinse off; spray q 48 h	Same	Do not use on animals under 4 weeks old; cholinesterase toxicity, treat with atropine and bathing; may stain hair yellow	0.5%-2% topical solution VM
Carbazole	*(see carbimazole)*				
Carbenicillin (Geocillin, Geopen, Pyopen)	Bacterial infections, broad-spectrum penicillin derivative	40-100 mg/kg IV, IM, SQ q 6-8 h (carbenicillin sodium; systemic infections); 10-33 mg/kg PO q 8 h (carbenicillin indanyl disodium; UTI)	Same, but do not exceed 55 mg/kg with parenteral formulation	*(see penicillin)*	382 mg T; 1, 2, 5, 10, 20, 30 g I HM
Carbimazole (Carbazole)	Hyperthyroidism; is metabolized to methimazole		Per cat: 5 mg PO total dose, q 8-12 h; titrate after 1-3 weeks based on response	Adverse effects similar to methimazole; not available nor approved in United States	5, 20 mg T HM
Carboplatin (Paraplatin)	Antineoplastic for many carcinoma and sarcoma therapies	300 mg/m^2 IV in D5W over 15 minutes every 3 weeks for 4 treatments See pp. 671, 677 for body surface area to body weight conversion chart.	200 mg/m^2 IV in D5W over 15 minutes every 4 weeks See pp. 671, 677 for body surface area to body weight conversion chart.	Myelosuppression; expensive; advantageous to *cis*-platinum (renal); use chemo precautions when handling or administering	50, 15, 450 mg I HM
Cardioxane	*(see dexrazoxane)*				
Cardizem	*(see diltiazem)*				
Cardoxin	*(see digoxin)*				
Caricide	*(see diethylcarbamazine)*				
Carmustine (BCNU)	Antineoplastic agent; gliomas, CNS lymphoma	50 mg/m^2 IV q 6 weeks See pp. 671, 677 for body surface area to body weight conversion chart.		Used in CNS malignancies because crosses blood-brain barrier; GI, myelotoxicity possible, risk heightened with cimetidine (avoid cotreatment); infused over 1-2 h, corrosive	33 mg/mL in 3 mL vial I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				if extravascular	
L-carnitine	AA transports fatty acids into mitochondria for energy metabolism; some dilated cardiomyopathy cases; feline hepatic lipidosis	50-100 mg/kg PO q 8 h	50-100 mg/kg PO q 24 h for hepatic lipidosis	Expensive in big dogs; to be used with other Tx; effects uncertain	250, 500 mg T/C; 100 mg/mL S HM
Carprofen (Rimadyl)	NSAID with analgesic and antipyretic effects	2 mg/kg PO q 12 h	—	Hepatotoxicity; do not use with bleeding disorders, inflammatory bowel disease, or GI ulcers; monitor liver values; do not use with corticosteroids or ASA; may decrease ACE inhibition	25, 75, 100 mg T VM
Carvedilol (Coreg)	α1-blocking agent with nonselective β-blockade; used in CHF and primary tachycardias	0.1-0.2 mg/kg PO q 24 h starting dose; may increase to 0.4 mg/kg PO q 12 h	Unknown	Lethargy; GI signs; iatrogenic relapse of CHF; if prior CHF, begin at low dose and increase slowly over several weeks; possible danger in asthmatics	3.125, 6.25, 12.5, 25 mg T HM
Cascara sagrada	Laxative	1-5 mg per dog PO q 24 h			100, 325 mg HM OTC
Castor oil	Irritant cathartic	8-30 mL PO	4-10 mL PO	Gripping catharsis may develop; do not use if obstructed or atonic	OTC, HM
CCNU	*(see lomustine)*				
CeeNu	*(see lomustine)*				
Cefa-Drops	*(see cefadroxil)*				
Cefadroxil (Cefa-Tabs, Cefa-Drops, Duricef)	First-generation cephalosporin antibiotic	22 mg/kg PO q 8 h	Same	First-generation cephalosporin; mainly active against G+	50, 100, 200 mg 1 g T; 50 mg/mL S, VM; 1 g T; 500 mg C; 25, 50, 100 mg/mL S HM
Cefa-Tabs	*(see cefadroxil)*				
Cefixime (Suprax)	Third-generation cephalosporin antibiotic	5-10 mg/kg PO q 12-24 h		Lower end of dosage range is used for cystitis	200, 400 T 20 mg/ mL S HM
Cefotaxime (Claforan)	Third-generation cephalosporin; G+ and G− organisms and many anaerobes	20-40 mg/kg slow IV q 8 h for 7 days	Same	Pain if injected IM; BM toxicity uncommon	500 mg, 1, 2, 10 g I HM
Cefotetan (Cefotan)	Second-generation cephalosporin antibiotic	30 mg/kg IV, SQ q 8 h			1, 2, 10 g vials I HM
Cefovecin (Convenia)	Long-acting injectable cephalosporin antibiotic	8 mg/kg SQ q 14 days	Same	Labeled for bacterial dermatitis but used extensively off-label. Extended elimination: 95% of dogs have therapeutic plasma cefovecin levels for	80 mg/mL I VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				7-14 days after one injection	
Cefoxitin (Mefoxin)	Cephamycin grouped with second-generation cephalosporins; some G+, G−, and anaerobic bactericidal activity	10-30 mg/kg IV q 6-8 h	Same	Pain if injected IM; BM toxicity uncommon	1, 2, 10 g vials I HM
Cefpodoxime (Simplicef, Vantin)	Once-daily oral third-generation cephalosporin antibiotic	5-10 mg/kg PO q 24 h	Same	Most common usage is for bacterial dermatitis	100, 200 mg T VM, HM; 10, 20 mg/ mL S HM
Ceftazidime (Ceptaz, Fortaz, Tazicef)	Third-generation cephalosporin antibiotic mainly indicated for G− sepsis	30 mg/kg IV q 8-12 h	Same		0.5, 1, 2, 6 g vials I, HM
Ceftiofur (Naxcel)	Third-generation cephalosporin	2.2-4.4 mg/kg SQ q 12-24 h	Same	—	1, 4 g vials I VM
Ceftriaxone (Rocephin)	Third-generation cephalosporin antibiotic; CNS infections	15-50 mg/kg IV q 12 h		May also be used for bacterial endocarditis in dogs	250, 500 mg; 1, 2 g vials I
Celestone	*(see betamethasone)*				
CellCept	*(see mycophenolate mofetil)*				
Centrine	*(see aminopentamide)*				
Cephalosporin antibiotics	Broad-spectrum bactericidal; β-lactamase inactivation although second- and third-generation more resistant	10-30 mg/kg PO, SQ, IM, IV q 12 h to q 6 h; review each product for specific dosage, handling, and administration	Same	GI side effects, penicillin contraindications; possibly nephrotoxic at high dosages or if used with aminoglycoside antibiotics	250, 500 mg C; 25, 50, 100 mg/mL S; 1, 2, 20 g vials I VM, HM
Cephulac	*(see lactulose)*				
Ceptaz	*(see ceftazidime)*				
Cerenia	*(see maropitant)*				
Cestex	*(see epsiprantel)*				
Cetirizine (Zyrtec)	Antihistamine; allergic disorders	5-10 mg/dog (up to maximum 2 mg/kg) PO q 12 h	5 mg/cat PO q 24 h		5, 10 mg T 1 mg/mL S HM
Charcoal	*(see activated charcoal)*				
Chemet	*(see succimer)*				
Cheque	*(see mibolerone)*				
Chitosan-based phosphate binder (Epakitin)	Hyperphosphatemia associated with chronic kidney disease	1 gram/5 kg body weight PO q 12 h	Same	Contains lactose, calcium carbonate, chitosan, and hydrolyzed soy protein	50, 150 g P VM
Chlorambucil (Leukeran)	Lymphoreticular neoplasia, chronic lymphocytic leukemia, macroglobulinemia, feline IBD	2 mg/m^2 PO q 24 h for 3 weeks beyond remission; then 1.5 mg/m^2 PO q 24 h for 15 days and then every third day; or 0.1-0.2 mg/kg PO q 24-72 h	1.5 mg/m^2 PO q 24 h as for dog, or 0.1 mg/kg PO q 48-72 h; or total dose per cat 2 mg/ cat PO q 48 h	BM suppression; usually a second-line agent often used with prednisone and/or other agents; use chemo precautions when handling or	2 mg T HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				administering; do not break or crush tablets	
Chloramphenicol (Chloromycetin)	Broad-spectrum bacteriostatic agent: *Mycoplasma, Rickettsia, Chlamydia,* and anaerobic bacteria; excellent lipid solubility (intracellular access) 1% ophthalmic ointment: corneal ulcers and infections; 0.5% ophthalmic solution: corneal ulcers and infections	30-50 mg/kg PO, IV, IM, SQ q 8 h; OO/ OS apply to eye q 6 h	15-50 mg/kg PO, IV, IM, SQ q 12 h; OO/OS apply to eye q 4-8 h	Hepatic microsomal enzyme inhibitor; may potentiate some Tx, use caution; do not use with "cidal" agents; monitor CBC and chemistries; caution in pregnancy/ neonates; avoid human exposure; risk of irreversible human BM suppression	100 mg/mL I; 100, 250, 500 mg; 1 g T VM, HM 1% OO, 0.5% OS VM, HM
Chlorhexidine 0.5% (Nolvasan)	Topical antiseptic shampoo Topical antiseptic solution	Shampoo every 3-7 days Dilute the solution 1:10 with water, and apply to lesions q 8-12 h	Same	—	OTC, HM, VM
Chloromycetin	*(see chloramphenicol)*				
Chlorothiazide (Diuril)	Diuretic/hypotensive, nonhormonal Tx for CDI and NDI, urolithiasis —decreased calcium elimination	20-40 mg/kg PO q 12 h	Same	Hyponatremia, hypokalemia; use cautiously with digitalis	250, 500 mg T; 50 mg/mL S HM
Chlorpheniramine (Chlor-Trimeton, ChlorTripolon)	Decongestant, antihistamine, antipruritic	Per dog: 2-8 mg PO total dose, q 8-12 h	Per cat: 1-2 mg PO total dose, q 8-12 h	May cause drowsiness or restlessness; anticholinergic side effects	10 mg/mL I; 0.4 mg/mL S; 2, 4, 8, 12 mg T OTC, HM
Chlorpromazine (Thorazine)	Tranquilization, antiemetic	Oral tranquilization: 1-3 mg/kg PO up to q 6 h Sedation: 0.1-1 mg/kg SQ, IM Antiemetic: 0.5 mg/kg IM or IV up to q 6 h	Same	Severe CNS depression with overdosage; may potentiate seizures; use sparingly or not at all in older or systemically ill patients; hypotension	10, 25, 50, 100, 200 mg T; 2 mg/ mL S; 25 mg suppository; 25 mg/mL I HM
Chlorpropamide (Diabexan, Diabinese)	Oral hypoglycemic; also potentiates renal action of ADH (diabetes insipidus)	10-40 mg/kg PO q 24 h		Variable clinical response; investigational use in VM at this time	100, 250 mg T HM
Chlorulon	*(see chorionic gonadotropin human)*				
Chlor-Trimeton	*(see chlorpheniramine)*				
ChlorTripolon	*(see chlorpheniramine)*				
Choledyl	*(see oxtriphylline)*				
Chorionic gonadotropin, human (hCG, Chorulon)	Male infertility; cryptorchidism/ testicular descent	Cryptorchidism: 100-1000 IU IM q 3-4 days × 4 Tx. Male infertility: 500-1000 IU IM q 2 weeks		Male infertility indication: notably if testicular degeneration is present or to increase libido prior to mating or collection	1000 IU/mL I VM
Chronulac	*(see lactulose)*				
Cialis	*(see tadalafil)*				
Ciloxan	*(see ciprofloxacin)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Cimetidine (Tagamet)	H2 receptor antagonist, esophagitis, gastric reflux, chronic gastritis, GI tract ulceration, hypergastrinemia, effects of mast cell tumors	5-10 mg/kg PO q 6-12 h; 5 mg/kg IV q 8 h	2.5-5 mg/kg PO q 8-12 h	Hepatic microsomal enzyme inhibitor; administer slowly IV	200, 300, 400, 800 mg T; 60 mg/ mL S; 150 mg/mL I HM
Ciprofloxacin (Cipro, Ciloxan)	Fluoroquinolone antibacterial agent, broad-spectrum "cidal"; *Mycoplasma*	5-15 mg/kg PO q 12 h	—	Incompletely bioavailable in dogs; see other fluoroquinolone comments under *Enrofloxacin*	100, 250, 500, 750 mg T HM
Cisapride (Propulsid, Prepulsid)	Prokinetic serotonergic for feline megacolon; gastroesophageal reflux; first- and second-degree GI motility disorders	0.1-0.5 mg/kg PO q 8-12 h	Per cat: 2.5-5 mg total dose PO q 8-12 h	Requires adjunctive Tx as stool softener, does not increase gastric secretions; increases esophageal peristalsis; reported to be associated with ventricular arrhythmias in HM and no longer available on the human market; toxic interaction with ketoconazole, cimetidine, macrolide antibiotics	10, 20 mg T; 1 mg/ mL S HM
Cisplatin (Platinol)	Solid carcinomas, osteosarcoma	50-70 mg/m^2 IV every 3-5 weeks; pretreat with IV fluids 12 hours before and after Tx. Intracavitary: same protocol, using 50 mg/m^2 dose diluted into 250 mg 0.9% sterile NaCl and administered into the peritoneal or pleural space immediately after effusion evacuation	None: do not use	Use antiemetic agent; BM suppression; renal toxicity; fatal pulmonary edema in cats; anaphylaxis; use chemo precautions when handling or administering	10 and 50 mg vials I HM
Citracal	*(see calcium citrate)*				
Citrate	*(see potassium citrate)*				
Claforan	*(see cefotaxime)*				
Clarithromycin (Biaxin)	Broad-spectrum macrolide antibacterial; resistant respiratory or skin infections	5-10 mg/kg PO q 12 h	Same	GI, liver disturbances; BM toxicity rarely	250, 500, mg T; 25, 50 mg/mL S HM
Clavamox	*(see amoxicillin/clavulanic acid)*				
Clemastine fumarate (Tavist products, Contac products, many others)	Antihistamine; allergic skin disease, other allergies, mast cell tumor	0.05-0.1 mg/kg PO q 12 h	0.3-0.6 mg/cat PO q 12 h	Lethargy/drowsiness or restlessness; caution: other active ingredients in OTC combo formulations	1.34, 2.8 mg T HM OTC
Cleocin	*(see clindamycin)*				
Clindamycin (Cleocin, Antirobe)	Lincosamide antibiotic, G+, *Streptococcus, Staphylococcus,*	5-10 mg/kg PO q 12 h; toxoplasmosis: 5-20 mg/kg PO q 12 h	Same; toxoplasmosis: 12.5-25 mg/kg PO q 12 h	May cause V/D and very rarely hepatotoxicity; do not use with erythromycin	150 mg/mL I: 25, 75, 150 mg C; 25 mg/mL S

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
	anaerobes, *Bacteroides,* toxoplasmosis, neosporosis, babesiosis, osteomyelitis			or chloramphenicol; oral solution has unpleasant taste	VM, HM
Clofazimine (Lamprene)	Mycobacterial infections		1 mg/kg PO q 24 h up to daily maximum of 4 mg/kg	Efficacy and safety poorly established in VM	50, 100 mg C HM
Clomicalm	*(see clomipramine)*				
Clomipramine (Anafranil, Clomicalm)	Separation anxiety, acral lick dermatitis; tricyclic antidepressant agent	1-2 mg/kg PO q 12 h	0.5-1 mg/kg PO q 24 h	Do not use in breeding dogs or if dog is receiving or has received MAO inhibitors (e.g., Anipryl, amitraz, etc.); vomiting, lethargy, diarrhea, and polydipsia are adverse reactions most often noted; caution in animals with GI motility or seizure disorders	5, 20, 40, 80 mg T VM
Clonazepam (Klonopin)	Seizure disorders, panic disorders, sedation	0.5 mg/kg PO q 8-12 h; titrate as required to effect	1/8-¼ of 0.5 mg tablet PO as feline appetite stimulant	Second-line seizure Tx; sedation, duration of action in dogs may be short (few hours)	0.5, 1, 2 mg T HM
Clopidogrel (Plavix)	Antiplatelet drug, thienopyridine drug	—	18.75 mg/cat PO q 24 h	Emerging application in cats at risk of thromboembolism. Clinical efficacy/safety promising but unproven.	75 mg T HM
Cloprostenol (Estrumate)	Abortifacient for mismating (early, prior to ossification of fetal bones)	1-2.5 mcg/kg SQ, q 24-48 h for 5 days	Same	Dilute 1:10 with sterile 0.9% NaCl for accurate dosing	250 mcg/mL I VM
Clorazepate (Tranxene)	Second- or third-line antiepileptic drug; benzodiazepine	0.5-1 mg/kg PO q 8 h	0.5-1 mg/kg PO q 8 h	New agent; safety and efficacy profile poorly defined at this time	3.75, 7.5, 15 mg T HM
Clotrimazole (Veltrim, Lotrimin, Mycelex)	Used topically for nasal aspergillosis; also externally for *Malassezia* and other fungi	PRN to fill nasal cavity for nasal aspergillosis (follow precautions and protocol) See p. 1308	—	Intranasal administration requires preplacing catheters surgically or via endoscope; use propylene glycol preparation for this indication	10 mg/mL topical solution OTC, HM
Coal tar (0.5% to 8%)	Shampoo; cornification disorders/seborrhea, dermatitis, eczema, keratolytic	Bathe every 3-14 days; leave in contact with skin for 10 minutes and rinse thoroughly	Same	May irritate skin	VM
Cobalamin (vitamin B12, cyanocobalamin)	Used for treating vitamin B12 deficiency from exocrine pancreatic disease, SIBO, and in giant schnauzers	Total dose: 250-1200 mcg (0.25-0.12 mg) per dog, SQ once weekly × 6 weeks, then q 14 d × 6 weeks, then PRN	Total dose: 125-250 mcg (0.125-0.25 mg) per cat IM, SQ; dosing schedule as for dogs		1000 mcg/mL (= 1 mg/mL) I HM, VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Codeine	Opiate antitussive	1-2 mg/kg PO PRN up to q 6 h		May cause sedation at higher doses; schedule C-II	15, 30, 60 mg T 3 mg/mL S HM
Cogentin	*(see benztropine)*				
Colace	*(see dioctyl sodium sulfosuccinate)*				
Colchicine	Hepatic fibrosis	0.03 mg/kg/day PO q 24 h	No reported use	Not well described; GI effects, BM toxicity, teratogenicity possible	0.5, 0.6 mg T HM
Colony-stimulating factor	*(see filgrastim)*				
Comfortis	*(see spinosad)*				
Compazine	*(see prochlorperazine)*				
Conofite	*(see miconazole)*				
Convenia	*(see cefovecin)*				
Cordarone	*(see amiodarone)*				
Coreg	*(see carvedilol)*				
Corid	*(see amprolium)*				
Corticotropin	*(see ACTH gel)*				
Cortrosyn	*(see ACTH-like solution, aqueous)*				
Cosequin	*(see glucosamine-chondroitin sulfate)*				
Cosmegen	*(see actinomycin D)*				
Cosyntropin	*(see ACTH-like solution, aqueous)*				
Coumadin	*(see warfarin)*				
Covera	*(see verapamil)*				
Cuprimine	*(see penicillamine)*				
Cyanocobalamin	*(see cobalamin)*				
Cyclophosphamide (Cytoxan, Neosar)	Lymphoreticular tumors, solid carcinomas, immune-mediated disease	50 mg/m^2 (or 2 mg/kg) PO, 4 days on, 3 days off, or use q 48 h; or 200-300 mg/m^2 IV q 3 weeks See pp. 671, 677 for body surface area to body weight conversion chart.	Same	GI signs; BM suppression; hemorrhagic cystitis, especially with higher (weekly) dose; alopecia; use with caution; use chemo precautions when handling or administering (see Chemotherapy; Adverse Reactions, p. 188); do not crush or break tablets. Caution: cyclosporine brand name almost identical (Neosar versus Neoral)	25, 50 mg T; 100, 200, 500 mg and 1 and 2 g vials I HM
Cyclosporine-ophthalmic (Optimmune)	T-lymphocyte inhibitor; KCS in dogs	0.2% ophthalmic ointment or solution in oil base; use one drop/short (¼-in) strip	Do not use	May be ophthalmic irritant; monitor for infections	HM, VM, OO, OS; 4 mL olive oil and 1 mL cyclosporine

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
		q 12 h in affected eye(s) until improvement occurs, then q 24 h			
Cyclosporine-systemic (Sandimmune, Atopica, Neoral)	IHA, ITP, perianal fistula, atopic dermatitis, feline necrotizing gingivitis, renal transplantation, other immunosuppressive purposes	Emulsion forms: (Neoral, Atopica): 2-5 mg/kg PO q 12 h (2-5 mg/kg PO q 24 h if concurrent ketoconazole administration) Nonemulsion form: (Sandimmune, very rarely available now): 5-10 mg/kg PO q 12 h (5-10 mg/kg PO q 24 h if concurrent ketoconazole administration) 2-3 mg/kg slow IV over 4 hours q 12 h; dilute to 1 mg/mL in D5W or 0.9% NaCl before IV administration	Same; cats should have a negative *Toxoplasma* titer to qualify for treatment	Adjust dose to attain good clinical response and 200-500 ng/mL blood level (for autoimmune diseases; 300-800 ng/mL for renal transplant patients). Oral doses based on greater absorption of emulsion forms versus nonemulsion forms; can cause nephrotoxicity (protein-losing nephropathy), gingival hyperplasia; anaphylaxis possible with IV; little clinical experience with IV to date. Caution: cyclophosphamide brand name is almost identical (Neoral versus Neosar)	25, 50, 100 mg C; 100 mg/mL S; 50 mg/mL I, HM; 10, 25, 50, 100 mg C VM
Cypip	*(see diethylcarbamazine)*				
Cyproheptadine (Periactin)	Serotonin and H1 antagonist: Appetite stimulant via hypothalamic action Feline pica Antihistamine Urine spraying Add-on for feline asthma	1 mg/kg PO q 8-12 h	Total dose = 1-4 mg/ cat PO q 12-24 h	Can cause excitability or depression, especially at higher doses; vomiting, aggressiveness	4 mg T; 0.4 mg/mL S HM
Cystorelin	*(see gonadotropin-releasing hormone)*				
Cytarabine	*(see cytosine arabinoside)*				
Cytobin	*(see triiodothyronine)*				
Cytomel	*(see triiodothyronine)*				
Cytosar	*(see cytosine arabinoside)*				
Cytosine arabinoside (Cytarabine, Cytosar, ARA-C)	Antineoplastic, lymphoma protocol	100 mg/m^2 SQ or slow IV q 24 h for 2-4 days	Same	Leukopenia-BM suppression, GI toxicity, reconstituted vial good for 48 hours; use along with cancer protocol; use chemo precautions when handling or administering	100, 500 mg, 1 and 2 g vials I HM
Cytotec	*(see misoprostol)*				
Cytoxan	*(see cyclophosphamide)*				
Dacarbazine (DTIC)	Melanoma, sarcoma	800-1000 mg/m^2 IV, CRI (8 hours) every 3-4 weeks	Not recommended	GI toxicity, BM suppression, extravasation injury	100, 200 mg vials, I

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
					HM
Dactinomycin	*(see actinomycin D)*				
Dalteparin	*(see heparin, low-molecular-weight)*				
Danazol (Danocrine)	Modified androgen; used for ITP, IHA; anabolic; used for prostatic hypertrophy or androgen-dependent neoplasia	5-10 mg/kg PO q 12 h	5 mg/kg PO q 12 h	Adjunctive Tx for ITP and IHA; hepatotoxicity; BM toxicity possible; immunosuppressive response may take weeks or months; androgen effects faster	50, 100, 200 mg C HM
Danocrine	*(see danazol)*				
Dantrolene (Dantrium)	Skeletal muscle relaxant; malignant hyperthermia	2-3 mg/kg IV; 1-5 mg/kg PO q 8 h	0.5-2 mg/kg PO q 12 h		100 mg C 0.33 mg/ mL I HM
Dapsone (Avlosulfon)	1. Antibacterial, antiinflammatory agent used for some skin disorders 2. Antiprotozoal/ antimycobacterial effects	1. 1 mg/kg PO q 8 h 2. 1 mg/kg PO q 8 h initially until remission, then 0.3 mg/kg maintenance	Rarely used in this species; 1 mg/kg PO q 24 h and 8 mg/kg PO q 24 h have been reported	Hepatotoxicity and BM suppression may occur early in therapy; hemolysis, GI signs, skin eruptions possible	25 and 100 mg T HM
Daranide	*(see dichlorphenamide)*				
Daraprim	*(see pyrimethamine)*				
Darbepoetin (Aranesp)	Erythropoietin analog; considered less antigenic; anemia of chronic kidney disease	0.45 mcg/kg SQ once weekly at first, then q 2-3 weeks adjusted for maintenance	Same	Considered less antigenic in dogs and cats than recombinant human erythropoietin	25, 40, 60, 100, 150, 200, 300, 500 mcg vials or preloaded syringes I HM
DDAVP	*(see desmopressin acetate)*				
DDVP	*(see dichlorvos)*				
DEC	*(see diethylcarbamazine)*				
Decadron	*(see dexamethasone)*				
Deca-Durabolin	*(see nandrolone decanoate)*				
Decholin	*(see dehydrocholic acid)*				
Decoquinate (Deccox)	Hepatozoonosis	20 mg/kg (or 1 teaspoon/10 kg mixed in food) PO q 12 h		Administer for 2 years, or until PCR testing is negative, to inhibit development of merozoites released from tissue cysts	6% preparation (60 g decoquinate per kg of product) oral premix VM
Dectomax	*(see doramectin)*				
Deferoxamine (Desferal, DFO)	Iron chelator; treatment of iron toxicity	10-15 mg/kg/hr IV CRI, then titrate based on serum iron levels. Alternatively, if CRI not possible, give 10-40 mg/kg IM q 8 h for	—	Arrhythmia, hypotension, wheezing if CRI too rapid; hypocalcemia, thrombocytopenia possible; do not use	500 mg vials I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
		24-72 hours, based on serum iron levels		in cases of renal failure; potential teratogen	
Dehydrocholic acid (Decholin)	Used to stimulate bile flow	10-15 mg/kg PO q 8 h for 7-10 days	Same	Do not use with biliary obstruction	HM
Delmadinone (Tardak)	Benign prostatic hyperplasia	1.5 mg/kg IM or SQ: 2 injections 8 days apart; may repeat 1 dose 1 month later		Remission of clinical signs in 83% of dogs.	10 mg/mL I VM
Demadex	*(see torsemide)*				
Demerol	*(see meperidine HCl)*				
Denosyl	*(see methionine, S-adenosyl)*				
Depakene	*(see valproic acid)*				
Depakote	*(see valproic acid)*				
Depen	*(see penicillamine)*				
Depo-Medrol	*(see methylprednisolone acetate)*				
Depo-Provera	*(see medroxyprogesterone acetate)*				
Deprenyl	*(see selegiline)*				
Deracoxib (Deramaxx)	COX-2-inhibiting NSAID drug; for treatment of osteoarthritis, perioperative pain management	1-2 mg/kg PO q 24 h (long-term use); 3-4 mg/kg PO q 24 h (max 7 days)	—	GI signs (vomiting, anorexia)	25, 75, 100 mg chewable T VM
Deramaxx	*(see deracoxib)*				
Dermathycin	*(see thyrotropin)*				
Derm caps	*(see fatty acid nutritional supplement)*				
DES	*(see diethylstilbestrol)*				
Desferal	*(see deferoxamine)*				
Desitin	*(see zinc oxide)*				
Desmopressin acetate (DDAVP)	Vasopressin analog (1-desamino-8-D-arginine-vasopressin) to manage central diabetes insipidus, von Willebrand disease	1-4 drops intranasally or in subconjunctival sac, q 6-24 h (diabetes insipidus) or 1-2 mcg/kg SQ, q 24 h to q 12 h; 0.1 mg/kg PO q 8 h (tablets)	Oral dose: 0.25-0.5 mg/cat PO q 8-12 h (tablets)	Rhinorrhea, hypersensitivity reactions, water retention; use nasal spray form topically (1.5-4 mcg/drop); 40 times stronger than parenteral (4 mcg/mL)	10 mcg/spray (= 0.1 mL) in 2.5- or 5-mL bottles; 4 mcg/mL I; 0.1 and 0.2 mg, T HM
Desoxycorticosterone pivalate (DOCP) (Percorten-V)	Replacement therapy for mineralocorticoid deficiency (hypoadrenocorticism); each 25 mg releases 1 mg DOCA/day for 21-26 days	1 mL/12 kg, q 25 days (i.e., 2 mg/kg) IM or SQ	—	Titrate dosage to effect; monitor serum electrolytes; no glucocorticoid activity; may require oral prednisolone 0.2-0.4 mg/kg per day as adjunctive therapy	25 mg/mL I VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Dexamethasone (Azium, Dexate, Decadron); Dexamethasone sodium phosphate (SP)	Potent glucocorticoid for antiinflammatory, immune suppression, hypoadrenocorticism, shock, pituitary-adrenal axis testing	Antiinflammatory: 0.1-0.2 mg/kg per day PO, SQ, or IV; immunosuppressive: 0.2-0.4 mg/kg per day PO, SQ, or IV; long-term oral: q 48 h best. Hypoadrenocorticism: 0.1-0.8 mg/kg IV (initial treatment; e.g., hypovolemic shock), but maintenance = <0.1 mg/kg PO PRN up to q 24 h. LDDST = 0.01 mg/kg IV; HDDST = 0.1 mg/kg IV	Same	HPA axis suppression, multiorgan steroid effects; very high CNS doses (e.g., 4-8 mg/ kg) of unproven clinical benefit and almost always associated with short-term adverse effects (e.g., severe GI bleeding): if more than several consecutive days of treatment, taper dose gradually before stopping	0.25, 0.5, 0.75, 1, 1.5, 2, 4, 6 mg T; 2, 8, 16 mg/mL I (dexamethasone); 4, 10, 20, 24 mg/mL I (dexamethasone SP) VM, HM
Dexasporin ophthalmic solution or ointment (Maxitrol)	Neomycin, polymyxin, and dexamethasone combination used for steroid-responsive ophthalmic inflammation where a combined antibiotic is desirable	1 drop in affected eye q 6-12 h	1 drop in affected eye q 6-12 h	Steroids are contraindicated in some specific eye diseases (e.g., corneal ulcers, feline herpetic keratitis); systemic corticosteroid side effects are possible	0.05% ointment, 0.1% solution HM
Dexate	*(see dexamethasone)*				
Dexdomitor	*(see dexmedetomidine)*				
Dexedrine	*(see dextroamphetamine)*				
Dexmedetomidine (Dexdomitor)	α2-agonist sedative-analgesic	Sedation/analgesia: 375 mcg/m^2 IV or 500 mcg/m^2 IM Preanesthetic: 125 mcg/m^2 IM	20-40 mcg/kg IM	Dextroenantiomer of medetomidine (levo-is inactive); therefore, double potency of medetomidine, but prepared at half concentration of medetomidine, so volume administered is same as medetomidine. See pp. 671, 677 for body surface area to body weight conversion chart. Reversal agent is atipamezole.	0.5 mg/mL (= 500 mcg/mL) I VM
Dexrazoxane (Zinecard, Cardioxane)	EDTA derivative that protects against doxorubicin-induced cardiomyopathy; may also be used for doxorubicin extravasation lesions	10:1 ratio to doxorubicin dose (i.e., administer 10 times more dexrazoxane [in mg] than doxorubicin); IV CRI over 30 minutes, begun 45 minutes prior to doxorubicin		Myelosuppression possible	250 and 500 mg vials I HM
Dextran (Rheomacrodex)	Hypovolemia, plasma volume expander	Approximately 20 mL/ kg IV, titrated to effect	Same	Platelet dysfunction, hemorrhage, circulatory overload	6% dextran in PSS or D5W I HM
Dextroamphetamine (Dexedrine)	Amphetamine; narcolepsy, hyperkinesis	5-10 mg total dose per dog PO q 8 h; 0.2-1.3 mg/kg PO PRN	—	CII drug	5 mg T; 5, 10, 15 mg ER C HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Dextromethorphan	Antitussive	0.5-2 mg/kg PO q 8 h	Same	Usually in association with other drugs (i.e., OTC cough syrup [e.g., Robitussin]); efficacy questioned; avoid with moist/ productive coughs; avoid aspirin-containing or acetaminophen-containing combination in cats (OTC)	Many OTC, HM
Dextrose 50%	Hypoglycemia	Administer 1-5 mL IV for hypoglycemic crisis; dilute with sterile water or 0.9% NaCl (3-5× the volume) before administering	1 mL IV for hypoglycemic crisis; dilute as for dogs	Dilution decreases viscosity and reduces risk of perivascular injury if extravasation; repeated dosing in insulinoma may worsen insulin secretion	50% dextrose = 500 mg/mL VM
DFO	*(see deferoxamine)*				
DHT	*(see dihydrotachysterol)*				
Diabinese	*(see chlorpropamide)*				
Diabeta	*(see glyburide)*				
Diabexan	*(see chlorpropamide)*				
Diamox	*(see acetazolamide)*				
Diastat	*(see diazepam)*				
Diazepam (Valium, Diastat)	1. Tranquilizer, component of anesthetic induction protocol 2. Anticonvulsant 3. Muscle relaxant 4. Appetite stimulant (cats) 5. Urine marking/ spraying (cats) 6. Sedative/anxiolytic	1. With ketamine for sedation/ anesthetic induction: 0.5 mg/kg IV or to effect, maximum 20 mg/ dose 2. 0.5-1 mg/kg IV to effect; enema: 1-2 mg/kg made up as 4 mg/mL enema solution; or IV CRI: 0.5 mg/kg/hr, titrated PRN 0.25-1 mg/kg 3. 3, 6. 0.05-0.2 mg/kg IV PO, PRN up to q 12 h	1. 1, 2. Total dose: 0.25-2 mg IV per cat, to effect 2. 3, 5. Total dose: 1-2 mg per cat PO q 12 h 3. 0.2 mg/kg IV prior to feeding 4. Same as for dog	Sedation ataxia; paradoxical excitement/ aggression; hepatopathy in some cats within days or weeks of starting PO; CRI: diazepam is inactivated by light and adsorbs onto plastic; use glass syringe and short tubing if possible; class IV	2, 5, 10 mg T; 5 mg/mL I; 2.5, 5, 10, 15, 20 mg (rectal gel) HM
Diazoxide (Proglycem)	Hypoglycemia associated with insulinoma	5-20 mg/kg PO q 12 h	None	Vomiting, anorexia	50 mg C; 50 mg/mL S HM
Dibenzyline	*(see phenoxybenzamine HCl)*				
Dichlorphenamide (Daranide)	Glaucoma; carbonic anhydrase inhibitor	2-4 mg/kg PO q 8 h	Same	Weakness; lethargy, diarrhea, hypokalemia, hyperchloremic metabolic acidosis	50 mg T HM
Dichlorvos (Task, Vapona, DDVP)	Hookworms, whipworms, roundworms; flea collars and tags	27-33 mg/kg PO once; 11 mg/kg PO once (puppies); change collar every 4 months	11 mg/kg PO once; change collar every 4 months	Organophosphate toxicity; do not use with constipation, intestinal obstruction,	10, 20 mg T; 68, 136, 204 mg C; 136, 204, 544 mg paste

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				or hepatic, cardiac, or heartworm disease; no effect on larval form of whipworms	VM
Dicural	*(see difloxacin)*				
Dicyclomine (Bentyl)	Irritable bowel syndrome, detrusor hyperspasticity causing urge incontinence	0.15 mg/kg PO q 8-12 h	—	—	10 mg C; 20 mg T HM
Didronate, Didronel	*(see etidronate)*				
Diethylcarbamazine (DEC, Caricide, Cypip, Filaribits)	1. Heartworm (HW) prophylaxis 2. *Crenosoma* lungworm treatment 3. Ascarid infections	1. 6-7 mg/kg PO q 24 h, from start of HW season to 2 months after end of HW season 2. 70 mg/kg PO q 12 h for 3 days 3. 55-100 mg/kg PO; repeat in 10-20 days	55-110 mg/kg PO once for ascarids	Vomiting; may decrease sperm count; anaphylaxis if microfilaria positive dog	50, 60, 100, 120, 180, 200, 300, 400 mg T; 60 mg/ mL S; other sizes VM, HM
Diethylstilbestrol (DES)	1. Estrogen-responsive incontinence 2. Perianal gland adenoma, benign prostatic hyperplasia	1. Total dose: 0.1-1 mg per dog PO q 24 h for 4-7 days, then once weekly 2. Total dose: 0.25-1 mg per dog PO q 24-48 h for 2-7 days	0.05-0.1 mg/day PO	May induce signs of estrus; decrease to lowest effective dosage; high dosages may cause anemia, leukopenia, thrombocytopenia; ineffective for pregnancy termination; limited availability in U.S. market	1, 5 mg T; 50 mg/ mL I; other sizes HM
Difloxacin (Dicural)	Fluoroquinolone antibacterial	5-10 mg/kg PO q 24 h; maximum = 30 days		GI effects, cartilage damage possible in pups; avoid in seizure animals	11, 45, 136 mg T VM
Diflucan	*(see fluconazole)*				
Digoxin (Cardoxin, Lanoxin)	Supraventricular tachyarrhythmias, systolic dysfunction; positive inotrope, negative chronotrope, negative dromotrope, baroreceptor upregulator	0.005 mg/kg PO q 12 h; maximum dose for largest dog = 0.25 mg PO q 12 h; can double dose for first 24 hours only	Total dose: ¼ of a 0.125 mg tablet per cat PO q 48 h	Injectable form not recommended; see also online chapter: Digoxin Toxicosis	0.125, 0.25 mg T; 0.05 mg/mL S HM
Dihydrotachysterol (DHT, Hytakerol)	Hypocalcemia	0.03-0.06 mg/kg PO q 24 h initially for 2-3 days; then 0.01-0.02 mg/kg PO q 24-48 h, titrated to response	Same	Risk of hypercalcemia; monitory serum calcium and patient until well stabilized; when stable, monitor long-term use	0.125, 0.2, 0.4 mg T; 0.125 mg C; 0.2 mg/mL S HM
Dilacor-XL	*(see diltiazem)*				
Dilantin	*(see phenytoin)*				
Dilaudid	(see hydromorphone)				
Diltiazem hydrochloride (Cardizem) (sustained release forms: Dilacor-XL, Cardizem CD)	Calcium channel blocking agent; hypertrophic cardiomyopathy (in felines), acute SVT	0.5-1.5 mg/kg PO q 8 h; for acute SVT: 0.01-0.02 mg/kg IV initial dose; repeat PRN; maximum cumulative IV dose = 1	0.8-2.5 mg/kg PO q 12 h to q 8 h; 10 mg/kg PO q 24 h, in sustained release form	Bradycardia, hypotension, anorexia; sustained-release form often causes adverse reactions (hepatic,	30, 60, 90, 120 mg T; 120, 180, 240, 320 mg C; 60, 90, 120, 240, 360, 420 mg; ER HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
		mg/kg; may start at 0.1-0.2 mg/kg IV if heart is structurally normal		GI) in cats; dose-dependent AV block	
Dimenhydrinate (Dramamine, Gravol)	Motion sickness	4-8 mg/kg PO, up to q 8 h	Total dose: 12.5 mg per cat PO up to q 8 h	Lethargy, drowsiness; administer 1 hour prior to travel for best antinausea effect	80 mg T; 12.5 mg/ 4 mL S; 50 mg/ mL I HM, OTC
Dimercaprol (BAL, British anti-Lewisite)	Chelating agent; heavy metal toxicosis, such as mercury, lead, and arsenic	2.5-5 mg/kg IM (dose of 5 mg/kg used only in acute cases and only on first day) q 4 h on days 1 and 2; q 8 h on day 3; q 12 h for next 10 days	Same	Injections sting; caution: renal insufficiency; sulfurous odor of breath	100 mg/mL I HM
Dimercaptosuccinic acid	*(see succimer)*				
Dimethyl sulfoxide (DoMoSo, DMSO)	Topical antiinflammatory Renal amyloidosis CNS trauma	Apply solution topically q 12 h to q 8 h; use 60% otic solution, q 12 h 80 mg/kg SQ q 48 h (dilute solution 1:4 with sterile water) 1 g/kg of 10% solution over 45 minutes IV	None	Erythema, pruritus; investigational except as otic solution; wear gloves; readily absorbed; sulfurous odor of breath; teratogen: not for breeding animals	90% gel; 90% solution; topical VM, HM
Diminazene (Berenil)	Antiprotozoal; babesiosis, trypanosomiasis	4.2 mg/kg IM q 21 days		May be dosed at 3.5-5 mg/kg IM twice, 24 hours apart; risk of neurotoxicosis	70 mg/mL I VM
Dinolytic	*(see prostaglandin)*				
Dinoprost	*(see prostaglandin)*				
Dioctyl sodium sulfosuccinate (docusate, DSS, Colace, Surfak)	Stool softener	1 or 2 50-mg capsules PO q 12-24 h; per rectum: 60-90 mL (8 mg docusate/mL)	1 50-mg capsule PO q 12-24 h	Also available as enema preparation for cats and small dogs	25, 50, 100 mg hard caplets OTC, HM, VM
Dipentum	*(see olsalazine)*				
Diphenhydramine HCl (Benadryl Allergy)	H1 receptor antihistamine	2-4 mg/kg PO q 12 h to q 8 h; 1-2 mg/kg IM, SQ, q 12 h	Same	Sedative, anticholinergic, antiemetic; use with caution in seizure animals; avoid IV use (seizures)	25, 50 mg C, T; mg/mL S; 10 mg/ mL I HM
Diphenoxylate HCl with atropine (Lomotil)	Antidiarrheal, nonanalgesic opiate	0.1-0.2 mg/kg PO up to q 8 h; total dose: 0.625-2.5 mg PO per dog, up to q 8 h	0.6-1.2 mg total dose per cat PO q 12 h	Sedation, constipation, ileus; use with caution in cats (opiate adverse effects) and in patients with respiratory or cardiovascular compromise	2.5 mg T; 0.5 mg/ mL S HM
Diprivan	*(see propofol)*				
Dipyridamole (Persantine)	Anticoagulant; thromboxane synthase inhibitor	4-10 mg/kg PO q 24 h		Investigational use; safety and efficacy unproven in VM	25, 50, 75 mg T 5 mg/mL I HM
Dipyrone (Novin)	Antipyretic Injectable NSAID	25 mg/kg SQ, IM, IV up to q 8 h	Same	Hypothermia, BM suppression; do not use if hyperthermia is	300 mg T; 500 mg/ mL I

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				not true fever (contraindicated if elevated temperature is due to heat stroke, seizures, brachycephalic crisis, etc.)	HM
Dirlotapide (Slentrol)	Obesity	0.01 mL/kg PO q 24 h. Can double dose after 2 weeks if needed, then adjust monthly; maximum 0.2 mL PO q 24 h.	Do not use	Gut microsomal triglyceride transfer protein (GMTP) inhibitor; vomiting, increased liver enzymes possible	5 mg/mL oil-based S VM
Disopyramide (Norpace)	Ventricular dysrhythmias, type IA agent	6-22 mg/kg PO q 8 h	None	Rarely used; may be used with quinidine or procainamide	100, 150 mg C; 100, 150 mg; ER HM
Dithiazanine	Microfilaricide	6.6-11 mg/kg PO q 24 h for 7-10 days	None	Stains stool purple, V/D, anorexia	10, 50, 100, 200 mg T VM
Ditrim	*(see trimethoprim/ sulfadiazine)*				
Diuril	*(see chlorothiazide)*				
Dizan	*(see dithiazanine iodide)*				
DMSO	*(see dimethyl sulfoxide)*				
DMSO with fluocinolone (Synotic)	*(see fluocinolone)*				
Dobutamine HCl (Dobutrex)	Inotropic agent for very severe dilated cardiomyopathy; short-term usage, only in ICU setting; β1-agonist	0.0025-0.02 mg/kg/min (2.5-20 mcg/kg/min) IV CRI in sterile LRS, 0.9% NaCl, or D5W	0.004-0.005 mg/kg/ min (4-5 mcg/kg/ min) IV CRI	Use 48 hours maximum; may increase HR; monitor for arrhythmias; continue usual cardiac therapy; cats are very sensitive to Tx and may have seizures; doses above 0.01 mg/kg/min (10 mcg/kg/min) in dogs are more likely to be arrhythmogenic	12.5 mg/mL I HM
Dobutrex	*(see dobutamine)*				
DOCP	*(see desoxycorticosterone pivalate)*				
Docusate	*(see dioctyl sodium sulfosuccinate)*				
Dolasetron (Anzemet)	Serotonin-inhibiting central antiemetic	0.6-1 mg/kg IV or SQ q 24 h	Same	Lower dosage for prevention of nausea; higher dosage for treatment of vomiting	20 mg/mL I; 50, 100 mg T HM
Domitor	*(see medetomidine)*				
DoMoSo	*(see dimethyl sulfoxide)*				
Dopamine HCl (Intropin)	α1, β1, and dopaminergic agent; inotropic agent for heart failure; pressor agent— hypotension	0.002-0.008 mg/kg/min (2-8 mcg/kg/min) IV CRI in LRS, 0.9% saline, or D5W	Same	Tachycardia, vasoconstriction; requires ICU monitoring. 1-3 mcg/ kg/min = visceral vasodilation; 3-10	40, 80, 160 mg/mL I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				mcg/kg/min = β1-agonist, positive inotrope; >10 mcg/kg/min = positive inotrope and chronotrope, α-agonist (may increase or decrease heart rate)	
Dopram	*(see doxapram)*				
Doramectin (Dectomax)	Avermectin antiparasitic; spirocercosis	0.2 mg/kg SQ q 2 weeks for 3 treatments; if lesions persist, additional treatment with 0.5 mg/kg PO q 24 h for 6 weeks has been successful	—	Currently the treatment of choice for canine spirocercosis; caution with avermectin-susceptible individuals and breeds (see p. 706)	10 mg/mL I VM
Dorzolamide (Trusopt)	Carbonic anhydrase inhibitor, glaucoma	1 drop per eye q 8 h, adjusted PRN	Same	Monitor for hypokalemia	2% OS; 5, 10, 15 mL HM
Doxapram (Dopram)	1. Respiratory stimulant 2. Diagnostic aid for laryngeal paralysis suspects	1. 1.5-10 mg/kg once IV; repeat if needed 2. 2.2 mg/kg IV	Same	For puppy/kitten respiratory stimulation, use 1-5 drops under tongue or via umbilical vein	20 mg/mL I HM
Doxepin (Sinequan)	Tricyclic antidepressant; pruritic dermatoses in dogs, especially if there is a behavioral component	0.5-5 mg/kg PO q 12 h		Some antihistamine effects; contraindicated if concurrent MAO inhibitors (e.g., Anipryl, amitraz)	10, 25, 50, 75, 100, 150 mg C; 10 mg/mL S HM
Doxorubicin (Adriamycin)	Lymphomas, carcinomas, solid tumors	According to chemo protocol; either 30 mg/m^2 IV CRI once every 3 weeks (for dogs >10 kg) or 1 mg/kg IV once every 3 weeks (for dogs ≤10 kg); not to exceed total cumulative lifetime dose of 250 mg/m^2	According to chemo protocol; 20-25 mg/m^2 once every 3 weeks IV CRI to maximum total dose of 90 mg/m^2	Anaphylaxis, BM suppression, GI toxicity, cardiotoxic, severe vesicant (extravasation injury); use chemo precautions when handling or administering drug and with patient's urine and feces; reddish discoloration to urine due to drug pigment	2 mg/mL I HM
Doxycycline (Vibramycin)	Tetracycline antibiotic; *Rickettsia, Ehrlichia, Haemobartonella/ Anaplasma,* and *Chlamydia* infections; brucellosis; intracellular penetration	5-10 mg/kg PO q 24 h; 2-5 mg/kg IV CRI q 12 h	Same	Do not use in puppies, kittens, or animals that are pregnant; may cause anorexia, vomiting, depression; hyperthermia in cats; photosensitization; administer water post pilling to reduce esophagitis risk	20, 50, 100 mg T/C; 5, 10 mg/mL S HM
Dramamine	*(see dimenhydrinate)*				
Dramamine II	*(see meclizine)*				
Drisdol	*(see ergocalciferol)*				
Droncit	*(see praziquantel)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
DSS	*(see dioctyl sodium sulfosuccinate)*				
DTIC	*(see dacarbazine)*				
Dulcolax	*(see bisacodyl)*				
Duragesic	*(see fentanyl)*				
Duricef	*(see cefadroxil)*				
Ecotrin	*(see acetylsalicylic acid)*				
ECP	*(see estradiol cyclopentane propionate)*				
Edrophonium (Tensilon)	Diagnostic agent for cholinergic stimulation; myasthenia gravis; may slow some supraventricular tachycardias	0.1-0.2 mg/kg IV; max = 5 mg total dose	Total dose = 0.25-1 mg IV per cat	Muscarinic signs	10 mg/mL I HM
EDTA	*(see calcium EDTA)*				
Elavil	*(see amitriptyline)*				
Eldepryl	*(see selegiline)*				
Elixophyllin	*(see theophylline elixir)*				
Ellence	*(see epirubicin)*				
Elmiron	*(see pentosan polysulfate)*				
Elspar	*(see asparaginase, L-)*				
Enacard	*(see enalapril maleate)*				
Enalapril maleate (Vasotec, Enacard)	ACE inhibitor, vasodilator; CHF, systemic hypertension, glomerulopathy	0.5 mg/kg PO q 24 h initially, then to q 12 h if necessary	0.25 mg/kg PO q 24 h	Hypotension, weakness, anorexia; avoid increasing furosemide dosage when initiating or increasing enalapril dosage; human adverse effects (renal effects, cough, hyperkalemia) very uncommon in the dog	1, 2.5, 5, 10, 20, mg T; 1.25 mg/mL I VM, HM
Enilconazole (Imaverol)	Nasal aspergillosis	10 mg/kg diluted with equal amount sterile water and administered intranasally via tubes placed in frontal sinuses	—	Not approved; possible allergic reactions	Use poultry-grade product; 10% emulsion
Enoxaparin	*(see heparin, low-molecular-weight)*				
Enrofloxacin (Baytril)	Broad-spectrum fluoroquinolone-class antibacterial	2.5-10 mg/kg PO, IM q 12 h; double dosage single administration per day may be equally effective	2.5-5 mg/kg PO q 24 h (this dose is the maximum in cats)	Do not use in puppies/ kittens (cartilage lesions); do not use >5 mg/kg/d in cats (permanent retinal lesions); caution in seizure patients; drug interactions (inhibits theophylline catabolism).	5.7, 22.7, 68, 136 mg T; 22.7 mg/mL I VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Enteric probiotic supplement (FortiFlora)	Nonspecific benign diarrhea	1 packet PO (on food or as treat) q 24 h	Same		1 gram/packet P VM
Entocort	*(see budesonide)*				
Epakitin	*(see chitosan-based phosphate binder)*				
Ephedrine	Bronchodilator Urinary incontinence Hypotension	1-2 mg/kg PO q 8-12 h; 0.3-1 mg/kg IV, IM for hypotension	2-5 mg per cat PO q 8-12 h	For bronchospasm: usually combine with sedative +/− bronchodilator; caution if heart disease or hypertension; CNS stimulation, restlessness	25, 50 mg C; 50 mg/mL I HM
Epinephrine (Adrenalin)	1. α-adrenergic agent and β-adrenergic agent used for inotropic and chronotropic support: 2. Cardiac arrest 3. Bronchodilation 4. Anaphylaxis 5. Hemostasis (topical)	1. 0.0025 mg/kg IV, repeated to effect (= 1 mL of 1 : 10,000 per 40 kg BW); triple if administering intratracheally 2. 2, 3. 0.025 mg/kg IV, IM, SQ 3. Topical use: place 1 or 2 drops after applying pressure to, and dabbing blood from, a persistently bleeding wound	Same	Arrhythmogenic; increases $M^{VO}2$; avoid high doses (tachycardia); vasoconstriction; avoid direct sunlight exposure; Note: 1:1000 and 1:10,000 solution both commonly available, so use caution (10-fold difference)	1:1000 (1 mg/mL) I; 1:10,000 0.1 mg/mL) Epipen: 0.15 mg (0.15 mL) or 0.3 mg (0.3 mL), one-time dose I HM
Epirubicin (Ellence, Pharmorubicin, 4′-epi-doxorubicin)	Anthracycline antineoplastic	Same as for doxorubicin according to chemo protocol (e.g., 30 mg/m^2 IV CRI q 21 days)	—	Same as for doxorubicin but with generally fewer adverse effects (especially lesser incidence and extent of cardiotoxicity)	10, 50, 200 mg I (2 mg/mL) HM
EPO	*(see erythropoietin)*				
Epoetin-α	*(see erythropoietin)*				
Epogen	*(see erythropoietin)*				
Epsiprantel (Cestex)	Tapeworms (cesticide)	5.5 mg/kg PO once	2.75 mg/kg PO once	GI signs possible	12.5, 25, 50, 100 mg, T VM
Ergocalciferol (vitamin D2, calciferol, Drisdol)	Hypocalcemia	500-2000 IU/kg PO q 24 h		Second or third choice after calcitriol, DHT	400 IU T 50 000 IU (1.25 mg) C 500 000 IU/mL (12.5 mg/mL) I HM
Erythromycin	1. Macrolide antibiotic, G+ drug, *Campylobacter, Mycoplasma, Rickettsia, Chlamydia* 2. GI prokinetic	1. 10-20 mg/kg PO q 8 h 2. 0.5-1 mg/kg PO q 8 h	Same	Hypersensitivity; GI upset	200, 250, 333 400, 500 mg T; 100 mg/mL I HM
Erythropoietin (EPO, Epoetin, Epogen, r-Hu EPO,	Recombinant human erythropoietin	100 U/kg 3× per week SQ until RBC levels	Same	Anaphylaxis, hypertension, GI	2000, 3000, 4000, 10,000, 20,000 I

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Procrit)		increase; then 1× per week thereafter, titrated based on response		signs; autoantibodies may develop	HM
Eskalith	*(see lithium carbonate)*				
Esmolol (Brevibloc)	β-blocker with very rapid onset and offset	0.05-0.1 mg/kg/min (50-100 mcg/kg/min) IV CRI, titrated to effect	Same	Contraindicated with preexisting bradycardia, CHF	10, 20 mg/mL HM
Esomeprazole (Nexium)	Proton pump inhibitor Gastric ulceration	1 mg/kg PO q 24 h		*S*-enantiomer of omeprazole (hence "*S*-omeprazole"), which may provide increased potency	20, 40 mg T, C (both ER) HM
Estradiol cyclopentane-propionate (ECP, estradiol cypionate)	Estradiol to terminate pregnancy	—	—	Repeatedly shown to be toxic to BM; unpredictable abortifacient; not recommended	—
Estrogen—conjugated (Premarin)	Estrogen derived from pregnant mare serum; used for treating postovariohysterectomy estrogen insufficiency causing urinary incontinence	0.625 mg = 1 mg DES; use PO for urinary incontinence *(see diethylstilbestrol)*	—	May induce signs of estrus	0.3, 0.625, 0.9, 1.25, 2.5 mg T HM
Estrumate	*(see cloprostenol)*				
Ethanol 20%	Ethylene glycol toxicosis	Dilute to 20% ethanol in saline; administer 5 mL/kg IV q 6 h × 5 Tx, then q 8 h × 4 Tx (see p. 369)	Dilute to 20% ethanol in saline; administer 5 mL/ kg IV q 6 h × 5 Tx, then q 8 h × 4 Tx (see p. 369)	May cause or exacerbate CNS depression; monitor hydration, electrolytes, acid-base status, perivascular damage. If alternatives are lacking, an 80-proof alcoholic beverage (40% ethanol) such as vodka may be diluted 1:1 in sterile 0.9% NaCl to create a 20% ethanol solution	—
Etidronate (Didronel)	Bisphosphonate antihypercalcemic agent	5-10 mg/kg PO q 12-24 h	Same	Main indication is severe paraneoplastic hypercalcemia; renal excretion, avoid in renal hyper-PTH	200, 400 mg T 50 mg/mL I HM
Etodolac (EtoGesic, Lodine)	NSAID; selective COX-2 inhibitor for DJD in dogs	10-15 mg/kg PO q 24 h		GI and renal toxicity; if long-term, use low dose; do not administer with ASA or corticosteroids; may cause KCS in dogs	150, 300 mg T VM; 200, 300 mg C; 400, 500 mg T HM
EtoGesic	*(see etodolac)*				
Etretinate (Tegison)	Synthetic retinoid used to treat disorders of keratinization in specific breeds (primarily cocker	1 mg/kg PO q 24 h	Total dose: 10 mg per cat PO q 24 h	Vomiting, anemia KCS, increased liver enzymes, expensive	10, 25 mg C HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
	spaniels)				
Excedrin	*(see acetaminophen)*				
Famotidine (Pepcid)	H2 receptor antagonist	0.5-1 mg/kg PO, IV q 12-24 h	0.5 mg/kg PO, IV q 24 h	Advantages over other similar agents: once-a-day dosage, minimal P450 inhibition	10, 20, 40 mg T; 8 mg/mL S; 10 mg/mL I HM, OTC
Factrel	*(see gonadotropin releasing hormone)*				
Fatty acid nutritional supplement (Derm Caps)	Dietary supplement, allergic skin disease, dry skin	1 regular capsule PO q 24 h per 9 kg BW; one ES capsule PO q 24 h per 25-30 kg BW; 1 "100s" capsule PO q 24 h per 45 kg BW	—	GI upset, increased bleeding times, "fishy" breath	Regular, ES, 100s, C VM
Febantel (Rintal)	Acaricidal, phenylguanidine, antiparasitic	10-15 mg/kg PO q 24 h for 3 days	Same	Is metabolized to fenbendazole and oxfendazole	27.2, 163.3 mg T VM
Felbamate (Felbatol)	Antiseizure drug used when seizures are refractory to phenobarbital and bromide	15 mg/kg PO q 8 h; can increase to 60 mg/kg PRN		Monitor for BM suppression; hepatotoxic; expensive	400, 600 mg T; 600 mg/tsp S HM
Felbatol	*(see felbamate)*				
Feldene	*(see piroxicam)*				
Felimazole	*(see methimazole)*				
Feliway	*(see pheromones, feline synthetic)*				
Fenbendazole (Panacur)	Hookworm, whipworm, roundworm, *Taenia, Paragonimus, Filaroides, Giardia, Capillaria,* lungworm *(Aelurostrongylus)*	50 mg/kg PO q 24 h for 3 days; repeat in 3 weeks; whipworms, also repeat in 3 months; lungworms: 50 mg/kg PO q 24 h for 10 days	Same; not FDA approved	Vomiting (rare); safe in dogs with heartworms	222 mg/g granules; 100 mg/mL S VM
Fentanyl (Duragesic, Sublimaze)	Transdermal opioid patch, usually lasts at least 72 hours; requires 12 hours to be effective; injectable is ultrashort acting	Patches: 5-10 kg = 25 mcg/h; 10-20 kg = 50 mcg/h; 20-30 kg = 75 mcg/h; >30 kg = 100 mcg/h Injectable: 0.01-0.04 mg/kg SQ, IM, IV; CRI: 0.003-0.006 mg/kg/hr (3-6 mcg/kg/hr) IV	2.5-mg patch	Apply a patch to a small clipped area on thorax; never cut patch; prevent human contact with gel surface of patches; avoid heat exposure (e.g., heating pad), increases absorption; respiratory depression and hypoventilation	2.5 mg (25 mcg/h), 5 mg (50 mcg/h), 7.5 mg (75 mcg/h), 10 mg (100 mcg/h) patches; 0.05 mg/ mL (50 mcg/mL) I, HM; former VM injectable (Innovar) was 8× more concentrated than human injectable; do not confuse.
Fenthion (Prospot, Spot-on)	Organophosphate insecticide	4-8 mg/kg topically to unbroken skin; follow instructions; do not apply more than once every 2 weeks	None	Do not use with other cholinesterase inhibiting agents; do not use in puppies or sick or debilitated dogs	5.6% and 13.8% solution VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Ferric cyanoferrate (Prussian blue, Radiogardase)	Thallium poisoning	100-200 mg/kg PO q 8 h	None	Administer as capsule or in a glucose solution orally; constipation, vomiting	500 mg C HM
Ferrous sulfate	Iron supplementation	Total dose: 100-300 mg per dog PO q 24 h	Total dose: 50-100 mg per cat PO q 24 h	Common side effects: minor GI upset; overdose: severe GI signs, hypotension, collapse; delayed toxicity = pulmonary edema, liver failure *(see deferoxamine)*	325 mg (65 mg Fe) T; 18, 44 mg Fe/5 mL S HM, OTC
Fertagyl	*(see gonadotropin releasing hormone)*				
Feverall	*(see acetaminophen)*				
Fiber (soluble dietary)	*(see psyllium mucilloid)*				
Filaribits	*(see diethylcarbamazine)*				
Filgrastim (Neupogen, r-Hu G-CSF)	Recombinant human granulocyte colony-stimulating factor; used for chemotherapy-induced neutropenia	1-5 mcg/kg per day SQ for 3-5 days maximum	1-5 mcg/kg per day SQ for 3-5 days maximum	Antibodies develop after several days of therapy	300 mcg/mL I HM
Finasteride (Proscar)	Used for treating benign prostatic hyperplasia by inhibiting enzyme that changes testosterone to active dihydroxy-testosterone	Total dose: 5 mg per dog (BW 10-40 kg) PO q 24 h	—	Little published objective information about use, efficacy, or side effects in canine medicine	1, 5 mg T HM
Fipronil (Frontline)	Topical parasiticide for fleas and ticks	9.7% solution; apply topically by weight once monthly	Same	Keep away from children, food, water; avoid contact with pet if fipronil is still wet on skin; use on puppies only if >10 weeks old, kittens if >12 weeks old	9.7% solution, 0.29% spray VM
Firocoxib (Previcox)	Nonsteroidal antiinflammatory drug, COX-2 inhibitor type	5 mg/kg PO q 24 h	1.5 mg/kg PO once only	Used mainly for osteoarthritis in dogs; safety not established for repeated dosing in cats	57, 227 mg T VM
Flagyl	*(see metronidazole)*				
Fleet	*(see phosphate enemas)*				
Flomax, Flomaxtra	*(see tamsulosin)*				
Florinef	*(see fludrocortisone)*				
Flovent	*(see fluticasone)*				
Fluconazole (Diflucan)	Imidazole antifungal compound: especially useful for cryptococcosis or CNS/ ocular mycoses	2.5-5 mg/kg PO q 24 h or divided q 12 h	Same; up to 50 mg PO total dose per cat q 12 h	Historically was expensive, though generic form now available (cheaper)	50, 10, 200 mg T; 2 mg/mL I HM
Flucort	*(see flumethasone)*				
Flucytosine (Ancobon, Ancotil)	Aspergillosis, cryptococcosis, candidiasis	100 mg/kg PO q 12 h, or 25-50 mg/kg PO q 6 h	Same	Renal, BM, and hepatotoxicity; may cause GI upset; do not administer to pregnant animals;	250, 500 mg C; 75 mg/mL S HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				neurologic side effects in cats	
Fludrocortisone (Florinef)	Hypoadrenocorticism, mineralocorticoid replacement therapy	0.1 mg/5 kg PO q 24 h or q 12 h; adjust dosage by need and laboratory testing	0.1 mg/5 kg per day PO; adjust dosage by need and laboratory testing	Systemic hypertension, PU/PD, weight gain. Cushing's-like side effects possible (some glucocorticoid activity)	0.1 mg T HM
Flumazenil (Romazicon)	Benzodiazepine antagonist, possibly management of hepatic encephalopathy	0.01-0.02 mg/kg IV (titrate depending on benzodiazepine dose)	Same	—	0.1 mg/mL I HM
Flumethasone (Flucort)	Antiinflammatory, corticosteroid	Total dose: 0.06-0.25 mg PO, IV, IM, SQ q 24 h per dog; intralesional, intraarticular	Total dose: 0.03-0.125 mg PO, IV, IM, SQ q 24 h per cat	Glucocorticoid-related side effects	0.0625 mg T; 0.5 mg/mL I VM
Flunixin meglumine (Banamine)	NSAID analgesic agent	0.25-1 mg/kg IV, IM, SQ q 24 h; maximum 3-5 days dosage	0.25 mg/kg IV, IM q 24 h; maximum 3-5 days dosage	Platelet dysfunction, ulcerative gastritis, kidney damage; multiple safer alternative drugs	50 mg/mL I VM
Fluocinolone 0.01% with 60% DMSO (Synotic)	Topical corticosteroid plus DMSO for severe otic inflammation	2-12 drops applied topically to ear, q 12 h	2-4 drops applied topically to ear, q 12 h	Systemic corticosteroid effects; wear gloves (to avoid transcutaneous absorption by owner/tech/vet)	0.1% otic solution VM
Fluorouracil (Adrucil)	Chemotherapy agent for carcinomas	150 mg/m^2 IV weekly or 2-10 mg/kg IV weekly	Do not use	Part of a chemotherapy protocol; BM toxicity, GI toxicity, and neurotoxicity possible	50 mg/mL I HM
Fluoxetine (Prozac, Reconcile)	Serotonin reuptake inhibitor	0.5-2 mg/kg PO q 24 h	0.5 mg/kg PO q 24 h	Used for treating behavioral disorders (e.g., acral lick dermatitis)	8, 16, 32, 64 mg chewable T VM 10 mg T; 10, 20, 40 mg C; 4 mg/mL S HM
Flurbiprofen 0.03% solution (Ocufen)	Topical ocular NSAID	1 drop instilled in eye q 12 h, adjusted PRN	—	Caution with corneal ulcers; contraindicated in infected corneal ulcers	2.5, 5, 10 mL OS HM
Fluticasone (Flovent)	Inhaled glucocorticoid	1 puff PRN, up to q 12-24 h	Same	Need inhaler apparatus; some patients are reluctant to accept placement of a mask at first; maximum effect only after 7-14 days of use; see p. 1289	7.9 g and 13 g inhalation canisters (0.044, 0.11, or 0.22 mg [44, 110, or 220 mcg] per puff) HM
Folate	B vitamin	Total dose: 2.5-5 mg PO per dog q 24 h	Total dose: 2.5 mg PO per cat q 24 h	—	0.4, 0.8, 1 mg/mL I; 5 mg T HM
Fomepizole (Antizol-Vet, 4-methylpyrazole, 4-MP)	Treatment of known or suspected ethylene glycol toxicity	22 mg/kg IV; then 15, 15, and 5 mg/kg IV at 12, 24, and 36 hours following initial dose;	—	Dilute drug properly; monitor renal, electrolyte, and hydration status	1.5-g kit I VM, HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
		then 3-5 mg/kg IV, q 12 h, until recovery			
Fondaparinux (Arixtra)	Anticoagulant; prophylaxis for prevention of thromboembolism in feline cardiomyopathy		0.06 mg/kg SQ q 12 h	Selectively binds antithrombin III, inactivating factor Xa. No effect on platelet function. No clinical trials to establish safety or efficacy in cats at this time.	2.5, 5. 7.5, 10 mg prefilled syringes I HM
Fortaz	*(see ceftazidime)*				
Fortekor	*(see benazepril)*				
FortiFlora	*(see enteric probiotic supplement)*				
Fosamax	*(see alendronate)*				
Fragmin	*(see heparin-low molecular weight)*				
Frontline	*(see fipronil)*				
Fulvicin	*(see griseofulvin)*				
Fungizone	*(see amphotericin B)*				
Furadantin	*(see nitrofurantoin)*				
Furazolidone (Furoxone)	1. Amebiasis 2. Enteric coccidiosis 3. Giardiasis	1. 2.2 mg/kg PO q 8 h for 7 days 2. 8-20 mg/kg PO q 24 h for 7 days 3. 4 mg/kg PO q 12 h for 7 days	Same	—	100 mg T HM
Furosemide (Lasix, Salix)	Potent loop diuretic agent; used in acute renal failure; hypercalcemia; hypertension, CHF (especially pulmonary edema), ascites, and fluid retention	0.5-6 mg/kg PO, SQ, IM, IV q 8-12 h	0.5-4 mg/kg PO, SQ, IM, IV q 8-12 h	Use lowest effective dosage; high doses reserved for IV use in acute severe pulmonary edema; monitor for hypokalemia, hyponatremia, and hypochloremic alkalosis; caution: azotemia and dehydration	12.5, 20, 40, 50, 80 mg T; 10 mg/mL S; 50 mg/mL I VM, HM
Furoxone	*(see furazolidone)*				
Gabapentin (Neurontin)	Pain, paresthesias; refractory seizures	10 mg/kg PO q 8 h	5-10 mg/kg PO q 8 h	Used for pain associated with caudal occipital malformation and other neurologic disorders	100, 300, 400, 600, 800 mg C, T 50 mg/mL S HM
Gammagard S/D	*(see immunoglobulin)*				
Garamycin	*(see gentamicin)*				
G-CSF	*(see filgrastim)*				
Gemcitabine (Gemzar)	Various forms of neoplasia	10 mg/kg IV CRI over 30 minutes; 275 mg/m^2 IV CRI	25 mg/m^2 diluted and given IV slowly twice weekly, according to chemo protocol	Emerging drug in veterinary oncology at time of this writing, with dosage, efficacy, and side effects still being characterized	200 mg, 1 g vials I VM, HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Gemfibrozil (Lipid)	Lipid-lowering agent	7.5 mg/kg PO q 12 h	—	—	300, 600 mg T HM
Gemzar	*(see gemcitabine)*				
Genoptic	*(see gentamicin, ophthalmic)*				
Gentamicin (Garamycin, Gentocin)	Broad-spectrum aminoglycoside antibiotic most effective against G− bacteria	6 mg/kg IV, q 24 h, or 2-4 mg/kg IM, SQ, IV q 8 h, max 7 days	Same	Higher dosage given q 24 h is preferred (less nephrotoxic); not effective orally; do not use in renal failure or dehydrated/ hypovolemic patients; reserved for serious identified infections only; not for anaerobic infections; nephrotoxic-ototoxic	50 mg/mL I VM, HM
Gentamicin, otic (Gentocin otic)	Ear infections, especially *Pseudomonas* or *Proteus*	Apply q 8 h	Apply q 8 h	Includes betamethasone 1 mg/mL, which can have topical and/or systemic corticosteroid effects; ototoxic risk (aminoglycoside)	3 mg/mL otic solution VM, HM
Gentamicin, ophthalmic (Gentocin, Genoptic)	Conjunctival/corneal infections, especially *Pseudomonas*	Apply q 4-8 h	Apply q 4-8 h	Rarely irritating; a preparation that contains corticosteroids also exists in nearly identical packaging; use caution when selecting product	3 mg/g OO; 3 mg/ mL OS VM, HM
Gentocin	*(see gentamicin)*				
Geocillin	*(see carbenicillin)*				
Geopen	*(see carbenicillin)*				
Glargine	*(see insulin)*				
Glipizide (Glucotrol)	Oral hyperglycemic agent; useful in some type II diabetes mellitus in cats	0.25-0.5 mg/kg PO q 12 h generally not recommended	0.25-0.5 mg/kg PO q 12 h	Hypokaemia, GI effects, hepatopathy; eventual loss of efficacy (very common); no objective information available on extended-release formulation in veterinary diabetic patients	5, 10 mg T HM
Glucagon	1. Provocative testing agent for insulinoma, diabetes mellitus, and hyperadrenocorticism 2. Insulinoma	1. 0.03 mcg/kg IV 2. 5 ng (0.005 mg)/kg/ min IV CRI	None	May induce hypokalemia; 1 unit = 1 mg Rare case report data but very positive response	1 mg/mL I HM
Glucantime	*(see meglumine)*				
Glucosamine-chondroitin sulfate (Cosequin)	Chondroprotective agent for osteoarthritis	Small- and medium-size dogs: 1-2 RS capsules PO q 24	1 RS capsule PO q 24 h	—	RS and DS, C VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
		h; big dogs: 1-2 DS capsules PO q 24 h, or 2-4 RS capsules PO q 24 h			
Glucotrol	*(see glipizide)*				
Glyburide (Diabeta, Micronase, Glynase)	Oral hypoglycemic drug; diabetes mellitus	0.2 mg/kg PO q 24 h	0.625 mg/cat PO q 24 h	In most cases, insulin therapy eventually becomes necessary	1.25, 2.5, 5 mg T HM
Glycerin 50% solution (oral) (Osmoglyn)	Glaucoma	1-2 mL/kg PO once	Same	50% solution = 500 mg/ mL; do not use if anuria, CHF, severe dehydration	220 mL S HM
Glycerin suppositories	Constipation	1 suppository per rectum	Same or 3 mL liquid per rectum	—	OTC, HM
Glycopyrrolate (Robinul)	Anticholinergic preanesthetic agent	0.01 mg/kg SQ, IM, IV	Same	Tachycardia, arrhythmias, intestinal ileus, mydriasis, and photophobia; avoid in narrow-angle glaucoma	0.2 mg/mL I VM, HM
Glycosaminoglycanpolysulfated (Adequan)	Chondroprotective agent; slows ± helps heal noninfectious, degenerative, and traumatic arthritis	2-4 mg/kg IM twice weekly for 4 weeks; then once every 2-4 weeks	2 mg/kg IM q 4 days for 6 doses; then PRN	Occasional pain at injection site; possibly	100 mg/mL I VM
Glynase	*(see glyburide)*				
GoLYTELY (polyethylene glycol-electrolyte solution)	Large bowel evacuant/ cathartic	22-33 mL/kg via stomach tube	20-30 mL/kg via stomach tube	Withhold food; administer twice q 2 h apart, 12 hours prior to GI endoscopic procedure	Powder or concentrate for dilution HM
Gonadotropin-releasing hormone (GnRH, gonadorelin, Fertagyl, Factrel, Cystorelin)	Male infertility; cryptorchidism/ testicular descent	2.2-3.3 mcg/kg IM	25 mcg/cat IM	Response may be clinical (overt physical signs) or endocrine (2- to 4-fold increase in serum testosterone levels)	50 mcg/mL I VM, HM
Goodwinol (Rotenone)	Demodicosis (localized)	Apply topically q 24 h	Same	Rotenone, orthophenyl phenol, and benzocaine mixture; efficacy not demonstrated	1.24% Rotenone O VM
Granisetron (Kytril)	Serotonin 5-HT3 inhibitor antiemetic	0.01 mg/kg IV	Same		1 mg T 1 mg/mL I 0.2 mg/mL S HM
Gravol	*(see dimenhydrinate)*				
Griseofulvin (Fulvicin)	Dermatophytoses	50-150 mg/kg PO q 24 h to q 12 h; 25-50 mg/kg q 24 h if using microsize product (U/F); 5-15 mg/kg PO q 12 h, if using ultramicrosize product (P/G)	Same	U/F prep better absorbed than regular: therefore, dosage is 50% lower for this formulation; P/G even more so: therefore, dosage is a further 30% lower for this formulation; GI signs, teratogen, granulocytopenia, anemia, hepatopathy	125, 250, 500 mg T; 250, 500 mg microsize formulation T; 125, 165, 250, 330 mg ultramicrosize formulation T; 125 mg/5 mL S VM/HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Growth hormone, human (Protropin, somatrem)	Pituitary dwarfism	0.1 IU SQ q 48-72 h × 4-6 weeks		Limited efficacy in dogs because human product often induces autoantibody formation; 3 IU = 1 mg	5, 10 mg vials I HM
hCG	*(see chorionic gonadotropin, human)*				
Havidote	*(see Calcium EDTA)*				
Heartgard-30	*(see ivermectin)*				
Hemoglobin glutamer (Oxyglobin)	Bovine hemoglobin-based oxygen-carrying fluid; used for hemolytic, blood loss, or ineffective erythropoietic anemias	10-30 mL/kg IV at 10 mL/kg/h in a one-time single infusion; some administer partial dosages daily instead	Not licensed; used IV by some at 15 mL/kg IV in a slow single dose or daily split doses	Overdosage may cause cardiopulmonary signs; hemoglobinuria; has no clotting factors; interferes with clinical pathologic testing; half-life *in vivo* = 18-43 hours	125 mL I; single-use bags VM
Heparin	1. Anticoagulation 2. DIC therapy	1. 200-300 IU/kg SQ or IV, q 8 h to q 6 h, for thromboembolism; increase PTT to 1.5-2.5 times normal or ACT to 1.2-1.4 times normal 2. 50-100 IU/kg SQ, q 6-8 h	75-150 IU/kg q 6-8 h SQ	Prolongs bleeding time; not thrombolytic; ineffective in the absence of antithrombin III (e.g., protein-losing diseases); "regular" heparin is unfractionated heparin (versus low-molecular-weight heparin)	1000, 2000, 5000, 10,000, 20,000, 40,000 mg/mL I HM
Heparin, low-molecular-weight (Dalteparin [Lovenox], Enoxaparin [Fragmin])	Anticoagulant	Dalteparin (Fragmin): 100-150 IU/kg SQ q 6-12 h	Dalteparin (Fragmin): 100-150 IU/kg SQ q 6-12 h Enoxaparin (Lovenox): 1 mg/kg SQ q 6-12 h	Outpatient (owner-administered) SQ anticoagulant; main differences versus unfractionated heparin: low-molecular-weight heparin is less antigenic (seemingly not important in VM), and much more expensive; clinical efficacy and advantages not yet proven in VM	Enoxaparin: 100 mg/mL I; 30, 40, 60, 80, 100, 120, 150 mg I (prefilled syringes) Dalteparin: 10,000 or 25,000 IU/mL I; 2500, 5000, 10,000 IU I (prefilled syringes) HM
Herplex	*(see idoxuridine)*				
Hespan	*(see hetastarch)*				
Hetacillin (Hetacin)	Similar to penicillin	10-20 mg/kg PO q 8 h	Same	Penicillin reactions	50, 10, 200 mg T VM
Hetacin	*(see hetacillin)*				
Hetastarch 6% (Hespan)	Colloid and plasma volume expansion, shock, sepsis, head trauma	10-20 mL/kg per day IV	10-15 mL/kg per day IV	Rapid IV bolus initially over 5-10 minutes; titrate crystalloids slowly; volume overload possible	500 mL package of 6% hetastarch in 0.9% NaCl I HM
Hu G-CSF	*(see filgrastim)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Human chorionic gonadotropin	*(see chorionic gonadotropin, human)*				
Human growth hormone	*(see growth hormone, human)*				
Humulin	*(see insulin)*				
Hycodan	*(see hydrocodone)*				
Hydralazine (Apresoline)	Arteriolar vasodilator, CHF	0.5-3 mg/kg PO q 8-12 h	2.5-5 mg/cat total dose PO q 12 h	Hypotension, tachycardia malaise, depression, anorexia	10, 25, 50, 100 mg T; 20 mg/mL S HM
Hydrea	*(see hydroxyurea)*				
Hydrochlorothiazide (HydroDIURIL)	Diuretic, nonhormonal therapy for CDI and NDI, urolithiasis (calcium containing)	2-4 mg/kg PO q 12 h, initially; then decrease by 50% or to q 24 h	1-2 mg/kg PO q 12 h, initially; then decrease by 50% or to q 24 h	Hypokalemia; exacerbates digitalis toxicity; dehydration	25, 50, 100 mg T HM
Hydrochlorothiazide/ spironolactone (Aldactazide)	Diuretic plus aldosterone blocker	Use on basis of 1 mg/ kg of spironolactone PO q 12-24 h	Rarely used	Often used in conjunction with furosemide in chronic, recurrent CHF	25/25 mg T; 50/50 mg T HM
Hydrocodone bitartrate (Hycodan)	Narcotic antitussive	0.22 mg/kg PO q 6-24 h PRN	Rarely used	Sedation; C-III substance; Hycodan contains hydrocodone 5 mg/tab and homatropine 1.5 mg/ tab; constipation (rare)	5 mg T; 1 mg/mL S HM
Hydrocortisone acetate 1% cream	Topical corticosteroid for focal dermatitis	Apply topically q 6-12 h	Same	Prolonged use may result in iatrogenic Cushing's syndrome	1% O HM
Hydrocortisone sodium succinate (Solu Cortef)	Intravenously injectable corticosteroid; hypoadrenal crisis	4-5 mg/kg IV acutely and/or 0.5 mg/kg/h IV CRI			100, 250, 500, 1000 mg vials I HM
HydroDIURIL	*(see hydrochlorothiazide)*				
Hydrogen peroxide 3%	Emetic	0.25-0.5 mL/kg PO (3% solution); repeat once in 5-15 minutes PO if emesis does not occur	Same	Do not use if a caustic agent was ingested, if level of consciousness is decreased, or if the patient is unable to swallow; see Vomiting, Induction of, p. 1364	3% topical solution HM OTC
Hydromorphone (Dilaudid)	Analgesia, preanesthetic	0.1-0.2 mg/kg SQ, IM, or IV once or PRN up to q 2-4 h	Same	Vomiting common immediately postinjection, bradycardia, second-degree AV block, dysphoria in some cats	1, 2, 4, 10 mg/mL I HM
Hydroxyurea (Hydrea)	Chemotherapeutic compound; disorders of RBC excess, especially polycythemia vera and right-to-left cardiac shunts	20-25 mg/kg PO q 12-24 h; when PCV decreases, then 25-50 mg/kg PO q 48 h and adjust based on PCV	10-15 mg/kg PO q 24 h; then q 48 h based on PCV	Anorexia, vomiting, BM suppression possible; monitor CBC regularly	500 mg C HM
Hydroxyzine (Atarax)	H1 receptor antihistamine for allergic skin disorders	1-2 mg/kg PO q 8-12 h	0.5-1 mg/kg PO q 12 h to q 8 h	Sedative, anticholinergic side effects	10, 25, 50, 100 mg T; 10 mg/5 mL S; 25, 50 mg/mL I

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
					HM
Hyoscyamine (Levsin)	Antimuscarinic, inhibits propulsive GI motility	0.003-0.006 mg/kg PO q 8 h	Same; infrequently used	Useful in irritable bowel syndrome and functional intestinal disorders; dry mouth; urinary retention; tachycardia	0.125 mg T; 0.125 mg/5 mL S; 0.375 mg C ER; 0.5 mg/mL I HM
Hytakerol	*(see dihydrotachysterol)*				
Ibafloxacin (Ibaflin)	Fluoroquinolone antibiotic	15 mg/kg PO q 24 h	Same	Packaged as dial-syringe for oral dosing	3% oral gel in 15 mL preloaded syringe VM
Ibuprofen (Advil, Motrin, Nuprin)	Nonsalicylate, NSAID	Not recommended	Not recommended	Frequently cause GI bleeding and irritation; many safer alternatives	OTC, HM
Idoxuridine (Herplex, Stoxil)	Used for treating feline herpesviral keratitis, KCS		1 drop q 4 h initially, then q 6-8 h	Occasional ophthalmic irritation	0.1% OS HM
Ifex	*(see ifosfamide)*				
Ifosfamide (Ifex)	Various neoplasms	350-375 mg/m^2 IV once every 3 weeks for 3 treatments maximum	—	Efficacy under investigation; dosing interval according to chemo protocol; pretreat with mesna and IV diuresis to reduce risk of hemorrhagic cystitis; neutropenia possible	50 mg/mL I
Imaverol	*(see enilconazole)*				
Imferon	*(see iron dextran injection)*				
Imidacloprid (Advantage)	Topical treatment for adult and larval stage of fleas	Apply topically to intact skin; dose monthly by BW from prepackaged cards	Same	Avoid contact with skin, food, or water; avoid eye exposure	9.1% topical solution VM
Imidapril (Prilium)	ACE inhibitor; treatment of heart failure caused by dilated cardiomyopathy or mitral regurgitation	0.25 mg/kg PO q 24 h		Oral liquid formulation (reconstituted lyophilized powder) Veterinary form not available in the United States	2.5, 5, 10 mg/mL S VM
Imidocarb (Imizole)	*Babesia gibsoni, Ehrlichia canis*; hepatozoonosis	5-7.5 mg/kg IM or SQ once, repeat in 2-3 weeks	—	Painful injection; give IM; cholinergic side effects	120 mg/mL I VM
Imipenem-cilastatin (Primaxin)	Broad-spectrum bactericidal carbapenem antibacterial	2-10 mg/kg slow IV (over 30 minutes), q 6-8 h for 3-5 days	Same	Adverse effects possible: GI, CNS, hypersensitivity; reduce dose if renal compromise; different formulations for IV and IM use	250, 500 mg vials I HM
Imipramine (Tofranil)	Tricyclic antidepressant; behavioral changes, narcolepsy, cataplexy, inappropriate elimination	0.5-2 mg/kg PO q 8-12 h	0.5 mg/kg PO q 12-24 h, or total dose 2.5-5 mg per cat PO q 12 h	Prolonged onset of action, drowsiness, behavioral changes	10, 25, 50 mg T; 125 mg/mL I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Imizole	*(see imidocarb)*				
Immiticide	*(see melarsomine)*				
Immunoglobulin (Gammagard S/D, human intravenous immunoglobulin G, IVIG)	Treatment of primary immunodeficient states; also IHA, ITP, and CLL	0.5-1.5 g/kg slow IV infusion	—	Must be given IV; very expensive; hypersensitivity; not reported as first-line therapy	2.5, 5, 10 g single-dose vials I HM
ImmunoRegulin	*(see* Propionibacterium acnes*)*				
Imodium	*(see loperamide)*				
Impavido	*(see miltefosine)*				
Imuran	*(see azathioprine)*				
Inderal	*(see propranolol)*				
Inocor	*(see amrinone)*				
Insulin (Humulin R, N, U, PZI, Vetsulin, Caninsulin, Glargine)	Diabetes mellitus, diabetic ketoacidosis, severe hyperkalemia	Regular: 0.5-1 U/kg initially IM or SQ; then q 4-6 h. NPH: 0.5-1 U/kg q 12-24 h SQ. IV CRI protocol: 0.05-0.1 U/kg/h, using regular insulin (Humulin R) only	NPH, Lente, Ultralente, glargine: Total dose (starting): 1-2 U per cat SQ q 24 h to q 12 h CRI: same	Dosage variable: adjust and monitor accordingly; these are average approximate dosages; maintain hydration; avoid hypoglycemia and hypokalemia	100 U/mL I HM, VM
Interceptor	*(see milbemycin)*				
Interferon-alfa (Roferon)	Immune modulator with antiviral and antiproliferative effects; used for FeLV and FAIDS, leukemia, lymphoma, FIP	1 IU/5 kg BW, PO every 2 weeks to stimulate appetite	Total dose: 30 IU per cat PO: 7 days on, then 7 days off	Dosages of up to 20,000 IU/cat IM and 2 million IU/m^2 SQ (dogs) have been used	3, 5, 6, 9, 10, 18, 36 million IU per vial I HM
Interferon-omega (Virbagen)	Immunomodulator; parvoviral enteritis, FeLV, FIV	2.5 million IU/kg IV q 24 h × 3 d	1 million IU/kg SQ q 24 h × 5 d		10 million IU/vial I VM
Intropin	*(see dopamine)*				
Iodides	*(see sodium iodide 20%)*				
Ipecac syrup	Induce vomiting	0.25-0.5 mL/kg PO; can repeat once after 5-15 minutes if not vomiting	Not recommended in cats; use 3% hydrogen peroxide PO instead	Do not use with activated charcoal (ineffective)	70 mg/mL S; OTC, HM; many oral OTC; 50 mg/mL I HM
Ipodate (Oragrafin)	Oral radiographic contrast agent with antithyroid effects; used for hyperthyroidism	—	Total dose: 15-100 mg per cat PO q 12 h; titrated based on clinical response and T3	Blocks T4 conversion to T3; therefore, blood monitoring = serum T3 levels	500 mg C HM
Irbesartan (Avapro)	Angiotensin receptor antagonist	5-60 mg/kg PO q 12 h		Used in humans intolerant to ACE inhibitors; efficacy of irbesartan has been demonstrated in the dog (RAAS effect) but clinical proof and long-term safety not yet determined	75, 150, 300 mg T HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Iron-dextran injection (Imferon)	Iron-deficiency anemia	10 mg/kg in divided doses IM or total dose 100-300 mg PO per day for one dog	Same: IM or total dose 50-100 mg PO per day for one cat	Irritating IM	Many oral OTC; 50 mg/mL I HM
Isoproterenol (Isuprel)	β-adrenergic agonist	0.2 mg in 250 mL 5% dextrose, IV CRI at a rate of 0.05-0.1 mcg/kg/min; titrate to effect, adequate HR	0.2 mg in 250 mL 5% dextrose, IV to effect, adequate HR	Increased HR, increased or decreased BP, CNS stimulation, arrhythmogenic	0.2 mg/mL (= 200 mcg/mL) I HM
Isoptin	*(see verapamil)*				
Isosorbide dinitrate	Orally administered vasodilator	0.5-2 mg/kg PO q 12 h	Same	No recognized therapeutic efficacy in small animals	5, 10, 20, 30, 40 mg T HM
Isotretinoin (Accutane)	Sebaceous adenitis, keratinization disorders, mycosis fungoides, feline acne	1-2 mg/kg PO q 12 h; reduce dosage after 1 month if improving	Total dose: 5-10 mg PO q 24 h per cat	GI and CNS effects may occur, if so, reduce dosage by 50% or stop; teratogen; KCS in dogs; other mucocutaneous side effects	10, 20, 40, mg C HM
Isuprel	*(see isoproterenol)*				
Itraconazole (Sporanox)	Antimycotic fungistatic imidazole compound for blastomycosis, coccidioidomycosis, cryptococcosis; histoplasmosis *M. canis*, dermatophytosis, candidiasis	5-10 mg/kg PO q 24 h	Same	Long-term therapy (months or more) often required; must be taken with food; open capsules and place pellets in food if necessary; antacid GI drugs will reduce efficacy (decrease absorption); monitor liver status	100 mg C; 10 mg/mL S HM
Ivermectin (Heartgard-30, Heartgard Plus, Ivomec)	GABA agonist, antiparasiticide 1. Heartworm prophylaxis, microfilaricide 2. Heartworm 3. Endoparasites 4. Sarcoptic mange 5. Demodectic mange 6. Otodectic mange 7. Cheyletiellosis	1. HW prophylaxis: 0.006 mg/kg (6 mcg/kg) PO, once monthly 2. HW microfilaricide; 0.05 mg/kg (50 mcg/kg) once PO, 2-4 weeks after adulticide Tx 3. 0.2 mg/kg (200 mcg/kg) PO 4. 0.3 mg/kg (300 mcg/kg) PO or 0.2 mg/kg (200 mcg/kg) SQ 2 times, 14 days apart 5. 0.05 mg/kg (50 mcg/kg) PO; increase to 0.3 mg/kg (300 mcg/ kg) by day 5; increase to 0.6 mg/kg (600 mcg/kg) once daily PO after 30 days if necessary	HW prophylaxis: 0.024 mg/kg (24 mcg/kg) SQ; repeat in 3-4 weeks (usually under 0.1 mL) Same Same Same	Do not use in collies or other dogs sensitive to drug (exception: collies and similar breeds usually tolerate low [HW prophylaxis] dose); CNS, vomiting, anaphylaxis; can give injectable solution PO; of questionable value in treating feline heartworm disease; consider testing individual patients prior to treatment for the MDR-1 gene mutation if ivermectin is the treatment of choice in patients where susceptibility to toxicosis is possible (see pp. 706 and 625)	68, 136, 272 mcg T or chewables; 10 mg/mL (= 10,000 mcg/ mL) I VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
		6. 0.3 mg/kg (300 mcg/kg) PO, SQ 2 times at 14 days apart	Same		
		7. 0.3 mg/kg (300 mcg/kg) SQ 2 times at 21 days apart	Same		
Ivomec	*(see ivermectin)*				
Jenotone	*(see aminopropazine*)				
Kaolin Pectin	GI tract protectant	1-2 mL/kg PO q 2-6 h	Same	May limit absorption of other medications; limited efficacy	Many OTC preparations; T/S VM, HM
Kabikinase	*(see streptokinase)*				
Kaon	*(see potassium salts oral supplement)*				
KBr	*(see bromide)*				
Keflex	*(see cephalosporin antibiotics)*				
Kenalog	*(see triamcinolone)*				
Keppra	*(see levetiracetam)*				
Ketamine HCl (Ketaset, Vetalar)	Dissociative anesthetic agent; short-action when given IV in healthy dogs/cats: 10-20 minutes	When diazepam (at diazepam dose of 0.5 mg/kg) given IV first: immediately follow with ketamine 5-7 mg/kg IV bolus for sedation and minor procedures (diazepam [5 mg/mL]: ketamine combination in ratio of 1:1 → use 0.5 mL/10 kg of each [in separate syringes] IV)	Restraint: 11 mg/kg IM; anesthesia (but does not provide deep analgesia): 22-33 mg/kg IM or 2.2-4.4 mg/kg IV	Eyes remain open: use ophthalmic ointment; salivation, seizures, respiratory depression, laryngospasm, hypothermia; do not use with renal failure or glaucoma; reduce dose by 50%-75% if stable but systemically ill; avoid if hypertrophic cardiomyopathy; controlled drug	100 mg/mL I VM, HM
Ketaset	*(see ketamine)*				
Ketoconazole (Nizoral)	Antifungal agent; protothecosis; inhibits glucocorticoid synthesis	10-15 mg/kg PO q 12 h; long-term 10 mg/kg PO q 24 h; hyperadrenocorticism Rx: 15 mg/kg PO q 12 h	5-10 mg/kg q 12 h PO or q 24 h; long term: 10 mg/kg q 48 h PO	Anorexia, nausea, vomiting, constipation, hepatotoxicity; monitor liver status; begin lower and titrate upwards to reduce risk of side effects; must be given with food (for good absorption); drug interaction potential: DMSO inhibitor; antacids decrease absorption	200 mg T HM
Ketoprofen (Orudis KT; Ketofen)	NSAID	0.5-1 mg/kg PO q 12 h; 1-2 mg/kg SQ, IM, or IV once or q 24 h up to 3 days maximum	Same	GI ulceration, renal effects possible	25, 50, 75 mg C; 12.5 mg T, HM, OTC; 5, 10, 20 mg T; 10, 100 mg/mL I, VM (not approved in United States) OTC, VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Kitten Milk Replacer (KMR)	Milk replacement	—	30 mL per ¼ lb BW PO daily, divided into 3-6 meals	—	OTC, VM
Klonopin	*(see clonazepam)*				
KMR	*(see kitten milk replacer)*				
Kytril	*(see granisetron)*				
Lactulose (Cephulac, Chronulac)	Hepatic encephalopathy is treated by acidifying colon contents, trapping NH4 that is then expelled; the drug is also a stool softener	0.25-0.5 mL/kg PO q 8-12 h As a retention enema: total volume = 10-20 mL/kg (consisting of 3 parts lactulose plus 7 parts water) per rectum	Total dose: 1-5 mL PO q 8 h per cat Enema: same as for dog	Loose stools/diarrhea; flatulence; cramping; may use per rectum in patients with hepatic coma	666 mg/mL S HM
Lacrilube	*(see artificial tears ointment)*				
Lamprene	*(see clofazimine)*				
Lanoxin	*(see digoxin)*				
Lansoprazole (Prevacid)	Proton pump inhibitor; gastric ulceration	1 mg/kg IV q 24 h	Same	Usage less well-documented in VM compared to omeprazole	15, 30 mg C 6 mg/mL I HM
Lantus	*(see insulin glargine)*				
Lasix	*(see furosemide)*				
Latanoprost (Xalatan)	Topical prostaglandin analog used in the treatment of glaucoma	1 drop to affected eye, q 12-24 h	—	Generally effective and potent; may combine with oral carbonic anhydrase inhibitor; 1 drop = approximately 0.0015 mg	0.05 mg/mL OS HM
Laxative paste (Laxatone, Cat-a-Lax, etc.)	Oral laxative, hairball Tx	½-2 inches PO daily until not constipated, then weekly or PRN	Same	Large amounts daily could result in malabsorption (e.g., fat-soluble vitamins)	OTC, S, VM
Leflunomide (Arava)	Autoimmune disorders (IHA, ITP, sterile meningitis, systemic histiocytosis)	1.5-4 mg/kg PO q 24 h	—	Beneficial and adverse effects variably documented to date; GI and BM effects possible; seek trough serum level of 20 mcg/mL	10, 20, 100 mg T HM
Leucovorin	Reversal of methotrexate activity; sulfa-associated myelotoxicosis	5-15 mg per dog PO	1 mg/kg q 24 h	Higher/repeated doses may be indicated for methotrexate toxicosis; can assess plasma methotrexate levels	5, 15, 25 mg T 3, 10 mg/mL I 50, 100, 350 mg vials I HM
Leukeran	*(see chlorambucil)*				
Levamisole (Levasole, Ripercol, Tramisol)	1. Heartworm microfilaricide 2. Immune stimulant 3. Feline lungworm	1. 10 mg/kg PO q 24 h 7-14 days as a microfilaricide 2. 2.5-5 mg/kg PO q 48 h for immune modulation	2.5-5 mg/kg PO q 48 h for immune modulation; 10-20 mg/kg PO q 48 h for	Salivation, vomiting, shock-like syndrome with excessive microfilaricide death, neurotoxic, sudden death; not FDA	184 mg T; 136 mg/ mL S; 11.5% gel VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
			Aelurostrongylus and *Capillaria*	approved for small animal medicine	50 mg T HM
Levarterenol	*(see norepinephrine)*				
Levasol	*(see levamisole)*				
Levetiracetam (Keppra)	Third-line anticonvulsant for refractory seizures	20 mg/kg PO q 8 h, in addition to KBr and phenobarbital	—	Few adverse effects reported; can be up-titrated if starting dose ineffective; expensive	250, 500, 750, 1000 mg T 100 mg/mL S 100 mg/mL I HM
Levophed	*(see norepinephrine)*				
Levothyroxine sodium (Soloxine, Synthroid, thyroxine)	Synthetic thyroid hormone replacement therapy	0.04 mg/kg PO q 12 h Myxedema coma: 0.005 mg/kg slow IV q 12 h	Total dose: 0.05-0.1 mg PO q 24 h per cat	Thyrotoxicosis; do not give only on basis of low T4 (assess clinical signs and other lab results); adjust dose based on response and blood levels; concurrent antiepileptics (e.g., phenobarbital) may affect levels; maximum dose for largest dog: 0.8 mg PO q 12 h	0.025, 0.05, 0.075, 0.125, 0.15 mg T HM 0.2, 0.5 mg/mL I 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.8 mg T VM
Levsin	*(see hyoscyamine)*				
Lidocaine (Xylocaine)	Ventricular arrhythmias, local anesthesia	2-4 mg/kg IV over 1-2 minutes, then 0.5-2 mg/kg every 20-60 minutes, or 0.04-0.08 mg/kg/min (40-80 mcg/kg/min) CRI IV; inject up to 4 mg/kg SQ for local anesthesia	0.25-1 mg/kg slowly over 5 minutes; give 1-4 mg bolus maximum over 5 minutes; use diluted solution as CRI 0.01-0.04 mg/kg/min (10-40 mcg/kg/min)	Give initial bolus slowly; seizures, hypotension; use lidocaine preparations *without* epinephrine for cardiac arrhythmia therapy; use only for life-threatening arrhythmias	20 mg/mL I HM
Lime sulfur solution (LymDyp, Sulfodip)	Bacterial and fungal dermatosis, sarcoptic mange	Dip once to twice weekly; let air dry; use 4-6 weeks (ideally until 2-3 fungal cultures are negative)	Same	Offensive odor; stains furniture; wear gloves to avoid hypersensitivity	2% dip VM
Lincocin	*(see lincomycin)*				
Lincomycin (Lincocin)	Staphylococcal and anaerobic infections, some *Mycoplasma* infections	15-25 mg/kg PO, IV, IM q 8-12 h	Same	Vomiting, hepatotoxicity; do not use in combination with chloramphenicol or erythromycin	100, 200, 500 mg T; 50 mg/mL S; 100 mg/mL I HM, VM
Liothyronine, T3	*(see triiodothyronine)*				
Liquiprin	*(see acetaminophen)*				
Lisinopril (Zestril, Prinivil)	ACE inhibitor; CHF, protein-losing nephropathy	0.5-0.75 mg/kg PO q 24 h	0.25 mg/kg PO q 24 h	Monitor BUN, creatinine; lethargy, anorexia	2.5, 5, 10, 20, 40 mg T HM
Lithane	*(see lithium carbonate)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Lithium carbonate (Eskalith, Lithane, Lithotabs)	Increased production of all cell lines by BM	21-26 mg/kg per day PO	Unknown	Nausea, diarrhea, vertigo	300 mg C; 450 mg T ER HM
Lithotabs	*(see lithium carbonate)*				
Lodine	*(see etodolac)*				
Lomotil	*(see diphenoxylate with atropine)*				
Lomustine (CCNU, CeeNu)	Nitrosourea alkylating agent for brain tumors, mast cell tumors, relapse or failure to respond to lymphoma therapy	60-90 mg/m^2 PO once every 3 weeks	—	Neutropenia may develop after 7 days; GI adverse effects, anemia; its active metabolites reach the CNS	10, 40, 100 mg C HM
Loperamide (Imodium)	Opiate antidiarrheal, acute colitis	0.1-0.2 mg/kg PO q 8 h	0.1-0.15 mg/kg PO q 12 h	Discontinue if not effective within 48 hours; collie sensitivity; CNS adverse effects possible in dogs and cats (see p. 706)	2 mg C; 1 mg/5 mL S HM, OTC
Lopid	*(see gemfibrozil)*				
Lopressor	*(see metoprolol)*				
Lorazepam (Ativan)	Benzodiazepine; anxiolytic. Phobias, anxiety disorders	0.02-0.1 mg/kg PO q 8-24 h PRN	0.125-0.25 mg/cat PO q 12-24 h		0.5, 1, 2 mg T 2 mg/mL S 2, 4 mg/mL I HM
Losec	*(see omeprazole)*				
Lotensin	*(see benazepril)*				
Lotrimin	*(see clotrimazole)*				
Lovenox	*(see heparin-low molecular weight)*				
Lufenuron (Program)	Insect development inhibitor; inhibits chitin synthesis 1. Prevents flea eggs from developing into adults 2. Coccidioidomycosis 3. Dermatophytosis	Administer PO in conjunction with food. 1. 10 mg/kg PO once every 30 days 2. 5-10 mg/kg PO q 24 h 3. 54-100 mg/kg PO once q 2-4 wk	30 mg/kg PO once monthly or 10 mg/ kg once every 6 months by SQ injection 51-266 mg/kg PO once	Expensive as long-term daily Tx for fungal disease; efficacy in dermatophytosis questionable; may be combined with milbemycin for control of fleas, heartworms, roundworms, whipworms	Sold in packets for varying BW by T, S, or 10 mg/mL T or I
Lutalyse	*(see prostaglandin F2-α)*				
Lym-DYP	*(see lime sulfur solution)*				
Lyrica	*(see pregabalin)*				
Lysine	Herpesviral keratitis palliation		250-500 mg/day in food	Lifelong therapy for lifelong infection	Many sizes and formulations OTC VM, HM
Lysodren	*(see o,p'-DDD)*				
Macrobid	*(see nitrofurantoin)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Macrodantin	*(see nitrofurantoin)*				
Magnesium hydroxide (Milk of Magnesia)	Antacid, laxative	Total dose: 5-10 mL PO q 4-6 h per dog	—	Cathartic agent at 3-5× the antacid dosage; rarely used because high dosing frequency and rebound acid secretion	77.5 mg/g S OTC, HM
Magnesium sulfate	Hypomagnesemia	0.75-1 mEq/kg/d as IV CRI; for hypomagnesemia-associated life-threatening ventricular arrhythmias: 0.15-0.3 mEq/kg slow IV (15-30 minutes) while monitoring for adverse effects	Same	Monitor for acute toxicosis: increased QT interval on ECG; lethargy, hypotension, weakness, collapse	100 mg/mL (0.8 mEq/mL), 125 mg/mL (1 mEq/mL), 500 mg/mL (4 mEq/mL) I HM
Mannitol 20%	Osmotic diuretic used for treating acute glaucoma, cerebral edema, and oliguria/ anuria; aids in elimination of certain toxins (e.g., ethylene glycol)	0.5-1 g/kg IV slowly over 15-20 minutes for anuria; double dosage for acute glaucoma or cerebral edema	Same	Rehydrate patient prior to use; can repeat twice if urine output is not increased; resolubilize (by warming) if crystallized, ensuring to cool to body temperature before administering; overzealous use: circulatory overload/ pulmonary edema	100 mg/mL (10%); 200 mg/mL (20%) I HM, VM
Marbofloxicin (Zeniquin)	Fluoroquinolone class antibiotic	2-4 mg/kg PO q 24 h	Same	Anorexia and vomiting; not recommended for rapidly growing dogs (possible arthropathy); caution in seizure patients (as with all fluoroquinolones)	25, 50, 100, 200 mg T VM
Marin	*(see silymarin)*				
Maropitant (Cerenia)	Antiemetic (motion sickness, enteritis, etc.); neurokinin-1 antagonist	1 mg/kg SQ or 2 mg/kg PO; up to 5 days	Not approved; experimental report: single dose 1 mg/kg PO, SQ, or IV was safe and effective in cats	Pain at injection site common; refrigeration may help.	16, 24, 60, 160 mg T 10 mg/mL I
Marquis	*(see ponazuril)*				
Matulane	*(see procarbazine)*				
Maxitrol	*(see dexasporin)*				
MCT oil	*(see medium chain triglycerides)*				
Mebendazole (Telmintic)	Hookworm, whipworm, and roundworm	22 mg/kg with food once daily for 3 days	—	Repeat as indicated; V/D may develop; hepatopathies have been incriminated in a small number of cases	40 mg/g powder VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Meclizine (Bonine, Dramamine II, Antivert)	Antiemetic, motion sickness	1.25 mg/kg PO q 24 h	12.5 mg per cat PO q 24 h	Lethargy, CNS depression possible	12.5, 25, 50 mg T OTC, HM
Medetomidine (Domitor)	Synthetic α-2 adrenoreceptor agonist; provides sedation-analgesia as chemical restraint for healthy exercise tolerant dogs; useful for sedation of cats that have compensated ("asymptomatic") hypertrophic cardiomyopathy	0.005-0.02 mg/kg (5-20 µg/kg) IM as a single agent; used by some at half or quarter dose in combination with butorphanol, ketamine, morphine, or oxymorphone	0.02 mg/kg (20 µg/kg) IM	Do not use if hypertensive; allow dog or cat to rest quietly after administration; do not use in older, younger (<12 weeks old), sick, or debilitated dogs or cats; reversed with equal volume of atipamezole; reflex bradycardia is result of drug-induced hypertension; do not attempt to "correct" bradycardia with atropine or other antibradycardiac drugs; nonopiate/not controlled; sedation outlasts analgesia	1 mg/ml I VM
Medium chain triglycerides (MCT oil)	Nutritional supplement used in protein-losing diseases (lymphangiectasia) and when long-term triglyceride intake should be reduced, such as in chylothorax	1-2 mL/kg daily in food	Same	May be unpalatable; efficacy not demonstrated; GI upset (V/D)	OTC, HM
Medroxyprogesterone acetate (Depo-Provera, Provera)	Long-acting progesterone compound used for decreasing male dog libido and aggression, rarely as a contraceptive; in cats, used for psychogenic and miliary dermatitis and inappropriate elimination	2-20 mg/kg IM, SQ every 4-6 months	Total dose: 10-100 mg IM, SQ every 4 months, per cat	Overdosage may cause cystic endometritis, diabetes mellitus, hypoadrenocorticism, and mammary hyperplasia/ adenocarcinoma; local alopecia may occur; carefully weigh risks versus benefits	2.5, 5, 10 mg T; 150, 400 mg/mL I HM
Mefoxin	*(see cefoxitin)*				
Megace	*(see megestrol acetate)*				
Megestrol acetate (Ovaban, Megace)	Oral progestogen used for delaying estrus and treating canine pseudopregnancy; canine and feline behavioral modification; eosinophilic granuloma and some chronic feline skin disorders	Anestrus Tx: 0.5 mg/kg PO q 24 h for 32 days; proestrus Tx: 2 mg/kg PO q 24 h for 8 days; behavior modification: 2-4 mg/ kg PO q 24 h for 14 days, then decrease and stop after 6 weeks	Estrus suppression total dose: 5-10 mg PO q 24 h per cat for 7 days, then twice weekly; same dose as for dog for behavior modification	See specific diseases; do not use in pregnant pets or pets with uterine problems; avoid use with mammary tumors or hyperplasia; may cause PU/PD, polyphagia, diabetes mellitus	5, 20 mg T, VM; 20, 40 mg T HM
Meglumine antimonite (Glucantime)	Antiprotozoal; leishmaniasis	100 mg/kg SQ or IM q 24 h for 3-4 weeks		Difficult to obtain in North America; widely available in Europe	300 mg/mL I HM
Melarsomine (Immiticide)	Organic arsenical for treatment of adult heartworms	2.5 mg/kg IM, once; then 30 days later, 2.5 mg/kg IM × 2 doses, 24 hours apart	None	Painful after few days: give in epaxial muscles; cellulitis or salivation may occur; PTE occurs when	50 mg/vial I VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				worms die; absolute cage rest for 4 weeks post Tx; not for class IV HW disease	
Melatonin (Regulin)	Hormone involved in diurnal cycle. Alopecia-X, recurrent flank alopecia	3-12 mg/dog PO q 8-24 h		Treatment response expected to take several weeks	Many forms available OTC HM
Meloxicam (Metacam, Mobic)	COX-2-inhibiting NSAID; for treatment of osteoarthritis; perioperative pain management	0.1 mg/kg PO, SQ q 24 h (may be preceded by single 0.2 mg/kg loading dose, PO, SQ, IV)	Chronic use: 0.025 mg/kg PO q 24 h (can be preceded by perioperative dose below as loading dose); perioperative pain control; 0.1-0.2 mg/kg PO, SQ, IV once only	GI signs (vomiting, anorexia), GI ulceration, perforation	1.5 mg/mL S; 5 mg/ mL I, VM; 7.5, 15 mg T HM
Melphalan (Alkeran)	Multiple myeloma; lymphoreticular and other neoplasms; alkylating agent	0.1 mg/kg PO q 24 h for 10 days, then 0.05 mg/kg PO q 24 h; or 1.5 mg/m^2 PO q 24 h for 7-10 days; or 7 mg/m^2 q 24 h for 5 days every 3 weeks	Same	Anorexia, nausea, vomiting, leukopenia, thrombocytopenia, anemia	2 mg T HM
Meperidine HCl (Demerol)	Narcotic analgesic with short-term (1-4 hours) effect	3-10 mg/kg IM or slow IV PRN	1-4 mg/kg IM PRN	Watch for signs of narcotic overdosage (i.e., sedation, depression, seizures, hypotension, [especially in cats]); can reverse with naloxone	25, 50, 75, 100 mg/ mL I; 50, 100 mg T; 10 mg/mL S HM
Mephyton	*(see vitamin K)*				
Mepron	*(see atovaquone)*				
Meropenem (Merren IV)	Carbapenem antibiotic, especially for G− bacteria (alternative to aminoglycosides)	12 mg/kg SQ q 8-12 h or 24 mg/kg IV q 24 h for UTI	—	Indications similar to those for imipenem; fewer adverse effects in people	500, 1000 mg (vial) I HM
Merrem IV	*(see meropenem)*				
Mesalamine (5-ASA, Asacol, Pentasa)	Inhibits prostaglandin production in the colon; irritable bowel syndrome, ulcerative colitis	10-20 mg/kg PO q 8 h	—	Clinical VM use very new at time of this writing; efficacy unproven; may be infused rectally (enema instructions)	400 mg T; 250 mg C; 4 g/60 mL enema HM
Mesna (Mexnex)	Urothelial protection preceding ifosfamide chemotherapy	Dose is 20% of ifosfamide dose	—	Administered as pretreatment before ifosfamide: reconstitute as 20 mg/ mL, and give calculated dose as IV bolus, followed by 9 mL/kg 0.9% NaCl IV over 30 minutes, then ifosfamide	100 mg/mL I HM
Mesnex	*(see mesna)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Mestinon	*(see pyridostigmine bromide)*				
Metacam	*(see meloxicam)*				
Metaflumizone (ProMeris)	Fleas, ticks *(Ixodes, Dermacentor, Rhipicephalus, Amblyomma),* demodicosis	20 mg/kg (=0.133 ml/ kg) topically q 4-6 weeks	Same	Compounded with amitraz (150 mg metaflumizone + 150 mg amitraz/mL), warranting caution if owner or patient is taking/exposed to other MAO inhibitors.	0.67, 1.33, 3.33, 5.33, 6.66 ml pipettes topical solution VM
Metamucil	*(see psyllium mucilloid)*				
Methazolamide (Neptazane)	Oral carbonic anhydrase inhibitor, glaucoma	5 mg/kg PO q 8-12 h		Induces mild metabolic acidosis (bicarbonaturia); GI and CNS adverse effects possible	25, 50 mg T, HM
Methigel	*(see methionine, DL-)*				
Methimazole (Tapazole, thiamazole, Felimazole)	Feline hyperthyroidism, palliative Tx for canine functional thyroid neoplasia	Total dose 2.5-5 mg PO q 12 h per dog	Total dose 2.5-5 mg PO q 8-12 h per cat	Possible side effects: anorexia, vomiting, and blood dyscrasias; intense facial pruritus; monitor CBC and T4; start at ½ dosage, then increase after 7-10 days based on clinical response and T4 level; monitor renal function	5, 10 mg T HM 2.5, 5 mg T VM
DL-methionine (Methigel, Albeta)	Urinary acidifier	0.2-1 g PO q 8 h per dog	0.2-1 g PO q 24 h per cat	Contraindicated for renal failure, acidosis, pancreatic disease, hepatic insufficiency/ encephalopathy; GI irritability; blood dyscrasias, in cats especially	15 mg/mL S; 200, 500 mg T, C OTC, VM, HM
S-adenosyl methionine (SAMe, Denosyl)	Adjunctive treatment for certain liver diseases, steroid hepatopathy, acetaminophen toxicity	Total dose per dog: 90 mg PO q 24 h (small dog), or 225 mg or more PO q 24 h (large dog)	Total dose per cat: 90 mg PO q 24 h	Also compounded with milk thistle extract (silymarin) as Denamarin	90, 225 mg T VM
Methocarbamol (Robaxin)	Muscle relaxant	20-45 mg/kg PO q 12 h to q 8 h; 44-220 mg/ kg slow IV (few minutes); use high end of dose range if strychnine, metaldehyde, tetanus; maximum = 330 mg/ kg per day	20-45 mg/kg PO q 8-12 h	Ataxia, sedation, ptyalism, emesis	100 mg/mL I; 500 mg T, VM; 100 mg/mL I; 500, 750 mg T HM
Methotrexate	Antimetabolite, antineoplastic agent that inhibits folic acid reductase; used to treat some cancers or for immunosuppression; sclerosing cholangiohepatitis	0.06 mg/kg PO q 24-48 h; or 2.5 mg/ m^2 PO q 24-48 h	2.5 mg/m^2 PO q 2-3 days	Leukopenia, GI bleeding, hepatotoxicity; see specific cancer or disease state	2.5, 5, 7.5, 10, 15 mg T; 25 mg/ mL I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Methylene blue (new methylene blue)	1. For treatment of methemoglobinemia in dogs 2. As intraop insulinoma Dx test	1. 1-2 mg/kg slowly IV, once 2. Dilute 3 mg/kg in sterile saline, and administer as CRI	—	Use once only; can induce Heinz body anemia; islet cell tumors = purple (versus pale blue background); best contrast 30 minutes after onset of CRI	10 mg/mL I HM
Methylprednisolone acetate (DepoMedrol)	Repositol corticosteroid; feline asthma, eosinophilic granuloma complex; for intralesional skin injections	1-2 mg/kg IM, SQ	Same, total dose: 10-20 mg per cat	Glucocorticoid contraindications and side effects; may cause CHF in cats with asymptomatic cardiomyopathy	20, 40, 80 mg/mL I VM, HM
Methylprednisolone sodium succinate (Solu-Medrol)	*See prednisolone sodium succinate*	30 mg/kg slow IV once, then 15 mg/kg IV in 2-6 hours	Same	GI ulcers very common; assess need for this Tx based on acuity (time frame) and severity	40, 125, 500, 1000, 2000 mg/vial I HM
Methyltestosterone	Anabolic drug, androgenic steroid; used in testosterone-responsive incontinence	0.5 mg/kg PO	Same	May increase creatinine and glucose levels	10, 25 mg C HM
Metoclopramide (Reglan)	Antiemetic with both central (chemoreceptor trigger zone) and peripheral (GI prokinetic) effects; increases LES pressure; promotes gastric emptying	0.2-0.5 mg/kg PO, SQ, q 6-12 h, or 1-2 mg/ kg per day given as IV infusion over 24 hours	Same	Do not use with GI obstruction, with phenothiazines, or with narcotic analgesics; atropine blocks effect; may increase seizure activity; extrapyramidal effects, avoid in epileptics	5, 10, mg T; 1 mg/ mL S; 5 mg/mL 1 HM
Metopirone	*(see metyrapone)*				
Metroprolol (Lopressor, Toprol XL)	Antiarrhythmic, β1-selective blockage	0.4-1 mg/kg PO q 8-12 h; q 24 h for extended release	Total dose: 2-10 mg PO q 12-24 h per cat	Lethargy, depression; decreased HR; β-blockade-induced CHF; always begin low and titrate up	25, 50, 100, mg T; 25, 50, 100, 200 mg ER; 1 mg/mL I HM
Metronidazole (Flagyl)	Anaerobic infections; antiprotozoal *(Giardia, Entamoeba, Balantidium, Pentatrichomonas)*; IBD, SIBO; *Helicobacter* therapy, colitis therapy	10-20 mg/kg PO q 12 h; for sepsis: 15 mg/kg slow IV (30 minutes infusion) q 12 h	Same	Anorexia and vomiting; neurotoxicity and hepatotoxicity may develop at high and/ or prolonged dosages; hepatic metabolism; use 7.5 mg/kg PO q 12 h if liver disease	250, 500 mg T; 500 mg/100 mL I HM
Metyrapone (Metopirone)	Feline hyperadrenocorticism		65 mg/kg PO q 12 h	Uncommon disorder; limited information	250 mg T HM
Mexiletine (Mexitil)	Type 1B antiarrhythmic drug used for treating ventricular arrhythmias; lidocaine-like oral agent	4-10 mg/kg PO q 8-12 h	—	Anorexia, depression; CNS stimulatory signs; side effects rare; increasingly difficult to obtain due to decreased use in human cardiology	150, 200, 250 mg C HM
Mexitil	*(see mexiletine)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Miacalcin	*(see calcitonin)*				
Mibolerone (Cheque)	Prevents estrus (dogs only); pseudocyesis; synthetic androgenic anabolic steroid	Total dose per dog: 30, 60, 120, 180 mcg PO q 24 h for dogs weighing 1-11, 12-22, 23-45, or >45 kg respectively. Begin 30 days before proestrus to suppress estrus.	—	Do not use in pregnant dogs or in those with hepatic or renal disease. Pseudocyesis: multiply dosage by 10, and administer for 5 days.	100 mcg/mL S VM
Miconazole (Conofite)	Topical antifungal	Apply q 12 h to lesion; continue after resolution of lesions for 2 weeks	Same	Contact hypersensitivity; caution: re. zoonosis if dermatophytosis (wear gloves)	OTC, topical cream, and solution HM
Micro-K extencaps	*(see potassium salts)*				
Micronase	*(see glyburide)*				
Midazolam (Versed)	Benzodiazepine tranquilizer; 3-4× more potent than diazepam	Preanesthetic dose: 0.1-0.3 mg/kg IV, IM, SQ (lower end of range if IV)	0.05-0.3 mg/kg IV, IM, SQ (mid- to lower end of range if IV and/or if combined with ketamine)	Caution if liver disease, avoid if glaucoma	1 mg/mL, 5 mg/mL I HM
Midol	*(see acetaminophen)*				
Midriacyl	*(see tropicamide)*				
Mifepristone (Mifeprex, RU-486)	Progesterone receptor antagonist	2.5 mg/kg PO q 12-24 h for 5 days	—	Abortifacient	200 mg T HM
Milbemycin (Interceptor)	1. Anthelmintic action in HW prevention, HW microfilaricide, hookworm, and roundworm control 2. Demodicosis 3. *Pneumonyssoides caninum*	1. 0.5-1 mg/kg orally once monthly 2. 0.5-2.3 mg/kg PO q 12-24 h 2-4 weeks for demodicosis, longer if skin scrapings fail to clear mites; may use low dose for 30 days, twice after if necessary 3. 0.5-1 mg/kg per week for 3 weeks	—	Also available as otic formula (Milbemite) and compounded with lufenuron (Sentinel) and lufenuron plus nitenpyram (Sentinel with Capstar)	2.3, 5.75, 11.5, 23 mg T 0.1% otic solution VM
Milk of Magnesia	*(see magnesium hydroxide)*				
Milk thistle extract	*(see silymarin)*				
Miltefosine (Miltex, Impavido)	Antiprotozoal; leishmaniasis	2 mg/kg PO q 24 h × 4 weeks		Coadministered with allopurinol 20 mg/kg PO q 24 h (allopurinol for 6-12 months)	50 mg C HM
Minipress	*(see prazosin)*				
Mintezol	*(see thiabendazole)*				
Mirtazapine (Remeron)	Tricyclic antidepressant drug used for appetite stimulation, particularly in cats	0.6 mg/kg PO q 24 h	3-4 mg/cat PO q 72 h maximum		7.5, 15, 30, 45 mg T HM
Misoprostol (Cytotec)	Prostaglandin E-1 analog; used for gastric ulcers	2-8 mcg/kg PO q 8-12 h	—	Secretory diarrhea, vomiting, anorexia;	100, 200 mcg T HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
	(especially those associated with NSAID use)			may induce abortion in pregnant mammals (also avoid client exposure); side effects are dose dependent	
Mitaban	*(see amitraz)*				
Mitotane	*(see* o,p′ *DDD)*				
Mitoxantrone (Novantrone)	Chemotherapeutic agent closely related to doxorubicin but no cumulative cardiotoxicity	5 mg/m^2 once every 3 weeks IV	6.25 mg/m^2 once every 3 weeks IV	Depression, GI signs, leukopenia, hepatotoxicity, extravasation injury	2 mg/mL I HM
Mobic	*(see meloxicam)*				
Morphine sulfate	Narcotic analgesic; acute CHF as adjunctive therapeutic agent to relieve anxiety	0.1-1 mg/kg q 2-6 h IM, SQ, IV, epidural; or sustained-release 1.5-3 mg/kg PO q 12 h (ER)	0.05-0.2 mg/kg IM, SQ q 2-6 h	Hyperexcitability in cats; vomiting, respiratory, and CNS depression; hypotension, especially if given IV; constipation	30 mg ER; 5, 10 20 mg suppository; 10, 20 mg/5 mL S; 15, 30 mg T: 2, 4, 5, 8, 10, 15 mg/mL I HM
Motrin	*(see ibuprofen)*				
Moxidectin (Proheart)	1. Avermectin antiparasitic 2. Heartworm prophylaxis, demodicosis	1. HW prevention: 3 mcg/ kg PO once monthly 2. Demodicosis: 0.2-0.4 mg/kg PO q 24 h	—	Available compounded with imidacloprid as Advantage Multi	30, 68, 136 mcg T; large animal product available as 11.3-g tube VM
Mucomyst	*(see acetylcysteine)*				
Mycelex	*(see clotrimazole)*				
Mycophenolate mofetil (CellCept)	Immunosuppression via inhibition of T- and B-cell proliferation; steroid-responsive meningitis-arteritis, necrotizing encephalitis, other immune-mediated disorders	20 mg/kg PO q 12 h; reduce to 10 mg/kg PO q 12 h after 3-4 weeks if ongoing treatment	—	Reported adverse effects include hemorrhagic diarrhea, vomiting, and myelosuppression	250 mg C, 500 mg T, 250 mg/mL I HM
Mycostatin	*(see nystatin)*				
Mydriacyl	*(see tropicamide)*				
Mylepsin	*(see primidone)*				
Myleran	*(see busulfan)*				
Naloxone (Narcan)	Narcotic antagonist	0.004-0.04 mg/kg IV, IM, SQ	Same	Repeat dosing if prolonged action of narcotic	0.02, 0.4, 1 mg/mL I HM
Naltrexone (ReVia)	Partial opiate antagonist; certain behavioral disorders	1-2.2 mg/kg PO q 12-24 h	25-50 mg PO q 24 h per cat	Contraindicated in hepatopathies; antagonizes opiate drugs (e.g., certain antitussives, antidiarrheals)	50 mg T HM
Nandrolone decanoate (Deca-Durabolin)	Anabolic steroid and bone marrow stimulant (erythropoiesis only)	1 mg/kg/week IM	0.5-1 mg/kg per week IM	Give deep IM; do not administer to pregnant or hepato-	100 and 200 mg/mL I

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				insufficient animals or animals with hormone-sensitive tumors; C-III drug	HM
Naprosyn	*(see naproxen)*				
Naproxen (Naprosyn, Aleve)	NSAID	1.2-2.8 mg/kg PO q 24-96 h	Do not use	Severe GI ulceration/ perforation very common; renal, CNS; not a preferred drug; serum half-life is 32-92 hours in dogs; many safer alternatives	200, 250, 375, 500 mg T; 125 mg/5 mL S HM
Narcan	*(see naloxone)*				
Naxcel	*(see ceftiofur)*				
Nembutal	*(see pentobarbital)*				
Nemex	*(see pyrantel pamoate)*				
Neomycin (Biosol)	Aminoglycoside used orally for SIBO, hepatic encephalopathy	10-20 mg/kg PO q 8-12 h	Same	Ototoxicity and nephrotoxicosis are rare with oral dosage; in severe intestinal disease, toxicosis may be more likely (systemic absorption)	25, 200 mg/mL S; 100, 500 mg, T VM, HM
Neoral	*(see cyclosporine-systemic)*				
Neosar	*(see cyclophosphamide)*				
Neostigmine (Prostigmin)	Anticholinesterase agent for myasthenia gravis	0.01-0.05 mg/kg IM, SQ PRN	Same	Muscarinic effects: vomiting, diarrhea, bradycardia are reversed by atropine	0.25, 0.5, 1, 2 mg/ mL I; 15 mg T HM
Neo-Synephrine	*(see phenylephrine)*				
Neptazane	*(see methazolamide)*				
Neupogen	*(see filgrastim)*				
Neurontin	*(see gabapentin)*				
New methylene blue	*(see methylene blue)*				
Nexium	*(see esomeprazole)*				
Niacinamide (nicotinamide)	Usually used in combination with a tetracycline for immune-mediated dermatopathies	<5 kg: 100 mg PO q 8 h; 5-10 kg: 250 mg PO q 8 h; >10 kg: 500 mg PO q 8 h	—	GI adverse effects possible	50, 100, 125, 250, 500 mg T HM
Niclosamide (Yomesan)	Tapeworm anthelmintic	154 mg/kg PO; fast 24 hours before; repeat in 2-3 weeks	Same	Occasionally soft stools; generally replaced by praziquantel	VM
Nicotinamide	*(see niacinamide)*				
Nilstat	*(see nystatin)*				
Nipride	*(see nitroprusside)*				
Nitenpyram (Capstar)	Flea adulticide; inhibits insect specific nicotinic receptors	Dogs up to 11 kg: total dose 11.4 mg PO per dog, maximum q 24 h;	Total dose: 11.4 mg PO per cat, max. q 24 h	Onset of action: rapid (minutes to hours), but duration of activity	11.4, 57 mg T VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
		dogs >11 kg: total dose 57 mg PO per dog, maximum q 24 h		limited (day[s])	
Nitrofurantoin (Furadantin, Macrobid, Macrodantin)	UTIs	4 mg/kg PO q 8 h	Same	Oral form used only for UTIs; GI, hepatotoxicity	50, 100 mg T; 5 mg/mL S; 25, 50, 100 mg macrocrystals C HM
Nitroglycerin 2% ointment (Nitrol ointment)	Transdermal venodilator for reducing cardiac preload in acute CHF	Apply ¼-2 inch strip q 6-8 h topically to skin	Apply 1/8- to ¼-inch strip q 8 h topically to skin	May cause hypotension; apply with glove to hairless region (i.e., pinna or inguinal area); clinical efficacy questionable; nitrate tolerance/loss of efficacy in 48 hours	2% O HM
Nitrol ointment	*(see nitroglycerin)*				
Nitroprusside (Nipride, Nitropress)	Arterial dilator, venodilator; reduces preload and afterload in CHF	1-7 mcg/kg/min IV CRI	1-2 mcg/kg/min IV CRI	Hypotension; use 2-3 days IV maximum; avoid extravasation	50 mg/vial I HM
Nizatidine (Axid)	H2 receptor antagonist	5 mg/kg PO q 24 h	2.5-5 mg/kg PO q 24 h (for colonic motility effects)	Has GI prokinetic effects (via anticholinesterase activity)	75 mg T 150, 300 mg C 15 mg/mL S HM
Nizoral	*(see ketoconazole)*				
Nolvasan	*(see chlorhexidine)*				
Norepinephrine (Levophed, Levarterenol)	β1- and α-agonist; used for treating shock	1-2 mg in 250 mL of 0.9% NaCl, IV CRI to effect	None	Hypertension, tachycardia	1 mg/mL I HM
Norpace	*(see disopyramide)*				
Norvasc	*(see amlodipine)*				
Novantrone	*(see mitoxantrone)*				
Novin	*(see dipyrone)*				
Numorphan	*(see oxymorphone)*				
Nuprin	*(see ibuprofen)*				
Nystatin (Nilstat, Mycostatin, Nystex)	Topical antifungal, oral candidiasis	50,000-150,000 IU PO q 6-8 h	100,000 IU PO q 6 h	Fungicidal; not appreciably absorbed in GI tract, so useful for topical oral application	100,000 IU/mL S HM
Nystex	*(see nystatin)*				
Octreotide (Sandostatin)	Somatostatin analog with primary inhibitory effect on intestinal and pancreatic secretions; insulinoma, glucagonoma	Total dose: 10-40 mcg (0.01-0.04 mg) SQ q 8 h per dog		Nausea, vomiting, abdominal discomfort	50, 100, 200, 500 mcg/mL I HM
Ocufen	*(see flurbiprofen)*				
Ofloxacin (Ocuflox)	Topical fluoroquinolone antibiotic for ophthalmic use	1 drop topically in affected eye q 12 h; adjust as necessary	Same	Bactericidal G− and G+	3 mg/mL OS HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Olsalazine (Dipentum)	Salicylate; antiinflammatory activity in ulcerative colitis (5-ASA)	5-20 mg/kg PO q 8 h	Unknown	*(see sulfasalazine)*	250 mg C HM
Omeprazole (Prilosec, Losec)	Proton pump acid blocker; used in reflux esophagitis and hyperacidity syndromes	0.7 mg/kg PO q 24 h	Total dose: 5 mg per cat PO q 24 h	Few side effects noted	10, 20, 40 mg C HM
Oncovin	*(see vincristine)*				
Ondansetron (Zofran)	5-HT3 receptor antagonist (serotonin inhibitor); used in conjunction with emetogenic cancer chemotherapy; used in protracted vomiting unresponsive to other treatments	0.1-0.2 mg/kg IV bolus q 12 h	Same	Used before and for 48 h following specific IV cancer Tx	4, 8 mg T; 2 mg/mL I; 1.25 mg/mL S HM
o,p' DDD (Lysodren, Mitotane)	Hyperadrenocorticism; selective necrosis of the zonae fasciculata and reticularis of the adrenal gland	25 mg/kg PO q 12 h with food to effect (approximately 5-10 days); then 25-50 mg/kg once every 7-14 days to effect (based on monitoring adrenocortical function); give with food	None	Vomiting, diarrhea, weakness, glucocorticoid ± mineralocorticoid deficiency; hepatotoxicity; best if given in divided doses; insulin dose in diabetes may need to be altered (see p. 1566)	500 mg T VM
Optimmune	*(see cyclosporine-ophthalmic)*				
Oragrafin	*(see ipodate)*				
Oral rehydration solution (ORS: Pedialyte)	Oral electrolyte and glucose replacement	Up to maintenance (60 mL/kg per day PO) and replacement (based on physical exam); PO divided into several doses as low-cost rehydration/ volume expansion	Same	—	Many HM, OTC
Orbax	*(see orbifloxacin)*				
Orbifloxacin (Orbax)	Fluoroquinolone antibacterial	2.5-7.5 mg/kg PO q 24 h	Same	May cause arthropathy in immature dogs; caution in seizure patients (as with all fluoroquinolones)	5.7, 22.7, 68 mg T VM
Ormetoprim-sulfadimethoxine	*(see sulfadimethoxine/ ormetoprim)*				
ORS	*(see oral rehydration solution)*				
Orthocide	*(see captan powder 50%)*				
Orudis KT	*(see ketoprofen)*				
Osaterone (Ypozane)	Benign prostatic hyperplasia	2.5 mg/kg PO q 24 h × 7 days		Remission of signs of benign prostatic hyperplasia for 6 months in approximately 83% of cases	1.875, 3.75, 7.5, 15 mg T VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Oseltamivir (Tamiflu)	Antiviral; canine influenza	1 mg/kg PO q 24 h		Not approved for dogs; controversial (viral resistance; may be needed in human outbreak)	30, 45, 75 mg C 12 mg/mL S HM
Osmoglyn	*(see glycerin 50% solution [oral])*				
Ovaban	*(see megestrol acetate)*				
Oxacillin (Prostaphlin)	Penicillin derivative used for staphylococcal skin infections	22-40 mg/kg PO q 8 h; 15-20 mg/kg IV q 6-8 h	Same	Best if not given with food; GI upset possible	250 mg/5 mL S; 250, 500 mg C; 250, 500 mg 1, 2 g I HM
Oxazepam (Serax)	Appetite stimulant (oral benzodiazepine agent)	—	Total dose: 2.5 mg per cat PO once; do not use long term, can lead to hepatotoxicity	Overdosage results in sedation and incoordination	10, 15, 30 mg C; 15 mg T HM
Oxtriphylline (Choledyl)	Bronchodilator (theophylline derivative)	4-10 mg/kg PO q 8 h	4-10 mg/kg PO q 8 h	Vomiting, diarrhea, hyperexcitability	100, 200 mg T; 400, 600 mg ER HM
Oxydex	*(see benzoyl peroxide)*				
Oxyglobin	*(see hemoglobin glutamer)*				
Oxymorphone (Numorphan)	Narcotic agonist for analgesia, anesthetic induction, and minor procedures	Preanesthesia: 0.1-0.2 mg/kg IM, SQ; 0.02-0.05 mg/kg IV; analgesia: 0.03-0.2 mg/kg IV, IM, SQ PRN	0.01-0.1 mg/kg IV, IM, SQ PRN	Respiratory and CNS depression; hypotension, sedation, bradycardia, feline hyperexcitability; panting (dogs); reverse with naloxone	1, 1.5 mg/mL I HM
Oxytetracycline (Terramycin)	Broad-spectrum bacteriostatic agent; also used for rickettsiae, *Mycoplasma* spp., spirochetes, and chlamydiae; used for treating SIBO	10-20 mg/kg PO q 8 h to q 6 h; as OO, apply q 12 h to q 6 h	Same	Do not use in pregnancy (last trimester) or in first month of life (dental staining); GI side effects; photosensitivity; caution with liver and kidney disease; do not administer with antacids, dairy products, or intestinal adsorbents	50, 125 mg/mL I; 250 mg C HM
Oxytocin (Pitocin, Syntocinon)	Pituitary hormone used for uterine inertia; to stimulate milk flow; vasopressive effects and as an antidiuretic	Obstetrics (uterine inertia): 5-25 U IM total dose, every 30 minutes, or 1-2 U/kg; milk production: 2-10 U IM or via intranasal spray	Obstetrics: 2 U/kg IM, every 30 minutes; milk production: 1 U IM	Do not use if birth canal obstructed; refrigerate vial and warm syringe before injection	10 U/mL I; 40 U/mL nasal spray HM
Oxtriphylline	*(see choledyl)*				
Palladia	*(see toceranib)*				
Pamidronate (Aredia)	Bisphosphonate compound; hypercalcemia (e.g., due to	0.65-2 mg/kg diluted in 0.9% NaCl and give as IV CRI	—	Avoid calcium-containing fluids like LRS	30, 60, 90 mg vials I

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
	cholecalciferol intoxication)				HM
Pamprin	*(see acetaminophen)*				
Panacur	*(see fenbendazole)*				
Panadol	*(see acetaminophen)*				
Pancreatic enzymes (Pancrelipase, Viokase)	Pancreatic exocrine insufficiency	½-2 tsp powder in 1 lb (500 g) of canned food or 2 cups of moistened dry food; allow to stand 15-30 minutes, then feed	Same proportional to size of feeding	Avoid inhaling powder dust; Viokase brand has superior efficacy; gingival bleeding possible	VM, HM
Pancrelipase	*(see pancreatic enzymes)*				
Pantoprazole (Protonix, Pantoloc)	Injectable proton pump inhibitor	0.7-1 mg/kg IV q 24 h		Indicated for nonobstructive vomiting	40 mg vials I HM
Paracetamol	*(see acetaminophen)*				
Paramite	*(see phosmet dip)*				
Paraplatin	*(see carboplatin)*				
Paregoric	Opiate antidiarrheal	0.05-0.06 mg/kg PO q 12 h to q 8 h	None	May cause constipation; controlled drug	HM, S
Parlodel	*(see bromocriptine)*				
Paroxetine (Paxil)	Selective serotonin reuptake inhibitor	1 mg/kg PO q 24 h, usually for a minimum of several weeks	Total dose: 1.25-2.5 mg PO q 24 h per cat	Behavioral changes, anorexia possible; avoid combining with MAO inhibitors (Anipryl, amitraz, etc.)	10, 20, 30, 40, mg T; 12.5, 25 mg ER (Paxil CR) T HM
Paxil	*(see paroxetine)*				
Pedialyte	*(see oral rehydration solution)*				
D-penicillamine (Cuprimine, Depen)	Orally active chelating agent for lead and copper; used for aiding in the prevention of cysteine urolithiasis, copper storage disease	10-15 mg/kg PO q 12 h	—	Administer on empty stomach if tolerable; may cause vomiting, skin eruptions, and vascular lesions; monitor CBC	250 mg (Depen) T; 125, 250 mg (Cuprimine) C HM
Penicillin, benzathine (Benzapen)	G+ infections; some activity against anaerobes; bactericidal	20,000-40,000 U/kg IM, SQ q 48-72 h	Same	Long-acting formulation; do not use with penicillin hypersensitivity; do not use if serious infection is suspected; IM or SQ injection only	150,000 U/mL I VM
Penicillin G potassium or sodium	G+ infections; some activity against anaerobes; bactericidal	20,000-40,000 U/kg IV, IM, SQ q 4-6 h	Same	Penicillin hypersensitivity contraindicates; may contain high levels K+ (administer judiciously and monitor); solution for injection should be completely transparent; not effective orally	1 million, 5 million, 10 million, and 20 million U vials I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Penicillin G procaine (Wycillin, many others)	G+ infections; some activity against anaerobes; bactericidal	20,000-40,000 units/kg IM, SQ q 12-24 h	Same	Solution for injection is opaque = for IM/SQ injection only; penicillin hypersensitivity contraindicates	300,000 U/mL I VM
Penicillin-V	G+ infections; bactericidal; effective orally	5.5-11 mg/kg PO q 6-8 h	Same	250 mg = 400,000 U; avoid if penicillin hypersensitivity; GI upset possible	250, 500 mg T; 125, 250 mg/5 mL S; many other sizes HM
Pentasa	*(see mesalamine)*				
Pentazocine (Talwin)	Narcotic agonist/ antagonist used for short-term analgesia	1-3 mg/kg IM, 2-6 mg/ kg PO	2-3 mg/kg SQ, IM, IV	May cause salivation and/or sedation; reverse with naloxone; may cause dysphoria in cats	30 mg/mL I, HM; often combined with other Tx VM, HM
Pentobarbital (Nembutal, pentobarbitone)	Status epilepticus, general anesthesia	Anesthesia: 10-30 mg/ kg IV slowly to effect; seizures: 3-15 mg/kg IV slowly to effect	Anesthesia: 10-30 mg/kg IV slowly to effect; seizures: 3-15 mg/ kg IV slowly to effect	Respiratory depression and hypotension may develop if used alone or especially with or after diazepam	50 mg/mL I; available as tablets, elixir, suppositories VM, HM
Pentosan polysulfate (Elmiron)	Glycosaminoglycan-like agent; osteoarthritis (dogs); idiopathic cystitis (cats)	10 mg/kg PO or 3 mg/ kg IM; given once weekly for 4 weeks	8 mg/kg PO q 12 h	Rare adverse effects (e.g., vomiting) in dogs; experimental drug with minimal clinical data in cats; efficacy and safety unproven	100 mg C HM
Pentostam	*(see sodium stibogluconate)*				
Pentothal	*(see thiopental)*				
Pentoxifylline (Trental)	Increases plasticity of RBC membranes; used in many dermatoses, including dermatomyositis	10-25 mg/kg PO q 12 h	—	Few adverse effects reported	400 mg T HM
Pepcid	*(see famotidine)*				
Pepto-Bismol	*(see bismuth subsalicylate)*				
Percogesic	*(see acetaminophen)*				
Percorten-V	*(see desoxycorticosterone pivalate)*				
Periactin	*(see cyproheptadine)*				
Persantine	*(see dipyridamole)*				
PGF2-alpha	*(see prostaglandin)*				
Pharmorubicin	*(see epirubicin)*				
Phenobarbital	Long-acting barbiturate used for seizure control; occasionally used as a sedative	1-2 mg/kg PO q 8-12 h; okay to titrate slowly up to 16 mg/kg per day in divided doses; may be given IV as a bolus of 2-15 mg/kg slowly for status epilepticus followed by 2-6 mg/h CRI if necessary; maintain trough serum	Same	Ataxia, sedation, PU/PD; long-term (especially if >35 mcg/mL serum levels) hepatotoxicity occurs; initial adjustment period is required (liver enzyme inducer); if using higher dose IV, monitor respirations; controlled	8, 16, 32, 65, 100 mg T; 15, 20 mg/5 mL S; 30, 60, 65, 130 mg/mL I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
		levels at 15-45 mcg/mL		substance; see also Phenobarbital: • Adverse Effects/ Toxicosis, p. 871	
Phenoxybenzamine HCl (Dibenzyline)	Adrenergic, α-receptor blocking agent; urinary incontinence due to detrusor sphincter dyssynergia	0.25-1 mg/kg PO q 12 h	Total dose: 2.5-5 mg PO q 12-24 h per cat	May result in vomiting, hypotension/ hypertension, rapid HR, miosis; long (4-7 days) onset of action; no effect on postprostatic urethra of cats	10 mg C HM
Phenylbutazone (Butazolidin)	NSAID	10-15 mg/kg PO q 8-12 h	Not recommended	Use lowest effective dosage; do not exceed 800 mg per day; may cause vomiting, GI ulceration, BM suppression, nephrotoxicity; incidence of toxicosis is high; not generally recommended	100, 400, 1000 mg T VM, HM
Phenylephrine (Neo-Synephrine)	1. Postsynaptic 2. α-adrenergic stimulant used as the following: 3. As nasal drops for rhinitis 4. As IV infusion for treatment of hypotension	1. 1-2 drops intranasal pediatric solution, q 8-24 h 2. 1-3 mcg/kg per minute as IV CRI, adjusted to effect	Same	May cause nasal irritation if used chronically; vasoconstriction (systemic hypertension) and pupillary dilation if given parenterally (constant BP monitoring necessary); arrhythmogenic in combination with halothane	10 mg/mL I; OS and intranasal OTC products HM
Phenylpropanolamine (Propalin, PPA)	α-adrenergic agonist used for treating hormone-responsive urinary sphincter hypotonus (incontinence) by increasing urethral smooth muscle activity	1 mg/kg PO q 8 h	1-2 mg/kg PO q 8-12 h	Anxiety, dizziness, hypertension, tachycardia, urinary retention; no longer available as human OTC product	25, 50, 75 mg T 25 mg/mL S VM
Phenytoin (Dilantin)	Anticonvulsant agent	—	—	No longer recommended	—
Pheromones, feline synthetic facial (Feliway)	Behavioral disorders, acclimation to new environment	—	Topical application to surroundings	Spray may be applied to objects, or diffuser disseminates product in room	Spray pump or diffuser VM
Phosmet dip (Paramite)	Organophosphate dip for fleas, ticks, and canine sarcoptic mange	2 tbsp (1 oz) per gallon H_2O; sponge on and let air dry	Do not use	Wear gloves to use; use once weekly maximum; do not use in puppies <8 weeks old; avoid eye exposure; fever, salivation, seizures, and CNS signs suggest organophosphate toxicity (if such signs	11.6% dip VM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				occur, use atropine injection and wash off dog)	
Phosphate (IV supplementation)	*(see potassium phosphate)*				
Phosphate enemas (Fleet)	Treatment of constipation, bowel evacuation	For large dogs, use one adult bottle; for medium dogs, use ½ bottle or a pediatric enema; not recommended for use in small dogs (toxicity: hyperphosphatemia/ hypocalcemia)	Not recommended	May cause severe hyperphosphatemia and hypocalcemia in patients weighing <10 kg; do not use if patient is dehydrated, with renal or cardiac failure, or in very sick patients	OTC, HM
Phytonadione	*(see vitamin K1)*				
Pilocarpine ophthalmic solution	Miotic (muscarinic) agent useful in glaucoma, KCS	1 drop in affected eye q 6-12 h For KCS: 2-5 drops of 1% or 2% solution in food q 24 h	Same	Ciliary spasm; systemic signs rare when used topically; adjust dose according to time and response; V/D and better alternatives (cyclosporine) have meant less use for KCS	0.25, 0.5, 1, 2, 3, 4, 6, 8% OS HM
Pimobendan (Vetmedin)	Oral positive inotrope and vasodilator; effective adjunct Tx in CHF caused by DCM in Dobermans but not cocker spaniels	0.25 mg/kg PO q 12 h on empty stomach	None	Indicated as part of treatment for heart failure when dilated cardiomyopathy or mitral valve disease are confirmed	1.25, 2.5, 5 mg C or chewable T VM
Piperacillin (Pipracil)	Broad-spectrum parenteral penicillin	25-50 mg/kg IM or slow IV (20-30 minute infusion) q 8-12 h	—	Penetrates blood-brain barrier; CSF: serum concentration ratio = 0.06 (noninflamed) to 0.3 (inflammatory diseases)	2, 3, 4, 40 g I HM
Piperacillin + tazobactam (Zosyn)	Broad-spectrum parenteral penicillin with β-lactamase inhibitor	50 mg/kg slow (30 minutes) IV infusion q 6 h	—	Not compatible with LRS	2, 3, 4 g (with 0.25, 0.375, 0.5 g tazobactam, respectively) I HM
Piperazine	Ascarid infection	50-100 mg/kg PO	Same	Repeat in 3 weeks; vomiting and diarrhea may occur at higher dosages	250 mg T; 100 mg/ mL S VM, HM
Pipracil	*(see piperacillin)*				
Piroxicam (Feldene)	NSAID: as primary or secondary Tx for bladder TCC due to immunomodulatory effect; for chronic sterile rhinitis in cats	0.3 mg/kg PO q 48 h or q 24 h	Chronic sterile rhinitis: same, plus doxycycline, for 2-6 weeks	GI irritation, renal damage possible; must open capsules and put in food for most animals; often coadministered with misoprostol	10, 20 mg C HM
Pitocin	*(see oxytocin)*				
Pitressin	*(see vasopressin)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Pivampicillin (Pondocillin)	Penicillin antibacterial	30 mg/kg PO q 12 h		Used as empirical antibacterial in aborting bitches, pending culture and sensitivity	500 mg T 35 mg/mL S HM
Platinol	*(see cisplatin)*				
Plavix	*(see clopidogrel)*				
Polyethylene glycol electrolyte solution for endoscopy prep	*(see GoLytely)*				
Polyflex	*(see ampicillin)*				
Polysulfated glycosaminoglycan	*(see glycosaminoglycan-polysulfated)*				
Ponazuril (Marquis)	Antiprotozoal-giardiasis, cryptosporidiosis	7.5-15 mg/kg PO q 24 h × 28 days		Adverse effects of neurotoxicosis, keratitis possible	15% oral paste VM
Pondocillin	*(see pivampicillin)*				
Potassium bromide (KBr)	*(see bromide)*				
Potassium chloride injection	Treatment and prevention of hypokalemia	Add to IV fluid per liter based on serum K^+ level; serum K: 3.5-5 mEq/L = add 20 mEq KCl/L; 3-3.4 mEq/L = add 30 mEq KCl/L; 2.5-2.9 mEq/L = add 40 mEq KCl/L; 2-2.4 mEq/L = add 60 mEq KCl/L; <2 mEq/L = add 80 mEq KCl/L	Same	Never infuse rapidly; rate of infusion must never exceed 0.5 mEq KCl/kg/hr; monitor serum K^+ regularly and adjust dosage accordingly	2, 10, 20, 30, 40, 60, 90 mEq/mL I HM
Potassium chloride, oral	*(see potassium salts)*				
Potassium citrate (Urocit-K)	Inhibits calcium oxalate crystal formation in urine; alkalinizing agent for urine	75 mg/kg PO q 12 h; 1-2 mEq/kg PO per day		GI irritation; 5 mEq = 540 mg	5, 10 mEq T HM
Potassium gluconate	*(see potassium salts)*				
Potassium phosphate	Hypophosphatemia	0.01-0.03 mM/kg/h IV	Same	Hyperphosphatemia; recheck serum levels after 6 hours and adjust or stop; for potassium phosphate, 1 mM phosphate = 33 mg/dL phosphate; avoid calcium-containing fluids	5, 10, 15, 30, 50 mL vials (3 mM PO4 and 4.4 mEq K per mL for all) I HM
Potassium salts (Kaon Elixir, Micro-K Extencaps, Tumil-K)	Potassium supplements in various oral formulations	¼-1 tbsp (or oral paste or caps) PO q 8-12 h	1/8-¼ tbsp (or oral paste or caps) PO q 8-12 h	Dose according to deficit; monitor serum K; may cause gastric irritation	Many OTC preparations, different sizes VM, HM
Pralidoxime chloride (2-PAM, Protopam)	Reactivates cholinesterase inactivated by organophosphate	20-50 mg/kg IM or SQ; then q 8-12 h PRN	20 mg/kg IM or SQ, q 6-8 h, PRN	Monitor patient continuously; avoid IV administration (may cause acute laryngospasm); do not use for carbamate toxicity	1 g vial I HM
Prevacid	*(see lansoprazole)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Praziquantel (Droncit)	*Taenia, Dipylidium, Echinococcus, Heterobilharzia*	Use according to instructions on product according to weight; PO or SQ, IM	Same	Fasting not required; do not use in puppies <4 weeks old or kittens under 6 weeks of age	23, 34 mg T; 56.8 mg/mL VM; 600 mg T HM
Prazosin (Minipress)	α-adrenergic antagonist; balanced vasodilator; decreases urethral smooth muscle tone	Total dose: 0.5-2 mg PO q 12 h or q 8 h per dog	Total dose: 0.5-1 mg PO q 12 h to q 8 h per cat	Hypotension, depression, malaise	1, 2, 5 mg C
Precose	*(see acarbose)*				
Pred Forte	*(see prednisolone, ophthalmic suspension)*				
Prednisolone, prednisone	1. Replacement therapy (hypoadrenocorticism) 2. Antiinflammatory: antipruritic 3. Immune system suppression 4. Antineoplastic chemotherapy	1. 0.25-0.5 mg/kg PO q 24 h 2. Antiinflammatory 0.5-1 mg/kg PO, IM, SQ per day 3. Immune suppression: 2-4.4 mg/kg, usually PO, per day 4. 40 mg/m^2 PO, per day for 7 days; then 20 mg/m^2 PO q 48 h. See pp. 671, 677 for body weight to body surface area conversion chart.	Same	PU/PD; polyphagia; suppression of HPA axis: Cushing's syndrome; hepatopathy; opportunistic infections; muscle wasting; connective tissue and skin fragility; taper dosage if used long term	1, 2.5, 5, 10, 20, 25, 50 mg T; 1 mg/ mL S; 10, 25 mg/ mL I HM, VM
Prednisolone, ophthalmic suspension (Pred Forte)	Steroid-responsive inflammation of the lids, conjunctiva, sclera, cornea, and anterior segment of the eye	1 drop to affected eye q 6-12 h	Same	Variable strength products (0.12-1%) used as required; do not use with purulent, viral, or fungal infection or with corneal ulcers; systemic side effects are possible but rare	0.12, 0.125, 1% OS HM
Prednisolone sodium succinate (Solu-Delta-Cortef)	Soluble corticosteroid used IV for shock of multiple causes	5-33 mg/kg IV slow bolus; repeat up to q 6 h; spinal injury: 30 mg/kg IV	Same	Causes vomiting if administered too rapidly; glucocorticoid precautions/risks	100, 500 mg vials I VM
Pregabalin (Lyrica)	Pain, paresthesias	2-4 mg/kg PO q 8-12 h		Indicated as part of treatment for caudal occipital malformation and other neurologic disorders	25, 50, 75, 100, 150, 200, 225, 300 mg C HM
Premarin	*(see estrogen-conjugated)*				
Prepulsid	*(see cisapride)*				
Prevacid	*(see lansoprazole)*				
Previcox	*(see firocoxib)*				
prilactone	*(see spironolactone)*				
Prilium	*(see imidapril)*				
Prilosec	*(see omeprazole)*				
Primaxin	*(see imipenem)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Primidone (Mylepsin)	Anticonvulsant medication hepatically converted to phenobarbital	3-8 mg/kg PO q 8 h; initially up to 16 mg/ kg PO q 8 h (adjust based on serum phenobarbital levels)		Causes PU/PD/PP, sedation, and ataxia. Often hepatotoxic with prolonged use. No benefit over phenobarbital; no longer recommended	50, 250 mg T; 50 mg/mL S HM
Primor	*(see sulfadimethoxine/ ormetoprim)*				
Prinivil	*(see lisinopril)*				
Pro-Banthine	*(see propantheline)*				
Procainamide (Pronestyl SR, Procan-SR)	Ventricular arrhythmias	6-20 mg/kg IV slowly over 30 minutes, then IV CRI 0.02-0.04 mg/kg/min (20-40 mcg/kg/min) if life threatening; 6-20 mg/kg IM or PO q 4 h (q 8 h PO if ER)	1-2 mg/kg bolus IV; then 0.01-0.02 mg/ kg/min (10-20 mcg/kg/min) IV CRI	Available as extended-release tablet for q 8 h administration (absorption questionable); optimum serum level = 3-20 mcg/mL); increasingly difficult to obtain, low demand in human cardiology	100, 500 mg/mL I; 250, 375, 500 mg C, T; 250, 500, 750, 1000 mg ER C, T HM
ProcalAmine	*(see amino acid solution 3% and glycerin injection with electrolytes)*				
Procan-SR	*(see procainamide)*				
Procarbazine (Matulane)	Lymphoma rescue protocol, granulomatous meningoencephalitis	25-50 mg/m^2 PO q 24 h		Crosses blood-brain barrier well; risk of myelotoxicosis, GI effects	50 mg C HM
Prochlorperazine (Compazine)	Antiemetic	0.11-0.44 mg/kg SQ, IM q 6-12 h	Same	Sedation, hypotension, anticholinergic side effects (dry mouth, GI hypomotility); do not use in epileptic patients; available also in suppository formulation	5 mg/mL I; 1 mg/ mL S; 5, 10, 25 mg T; 10, 15, 30 mg ER HM
Procrit	*(see erythropoietin)*				
Proglycem	*(see diazoxide)*				
Prograf	*(see tacrolimus)*				
Program	*(see lufenuron)*				
ProHeart	*(see moxidectin)*				
PromAce	*(see acepromazine)*				
ProMeris	*(see metaflumizone)*				
Pronestyl	*(see procainamide)*				
Propalin	*(see phenylpropanol-amine)*				
Propantheline (Pro-Banthine)	Anticholinergic agent used for treating diarrhea, bradycardia syndromes, and detrusor hyperreflexia	0.2-0.5 mg/kg PO q 8-24 h; increase to effect for bradycardia syndromes	Same	Tachycardia, dry mouth, constipation, mydriasis, ileus, urinary retention	7.5, 15 mg T HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Propionibacterium acnes (Immunoregulin)	Immune modulator/ potentiator	0.03-0.07 mg/kg IV at 2-3 day intervals	Total dose: 0.2 mg per cat IV 1-2 times a week	No controlled studies	0.4 mg/mL I VM
Propofol (Diprivan, Rapinovet)	Ultrashort (5-7 minutes) acting anesthetic; no cumulative effect with repeated administration	3-6 mg/kg IV	Same	Give slowly over 1-2 minutes in equal dosages to effect; agent provides no analgesia: consider opiate premed and/or inhalant anesthetic if minor (or other) surgical procedures	10 mg/mL I HM, VM
Propranolol (Inderal)	β-Adrenergic blocking agent used for treating supraventricular arrhythmias, some ventricular arrhythmias, and feline hypertrophic cardiomyopathy	For acute tachycardias: 0.1-0.5 mg IV total dose per bolus; no more frequently than 1 bolus q 1-3 min to 5 mg maximum (largest dog); administer until the rate slows; chronic use: 0.2-1 mg/kg q 8-12 h PO, usually start low and titrate dosage upward to effect	0.1-0.5 mg IV bolus slowly; 2.5-5 mg PO q 8-12 h, begin low and titrate dosage	Anorexia, apnea, depression, ataxia; bradycardia, negative inotropic effect: potentiates AV nodal depression of digoxin and calcium channel blockers; underlying cause of tachycardia (e.g., heart failure, hypovolemia) must be addressed before IV propranolol; beta-2 effects = contraindicated if asthma	10, 20, 40, 60, 80, 90 mg T; 60, 80, 120, 160 mg ER; 4, 8, 80 mg/mL S; 1 mg/mL I HM
Propulsid	*(see cisapride)*				
Propylthiouracil (PTU)	Feline hyperthyroidism	Not used	10 mg/kg PO q 8-12 h	Immune-mediated hemolytic anemia and thrombocytopenia; anorexia, vomiting, and lethargy; risk of adverse effects frequently outweighs potential benefit	50 mg T HM
Proscar	*(see finasteride)*				
ProSpot	*(see fenthion)*				
Prostaglandin (PGF2-α, Lutalyse, Dinoprost, Dinolytic)	1. Open-cervix pyometra 2. Abortive agent at 31-35 days	1. Day 1: 0.1 mg/kg SQ once; day 2: 0.2 mg/ kg SQ once; days 3-7: 0.25 mg/kg SQ, q 24 h 2. 0.1 mg/kg SQ, q 8 h for 2 days, then 0.2 mg/kg SQ, q 8 h for 3-7 days (or until fetuses are expelled)	0.1 mg/kg SQ, q 12 h for 5 days 0.5-1 mg/kg SQ for 2 days	Panting, salivation, vomiting, diarrhea, colic, and tachycardia lasting about 30 minutes; should be given under hospital supervision	5 mg/mL I VM
Prostaphlin	*(see oxacillin)*				
Prostigmin	*(see neostigmine)*				
Protonix	*(see pantoprazole)*				
Protopam	*(see pralidoxime)*				
Protopic	*(see tacrolimus)*				
Protropin	*(see growth hormone, human)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Proventil	*(see albuterol)*				
Provera	*(see medroxyprogesterone acetate)*				
Prozac	*(see fluoxetine)*				
Prussian blue	*(see ferric cyanoferrate)*				
Pseudoephedrine	Urethral sphincter mechanism incompetence/ incontinence; retrograde ejaculation	0.2-0.4 mg/kg PO q 8-12 h	—	Narrow window between therapeutic and toxic doses; use with caution if sympathetic drive could be harmful (heart disease, hypertension, hyperthyroidism, etc.) or if CNS abnormalities	30, 60, 120 mg T HM, OTC
Psyllium mucilloid (Metamucil)	Bulk laxative, stool softener	2-10 g PO, q 12-24 h in moistened food	2-4 g PO, q 12-24 h, in moistened food	Titrate dose based on stool consistency; may also be used for treating fiber-responsive diarrhea	OTC, HM
PTU	*(see propylthiouracil)*				
Pyoben	*(see benzoyl peroxide)*				
Pyopen	*(see carbenicillin)*				
Pyrantel pamoate (Nemex, Pyr-A-Pam, Strongid-T)	Roundworm and hookworm anthelmintic	5-10 mg/kg PO	10 mg/kg PO	Repeat in 3 weeks; safe at recommended dosages, including in dogs with heartworms	22.7, 113.5 mg T; 2.27, 4.54, 50 mg/ mL S VM
Pyr-A-Pam	*(see pyrantel pamoate)*				
Pyridostigmine bromide (Mestinon)	Anticholinesterase agent used for treating myasthenia gravis	0.2-2 mg/kg PO q 8-12 h	0.25 mg/kg PO maximum of once daily	Available as soft tablet and syrup (60 mg/5 mL); vomiting, diarrhea, salivation, and weakness may develop	60 mg T; 180 mg ER; 12 mg/mL S; 5 mg/mL I HM
Pyrimethamine (Daraprim)	Folic acid antagonist, toxoplasmosis, neosporosis, hepatozoonosis	0.5-1 mg/kg PO q 24 h for 48 hours, then 0.25 mg/kg PO q 24 h for 14 days	Same	Often used with sulfonamides to treat toxoplasmosis; BM suppression due to folate deficiency; may need to supplement with folic or folinic acid; teratogenic	25 mg T HM
PZI	*(see insulin)*				
Quibron	Bronchodilator expectorant; combination of theophylline and guaifenesin	1 capsule PO q 8-12 h in large breeds only	Not recommended	Hyperexcitability, vomiting	150, 300 mg C; 300 mg T; 300 mg ER HM
Quinacrine (Atabrine)	Giardiasis, enteric coccidiosis	10 mg/kg PO q 24 h for 5-12 days	11 mg/kg PO q 24 h for 5 days	May cause enteric signs; considered second line agent	100 mg T HM
Quinaglute	*(see quinidine)*				
Quinidex	*(see quinidine)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Quinidine (Quinaglute, Quinidex)	Type Ia antiarrhythmic agent; used mostly for ventricular dysrhythmias; conversion of acute-onset atrial fibrillation	6-20 mg/kg PO, IM q 6-8 h	Not recommended	Do not give IV or use with digitalis; increasingly difficult to obtain due to decreased use in human cardiology	100, 200, 300 mg T; 275, 300, 330 mg ER; 80 mg/mL I HM
Radiogardase	*(see ferric cyanoferrate)*				
Ramipril (Altace, Vasotop)	ACE inhibitor	0.125 mg/kg PO q 12 h	0.5 mg/kg PO q 24 h	Licensed for VM use in Europe	1.25, 2.5, 5, 10 mg C HM 0.625, 1.25, 2.5, 5, 10 T, VM
Ranitidine HCl (Zantac)	H2 histamine receptor antagonist; promotility agent (e.g., cats with constipation)	1-2 mg/kg PO, SQ, IM, slow IV q 8-12 h	Same	GI prokinetic effects due to anticholinesterase activity; slow IV (bolus may cause immediate vomiting); shown to fail to reduce gastric pH in the dog	75, 150, 300 mg T; 15 mg/mL S; 25 mg/mL I HM
Rapinovet	*(see propofol)*				
Reconcile	*(see fluoxetine)*				
Reglan	*(see metoclopramide)*				
Regulin	*(see melatonin)*				
Remeron	*(see mirtazapine)*				
Requa	*(see activated charcoal)*				
Retrovir	*(see azidothymidine)*				
ReVia	*(see naltrexone)*				
Revolution	*(see selamectin)*				
Rheomacrodex	*(see dextran)*				
r-Hu-EPO	*(see erythropoietin)*				
Ridaura	*(see auranofin)*				
Rifadin	*(see rifampin)*				
Rifampin (Rifadin)	Antimycobacterial antibacterial agent	5-10 mg/kg PO, IV q 12-24 h	5-10 mg/kg PO, IV q 24 h	A part of protocols with other antiinfectives for better efficacy, less resistance	150, 300 mg T; 600 mg I HM
Rimadyl	*(see carprofen)*				
Rintal	*(see febantel)*				
Ripercol	*(see levamisole)*				
Robamox-V	*(see amoxicillin)*				
Robaxin	*(see methocarbamol)*				
Robinul	*(see glycopyrrolate)*				
Rocaltrol	*(see calcitriol)*				
Rocephin	*(see ceftriaxone)*				
Roferon	*(see interferon-alfa)*				
Romazicon	*(see flumazenil)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Rompun	*(see xylazine)*				
Ronidazole	Trichomoniasis		30 mg/kg PO q 12 h × 14 days	Neuro adverse effects possible; must be compounded into capsules for palatability	10% powder (100 mg/g) VM
Rotenone (topical ointment)	*(see Goodwinol)*				
RU-486	*(see mifepristone)*				
Rutin	Chylothorax; benzopyrone recommended for treatment of chylous pleural effusion; reportedly potentiates macrophage function	—	50 mg/kg PO q 8 h; total dose 250 mg PO q 8 h per cat or 500 mg PO q 12 h per cat	Generally purchased in health food stores	500 mg T OTC
S-adenosyl methionine	*(see methionine, S-adenosyl)*				
Safe-Guard	*(see fenbendazole)*				
Salix	*(see furosemide)*				
Salbutamol	*(see albuterol)*				
Salmeterol (Serevent)	Inhaled long-acting β2-agonist bronchodilator	1 puff PRN q 12-24 h	Same	Takes >1 hour to take effect	6.5, 13 g inhalation canisters (0.025 mg [25 mcg] per puff) HM
SAMe	*(see methionine, S-adenosyl)*				
Sandimmune	*(see cyclosporine-systemic)*				
Sandostatin	*(see octreotide)*				
Scolaban	*(see bunamidine)*				
Selamectin (Revolution)	Endectoside; topical for fleas, ticks, ear mites, heartworm prevention, sarcoptic mange, intestinal hookworms, and roundworms	Approximately 6 mg/kg topically according to dosage on packaging; 1 application per month	Same	Use in dogs or cats >6 weeks old; for heartworm prevention: give within 1 month of first exposure to mosquitos and continue until within 1 month of last exposure	Prepackaged doses (topical liquid in plastic ampules) VM
Selegiline (deprenyl, Anipryl, Eldepryl)	Restores central dopamine levels: MAO inhibitor; used for treating cognitive dysfunction syndrome; may be helpful in selected PDH canine Cushing's cases	PDH: 1 mg/kg PO per day for 30 days, then may increase dosage to 2 mg/kg per day if no response; CDS: 0.5 mg/kg daily; may double dose after 1 month if ineffective	Not recommended	Low level of effectiveness reported; not to be used with other MAO inhibitors (e.g., antidepressants, amitraz)	2, 5, 10, 15, 30 mg T, VM; 5 mg C, T HM
Sentinel	*(see mibemycin)*				
Septra	*(see trimethoprim/sulfamethoxazole)*				
Serax	*(see oxazepam)*				
Serevent	*(see salmeterol)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Sertraline (Zoloft)	Selective serotonin reuptake inhibitor	0.25-1 mg/kg PO q 24 h	0.5-1 mg/kg PO q 24 h	Anxiety, aggression, or obsessive-compulsive disorders; inappropriate elimination.	25, 50, 100 mg T 20 mg/mL S HM
Sildenafil (Viagra)	Pulmonary hypertension	0.5-1 mg/kg PO q 8 h	—		25, 50, 100 mg T HM
Silvadene cream	*(see silver sulfadiazine)*				
Silver sulfadiazine (Silvadene cream)	Topical antiinfective preparation for complications of burns	Apply to burn area q 12 h as necessary	Same	Hypersensitivity to sulfonamides; KCS; Dobermans	10 mg/g O HM
Silymarin (milk thistle extract, Marin)	Hepatopathy	50-250 mg PO q 24 h	4-8 mg/kg PO q 24 h	Nutraceutical; also compounded with SAMe (Denamarin); wide range of safety	9, 24, 70 mg T VM
Simplicef	*(see cefpodoxime)*				
Sinequan	*(see doxepin)*				
Slentrol	*(see dirlotapide)*				
Slo-Bid	*(see theophylline, sustained action)*				
Sodium bicarbonate	Metabolic acidosis, urine alkalinization (e.g., intoxication)	mEq/day = (desired serum [HCO3] − present serum [HCO3]) × 0.3 × BW (kilograms); administer 50% over 15 minutes and recheck serum levels; then give the balance over 24 hours	Same	Alkalosis, hypernatremia, CHF, hypokalemia; correct inciting factors concurrently (or prior to HCO3 Tx); 84 mg NaHCO3 contains 1 mEq HCO3	0.6, 1 mEq/mL I; 5, 10 grain T HM
Sodium iodide 20%	Sporotrichosis	15 mg/kg PO q 8 h; some higher doses reported	Same	Monitor for iodinism: fever, ptyalism, GI signs; contains 0.1 mg iodine/mL	20% (200 mg/mL) S VM
Sodium stibogluconate (Pentostam)	Leishmaniasis	30-50 mg/kg SQ, IV q 24 h; or 10-20 mg/ kg IM q 24 h for 20-28 days	—	Not available in United States except through the Centers for Disease Control and Prevention	100 mL vials (100 mg/mL) I HM
Solganal	*(see aurothioglucose)*				
Soloxine	*(see levothyroxine sodium)*				
Solu-Cortef	*(see hydrocortisone sodium succinate)*				
Solu-Delta-Cortef	*(see prednisolone sodium succinate)*				
Solu-Medrol	*(see methylprednisolone sodium succinate)*				
Somatrem	*(see growth hormone, human)*				
Soriatane	*(see acitretin)*				
Sotalol (Betapace)	Classes II and III antiarrhythmic agent; used primarily for treating ventricular	1-3 mg/kg PO q 12 h	Total dose: 10-40 mg PO q 12 h per cat; very little	β-blocking effects seen at low dosages; type III effects at higher levels; begin	80, 120, 160, 240 mg T HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
	tachyarrhythmias		published experience with drug in cats	low and titrate upwards to effect	
Spinosad (Comfortis)	Flea infestation	30-60 mg/kg PO q 30 days		Acts within 30 minutes, duration of effect = 1 month. Side-effects can include vomiting, CNS signs; ensure dose <60 mg/kg in epileptics (or use alternative).	140, 270, 560, 810, 1620 mg T VM
Spironolactone (Aldactone, Prilactone)	Potassium-sparing diuretic; inhibits aldosterone	1-4 mg/kg PO q 12-24 h	Same	Usually used with other diuretic agents; monitor potassium (hyperkalemia); mild to no diuretic effect as monotherapy in the dog; licensed for VM in Europe; relatively contraindicated in cats (33% incidence of severe ulcerative facial dermatitis)	25, 50, 100 mg T HM 10, 40, 80 mg T VM
Sporanox	*(see itraconazole)*				
Spot-on	*(see fenthion)*				
Stadol	*(see butorphanol)*				
Stanozolol (Winstrol)	Anabolic steroid used for treating anorexia, debilitation, and anemia	0.1-0.2 mg/kg PO q 12-24 h; total dose: 25-50 mg IM weekly per dog	0.1-0.2 mg/kg PO q 24 h to q 12 h; total dose: 12.5-25 mg IM weekly per cat	Contraindicated in pregnancy; hepatotoxicity in cats; controlled drug	2 mg T; 50 mg/mL I VM, HM
Stibogluconate	*(see sodium stibogluconate)*				
Stoxil	*(see idoxuridine)*				
Streptase	*(see streptokinase)*				
Streptokinase (Kabikinase, Streptase)	Thrombolytic drug; arterial or pulmonary thromboembolism	90,000 IU/kg IV over 30 minutes, then 45,000 IU/kg per hour for 7-12 hours based on response	Same	Bleeding diathesis; hyperkalemia from reperfusion; intracardiac thrombus is an absolute contraindication; complications cancel benefits in feline aortic thromboemboli	250,000, 600,000, 750,000, 1.5 million U vials I HM
Streptozotocin (streptozocin, Zanosar)	Insulinoma chemotherapy	500 mg/m^2 infusion preceded and followed by extensive IV fluid diuresis	—	Nephrotoxicity; hepatotoxicity; BM suppression	1 g I HM
Strongid-T	*(see pyrantel pamoate)*				
Sublimaze	*(see fentanyl)*				
Succimer (*meso*-2, 3 dimercaptosuccinic acid, Chemet)	Lead toxicity chelating agent	10 mg/kg PO, q 8 h, for 10-17 days	Same	May need second course of therapy; accesses intracellular sites, including CNS; vomiting, sulfurous odor of breath	100 mg C HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Sucralfate (Carafate, Sulcrate)	Complexes with proteinaceous material in stomach, thereby preventing undesirable effects of acids on the gastric mucosa	Total dose: 250-1000 mg PO q 6-8 h per dog	Total dose: 250 mg PO q 6-12 h per cat	May constipate; interferes with absorption of many drugs administered concurrently	1 g T, 100 mg/mL S HM
Sudafed	*(see pseudoephedrine)*				
Sulfadiazine (Sulfadyne, Sulcrate)	1. Bacteriostatic agent used for treating toxoplasmosis, nocardiosis 2. Soft tissue/UTIs	1. 80 mg/kg PO q 8 h 2. 30 mg/kg PO q 24 h	Same	Sulfonamide precautions, KCS, idiosyncratic toxicities, Dobermans	500 mg T VM, HM
Sulfadiazine/ trimethoprim	*(see trimethoprim/ sulfadiazine)*				
Sulfadimethoxine (Bactrovet, Albon)	Bacteriostatic agent used for treating toxoplasmosis, nocardiosis, and coccidiosis	50 mg/kg PO day 1; then 25 mg/kg PO q 24 h	Same	KCS, nephrotoxicity, hypersensitivity	400 mg/mL I; 125, 250, 500 mg T; 50, 125 mg/mL S VM, HM
Sulfadimethoxine/ ormetoprim (Primor)	Potentiated sulfonamide	27-55 mg/kg PO q 24 h on day 1; then 13.5-27.5 mg/kg q 24 h thereafter for a maximum of 21 days	None	Sulfonamide contraindications; each tablet is 83% sulfa and 17% ormetoprim	120, 240, 600, 1200 mg T VM
Sulfadyne	*(see sulfadiazine)*				
Sulfamethoxazole/ trimethoprim	*(see trimethoprim/ sulfamethoxazole)*				
Sulfasalazine (Azulfidine)	Antiinflammatory effect on the colon; ulcerative and idiopathic colitis	22-55 mg/kg PO q 8 h	10-20 mg/kg PO q 12 h for 3-5 days	Avoid prolonged treatment; KCS, blood dyscrasias, vomiting; caution in cats: salicylate component could be toxic	500 mg T HM
Sulfodip	*(see lime sulfur solution)*				
Suprax	*(see cefixime)*				
Surfak	*(see dioctyl sodium sulfosuccinate)*				
Surital	*(see thiamylal Na)*				
Symmetrel	*(see amantadine)*				
Synotic	*(see fluocinolone 0.01% with 60% DMSO)*				
Synthroid	*(see levothyroxine sodium)*				
Syntocinon	*(see oxytocin)*				
Syprine	*(see trientene)*				
Tabloid	*(see thioguanine)*				
Tacrolimus (Prograf, Protopic)	Immune-mediated hemolytic anemia and other autoimmune disorders; topical: atopy, perianal fistula	0.16 mg/kg IM q 24 h; 1 mg/kg PO q 24 h	—	Sparsely reported systemic use at the time of this writing; narrow therapeutic-toxic range, with frequent negative side effects; these doses are	1 mg, 5 mg T; 5 mg/mL, I; 0.3% lotion HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
				associated with adverse effects, so titrate to keep trough serum level 0.1-0.4 ng/mL (dogs); vasculitis, anorexia, intussusception; wear gloves when applying topical formulation	
Tadalafil (Cialis)	Longer-acting phosphodiesterase inhibitor; pulmonary hypertension	1 mg/kg PO q 48 h	—	Very new drug; investigational and unsupported use in veterinary medicine at this time; case reports and anecdotal descriptions of benefit, but side effects poorly documented	5, 10, 20 mg T HM
Tagamet	*(see cimetidine)*				
Talwin	*(see pentazocine)*				
Tamiflu	*(see oseltamivir)*				
Tamsulosin (Flomax, Urimax)	α1a-adrenergic antagonist; benign prostatic hyperplasia	0.01 mg/kg PO q 12-24 h		Efficacy and safety unproven in VM; investigational	0.4 mg C HM
Tapazole	*(see methimazole)*				
Tardak	*(see delmadinone)*				
Task	*(see dichlorvos)*				
Taurine	Feline DCM; canine DCM in American cocker spaniels, retriever breeds, many others; retinopathy	50 mg/kg PO q 8-12 h; or total dose 500-1000 mg PO q 12 h per dog	Total dose: 125-250 mg PO q 12 h per cat	Switch to taurine-enriched diet if relevant (many are already on balanced diet)	250 mg T OTC, HM
Tavist	*(see clemastine fumarate)*				
Tazicef	*(see ceftazidime)*				
Tegison	*(see etretinate)*				
Telazol	*(see tiletamine-zolazepam)*				
Telmintic	*(see mebendazole)*				
Temaril-P	*(see trimeprazine)*				
Tempra	*(see acetaminophen)*				
Tenormin	*(see atenolol)*				
Tensilon	*(see edrophonium Cl)*				
Tepoxalin (Zubrin)	NSAID (broad-spectrum COX and leukotrienes)	10 mg/kg PO q 24 h	—	Gastritis, diarrhea, hepatopathy, renal effects	30, 50, 100, 200 mg T VM
Terbutaline (Brethine)	Bronchodilator via specific β2 stimulation	Total dose: 0.625-5 mg PO q 8-12 h per dog	Total dose: 0.625-1.25 mg PO q 12 h per cat. Acute: 0.05-0.1 mg/kg IM or SQ	Excitability, vomiting, tachycardia; may also be used for halting premature uterine contractions	2.5, 5 mg T; 1 mg/mL I HM
Terramycin	*(see oxytetracycline)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Testosterone	Testosterone responsive incontinence in male dogs and cats	2.2 mg/kg IM monthly	Total dose: 5-10 mg IM per cat.	Hepatopathy; behavioral changes; controlled drug	25, 50, 100, 200 mg/mL I HM
Tetracycline	Broad-spectrum antibiotic; bacteriostatic; used especially for *Brucella, Chlamydia, Leptospira, Mycoplasma*, and *Rickettsia;* used for pleurodesis; used with niacinamide for autoimmune dermatopathies; used as an ophthalmic ointment	10-22 mg/kg q 8 h PO for 3 weeks; pleurodesis: 20 mg/ kg in 4 mL saline/kg intrapleural; ophthalmic ointment: apply q 6-8 h	Same	Fever, vomiting, diarrhea, photosensitivity; do not administer with dairy products, antacids, intestinal adsorbents; do not give in last 3 weeks of pregnancy or to newborns/pediatric animals; cats more sensitive to adverse effects	100, 250, 500 mg T/C; 25 mg/mL S; 250, 500 mg/vial I; 10 mg/g OO; 10 mg/mL OS HM, VM
Theo-Dur	*(see theophylline, sustained action)*				
Theophylline elixir (Elixophyllin)	Bronchodilator	6-11 mg/kg PO q 8 h	Rarely used: 8 mg/kg PO q 12 h	*(see aminophylline);* restlessness, vomiting	16 mg/mL S HM
Theophylline, sustained action (Slo-Bid, Theo-Dur)	Long-acting bronchodilator	5-15 mg/kg PO q 12-24 h	Same but infrequently utilized (adverse effects)	Hyperexcitability common; nausea or vomiting: stop drug	100, 200, 300 mg ER HM
Thiabendazole (Mintezol)	Aspergillosis, penicilliosis, *Filaroides (Oslerus)*, and feline eosinophilic granuloma complex; topical: ear mites dermatophytes	50 mg/kg PO q 24 h for 3 days; repeat in 1 month	5-10 mg/kg PO q 24 h 3 times weekly	Not licensed for feline use; dachshunds uniquely sensitive	500 mg T; 100 mg/ mL S VM
Thiacetarsemide (Caparsolate)	Heartworm adulticide; hemobartonellosis *(Mycoplasma haemofelis)*	2.2 mg/kg q 12 h slow IV for 4 doses	1.1-2.2 mg/kg q 12 h slow IV for 4 doses; often not recommended	Largely replaced by melarsomine; vomiting, depression, hepatotoxicity (icterus), nephrotoxicity; thromboembolic phenomena 7-28 days post Tx; perivenous injection causes sloughing; acute pulmonary edema in cats	10 mg/mL I VM
Thiamazole	*(see methimazole)*				
Thiamine (vitamin B1)	Thiamine deficiency; lead poisoning	Total dose: 10-100 mg IM, IV, PO q 12 h per dog	Total dose: 50 mg IM, IV, PO q 12 h per cat	Stings IM	100, 200 mg/mL I; 5, 10, 25, 50, 100, 250, 500 mg T; HM
Thiamylal Na (Surital)	Ultrashort-acting barbiturate anesthetic	11-17.5 mg/kg IV titrated to induction of anesthesia	Same	*(see thiopental)*	Not available currently; may return to the market; 1, 5, 10 g vials I
Thioguanine (Tabloid)	Antineoplastic, acute leukemias	40 mg/m^2 PO q 24 h for 4-5 days, then every 3 days	25 mg/m^2 PO q 24 h for 1-5 days, then every 30 days	BM, GI, hepatic adverse effects possible	40 mg T HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Thiopental sodium (Pentothal)	Ultrashort-acting anesthetic	13-26 mg/kg IV titrated to induction of anesthesia	Same	Respiratory and cardiac depression; avoid perivenous administration; ventricular bigeminy common; sight hounds more sensitive	1, 2.5, 5 g vials I HM
Thorazine	*(see chlorpromazine)*				
Thytropar	*(see thyrotropin TSH)*				
Thyrotropin TSH (thyroid-stimulating hormone, Dermathycin, Thytropar)	Hormone used for diagnosis of hypothyroidism	Total doses: 5 U per dog to 10 kg IV, IM, SQ; 10 U per dog over 10 kg IV, IM, SQ	Total dose: 2.5 U per cat IM or IV	Follow protocol for testing; preinjection and 6 hours post-IM or post-IV injection	5, 10 U/vial I VM, HM
Thyroxine	*(see levothyroxine sodium)*				
Ticarcillin-clavulanate (Timentin)	Broad-spectrum penicillin-clavulanic acid combination	50-100 mg/kg slow IV q 8 h	40-50 mg/kg IM or slow IV q 6-8 h	GI upset	3 g vials I HM
Tigan	*(see trimethobenzamide)*				
Tiletamine zolazepam (Telazol)	Tranquilizer, dissociative anesthetic combination agent; used for chemical restraint or minor surgical procedures	5-12 mg/kg IM	Same	Rapid onset; respiratory depression may occur quickly (be prepared for intubation); controlled drug	100 mg/mL combined (50 mg each per mL) I VM
Timentin	*(see ticarcillin-clavulanate)*				
Timolol solution (Timoptic)	β-blocking topical agent used for decreasing intraocular pressures due to glaucoma	1 drop in eye q 12 h	Same	Potentiation of β-blocking effects possible (asthmatics, cardiac patients); avoid 0.25% solution (ineffective); often used in combination with other glaucoma drugs (weak action)	0.25, 0.5% OS HM
Timoptic	*(see timolol solution)*				
Titralac	*(see calcium carbonate)*				
Tocainide (Tonocard)	Class Ib antiarrhythmic agent for ventricular tachyarrhythmias	15-20 mg/kg q 8-12 h PO	—	Anorexia, GI signs, weakness, head bobbing, other CNS effects possible (lidocaine-like), corneal dystrophy; possibly adverse renal effects; may need to use with other class Ia drugs for maximum effect	400, 600 mg T HM
Toceranib (Palladia)	Mast cell tumor	2.5-3.25 mg/kg PO q 48 h		Tyrosine kinase inhibitor; possibly effective in treating other malignancies; consider just 3× /wk (Mon-Wed-Fri) if other illnesses, drug intolerance	10, 15, 50 mg T VM
Tocopherol	*(see vitamin E)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Tofranil	*(see imipramine)*				
Tolfedine	*(see tolfenamic acid)*				
Tolfenamic acid (Tolfedine)	Oral/injectable NSAID	4 mg/kg SQ or IM once, then PO q 24 h for 2-4 days; may continue oral regimen 3-5 consecutive days per week	4 mg/kg SQ or IM once, then PO q 24 h for 2-4 days	Approved for veterinary use in Canada and Europe but not in the United States	6, 30, 60 mg T; 40 mg/mL I VM
Tonocard	*(see tocainide)*				
Toprol-XL	*(see metoprolol)*				
Torbugesic	*(see butorphanol)*				
Torbutrol	*(see butorphanol)*				
Torsemide (Demadex)	Loop diuretic	0.2 mg/kg PO q 12 h		Possibly less diuretic resistance than furosemide in dogs; monitor serum renal values and electrolyte levels	5, 10, 20, 100 mg T 10 mg/mL I VM
Toxiban	*(see activated charcoal)*				
Tracrium	*(see atracurium)*				
Tramadol (Ultram)	Analgesia; orally active opiate (mu-receptor agonist)	1-4 mg/kg PO q 8-12 h	1-2 mg/kg PO q 12 h	Tramacet, Ultracet are tramadol + acetaminophen (do not use in cats); partial antagonism possible with naloxone	50 mg T HM
Tramisol	*(see levamisole)*				
Tranxene	*(see clorazepate)*				
Trental	*(see pentoxifylline)*				
Tresaderm	Otitis externa with allergic/bacterial/fungal component(s)	2-12 drops per ear (proportional to size of ear) q 12 h	2 drops per ear, q 12 h	Combination neomycin + thiabendazole + triamcinolone; corticosteroid absorbed systemically; avoid prolonged daily use	Neomycin 0.25% + thiabendazole 4% + triamcinolone 0.1% otic VM
Triamcinolone (Vetalog, Kenalog)	Intermediate-acting corticosteroid used PO; by injection IM, SQ, or intralesional	0.1-0.22 mg/kg IM, SQ, PO	Same	Corticosteroid effects	0.5, 1.5 mg T; 2, 6 mg/mL I HM, VM
Tribrissen	*(see trimethoprim/ sulfadiazine)*				
Trientine (Syprine)	Alternative to penicillamine to chelate copper	10-15 mg/kg PO q 12 h	—	*(see penicillamine)*	250 mg C HM
Trifluridine (Viroptic)	Antiherpetic viral agent	—	At least 2-4× daily to eyes	—	1% OS
Triiodothyronine (T3, Cytomel, Cytobin, Liothyronine)	Hypothyroidism; used when patient is unable to convert thyroxine to triiodothyronine; also diagnostically as T3 suppression test	0.004-0.006 mg/kg (4-6 mcg/kg) PO q 8 h	0.0044 mg/kg (4.4 mcg/kg) PO q 8-12 h; T3 suppression; 0.025 mg (25 mcg) total	Thyrotoxicosis, PU/PD, polyphagia, nervousness, panting, tachycardia	5, 25, 50 mcg T

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
			per-cat dose PO q 8 h for 7 doses, then blood for T4 and T3 (control)		
Trilostane (Vetoryl)	Steroid analog (competitive inhibitor of 3β-hydroxysteroid dehydrogenase); treatment for pituitary-dependent hyperadrenocorticism	1-9 mg/kg PO q 24 h; divided doses (q 12 h) better tolerated by some dogs; begin low and uptitrate	—	Adrenal necrosis possible; with long-term treatment, make adjustments in 20- or 30-mg increments as dictated by clinical response and ACTH stimulation testing	60, 120 mg T, C VM
Trimeprazine (Termaril-P, Vanectyl-P)	Antiinflammatory antipruritic antitussive antihistamine agent; usually combined with prednisolone	Total dose: ½-2 tablets PO q 12 h per dog to effect	Total dose: ¼-½ tablet PO q 12-24 h per cat to effect	Steroid effect; drowsiness; Temaril-P contains 5 mg trimeprazine, 2 mg prednisolone per tablet	5 + 2 mg T; 3.7 mg + 1 mg C; 7.5 mg + 2 mg C VM
Trimethobenzamide (Tigan)	Antiemetic	3 mg/kg IM, PO q 8-12 h	None	CNS reactions; hypersensitivity; many safer and more effective alternatives	100, 250 mg C; 100, 200 mg suppositories; 100 mg/mL I HM
Trimethoprim/ sulfadiazine (Tribrissen, Ditrim)	Potentiated sulfonamide; bactericidal broad-spectrum combination agent against G+ and G− bacteria, *Toxoplasma, Nocardia, Pneumocystis*	Routine infections: 15 mg/kg PO, SQ, IM q 12 h; toxoplasmosis; 30 mg/kg PO q 12 h	Routine infections: 15 mg/kg PO, SQ, IM q 12 h; toxoplasmosis: 30 mg/kg PO q 12 h	Cats: salivation; dogs: KCS syndrome; Dobermans: polyarthropathy; ITP; hepatotoxicity and blood dyscrasias have been reported	30, 120, 480, 960 mg T; 60 mg/ mL S; 24, 48% I VM, HM
Trimethoprim/ sulfamethoxazole (Bactrim, Septra)	Same as for trimethoprim/ sulfadiazine	Same as for trimethoprim/ sulfadiazine	Same as for trimethoprim/ sulfadiazine	Same as for trimethoprim/ sulfadiazine	Same as for trimethoprim/ sulfadiazine
Tropicamide ophthalmic solution (Mydriacyl)	Anticholinergic mydriatic agent for eye examination	1 drop 15 minutes prior to ophthalmic examination	Same	Causes mydriasis and photophobia; do not use in suspected cases of glaucoma	0.5, 1% OS HM
Trusopt	*(see dorzolamide)*				
Tumil-K	*(see potassium salts)*				
Tums	*(see calcium carbonate)*				
Tylan	*(see tylosin)*				
Tylenol	*(see acetaminophen)*				
Tylosin (Tylan)	Macrolide antibiotic used for treating colitis and small-bowel bacterial overgrowth syndrome	5-10 mg/kg PO q 12 h; may increase slowly to 40 mg/kg PO q 12 h	5-10 mg/kg PO q 12 h	Usually used as powder sprinkled on food; bitter taste	50, 200 mg/mL I; 3000 mg/5 mL P VM
Ultram	*(see tramadol)*				
Unasyn	*(see ampicillin-sulbactam)*				
Unique E	*(see vitamin E)*				
Urecholine	*(see bethanechol)*				
Urimax	*(see tamsulosin)*				
Urocit-K	*(see potassium citrate)*				

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
Uroeze	*(see ammonium chloride)*				
Ursodeoxycholic acid (ursodiol, Actigall)	Synthetic hydrophilic bile acid; suppresses hepatic secretion and synthesis of cholesterol; choleretic agent via solubilizing cholesterol (sludged bile) and increase in gallbladder contractions	10-15 mg/kg PO q 12-24 h	7.5-15 mg/kg PO q 12-24 h	Anecdotal reports of beneficial effects in sclerosing cholangitis and biliary cirrhosis; may induce diarrhea; contraindicated if gallbladder obstruction; minimal contribution (<10%) to endogenous measured serum bile acids level	300 mg C 250, 500 mg T HM
Ursodiol	*(see ursodeoxycholic acid)*				
Valacyclovir	Antiviral	—	Do not use	Severe BM, renal, and hepatic toxicities common even at subtherapeutic doses	—
Valbazen	*(see albendazole)*				
Valium	*(see diazepam)*				
Valproic acid (Depakene, Depakote)	Seizures	60-100 mg/kg PO q 8 h	Unknown	CNS depression, GI disturbances initially; hepatotoxicity with chronic use; considered third-line therapeutic drug	125, 250, 500 mg T; 250 mg C; 50 mg/mL S HM
Vancomycin (Vancocin)	Bactericidal glycopeptide antibacterial	10-20 mg/kg slow IV (30-60 minutes) q 6-12 h for 7-10 days	—	Reserved for resistant *Staphylococcus, Enterococcus, Clostridium difficile*, especially when sepsis possible or present and when resistance to other agents is documented	500 mg, 1 g, 5 g I HM
Vanectyl-P	*(see trimeprazine)*				
Vantin	*(see cefpodoxime)*				
Vapona	*(see dichlorvos)*				
Vasopressin (vasopressin aqueous, Pitressin)	Diagnostic agent for central or nephrogenic diabetes insipidus; emerging application in cardiopulmonary cerebral resuscitation (CPCR)	Diagnostic: 0.5 U/kg IM to maximum 5 U after 5% weight loss from water deprivation CPCR: 0.4-0.8 IU IV +/− 1-4 milli U/kg/min IV CRI	Diagnostic: same CPCR: unknown	Not available as tannate in oil	20 U/mL I HM
Vasotec	*(see enalapril)*				
Vasotop	*(see ramipril)*				
Velban	*(see vinblastine)*				
Veltrim	*(see clotrimazole)*				
Ventolin	*(see albuterol)*				
Verapamil (Calan, Covera, Isoptin, Verelan)	Ca channel-blocking agent used principally to treat supraventricular tachyarrhythmias	1-4.4 mg/kg PO q 8-12 h; 0.05 mg/kg slowly IV; may repeat twice, 5-30 minutes between doses	Not recommended as oral calcium channel blocker for cardiomyopathy;	Not suggested for IV use clinically if structural heart disease or systemic illness (e.g., hypovolemia) present;	40, 80, 120 mg T; 120, 180, 240, 360 mg ER; 2.5 mg/mL I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
			(see diltiazem instead)	negative inotropic agent; usually do not use with β-blockers; may cause heart block	
Verelan	*(see verapamil)*				
Versed	*(see midazolam)*				
Versenate	*(see calcium EDTA)*				
Veta-K1	*(see vitamin K1)*				
Vetalar	*(see ketamine HCl)*				
Vetalog	*(see triamcinolone)*				
Vetmedin	*(see pimobendan)*				
Vetoryl	*(see trilostane)*				
Vetsulin	*(see insulin)*				
Vfend	*(see voriconazole)*				
Viagra	*(see sildenafil)*				
Vibramycin	*(see doxycycline)*				
Vidarabine (Vira-A)	Antiherpetic antiviral agent	—	Apply 4-6× daily to eyes	—	3% OO HM
Vinblastine (Velban)	Vinca alkaloid used in cancer chemotherapy, esp. lymphoreticular and mast cell cancers; also ITP	2 mg/m^2 IV q 1-2 weeks See pp. 671, 677 for body weight to body surface area conversion table.	Same	*(see vincristine)*	1 mg/mL I HM
Vincristine (Oncovin)	Vinca alkaloid *(see vinblastine, above)* used also for TVT	0.5 mg/m^2 IV weekly; TVT: 0.025 mg/kg IV weekly, maximum 1 mg per dose See pp. 671, 677 for body weight to body surface area conversion table.	Same	Perivascular irritant, leukopenia, constipation, local neuropathy (especially in cats)	1 mg/mL I HM
Viokase	*(see pancreatic enzymes)*				
Vira-A	*(see vidarabine)*				
Virbagen	*(see interferon-omega)*				
Viroptic	*(see trifluridine)*				
Vitamin B1	*(see thiamine)*				
Vitamin B12	*(see cobalamin)*				
Vitamin D2	*(see ergocalciferol)*				
Vitamin E (tocopherol, Unique E)	Antioxidant; steatitis, discoid lupus, dermatitis	Total dose: 100-400 IU PO, q 24 h per dog	Total dose: 30 IU PO, q 24 h, per cat	May use serum tocopherol levels to adjust dose	700 mg C HM
Vitamin K1 (Phytonadione, Aqua-MEPHYTON, Mephyton, Veta-K1)	Coumarin, indanedione, diphacinone, brodifacoum, and other anticoagulant rodenticide intoxications and coagulopathy due to decreased levels of vitamin K–dependent clotting factors	Load with 2.5-3.3 mg/kg SQ multiple sites, then 1.1-3.3 mg/kg q 12 h PO; do not give IV; for replacement therapy in chronic hepatopathies: 2.5 mg SQ, IM, or PO q 12 h	Same	Anaphylaxis risk if given IV; second-generation anticoagulants usually require 3-4 weeks of therapy; use parenteral form if inhibited absorption	5 mg T; 25 mg C; 2, 10 mg/mL I VM, HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
		for 3-5 days, then once weekly		(small-gauge needle to minimize hematoma risk in rodenticide patients); hepatotoxicity risk with chronic use	
Volmax	*(see albuterol)*				
Voriconazole (Vfend)	Systemic fungal infections	6 mg/kg PO or IV q 12 h × 48 h loading dose, then 3-4 mg/kg PO q 12 h until clinical resolution and beyond		Derived from fluconazole; promising therapy but prohibitively expensive in many cases	200 mg vial (10 mg/mL) I 50, 200 mg T HM
Warfarin (Coumadin)	Anticoagulant; inhibits vitamin K epoxide reductase, blocking activation of vitamin K–dependent factors	0.1-0.2 mg/kg PO q 24 h, to maintain PT at 1.5-2 times the baseline	Total dose: 0.2-0.5 mg PO q 24 h per cat for most cats	Fatal or nonfatal hemorrhage; widely variable interindividual effects requiring close monitoring	1, 2, 2.5, 3, 4, 5, 6, 7.5, 10 mg T; 2 mg/mL I HM
Winstrol	*(see stanozolol)*				
Wycillin	*(see penicillin G procaine)*				
Xalatan	*(see latanoprost)*				
Xanax	*(see alprazolam)*				
Xylazine (Rompun)	α-adrenergic agonist agent with sedation and analgesia of 15-30 minutes; emetic effect in cats	0.66-2 mg/kg IM; 0.66-1.1 mg/kg IV	Emetic agent: 0.44-1.1 mg/kg IM or IV	Many side effects include arrhythmias, transient second-degree AV block, hypotension, increased sensitization to catecholamines in halothane anesthesia; reversal with yohimbine	20 mg/mL I VM
Xylocaine	*(see lidocaine)*				
Yobine	*(see yohimbine)*				
Yohimbine (Yobine)	α2-(xylazine) antagonist	0.1-0.25 mg/kg slow IV; 0.2-0.5 mg/kg IM, SQ	Same	Apprehension, salivation, tremors, excitability	2 mg/mL I VM
Yomesan	*(see niclosamide)*				
Ypozane	*(see osaterone)*				
Zafirlukast (Accolate)	Leukotriene receptor antagonist; feline asthma; not for acute attacks	—	Total dose: 5 mg per cat PO q 12-24 h	Rare anecdotal reports of efficacy in asthmatic cats	10, 20 mg T HM
Zanosar	*(see streptozotocin)*				
Zantac	*(see ranitidine)*				
Zeniquin	*(see marbofloxacin)*				
Zestril	*(see lisinopril)*				
Zidovudine	*(see azidothymidine)*				
Zinc oxide (Desitin)	Promotes healing of irritated or abraded skin	Apply a thin film q 12 h	Same	GI effects and hemolytic anemia if chronically ingested	OTC, HM, O
Zinc sulfate, acetate, gluconate, or methionine	Zn responsive dermatoses; copper storage disease	5-10 mg/kg elemental Zn PO q 12 h	1-2 mg/kg elemental Zn PO q 24 h, for	GI irritability; administer with food; Zn-induced hemolysis if plasma levels exceed 1000	66, 100, 200, 220 mg T; 1 mg/ mL I HM

Generic Name (Trade Name)	Indications/Drug Type	Canine Dose	Feline Dose	Comments	How the Drug Is Supplied
			hepatic lipidosis	mg/dL; blood Zn levels require special blood tubes (normal rubber caps contain Zn) Zn acetate = 30% elemental Zn Zn sulfate = 23% elemental Zn Zn gluconate = 14% elemental Zn	
Zinecard	*(see dexrazoxane)*				
Zithromax	*(see azithromycin)*				
Zofran	*(see ondansetron)*				
Zoloft	*(see sertraline)*				
Zonisamide (Zonegran)	Sulfonamide-based compound; second- or third-line antiepileptic drug	5-10 mg/kg PO q 12-24 h	—	Sulfa precautions; often used concurrently with phenobarbital	100 mg C HM
Zosyn	*(see piperacillin + tazobactam)*				
Zubrin	*(see tepoxalin)*				
Zyloprim	*(see allopurinol)*				
Zyrtec	*(see cetirizine)*
