Switching lighting on and off in response to a photosensor is relatively inexpensive since it can be performed with a photosensor and simple relay. Photosensor dimming of fluorescent lighting systems requires dimming ballasts in each luminaire, which leads to higher system costs. The benefits of a dimming system are that adjustments to electric lighting can be transparent to occupants, and savings can be achieved even at low daylight levels.

16.3.5.1 General Operation

Most photosensors are configured to sense light arriving at the sensor from different directions, with the directional sensitivity dictated by the photosensor's optical features. Figure 16.18 illustrates performance for a number of different products. There is no recognized optimum distribution. Wide distributions are less susceptible to localized changes in reflectance since they integrate daylight and electric light over a wide range of angles. They are more likely to be influenced by sunlight patches or bright windows within their field of view. Sensors with narrow distributions are more susceptible to localized changes in reflectance, such as a desk surface covered with white paper, but can restrict the photosensor's view to avoid receiving strong signals from a bright window or a portion of the room that experiences direct sunlight. Photosensor performance is ultimately based on how well the signal received by the photosensor tracks the daylight or total light within a space.

Microprocessors in the photosensor system contain embedded control algorithms that interpret the signal received by the photocell, then signal a relay, panelboard, or ballast to switch or dim the controlled lighting zone accordingly. In some systems, the photosensor contains this microprocessor, while in others, the photosensor signal is communicated to a separate device which processes the photosensor signal through the control algorithm.

Photosensor systems are generally classified in four ways:

1. By the type of control they provide, either switching or dimming.
2. By their intended location, for use in interior or exterior environments.
3. By the control algorithm they apply.
4. By the communication protocol they use.

16.3.5.2 Switching versus Dimming

Photosensor-based switching is a less expensive means of automatic control that involves the use of a relay to switch luminaires within a daylit zone. This approach is common outdoors, but it is also applied indoors where daylight levels permit lighting to be switched off for long periods of time. Switching control is best applied in public spaces, such as circulation areas, where occupants are less likely to be disturbed or distracted by a sudden drop in illuminance. It is also applied as a low cost method to control the perimeter row of lighting equipment in some classrooms and offices. Figure 16.19 provides a wiring schematic for a room that contains two lighting zones; both are controlled by an occupancy sensor, with one of these also being switched by a photosensor.

Photosensor-based dimming of electric lighting is required in daylit spaces where minimal detection of changes to the electric lighting condition is desired. To provide sufficient energy savings to justify the added expense of these systems, significant dimming must occur over relatively large spans of time. Additional energy savings may be possible by providing occupants with personal control, since some occupants prefer output levels below the maximum level even when no daylight is present.

Some photosensor systems can be configured to apply stepped-level switching, where light output changes aren't as severe, but are still detectable. See Figure 16.20 for an example.

16.3.5.3 Exterior Applications

In most exterior applications, photosensor control is relatively simple. The photosensor signals one or more relays, which may be located within a lighting control panel, to turn

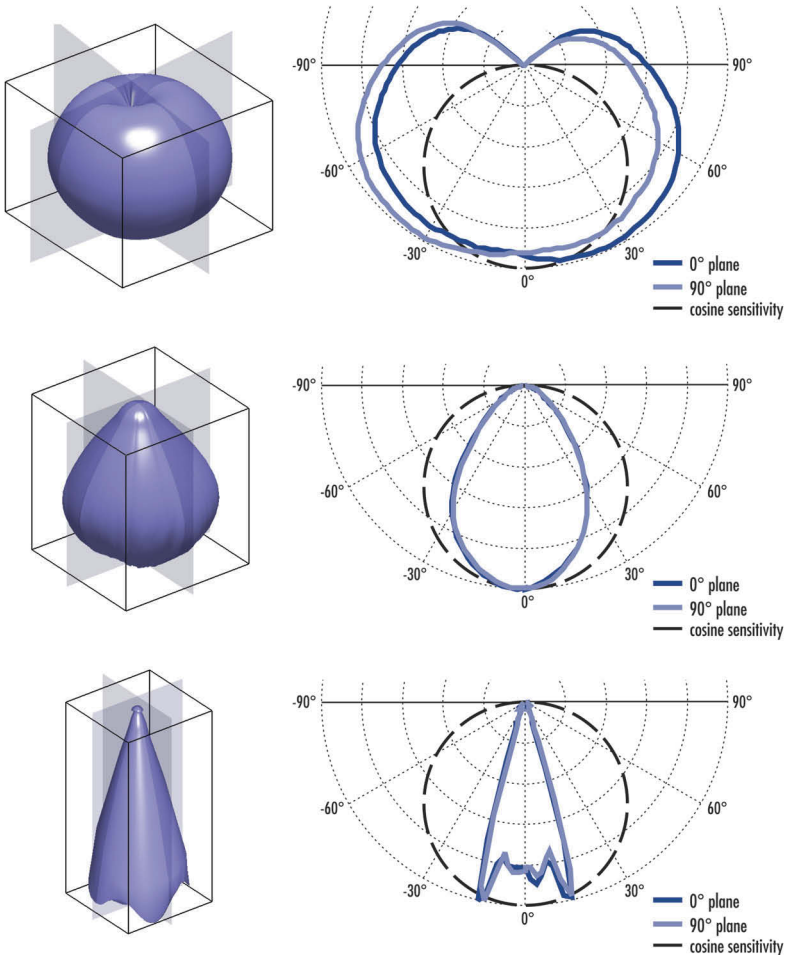

Figure 16.18 | Photosensor Spatial Sensitivity

lighting circuits on or off based on a daylight reading. The sensor may be mounted on the building or on a luminaire. In some cases, lights that are turned on with a photosensor may be turned off with a time clock to comply with a curfew or prevent them from operating unnecessarily throughout the night. Photosensors designed for controlling exterior lighting should not be used to control interior lighting due to their limited sensitivity.

16.3.5.4 Interior Applications

In building interiors, photosensors are generally designed to switch or dim the electric lighting system using either a closed- or open-loop control algorithm as described below, or some variation of these. In sidelighting situations, photosensors are typically located on the ceiling a short distance from the window, typically 2.5-4m (8-12 ft). For skylight systems, the photosensor may be located on the ceiling to assess the amount of light within the space, or within a skylight well to monitor the amount of daylight passing through the well.

The luminaires controlled by a photosensor must provide a work plane illuminance distribution that correlates well with the area illuminated by daylight. With most dimming systems, all luminaires within a controlled lighting zone are dimmed to the same level, although some systems can dim up to three luminaire zones to different levels, based on a zone's proximity to the daylight aperture. A more advanced approach applies individual sensors to different rows of luminaires, allowing luminaires closer to a window to operate at lower output than those deep within a space. Photosensor location and spatial sensitivity must be carefully selected to avoid photosensor readings that are influenced by control actions in adjacent zones.

When located within a space, the signal from electric light should be negligible compared to the daylight signal for the system to operate in open-loop mode, perhaps not more than

5-10% of the daylight signal required for full dimming of the electric lighting. One common application of open-loop control is skylighting, where the photosensor is mounted within the skylight well, preferably on the south side of the well facing away from the sun, or facing upward toward the glazing material [26].

Open-loop Dimming
A standard open-loop dimming control algorithm assumes a nighttime signal of zero and adjusts electric light output in proportion to the daylight signal received. The slope of this function is set at system calibration. Often this is referred to as the "gain" of the system (See Figure 16.21).

Calibration of an open-loop sensor consists of establishing the relationship between the photosensor reading and the daylight delivered to a critical location on the task plane at a representative daylight condition (that which is present at calibration time). The calibration setting determines the linear relationship between the photosensor signal and desired dimming level that is applied under all other daylight conditions.

Most open-loop systems control a single zone of lighting equipment, however products are available that control up to three zones at different dimming levels using a single photosensor. The first, second, and third row of luminaires along the perimeter of a space can therefore operate at different output levels to account for reduced daylight levels deep within a space.

Open-loop Switching
Open-loop switching is designed to turn the electric lighting system on when the daylight condition fails to meet the target illuminance at one or more task locations within the controlled lighting zone, and off when daylight levels meet the desired target. Any contribution from interior lighting that is not controlled by the system should also be considered. With switching control, the signals at which the on and off actions occur must be input to the control algorithm at system calibration. A deadband is generally applied between these two signals to avoid fluctuations between the two control conditions (see Figure 16.22). Most switching systems also apply an adjustable time-delay setting, which is the period of time over which the sensor must continuously register a shutoff reading before this action may occur.

16.3.5.6 Closed-loop Control

In closed-loop control, the photosensor is located within a space and its signal is influenced by both daylight and electric light. The ratio of the photosensor signal to work plane illuminance (S/E) at the critical task location for both daylight and electric light is a key determinant of system performance.

For closed-loop control to operate properly, the S/E ratio for daylight must be greater than or equal to that for electric light. This ratio is a function of the following:

- The spatial distribution of the photosensor
- The location of the photosensor with respect to the daylight apertures and the electric lighting system
- The spectral response of the photosensor

The spatial distribution of the photosensor determines the range of angles from which it receives light, and how sensitive it is to light from each direction. A wide distribution is more likely to receive direct light from a window when located on the ceiling, which will produce a higher daylight S/E ratio. If a photosensor receives significant direct light from luminaires, which can occur if mounted too close to indirect lighting, the electric light S/E ratio will be

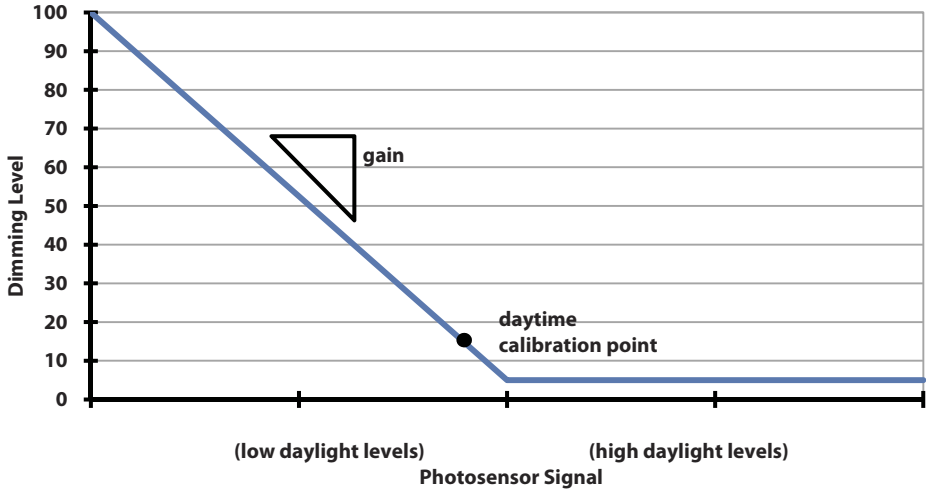

Figure 16.21 | Open-loop Dimming Control Algorithm.
A single daytime condition is used to determine the system gain, with a daylight signal of zero corresponding to full output of the controlled lighting zone.

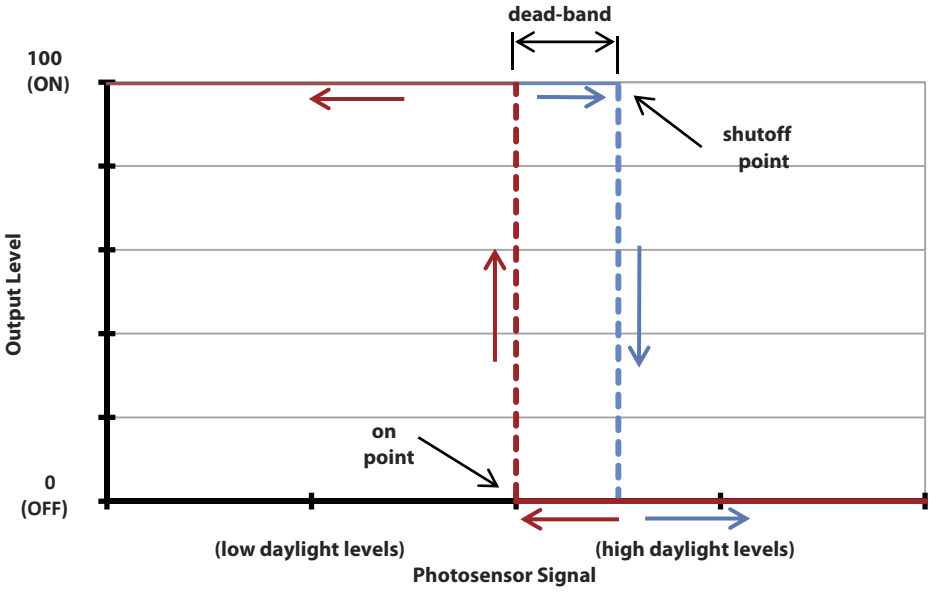

Figure 16.22 | Open-loop Switching Control Algorithm
The algorithm turns the system off and on at specified signals that are separated by a dead band. The on signal is configured to be just below the target illuminance level. Arrows in this diagram indicate control operation as rising and falling daylight levels are recorded through the photosensor signal.

high. The photosensor's spectral response function may also affect the S/E ratios, particularly when it is not closely aligned with the photopic sensitivity curve, V(λ) [27].

There are two different types of closed-loop dimming control: constant setpoint, which is also referred to as integral reset control, and linear proportional control, which is sometimes referred to as sliding setpoint control [24].

Constant Setpoint Control

Constant setpoint control is a relatively simple control approach where the control system attempts to maintain a constant photosensor signal by adjusting electric light output (Figure 16.23). This is what would be required in a control algorithm for a photosensor located at the task plane. When located on the ceiling, this approach is valid when the photosensor signal to critical work plane point illuminance (S/E ratio) is the same for both electric light and daylight, allowing an equal trade-off between daylight and electric light at both the photosensor and the work plane. This requires the photosensor to receive minimal input from the window or other bright surfaces, such as the floor adjacent to a window. If the S/E ratios are identical, this algorithm permits the system to be self-calibrating by configuring the system using the electric lighting system nighttime signal, which also permits automatic and periodic recalibration to account for changes in room surface reflectances or furnishings over time.

If the photosensor signal to work plane illuminance ratio is higher for daylight than for electric light, which is common in most sidelighting applications, an integral reset control system will dim the electric lighting too low when daylight is present if it has been calibrated to the nighttime electric light signal. To provide reasonable control in these situations, the system's setpoint can be increased, which will cause the electric lighting to dim only after a predetermined daylight contribution is received. The presence of different S/E ratios is likely to result in incorrect self-calibrations, unless the setpoint can be adjusted upward from the nighttime signal during the calibration process and in any recalibration.

Because daylight often produces a higher S/E value than received from the electric lighting system, following calibration the performance should be checked at one or more daylight conditions that require partial dimming to verify that appropriate dimming levels are being applied. This verification should be included as part of the commissioning process.

Proportional Control

Proportional control is a more flexible control algorithm that accommodates the different S/E ratios for daylight and electric light that are likely to occur with sidelighting systems. With proportional control, electric lighting is dimmed as the photosensor signal increases, with the exact relationship established at system calibration. A proportional control dimming algorithm generally requires two input conditions from which to construct a linear

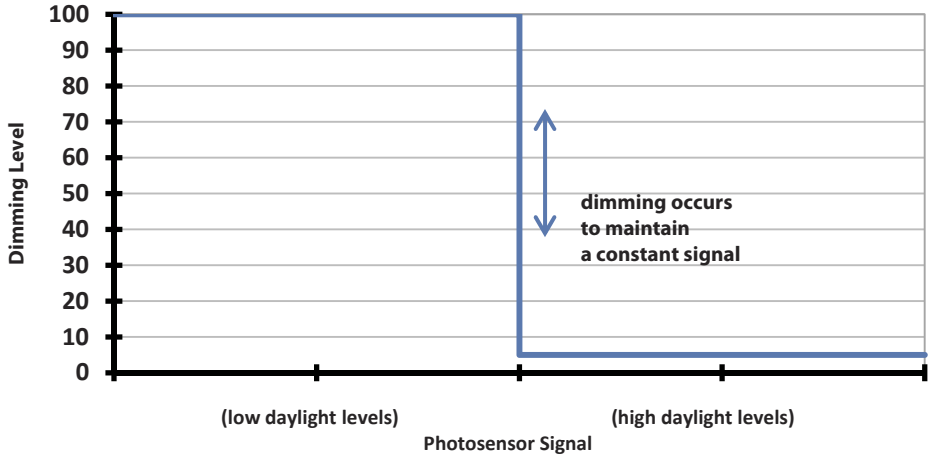

Figure 16.23 | Closed-loop Constant Setpoint Control Algorithm
This algorithm varies the output from the controlled lighting zone to maintain a constant photosensor signal. Once daylight exceeds the level provided by the electric lighting system, the electric lighting system is at its minimum dimming level.

relationship between the photosensor signal and the preferred dimming level (Figure 16.24). The first of these points is the signal received from the electric lighting system at night. Some systems automatically record the electric light signal during the calibration process by taking a reading with the electric lights both on and off. The second condition for determining the slope of the dimming curve considers a representative daylight condition. At this condition, the controlled lighting zone's dimming level is set to provide the desired daytime target illuminance at the critical task point (See the daytime calibration point in Figure 16.24). This daylight condition must result in a dimming condition above the minimum, but preferably close to it. If too much daylight is present, it may be necessary to adjust shading devices to lower the daylight level to a setting that requires a dimming level above the minimum. With proportional control, it is also possible to tune the nighttime condition to a target illuminance that will provide for lumen maintenance, which will save additional energy when a system is new and clean (See 16.2.8 Lumen Maintenance).

In selecting a daylight condition to use for calibration, it is best to select one that provides a strong daylight contribution to the photosensor and requires significant dimming of the controlled electric lighting zone. A strong signal may be achieved when the ground viewed by the photosensor through the window receives direct sunlight, or when horizontal blinds are angled to maximize the photosensor's signal relative to the work plane illuminance. Calibration at a high S/E ratio will cause the system to deliver more light than needed at daylight conditions when lower S/E ratios are present. Calibrating a closed-loop control system under a daylight condition with a low S/E ratio, such as under an overcast sky, should be avoided, since this will result in overdimming of the electric lighting system under daylight conditions with higher S/E ratios, and could draw complaints from occupants. Generally, a photosensor should not be calibrated with direct sunlight entering a space, unless the system is expected to operate under these conditions.

Calibration of both open-loop and closed-loop photosensors should be conducted after the space is furnished to account for the effect of furniture and shading devices on both the photosensor signal and the work plane illuminance.

Switching Control

Closed-loop switching is very similar to open-loop switching except that a drop in the photosensor signal occurs when the electric light is turned off (See Figure 16.25). The difference between the signal at which the electric light is turned on and the signal at which the electric light is turned off, the deadband, must account for both the electric light signal from the controlled lighting zone and an additional amount to prevent oscillation of the lighting system on/off condition. A time-delay setting is also generally provided.

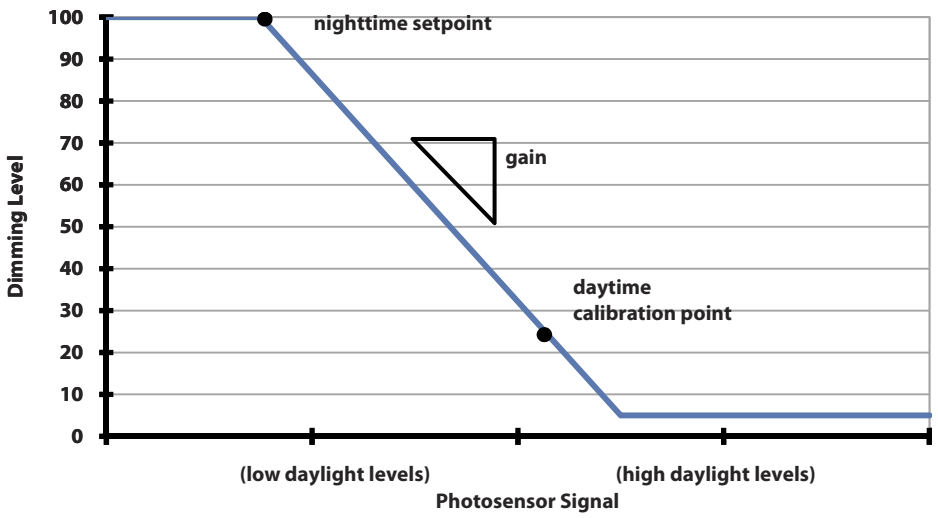

Figure 16.24 | Closed-loop Proportional Control Algorithm
A nighttime setting and a daytime calibration point are used to create a relationship between the photosensor signal and dimming level for the controlled lighting zone. A daylight condition that produces a relatively high photosensor signal and requires light output near the minimum dimming level is preferred.

16.3.5.7 Dual-loop Control

Photosensor control algorithms that employ both a closed-loop (downward oriented) and open-loop (upward oriented) photosensor have been developed for skylighting [28]. This dual sensor approach recalibrates the closed-loop sensor each night under full electric lighting to account for changes in objects and surface reflectances beneath the sensors. During the daytime, it assesses readings from both sensors, then responds accordingly.

16.3.5.8 Photosensor Placement

Open-loop sensors are typically placed outdoors, or at the daylight aperture, such as at a window (facing outward) or within a skylight well. The location must provide a photosensor signal that is correlated to the amount of daylight entering a space. With open-loop control, the signal contribution from electric light must be eliminated or be very low relative to the daylight signal it receives.

In sidelighting situations, closed-loop control is typically applied with photosensors located on the ceiling. In private offices, research has shown that a sensor facing the wall opposite the window can also provide effective control [29]. Closed-loop sensors generally are located a short distance into the room (2.5- 4m or 8-12 ft), with a mounting position that minimizes direct light from both the electric lighting system and the daylight apertures, while still maintaining a relatively strong daylight signal. When ceiling mounting is applied with pendant luminaires and uplight, the photosensor is best placed midway between rows with a directional sensitivity that limits the signal it receives from the luminaires. Photosensors may also be integrated into pendant luminaires facing downward with either integral reset or sliding setpoint control. One drawback of this approach is that it places the photosensor closer to the work plane which limits the area being viewed, making the system more susceptible to localized changes in reflectance.

16.3.5.9 Photosensor System Design and Layout

In designing a photosensor control system, the designer must decide on the type of control that is appropriate for a space, considering both the method of daylight delivery and the electric lighting system being controlled. Key decisions involve the selection of dimming versus switching, and whether an open- or closed-loop system is more appropriate for the daylighting system and space. Table 16.3 contains a list of photosensor control system characteristics to consider when selecting hardware. This assessment, plus the anticipated system costs, will lead to one or more preliminary system selections, for which the designer must then investigate equipment options, system layout, and, where possible, performance.

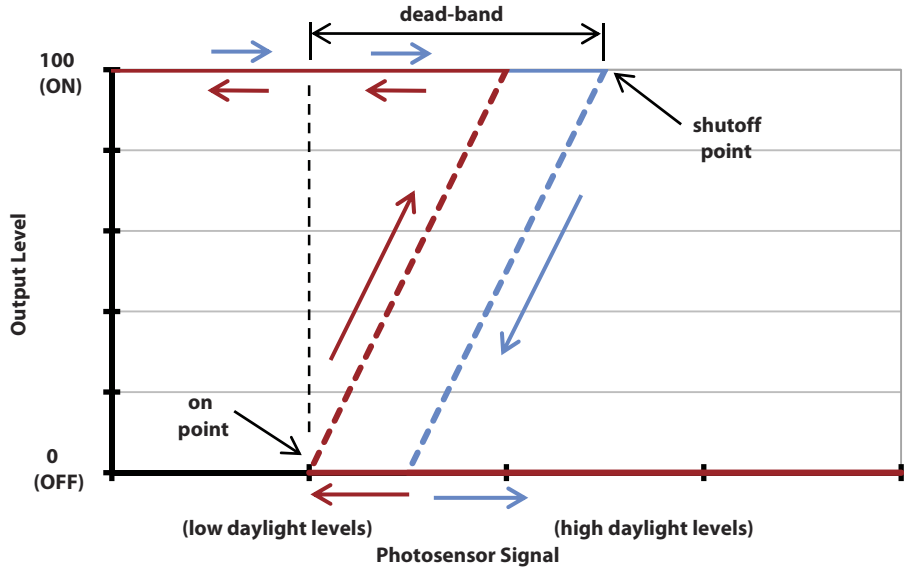

Figure 16.25 | Closed-loop Switching Control Algorithm
The difference drop or rise in signal when the lighting system is turned on and off represents the controlled lighting zone signal. The deadband must be greater than this signal to prevent oscillation of the lighting control zone operating condition. The blue line is the signal path for increasing daylight levels, while the red path is the signal path as daylight levels are decreasing.

With photosensor control, the controlled lighting zone must provide a work plane illuminance distribution that correlates well with the daylight coverage area. If the electric lighting system to be dimmed or switched extends beyond the daylight zone, energy savings will be limited, or a portion of the space will be underlit. Lighting analysis software can be applied to assist in the layout of the controlled lighting zone as shown in Figure 16.26.

16.3.5.10 The Critical Task Location

In calibrating a photosensor control system, system performance is aligned with work plane illuminance at one or more points. The system should be calibrated to a task location that requires the most light from the controlled lighting zone. If the target illuminance is met at this point, then all other work plane points within the daylit area should also meet their target illuminance. Usually this critical task point is located near the interior boundary of the controlled lighting zone, most likely to one side of the space, near a wall where daylight levels are lower. Figure 16.27 illustrates how the location of this point can be determined for a large open space that contains both a dimmed and non-dimmed lighting zone.

When calibrating a system, this point can be located using the following steps:

1. Turn the controlled lighting zone off and determine the task location within or adjacent to the controlled lighting zone that falls farthest below the target level when only daylight and non-photosensor controlled lighting are considered.

2. Activate the photosensor-controlled zone and calibrate the control system to provide the desired illuminance at the point selected in Step 1, then determine if any other task location within or just outside the controlled lighting zone remains below the target illuminance. If so, recalibrate for the location that requires the highest light output setting.

16.3.5.11 Energy Modeling of Photosensor Control Systems

Recent software advancements permit the analysis of annual energy savings for photosensor control and offer the ability to assess and compare how well a photosensor's signal and control algorithm track daylight levels within a space [30].

Some programs estimate energy savings based on work plane illuminance, assuming the control system will operate in an ideal manner. In building energy modeling software such as eQuest (DOE2) or Energy Plus [31] [32], or in lighting software that models annual lighting energy savings, the user is often asked to input the following.

- a reference point at which the output level from the controlled lighting system will be evaluated (which should be the critical task point described above)
- the target illuminance at this point
- the controlled lighting system power

These analysis tools generally determine light output and power consumption in the dimmed zone based on the reference point illuminance. When only a portion of the electric

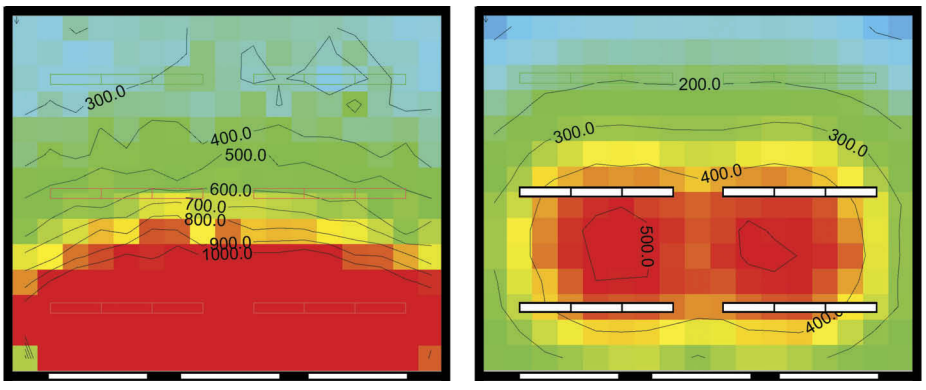

Figure 16.26 | Aligning the Controlled Zone with the Daylight Zone
The daylight distribution (left) and the electric light provided by the first two rows of luminaires provide relatively similar distributions along the edge of the controlled lighting zone and therefore are well correlated. The 400 lux contour in the left image is closely aligned with the 300 lux contour in the right image.

Table 16.3. Photosensor Control System Feature and Options

Photosensor Features	Options/Comments
Directional Response	• Narrow – affected more by localized changes; restricts view to area beneath photosensor. Better for constant setpoint sensors. • Wide – integrates over greater area; signal is influenced by windows and sunlight patches
Color Correction	• Preferred, especially for constant setpoint control
Control Action	• Single zone switching • Multi-level switching • Single zone dimming (to minimum dimming level or off) • Multi-zone dimming
Control Algorithm	• Open-loop switching • Open-loop dimming • Closed-loop constant setpoint • Closed-loop proportional • Closed-loop switching
Calibration Process & Adjustments	• Self-calibrating – no additional devices needed • Self-calibrating with remote device • Manual with remote device • Setting adjustments require access to photosensor
Signal Response Range	• Generally listed in lux, but will vary with source direction for most sensors
Control Protocol	• 0-10 V dimming • 2-wire dimming • 3-wire dimming • DALI
Mounting	• Suspended ceiling • Drywall • Integral to luminaires
Power Supply	• Power pack • Dimming panel • Ballast • Battery • DALI loop

light received at this point is controlled by the photosensor, the target illuminance entered should be the daylight illuminance required to achieve minimum lighting power (the minimum dimming level). For example, in Figure 16.27, if 500 lux is desired and 200 lux is provided at the critical target point by an interior lighting zone with 300 lux provided by the controlled lighting zone, the analysis of the energy saved by a photosensor control system should be based on a 300 lux daylight target value at this analysis point.

In conducting either an energy study or a signal correlation study, it is important to consider the impact of operable shading devices at the daylight aperture, since the admission of direct sunlight into a space presents an extreme daylight condition that will likely result in discomfort and poor photosensor performance when bright sunlight patches fall within

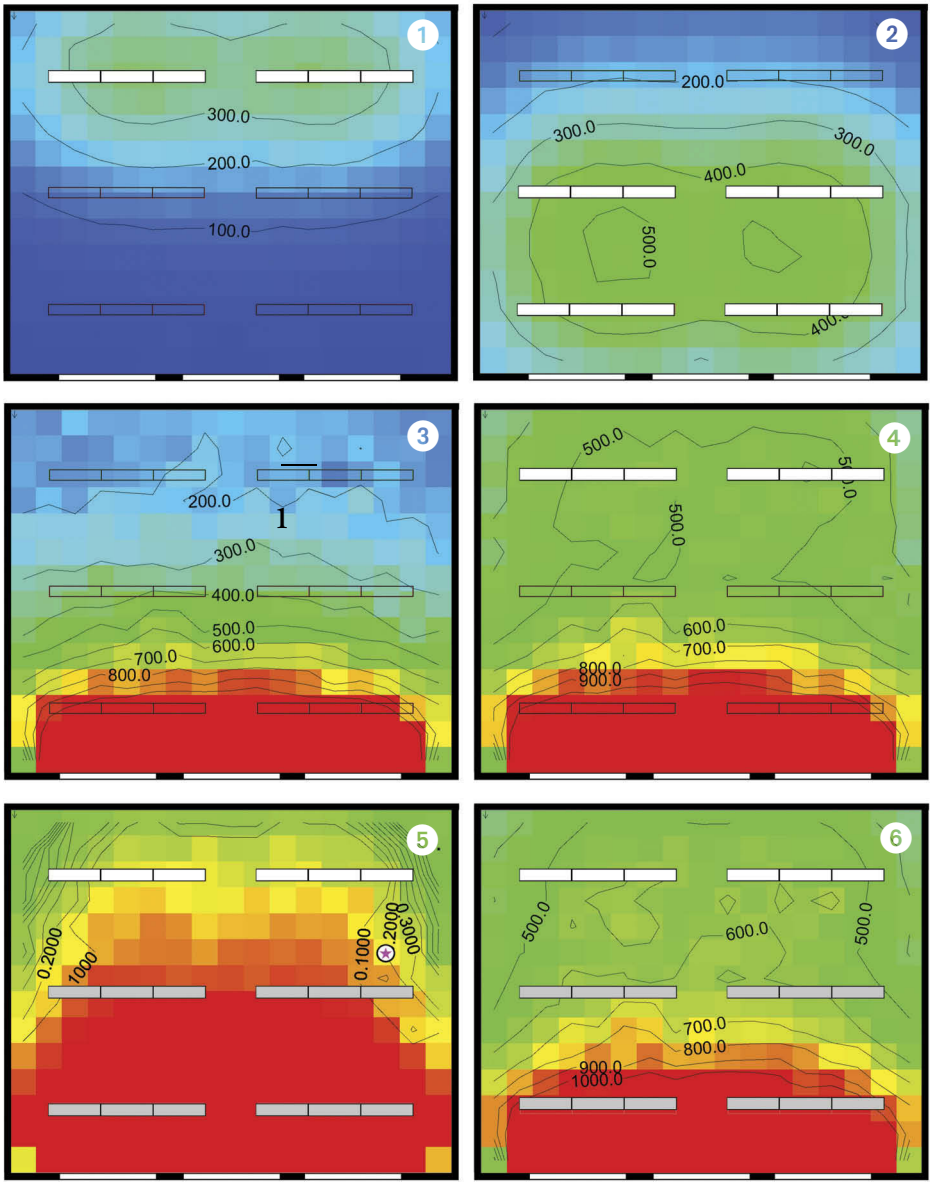

Figure 16.27 | Establishing a Critical Task Location
These images illustrate the source contributions and process for calibration of a photosensor-controlled daylight dimming system in a room with sidelighting provided by three windows. Illuminance contours are in lux (❶-❹, and ❻). ❹ shows that illuminance values are below the desired value of 500 lux on the sides of the room beyond the second row of luminaires. Line contours in ❺ indicate the dimming level required from the dimmed zone to meet 500 lux at each work plane point across the space. The critical task point has been placed at the star in ❺. ❻ shows system performance following calibration to the critical task point with the dimmed zone operating at 22% of full output.

the photosensor's field of view. If occupants are likely to apply shades or blinds under these conditions, the analysis should consider the same.

For a photosensor control system to operate properly, the signal received by the photosensor must be highly correlated to the daylight levels within a space. Some software tools provide feedback on this correlation by providing a plot of the photosensor signal versus dimming level (or daylight contribution) under a range of sky conditions. High correlations are not guaranteed when photosensors are located on the ceiling, since the illuminance being controlled is at the work plane. The sample correlation graphs shown in Figure 16.28 illustrate the nature of these variations – the tighter the fit, the better the control system will perform when properly calibrated. If S/E is identical for both electric light and daylight (the assumption under constant setpoint control), the slope of this graph will be vertical.

16.3.5.12 Commissioning

The commissioning process for a photosensor-based dimming control system typically involves calibrating the control algorithm under a representative daylight condition. Depending on the control algorithm applied, it may also require a nighttime signal. Most photo-

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

sensor systems are now calibrated using a wireless handheld device. An illuminance meter is also necessary for calibration, and in some cases this meter is included in the remote device. For dimming control, daytime calibration involves placing an illuminance meter at the critical task location, then the dimmed zone output is adjusted to produce the desired illuminance at this point. Other task locations should then be checked to determine if they require a higher setting from the controlled lighting zone.

The daylight condition used for calibration should meet the following conditions:

1. The daylight condition should provide a dimmed zone setting slightly above the minimum dimming level. It may be necessary to adjust blinds or shades on the windows to achieve an appropriate daylight level.

2. The daylight condition selected should provide a relatively high S/E ratio. If horizontal blinds are applied, they should be angled to provide a high photosensor signal (which may be based on the ceiling illuminance at the photosensor) in relation to the critical point illuminances. Calibration under overcast sky conditions should be avoided with sidelighting applications since these usually provide low S/E ratios that result in underlit environments under other sky conditions.

The calibration process and means of adjustment are important product characteristics that should allow for fast and simple system calibration. Some products are self-calibrating, others are calibrated remotely using a wireless device, while some require direct access to the photosensor to manually set switches or dials. When calibration can only be performed through direct adjustment to switches or dials on the photosensor, calibration is complicated by the fact that an individual alters the photosensor signal when making these adjustments. The appropriateness of a setting can only be evaluated once the area beneath a photosensor is vacated (including removal of the ladder). Self-calibrating photosensors provide control algorithm settings based on assumptions that may not be present in all installations; performance must therefore be verified following system self-calibration. The ability to manually recalibrate (override) these systems is often provided for the case where self-calibration does not produce an adequate control setting.

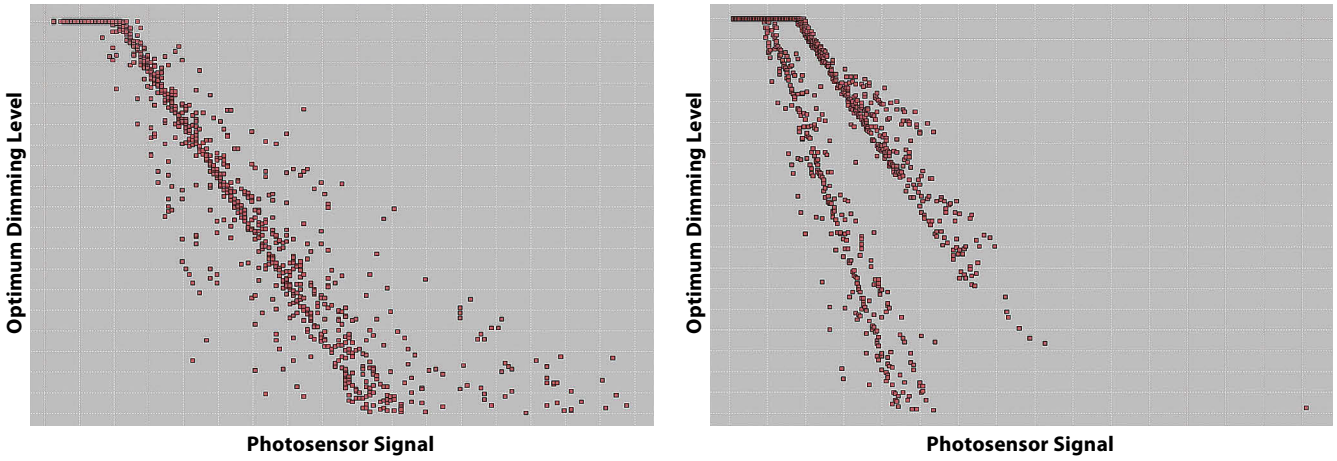

Figure 16.28 | Photosensor Signal Correlation Graphs
The relationship between photosensor signal and optimum dimming levels can be used to assess photosensor system performance across a range of daylight conditions. A tight linear collection of points is desired. The right graph illustrates significant diff erences in the photosensor signal when shades are applied compared to an unshaded window. This arrangement will result in either overdimming or underdimming, depending on the condition used for calibrating the system. To avoid overdimming (providing too little electric light), the system should be calibrated to the points with the higher signal. A better solution is one where all daylight conditions are more closely aligned. Different photosensor positions and directional sensitivities may provide a more linear dimming level-to-signal response pattern.

In the case of a photosensor switching system, the user may need to enter switch point settings, which can then be tested by closing blinds to reduce the daylight level (with a short time delay setting applied for testing purposes).

16.4 Integration with Emergency Lighting

Emergency lighting systems (See Chapter 44| EMERGENCY, SAFETY, AND SECURITY) must operate when normal power is interrupted [33]. In many spaces, a small number of luminaires that regularly illuminate the space also serve as emergency luminaires and are powered through a separate normal/emergency panelboard. This panelboard receives power through the utility connection for general operation, but in the case of a power outage is converted to the emergency power system through an automatic transfer switch. Emergency power is provided by a generator or alternate power source. In the simplest arrangement, these luminaires are placed on 24-hour operation, which can lead to energy waste. In many spaces, it is preferred to control this equipment through local switches, dimmers, occupancy sensors and photosensors. Special hardware is required to ensure that local control devices are overridden in the case of an emergency.

With standard switches, dimmers, occupancy sensors and photosensor switching, the emergency circuit can be controlled via a separate device that is UL 924-listed for automatic load control [34]. These components operate to shunt a control device that is applied to normal/emergency lighting equipment, or switch between a normal power wire that has passed through a control device and a separate unswitched emergency line that powers emergency equipment when required. See Figures 16.29 and 16.30 for examples.

16.5 Control Protocols

A number of different communication protocols are applied in lighting control products. These include both analog and digital formats to communicate the desired output level to dimming ballasts from wall stations, photosensors, or other control equipment. Most analog approaches simply deliver a signal that communicates the desired dimming function. Digital protocols include additional features and the opportunity for two-way communication. With two-way communication, information on power consumption, operating status, and control settings can be returned to a master control device. Standard protocols permit products from different manufacturers to be interchangeable and compatible. A few proprietary protocols also exist. These were developed by manufacturers for use within their product lines and limit the ability to apply equipment from another manufacturer.

This section covers the most common control system communication protocols. It is important to understand that both the control device (which may be a wall switch, photosensor, or other device) and the ballast or other equipment must operate under the same protocol to be compatible.

16.5.1 0-10 V Control

The most common control protocol for fluorescent dimming ballasts up to now is based on an analog 0-10 V signal supplied to the ballasts through a pair of control wires that connect to each ballast, and are separate from the standard phase, neutral and ground wire. This approach is also used for LED systems that are not controlled digitally. If the control wires are run outside the electrical conduit, they can be Class 2 wiring and routed with communication wires. The magnitude of the voltage on these control wires determines the output level at which the ballast will operate the lamps. While this protocol has been widely adopted, there is no official standard to which these systems must adhere within the architectural

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

lighting industry. This results in differences in output across manufacturers for ballasts receiving the same signal voltage, as shown in Figure 16.31. Note that all three ballasts in this figure begin to dim only after the voltage has dropped below approximately 8 volts.

16.5.2 Two-wire Control

This approach involves either pulse width modulation (PWM), which utilizes a high frequency squarewave to dim lamps down to approximately 5-10% of maximum output, or phase control that removes a portion of the voltage sine wave. Phase control eliminates the voltage from its zero crossing point up to approximately the midpoint of the waveform, depending on the dimming level desired. Two-wire systems utilize only a dimmed hot and a neutral wire, which is convenient for retrofit situations since it can utilize existing wiring. In most systems, a ground wire is also provided.

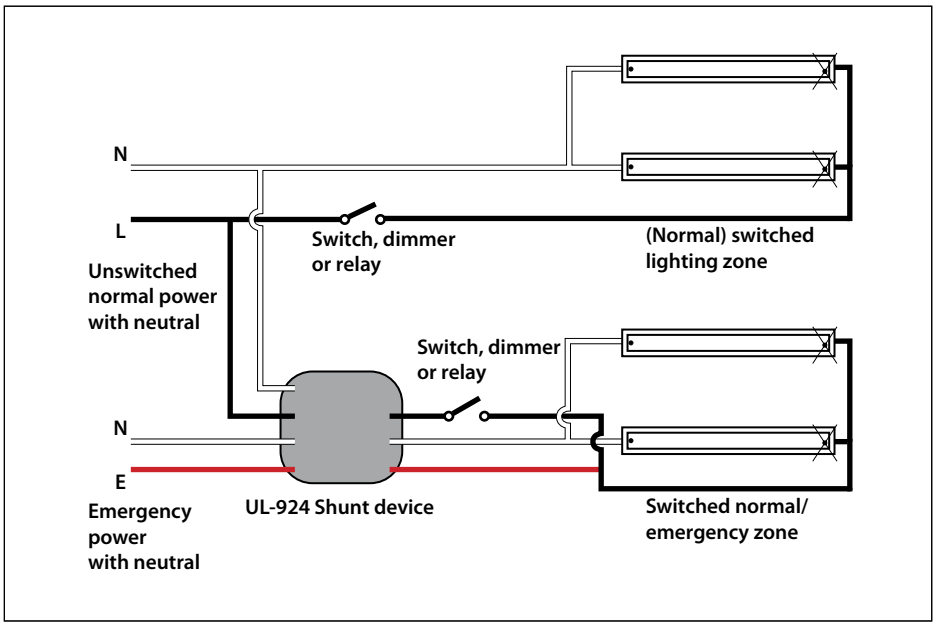

Figure 16.29 | A UL-924 Listed Device Shunts Power Around a Switch
A dimmer or relay controls only the normal/emergency circuit in this arrangement.

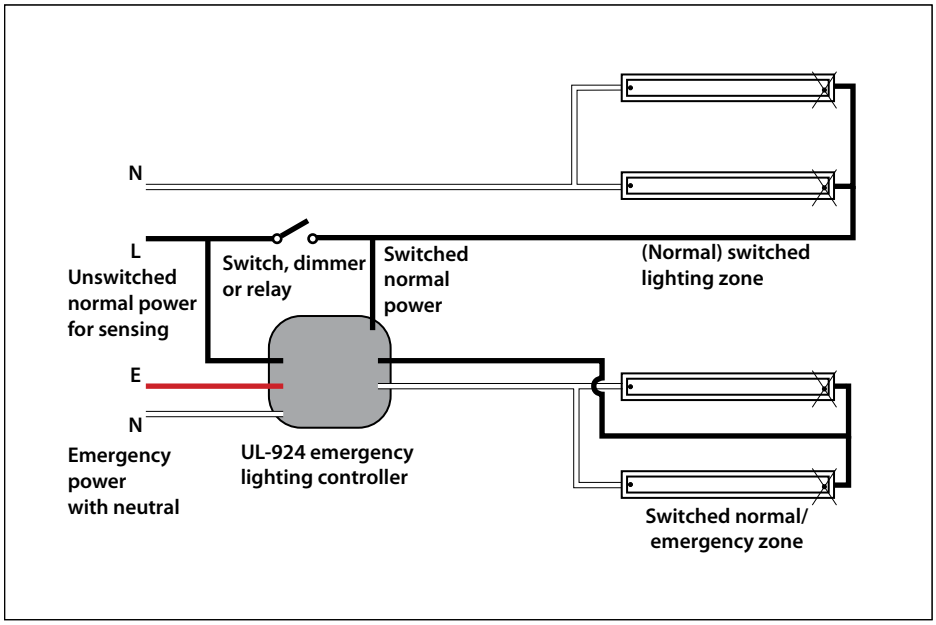

Figure 16.30 | A UL-924 Listed Device Controls Power to Normal/Emergency Luminaires
The device provides switched power to a normal/emergency circuit under normal operating conditions, and supplies emergency power when normal power is not available. This permits both the normal and normal/emergency luminaires to be controlled by the same device. The configuration for a two-wire dimming system is identical, while a three-wire dimming system requires a slight modification.

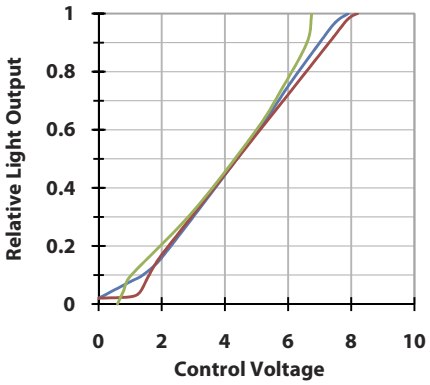

Figure 16.31 | 0-10V Dimming Curves for Three Ballasts
Output of three 0-10V fluorescent dimming ballasts at different control voltages. Dimming does not occur for each until the control voltage is below approximately 8 volts [14].

16.5.3 Three-wire Phase Control

Three-wire phase control is a proprietary three-wire system that sends a signal over a third wire which is referred to as the dimmed hot wire; with the other two wires being the standard phase wire (hot wire) and the neutral. This approach provides a wide range of control with dimming to 1% or less of full light output. Since there is minimal load on the dimmed hot wire, heat generation is minimized at the control device, allowing dimming equipment to be smaller. Dimming with this approach offers good uniformity and stability, but is generally more expensive than some of the other protocols. The need for three wires makes this approach more suitable for new construction.

16.5.4 Digital Control

The primary digital control protocol in use today is referred to as DALI (Digital Addressable Lighting Interface) [35]. With DALI, up to 64 devices (ballasts, relays, switches, zone controllers, occupancy sensors, photosensors, etc.) may be networked together on a single control bus via a pair of polarity-free control wires using a combination of daisy-chaining and branching (See Figure 16.32). These wires can be run within electrical conduit (Class 1) or as separate communication wires following Class 2 requirements. Electrical circuiting of the ballasts is independent of how they are controlled since each device (relay, ballast, switch, sensor) on the network is separately addressed to provide for individualized control. Digital control offers distributed intelligence through the microprocessor located within each device. In addition to individual control, ballasts may be assigned to one or more of 16 control groups per bus, as well as an output level in up to 16 different scenes. Control can be via individual address, group, or scene or by directive to all devices on a bus. An assortment of additional commands is also available.

Communication on a digital network is two way, with the ballasts capable of reporting lamp burnouts, and the system able to recognize faulty ballasts. Ballasts may be queried for their power level, maximum and minimum output settings, fade time, device type, and other information.

The primary benefit of digital control is the flexibility permitted in both equipment layout and configuration. Ballasts may be assigned to switches, occupancy sensors, photosensors, control groups and scenes through software or in some cases via one of the control devices without the need to rewire the equipment as space functions and layout change.

Commissioning of a building-wide DALI control system requires significant effort, since each ballast or relay must be located on the system and assigned to its respective control devices, groups and scenes using the control system's software. Control loops may be connected to a router and assigned an Internet address for centralized or schedule control. The user interface and functions provided by the digital lighting control software are important system features. For those who will operate the facility, it is essential to select a system that is easy to for facility personnel to operate, configure and understand.

Power for the DALI control circuit (the control wires) is provided by a power pack or other power source. Up to 250 mA may be provided to each control loop. In laying out a system, the current drawn by all devices placed on a single DALI loop cannot exceed the rating of the power supply for that loop.

Similar proprietary digital control protocols are also available. Some manufacturers apply digital control for communication between scene controllers, sensors, and other devices. These systems apply either Cat5 cable or twisted pair wiring.

16.5.5 BACnet

BACnet [36] is a control protocol used for building automation systems that is commonly applied on large campus networks to control equipment in multiple buildings. BACnet was developed by ASHRAE to allow communication with HVAC, lighting, fire protection,

and other building systems. Lighting panelboards and other lighting control devices from a variety of manufacturers may be linked to a BACnet system either directly or through an interface module. This module, which is often referred to as a gateway, converts BACnet commands to the control protocol used by the lighting equipment, and likewise converts data from the control system to BACnet when communicating in a reverse direction.

16.5.6 DMX512

DMX512 [37] is a control protocol that originated in the theatre industry to control stage lighting and related equipment. It is a one-way system that permits instructions to be sent from a controller to individual devices to control source output as well as motorized lighting devices. Its most common application in the architectural lighting industry is for control of RGB solid state lighting (SSL). In many installations, SSL equipment is programmed into timed sequences or shows, like in a theatrical performance. DMX operates with shielded twisted pair cable that is daisy-chained from one device to the next. A few manufacturers offer DMX control through wireless, radio frequency signals.

17 | ENERGY MANAGEMENT

Obviously, the highest type of efficiency is that which can utilize existing material to the best advatage.
Jawaharlal Nehru, India's First Prime Minister

Lighting energy management is the process of meeting lighting quality requirements as well as space, task and user needs with low energy consumption, through energy efficient lighting system design and operation. Lighting energy use in buildings is important due to the substantial energy consumed by a lighting system over its lifetime. Averaged across all commercial buildings, lighting consumes approximately 19% of total building site energy, 25% of the primary energy, and 32% of the electrical energy [1]. In recent years, power density limits and control requirements imposed by energy codes and standards have helped to significantly reduce lighting energy consumption in new buildings.

Existing lighting systems that were installed decades ago are likely to consume significantly more energy than code compliant new construction. Fortunately, lighting energy in existing buildings can be reduced through a cost effective retrofit or complete lighting system redesign that applies energy efficient lighting equipment and control technology to supply task illuminance and lighting quality that meet current IES recommendations.

In lighting design, decisions related to nearly every lighting system component can affect energy consumption, including the choices of lamp, ballast, luminaire, luminaire layout, circuiting, control devices, and system maintenance. Since installed systems operate for decades, energy efficiency must be a major lighting design consideration. This chapter outlines many of the key opportunities for enhancing the energy efficiency of new and existing lighting systems. More specific details on available technologies, system components, and design strategies can be found in other chapters of this handbook. Reference to more detailed discussions included in other chapters are provided in the margins throughout this chapter.

17.1 Basic Strategies

Fundamental lighting energy management strategies can be classified into three primary areas: daylighting, electric lighting, and lighting control systems. Control systems can address daylight or electric lighting alone, or the integration of these sources.

17.1.1 Daylighting

The incorporation of daylight into a building's design offers significant potential for minimizing a building's electric lighting energy across a variety of applications. Daylight is abundant for a large portion of the day, provides excellent spectral quality, and is desired by most building occupants. A building's architecture, electric lighting systems, and associated lighting control systems must all be properly designed and operated to achieve savings in electric lighting energy through daylighting [2].

17.1.2 Electric Lighting

Electric lighting is required when daylight fails to meet task requirements. Lighting energy can be minimized through the use of energy efficient sources, luminaires, and system layout in combination with lighting control equipment that minimizes operating time.

Current energy codes restrict lighting power densities (LPDs) to the point where only energy efficient equipment and systems may be applied in new designs, making solutions that "beat" these requirements with even lower LPDs challenging, but still possible. Still, energy goals should not be achieved at the expense of lighting quality. A low energy design must meet the lighting goals and recommendations for space tasks and functions and provide a comfortable, productive, and pleasing luminous environment. In work spaces, costs associated with even small changes in worker productivity that may be compromised by poor lighting quality will far outweigh any lighting energy cost savings.

IESH/10e Control Systems Resources

> 16.2.5 Occupancy Sensing and Control

> 16.3.4 Occupancy/Vacancy Sensors

> 16.2.6 Time Control

17.1.3 Lighting Controls

Since energy is equal to the product of power and time (Energy = Power x Time), lighting energy can be minimized by reducing lighting power or by limiting its operating time. Lighting controls and proper zoning of lighting equipment can help reduce operating time or, in the case of dimming or multilevel switching systems, allow the electric lighting system to be operated at reduced power levels.

Most energy codes require automatic shutoff of lighting equipment to minimize energy waste [3] [4]. Control products that meet this requirement apply some form of occupancy or time-based control. The suitability of different lighting control systems or components must be evaluated for each space or project, considering their cost, operation, and energy savings potential. For example, occupancy sensors can save significant energy (20-40%) in private offices and shared spaces that are vacant for portions of a day, but would be inappropriate for other spaces, such as a large entrance lobby to a building. Time clocks can be applied in areas that are not suitable for occupancy control to ensure that lighting is turned off when a business is closed.

17.2 New Construction

In new construction, a high level of energy efficiency is required of lighting systems based on current energy codes. In addition, green building rating systems such as LEED [5] [6] [7] [8] [9], as well as green building construction codes [10] [11], encourage or require additional efficiency measures or targets, such as the application of daylight over most of the regularly occupied interior area.

IESH/10e Daylighting Design Resources

> 14.2.4 Schematic Design: Building Form and Siting

> 14.4 Building Orientation

> 14.5 The Building Design

17.2.1 Designing for Daylighting

A major strategy for minimizing lighting energy in new buildings is the application of daylight as the primary source for interior illumination. In new building design, daylighting influences the design through siting, space layout and daylight aperture configurations. A successful design is accomplished through a coordinated effort across the entire design team from the earliest phases of the design, addressing daylight quantity and quality, as well as total building energy consumption. The key to daylight quality lies in the architectural design, space configurations, daylight aperture placement and sizing, shading devices, and light redirecting elements. See Figure 17.1 for an example of a building that contains shading elements to protect south facing windows from direct sunlight.

IESH/10e Integrated Daylighting Control Resources

> 16.3.5 Photosensors

Daylighting requires careful design due to its dynamic nature which results from both atmospheric conditions and the ever changing position of the sun. Successful designs deliver quality daylighting while controlling solar gain, HVAC loads, and sunlight penetration that may cause glare and discomfort.

Energy savings are achieved when electric lighting is dimmed or switched off during times when interior daylight levels are sufficient to satisfy space and task needs (See Figure 17.2). This is best achieved through lighting that is controlled by photosensors in daylit areas. Lighting energy savings in daylit portions of a building can range from 30-60% of the energy required when no photosensor control is applied.

17.2.2 Electric Lighting Equipment

When a space is occupied and electric lighting is required, energy is managed through the use of energy efficient lighting equipment, proper layout of this equipment to conform to daylight and occupancy zones, and a control system that minimizes lighting energy waste. Localized task lighting is a design approach that helps to minimize lighting energy consumption, since higher levels required of specific tasks can be applied precisely where necessary, with lower ambient levels provided away from these tasks. The ambient system must meet recommended task to background luminance ratios and provide adequate illuminance for the non-critical tasks. A somewhat non-uniform, layered approach to lighting that considers the needs of different areas and surfaces within a space can enhance space appearance while saving energy compared to a uniform, general lighting system designed to the most critical visual task, which might occur infrequently and within a defined and limited area.

To design a low energy lighting system requires energy efficient equipment. However, the lamp or lamp-ballast system with the highest luminous efficacy (lumens per watt) does not always deliver the lowest installed lighting system energy that would meet the goals of a design. A less efficient source may provide better lighting control and consume less energy over its operational life while achieving the desired system performance. In some cases, lighting quality considerations may rule out specific sources due to color, controllability, size, available source lumens, candlepower requirements, or other source properties. The preferred solution is the one that meets all space lighting requirements while minimizing lighting system watts.

Specifiers and others who purchase lighting equipment must be wary of "energy saving" labels on lamps and other components. In many cases, energy saving products consume less power than the standard equipment they are designed to replace, but often at the expense of light output. These products are best applied in retrofit situations where reductions in lumen output would still meet standards and recommendations. The application of reduced output energy saving lamps or ballasts in new design provides no benefit if it requires more

lamps or luminaires, since this may only serve to increase system cost and provide little to no energy savings. In certain applications, energy saving lamps or ballasts may be useful for tuning light output that would otherwise exceed target levels given luminaire spacing or other layout requirements. Care should be taken to ensure that energy efficiency is delivered on a system level, which requires the use of energy efficient products, as well as energy efficient design and control strategies.

Electronic ballasts are the norm for fluorescent systems and are now available for many low and medium wattage HID lamps. They offer significant energy savings through significantly lower internal losses compared to standard magnetic ballasts.

The Ballast Efficacy Factor (BEF) rating system can be used to compare ballasts that operate a particular lamp. The BEF is equal to the ballast factor divided by the ballast input watts. The product of the BEF and the lamp lumen rating is the lamp-ballast efficacy in lumens per watt provided by a particular lamp-ballast combination. It is not appropriate to compare BEFs across different lamp types, and BEF will not directly correlate to lighting system power if the required number of luminaires changes with the ballast being applied.

When selecting luminaires, the system watts required to meet the design goals are key. To provide a more general metric for comparing across luminaires, the Target Efficacy Rating (TER) was developed by NEMA [12]. This rating system replaced the previous Luminaire Efficacy Rating (LER) system [13]. TER is equal to the luminaire lumens that reach the target area under prescribed conditions for that luminaire's application class, divided by the power input to the luminaire.

In the previous system, LER was defined as the ratio of the total emitted luminaire lumens (incorporating ballast factor and thermal effects) to the system input wattage. The LER metric did not account for the efficiency at which a luminaire delivers light to a task plane when applied in a real space. For interior luminaires, TER accounts for system performance in delivering lumens to a horizontal work plane at two different room sizes and a given set of room surface reflectances. The TER uses the average of the coefficients of utilization for these two room conditions, which vary across the 16 different interior luminaire classifications. This system, like LER, includes the impact on efficiency of each system component: fixture, lamp, and ballast. TER is a simplified energy metric for comparing the relative efficacy of alternate luminaires under standardized conditions, and therefore is of limited value since it does not address lighting quality or application specific performance measures.

For exterior lighting, the TER system considers 14 different luminaire classifications and applies either roadway coefficients of utilization (the lumens delivered to a specific target area based on mounting height) or luminaire photometric efficiency, depending on the luminaire type.

17.2.3 Lighting Controls

Energy can be saved by not operating lighting equipment that is not needed. The installed lighting system establishes the maximum lighting power that can be consumed at any point in time, while the lighting control system and occupants govern the amount of light and the length of time the system operates. Occupancy and time-based automatic lighting control systems can minimize or reduce operating time, while photosensors can dim or switch off electric lighting when daylight is available (See Figure 17.3). Variable-level, occupant-based control that applies dimming, multilevel switching, or zone-based switching can provide additional savings as some users will elect to operate a lighting system at less than full load under certain conditions.

Many of today's energy codes require automatic shutoff of lighting equipment in most spaces, either through the use of an occupancy sensor or time-based control. Occupancy sensors help to minimize lighting system operation by turning lighting equipment off when spaces

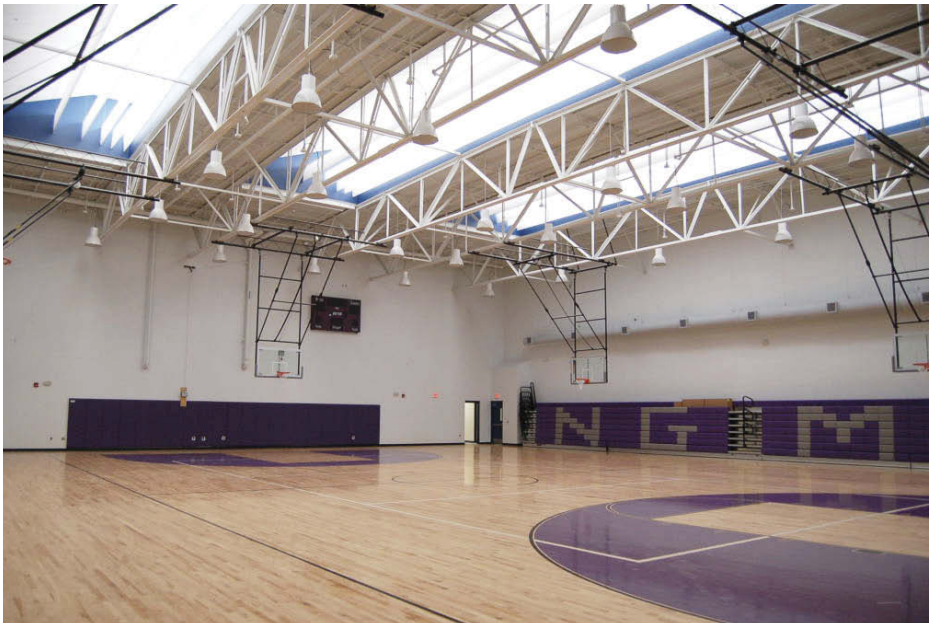

Figure 17.3 | A Daylit Gymnasium
Daylight is provided through south-facing clerestories that utilize clear glazing and fabric baffles to block direct sunlight in this gymnasium. The lighting control system has turned off the electric lighting due to the abundance of daylighting.
» Image ©Innovative Design

are vacant, while time clock control operates equipment during the time period when occupancy is expected, such as during normal business hours. The use of only time clock control in office or classroom settings will result in energy waste when spaces are unoccupied and lighting remains on. Many time-based systems conduct sweeps at preset times to turn lights off, such as at the end of the work day. A shutoff warning is generally provided to which occupants can respond with a request to override the shutoff action. In a typical application, additional sweeps at selected times throughout the evening help to de-energize lights in areas where shutoff was overridden during earlier sweeps, or where lighting may have been subsequently re-activated by janitorial staff or other individuals.

The size of lighting control zones influences energy consumption in most applications, since control zone size dictates how much power must be expended to illuminate a single work station, a circulation area, or a general task area when a large space, such as an open office area, is occupied by a single individual. Smaller zone sizes will improve energy savings. Flexibility in control can also be beneficial. Personal control of electric lighting in the form of dimming or multilevel switching has been shown to provide savings of approximately 10% [14].

For task lighting, plug load power strips with integrated occupancy sensors are available to turn off task lighting, computer monitors and other non-critical loads when a work station is vacant. These devices often contain surge protection and non-switched circuits to continuously power personal computers and other devices.

A list of available control technologies for managing lighting energy is provided in Table 17.1. Many of these technologies can be applied in new design, relighting and retrofits.

17.2.4 Space Design and Material Selection

Since a portion of the light arriving at any point within a space is reflected from room surfaces, the reflectance of these surfaces plays a role in the amount of light a system delivers. This is particularly important where light is directed from luminaires to room surfaces, such as with indirect or direct/indirect lighting, cove lighting, wallslot and wallwash systems. In the case of standard indirect lighting systems, light must reflect off the ceiling. Ceiling manufacturers now provide high reflectance ceiling panels that reflect as much as 90% of the incident light, compared to standard products which range between 75 and 80%.

Table 17.1 | Lighting Control Options for Energy Management
Control options for new construction, relighting and retrofit applications.

Technology	Advantages	Limitations & Comments	Best Applications
Digital Time Switch	• Automatically turns lights off after a set time period • Replaces standard toggle switch	• Lights remain on until timer counts down even if space is unoccupied	• Storage rooms
Wall-Switch Occupancy Sensor	• Turns lights off when space is unoccupied • Replaces standard toggle switch • Bi-level occupancy sensor wall switches are also available	• Mounting position limits view across space	• Storage rooms, small private offices
Ceiling-Mounted Occupancy Sensors	• Turns lights off when a space is uoccupied • Wide coverage area • Can also be used for high/low control configuration	• Some rewiring needed unless wireless models are applied • Must comply with local fire and egress codes • Must be cablibrated/commissioned • Recalibration requires trained personnel	• Large private offices, open offices, classrooms, restrooms, gymnasiums hallways, warehouses
Photosensors	• Take advantage of natural daylight • Can be used with dimming or switching control	• Must be properly located • Must be cablibrated/commissioned • Require dimming ballasts and appropriate wiring • Recalibration requires trained personnel	• Daylight harvesting in classrooms, offices, warehouses, gymnasiums, and exterior applications
Lighting Control Panel with Integral Clock and Automatic Switch	• Provides programmable time-based circuit control • Override switch replaces toggle switch in space	• Additional space may be required in electrical closet	• Big box retail, warehouse, open offices, private offices
Remotely-Operated Circuit Breaker	• Offers time-based circuit control • Replaces manual breaker • No additional control wiring is needed	• Provides control of entire circuits only	• Big-box retail, warehouses, offices, circulation
Occupancy-Based Plug Load Control	• Controls task lighting and other workstation power loads based on occupancy • Can be easily relocated if space layout changes • Also serves as a surge protector	• Limited by number of controllable outlets • User must be instructed on use • Can be easily disabled	• Private offices, open office cubicles
Luminaire-Integrated Occupancy Sensors	• Turns luminaire off or operates luminaire at reduced output when space is unoccupied • Provides full light output upon occupancy • Requires no additional control wiring	• Must comply with local fire and egress codes	• Open office spaces, stairwells, corridors • Parking garages, parking lots, pathway lighting

Higher wall and floor reflectances also help to increase reflected light for all lighting system types. Wall reflectances are especially critical in tall or narrow spaces, where more light emitted from the luminaires and reflected from the ceiling is likely to strike the walls rather than the work plane. In tall spaces, luminaires with a concentrated downward distribution will more efficiently illuminate a horizontal plane at the floor, although attention must be paid

to the appearance and luminance of the walls, which can appear dark under these conditions. Because the ceiling will reflect a significant amount of light to the walls, a predominantly uplight luminaire in a tall space will be relatively inefficient at delivering illuminance to the floor.

For daylighting, higher room surface reflectances, particularly on the ceiling, walls and floors adjacent to and facing a window, provide more reflected daylight to an interior space and lessen the need for electric lighting. Another important benefit of higher reflectances is that surfaces adjacent to a window will achieve a higher luminance, reducing the contrast between the window and these adjacent surfaces. This provides a more comfortable viewing condition that may reduce the tendency for occupants to apply window shading devices, and therefore deliver higher interior daylight levels that contribute to energy savings through automatic electric lighting control. See Figure 17.4.

Figure 17.4 | A Daylit Kindergarten Classroom
This classroom applies high ceiling and wall reflectances to help distribute daylight from the north-facing windows and clerestory. The white paint also reduces the contrast between the apertures and the adjacent interior surfaces. Significant energy savings is possible with a properly configured and calibrated lighting control system.

17.2.5 Lighting System Maintenance

In the design of new systems, the owner's maintenance practices, which include relamping and luminaire cleaning, determine the light loss factors that are applied in lighting system design calculations. These in turn affect the number of lamps or luminaires required in the space. Proper maintenance can therefore help to achieve a low energy design. A lighting system that is regularly cleaned will result in less luminaire dirt depreciation and require fewer luminaires, which reduces the system's initial cost, installed lighting power, and lighting energy consumption. Similarly, group relamping can help maintain higher lamp lumen depreciation factors.

In some cases, it may be necessary to educate the owner or facility operator on the importance of good maintenance practices, and the impact these practices have on the installed lighting power and the associated initial and operating costs.

17.3 Lighting System Upgrades

Since new lighting technology has significantly improved the energy efficiency of lighting systems in recent years, and since illuminance requirements in some spaces require less illuminance with modern tasks than was required when the older lighting systems were installed, significant reductions in lighting energy are achievable in buildings that are more than 20 years old. Modifications to a lighting system include the full range from simple component replacements (a lamp or ballast retrofit) to a complete lighting system redesign (which is often referred to as relighting). This process typically begins with an energy audit that reviews the existing systems and their energy consumption. Utility bills can confirm overall building energy use, however data from these records include a significant amount of non-lighting equipment. Pre and post upgrade energy data on feeders and branch circuits can be used to assess the actual level of lighting energy savings achieved.

IESH/10e Sources and Ballasts Resources

> 7 | LIGHT SOURCES: TECHNICAL CHARACTERISTICS

Simple retrofits may include changes to lamps, ballasts, optical materials, new luminaires, and the addition of new lighting controls. In a simple retrofit, the designer must verify the layout of the existing system provides sufficient lighting quality for the space and its tasks when fitted with the new components. Refer to the Illuminance Determination Table in the respective Handbook chapter for illuminance recommendations, and to the discussions in the general lighting design and application chapters of this Handbook (Chapter 12 | COMPONENTS OF LIGHTING DESIGN, Chapter 15 | DESIGNING ELECTRIC LIGHTING and Chapter 16 | LIGHTING CONTROLS) for additional lighting quality criteria and considerations.

If an existing system provides higher work plane illuminance than required by current standards, lighting energy savings can be achieved by lowering the illuminance. This may be accomplished through the use of lamps, ballasts, or luminaires which reduce both input power and light output, provided that lighting quality (including visual comfort, uniformity and other measures) is not adversely affected. In some cases, lamps with reduced lumen output or ballasts with low ballast factors are a simple and cost-effective solution. Some energy saving lamps, however, are incompatible with dimming equipment, which may limit the available options.

When considering a lighting system upgrade, it is helpful to rank the overall goals of a project. The general goals to consider generally will relate to one of the following.

- Energy Efficiency
- Lighting Equipment and Maintenance Costs
- Lighting Quality
- Appearance

IESH/10e Lighting System Economics Resources

> 18 | ECONOMICS

A retrofit of a poor quality existing lighting system should upgrade both its lighting quality and its energy efficiency. Therefore, it is important to study the existing system's energy performance, lighting quality, and operational costs, followed by a similar analysis for each of the retrofit options being considered. An economic analysis can determine the payback period for lighting retrofits based on the associated retrofit costs and the resulting savings in lighting energy and maintenance. Utility rebates or tax incentives may also be available to offset a portion of the costs associated with specific energy efficiency improvements.

Lighting service companies and performance contractors offer financing for many types of retrofit projects. Typical contracts require the owner to pay off the cost of the retrofit as a percentage of the energy cost savings. In this manner, retrofits can be applied with no increase in annual outlay.

Underwriters Laboratories (UL) certifies the safety of products and systems when used as directed by the manufacturer. Most luminaires have a UL certification for use with a specific type and wattage of lamp. Lighting retrofit kits that contain multiple components

may also be UL certified. When a retrofit involves a change in lamp type, self-ballasted lamps, like a CFL or LED PAR replacement lamp, for example, may be applied as a direct replacement for a filament lamp, provided the retrofit lamp wattage does not exceed the filament lamp wattage listed on the luminaire, and provided that such use is not disallowed through markings on the lamp (such as a label indicating that a lamp is not to be used in an enclosed luminaire) [15].

Although a lamp may be permitted to be used within a particular luminaire, UL certification only indicates that an unsafe application is not likely to be created. CFL and LED sources could be subject to reduced light output and premature burnout if the lamps and other internal components are exposed to excessive heat, which may occur when they are used within recessed or enclosed luminaires. Thermal tests may be necessary to validate that operating conditions are within those recommended for a particular lamp. Consult with the luminaire manufacturer, the lamp, ballast, driver, or transformer manufacturer, and the controls manufacturer to confirm appropriateness of any planned retrofit.

In the sections that follow, a number of different retrofit options for lamps, ballasts, luminaires and lighting control systems are discussed. These are summarized in Table 17.2. For broader coverage of retrofit topics, refer to IESNA LEM-3, Guidelines for Upgrading Lighting Systems in Commercial and Institutional Spaces [16].

17.3.1 Lamps

In existing systems, a lamp retrofit may save significant energy while delivering similar or higher lighting quality. One common retrofit is the replacement of filament A lamps with an equivalent screw-based compact fluorescent or LED lamp. Federal legislation that bans certain filament lamps by 2012 will significantly increase this activity. CFLs provide light at about four times the efficacy of filament lamps, but a CFL replacement may not be appropriate due to the resulting changes in system performance. For example, an existing luminaire's optical system is designed to operate with the A lamp's size and shape. If the replacement screw-base CFL is of different size or shape, a reduction in luminaire optical efficiency results, lowering the emitted lumens and changing the luminaire's photometric distribution (where the luminaire sends light). These changes may not only affect the amount of light delivered to a task, but also the uniformity of this light, in addition to luminaire and space appearance.

IESH/10e Sources and Ballasts Resources

> 7.2 Filament Lamps

> 7.3 Fluorescent

Tests on a mockup can be performed using a single or group of luminaires within a space to assess the impacts of an alternate lamp on a luminaire's distribution by taking measurements at multiple points beneath a luminaire. In testing a single luminaire, lamps may be removed from neighboring luminaires, or measurements can be made with the test luminaire turned on and off to isolate its contribution. Comparison measurements should be conducted with new lamps of each type, so as not to bias the readings toward a retrofit lamp by testing it against an aged lamp with depreciated lumen output. When comparing an existing lamp to a retrofit lamp, it is important to also assess luminaire appearance, since differences in luminaire luminance, direct glare, and source visibility may occur at different viewing angles. If the luminaire is adjacent to a wall, the distribution pattern produced on the wall should also be evaluated. Tests of fluorescent and HID systems should allow the lamp to first be seasoned for 100 hours, and both discharge sources and LED equipment must reach thermal equilibrium within the luminaire prior to conducting any measurements, since lamp output for these sources can vary with temperature. When using CFL's in enclosed luminaires, amalgam lamps can limit temperature effects on lumen output.

When existing systems use filament lamps on a dimming system, replacement lamps must be compatible with the dimming hardware. Some CFLs are labeled as compatible with filament lamp dimming systems, however dimming equipment manufacturers should be contacted regarding the compatibility of these lamps with the dimming hardware, since the use of these lamps may void product warranties.

In the case of filament reflector lamps, lamp retrofit options include halogen IR, self-ballasted metal halide, and LED sources. Some CFL reflector lamps are also available, but are likely to provide very wide beams that may significantly alter luminaire performance. Tests should be conducted to assess retrofit lamp performance and luminaire appearance.

A common retrofit for older linear fluorescent systems is to convert T12 lamps to T8 versions, which also requires replacement of the ballast. In most systems, the T12 lamps in use are a 34 W version powered by magnetic ballasts which have high internal losses. A conversion to T8 lamps with electronic ballasts offers significant energy savings, relatively

Table 17.2 | Energy Efficiency Retrofit and Lighting System Upgrade Options

Existing Lamps	Lamp Replacement Options
Filament - Medium Screw or Candelabra Base	• CFL with similar base and lamp shape • LED replacement lamp
Filament - Reflector	• Halogen IR reflector • Metal halide reflector with integral ballast • CFL reflector (for very few wide angle applications) • Induction reflector lamp (for very few wide angle applications) • LED PAR or MR
T12 Fluorescent T8 Fluorescent Fluorescent Lamps in Freezers	• T8 with electronic ballast • Lower wattage T8's if reduced lumen output is acceptable • LED retrofit kit
Mercury High Pressure Sodium (HPS) Standard Metal Halide (MH)	• Upgrade lamp and ballast to probe start or ceramic MH • Induction lamp retrofit
MH - Street/Area Lighting HPS - Street/Area Lighting Neon - Sign Lighting	• LED retrofit kit with proper performance
Existing Ballasts	**Ballast Replacement Options**
Fluorescent Magnetic Ballasts	• Electronic ballast with BF to deliver required task illuminance • Dimming or stepped-dim ballast with appropriate controls
MH Magnetic Ballasts	• MH electronic ballasts (limited wattages)
Existing Luminaires	**Luminaire Retrofit Options**
Filament	• Energy efficient CFL or LED luminaire with appropriate performance
Linear Fluorescent Industrial or Commercial	• Retrofit of optical components: lens, reflector, or louver • Reduce number of lamps
Any Luminaire with Low Efficiency or Degraded Performance	• Energy efficient replacement delivering suitable distribution and lighting quality
MH - Industrial	• Replace with CFL, T8 or T5 HO industrial luminaire and consider multi-level switching
Existing Controls	**Control System Upgrades**
Standard Switching or Relays	• Occupancy sensors • Multi-level controls for stepped ballasts • Dimming with wall or personal controls • Photosensors in daylit zones • Replace with digital ballasts and controls to permit rezoning and dimming

short payback, and improved color quality. In spaces that are overlit relative to current standards, lower ballast factors may be applied or the number of lamps may be reduced (which requires rewiring of the luminaire) to deliver appropriate work plane illuminance values. If the number of lamps is reduced, this modification should not degrade luminaire appearance or distribution. With parabolic troffers, a change in lamp position will alter the lamp shielding angle and the luminaire's candlepower distribution, and both should be assessed prior to committing to such a retrofit.

17.3.2 Ballasts

IESH/10e Ballasts Resources

> 7.3.6.5 Ballasts (Fluorescent)

> 7.4.3 Ballasts (HID)

In addition to increased efficiency, conversion from fluorescent magnetic to electronic ballasts improves lighting system quality through high frequency lamp operation, improved acoustical performance, and heat reduction within the luminaire. NEMA's Premium Electronic Ballast Program identifies the most energy efficient T8 ballasts for both conventional and dimming ballasts [17].

Standard metal halide systems can be converted to pulse-start lamps and ballasts to deliver improved lighting quality and energy efficiency. These retrofit lamps offer longer lamp life and higher lumen maintenance that can decrease maintenance costs and deliver energy savings. A retrofit that applies ceramic metal halide lamps will deliver similar benefits with improved color quality.

Additional options for fluorescent and HID systems include converting to stepped ballasts to allow lamps to operate at lower output levels whenever possible. Load shedding ballasts are also available that provide reduced output levels (66% of full output) with control via a power line signal.

When analyzing potential energy savings, it is recommended that power measurements be conducted on existing circuits, since high internal luminaire temperatures generated by standard magnetic ballasts may cause fluorescent lamps to operate at less than optimum temperature conditions. This will result in ballast input power that is below catalog data. When an electronic ballast is applied in a retrofit, ballast heat is significantly reduced, and the system is likely to operate closer to the ballast manufacturer's rated input watts. The net result is that both power and energy savings may not be as great as indicated by manufacturer's catalog data.

17.3.3 Luminaires

Retrofit options for some types of luminaires include the insertion of specular or diffuse high reflectance reflectors to improve the optical efficiency of the luminaire. These reflectors may alter the photometric distribution of the luminaire. A new lens, a parabolic louver system, or a modern lens/reflector combination are options for lensed fluorescent luminaires. Retrofits involving changes to a luminaire's optical components are often combined with lamp/ballast retrofits, which may include a reduction in the number of lamps used within a luminaire. Evaluation of these retrofit options must consider how changes to the optical distribution influence both lighting quality and task illuminance, as well as room surface and luminaire appearance. Any measurements of the existing system should address that system's performance when operated with new lamps and clean luminaire surfaces.

IESH/10e Luminaires Resources

> 8 | LUMINAIRES: FORMS AND OPTICS

In some cases, the best retrofit option involves changing the entire luminaire, but retaining existing mounting locations (See Figure 17.5). This may be necessary because alternate lamping options are not available, luminaire materials have degraded over time, or because system performance is unacceptable with the existing luminaire and could be improved with a different luminaire. In still other cases, a redesign that involves a modified luminaire layout may be the best option to reduce energy and achieve the desired lighting quality for task and space conditions. Infrastructure work may be necessary to achieve proper suspension or ceiling support. Any redesign should consider alternate luminaire circuiting and control options that would deliver additional energy savings. In some situations, a complete lighting system upgrade may be nccessary to comply with existing energy codes.

IESH/10e Lighting Controls Resources
> 16 | LIGHTING CONTROLS
> 16.3.4 Occupancy/Vacancy Sensors
> 16.3.5 Photosensors
> 16.5 Control Protocols

17.3.4 Lighting Controls

Any retrofit should consider upgrades to the lighting controls to save additional energy. Existing controls may involve simple manual control at wall switches, or relay and time-clock devices that control large blocks of lighting at one time. In private offices, retrofit options include replacing standard wall switches with wall switch occupancy sensors. In larger spaces, occupancy sensors may be mounted to the ceiling or high on a wall. These devices are commonly linked to a power pack that contains a relay to control the lighting circuit. Wireless, battery operated occupancy sensors are also available to eliminate the need to run wiring to the sensors. Occupancy sensors have the potential to save significant energy (20-40% or more) in private offices and in a variety of shared spaces such as conference rooms, classrooms, restrooms, break areas, open office areas and others. The level of savings achieved depends on the habits of space users.

Additional control options include the application of automatic lighting control in daylit areas using either dimming ballasts or on/off control. These systems require the installation of photosensors, which are available in both wired and wireless configurations and are typically installed on the ceiling. The controlled lighting zone layout and system calibration are critical for establishing a proper lighting control response to daylight levels and for maximizing energy savings within a space. Digital control systems, such as DALI, permit the controlled lighting zone to be independent of how luminaires are circuited, which can be valuable in retrofit applications. A retrofit to a DALI control system requires ballast replacement as well as additional control wires to be connected to each ballast in the system.

When considering a retrofit that includes occupancy sensors, inexpensive data loggers make it is possible to study occupancy and lighting system operating conditions within a space over an extended period of time (days or weeks) to evaluate potential energy savings. See Figure 17.6. These loggers are mounted to the walls or ceiling and record changes in both occupancy and lighting system on/off status for later analysis. The logger software that analyzes these data provides daily occupancy and lighting system operation profiles which can be used to determine the number of hours the space is unoccupied with the lighting system in operation, and the annual energy savings likely to be achieved when occupancy sensors are installed in the space. See Figure 17.7 for an example report.

Figure 17.6 | Examples of Loggers for Light and Occupancy Sensing
These loggers record time-stamped changes in both lighting conditions and space occupancy in existing spaces for analysis of potential energy savings through the addition of occupancy sensors.
» Left Image ©Wattstopper
» Right Image ©Sensor Switch

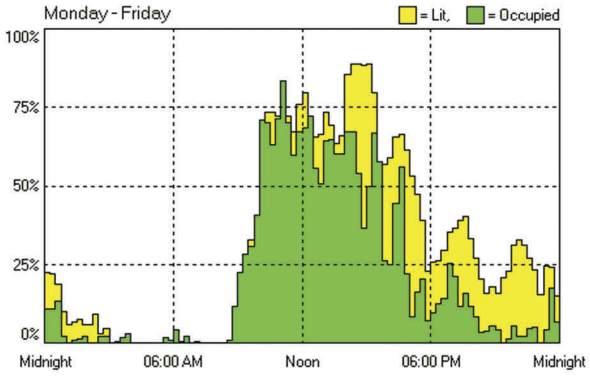
To realize energy savings, it is critical that control devices be properly commissioned, calibrated and maintained in a mode that optimizes energy savings. In many spaces, lighting

is required only when a space is occupied, and in the case of daylit spaces, when daylight levels are insufficient for space tasks. Time clock control should be configured to conform to space occupancy, which may change with season. Periodic follow-up checks should be conducted by the building's maintenance personnel to evaluate system performance.

The subject location was monitored from Thursday, October 25, 2007 3:50:00 PM to Wednesday, November 21, 2007 2:33:00 PM by InteliTimer Pro serial number RP0102C. Of the total elapsed time (646.72 hours), the lighting remained on with the monitored location vacant 10.18% of the time.

Based on these measurements, installing occupancy-controlled lighting controls in this location would save approximately 892.0 power-on hours per year. Assuming an energy cost of $0.08 per kWhour, and an additional 10% savings from reduced heating and cooling requirements, the potential yearly savings with a controlled load of 1,000 watts is:

Electricity saved:	$71.36
Reduced heating/cooling costs:	$7.14
Total savings:	$78.49



Additional savings may be possible from lighting load reductions during peak demand hours.

LIGHTING/OCCUPANCY SUMMARY

On+Occupied	86.38 hours	13.4%
On+Vacant	65.85 hours	10.2%
Off+Occupied	18.02 hours	2.8%
Off+Vacant	476.47 hours	73.7%

LIGHTING STATISTICS		OCCUPANCY STATISTICS	
Total On time:	152.23 hours	Total Occupancy time:	104.40 hours
Average On period:	1.12 hours	Average Occupancy period:	0.30 hours
Shortest On period:	0.02 hours	Shortest Occupancy period:	0.08 hours
Longest On period:	7.72 hours	Longest Occupancy period:	3.40 hours
Total On/Off cycles:	135	Total Occupancy cycles:	351
On/Off cycles per day:	5.0	Occupancy cycles per day:	13.0

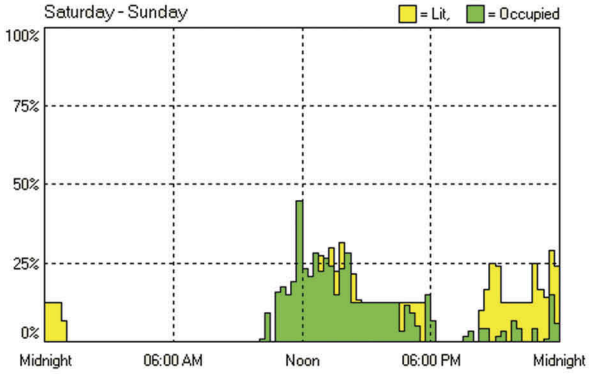


Figure 17.7 | Sample Light and Occupancy Logger Output
The results of a light logger installed in a university classroom for approximately four weeks illustrate savings opportunities with vacancy sensor control in this space. The yellow regions in the graphs represent time when the lighting systems is operating and the space is vacant. The listed cost savings are per kilowatt of connected load.

IESH/10e Ballast Efficacy Factor Resources

> Table 7.5 | U.S. and Canadian Standards for Ballast Efficacy Factor

17.3.5 Exit Sign Upgrades

Older exit signs provide significant opportunities for energy savings and reduced maintenance through lamp or complete sign replacement. Long hours of operation (typically 24 hours per day) provide significant cost savings with reduced wattage sources. Maintenance cost savings alone can provide short payback periods due to the longer life of retrofit lamps. When considering an exit sign upgrade, it is important to investigate code issues related to source replacement. Sign visibility is critical, and is based on the uniformity and luminance of the sign's letters. Figure 17.8 illustrates an exit sign retrofit that delivers substandard uniformity. All types of older exit signs are potential candidates for retrofits or upgrades, with most replacement options applying SSL sources. See Figure 17.9 for one type of exit sign replacement lamp. SSL exit signs utilize roughly 40% of the energy of CFL signs and 15% or less of the energy of signs operated with filament lamps [18]. SSL source life is also in the 35,000-50,000 hr range, so maintenance costs should be minimal, and building safety will be improved. The presence of internal batteries to deliver emergency power or integral lighting to illuminate an exit pathway may limit the retrofit options that meet code provisions.

17.3.6 Disposal

Disposal of old lighting equipment may require special consideration. Certain lamps and ballasts must be treated as hazardous waste, such as pre-1979 fluorescent ballasts that contain PCBs, and lamps with mercury or lead solder (which includes fluorescent, MH and HPS). Consult federal, state, and local regulations regarding proper disposal of lamps and ballasts. Many of these lamps can be recycled. If luminaires are replaced, aluminum and steel parts should be recycled.

17.4 Lighting Efficiency Codes, Regulations and Standards

Lighting efficiency standards and codes are designed to ensure that energy efficient lighting systems are installed in buildings. Legislation on lighting system efficiency generally falls into one of two forms, equipment regulation and application standards.

Equipment regulation occurs when governments at the national, state or provincial level enact regulations that ban the sale or use of certain types of lighting equipment. Building design regulations apply application standards, limiting installed lighting power, placing limits on luminaire distributions (as in requiring full cutoff outdoor luminaires for certain wattages and applications), or requiring specific lighting control equipment to reduce operating time and minimize lighting energy consumption. A designer's goal is to meet or exceed the requirements of the applicable codes or standards without compromising the quality of a lighting design.

17.4.1 Applications Standards/Codes

Lighting energy codes and standards prescribe energy conscious design techniques but do not prescribe the use of specific technologies. The selection of equipment that satisfies space and task requirements in a cost effective and energy efficient manner is the responsibility of the lighting designer. Life cycle cost models can justify the economic merits of increased equipment efficiency.

The purpose of these codes and standards are to:

- Set minimum requirements for the energy efficient design of new buildings so they may be constructed, operated, and maintained in a manner that minimizes the use of energy without constraining building function or the comfort and productivity of the occupants.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

- Provide criteria for energy efficient design and methods for determining compliance with these criteria.
- Guide energy efficient design.

In Canada, each province has its own building code which includes lighting energy provisions. The national model code, the Model National Energy Code of Canada for Buildings (MNECB) [19], has been adopted in its entirety by only a few locations [20].

In Mexico, the Comision Nacional de Ahorro de Energia (CONAE) has developed building energy standards which include NOM-007-ENER-2004: Energy Efficiency for Lighting Systems in Non-Residential Buildings [21].

At press time, most U.S. states have adopted either the International Code Council's International Energy Conservation Code (IECC) or the ANSI/ASHRAE/IESNA 90.1, Energy Standard for Buildings Except Low-Rise Residential Buildings. The 2009 IECC Code permits buildings to achieve compliance by meeting the 90.1 Standard. The American Recovery and Reinvestment Act of 2009 [22] established the ANSI/ASHRAE/IESNA 90.1-2007 Standard as a minimum requirement in state energy codes in order for a state to receive federal energy assistance grants. States are also required to meet future releases of this code, following confirmation by the U.S. Department of Energy that the updated version improves building energy efficiency.

In Standard 90.1, the basic lighting requirements include minimum criteria for lighting controls as well as power limits for interior and exterior building lighting. For interior lighting power, the Standard offers a choice of three compliance methods: an energy cost budget (ECB), a prescriptive path based on building type (Building Area Method), and a prescriptive path based on the spaces within a building and their area (Space-by-Space Method).

The ECB method is the most encompassing and complex approach for assessing compliance. A whole-building energy model is used to predict energy use and must equal or beat that of a building designed using the prescriptive approach. It allows the designer to trade off lighting energy with other energy systems (such as the HVAC system). Although the method is flexible, it requires sophisticated analysis tools and can be time consuming.

The Building Area Method addresses the need for a quick and simple process for calculating the interior lighting power allowance (ILPA) for selected building types or areas within a building. This method does not address unique project requirements and is intended primarily for generic building types, core and shell buildings, or for use during the preliminary design phase. The ILPA is calculated by selecting the lighting power density for the respective building type from a table in the standard, then multiplying it by the gross building floor area represented by that building type. Different sections of a building may be assigned to different building types.

The Space-by-Space Method provides a detailed calculation procedure to determine the ILPA. The ILPA is totaled room by room and is task specific. Lighting power densities for a variety of space types are listed in a table. The ILPA for the building is the sum of the individual lighting power allowances from each of its spaces.

In all cases, a single space does not need to meet its allowance, but the total lighting power used in a building must not exceed the total building's ILPA. Similarly, the exterior lighting power allowance is the sum of individual lighting power allowances for a variety of exterior applications/areas, some of which may be traded between applications.

The IECC approach is similar to the 90.1 standard, except that it only lists a Building Area Method for determining the interior lighting power allowance. Future versions may include a Space-by-Space Method.

17.4.2 Equipment Regulations

In both the United States and Canada, the government has played a major role in lighting energy reduction in recent years by attempting to reduce lighting energy consumption through stricter regulations on lighting system components. The primary institutions responsible for these national standards are the U.S. Department of Energy (DOE) and Natural Resources Canada (NRCan). The standards are relatively similar in these two countries so that (1) lower efficiency products are not dumped from a country with regulations to one without, (2) manufacturers can design products according to one standard instead of several, and (3) the regulatory burden is decreased.

17.4.2.1 U.S. Regulations

Over the past 20 years, a number of laws have mandated the use of efficient lighting components (lamps and ballasts): the National Appliance Energy Conservation Amendments of 1988 (NAECA) [23], the Energy Policy Acts of 1992 and 2005 (EPACT) [24] [25], and The Energy Independence and Security Act of 2007 (EISA 2007) [26].

The EPACT legislation and EISA have mandated energy efficiency standards for a number of common lamps used in the United States, such as R, PAR, and certain fluorescent lamps. As of July 1, 2010, nearly all fluorescent ballasts that are manufactured for T12 lamps in the U.S., including replacement ballasts, with the exception of some dimming and low temperature versions, must be electronic. This is the result of minimum BEF values established by DOE. For this reason, lamps and ballasts found in older lighting systems may no longer be available, and must be replaced with high efficiency models.

EISA 2007 effectively banned many of the standard forms of filament lamps by instituting minimum performance standards for these lamps that cover wattage, lumen output and life. These regulations will phase out non-compliant lamps by 2012-2014. EISA 2007 also added a number of different reflector lamps (BR, ER, and R lamps of specific wattage and size) to the efficiency requirements initially prescribed in EPACT 1992. These lamps were previously exempt from these regulations.

EPACT 1992 called for a voluntary national testing and information program for widely used luminaires that offer the potential for significant energy savings. As a result, the LER metric was developed by the National Lighting Collaborative, which was composed of NEMA (National Electrical Manufacturers Association), the American Lighting Association (ALA), and other interested organizations representing lighting designers, energy efficiency advocates, research, government, and electric utilities. LER was recently replaced by TER (see 17.2.2 Electric Lighting Equipment).

17.4.2.2 Canadian Standards

Natural Resources Canada has regulatory powers under the Energy Efficiency Act of 1992 [27], with the first Energy Efficiency Regulations were published in 1994 [28]. Federal standards do not take precedence over provincial standards, in contrast with the United States where federal standards preempt state standards on a specific product. National standards apply to products imported into Canada or shipped between provinces. Provinces may choose to adopt these standards for products sold within their borders. Canadian lamp regulations are similar to U.S. EPACT standards for filament reflector and linear fluorescent lamps. These standards took effect in 1996. Canada's regulation and phase out of filament lamps is stricter than U.S. regulations and will eliminate the sale of some lamps two years earlier than occurs in the U.S. [29]

17.4.2.3 Mexican Standards

Mexico's energy efficiency standards are developed by the Ley Federal Sobre Metrologia y Normalizacion (Federalo Standards and Metrology Laws). Energy efficiency standards are the responsibility of the Energy Secretariat, through its Comision Nacional para el Ahorro de Energia (CONAE). Many of Mexico's standards are voluntary, except for its CFL

standard, which lists minimum efficacies [30]. The country also has a voluntary energy efficiency endorsement seal provided by the Fidelcomiso para el Ahorro de Energia Electrica (FIDE). Mexico has lighting standards for commercial buildings as well as for exterior lighting.

17.4.3 Nonregulatory Government Programs

Government agencies also promote energy efficiency and energy conservation through voluntary programs. The Energy Star Building Program administered by the U.S. Environmental Protection Agency (EPA) is a comprehensive building initiative that encourages use of energy efficient technologies for all major building systems, including lighting. A partnership agreement is signed between a luminaire manufacturer and EPA and the U.S. Department of Energy (DOE). EPA and DOE work with the luminaire manufacturer to promote superior products that qualify for the EPA/DOE Energy Star label. Products that carry the Energy Star label meet energy efficiency and quality criteria in an effort to ensure consumers do not sacrifice performance to save energy.

17.4.4 Green Building Codes and Rating Systems

The design of green and high performance buildings often involves an attempt to achieve a particular rating level on one of the green building rating systems, such as LEED, BOMA BESt [31], or Green Globes [32]. Daylighting and electric lighting (both interior and exterior) are two of the numerous system areas addressed within these rating systems. Green building standards and codes that have been approved, or are nearing the final stages of approval, include ASHRAE/IESNA 189.1, Standard for the Design of High Performance Green Buildings, and the International Green Construction Code (IgCC) from the International Code Council (ICC).

In the lighting systems area, these codes focus primarily on the implementation of daylighting and energy efficient lighting controls, since significant reductions in lighting power density may not be possible without sacrificing lighting quality. For example, the 189.1 standard contains allowable lighting power densities that are 90% of those in the 90.1 standard, while the IgCC simply requires that a building meet the values in the International Energy Conservation Code (IECC). However, in most of these green building codes and standards, daylight must meet a prescribed level across a percentage of the occupied building area, often specified using one or more set time/sky analyses, with integrated automatic lighting control applied in the daylit areas.

Daylighting code or standard compliance may take the form of either a prescriptive or performance approach. The performance approach requires extensive building energy modeling, but places less restriction on the amount of glazing area and glazing material used. Permitted glazing properties under the prescriptive path are limited in both 189.1 and the IgCC by specified maximum solar heat gain coefficients (SHGC) and limits on the fraction of exterior wall and roof area that may contain windows or skylights. An integrated design approach is essential to achieving quality daylighting and low overall building energy consumption.

18 | ECONOMICS

The highest use of capital is not to make more money, but to make money do more for the betterment of life.
Henry Ford

Economics plays a role in every lighting design decision, regardless of whether the project is large or small. Economic analysis methods permit designers and owners to evaluate alternative systems or investments on a life cycle cost basis in considering which alternative to choose. This chapter outlines basic economic analysis approaches that can be applied to lighting systems, as well as the relevant cost information that can affect the economic evaluation of a lighting system, component, or its means of operation and maintenance. It is of value to building owners, maintenance staff, manufacturers and designers for evaluating different lighting and maintenance options based on evaluations of life cycle cost.

18.1 The Role of Economic Analyses

A lighting design must be responsive to the needs of the users and the owner, including their economic needs. In the design and construction of a project, economic concerns play a role in many decisions, and are often considered the antagonist of aesthetic and quality concerns. Early in the design process, a lighting designer establishes a list of needs and criteria (See 11.3.2.1 Programming) that are considered to be essential; then begins the complicated process of prioritizing criteria other than budget and determining which can be accommodated by the budget, or if and how the budget is to be revised. [1-4]

Rather than consider economic analyses as the antithesis of good engineering or aesthetic design, it should be viewed as a framework within which the project's needs must be addressed. Failure to provide a quality lighting condition for users can negatively impact comfort, satisfaction, and/or productivity and have financial consequences. In addition, a lighting design that fails to address the aesthetic requirements of a space may result in lower rental values, or in the case of a restaurant and certain retail applications, reduced business. A lighting design that properly addresses the users' needs and complements the architecture will address a number of important economic concerns that are by nature difficult to quantify. In general, aspects related to occupant performance, preference, and behavior are not included in a formal economic analysis of lighting system alternatives.

Economics can impact nearly every major component of a lighting design, from sources, luminaires and controls to long-term maintenance that includes cleaning and relamping. An economic evaluation is equally important for new construction as well as for retrofit projects. A comprehensive economic analysis of a proposed design will consider a variety of different economic concerns, such as:

- A comparison of alternative systems or components
- The benefits provided by a lighting system or component relative to its cost
- Evaluation of maintenance techniques and procedures
- Evaluation of energy management technologies and strategies
- Impact of lighting on other building systems and the associated costs
- The project's budget constraints

Many of these economic concerns are straightforward to analyze. A more expensive lighting or control system may save energy or reduce maintenance costs over time to justify its higher initial cost. The question of whether the costs associated with a lighting system can be justified by the savings or benefits it provides is one of economics, and often must be considered by the design team during design development, or in defense of a design. In any economic evaluation, the lighting quality provided by different options being considered should be equal to justify a comparison based solely on initial and operating costs.

This chapter will address standard approaches to economic analyses and describe the associated system costs that generally apply to a cost/benefit analysis of lighting system design alternatives. It includes a discussion of a few low level analysis methods: simplified metrics that may provide a general economic assessment. These approaches are followed by a discussion of Life Cycle Cost Benefit Analysis (LCCBA), the recommended approach for analyzing the economics of system alternatives. First, a brief discussion follows on costs and where a lighting practitioner can turn to obtain these costs.

18.2 Estimating Costs

A lighting system can impact economics in a variety of ways. The obvious ones include the cost to purchase and install the system, as well as the annual or periodic energy and maintenance costs. Additional costs or savings may be accrued through taxes and HVAC system costs (both initial and operating). In commercial settings, issues such as worker productivity, safety, health, and employee retention, as well as customer attraction or increased sales, or increased rental income are difficult to quantify and are not typically addressed in economic comparisons. In commercial and industrial settings, worker salaries far exceed the other costs associated with construction and operation of a building , but the impact on worker productivity is too complicated to quantify, but is a critically important factor to consider. As such, an economic analysis of design alternatives will consider the costs associated with its installation and operation. With energy saving options such as alternative lighting control strategies, the question often is: Do the savings provided by a system or component justify a higher initial cost? Such a condition is relatively simple to assess through an economic analysis that considers a best estimate of all initial and operating costs, which includes energy costs. In the case of a retrofit, one option might be to maintain the existing system, in which case the initial costs for that option can be zero, or the costs associated with basic maintenance that will be performed in place of the retrofit, such as relamping. If no relamping will occur, it is important to consider that lamp and ballast replacement costs will be higher for an existing system early in the study period than for a newly installed system.

To evaluate design alternatives, the owner may wish to know how quickly higher initial costs will be recovered (a system's payback period), or the rate of return on the investment (which is analogous to the interest received on any additional investment). A detailed economic analysis can assist the building owner or a company's financial officer in determining whether it is better financially to invest in cost saving building equipment or to invest it elsewhere within the company based on a comparison of the expected returns.

In performing a cost analysis, it is important to gather representative cost data associated with the design, construction, and operation of a system. This information consists of best estimates for all cash flow related to the lighting system. In some cases, it may be appropriate to apply conservative estimates when there is uncertainty in predicting future costs. Table 18.1 provides some guidance regarding the type of information that must be gathered and sources for obtaining these data. Note that in a comparison of design alternatives, it is only necessary to assess the differences in cash flow between systems to determine which is the least expensive over the system's life, or to assess the payback period for one alternative relative to another.

Table 18.1 | Lighting Related Costs and Sources for These Costs

Cost Category	Item	Source for Values
Initial Costs	**Equipment**	• Manufacturer's representatives • Previous projects • Electrical distributor or contractor • RSMeans [5,6]
	Labor	• Previous projects • Electrical distributor or contractor • RSMeans [5,6] • Previous projects
	HVAC Equipment & Labor	• Mechanical system designer
Annual Costs	**Energy Charges**	• Lamp or ballast wattages • Electrical rates from utilities • Operating hours (considering impact of lighting controls) • Mechanical system designer for differences in HVAC Energy
	Demand Charges	• Lamp or ballast wattages • Utility rates • Mechanical system designer for differences in HVAC peak demand
	Lamp or ballast replacement costs	• Local distributors/suppliers of lighting products • Manufacturer's data for life expectancy • Operating schedules
	Labor for lamp or ballast replacement	• Labor rates for maintenance staff, including benefits • Time required to replace lamp or ballast or • Lighting services company charge
	Lamp disposal costs	• Lamp recycling or disposal companies
	Luminaire cleaning costs	• Labor rates for maintenance staff, including benefits • Time required per luminaire • Cleaning material costs or • Lighting services company charges
Other Costs	**Utility rebates**	• Local utility provider
	Tax impacts	• Local, state, and federal tax laws for tax credits, depreciation and other expense deductions
	Insurance	• Insurance company
	Disposal Costs	
	Salvage costs	• Waste disposal companies
	Recycling costs	• Recyclers
	Residual value	• Companies specializing in demolition or resale of used building products

As previously noted, these analyses cannot account for productivity and therefore should be judged accordingly. If lighting system option A exhibits a lower cost value than option B, but option A is know to create more glare, or exhibits light distributions that create dark ceilings and upper walls, then option A is rightly an inappropriate choice.

18.3 Simple Payback

Simple payback is a general, first-level method commonly applied in comparing design alternatives. The simple payback period is an approximation to the amount of time required to pay off an investment. It is the incremental initial cost of a system divided by the additional annual cash flow (financial benefit) it provides

$$PP = \frac{I}{A} \tag{18.1}$$

Where:

PP = simple payback period (years)
A = incremental annual cash flow (annual savings)
I = incremental investment

Simple payback does not consider the time value of money, which considers that a given monetary amount is worth more today than at some point in the future. Therefore, the use of the simple payback method is appropriate only when payback occurs quickly (within a couple years) and not well into the system life of the systems. Simple payback is not an IES recommended practice to evaluate alternative lighting systems because a low cost system or retrofit may not prove to be the best system financially when a longer time period is considered. The use of Life Cycle Cost Benefit Analysis is a more rigorous second level method (See 18.6 Life Cycle Cost Benefit Analysis (LCCBA) and 18.7 Discounted Payback and Rate of Return).

18.4 Simple Rate of Return

The simple rate of return (ROR), which is often referred to as simple return on investment (ROI), is the reciprocal of the simple payback period. It is the annual benefit provided by an investment divided by the initial cost of that investment.

$$ROR = \frac{A}{I} \times 100\% \tag{18.2}$$

Where:

ROR = simple rate of return
A = incremental annual cash flow
I = incremental investment

ROR, as defined here, does not consider the time value of money. A more rigorous second-level discounted rate of return is defined in 18.7 | Discounted Payback and Rate of Return.

18.5 Cost of Light

The cost of light is a general lighting cost analysis metric that considers the costs incurred over the life of a lamp in relation to the cumulative lumen-hours it will produce over its lifetime. This metric is only valid for comparing lamps that produce the same general light distribution , are interchangeable within luminaires, and have no resulting impact on a luminaire's optical efficiency. The cost of light in dollars per million lumen-hours is expressed by the following equation:

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

$$U_{lamp} = \frac{1000}{\phi_{lamp}}\left[\frac{1000(C_{lamp} + C_{labor})}{L_{lamp}} + P_{lamp}\,C_{energy}\right] \quad (18.3)$$

Where:

U_{lamp} = unit cost of light for a lamp in $/lm-hr
ϕ_{lamp} = mean lamp lumens
C_{lamp} = lamp price ($)
C_{labor} = labor cost to replace one lamp ($)
L_{lamp} = average rate lamp life (hrs)
P_{lamp} = mean input power per lamp (including ballast losses)
C_{energy} = energy cost ($/kwh, including any demand charges)

18.6 Life Cycle Cost Benefit Analysis (LCCBA)

Life cycle cost benefit analysis (LCCBA) is a robust economic analysis method capable of addressing all quantifiable costs in a project, is widely endorsed and required on government projects, and is the economic analysis method recommended by IESNA [3]. This method compares systems or hardware alternatives under consideration by analyzing their differential costs. This generally requires all known costs over the life of the system to be evaluated. [3] [4] [7] [8]

18.6.1 The Time Value of Money

The time value of money is considered in the LCCBA approach. Under this approach, payments and receipts in the future are valued less than current transactions. All costs that are incurred over the life of the system must be converted to their equivalent value at a single point in time, generally the current value of a currency, or its "present worth." Once all costs are converted to present worth, systems can be compared to determine which is least expensive over the life of the system.

To convert future expenses to present worth, it is necessary to select a rate for the time value of money. This value is a percentage rate that represents the opportunity cost to an owner, which is the interest rate an owner would expect to make on an investment of similar risk, or the firm's cost of capital. This rate will differ depending on how inflation is handled in the analysis. Inflation can either be included or ignored in the analysis, but this will change the proper rate to apply for the time value of money. If included in the analysis, costs will increase each year throughout the analysis period, and different types of costs, such as labor, equipment and energy, may increase at different rates. If inflation is ignored, all costs are expected to escalate with the general rate of inflation, and the rate used for the time value of money is adjusted to account for this. In such an analysis, if an annual cost such as energy will increase at a higher or lower rate, the difference between its escalation rate and the general rate can still be included in the analysis.

Market interest rates generally consider that inflation will occur, so if a market interest rate is being used, inflation rates should be considered for all costs. An interest rate for the time value of money that accounts for inflation, permitting general inflation to be ignored, can be determined from an equivalent market rate through the following equation.

$$i = \left[\frac{1 + i_m}{1 + r}\right] - 1 \quad (18.4)$$

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Where:

i = interest rate to convert future costs to current dollars that permits inflation to be ignored
i_m = market-based interest rate (accounting for inflation)
r = rate of inflation

18.6.2 General Assumptions

In applying LCCBA or any other economic analysis method, all systems are assumed to fulfill the functional requirements of the design equally. They are of the same general quality, and impact productivity in a work environment and other performance measures such as sales in a retail environment similarly. In many retrofit situations, lighting quality is improved, in which case the results of an economic analysis can be further strengthened.

18.6.3 Considering Systems with Unequal Lives

To compute the total life cycle cost of each system, it is necessary to perform an analysis over the expected life of the system. If a present worth analysis is being conducted to compare the costs of systems with different lives, the systems must be evaluated over the same number of years. If the systems being compared have different life spans, then a time period that is the least common multiple of these time periods should be applied to the analysis. With this approach, the initial costs of a system are incurred at the beginning of each new life cycle.

An alternate approach is to determine the present worth of each system over their respective lifetimes, then convert these present worth values which include both initial and annual costs to a total uniform annual cost over the life of that system using Eq. 18.8. The system with the lower total annual cost is the less expensive system.

18.6.4 Converting Costs to Present Worth

The total present worth of each system considers all costs that are expected over the life of the system. To determine the lowest cost system over their lifetime, it is only necessary to consider the cost differences between the systems. If a particular cost, such as the labor for system installation, is the same for all systems being analyzed, then this cost does not need to be considered. If, however, the analysis is being conducted to determine the relative magnitude of the costs associated with alternate systems, then full and accurate costs are required for all expense categories.

The process of determining the total present worth of a system involves first determining all costs that are to be considered. A list of items to consider in the analysis of a lighting system is provided in Table 18.2. These costs are converted to present worth using the appropriate equation from Table 18.3. One approach is to list the costs incurred in each year of the analysis, total them by year, then convert each of these values to present worth. Table 18.4 lists present worth conversion factors derived from Eq. 18.5 to use in converting future costs or income to present worth for interest rates up to 15% and time periods through 20 years. Two examples are provided in 18.8 Present Worth Example Problems.

If a cost is repeated each year over the system life, an optional approach is to convert the repeated annual cost directly to present worth using either Eq. 18.6 or 18.7. Note that some costs, such as group relamping costs, may not be incurred in every year. These should be converted to present worth individually. Costs that occur sometime during a particular operating year should be considered to occur at the end of that year in assessing the number of years to consider for the present worth conversion factor.

Once a total present worth value is determined, these costs can be converted to an equivalent annual cost using (18.8). The initial costs are then distributed across all of the years of the analysis.

18.6.5 The LCCBA Worksheet

The simplified LCCBA worksheet provided in Table 18.2 lists lighting system and other related costs that are typically addressed in a lighting system economic analysis. Not all costs may be considered in every analysis. Remember that only those costs which are different need to be included to assess which system is less costly over the life of the system. Detailed notes are provided to explain the data entered on each line of the worksheet.

18.6.5.1 Line-by-line notes for Table 18.2 | LCCBA Worksheet:
Line 1: Establish the anticipated life in years of the lighting systems (identical for all systems).

Line 2: Determine an interest rate associated with borrowing money, alternative investments, or simply the escalation for the life of the lighting system.

Line 4: Estimate the material costs for the lighting system, remembering to include any differences in wiring costs.

Line 5: Estimate the labor costs to install the system.

Line 6: A lighting system introduces heat into the building which must be removed by the HVAC system in spaces that are cooled. If the lighting system choice alters the size of the HVAC equipment, the appropriate differential costs should be entered here. Note: If a daylighting system is being analyzed, the HVAC loads and equipment sizes may be affected. The project mechanical consultant should be consulted for this information. 1 ton of cooling can remove the heat provided by approximately 3.5 kW of lighting. Cooling equipment pricing is approximately $1500-$2500 per ton.

Line 7: Energy efficient lighting systems may increase the heating load for a building due to reduced internal gains. If the size of heating equipment differs between lighting systems being compared, enter the differential cost of the systems here. The project mechanical consultant should be consulted for this information. 1 kW of heat is equal to 3.4 kBtu/h, which corresponds to about $60-$100 for the incremental heating equipment costs if the equipment size changes.

Line 8: Electric utilities may offer incentives for end users who retrofit or install energy efficient lighting equipment in their buildings. Enter financial incentives to be received as a negative number.

Line 9: Include any other differential costs, such as design fees or tax credits here.

Line 10: Enter any taxes that are not already included in the price of the equipment.

Line 11: Sum the total initial costs of the systems. This is the present worth of the initial costs.

Line 13: Determine the annual energy consumption (kwh) for each system, considering the building occupancy schedule and the impact of control systems, such as occupancy and dimming controls. Multiply the energy consumption by the utility charge for energy ($/kwh). Note that rates may vary by time of day and season.

Line 14: Monthly demand charges may be incurred if the lighting system is operating during the peak demand period. Estimate the impact on the monthly demand reading for the system and apply the electric utility's demand charge, if demand metering is to occur.

Line 15: Annual cooling costs should be obtained from a detailed energy load study conducted by the mechanical consultant since these are based on aspects such as the system efficiency, fuel type, and economizer applications. [13] These values may be particularly important in studying alternative daylight delivery systems.

Line 16: Annual heating costs should be obtained from a detailed energy load study conducted by the mechanical consultant since these are based on aspects such as the system efficiency, fuel type, and economizer applications. [13] These values may be particularly important in studying alternative daylight delivery systems.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Line 17: Lamp replacement costs will depend on the lamp life, operating schedule, and lamp replacement strategy. Both material and labor costs should be included. A rough approximation considers the number of lamps to be replaced per year based on operating hours and lamp life. Note that non-uniform annual costs are likely to occur with group relamping. The impact of this effect can only be evaluated through non-uniform annual costs.

Line 18: Ballasts generally have relatively long lives. Ballast replacement costs are unlikely in the early years of a system, but may eventually reach a steady-state condition where the number of ballasts replaced is equal to the number of ballasts divided by the ballast life. Both material and labor costs should be included.

Line 19: Luminaire cleaning may be conducted on a regular basis, or may be conducted only when lamps are changed. In the latter case, these costs may be included in the lamp replacement costs. Consider both material and labor costs. For use in this spreadsheet, approximate these costs based on an average cost per year.

Line 20: Enter the expected impact on annual property taxes here.

Line 21: Enter any additional annual costs here.

Line 22: Sum all of the annual costs here to obtain the approximate cost of the system on an annual basis.

Line 23: Calculate the present worth factor for each system to convert annual costs over the life of the system to its equivalent total present worth using Equation 18.6.

Line 24: Multiply the present worth factor (line 23) by the total annual costs (line 22).

Line 25: Tax laws permit equipment to be depreciated over a set number of years on tax returns. In the U.S., lighting equipment that is incorporated into furniture can be depreciated over 7 years rather than the standard 39 year period. In additionaaddition, a commercial building tax deduction is available in the form of accelerated depreciation for energy efficient lighting equipment through 2013. Input the annual tax savings to the owner and the time period as a negative number.

Line 26: Calculate the present worth factors for each system to convert the annual tax savings to an equivalent total present worth for the listed depreciation period using Equation 18.6.

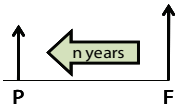
Line 27: Multiply the present worth factor (line 26) by the annual tax savings (line 25) to obtain the equivalent present worth of these savings.

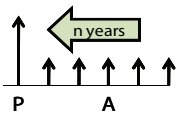
Line 28: The amount the system will be worth or the cost to the owner to dispose at the end of its economic life. This value is negative if money is received and positive if a cost is incurred to dispose of the system.

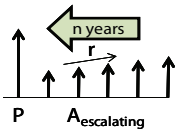
Line 29: Calculate the present worth factor to convert salvage value at the end of system liflife to its equivalent total present worth using Equation 18.5.

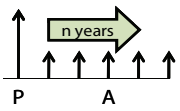
Line 30: Multiply the present worth factor (line 29) by the salvage value (line 28).

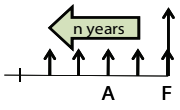
Line 31: Sum lines 11, 24, 27 and 30 to determine the total present worth of the systems. The lower value is the less expensive option over the life of these systems.











18.6.5.2 General Assumptions for Table 18.2 | LCCBA Worksheet:
1) The systems are assumed to provide equal benefits and lighting quality in all areas not assessed by this worksheet.

2) The systems being compared have identical system lives.

3) The interest rate used to determine the present worth factors accounts for inflation. Individual escalation rates could be applied to each of the costs in section B if they are each converted individually to present worth using Equation 18.5.

Table 18.3 | Equations Relating Present Worth, Future Worth and Annual Costs
(i is the opportunity cost or interest rate; r is the inflation rate, in decimal format: 0.01=1%)

To Compute	Given	Equation		Graphic
Present Worth (P)	F	$P = F \times \frac{1}{(1+i)^y}$	(25.5)	
	A	$P = A \times \frac{(1+i)^y - 1}{i(1+i)^y}$	(25.6)	
	A , r	$P = A \times \frac{(1+r)\left[(1+i)^y - (1+r)^y\right]}{(i-r)(1+i)^y}$	(25.7)	
Annual Cost (A)	P	$A = P \times \frac{i(1+i)^y}{(1+i)^y - 1}$	(25.8)	
	F	$A = F \times \frac{i}{(1+i)^y - 1}$	(25.9)	

18.7 Discounted Payback and Rate of Return

If the cumulative present worth of all costs through any year of the analysis is considered, it is possible to determine a discounted payback period for a system that has a higher initial but lower operating costs. It is also possible to determine a discounted rate of return (DROR) that considers the time value of money. The DROR is the rate for the time value of money that creates identical total system present worth values over the life of the systems.

18.8 Present Worth Example Problems

This section contains two examples, showing how present worth is considered in the economic analysis of actual lighting system decisions.

18.8.1 Present Worth Example 1

Consider an existing lighting system that is spot relamped. The system consists of 100 lamps which cost $3 each. The lamp life is 10,000 hrs and the lamps are burned for 2,500 hrs per year. The option being considered is a change to group relamping every three years (to occur at 75% of rated life). The cost to spot relamp is $10 of labor per lamp, whereas the cost to group relamp is $4 per lamp. Which is the more economical approach considering an interest rate of 10%? This analysis will consider the number of spot relampings that will occur between group relampings based on a lamp mortality curve.

Solution: Table 18.5 lists the costs incurred initially and in each year of the study period, which is considered as one relamping cycle. These costs are converted to present worth using the appropriate multipliers from Table 18.4, and then totaled.

15.0	.870	.756	.658	.572	.497	.432	.376	.327	.284	.247	.215	.187	.163	.141	.123	.107	.093	.081	.070	.061

Table 18.5 | Present Worth Analysis for Example 1

The Relamping costs for the two systems in Example 1 are converted to their equivalent present worth values then totaled. The initial costs for the group relamping option are considered to already be at present worth.

		OPTION 1 - Spot Relamping				OPTION 2 - Spot + Group Relamping			
Year	PW Factor	# of Lamps Replaced	Relamping Type	Annual Cost	PW	# of Lamps Replaced	Relamping Type	Annual Cost	PW
Initial	1.000			$0		100	Group	$700	$700
1	0.909	25	Spot	$325	$295	0		$0	$0
2	0.826	25	Spot	$325	$269	0		$0	$0
3	0.751	25	Spot	$325	$244	7	Spot	$91	$68
TOTAL		75		$975	**$808**	107		$791	**$768**

The difference between the two options in this example is much greater when actual costs are totaled, but this does not address the time value of money. Since costs in future years are discounted in a present worth analysis, the system with more of its costs deferred to the future benefits from a present worth analysis. When the time value of money is considered, Option 2 still is the least expensive, but the difference between the two systems is much less. Note that regardless of how many full relamping cycles are considered, the ratio of the two costs will not change, since identical costs are repeated in future years.

18.8.2 Present Worth Example 2

This example considers two options for design that applies recessed downlights. One applies CFL Lamps and the other LED sources. Details on these systems are provided below. All values are hypothetical and are provided solely for use in this example.

General Details:

- 20 year operational life with 10 hr/day operation, 365 days/year.
- Energy cost: $0.10/kwh
- Installation labor rate: $60/hr
- Maintentance labor rate: $30/hr

System #1:

- (54) 18 W CFL recessed downlights at $350 each
- 12000 hr lamp life
- 20 input watts

System #2:

- (48) LED recessed downlights at $450 each
- 50000 hr lamp life
- 12 input watts

System #1 Cost Calculations:

- Initial installed cost:
  54 luminaires × ($350/luminaire + 0.75 hr labor × $60/hr) = $21,330
- Annual energy cost:
  54 luminaires × 20 W × 10 hr/day × 365 days/yr / 1000 W/kwh × $0.10/kwh = $394/yr
- Annual relamping cost:
  (3,650 hrs/yr) /12,000 hr/lamp × ($8/lamp + 0.2 hr labor × $30/hr) = $123
- Annual cleaning cost:
  54 luminaires × $0.1 hrs labor /luminaire × $30/hr = $162

System #2 Cost Calculations:

- Initial cost:
  48 luminaires × ($450/luminaire + 0.75 hr labor × $60/hr) = $23,760
- Annual energy cost:
  48 luminaires × 12 W × 10 hr/day × 365 days/yr / 1000 W/kwh × $0.10/kwh = $210
- Group relamping cost:
  48 luminaires × ($30/LED module + 0.2 hrs/lumininaire × $30/hr) = $1,728 (years 1 and 4)
- Annual cleaning cost:
  48 luminaires × $0.1 hrs labor /luminaire × $30/hr = $144

Table 18.6 illustrates the calculation of both simple payback and discounted payback using a 4% interest rate that does not require inflation to be considered. System 2 is the more expensive system initially, but incurs lower annual costs. The bolded values indicate times when the cumulative costs associated with System 2 are less expensive than the same costs for System 1. Simple payback for System 2 occurs when the cumulative total of all payments for that system is less than those for System 1. This occurs at about the 7 year

Table 18.6 | Present Worth Analysis for Example 2

System 2 costs more initially, but is less expensive to operate and maintain. The bold values in the Total of Payments and Total PW columns indicate the year in which these cummulative totals become less expensive for System 2.

		System 1							
Year	PW Factor	Energy Cost	Maint. Cost	Annual Cost	Annual Cost PW	Total of Payments	Total PW (i=4%)		Total PW (i=11%)

point (6.99 years). Discounted payback, which considers the time value of money, occurs when the cumulative present worth of all payments is less than the same payments for System 1. This occurs at approximately 8.12 years. Over the 20 year system life, in today's dollars, System 2 is $2,044 less expensive than System 1. Averaged over the life of the system, the discounted Rate of Return (ROR) is equal to the interest rate that provides identical 20-year present worth values. The rightmost column shows this occurs at an interest rate of 11%, which is the ROR.

18.9 Economic Analysis Software

In general, it is quite easy to perform a lighting system economic analysis in a spreadsheet. Costs should be categorized as one of the following

- Initial costs, which are already at present worth.
- Annual costs that are unchanged over the system's lifetime.
- Intermittent costs that occur at recurring intervals throughout the system's life, but change from year to year.
- Salvage costs that occur at the end of the system's life.

The latter three are converted to an equivalent present worth using the appropriate multipliers.

A number of different economic analysis tools are available to perform these functions [9-12]. Some of these are standalone programs, while others are modules attached to another lighting analysis program.

18.10 Summary

The consideration of economics in the design and selection of lighting equipment and lighting systems will help to provide maximum long term benefit to a building owner by providing a quality lighting solution at lower net cost. Remember that the types of economic analysis described in this chapter are intended for the evaluation of systems that offer equivalent lighting quality, otherwise the additional cost or savings between two systems reflects the costs incurred or savings gained in moving to a higher or lower level of lighting quality. Keep in mind that differences in lighting quality are likely to have financial implications beyond what is reflected in most economic analyses.

Applying sustainable approaches to building design has gained wide acceptance in recent years in response to concerns about climate change, depletion of the world's natural resources, pollution, and concerns about human health and well-being. The United Nations World Commission on Environment and Development, in 1987, declared that "sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs."[1] In the lighting profession, the IES and International Association of Lighting Designers (IALD) have defined sustainable lighting design as "meeting the qualitative needs of the visual environment with the least impact on the natural environment." [2] [3] Sustainable design attempts to balance our current needs with that of future generations by using natural resources wisely and protecting the natural environment.

Lighting is a major component of sustainable building design, due to its potential impact on the environment and on society. The electricity used to power lighting systems consumes 25% of commercial building primary energy [4]. Electricity production in the United States is largely based on fossil fuel burning power plants, which release carbon dioxide, mercury, sulfur dioxide and nitrous oxides that contribute to global warming and acid rain. Hazardous materials such as mercury and lead solder are used in the production of certain lamps. The manufacture of lighting equipment also consumes natural resources and energy; most lamp and luminaire components consist of steel, aluminum, copper, other metals, glass, and plastic [5].

Lighting also impacts the quality of the visual environment. Lighting affects human health, comfort and performance in building interiors, where many people spend the majority of their waking hours. Understanding how design decisions affect both occupants and the natural environment is necessary to achieve more sustainable design solutions.

Sustainable design begins with a set of goals that are developed at the initial project programming stage. These include lighting performance, energy performance and environmental impacts of a design that span from the materials used in the manufacture of the lighting products, to the installation and operation of the lighting system, and finally to disposal of these components at end of life.

19.1 Basic Concepts

Sustainable design considers a building's economic , societal, and environmental impacts, which McDonough has labeled as economy, equity and ecology [4]. Products should be designed and utilized to have a positive impact on nature and society, while creating economic value. McDonough's "cradle to cradle" concept suggests that products should be designed so that upon end of useful life their materials can be converted into new products, such as occurs with recycled steel, glass, and aluminum. If a product is made of a synthetic material, that material should be one that can be recycled. Metals and glass are the primary ingredients in most lighting products, so many of these products can both apply recycled

content and be recycled when decommissioned. This approach is preferred to over a "cradle to grave" approach where a product is sent to the landfill, and its replacement must be created from scratch using the basic raw materials. This can consume greater amounts of energy and more of the earth's available resources than would occur using recycled materials. The recycling of lamps containing mercury helps to recover that mercury for use in new products and keep it out of landfills and the environment.

With lighting, a major focus of sustainability is the energy required to operate a lighting system over its lifetime, which can be significant. Reduced energy consumption can be accomplished through the use of daylight and energy efficient lamps, luminaires, layouts and lighting control systems. Some lighting system components, such as poles for exterior lighting and luminaire housing materials, have no end use energy impact and can be evaluated like most other building materials.

19.2 Elements of Sustainable Lighting Design

Sustainable building design considers the impact of all building materials and systems on both the occupants and the environment. Emphasis is placed on the quality of the interior environment, energy consumption, and environmental influences of all related activities – from raw material extraction to the eventual retirement and disposal of the system, as well as on the embodied energy of the equipment being used, and on the release of harmful materials to the environment.

Sustainable lighting can be addressed in a variety of areas: system and component design, system operation, quality of the visual environment, and disposal. A number of key considerations are listed below.

1. Apply quality daylighting as the primary source of light at appropriate levels. This will reduce reliance on electric lighting, save lighting energy, and extend in-service lamp life when luminaires are switched off during daylight hours.

2. Enhance work environments by connecting occupants to the exterior through daylight and view apertures.

3. Minimize electric lighting energy consumption through energy efficient equipment, integrated building design [7] and energy saving lighting controls. Apply the correct amount of electric lighting only where and when it is needed to conserve energy and reduce electrical demand based on time of day, occupancy and available levels of daylight. Flexible personal control of lighting equipment can save additional energy when reduced levels are selected by occupants [8] [9] [10].

4. Provide a pleasing and comfortable visual environment that enhances occupant performance, health and general well-being.

5. Employ systems and equipment that offer flexibility (which may include system reconfiguration), durability, and ease of maintenance. These features ensure the system will be in place for many years, adding to the sustainability of the design by avoiding the need to change equipment as space functions change.

6. Specify equipment made with environmentally responsible materials that minimize chemical and material waste and environmental pollution

7. Consider options that reduce packaging material and transportation requirements.

8. Provide for proper commissioning, and document system operation, maintenance, commissioning and lamp recycling procedures in a lighting systems operation and maintenance manual.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

9. Minimize light pollution and light trespass by applying outdoor lighting according to the environmental zone at the building site and by stepping back or eliminating lighting at a given curfew.

10. Specify that all lighting products be appropriately recycled or disposed at end of useful life.

Sustainability should be considered at all phases of the lighting design process, beginning at the project programming stage. Sustainability is often dictated by the project client who desires a building that meets a given level of sustainability as qualified through a green building rating system. Even without such a requirement, many of the elements of sustainable design represent good design practice and should be considered. More details on each these design elements that can contribute to sustainability are described in the following sections.

19.2.1 Daylighting

Since daylight availability corresponds to the standard work day and most building occupancy schedules, lighting energy can be minimized through the application of daylighting to partially or fully illuminate building interiors. In addition to saving energy, daylight can enhance the quality and appeal of a space through its dynamic nature, higher luminances, and excellent color quality. Occupant well-being is improved through connections to the exterior environment provided by view windows and daylight apertures. See Figure 19.1. To achieve a quality daylit environment, direct sunlight and glare through daylight apertures must be controlled. Daylighting designs that meet occupant and space needs with net energy savings (considering both lighting and HVAC energy) demand an integrated design approach by the project team, since daylighting affects multiple building systems and design decisions (see 14.2 Daylighting Design Process). Building siting and layout, selection of glazing material, aperture sizing and placement, and sunlight control are critical to overall system performance and energy savings potential. Excessive glazing can lead to glare and high heating and cooling loads. Automatic control of daylight is necessary to ensure energy savings are achieved.

Figure 19.1 | A Daylit Office
Workers in this open office area are provided with daylight and a view. Note that no electric lighting is operating. The skylight well contains baffles to block direct sunlight and provides daylight to wash an interior wall on a lower level.

19.2.2 Electric Lighting

A sustainable electric lighting system requires energy efficient equipment, a well-planned layout, and in some cases flexible or automatic lighting control. Current building energy codes restrict lighting power densities and require specific lighting control features to guarantee that base levels of energy efficiency are achieved. Additional energy can be saved by designing systems with even lower installed lighting power, or by controlling the system to reduce system operating power or hours of operation. Quality lighting must be maintained under all conditions.

In the design of electric lighting, a layered lighting approach helps to achieve energy savings. Under such an approach, required task levels may only be provided over the immediate task area with general ambient lighting at a lower level to maintain visual comfort and performance while enhancing space appearance. See Figure 19.2 and 15.1 Electric Lighting Systems. Sustainable designs must be both functional and pleasing in addition to addressing energy and environmental concerns. Designs and equipment that permit easy reconfiguration are desirable in spaces that may be rearranged periodically. If the lighting design is lacking in any way, including aesthetics, a space may not be used to its fullest intent, or the lighting system is likely to be removed and replaced, both of which are an inefficient use of resources.

19.2.2.1 Equipment Considerations

To address sustainability in the selection of lighting equipment, the following aspects of the lighting equipment should be considered.

- energy efficiency
- lighting quality relative to task visibility, visual comfort and aesthetics
- controllability
- recycled and recyclable materials
- embodied energy
- hazardous waste or by-products (through manufacturing, use, or disposal)
- required maintenance

Figure 19.2 |Task Lighting
Task lighting within an office cubicle supplies the desired work surface illuminance, while ambient lighting provides lower general levels of illuminance across the space, which saves energy. Indirect lighting helps to increase the overall perception of space brightness. The left side of this workstation applies an undercabinet task light that also helps to balance luminance ratios within the work station, while the right side contains a flexible LED desktop luminaire.

- life/durability
- packaging and transportation requirements

19.2.2.2 Lamps

Section 13.11 Sustainability provides an overview of the sustainability issues pertaining to lamps. Figures 13.1a and 13.1b provide information on lamp efficacy and lamp life, both of which are related to sustainability. Lamp efficacy, while it contributes to energy efficiency, does not always predict the most energy efficient lighting system. General comments on each of the primary source types are provided below.

Filament

The lamps in this family are among the least efficacious and their use should be minimized. Both luminous efficacy and lamp life are low. Their use for general ambient lighting should be avoided, but may be appropriate for some accent lighting and in limited historic settings. The most efficient forms apply halogen infrared (IR) technology. Filament lamps have relatively low embodied energy and no hazardous waste.

Fluorescent lamps

Fluorescent lamps, even though they contain mercury, couple energy efficiency with long life to contribute to a more sustainable design. Mercury content of fluorescent lamps has been significantly reduced over the past 25 years as shown in Figure 19.3 [11]. All varieties of fluorescent lamps should be recycled to avoid placing mercury into landfills or incinerators. CFLs are an energy efficient replacement for general service filament lamps in many applications. Fluorescent lamps reduce mercury emissions to the atmosphere relative to less efficient filament lamps when powered by an oil- or coal-sourced utility [13].

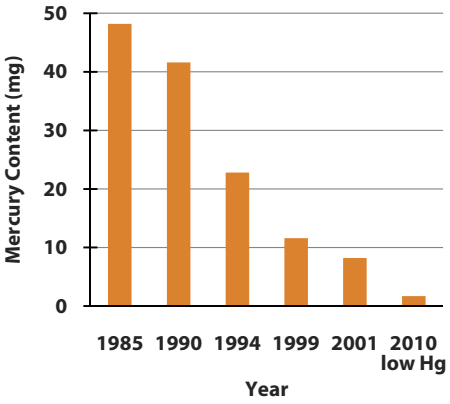

Figure 19.3 | Average Mercury Content of Four-foot Fluorescent Lamps
Mercury content of fluorescent lamps has been significantly reduced over the past few decades. Some four-foot lamps in 2010 have mercury content under 2mg [12], but an industry average is not available.

HID

Many HID lamps contain mercury and lead-based solder and therefore should be recycled. Some HPS lamps are now available with no mercury or lead. HID lamps can be a sustainable design option since the application of high output lamps may reduce the number of luminaires required, provided relevant quality criteria are met, especially those related to glare. HID lamps have relatively long lives, particularly in relation to filament lamps. Ceramic metal halide lamps offer excellent color quality and high efficacy, and can be used to replace filament lamps in a variety of applications, including those requiring reflector lamps. In some applications, such as industrial and high bay applications, fluorescent lamps have replaced HID lamps due to their longer life and more flexible control options.

Solid State

Solid State Lighting (SSL), if properly applied, can have very long lamp life, as in the case with most LEDs, that reduces the need for replacement. This, in itself, can be considered a sustainable feature. LEDs also offer small size, good energy efficiency (which is continuously improving and expected to exceed that of all other known electric sources [14]). LEDs can compete with both halogen and CFL downlight equipment in terms of energy and photometric performance. They offer exceptional directional control and the opportunity for dimming or multilevel switching. In exterior lighting, multilevel switching is possible using occupancy sensors to reduce energy in parking areas when these areas are unoccupied. The requirement for drivers and heat sinks must be considered in evaluating LED systems.

As of this writing, LEDs are powered by low voltage DC current, which makes them excellent candidates for application with photovoltaic systems. Wiring distances, however, can create a challenge with DC systems since current flow is much higher at low voltages, which contributes to increased wire losses and voltage drop. When lighting is powered by site-generated photovoltaic systems, the savings in primary energy are greater than simply the load removed from the grid due to inefficiencies in power generation and distribution. The national average for the ratio of source to site power is roughly 3.4, which means that it takes more than three times as much energy to be consumed at a power plant to operate a given load within a building.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

19.2.2.3 Ballasts

Fluorescent ballasts should be electronic to minimize ballast losses. Dimming ballasts provide the opportunity to achieve energy savings when the occupant desires reduced space brightness, or when daylight is available. Digitally addressable dimming ballasts offer highly flexible control options, and the ability to monitor energy consumption, institute load shedding, and be informed of equipment failures. Some fluorescent ballasts are designed to provide stepped dimming or peak load reduction.

For HID luminaires, magnetic HID ballasts use significant quantities of copper and iron in their windings, requiring more raw material to be mined and processed. Electronic ballasts are now available for a number of low wattage HID lamps, offering energy savings and requiring less raw material to manufacture. Stepped-dimming ballasts permit HID lighting levels to be lowered, with resulting energy savings.

19.2.2.4 Luminaires

In selecting luminaires, the ability to deliver high quality, low glare lighting with low environmental impact is critical. Along with quality, high system energy efficiency is key, and results from a combination of both lamp efficacy and luminaire optical performance. Other attributes such as materials used, durability, life, maintenance, and adaptability to changes in space use or layout further determine the ultimate sustainability of a particular product or design. Components of luminaires generally consist of steel, aluminum, plastic and glass, most of which is recyclable. Both the recycled content and the ability to recycle components at end of life affect the sustainability of a product. When used as a common reflector material, aluminum is often anodized, which is a relatively environmentally responsible process since it generates no hazardous waste and does not complicate the recycling process. Painting of metal parts is typically performed with powder coatings that emit little to no volatile organic compounds (VOCs).

19.2.2.5 Controls

Controls, including local, scene, timer-based, occupancy-based, photosensor, and personal controls are key energy saving features of electric lighting systems (See 16 | LIGHTING CONTROLS for details on each of these systems). Once a lighting system is installed, the control system and occupant behavior largely determine energy consumption. To function properly, automated lighting control systems must be properly selected, designed and commissioned. For best results, commissioning of scene, occupancy and photosensor systems should occur after spaces are furnished. A plan for how a system will be commissioned and operated should be addressed during the design process. A third-party commissioning agent is typically responsible for this work. This person is often involved in planning and review throughout the building design process, to ensure that the owner's needs are continuously addressed through an integrated design process [15].

Since lighting needs and preferences vary by individual, personal or occupant controls are recommended in most work areas. These may take the form of low wattage task lighting with local control or an adjustable overhead system in a private office. The ability to dim or switch to achieve different lighting levels will save energy for occupants who prefer less than full system output. The establishment of appropriate lighting scenes in spaces with scene control enhances system flexibility and performance while contributing to energy savings.

Smart zoning limits the portion of a lighting system that must be operated based on occupancy or daylight conditions. Flexible control settings permit lighting in daylighted areas to be adjusted to appropriate levels through either dimming or switching to provide energy savings, even when no automatic photosensor control system is installed. Occupancy sensors can be used to save lighting energy in a wide variety of spaces, including work spaces, classrooms, conference rooms, break rooms, supply and print rooms, resetrooms, corridors, stairways and outdoor spaces. Automatic-off technologies should turn lighting off when not needed or when the space is unoccupied. In some of the spaces, reduction to a lower illuminance is preferred to complete system shutoff. Consult codes to verify which types of control are permitted in different spaces.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Systems that minimize operating time may also contribute to longer in-service equipment life, reducing waste and conserving resources through less frequent component replacement.

19.2.2.6 System Maintenance

Regular luminaire maintenance in the form of cleaning and relamping helps to minimize installed lighting power through the application of higher light loss factors in design calculations (see 10.7.1.2 Recoverable Light Loss Factors). At the design stage, knowing that good maintenance practices will be in place can result in fewer luminaires being required to maintain target illuminance values, lowering installed lighting power levels which leads to reduced energy consumption.

19.2.2.7 Room Surface Materials

Sustainable building designs often attempt to minimize the use of paints and apply materials in their natural state. Typically the reflectance of these materials is lower than what is recommended for efficient lighting system design. Lower reflectances result in greater energy costs through reduced daylight levels and greater installed lighting system power. A life cycle cost analysis should be performed to determine the net effects of applying unpainted versus painted surfaces.

19.2.2.8 Packaging and Transportation

Sustainability can also be addressed in the environmental costs associated with packaging and transporting a particular product from its manufacturing site to the location where it will be installed. Packaging materials can be minimized, utilize recycled materials, and be reusable or biodegradable to improve sustainability. The specification of smaller, lighter weight products can also reduce the energy required to transport these items. Similarly, purchasing products from local manufacturers that make use of locally supplied components will reduce transportation energy.

19.3 Light Pollution and Trespass

Light pollution involves light that is directed skyward, hindering or eliminating the view of the starlit sky on clear nights (see Figure 19.4). Light trespass, on the other hand involves light that leaves a site and strikes a neighboring property, which may be considered a

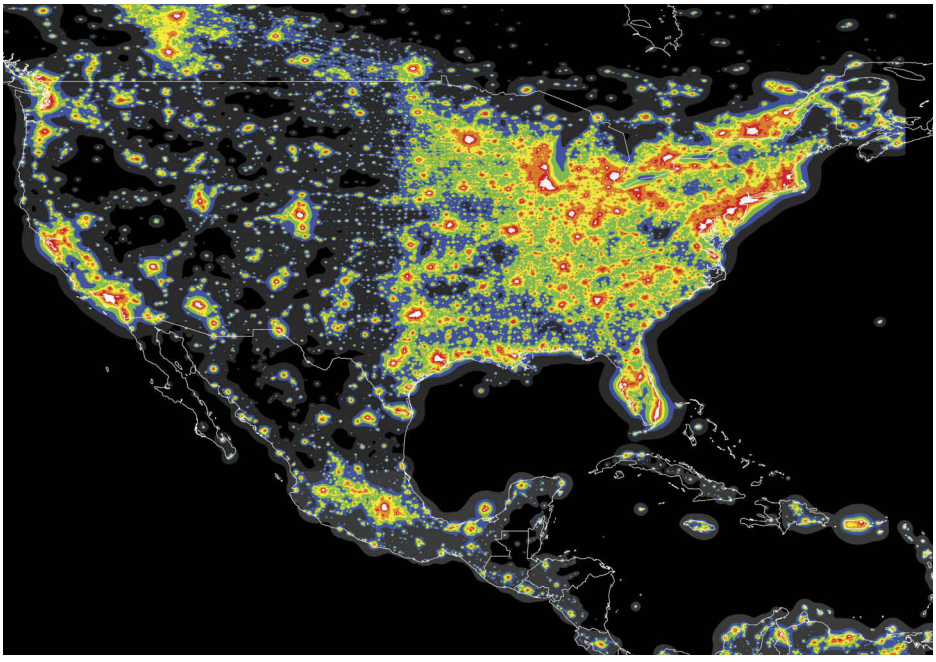

Figure 19. 4 | Light Pollution Map
This map shows calculated levels of sky luminance across Mexico, the United States and Canada [16]. High population areas produce higher levels of light pollution.

nuisance. Sky glow and light trespass both represent poor lighting design since they waste energy by directing light to areas other than the intended target.

In exterior lighting for buildings, signage, landscape and hardscape, light pollution and trespass can be limited by minimizing the use of light to what is essential for safety, with decorative lighting limited to selective accents rather than wide area floodlighting (which can enhance aesthetic appeal as well as energy efficiency), by directing light downward and through careful optical control. At the time of this handbook's printing, the IES and the International Dark Sky Association are working toward development of a Model Lighting Ordinance (MLO) that provides municipalities with suggested language and guidelines for use in formulating local ordinances. Lumens emitted in the upward zones of the BUG rating system may be limited based on the environmental zone in this or similar outdoor lighting ordinances (see 8.2.2.6 Outdoor Environmental Classification).

Light trespass can be avoided by selecting luminaires with appropriate optical control and by applying a layout that directs light primarily toward the intended targets. Shielding attachments can help eliminate spill light onto neighboring properties and toward the sky. Both well-designed optical systems and timers that turn lights off at a predetermined time can help limit both light trespass and light pollution. Illuminance levels should be as close as possible to IES recommended values, avoiding excess wherever possible to minimize energy consumption. See Figure 19.5 for a gas station canopy example. Bi-level switching of luminaires in outdoor areas is available with some equipment to help limit light pollution and save energy by reducing illuminance when areas are not occupied.

In some situations, lighting must be controlled to avoid detrimental effects on wildlife [17]. Sea turtles lay their eggs on the beach. When the turtles hatch and emerge during the night they are attracted to the sea, which is typically brighter than the land. Neighboring streetlights and houselights can cause the turtles to travel inland, where they are likely to perish. Exterior lighting is also known to disrupt the flight of nocturnal migratory birds, who may be attracted to structures such as lighthouses and radio towers. Continuously operating lights, particularly red have been shown to be most problematic. The birds can become disoriented and crash into the structure or its support devices. Other creatures known to be attracted to light include certain insects, and specific species of bats and fish. Lamps with UV radiation have a higher attraction rate than HPS, while low pressure sodium offers little in the way of attraction. Studies on nocturnal mammals have shown reduced movement and feeding under full moonlight for a number of species, most likely to reduce predation

Figure 19.5 | A Fuel Service Station
This lighting system was designed to strict light pollution criteria. Illuminance at the pumps is approximately 10 fc and most of the light is concentrated under the canopy. The local exterior lighting ordinance focusses on providing dark skies by limiting emitted lumens based on canopy area. Spill light from the drop lens luminaires and canopy provide low level lighting for adjacent pavement areas, but may contribute to light trespass onto neighboring properties. The canopy serves as a cutoff optic for these luminaires to prevent direct light from leaving the canopy area above horizontal. Recessed, flat lens luminaires would further control spill light and light trespass in a canopy application. The sign uses colored luminous letters on a black background to minimize the emitted lumens.

risk. Further research is needed in many of these areas to better understand the effects of modern lighting equipment, including more modern sources such as LEDs.

19.4 Assessing Sustainability

Individual products can be assessed with regard to sustainability in a number of ways. The primary approach involves a technique known as Life Cycle Assessment (LCA) [18] [19]. LCA evaluates a product's cumulative impact on the environment throughout its lifetime or another time period, which is addressed through the following four life cycle stages:

- Raw materials and their acquisition
- Manufacturing and transportation
- Installation, maintenance and operation
- Disposal and recycling

At each of these stages, inputs of energy and raw materials are considered, along with outputs that include the desired product along with atmospheric emissions, waterborne and solid wastes, and other by-products (see Figure 19.6). These emissions are characterized according to their potential to cause several environmental impacts such as global warming, ozone depletion, and acidification, among others. A LCA is applied to compare alternative solutions or products to determine which offers the least environmental impact.

A number of different software tools [20] [21] are available to address LCA for building materials, products and projects; however none currently contains detailed information on lighting systems or equipment. Hence, the ability to conduct a full LCA on a lighting

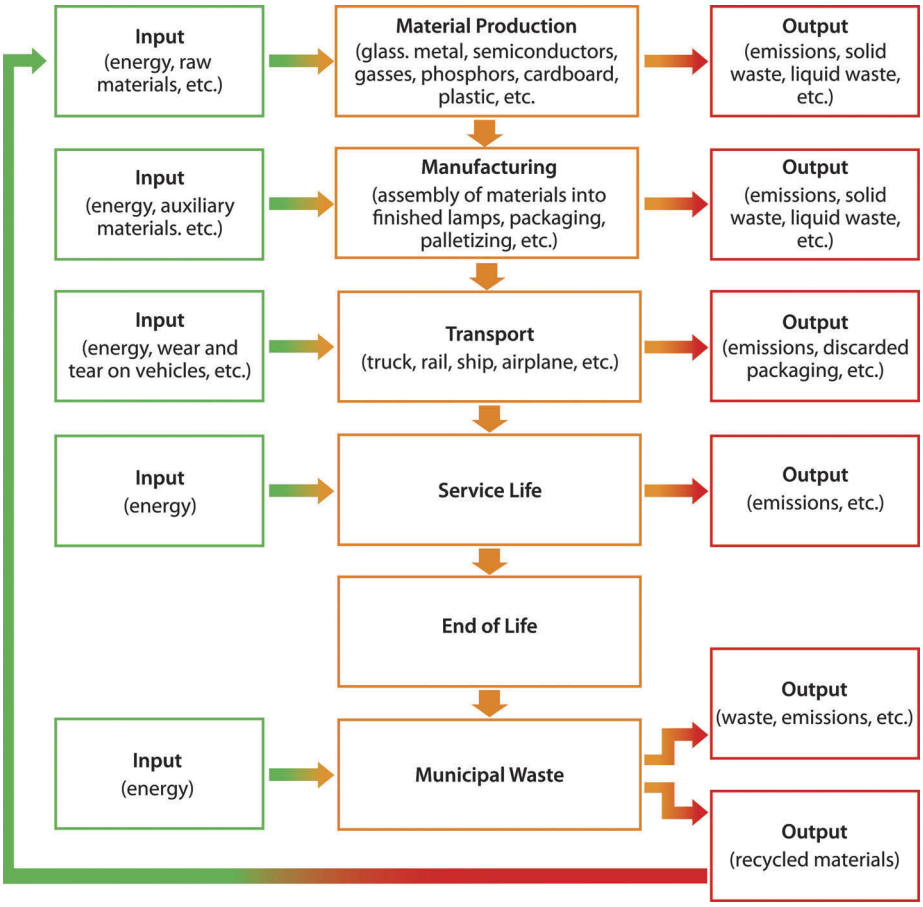

Figure 19.6 | Life Cycle Analysis (LCA) Input and Output
LCA considers the social, environmental and economic impacts of the production, operation, and disposal of the materials used in a system or product. This flowchart addresses the different aspects of a product's life cycle that can be addressed in LCA.

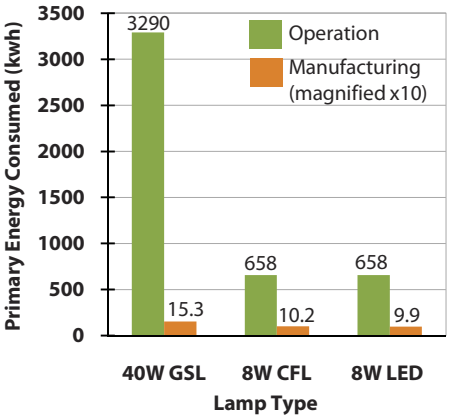

Figure 19.7 | Primary Energy Consumption: Lamp Use versus Lamp Manufacturing
The primary energy required to manufacture and operate three lamp types (including ballast losses) over a 25,000 hr period is shown for a 40W filament General Service Lamp (GSL), an 8-watt CFL and an 8-watt LED lamp. Operating energy is 60 times more than manufacturing energy even for low-wattage lamps and 200 times more for the filament source. Energy required to manufacture the ballasts, drivers and heat sinks are included. The short life of the GSL (1000 h) requires more frequent relamping for this lamp over the life of the study. [22]

Table 19.1 | Sustainability Categories Used in Green Building Rating Systems (2010)

LEED (USGBC, CanGBC)
• Sustainable sites
• Water efficiency
• Energy and atmosphere
• Materials and resources
• Indoor environmental quality
• Innovation and design process
BOMA BESt / Green Globes
• Integrated design process

• Water
• Resources
• Environmental management
• Indoor environment

system is not practical for a lighting designer. Manufacturers are more likely to have access to the information required to assess alternate product or material decisions and some have conducted such analyses in refining their products to make them more sustainable.

In many situations, simplified measures that address only a subset of the quantities considered in a full LCA are applied. One example is embodied energy – the total energy required to make, install, and dispose of a product. Assessment of lamps has shown that operating energy is likely to be many times the energy required to produce a product [22], which explains the importance that energy consumption plays in quantifying the sustainability of building lighting systems (see Figure 19.7). A similar metric is carbon footprint, which consists of CO_2 emissions of a product or system throughout its life cycle. Carbon footprint is applied not only to products, but may be applied to larger entities such as a complete facility, or even to an entire country. Energy consumption is directly linked to carbon footprint, which largely comprises carbon dioxide (CO_2) emissions from electricity generation.

19.5 Sustainable Building Design Rating Systems, Codes and Standards

Since its release in 1998, the Leadership in Energy and Environmental Design (LEED®) Green Building Rating System [23], developed by the U.S. Green Building Council (USGBC) has transformed building design practice. Many buildings have received LEED certification and achieved a green building rating. Many owners, large institutions and end users now demand some level of green building design even when buildings are not submitted for formal recognition or rating. The Canada Green Building Council (CaGBC) operates a similar system in Canada [24]. The more popular Canadian green building certification system is Green Globes, which is operated in the U.S. by the Green Building Initiative (GBI) [25]. Both LEED and Green Globes offer certification credentials for building professionals. BOMA BESt from the Building Owners and Managers Association Canada is a similar system for existing buildings to which the Canadian government subscribes (earlier versions were named Go Green and Go Green Plus) [26]. The UK's Building Research Establishment Environmental Assessment Method (BREEAM) [27] is widely used outside North America, and was established a few years prior to LEED.

These green building rating systems typically award points to a project based on the inclusion or presence of different sustainable design and site features. The number of total points amassed determines the level of certification achieved. Both LEED and BOMA BESt/Green Globes offer four award levels. In the Green Globes system, they are one to four globes, while LEED classifies the four levels as certified, silver, gold and platinum. Within these systems, points are currently awarded within the categories shown in Table 19.1.

The USGBC developed different LEED rating systems for different project types. A list of the different rating systems based on building type is provided below. All of these contain provisions related to lighting.

- New Construction (NC)
- Existing Buildings – Operations and Maintenance
- Commercial Interiors
- Core and Shell
- Schools
- Retail
- Healthcare
- Homes
- Neighborhood Development

Table 19.2 | 2009 LEED-NC Credit Opportunities Related to Lighting Systems

Credit*		Points	Requirements
IEQ 6.1	Controllability of Systems - Lighting	1	• Task lighting/individual control for 90% of occupants • Flexible controls in shared spaces
IEQ 8.1	Daylight and Views - Daylight	1 (1-2 SC) 2	• Daylight coverage - 75% of regularly occupied spaces • Daylight coverage - 90% of regularly occupied spaces
IEQ 8.2	Daylight and Views - Views	1	• Direct line of sight to outdoors via vision glazing from 90% of regularly occupied area
SS 8	Light Pollution Redution	1	• Limit interior light transmitted to the exterior from 11pm to 5am • Exterior - light only those areas required for for safety and comfort, limit direct light above horizontal • Exterior - limit illuminance at property line.
EA Prereq 1	Fundamental Commissioning of Building Energy Systems	-	• Required
EA Prereq 2	Minimum Energy Performance	-	• Energy costs are 10% lower than baseline building
EA 1	Optimize Energy Performance	1 to 19	• Points are based on energy savings relative to a baseline building and apply to all building systems that consume energy
EA 3	Enhanced Commissioning	2	• Early involvement of commissioning agent

* IEQ = Indoor Environmental Quality, SS = Sustainable Site, EA = Energy and Atmosphere

For LEED NC, a total of 40 points are needed to achieve the lowest LEED certification level, in addition to meeting specified prerequisite requirements. The credits currently available in 2009 LEED-NC [23] that relate to lighting systems are listed in Table 19.2. These are likely to change with each revision of the rating system.

In addition to building rating systems, green building construction standards are now available or are nearing completion. These documents are written in code language to be adopted by local municipalities. ANSI/ASHRAE/USGBC/IES Standard 189.1[28] was released in January 2010 and the International Green Construction Code (IgCC) [29] is currently under development and intended for release in 2012. These codes contain requirements for lighting power densities, automatic lighting controls (interior and exterior), daylight coverage across occupied spaces, lamp recycling, light pollution, and system commissioning. Standard 189.1 contains mandatory provisions as well as both a prescriptive and performance-based approach to address compliance with provisions of the code. The prescriptive approach involves meeting relatively simple performance requirements or metrics, whereas the performance approach involves more detailed daylight simulation and energy modeling.

The IgCC in its current draft has several project electives as well as jurisdictional electives. Project electives allow designers flexibility in meeting compliance on a project by project basis, while jurisdictional electives are meant to be set by an authority having jurisdiction for all projects in a state or territory. Standard 189.1 is one of the jurisdictional electives for the IgCC.

The U.S. Environmental Protection Agency provides an Energy Star label for buildings whose documented energy performance places them in the top 25% of the existing building stock of a similar type [29]. The rating system used to evaluate performance is the source Energy Use Intensity (EUI), measured in source energy per unit of building floor area per year (kBtu/ft^2/yr). The system accounts for differences in occupancy and operating conditions, regional weather data, fuel sources, and other details across different buildings. The

existing building data set is taken from the Commercial Building Energy Consumption Survey (CBECS), a national building survey that occurs every four years. An Energy Star label applies to a specific year of operation, with renewal based on documented performance in future years relative to the most current evaluation of similar building stock.

20 | CONTRACT DOCUMENTS

The whole difference between construction and creation is exactly this: that a thing constructed can only be loved after it is constructed; but a thing created is loved before it exists.
Charles Dickens

Quality of documentation ultimately determines the quality and success of the finished lighting design. Documenting a design for purposes of construction requires careful preparation of plans, details, and specifications. Contract documents (CDs) that are clear, concise, and unambivalent are the objective. This chapter identifies the main components involved in contract documents for lighting. These are typically used as part of the package of project documents delivered to contractors for bidding and then subsequently used for procurement and installation. The design efforts outlined in the previous chapters culminate here.

20.1 Responsibilities

The team member acting as the lighting designer is charged with documenting the lighting design. As noted previously, that team member may have other project responsibilities such as that of architect, interior designer, or electrical engineer. What follows is guidance for documenting a lighting design. Team members responsible for architecture, interiors, and electrical engineering have other tasks not necessarily outlined here, but which support or are related to lighting design documentation. Those other tasks include, for example, development of elevations, sections, details, mounting and support requirements, integration with other systems and devices, life-safety lighting, circuiting, and detailed control device and equipment layouts and specifications related to lighting. Tasks and responsibilities should be addressed in fee proposals and project scopes and clarified well before lighting design commences. Specific scope or jurisdictional requirements, including code compliance, will dictate which of the design team members is responsible for the development, review, and delivery of some or all of the documentation. See Table 11.1 | Example Lighting Scope and Deliverables. Coordination of responsibilities, documentation preparation, and scheduling of work efforts is necessary prior to project commencement. A project organizational chart typically puts the lighting design role in perspective with other design and engineering roles. [1]

Contract documents as presented here do not identify all of the specific details necessary to address the variety of project types typically encountered. For example, new construction documentation need not address the vagaries of existing conditions or conditions that may be found once demolition occurs on renovation or restoration projects. The designer must coordinate the documentation effort with the project type as determined by the licensed or registered professional in charge.

Procedures outlined here are intended to advance the practice of lighting design by whichever team member fills the role of lighting designer. The focus in this handbook is on what must and should be done rather than what traditionally has been done and accepted as lighting design.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

20.2 Documentation

The lighting design role of the team member charged with that effort involves preparation of documentation that describes, specifies, and illustrates the lighting solution. This documentation may be referenced or subsumed partially or entirely by other disciplines, such as architecture, engineering, landscape architecture, or interior design, or may stand as independent material. Regardless, the integrity of the documents is crucial to everyone's understanding of the lighting design. Everyone being the participants in the design, engineering, procurement, and installation, including architect, interior designer, electrical engineer, lighting consultant, owner, energy engineer, sustainability consultant, lighting representative, lighting manufacturer, contractor, and distributor. Documents should leave no doubt that altering any component in any way may be detrimental to any, many, or all of the programming requirements and may have a domino effect on other disciplines' designs and documentation.

Lighting contract documents should include drawings and specifications, cutsheets, and initial preset schedules. If any of these documents are not of sufficient integrity, the end result may be disappointing because of any or all of these results: 1) inappropriate substitutions, 2) procurement of incorrect equipment, 3) overlooked equipment; 4) incongruous layouts, 5) misaiming, 6) scrambled controls, 7) unfulfilled energy savings, and 8) dissatisfied clients.

Another component of lighting documentation involves review of at least key documents prepared by team members serving other roles. For example, daylighting, electric lighting integration into electrical plan set, lighting-related sections, elevations, and details should be checked for conformance to the lighting design intent.

What follows is indicative of the documentation necessary to convey the lighting design and outline requirements and expectations of the contractor.

20.3 Drawings

Plans are the most common drawings that are part of the lighting documentation. Additionally, architectural elevations, sections, and details may be necessary. Plans endeavor to illustrate the layout of lighting equipment, identify luminaire types, establish control zoning, and indicate control devices. Architectural elevations, sections, and details elaborate specific items for which the plan and specification do not provide clarity of intent.

20.3.1 Lighting Plans

Ultimately, lighting plans must document all lighting on the project. Debates may arise about the interpretation of reflected ceiling plans (RCPs) and what lighting information is to appear on the RCPs. Nevertheless, the plans must convey to the team, client, jurisdictional authorities, and the contractor all of the lighting equipment that is to be installed. These plans are also the basis for the client's as-built set of documents identifying all lighting equipment to be maintained. So it is, then, that not only lighting equipment in and on the ceiling must be shown, but the lighting in and on walls, in and on millwork and other built-in and freestanding elements, and in and on floors also must be shown. The team must resolve on which plans these different types of luminaires are to be shown and how these plans are to be labeled. EL sheets, using National CAD Standard "E" for "Electrical" and "L" for "Lighting", is a means of conveying all lighting equipment on a single set of plans. [2]

Given their influence and reliance on architectural configurations, daylighting elements are part of the inherent architecture and so are detailed on architectural plans and in architectural specifications. This includes daylight apertures, glazing, shading, and surface configurations and reflectances. These architectural daylighting components should be evident on the architectural backgrounds used for the lighting plans and are inevitably used as reference locations for development of electric lighting layouts and control zoning.

EL sheets or the work represented on them may be subsumed into architectural and electrical sheets. For example, the electrical engineer may show control zoning information on electrical sheets along with circuiting. Reiterating, the division of work and what information is shown where must be established early in the design process. Also reiterating, the outline here attempts to identify all of the documentation necessary to illustrate the lighting design in its entirety and is not proposing which disciplines show which portion of the work on which documents.

Lighting plans should convey luminaires, their types, locations, and control zones. Table 20.1 identifies the plan drawing components for typical 2D implementation. National CAD Standards and ANSI-IES standard symbol sets offer basic symbols. However, additional degrees of visual information are appropriate in a time when accurate deployment of lighting is crucial to its efficient and effective operation. [3] [4] Symbols across disciplines require coordination early in design to avoid, for example, luminaire symbols matching mechanical device symbols. Figures 20.1a, 20.1b, 20.1c, and 20.1d introduce a visually informative luminaire symbol set for 2D planning primarily for interior lighting. Figures 20.2a and 20.2b introduce a set for exterior lighting. Figure 20.3 introduces controls symbols. This detail in layout designation can also serve as a quality-control check and confirmation on design intent during documentation as luminaires are seen against final architectural and landscape backgrounds. CAD allows for ready implementation of these visually informative symbols. A more literal representation of the luminaire in plan helps distinguish one variety from another. Since the installers in the field are likely to reference just plans, the more concise the information that can be conveyed on the plan the better. As additional lighting technology and techniques advance, additional embellishments and symbols can be employed to distinguish these variations. The print copy of the lighting plan might be done with the lighting information printed in normal black while background information is halftoned as exemplified in Figure 20.4.

Symbols for 3-dimensional CAD should be scaled 3D representations of their real-world counterparts. Luminaire vendors offer Building Information Modelling (BIM) symbols of their respective and various luminaires. While this minimizes the designer's time on developing 3D models of specific selections, it can inadvertently identify forms, shapes, and dimensions not entirely representative of all of the brands specified. At the project's outset where 3D CAD is required, a generic set of 3D luminaire models should be established which encompasses rough styling of the luminaire families and provides anticipated maximum sizes. As the project progresses, these luminaire models should be refined. After several such projects, a robust library of luminaire models will then be available. Models should represent 3-dimensional characteristics of likely luminaire candidates, covering the range of the number of acceptable versions. Complete and rather accurate modeling is needed if clash-detection, fit, and renderings are to be employed. Table 20.2 outlines some characteristics typically embodied by and embedded in 3D luminaire models which are commonly used in BIM or 3D CAD building models. The more detailed this information becomes, the higher the risk of error if this same information is to be reported in luminaire specifications, since this demands that the information be tracked and accurately transcribed in more than one location. For this information to reside solely in the 3D model risks that contractors will not reference specifications, which is where more complete information is placed regarding luminaires installation, aiming, lamping, finish, orientation, and the like. Further, few field

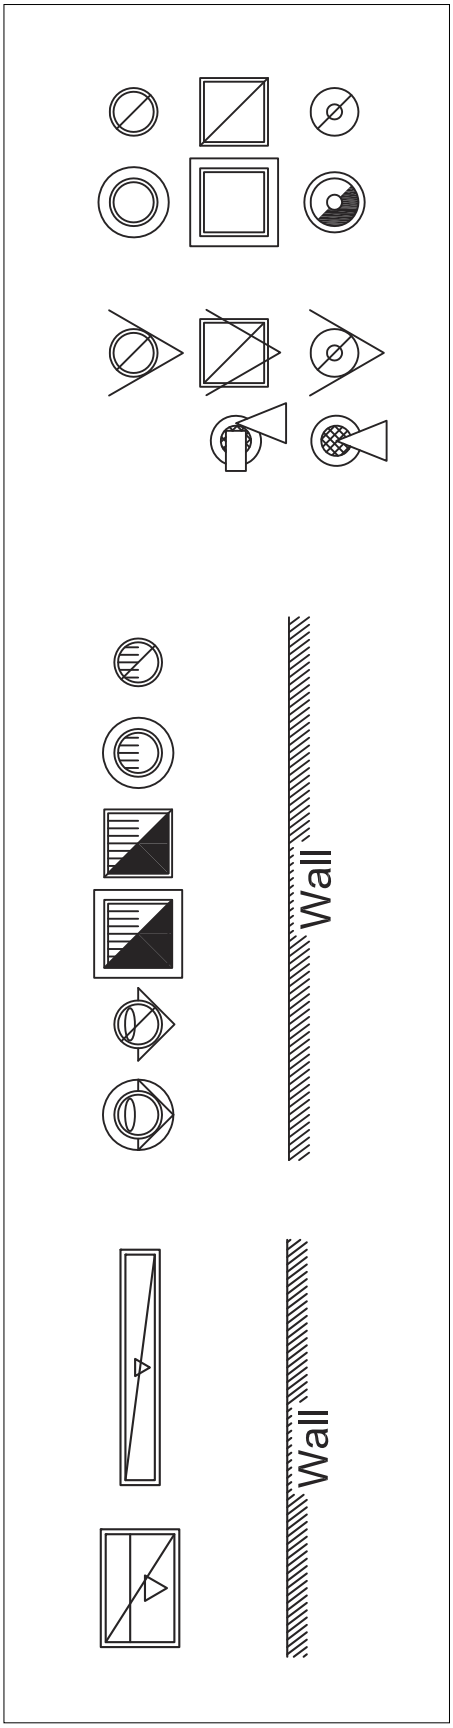

Table 20.1 | Plan Drawing Components

Component	Representation
Luminaire	Basic function • accent • downlight • pendant • wallwash
	Shape
	Size
	Symbol • 2D for 2D cad • 3D for 3D cad
Type	Designation • unique alphanumeric tag
Location	Position • hard dimension • *obvious dimension*
	Hosting surface • ceilings • floors • furnishings • walls
Control	Zone • unique alphanumeric tag • looping

Obvious dimension as used here is a reference to an apparent specific location, such as the center of a 2'x2' tile where a downlight is located. Typically, a hard dimension is not applied as the exact location is obvious.

Figure 20.1a | Downlight, Accent, and Wallwash Luminaires 2D Symbol Set

Downlights

- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- diagonal line (from lower left to upper right) to denote recessed
- add outer line representing housing enclosure for surface mounts (illustrated on bottom three)
- with diagonal fill to denote emergency lighting

Adjustable accents

- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use arrowhead to indicate aiming direction for recessed adjustable luminaires
- diagonal line (from lower left to upper right) to denote recessed
- use Isosceles triangle orienting short leg in direction of light throw for monopoints
- monopoint on far left shown with transformer/driver housing which may affect installation/aiming orientation
- with diagonal fill to denote emergency lighting

Wallwashers

- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use arrow or hatching (open area oriented to wall surface being washed) to indicate orientation
- diagonal line (from lower left to upper right) to denote recessed
- add outer line representing housing enclosure for surface mounts (illustrated in 2nd, 4th, and 6th from top of series)
- with diagonal fill to denote emergency lighting

Linear or rectilinear wallwashers

- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use pointer to indicate aiming direction
- diagonal line (from lower left to upper right) to denote recessed"
- add outer line representing housing enclosure for surface mounts (not shown)
- use line work to represent identifiable baffle or reflector scoop
- with diagonal fill to denote emergency lighting (not shown)

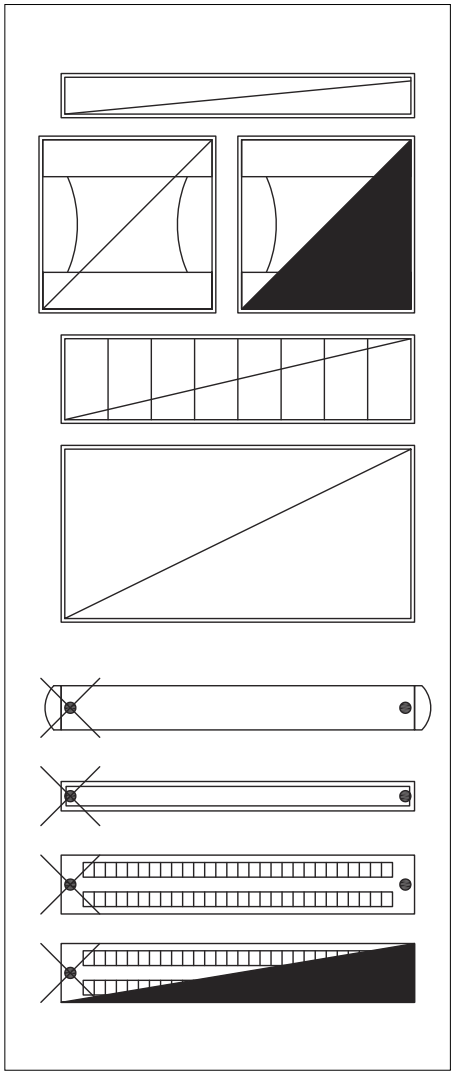

Figure 20.1b | Ambient Luminaires 2D Symbol Set

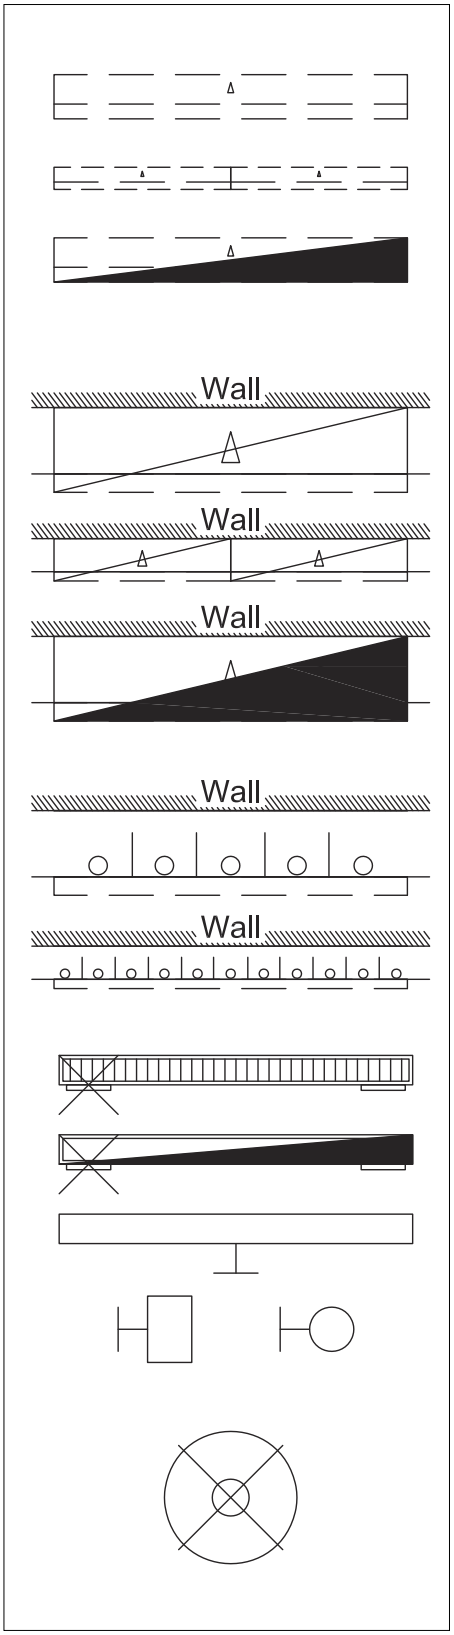
Linear or large area luminaires

- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- diagonal line (from lower left to upper right) to denote recessed
- add outer line representing housing enclosure for surface mounts
- use line work to represent identifiable luminaire characteristics (e.g., side baskets, parabolic or blade baffles or louvers, lens or door configuration, etc.)
- with diagonal fill to denote emergency lighting

Linear suspended luminaires

- draw symbol to match size and shape
- adjust scale and line weight if necessary for visibility on plan
- solid circles indicate suspension point locations, match layout to correspond with design intent
- "X" used to indicate power feed location(s)
- use line work to represent identifiable luminaire characteristics (e.g., baffles or louvers, lens or door configuration, end caps, etc.)
- with diagonal fill to denote emergency lighting



installers have access to or wish to encumber themselves with the equipment and skills necessary to view and interpret the 3D computer models in the field. Clearly a challenge that goes well beyond lighting and must be left to the architects, clients, and contractors to coordinate and resolve.

Luminaire layouts include dimensioned or dimensionally-obvious locations and type designations. Where luminaires are in non-modular construction, such as drywall, plaster, wood, stone, grade, and ground planes, their locations should be dimensioned. Otherwise, the contractor or installer might be inclined to scale drawings which, generally, increases risk of error. Where luminaires are in modular construction, such as standardized lay-in grid ceilings, luminaire locations are dimensionally obvious unless they are not centered in the ceiling module, in which case dimensions are necessary. Figure 20.4 illustrates lighting diagrammed in drywall and lay-in ceiling conditions.

Coordination efforts are made by the architect and engineer either of whom may fill the role of lighting designer. The lighting plan is typically overlaid onto the architectural RCP and lighting is then coordinated with exit signs, signage, standalone exit lighting, sprinklers, speakers, expansion joints, mechanical diffusers, smoke detectors, occupancy sensors, security devices such as glass-break detectors and other intruder-detectors,

Figure 20.1c | Cove, Slot, Wallmount, Pendant Luminaires 2D Symbol Set

Cove (indirect lighting detail)

- draw symbol to match size and shape of individual units
- repeat units as necessary to convey design intent for layout (butted end-to-end as shown to limit/avoid socket shadows; butted front-corner-to-front-corner for inside curves and back-corner-to-back-corner for outside curves)
- adjust scale and line weight if necessary for visual clarity with dashed lines to indicate luminaire is above the visible ceiling
- use pointers to indicate orientation for asymmetric luminaires
- with diagonal fill to denote emergency lighting

Wallslot (wall grazing) from linear source (fluorescent, linear LED)

- draw symbol to match size and shape of individual units
- repeat units as necessary to convey design intent for layout
- adjust scale and line weight if necessary for visual clarity with dashed lines to indicate that portion of the luminaire which is above the visible ceiling (typically the offset for lamp position)
- use pointers to indicate orientation toward wall being grazed
- with diagonal fill to denote emergency lighting

Wallslot (wall grazing) from point source (CMH, halogenIR$_{LV}$, LED)

- draw symbol to match size and shape of individual units, showing individual lamps and baffles
- repeat units as necessary to convey design intent for layout
- adjust scale and line weight if necessary for visual clarity with dashed lines to indicate that portion of the luminaire which is above the visible ceiling
- use line work to indicate baffles if used between lamps
- with diagonal fill to denote emergency lighting (not shown)

Wall mounted luminaires

- draw symbol to match size and shape
- adjust scale and line weight if necessary for visibility on plan
- small boxes and/or arms represent mounting point/bracket locations, match layout to correspond with design intent
- "X" used to indicate power feed location(s) when necessary
- use line work to represent identifiable luminaire characteristics, such as baffles or louvers, lens or door configuration, and end caps
- with diagonal fill to denote emergency lighting

Pendant luminaires

- draw symbol to match size and shape
- adjust scale and line weight if necessary for visibility on plan
- use line work to represent identifiable luminaire characteristics., such as concentric-ring louvers, lensing, lamp shields
- with diagonal fill to denote emergency lighting (not shown)

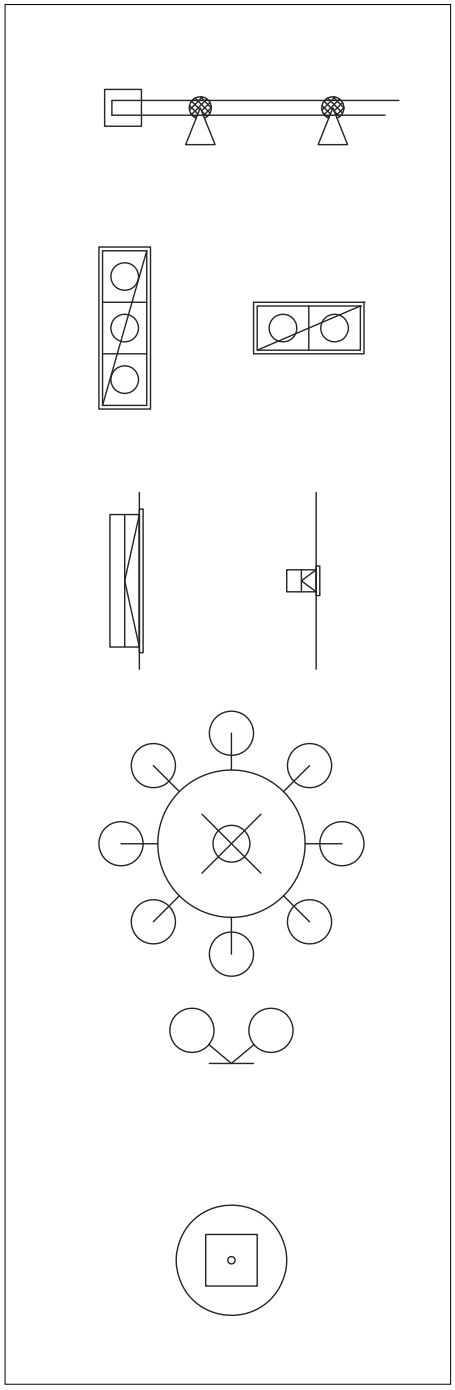

Figure 20.1d | Assorted and Miscellaneous Luminaires 2D Symbol Set

Track
- draw symbol, including power feed location, to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use Isosceles triangle orienting short leg in direction of light throw for track luminaires

Multi-lamp accents
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use directional arrowhead to indicate aiming direction of each lamp, if known (not shown)
- diagonal line (from lower left to upper right) to denote recessed

In-wall luminaires (steplights, indirect uplights, flush sconces, indicators, nightlights)
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan

Traditional chandelier and pendant luminaires
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use additional line work to represent identifiable luminaire characteristics, such as scalloped globes, bowl configurations, lamping layouts within bowls, shades, and bracket dimensionality

Traditional wall bracket luminaires
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use additional line work to represent identifiable luminaire characteristics, such as scalloped globes, number of globes, shades, and bracket dimensionality

Traditional torchiere luminaires
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use additional line work to represent identifiable luminaire characteristics, such as bowl configurations, lamping layouts within bowls, shades, bracket dimensionality, and feet

surveillance devices such as cameras, wireless service devices, remote control detectors such as those required for some lighting control setups, projectors, access panels, and the like. However, in most situations, the lighting layout will probably take precedence over layouts of other systems since lighting is typically planned for both its functional performance and its visual effects—any luminaire off-center of artwork or feature walls or distinguished architectural features or furniture layouts or floor and ceiling configurations typically creates an obvious and undesirable asymmetric visual effect and may also exhibit functional deficiencies. Even where other systems appear to deem priority, a review of technologies and long-term affects is warranted. Lighting systems are likely in

place for decades before upgrade or replacement. Other technologies such as cameras or AV equipment may be outdated and more likely replaced in a few years. Changing layouts and effects of a permanent system such as lighting to accommodate more ephemeral systems may not be a viable long-term solution.

20.3.2 Elevations

The architect, landscape architect, and interior designer generate elevations illustrating devices, furnishings, architectural details, and other dimensional objects. These should include lighting equipment such as wall sconces, steplights, lighted handrails, chandeliers, pendants, and control devices. In combination with plans, these elevations clarify vertical and horizontal locations and are used for coordination with ceiling heights, door swings, door and window jambs or casework, and coves and soffits. Elevations also help the team understand, coordinate, and collect all manner of objects and devices for a neat and orderly appearance and improved operational convenience. Lighting control devices might be ganged with or at least symmetrically spaced with respect to other devices such as environmental controls, volume controls, call buttons, security pads, and the like. Lighting control devices need to be spaced in accordance with respective vendor's requirements for heat dissipation or functionality. If the architect, landscape architect, or interior designer is not designing the lighting, then appropriate dimensional information for luminaire locations is required from the lighting designer.

Table 20.2 | 3D Luminaire Components

20.3.3 Sections and Details

For additional clarity, the architect, landscape architect, and interior designer generate sections and details. Where appropriate to meet programming requirements, lighting is included in coves, slots, niches, shelving, and millwork details. To assure proper luminaire positioning and orientation, lighting details show critical dimensions, positions, and orientations to meet the anticipated performance requirements for the project, exemplified in Figure 20.5. Although the conceptual detail illustrated in Figure 20.5 may be included as part of the lighting specification for convenient contractor reference, many times these details are subsumed into architectural details on architectural sheets so that all trades have access to accurate detail information.

20.3.4 Luminaire Schedules

Luminaire schedules are an artifact of a bygone era. By their very nature, luminaire schedules are brief and typically embedded on drawing sheets. Schedules are prone to conveying insufficient information. These offer little or no guidance on key installation parameters like overall-suspension-lengths-relative-to-given-ceiling heights, field-dimension-confirmations by contractor of architectural details accommodating lighting, and coordination efforts between the contractor and other related trades. The simplicity of a schedule implies substitutions are of little consequence. A lighting specification that details salient features, dimensions, operational characteristics, ballast, and control and installation requirements along with substitution procedures is a necessity. Lighting now must meet LPD, energy, whole-building-performance, and code requirements in addition to a host of other analytic and aesthetic criteria established during the design process. There is very little allowance for the vagaries of "or equals" as determined by other-than-the-designers to address all of these aspects.

Additionally, if schedules are used in conjunction with the more detailed requirements of specifications, the former present a risk management issue: two locations in the contract documents that must bear identical information and, therefore, must be updated simultaneously whenever a revision to one is made.

On small projects, a simple schedule that does not identify luminaire or lamp catalog number may be warranted for team and jurisdictional reference. One such example is shown in Figure 20.4. Otherwise specifications are a superior means of conveying all salient information on the equipment required and its installation.

20.4 Specifications

Lighting specifications cover a comprehensive list of requirements related to lamps, ballasts, drivers, transformers, luminaires, procurement, specific equipment from specific vendors, installation, operations and maintenance manuals, warranties, and turn-over of the finished installation. Such a volume of information is much too onerous to distill into a luminaire schedule or drawing. Specifications follow industry formats, most notably those espoused by the Construction Specifications Institute (CSI) and Construction Specifications Canada in MasterFormat® [5]. Although the format was significantly overhauled in 2004, some project managers and clients subscribe to the 1995 version, support and licensing for which were discontinued by CSI on December 31, 2009. The electrical division, in which lighting is a subdivision, was numbered 16 for the 1995 format edition and 26 for the 2004 and subsequent format editions. Depending on the depth and breadth of project electrical work, the lighting specification typically encompasses 26 50 00. Table 20.3 identifies the formal numbering and associated lighting subdivisions. Specific references in the lighting specification should be made to other supporting and relevant specification sections, such as those for gas lighting or those related to complementary components and systems integration such as integrated ceiling assemblies, luminous ceilings, illuminated panel signs, illuminated handrails when these types of sytems are employed.

There are a number of specification types, but for purposes of this discussion two basic types are considered: performance and prescriptive. Performance specifications cite the qualitative and quantitative performance parameters of a given luminaire that are determined necessary during design, but allowing others to determine which products meet these performance parameters. This specification typically defines luminaire shape and profile, dimensions, material, construction, finish, optical media and performance, lamp type, wattage, ballast, transformer, or driver type, control aspects, lamp compartment access, suspension means, and so on. The designer must take care to not incorporate performance or function details that are proprietary or covered by patents or copyrights. Any parameters not specifically addressed are at the discretion of the contractor and may result in surprise and disappointment. Even where all parameters that the designer considers important are addressed, if their specific features are not fully detailed, results may be unexpected. For example, if a traditional chandelier is to have chain suspension, but the type, size, thickness, and finish of chain links are not identified, the chain on the supplied luminaire may look too small or delicate relative to the scale of the luminaire lantern with a finish uncoordinated with the interior scheme.

Prescriptive specifications identify the specific product or products by brand and model for a given luminaire that are determined necessary during a design. These specifications allow little or no flexibility on brand and model deviation. Prescriptive specifications may also include citation of performance details for clarity of intent and to identify distinguishing features with the specified brands and models. Here, if only one brand and model are listed, the cost-to-owner may be suspect. Although careful attention to pricing during design can limit these concerns, the vagaries of the purchasing chain ultimately determine costs. The designer is obligated to thoroughly assess the luminaire options available, otherwise single- or multiple-name prescriptive specifications may be indefensible. Knowledge of brands and models is a must.

The type of specification used will depend on the type of project, the client, and the degree to which performance variances are acceptable on any, many, or all parameters. The type of specification must be determined early in the design process. The benefits and drawbacks should be reviewed with the team and client. A desire to use performance specifications may be driven by expectations of greater competition and low first cost. However, life-cycle costs, long-term performance, durability, and occupant satisfaction should be paramount.

Regardless of the type of specification, the format involves three parts: general; products; and execution. Table 20.4 outlines sections typically found within these three parts of the

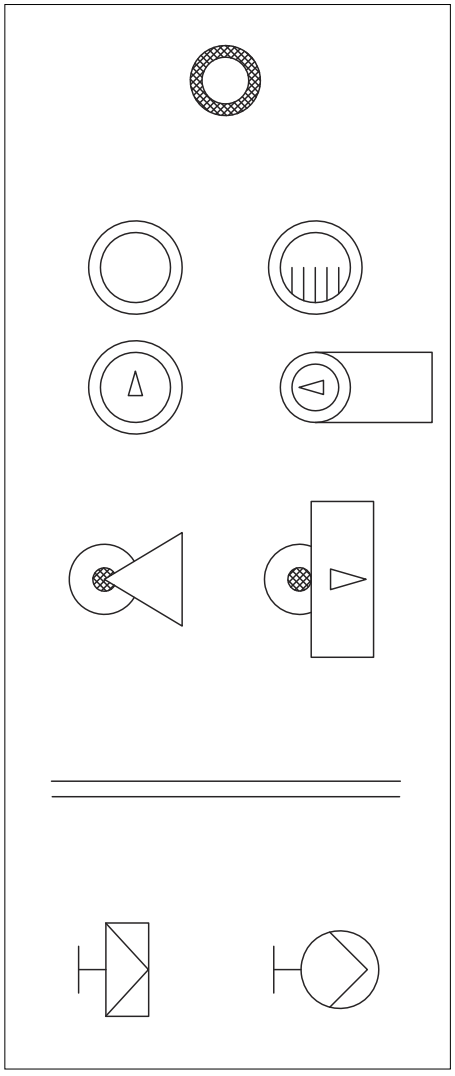

Figure 20.2b | Exterior Local-light and Accent Luminaires 2D Symbol Set

Bollards
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use pointers to indicate orientation if unit is asymmetric

In-grade uplights
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use pointers for accents or hatching for wallwashers (with open area oriented to surface being washed) to indicate orientation

Above-grade uplights
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use pointers for orientation as needed or hatching for wallwashers (with open area oriented to surface being washed [not shown]) to indicate orientation

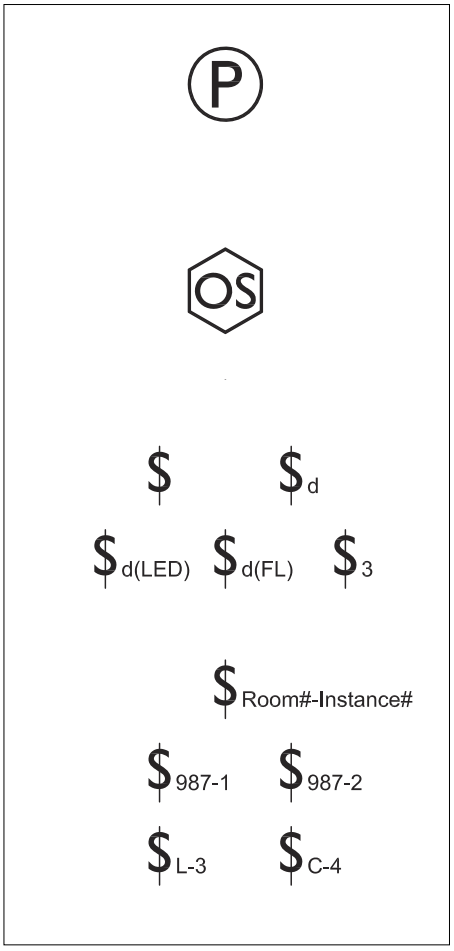
Handrail-integrated lights
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- close ends at each end of handrail run

Wallmount cutoff area lights
- draw symbol to match size and shape
- adjust scale and line weight as necessary for visibility on plan
- use arrowhead to indicate major throw orientation

Luminaire Specification Schedule, but this is a detailed fully-descriptive specification section not to be confused with the less-informative spreadsheet commonly called "Luminaire Schedule" and placed on drawing sheets.

20.4.1 Description (Specification Section 1.01)

At the outset, the need for UL/CSA/NOM tested, listed, and labeled equipment must be clear. One specification entry addressing this aspect might read:



> 1. All equipment and parts specified herein shall bear the "U.L. Approved" label (or other NRTL label) indicating compliance with UL requirements or as otherwise allowed in Section 1.04.G [1.04.G is a citation in the "References" Section of the specification regarding listing and labeling requirements]. All luminaires shall be UL/NRTL [or CSA or NOM] listed and labeled for installation in fireproof or non-fireproof construction, dry, damp, or wet locations as required.

20.4.2 Submittals - General (Specification Section 1.06)

Submittals are a process whereby the contractor secures shop drawings from the vendors selected to provide lighting equipment and submits these to the design team for review and disposition with respect to the contract documents. These submittals identify equipment appearance and performance hopefully in accordance with the specification.

Figure 20.3 | Lighting Controls Symbol Set

Photocell

- draw symbol to legible scale
- provide engineered layout or float symbol in proximity of use with explanatory note on drawing indicating design intent for engineering
- loop control to respectively controlled luminaire zone(s) or indicate luminaire control intent with note

Occupancy Sensor

- draw symbol to legible scale
- provide engineered layout or float symbol in proximity of use with explanatory note on drawing indicating design intent for engineering
- loop control to respectively controlled luminaire zone(s) or indicate luminaire control intent with note

Dimmers and Switches

- draw symbol to legible scale
- provide engineered layout or float symbol in proximity of use with explanatory note on drawing indicating design intent for engineering and architectural detailing of elevations
- loop control to respectively controlled luminaire zone(s) or indicate luminaire control intent with note
- add information, such as 3- or 4-way switching or loads to be dimmed, for clarity

Dimmers and Switches and Keypads and Preset Controls

- draw symbol to legible scale
- assign room number to symbol
- assign instance number to symbol where more than one control is used in a room or area
- provide engineered layout or float symbol in proximity of use with explanatory note on drawing indicating design intent for engineering and architectural detailing of elevations
- indicate control function in specification and with preset schedules were applicable
- information, such as 3- or 4-way switching or loads to be dimmed, number of buttons, override functions, and finish along with controls vendors catalog numbers are conveyed in specification

For some equipment so specified, this may also include vendors' proposed equipment layouts to address, for example, sensors or panels or modules required as part of the vendor's equipment package. Substitution submittals involve design assessment. This may be an inconsequential effort or may require significant time by many team members. For example, if a proposed substitution exhibits just a 5% efficiency variance, on a large project this may ultimately influence LPD compliance, power distribution systems, mechanical systems and architectural RCPs. The time and fees involved in evaluating these effects are large, should be covered by the substitution proposer, and must be agreed to in advance and in a transparent-to-the-team-and-client fashion. Such a process is detailed below in item 4. Several specification entries addressing submittals might read:

1. The Contractor shall be responsible for supplying equipment product data, and as indicated in the specification, partial or complete working samples of the specified equipment in a timely fashion for design team approval, prior to releasing orders on equipment. Contractor shall be responsible for coordinating all aspects of order placement, deposits, shop drawing procurement, order release, order follow-up, delivery tracking, etc. with Distributor in a timely fashion. Some luminaires may require at least 12 to 16 weeks of lead time or more - the Contractor is responsible for allowing sufficient time for the order-and-deposit process, shop drawing procurement, submittal, and review process. Substitutions will not be accepted on the basis of the contractor's obligation to make any deadlines, contractual or otherwise, agreed by the contractor toward the completion of this project. Lamp submittals are as important and necessary as luminaire submittals and must be supplied by the Contractor to assure correct lamp wattage, color and efficacy.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

2. All submittals shall be generated by respective factories with their seals or other authentication marks and each submittal sheet shall be clearly labeled with respective luminaire type, complete catalog number relevant to submitted luminaire, date of submittal generation and name, phone number, and email address of submittal author in order to track provenance of information. The Architect may contact respective factory submittal source.

3. The lighting equipment specified herein has been carefully chosen for its ability to meet the luminous environment requirements of this project. Calculations (with {insert software name here} or other such software) were typically made to determine luminances, luminance ratios, and/or horizontal and vertical illuminances and uniformities. In some instances, virtual reality "images" were generated with lighting calculation software to assist the Design Team and/or the Client in assessing the lighting quality of the spaces or areas. Equipment and/or manufacturers which have been shown to comply with the established criteria, including ASHRAE/IES 90.1 or California Title 24 or other such energy code as applicable by ordinance, code, Federal law, or mandate, and/or intended LEED or other green-building certification, is specified herein. Substitutions in all likelihood will be unable to meet all or some of the salient criteria as the specified equipment.

4. Where permitted, substitution submittals shall consist of a physical description, detailed dimensioned drawing and complete photometric and electric data of the proposed lamp, ballast, driver, or transformer as required, and luminaire. Working samples of lamp and luminaire substitutions must also be supplied at time of substitution request for visual check of finish, operating and photometric characteristics, and functional and aesthetic design. Photometric reports must list the actual candela values of the luminaire's distribution with specified or similar lamp in at least five horizontal planes with elevation angles in increments not greater than 5° from nadir to zenith. If additional data is required to account for asymmetric distributions, then this shall also be supplied. Candela curves, lux or footcandle and lumen tables and iso-lux-or-footcandle contours are not acceptable. The Contractor shall be responsible for negotiation with the Client, Lighting Designer, Architect, and Electrical Engineer prior to substitution submittal to assure fees are available to: redesign project based on proposed substitutions; or review by Lighting Designer, Architect, and Electrical Engineer of all photometric, sample, design and calculation documentation and virtual reality renderings (provided by Contractor) for proposed substitutions. All substitutions must be identified and approved prior to bid date; and all contractor negotiations re: additional fees for redesign work due to substitutions must occur prior to bid date. A Substitution Request Form (on the following page) shall be completed, submitted, and postmarked along with all relevant documentation required on the Substitution Request Form two weeks prior to bid date. No substitutions will be considered without compliance with this paragraph. Contractor's bid value and/or schedule commitments shall not be based on substitutions in expectation of design team approval, nor on Contractor estimated value of specified equipment. If submitted substitution fails to comply with any specification requirements or is rejected for any or no reason whatsoever, Contractor will furnish specified equipment at no additional cost or delay to the Owner.

5. The Contractor shall be responsible for obtaining from his supplying lighting manufacturers, for each luminaire, a recommended maintenance manual including:

- Vendor and local representative's contact information
- Tools required
- Instructions
- Types of cleaners to be used
- Replacement parts identification lists
- Equipment product data (high-quality reproducible copies)
- Warranty documentation

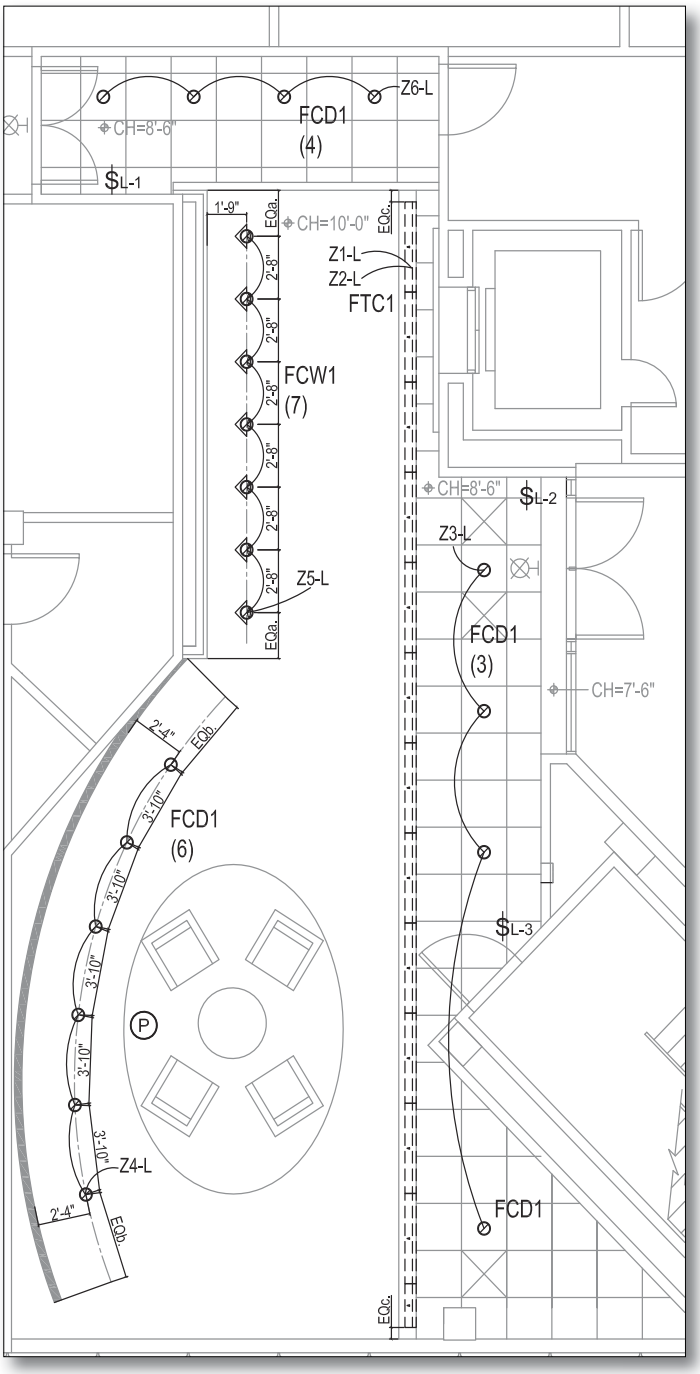
Type	What	Description	Catalog Number	Input Watts
FCD1	CFL Downlight	18W DTT lensed, 7" aperture	See 26 51 00 Specification	19.0
FCW1	Fluorescent Wallwash	42W triple-tube lensed, 6" aperture	See 26 51 00 Specification	46.0
FTC1	Fluorescent Cove	1-lamp F28T5/F14T5 asymmetric cove light, continuous row (48')	See 26 51 00 Specification	402.0

GENERAL NOTES



1. All lighting shall be installed in accordance with the NEC and all local codes.
2. Coordinate all final luminaire locations with Architect prior to any installation work.
3. This lighting plan addresses normal power architectural lighting. Controls Systems Specification and egress/emergency lighting shall be developed by registered professionals as identified by the Owner.
4. Reference Lighting Specification Section 26 51 00.

Figure 20.4 | Lighting Plan Excerpts

Excerpt above from a lighting plan exemplifies a luminaire schedule. Sometimes catalog information from the respective acceptable vendors is also cited under "Catalog Number." Use of "or equal" is not recommended as this leaves interpretation of "equal" up to individuals without explicit knowledge of all pertinent lighting programmed criteria and wherewithal to perform and/or assess necessary calculations and renders.

Excerpt at right from a lighting plan illustrates a portion of a lighting plan with luminaire locations, types, dimensions as necessary, and control looping and zones identified. A skylight over the seating area is fitted with a photocell which then controls the six FCD1 luminaires on Z4-L. North orientation is to the right. The specification or a controls schedule is used to outline functionality of keypads.

20.4.3 Luminaire Specification Schedule (Specification Section 2.12)

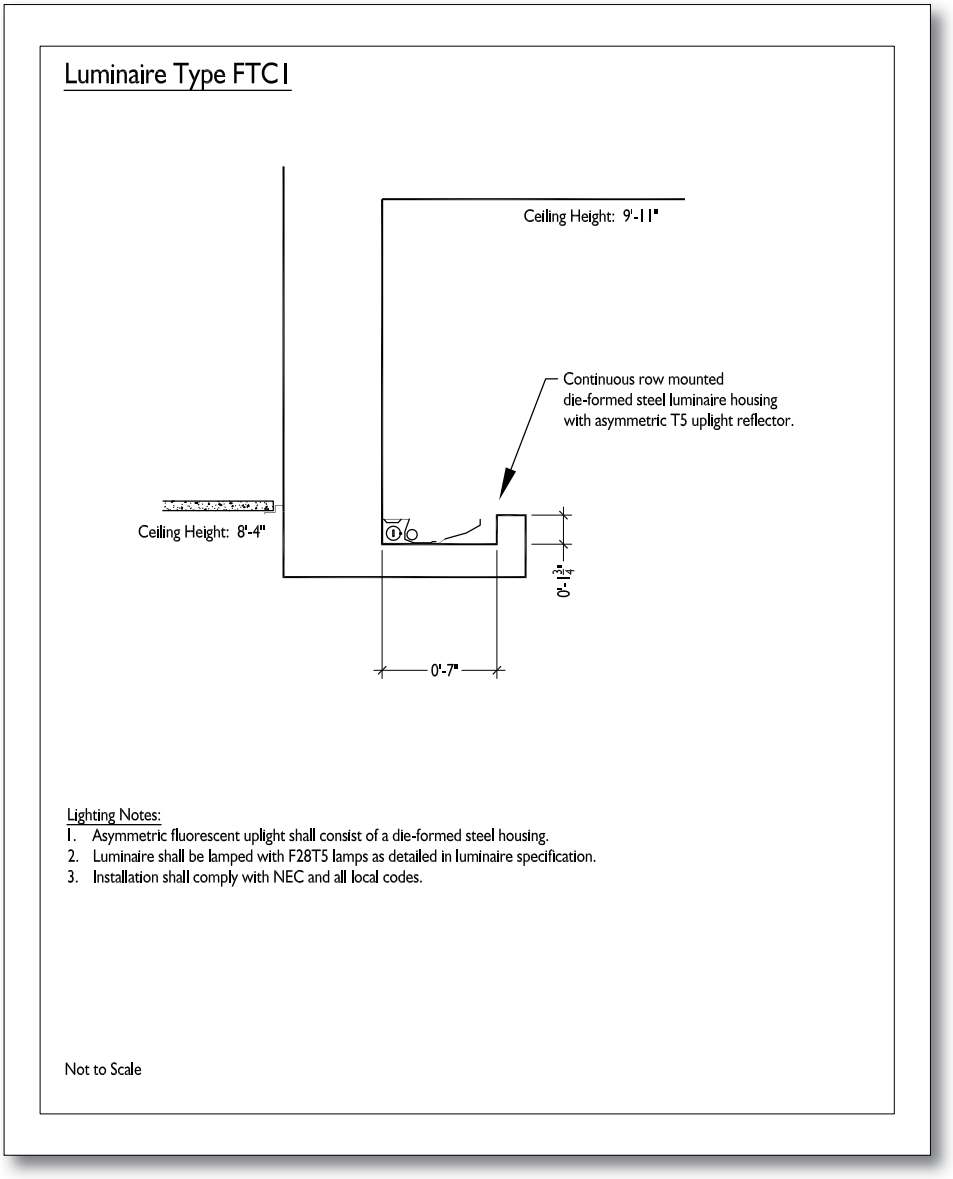
This specification section is not to be confused with a simple luminaire schedule. Procuring the correct lighting equipment is fundamental to an installation's success in meeting the design criteria. So it is that a complete description of the physical size, geometry, fit, finish, optics, lamps, ballasts, drivers, transformers, mounting, voltage, connected load, accessories, and other salient features is provided for clarity to those in the procurement and installation chain, including the contractor, distributor, lighting representative, and factory. This is done for each luminaire type on the project.

Lifting specification templates from vendors' catalogs is not recommended unless this material is carefully reviewed and purged of proprietary features, unless a prescriptive, single-name specification is desired. Even then, however, the template must be reviewed to assure there are no conflicts with the designer's standard of care or with any other lighting equipment or strategies on the project. Templates should also be reviewed for loopholes or simply loose or nonexistent detail on the salient features of the equipment.

Any special features or requirements are also noted in the description of each luminaire. For prescriptive specifications, a cutsheet from at least one of the listed vendors for each luminaire type is typically shown for instant recognition of generally what's involved. An example description is shown in Figure 20.6. A few special features cited in this example are related to how the wallwash lens is to be installed and the care with which the contractor installs the housing to assure proper orientation of the wallwash optic. Table 8.6 Factors in the Evaluation and Specification of Luminaires offers a checklist of items that are worthy of specification consideration.

The specification is the place to indicate special relationships between different luminaire types. For example, a wall bracket may exhibit a lantern, globe, or bowl that matches those used in a pendant or chandelier. Such is noted in the specification to ensure this detail is not overlooked and the family remains intact. More mundane, but important aspects that are noted in the luminaire specification include power feed positions and suspension points on linear pendants, for example, and, where occurring in close proximity, the need for these items to be oriented similarly and aligned for a neat appearance.

Custom luminaires or modifications require additional specification information, including a sketch or drawing illustrating the intended appearance and scale (see Figures 15.19c and 15.19d). Any samples or mockups required during shop drawing submittals are outlined in the specification. This typically involves review of casting patterns, glass and acrylic samples, metal finish samples and, where designs are unique, full-luminaire mockups. These mockups also provide an opportunity for obtaining actual photometric reports for the custom luminaire to confirm performance and calculations during submittals against those made during the design phase.



20.4.4 Installation (Specification Section 3.01)

The integrity of the lighting installation is established by the degrees of attention given to various aspects of installation including coordination between various lighting equipment vendors, such as controls and luminaires, care of visible aspects, such as leveling of luminaires, and lamp seasoning. All affect the photometric, lighting effect, and appearance qualities of the lighting system. In the specification section on references (1.04) NECA/IESNA jointly-developed installation standards are cited (see Table 20.4). Several lighting specification entries addressing installation might read:

1. Install lighting equipment, including but not limited to luminaires, controls, auxiliary devices and the integration of same in strict conformance with all manufacturers' recommendations and instructions the securing of which shall be the responsibility of the Contractor.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Figure 20.5 | Lighting Detail
Luminaire type FTC1 shown on the lighting plan in Figure 20.4 is intended to be housed in an architectural cove. For best lighting efficiency, an asymmetric luminaire is selected. Salient dimensions and orientation related to the luminaire are depicted in this simple sketch for the architect's development of the architectural cove detail.
» Graphic ©Gary Steffy Lighting Design Inc.

2. Luminaires shall be integrated with controls in accordance with respective luminaire manufacturers' and controls manufacturers' recommendations and instructions and to provide a complete, trouble-free operation without compromising safety, code and UL/CSA/NOM requirements.

3. Contractor shall be responsible for sealing all outdoor luminaires for wet locations (i.e. all knock-outs, all pipe and wire entrances, etc.) as is standard industry practice to prevent water from entering luminaires.

4. The Contractor shall coordinate the lighting system installation with the relevant trades so as to eliminate interferences with hangers, mechanical ducts, sprinklers, pipes, steel, etc.

5. For installation in suspended ceilings, ensure that the luminaires are supported such that there is no resultant bowing or deflection of the ceiling system greater than 1/360 of the length of the total span of the ceiling member.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

6. Mounting heights and configuration of the luminaires shall be as specified in the Luminaire Schedule portion of the Specification or indicated on the drawings, and where conflicts exist, as approved by the Architect.

7. All luminaires shall be installed plumb and true and level as viewed from all directions unless specifically identified otherwise in the Luminaire Schedule portion (Section 2.12) of this Specification. Luminaires shall remain plumb and true without continual adjustment or visibly obvious means beyond what is shown on luminaire submittal drawings.

8. Suspended luminaires shall be installed plumb and true and level unless specifically identified otherwise in the Luminaire Schedule portion (Section 2.12) of this Specification and at a height from finished floor as specified on the drawings, details and Luminaire Schedule. In cases where this is impractical, refer to the Architect for a decision. All appurtenances shall be consistently organized for a neat, uniform appearance.

9. Luminaire finishes which are disturbed in any way during construction shall be touched up or refinished in a manner satisfactory to the Architect.

10. Reflector cones, louvers, baffles, lenses, trims and other decorative elements shall be installed after completion of ceiling tile installation, plastering, painting and general cleanup.

11. Whenever a luminaire or its hanger canopy is installed directly to a surface mounted junction box, a finishing ring painted to match the ceiling, shall be used to conceal the junction box.

12. All lamps shall be seasoned for a minimum of 12 hours and a maximum of 100 hours in full-on mode without dimming. All lamps used for convenience lighting during construction shall be replaced with identical New lamps, which shall then be seasoned as described above, immediately prior to the date of substantial completion as determined by the Architect.

13. All accessories shall be properly installed and adjusted by Contractor in accordance with specification and installation instructions. Any spare items shall be clearly labeled (indicate type of accessory and associated luminaire types).

20.4.5 Testing and Adjustment (Specification Section 3.02)

Photometric performance of adjustable luminaires is of no benefit unless these luminaires are aimed, focused, and locked. The effort to achieve this involves the contractor as well as the team member serving in the role of lighting designer. Several specification entries addressing testing and adjustment might read:

1. As required, all adjustable luminaires shall be aimed, focused, locked, etc., by the Contractor under the observation of the Architect. As aiming and adjusting is completed, locking setscrews and bolts and nuts shall be tightened securely by the Contractor.

2. All ladders, scaffolds, lifts, etc. required for aiming and adjusting luminaires shall be furnished by the Contractor.

3. The Contractor shall be responsible for notifying the Architect of appropriate time for staking any outdoor luminaire locations which are called out as “to be field located” on drawings and Luminaire Schedule, and shall supply equipment and personnel for staking at the direction of the Architect.

4. Where possible, units shall be focused during the normal working day. However, where daylight interferes with seeing lighting effects, aiming shall be accomplished at night.

Table 20.4 | Key Specification Sections

Section		Topic	Typical Content
Part I GENERAL	1.01	**Description**	• Name and location of project for which specification is generated • General caveats and/or requirements (e.g., equipment shall be UL/NRTL listed/labeled) • Notice of means for identifying revisions (underlining and strikeouts) • Notice that cutsheets are copyrighted and are for procurement of specified equipment only
	1.02	**Related Documents**	• Notice that all work shall comply with terms of project's contract documents
	1.03	**Work Included**	• Outlines work required of the contractor
	1.04	**References**	• Citation of relevant related safety, operational, and performance references and codes, such as • American National Standards Institute (ANSI) • Canadian Standards Association (CSA) • Illuminating Engineering Society (IES) • National Electrical Contractors Associaton (NECA) • National Electrical Manufacturers Associaton (NEMA) • National Fire Protection Association (NFPA) • Norma Oficial Mexicana (NOM) • Underwriters Laboratories Standards (UL)
	1.05	**Quality Assurance**	• Workmanship requirements • Requirements for unit pricing and proposed vendor citations in bid
	1.06	**Submittals - General**	• Requirements for submittal drawings • Requirements for substitutions, if permitted
	1.07	**Submittals - Samples**	• Requirements for submittal samples
	1.08	**Delivery - Storage - Handling**	• Requirements for taking delivery, storing, and handling lighting equipment
Part II PRODUCTS	2.01	**Lamps - General**	• Outlines general operational and performance requirements of lamps
	2.02	**Lamps - Neon/Cold Cathode**	• Outlines operational and performance requirements specific of neon/cold cathode lamps
	2.03	**Ballasts - Fluorescent**	• Outlines operational, performance, and warranty requirements for fluorescent ballasts
	2.04	**Ballasts - HID**	• Outlines operational, performance, and warranty requirements for HID ballasts
	2.05	**Drivers - LED**	• Outlines operational, performance, and warranty requirements for LED drivers
	2.06	**Transformers - Low Voltage**	• Outlines operational, performance, and warranty requirements for low-voltage-lamp transformers
	2.07	**Transformers - Neon/Cold Cathode**	• Outlines operational, performance, and warranty requirements for neon/cold cathode transformers
	2.08	**Luminaires - General**	• Outlines general operational, fit, and performance requirements of luminaires
	2.09	**Luminaire Reflectors and Trims**	• Outlines general operational, fit, and performance requirements of reflectors and trims
	2.10	**Luminaire Lenses**	• Outlines general operational, fit, and performance requirements of lenses
	2.11	**Vendor Support**	• Outlines requirements for vendors' warranty, proficiency, and support
	2.12	**Luminaire Specification Schedule**	• Identifies and describes specific requirements for each luminaire, including vendor(s) catalogic
Part III EXECUTION	3.01	**Installation**	• Outlines requirements for installation (e.g., coordination/integration, plumb/level, lamp seasoning)
	3.02	**Testing and Adjustment**	• Outlines requirements for aiming and focusing prior to turn-over
	3.03	**Cleaning**	• Outlines requirements for cleaning lighting equipment prior to turn-over

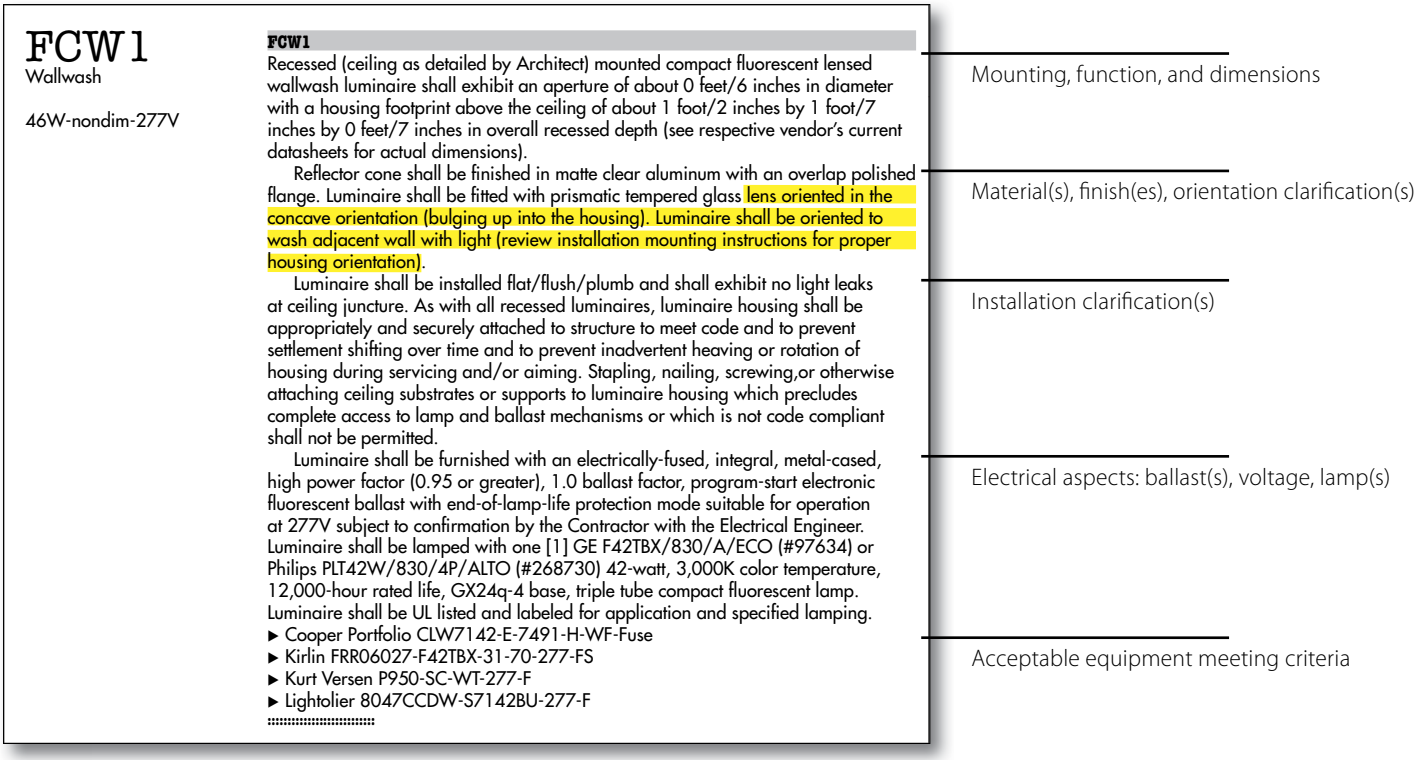

Figure 20.6 | Luminaire Specification Schedule Excerpt
Using the project illustrated in Figure 20.4 as example, a luminaire specification for Type FCW1 identifies the salient features of the luminaire in writing, including lamping and ballasting. Clarifications (highlighted for emphasis here) on optics and orientation are made based on previous experience and/or a review of vendors' catalog cutsheets and/or discussions with manufacturers' representatives. Acceptable manufacturers' catalog number is listed.

20.4.6 Cleaning (Specification Section 3.03)

The effects of dirt accumulation on lighting performance are well documented. However, construction dirt and debris are more significant than the typical environmental dust encountered during normal operations at most project sites. Cleaning of lighting equipment by the contractor immediately prior to project completion is critical to optimal system performance. A specification entry addressing cleaning might read:

> All luminaires and accessories shall be thoroughly cleaned after being installed. All fingerprints, dirt, tar, smudges, drywall mud and dust, etc. shall be removed by the Contractor from the luminaire bodies, reflectors, trims, and lens or louvers prior to final acceptance. All reflectors shall be free of paint other than factory-applied, if any. All reflectors, cones and lenses shall be cleaned only according to manufacturers' instructions.

20.5 Controls Preset Schedule

Lighting controls save significant amounts of lighting energy when designed and implemented appropriately for the situation. Controls also serve to establish various settings or scenes based on functional or time-of-day needs (see 16 | LIGHTING CONTROLS). Documenting the control zones and proposed schedule and manner of operation are, therefore, an important part of contract documents. Figure 20.7 illustrates a simple example taken from the project illustrated in Figure 20.4. In this example, occupancy sensors, automated time scheduling, and bi-level switching are employed. Electric shades, photocells and keypads are also identified in the preset schedule where these devices are

8	Z6-L	FCD1	CFL downlights	FL switched	ON	ON	OFF	

Figure 20.7 | Initial Preset Schedule
A spreadsheet outlines the proposed initial preset schedule for the project illustrated in Figure 20.4. The intent is to provide light only when deemed necessary. Keypad labels are identified as on, dim, and off for the override functions. Line numbers are used to the left for convenient reference (most helpful on large schedules).

used for interface with and/or control of electric light. Control zones must be checked against daylight zones for effective daylight harvesting.

Preset schedules are usually identified as "initial" since final settings are likely to be influenced by the client soon after the time of project completion. Preset schedules are shown on plans or in the specifications. Where the project is relatively small or where the lighting designer is not the electrical engineer, the spreadsheet might appear in the lighting specification (26 51 00) or used by the electrical engineer in development of the controls specification. MasterFormat™ for controls 26 09 00 Instrumentation and Control for Electrical Systems is the section within which complete controls specifications are made. The engineered controls layout and specification are typically the responsibility of the electrical engineer.

20.6 Commissioning

Control systems require commissioning to assure their effective and intended operation at the time the project is turned over to the client. Commissioning is an aspect most commonly addressed by the electrical engineer in Section 26 08 00 Commissioning of Electrical Systems. Commissioning is typically not undertaken until all devices are in place and set in accordance with submittals and vendors instructions. Key lighting aspects to be included in the specification section on control systems commissioning are: [10]

1. Sensor placement and orientation for all sensor types.
2. Occupancy sensor function, sensitivity, and time delays.
3. Daylight harvesting sensor calibration.
4. Automated shade operation.
5. Manual control placement and operation.
6. Automated control operation, including scheduled on/off functions and dimming trims and presets.
7. Override operation, access, and functionality.
8. Centralized control interfaces and operation.
9. Client education of operations.
10. Documentation archived to client.

20.7 Plan Checks

Throughout CD, if not the entire project, a round-robin approach to plan checking is recommended. Lighting plans, architectural RCPs, electrical plans, mechanical plans, AV plans, food-service plans, landscape plans, etc. should be exchanged amongst all team members and reviewed for potential conflicts or clashes and for missed or changed design opportunities. Near the end of CDs, and presumably after previous round-robins have resolved many of these items, careful review by the team members responsible for lighting, architecture, and electrical engineering of their respective plans and the plans of their fellow team members is in order. This may result in the exchange of red-lined drawings or a series of Internet-based conferences.

Lighting efficiency and planning of its effects and intensities are closely tied to architectural configurations, surface reflectances, and a proper placement and accounting of all lighting equipment. Therefore, it is imperative for configurations to remain as used in lighting and energy models. Surface reflectances cannot be changed by a few percentage points without risking non-compliance on connected load, energy use, or illuminance criteria. Last-minute, uncoordinated, and so-called themed decorative lighting additions, whether portable or permanent, work against the project-long effort to minimize energy use and heat-generation while maintaining satisfactory luminances and illuminances.

If daylighting aspects are not employed to the extent the team anticipated during design development, then the electric lighting system may fail in its goals to meet various criteria, including energy expectations. Additionally, the project may fail to provide daylighting that is comfortable for users if shades are not automated and luminances balanced and re-balanced throughout the day, for example. The architectural and interior design plans and specifications related to daylighting aspects, including glazing, electric shades, surface finishes, architectural enhancements such as light shelves, fins, light-direction-media, brise soleils, skylight and monitor wells and/or splays, and the like must be reviewed and confirmed. Table 20.5 outlines key items affecting daylighting integrity.

Typically, the most low-tech aspect of daylighting, the finishes, is modified between design development and final contract documents. For daylight success in many commercial, healthcare, institutional, industrial, and hospitality situations, IES-recommended reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) are typically minimums. These reflectances also have significant effect on the efficiency and quality of the electric lighting system.

APPLICATIONS

The IES introduces a broad range of criteria to address many situations encountered by the designer. In an era when vision is known to change significantly with age, where tasks vary greatly by application and observers, where energy and earth resources are scarce, and where users expect productive, comfortable settings, a robust set of criteria is appropriate. Lighting applications are arranged here alphabetically and generally follow architectural namesakes. Applications featured are those commonly encountered or that are significant to society or where lighting can make an important contribution to the overall quality of space for living or working. The breadth and depth of these applications is believed sufficient that new or different applications can likely be correlated with some aspects of those featured here, thereby giving the designer a basis for developing criteria and, subsequently, designs.

Analytic or quantitative lighting criteria recommendations are presented here for the development of normal power architectural lighting systems. IES recommendations identify illuminances and uniformities deemed necessary for users to perform various functions and tasks in a wide range of applications. Meeting these criteria can result in a technically-competent and aesthetically appropriate lighting solution. However, results are typically only as good as the time and effort given to ideating and analyzing, the breadth and depth of background information available through programming, design team and client input, the extent to which criteria outlined in the preceding Design Section are employed, and the level of detail applied to solving the design problem.

Illuminance is extraordinarily robust, but only when manipulated to address luminance and luminance ratio needs of specific observers in specific situations. Newly revised application and task lists and age ranges offer unprecedented depth and breadth in setting criteria for specific projects. A new emphasis on vertical illuminance criteria and on accenting assists in the designer's goal of meeting users' vision needs. Forms of accenting offer observers visual relief and contribute to brightness perceptions, visual attraction, and wayfinding.

On the following double-page spread, a succinct User's Guide identifies the main writing and graphical components used to convey the IES recommendations.

The English language has its quirks. One word can have multiple definitions. Read with care and within context.

This is not a code compliance manual nor a list of all code requirements. Codes, standards, and mandates may supersede any of the IES criteria. The designer is responsible for identifying those applicable to any given project and must design accordingly.

For greater detail on lighting design and criteria related to specific application types, the IES offers Recommended Practices, Design Guides, and Technical Memoranda. These are available at IES Bookstore at www.ies.org. Application-related documents published after 2010 will offer material consistent with or more current than this handbook.

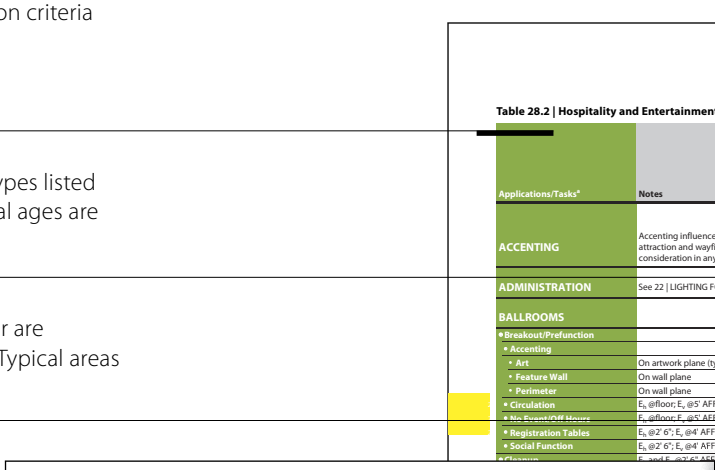
User's Guide

Criteria Summary
A criteria summary presented as a checklist is near the beginning of most chapters. References to relevant chapters, sections, and tables are cited for convenient reference to criteria relevant to the application under consideration.

Notes on Application Types
Discussions on various application types key on lighting aspects that are important to successful designs for the specific application types and tasks. For example, depending on the application type, notes might be made on controls, color rendering or color temperature, on challenges specific to the application, on energy, sustainability, light trespass or light pollution, on specific illuminance criteria, or on the affects of unique architectural situations on criteria and design.

Illuminance Recommendations
Easy to read tables outline illuminance recommendations for various application types listed alphabetically. Horizontal and vertical illuminance targets based on observers' visual ages are presented with respective uniformity criteria.



Collateral Guidance
Application types and tasks where daylighting is considered a potential contributor are identified. Where veiling reflections are a potential threat to visibility, this is noted. Typical areas of illuminance coverage from task proper to large area are also indicated.

Application Notes
Notes related to specific applications and tasks are conveniently located alongside each instance of the table.

Examples
Photographs exemplify lighting of some of the various application types. Captions identify relevant criteria aspects or significance of lighting effects. Where specific information is available on illuminance criteria, lamps, luminaires, techniques, or details, this is reported. A few carefully selected photographs are used in each chapter as inspiration on lighting effects and techniques. Some exhibit photo-fill light, others have been digitally enhanced, and some are quite candid. Yet these were all selected for their ability to convey the essence of the applications and tasks and of the lighting. Nothing, however, compares to experiencing settings first hand.

Sidebars
Special criteria, architectural features, or new or uncommon terms are explained in sidebars.

Resource References (not shown here)
In addition to sidebars, resource reference text boxes are positioned in side margins guiding the reader to related areas of the handbook for more detail on background information.

28.1 Project Type and Status

An understanding of the project type and scope is necessary before commencing design work. This will establish the extent to which daylighting can address the lighting goals. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. For some applications and tasks, daylighting can be the primary light source. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

28.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the hospitality and entertainment space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds.

- Client wishes and architectural desires
- Degree to which clientele or business prospects visit administrative operations
- View between administrative areas and hospitality or entertainment areas
- Management style and immersion in hospitality or entertainment functions

28.2.3 Ballrooms

Ballrooms are typified by their size and flexibility in use. Ballrooms are typically configurable from one very large space to multiple smaller spaces. Lighting and controls must be laid out to address the various sizes and configurations. Functions are quite varied even within designations dining, exhibition, demonstration, and presentations. This usually requires design of a controls system that may demand operators instructed in the use of the system. Additionally, in smaller meeting room setups it may be necessary to have simplified controls accessible to participants to accommodate AV presentations and overhead projection without the need for professional staffing.

Challenges include lighting system efficiency given high ceilings and large space volumes. Light-finish ceiling and wall surfaces are important. Provisions for entertainment lighting are usually required. Some ballroom designs include sound and light locks where lighting should be designed to manage the luminance change from a darkened ballroom to the adjacent prefunction space. See Figure 24.2 | Sound and Light Lock. If no sound and light locks are employed, then the adjacent prefunction and circulation areas should be designed to limit brightness distractions. This may involve linking the lighting in the prefunction and circulation areas with ballroom lighting controls so that lighting tracks ballroom presets.

Figure 28.2 illustrates a typical ballroom setup and identifies the architectural lighting to support that and other setups.

Figure 28.2 | Ballrooms
This ballroom can be reconfigured into as many as five smaller ballrooms or meeting rooms. Lighting layouts and control zoning and the controls are arranged to accommodate the variations. A combination of cove lighting (not energized here), chandeliers, and recessed downlights (not energized here) are employed. The coves use dimmable long compact fluorescent lamps, the chandeliers use nondim CFLs, and the downlights and accents use halogenIR$_{120V}$. The chandeliers use two zones of control for 2-level lighting. Lamp CCT is 3000 K and CRI is ≥82 and the chandelier lenses are color-tuned to achieve the look of a filament-lamp glow. Stage lighting rigging and instruments are in place for entertainment lighting at this dinner banquet.

Notes for Table 28.2
The table column headings are discussed in detail in 28.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 28.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 28.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.
b. Values cited are to be maintained over time on the area of coverage.
c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 28.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.
d. Targets are intended to apply to the respective plane or planes of the task.
e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.
f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.
g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.
h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.
i. "High Light Setting" typically employed where exhibit displays have little or no internal lighting and where no theatrical rigging is used. "Low Light Setting" typically employed where exhibit displays have significant internal lighting or where theatrical rigging and instruments are used. "Low Light Setting" used for set-up, tear-down, and cleanup.
j. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.
k. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.
l. Make half the illuminance available from lamps exhibiting CCTs of 5000 K or 6500 K and CRI ≥85 and half from lamps exhibiting CCTs of 2700 K or 3000 K and CRI ≥85. Provide three control settings: for one CCT; for the other CCT; and for both CCTs to be energized for maximum viewing flexibility.

and dimmable task lighting illuminating control boards and notes. If programming determines that the control board devices and readouts are backlighted and if notes are displayed on computer, then only floor illuminance is needed during performances. Significant illuminances may be necessary for cleanup and for set-up and tear-down, depending on the permanence of the equipment in the booth. Figure 28.4 illustrates a typical control booth location as seen from the house.

28.2.8 Exhibit Halls

Convention centers and some hotels have exhibit halls of varying sizes. These multipurpose facilities, depending on their size and geographic locale may temporarily house training sessions, trade shows, religious gatherings, vehicular and sports shows, and large corporate and union functions. The normal power architectural lighting system typically accommodates set-up, tear-down, and some amount or all of the functional requirements of some of these various events. Luminaires are typically controlled in small groups to allow for efficient operation of incrementally smaller or larger events or permit some degree of tuning of light levels to types of displays. However, considerable electrical and structural infrastructure is necessary for theatrical rigging and for exhibit-integrated lighting to accommodate all situations. Figure 28.5 identifies just a few basic approaches. These facilities are made more appropriate for activities beyond exhibit displays if wall and/or ceiling surfaces are lighted. This addresses some elements identified in 12.2 Spatial Factors.

28.2.9 Fitness Centers

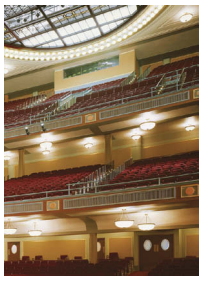
The fitness center involves a number of situations where, although workout and conditioning are "the tasks," how people look and feel about themselves and their depth of engagement in exercising are as important. Lighting should be flattering and accommodate conversation and video-watching. Video watching may be susceptible to veiling reflections, so harsh directional lighting should be avoided. Well-shielded direct or totally indirect lighting are often appropriate given the potential for users looking to the ceiling during exercise sessions.

Many fitness centers, even in hotels, are a revenue stream and operate like a club. Here, reception and waiting, locker rooms and showers, and even retail areas are common. Lighting should be sympathetic to the fitness experience and to a club atmosphere. These facilities typically have swimming pools and hot tubs indoor or outdoor. Overlighting or gymnasia-like techniques should be avoided as these risk the potential for direct glare and wasted energy. For indoor pools, the anticipated activity level determines illuminance recommendations. See Table 22.4 for indoor activity level definitions. Lighting within the pools and hot tubs is necessary for observation of occupants and for comfortable use during dark-hours of operation or when daylight is insufficient. Vendors of such equipment should be consulted for recommendations on underwater luminaire wattage and lumen requirements for a given situation.

All pool criteria outlined in Table 28.2 are intended for relaxation and non-competitive exercising. For competitive situations, see 37 | LIGHTING FOR SPORTS AND RECREATION. Figure 28.6 illustrates an indoor hospitality pool application. Pool lighting should be planned with respect to maintenance and addressed with the client prior to final layouts and specifications.

Veiling reflections from pools are common in indoor and outdoor situations depending on view angles and sight lines. Daylighting and electric lighting can be arranged to limit veiling reflections, but this is practical where a fixed position view, such as that of a lifeguard can be planned or where polarized-lens eyewear is used as in outdoor situations.

With outdoor pools, the activity level and the nighttime outdoor lighting zone determine illuminance recommendations. See Table 22.4 for nighttime outdoor activity level



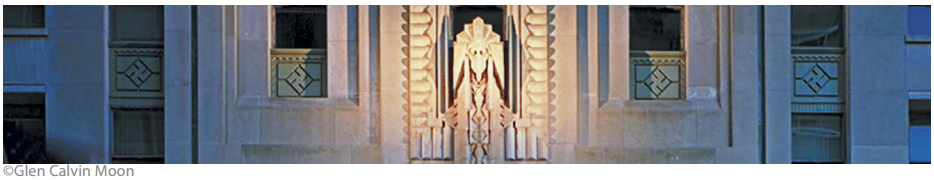


Figure 28.4 | Control Booth
The sound and light booth for this large auditorium (top center) houses sound and lighting control boards and can accommodate follow spots. Some of the theatrical lighting instruments controlled from the booth are just visible in a "seam" in the *laylight* (top left).
» Image ©Balthazar Korab Photography Ltd.

Laylight is an architectural feature or element that is a decorative light diffuser typically positioned below a skylight or roof monitor. Patterns of obscuring decorative glass or acrylic diffuse the light. Where no skylight or monitor exists or during dark hours, electric light is used to backlight the decorative diffuser [4].

21 | LIGHTING FOR ART

The moment you cheat for the sake of beauty, you know you're an artist.
David Hockney, English Artist [1]

Art *is* in the eyes of the beholder and as such possesses value to at least one person. Valued objects for museum collections are those of scientific, artistic, or historical importance and commonly include fine art, antiquities, and artifacts. For commercial, other institutional, or private interests, valued objects may also be those of sentimental importance, corporate or institutional significance, or of considerable monetary value. The purpose, value, and intended display of the objects greatly influence their lighting. Unlike other applications, lighting for art may, indeed, be more about lighting for the task, in this case the artwork, than for the observer. Where artworks are deemed preservation-worthy, optical radiation must be limited in magnitude and spectra, otherwise damage to the objects will be induced or accelerated. This chapter discusses lighting for artwork regardless of its display venue. Lighting for museum facilities is also addressed here.

Comprehensive design efforts involve synthesizing the information in this chapter with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING, 15 | DESIGNING ELECTRIC LIGHTING, and, for non-museum facilities, the application chapter of the venue of art display. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance specifics related to lighting for art and for museum applications which should influence luminaire optical selections, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous IES related documents provide archival reference [2] [3].

Careful thought must be given to details beyond the illuminance citations in this chapter. For example, in Table 21.2 the citation EXHIBITS AND GALLERIES/Objects/ High Sensitivity to Light identifies illuminance for those objects deemed highly sensitive to light. These criteria are maxima. If such an object or objects were displayed on the wall in an office, conference room, or lobby, then the designer must evaluate the vertical illuminance falling on the objects from all of the lighting producing media, including daylight, in the space to determine that this does not exceed the recommended maximum illuminance. This is counter intuitive to the notion of adding light specifically to highlight the displayed objects. There may be no need to introduce lighting equipment solely to illuminate the objects. Indeed, the lighting equipment used in these spaces for ambient, task, and other accenting may significantly over light the objects and accelerate damage to the objects. Such an analysis may not appear necessary or even obvious, yet the designer must be concerned about the effects of all lighting in a space. Table 21.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

21.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. New, renovation, and restoration projects each offer varying opportunities. As do the kinds of artworks displayed and the intent of their display. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. This will establish the extent to which daylighting can address the lighting goals for artworks. Although every opportunity should be given to daylight as a light source, the sensitivity of the artworks to light must have direct bearing on the applicability of daylighting. Daylight demands attention to moderate or eliminate glare and balance the visible and thermal energy which may damage artworks.

21.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational aspects, the art application space types under consideration and consequently the anticipated occupants, functions, and tasks are inventoried (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 21.2 | Art Facilities Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 21.2.

Art applications must be carefully defined. Preservation-worthy objects are typically categorized according to their sensitivity to light:

- High sensitivity
- Low sensitivity
- No sensitivity

Table 21.3 identifies the light sensitivity categories for displayed objects and cites examples.

Intended viewing situations may significantly affect the display lighting. Consider the implications of an object highly sensitive to light in a private collection in the wine cellar of a summer home versus a similar object in a museum collection. The risk of damage from light exposure in the museum is likely greater than that in the private collection example. Regardless, in any situation with such sensitive objects, the lighting designer is obligated to document and report IES criteria recommendations, but address client wishes.

The following discussion is keyed to major application headings in Table 21.2. Couple this with topics in Table 21.1 for comprehensive qualitative and quantitative criteria.

21.2.1 Accenting

In many applications accenting can be used to positively affect people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction and wayfinding. Default accent lighting techniques and criteria are identified in Table 21.2. Also see 15.1.1.3 Accent Lighting. Accenting of artwork introduces focal points of visual relief in work settings. Softly accenting selective artwork promotes an impression of relaxation (see Table 12.2 | Subjective Impressions). While good for people, accenting artwork may damage the artwork.

The team must understand the client's intention with art objects. Where art is a collection of valuables under the care of a client for future generations, then depending on the composition of the objects, exposure to visible and UV radiation must be well-controlled in intensity, time of exposure, or both. Illuminance criteria should follow those recommendations in Table 21.2 under EXHIBITS AND GALLERIES and discussed in 21.2.7 Exhibits and Galleries. Where art objects are readily replaceable or considered a commercial commodity and where the client has no expectations for the longevity of the works, illuminance criteria may follow the recommendations in Table 21.2 under ACCENTING. The design challenge is securing clear definition of the client's intention with the art objects.

There are methods for displaying seemingly highly light-sensitive objects in work and public settings and lighting these for the benefit of the viewing public with little regard for damaging the objects. Some reproduction techniques like that shown in Figure 21.1 can themselves display iconic imagery in cost effective and easily reproduced media. Figure 21.2 illustrates the lighting of historic flag replicas in a historic setting.

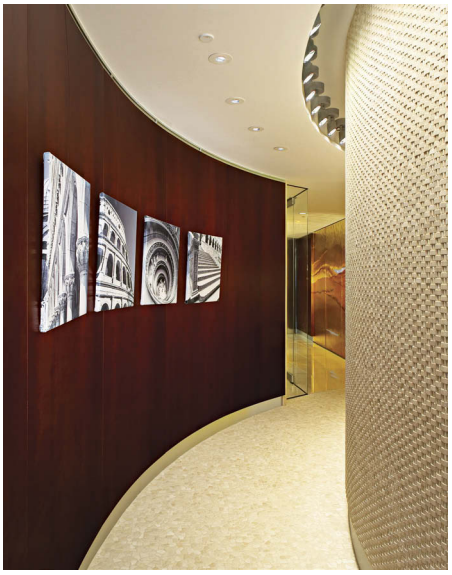

Figure 21.1 | Artwork Media
Iconic imagery reproduced on canvas may not be considered as preservation-worthy and, therefore, deemed not as light sensitive as original photographs. Pinhole linear-spread lens wallwashers lamped with 37 W MR16/NFL halogenIR$_{LV}$ lamps meet criteria for objects of low sensitivity to light and softly highlight the wall and art.
» Image ©Beth Singer Photographer, Inc.

21.2.2 Administration

In museum and gallery projects, administrative areas may be part of the project scope. Lighting for these administrative areas is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The architectural scheme and even task specifics may vary based on the associated art facility, from a gallery in a higher education setting to public and private museums. These distinctions may affect the lighting design by influencing the kinds of lighting effects, the lighting equipment styling, and the luminances and illuminances.

On large projects, the administrative areas may be dispersed throughout an art facility or complex or may be centralized into a single area, wing, or building. Depending on client wishes and architectural desires, this centralization or decentralization may affect the degree to which the lighting design in administrative areas is sympathetic to or different from that of the other applications and tasks at the art facility in question.

21.2.3 Atria and Courtyards

Lighting for atria and courtyards is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. However, in art facilities these spaces may be specifically designed to display objects in addition to being places of respite. Where artworks are involved, great care must be taken in defining the objects' sensitivities to light and designing accordingly.

21.2.4 Auditoria

Lighting for auditoria is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

21.2.5 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

21.2.6 Conservation Labs

Although conservation of artworks relies on scientific analyses to establish the underlying substrates, designs, and colors, conservation work involves highly artistic and delicate procedures. The available illuminance and the directionality of light can greatly aid or hinder conservation. Additionally, the act of lighting itself is damaging to many of the works to be conserved. Labs are typically independent spaces or even standalone facilities where lighting is highly flexible and discretely controlled to aid the conservation process while limiting exposure. Conservation illuminances may be best achieved with a task lighting system which should be on dimmer control to allow for tuning to specific object's materiality, finish, and level of conservation. Ambient lighting should be on dimmer control as well and zoned to permit relatively small areas to be set as needed. All lamps in

Notes for Table 21.2

The table column headings are discussed in detail in 21.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 21.4 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 21.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage as needed.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 21.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches. A shaded icon ◪ indicates applications and tasks are sensitive to daylight and appropriate measures, including blackout capabilities, must be taken to limit daylight exposure, if daylight is deemed a suitable source of light.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Use motion-sensing control to toggle lighting off or dim to standby setting when spaces or areas are unoccupied. Use instant-on lighting equipment.

j. Filter UV from daylight and electric light sources where UV radiation exceeds 75 µW/lumen below 400 nm.

k. Use lamps exhibiting CRI ≥85.

l. Equip conservation laboratories with adjustable portable luminaires for treatment efforts.

m. The circulation and general lighting in an exhibit or gallery space should establish the background against which the displayed objects are to be experienced. This circulation/general lighting must therefore be based on the intended display experience and the display reflectance values. Room surface reflectance's are assumed to be IES-recommended values of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively). Lower room surface LRVs will result in more dramatic lighting contrasts. In no event should illuminances on preservation-worthy objects exceed the maximum values cited.

n. Where any doubt exists, assigning objects to categories of higher sensitivity to light with concomitant reduction in illuminance criteria is recommended.

o. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 21.2

The table column headings are discussed in detail in 21.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 21.4 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 21.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage as needed.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 21.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches. A shaded icon indicates applications and tasks are sensitive to daylight and appropriate measures, including blackout capabilities, must be taken to limit daylight exposure, if daylight is deemed a suitable source of light.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Use motion-sensing control to toggle lighting off or dim to standby setting when spaces or areas are unoccupied. Use instant-on lighting equipment.

j. Filter UV from daylight and electric light sources where UV radiation exceeds 75 µW/lumen below 400 nm.

k. Use lamps exhibiting CRI ≥85.

l. Equip conservation laboratories with adjustable portable luminaires for treatment efforts.

m. The circulation and general lighting in an exhibit or gallery space should establish the background against which the displayed objects are to be experienced. This circulation/general lighting must therefore be based on the intended display experience and the display reflectance values. Room surface reflectance's are assumed to be IES-recommended values of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively). Lower room surface LRVs will result in more dramatic lighting contrasts. In no event should illuminances on preservation-worthy objects exceed the maximum values cited.

n. Where any doubt exists, assigning objects to categories of higher sensitivity to light with concomitant reduction in illuminance criteria is recommended.

o. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Table 21.3 | Light Sensitivity Categories

Sensitivity to Light	Example Objects[a,b]
High	books, botanical specimens, costumes, cotton, drawings, dyed leather, feathers, fugitive dyes, fur, gouache, insects, manuscripts, miniatures, paintings in distemper media, paper, prints, silk, skins, some minerals, some photographs, stamps, tapestries, textiles, wallpapers, watercolors, wool, and writing inks
Low	bone, horn, ivory, lacquer, leather, oil paintings, some plastics, some photographs, tempura paintings, textiles with stable dyes, and wood finishes
No	ceramics, enamel, glass, jewels, metal, most minerals, stone, and wood

a. Example distinctions are based on several references [4] [5] [6] [7]. Where any doubt exists, assigning objects to categories of higher sensitivity to light with concomitant reduction in illuminance criteria is recommended.

b. Objects or artworks consisting of a variety of the exemplified materials should be categorized in the most sensitive category. Some objects, such as ceramics or metal, may exhibit fugitive finishes and should be assigned to the high-sensitivity-to-light category.

c. Consult with conservator to establish light sensitivity categories for given objects.

task lighting systems in conservation labs should exhibit CRI of 100. Lamps in ambient lighting systems should exhibit CRI ≥85. Lamps or dimming techniques should not result in color shifting or reduction in color rendering. For many situations, though not all as Figure 21.3 illustrates, any use of daylight must be well controlled and permit total blackout. Vacancy sensors should be used to strictly limit light exposure.

21.2.7 Exhibits and Galleries

Artworks, artifacts, antiquities or other preservation-worthy objects must be defined and placed in plan in order to develop appropriate lighting solutions. These objects are classified according to their sensitivity to light for which consultation with a curator may be necessary. For preservation purposes, Table 21.2 cites maximum recommended illuminances. There is no avoiding the obvious, however draconian: preservation-worthy objects are best preserved in the dark. This may bear repeating for the project record. Other environmental aspects, such as humidity and temperature, are likely to be as, if not more, damaging to objects as are visible and UV radiation from daylight and other sources. Lighting is a sufficient contributor to damage for some objects that designs must be developed accordingly.

The reasons for displaying preservation-worthy objects is their effect on the human psyche, an understanding of our past, an appreciation of the contribution or significance of fellow humans and nature, or all of this. Such object displays are, therefore, celebrated with light. The levels of light and the durations of exposure can be manipulated to allow for this celebration while minimizing damage to the objects.

Time exposure should be limited to minimum practical for patrons' viewing. Vacancy sensors or timers or some combination should be considered to limit exposure.

21.2.7.1 Circulation/General

The circulation and general lighting in an exhibit or gallery space should establish the background against which the displayed objects are to be experienced. This circulation/general lighting must therefore be based on the intended display experience and the display reflectance values. For the following recommendations, room surface reflectances are assumed to be IES-recommended values of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively). Lower room surface LRVs will result in more dramatic lighting effects.

Display experiences are categorized for dramatic focal points, moderate focal points, and subdued focal points. These may relate to the experience programmed by the client or curator of the exhibit or by the design team or by the lighting designer, depending on the level of project involvement by an informed client or the availability of a curator. Objects' reflectance values are categorized as ≥0.5 (greater than or equal to 50% reflectance) or <0.5 (less than 50% reflectance). These, too, are programmed or designer-assigned. Though security camera technologies now require little light for effective function, the designer should confirm illuminance minimums for cameras. In any event, for purposes of comfortable and convenient circulation throughout exhibits and galleries, horizontal illuminance on the floor plane should be no less than 10 lx.

Where dramatic displays are desired, the circulation/general illuminance should be just 10 percent of the display illuminance for a display exhibiting at least a 50% reflectance, but no less than 10 lx. If the display exhibits a reflectance lower than 50% reflectance, then the circulation/general illuminance should be just 5 percent of the display illuminance, but no less than 10 lx. That is, since the display is relatively dark in tone, the circulation/general lighting must be that much lower in order for the display to appear dramatically illuminated.

Where moderate focal points are desired, the circulation/general illuminance should be 20 percent of the display illuminance for a display exhibiting at least a 50% reflectance, but no less than 10 lx. If the display exhibits a reflectance lower than 50%, then the circulation/general illuminance should be just 10 percent of the display illuminance, but no less than 10 lx.

Figure 21.2 | Historic Objects
The original flags displayed for a hundred-plus years in the cases encircling the rotunda floor of the Michigan Capitol were found to be disintegrating during the capitol's restoration in 1989. A fisheye view of the entire rotunda is on the left. Flags now displayed here are replicas of the Civil War era counterparts which are themselves now preserved in the state historical museum. [7] Fluorescent lamps concealed above wood louvers and opal lensing along with exposed filament lamps illuminate the replicas to criteria appropriate for preservation-worthy objects of low sensitivity to light. Even the replicas are handled with care. This lighting is more consistent with the flags' presentation in a historic landmark than would be the more dramatic accenting that would be achieved by selecting illuminance criteria from ACCENTING in Table 21.2.

Oil paint portraits of governors on the second and third floor rotunda balconies, seen more clearly in the image on the right are lighted with low wattage fluorescent picture lights fitted with UV filters.

» Left image Dietrich Floeter Photography ©1992
» Right image ©Richard Cummins/Corbis

For subdued focal points, the circulation/general illuminance should be half of the display illuminance for a display exhibiting at least a 50% reflectance, but no less than 10 lx. If the display exhibits a reflectance lower than 50%, then the circulation/general illuminance should be 20 percent of the display illuminance, but no less than 10 lx.

21.2.7.2 Objects

Lighting of preservation-worthy objects on display must respect the objects' sensitivities to light. Table 21.2 outlines illuminance criteria. Where light sources exhibit UV radiation, apply reduction filters to the lamps or luminaires. Daylighting should only be considered where objects are not sensitive to UV and visible radiation or where automated and fail-safe control of daylight is employed.

Direct sun can be most destructive, causing damage in a very short time. North skylight was arguably the source of choice for masters in painting. With orientation and geometry, north skylight can be properly controlled to avoid direct sun at all times. Glazings and geometries can be used to greatly reduce daylight levels. Glazing interlayers and films can reduce UV, however, specifications must cover the range below 400 nm. Skylight wells', tubes', and splays' finishes consisting of titanium dioxide can be used to further reduce UV for sensitive objects. Shades, louvers, and other mechanical devices should be automated to limit daylight to the maximum allowed for a given object or series of objects. Fail-safe modes should block all daylight. Very close scrutiny of the program and close collaboration with the curators, conservators, and directors of facilities in which sensitive objects are to be displayed is a must where daylight is under consideration. Such systems can only be successful if careful analyses and mockups are undertaken. Figure 21.4 illustrates a unique approach to daylighting for exhibits.

Ultraviolet radiation induces photochemical damage on many materials and is generally more detrimental than visible radiation. Photochemical damage is evidenced by color change and physical deterioration and is irreversible. [8] For purposes of this discussion, UV radiation is that which is ≤400 nm. A maximum recommended value of UV radiation is 75 µW/lm. If lamps exceed this value, then UV reduction filters should be applied to limit UV.

Filters should be selected that eliminate as much radiation as practical in the respective region of the spectrum. This requires detailed review of the specific spectral power distri-

Table 21.4 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

Figure 21.3 | Art Conservation Labs
Unlike many conservation labs, daylight and ample fluorescent backlight are used in this lab for conservation work on stained glass. The designer must review the programming information and consult with the art conservators and curators to understand the vision and lighting needs for a given lab. This may necessitate criteria other than that recommended by the IES. Such criteria anomalies should be documented and agreed to by the team and client.
» Image ©Camille Moirec/Hemis/Corbis

butions for the lamps and filters under consideration. Lamp technologies vary too much and evolve too frequently to cite any reliable UV performance data of lamps here. The significance of the UV radiation depends on lamp wattage, center beam candlepower and beam spread, and distance between lamp and preservation-worthy material and exposure duration. If doubt exists and credible documented UV radiation data is unavailable, use UV filters. Filters should be scrutinized for their range of effectiveness and the degree of reduction.

Where daylight is under consideration in collection areas for high- or low-sensitivity-to-light preservation-worthy objects or materials, the magnitude of daylight must be well-controlled or automatically responsive to available daylight or both. Films on glass and interlayers in laminated glazing can reduce UV. However, the magnitudes experienced with daylight are so significant, that review of the remaining UV component must be made to assure the residual levels are acceptable. Regardless of UV mitigation, visible radiation from daylight may also be damaging given its potential magnitude. Glazing should be selected for its relative damage-factor transmittance, T_{df}, where lower is better. T_{df} accounts for radiation in the 300 nm to 600 nm range [10] [11].

Figure 21.5 exemplifies a gallery set for an exhibit of middle east stone panels, carvings, and bas reliefs and other artifacts that are thousands of years old. Figure 21.6 illustrates an exhibit featuring displays of 18th, 19th, and 20th century puppets.

The illuminance criteria outlined in Table 21.2 for EXHIBITS AND GALLERIES/Objects are not limited to objects displayed in museum exhibits and galleries, but apply to preservation-worthy objects displayed in any application. Preservation-worthy objects may encompass items considered of value and worthy of preservation for future generations. So, for example, where decorative ceilings and walls and painted graphics in historic facilities are to be lighted, citations under EXHIBITS AND GALLERIES/Objects in Table 21.2 are recommended. These criteria were used to illuminate the decoratively painted historic ceiling in Figure 21.7 and the historic ceiling mural shown in Figure 21.8.

Some objects have very little, if any, sensitivity to light. However, these objects should be lighted relative to their setting. For example, the sculpture shown in Figure 21.9 is illuminated in the context of its surround.

In addition to illuminance criteria based on objects' sensitivities to light, lighting objects depends on the viewing conditions and the objects' finishes or, if under glass or acrylic, the design and orientation of the glass or acrylic. The 2- and 3-dimensional nature of these objects, the nearly infinite number of finishes and materials used in their creation, and the many vantage points from which these are viewed limit the utility of general rules of thumb on the types of lighting equipment and the number of lighting positions and aiming angles to consider. Calculations are useful, but mockups are most informative.

Expressed previously, an object's sensitivity to light can be mitigated by not exposing the object to light. A less draconian technique is to limit the illuminance on a light-sensitive object and limit duration of exposure to UV and visible radiation. Continuous exposure to even low illuminance will ultimately deteriorate a light-sensitive object. Limiting the duration of light exposure through hours of operation, time clock operation of object lighting, in a lobby, for example, and rotating artworks from display to storage periodically are all methods of limiting the duration of exposure. To this end, some attempts have been made to establish lux-hour limits for artworks based on light sensitivity. The rationale is to allow greater illuminances for shorter time periods on sensitive objects or extend display durations by reducing illuminances. For high-sensitivity-to-light objects, an annual cumulative exposure should not exceed 150,000 lx-hours. For low-sensitivity-to-light objects, an annual cumulative exposure should not exceed 600,000 lx-hours. [12] However, it is important to consider these exposures as maximums and not entitlements.

21.2.7.3 Patrol

Where facilities exhibiting preservation-worthy objects use human patrols for security, lighting must be available during the patrol period to assist in live visual surveillance. This lighting should only be energized when the area is occupied. Occupancy sensing may be best, though switches with timers strictly limited to the time required for the patrol surveillance may be appropriate. Instant-on lighting equipment must be used to provide on-demand lighting.

21.2.7.4 Work Light

During periods of exhibit installation and closing and dismantling, sufficient light should be available to assist in the basic tasks involved. This lighting scheme is also appropriate for cleaning.

21.2.8 Classrooms

Lighting for classrooms is discussed in 24 | LIGHTING FOR EDUCATION.

21.2.9 Conferencing

Lighting for conferencing facilities is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

21.2.10 Food Service

Lighting for food service is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

21.2.11 IT

Lighting for IT facilities is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

21.2.12 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS.

21.2.13 Pedestrian Ways

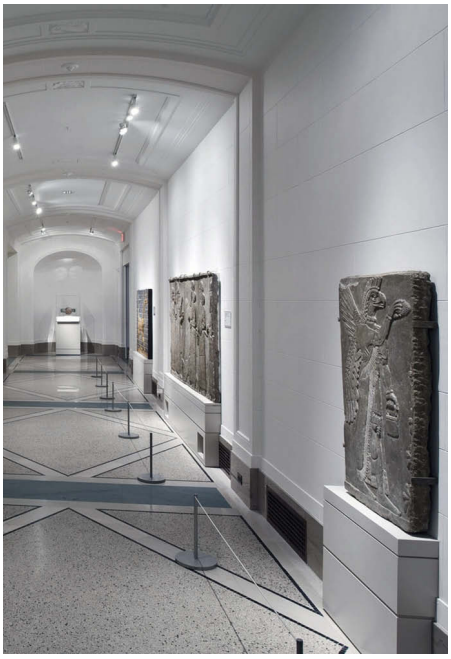
Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS.

21.2.14 Support Spaces

These relatively back-of-house citations are self-explanatory. For dock areas, outdoor nighttime lighting zones determine which illuminance criteria are appropriate. In any event, these are applied immediately at the exterior of the dock overhead door. Lighting equipment should direct all light downward (see Figure 22.4). Lighting the outdoor parking or dock staging area should conform to criteria identified in 26 | LIGHTING FOR EXTERIORS.

Lighting for storage spaces for preservation-worthy objects should be on vacancy sensors with short time-outs to limit light exposure. Lighting layouts and control zoning should accommodate circulation/general lighting and discrete zones of additional lighting should accommodate inspection on an as-needed basis to limit exposure to high illuminance.

21.2.15 Toilets/Locker Rooms



Lighting for toilets and locker rooms is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Addressing the plumbing fixtures (for example, toilets, urinals, vanities) will provide sufficient light where needed without overlighting the entire toilet room.

Figure 21.4 | Daylighting
A passive daylighting system consisting of north oriented skylight elements provides soft, diffuse light on horizontal and vertical surfaces, including displayed objects. [9] Electric lights are used to supplement or supplant daylight as necessary. See also Figure 11.1.

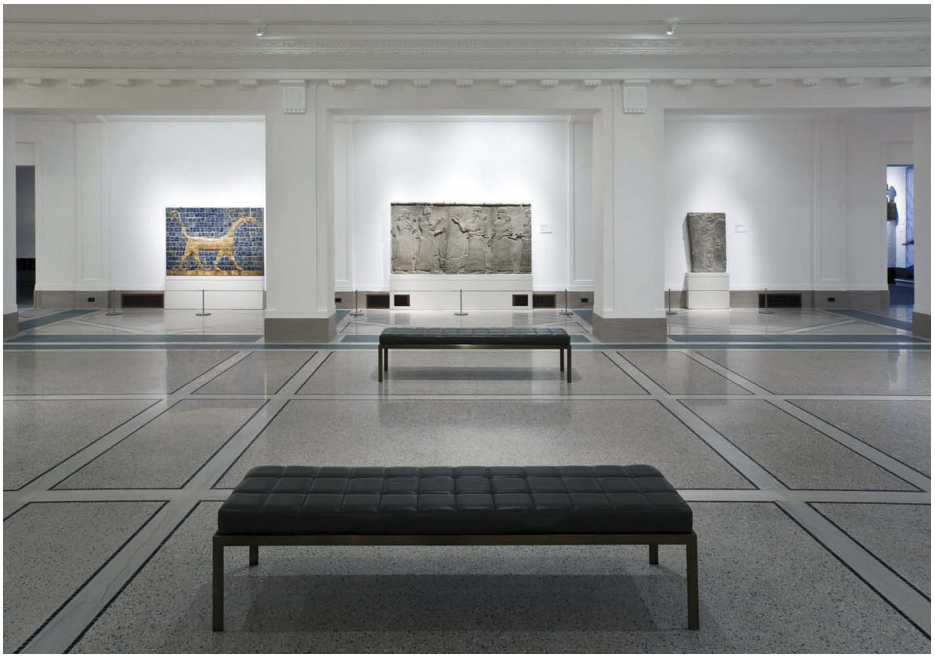

Figure 21.5 | Exhibit Displays
The Ancient Middle East Exhibit at the Detroit Institute of Arts is illuminated with 20 W MR16 halogenIR$_{LV}$ lamps of varying beam spreads to meet criteria for objects of low sensitivity to light. Circulation/general lighting meets criteria appropriate for displays as moderate focal points. Surface mounted tracks are strategically positioned to provide aiming angles between 25° and 40° as shown in the top left image.
» Images ©Detroit Institute of Arts

21.2.16 Transition Spaces

Most of these spaces are self-explanatory. However, attention should be given to the illuminances of spaces adjacent to exhibits and galleries. Harsh transitions to and from the exhibit areas should be avoided. Maintaining a 5-to-1 ratio from one room illuminance to another minimizes the disorientation when traversing from high-illuminance zones to low-illuminance zones. This may necessitate *light locks* if one space, say a daylighted lobby or corridor, is overly bright and located adjacent to a gallery of high-sensitivity-to-light objects. Harshness can also be minimized if low-illuminance spaces use high reflectance ceilings, walls, and floors and if high-illuminance spaces use lower reflectance ceilings, walls, and floors. See Figure 24.2 | Sound and Light Lock.

Light locks as used here is reference to a space separating a bright space from a dark space to avoid disturbing flashes of brightness as people enter/exit the dark space. The light lock is usually large enough to prevent a person from holding open the door to the bright space while simultaneously holding open the door to the dark space. Sometimes light locks are also used as sound locks to minimize sound transmission from louder spaces to quieter spaces are people enter/exit the quieter space. These are called sound and light locks.

21.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 21.2.

21.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 21.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 21.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

the unique applications or tasks. Curators and conservators will have valuable input on lighting requirements. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

21.3.2 Notes

The notes in Table 21.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

21.3.3 Recommended Maintained Illuminance Targets

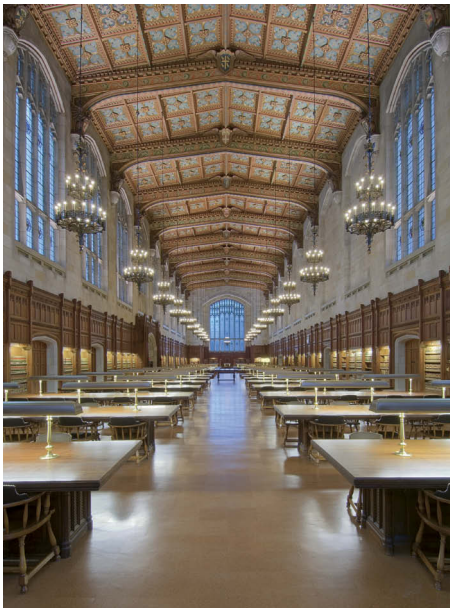
Values cited are maintained on the area of coverage for the task under consideration as needed. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. For objects worthy of preservation for future generations, illuminance targets are maxima. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 21.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for lighting white boards, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

21.3.3.1 Target Planes



Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. Additionally, most tasks are expected to have both a

Figure 21.6 | Exhibit Displays
LEDs offer a means of introducing color contrast for visual attraction where illuminance must be kept low and heat directed away from displays. RGB LEDs also allow for color change over time introducing a unique capability that enhances the theatrical nature of this display and better engages patrons.

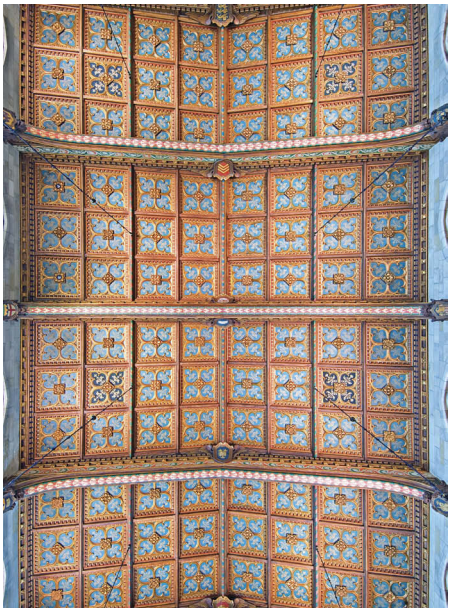

Figure 21.7 | Decorative Painting
Uplighting the decorative ceiling in this 1931 library reading room was introduced during restoration work to better balance room and task contrasts and improve overall brightness perceptions. The ceiling surface is illuminated to criteria appropriate to low-sensitivity-to-light objects. 39 W PAR20 CMH lamps exhibiting 10° beam spread, CCT of 3000 K, and 86 CRI were added at window sills to uplight the cleaned and refinished ceiling. Uplights are step-switched in accordance with daylight availability. Uplights are lensed with UV filters. See also Figure 29.7.
» Images ©Curt Clayton

horizontal illuminance component (E_h) and a vertical illuminance component (E_v). Where these illuminance components are intended at differing planar elevations, such is indicated under "Notes." For example, in art storage rooms, horizontal illuminances apply to what might be table height of 2' 6" AFF and vertical illuminances apply to what might be hanging or stacking systems at 4' AFF. In situations where art objects are stored on planes of different elevations or orientations, then those elevations and orientations must be established and criteria applied to the respective planes of interest.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation. For example, in a gallery with 2-dimensional objects mounted on walls there is only one plane and one orientation per wall. However, 3-dimensional objects mounted on pedestals in the middle of galleries may deserve several vertical planes and orientations. The illuminance criteria apply to these planes.

21.3.3.2 Visual Ages of Observers
Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. It may be reasonable to assume that in a gallery some majority of the patrons at some of the time may be over 65 years of age. However, since there are no time or accuracy constraints associated with viewing artworks, it may be determined acceptable that design targets should be set for a majority of patrons between the ages of 25 and 65 years old.

21.3.3.3 Illuminance Categories
Illuminance categories are designated by letters A through Y. These are shown in Table 21.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

21.3.3.4 Gauge
The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

21.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances, all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h).

21.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

21.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

21.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

21.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. A shaded sunburst icon indicates applications and tasks are sensitive to daylight and appropriate measures, including blackout capabilities, must be taken to limit daylight exposure, if daylight is deemed a suitable source of light. Where users are willing to cede to automation, photocells and stepped-dimming or continuous dimming can be used to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

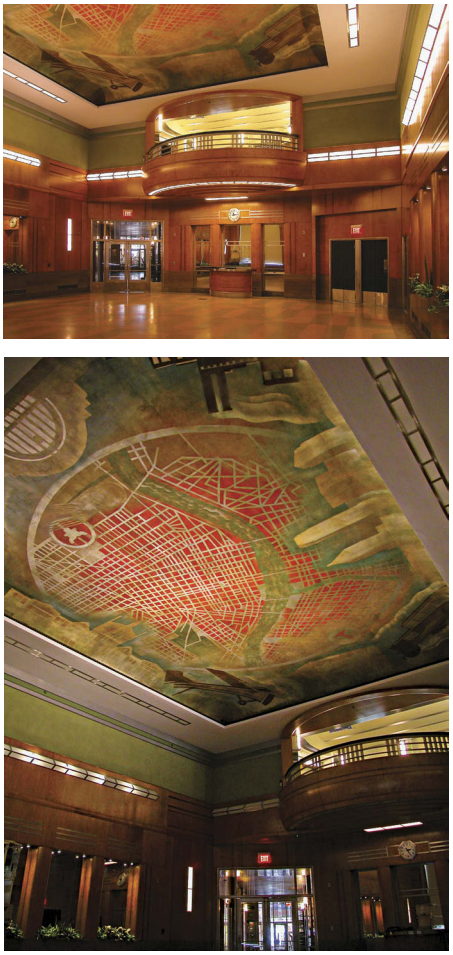

Figure 21.8 | Murals
Uplighting the mural, a stylized layout of the City of Cincinnati completed in 1933, in this dining room in the historic Cincinnati Union Terminal highlights this restored feature for banquet, party, and meeting guests. The top image illustrates a MEETING scene while the bottom image illustrates a COCKTAIL scene. The ceiling surface is illuminated to criteria appropriate to low-sensitivity-to-light objects in each scene. Uplight lamps are 20 W MR16 ceramic metal halide spots exhibiting CCT of 3000 K and CRI of 81 and are on switching channels separate from the dimmable lighting in the room. Uplights are lensed with UV filters. Cincinnati Union Terminal is now home to Cincinnati Museum Center.

IESH/10e CSA/ISO

> 12.5 Task Factors
- for information on CSA/ISO computer screen qualities

21.3.6 Veiling Reflections

Tasks with specular components, such as artifacts under horizontal glass or artworks under vertical glass are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are particularly annoying in art viewing situations. Where objects are displayed behind glass or acrylic, careful study of the orientation of the display glass or acrylic and lighting positions is necessary to avoid or minimize the effects of veiling reflections. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated so that distant bright sources not associated with lighting the particular task or object are essentially masked. Other effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. In display cases, internal lighting can greatly limit, if not eliminate, veiling reflections, though the issue of proximity of light source to artifact and any associated heat issues must be considered. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

21.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Applications and Tasks and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 21.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or homeowner. The area-of-coverage citations in Table 21.2 are based on traditional notions.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

21.4 Designing

Information provided here is specific to art facilities or wherever preservation-worthy objects are displayed and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing

all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

22 | LIGHTING FOR COMMON APPLICATIONS

New opinions are always suspected, and usually opposed, without any other reason but because they are not already common.

John Locke, 17th Century, Philosopher and Physician

Contents

22.1 Project Type and Status. . . 22.1
22.2 Application Types 22.2
22.3 Illuminance Criteria 22.35
22.4 Designing. 22.39
22.5 References 22.40

There need not be anything commonplace about lighting for applications that are common to many building projects. Some of these applications, such as lobbies, make first impressions. Others, like conferencing and food service can be the amenities that set one employer apart from others. Lighting for these applications is important and can infuse a facility with uncommon character. Daylighting is quite effective in addressing illuminances in many of these applications.

Comprehensive design efforts involve the information in this chapter combined with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance criteria for common applications which should influence luminaire optical selections, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous IES related documents serve as archival reference sources [1].

Deliberate thought must be given to details beyond the recommended illuminances in this chapter. For example, in FOOD SERVICE/Bar/Back Bar, the vertical illuminance citation does not necessarily demand a uniform array of low-wattage wallwashers. Such lighting can be achieved with uplight or downlight in each shelf, a perimeter slot-like detail along the back bar elevation, adjustable accents, the smallest of daylight-slots in the top of the back bar (for at least the daytime condition) or some combination of these. Each of these can achieve the target illuminance, but each has a distinctly different appearance and requires different architectural detailing. Such specific details are not enumerated for all tasks. Table 22.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

22.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. This will establish the extent to which daylighting can address most or many or some of the lighting goals. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. For some applications and tasks, daylighting can be the primary light source. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

22.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the common applications space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 22.2 | Common Applications Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 22.2.

The following discussion is keyed to major application headings in Table 22.2. Couple this with topics in Table 22.1 for comprehensive qualitative and quantitative criteria.

22.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction and wayfinding. Default accent lighting techniques and criteria are identified in Table 22.2. Also see 15.1.1.3 Accent Lighting.

22.2.2 Administration

Administrative functions on many projects typically include circulation, conferencing, counseling, lounges, filing or records, interviewing, lobbies, mail sorting, and officing. Each of these in turn may involve a number of specifics including some form or degree of acknowledgment, conversation, reading, periods of respite or relaxation, and writing—all tasks within applications. Acknowledgement of other people and conversation, for example, require some vertical illuminance at face height (seating or standing depending on the nature of the application). Vertical illuminance criteria are cited for such applications.

The architectural scheme and even task specifics will vary based on the associated facility function and type. These variations should affect the lighting design—from kinds of lighting effects to lighting equipment styling to luminances and illuminances.

The administrative areas may be dispersed throughout a facility or complex or may be centralized into a single area, wing, or building. Depending on client wishes and architectural desires, this centralization or decentralization may affect the degree to which the lighting design in administrative areas is sympathetic to or different from that of other applications.

See also 32 | LIGHTING FOR OFFICES.

22.2.3 Atria and Courtyards

Atria and courtyards are many times synonymous with daylighting. Where these spaces are used for circulation and where adjacent spaces are appropriately shielded from direct solar penetration, daytime lighting can be achieved without electric lighting. During dark hours, electric lighting must respond to function. Circulation can be achieved with relatively low-to-the-floor electric lighting techniques or with spill lighting from adjacent spaces.

Challenges include maintaining a sense of nighttime volume and limiting outdoor light pollution. Where live plants are used, daylighting and electric lighting must provide sufficient illuminance of an appropriate spectrum and for an appropriate duration to maintain the plants or provide plant growth. See 22.2.10 Plants for more information.

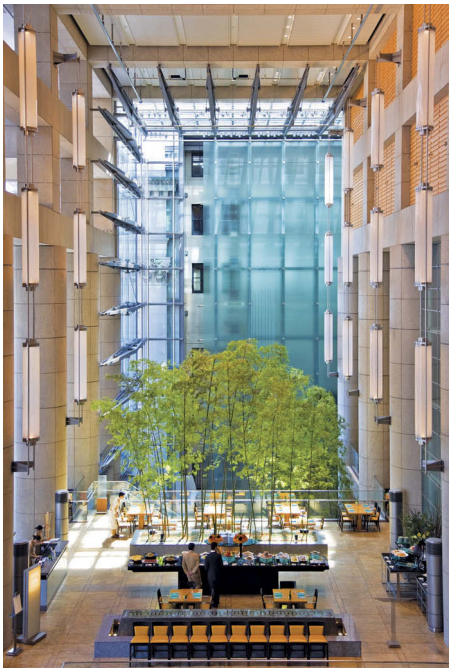

Figure 22.1 | Atria
Daylight and decorative lighting are arguably hallmarks of both atria. The lighting in the atrium on the far left is of a scale and cadence designed to complement the scale of the atrium—defining it as a room. Each luminaire provides a soft light. These are energized during the day to welcome guests and enhance place and character. Live plants require attention to the duration and quantity of illuminance at canopies. See 22.2.10 Plants.

Lighting in the atrium on the near left is contained within balcony setbacks and at the main floor. This solution reflects the history of the structure and how early electric lighting was introduced into buildings.

» Far Left Image ©B.S.P.I./Corbis
» Near Left Image ©Richard T. Nowitz/Corbis

Usually the architecture, the nature of the functions, and the illuminances involved help minimize outdoor environmental lighting effects from atria and courtyards. Where overhead glazing is used, aiming lights toward the glazing should be avoided unless these are controlled-beam luminaires lighting artwork or features suspended in the space. In-floor or on-wall uplights to highlight foliage or architecture should exhibit controlled-beam optics fitted with louvers, snoots or barn doors to trim light spill. This also minimizes glare to occupants of the space. Nighttime curfews should be established whereby this interior lighting is dimmed or stepped-back to only those levels necessary for low-activity circulation. Unless the architectural finishes are, say, <20% over a significant portion of the space, even a small amount of light will create some surface luminance and a sense of volume during dark hours. This is most successful, however, if occupants enter the space from adjacent spaces exhibiting transitional brightnesses. Figure 22.1 illustrates two very different hotel atria.

Atria and courtyards typically involve a significant amount of skylight or roof, or some combination. With the advent of building integrated photovoltaics (BIPVs), overlighting, glare, and cooling loads associated with daylighting can also be addressed by BIPVs. BIPVs can integrate with glazing in much the same way that frit covers glazing—allowing for some visible transmittance while blocking a significant amount of visible and solar radiation. Figure 22.2 illustrates a study series for a small atrium space identifying BIPV-glazed surfaces (graphically shown in white and oriented south) and clear-vision-glazed surfaces (shown in "clear" and oriented north).

22.2.4 Building Entries

For building entries several conditions influence lighting:

- Degree to which entries are covered from the elements
- Proximity of vehicular traffic to pedestrian traffic
- Anticipated nighttime activity levels
- Nighttime outdoor lighting zone for the project under consideration
- Security

Table 22.2 outlines an extensive list of entry types and situations. Although exterior situations predominate, the interior lighting of vestibules must relate to the exterior lighting condition for comfortable transition between the interior and exterior and vice versa.

Notes for Table 22.2

The table column headings are discussed in detail in 22.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 22.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 22.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 22.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

n. Make electrical provisions for portable work lights.

Notes for Table 22.2

The table column headings are discussed in detail in 22.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 22.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 22.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 22.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

n. Make electrical provisions for portable work lights.

Notes for Table 22.2

The table column headings are discussed in detail in 22.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 22.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 22.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 22.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

n. Make electrical provisions for portable work lights.

Notes for Table 22.2

The table column headings are discussed in detail in 22.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 22.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 22.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 22.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

n. Make electrical provisions for portable work lights.

Notes for Table 22.2

The table column headings are discussed in detail in 22.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 22.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 22.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 22.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◥ signals high likelihood; gray and white ◥ signals moderate likelihood; pale gray and white ◥ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

n. Make electrical provisions for portable work lights.

Notes for Table 22.2

The table column headings are discussed in detail in 22.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 22.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 22.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 22.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◥ signals high likelihood; gray and white ◥ signals moderate likelihood; pale gray and white ◥ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

n. Make electrical provisions for portable work lights.

Notes for Table 22.2

The table column headings are discussed in detail in 22.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 22.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 22.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 22.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

n. Make electrical provisions for portable work lights.

Notes for Table 22.2

The table column headings are discussed in detail in 22.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 22.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 22.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 22.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

n. Make electrical provisions for portable work lights.

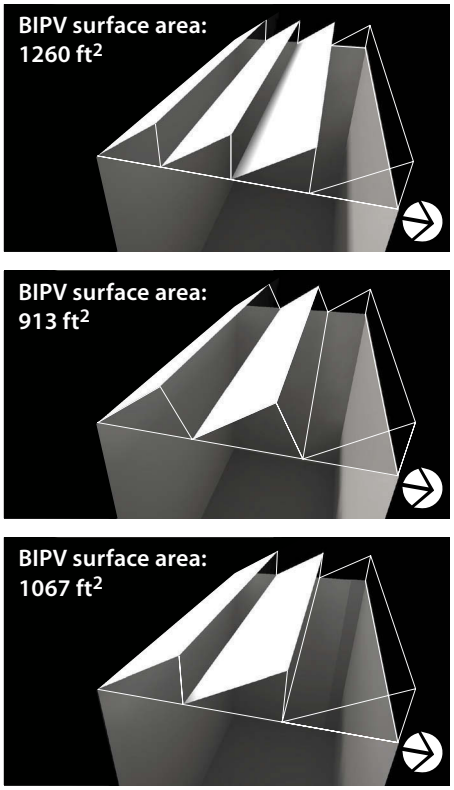

Figure 22.2 | Atria, Daylight, and BIPVs
Generally, transmittance of glazing on tops of large-area atria and courtyards must be low to limit visual discomfort and cooling loads. Advances in Building Integrated Photovoltaics (BIPVs) offer a means to limit transmission of those glazed planes while generating some electricity. Here, a series of studies was made to assess area of coverage available for south-facing BIPVs (shown in white) versus daylight availability. North is as indicated. Sensitivity of the BIPVs and the effective surface area must also be considered.

Vision glass without BIPVs on the vertical or near vertical media admit north light. Vision glass without BIPVs on the north-most skylight segment allows a stronger wallwash effect from daylight on the north wall of the atrium.

If plants are programmed for the atrium or courtyard, the studies would either reveal the daylight availability to which plant selection should be matched or would yield glazing designs to meet the selected plants' needs.

» Images ©GSLD

Entries with no canopies should be lighted to announce the entry threshold proper. Some portion of the path, typically to the curb, is lighted to a lesser degree for sake of efficiency and minimizing deleterious effects on the night environment while still meeting vision requirements for movement, but not to the levels found under canopies of porte cocheres. If the path is longer than perhaps 50 feet, the full length of the path need not be lighted to the path-to-curb criteria cited. A 10-foot section of the path closest to the entry and a 10-foot section closest to the curb should be lighted to meet the cited criteria. For control of lighting in LZ0, motion-sensor control is appropriate. This limits lamp selection to instant-full-on varieties. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and the requirements and design of which must be coordinated amongst the design team.

Canopied entries are an extension of the building, much like a porch (see Figure 22.3). For such areas under cover where there is expectation for some passing conversation and acknowledgement and for a larger crowd of people, somewhat higher illuminances are appropriate than those for open entry paths. Porte cocheres by their nature involve a mix of vehicular and pedestrian traffic. In these situations, still higher illuminances are appropriate.

Outdoor nighttime activity levels vary by type of facility, such as office, school, and hotel, and by specific schedules. For example, office activity may be quite low after 6 p.m. Schools may have high activity, but only for short durations as extra-curricular activities, sports, social, or other events end. Hotels might experience a constant din of activity, with bursts during dinner, after shows, or at particular events. All of this may demand a control system capable of addressing various settings on various evenings through manual intervention, automated time clock, and photocell functions. Table 22.4 distinguishes the various indoor and nighttime outdoor activity levels. The designer must coordinate with the team and client to establish the activity level or levels appropriate to a given project. Where activity levels are anticipated to be quite different or changeable throughout hours of operation, it may be most appropriate to design for a number of activity levels rather than design to highest anticipated activity levels at all times. A number of activity levels can then be accommodated with controls and use of time clock or occupancy sensor inputs.

The nighttime outdoor lighting zone within which the facility is located or to which the team and client elect to design affects the illuminance criteria for outdoor tasks. Nighttime outdoor lighting zone designations vary by local ordinance, sustainability guides, or the team's own definition of place. These are discussed in 26 | LIGHTING FOR EXTERIORS. Also see Table 15.6 | Nighttime Operational Strategies for Improved Outdoor Environmental Regard.

After-hours security requirements, such as on-site or remote monitoring, and lighting at vulnerable areas or 24-hour exits may require that some lights at building entries be available when approached (for example, via occupancy sensors) or remain energized through the night (see Figure 22.4). Control zones and time clock functions must be designed accordingly. Where remote monitoring is done with infrared cameras, lighting may be unnecessary for the cameras, though some light may be of comfort to pedestrians and may be a deterrent to criminals.

Outdoor lighting, regardless of the illuminance, will not necessarily reduce or eliminate crime [2]. Where lighting that addresses normal criteria is introduced as a means to advance public nighttime activity, it might function as a potential deterrent to criminal activity and provide pedestrians with a sense of security (and a sense of safety). Lamps with CRIs ≥80 help people better identify and distinguish colors. It is also important that the lighting is tuned to the nighttime outdoor lighting zone to avoid adaptation issues. Addressing CRI, nighttime outdoor lighting zones, and normal criteria enable users to see and identify surroundings and potential perpetrators. It is this identification that serves to indirectly deter criminal activity. Perpetrators will learn that their risk of exposure and identification is

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

greater in such well-designed areas. Adding high-wattage, wide-area floodlights and tripling or quadrupling illuminances is generally counter-productive. Where additional lighting at entries or public pedestrian areas is deemed necessary for purposes of security surveillance, this should be relatively low-wattage equipment directing light down and across the limited area of coverage and contributing an average of 10 lx, 25 lx, and 50 lx on the ground plane respectively in rural, suburban, and urban areas [3]. See Figure 22.4.

Building entries also include an interior component. Named here as vestibules, these spaces are immediately inside the entry threshold. These spaces provide immediate shelter, a place to collect oneself, and generally transition from outside to inside and vice versa. Illuminance criteria vary from day to night to assist with luminance adaptation, particularly as it relates to daytime exterior-to-interior. These spaces may also be lobbies and should be designed according to criteria outlined for TRANSITION SPACES/Lobbies in Table 22.2.

22.2.5 Conferencing

Conferencing runs the gamut from very simple single-purpose functionality (for example, meet to discuss) to rather complex multipurpose tasks (for example, meet to discuss, present, strategize, and learn, or video conference with others). The lighting is influenced accordingly and also by the formality of the setting. Where presentations are common, such as a board room or a meeting room, and where the participants might number two dozen, the lighting should help define the formality and procedural aspects of the meeting. Accenting on presenter positions is appropriate. Some conference settings strike a balance. In these situations, presentations are common, but intended as a group-think-discuss learning situation. Here, although presentation surfaces are still accented, presenters might not be illuminated. In larger spaces, lighting presets are used to respond to room setups and functions. Figure 22.5 illustrates a common conferencing setup. See also Figures 15.5d, 15.16, 32.3, 32.4, and 32.5.

Video conferencing criteria are directly related to camera technology and user expectations. Vertical illuminances and uniformity criteria at faces and background wall surfaces are most important. Coordinate illuminance criteria with latest camera requirements. Telepresence is a variation on video conferencing. Portable all-in-one camera and monitor setups, from single to multiple monitors, offer video conferencing in non-dedicated settings. Preset controls should be used for convenient and consistent toggling between typical conferencing functions and video conferencing.

22.2.6 Food Service

Lighting for food service addresses the dining situation. Fast-food and grab-and-go-food are generally lighted to usher along the decision and experience. Casual dining and fine dining are more about the food, the service, and the setting making the experience at least pleasurable if not memorable. Accent lighting is appropriate in many dining situations and criteria guidelines are offered in Table 22.2. Figures 12.12, 28.7, 28.8, and 32.6 illustrate several dining and bar situations.

Sometimes plan designations are not entirely descriptive. For example, if the lunch room or canteen (a more recent convention on architectural plans denoting a cafeteria) is intended to be a large space servicing employees and clientele (visitors), then citations under FOOD SERVICE should be studied.

Food service lighting can be categorized as food preparation and handling, food consumption, and cleanup. Commercial and institutional food preparation must meet US FDA Food Code requirements for minimum illuminance which have basis in IES guidelines [4]. These illuminance criteria address the safety of those handling and preparing the food and the safety of the food for consumption, which involves inspection, and cleanliness of food stuffs and facilities. Apparently due to metrication, code requirements are within 10% of IES recommendations. Regardless, a lighting design must meet code.

Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions

Activity Level	Definition	Application Examples
Indoor	**Indoor activity levels during daytime or nighttime hours**	
• **High**	Areas with relatively high volumes of activity. Activity level is relative to a facility's population, intended density, and proximity to other applications. Typified by consistently high volumes of people or extreme swings of very high volumes over short time periods. Indoor facilities typical of large population centers.	• Stairs during class changes at educational facilities • Indoor pools at family hotels, water parks, and community recreation centers • Urban mall, major-league sports' venue, and large transportation entry vestibules
• **Medium**	Areas with relatively moderate volumes of activity. Activity level is relative to a facility's population, intended density, and proximity to other applications. Typified by some amount of constant activity by people over extended periods or swells of activity from time to time. Indoor facilities typical of small-to-moderate population centers.	• Indoor pools at business hotels and fitness centers • Civic building, shopping center, and minor-league sports' venue entry vestibules
• **Low**	Areas with relatively low-to-very-low volumes of activity. Activity level is relative to a facility's population, intended density, and proximity to other applications. Typified by little activity by people over extended periods or clusters of activity from time to time. Indoor facilities typical of suburban and rural population centers..	• Indoor pools at resorts or spas • Civic building entry vestibules
Outdoor	**Outdoor activity levels during nighttime hours**	
• **High**	Areas with relatively high volumes of pedestrians and vehicles or solely people during dark hours. Activity level is relative to a locale's population, density of related applications, and general expected norms across the community. Typified by consistently high volumes or extreme swings of very high volumes over short time periods. Outdoor facilities typical of large population centers.	• Entertainment districts • Outdoor pools at family hotels and community recreation centers • Shopping districts and sports' venues • Transportation hubs • University campuses
• **Medium**	Areas with relatively moderate volumes of pedestrians and vehicles or solely people during dark hours. Activity level is relative to a locale's population, density of related applications, and general expected norms across the community. Typified by some amount of constant activity over extended periods. Outdoor facilities typical of small-to-moderate population centers.	• Civic and cultural districts • College campuses • Libraries • Office complexes • Outdoor pools at business hotels and community recreation centers • Recreation centers • Residential complexes • Small shopping areas or centers • Transit lines • Urban central and waterfront parks
• **Low**	Areas with relatively low-to-very-low volumes of pedestrians and vehicles or solely people during dark hours. Activity level is relative to a locale's population, density of related applications, and general expected norms across the community. Typified by little activity over extended periods. Outdoor facilities typical of suburban and rural population centers.	• Outdoor pools at resorts and spas • Residential neighborhoods • Small apartments • Small college campuses • Small commercial establishments

To avoid food contamination from violent lamp failure, lamps used over food preparation areas should be suitably protected or used in enclosed luminaires. New technologies, including LEDs and OLEDs, have not been vetted for violent failure. Consult with AHJ and lamp and luminaire manufacturers for suitability and application.

22.2.7 IT

Lighting for information technology (IT) facilities generally addresses administrative areas, machine or equipment areas, and media storage areas. Administrative functions may include significant if not dedicated and intensive computer use. Criteria and solutions should be established accordingly. In storage areas and in equipment rooms, general diffuse light may be appropriate given the nature of storage and equipment configurations. However, this should be reviewed carefully in programming as storage setups may involve library-like shelving tightly spaced and equipment may involve tall and continuous racks also tightly spaced, where a directed wash of light is most effective (see Figure 22.6). Dual-level lighting may also be appropriate in these areas to allow for periodic review of backlit readouts or, alternatively, maintenance work.

22.2.8 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS.

22.2.9 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS.

22.2.10 Plants

Where live plants are programmed illuminance criteria are based on the types of plants, their sizes, and the goal of maintaining or sustaining the plants. Criteria are based on a 14-hour exposure cycle in each 24-hour period. Exposure to most any white light source will suffice. Daylighting is best for efficiency and spectral quality.

Consultation with a horticulturist or landscape architect is recommended in order to establish illuminance criteria and spectral requirements for plant growth.

22.2.11 Reading and Writing

Reading and writing tasks occur within various applications. Familiarity with these tasks will aid with assessment of specific application tasks and activities. This may result in the recommendation of illuminance criteria different than that proposed in Table 22.2 for a particular application. For example, if reception lobbies at various floors in a commercial building are more than security monitoring stations and involve extended periods of reading and writing of paperwork, then illuminance criteria should be determined from the READING AND WRITING applications and tasks and not the TRANSITION SPACES/Lobbies/Reception Lobbies/Desk Top application/task.

22.2.12 Support Spaces

Typical support spaces are cited in Table 22.2. Some applications may have unique support spaces or illuminance criteria peculiar to that application—these are outlined in the respective application chapters.

Familiar back-of-house support spaces are janitor's closets and storage rooms. Lighting need be basic and functional. However, consideration should be given to the need for lamp protection to avoid the obvious. Besides lensing, wire guards or lamp sleeves or lamps with integral sealed containment envelopes are methods to protect the lamp.

Break or lunch rooms and copy print rooms may need design attention. Break and lunch rooms are essentially employee amenities. How lighting is applied, not its cost, can significantly enhance a break experience. See Figure 15.12.

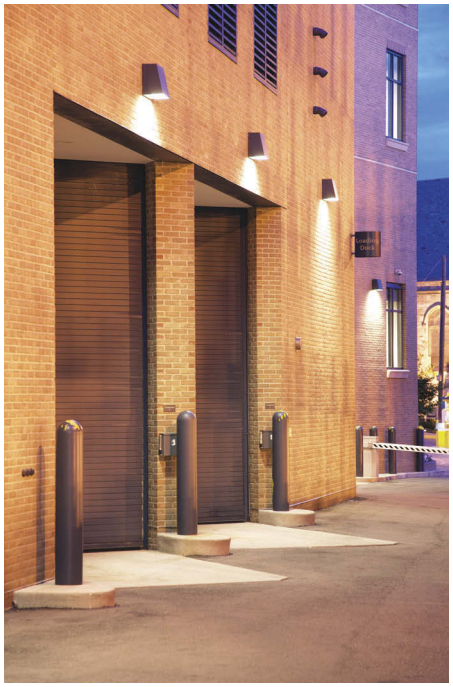

Figure 22.4 | Security Lighting
Service docks and an access alley are lighted with 26 W CFL cutoff wallmounts. Such an approach is visually comfortable, unobtrusive to neighboring properties, and relatively uniform in application of horizontal and vertical illuminance in the vicinity of use.

Figure 22.5 | Conferencing
Conferencing might involve laptop presentations (displayed onto larger screens), white board, tack board presentation surfaces, and paper reading and writing tasks. To accommodate the varying tasks and focuses, lighting might include task, ambient, and accent lighting systems. Direct/indirect linear pendant luminaires were found most efficient for the task/ambient lighting. The indirect component provides a general or background ambient light to the entire room. The direct component provides additional light at the table to accommodate the reading and writing tasks. The direct/indirect lighting also provides vertical illuminance sufficiently soft to light faces and yet sufficiently direct to avoid hazy washout. The linear pendant luminaires are dimmable to allow for focus on the presentation surfaces which themselves are illuminated with recessed adjustable accent luminaires.

Preset scenes in this situation are arranged around activities such as WELCOME, COLLABORATION, DISPLAY, and PASSIVE. The WELCOME scene has luminaire outputs adjusted to a mid-level of available light to accommodate pre-meeting discussions. The COLLABORATION scene has outputs adjusted to full-level to accommodate collaboration with analog and digital tasks. The DISPLAY scene has outputs adjusted to dim-level to accommodate video display or projection information sharing. The PASSIVE scene acts as a placeholder before or between meetings where LED amber nightlights are energized.

An automated time clock is programmed to sweep lights off after hours.

» Image ©Workspring

22.2.13 Toilets/Locker Rooms

Restrooms are best addressed by highlighting specific task areas. This offers efficiency while meeting the different illuminance criteria involved. Highlighting toilets, urinals, and vanities offers a more clean, crisp appearance than the haze of general diffuse lighting. Vanity positions require vertical illuminance on an imaginary facial plane (roughly a zone of sufficient size to encompass faces at standing or seated height) in front of the mirror. Figure 22.7 identifies several methods of vanity lighting. Color of light is important for grooming. Lamps exhibiting 2700 K to 3500 K CCT and CRI ≥82, using triphosphor CFLs as benchmark, are appropriate.

22.2.14 Transition Spaces

Typical transition spaces are cited in Table 22.2. Each application may have unique transition spaces or criteria for transition spaces peculiar to that application—these are outlined in the respective application chapters.

How front-of-house transition spaces in many applications are designed and lighted defines the place and welcomes employees and guests. These spaces are transitions from exterior to interior and vice versa or from one kind of interior space to another. Illuminance criteria and accents are an important aspect of making comfortable and safe transitions.

Many of the public spaces may be of a particular sequence of passage, ceremonial in nature, or of special importance. To appropriately serve these roles, subjective impressions outlined in Table 12.2 should guide the application of lighting effects. Illuminances associated with artwork and features that assist with these subjective impressions are outlined in Table 22.2. Throughout the various application chapters examples are presented of some transition spaces.

Adjacency passageways refer to a condition where circulation areas are encompassed by larger work or task areas. Given their adjacency to the open and visually accessible work or task areas, their illuminances, confined to the passageway proper, should be ratios of the nearby task illuminances. This avoids annoying contrasts within the work setting that may result in visual fatigue or discomfort.

For purposes of visual consistency and of maintenance convenience, lamp types and color qualities should match those used elsewhere.

22.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 22.2.

22.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 22.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 22.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

22.3.2 Notes

The notes in Table 22.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

22.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

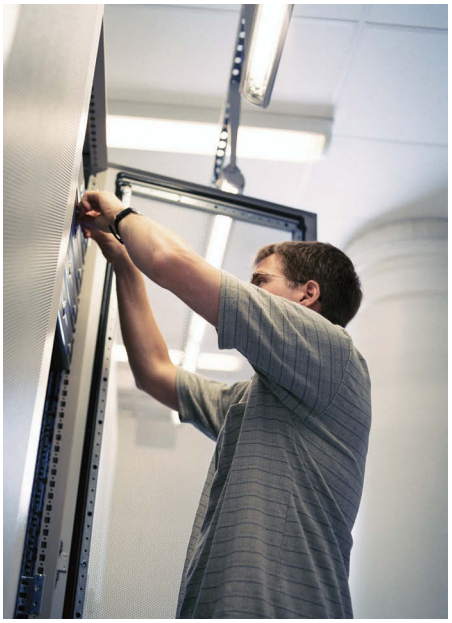

Figure 22.6 | Server Room
General diffuse luminaires running perpendicular to the server racks provide some ambient light. Linear fluorescent wallwashers or sign lights running the length of the server racks provide task lighting.

Figure 22.7 | Vanities
Front lighting on faces is critical at vanities. Meeting illuminance criteria requires some amount of frontal lighting from the mirror toward the face, but rather softly to avoid glare conditions. In the top image, wall sconces between mirrors are lamped with 13 W CFLs. An overhead wall slot provides overall room ambient and also contributes to the face-plane illuminance. A wall slot on the opposite wall illuminates the toilet and urinal areas and provides some backlighting.

In the middle image, spherical pendants lamped with 13 W CFLs at the mirror provide an ambient glow and sufficient light on the face. Wallwashers opposite the mirror provide some backlighting for primping and are strategically placed to highlight art.

Mirror-integrated lighting in the bottom image is achieved with linear T5 lamps (which can be dimmable) behind etched glass and procured as a complete unit.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 22.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for lighting white boards, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on at least one plane of a task. A 0 indicates no light or zero light is recommended for the task or application.

22.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane. For example, if mail sorting primarily involves vertically-stacked mail slots or boxes and sorted in a standing position, then the illuminance target cited in Table 22.2 (ADMINISTRATION/Mail Sorting), which is for a dominant horizontal orientation, must be applied to the vertical plane of the mail boxes.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." For example, for most corridors (TRANSITION SPACES/Circulation Corridors), horizontal illuminances apply to the floor plane while vertical illuminances apply to standing-face-plane height of 5' AFF oriented in the two main directions of travel. In applications where the majority of users are children or wheelchair-bound adults, the designer may elect to set the elevation for vertical illuminance at 3' AFF. Note the implication for observers' visual ages. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation. For example, in a commercial kitchen, E_v at preparation surfaces (FOOD SERVICE/Kitchens/Food Preparation), the number and orientation of vertical planar points assessed depends on the preparation surface. On a counter against a full-height wall, the vertical planes of most interest are the one facing the preparer and the two planes perpendicular to the preparer

(one oriented toward the right and one toward the left). The criteria apply to these three planes. On an island or peninsula which may be used from more than one side, there are four planes of interest.

22.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. It may be determined that illuminance criteria for an age group other than that representing the majority of the intended observers is appropriate. However, this may result in overlighting, underlighting, harsh lighting, visual displeasure, or visual discomfort for many of the observers. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance. In some situations, such as video conferencing, lighting must meet the requirements of the camera technology and, therefore, is not tied to ages of observers.

22.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 22.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

22.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, “Avg” is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is “Min” or “Max” respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

22.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

22.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

22.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

22.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

22.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

IESH/10e CSA/ISO

> 12.5 Task Factors
- for information on CSA/ISO computer screen qualities

22.3.6 Veiling Reflections

Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

22.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Tasks and Applications and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 22.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 22.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

22.4 Designing

Information provided here is specific to common applications and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. Equipment selection and location strategies may need to address the possibility of lighting equipment abuse in some situations. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

23 | LIGHTING FOR COURTS AND CORRECTIONAL FACILITIES

The place of justice is a hallowed place.
Francis Bacon, 16th and 17th Century English Jurist, Lawyer, Statesman, Scientist, and Philosopher

Contents

23.1 Project Type and Status. . . 23.1
23.2 Application Types 23.2
23.3 Illuminance Criteria 23.26
23.4 Designing. 23.30
23.5 References 23.31

The buildings in which justice is rendered and served require lighting that supports tasks in what are sometimes matters of the gravest consequences. Viewing evidence, considering fellow deliberators, maintaining security, guarding the incarcerated are all important functions supported by lighting. But the rule of law, and the dignity of the buildings in which justice functions, is also a matter of perception, and lighting can infuse a facility with the character required of such important spaces.

Comprehensive design efforts involve the information in this chapter combined with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance criteria for courts and correctional facilities which should influence luminaire optical selections, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous IES related documents serve as archival reference sources [1].

Deliberate thought must be given to details beyond the recommended illuminances in this chapter. For example, with CORRECTIONAL FACILITIES/Circulation Corridors, the illuminance citations do not necessarily satisfy the amount and distribution requirements for security cameras. The designer must know the requirements of the security equipment being used. Such specific details are not enumerated for tasks. Table 23.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

23.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. This will establish the extent to which daylighting can address most or many or some of the lighting goals. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. For some applications and tasks, daylighting can be the primary light source. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

23.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the courts and correctional facilities space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 23.2 | Courts and Correctional Facilities Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 23.2.

In many situations in courts and correctional facilities, security is an inherent part of the task: securing detainees and prisoners to prevent their escape or destructive actions to property, self, or others; securing key personnel of courts and correctional facilities from harm. Lighting plays a role, but only as part of a much broader security program to be effective. Lighting hardware itself must be considered a target of destructive behavior in some of these situations. The designer must review the programming information and consult with the team and owner to establish the full extent of security issues affecting lighting.

The following discussion is keyed to major application headings in Table 23.2. Couple this with topics in Table 23.1 for comprehensive qualitative and quantitative criteria.

23.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction, inspection, and wayfinding. Accenting enhances architectural spatial forms and limits and impressions of spatial volume. See Tables 12.1a, 12.1b, and 12.2. Accenting can make spaces appear less institutional. Several perimeter accenting techniques are illustrated in Figure 23.1.

23.2.2 Administration

Lighting for administrative areas is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The architectural scheme and even task specifics will vary based on the courts and correctional facilities involved. In some projects these details should affect the lighting design, from the kinds of lighting effects to lighting equipment styling to luminances and illuminances. In other projects, notably more secure prisons, the straightforward requirements of security and abuse will override some lighting effects and equipment styling aspects.

The administrative areas are typically consolidated into a single area, wing, or building of courts and correctional facilities. Several aspects may affect the degree to which the lighting design in the administrative area is sympathetic to or different from that of the other applications and tasks at the facility in question:

- Owner wishes and architectural desires
- Visual connection between administrative areas and other areas of the facility
- Management style

Figure 23.1 | Courtroom Lighting
Top left is view from judge's bench. Bottom left view is from audience seating area. Right view is a detail of the feature stone wall behind the judge's bench. Perimeter accenting contributes to pleasantness and spaciousness in this courtroom. The diffuse reflected light of the wall accenting and the cove contributes greatly to vertical illuminances which assist in facial modeling. Downlighting contributes here to visual clarity and horizontal illuminances for reading and writing tasks.

Ambient lighting consists of the cove lighting ❶ which uses an asymmetric reflector housed in a drywall detail. The asymmetric reflector is lamped with T5 standard output linear fluorescent lamps exhibiting 3000 K CCT and 85 CRI. Task lighting consists of the downlights ❷ which are open reflector and lamped with 32 W triple-tube CFLs exhibiting 3000 K CCT and 82 CRI. Accenting consists of one approach, perimeter lighting. This is achieved with two techniques. Spread lens wallwashers ❸ lamped with 32 W triple-tube CFLs are used along two side walls. A linear wallslot detail ❹ grazes the stone feature wall behind the bench also shown in the detail image to the right. The wallslot is a drywall detail consisting of monopoints on 15″ centers. The monopoints are lamped with 20 W T4.5/GU6.5 CMH lamps exhibiting 3000 K CCT and 80 CRI.

Downlights are dimmable and grouped in three zones: a zone at the bench; a zone in the middle of the room to address the well; and a zone at the public seating area. Cove lighting is dimmable and is on an independent zone. Perimeter wall washing is dimmable and on three zones: one for each side and one at the main entrance wall. The front wallslot is nondim on a single zone. This level of control permits presets that might include these scenes: ADMIN, SESSION, AV, SPECIAL, and OFF.

Notes for Table 23.2

The table column headings are discussed in detail in 23.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 23.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 23.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 23.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches. A shaded icon indicates applications and tasks are sensitive to daylight and appropriate measures, including blackout capabilities, must be taken to limit daylight exposure, if daylight is deemed a suitable source of light.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Control architectural lighting with dimmers to accommodate varied needs.

j. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

k. Use lamps with CCTs of 5000 K and CRIs ≥85.

l. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

m. Use lamps with CRIs ≥85.

n. Equip physical analyses laboratories with adjustable portable luminaires for analysis efforts.

o. Make electrical provisions for portable work lights.

p. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 23.2

The table column headings are discussed in detail in 23.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 23.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 23.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 23.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches. A shaded icon indicates applications and tasks are sensitive to daylight and appropriate measures, including blackout capabilities, must be taken to limit daylight exposure, if daylight is deemed a suitable source of light.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Control architectural lighting with dimmers to accommodate varied needs.

j. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

k. Use lamps with CCTs of 5000 K and CRIs ≥85.

l. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

m. Use lamps with CRIs ≥85.

n. Equip physical analyses laboratories with adjustable portable luminaires for analysis efforts.

o. Make electrical provisions for portable work lights.

p. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 23.2

The table column headings are discussed in detail in 23.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 23.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 23.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 23.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches. A shaded icon ▨ indicates applications and tasks are sensitive to daylight and appropriate measures, including blackout capabilities, must be taken to limit daylight exposure, if daylight is deemed a suitable source of light.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Control architectural lighting with dimmers to accommodate varied needs.

j. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

k. Use lamps with CCTs of 5000 K and CRIs ≥85.

l. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

m. Use lamps with CRIs ≥85.

n. Equip physical analyses laboratories with adjustable portable luminaires for analysis efforts.

o. Make electrical provisions for portable work lights.

p. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 23.2

The table column headings are discussed in detail in 23.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 23.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 23.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 23.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches. A shaded icon indicates applications and tasks are sensitive to daylight and appropriate measures, including blackout capabilities, must be taken to limit daylight exposure, if daylight is deemed a suitable source of light.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Control architectural lighting with dimmers to accommodate varied needs.

j. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

k. Use lamps with CCTs of 5000 K and CRIs ≥85.

l. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

m. Use lamps with CRIs ≥85.

n. Equip physical analyses laboratories with adjustable portable luminaires for analysis efforts.

o. Make electrical provisions for portable work lights.

p. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Table 23.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

23.2.3 Atria and Courtyards

Lighting for atria and courtyards is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

23.2.4 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

23.2.5 Circulation

Given varying security requirements, lighting for circulation is addressed in respective application areas of courts and correctional facilities.

23.2.6 Classrooms

Training and education are important components of the judicial and correctional fields. Lighting for classrooms is discussed in 24 | LIGHTING FOR EDUCATION.

23.2.7 Conferencing

Various forms of conferencing are used in courts and correctional facilities. Lighting for conferencing is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

23.2.8 Correctional Facilities

Incarceration is detention generally intended as punishment or deterrent. As such the criteria citations for some of the applications and tasks associated with correctional facilities identify illuminance criteria that are sensible and expedient, but not necessarily most appropriate. For example, a commissary is a retail application cited in Table 23.2. The designer could consider a more refined approach to retail lighting espoused in 34 | LIGHTING FOR RETAIL which may suit a specific type of commissary in a specific type of correctional facility for a specific owner. Yet, the commissary clientele or the authority funding a project for punishment or deterrence may not appreciate the lighting approach and techniques this degree of attention yields. The vendor running the commissary, however, may welcome some degree of retail lighting to assist sales in such a controlled market. Hence very straightforward criteria espousing a basic retail strategy are cited in Table 23.2 for the commissary. On applications or tasks where other and better detailed lighting criteria exist, such as chapels (Table 37.2), food service (Table 22.2), libraries (Table 29.2), and medical and dental (Table 27.2), the designer might review and propose criteria from the other application chapters, but recognizing the restrictive requirements of the project at hand.

Lighting effects and hardware styling and sizes in correctional facilities can contribute to a sense of calm and order. Daylighting is considered a significant benefit to those with little opportunity for outdoor activity. Electric lighting equipment must withstand the potential for intentional primary abuse or collateral damage. Review of the design program and consultation with the design team and client should provide insight to the degree and likelihood of such abuse and damage. Daylighting must be designed to prevent abuse of the daylight media and prevent methods of escape or impermissible communication with the outside community. Design techniques and hardware selections and detailing must be addressed accordingly by the lighting designer and team. Some key applications and tasks are discussed below.

Careful deliberation on lighting controls is necessary. Where these are located, what they control, who has access, which controls can be overridden, interaction with emergency and lock-down systems are among the variables to consider.

23.2.8.1 Cells

General lighting should be commensurate with time of day and might be achieved with all daylight or some combination of daylight and electric light during daylight hours. Task lighting should be provided at one or several key task areas. Depending on the nature of the facility and degree of security, this might include the desk, head-of-bed, or grooming area. Figure 23.2 illustrates a technique. Luminaire construction needs to be rugged to withstand tampering and physical abuse. Lamps insensitive to sudden shock are appropriate. Special luminaire mountings often must be used to accommodate recessed lighting in security plaster ceilings or in concrete, or surface mounting to concrete. Generally, smaller apertures are preferable with heavy gauge back boxes or housings where these are not embedded in concrete. Equipment should be securely lensed. Concealed security screws in luminaire construction can preclude the hiding of contraband by inmates or disassembling components for use as weapons or in the construction of incendiary devices.

Lighting control varies for different security levels and may be based on specific client requirements. Lighting for medium- and maximum-security cells is typically controlled from the security control posts or a secure operations center. Minimum-security cell lighting may be controlled locally with a central override. Automated time clocks or photocells can be used to adjust day-to-night lighting, though automated systems must be highly secure electronically and electrically. Design programming for some facilities may require specific lock down switching schemes.

Figure 23.2 | Cell Lighting
A wall mounted luminaire exhibits an uplight and a downlight component. Versions are available where each distribution is separately lamped and switched to provide low-level ambient (uplight only), moderate ambient (uplight and downlight) or only task lighting (downlight only).
» Image ©Lizzie Himmel/Sygma/Corbis

23.2.8.2 Circulation Corridors

Corridors in correctional facilities consist of public (non secure), detention (secure), and staff areas. Corridors in detention areas are used for inmate traffic (both escorted and unescorted) and, depending on the facility, may serve as temporary holding. Corridor lighting must be adequate for both direct-view and video-view observations. Consultation with the design program and team and client is appropriate to establish the use of secure corridors and the desired degrees of direct- or video-viewing to and from these corridors. This must be coordinated with the control posts and their intended arrangement: as direct-view observation posts or as video-view observation posts. For direct-view observation posts, lighting within the post must be well-coordinated with that of the areas being viewed. Security glass and its finish, tint, and planar tilt, if any, influence the success of viewing conditions where the goal is to optimize outward view by security personnel and restrict inward view by detainees.

23.2.8.3 Control Posts

The lighting of control posts depends on the function of the posts and the required degree of security. Where security officers undertake anonymous direct-view observation in an enclosed room, lighting within the post must be very well controlled at the discretion of the officers to adjust for any change in lighting conditions of the areas being viewed and to limit direct-view into the control post by inmates. Low LRVs are best in this situation. Optically-controlled lighting positioned close the to surfaces intentionally deserving of light, such as floor or work surface, is best. This avoids the potential for floodlighting or spotlighting of security officers' heads and movements. If control panels are not electronic and require front lighting, optically-controlled and dimmable equipment should be used for the front lighting. Lighting of the area being observed must be addressed accordingly.

23.2.8.4 Vehicle Sally Ports

The secure movement of detainees or prisoners, protected witnesses, or even dignitaries requiring security protection is facilitated by a sally port where secure vehicles have access to secure entries to courts or correctional facilities. Sally ports are usually fully enclosed porte cocheres or garages. Lighting serves both an adaptation function as vehicles move from exterior to interior and vice versa and as a security function. Although daylighting can be used to limit energy use, its application must be made with great care. Daylight

media must itself be secure of breach by people or gunfire and must prevent direct-view situations from any vantage point outside the sally port to limit identification and tracking of those inside.

23.2.9 Forensics Laboratories

Crime laboratories range from relatively basic setups to all-inclusive facilities, depending on the resources of the agency and the breadth and depth of crimes needing analysis. Labs fitted with electronic analyzers involving computer displays and digital readouts should be lighted to accommodate the dissection of physical samples, mixing of solutions, and insertion of materials of reading of the displays. Where more physical analysis is required, lighting must address the visual aspects of inspection, including that undertaken with microscopes. Some laboratory setups consist of both the electronic analyses and physical inspection side-by-side. All-inclusive facilities may have labs segregated based on the analyses. Controls for variability to accommodate a very wide range of visual tasks and portable task lighting for inspection are important. See Figures 23.3 and 23.4.

23.2.10 IT

Lighting for IT facilities is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

23.2.11 Judicial Facilities

Although judicial facilities encompass many applications, the most important and unique are the courtrooms, of which there may be several in one facility. Justice is a foundation of democracy. Lighting should serve to enhance the dignity of these facilities and support fair and speedy trials. Accenting is a functional and aesthetic necessity. Color rendering of electric light sources should be ≥85 CRI for purposes of rendering skin tones and clothing colors fully for purposes of inspection and identification of witnesses, defendants, and evidence, and self-confidence.

Courtrooms consist of two basic components: the audience and the area of proceedings. The area of proceedings includes the judge's bench, attorneys' tables, a lectern or podium, witness stand, court clerk, court recorder, and jury box. An evidence table may also be necessary, as may display easels and audiovisual equipment. Visual tasks are quite varied. Cameras may be involved for recording and security purposes. Lighting needs can be varied, but readily addressed with well-planned lighting layouts and control zones, dimmable sources, and controls. Controls must be simple for expedient application. Where these are located, what they control, who has access, which controls can be overridden, and interaction with emergency and lock-down systems are among the variables to consider. With the exception of AV requirements, vertical illuminances are relatively high, but readily achieved with diffuse lighting techniques. See Figure 23.1. For AV situations using front-projection systems, the position of the screen must be established and lighting controlled to limit illuminance over the surface of the screen. Illuminance criterion cited is maximum on the screen and can certainly be lower than this value. Uniformity over the screen is important to minimize distracting striations. Where video display monitors are used, these are generally much less forgiving than front-projection systems. However, some of these have highly specular screens and the position and tilt of the screen relative to energized lights must be considered.

Daylighting works well in courtrooms where very little, if any, AV is anticipated, such as might be expected in bankruptcy court. In other courts, daylighting must be designed to accommodate AV situations and this might involve automated shades adjusting to AV scene settings. Regardless, the security aspects of daylight media must be addressed. The design team must coordinate with the security consultant to establish appropriate daylight media, sizes, and orientations for the project's given locale.

Figure 23.3 | Forensics Laboratory
Ambient lighting from linear indirect pendant luminaires accommodates electronic analyses. In multi-lamp pendants, switching can achieve a range of illuminances. Where physical analyses occur, portable task lights are used for inspection.
» Image ©Christopher Lark

23.2.12 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS. In secure parking situations, lighting must accommodate camera and surveillance requirements.

23.2.13 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS. In secure pedestrian-way situations, lighting must accommodate camera and surveillance requirements.

23.2.14 Support Spaces

Lighting for support spaces is briefly addressed in 22 | LIGHTING FOR COMMON APPLICATIONS. Barber and beauty shops are cited here since these amenities are likely a part of correctional facilities. Illuminance criteria are outlined in Chapter 28.

Coat rooms and copy centers are considered support spaces, though these may be decentralized. For example, a judge's chamber might need both a coat room and a copy center to address the volume of use and security requirements afforded by in-suite facilities.

Mail rooms may be relatively small, but there is likely need for an area and lighting to address sorting and to address security inspection. If inspection is an inherent part of sorting, then the security inspection criteria should be applied at all mail room work areas.

23.2.15 Toilets/Locker Rooms

Restrooms are best addressed by highlighting specific task areas. This offers energy efficiency while meeting the different illuminance criteria involved. Highlighting toilets, urinals, and vanities offers a more clean, crisp appearance than the haze of general diffuse lighting. Vanity positions require vertical illuminance on an imaginary facial plane (roughly a zone of sufficient size to encompass faces at standing or seated height) in front

Figure 23.4 | Forensics Laboratory
Vehicle inspections require relatively high ambient illuminances with portable task lighting as needed. Here, direct/indirect linear pendants were determined most efficient in meeting illuminance criteria. Portable fluorescent studio lights are used for their intensity, efficiency, and minimal heat.
» Image ©Christopher Lark

of the mirror. Figure 22.7 identifies several methods of vanity lighting for non secure toilet facilities. Color of light is important for grooming. Lamps exhibiting 2700 K to 3500 K CCT and CRI ≥82, using triphosphor CFLs as benchmark, are appropriate.

23.2.16 Transition Spaces

How front-of-house transition spaces in many applications are designed and lighted defines the place and welcomes employees and guests. These spaces are transitions from exterior to interior and vice versa or from one kind of interior space to another. Illuminance criteria and accents are an important aspect of making comfortable and safe transitions.

Many of the public spaces in judicial facilities may be of a particular sequence of passage, ceremonial in nature, or of special importance. To appropriately serve these roles, subjective impressions outlined in Table 12.2 should guide the application of lighting effects. Illuminances associated with artwork and features that assist with these subjective impressions are outlined in Table 23.2.

Security screening areas in public spaces such as lobbies require some additional horizontal and vertical illuminance relative to the background lighting necessary for the normal space function. See Figure 25.1. Where special security procedures demand private screening, horizontal and vertical illuminance criteria should accommodate the situation. Illuminances and lighting hardware locations and light distributions must be coordinated with security cameras. Controls for these rooms may be purposely centralized or limited to motion sensors. The designer must coordinate requirements with the security consultant.

For purposes of visual consistency and of maintenance convenience, lamp types and color qualities should match those used elsewhere.

23.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 23.2.

23.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 23.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 36.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

23.3.2 Notes

The notes in Table 23.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

23.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 23.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for perimeter display walls in a trial jury suite, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on at least one plane of a task, such as the vertical plane at 5' AFF for CORRECTIONAL FACILITIES/Control Posts/Direct-view Observation. A 0 indicates no light or zero light is recommended for the task or application.

23.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." Note the implication for observers' visual ages. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation.

23.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. It may be determined that illuminance criteria for an age group other than that representing the majority of the intended observers is appropriate. However, this may result in overlighting, underlighting, harsh lighting, visual displeasure, or visual discomfort for many of the observers. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance. In some situations, such as front projection AV presentations, lighting must meet the requirements of the screen technology to maximize visibility for all age groups and, therefore, is not tied to ages of observers.

23.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 23.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

23.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

23.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h).

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

23.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

23.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

23.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

23.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. However, this may not be practical in courtrooms unless continuous dimming is used on slow response rates. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities.

23.3.6 Veiling Reflections

Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance

IESH/10e CSA/ISO

> 12.5 Task Factors

recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

23.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Applications and Tasks and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 23.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 23.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

23.4 Designing

Information provided here is specific to courts and correctional facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. Equipment selection and location strategies may need to address the possibility of lighting equipment abuse. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. Dimming response to daylight may be impractical. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers of significance intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production, holding, and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

- using highest-efficiency luminaires that meet aesthetic, abuse, and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers of significance is the paramount design tenet and must be kept in perspective during all aspects of design. Here, the designer must establish the significant observers and their related lighting reqiurements. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

24.4 Designing. 24.25
24.5 References 24.26

Knowledge acquisition and the process of learning involve the visual exploration of tangible forms and the discovery of concepts from written and graphical displays on paper, computer, and projection. Lighting's role is fundamental. However, lighting also sets the scene for listening, developing social skills, comprehending situations, and recognizing and understanding places. For the normal- and partial-sighted, lighting contributes to life and learning in ways that cannot be accounted in a conventional present worth analysis. Although electric lighting accounts for about 30% of the electricity used in K-12 schools (see Figure 24.1), this amounts to roughly ¾ of 1 percent of total expenditures [1] [2]. Addressing lighting-energy costs must not be allowed to compromise lighting for education. Proper use of daylight and efficient electric light enhance the learning environment. What follows is a discussion of the key aspects affecting lighting for people in educational facilities: project status; space types; activities; application-specific design goals, and illuminance criteria.

Comprehensive design efforts must also rely on material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. The designer should have a thorough understanding of the design tenets outlined in those chapters, must identify those deemed appropriate and develop lighting goals and strategies accordingly. This chapter primarily addresses specifics related to lighting for education which should influence luminaire optical selections, lamping, and final layouts based on previously developed thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous and current IES related documents serve as archival and reference sources [3] [4].

Deliberate thought must be given to details beyond the recommended illuminances in this chapter. For example, in art classrooms color quality of light is important. In some situations, very important. This information is usually available from project programming. Review relevant material in Chapter 12 and address the need by selecting lamps of a CCT and CRI deemed appropriate to the situation. Such specific details are not enumerated for all tasks. Table 24.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

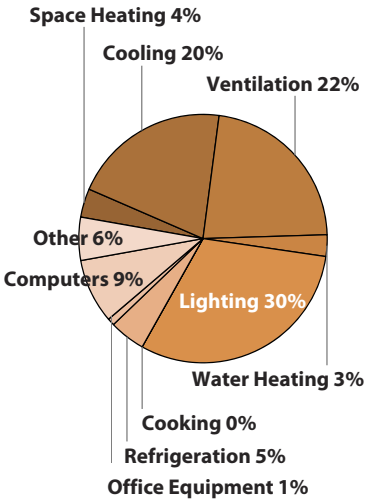

Figure 24.1 | Electricity Use of Education Buildings
Based on 2003 data from the US DOE's Energy Information Administration, lighting accounts for 30% of electricity use in education buildings (electricity use for Cooking rounds to 0%). Education buildings themselves account for about 10% of electricity use by all commercial and institutional buildings.

24.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. A clear understanding of the

project type and scope will help establish the extent to which daylighting can address most or many or some of the lighting goals. At every opportunity the lighting designer should consider daylighting as a light source. Given hours of operation of at least K-12 schools, daylighting can be the primary light source. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands determined attention to address glare and balance visible and thermal energy.

24.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the educational space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 24.2 | Educational Facilities Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 24.2.

The following discussion is keyed to major application headings in Table 24.2. Couple this with topics in Table 24.1 for comprehensive qualitative and quantitative criteria.

24.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction and wayfinding. Default accent lighting criteria are discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Also see 15.1.1.3 Accent Lighting.

24.2.2 Administration

Lighting for administrative areas is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The architectural scheme and even task specifics may vary based on the associated educational facility, from K-12 to vocational technology to community college to college and university to adult education. These distinctions may affect the lighting design by influencing the kinds of lighting effects, the lighting equipment styling, and the luminances and illuminances.

The administrative areas may be dispersed throughout an educational facility or campus or may be centralized into a single area, wing, or building. Depending on client wishes and architectural desires, this centralization or decentralization may affect the degree to which the lighting design in administrative areas is sympathetic to or different from that of the other applications and tasks at the educational facility in question.

24.2.3 Auditoria

Auditoria are typified by their flexibility in use. Functions are quite varied even within designations as lecture halls or multipurpose or performance spaces. This usually requires design of a controls system that may demand operators instructed in the use

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

of the system. Additionally, in more intimate auditoria, simplified controls for speakers and students may be appropriate to accommodate small sessions without the need for additional staff.

Challenges include aisle lighting during dark-house performances as well as sound and light lock lighting. *Sound and light locks* serve as transitions from the auditorium to the adjacent lobby, concourse, or other transition space. The aisle lighting must function appropriately during various kinds of performances and their intermissions and pre- and post-performances. For example, during dark-house performances, people leaving or entering the auditorium should not create a visual distraction. Sound and light lock lighting should be designed to manage the luminance change from the auditorium aisles to the adjacent spaces. This may involve adjusting floor reflectances and illuminances between aisles, sound and light locks, and lobbies. Dimmed decorative lighting or optically-controlled architectural lighting or localized lighting from steplights or handrails are typically options. See also 28.2.7 Control Booths and 28.2.19 Theaters.

Sound and light lock is a reference to a doored room with no daylight access and which separates a light sensitive space, such as a darkened auditorium, dining room, or theater, from an active space where relatively higher illuminances are necessary, such as a daylit lobby, kitchen, or foyer. The lock acts like a sound and light baffle so that as people enter and exit the light sensitive space no extraneous sound or light from the brighter active space disrupts people's experience in the light sensitive space. See Figure 24.2.

24.2.4 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. For educational facilities one distinct variable is time of need. Other variables include anticipated levels of activity and the nighttime outdoor lighting zone. Nighttime activity levels may vary by type of educational facility, such as primary versus secondary, and by specific schedules, such as extra-curricular activities, sports, social, or other events. All of this may demand a control system capable of addressing various settings on various evenings through manual intervention, automated time clock, and photocell functions.

The nighttime outdoor lighting zone within which the facility is located or to which the team and client elect to design affects the illuminance criteria for outdoor tasks. Nighttime outdoor lighting zone designations vary by local ordinance, sustainability guides, or the team's own definition of place. These are discussed in 26 | LIGHTING FOR EXTERIORS. Also see Table 15.6 | Nighttime Operational Strategies for Improved Outdoor Environmental Regard.

After-hours security needs, such as on-site or remote monitoring or recording, may require that some luminaires at building entries remain energized through the night or placed on motion sensors or interconnected with camera operations. Control zones and time clock functions must be designed accordingly. Where remote monitoring is done with infrared cameras, lighting may be unnecessary.

Figure 24.2 | Sound and Light Lock
This sound and light lock separates a daylit lobby (out of view to the left, but the effect of which is visible through an open door) from a large auditorium (through the door to the right).

At pre- and post-performance times and during intermission, electric lighting is set to the levels seen here. At actual performance and lecture times, the overhead luminaires are extinguished and steplights are dimmed. Note how even the door to the auditorium is hinged on the far side to further baffle extraneous light from the unseen and possibly opened door along the left wall to the brighter lobby.

» Image ©Balthazar Korab Photography Ltd.

24.2.5 Classrooms

In addition to task visibility and visual performance, classroom lighting influences attention. Here, it is necessary to define and address all anticipated visual tasks—many of which are vertically-oriented. Although lighting effects should not be the focus of attention, lighting should be developed that helps the eye maintain focus and user maintain attention on specific task areas as the pedagogy requires.

Ages of observers must be deliberated with care in classrooms. A sense of comfort and place as well as appropriate energy use can only be achieved if illuminance levels are targeted for the intended audience. Illuminance criteria are presented based on age groupings associated with at least half the observers in a particular application. The designer is always at liberty to reselect criteria based on her own experience or on client direction. Where age groupings conflict, such as might happen with day classes in primary or secondary schools for the children and adolescents and night classes in the same facilities for adults, lighting controls allow for appropriate and efficient lighting to address both situations.

Notes for Table 24.2

The table column headings are discussed in detail in 24.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 24.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 24.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Exterior tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 24.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Alternatively, design to specific tasks, if known, from READING AND WRITING.

j. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

k. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

l. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 24.2

The table column headings are discussed in detail in 24.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 24.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 24.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Exterior tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 24.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ↶ signals high likelihood; gray and white ↶ signals moderate likelihood; pale gray and white ↶ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Alternatively, design to specific tasks, if known, from READING AND WRITING.

j. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

k. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

Notes for Table 24.2

The table column headings are discussed in detail in 24.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 24.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 24.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Exterior tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 24.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Alternatively, design to specific tasks, if known, from READING AND WRITING.

j. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

k. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

l. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 24.2

The table column headings are discussed in detail in 24.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 24.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 24.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Exterior tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 24.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. Alternatively, design to specific tasks, if known, from READING AND WRITING.

j. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

k. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

l. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Table 24.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

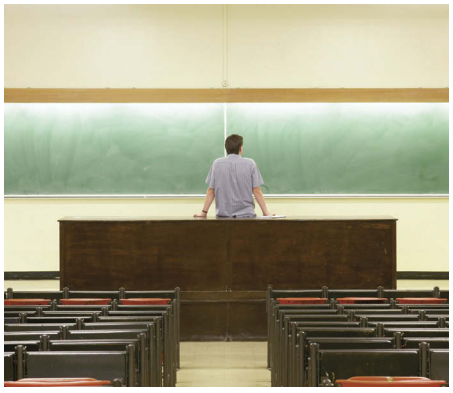

Figure 24.3 | Chalkboards
Lighting chalkboards greatly improves their visibility and better maintains observer attention. Grazing light creates strong luminance near the source of light. Placement of room lighting to brighten the bottom portion of the board can balance this effect.

Luminaires cantilevered from the wall or ceiling or recessed in the ceiling at some distance from the board are most effective when optics provide an asymmetric distribution of relatively diffuse light oriented toward the board (see wallwash lighting on the white boards in Figure 24.4)

IESH/10e CSA/ISO

> 12.5 Task Factors
- for information on CSA/ISO computer screen qualities

Lighting for audiovisual presentations depends largely on the presentation media and the intended use. Most available display systems exhibit luminances and resolutions that make for readily visible presentations under many classroom lighting conditions. If dedicated electronic-display presentations, that is, exclusive viewing of the display, are part of the pedagogy, then provisions should be made to meet the criteria cited in Table 24.2 for CLASSROOMS/General Classrooms/Learning/teaching/AV (dedicated AV viewing). This may necessitate a separate preset scene and the deployment of daylight shades.

Daylighting success is facilitated where seamless, simple-for-the-instructor operation of electric and daylighting mechanisms, such as shades, occurs. Functional variation, including room-darkening for AV, must be easily available to the instructor. For classrooms, these aspects deserve particular attention:

1. Automate dimming or brief client on stepped-dimming functionality
2. Avail instructors of simple dimming overrides to brighten or darken rooms on demand
3. Care in the design of any east- and west-elevation daylighting relative to glare
4. Automate window treatment or avail instructors of convenient manual operation and expected time of use
5. Introduce daylight apertures on orientations different from primary or secondary instruction positions or display/presentation positions
6. Arrange glazing to allow sufficient wall space for posting teaching aids, student work, etc.
7. Maintain some degree of exterior view
8. Avoid daylight designs requiring near-continual or complete shade deployment
9. Perform daylight simulations to limit areas of overlighting and assist with glazing transmittance and shading treatment selections [5] [6] [7] [8]

Laboratories, industrial and electronics shops, and art studios may have special requirements related to the kinds of light necessary for processes and viewing and related to the kinds of luminaires appropriate to the hazards of the environment. Such special requirements should be identified in programming and researched during design. This may involve vendors of special equipment, rooms, or booths, which are many times purchased as turnkey packages. Determination of lighting needs requires close coordination amongst the design team, client, and turnkey-package vendors. Some examples and related lighting needs are:

1. Fume hoods and paint and finishing booths: Where fume hood or paint or finishing booth packages do not include integral lighting, design of lighting for the hazardous location is necessary. See Table 25.4 | Hazardous Location Classifications.
2. Motor and motor vehicle servicing, prototyping, and experimentation: Design of lighting for the hazardous location is necessary. See Table 25.4 | Hazardous Location Classifications.
3. Lab experiment stations and observation booths: Where equipment or booth vendors do not provide integral lighting, lighting needs must be established. Where processes involve hazardous chemicals, design of lighting for hazardous locations is necessary. Where processes are spectrally sensitive, such as some curing procedures, select lamps accordingly. Where processes are spectrally and intensity sensitive, such as plant-growth, select lamps accordingly. In some situations the luminaires may need to accommodate directed water spray or wash down procedures in which case wet-rated luminaires are necessary and which should carry IP ratings specific to the situation. See 15.1.2.1 Luminaires.

Maintenance and cleaning of the lighting equipment must be well considered in process areas. Where wash-down is convenient or necessary due to task processes, then lighting equipment must be specified accordingly. Where color discrimination is important to

Figure 24.4 | Electric and Daylighting
The continuous clerestory offers an opportunity to harvest daylight along the half of the classroom closest to the exterior wall. The linear pendant luminaires in the classroom exhibit two lamps in cross section. At the perimeter luminaire ❶ the rows of lamps are wired for two zones of control. The outboard lamp row (the row of lamps closest to the exterior) is switched separately from the inboard row. When a photocell senses that enough daylight is present, one row is automatically extinguished. Which zone is extinguished can be alternated on a daily basis to equalize and extend in-service life of the ballasts and lamps. If not considered too disruptive, both lamp rows could be extinguished when sufficient daylight is available, and this is the typical approach. No window treatment can be a successful approach on north facades and where T_{vis} is of moderate value, but which depends on geographic location, typical sky conditions, and reviews of daylight simulations. Otherwise, automated shades are best.

Wallwashers are used to highlight white boards ❷. Controls establish preset scenes that extinguish these luminaires during AV presentations.

Present-day projection systems are sufficiently powerful to permit view during full-light conditions. This is useful when the presentation is mixed with traditional reading and writing tasks. However, to optimize viewing conditions and maximize energy savings, staff instruction on the use of controls is necessary.

High-reflectance matte wall and ceiling finishes greatly improve the effectiveness of daylight and electric light ❸.

» Image ©Bill Lindhout Photography

the task process, such as assessing chemical reactions in experiments or paint color and matching or finish quality in shops, CRI may need to be ≥90 and CCT may need to be 5000 K or 6500 K. Also see Table 6.1 | Color-related Design Questions.

In any of the classroom applications, control systems are key to providing the functional variation, daylight integration, and simple-for-the-instructor operation.

Figures 24.3, 24.4, and 24.5 illustrate some classroom lighting techniques

24.2.6 Conferencing

The lighting of conferencing facilities is addressed in 22 | LIGHTING FOR COMMON APPLICATIONS. Where conferencing facilities are essentially multipurpose meeting rooms, controls are used to establish appropriate settings for various tasks. Figure 24.6 illustrates a dedicated video conference classroom.

24.2.7 Dormitories

Lighting for living is as much about visual comfort, sense of place, and distinction from classroom and administrative settings as it is about illuminance values. Much of the lighting for dormitory applications is task-oriented or relatively low-level ambient. This more discrete approach to lighting combined with the typical age groupings has additional advantage in low connected load. With occupancy sensors this yields low energy use.

Depending on the nature of the dormitory facilities, criteria cited in 28 | LIGHTING FOR HOSPITALITY AND ENTERTAINMENT may be suitable. For example, dorms may be used as housing for business executives on multi-week training and education missions. Some school and academy markets expect and will bear the cost of upscale housing.

24.2.8 Food Service

Lighting for food service is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

24.2.9 IT

Lighting for IT tasks is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Figure 24.5 | Science Lab
Ambient and task lighting systems combine to achieve horizontal and vertical illuminances at tables and faces. Lensed task lighting is integrated into overhead lab utility carriers. For lab work, tables are reconfigured to be directly centered below the overhead lab utility carriers. Ambient lighting consists of lensed 1x4 luminaires. Outside row is strategically positioned (near clerestory at top of image) to illuminate glass-front storage cabinets. Accenting of the white boards is achieved with ceiling-recessed rectilinear wallwashers lamped with long compact fluorescent lamps. Each of these three lighting systems is separately controlled to accommodate a number of teaching situations.
» Image ©Bill Lindhout Photography

24.2.10 Libraries

Lighting for libraries is discussed in 29 | LIGHTING FOR LIBRARIES.

24.2.11 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS.

24.2.12 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS.

24.2.13 Reading and Writing

Reading and writing tasks occur within various applications. Familiarity with these tasks will aid with assessment of specific application tasks and activities. This may result in the recommendation of illuminance criteria different than that proposed in Table 24.2 for a particular application. For example, if the computer tasks in AUDITORIA/Multipurpose/Testing or those in CLASSROOMS/General Classroom/Dedicated VDT Screens are known to involve CSA/ISO Type III negative-polarity screens, then the task citation under READING AND WRITING/VDT Screen and Keyboard/CSA/ISO Type III/Negative Polarity is an appropriate recommendation and should be deliberated with the client. Figure 24.7 illustrates a computer lab application with CSA/ISO Type I positive-polarity screens.

24.2.14 Sports

Depending on the size and extent of sports programs, if any, the lighting designer may find more appropriate criteria discussed in 36 | LIGHTING FOR SPORTS AND RECREATION. Recommendations are made in Table 24.2 where a basic fieldhouse is programmed or where a gymnasium is used for assembly and physical education classes.

24.2.15 Support Spaces

These relatively back-of-house citations are self-explanatory.

24.2.16 Toilets/Locker Rooms

Lighting for toilets and locker rooms is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Addressing the fixture functional areas, such as toilets, urinals, vanities, will provide sufficient light where needed without overlighting the entire toilet room. Vanities are problematic when little or no vertical illuminance is designed to illuminate an imaginary facial plane (roughly a zone of sufficient size to encompass faces) in front of the mirrors. Wall slot details illuminating light-colored upper walls above the mirror or discrete, lensed ceiling-recessed luminaires or some combination are appropriate techniques here.

Vertical light on the faces of lockers will assist with locker use.

24.2.17 Transition Spaces

Most of these spaces are self-explanatory, but one deserves discussion. Adjacency passageways refer to a condition where circulation areas are encompassed by larger work or task areas. Given their adjacency to the open and visually accessible work or task areas, their illuminances, confined to the passageway proper, should be ratios of the nearby task illuminances. This avoids annoying contrasts within the work setting.

For purposes of maintenance convenience, lamp types and color qualities should match those used elsewhere. Figure 24.8 illustrates benefits of daylighting. Figure 24.9 identifies some lighting aspects associated with stairs.

24.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 24.2.

24.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 24.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 24.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

24.3.2 Notes

Notes may refer to other application and task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

24.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Figure 24.6 | Video Conference
Present-day video systems and large-format flat screens are available with matte screens and exhibit sufficient brightness to work well even when illuminances are relatively high and diffuse. These relatively high and diffuse illuminances accommodate recording/transmission of high quality images of facial detail, clothing, and tasks.
» Image ©Bryan Denton/Corbis

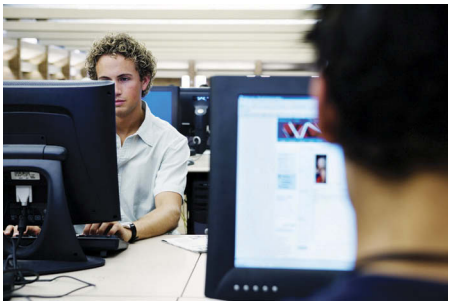

Figure 24.7 | VDT Screens
CSA/ISO Type I and II positive-polarity screens offer excellent inherent contrast. Indirect or direct/indirect lighting typically yields glare-free viewing conditions for these screens and results in no veiling reflections. The indirect lighting component reflects diffuse light from the ceiling which produces vertical illuminances that facilitate facial recognition.
» Image ©Anderson Ross/Blend Images/Corbis

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Figure 24.8 | Daylighting
Code interpretation permitting, daylight can exclusively meet illuminance criteria during daylight hours. In some applications, such as circulation areas, daylight illuminances exceeding IES recommendations are acceptable, even desirable providing glare is addressed. However, where transition is made to dark spaces, such as a performance auditorium, overlighting adjacent circulation areas is problematic.
» Image ©Emely/Corbis

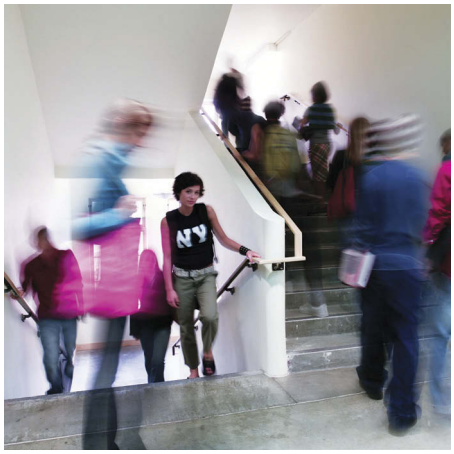

Figure 24.9 | Stairs
Highly-loaded stairs, typically encountered during class change, require higher illuminance than normal-situation counterparts. Controls, such as time clocks synchronized with class change or occupancy sensors are used to adjust lighting according to use patterns.
» Image ©Ocean/Corbis

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 24.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for perimeter lighting in indoor retailing situations, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on at least one plane of a task. A 0 indicates no light or zero light is recommended for the task or application.

24.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane. For example, if an art studio is intended to be used exclusively for easel painting, then the illuminance target cited in Table 24.2, which is for a dominant horizontal orientation, must be applied to the plane of the easels. This, however, pressures the designer to attend to glare issues associated with higher vertical illuminances.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. In some applications, like conventional art studios accommodating a variety of media, art forms, and genres, horizontal- and vertical-plane illuminances address the common studio situation where simultaneously some work or some portion of the work is on horizontal planes while other work or portion is on vertical planes.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." For example, for most corridors (TRANSITION SPACES/Circulation Corridors), horizontal illuminances apply to the floor plane while vertical illuminances apply to standing-face-plane height of 5' AFF oriented in the two main directions of travel. In primary schools, the designer may elect to set the elevation for vertical illuminance at 3' AFF. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation. For example, in a dormitory kitchen, E_v at preparation surfaces, the number and orientation of vertical planar points assessed depends on the preparation surface. On a counter against a full-height

wall, the vertical planes of most interest are the one facing the preparer and the two planes perpendicular to the preparer (one oriented toward the right and one toward the left). So, the criteria apply to these three planes. On an island or peninsula which may be used from more than one side, however, four planes are of interest.

24.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. In many education settings, more than half the total observers are under 25 years of age. Although implications to energy use are significant, this alone should not predetermine illuminance targets. More than half the instructors, administrators, and staff are likely to be in the 25-to-65 age group and their visual tasks encompass a broader array of reading and writing tasks. Further, their ability to read facial features and the mouthing of words is important to assessing and directing student achievement. The designer must work to reconcile the task, age, and subsequent illuminance differences. In some situations, it might be acceptable to the client to select illuminance targets for people under 25 years of age. In other situations, the client might demand illuminance targets for people ranging from 25 to 65 years of age. In still other situations, it may be desirable to light student areas to illuminance targets for people under 25 years of age while lighting instructor areas to illuminance targets for people between 25 to 65 years of age. For a classroom setting, this age-and-task-driven lighting approach has the benefit of directing students' attention to the instructor area. In any event, the aspect of observers' ages, task sets for age groups, and illuminance targets should be resolved during programming with the client. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance.

24.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 24.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

24.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

24.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

24.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

24.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

24.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

24.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

24.3.6 Veiling Reflections

Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

24.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Tasks and Applications and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 24.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 24.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

Figure 24.5 illustrates a science lab where task and ambient lighting systems are applied. The task area is considered the lab table zone, designed to a "demonstration area" illuminance criteria. The ambient coverage area is the entire room.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

24.4 Designing

Information provided here is specific to educational facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells

- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

25.3 Illuminance Criteria 25.12
25.4 Designing. 25.16
25.5 References 25.16

Collaboration on architectural lighting is a must as borne out in the other application and design chapters. The designer of the architectural lighting (aka lighting designer) must work with designers of the architecture, interiors, and landscape to achieve project success. If the lighting designer is not an electrical engineer, then collaboration between the two may benefit the project on matters of at least emergency lighting and perhaps safety and security lighting. The topics discussed in this chapter are by nature quite analytic, though some discussion outlines aesthetic aspects and IES criteria in context with some code-mandated criteria related to emergency lighting. Lighting for safety and security are also addressed.

Comprehensive design efforts involve the information in this chapter combined with material in 12 | COMPONENTS OF LIGHTING DESIGN, 14 | DESIGNING DAYLIGHTING, 15 | DESIGNING ELECTRIC LIGHTING, and respective application chapters relevant to the project at hand. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance specifics related to Lighting for Emergency, Safety, and Security which should influence illuminance criteria, luminaire ratings, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 14, 15, and relevant application chapters will likely lead to unsatisfactory results. That is, even though the application may be considered code compliant, safe, and secure, the users may find its utility for the intended functions inappropriate or unacceptable. Previous IES related documents serve as archival reference sources [1].

Table 25.1 offers a checklist of IES lighting topics and criteria related to emergency, safety, and security lighting.

25.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. The scope and work assignments associated with lighting for emergency, safety, and security should be clearly understood prior to project commencement. New, renovation, and restoration projects each offer varying challenges. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design.

25.2 Application Types

Emergency, safety, and security lighting are perhaps the design team's greatest challenges. Codes, ordinances, and mandates establish the minimum requirements of construction to protect public health, safety, and welfare. What follows is indicative rather than exhaustive.

The lighting recommendations throughout this handbook are made on the basis of effective visual performance for the intended application and task situations. The Safety and Security Illuminance Recommendations in Table 25.2 should be reviewed against the project knowns and an assessment should be made on their relevance to the various application and task situations on the project. Codes, ordinances, or mandates may supersede any of the IES criteria cited throughout this handbook for any of the application and task situations and the designer must design accordingly or seek variance from the appropriate authority having jurisdiction (AHJ). This should be documented.

25.2.1 Codes, Ordinances, and Mandates

A rigorous review by the design team is necessary to identify all codes and ordinances that affect lighting on every project. The requirements of these codes, ordinances, and mandates must be identified and defined by the registered and licensed professionals. Regardless which design team members ultimately address these citations, they *must* all be addressed. The designs to address them must be coordinated amongst the design team and are likely to involve architecture, interior finishes, materials, and contrasts, landscape, electrical engineering, and lighting. What follows is discussion on some code- and ordinance-related topics and on some common practices related to lighting for emergency, safety, and security. This is not and cannot be a complete recitation and review of all codes, ordinances, and mandates that might be applicable on any and every project at the time of project design.

The work by installers and licensed and registered architects and engineers must conform to electrical and life safety codes. Where the designer of the lighting is not one of these professionals, then he or she should have some familiarity with the electrical and life safety codes. This familiarity will help on collaborative design efforts and will minimize the likelihood of the lighting designer developing impractical, impossible, or inappropriate design layouts or luminaire selections or, in the case of emergency lighting of the egress paths, may help minimize the need for an egress lighting system entirely independent of the *normal power* architectural lighting system. There are typically economic and aesthetic advantages to connecting some of the architectural lighting system equipment to the *emergency power* system.

Relevant codes, ordinances, and mandates (legal requirements) are defined and enforced at the discretion of the AHJ and may be different from project to project and locale to locale. It is not uncommon for different versions of the same code to be required on different projects. These should be identified and their implications reviewed and documented by the design team early in the project. Work scopes should be clearly delineated at that time to avoid later confusion or the potential of non-compliance issues.

Table 12.9 | Typical Prescribed Lighting Design Factors offers a short list of some relevant codes, ordinances, and mandates along with some certification programs. This is a tentative list and should not be considered exhaustive or even complete. See Section 12.7 Prescribed Factors.

In the United States there is a proliferation of legal requirements. Some of these conflict with each other. Some conflict with sustainable practices. The design team must identify all codes, ordinances, and mandates that apply to a project, identify conflicts and determine resolution. The team should subsequently identify any that are deemed unnecessarily restrictive to the project goals, develop proposed resolution and consult with the AHJ. Where more than one AHJ is involved, a determination will need to be made on which authority and code takes precedent. Typically codes involving life safety override conflicting requirements of other codes, ordinances, and mandates.

25.2.1.1 Code Prescriptions for Lighting Equipment

All lighting equipment, including, but not limited to ballasts, drivers, transformers, and lamps, and the luminaires which combine these components into light-producing containers suitable for installation in their intended application and lighting controls should or must

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

meet basic safety and operational expectations. Underwriters Laboratories (UL) in the United States, Canadian Standards Association (CSA) in Canada, and Norma Oficial Mexicana (NOM) in Mexico have defined standards to which lighting equipment should be certified for their respective markets of use. In each North American Country, government authorized certification bodies test and certify lighting equipment to the respective standards for various applications, such as a wet location application. For example, in the United States Nationally Recognized Testing Laboratories (NRTLs) perform certification testing to the UL standards. A successful certification results in listing and labeling to the UL standards, evidenced by labeling on the respective component or luminaire. Although exceptions are possible and sometimes warranted, generally the listing and labeling should not be waived. UL/CSA/NOM is used as a generic catch-all reference throughout this handbook to related standards and certifications and the associated testings, listings, and labelings for lighting equipment in respective countries. UL/NRTL is a catch-all reference to the procedure in the U.S. whereby one of many testing labs test, list, and label products to the UL standards.

In addition to basic safety and operational expectations, lighting equipment must meet criteria for its application or use. The National Electrical Code (NEC) in the U.S., the Canadian Electrical Code (CEC), and the Mexican Electrical Code (MEC) establish lighting equipment application requirements.

Normal power is a reference to the electricity normally used when the premises are occupied. When this normal power flows to the architectural lighting equipment, normal power architectural lighting results.

Emergency power is a reference to the electricity provided for use when the normal power supply fails. When this emergency power flows to architectural lighting equipment or emergency lighting equipment or some combination, emergency lighting results.

Hazardous Location Applications

Equipment safety criteria are different for different applications. Where the design program, the licensed and registered architect or engineer, or the AHJ identify applications as hazardous, the lighting equipment and controls must be specified accordingly. Table 25.4 identifies the matrix of hazardous location categories from NFPA 70 (National Electrical Code), a United States code. The lighting designer must seek specific direction from the licensed and registered team professionals on the appropriate hazardous categories for a given application, room, or area. For example, a Class I, Division 2, Group D, T1 hazardous location requires lighting equipment exhibiting those ratings.

Other Location Applications

Equipment for all other locations should be appropriately tested, listed, and labeled for those respective applications. Reference guides to the available listing markings for luminaires for many applications are available [3] [4]. The designer must track, for example, if the intended application is dry, damp, or wet. If wet, is the luminaire likely to receive direct water spray or be submersed? If submersed, to what depth and will this be sustained for the life of the installation except for maintenance or will there be extended periods of dryness, but where the luminaire is expected to continue to operate or where operation is to cease? There are numerous subcategories and branches of testing and rating procedures. The designer must determine the intended application and research product requirements. Luminaires must be specified accordingly.

Required or Desired Luminaire Ratings

The designer must review programming against code, ordinance, and mandated requirements for lighting equipment safety and against client-, team-, or non-lighting-industry-practice requirements or suggestions. It is not uncommon to design lighting to also meet other standards for such applications as clean rooms, containment areas, pharmaceutical research and development and production, and food processing. Some of these standards might be codified by the AHJ while others may be imposed or suggested with good intentions, but unknown lighting provenance. The designer should identify those considered valid to the tasks and lighting involved and review with the team and client. Where conflicts arise with legal requirements or good lighting judgement, these must be resolved with the relevant parties.

Installation

The contractor is expected to follow installation requirements set forth by codes and manufacturers. Although not a responsibility of the designer, some familiarity with installation

Notes for Table 25.2

The table column headings are discussed in detail in 25.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 25.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 25.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 25.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours.

g. Tasks with specular components, like some stone floors, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Table 25.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

aspects is recommended. The designer of the lighting, if not also the designated licensed and registered architect or engineer on the project, must coordinate luminaire specifications with respect to any installation and other application requirements as directed by the licensed and registered professionals. For example, this can include earthquake clips and safety cables or other such items affecting equipment safety and that can be specified as part of the luminaires.

Junction boxes supporting luminaires weighing 50 pounds or less must be rated and properly installed to support the weight of the luminaire. Otherwise the luminaire must be independently supported. For chandeliers over 50 pounds, for example, independent support is needed as is additional independent support to accommodate one or several safety cables. This structural support work must be coordinated by the registered professionals with the installer and may involve structural engineers. Coordination with the manufacturer of the specified lighting equipment may also be necessary.

25.2.1.2 Code Prescriptions for Illuminance

Illuminances for a number of applications are now prescribed by a variety of codes, ordinances, and mandates. The design team must coordinate and reconcile with the AHJ any instances where codes, mandates, standards, and green ratings conflict. The illuminance values and the number of applications vary by jurisdiction and change from time to time. Some illuminance mandates are accompanied by uniformities. Application examples, which vary by code and jurisdiction, include, but are not limited to:

Normal Power Prescriptions

Subject to the design team's and AHJ's interpretation, these prescriptions are for the noted application during normal power (non-emergency) situations.

- Barber shops
- Beauty salons
- Classrooms
- Facilities for the disabled
- Egress (designated exit circulation) paths
- New egress stairs
- Old egress stairs
- Elevator landing sills or thresholds on both sides of elevator door
- Escalator treads and landings
- Food service areas
- Machine rooms
- Moving walkways
- Occupied spaces with limited or no daylight
- Pools and Spas
- Restrooms

Emergency Power Prescriptions

Subject to the design team's and AHJ's interpretation, these prescriptions are for the noted application during emergency situations.

- Egress paths
- Egress stairs
- Outdoor paths to some safe distance

Most of these prescriptions involve illuminance minima. At this writing, some of the minima prescribed for normal power situations, are high. This results in relatively significant average illuminance values that require relatively large proportions of the project's available energy. Typically, average illuminances are two to three times greater than minima, which for corridors in the vicinity of elevator landing sills as well as for new stairs might need to be as high as 200 to 300 lx. Additionally, the resulting surface luminances in these normal power situations may be disturbingly greater than those of adjacent areas. With-

Table 25.4 | Hazardous Location Classifications[a]

Category	Definition
Class	**Type of explosive danger in the area**
	• Class I: Flammable gases or vapors
	• Class II: Combustible dusts
	• Class III: Combustible fibers or flyings
Division	**Likelihood of a hazardous atmosphere**
	• Division 1: Flammable or combustible concentrations likely under normal operating conditions
	• Division 2: Flammable or combustible concentrations unlikely under normal operating conditions
Group	**Rating of the fire and explosion characteristics of a material**
	• Groups A, B, C, and D: Flammable gases and vapors
	• Groups E, F, and G: Combustible dusts
Temperature	**Maximum safe equipment operating temperature allowed for the hazardous atmosphere**
	• T1 to T6 (highest to lowest) temperature classifications

a. See NFPA 70 National Electrical Code Article 500 [2].

out code rewrites, the best alternatives to such high normal power illuminance situations are seeking documented variances to code prescriptions in favor of the normal power IES criteria cited throughout the handbook for various applications and tasks or design to code and make and document the required design and power budget adjustments. Regardless, all must be reviewed by the team and agreed upon by the licensed and registered professionals and client and accepted by the AHJ.

Early in project planning, the design team must at least identify where collaborative techniques may be beneficial in addressing emergency lighting. Benefits might include cost efficiencies, improved architectural and equipment integration, improved aesthetics, and improved maintenance where normal power architectural lighting can partially or wholly address emergency lighting. The lighting designer supports the engineer and architect and may be directed to adjust architectural lighting equipment specifications or even layouts to accommodate their interpretation of codes and, ultimately, that of the AHJ on emergency lighting requirements.

25.2.1.3 Beyond Code Prescriptions

Code prescriptions aside, the project program or local AHJ may require that provisions be made for sufficient illumination for specific processes or functions such as security, hazardous processes, or the continuity of critical operations. Such applications include, but are not limited to:

- Health care critical care areas
- Security centers
- Gatehouses
- First aid areas
- Critical mechanical, electrical, IT, and communications rooms
- Control rooms
- Hazardous material processing areas
- Other areas deemed critical to the viability of the operation and safety of personnel

The designer of the lighting must coordinate with the electrical engineer, if not one in the same, to establish what constitutes "sufficient illumination" and then lighting and controls and power should be planned accordingly by the respective responsible parties.

The normal power may fail due to a number of situations, and the design team should consider the implications of these when designing the normal power and emergency power lighting, control, and power distribution. This may affect all or selective normal power architectural lighting luminaire and lamp selections, layouts, optional auxiliary power devices within luminaires, and their proposed control. An emergency may include any, several, or all of the following:

- Utility power failure
- Utility power voltage reduction (brownout) potentially negatively affecting lamp, ballast, driver, or transformer operation
- Power interruption within the premises including total power loss or individual phase or branch circuit failures
- Fire and/or smoke
- Earthquake, flood, hurricane, tornado, or other natural disaster.

25.2.2 IES Safety Lighting

Safe conditions are essential to any inhabited space and the effect of light on safety must be considered. The environment should be designed to help compensate for the limitations of human capability. Any factor that aids visual effectiveness increases the probability that a person will detect a hazard and take appropriate action. In many instances where illumination is associated with accidents, the cause may be attributed to inadequate illuminance levels or poor quality of illumination. All of which can result in poor visibility. However, there are other factors associated with poor visibility which may contribute to accidents. Some of these are: low contrast, direct glare, reflected glare, and harsh shadows. Visual fatigue itself may be an element contributing to accidents. Accidents may also be prompted by delayed adaptation a person experiences when moving from bright settings into dark ones and vice versa.

Visibility for safety is affected by lighting as well as architectural planning, finishes and contrasts, and layouts. Hazards such as curbs, steps, and sloped walkways, for example, should be visible. Where these occur in a consistent or regular fashion with appropriately contrasting finishes and detailing such that they are considered slight hazards, little light is needed for detection. Where hazards occur in an inconsistent or irregular manner, where contrasts are low or nonexistent, or where their sizes and contrasts may be variable such that they are considered high hazards, more light is needed for detection. Where finishes are coordinated to assist visibility, lamps with CRI ≥80 are recommended to improve color contrast.

Where illuminances or luminances are very low or designed to create a special effect or scene, such as in auditoria, clubs, hotels, museums, restaurants, theaters, and the like, care must be taken to identify changes in elevation and direction without detracting from the visual effectiveness of the architectural lighting. These situations are typically considered dark and where low activity occurs.

Table 25.2 identifies IES illuminance criteria related to safety. [5] Baseline criteria address most indoor situations and might be deemed appropriate for some outdoor situations. A citation for dark situations is appropriate where dark settings are expected as a part of the overall function or activity of the application.

In situations where safety lighting is considered appropriate, uniformities contribute significantly to the overall effectiveness. Maximum-to-minimum uniformities for basic safety situations should be no greater than 10-to-1 (10:1).

25.2.3 Security Lighting

Establish the rationale for a need for security lighting. Implementing security lighting will likely involve an increase in illuminance and lighting power densities of at least 50%.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Issues of unwanted attention from higher illuminances, glare, accommodating additional hardware, and, in outdoor settings, light trespass and light pollution must be addressed. Security lighting should be applied in a limited and strategic manner and only where normal application illuminances are considered inadequate. Refer to other application illuminance tables where some references to security illuminance criteria are made, such as Table 22.2 | Common Applications Illuminance Recommendations/TRANSITION SPACES/Lobbies/Security Screening. See Figure 25.1.

In security situations where color recognition is important, lamps should exhibit CRIs ≥ 80. This will assist with the distinguishing of vehicular colors, skin tonal differences, and clothing colors.

Where lighting is deemed necessary for security and no criteria is available in other application chapters, check the bookstore at www.ies.org for updates on security lighting dated 2011 or later. If no updates are available, then document criteria using the procedure outlined below based on IES G-1-03 | Guideline for Security Lighting for People, Property, and Public Spaces. Alternatively, establish and document criteria using the procedure below based on Table 4.1 | Recommended Illuminance Targets. Regardless, at the designer's discretion, adjustments may be deemed appropriate to account for activity levels, nighttime outdoor lighting zones, and mesopic adaptation. Age determination should be well-deliberated and based on anticipated use. All adjustments should be documented and the recommended criteria reviewed with the team and client. BUG ratings may be mandated and must be addressed during development of design techniques and selection of luminaires.

Document the following procedure to establish recommended security lighting illuminance criteria to review with the team and owner for the project at hand.

1. Review Section 4.12 An Illuminance Determination System.
2. Establish an illuminance category for each security activity and task appropriate to the level of activity, the nighttime outdoor lighting zone, and background ambient.
3. Assess observers' ages and determine appropriate horizontal and vertical illuminance targets.
4. Determine design gauge (average, minimum, maximum) and uniformities.
5. Determine if mesopic multipliers are appropriate.
6. Finalize recommended security illuminance criteria for the project.

An Illuminance Determination System

Section 4.12 outlines the latest IES system for determining illuminance criteria. Illuminance categories are identified in Table 4.1 | Recommended Illuminance Targets. Security situations may involve interior and exterior settings during daytime or nighttime hours or both. Precedent suggests illuminance categories that increase normal application illuminances by between 50% and 100% make an appropriate pool from which to determine security illuminance criteria. There are situations where less light is appropriate for enhanced security, such as in control rooms and one-way-viewing situations. However, the designer must assess these criteria in the context of activity level and lighting zone.

Activities and Tasks

Outline the various activities and tasks to be addressed with security lighting. This may be a lifting, extension, or modification of those activities and tasks cited in other application illuminance tables or a completely different assessment by the designer based on a task survey (see Table 12.3 | Sample Visual Task Survey). Some activities and tasks addressed in other chapters, such as stairs or elevator lobbies (see Table 22.2 | Common Applications Illuminance Recommendations), may be deemed appropriate. In any event, most, if not all, activities and tasks will have a need for horizontal and vertical illuminance criteria.

Figure 25.1 | Security Screening
Here additional lighting was used to define a security task zone consisting of an X-ray machine to the far left and an adjacent metal detector. Horizontal illuminance assists in the event of a search of a purse, brief case, or other personal belonging. Vertical illuminance assists with overall visual assessment of approaching visitors (see TRANSITION SPACES/Lobbies/Security Screening in Table 22.2)
» Image ©Photographer: James Haefner

The designer must define and track these planar requirements. For security situations, horizontal illuminance criteria are at the plane of particular interest, many times pavement or floor plane or desk, counter, or transaction height. Vertical illuminance criteria are related to seated, standing, or walking face height. The designer must establish which viewing directions are most important with a minimum of two directions of travel and sometimes up to four when walking is involved. This depends on the intended perspective or points of observation and whether observation is live-on-site or monitored or recorded.

Preliminary Illuminance Categories
For each of the activities and tasks and planes of interest, identify a preliminary illuminance category based on experience, IES precedent, or study of the categories' typical application and task characteristics and the visual performance description in Table 4.1. Developing a table outlining criteria for all three methods would allow the designer to use averaging or at least understand the extent of the variances. The goal is to establish the lowest illuminance criteria appropriate to the security need. Overlighting as a convenience is inappropriate.

Activity Level
For some indoor and many nighttime outdoor applications, activity levels influence illuminance criteria. Nighttime outdoor high activity levels, for example, demand greatest illuminances to address the volumes of vehicular and pedestrian traffic. From Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions, identify the anticipated activity level. For those activities and tasks where vehicles are involved or where vehicles and pedestrians interact, use the outdoor activity level category. For those activities and tasks where only people are involved, use the indoor activity level category. If the activity level is expected to change according to time of day, identify the various activity levels and their durations. Generally, a "high activity" level gives merit to the highest illuminance under consideration. A "medium activity" level gives merit to the moderate illuminance under consideration. A "low activity" level gives merit to the lowest illuminance under consideration.

Nighttime Outdoor Lighting Zone
In outdoor situations, lighting zones influence illuminance criteria. Lighting zones in more urban areas require greater illuminances given densities of nighttime activity and a need to maintain states of adaptation consistent with surroundings. If not codified as part of an ordinance, code, or sustainable initiative, then from Table 26.4 | Nighttime Outdoor Lighting Zone Definitions determine the most appropriate lighting zone descriptor

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

for the environmental setting within which the project is located. Generally, Z4 and Z3 give merit to the highest illuminance under consideration. For each step reduction in lighting zone, a concomitant step reduction in illuminance category is merited. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits. This typically precludes the use of adjustable spot or flood lights and restricts the wattage and output of shielded and optically-controlled area luminaires.

Background Ambient

Where security lighting is intended to accentuate an area for purposes of visual surveillance, the immediate background brightnesses affects the security illuminance. Higher security illuminances are necessary where backgrounds are brighter. Similarly, darker immediate backgrounds require lower security illuminances.

Assess Observers' Ages

The illuminance categories outlined in Table 4.1 each consist of a range of three illuminance targets with: a low value associated with situations where the visual ages of at least half the observers are less than 25 years old; a middle value associated with situations where the visual ages of at least half the observers are between 25 and 65 years old; and a high value associated with situations where the visual ages of at least half the observers are greater than 65 years old. Deliberation might include the hours of operation and the security personnel demographics at various times of day and night. Where observers' visual ages are equally split among the three age groups, the designer must establish recommendations based on other techniques, such as combining two groups to establish a majority and using the older group's illuminance criteria or using the 25-65 age group's illuminance criteria, and reviewing the outcome with the team and client. Once visual ages are established, the designer can identify recommended illuminance targets for the security activity and task.

Design Gauges and Uniformities

Security illuminance targets must be calculated and measured against a gauge of average, minimum, or maximum. Using average as a gauge is recommended along with a uniformities of average-to-minimum and of maximum-to-minimum defines the upper and lower limits on illuminance. This assures some minimal illuminance for detection and adaptation purposes while also minimizing the detrimental effects of overlighting were no maximum to be set. Uniformities vary greatly depending on the kind of surveillance. Average-to-minimum ratios for live, on-site surveillance may be as great as 8-to-1 (8:1). Remote monitoring and recording with cameras may demand tighter uniformities to meet the capabilities of the cameras. The tighter the maximum-to-minimum uniformity ratio, the more consistent the illuminance.

Mesopic Multipliers

As identified in 4.12.3 Spectral Effects, an additional modifier for low luminance situations accounts for users' adaptation states. Adaptation state is important in developing recommended illuminance criteria for low-light activities and tasks which may correspond to nighttime outdoor or indoor patrol.

Generally, as eyes adapt to the lower luminances experienced in low-illuminance settings, mesopic adaptation occurs, typically at or below 3 cd/m^2. See Table 2.1 | Vision Adaptation States. These are luminances that might be experienced in low-light situations with moderate-to-low surface reflectances or in very-low-light situations with moderate-to-high reflectances. Such as might occur in some security situations. Under mesopic adaptation, lamps with spectra exhibiting shorter wavelengths (cooler-toned color quality) are more efficacious than longer wavelength (warmer-toned counterparts). It is quite possible, especially where illuminances are less than 10 lx, to find a specific design situation where an assessment of background luminance shows, for example, that a lighting system using standard 2000 K HPS lamps is 13 percent less efficacious than one using 3000 K CMH lamps or 19 percent less efficacious than one using 4000 K CMH

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.

lamps. See Table 12.7 | Pedestrian Way Mesopic Multiplier Example Worksheet and Table 26.6 | Parking Deck Mesopic Multiplier Example Worksheet. Both examples outline steps involved in determining if observers are likely to be in the mesopic adaptation state and, if so, the affect of various lamping options on illuminance criteria for the example.

Using the method outlined in 4.12.3 and Figure 4.27, mesopic multipliers adjust the illuminance criteria to account for the anticipated photopic background luminance and the spectra of the lamps under consideration. In the example in Table 26.6, in the design phase, this means illuminance criteria would need to be increased if HPS lamps are under consideration for the specific design situation discussed here or decreased if CMH lamps are under consideration. This can affect lamp wattages or luminaire layouts or both and may greatly affect connected loads or control schemes for night operation and curfew situations.

Finalize Recommended Illuminance Criteria
Itemize nighttime and daytime horizontal and vertical security illuminance and uniformity criteria.

25.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks or simply overlighting areas for convenience of design will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various aspects outlined in Table 25.2.

25.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 25.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural, landscape, or civil engineering conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 25.2 or those in other application chapters may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

25.3.2 Notes

Notes may refer to other application and task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

25.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of functional and accent lighting techniques is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors. Lighting for emergency and lighting for safety is tested periodically, at least as frequently as code requires.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice, will result in excess energy use and in many exterior situations, will result in more significant glare, light pollution, and light trespass. Ratcheting illuminances is not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 25.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the horizontal plane for safe circulation. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other applications or tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

25.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. In many exterior pedestrian applications, horizontal- and vertical-plane illuminances address the common situation where simultaneously walkway pavement visibility is related to horizontal illuminance while facial recognition is related to vertical illuminance.

Some illuminance targets, such as those for some security situations where task visibility and facial recognition are intended at differing planar elevations and must be deliberated and established by the designer. For criteria purposes, standing face height is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel and centered at 5' above finished grade (AFG). Illuminance criteria are applied to one

or both sides of this plane at consistent spacing increments along the length of the area under surveillance, for example, depending on the direction of observation. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. In some security situations involving pedestrians, at least two vertical planes are of interest, both perpendicular to the direction of main travel on the path, one opposing the other. This is an important distinction for luminaire optical selection and orientation capabilities and for layout, calculations, and field measurements.

25.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. The designer must coordinate with the design team and client to establish the age group of the intended observers. During deliberations, the designer and client should review precedents as well as implications of tentative criteria proposals on infrastructure, cost, and user performance. The aspects of observers' ages and illuminance targets should be resolved during programming with the client. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance.

25.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 25.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

25.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

25.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

25.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

25.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

25.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

25.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-switching, stepped-dimming, or continuous dimming to reduce or eliminate electric lighting when not needed during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

25.3.6 Veiling Reflections

Tasks with specular components, which in exterior settings include glossy metal, stone, or glass surfaces as might be found on facades, walls, or artworks and wet or dry pavement, are prone to specular reflections. Where such reflections veil important task information, such as grade changes, then these are known as veiling reflections. Diffuse-optic, low-wattage, and multiple luminaires can minimize the effects of veiling reflections, but not eliminate them. Diffuse-finish materials for walls, flooring, pavements, facades, and the like are helpful.

25.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is “task proper or task area.” Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. In some situations, such as accenting, the “task” area may consist of the entire wall when “feature wall” or “perimeter” accenting is desired.

Another area of coverage is “room or designated area.” In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the functional layout, such as that for a parking deck, but should be scrutinized by the design team. An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

25.4 Designing

Information provided here is specific to emergency, safety, and security and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. Coordinate this emergency, safety, and security lighting with that criteria selected from other application chapters. Addressing all code requirements is a must. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production, circulation, and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

26 | LIGHTING FOR EXTERIORS

Discontent is the first necessity of progress.
Thomas Alva Edison, 19th and 20th Century Inventor, Scientist, and Businessman

Contents

26.1 Project Type and Status. . . 26.1
26.2 Application Types 26.2
26.3 Illuminance Criteria 26.25
26.4 Designing. 26.29
26.5 References 26.30

Any lighting of any exterior demands a disciplined procedure equal that known to be successful for interior lighting applications. Illuminances and luminances must be carefully determined to advance commerce, culture, satisfactory perceptions of safety and security, and nighttime enjoyment of the natural and built scenery which is quite different from that experienced under daylight. All of this must be balanced with minimal energy use and respect for the natural night environment and fellow humans. What follows is a discussion of the key aspects affecting lighting for people in exterior applications: project status; space types; activities; application-specific design goals, and, where available, illuminance criteria.

Comprehensive design efforts must also rely on material related to outdoor settings in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. The designer should have a thorough understanding of the design tenets outlined in those chapters, must identify those deemed appropriate for outdoor settings, and develop lighting goals and strategies accordingly. This chapter primarily addresses specifics related to lighting for exteriors which should influence luminaire optical selections, lamping, and final layouts based on previously developed thought-starters (see 15.2 A Lighting Scheme). Using material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous and current IES related documents serve as archival references [1] [2] [3].

Considerable deliberation is in order for many of the exterior applications outlined in this chapter. The application-specific interior and exterior illuminance recommendations outlined in other chapters of this handbook are based on the current IES illuminance determination procedure [4]. Exterior illuminance criteria related to parking lot, parking structure, pedestrian sidewalks and paths, and street and roadway are not yet aligned with this procedure and remain under development at this writing. For these applications, and until appropriate updates are available, reference to archival information and to 4.12 An Illuminance Determination System are resources.

Table 26.1 offers a checklist of IES lighting topics and criteria related to outdoor lighting. The design team is responsible for determining and addressing outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

26.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. A clear understanding of the project type and scope will help establish the extent to which daylighting can address most or many or some of the lighting goals for parking garages. At every opportunity the lighting designer should consider daylighting as a light source.

26.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the exterior space, area, or feature types under consideration and the anticipated users, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Outdoor application definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, energy, and night-environment compliance. Area names, from which functions can be deduced, and boundaries for tracking should be clearly marked on architectural, landscape, or civil engineering backgrounds. The applications and tasks cited in Table 26.2 | Exterior Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of outdoor areas, and the available application and task citations in Table 26.2.

Outdoor lighting, unlike indoor lighting, has no built architectural enclosure to contain, capture, and redistribute the light. Any and all outdoor lighting should be employed only when deemed necessary and applied with great care. See Table 15.6 | Nighttime Operational Strategies for Improved Outdoor Environmental Regard. Otherwise, energy waste and light pollution are likely. Where outdoor lighting is deemed necessary, attend to the following:

- Establish and confirm the need for light
- Carefully define areas of application and the application itself
- Establish the lowest illuminance criteria appropriate to the need
- Independently address unique areas of interest
- Design lighting layouts to address only those areas of interest
- Select equipment with distribution and optical control to address criteria
- Use controls to energize, dim, and extinguish lighting to address activity levels

Establish and confirm the need for light. Although convenient to apply lighting to many, every, or most situations, this may be quite unnecessary. For example, on a corporate or college campus pedestrian paths may evolve over time. Some are paved, some are gravel, and others may simply be well-worn earth. It is not necessary or even desirable to illuminate all of these paths, if any of them. Based on programming, determine the typical activity levels of the project. After dusk and before dawn, few if any people may use the paths or a reasonable number of people may use a few key paths. Additionally, project administrators or design team members may determine that a single path or perhaps just a few paths should be designated as the most appropriate for nighttime outdoor circulation. Lighting all paths would likely result in the following: visual clutter with too many luminaires on crisscrossed layouts; some energy waste; some unnecessary light pollution; and some unnecessary initial and operational costs. Lighting one or a few paths in a complete and appropriate manner is a much better result than just meeting horizontal illuminance criteria on pavement for miles of pavement.

Defining finite areas to be illuminated is critical to an efficient and cost-effective design. Assessing how much, if any, light spills beyond those defined areas is a necessary part of the design process. It is unacceptable to define the edges of parking lot pavement, for example, in a calculation study and only assess criteria compliance on the parking lot pavement. An equally important part of the assessment is reviewing illuminances beyond the pavement and limiting these as much as practical.

The application must be well defined. For example, is the parking lot used at night? If so, until what time? What is its busiest time of use and what level of activity is involved? What ages are the majority of drivers at that time?

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

The IES Illuminance Determination System discussed in Section 4.12 requires the designer to make many judgments. A single-value illuminance for all tasks and all activity levels and all populations in all situations is generally not appropriate. The designer must make every effort to establish the lowest illuminance criteria appropriate to the need.

Independently addressing unique areas of interest with layouts addressing only those areas helps target lighting energy and coincidentally creates a more visually interesting setting. For example, parking lots, pedestrian paths, plazas, and circulation drives and streets, even where the architectural landscape plans promote compact adjacencies, should not be illuminated to a common-denominator illuminance that conveniently "blankets all of them" using tall poles and high-wattage floodlights. More task-oriented approaches unique to each application should be considered.

Outdoor situations are typically unlike interior situations where background luminance from walls and ceilings helps mitigate glare and helps contain light within close proximity to the luminaires. Luminaires must be selected on the basis of optical control. Floodlights and luminaires that direct light outward and upward should be selected as exceptions for feature accenting and extinguished at mandated or client-imposed curfew. In any event, indiscriminate floodlighting or spotlighting techniques involving the aiming of the photometric-maximum-candlepower (the main beam of light) outward or upward into free air without benefit of louvers or snoots or shields, where no vertical or overhead horizontal surfaces are the intentional targets, and to illuminate distant ground-plane surfaces is inappropriate. Using high-wattage wide-beam (flood-distribution) equipment to illuminate a focal or task area instead of low-wattage targeted-beam equipment is also inappropriate.

Controls alone can save significant amounts of energy and greatly reduce light pollution. Switching all or step-switching some lights off or dimming them at curfew times is appropriate and effective. Programming information should indicate hours of operation and the need, if any, for patrol surveillance lighting. Pending the team's review of reliability for specific applications, motion sensors may offer a means to meet illuminance criteria over limited areas for limited times when activity levels are extremely low.

Color rendering and color temperature for outdoor lamping have a strong influence on users' sense of normalcy and impressions of visual attraction and visual aesthetic of the setting. Operational mockups of lamps under consideration on a project should be reviewed in nighttime outdoor settings similar to those under design. This is especially important where lamp CRIs dip below 80 and where CCTs extend outside the range of 2700 K to 4100 K.

Outdoor lighting, regardless of the illuminance, will not *necessarily* reduce or eliminate crime [5]. However, lighting that addresses normal criteria appropriate for public nighttime activity may be a potential deterrent to criminal activity and provide pedestrians with a sense of security (and a sense of safety). Lamps with CRIs ≥80 help people better identify and distinguish colors. It is also important that the lighting is tuned to the nighttime outdoor lighting zone to avoid adaptation issues. Addressing CRI, nighttime outdoor lighting zones, and normal criteria enable users to see and identify surroundings and potential perpetrators. It is this identification that serves to indirectly deter criminal activity. Perpetrators will learn that their risk of exposure and identification is greater in such well-designed areas. Adding high-wattage, wide-area floodlights and tripling or quadrupling illuminances is generally counter-productive. Where additional lighting at entries or public pedestrian areas is deemed necessary for purposes of security surveillance, this should be relatively low-wattage equipment directing light down and across the limited area of coverage and contributing an average of 10 lx, 25 lx, and 50 lx on the ground plane respectively in rural, suburban, and urban areas [6]. See Figure 22.4.

The following sections are keyed to the major application and task headings in Table 26.2. These discussions, those identified in Table 26.1, and the material in Table 26.2 offer comprehensive qualitative and quantitative criteria.

Uniformity Targets[e] Over Area of Coverage: 1st ratio $E_h/2^{nd}$ ratio E_v if different uniformities apply			[f] [g] Typical Area of Coverage[h]	
Max:Avg	Avg:Min	Max:Min	Task Proper or Task Area	Room or Designated Area

Notes for Table 26.2

The table column headings are discussed in detail in 26.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 26.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 26.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 26.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some general retail sales, the typical area of coverage is "Room or Designated Area" at the planar elevations noted. For applications where task position is known, such as fixed displays or specific gondola layouts, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area" and which may involve different planar elevations that the designer must accommodate.

Table 26.2 | Exterior Illuminance Recommendations

Applications and Tasks[a]	Notes	Recommended Maintained Illuminance Targets (lux)[b, c, d] Horizontal (E_h) Targets — Visual Ages of Observers (years) where **at least half** are: <25 (Category)	25-65	>65 (Gauge)	Vertical (E_v) Targets — Visual Ages of Observers (years) where **at least half** are: <25 (Category)	25-65	>65 (Gauge)
FOUNTAINS	See 26.2.4 for discussion.						
PARKING DECKS	Covered parking facilities. See PARKING LOTS for top of deck lighting. See 26.2.5 for discussion. A checklist of probable application tasks and areas follows for which illuminance criteria should be established.						
• **Dedicated Corners/Ramps**	Lighting should address corners and ramps dedicated primarily, if not exclusively, to vehicular activity with no adjoining parking. E_h @finished floor; E_v @5' AFF in at least the two primary directions of travel. The face is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel. Illuminances on both sides of the plane are assessed. Coordinate illuminance criteria with observers' ages and high, medium, or low activity level.[i]						
• **Drive Aisles/Parking Areas**	Lighting should address drive aisles and adjacent parking with mixed pedestrian and vehicular activity. E_h @finished floor; E_v @5' AFF in at least the two primary directions of travel. The face is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel. Illuminances on both sides of the plane are assessed. Coordinate illuminance criteria with observers' ages and high, medium, or low activity level.[i]						
• **Drop-off/Pickup Areas, Interior Vehicle Transaction Areas and Valets**	Lighting should address courtesy drop-off and pickup areas and valets with mixed pedestrian and vehicular activity. Lighting should address vehicle transaction areas distant from covered entry/exit portals. E_h @finished floor; E_v @5' AFF in at least the two primary directions of travel. The face is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel. Illuminances on both sides of the plane are assessed. Coordinate illuminance criteria with observers' ages and high, medium, or low activity level.[i]						
• **Elevator Lobbies, Pedestrian Transaction Areas, and Stairways**	Lighting should address the lobby proper and pedestrian parking-fee transaction areas. E_h @finished floor; E_v @5' AFF in at least the two primary directions of travel. The face is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel. Illuminances on both sides of the plane are assessed. Coordinate illuminance criteria with observers' ages and high, medium, or low activity level.[i]						
• **Vehicular Entries and Exits**	Lighting should address vehicular entries and exits and adjacent parking and pedestrian areas. E_h @finished floor; E_v @5' AFF in at least the two primary directions of travel. The face is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel. Illuminances on both sides of the plane are assessed. Coordinate illuminance criteria with observers' ages and high, medium, or low activity level.[i]						
PARKING LOTS	Open parking facilities, including tops of parking decks. See 26.2.6 for discussion. A checklist of probable application tasks and areas follows for which illuminance criteria should be established.						
• **Drive Aisles/Parking Areas**	Lighting should address drive aisles and adjacent parking with mixed pedestrian and vehicular activity. E_h @grade; E_v @5' AFG in at least the two primary directions of travel. The face is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel. Illuminances on both sides of the plane are assessed. Coordinate illuminance criteria with observers' ages and high, medium, or low activity level.[i]						
• **Pedestrian Transaction Areas**	Lighting should address pedestrian parking-fee transaction areas. E_h @grade; E_v @5' AFG in at least the two primary directions of travel. The face is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel. Illuminances on both sides of the plane are assessed. Coordinate illuminance criteria with observers' ages and high, medium, or low activity level.[i]						
• **Vehicle Transaction Areas and Vehicular Entries/Exits**	Lighting should address vehicle transaction areas and vehicular entries and exits.. E_h @grade; E_v @5' AFG in at least the two primary directions of travel. The face is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel. Illuminances on both sides of the plane are assessed. Coordinate illuminance criteria with observers' ages and high, medium, or low activity level.[i]						
PEDESTRIAN MALLS	See Table 34.2 | Retail Illuminance Recommendations/CENTERS, OUTDOOR

Table 26.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

26.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief and can be used for visual attraction and wayfinding. Accenting illuminance criteria are based on the intended significance of the accented feature and the horizontal illuminance in the locale of observers. Also see 15.1.1.3 Accent Lighting. See Figure 26.1.

26.2.2 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

For building entries, variables affecting recommended illuminance criteria include anticipated levels of activity and the nighttime outdoor lighting zone. Nighttime activity levels may vary by type of facility, by neighborhood, by specific schedules, such as which night of the week, and by other events or activities, such as holidays or overtime work schedules. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions. All of this may demand a control system capable of addressing various settings on various evenings through manual intervention, automated time clock, and photocell functions.

The nighttime outdoor lighting zone within which the facility is located establishes the categories of illuminance for outdoor tasks. Nighttime outdoor lighting zones vary by local ordinance, sustainability guides, or the team's own definition of place. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions.

Business- and after-hours security needs, such as on-site or remote monitoring or recording, may require specific luminaire placement and specific illuminances coordinated with security cameras, and, after hours, may require that some luminaires at building entries remain energized through the night or placed on motion sensors or interconnected with camera operations. Control zones and time clock functions must be designed accordingly. Where remote monitoring is done with infrared cameras, lighting may be unnecessary.

Entry lighting should transition between the indoor and outdoor lighting condition. Both interior and exterior entry illuminances, uniformities, and luminances are important. Entries should be inviting and reflect the indoor setting. Unless a distinct design "break" is part of the scheme, lamp CCTs and CRIs should be based on indoor lamping color. This can even extend to parking and driveway lamp selections.

Figure 26.1 | Accenting
Flags and fountain features are dramatic focal points (see Table 15.2) and designed to 200 lx average (using an assumption of 10 lx for street illuminance [behind the camera]). The trees were considered moderate focal points with canopy illuminance designed to 100 lx average. The tree lighting establishes a visual outdoor perimeter, avoids a black hole effect, and serves as a backdrop for silhouetting effective for security surveillance.

Wet/dry-rated luminaires fitted with 250W/PAR38/SP quartz halogen lamps exhibiting 40,000 cd center beam are centered under each water feature.

Table 26.4 | Nighttime Outdoor Lighting Zone Definitions

Zone	Outdoor Lighting Situation	Definition
LZ4	High Ambient Lighting	Areas of human activity where the vision of human residents and users is adapted to high light levels. Lighting is generally considered necessary for safety, security and/or convenience and it is mostly uniform and/or continuous. After curfew, lighting may be extinguished or reduced in some areas as activity levels decline.
LZ3	Moderately High Ambient Lighting	Areas of human activity where the vision of human residents and users is adapted to moderately high light levels. Lighting is generally desired for safety, security and/or convenience and it is often uniform and/or continuous. After curfew, lighting may be extinguished or reduced in most areas as activity levels decline.
LZ2	Moderate Ambient Lighting	Areas of human activity where the vision of human residents and users is adapted to moderate light levels. Lighting may typically be used for safety and convenience but it is not necessarily uniform or continuous. After curfew, lighting may be extinguished or reduced as activity levels decline.
LZ1	Low Ambient Lighting	Areas where lighting might adversely affect flora and fauna or disturb the character of the area. The vision of human residents and users is adapted to low light levels. Lighting may be used for safety and convenience but it is not necessarily uniform or continuous. After curfew, most lighting should be extinguished or reduced as activity levels decline.
LZ0	No Ambient Lighting	Areas where the natural environment will be seriously and adversely affected by lighting. Impacts include disturbing the biological cycles of flora and fauna and/or detracting from human enjoyment and appreciation of the natural environment. Human activity is subordinate in importance to nature. The vision of human residents and users is adapted to the darkness, and they expect to see little or no lighting. When not needed, lighting should be extinguished.

26.2.3 Facades

Facade lighting can address a number of goals from functional to decorative or both. Opportunity exists to use facade lighting as a contributor to functional outdoor tasks such as walking, dining, or socializing in some situations, as illustrated in Figure 26.2.

The need or desire for facade lighting should be established during programming. However, the design opportunities for facade lighting may not be known until architectural design schemes have been sufficiently developed. There are three general approaches to facade lighting, where such is deemed essential:

- Lighting facade features or details
- Lighting facade fields
- Some combination

Any of these techniques can be quite effective. However, overlighting, both in intensity and area of coverage, as a result of improper lamp wattage, luminaire optic, or poor layout geometry is inappropriate. Where facades are glass or specular or semi-specular metal, lighting is discouraged. Most techniques on these facade types contribute greatly to light pollution since most of the light reflects up and into the night sky when uplighting is used. Little, if any, worthwhile lighting effect results.

Lighting facade features can be highly effective, energy savvy, and most respectful of the night sky. Overlighting must be avoided. If the intensity is too great, then the detail appears to levitate from the building or is visually washed out. If the area of coverage is too big, the detail blends with the surrounds and loses appeal. There are no uniformity criteria associated with lighting of facade details. Figures 26.2 and 26.3 illustrate lighting of facade details.

Table 26.5 | Recommended Light Trespass Illuminance Limits

Lighting Zone	Limit in lux[a] Pre-curfew	Post-curfew
LZ4	15	6
LZ3	8	3
LZ2	3	1
LZ1	1	0
LZ0	0.1	0

a. Maximum initial illuminance on a plane perpendicular to the line of sight to the luminaire(s). Plane located at observer position where light trespass is under review. [7]

Figure 26.2 | Facade Detail
Each column in the colonnade is illuminated with two uplights lamped with 100W/CMH/PAR38 lamps exhibiting 3000 K and 82 CRI. Uplights are positioned to each side of the columns on a line parallel with the front face of the columns. This introduces visual depth to the facade and accentuates the stone detailing of the columns and capitals.
» Image ©Glen Calvin Moon

Where facades are of a material that is opaque and matte in finish or of a design that consists of decorative screening comprised of opaque and matte materials, lighting facade fields can be appropriate. These fields might consist of large repetitive areas related to architectural modules or scale or might consist of the entire facade. The challenge is selecting luminaires and establishing a layout that minimize strong gradients or streaks and limit spill beyond the areas of intended coverage.

Combining the facade fields approach with the facade details approach can provide visual interest and depth and establish an overall nighttime building context not achieved with just one or the other approaches. Figures 11.3 and 26.4 illustrate combination approaches to facade lighting. In any event, lamps exhibiting CRIs ≥80 are appropriate for most facade types and finishes unless a specific color effect is desired. CCTs can be used to accentuate dimensionality (such as 3000 K lamping on foreground surfaces and 5000 K lamping on background surfaces) or for dramatic effect (such as 6500 K) or for traditional effect (such as 2700 K).

Where buildings have glass exterior walls in proximity to interior spaces that themselves exhibit highlighted walls or ceilings, the facade will have a presence during occupied hours as shown in Figure 26.1. Light spill to the outdoors can be limited by using optically controlled luminaires or shielding luminaires, orienting them away from windows, and using sensible lighting criteria for the interior spaces. Automated shades can be used to block interior light from escaping after some predetermined and reasonable curfew if none is mandated.

Facade lighting in the traditional sense is not necessary or appropriate in many situations. The context of viewing and use of the areas in close proximity to the building and activity levels should affect the decision to light or not light the facade and, if to be lighted, should affect the design approach for lighting. Some buildings have a landmark or cultural status and a community reverence. Some buildings are on key vehicular or pedestrian routes and can help define the route or the place, serve as destination markers, and contribute to perceptions of safety or security.

Techniques to lighting facades include downlighting, uplighting, and backlighting or the interior lighting discussed above. Downlighting can limit light pollution providing appropriate wattages and optical selections are made. However, light spill to adjacent properties, direct glare, the visual aesthetic of the equipment mounted to the facade, and more difficult maintenance procedures must be assessed.

Uplighting must be optically controlled and carefully adjusted and locked in place in order to limit light pollution. Walk-over, heat, water-management, and ease of maintenance and adjustment must be assessed.

26.2.4 Fountains

Fountain accenting can serve the accenting function identified previously in section 26.2.1. However, establishing illuminance criteria for water effects is elusive. The dispersion and attenuation of light in water is affected by the depth of the water over the light source. The aeration of the water through nozzles, if such is the design of the fountain, affects the quality of light refracted and reflected. Where waterfalls or cascades are the fountain effects, the spill height and aeration affect the quality of the lighting effects. Generally, luminaires must be positioned within a few inches of the waterline to be effective. For classic fountains consisting of long and medium throw streams, center beam candlepower is more important than wattage. Tighter beams are generally best for longer water sprays with one luminaire per spray nozzle positioned as close to the base of the stream as possible. At waterfalls or cascades, luminaires should be centered at the target position of the falling water. Consult with fountain designers and luminaire vendors to determine lighting equipment appropriate for the planned water effects. Equipment must

Figure 26.3 | Facade Detail
Here "details" of this 1931 Moderne structure are themselves quite simple and large. Lighting these repetitive elements does not highlight any inherent decorative detailing, but helps establish a nighttime building presence without floodlighting the entire facade. The backlighting creates a more dimensional effect than floodlighting. Here, straw filters are added to metal halide uplights backlighting the facade apertures to give an appearance of a filament lamp glow from within the building.
» Photography ©Brad Feinknopf 2004

be certified to UL/CSA/NOM standards for underwater application. The designer must assess needs for wet/dry equipment and IP68 ratings. See Figures 26.1 and 26.5.

Although seemingly convenient, lighting fountains and other water features from outside of the water element is typically unsuccessful. Unless very close in proximity to the water feature, literally within feet if not inches, or extraordinarily powerful, the aerated sprays, waterfalls, or cascades will appear flat and very dim. Reflecting pools or still-water features will simply reflect the focal light off into the direction opposite that of the incoming light. This is glary, obscures any detail or visual interest, and is only visible from one very specific observation point.

Consistent with design practice for all lighting applications, the design team must research and determine and address codes and standards specific to water-feature lighting. Factors affected may include luminaire rating, labeling, and listing requirements, lamp types, operating voltages, cutoff requirements, among others.

26.2.5 Parking Decks

The lighting of parking decks and undergrounds is most effective when the following details are addressed:

- Assess daylighting opportunities
- Define activities and tasks
- Define surface reflectances
- Define accenting
- Establish horizontal illuminance criteria, including uniformities
- Establish vertical illuminance criteria, including uniformities
- Establish accenting criteria

Above-ground structures, parking decks, are a cross between indoor and outdoor space. Daylighting opportunities should be explored early in the project. The "design" of many

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Figure 26.4 | Facade Field and Features
The field of the lower facade is illuminated and serves to provide sufficient horizontal and vertical illuminance at the terrace for circulation or a catered event. The lantern pendants are decorative and lamped with a filament lamp.

Features are accented on the second floor facade. Window frames are uplighted as is the gable detail. Automated controls allow for convenient setbacks through switching and dimming.

» Images www.jmaconochie.com

parking structures is sufficiently formulaic that most daylighting can only be fractional. That is, for above-ground structures, the structure itself is not oriented or designed to take advantage of daylighting, thereby leaving only the piecemeal option of switching off some lights near daylight apertures if and when daylight should meet the illuminance target. See 11.3.2.4 Design Strategies. Undergrounds, intentionally constructed under buildings, typically have no daylighting opportunity.

Defining the activities and tasks within the deck helps in the development of a comprehensive lighting design addressing users' needs. Overlighting and energy use are more likely to be minimized and a more visually engaging environment may result. For example, by understanding and addressing the tasks at key functional areas such as vehicular and pedestrian entrances and exits, elevator lobbies, pay stations, and passenger or valet drop-offs, lighting is better tuned to function. Review the list in Table 26.2 and visit several parking decks to understand uses. This information is used to establish illuminance criteria.

Surface reflectances significantly affect electric light and daylight efficiencies. Recommending light reflectance values (LRVs) of 50% on most columns and walls and at least 65% on ceiling surfaces are appropriate. Where color accents for coding floors and guiding users are used, LRVs should be at least 30%. As Figure 26.6 illustrates, high LRVs and appropriate luminaire light distributions greatly improve luminances and overall perceptions. High LRVs have the following advantages:

1. Assist with vertical illuminances at face heights and at columns and walls, allowing for lower wattage luminaires.
2. Assist with better uniformities on horizontal and vertical illuminances, reducing wattages and equipment quantities.
3. Reduce glare by increasing background luminance against which luminaires are seen.
4. Improve users' perceptions.

In addition to surface reflectances contributing to overall lighting system efficiency, controls contribute greatly to overall energy use and tune illuminances to activity levels and curfews. Automated astronomical time clock, photocell, and motion-sensor operation will help maintain a consistent and efficient operation. Instant-on and readily dimmed light sources can be used with these control techniques to ramp-up illuminances based on occupant sensing as needed during low-activity periods or after curfew.

Figure 26.5 | Fountain Accenting
Fountains might be centerpieces in parks, plazas, or public lawns. Although lighting will contribute little illuminance to the surrounding area, the luminance qualifies these as dramatic or feature focal points. This luminance can be made more dramatic with low illuminance, if any, in the vicinity of the fountain.

Underwater luminaires are lamped with filament or LED lamps and are typically dimmed. LEDs offer the advantage of saturated color or color effects synchronized to dynamic fountain effects with much greater efficiency than filament counterparts.

Where water features function as reflecting pools, no underwater lighting effects are introduced.

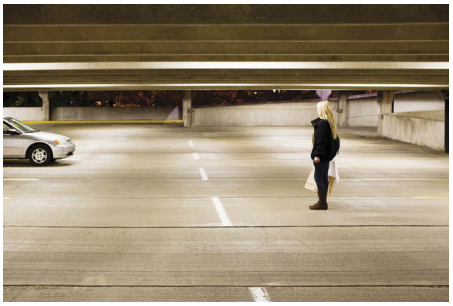
26.2.5.1 Parking Deck Illuminance Criteria

Check the bookstore at www.ies.org for updates on lighting for parking facilities dated 2011 or later. If no updates are available, then document the following procedure to establish recommended illuminance criteria to review with the team and owner for the project at hand.

1. Review Section 4.12 An Illuminance Determination System.
2. Establish an illuminance category for each activity and task appropriate to the level of activity and the nighttime outdoor lighting zone.
3. Assess observers' ages and determine appropriate horizontal and vertical illuminance targets.
4. Determine design gauge (average, minimum, maximum) and uniformities.
5. Determine if mesopic multipliers are appropriate.
6. Finalize recommended nighttime and daytime illuminance criteria for the project.



An Illuminance Determination System

Section 4.12 outlines the latest IES system for determining illuminance criteria. Illuminance categories are identified in Table 4.1 | Recommended Illuminance Targets. Parking decks are a cross between interior and exterior space. Precedent suggests categories A through K make an appropriate pool from which to determine nighttime illuminance criteria for many activities and tasks in parking decks. However, the designer must assess these criteria in the context of activity level and lighting zone.

Activities and Tasks

Outline the various activities and tasks to be addressed in the parking deck. This may be a lifting, extension, or modification of those cited in Table 26.2 or a completely different assessment by the designer based on a task survey (see Table 12.3 | Sample Visual Task Survey). Some activities and tasks addressed in other chapters, such as stairs or elevator lobbies (see Table 22.2 | Common Applications Illuminance Recommendations), may be deemed appropriate. In any event, most, if not all, activities and tasks will have a need for horizontal and vertical illuminance criteria. The designer must define and track these planar requirements. For parking deck situations, nearly all horizontal illuminance criteria are at finished grade or floor. Vertical illuminance criteria are related to standing or walking face height, typically identified at 5 feet above finished grade. The designer must

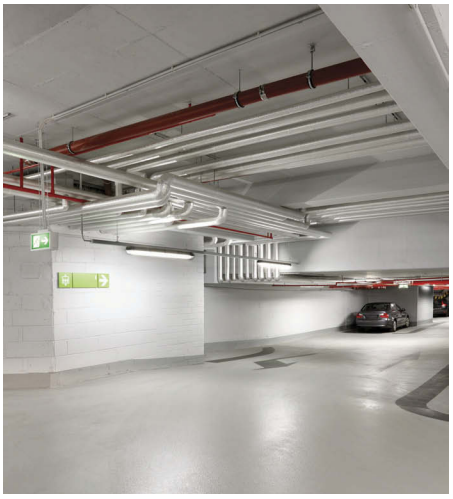

Figure 26.6 | Parking Decks
Uniformity of illuminance, both horizontal and vertical at face height, is important to visibility at all times and in all directions, to states of adaptation, and to perceptions. The middle and bottom images illustrate the effectiveness of painting ceiling, wall, and column surfaces. This significantly improves light distribution and efficiency and minimizes glare.

Luminaires and lamps exhibiting general-diffuse optical qualities, like the fluorescent varieties shown here, result in significantly less glare. Lamps with CRIs ≥82 offer improved color discrimination.

Strategically positioning luminaires to highlight perimeter vertical surfaces helps define architectural boundaries, destinations such as elevators and stairs, and signage.

» Top Image ©Image Source/Corbis
» Middle Image ©Jack Lacey/Corbis
» Bottom Image ©Gregor Schuster/Photographer's Choice/Getty

establish which viewing directions are most important with a minimum of two directions of travel and sometimes up to four.

Preliminary Illuminance Categories
For each of the activities and tasks and planes of interest, identify a preliminary illuminance category based on experience, IES precedent, or study of the categories' typical application and task characteristics and the visual performance description in Table 4.1. Developing a table outlining criteria for all three methods would allow the designer to use averaging or at least understand the extent of the variances. The goal is to establish the lowest illuminance criteria appropriate to the need. Overlighting as a convenience is inappropriate.

Activity Level
Activity levels influence illuminance criteria. High activity levels demand greatest illuminances to address the volumes of vehicular and pedestrian traffic. Reaction times are typically shortest as the likelihood of vehicle and pedestrian interaction is greatest. From Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions, identify the anticipated activity level. For those activities and tasks where vehicles and pedestrians interact, use the outdoor activity level category. For those activities and tasks where only people are involved, use the indoor activity level category. If the activity level is expected to change according to time of day, identify the various activity levels and their durations. Generally, a "high activity" level gives merit to the highest illuminance under consideration. A "medium activity" level gives merit to the moderate illuminance under consideration. A "low activity" level gives merit to the lowest illuminance under consideration.

Nighttime Outdoor Lighting Zone
Lighting zones influence illuminance criteria. Lighting zones in more urban areas require greater illuminances given densities of nighttime activity and a need to maintain states of adaptation consistent with surroundings. If not codified as part of an ordinance, code, or sustainable initiative, then from Table 26.4 | Nighttime Outdoor Lighting Zone Definitions determine the most appropriate lighting zone descriptor for the environmental setting within which the project is located. Generally, Z4 and Z3 give merit to the highest illuminance under consideration. For each step reduction in lighting zone, a concomitant step reduction in illuminance category is merited.

Assess Observers' Ages
The illuminance categories outlined in Table 4.1 each consist of a range of three illuminance targets with: a low value associated with situations where the visual ages of at least half the observers are less than 25 years old; a middle value associated with situations where the visual ages of at least half the observers are between 25 and 65 years old; and a high value associated with situations where the visual ages of at least half the observers are greater than 65 years old. Where observers' visual ages are equally split among the three age groups, the designer must establish recommendations based on other techniques, such as combining two groups to establish a majority and using the older group's illuminance criteria or using the 25-65 age group's illuminance criteria, and reviewing the outcome with the team and client. Deliberation might include the hours of operation and the user demographics at various times of day and night. There may be situations where more than half the clientele have visual ages greater than 65 years old, but the clientele are outnumbered by staff, such as might occur at a hospital where staff and visitors and patients share the same parking deck. Designing for the clientele is a reasonable conclusion. Once visual ages are established, the designer can identify recommended illuminance targets for the various activities and tasks.

Design Gauges and Uniformities
Illuminance targets must be calculated and measured against a gauge of average, minimum, or maximum. Using average as a gauge along with uniformities of average-to-min-

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

imum and of maximum-to-minimum defines the upper and lower limits on illuminance. This assures some minimal illuminance for detection and adaptation purposes while also minimizing the detrimental effects of overlighting if no maximum were set. For parking decks maximum-to-minimum ratios should not exceed 10-to-1 (10:1). The tighter the maximum-to-minimum uniformity ratio, the more consistent the illuminance, resulting in less glare and adaptation effects for people traveling through the deck and yielding fewer shadowed areas thereby improving senses of safety and security.

Mesopic Multipliers

As identified in 4.12.3 Spectral Effects, an additional modifier for low luminance situations accounts for users' adaptation states. Adaptation state is important in developing recommended illuminance criteria for low-light activities and tasks. In order to have some understanding of adaptation state, a tentative lighting approach must be identified. In a very rough sense, direct lighting (downlight only) in a parking deck will result in a lower adaptation state than will all indirect lighting or some combination of direct and indirect.

Generally, as eyes adapt to the lower luminances experienced in low-illuminance settings, mesopic adaptation occurs, typically at or below 3 cd/m^2. See Table 2.1 | Vision Adaptation States. These are luminances that might be experienced in low-light situations with moderate-to-low surface reflectances or in very-low-light situations with moderate-to-high reflectances. Such as might occur in some parking deck, parking lot, and pedestrian walkway situations. Under mesopic adaptation, lamps with spectra exhibiting shorter wavelengths (cooler-toned color quality) are more efficacious than longer wavelength (warmer-toned counterparts). It is quite possible, especially where illuminances are less than 10 lx, to find a specific design situation where an assessment of background luminance shows, for example, that a lighting system using standard 2000 K HPS lamps is 13 percent less efficacious than one using 3000 K CMH lamps or 19 percent less efficacious than one using 4000 K CMH lamps. Table 26.6 | Parking Deck Mesopic Multiplier Example Worksheet outlines steps involved in determining if observers are likely to be in the mesopic adaptation state and, if so, the affect of various lamping options on illuminance criteria for this example.

Using the method outlined in 4.12.3 and Figure 4.27, mesopic multipliers adjust the illuminance criteria to account for the anticipated photopic background luminance and the spectra of the lamps under consideration. In the example in Table 26.6, in the design phase, this means illuminance criteria would need to be increased if HPS lamps are under consideration for the specific design situation discussed here or decreased if CMH lamps are under consideration. This can affect lamp wattages, luminaire selections, and luminaire layouts or both and may greatly affect connected loads or control schemes for night operation and curfew situations. If LED lamps are under consideration, then S/P data and photometry are required.

Finalize Recommended Illuminance Criteria

Itemize nighttime and daytime horizontal and vertical illuminance and uniformity criteria. Generally, nighttime illuminances are consistent throughout the vehicular access areas, including drive aisles and parking bays, ramps and corners, and entries and exits. This is considered a baseline illuminance condition. Daytime illuminances respond to the nature of the tasks and states of adaptation with respect to the outdoor daylight. Daytime illuminances at drive aisles and parking bays are consistent with the nighttime baseline illuminances. However, ramps and corners might be illuminated to 2 times baseline during daylight hours of operation while entries and exits are illuminated to 10 times baseline during daylight hours of operations. See Figure 26.7. Additionally, surface finishes of walls and ceilings, particularly in the vicinity of ramps and corners and entries and exits, should exhibit high LRVs. During daylight hours of operations, employ strategies using any combination of daylighting and electric lighting to achieve target values. Daylighting may require unconventional architectural approaches.

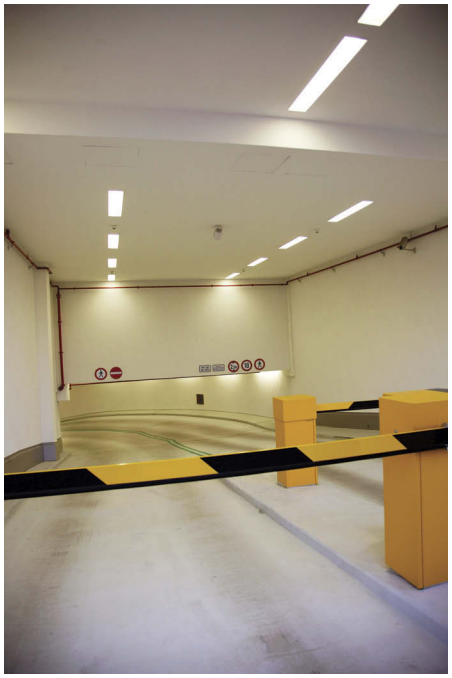

Figure 26.7 | Parking Deck Entries

Luminances at the entries to and exits from parking decks, both above ground and underground varieties are critical to drivers' adaptation states as they enter or exit the relatively dark parking structure during daylight hours.

Relatively high surface LRVs are important to achieving transitional luminances from exterior to interior and vice versa during daytime hours of operation. Architectural designs transitioning from 2- or 3-story exterior openings down to 1-story interior circulation drives great assist with daylighting of these areas.

During nighttime hours of operation, illuminances at entries and exits are reduced through selective switching or dimming to trim illuminances to match those of baseline conditions at drive aisles and parking bays within the parking structure.

Table 26.6 | Parking Deck Mesopic Multiplier Example Worksheet

Step	Process	For This Example
1	**Tentative Design Approach**	
	To best judge the photopic luminance ($L_{photopic}$) in a low-light interior or interior/exterior situation such as might be found in a low-activity parking deck in a Z1 nighttime outdoor lighting zone, determine tentative lighting approach: direct; direct/indirect; indirect.	Say direct/indirect with 85% direct light and 15% indirect light as might be achieved with some fluorescent or HID systems.
2	**Establish Recommended Photopic Illuminance Criteria**	
	Illuminance affects photopic luminance. Identify photopic horizontal (E_h) and vertical (E_v) illuminance criteria from Table 4.1.	• $E_{hphotopic}$ = 6 lx average, maintained
		• $E_{vphotopic}$ = 2 lx average, maintained
3	**Propose Surface Reflectances**	
	Reflectances also affect photopic luminance. Propose preliminary reflectances.	
	Ceiling reflectance ($\rho_{ceiling}$)	65 percent (0.65)
	Floor reflectance (ρ_{floor})	40 percent (0.40)
	Wall reflectance (ρ_{walls})	40 percent (0.40)
4	**Determine Photopic Luminance**	
	For the average $L_{photopic}$ in observer's field of view, sum and average relevant luminances.	
	a. $L_{photopic}$ of floor = $(E_h \times \rho_{floor}) \div \pi$	0.76 cd/m^2
	b. $L_{photopic}$ of walls = $(E_v \times \rho_{walls}) \div \pi$	0.25 cd/m^2
	c. $L_{photopic}$ of ceiling from 85% direct light $= 0.85 \times ((E_h \times \rho_{floor} \times \mathbf{0.8}) + (E_v \times \rho_{walls} \times (1-\mathbf{0.8}))) \times \rho_{ceiling} \div \pi$	0.36 cd/m^2
	d. $L_{photopic}$ of ceiling from 15% indirect light $= 0.15 \times ((E_h \div \mathbf{0.8}) \div \pi)$	0.36 cd/m^2
	e. $L_{photopic}$ total of ceiling = $L_{photopic}$ direct light+$L_{photopic}$ indirect light	0.72 cd/m^2
	f. $L_{photopic}$ of environment = Average contribution of $L_{photopic}$ identified in a, b, and e above.	
	$L_{photopic}$ of environment = $((2 \times L_{photopic}$ of floor$) + (2 \times L_{photopic}$ of ceiling$) + (1 \times L_{photopic}$ of walls$)) \div 5$	0.64 cd/m^2
5	**State of Adaptation**	
	Confirm luminance of environment puts observer in mesopic state of adaptation (≤3 cd/m2).	
6	**Mesopic Multipliers**	
	Determine multipliers to adjust recommended photopic illuminance target values for mesopic adaptation.	
	• 2000 K HPS illuminance criteria multiplier	1.07
	• 3000 K CMH illuminance criteria multiplier	0.95 (13% better than 2000 K HPS)
	• 4000 K CMH illuminance criteria multiplier	0.9 (19% better than 2000 K HPS)
7	**Recommended Mesopic Illuminance Criteria**	
	Adjusted recommended illuminance target based on lamp selection.	
	2000 K HPS (multiply photopic illuminance targets by 1.07)	• $E_{hmesopic}$ = 6.4 lx average, maintained • $E_{vmesopic}$ = 2.1 lx average, maintained
	3000 K CMH (multiply photopic illuminance targets by 0.95)	• $E_{hmesopic}$ = 5.7 lx average, maintained • $E_{vmesopic}$ = 1.9 lx average, maintained
	4000 K CMH (multiply photopic illuminance targets by 0.9)	• $E_{hmesopic}$ = 5.4 lx average, maintained • $E_{vmesopic}$ = 1.8 lx average, maintained

Reference and Rationale
See photometric report to determine percent direct lumens and indirect lumens for a potential luminaire.This is a "what-if" scenario to test a luminaire for consideration and determine if observers will be in a mesopic state of adaptation and, if so, the extent of light source spectral effects on final recommended illuminance criteria. Mesopic adaptation is typical in situations where illuminance is likely to be 10 lx or less, average, maintained.
Designer's discretion for recommendation to team and client based on Table 4.1 Category D, average maintained illuminance, visual ages of at least half the observers are 25 to 65 years old, low activity level, Z1 nighttime outdoor lighting zone.
Designer's discretion and typically ⅓ to ½E_h
Painting ceilings improves efficiency and uniformity. Periodic cleaning and repainting required.
Painting floors or using high-reflectance concrete improves efficiency. Periodic cleaning and repainting required.
Painting walls improves efficiency. Assuming here some walls are white and some are colored. Periodic cleaning and repainting required.
The **0.8** value is an assumed form factor, representing the amount of flux emitted by the respective surfaces (floor and walls in this case) that is likely to reach the ceiling. In relatively low-ceiling, wide spaces, form factors between floor and ceiling approach 1. See 10.4.2.1 Radiative Transfer for more information.
The **0.8** value is an assumed form factor. See 10.4.2.1 Radiative Transfer for more information.
Observer's binocular field of view can be defined for some relatively central location in a parking deck with the floor and ceiling subtending about 2 steradians of solid angle each and the walls subtending 1 steradian of solid angle for a total of 5 steradians.
Averaging photopic luminances by solid angles (in steradians) yields the photopic luminance value to be used in Figure 4.27.
See Table 2.1 | Vision Adaptation States.
Use the "$L_{photopic}$ of environment value" of 0.64 cd/m2 from Step 4 to determine multipliers from Figure 4.27.
Multiplier to adjust recommended photopic illuminance target value for mesopic adaptation for 2000 K HPS lamps with S/P of 0.60 for this specific example.
Multiplier to adjust recommended photopic illuminance target value for mesopic adaptation for 3000 K CMH lamps with S/P of 1.38 for this specific example.
Multiplier to adjust recommended photopic illuminance target value for mesopic adaptation for 4000 K CMH lamps with S/P of 1.81 for this specific example.
Recommended mesopic illuminance criteria if 2000 K HPS lamps with S/P of 0.60 are proposed for this specific example.
Recommended mesopic illuminance criteria if 3000 K CMH lamps with S/P of 1.38 are proposed for this specific example.
Recommended mesopic illuminance criteria if 4000 K CMH lamps with S/P of 1.81 are proposed for this specific example.

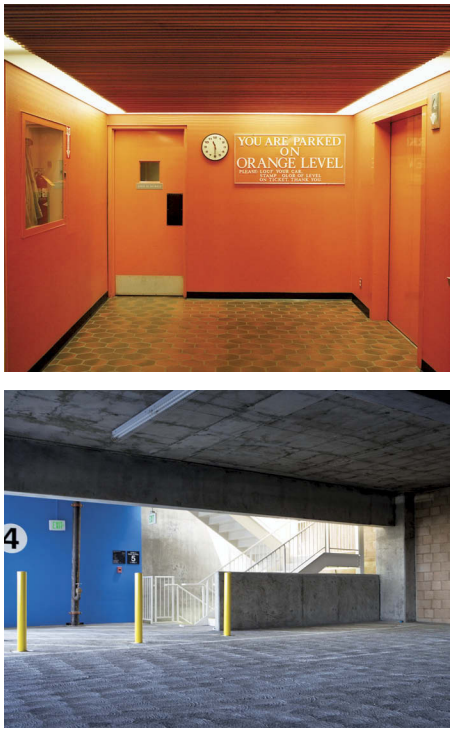

Figure 26.8 | Circulation Lobbies
Many times color is used for wayfinding. In the top image, walls are electrically lighted for accenting. If the elevator is open to the parking deck, the lighted and colorful walls would be visible for some distance.

Daylight is used in the bottom image to highlight the pedestrian exit area. Where daylight is also sufficient to meet illuminance in parking bay and drive aisles, electric lights are extinguished.

» Bottom Image ©CGIBackgrounds.com/Collection Mix:Subjects/Getty

26.2.5.2 Parking Deck Accenting Criteria

Accenting is used to visually lead users to important activity areas and will help with users' overall brightness perceptions. Some areas typically worthy of accenting include color coded markers at elevators or stairs, signage, and public art. The significance of the accent focal areas or points must be determined. Generally, annotate a plan with accenting opportunities or requirements and indicate visual hierarchies or priorities. Elevator and stair locations are usually of keen interest to users. These might be directly visible from the parking deck drive aisles and parking bays. Examples of vertical surface accenting of elevator and stair lobbies are shown in Figure 26.8. Lighting perimeter walls helps define the architectural boundaries, provides walking- and driving-distance references and can be used as wayfinding. See middle and bottom images in Figure 26.6 and see Figure 26.9. As noted in Table 26.2, accenting criteria can be derived from Table 15.2 | Accent Illuminance Ratios.

26.2.6 Parking Lots

A strategy similar to that for parking decks is appropriate to the lighting of parking lots:

- Define activities and tasks
- Define surface reflectances
- Define accenting
- Establish horizontal illuminance criteria, including uniformities
- Establish vertical illuminance criteria, including uniformities
- Establish accenting criteria

Defining the activities and tasks within the parking lot is necessary to develop a comprehensive lighting design addressing users' needs.

Controls contribute greatly to overall energy use and tune illuminances to activity levels and curfews. Automated astronomical time clock, photocell, and motion-sensor operation will help maintain a consistent and efficient operation. Instant-on and readily dimmed light sources can be used with these control techniques to ramp-up illuminances as needed during low-activity periods or after curfew.

The six step process outlined in 26.2.5.1 also applies to parking lots. Mesopic multipliers apply to parking lot situations, however, unlike parking decks, no ceiling luminance exists. "Wall" luminances might consist of the effects of actual walls, adjacent building surfaces, and landscaping.

Ordinances, codes, or sustainable guides may dictate luminaire backlight, uplight, and glare (BUG) ratings. This criteria must be addressed during selection of luminaires. See 8.2.1.5 IES Luminaire Classification System for Outdoor Luminaires and 8.2.1.6 Outdoor Environmental Classification. BUG ratings identify the extent of uplight, if any, allowed for lighting equipment used in specific nighttime outdoor lighting zones. Figures 26.10 and 26.11 illustrate the use of optically well-controlled luminaires.

Where parking lots and pedestrian ways abut, the parking lot lighting and the pedestrian way lighting may be achieved by a single system or multiple systems. In the top image of Figure 26.11 pedestrian post lights contribute to the lighting of the pedestrian way and the parking area in the near vicinity while shoebox luminaires (out of the photographic frame) also contribute to the lighting of the pedestrian way and the parking area in the vicinity of the pedestrian way. In situations where nighttime pedestrian activity is anticipated or encouraged on dedicated walkways throughout early evening, smaller-scale pedestrian postlights offer a human-scale approach unachievable with the ubiquitous and institutional shoebox-on-a-pole-everywhere. See Pedestrian Ways and Bike Ways below.

26.2.7 Pedestrian Malls

Lighting criteria for pedestrian malls are outlined under CENTERS, OUTDOOR in Table 34.2 | Retail Illuminance Recommendations. BUG ratings may be mandated and must be addressed during development of design techniques and selection of luminaires.

26.2.8 Pedestrian Stairs

Lighting criteria for pedestrian stairs are outlined under CENTERS, OUTDOOR in Table 34.2 | Retail Illuminance Recommendations. BUG ratings may be mandated and must be addressed during development of design techniques and selection of luminaires.

Accenting of walls or grade features, sculpture, or landscaping might be appropriate where stairs are part of a ceremonial area such as a plaza or civic, cultural, or corporate pedestrian way of significance and where nighttime activity is anticipated.

26.2.9 Pedestrian Ways and Bike Ways

Pedestrian and bike ways are considered outdoor applications. For covered or partially- or fully-enclosed pedestrian ways, the designer must determine if lighting for the area is better-designed for an outdoor condition or an indoor condition. Outdoor situations are addressed here. Indoor situations are considered circulation corridors.

Where lighting is deemed necessary for pedestrian or bike ways, the lighting depends on proximity to vehicular traffic, on activity level, and on nighttime outdoor lighting zone. A strategy similar to that for parking decks is appropriate to the lighting of parking lots:

- Define activities and tasks
- Define surface reflectances
- Define accenting, if deemed necessary
- Establish horizontal illuminance criteria, including uniformities
- Establish vertical illuminance criteria, including uniformities
- Establish accenting criteria, if accenting deemed necessary

Adjacency to vehicular traffic generally warrants greater horizontal and vertical illuminances on pedestrian and bike ways. Higher activity levels generally warrant greater horizontal and vertical illuminances. LZ3 and LZ4 lighting zones generally warrant greater horizontal and vertical illuminances. Accenting of walls or grade features, sculpture, or landscaping might be appropriate where a path is part of a ceremonial area such as a civic, cultural, or corporate campus of significance and where nighttime activity is anticipated. See tree accenting in Figure 26.1. A criteria example is shown in Table 12.7 | Pedestrian Way Mesopic Multiplier Example Worksheet.

Figures 26.12, 13, 14, and 15 illustrate several approaches to pedestrian way and bike way lighting. Where pedestrian activity is anticipated and encouraged and a more sociable setting is desired, attention to factors other than optical control and efficiency is also important. Luminaire scale, light intensity and distribution from the luminaires, color of light, styling and finishes of luminaires, and the lighting effects on and from adjacent buildings or landscaping must be considered, if not orchestrated, by the designer.

BUG ratings may be mandated and must be addressed during development of design techniques and selection of luminaires.

26.2.10 Plazas

Lighting criteria for pedestrian plazas are outlined under CENTERS, OUTDOOR/Plazas and Town Squares in Table 34.2 | Retail Illuminance Recommendations. BUG ratings may be mandated and must be addressed during development of design techniques and selection of luminaires.

Figure 26.9 | Perimeter Wall Lighting
Perimeter walls when made distinctly visible can help the user judge distance and identify location or position within the parking structure. These walls can also help guide users to pedestrian circulation paths. Here, the color of the lighted perimeter wall adds interest and further assists in defining location.

Figure 26.10 | Parking Lots
For many parking lot, top-of-parking-deck, and roadway situations where there is a need for large areas of contiguous lighting, shoebox (so named for their shallow rectilinear) or stylized shoebox luminaires on poles typically ranging from 15′ to 40′ in height are common. The best of these use well-controlled optics to direct the light downward and limit uplight and glare.

Optics and house-side shields can be used to limit spill light beyond the parking pavement. Optics and pole heights and spacings are responsible for meeting illuminance criteria, including horizontal and vertical uniformities.

Well-controlled optics should always be employed for best efficiencies and limited light trespass. Where BUG ratings are mandated, even more precise optical control and use of shields are employed. Strategic layout of luminaires is even more important to limit light spill at property lines. These techniques intentionally result in darker-appearing settings.

Lighting not warranted after curfew should be extinguished or placed on motion-sensor to be available as needed.

26.2.11 Pools, Outdoor

Lighting for outdoor pools is discussed in 28 | LIGHTING FOR HOSPITALITY AND ENTERTAINMENT. BUG ratings may be mandated and must be addressed during development of design techniques and selection of luminaires.

26.2.12 Residential Exteriors

Lighting for residential exteriors is discussed in 33 | LIGHTING FOR RESIDENCES. Luminaire shielding requirements and lumen limits may be mandated and must be addressed during development of design techniques and selection of luminaires.

26.2.13 Retailing, Outdoor

Lighting for outdoor retail is discussed in 34 | LIGHTING FOR RETAIL. BUG ratings may be mandated and must be addressed during development of design techniques and selection of luminaires.

26.2.14 Roadways

Establish the rationale for a need for roadway lighting. Where lighting is deemed necessary for roadways, check the bookstore at www.ies.org for updates on roadway lighting dated 2011 or later. If no updates are available, then document criteria based on IES RP-8-00 | Roadway Lighting. Alternatively, establish criteria based on Table 4.1 | Recommended Illuminance Targets using the process identified in Section 26.2.5 Parking Decks. At the designer's discretion, adjustments may be deemed appropriate to account for activity levels, nighttime outdoor lighting zones, and mesopic adaptation. Adjustments for mesopic adaptation should not be made to illuminances or luminances for roadways where the speed limit is greater than 25 mph. Age determination should be well-deliberated and based on anticipated use. All adjustments should be documented and the recommended criteria reviewed with the team and client. BUG ratings may be mandated and must be addressed during development of design techniques and selection of luminaires.

26.2.15 Roundabouts

Establish the rationale for a need for roundabout lighting. Where lighting is deemed necessary for roundabouts, check the bookstore at www.ies.org for updates on roadway lighting dated 2011 or later. If no updates are available, then document criteria based on IES DG-19 | Design Guide for Roundabout Lighting. Alternatively, establish criteria based on Table 4.1 | Recommended Illuminance Targets using the process identified in Section 26.2.5 Parking Decks. At the designer's discretion, adjustments may be deemed appropriate to account for activity levels, nighttime outdoor lighting zones, and mesopic adaptation. Adjustments for mesopic adaptation should not be made to illuminances or luminances for roadways where the speed limit is greater than 25 mph. Age determination should be well-deliberated and based on anticipated use. All adjustments should be documented and the recommended criteria reviewed with the team and client. BUG ratings may be mandated and must be addressed during development of design techniques and selection of luminaires.

26.2.16 Tunnels

Check the bookstore at www.ies.org for updates on roadway lighting dated 2011 or later. If no updates are available, then document criteria based on IES RP-22 | IESNA Recommended Practice for Tunnel Lighting. Alternatively, establish criteria based on Table 4.1 | Recommended Illuminance Targets using the process identified in Section 26.2.5 Parking Decks. At the designer's discretion, adjustments may be deemed appropriate to account for activity levels, nighttime outdoor lighting zones, and mesopic adaptation. Adjustments for mesopic adaptation should not be made to illuminances or luminances for tunnels where the speed limit is greater than 25 mph. Age determination should be

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.

well-deliberated and based on anticipated use. All adjustments should be documented and the recommended criteria reviewed with the team and client. Although BUG ratings may be mandated for the locale, tunnel applications will be inherently well-controlled when low-glare equipment is employed and illuminances and luminances appropriately adjusted for the activity level and nighttime outdoor lighting zone.

26.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various aspects outlined in Table 26.2.

26.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 26.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural, landscape, or civil engineering conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 26.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

26.3.2 Notes

Notes may refer to other application and task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

26.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of functional and accent lighting techniques is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice, will result in excess energy use and in many exterior

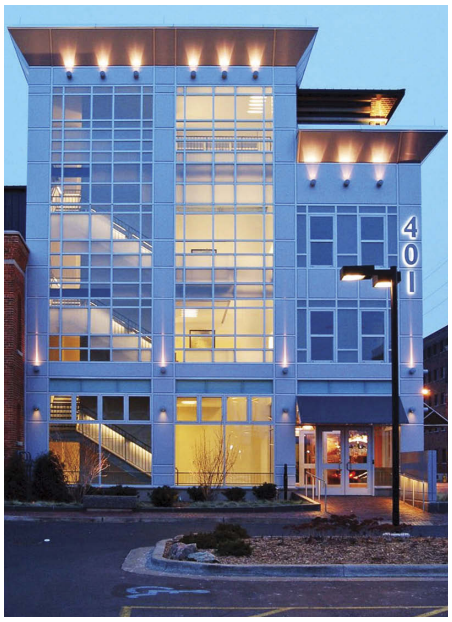

Figure 26.11 Parking Lots
The parking lots in top images are illuminated partly or entirely with 3000 K, 82 CRI 100W/CMH/ED17 shoebox luminaires shown in the bottom image. Luminaires near parking lot perimeters use house side shields. Coated lamps are used to soften harsh striations, shadows, and glare. Compliance with any BUG mandates must then be shown with coated-lamp photometry. E_h for the medium activity lot in the middle image is 20 lx average, maintained with 3:1 avg-to-min and 14:1 max-to-min ratios.

Figure 26.12 | Outdoor Direct Lighting for Pedestrian Ways
Where lighting is deemed necessary into the late night, if not all night, well-controlled luminaire optics directing light only downward may be most appropriate or mandated. If no other lighting is used or is permitted as part of the scene, then the effect is stark and dark appearing. In these situations, the desire to increase illuminances to overcome this effect is self-defeating as higher pavement illuminances and, therefore, luminances exacerbate the contrast with the dark surrounds and contribute to greater light pollution. Lighter-toned building surfaces and pavement can be helpful to a limit, but these, too, exacerbate contrast unless the designer adjusts illuminance criteria to lower values to account for these higher surface reflectances.
» Image ©Michael Mohr/PhotoAlto/Corbis

Figure 26.13 | Outdoor Indirect Lighting for Pedestrian Ways
Where pedestrian activity is encouraged through curfew at which point lighting can be extinguished or reduced and where more social interaction is expected, an indirect technique may be appropriate. The luminaire styling and lighting effect can contribute to the pedestrian experience and help define place. Even during the day, when extinguished, these modern decorative luminaires contribute to the architectural scene. Versions of these luminaires are available with dimensionally articulated reflective discs combined with well-controlled uplight optics to trap upward light from escaping beyond the reflective disc. See also Figure 15.10.
» Image ©Christian Kober/Robert Harding World Imagery/Corbis

Figure 26.14 | Outdoor Architectural Lighting for Pedestrian Ways
Here, uplighting an architectural canopy on the left and downlighting the architectural colonnade on the right illuminate the pedestrian way. The combined techniques must collectively address all criteria, including horizontal and vertical illuminances and uniformities and light trespass and light pollution. One scenario at curfew might extinguish the uplighting on the left, but retain the downlighting on the right. This would address designer-recommended and client-accepted post-curfew criteria where vertical illuminance is very low or non-existent. Alternatively, the width of the path itself is redefined to be a zone within 6' of the building facade on the right. The infrequent pedestrians could then choose to walk the lighted path.
» Image ©Jon Hicks/Corbis

Figure 26.15 | Outdoor Decorative and Architectural Lighting for Pedestrian Ways
Traditional decorative lanterns on postlights can exhibit optical control which, when combined with relatively low-wattage lamps, offer mostly downlight with some amount of general outward and upward glow intended to illuminate building and tree canopies in close proximity as may be desired in shopping districts with narrow streets or pedestrian malls. Depending on the luminaire style, optical control might involve use of internal refractors or louvered reflectors covering the lamps, lantern lenses with refractive designs, top reflectors, or some combination of these. Some varieties exhibit such well-controlled light patterns that the resulting lighting effects may appear inappropriate to the civic, cultural, or shopping pedestrian applications. Mockups, even if just of an operable lantern, or visits to sites of similar installations are appropriate.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

situations, will result in more significant glare, light pollution, and light trespass. Ratcheting illuminances is not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 26.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for facades, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other applications or tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on one or both planes of a task. A dash indicates no light or zero light is recommended for the task or application, such as facades after curfew in LZ1 settings.

26.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. In many exterior pedestrian applications, horizontal- and vertical-plane illuminances address the common situation where simultaneously walkway pavement visibility is related to horizontal illuminance while facial recognition is related to vertical illuminance.

Some illuminance targets, such as the pedestrian walkway pavement visibility and facial recognition are intended at differing planar elevations and must be deliberated and established by the designer. For criteria purposes, standing face height is defined by an imaginary vertical plane oriented perpendicular to the primary direction of travel and centered at 5’ above finished grade (AFG). Illuminance criteria are applied to both sides of this plane at consistent spacing increments along the length of the walkway. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. In pedestrian walkway situations, at least two vertical planes are of interest, both perpendicular to the direction of main travel on the path, one opposing the other. This is an important distinction for luminaire optical selection and orientation capabilities and for layout, calculations, and field measurements.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

26.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. The designer must coordinate with the design team and client to establish the age group of the intended observers. During deliberations, the designer and client should review precedents as well as implications of tentative criteria proposals on infrastructure, cost, and user performance. The aspects of observers' ages and illuminance targets should be resolved during programming with the client. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance.

26.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 26.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

26.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

26.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

26.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

26.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

26.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

26.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-switching, stepped-dimming, or continuous dimming to reduce or eliminate electric lighting when not needed during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

26.3.6 Veiling Reflections

Tasks with specular components, which in exterior settings include glossy metal, stone, or glass surfaces as might be found on facades, walls, or artworks and wet pavement, are prone to specular reflections. Where such reflections veil important task information, then these are known as veiling reflections. Diffuse-optic, low-wattage, and multiple luminaires can minimize the effects of veiling reflections, but not eliminate them. Diffuse-finish materials for walls, pavements, facades, and the like are helpful.

26.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the functional layout, such as that for a parking deck, but should be scrutinized by the design team. An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

26.4 Designing

Information provided here is specific to exteriors and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient tem-

perature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on those respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

27 | LIGHTING FOR HEALTH CARE

Vision is not enough, it must be combined with venture. It is not enough to stare up the steps, we must step up the stairs.

Vaclav Havel , Czech Author, Dissident, Playwright, and Politician

Contents

27.1 Project Type and Status. . . 27.2
27.2 Application Types 27.2
27.3 Illuminance Criteria 27.44
27.4 Designing. 27.49
27.5 References 27.50

As with many applications, lighting for health care facilities is about balancing the aesthetic aspects with the analytic aspects. Undoubtedly, life itself or even treatment of pain is worth glare and overlighting from the conscious patient's perspective as long as the caregivers can see to perform their magic accurately and quickly and repeat as needed. Application of light is sometimes less about patient comfort and more about caregiver performance. During recuperation or for diagnostics and treatments, lighting collaborates with interior planning and architecture to establish a comfortable backdrop to the angst and unpleasantries of consultations, procedures, waiting, and convalescing. This chapter outlines lighting criteria for health care facilities. Electric lighting accounts for about 42% of the electricity used in health care facilities (see Figure 27.1) [1]. Efficient lighting and its careful application are critically important. What follows is a discussion of the key aspects affecting lighting: project status; space types; activities; application-specific design goals, and illuminance criteria in health care facilities.

For complete design efforts, rely on and reference material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. The designer should have a thorough understanding of the design tenets outlined in those chapters, must identify those deemed appropriate and develop lighting goals and strategies accordingly. This chapter primarily addresses illuminance specifics related to health care facilities which should influence luminaire optical selections, lampings, and final layouts based on previously developed thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous and current IES related documents serve as archival and reference sources [2] [3].

Deliberate thought must be applied to the lighting problem and solution. Many times rote solutions are based on expedience of application, procurement, installation, or cost with little regard for the purpose at hand: create a healing environment for the patient. Venturing beyond these rote solutions can yield remarkable returns on the very minimal investment that lighting requires relative to the overall health care facility costs. For example, for the lighting of an exam table in an examination room, illuminance criteria are based on the need for caregivers' assessments of the patients' conditions. Architectural lighting for this examination task might be accomplished with one or two over-scaled 2'×4' ceiling recessed luminaires. Although this banal approach may well meet cleaning, cost, and ceiling integration expectations, it does not excuse an all-on/all-off switching arrangement or the cheapest, but most glary optical selection. The design should address patient needs of pre- and post-examination with reduced illuminances and of less harshness during full-on when viewed from the supine position on the exam table. Venturing from the conventional can contribute, in part, to more satisfied patients and caregivers, less aversion, however minutely, to examinations by patients, and ultimately more revenue. Specific details like these are not enumerated for applications and tasks and may only be obvious after careful thought of the medical procedure. This might help avoid misapplication of basic prismatic luminaires where outlines of glary lamps are visible from below or of so-called low-glare-

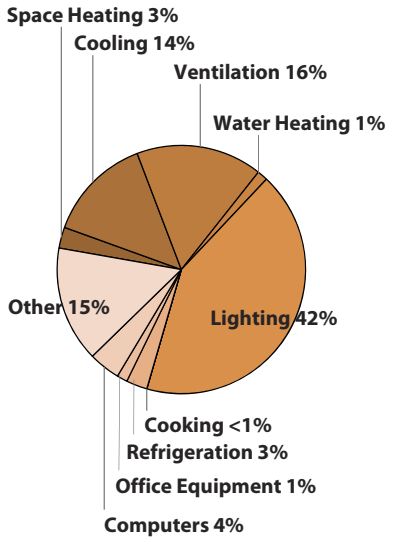

Figure 27.1 | Electricity Use of Health Care Buildings
Based on 2003 data from the US DOE's Energy Information Administration, lighting accounts for 42% of electricity use in health care buildings (electricity use for cooking rounds to 0%). These buildings themselves account for 7% of electricity use by all commercial and institutional buildings.

louvered luminaires where harsh bare lamps are visible from directly below. Table 27.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

27.1 Project Type and Status

An understanding of the project type and scope is necessary before commencing design work. This will establish the extent to which daylighting can address the lighting goals. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. For some applications and tasks, daylighting can be the primary light source. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

27.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the health care space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 27.2 | Health Care Facilities Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 27.2.

Unlike most other applications, highly specialized procedures, tasks, and applications are prevalent in health care facilities. These facilities may be community clinics, physicians' offices, infirmaries, for-profit imaging centers, and Level 1 Trauma Centers, to name a few. Each of these have unique power, lighting and control requirements. Beyond the aspects discussed in 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY, lighting must be coordinated with the electrical engineer's efforts to address normal, critical care, and life safety classifications.

Medical procedures, and consequently tasks and applications, change frequently and, in some instances, even become obsolete. Many procedures supported by analog devices and visual tasks have recently or are now converting to digital devices and visual tasks. Lighting requirements can be dramatically different. The designer must review the program for the specific facility in question and closely coordinate the design with the programmed tasks and review frequently and completely with the team and owner.

Health care projects are complex and costly. Lighting is one convenient target when budget shortfalls arise. So-called value engineering efforts which are typically cost-driven substitutions with lighting equipment that does not meet all of the project criteria will usually yield

insipid institutional settings of glary lighting, unaddressed accenting, one-level-control, and poor-quality hardware. Vigilance by the design team and owner is warranted.

Several general guidelines should be at the forefront throughout design. These are: color quality of light; germ and dust management; lighting controls; systems coordination; hazardous materials; medications; and medical equipment interference.

Color quality of light has direct affect on skin tones which, in turn, affects caregivers' assessments of patients' conditions and affects patients' self-esteem. All lamps should exhibit CRIs ≥82. In acute-care situations, lamps with CCT of 5000 K are also appropriate.

Germ and dust management is an ongoing effort in any health care facility. Luminaire finishes, lenses, and dust covers can assist. Antimicrobial finishes are available on many painted components. Most luminaires, even if made to be unlensed, are available with dust covers. Programming should identify these and other special requirements, such as wash-down after procedures, which influence luminaire UL and IP ratings.

With the exception of storage rooms and closets, most spaces in health care facilities are well-served by multi-level controls. In some instances, this helps convey an interest in the patient's well-being as caregivers toggle or dim lighting based on functional need or visual comfort. At the least, multi-level switching should be employed in patient clinical spaces. Access to lighting controls and where these should be located should be established during programming. Controls for patient courtesy lighting are readily available to the patient. Otherwise, controls are most convenient to staff. In some situations, such as mental health and secure patient areas, controls are purposely limited to staff access.

The demands made of all building systems in health care facilities are extremely high. Unlike many other applications where lighting layouts may well influence ductwork or even structural layouts, health care design is much less tolerant of such influence. Further, systems not found in other building types may affect lighting layouts and equipment selections. For example, in patient rooms where lift systems are employed to assist caregivers in transferring patients to and from beds, lighting is subservient to the lift track and mechanism. Advance programming and coordination is a necessity.

Hazardous and flammable materials are found in various methods of health care diagnoses and treatments. Where this material is stored, handled, and queued for disposal, lighting must accommodate the function and, if necessary, address stricter hardware safety requirements. The design team must research and establish which areas involve such hazards and address relevant codes and standards.

Medications are a key component of treatments. Wherever medications are stored, processed, and dispensed, lighting must address the reading, coding, and dosage tasks.

Review programming for any special electrical or mechanical requirements of the lighting equipment to avoid undesirable or even catastrophic interferences with medical equipment. In operating rooms lighting equipment must meet rigid electromagnetic interference (EMI) requirements. EMI potentially disrupts diagnostic and procedural equipment electronics. Determine which treatments and procedures are EMI-sensitive during programming. At this writing, specifying luminaires certified to MIL-STD-461F are one method of limiting the effects of EMI [4].

In some diagnostic and treatment spaces where radiation is involved, lighting equipment must be made of non-ferrous materials and operate on shielded direct current. The advent of LEDs and remote 12V and 24V drivers has improved longevity, efficiency, and optical selections. Special wiring requirements must also be followed. Medical technologies advance rapidly and requisite lighting effects and equipment parameters continually change. The designer must maintain familiarity with the most current project program and consult with the design team and medical equipment consultants and lighting equipment vendors to determine if and where lighting equipment with non-ferrous materials is required.

Notes for Table 27.2

The table column headings are discussed in detail in 27.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 27.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 27.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ↓ signals high likelihood; gray and white ↓ signals moderate likelihood; pale gray and white ↓ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. See Section 27.2.4 Ambulatory Care for additional information.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

l. Use lamps with CRIs ≥85.

m. Use lamps with CCTs of 5000 K and CRIs ≥85.

n. Control architectural lighting with dimmers to accommodate varied needs.

o. Provisions should be made for secure lighting equipment and controls.

p. Independently control lighting for use as necessary during procedures.

q. Use nightlights producing spectra at between 600 to 620 nm. See 12.4 Physiological Factors.

r. Some scanning equipment affects ferrous metals with potentially catastrophic results. See Section 27.2.36 Radiology for more information.

s. Make electrical provisions for portable work lights.

t. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 27.2

The table column headings are discussed in detail in 27.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 27.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 27.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ↓ signals high likelihood; gray and white ↓ signals moderate likelihood; pale gray and white ↓ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. See Section 27.2.4 Ambulatory Care for additional information.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

l. Use lamps with CRIs ≥85.

m. Use lamps with CCTs of 5000 K and CRIs ≥85.

n. Control architectural lighting with dimmers to accommodate varied needs.

o. Provisions should be made for secure lighting equipment and controls.

p. Independently control lighting for use as necessary during procedures.

q. Use nightlights producing spectra at between 600 to 620 nm. See 12.4 Physiological Factors.

r. Some scanning equipment affects ferrous metals with potentially catastrophic results. See Section 27.2.36 Radiology for more information.

s. Make electrical provisions for portable work lights.

t. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 27.2

The table column headings are discussed in detail in 27.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 27.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 27.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◥ signals high likelihood; gray and white ◥ signals moderate likelihood; pale gray and white ◥ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. See Section 27.2.4 Ambulatory Care for additional information.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

l. Use lamps with CRIs ≥85.

m. Use lamps with CCTs of 5000 K and CRIs ≥85.

n. Control architectural lighting with dimmers to accommodate varied needs.

o. Provisions should be made for secure lighting equipment and controls.

p. Independently control lighting for use as necessary during procedures.

q. Use nightlights producing spectra at between 600 to 620 nm. See 12.4 Physiological Factors.

r. Some scanning equipment affects ferrous metals with potentially catastrophic results. See Section 27.2.36 Radiology for more information.

s. Make electrical provisions for portable work lights.

t. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 27.2

The table column headings are discussed in detail in 27.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 27.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 27.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◥ signals high likelihood; gray and white ◥ signals moderate likelihood; pale gray and white ◥ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. See Section 27.2.4 Ambulatory Care for additional information.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

l. Use lamps with CRIs ≥85.

m. Use lamps with CCTs of 5000 K and CRIs ≥85.

n. Control architectural lighting with dimmers to accommodate varied needs.

o. Provisions should be made for secure lighting equipment and controls.

p. Independently control lighting for use as necessary during procedures.

q. Use nightlights producing spectra at between 600 to 620 nm. See 12.4 Physiological Factors.

r. Some scanning equipment affects ferrous metals with potentially catastrophic results. See Section 27.2.36 Radiology for more information.

s. Make electrical provisions for portable work lights.

t. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 27.2

The table column headings are discussed in detail in 27.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 27.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 27.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◥ signals high likelihood; gray and white ◥ signals moderate likelihood; pale gray and white ◥ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. See Section 27.2.4 Ambulatory Care for additional information.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

l. Use lamps with CRIs ≥85.

m. Use lamps with CCTs of 5000 K and CRIs ≥85.

n. Control architectural lighting with dimmers to accommodate varied needs.

o. Provisions should be made for secure lighting equipment and controls.

p. Independently control lighting for use as necessary during procedures.

q. Use nightlights producing spectra at between 600 to 620 nm. See 12.4 Physiological Factors.

r. Some scanning equipment affects ferrous metals with potentially catastrophic results. See Section 27.2.36 Radiology for more information.

s. Make electrical provisions for portable work lights.

t. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 27.2

The table column headings are discussed in detail in 27.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 27.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 27.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. See Section 27.2.4 Ambulatory Care for additional information.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

l. Use lamps with CRIs ≥85.

m. Use lamps with CCTs of 5000 K and CRIs ≥85.

n. Control architectural lighting with dimmers to accommodate varied needs.

o. Provisions should be made for secure lighting equipment and controls.

p. Independently control lighting for use as necessary during procedures.

q. Use nightlights producing spectra at between 600 to 620 nm. See 12.4 Physiological Factors.

r. Some scanning equipment affects ferrous metals with potentially catastrophic results. See Section 27.2.36 Radiology for more information.

s. Make electrical provisions for portable work lights.

t. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 27.2

The table column headings are discussed in detail in 27.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 27.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 27.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. See Section 27.2.4 Ambulatory Care for additional information.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

l. Use lamps with CRIs ≥85.

m. Use lamps with CCTs of 5000 K and CRIs ≥85.

n. Control architectural lighting with dimmers to accommodate varied needs.

o. Provisions should be made for secure lighting equipment and controls.

p. Independently control lighting for use as necessary during procedures.

q. Use nightlights producing spectra at between 600 to 620 nm. See 12.4 Physiological Factors.

r. Some scanning equipment affects ferrous metals with potentially catastrophic results. See Section 27.2.36 Radiology for more information.

s. Make electrical provisions for portable work lights.

t. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 27.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◥ signals high likelihood; gray and white ◥ signals moderate likelihood; pale gray and white ◥ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. See Section 27.2.4 Ambulatory Care for additional information.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

l. Use lamps with CRIs ≥85.

m. Use lamps with CCTs of 5000 K and CRIs ≥85.

n. Control architectural lighting with dimmers to accommodate varied needs.

o. Provisions should be made for secure lighting equipment and controls.

p. Independently control lighting for use as necessary during procedures.

q. Use nightlights producing spectra at between 600 to 620 nm. See 12.4 Physiological Factors.

r. Some scanning equipment affects ferrous metals with potentially catastrophic results. See Section 27.2.36 Radiology for more information.

s. Make electrical provisions for portable work lights.

t. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 27.2

The table column headings are discussed in detail in 27.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 27.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 27.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. See Section 27.2.4 Ambulatory Care for additional information.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Illuminance targets cited are for target area so noted and achieved with a minimum of 3-level control, if not dimming control, of architectural lighting.

l. Use lamps with CRIs ≥85.

m. Use lamps with CCTs of 5000 K and CRIs ≥85.

n. Control architectural lighting with dimmers to accommodate varied needs.

o. Provisions should be made for secure lighting equipment and controls.

p. Independently control lighting for use as necessary during procedures.

q. Use nightlights producing spectra at between 600 to 620 nm. See 12.4 Physiological Factors.

r. Some scanning equipment affects ferrous metals with potentially catastrophic results. See Section 27.2.36 Radiology for more information.

s. Make electrical provisions for portable work lights.

t. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Table 27.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

The following discussion is keyed to major application headings in Table 27.2. Couple this with topics in Table 27.1 for comprehensive qualitative and quantitative criteria.

Although many health care applications include dedicated waiting areas, all waiting areas are addressed in Table 27.2 at TRANSITION SPACES/Lobbies and Waiting Rooms.

27.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction and wayfinding. In health care facilities, accenting affects both the patient and caregiver experiences. Accenting contributes to a less intimidating and less institutional setting. Default accent lighting criteria are discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Also see 15.1.1.3 Accent Lighting.

Where situations arise that cost or power budgets preclude complete implementation of accenting, color contrast can be an effective alternative to luminance contrast. Here, where lighting power densities drive neutral and light-toned finishes, colorful finish accents to small areas of ceilings or walls are helpful. However, color contrast as accenting should be limited to small and bold applications in areas where vertical illuminances or ceiling lighting effects are moderate to high. Otherwise, the effect is lost.

Health care facilities may be heavily signed. Signage can be internally illuminated, frontal accented, or lighted by the general light in a space or area. The amount of signage, the hierarchies and priorities of if and how signage is illuminated, and placement, size, and inherent contrast must be part of the programming. Coordination with other team members, including signage or graphics consultants is necessary.

27.2.2 Activity Areas

Activity areas are common spaces where patients, and sometimes visitors, can partake in arts and crafts and games. The design team should take advantage of what might be the only areas of respite from the more institutional nature of diagnoses, treatments, and even convalescing. Programming of the activities is important to tune lighting by space or area to the tasks. Although age plays a role in determining illuminances, it is important to note that these sorts of tasks or activities are not pressured by high degrees of accuracy or speed.

27.2.3 Administration

Lighting for administrative areas is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The architectural scheme and task specifics vary based on the associated health care facility or campus and patient base. These details should affect the lighting design, from the kinds of lighting effects to lighting equipment styling to luminances and illuminances.

Administrative areas are typically consolidated into a single area, wing, or building. Several aspects may affect the degree to which the lighting design is sympathetic to or different from that of the other applications and tasks at the health care facility in question:

- Owner wishes and architectural desires
- Degree to which clientele or business prospects visit administrative operations
- View between administrative areas and health care areas
- Management style and immersion in health care functions

27.2.4 Ambulatory Care

Also called outpatient, ambulatory care is the department or building or buildings that accommodate patients generally not in need of admission to a hospital. Many outpatients are scheduled for diagnoses or treatments. An emergency department may be associated with ambulatory care. Nighttime illuminance targets for the porte cocheres are intended for application during dark hours of operation where lighting is deemed necessary or de-

sirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits.

To provide less intimidating settings for patients and more flexible viewing conditions for caregivers, many ambulatory care facilities should be fitted with multi-level switching, if not dimming, systems. Exam rooms can then be set to a pre- and post-exam setting where lighting is somewhat subdued and can be more conducive to consultation and interviewing tasks. Depending on room sizes and geometry, an ambient lighting system on 3-level switching or dimming might meet most all lighting needs in an exam room except the charting task at the charting station. Here, task lighting is typically employed which, when used during the pre- or post-exam setting provide a more visually interesting, less institutional setting. This switching or dimming arrangement has the added benefit of reduced energy use compared to all lights full-on at all times.

Coordinate with the medical equipment consultant to determine if additional task-specific portable or permanent surgical, treatment, or exam lighting solely dedicated to respective tasks is necessary. This equipment, also known as procedure luminaires, is usually specified by the medical equipment consultant. Otherwise, research prescriptive lighting requirements as these vary greatly and are based on type of procedure, visual requirements, and medical equipment vendors' recommendations. For example, manual clinical techniques with direct view may have very different requirements than robotic techniques with video view and both may need to be accommodated.

27.2.5 Anesthesia

Administering anesthesia and observing patients under anesthesia is a critical task. Confirm that the anesthetics involved are nonflammable, otherwise lighting and switching equipment rated for hazardous locations is necessary where this material is handled and stored. Consult the AHJ and the design team.

27.2.6 Atria and Courtyards

Lighting for atria and courtyards is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. In large health care facilities and campuses, atria and courtyards play an important role as areas of respite. Lighting should be consistent with the functions of these areas while enhancing their roles of spatial and visual relief. Figure 27.1 illustrates a lighting approach for a large atrium.

27.2.7 Auditoria

Lighting for auditoria is discussed in 24 | LIGHTING FOR EDUCATION.

27.2.8 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The lighting of building entries for health care facilities contributes significantly to the nighttime arrival sequence where clarity of destination is important. At the entry, vertical and horizontal illuminance are important to assist in pedestrian/vehicular interaction. Lamps with CRI ≥82 enhance skin tones and clothing and vehicle color. Lamps with CCTs ≤3500 K offer a more inviting and less institutional appearance than higher color temperature counterparts.

One variable affecting criteria is activity level during the nighttime hours. Another variable is the nighttime outdoor lighting zone. Nighttime activity levels may vary by type of facility, such as a standalone specialty clinic, urgent care clinic, or full service hospital. The nighttime outdoor lighting zone within which the facility is located or to which the team and client elect to design affects the illuminance criteria for outdoor tasks. Nighttime outdoor lighting zone designations vary by local ordinance, sustainability

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.

guides, or the team's own definition of place. These are discussed in 26 | LIGHTING FOR EXTERIORS. Also see Table 15.6 | Nighttime Operational Strategies for Improved Outdoor Environmental Regard. The kind of facility, schedule of operation, activity-levels, and nighttime outdoor lighting zones must be established in programming. Figure 27.2 illustrates lighting of an entry to a heart care center.

27.2.9 Chapel/Meditation

Lighting for places of worship and meditation is discussed in 37 | LIGHTING FOR WORSHIP. In health care facilities, worship spaces are typically nondenominational. If these are programmed for use by a variety of religious orders, then preset scene controls may be convenient, if not a necessity. Figure 37.2 illustrates a hospital meditation chapel.

27.2.10 Classrooms

Many full service hospitals are associated with universities and may have need for classrooms. Regardless, most larger health care facilities have need for periodic, if not frequent, training. The lighting of classrooms is addressed in 24 | LIGHTING FOR EDUCATION.

27.2.11 Consultation

Consultation with patients may occur in spaces dedicated to the tasks of consulting and interviewing or may occur in clinical spaces, such as exam or treatment rooms. Controls should be used to address the needs for varying illuminances. This reduces energy consumption and helps contributes to a more patient-oriented experience.

27.2.12 Conferencing

The lighting of conferencing facilities is addressed in 22 | LIGHTING FOR COMMON APPLICATIONS.

27.2.13 Corridors

Corridor illuminances are related to adjacent space types in order to minimize extreme transitions from one space to another. Where intensive clinical procedures are part of the application and therefore task illuminances are great and where there is a likelihood of frequent patient or staff circulation in and out of these spaces, such as might occur in a dental suite, corridor illuminance is relatively greater than that of non-clinical situations.

In applications where patients are confined to bed, corridor illuminances typically correspond to day and night cycles. This necessitates controls and task-oriented lighting approaches at work areas to minimize nighttime annoyance of patients while accommodating nursing duties.

Codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and the requirements and design of which must be coordinated amongst the design team.

27.2.14 Dental Suite

Architectural lighting must provide appropriate background illuminance for dental procedures, treatments, and surgery. To accommodate the needs of the caregiver and the direct view techniques common in dentistry, architectural lighting should establish a minimum condition of 3-level control or, preferably, dimming which can then be used in conjunction with an exam or procedure luminaire or headlight on the primary caregiver.

Color temperature and color rendering must be appropriate to the procedure. In exam, treatment, and surgical spaces and where procedures involve color matching, such as prosthodontics, lamps should exhibit 5000 K CCTs and CRIs ≥85. Matching color of artificial

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

versus natural teeth poses a great challenge, considering that the teeth will be seen under a variety of light sources. Daylighting is beneficial along with the 5000 K, 85+ CRI lamps.

27.2.15 Diagnostic Procedures

Some clinical situations involve minimally-invasive procedures or detailed surface or cavity examinations where highly-specialized articulated-arm exam or surgical luminaires (procedure luminaires) are used in addition to the architectural lighting. Most if not all of these procedure luminaires are specified by medical equipment consultants or supplied by the vendors providing the diagnostic and treatment equipment. Their type, such as ceiling-mount or portable, and the extent of their use depend on the procedure and the view techniques employed: direct view or video view. Procedure luminaire quantities and locations take priority. The architectural lighting must be planned accordingly and must provide appropriate background luminance and, consequently, illuminance. To accommodate the needs of the caregivers and the direct view and video view techniques, architectural lighting should be available incrementally through a minimum 3-level control or, for video view, preferably through dimming. Additional coordination and planning with medical procedure equipment providers and staff are recommended where video view techniques are involved so that the controls and illuminances available from architectural lighting are appropriately tailored.

Where procedure luminaires are used, appropriate luminance ratios between task and background are achieved with very high illuminances from procedure luminaires illuminating dark cavities or dark-toned areas exposed by incision versus relatively low to moderate illuminances from architectural lighting illuminating light-toned room surface finishes. These finishes are typically neutral to avoid any undesirable color shift in the available light.

Color temperature and color rendering must be appropriate to the procedure. In exam, treatment, and surgical spaces and where procedures involve color matching lamps should exhibit 5000 K CCTs and CRIs ≥85.

Where a neutral, nearly meditative environment is desired for diagnoses, such as that for electrocardiography, indirect lighting techniques are recommended for the general lighting.

Figure 27.1 | Atria
This daylighted atrium contains a lot of volume which can pose significant challenge to meeting illuminance criteria, lighting power densities, and overall spatial luminances. Three lighting approaches are used throughout the atrium: ambient, task, and accent.

Ambient lighting contributes much of the overall illuminance at floor level and is achieved primarily with indirect lighting techniques. Bulkheads are illuminated with 4″ diameter linear lensed tubular luminaires using lamps of 85 CRI and 3500 K CCT. Luminaires are cantilevered off the bulkhead about 8″ with optics oriented up and onto the bulkhead (see image above) ❶. Fluorescent cove lighting is used to light the ceilings at the circulation zones on each floor ❷. Fluorescent slot lights emphasize some art walls ❸.

Display cases and reception desk (not shown) exhibit internal task lighting.

39W/PAR20/CMH 30°-beam flood lamps fitted with 55° spread lenses and UV filters accent artwork ❸ and ❹.

Figure 27.2 | Entry and Porte Cochere
The arrival and departure sequence at this health care facility are similar: patients and visitors experience a relatively bright porte cochere achieved with indirect lighting techniques. In-grade uplights wash large planar surfaces of column and service enclosures. Where these enclosures are perpendicular to the traffic flow, ceiling-recessed slots engage the enclosures and continue across the traffic lanes. A pattern of shorter recessed slots define the arrival/departure lane. The ceiling slots are dimensional troughs with lensed lighting equipment recessed into the vertical planes facing away from incoming traffic. This creates an impression of a softly glowing trough with no visible hardware. This also avoids the unseemly appearance of uncleaned lenses at the ceiling plane.

The indirect lighting techniques meet horizontal and vertical illuminances appropriate for areas where pedestrians and vehicles must interact.

All lamps exhibit CCTs of 3000 K with CRIs ≥82 for a warm and calming effect where skin tones and clothing and vehicle colors are accurately identifiable. The in-grade uplights use 70 W T6 CMH lamps. Decorative postlights are lamped with 150 W T6 CMH lamps. Recessed ceiling troughs use fluorescent luminaires lamped with 32 W T8 lamps. Note the contrast between "standard" 4100 K metal halide used in vehicular circulation in the left background of the top image versus the CMH and fluorescent 3000 K in the patient and visitor exterior zones.

» Images ©Tim Griffith

27.2.16 Dialysis Centers

The patient experience is greatly enhanced if lighting is planned and controlled to accommodate specific tasks, but only as needed. For example, during the initial steps of treatment, the patient is connected to a hemodialysis machine. Illuminance must be sufficient, but only for the time necessary to allow for cleaning of the insertion points and to make the machine-to-patient connection quickly and accurately. During treatment, the patient might read, watch TV, or sleep and the lighting and controls should accommodate these various tasks.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

27.2.17 Ear, Nose, and Throat (ENT)

Architectural lighting for ENT clinics must accommodate the various test procedures, many of which involve backlighting, projected images, and lighting integral with the testing equipment. An inventory of these procedures and their use of light can be used to establish which rooms or suites require dimmable architectural lighting.

27.2.18 Food Service

Food service lighting is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

27.2.19 Gift Shop

Retail lighting is discussed in 34 | LIGHTING FOR RETAIL.

27.2.20 IT

Lighting for IT facilities is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

27.2.21 Intensive Care

The physical status of patients is of prime importance and lighting must address such tasks as examination, emergency procedures, observation, and comfort. However, patient well-being can also be accommodated with attention to controls, glare, and adjacent-area lighting. Controls should be used to incrementally add or subtract light for the respective tasks. For example, lighting for observation might be accomplished comfortably with a wall-mounted luminaire at the head wall exhibiting an indirect component separately switched from a direct component. Observation from a distance is made with just the indirect component energized. Close-up observation is made with both the indirect and direct components energized (as illustrated in Figure 27.3). The direct component may also provide reading and visitation light for conscious patients.

27.2.22 Laboratories

Laboratories are typically found throughout a health care facility. Some labs are dedicated to research while most are dedicated to diagnostics and treatments. Default illuminance criteria are cited in Table 27.2 under LABORATORIES for those labs not specifically identified as part of other health care applications.

Where lab benches are fitted with overhead storage or shelving, it is common and typically most efficient to place task lighting under the overheads. The control of these task lights must be deliberated to balance energy use versus function. Occupancy sensors, group switching or dimming, individual switching or dimming or some combination are all options. Space and lab bench layouts and lab task setups should influence the design of the controls.

27.2.23 Laundry

The laundry is typically a standalone department or building and is the central collection, cleaning, pressing, packaging, and distribution of linens. For purposes of maintenance convenience and where these spaces adjoin occupied areas, lamp types and color qualities should match those used elsewhere in the facility under design.

27.2.24 Library

Lighting for libraries is discussed in 29 | LIGHTING FOR LIBRARIES.

27.2.25 Linen

Linens are handled in soiled and cleaned condition throughout a facility or campus. For purposes of maintenance convenience and where these spaces adjoin occupied areas, lamp types and color qualities should match those used elsewhere in the facility under design.

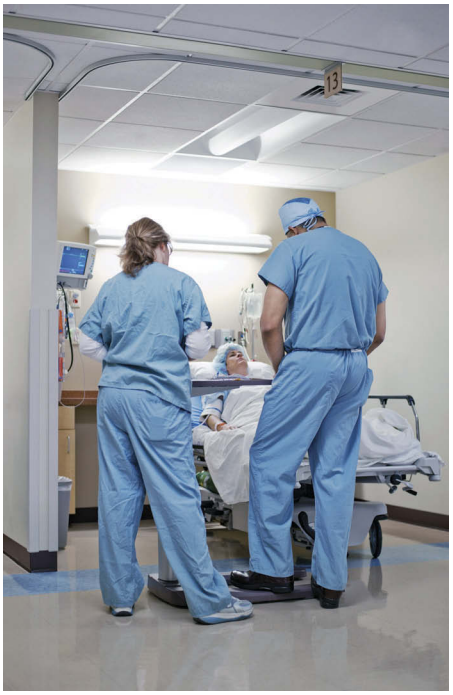

Figure 27.3 | Observation
Two luminaires with various switching or dimmer combinations provide sufficient illuminance and appropriate lighting effects for various tasks. Observation of the patient by caregivers can occur with the head wall luminaire in the direct, indirect, or combination mode. For conscious patients, the head wall luminaire offers indirect light for wakeful rest, direct light for reading, or combination for visitation, for example.

An overhead ceiling-recessed direct architecturally-dimensional luminaire is used here for examination. With variations on lamping, switching, or dimming, this arrangement can meet the needs for intensive care, patient rooms, and recovery. Depending on optical options and lamping, the direct architecturally-dimensional luminaire may be no less glary than conventional direct lensed luminaires when all lamps are energized. However, the architecturally-dimensional luminaires allow for multiple-lamp switching without obvious lamp streaking. Additionally, in the one- or two-lamp mode, the architecturally-dimensional versions are typically less glary than conventional lensed counterparts.

Antimicrobial finishes and dust covers are important for all luminaires used in these situations. This may limit choices on architecturally-dimensional luminaires.

27.2.26 Medication

Lighting where medications are dispensed and stored should facilitate timely and accurate assessment. Since color discrimination is important, lamps exhibiting CRIs ≥85 are recommended.

27.2.27 Morgue

Lighting in autopsy rooms is similar to that found in operating rooms in surgical suites. Illuminances from procedure luminaires, however, may be somewhat lower as speed and precision are not as urgent.

27.2.28 Nuclear Medicine

Lighting in procedure spaces must accommodate two distinct uses: 1) preparation and clean up; and 2) patient procedures. Lighting for patient procedures should be dimmable and provide a calming, no-glare condition. Where patients will likely spend time on their backs, viewing backlighted art or photomural panels are typically introduced on the ceiling as a calming technique. This is an effective approach in any diagnostic or treatment space where low illuminances are appropriate during the procedure. See Figure 27.4.

Lighting equipment in proximity to the medical equipment that produces radiation in nuclear medicine typically must be made of nonferrous components and operated on shielded direct current. Consult the project design program, the design team, and scanning equipment specifications to determine or confirm these and any other limitations affecting luminaires and lighting controls. LED luminaires and remote drivers are available that meet these requirements.

Control booths or areas are used frequently during diagnostics and treatment radiation. Lighting in the control booths should be independently dimmed from the lighting in the patient treatment room.

27.2.29 Nurses' Stations

Tasks at nurses' stations involve written and printed paperwork, computer screens, and conversation on a 24-hour, 7-day basis. If programming identifies other tasks or tasks which are not considered typical paper- and computer-based, see READING AND

Figure 27.4 | Single Photon Emission Computed Tomography (SPECT)
As a diversion and a calming technique, photomurals backlighted by LEDs are placed above the scanning bed in locations where patients have lines of sight during the procedures. Where ceiling plenum depth permits, deep regressed wells at the backlighted panels can further allude to a skylight effect.

With the advent of useful lumen and optical packages from LEDs, under cabinet task lighting, overhead preparation and clean up lighting, and dimmable downlighting can more conveniently meet strict requirements for lighting equipment in vicinity of medical radiation equipment.

WRITING in Table 22.2. At the actual task location, illuminance should be consistent day and night. This might best be achieved with task lighting integrated in the desk. Alternatively, a localized layout of ceiling-integrated equipment might meet the task lighting need, but the light distribution of such an approach should not create glare or annoying brightness at night that is disruptive to patients in nearby rooms. General circulation lighting in the vicinity of the station should cycle automatically from day (higher illuminance) to night (lower illuminance). This day-to-night transition is most dramatic in typical patient bed areas and less so in emergency and intensive care areas. In patient bed areas, patients are conscious and under periodic observation. The night cycle is an important aspect of normalcy. In emergency and intensive care areas, patients may be unconscious and are more likely to be under continual or frequent observation for life-changing if not life-threatening changes in condition. See Figure 27.5.

27.2.30 Obstetrics

Patients are likely to be in supine positions for long periods of time. Visual comfort is achieved with indirect or low-glare direct lighting with no visible lamping. Many facilities offer birthing suites where lighting is more home-like and typically achieved with wall sconces, coves, and wall slots or wallwashing techniques. Procedure lighting is disguised in ceiling recesses or even in lifts that deploy only when needed. Controls address the various situations. For example, localized lighting at a casual chair is switched independently for nighttime visitor use to limit patient disturbance. Labor rooms have evolved to less-harsh settings, but may retain the more obvious ceiling mounted articulated procedure luminaires.

27.2.31 Oncology

During preparation of the patient, lighting must accommodate intravenous therapy set up. However, during the treatment procedure, the patient should be made as comfortable as practical within the confines of the medical setting. Dimmable lighting is appropriate during treatment to accommodate a variety of patient tasks from reading to resting and sleeping as well as intermittent observation by the caregiver.

27.2.32 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIOR. Parking facilities are patients' and visitors' first and last experiences. Unlike parking at work or retail applications where frequent use yields reduced anxiety, health care facilities are used infrequently by many patients and visitors. Lighting should provide a relatively bright and uniformly lighted appearance with low glare to assist in comfortable navigation of the parking facilities. Painted ceilings and walls of LRVs of ≥65% greatly improve appearances and lighting system efficiencies.

27.2.33 Patient Services

Although a host of tasks are cited, the patient room is of great interest. The patient experience is enhanced if lighting is planned and controlled to accommodate various tasks in an efficient and comfortable manner. While strategically placed 2x4 luminaires alone over the bed could be lamped and switched to meet the various illuminance criteria in a patient room, such an approach is quite harsh, institutional, and simply dehumanizing.

Lighting for periodic examination and observation can be effectively delivered from overhead ceiling-recessed luminaires. For example, 2x2 or circular luminaires with deep regressed opal or microprismatic lenses exhibit a less intimidating scale and resemble the appearance of shallow skylights. At a minimum, these lights should exhibit 3-level switched control, but preferably are dimmed. This addresses varying degrees of examination and observation as caregivers determine necessary for the patient's condition. Ceiling-recessed luminaires may need to be arranged around a patient lift system which has an unforgiving location.

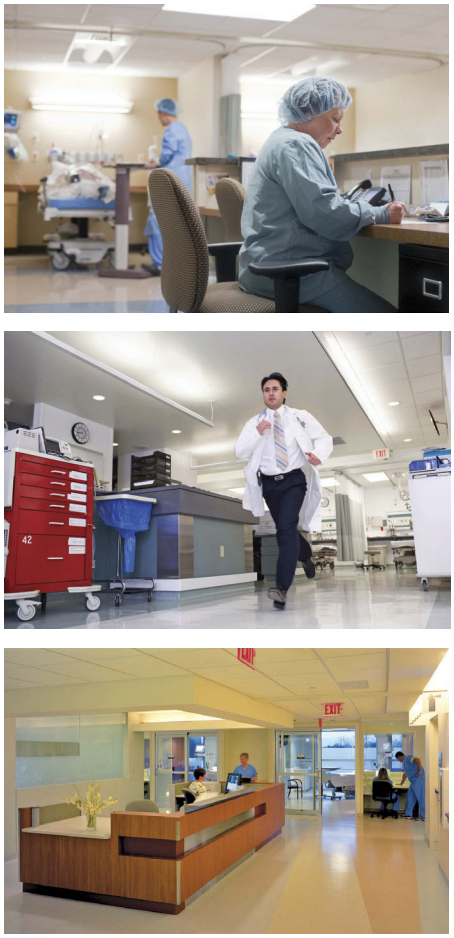

Figure 27.5 | Nurses' Stations
Lighting at and in the vicinity of the nurses' station depends on the care setting. The top two images illustrate situations where patients are under frequent observation and examination given the temporary severity of their conditions. General direct lighting illuminates the station in the top photo with no integral task lighting. In these situations, overhead lighting cannot be dimmed much, if at all, during nighttime operation without compromising illuminance criteria on the writing surface.

In the middle image, a linear indirect pendant luminaire provides some light to the nurses' station. The indirect lighting is less harsh than direct lighting. At night, this can be dimmed if task lighting is integrated into the nurses' station for charting.

In a nurses' station in a typical patient room corridor, bottom image, a cove at the nurses' station confines brightness to the station and can be dimmed at night if task lighting is integrated into the station.

Lighting for reading at beds may take a number of forms, though wall- and ceiling-mounted options are preferred from a cleaning and germ-control perspective. Wall-mounted luminaires can offer multiple levels of illumination for patient use. A downlight only setting provides light for reading. Uplight-only provides light for computer, personal digital assistant, smart phone, or electronic reader use, television viewing or music listening. The combination of downlight and uplight might be used during visitation or for more intensive reading and writing tasks. See Figure 27.3.

Care should be taken by the design team to make efforts to accommodate a sleep cycle with no light between caregiver status checks and medication cycles. Nightlights are appropriate to assist with circulation to the toilet during the night or to assist caregiver circulation. A strategically placed architecturally-integrated steplight or several can serve this function. To limit sleep disturbance these should be tied to occupancy sensors on timers or photocells. To best limit the disturbance to the circadian rhythm during the sleep cycle, long wavelength sources such as LEDs that produce spectra between 600 and 620 nm are appropriate. However, there should be no direct view of the source or optical media and illuminances should be very low.

Caregiver stations near the room entrance can be problematic as these are usually in the patient's line of sight. Overlighting or use of glary equipment will disturb the patient.

Controls must be well planned to avoid disturbing on-off-dimming sequences and to minimize overwhelming patient or caregiver. Patient access to various lighting scenes is typically achieved through the patient control pad used for bed adjustment and nurse calls. Door- or bed-side control stations are typically used for control of exam lighting, observation lighting, caregiver station lighting, and visitor lighting, though the options and number of control points should be limited to barest minimum.

27.2.34 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIOR.

27.2.35 Pharmacies

Lighting where medications are dispensed and stored should facilitate timely and accurate assessment. Since color discrimination is important, lamps exhibiting CRIs ≥85 are recommended.

27.2.36 Radiology

Lighting equipment in proximity to medical equipment that produces radiation must be made of nonferrous components. Consult the project design program, the design team, and scanning equipment specifications to determine or confirm these and any other limitations affecting luminaires and lighting controls.

Control booths or areas are used frequently during diagnostics and treatment radiation. Lighting in the control booths should be independently dimmed from the lighting in the patient treatment room.

Where patients will likely spend time on their backs or seated, backlighted art or photomural panels are typically introduced on the ceiling or walls as a calming technique.

27.2.37 Retail

Retail lighting is discussed in 34 | LIGHTING FOR RETAIL.

27.2.38 Shops

Industrial workshops are common in large health care facilities. These are lighted to address a myriad of electrical, mechanical, and woodworking repair, maintenance, and small construction projects.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

27.2.39 Spas

Lighting for spas is discussed in 28 | LIGHTING FOR HOSPITALITY AND ENTERTAINMENT.

27.2.40 Sterile Processing and Distribution (SPD)

Health care facilities maintain strict sterilization procedures involving the collection, sterilization, and distribution of instruments and devices used in medical procedures. Illuminance criteria are cited for the various tasks involved

27.2.41 Support Spaces

Many of these spaces are back-of-house and are self-explanatory. For purposes of maintenance convenience and where these spaces adjoin occupied areas, lamp types and color qualities should match those used elsewhere in the facility under design.

27.2.42 Surgical Suites

Lighting must accommodate efficient and precise work and is primarily about operating room (OR) staff visual needs rather than patient comfort. To accommodate varying viewing conditions in ORs for surgical staff, multi-level switching, if not dimming, is recommended. Dimming is best where surgeries are based on video view techniques. Color quality is critical in ORs and lamps with 5000 K CCT and CRI ≥85 are recommended for the all or the majority of the lamps. For minimally-invasive procedures, monitors are arranged for direct video-view of the procedure by surgeons. The video-view tasks are best accommodated by low-level general room lighting or background wall lighting. Some surgeons prefer this lower level background lighting to be generated with green (~550 nm) lamps. This can be accommodated if some lamps in multi-lamp luminaires are green and placed on independent control zones. The need for green lamps should be determined during the programming phase. Since many ORs must be flexible to accommodate a variety of surgical teams and the video-view procedures as well as the traditional direct-view procedures, dimming for the architectural lighting is appropriate. Coordinating the number of control zones for the architectural lighting to achieve flexible switching and dimming control and address normal power, emergency power, and battery backup circuiting must be done with the electrical engineer where the designer of the lighting is not the electrical engineer is necessary to properly specify the luminaires. See Figure 27.6.

OR ceilings are filled with equipment such as sensors, air diffusers, utility connections, fire-suppression devices, and surgical luminaires. Architectural lighting luminaires must be laid out in conjunction with this equipment and are typically 1x4 or 2x4 lensed varieties for efficiency of general light distribution and layout integration.

In addition to architecturally-integrated lighting, multiple surgical lights each typically capable of producing in excess of 25,000 lx are on booms and positioned on the ceiling to accommodate most any aiming situation and limit shadowing by the surgeons. LED surgical lights offer optional CCT selections to better accommodate surgeons' preferences. See Figure 27.6 middle image. Some include optional integral cameras. LEDs can reduce shadowing compared to halogen counterparts, and exhibit reduced radiant energy and beam temperature. Selection of surgical lights and their specification should be coordinated with, if not made by, the medical equipment consultant.

In recovery rooms or areas, lighting should provide for localized examination, observation, and patient rest. Independent controls or dimming are necessary to achieve the various illuminance criteria. Some attention to glare and optical control for the equipment is in order for patient comfort.

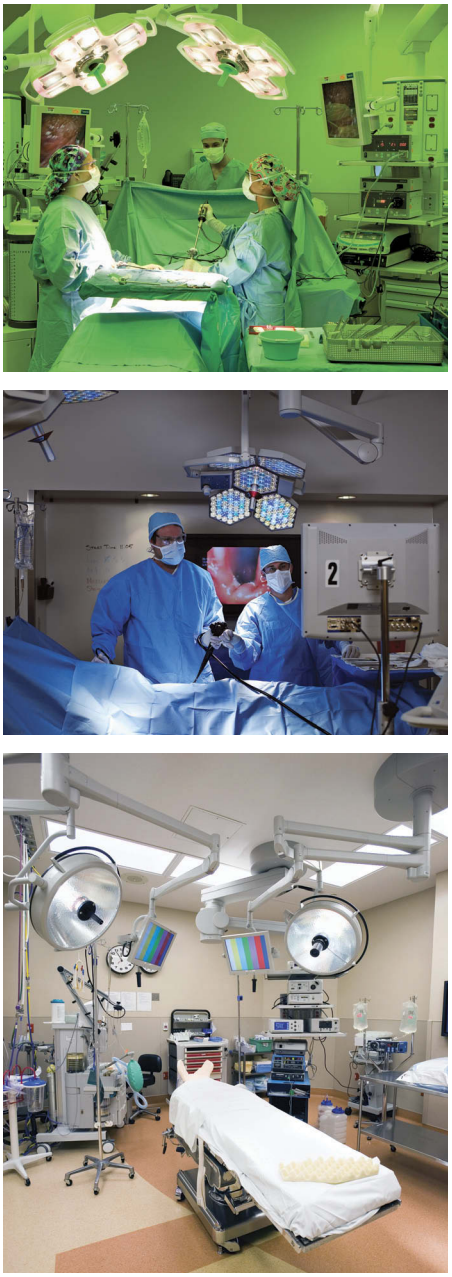

Figure 27.6 | Operating Rooms
Video-view is common for minimally-invasive surgery. Top image illustrates low-level green (~550 nm) background lighting. For direct-view surgery, all lamps, the majority of which are white-light, are energized in the architectural lighting equipment (not in view).

In the middle image, video-view is accommodated with low-level background white light. Here the surgical luminaires are LED.

In the bottom image, all lighting is energized for traditional direct-view surgery.

Figure 27.7 | Lounges
Ambient lighting techniques of downlighting and cove lighting are used to provide general background illuminances. The luminances introduced from the cove help make the area feel bright.

Accenting artwork (far left background) and drinking fountain and phone niches (to the left) provide light at those functions and introduce peripheral luminances that contribute to senses of preference and relaxation (see Table 12.2 | Subjective Impressions).

» Image www.jmaconochie.com

27.2.43 Therapy

Lighting for therapy tasks must allow caregivers to assess patients' conditions and progress. Vertical illuminances at face height are important and take priority over patient visual comfort. Although not a requirement, lamp CRIs ≥85 will enhance patient self-esteem.

27.2.44 Toilets/Locker Rooms

Lighting for toilets and locker rooms needs to meet the functional requirements of illuminance criteria outlined in Table 27.2. Addressing the plumbing fixture will provide sufficient light where needed without overlighting the entire toilet room. Vanities are most problematic when little or no vertical illuminance is designed to light an imaginary facial plane (roughly a zone of sufficient size to encompass faces) in front of the mirror.

Vertical illuminance over the faces of lockers will assist with locker use.

27.2.45 Transition Spaces

Most of these spaces are self-explanatory, but several deserve discussion. Freight and visitor/staff passenger elevators are illuminated for basic utility. Patient elevators involving the transfer of patients from horizontal circulation to vertical circulation mode with IVs, monitors, and possible other tethered equipment are illuminated for basic observation by caregivers during the transfer-transportation process. Since patients are likely face-up on gurneys, attention to visual comfort is warranted.

Lobbies and waiting rooms should be lighted to general background levels for circulation and conversational seating. Where reading or reception or security screening are programmed, these should be illuminated accordingly.

Lounges should be lighted to levels and effects evoking living room or family room settings and conducive to conversation, television viewing, analog or digital games, and reading as programming requires. See Figure 27.7.

Stairs are lighted based on anticipated activity levels.

Codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and the requirements and design of which must be coordinated amongst the design team.

27.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 27.2.

27.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 27.2 and may warrant different illuminance criteria. This is especially likely in health care situations where technologies, diagnoses, and treatments are constantly updated, if not reinvented. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 27.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. An additional resource in health care situations are the vendors of the medical equipment who typically have experience with their product in various settings and may be familiar, if not specific, with lighting criteria. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

27.3.2 Notes

The notes in Table 27.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

27.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 27.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the horizontal plane for needle insertion during dialysis treatment, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

27.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. In some applications, like oral surgery chair situations, horizontal- and vertical-plane illuminances address a variety of patient chair positions and caregiver viewing positions with architectural lighting to set the background against which the articulated surgery luminaire illuminates the oral cavity.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." For example, for DIAGNOSTIC PROCEDURES/Electroencephalography/Physician's Reading/Electronic Monitor, horizontal illuminances apply to the work surface plane at 2' 6" AFF while vertical illuminances apply to the screen monitor plane at 3' 6" AFF. This accommodates some degree of notetaking and reading while also analyzing the digital image. Although the nature of architectural lighting in many of these situations is such that the target illuminance will coincidentally be met on work surface elevations of 3' or 3' 6" for tall sit-down benches or stand-up benches respectively and on computer screens at 4' AFF or 4' 6" respectively, the designer may elect to set the criteria elevation for a specific condition as design plans might outline. Establishing and tracking task orientations and elevations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation. For example, in a lounge at a game table (ACTIVITY AREAS/Games/Analog Games/Competitive table games) the number and orientation of vertical planar points assessed depends on the size of the table involved or the area of multiple tables, and likely number of players. For most such situations, a universal layout is appropriate and, therefore, at least four vertical planes are of interest. One in each of the four cardinal directions of the plan over the intended area of game tables.

27.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. It may be determined that illuminance criteria for an age group other than that representing the majority of the intended observers is appropriate. However, this may result in overlighting, underlighting, harsh lighting, visual displeasure, or visual discomfort for many of the observers. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance. In health care situations, it is important to carefully assign tasks to observers and then establish visual ages. For example, in a patient room, examination

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

lighting is for the visual benefit of the caregivers. As such, the visual ages of more than half the caregivers likely to use the examination lighting must be established. However, the reading and television viewing lighting is for the visual benefit of the patient. As such, the visual ages of more than half the patients likely to use the reading and television lighting must be established. For some projects, it may be straightforward to determine patients' ages. On other projects, this may be impractical or impossible. The designer must then consider the implications of selecting the wrong age group.

27.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 27.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

27.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

27.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

27.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

27.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

27.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

27.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

27.3.6 Veiling Reflections

Tasks with specular components, such as some video game consoles and display monitors, which may be in different planes, are prone to veiling reflections. The likelihood of particular applications/tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of daylight with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks can be effective.

27.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Tasks and Applications and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 27.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications/tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 27.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

27.4 Designing

Information provided here is specific to health care facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production, circulation, and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

28 | LIGHTING FOR HOSPITALITY AND ENTERTAINMENT

A room is like a stage. If you see it without lighting, it can be the coldest place in the world.
Paul Lynde, 20th Century American Actor

Contents

28.1 Project Type and Status. . . . 28.2
28.2 Application Types 28.2
28.3 Illuminance Criteria 28.28
28.4 Designing. 28.32
28.5 References 28.33

Lighting in most any application is as much about the aesthetic as it is about the analytic. In hospitality and entertainment facilities, the aesthetic is the priority. Although consequences of analytic failure are great, the aesthetics of lighting equipment and lighting effects should remain at the forefront. This chapter outlines lighting criteria for casinos, exhibition halls, fitness centers, hotels, restaurants, spas, and theaters. Electric lighting accounts for about 36% of the electricity used in the food service and lodging industries (see Figure 28.1) [1]. Efficient lighting and its careful application are, therefore, critically important. What follows is a discussion of the key aspects affecting lighting: project status; space types; activities; application-specific design goals, and illuminance criteria in hospitality and entertainment facilities.

For complete design efforts, there must be significant reliance on and reference to material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. The designer should have a thorough understanding of the design tenets outlined in those chapters, must identify those deemed appropriate and develop lighting goals and strategies accordingly. This chapter primarily addresses illuminance specifics related to hospitality and entertainment facilities which should influence luminaire optical selections, lampings, and final layouts based on previously developed thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous and current IES related documents serve as archival and reference sources [2] [3].

Deliberate thought must be applied to the lighting problem and solution. For example, for the informal meeting area in a hotel business center, illuminance criteria are based on common social activity and viewing of large or high-contrast tasks. Average-to-minimum (avg:min) uniformity is 2-to-1 (2:1) and the illuminance is intended to be average over the designated informal meeting room or area. Although the vertical illuminance criteria, intended for application at seated face height, might be accomplished with two over-scaled 2'×4' ceiling recessed luminaires, that solution would make for an awkward and sterile institutional setting, let alone a viable hospitality setting. Here, a series of narrow, discrete, linear ceiling recessed luminaires and an art accent for a modern design or a decorative, yet efficient and functional pendant luminaire plus some art accents or sconces or wallwashing of one or two walls for a traditional design are worthy. Such aesthetic integration with the space type and functions can contribute, in part, to increased use, repeat business, and ultimately more revenue. Specific details like these are not enumerated for applications and tasks. Table 28.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

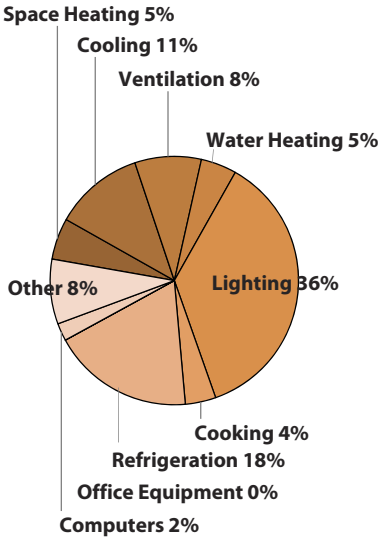

Figure 28.1 | Electricity Use of Food Service and Lodging Buildings
Based on 2003 data from the US DOE's Energy Information Administration, lighting accounts for 36% of electricity use in food service and lodging buildings (electricity use for Office Equipment rounds to 0%). These buildings themselves account for 13% of electricity use by all commercial and institutional buildings.

12.5.1 Visual Tasks
Table 12.3 | Sample Visual Task Survey

28.1 Project Type and Status

An understanding of the project type and scope is necessary before commencing design work. This will establish the extent to which daylighting can address the lighting goals. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. For some applications and tasks, daylighting can be the primary light source. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

28.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the hospitality and entertainment space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 28.2 | Hospitality and Entertainment Facilities Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 28.2.

The following discussion is keyed to major application headings in Table 28.2. Couple this with topics in Table 28.1 for comprehensive qualitative and quantitative criteria.

28.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction and wayfinding. Default accent lighting criteria are discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Also see 15.1.1.3 Accent Lighting.

Unlike many other applications, hospitality and entertainment facilities may be heavily signed. Signage can be internally illuminated, accented, or lighted by the general light in a space or area. The amount of signage, the hiearchies and priorities of if and how signage is illuminated, and placement, size, and inherent contrast must be part of the programming. Coordination with signage or graphics consultants and other team members is necessary.

28.2.2 Administration

Lighting for administrative areas is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The architectural scheme and even task specifics will vary based on the associated hospitality or entertainment facility and clientele. These details should affect the lighting design, from the kinds of lighting effects to lighting equipment styling to luminances and illuminances.

The administrative areas are typically consolidated in a hospitality or entertainment facility or campus into a single area, wing, or building. Several aspects may affect the degree to which the lighting design in the administrative area is sympathetic to or different from that of the other applications and tasks at the hospitality or entertainment facility in question:

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

- Client wishes and architectural desires
- Degree to which clientele or business prospects visit administrative operations
- View between administrative areas and hospitality or entertainment areas
- Management style and immersion in hospitality or entertainment functions

28.2.3 Ballrooms

Ballrooms are typified by their size and flexibility in use. Ballrooms are typically configurable from one very large space to multiple smaller spaces. Lighting and controls must be laid out to address the various sizes and configurations. Functions are quite varied even within designations dining, exhibition, demonstration, and presentations. This usually requires design of a controls system that may demand operators instructed in the use of the system. Additionally, in smaller meeting room setups it may be necessary to have simplified controls accessible to participants to accommodate AV presentations and overhead projection without the need for professional staffing.

Challenges include lighting system efficiency given high ceilings and large space volumes. Light-finish ceiling and wall surfaces are important. Provisions for entertainment lighting are usually required. Some ballroom designs include sound and light locks where lighting should be designed to manage the luminance change from a darkened ballroom to the adjacent prefunction space. See Figure 24.2 | Sound and Light Lock. If no sound and light locks are employed, then the adjacent prefunction and circulation areas should be designed to limit brightness distractions. This may involve linking the lighting in the prefunction and circulation areas with ballroom lighting controls so that lighting tracks ballroom presets.

Figure 28.2 illustrates a typical ballroom setup and identifies the architectural lighting to support that and other setups.

Figure 28.2 | Ballrooms
This ballroom can be reconfigured into as many as five smaller ballrooms or meeting rooms. Lighting layouts and control zoning and the controls are arranged to accommodate the variations. A combination of cove lighting (not energized here), chandeliers, and recessed downlights (not energized here) are employed. The coves use dimmable long compact fluorescent lamps, the chandeliers use nondim CFLs, and the downlights and accents use halogenIR_{120V}. The chandeliers use two zones of control for 2-level lighting. Lamp CCT is 3000 K and CRI is ≥82 and the chandelier lenses are color-tuned to achieve the look of a filament-lamp glow. Stage lighting rigging and instruments are in place for entertainment lighting at this dinner banquet.
» Image ©Kevin Beswick, www.ppt-photographics.com

28.2.4 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The lighting of building entries for hospitality and entertainment facilities contributes significantly to the nighttime arrival sequence. Hospitality and entertainment destinations are often intended as social occasions (breaks, getaways, or celebrations) or as business occasions (retreats or advances, learning, and fraternizing). All of this involves a sense of anticipation and desire. The entry architecture and lighting can further these sentiments and popularize places as highly desirable or even necessary destinations. See Figure 28.3.

One variable is activity level during the nighttime hours. Another variable demanding attention prior to establishing illuminance criteria is the nighttime outdoor lighting zone. Nighttime activity levels may vary by type of facility, such as hotel, restaurant, or theater. The hotel is likely to have low-to-medium steady activity over some period of time, but if ballroom and meeting facilities are involved, then short bursts of high activity are likely. Activity at theaters is typified by the number of screens in film theaters and the timing of performances in stage theaters. Multi-screen film theaters may exhibit medium to high activity over multiple half-hour periods. Stage theaters typically exhibit medium to high activity over single half-hour period pre-show and again post-show. All of this may demand a control system capable of addressing various settings on various evenings through manual intervention, automated time clock, and photocell functions. These and other aspects of schedule, activity-levels, and nighttime outdoor lighting zones must be established in programming.

The nighttime outdoor lighting zone within which the facility is located or to which the team and client elect to design affects the illuminance criteria for outdoor tasks. Nighttime outdoor lighting zone designations vary by local ordinance, sustainability guides, or the team's own definition of place. These are discussed in 26 | LIGHTING FOR EXTERIORS. Also see Table 15.6 | Nighttime Operational Strategies for Improved Outdoor Environmental Regard.

Notes for Table 28.2

The table column headings are discussed in detail in 28.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 28.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 28.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 28.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ☁ signals high likelihood; gray and white ☁ signals moderate likelihood; pale gray and white ☁ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. "High Light Setting" typically employed where exhibit displays have little or no internal lighting and where no theatrical rigging is used. "Low Light Setting" typically employed where exhibit displays have significant internal lighting or where theatrical rigging and instruments are used. "Low Light Setting" used for set-up, tear-down, and cleanup.

j. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

k. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

l. Make half the illuminance available from lamps exhibiting CCTs of 5000 K or 6500 K and CRI ≥85 and half from lamps exhibiting CCTs of 2700 K or 3000 K and CRI ≥85. Provide three control settings: for one CCT; for the other CCT; and for both CCTs to be energized for maximum viewing flexibility.

Notes for Table 28.2

The table column headings are discussed in detail in 28.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 28.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 28.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 28.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ↑ signals high likelihood; gray and white ↑ signals moderate likelihood; pale gray and white ↑ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. "High Light Setting" typically employed where exhibit displays have little or no internal lighting and where no theatrical rigging is used. "Low Light Setting" typically employed where exhibit displays have significant internal lighting or where theatrical rigging and instruments are used. "Low Light Setting" used for set-up, tear-down, and cleanup.

j. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

k. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

l. Make half the illuminance available from lamps exhibiting CCTs of 5000 K or 6500 K and CRI ≥85 and half from lamps exhibiting CCTs of 2700 K or 3000 K and CRI ≥85. Provide three control settings: for one CCT; for the other CCT; and for both CCTs to be energized for maximum viewing flexibility.

Notes for Table 28.2

The table column headings are discussed in detail in 28.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 28.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 28.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 28.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ↕ signals high likelihood; gray and white ↕ signals moderate likelihood; pale gray and white ↕ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. "High Light Setting" typically employed where exhibit displays have little or no internal lighting and where no theatrical rigging is used. "Low Light Setting" typically employed where exhibit displays have significant internal lighting or where theatrical rigging and instruments are used. "Low Light Setting" used for set-up, tear-down, and cleanup.

j. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

k. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

l. Make half the illuminance available from lamps exhibiting CCTs of 5000 K or 6500 K and CRI ≥85 and half from lamps exhibiting CCTs of 2700 K or 3000 K and CRI ≥85. Provide three control settings: for one CCT; for the other CCT; and for both CCTs to be energized for maximum viewing flexibility.

Notes for Table 28.2

The table column headings are discussed in detail in 28.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 28.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 28.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 28.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. "High Light Setting" typically employed where exhibit displays have little or no internal lighting and where no theatrical rigging is used. "Low Light Setting" typically employed where exhibit displays have significant internal lighting or where theatrical rigging and instruments are used. "Low Light Setting" used for set-up, tear-down, and cleanup.

j. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 28.2

The table column headings are discussed in detail in 28.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 28.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 28.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 28.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. "High Light Setting" typically employed where exhibit displays have little or no internal lighting and where no theatrical rigging is used. "Low Light Setting" typically employed where exhibit displays have significant internal lighting or where theatrical rigging and instruments are used. "Low Light Setting" used for set-up, tear-down, and cleanup.

j. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

k. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

l. Make half the illuminance available from lamps exhibiting CCTs of 5000 K or 6500 K and CRI ≥85 and half from lamps exhibiting CCTs of 2700 K or 3000 K and CRI ≥85. Provide three control settings: for one CCT; for the other CCT; and for both CCTs to be energized for maximum viewing flexibility.

Notes for Table 28.2

The table column headings are discussed in detail in 28.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 28.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 28.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 28.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. "High Light Setting" typically employed where exhibit displays have little or no internal lighting and where no theatrical rigging is used. "Low Light Setting" typically employed where exhibit displays have significant internal lighting or where theatrical rigging and instruments are used. "Low Light Setting" used for set-up, tear-down, and cleanup.

j. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

k. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

l. Make half the illuminance available from lamps exhibiting CCTs of 5000 K or 6500 K and CRI ≥85 and half from lamps exhibiting CCTs of 2700 K or 3000 K and CRI ≥85. Provide three control settings: for one CCT; for the other CCT; and for both CCTs to be energized for maximum viewing flexibility.

Figure 28.3 | Entries as Arrivals
The porte cochere on this 21-story urban hotel provides a unique and visually exciting arrival. The 1 W-blue-LED-lamped porte cochere acrylic cylinders and 3 W-6500 K-LED-lamped 10°-beam downlights ❶ integrated into the structure meet the illuminance recommendations for BUILDING ENTRIES/Porte Cocheres/High Activity/LZ4 in Table 22.2.

Various lighting effects are used to figuratively and literally lead people into the foyer and registration lobby. The criteria outlined in Table 28.2 under TRANSITION SPACES/Accents/Significant Focal Point were used on the interior feature wall ❷. This is lighted with a continuous wall slot lamped with 39W/PAR20/CMH 10°-beam spot lamps fitted with linear spread lenses to generate strong luminance for visual attraction. Lamp CCT is 3000 K and CRI is ≥82, a further contrast to the exterior porte cochere contributing to dimensional distinction and visual attraction.

28.2.5 Business Centers

Although business centers are a utilitarian amenity in hospitality facilities, their lighting can help distinguish these from uninspired back-room spaces. Every public space in a hospitality or entertainment facility contributes to the clientele's experience and overall satisfaction.

28.2.6 Conferencing

The lighting of conferencing facilities is addressed in 22 | LIGHTING FOR COMMON APPLICATIONS. In hospitality and entertainment facilities, conference spaces are most likely to be used by uninitiated clientele. Here, simple preset controls are best with two to four scenes and clearly marked keypad buttons (for example, MEET, AV, VIDEOCON, and OFF). If daylight control is necessary for any of these scenes, this too is automated with the lighting presets for convenience. A photocell may be interfaced with the preset lighting control system for optimal viewing conditions and energy savings. However, this may warrant introduction of a daylight control override which itself is likely to cause operator confusion. These are details to address with the client during programming and design.

Similar to situations involving ballrooms with no sound and light locks, the prefunction or circulation areas adjacent to conference centers may require close design scrutiny to avoid annoying distracting brightnesses as meeting attendees come and go. Lighting in adjacent circulation or prefunction areas can be tied into conference room presets. Alternatively, lighting effects and strategic location of low-reflectance surface finishes in adjacent circulation areas can limit visual distraction as conference room doors open and close.

28.2.7 Control Booths

Control booths are used wherever sound or light control or both are required from an isolated space with visual connection to the space under control. These may be used in auditoria, ballrooms, exhibit halls, and theaters. Control booths are also used in radio and broadcast studios. Programming must determine if the booth needs to be darkened and inconspicuous or if it is to be a part of the space under control where two-way viewing and observation is desirable. Where a dark booth is necessary during performances, steplights might be used to illuminate the floor with very discrete, optically well-controlled,

Table 28.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

and dimmable task lighting illuminating control boards and notes. If programming determines that the control board devices and readouts are backlighted and if notes are displayed on computer, then only floor illuminance is needed during performances. Significant illuminances may be necessary for cleanup and for set-up and tear-down, depending on the permanence of the equipment in the booth. Figure 28.4 illustrates a typical control booth location as seen from the house.

28.2.8 Exhibit Halls

Convention centers and some hotels have exhibit halls of varying sizes. These multipurpose facilities, depending on their size and geographic locale may temporarily house training sessions, trade shows, religious gatherings, vehicular and sports shows, and large corporate and union functions. The normal power architectural lighting system typically accommodates set-up, tear-down, and some amount or all of the functional requirements of some of these various events. Luminaires are typically controlled in small groups to allow for efficient operation of incrementally smaller or larger events or permit some degree of tuning of light levels to types of displays. However, considerable electrical and structural infrastructure is necessary for theatrical rigging and for exhibit-integrated lighting to accommodate all situations. Figure 28.5 identifies just a few basic approaches. These facilities are made more appropriate for activities beyond exhibit displays if wall and/or ceiling surfaces are lighted. This addresses some elements identified in 12.2 Spatial Factors.

28.2.9 Fitness Centers

The fitness center involves a number of situations where, although workout and conditioning are "the tasks," how people look and feel about themselves and their depth of engagement in exercising are as important. Lighting should be flattering and accommodate conversation and video-watching. Video watching may be susceptible to veiling reflections, so harsh directional lighting should be avoided. Well-shielded direct or totally indirect lighting are often appropriate given the potential for users looking to the ceiling during exercise sessions.

Many fitness centers, even in hotels, are a revenue stream and operate like a club. Here, reception and waiting, locker rooms and showers, and even retail areas are common. Lighting should be sympathetic to the fitness experience and to a club atmosphere. These facilities typically have swimming pools and hot tubs indoor or outdoor. Overlighting or gymnasia-like techniques should be avoided as these risk the potential for direct glare and wasted energy. For indoor pools, the anticipated activity level determines illuminance recommendations. See Table 22.4 for indoor activity level definitions. Lighting within the pools and hot tubs is necessary for observation of occupants and for comfortable use during dark-hours of operation or when daylight is insufficient. Vendors of such equipment should be consulted for recommendations on underwater luminaire wattage and lumen requirements for a given situation.

All pool criteria outlined in Table 28.2 are intended for relaxation and non-competitive exercising. For competitive situations, see 35 | LIGHTING FOR SPORTS AND RECREATION. Figure 28.6 illustrates an indoor hospitality pool application. Pool lighting should be planned with respect to maintenance and addressed with the client prior to final layouts and specifications.

Veiling reflections from pools are common in indoor and outdoor situations depending on view angles and sight lines. Daylighting and electric lighting can be arranged to limit veiling reflections, but this is practical where a fixed position view, such as that of a lifeguard can be planned or where polarized-lens eyewear is used as in outdoor situations.

With outdoor pools, the activity level and the nighttime outdoor lighting zone determine illuminance recommendations. See Table 22.4 for nighttime outdoor activity level

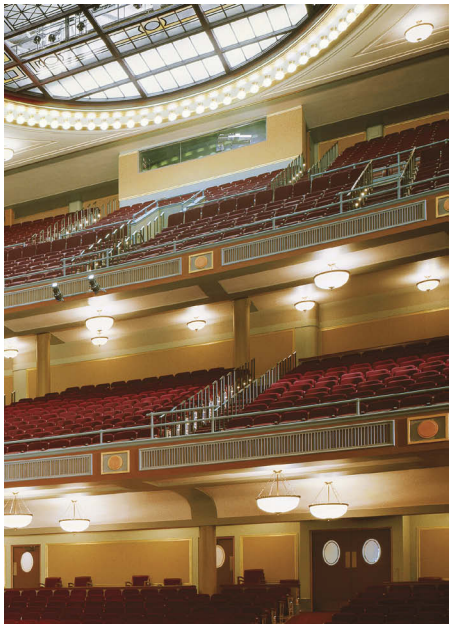

Figure 28.4 | Control Booth
The sound and light booth for this large auditorium (top center) houses sound and lighting control boards and can accommodate follow spots. Some of the theatrical lighting instruments controlled from the booth are just visible in a "seam" in the *laylight* (top left).
» Image ©Balthazar Korab Photography Ltd.

Laylight is an architectural feature or element that is a decorative light diffuser typically positioned below a skylight or roof monitor. Patterns of obscuring decorative glass or acrylic diffuse the light. Where no skylight or monitor exists or during dark hours, electric light is used to backlight the decorative diffuser [4].

Figure 28.5 | Commercial Exhibit Halls
Techniques that have since made their way into retail and even into other architectural lighting applications are ceiling slots (in top photo) that can contain both exhibit accent lighting and general lighting for circulation, set-up, tear-down, and cleaning. Finished ceilings offer spatial definition and a refined appearance, but may only accommodate certain exhibits and clientele. These are aspects which must be explored in programming.

In the bottom photo, general lighting is achieved in a distinctly different manner. Theatrical rigging is used for mounting lighting instruments where exhibits require such focal lighting.

Although exhibit halls do not traditionally make use of daylight, novel approaches to daylighting combined with improved daylight media can provide a dynamic luminous environment that is characteristic of daylight along with energy savings.

» Bottom Image ©Car Culture/Corbis

definitions. Lighting within the pools and hot tubs is necessary for observation of occupants and for comfortable use.

Direct glare in any of the fitness applications can be minimized with approaches using low-wattage equipment, lensed or louvered equipment, deeply regressed optics, and indirect lighting.

Codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and the requirements and design of which must be coordinated amongst the design team.

28.2.10 Food Service

Food service lighting is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

Most pronounced and problematic is the transition from kitchen to dining room. Sound and light locks work well, but may create circulation problems for wait staff. Transition zones where no food preparation takes place can be used to segue from the dining room to the kitchen. A common problem is a lack of visual consistency and glare control between kitchen and dining room lighting. This can be avoided by selecting luminaires and lighting techniques that minimize glare as well as selecting lamps that are compatible with the color temperature and color rendering of those found in the dining room. Door operators that quickly and quietly swing shut also minimize any light disturbance from the kitchen.

Dining rooms and bars are lighted to engage the clientele or, in some instances, usher the process along. The intent must be established in programming. Subjective impressions outlined in Table 12.2 should guide the application of lighting effects. Illuminances associated with artwork and features that assist with these subjective impressions are identified as Accenting in Table 28.2. Figure 28.7 and 28.8 illustrate effects of accenting and feature lighting in dining and bar lighting applications on senses of preference and relaxation.

28.2.11 Gaming

In casinos the lighting establishes mood, directs and holds attention, provides task lighting for game involvement, and accommodates critical and necessary surveillance. Meeting the visual requirements of one or several of these functions might be straightforward, however, meeting requirements for all of these simultaneously is a complex undertaking. Although programming and scope outline the various applications, tasks, and activities involved, consultation with regulators and surveillance specialists is necessary to develop illuminance criteria. Illuminance levels and uniformities are extremely important. Assessment of tasks for veiling reflections is a requirement if tasks are to be visible to clientele and security personnel in situ or remote-monitoring positions. Lamp CCTs typically in the 2700 K to 3000 K range with CRI ≥82 are appropriate in these festive or club-like settings.

In the vicinity of game tables, vertical illuminances should softly and uniformly light players' faces. Tables are typically illuminated from a variety of positions to minimize shadowing and glare effects of single sources. This also allows for continuation of play should one luminaire fail. Gentle lighting of background surfaces or iconic or artistic features will limit harsh contrast between game areas and backgrounds.

Many games are internally illuminated and subject to veiling reflections. Task orientations must be analyzed with respect to lighting techniques and direction of light. This may involve a series of virtual-model studies and ultimately a physical mockup.

During criteria review with regulators and surveillance specialists, an assessment must be made of the likely visual ages expected of more than half the observers and how this affects illuminance determination for those observers and for surveillance. It is important to reconcile any disparities prior to any final design work.

28.2.12 Guest Rooms

The guest experience begins at the entry to the hotel, continues to the registration lobby, the elevator lobby, corridor, and, finally, the guest room itself. The lighting of each of these spaces should be consistent with the desired experience as established during programming. The guest room serves as home-away-from-home and as a getaway if for pleasure or business. The lighting effects will be commensurate with:

- Hotel's desired stature, such as in travel ratings
- Marketplace, such as a resort, first-class business property, or economy lodging
- Pricing strategy
- Competition
- Guest's likely age

Even where the most basic of properties and amenities are involved, lighting must meet common needs of living. The illuminance criteria outlined in Table 28.2 are primarily intended as task-oriented. Multi-lamp overhead luminaires in the living area and bathroom generally result in inadequate and unsatisfactory lighting. Where table and floor luminaires are used, these should be lamped with dedicated-socket non-filament lamps for efficiency and system longevity. Although retrofits are considered an acceptable stop-gap measure on existing properties, new and renovation projects should seek portable lights that are listed and labeled as meeting UL/CSA/NOM requirements for dedicated socket lamps. Further, luminaire vendors should do heat testing to confirm lamp/ballast/driver configurations will remain within component manufacturers' tolerances for efficient, warranted operation.

Where quality art is an important part of the decor, accenting a piece can significantly improve the overall appearance of the room and enhance the relaxation experience or even offer a visual break from work tasks.

Lighting for reading at beds may take a number of forms, from the traditional table-side luminaire to the headboard-mounted LED gooseneck. Both require some amount of user adjustment either of the luminaire position or intensity or of the task orientation to achieve satisfactory results. The luminaire wattages, light distribution, and placement should be sufficient to meet illuminance criteria in Table 28.2. Although Figure 28.9 illustrates a guest suite bedroom at a 4-star hotel, the concepts illustrated for lighting at the head of bed are increasingly common in standard rooms.

Where steps are involved, lighting should be used to demarcate the tread elevation changes. Depending on the design of the step or steps, contrast stripes may suffice. Otherwise, contrast stripes with lighting from overhead or steplights integrated into side walls or risers or tread overhangs is necessary.

Care should be taken by the design team to accommodate a sleep cycle with no light. Nightlights might be appropriate in larger suites, rooms with steps, or where the bathroom is not directly aligned with the bed. A strategically placed architecturally-integrated steplight or several can serve this function. To limit sleep disturbance these should be tied to timers or photocells and occupancy sensors. To best limit the disturbance to the circadian rhythm during a middle-of-the-night quick-trip to the bathroom, long wavelength sources such as LEDs producing spectra between 600 and 620 nm are appropriate.

Closets can be problematic as these are usually tiny spaces where code limitations on luminaire placement and size may preclude all but a token luminaire over the door header. In these situations, luminaires outside, but immediately adjacent to the closet may be advantageous. At the least, closet lighting should consist of efficient, long-life lamping suitable for frequent switching cycles. Luminaires internal to closets should be controlled by door contact switches or occupancy sensors. Occupancy sensors must be positioned to immediately sense closet activity without false-starts from adjoining room activity.

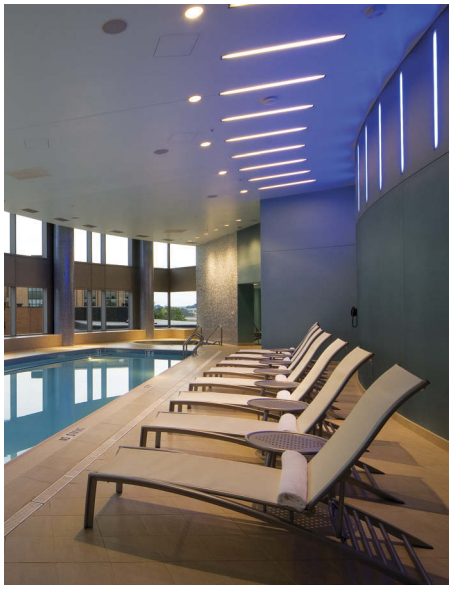

Figure 28.6 | Indoor Hotel Pool
The simple lighting scheme illustrated here involves narrow, discrete, ceiling recessed fluorescent luminaires and a wall-recessed version, wallwashers, accent spot luminaires, and general downlights. With the exception of the lamps in the wall-recessed luminaires, all lamps exhibit a CCT of 3000 K with CRI ≥82. Wall-recessed narrow slot lights at the right are lamped with blue linear fluorescent lamps for visual interest beyond the normal white-light-luminance-balance with the daylight media (such as the CMH wallwashers used at the far end). The narrow discrete, ceiling recessed fluorescent luminaires and the downlights are separately switched.

Veiling reflections are common with bodies of water. Eliminating or significantly controlling daylight is generally contrary to the premise behind daylighting of indoor pools. Early planning of daylight orientation, fixing key viewing positions, such as lifeguard locations, and arranging electric lighting accordingly is necessary if veiling reflections are to be minimized. Eyewear with polarized lenses can also minimize the effect of veiling reflections.

Illuminance criteria are applied to the deck and pool area noted in Table 28.2. Depending on pool size, room geometry, luminaire spacings and optics, there may be no need for luminaires over the body of water. This aids lamp and ballast maintenance.

Figure 28.7 | Dining
Task lighting combines with decorative lighting to meet illuminance criteria and enhance the material and color variations in this dining room. With the exception of the curvilinear copper-colored neon slot and the fluorescent kitchen luminaires, lighting is achieved with 2700 K and 3000 K LEDs exhibiting CRIs ≥82. The slot detail paint color was matched to the neon lamp color through mockup for optimal visual effect. The open kitchen is illuminated with 2x2 recessed luminaires with deep ribbed-blade-louvers with overlay lenses to meet requirements of food preparation areas. Fluorescent lamps are 2700 K for a seamless light color with the dining room.
» Image ©Gary Steffy Lighting Design Inc.

A master control of all lighting within the guest room that is tied to occupancy is most effective at minimizing energy consumption and maximizing in-service life of the system. One system employs a card-key switch at the entry to the room which activates power to all light switches in the guest room once the guest places the room card key into the card-key slot. When the key is removed from the card-key slot, all power to all lights is cut.

28.2.13 IT

Lighting for IT facilities is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

28.2.14 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS.

28.2.15 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS.

28.2.16 Reading and Writing

Lighting for reading and writing is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Reading and writing tasks occur within various applications. Familiarity with these tasks will aid with assessment of specific application tasks and activities. This may result in the recommendation of illuminance criteria different than that proposed in Table 28.2 for a particular application. For example, if the reception desk in a fitness center doubles as a work desk for employees, then a task citation of 8- and 10-pt. font on matte paper or with matte ink may be an appropriate recommendation and should be deliberated with the client.

28.2.17 Spas

Spas are the most indulgent of applications where the unquestionable goals of rest, relaxation, and esteem are achieved with pampering to body and mind. Perhaps in no other application is the performance of light so critical and where less illuminance is more. As with other hospitality applications, lamp CCTs of 2700 K to 3000 K with CRI ≥82 are appropriate to mimic the more comforting effects of traditional filament lighting.

High illuminances are necessary at the task areas where hair styling, manicures, and pedicures are performed. However, the illuminances associated with manicures and pedicures are best when limited closely to the approximate task area involved. Lighting equipment with well-controlled optics to avoid glare is best. For hair styling, an overall "head-glow" is necessary for the stylist's work and for the clientele's periodic mirror-reflection views. Here, lighting should be relatively soft and multi-directional from overhead and front. This avoids shadows and harsh glare and limits unbecoming shadows under eyes, noses, and chins. In the hair color lab, a combination lighting system is best where lamps with CCTs of 2700 K to 3000 K and CRIs ≥82 are available on one control zone and lamps with CCTs of 5000 K to 6500 K and CRIs ≥85 are available on a second control zone. This offers three conditions under which to review color.

Careful programming is required to establish which spaces demand wet-rated and IP-rated equipment. See Table 15.4 | IP Rating System.

Saunas and steam rooms are difficult environments for most lighting equipment, even that which is UL/NRTL wet-rated in the USA, for example. The steam is pervasive and the temperature swings can wick water into gasketed equipment. Where these spaces are involved, consult with the supplier of the room templates and equipment and with luminaire vendors prior to selection and specification.

Secondary lighting systems provide lighting necessary for cleanup in many of the treatment and other low-light spaces.

28.2.18 Support Spaces

These relatively back-of-house citations are self-explanatory. For purposes of maintenance convenience and where these spaces adjoin occupied areas, lamp types and color qualities should match those used elsewhere in the facility under design.

28.2.19 Theaters

Film and stage theaters serve different functions and have different lighting requirements even though many of the application and task names are common to each. Stage theaters use lighting instruments selected, laid out, and controlled in accordance with professional theater lighting designers' specifications and plans in order to illuminate performers and scenery to the requirements of the specific production for the benefit of the audience's entertainment experience. This stage lighting requires an extensive infrastructure for mounting, power, and control.

The architectural or "house" lighting in the theater proper must exhibit excellent dimming range and very high color rendering (CRI ≥85). All lamps should be capable of tracking each other at similar, if not identical, rates and quality of dimming. Otherwise, abrupt lighting changes, unsynchronized dimming between luminaire types, such as decorative sconces and steplights and chandeliers, or unsettling color shifts, will diminish the quality of patrons' event experiences.

CCT and CRI of lamps in luminaires at the delivery and staging work areas should be similar if not identical to those used in the theatrical stage instruments to avoid undesirable color appearance of scenery and props at showtime.

Acoustics, dimming ranges, and the amount, if any, of remote hardware are important considerations when selecting lamps, luminaires, and controls for the architectural or house lighting for the theater proper, especially for live performance theaters. Acoustics alone may preclude the use of fluorescent and LED lamps in some applications. Carefully scrutinize lamp, luminaire, ballast, driver, transformer, and controls devices. Operational mockups are best. *Performance-quality dimming* is appropriate. Figure 28.10 is an illustration of house lighting in a stage theater with a few theatrical instruments energized to highlight or "warm" the curtain (hence, these are commonly called curtain warmers).

Aisle lighting requirements before, during, and after an event must be planned to allow for safe and convenient access into and out of the house at any time without creating disturbing shadows or reflections from people as they make their way to and from seats. When films are projected, as little ambient light as practical from the normal power architectural lighting system on the screen proper is best. Depending on jurisdictional requirements, the type of theater, and client programming requirements, use of direct-view floor-mounted miniature walk-over LED strip lighting may be appropriate to demarcate elevational changes.

28.2.20 Toilets/Locker Rooms

Lighting for toilets and locker rooms needs to meet the functional requirements of illuminance criteria outlined in Table 28.2. Addressing the plumbing fixture will provide sufficient light where needed without overlighting the entire toilet room. Vanities are most problematic when little or no vertical illuminance is designed to light an imaginary facial plane (roughly a zone of sufficient size to encompass faces) in front of the mirror. Wall sconces, small pendants between each sink, wall slot details illuminating light-colored upper walls above the mirror or some combination are all appropriate techniques. See Figure 22.7.

Vertical light over the faces of lockers will assist with locker use.

Figure 28.8 | Bar
There are times when, regardless of daylight availability, some lighting remains energized to simply identify an establishment as open-for-business. In this hotel bar, the back bar is illuminated as is the peninsula focal point. Decorative lighting overhead consists of multi-lamped pods arranged in a somewhat curvilinear and undulating pattern. The two-zone lamping allows for one zone to be extinguished while allowing the shades to glow. Alternating operating schedules of which zone is extinguished on which days can prolong in-service life of ballasts and lamps. This extends group relamping. Lamp CCT is 3000 K with CRI ≥82. Shade materials are color tuned with the CFL lamping to provide a filament-lamp color quality.
» Image ©Kevin Beswick, www.ppt-photographics.com

Performance-quality dimming as used here refers to smooth and continuous dimming from full output (100%) to extremely low output (≤0.1%) and vice versa. This dimming is achieved at a consistent and programmable or manual fade rate and can maintain a static steady state at any point along the continuum for a quality equal to that achieved when proper dimming of filament lamps is employed. Striations, visual steps, intermittent bright "surges", or sudden flashes or cutouts, color shifts, or other visual disturbances are unacceptable during dimming or static conditions. Performance quality dimming is appropriate where a continuous and complete fade to black is part of the experience, such as transitioning from intermission to show in a theater.

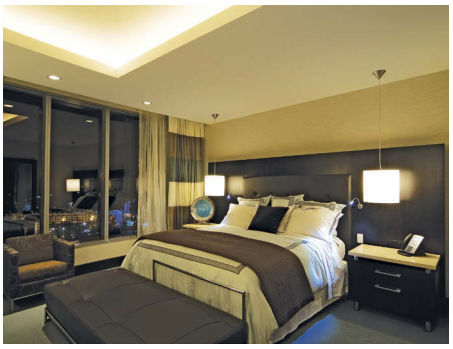

Figure 28.9 | Guest Suite
Bedside pendant luminaires and gooseneck LED reading luminaires are combined with the ambient lighting from a ceiling cove. Perimeter downlights provide sitting-area lighting. Preset scenes available from bedside and door-side keypads are DRESS, READ, TV, NIGHTLIGHT, and OFF.
» Image ©Kevin Beswick, www.ppt-photographics.com

28.2.21 Transition Spaces

In hospitality and entertainment facilities, a number of spaces transition from one application to another. Some of these are considered back-of-house and available to employees only. Most are public spaces and many of these might be of a particular sequence of passage, ceremonial in nature, or of special importance. To appropriately serve these roles, subjective impressions outlined in Table 12.2 should guide the application of lighting effects. Illuminances associated with artwork and features that assist with these subjective impressions are outlined in Table 28.2. Figures 28.11 and 28.12 illustrates a hotel lobby lighted to the illuminances outlined in Table 28.2 using ambient, task, and accent lighting systems. Figure 28.12 illustrates lighting of a motel lobby.

28.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 28.2.

28.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 28.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 28.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

28.3.2 Notes

The notes in Table 28.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

28.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document

Figure 28.10 | Theater
Renovation of this theater involved reuse of existing ceiling downlights, introduction of a catwalk at the proscenium, and new seating, flooring, and walls. Prior to the renovation, only downlighting existed as house lighting. To brighten the house and introduce visual interest for the pre-show and intermission, a sequence of linear wall brackets with varying sizes and spacings of sconces was introduced.

Sconces consist of a modular glass luminaire (right detail) used in single and multiple groupings as the design team deemed necessary to flow with the wall height, floor slope, and balcony configurations. Each sconce module is lamped with halogen filament lamps selected for quiet operation, smooth, continuous, and deep dimming, and no remote equipment requirements. Lamp reflections from the satin wood finish are usually considered acceptable if not desirable from the "point source" of the halogen filament lamps. However, reflections from "tiny point source" LEDs and from "large area source" fluorescent lamps are typically undesirable.

The catwalk, added to introduce better stage lighting positions, forced removal of a row of downlights. To maintain lighting at the orchestra seating positions, architectural light slots were introduced. Existing downlights were relamped with lower wattage halogenIR_{120V} PAR38 lamps.

A few theatrical instruments are also energized in this view to highlight or "warm" the curtain (hence, these are commonly called curtain warmers).

» Image ©Ron Blunt Photography

IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 28.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for lighting white boards, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on at least one plane of a task. A 0 indicates no light or zero light is recommended for the task or application.

28.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane.

Figure 28.11 | Hotel Lobby
A multi-story lobby/lounge/registration area is lighted using ambient, task, and accent lighting approaches combined. This view is of the lounge as seen from the registration lobby. Ambient lighting is based on illuminance criteria from Table 28.2 for TRANSITION SPACES/Lounges/Social/Waiting Areas. Task lighting is based on illuminance criteria from TRANSITION SPACES/Lounges/Reading/Work Areas. Accent lighting is based on TRANSITION SPACES/Accenting/Feature Wall Table 15.2/Soft (~5-to-1 from feature wall E_v to ambient E_h).

To introduce contrast beyond that achieved with accenting, colored light is used. The linear ambient luminaires are ceiling slots generating an indirect glow using T5HO blue fluorescent lamps. All other luminaires are lamped with CFL or CMH lamps exhibiting CCT 3000 K and CRI ≥82.

» Image ©Kevin Beswick, www.ppt-photographics.com

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. In some applications, like conventional art studios accommodating a variety of media, art forms, and genres, horizontal- and vertical-plane illuminances address the common studio situation where simultaneously some work or some portion of the work is on horizontal planes while other work or portion is on vertical planes.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." For example, for most corridors (TRANSITION SPACES/Circulation Corridors), horizontal illuminances apply to the floor plane while vertical illuminances apply to standing-face-plane height of 5' AFF oriented in the two main directions of travel. Although the nature of architectural lighting in many corridors is such that the target illuminance will coincidentally be met at the elevations of 3' and 4' AFF, the designer may elect to set the criteria elevation for vertical illuminance at 3' AFF or a range of 3'-5' AFF to assure facial lighting for children and those in wheelchairs meets target. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation. For example, in an exhibition hall, for E_v (EXHIBIT HALLS/General Exhibition for both High Light Setting and Low Lighting Setting), the number and orientation of vertical planar points assessed depends on the exhibit hall layout. For most, a universal layout is appropriate and, therefore, at least four vertical planes are of interest. One in each of the four cardinal directions of the plan.

28.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. It may be determined that illuminance criteria for an age group other than that representing the majority of the intended observers is appropriate. However, this may result in overlighting, underlighting, harsh lighting, visual displeasure, or visual discomfort for many of the observers. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance. In some situations, such as video conferencing, lighting must meet the requirements of the camera technology and, therefore, is not tied to ages of observers.

28.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 28.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

28.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

Figure 28.12 | Motel Lobby
Well-spaced downlights exhibiting a flood distribution at the registration desk can provide effective illuminance on the wall for accent and on the registration counter for task. Downlighting concentrated at seating and feature areas provides ambient light, but with some degree of accent highlight that would be lost with a general pattern of downlighting. Decorative pendant and sconces themselves provide some accent and help with human scale and visual interest and soften the harshness of downlighting alone.
» Image ©Jonathan Ross/Space Images/Corbis

28.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

28.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

28.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

28.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

28.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candi-

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

date, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

28.3.6 Veiling Reflections

Tasks with specular components, such as some video game consoles and display monitors, which may be in different planes, are prone to veiling reflections. The likelihood of particular applications/tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of daylight with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks can be effective.

28.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Tasks and Applications and Figure 12.21 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 28.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications/tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 28.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

28.4 Designing

Information provided here is specific to hospitality and entertainment facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

29 | LIGHTING FOR LIBRARIES

Books are the ever burning lamps of accumulated wisdom.
George William Curtis, 19th Century American Writer

Contents

29.1 Project Type and Status. . . 29.1
29.2 Application Types 29.2
29.3 Illuminance Criteria 29.19
29.4 Designing. 29.25
29.5 References 29.26

Libraries fulfil the information needs of a wide public. For example, in the United States in 2007, circulation was near 2.2 billion, with children's circulation accounting for about 35% of that. 292 million Americans were served by public libraries. [1] Libraries are an integral component of education, whether the school library or the public community library. Libraries are reference archives, interest-free lending institutions, gateways to the World Wide Web, and living rooms and study halls. Lighting plays a role to entice people to use libraries and, once there, to use library resources with efficiency and comfort. Engaging and functional are broad attributes to which library lighting design must aspire. Daylighting and views can make powerful contributions. What follows is a discussion of the key aspects affecting lighting: project status; space types; activities; application-specific design goals, and illuminance criteria in library facilities.

Comprehensive design efforts involve the information in this chapter combined with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance criteria for libraries which should influence luminaire optical selections, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous and current IES related documents serve as archival and reference sources. [2] [3].

Deliberate thought must be given to details beyond the recommended illuminances in this chapter. For example, in audio listening rooms, the quality of the sitting room must compel potential patrons to enter and engage in the process. Visual interest is appropriate and cannot generally be achieved simply on the basis of task or application illuminance criteria. Accenting is in order or spectacular views both day and night. Another example: shelving in periodicals demands vertical illuminances to attract and hold the patron's attention. Achieving these with ceiling mounted or recessed wallwashers or accents may only lead to a shadow problem as patrons approach the shelving to view periodicals. These situations must be studied carefully before solutions are recommended, particularly those that seem obvious. These kinds of specific details are not enumerated for most tasks. Table 29.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

29.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. This will establish the extent to which daylighting can address most or many or some of the lighting goals. New, renovation, and restoration projects each offer varying opportunities.

Table 12.3 | Sample Visual Task Survey

See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. Given hours of operation of K-12 schools and public libraries, daylighting can be a primary light source for many libraries. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands determined attention to moderate or eliminate glare and balance visible and thermal energy.

29.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the library space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 29.2 | Library Facilities Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 29.2.

The following discussion is keyed to major application headings in Table 29.2. Couple this with topics in Table 29.1 for comprehensive qualitative and quantitative criteria.

29.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction and wayfinding. Default accent lighting criteria are discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Also see 15.1.1.3 Accent Lighting.

29.2.2 Administration

Lighting for administrative areas is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The architectural scheme and even task specifics will vary based on the associated library facility, from school to public to community college to college and university to senior housing complexes. These distinctions may affect the lighting design—from kinds of lighting effects to lighting equipment styling to luminances and illuminances.

Library administration may be dispersed throughout a facility or campus or may be centralized into a single area, wing, or building. Depending on client wishes and architectural desires, this centralization or decentralization may affect the degree to which the lighting design in administrative areas is sympathetic to or different from that of the other applications at the library facility. Some libraries may not have a dedicated administrative area, but share administration with the larger entity, such as school or senior housing complex.

29.2.3 Auditoria

Lighting for auditoria is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. For public libraries, auditoria function as lecture halls, informational presentations and public messages, testing sites, debate forums, and community boards' meeting facilities. Controls and their ease of use are particularly important in these public settings where library staff may not be available and users are unfamiliar with the lighting system operation. Here, simple 3- or 4-scene presets with well-labeled keypads

available at ingress/egress points and at or near the presentation position are appropriate. All the use of the system is simple and convenient, the design to achieve this simplicity must accommodate the various tasks expected in each scene. For example, in an AV PRESENTATION scene, house lights might be very dim or off if aisle lights are available. Speaker accents are energized, perhaps to a dimmed level. However, this accenting must be designed so that spill light is not present on the adjacent or nearby AV screen. Therefore, this speaker accenting may be achieved with different luminaires and lamps than used in a LECTURE scene where no AV is involved. The designer must track the various tasks and address each, perhaps differently, in each scene. Figure 29.1 illustrates a small auditorium with fixed seating at a community library.

29.2.4 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Since many libraries are used extensively in the evening hours, levels of activity can be high at entries. Hours of operation may change based on the day of the week. This information should be evident from the program and lighting criteria should address the level of activity. Another variable demanding attention prior to recommending illuminance criteria is the outdoor nighttime lighting zone. All of this may demand a control system capable of addressing various settings on various evenings through manual intervention, automated time clock, and photocell functions.

The nighttime outdoor lighting zone within which the facility is located or to which the team and client elect to design affects the illuminance criteria for outdoor tasks. Nighttime outdoor lighting zone designations vary by local ordinance, sustainability guides, or the team's own definition of place. These are discussed in 26 | LIGHTING FOR EXTERIORS. Also see Table 15.6 | Nighttime Operational Strategies for Improved Outdoor Environmental Regard.

After-hours security needs, such as on-site or remote monitoring, may require that some luminaires at building entries remain energized through the night. Control zones and time clock functions must be designed accordingly. Where remote monitoring is done with infrared cameras, lighting may be unnecessary if not undesirable.

29.2.5 Classrooms

Lighting for classrooms is discussed in 24 | LIGHTING FOR EDUCATION.

29.2.6 Conferencing

The lighting of conferencing facilities is addressed in 22 | LIGHTING FOR COMMON APPLICATIONS. In multipurpose meeting rooms, preset controls establish appropriate settings for various tasks. Controls should be simple to operate and clearly labeled. Where meeting rooms are likely to be used for hobby interests, such as stamp and coin collecting or knitting and quilting, the designer should review the likelihood and frequencies as well as the design implications with the client. Criteria for these specific tasks in a meeting or conference room must then be determined by the designer. Criteria may be available from other application chapters, such as 33 | LIGHTING FOR RESIDENCES where citations of RESIDENTIAL INTERIORS/Arts, Crafts and Collecting and RESIDENTIAL INTERIORS/Sewing/Hand Sewing or Knitting can be found.

29.2.7 Exhibit Galleries

Lighting for exhibit galleries is covered in 21 | LIGHTING FOR ART. Many libraries possess collections of history, memorabilia, distinguished, if not rare, books, and popular culture. Libraries also have access to visiting exhibits. Dedicated exhibit spaces are common as are placeholders for temporary exhibits which are interspersed throughout the book collections. Lighting must be planned accordingly for these permanent and temporary exhibits and displays. Lighting solutions should limit or eliminate UV and IR radiation

Figure 29.1 | Library Auditoria
As part of a larger conference center for this community library, a fixed-seating auditorium is used for lectures and presentations. Lighting flexibility is important, but need not include more than three or four scenes (such as BRIGHT [shown here], DIM, AV, and OFF). Indirect lighting from the coves offers soft diffuse light and when combined with the downlighting provides good facial modeling which is important for feedback purposes to a lecture speaker or panel.

From this view, specular reflection of the cove lighting occurs in the wood ceiling. This is not seen by the audience except as people exit the auditorium. Matte finishes would reduce the effect, but the trade-off is a loss in depth and texture of the wood grain.

» Image ©2005 Gene Meadows

Figure 29.2 | Library Exhibits
For large libraries, temporary and permanent exhibits are an important part of community service and attracting patrons. Here, a temporary exhibit in 2007 at the Santa Monica Public Library showcases the best of Nordic furnishings and lighting. Lighting must be planned into the architecture and controlled in the event no exhibits are on display but other programmed functions take place, such as reading areas between exhibit cycles.

Programming might call for permanent display cases to be interspersed throughout book collections or located in dedicated exhibit galleries where walls might accommodate hanging art or displays. Lighting must be developed to support these applications.

Notes for Table 29.2

The table column headings are discussed in detail in 29.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 29.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 29.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 29.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Alternatively, design to specific tasks, if known, from READING AND WRITING.

k. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

l. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

m. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 29.2

The table column headings are discussed in detail in 29.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 29.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 29.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 29.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Alternatively, design to specific tasks, if known, from READING AND WRITING.

k. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

l. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

m. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 29.2

The table column headings are discussed in detail in 29.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 29.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 29.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 29.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Alternatively, design to specific tasks, if known, from READING AND WRITING.

k. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

l. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

m. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Table 29.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

in the vicinity of exhibits. This may require careful lamp selection or selecting luminaires with filter options. Exhibits and their scale relate to the size of the library and community interests. Figure 29.2 illustrates a relatively large temporary exhibit.

29.2.8 Exteriors

Exterior lighting beyond building entries, including site paths, parking, facades, landscape, and flags, are addressed in 26 | LIGHTING FOR EXTERIORS. Also see Table 15.6 | Nighttime Operational Strategies for Improved Outdoor Environmental Regard. The program should outline the library site, intended functions, and hours of operation. This information, the anticipated levels of activity, and outdoor nighttime lighting zones will be used to determine appropriate illuminance criteria for the various applications.

Nighttime book drop or book pickup and drop facilities deserve attention. Illuminance criteria for these are outlined in Table 29.2. Lighting for book bins of either the drive-up or walk-up variety should encompass the book bin and a margin extending 1' 6" beyond all exposed sides of the bins. Lighting should be positioned to avoid strong shadows on the drop aperture or drop-door handle as a vehicle or pedestrian approaches. Bins should be sufficiently freestanding from obstructions or plants to avoid shadows or areas of cover for potential perpetrators. If bins are screened in any way, lighting should be developed to reduce areas of cover and minimize shadowing. This does not require and should not result in high wattage, direct-beam spot lights or flood lights nor result in illuminances greater than those cited in Table 29.2. Such techniques would compound the problem and introduce adaptation issues experienced when viewing from bright to shadowed areas.

29.2.9 Food Service

Food service lighting is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

29.2.10 IT

Lighting for IT facilities is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

29.2.11 Library Proper

Applications and tasks which relate most directly to public use of the library are outlined as those of Library Proper in Table 29.2. Horizontal and vertical illuminances and

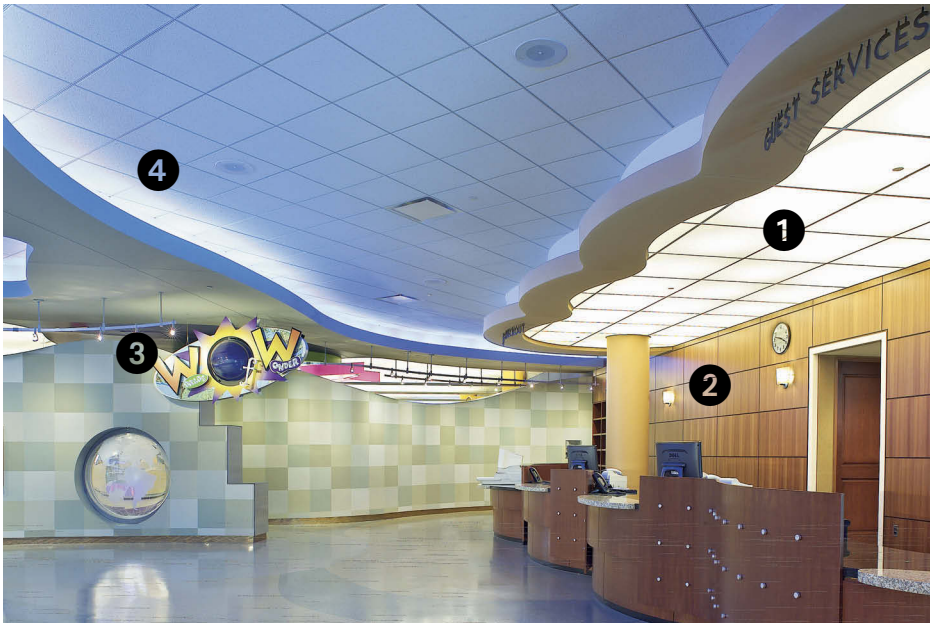

Figure 29.3 | Service Desks
At this relatively large public library a long desk serves two functions—book checkout at the far end and guest services at the near end. 40 W long CFLs are used above the luminous ceiling ❶. Wall sconces are lamped with CFLs ❷. Super graphics are lighted with halogenIR$_{LV}$ lamps ❸. 40 W, 4100 K, long CFLs with blue gels in the cove illuminate the ceiling ❹. The cove and luminous ceiling combine to meet the general and task illuminance criteria. The sconces are decorative. The "WOW" graphic lighting was designed to meet the "moderate attraction" criterion in Table 15.2. For a sign anticipated to have a reflectance >50%, the illuminance on "WOW" was designed to meet a focal-to-task illuminance ratio of 5-to-1. The lobby floor illuminance was considered that of the "task".

respective uniformities should all be addressed. Vertical illuminances assist with various task orientations as patrons adjust positions from time to time. Vertical illuminances also assist with facial recognition. Cited uniformities are used to establish baseline conditions while accenting will introduce visual interest and spatial contrast.

Figure 29.3 illustrates lighting at a desk serving dual functions: guest services and checkout. The luminous ceiling illuminates the desk top, the back wall, and faces in the vicinity. The luminance of the backlighted panels attracts attention. Figure 29.4 illustrates lighting of a feature within youth services. An adult group reading area is shown in Figure 29.5.

In addition to task visibility and facilitating visual performance, library lighting influences attention and the desire to remain engaged. Define and address all anticipated visual tasks while recognizing the variability of task orientation, from horizontal to near-vertical, and task types including hardcopy, electronic books, and computers. Although the effects of task lighting should not be the focus of attention, task lighting should help the patrons maintain focus and attention on specific task areas as the library program defines.

Daylighting success in libraries is facilitated when there is seamless operation of electric lighting and daylighting mechanisms, such as automated continuous dimming and shade control respectively. Functional variation, including room-darkening for those spaces using AV or where dimness is functionally desirable, must be easily available to the occupants or staff. These aspects, several of which are excerpted from 24.2.5 Classrooms, deserve particular attention:

1. Automate dimming preferably with continuous-dimming functionality for least visual disruption
2. Great care in design of any east- and west-elevation daylighting relative to glare
3. Automate window treatment with quiet and slow continuous-roller-operation with long change cycles
4. Avoid daylight designs requiring near-continual/complete shade deployment
5. Arrange primary reading positions or display/presentation positions perpendicular to daylight apertures
6. Maintain some degree of exterior view
7. Perform daylight simulations to limit areas of overlighting and assist with glazing transmittance and shading treatment selections
8. Eliminate direct solar penetration in all but transitional circulation spaces distant from reading areas
9. Use matte high reflectance architectural finishes to best distribute and diffuse daylight
10. Use matte high reflectance table finishes in reading areas

Automated control systems are key to achieving daylight integration. Where fluorescent luminaires are extinguished on a frequent basis, such as 3 times or more in a typical work day for reasons of daylighting or occupancy-sensing, program start ballasts minimize premature lamp failures. Consult ballast, lamp, and controls vendors on these aspects prior to finalizing designs. See 7.3.6.3 Lamp Life and Failure Mechanism. Figures 29.6 and 29.7 illustrate some reading room electric lighting and daylighting techniques.

Larger libraries contain a number of collections of such size that it is not practical to combine these into a single area. Adult, youth, and teen services are typically distinguished. Figure 29.8 illustrates a youth services area in a library. For visual interest in situations where these collections themselves are rather large, architectural planes, details, and finishes are varied to some degree within each collection. Lighting within each collection should also follow this approach. The challenge is to limit wild fluctuations in aesthetic style of

Figure 29.4 | Features
Colorful playful areas are lighted to encourage reading and play. HalogenIR_{LV} lamps of 3000 K and 100 CRI on flexible track rail highlight the patchwork wall and signage. The lime-green ceiling corkscrew detail is lighted with 3000 K and 82 CRI neon tubing to conform to the detail shape while exhibiting low-glare when directly viewed. 40 W, 4100 K long CFLs with blue gels uplight the lay-in ceiling from a cove detail.

Figure 29.5 | Reading Areas
Lap-height illuminances are achieved with ambient lighting in the perimeter coves and task lighting from the overhead chandelier. Coves are lamped with 28 W T5 lamps of 3500 K and 85 CRI and chandeliers with six 26 W CFL lamps of 2700 K CCT and 82 CRI. An adjacent background wall is accented with 20 W PAR20 CMH lamps of 3000 K and 81 CRI.

Lamp CCT selection should be deliberate. On many projects, there is rationale to select one common CCT for all lamps. On some projects, there may be a rationale for employing different CCTs. In this setting, lighting considered "background" architectural (cove and recessed luminaires) were assigned a neutral CCT of 3500 K. "Decorative" architectural lighting, that which is physically closer to patrons, were assigned a very warm incandescent-like CCT of 2700 K for a more home-like and familiar look. Accent lighting employing CMH lamps is only available in 3000 K or 4000 K. To better blend with the decorative architectural lighting, the 3000 K CCT was selected. Since exact CCT matches are impractical, then CCTs across different lamp types that are within 200 K or 300 K of each other are considered "matching". However, when seen side-by-side, and also depending on CRI (lamp CRIs should also be matched), few of these are very good matches. Such are the inequities between technologies and manufacturers' processes.

The lighting from the chandelier and coves provides both horizontal and vertical illuminances suitable for reading 8- and 10-pt font printed material or electronic readers and also for assessing facial detail without glare.

» Image ©Balthazar Korab Photography Ltd.

the luminaires and quality of light within a collection. These are eye-of-the-designer issues that are vetted with the design team, by reviewing luminaire samples or mockups, and by experiencing and evaluating existing settings.

Figure 29.9 illustrates a story room where lighting effects are used to engage patrons and where lighting controls are used to establish scenes for personal reading time or story time.

For rare book and history collections, care must be taken on UV and IR exposure and time duration exposure to visible light. See 21 | LIGHTING FOR ART.

Perhaps the most significant challenge in lighting libraries centers around reading media. Print materials, electronic readers, and computers are all readily available. Designing to one media or to a single-value illuminance will likely yield unsatisfactory results. Programming may address these various media (and others as new technologies evolve or are developed) through variety of space types and variety of areas within space types. An "e-reader lounge" might be programmed into the Teen Reading Room, for example. The designer must review the available technologies and determine the most common e-reader screen type or, alternatively, design to the worst-case screen type. Flexibility through controls may be appropriate, though issues of access to the controls and how the change from one setting to another is determined may require uncomfortable or complicated decisions. Establishing multiple e-reader lounges to accommodate LCD and LED readers (backlighted) as one category and to accommodate electronic-ink readers (front-lighted) as another category combined with zoned area controls to allow long-term planning changes may be most appropriate.

Computer rooms, also known as labs, centers, or lounges, must be designed to address the likely computer task and, where appropriate, the related paperwork, such as notetaking or reading of supplementary print materials. Computers might be any one of several types cited in Table 29.2 or even newer, evolved technologies. Programming these possibilities is important to developing a lighting design tailored to the intended uses. Controls and the use of task and ambient lighting systems may be most effective in achieving satisfactory results and allowing for future technology advancements. Figure 29.10 illustrates a library computer center. A library teen lounge with computers is illustrated in Figure 29.11.

Just like online searches and retrievals can be sticking points when using the Internet, the storage and retrieval of books can be a sticking point for patrons in the process of visiting the library. The more convenient the access to these stored books and the easier to survey and identify titles, the greater the likelihood of exploration of the stacks. For those with a distinct title in mind, lighting can greatly limit time-to-retrieval. Figure 29.12 illustrates a stack lighting example.

29.2.12 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS.

29.2.13 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS.

29.2.14 Reading and Writing

Reading and writing tasks occur within various applications. Familiarity with these tasks will aid with assessment of specific application tasks and activities. This may result in the recommendation of illuminance criteria different than that proposed in Table 29.2 for a particular application. For example, if the reading tasks in LIBRARY PROPER/Teen Services/Reading Rooms are anticipated to be electronic readers, and especially of the LCD or LED variety identified in READING AND WRITING/Electronic Readers, then the illuminances at reading task locations should correspond to those cited for electronic

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

readers. Otherwise, the task area will likely be overlighted and uncomfortable. Alternatively, if reading rooms or study rooms have a need to accommodate both hardcopy reading tasks and electronic readers, lighting and controls should be designed accordingly.

Glare, especially in reading areas, is unacceptable. In libraries, lamps should be concealed behind lensing or within indirect luminaires or carefully shielded with louvers or baffles or of low wattage and relatively large area and difficult to see; table luminaire size and geometry can limit seated patrons' sight lines to lamps. An exposed low wattage CFL or linear fluorescent lamp is typically more tolerable to the eye when seen only periodically or intermittently than is a LED lamp of equivalent output. CMH and LED luminaires intended for long throws and strong effects should employ reflectors and lenses to control light. Relatively deep ceiling trim cones can be effective for recessed CMH and LED equipment. Surface mounted CMH and LED accent luminaires, such as monopoints or trackheads, should be fitted with snoots, barn doors, or louvers where they are in close proximity to and aimed in the general direction of readers. The conundrum is that luminaires with glare control are less efficient than those with the brute force of bare or nearly-bare lamping. A setting will be more sustainable if users actually want to and do use it than if it is uncomfortable and intolerable, but deemed "efficient." Glare aspects are best judged through sample reviews and mockups and experience within various settings.

29.2.15 Support Spaces

These relatively back-of-house citations are self-explanatory. For dock areas, outdoor nighttime lighting zones determine which illuminance criteria are appropriate. In any event, these are applied immediately at the exterior of the dock overhead door. Lighting equipment should direct all light downward (see Figure 22.4). Lighting the outdoor parking or dock staging area should conform to criteria identified in 26 | LIGHTING FOR EXTERIORS.

29.2.16 Toilets/Locker Rooms

Lighting for toilets and locker rooms is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Addressing the plumbing fixtures (for example, toilets, urinals, vanities) as recommended works in conjunction with low-level general lighting throughout the toilet rooms to provide sufficient light where needed without overlighting the entire toilet room.

29.2.17 Transition Spaces

Most of these spaces are self-explanatory, but one deserves discussion. Adjacency passageways refer to a condition where circulation areas are encompassed by larger areas. Given their potential adjacency to the open and visually accessible reading areas, their illuminances, confined to the passageway proper, should be ratios of the nearby task illuminances. This avoids annoying contrasts within the work setting.

29.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 29.2.

29.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 29.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Figure 29.6 | Reading Rooms
Ambient lighting requirements can be partially or fully met by daylighting during daytime hours. Orientation and glazing selection are critical to success. Luminaires at reading tables can provide task lighting. Local switching at task luminaires or occupancy dimming or switching can further reduce energy use. However, the design of these controls must be evaluated for potential disruption and ease-of-use for patrons. Occupancy sensor coverages must be carefully tuned to table sizes, number of patrons per table, and spacings between tables. Mockups are best before finalizing designs of these approaches.
» Image ©Art on File/Corbis

conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 29.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

29.3.2 Notes

The notes in Table 29.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

29.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work.

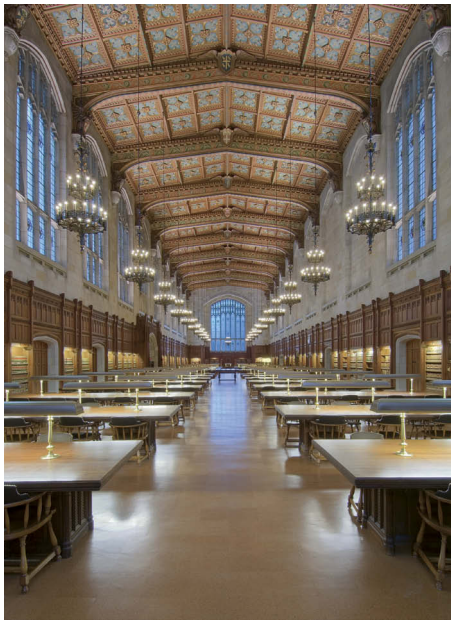

Figure 29.7 | Historic Reading Rooms
After 80 years of dirt build-up, the ceiling in this reading room provided little reflectance and created a high-contrast interior with luminance imbalance (far left). White paper and CSA/ISO positive-polarity laptop tasks were too bright relative to the architectural surfaces. Daylight no longer met the expected norms for lighting when reading and writing. A lighting renovation was undertaken and the ceiling cleaned, the floor replaced, and the tables refinished. Surface reflectances improved significantly. Table lights were retrofitted with 28 W T5 lamps of 3000 K and 85 CRI; stack lights retrofitted with 18 W long CFLs of 3000 K and 82 CRI. New luminaires lamped with 39 W PAR20 CMH lamps of 3000 K and 86 CRI were added at window sills to uplight the cleaned ceiling and better balance luminances. Uplights and table task lights are step-switched in accordance with daylight availability. Also see Figure 21.7.
» Images ©Curt Clayton

Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 29.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for lighting white boards, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on at least one plane of a task. A 0 indicates no light or zero light is recommended for the task or application.

29.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane.

Figure 29.8 | Youth Services
Architectural variety is used within one area to maintain visual interest and help define specific activity zones. Lighting techniques vary accordingly, however, the overall visual effect and illuminances maintain an aesthetic consistency. In this youth services area, the main information and circulation desk is featured with an overhead architectural chandelier of colorful graphics panels. These are lighted from above with 100 W PAR38 CMH lamps of 3000 K and 81 CRI and are fitted with snoots and neutral density filters to control light spill and intensity. The graphic art panels act to limit direct view to most of these lamps. These CMH accents also produce a significant proportion of the task lighting at the desk area.
» Image ©Balthazar Korab Photography Ltd.

Figure 29.9 | Story Rooms
Art accent lighting from a 70 W CMH-lamped ellipsoidal theatrical highlights the astronaut model in this story room. 39 W PAR30 CMH downlights on several control zones allow for varying illuminances at the floor for story-telling or personal reading. Colored LED downlights and in-floor uplights are used for visual interest.
» Image ©2003 Gene Meadows

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. In some applications, like youth services (Table 29.2 LIBRARY PROPER/Youth Services/Reading Rooms), general horizontal illuminance is intended for application at floor plane and general vertical illuminance is intended for application at 5' AFF—which is roughly face height for an adult. Although facial recognition and discrimination of an adult's facial features are important for a child, the designer and client may determine that facial recognition and discrimination by children of other children or by adults of children are a better priority. In which case general vertical illuminance at 3' AFF is appropriate. A similar assessment of criteria at reading tables is in order. Are table tops at 2' 6" AFF? Are seated face heights at 4' AFF?

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented a number of directions and the designer must determine which are most appropriate for the situation.

29.3.3.2 Visual Ages of Observers

Ages of observers must be deliberated with care in libraries. A sense of comfort and place as well as appropriate energy use can only be achieved if illuminance levels are targeted for the intended audience. Illuminance criteria are presented based on age groupings associated with at least half the observers in a particular application. The designer is always at liberty to reselect criteria based on her own experience or on client direction. In libraries, collections are typically categorized by age group. Arguably, lighting should then be developed specific to the age group targeted within each collection. An item which must be resolved by the designer and client is which illuminance age grouping to use for youth services and teen services. It might be argued that although more than half the observers are under 25 years of age, those in charge of overseeing these areas may be in the 25-to-65-year-old-range. However, unless full-time live surveillance of the areas is deemed necessary or these areas are also to be available to older observers, it is unlikely illuminances must cater to the older category at all task locations. Where older observers are stationed, however, such as at information or circulation desks, illuminance criteria should be based on the anticipated age group of at least half of those older observers. Where age group-

ings conflict, such as might happen with the use of various conference rooms or computer training sessions, lighting controls allow for appropriate and efficient lighting to address several age groups providing, of course, the room function and time of use are coordinated by age group.

In any event, implications to energy use are significant. This aspect of visual ages should be resolved during programming with the client. It may be determined that illuminance criteria for an age group other than that representing the majority of the intended observers is appropriate. However, this may result in overlighting, underlighting, harsh lighting, visual displeasure, or visual discomfort for many of the observers. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance.

29.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 29.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

29.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

29.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

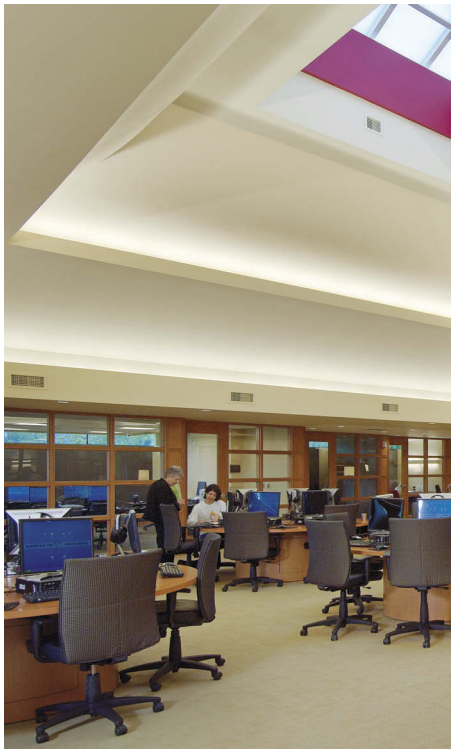

Figure 29.10 | Computer Center
Large, flat-screen monitors exhibiting CSA/ISO Type I finishes are available in this library computer center. Internet content is streamed in its native positive- or negative-contrast form. The electric-light coves splay to the relatively small skylight kept purposely somewhat out of direct field of view.

Figure 29.11 | Teen Lounge
This teen lounge exhibits low general lighting (see Table 31.2 TRANSITION SPACES/ Lounges/Clubs and Game Rooms) and low surface reflectances for a setting conducive to web surfing and table games. Gelled fluorescent lamps in coves indirectly light a lay-in ceiling which is above a secondary ceiling plane of open mesh metal panels.

General lighting of the floor and task lighting at table height is accomplished with 39 W PAR30 CMH flood-lamp downlights above the metal mesh ceiling plane. These provide a pattern of light and dark areas.

Lighting from 70 W CMH ellipsoidal framing projectors fitted with pattern gobos create the luminous pattern effects on the foreground floor. These were not included as part of the design to meet illuminance criteria, but contribute significantly in defining place and, therefore, desirability to users.

IESH/10e CSA/ISO

> 12.5 Task Factors
- for information on CSA/ISO computer screen qualities

29.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

29.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

29.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

29.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

29.3.6 Veiling Reflections

Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

29.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Tasks and Applications and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or

Figure 29.12 | Stacks
Stack illuminance criteria outlined in Table 29.2 under LIBRARY PROPER/Book Circulation/Conventional Book Stacks are demanding. This assures sufficient illuminance across the length and height of the stack face for reading of spines and, if pulled from the shelf, for reading of cover, flap, or body text excerpts. Light-toned floors help by reflecting light to the lower shelves. Stack lights can be continuously dimmed (preferred) or step-dimmed during times of vacancy. The design of these control techniques must account for the annoyance factor to nearby or even somewhat distant readers with peripheral view of these areas. This may determine if continuous dimming is used, the duration of dimming cycles (which may be different on the ramp-to-dim scene from the ramp-to-bright scene), and the total dimmed illuminance level selected.

The relatively dark ceiling shown here (not normally desired for efficient light distribution) helps define the stacks as focal area. If the book spines were primarily white, the ceiling would then need to be white for balance. In this situation, some ambient illuminance is generated with the cove lighting and the wood ceiling, but this is proportionally small. The ceiling cove serves the purpose of defining the background architectural planes and establishing some background luminance. The stack task lighting is accomplished with totally-direct luminaires mounted at the top of the stacks—the wood ceiling plane has little to do with the efficiency of the stack lighting.
» Image www.jmaconochie.com

accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 29.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 29.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

29.4 Designing

Information provided here is specific to library facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. Equipment selection and location strategies may need to address the possibility of lighting equipment abuse. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production and work-oriented spaces

- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

30 | LIGHTING FOR MANUFACTURING

There exist limitless opportunities in every industry. Where there is an open mind, there will always be a frontier.

Charles Kettering, Inventor

Contents

30.1 Project Type and Status. . . 30.1
30.2 Application Types 30.2
30.3 Illuminance Criteria 30.74
30.4 Designing. 30.78
30.5 References 30.79

A well-designed lighting system makes an important contribution to the success of an industrial facility. Lighting helps provide the visibility necessary for complex, often three-dimensional tasks that must be performed efficiently and safely. Industrial applications present some of the most difficult, dangerous, and demanding tasks that are performed, and appropriate lighting is essential. The industrial environments in which these lighting systems must perform are unique: extremes of temperature, difficult maintenance, high-speed movement, and recessed or shadowed immediate work areas are often encountered. All represent a lighting design challenge that requires extensive information and good planning.

Comprehensive design efforts involve the information in this chapter combined with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance criteria for industrial applications which should influence luminaire optical selections, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous IES related documents serve as archival reference sources [1] [2].

Deliberate thought must be given to details beyond the recommended illuminances in this chapter. For example, in INSPECTION/Difficult, the illuminance citations do not reveal the need to understand the requirement for either diffuse or directional illumination. Either form can produce the requisite illuminance, but a detailed knowledge of the task at hand usually dictates the directional requirements of the illumination: whether to highlight a pulled thread with grazing light, show a scratch with many small sources, or reveal the graduations on a caliper with diffuse light. Each of these types of illumination can achieve the target illuminance, but each has an appropriate geometry dictated by the task that can require different equipment and different placements. Such specific details are not enumerated for all tasks. Table 30.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

30.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. This will establish the extent to which daylighting can address some of the lighting goals, particularly in some industrial facilities such as warehouses and office spaces. New, renova-

tion, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. For some applications and tasks, daylighting can be the primary light source. Critically, this means addressing the host of lighting factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

Manufacturing environments can be quite complex, involving significant infrastructure and multiple building systems vying for the same locations. These facilities demand attention to systems integration and planning. See Figure 30.1.

30.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the spaces under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. The applications and tasks cited in Table 30.2 | Industrial Illuminance Recommendations should be reviewed against the project knowns and correlated with the space types, tasks, and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information and the available application and task citations in Table 30.2.

The following sections describe identifiable application areas and general task types commonly found in industrial environments. These discussions, those identified in Table 30.1, and the available applications and tasks identified in Table 30.2 offer comprehensive qualitative and quantitative criteria.

30.2.1 Administration and Management

Many industrial facilities with have buildings or parts of buildings that house administrative and management functions, and typically include circulation, conferencing, lounges, filing or records, interviewing, lobbies, mail sorting, and officing. Each of these in turn may involve a number of specifics including some form or degree of acknowledgment, conversation, reading, periods of respite or relaxation, and writing—all tasks within applications. Acknowledgement of other people and conversation, for example, require some vertical illuminance at face height (seating or standing depending on the nature of the application). Vertical illuminance criteria are cited for such applications.

The architectural scheme and even task specifics will vary based on the associated facility function and type. These variations should affect the lighting design—from kinds of lighting effects to lighting equipment styling to luminances and illuminances.

The administrative and management areas may be dispersed throughout a facility or complex or may be centralized into a single area, wing, or building. Depending on client wishes and architectural desires, this centralization or decentralization may affect the degree to which the lighting design in administrative and management areas is sympathetic to or different from that of other applications.

Figure 30.1 | Complex Manufacturing Environments
Industrial environments are often voluminous, filled with large machinery and supporting structure for conveyors, catwalks, and cableways that are suspended at varying elevations. This arrangement makes luminaire placement difficult. The machinery can be occluded by other equipment or structure and getting proper illumination to machines and inspection and control stations from a general lighting system is challenging.

High reflectance surfaces can improve the condition by increasing the interreflected component of light in the space. This also helps balance luminances and control uniformity ratios.

Modern machinery is often operated while being viewed through protective transparent panels. These can pose serious veiling reflections at the direct-view working position if luminaires are improperly placed.

Great mounting heights and suspended-equipment and support sructure make lighting system maintenance difficult. Luminaire locations, lamping, and the affect of lighting system maintenance on production should all be addressed with the client during design.

» Image ©Serge Kozak/Corbis

30.2.2 Areas with Extreme Humidity or Temperatures, or with Corrosive Atmospheres

High humidity or corrosive atmospheres are likely to be present in at least some areas in a typical plant. Such areas usually require special luminaires. Further, outdoor lighting locations may be exposed to rain, snow, fog, wind, high humidity and salt-laden sea air.

The usual methods to protect against these atmospheres include the use of materials that resist corrosion, special surface preparations and corrosion resistant coatings or paint for luminaires such as epoxy, polyester or polyvinyl chloride. In addition, robust modes of paint application such as electrostatic coating or powder coating may be used. Luminaries that have non-metallic outer housings are also available. Some luminaries for classified locations are constructed in a manner that makes them suitable for high-corrosion areas.

Abnormally high ambient temperatures are often present in industrial applications, especially near the ceiling where the luminaries are installed. Industrial luminaries are available with ratings for ambient temperature conditions of 40° C, 55° C and 65° C (104° F, 131° F, 149° F). The temperature rating of the selected luminaire is important and should be at least as high as the temperature in which it is to operate during the warmest season of the year. The limiting factor can be any of several components within the luminaire. If the limiter is a ballast component, the ballast housing may often be remotely mounted in a cooler location.

Except for ignitor-start lamps (high pressure sodium and pulse-start metal halide), the only distance limitation to remote ballast location is the wire gauge. This is sized for the distance, according to the ballast manufacturer's recommendation, to hold voltage drops to a comfortable minimum.

With any system that has a pulse-igniter, the maximum distance the ignitor can be removed from the lamp is limited. In some cases the igniter can be placed in a compartment that has suitable heat sinking and remain with the optical portion of the luminaire (the other heat-sensitive components can be mounted remotely). Otherwise, a "long range ignitor" should be used to increase the remote distance. The ballast manufacturer should be consulted for exact limitations.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Notes for Table 30.2

The table column headings are discussed in detail in 30.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 30.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 30.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or polished metalic surfaces, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

Figure 30.2 | Cleanrooms
Special luminaires are usually required in cleanrooms. Power supply and mounting requirements may be unique. Special seals to achieve specific IP ratings may be necessary. Depending on the production processes involved, spectral filtering is used to eliminate optical radiation interference.
» Image ©Chris Close/The Image Bank/Getty

Abnormally low ambient temperatures are usually found in commercial food processing and distribution facilities. Temperatures become an issue if they are below 10° C (50°F) for fluorescent lamps, and -29° C (-20° F) for HID lamps. Fluorescent systems generally require a ballast for low temperature starting if the ambient temperature is lower than 10° C (50° F) for standard lamps and -18° C (0° F) for 800 ma and 1500 ma lamps. At temperatures less than 20° C (68° F) fluorescent lamps stabilize at rated watts but at less than rated lumens. Enclosing the bulb-wall, either with a plastic sleeve or an enclosed optical area, will improve the lumen output. Depending on the type of enclosure and the ambient conditions, the lamp or lamps may heat up the enclosure to normal operating temperature to produce rated lamp lumens.

Most ignitor-start HID ballasts are rated to start a lamp (pulse-start metal halide or high pressure sodium) in temperatures to -40° C (-40°F). Temperatures below this require auxiliary incandescent sources, which warm up the interior of the luminaire until the HID lamp starts. These are usually coupled with a relay, which turns off the incandescent source when the HID lamp starts.

30.2.3 Classified Areas

Classified Areas are where flammable gas or vapors or combustible dust or easily ignitable flyings or fibers are or can be present. These are defined in the National Electric Code (NEC) in the United States in terms of Classes (gas, dust) and Divisions, which define the conditions and manner in which the material is present. The National Fire Protection Association (NFPA) defines the hazardous nature of the space and the requirements for luminaries suitable for application in classified areas. The designer should check with the insurance carrier for the industrial site to determine the exact Class and Division for individual areas. Luminaires that have undergone special testing and subsequently rated for use in these special areas must be used. These involve special gasketing, exterior surfaces, limited maximum operating temperatures, and lamp power.

30.2.4 Cleanrooms

Clean room lighting uses entirely different luminaries than other industrial environments. Clean rooms are sealed, controlled environments designed to eliminate microscopic particles of a specified size. The particle may be dirt, which at a certain size (usually measured in microns) causes quality problems of the manufactured product, such as a silicon chip. The particle could also be an organism, such as a microbe that must be eliminated from an operating room. The Institute of Environmental Sciences (IES) categorizes generic clean rooms by a series of classifications based upon the number of micron particles found in a cubic foot of air inside the room. The categories start at 100,000 parts per cubic foot and get cleaner by factors of ten. Class 10,000, class 1,000, class 100 and class 10 Clean Rooms are all defined by this organization. Quite often, class 100 clean rooms are found inside class 1,000 clean rooms. See Figure 30.2.

Clean room structure usually includes t-grid ceilings of a type not found outside this application. The t-grid is of a larger cross-section, such as 1" or 2" wide and is always gasketed in some fashion. Many of these ceilings are made for walking upon so that the fixtures and High Efficiency Particulate Air (HEPA) filters can be serviced from above.

There are four main types of luminaries used in clean-rooms:

1. Gasketed recessed (troffer) fluorescent
2. Tear-drop surface fluorescent Flow-thru
3. Recessed fluorescent Recessed T5
4. Fluorescent integral to the T-grid

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Gasketed recessed fluorescent luminaries are usually used in the class 100,000 and class 10,000 spaces, and the other three types are used as more and more of the grid-spaces are taken up with filters and cannot be occupied with luminaries.

In most of these construction styles, the important issues are that gasketing seals the room from the outside environment and that the outside surfaces are smooth and cleanable. Prismatic lenses, for example normally are installed "prisms-up" to present a smooth surface to the space.

30.2.5 Components Sub- and Final Assembly

This phase of manufacturing has special requirements not usually found in other industrial operations. Modern industrial requirements have necessitated the construction of buildings with clear bay areas, which may exceed 26,000 m^2 (300,000 ft^2) and truss heights of more than 24 m (80 ft) from floor level. The lighting problems in buildings of this size are not confined to the engineering and design concepts but include the task of maintenance and lamp replacement The use of either a system of catwalks or traveling-bridge cranes may be appropriate to allow access to the lighting units. In some cases, mobile telescoping cranes can be used to reach luminaries from the floor, but the heights involved and obstructions on the floor may make this method of maintenance impractical. Where access is available from the floor, disconnecting hangers and lowering chains can be an effective method for maintaining luminaries in high-bay areas.

One special problem in lighting certain assembly tasks, is that the lighting is usually designed to specific task levels with the assumption that the areas will be completely open, whereas in reality that is seldom so. The lighting from overhead systems is often reduced by the presence of large assemblies or large production equipment. A knowledge of the size and placement of such obstructions is necessary in order for design calculations to accurately predict how a proposed lighting system will perform. See 10 | CALCULATION OF LIGHT AND ITS EFFECTS.

Typical of the types of assemblies found in these facilities are aircraft and automobile subassemblies and the installation of sub-systems in these assemblies for which supplementary lighting is often required.

Assembly of large aircraft sections, for instance, can present special lighting problems. Exterior lighting for joining together these sections requires both horizontal and vertical illuminance as well as lighting installed in such a manner that it will light the underside of the body and wings. Use of floodlights can give both components of light on the exterior body and also provide light to the undersides of the body and wings. Specially mounted luminaries or portable lighting are required to light areas such as landing-gear pockets. High reflectance floor finishes will aid in lighting the underside of assemblies but supplementary lighting is still usually required.

30.2.6 Control Rooms

The control room is the nerve center of facilities such as electric generating plants, electric-dispatch facilities, steam or hot water generating plants, and chemical plants, and it must be continuously monitored. Lighting must be designed with special attention on the comfort of the operator; direct and reflected glare and veiling reflections must be minimized, and luminance ratios must be low. Along with ordinary office-type seeing tasks, the operator has to read gauges, meters and other monitoring devices, often at distances of 3-4.5 m (10-15 ft) away. Reflected glare and veiling reflections must be eliminated from these indicating devices, including those with curved glass faces.

While the practice is not standardized, most control-room lighting involves one of two general categories: diffuse lighting or directional lighting. Diffuse lighting may be from low-luminance, indirect lighting equipment, solid luminous plastic ceilings or louvered

Table 30.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

Figure 30.3 | Inspection with General Lighting
Many inspection tasks involve viewing moving items, recognizing defects, and removing the items. The moving items are visually tracked by move the head. General lighting, such as provided by the Low-Bay luminaires used here, is often sufficient.
» Image ©Jim Richardson/CORBIS

ceilings. Directional lighting may be from recessed troffers, which follow the general contour of the control board. (These luminaries must be accurately located to keep reflected light out of the glare zone.) Lighting for the rest of the room may be from any type of low-luminance general lighting equipment.

As control room data displays are more and more digital, the problems concerning lighting and VDTs are more in evidence. Many operators like to have black or dark colored backgrounds on their VDTs in order to increase the contrast between pixel derived data and its background. In this instance the veiling reflection problems are increased over those with light background panel meters. Under these conditions light surfaced walls behind the operator, walls and lighting outside of glass partitions, floors and even light reflecting off the operator's clothing and the table surfaces next to the operator can show up as a veiling reflection in the VDT.

Often, the orientation and tilt angle of the VDT may not be easily adjusted to reduce objectionable screen reflections. In these cases, control of sources of direct and reflected light relative to the screens and operators is even more critical.

30.2.7 Emergency, Safety, and Security Lighting

See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

30.2.8 Food and Drug Processing

Food and drug processing areas generally have additional requirements for construction and materials used in the luminaire. The requirements are documented by sanitation-regulating entities, such as the National Sanitary Foundation (NSF) or the US Department of Agriculture (USDA), and can classify different sections of the food processing area by the proximity of the luminaire to the food. Some classifications call for smooth exterior surfaces to eliminate areas for particle accumulation or bacterial growth. One constant is that glass cannot be exposed. This means that open-lamp and glass-enclosed luminaries are not suitable. In many food processing areas, scheduled pressure washing is required and therefore luminaries must be gasketed to withstand washing. Each facility's pressure washing equipment is different, producing different pressure and flow rates. This information should be obtained from the plant engineering office and luminaire capabilities matched to it. Paint is required to be non-toxic and environmentally neutral, in case it chips or flakes off. Unfinished stainless steel luminaries are popular in the extremes of this type of application. Figure 30.3 illustrates an example of a food processing task.

The color rendering properties of light sources used in food inspection areas are important when examination is based on color appearance.

30.2.9 Inspection

The color of light can be used to increase contrast by either intensifying or subduing certain colors inherent in the seeing task. To intensify a color, the light source should be strong in that color; to subdue a color the source should have relatively low spectral power in that color. For example, it has been found that using a bluish light such as a daylight fluorescent lamp can emphasize imperfections in chromium plating over nickel plating.

Three-dimensional objects are seen in their apparent shapes because of the shadows and highlights resulting from a strong directional component in the incident light. This directional effect is particularly useful in emphasizing texture and defects on uneven surfaces.

Silhouette is an effective means of checking contour with a standard template. Illumination behind the template will show brightness where there is a difference between the contour of the standard and the object to be checked.

Fluorescence under ultraviolet radiation is often useful in creating contrast. Surface flaws in metal and nonporous plastic and ceramic parts can be detected by the use of fluorescent materials.

The detection of internal strains in glass, lenses, lamp bulbs and transparent plastics may be facilitated by transmitted polarized light. The nonuniform spectral transmittance of strained areas causes the formation of color fringes that are visible to an inspector. With transparent models of structures and machine parts, it is possible to analyze strains under operating conditions.

Successful inspection of very small objects is greatly improved by viewing them through lenses and providing suffiicient illuminance. See Figure 30.4. For production work, the magnified image may be projected on a screen. Because the projected silhouette is many times the actual size of the object, any irregular shapes or improper spacings can be detected readily. Similar devices are employed for the inspection of machine parts where accurate dimensions and contours are essential. One typical device now in common use projects an enlarged silhouette of gear teeth on a profile chart. The meshing of these production gears with a perfectly cut standard is examined on the chart.

There are occasions when moving parts must be inspected or studied while they are operating. Stroboscopic illumination can be effective in this process by adjusting the rate of "strobe" to stop or slow the apparent motion of constant-speed rotating or reciprocating machinery. Stroboscopic lamps give flashes of light at controllable intervals (frequencies). The flashing can be so timed that when the flash occurs, an object with rotating or reciprocating motion is always in exactly the same position and appears to remain stationary. This technique can be very effective in allowing inspection of rotating parts without the necessity of stopping the process.

Some inspection tasks involve large surface areas and the detection of irregularities and finish imperfections. Reflected images of linear light sources can be used to reveal such irregularities and imperfections. See Figure 30.5.

There is a potentially dangerous stroboscopic effect unintentionally produced by fluorescent and HID lamps and other sources operated on magnetic ballasts when flicker occurs on rotating equipment such as drilling, milling and lathe machines. At some rotational speeds, these parts can appear to be stopped when, in fact, they are rotating at a dangerous speed. The use of electronic ballasts to operate lamps at high frequency can virtually eliminate flicker and strobe effects.

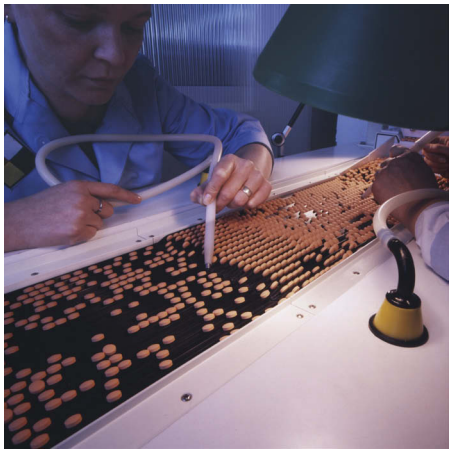

Figure 30.4 | Inspection with Localized Lighting
Some inspection tasks involve not only motion but small items and hand-manipulated instrments. The illuminance levels required are best achieve with local lighting placed close to the task.
» Image ©doc-stock/Corbis

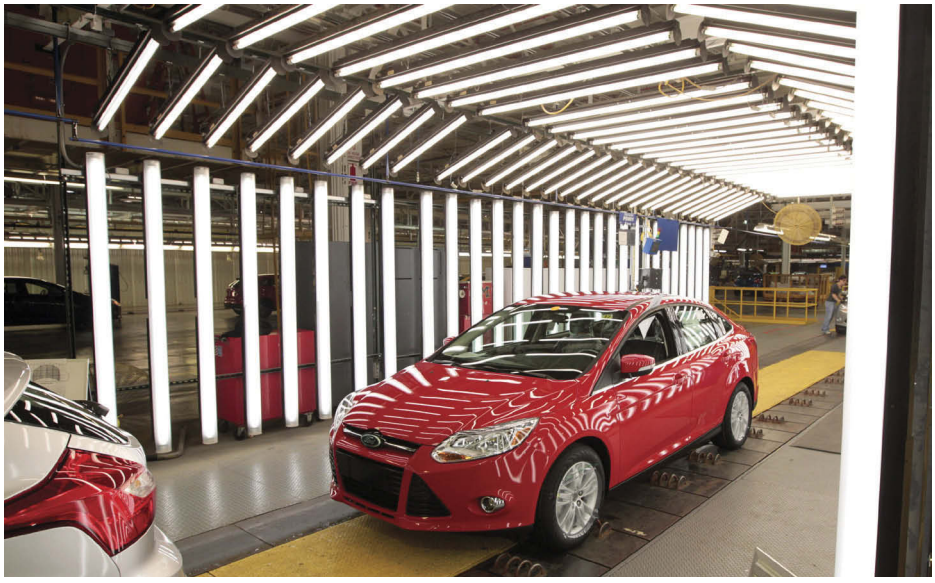

Figure 30.5 | Inspection Using Source Images
Some inspection tasks involve detecting imperfections in surface finishes. This is often best accomplished with multiple sources that are small in at least one dimension, such as the multiple fluorescent strip luminaires used here. Distinct, multiple incident directions of light help model and reveal imperfections. The regular geometric pattern of the reflected source images also help show surface irregularities.

30.2.10 Machining and Working with Materials

While computer numerically controlled (CNC) machines do most precision work, there is still considerable hand work, especially as pertaining to set-up work. Machining of metal parts consists of the preparation and operation of machines such as lathes, grinders (internal, external and surface), millers (universal and vertical), shapers and drill presses, bench work, and inspection of metal surfaces. The precision of such machine operations usually depends upon the accuracy of the setup and the careful use of the graduated feed-indicating dials rather than the observation of the cutting tool or its path. The work is usually checked by portable measuring instruments, and only in rare cases is a precision cut made to a scribed line. The fundamental visual task is to discriminate detail on planar or curved metallic surfaces.

Most of the visual tasks in the machining of metal parts are best lighted by large-area low-luminance sources. The ideal general lighting system would have a large indirect component. While both fluorescent and high-intensity discharge sources can be used for general lighting, fluorescent luminaries, particularly in a grid pattern, are sometimes preferred for low mounting heights. High-reflectance room surfaces improve illumination and visual performance. Luminaire placement is often constrained by the location and size of building structure and other occluding elements, as well as the size and position of the equipment that needs to be lighted. These constraints often help define the required optics and intensity distribution of the luminaires to be used. See Figure 30.6.

Workers often refer to information on a VDT or other digital display, so the potential for veiling reflections produced by luminaries, light surfaced walls, and windows must anticipated.

Industrial visual task often involve surfaces (metallic or otherwise) that are shaped and exhibit nondiffuse reflectance. These characteristics are important considerations in choosing and placing lighting equipment.

Convex Surfaces
Discriminating detail on a convex surface, as in reading a convex scale on a micrometer caliper, is a typical seeing task. The reflected image of a large-area low-luminance source on the scale provides excellent contrast between the dark figures and divisions and the bright background without producing reflected glare. The use of a near-point source for such applications results in a narrow, brilliant band that obscures the remainder of the scale because of the harsh specular reflection and loss of contrast between the figures or divisions and the background.

Flat Surfaces
In viewing a flat surface, such as a flat scale, the seeing task is similar to that in reading a convex scale. With a flat scale, however, it is possible, depending on the size, location and shape of the source, to reflect the image of the source either on the entire scale, or only on a small part of it. If the reflected image of the source is restricted to too small a part of the scale, the reflection is likely to be glaring.

Scribe Marks
The visibility of scribed marks depends upon the characteristics of the surface, the orientation of the scribed mark and the nature of the light source. Directional light produces good visibility of scribed marks on untreated cold-rolled steel if the marks are oriented for maximum visibility, so that the luminance of the source is reflected from the side of the scribed mark to the observer's eye. Unfortunately, this technique reduces the visibility of other scribed marks. Better results are obtained with a large-area low-luminance source. If the surface to be scribed is treated with a low-reflectance dye, the process of scribing will remove the dye and expose the surface of the metal. Such scribing appears bright against a dark background. The same technique is appropriate for lighting specular or diffuse aluminum. In this case, the scribed marks will appear dark against a bright background.

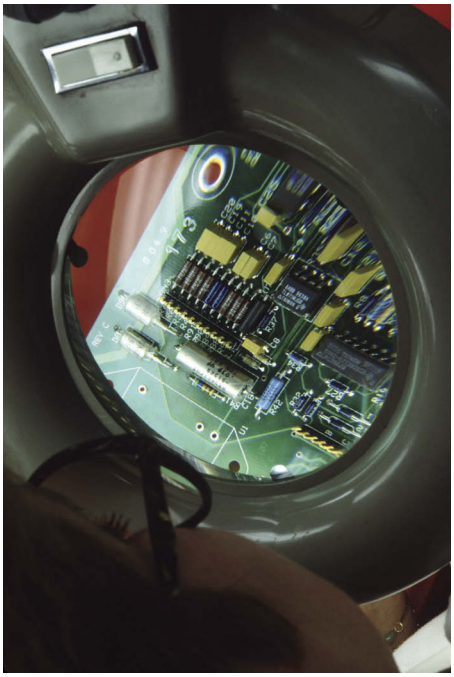
Figure 30.6 | Machining
Luminaires carfully located with respect to overhead obstructions and machines can provide the general lighting needed in many industrial areas. The fluorescent wrap-around luminaires used here, along with the high reflectance ceiling provide efficient horiztonal and vertical illuminances at all task locations.
» Image ©moodboard/Corbis

Center-Punch Marks
A visual task quite similar to scribing is that of seeing center-punch marks. Maximum visibility is obtained when the side of the punch opposite the observer reflects the luminance of a light source. A directional source located between the observer and the task provides excellent results when the light is at an angle of about 45° with the horizontal.

Concave Specular Surfaces
The inspection of concave specular surfaces is difficult because of reflections from surrounding light sources. Large-area, low-luminance sources provide the best visibility. In the machining of small metal parts, a low-luminance source of approximately 1700 cd/rn^2 is desirable. The size of the source depends on the shape of the machined surface and the area from which it is desired to reflect the brightness. The techniques applicable to specular reflections can also be applied to semispecular surfaces.

30.2.11 Outdoor Area Lighting



Two different systems of lighting are commonly used to illuminate large, outdoor areas of industrial facilities: projected (long-throw) lighting and distributed lighting. Each has its advantages under specific situations.

Projected Lighting Systems
The function of this system is to provide illumination from a minimum of locations throughout the various outdoor work areas. This is usually accomplished by use of aimmable floodlighting luminaries.

Projected outdoor area lighting has the fewest locations and thus requires the least amount of aerial structure. Structures are usually the most expensive part of the lighting system.

Distributed Lighting Systems
In distributed lighting systems luminaries are installed at many locations. Wall mounted equipment is often used at personnel and loading dock doors. Wall mounted equipment, however, should rarely be used to cover a transverse dimension greater than two mounting heights and a longitudinal (horizontal, to the side) area more than 4 mounting heights. This would place continuous area lighting equipment on 4 mounting height spacing along a wall.

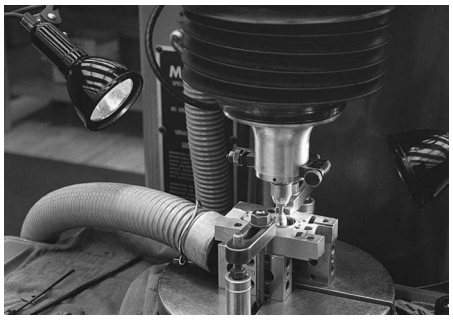

Figure 30.7 | Supplementary Task Lighting
Top Image. Some tasks are sufficiently small to require supplementary lighting as well as manifcation. Here, a circular fluorescent lamps is used around the magnifiying lens in a single supplementary task lighting luminaire.

Bottom Image. Some machining tasks are performed on equipment that is so large that only supplementary lighting can provide the necessary illuminance. Here a small adjustable, high intensity luminaire, can be moved with work and/or machine

» Top image ©Robert Essel NYC/Corbis

Distributed outdoor area lighting systems have the least amount of glare because mounting heights can be lower. When floodlights are used, aiming angles can be less oblique, thus permitting glare control media such as louvers and visors to work. Care should be taken to keep aiming angles below 65 degrees above nadir.

See also 26 | LIGHTING FOR EXTERIORS.

30.2.12 Supplementary Task Lighting

Difficult visual tasks, such as inspection, often require a specific quality and quantity of light that cannot readily be obtained by general lighting methods. Supplementary luminaries are often used to:

- Provide higher illuminances
- Direct attention on small or restricted areas
- Achieve a certain luminance
- Provide a specific color rendition
- Permit special aiming or positioning of light sources to produce/avoid highlights or shadows
- Reveal the details of the visual task.

The specific requirement of each visual task need to be evaluated before supplementary task lighting can be specified. Simply adding lighting at the task with no consideration for the light reflecting or transmitting characteristics of the object(s) observed will be ineffective. An improvement in the visibility of the task will depend upon improvement of one or more of the four fundamental visibility factors - luminance, contrast (chromatic or achromatic), size and time.

The planning of supplementary task lighting also requires consideration of the visual comfort of workers performing the task and other workers in the immediate area. Supplementary equipment must be carefully shielded to prevent glare for the user and neighboring workers. Luminance ratios should be carefully controlled.

Wherever possible, supplementary luminaries should be permanently mounted in the location where they can produce the best lighting effect and maintenance after assembly. Portable equipment, however, can be used to good advantage where it must be moved in and around movable machines or objects, as in airplane assembly, or in maintenance operations where internal surfaces must be viewed. The luminaries must be mechanically and electrically rugged to withstand possible rough handling. Lamps should be guarded and of the rough-service type. Guards or other means should protect the user from excessive heat. Precautions, such as the use of ground fault circuit interrupters for personnel protection, should be taken to prevent electrical shock, and electrical connections must be suitable for the service to which they will be subjected. See Figure 30.7.

30.2.13 Visibility of Objects

The visibility of objects in industrial facilities is necessary not only for the correct and efficient performance of visual work, but the safety of workers as well. In addition to the recommended illuminances shown in Table 30.2, task visibility in an industrial environment often requires particular attention to contrast, flicker, modeling, source geometry, and shadowing as fundamental components of task visibility.

Contrast
Luminance and color contrast can be enhanced with appropriate choices of materials and sources. Color contrast and color rendering may be the most important aspect of a tasks visibility. See 6 | COLOR.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Flicker

Flicker is the rapid variation in light source intensity, usually most noticeable in peripheral vision. The output of lighting systems that operate on alternating current power varies in output at a rate that is twice the cyclic frequency of the input power. Sometimes this "strobe effect" appears to slow or even stop the movement of objects. This can be annoying or dangerous for operators of rotating or other rapidly cycling equipment.

The "flicker index" has been established as a reliable relative measure of the cyclic variation in output of various light sources at a given power frequency and takes into account the waveform of the light output as well as its amplitude. The flicker index assumes values from 0 to 1.0 with zero for steady light output. Higher values indicate increased possibility of noticeable stroboscopic effect as well as lamp flicker.

Most fluorescent lamps have low flicker indices, and typically do not cause problems when operating on a 60-Hz power supply. Their visible flicker is virtually eliminated when operated at high frequency on electronic ballasts. Sensitivity to flicker varies among individuals, varies across the visual field and often will be unnoticed. Designers are cautioned to consult with a lamp manufacturer about the flicker index of a particular fluorescent lamp/ballast combination before it is used in an area where flicker or strobe could be a problem.

The flicker in HID lamps depends on the lamp type and the ballast circuit. The flicker index is considerably higher in 50-Hz power systems. Using electronic ballasts having high-frequency or rectangular wave characteristics can be effective in reducing the flicker effect. Operating fluorescent or HID lamps on alternate phases of a three-phase power supply will reduce observed flicker when the light from luminaries connected to all three phases is well mixed before it reaches the workplane. This is accomplished by using luminaries with a wider spacing criterion, designing for 50 percent light pat tem overlap, and powering adjacent luminaries from alternate phases.

Modeling

Lighting will reveal the depth, shape and texture of an object. In industrial applications, modeling of the visual task can be critical to assessing quality of raw materials, quality of finished goods and degree of consistency in manufacturing processes. Appropriate direction and distribution of light may vary depending on material and task. Diffuse ambient lighting is often inadequate for assessing fine texture; task lighting may be used to provide the required direction, distribution and intensity of light. See Figure 30.8.

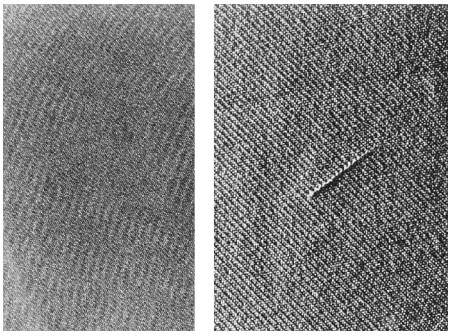

Figure 30.8 | Modeling
Diffuse lighting (left) does not show pulled thread but grazing or directional lighting (right) reveals a pulled thread by generating its shadow.

Source-Eye Geometry

The angular relationships between the viewer, the task and the luminaire are frequently critical to task visibility. Industrial tasks are often three-dimensional, and they often move. Because viewing angles are dynamic, the source/task/eye geometric relationships must be understood for individual work areas. The geometry can enhance contrast (such as scribed marks on a micrometer) or reduce it (such as viewing a meter dial through glass).

Shadows

Shadows can interfere with task visibility by placing detail in darkness (for example, a body shadow on a machine task), or they can enhance definition of three-dimensional details (such as imperfections in textiles). Point sources (such as incandescent or high intensity discharge lamps) create more defined shadows than fluorescent lamps, which produce diffuse shadows.

Generally, a large area of shadow, covering the whole task area, will simply lower the task illuminance. Shadows cast by the structure of the task may reveal detail, or may mask what needs to be seen. High reflectance surroundings help fill in and modify shadows, as do luminaries with 10 percent or more uplight when the ceiling cavity reflectance is over

Figure 30.9 | Warehouse Lighting
The tall narrow aisles established by warehouse shelving and stock require relatively uniform vertical illuminances. Here, HID high bay luminaires with an intensity distribution appropriate to the aisle width and stack height illuminate the vertical surfaces.
» Image ©moodboard/Corbis

50 percent. A combination of supplementary task lighting and general illumination is often the best approach, if care is taken to minimize glare.

The presence of shadows may be desirable, and the interplay of highlight and shadow helps to define the form of many visual tasks. Lighting vertical surfaces to at least half the horizontal illuminance level often brings the ratio of highlight to shadow into a tolerable range for three-dimensional tasks. Some shadow will still be present, which helps to model the task and reveal form. Since each visual task has an optimum range of modeling, a careful evaluation of critical visual tasks should be made to determine the effects of various ratios of horizontal vs. vertical illuminance on visibility.

Obstructions below the luminaire mounting plane, such as pipes and ducts, and the location and orientation of the task, affect the availability of vertical illuminance. Obstructions can also produce shadows, as can an operator positioned between the task and the luminaries. When a task is close to a wall, and the operator is facing the wall, relatively few luminaries are likely to contribute to task illuminance. In these cases, high wall reflectances (greater than 60 percent) can improve task visibility

30.2.14 Warehouses

Placing items in storage, accounting for them and later retrieving them are some of the most widespread activities requiring electric lighting in industrial facilities. Storage activities are found in business operations of every type, ranging from small local operations to multinational corporations.

Since rapid changes are taking place, the traditional concept of the warehouse must be expanded to encompass new techniques, including automation, high-rise storage, bar coding, cold storage, and shrink-wrap packaging. Warehouses may contain any of the following areas and activities.

Storage Systems
A variety of warehouse areas and storage systems requiring specific tasks may occur in warehouse usage. In each case the nature of the storage area determines the task plane and the nature of objects that can produce unwanted shadowing.

- Open Storage. Areas of material stored without the use of rack systems. This includes storage on the floor and on pallets, which may be stacked on each other.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Figure 30.10 | Warehouse Lighting
Here, fluorescent high bay luminaires illuminate vertical warehouse stock surfaces. Sensor and controls systems can be used to dim the luminaires and take advantage of the daylight available from skylights.
» Image ©Ian Lishman/Juice Images/Corbis

- High Rise. Areas generally automated, where storage bins may be rotated so that unused bins are kept high up, and with storage levels rising to over 30.5 m (100 ft).
- Fixed Racking. Areas with fixed racking may range from 1-4 m (3-12 ft) wide and from 2.5-9 m (8 to 30 ft) high. Items may be in bins, on racks, or in various types of containers. Labeling of the racks, containers or bins can vary from large black-on-white lettering to small, hard-to-read hand written labels.
- Mobile Racking. A storage system now widely used in North America. Entire blocks of racking move on floor-mounted rails to open and close aisles as needed. In order to obtain maximum use from any lighting provided, the definition of the actual seeing task should be considered.
- Stockroom Area. Identification marks on the sides of bulky materials, rolls of paper, and crates or boxes require vertical illumination. Additional lighting should be provided over the aisles where high piles of stock interfere with general lighting.
- Cold Storage. Areas that warehouse normally perishable food items and require low (sometimes below freezing) temperatures. See 30.2.2 Areas with Extreme Humidity or Temperatures, or with Corrosive Atmospheres.

Figures 30.9 and 30.10 illustrate HID and fluorescent warehouse lighting approaches.

Hazardous Materials
Areas where hazardous gases, vapors, or dust are or could be present require specific methods of storage. Local building code requirements should be checked as to permissible luminaries for lighting areas where hazardous materials are stored or used. See 30.2.3 Classified Areas

Shipping and Receiving
Areas where materials are received into the warehouse for sorting and placement in storage areas. Areas that serve as staging areas for coordination of products to be sorted and placed on trucks or trains to be shipped. One of the most difficult visual tasks is reading markings on shipments, labels and bills of lading. General illumination may provide sufficient light for these tasks and for the operation of manual or powered forklift trucks, as well as for general traffic in the area.

Supplementary lighting may be necessary for the interior of transport carriers bringing material to the plant. Angle or projector-type luminaries may be utilized, but care must

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

be taken to avoid glare from these sources. If the conveyances are deep, reel-type or other portable lighting equipment may be necessary. Yard or loading-dock lighting should be installed for night operation.

Loading Docks and Staging
Areas, generally just outside the shipping area, that may be outdoors but are often covered and that are used to place items on and off trucks and railroad cars and to assemble goods.

Maintenance
This includes maintenance shops, fork lift recharging areas and refrigeration equipment rooms. Locations where general plant housekeeping activities occur. Separate areas or rooms are generally set aside for these purposes.

Daylighting
While daylight can be used to help light warehouses, care should be taken to control the quantity and distribution of the light. Daylighting is most effective for many interior warehouse spaces when used as ambient illuminance, but if energy is to be save and its variability managed, an electric lighting system under daylight control is required. See also 14 | DESIGNING DAYLIGHTING.

30.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance over a large area housing machines, is unlikely to satisfy the requirements for the varied tasks being performed. It is unlikely that this will get the most from the energy expended or, worse, will waste energy. Following are notes related to various topics outlined in Table 30.2.

30.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 30.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. This is based on similarities of visual size, reflecting properties, difficulty, and importance. Reviewing the list in Table 30.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

30.3.2 Notes

The notes in Table 30.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

30.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and supplemental lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice and for purposes of sustainability can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 30.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task. For industrial environments, this is typically, but not always, horizontal or vertical.

30.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane. The task may be three-dimensional and no particular plane is more important than another and it may be necessary to provide the required illuminance on several planes at the task position.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." Note the implication for observers' visual ages. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

designer must determine which are most appropriate for the situation. Understanding the machinery and its operation, the process involved, and the position of the machine operator, is necessary.

30.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. It may be determined that illuminance criteria for an age group other than that representing the majority of the intended observers is appropriate. However, this may result in overlighting, underlighting, harsh lighting, visual displeasure, or visual discomfort for many of the observers. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance. In some situations, such as video conferencing, lighting must meet the requirements of the camera technology and, therefore, is not tied to ages of observers.

30.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 30.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

30.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, “Avg” is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is “Min” or “Max” respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

30.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

30.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

30.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

30.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

30.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

30.3.6 Veiling Reflections

Some industrial tasks, like computers with CSA/ISO Type III screens, printed tasks with glossy ink or glossy paper, and many objects made of metals and plastics are prone to specular reflections. In some cases these reflections can help (such as seeing scratches in an otherwise smooth finish), but it others they reduce visibility by causing veiling reflections. The likelihood of particular applications and tasks predisposed to specular reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

30.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Applications and Tasks and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task"

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 30.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 30.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

30.4 Designing

Information provided here is specific to manufacturing facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. Equipment selection and location strategies may need to address the possibility of lighting equipment abuse. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. Dimming response to daylight may be impractical. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the safety and productivity of the workers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production, holding, and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic, abuse, and luminance criteria
- using accenting to provide luminance balancing
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical timeclocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting

- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the safety and productivity of the workers is the paramount design tenet and must be kept in perspective during all aspects of design. If the workers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

31 | LIGHTING FOR MISCELLANEOUS APPLICATIONS

Science is organized knowledge. Wisdom is organized life.
Immanuel Kant, 18th Century German Philosopher [1]

Contents

31.1 Project Type and Status. . . 31.2
31.2 Application Types 31.2
31.3 Illuminance Criteria 31.25
31.4 Designing. 31.29
31.5 References 31.30

There are several sets of applications and tasks that are not conveniently categorized with those of other chapters. They are collected here in the format similar to other application chapters in this handbook, though their only relationship to one another is that they arguably qualify as institutional facilities. Certainly all are important applications with demanding tasks supporting commerce, liberties, safety, and security. Lighting addresses the visual needs of users, ranging from 911-call-center tasks to facilitating public forums in council chambers. The applications that are consolidated here are:

- Financial Facilities
- Municipal Facilities
- Post Offices

Financial facilities include banking and trading. Municipal facilities include city halls and fire and police stations. Post offices include consumer services and sorting.

Comprehensive design efforts involve the information in this chapter combined with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance criteria for miscellaneous facilities which should influence luminaire optical selections, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous IES related documents serve as archival reference sources [2].

Deliberate thought must be given to details beyond the recommended illuminances in this chapter. For example, with MUNICIPAL FACILITIES/Fire Stations/Apparatus Bays/General in Table 31.2, the illuminance citations are intended to apply to the general room in which the emergency vehicles will be secured. This allows for equipment inspection and cleaning on rigs and for basic service and maintenance activities on components in empty bays. However, it is not uncommon for fire stations to serve various civic functions, such as election polling. Should such a situation be programmed, the designer must review the likely voting tasks and determine if the general illuminance for apparatus bays will suffice. The design must know what, if any, additional tasks must be accommodated. A task survey, such as that exemplified in Table 12.3 | Sample Visual Task Survey, should be undertaken. Such details are not enumerated for tasks. Table 31.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

31.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. This will establish the extent to which daylighting can address most or many or some of the lighting goals. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. For some applications and tasks, daylighting can be the primary light source. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

31.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the miscellaneous facilities space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 31.2 | Miscellaneous Applications Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 31.2.

In many situations in courts and correctional facilities, security is an inherent part of the task: securing detainees and prisoners to prevent their escape or destructive actions to property, self, or others; securing key personnel of courts and correctional facilities from harm. Lighting plays a role, but only as part of a much broader security program to be effective. Lighting hardware itself must be considered a target of destructive behavior in some of these situations. The designer must review the programming information and consult with the team and owner to establish the full extent of security issues affecting lighting.

The following discussion is keyed to major application headings in Table 31.2. Couple this with topics in Table 31.1 for comprehensive qualitative and quantitative criteria.

31.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction, inspection, and wayfinding. Accenting enhances architectural spatial forms and limits and impressions of spatial volume. See Tables 12.1a, 12.1b, and 12.2. Accenting can make spaces appear less institutional.

31.2.2 Administration

Lighting for administrative areas is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The architectural scheme and even task specifics will vary based on the miscellaneous facilities involved. In some projects these details should affect the lighting

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

design, from the kinds of lighting effects to lighting equipment styling to luminances and illuminances. In other projects, notably more secure areas of police stations, the straightforward requirements of security and abuse will override some lighting effects and equipment styling aspects.

The administrative areas are typically consolidated into a single area, wing, or building. Several aspects may affect the degree to which the lighting design in the administrative area is sympathetic to or different from that of the other applications and tasks at the facility in question:

- Owner wishes and architectural desires
- Visual connection between administrative areas and other areas of the facility
- Management style

See also 32 | LIGHTING FOR OFFICES.

31.2.3 Atria and Courtyards

Lighting for atria and courtyards is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

31.2.4 Banking

See Section 31.2.8 Financial Facilities.

31.2.5 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

31.2.6 Circulation

Given varying security requirements, lighting for circulation is addressed in respective application areas of miscellaneous facilities. Default criteria are cited in TRANSITION SPACES.

31.2.7 Conferencing

Various forms of conferencing are used in miscellaneous facilities. Lighting for conferencing is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

31.2.8 Financial Facilities

Banking and trading applications involve a wide range of visual tasks. Some involve extended reading of multiple computer screens or paperwork or facial assessment or some combination. Additionally, some lighting is closely integrated with the retail brand of the respective financial corporation. Across these tasks and branding strategies is a level of security typically involving surveillance or recording cameras. Camera locations and orientations should be coordinated with lighting layouts to minimize image washout. Additionally, uniformity ratios should be confirmed against camera capabilities to avoid situations where cameras lose images while panning across space.

Lighting effects and hardware styling, sizes, and layouts can contribute to an urbane setting. Daylighting is considered a significant benefit, but the type, location, and size of daylight media must be coordinated with the security consultant.

Lighting for a few key applications and tasks is outlined below.

Notes for Table 31.2

The table column headings are discussed in detail in 31.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 31.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 31.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 31.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, or conference table a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 31.2

The table column headings are discussed in detail in 31.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 31.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 31.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 31.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon ■ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ■ signals high likelihood; gray and white ■ signals moderate likelihood; pale gray and white ■ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, or conference table a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

Notes for Table 31.2

The table column headings are discussed in detail in 31.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 31.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 31.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 31.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, or conference table a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, or conference table a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

m. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 31.2

The table column headings are discussed in detail in 31.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 31.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 31.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 31.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like object under glass or CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

l. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, or conference table a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

Table 31.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

IESH/10e CSA/ISO

> 12.5 Task Factors
- for information on CSA/ISO computer screen qualities

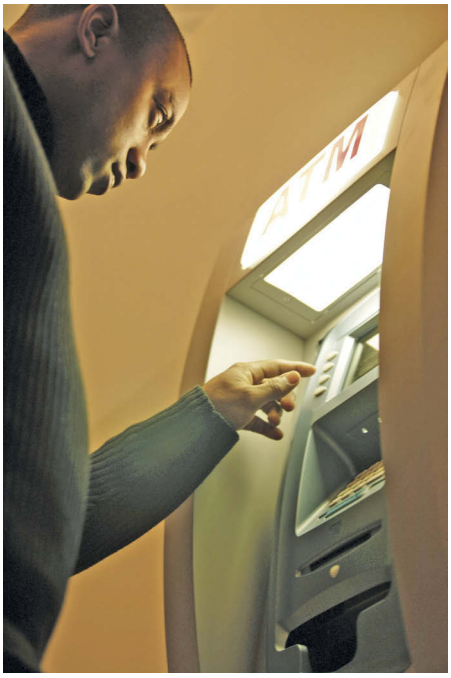

Figure 31.1 | ATM
Integrated electric lighting might satisfy illuminance criteria for the visual tasks at the ATM when daylight is insufficient. If there is no integrated lighting or if it is insufficient, then lighting design should address criteria in Table 31.2.
» Image ©Ocean/Corbis

31.2.8.1 ATMs
Ubiquitous automated teller machines may have sufficient lighting from within to address the visual tasks. This may be the most efficient way to light the task area (see Figure 31.1). If the designer determines that the ATM's integral lighting is insufficient, then provisions should be made to meet criteria cited in Table 31.2. In outdoor situations, criteria are cited for the immediate vicinity and for the face of the transaction device. Depending on the nature of the facility and degree of security, luminaire construction may need to be rugged to withstand tampering and physical abuse. Lamps insensitive to sudden shock are appropriate. Motion sensors on time clock to energize luminaires on demand after curfew should be considered regardless of nighttime outdoor lighting zone.

31.2.8.2 Banking Lobbies
Lobbies for retail banking might simply comprise a queue, teller stations for cash and check transactions, and a courtesy transaction table. Visual tasks are not overly complicated, but involve a high degree of accuracy. For face-to-face transactions, illuminances need not accommodate a high degree of speed, though bank personnel and security cameras should be able to assess facial features and demeanor. See Figure 31.2.

Teller stations may be separated from the banking lobby with security glazing. This introduces veiling reflections and, if high-wattage luminaires are used, reflected glare. Consideration should be made for eliminating or minimizing these effects in the customer transaction zone, though it is unlikely these can be addressed for those in the queue. Indirect lighting can minimize harshness, though veiling reflection patterns are likely to be larger. Low-wattage direct luminaires can minimize harshness, though the number of veiling reflection patterns will increase.

In facilities offering additional banking services, such as loans and account applications and closings, workstations adjacent to the lobby or in spaces independent of the lobby are used. A review of reading and writing tasks by the designer is in order to establish recommended illuminance criteria.

31.2.8.3 Processing Centers
Checks are processed for payment between banks to cover client transactions. Visual tasks include deciphering payment amounts and encoding checks accordingly. The designer must survey tasks in the processing centers to determine if paper or computers are predominant. Illuminance criteria may need to be revised to address the respective reading and writing tasks.

31.2.8.4 Safe Deposit Boxes
Lighting here should address the vertical face of the deposit boxes to allow for box identification. Inspection tables should be illuminated to allow for convenient review of box contents.

31.2.8.5 Trading
Some financial facilities are involved in trading commodities, equities, or other assets. The trading task typically includes interaction with computers, other people, and paper. This might be on the scale of one or several workstations or entire building floors. Default illuminance criteria cited in Table 31.2 accommodate most paper tasks and computer tasks. However, if programming or task surveys reveal tasks specifics, the designer should establish illuminance criteria based on the specific reading and writing tasks by using the READING AND WRITING task citations in Table 31.2. See Figure 31.3.

31.2.9 IT

Lighting for IT facilities is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

31.2.10 Municipal Facilities

Municipal facilities include city halls, emergency call centers, fire stations, and police stations. Those used for emergency calls, fire, and police demand lighting that is efficient and effective in facilitating performance of the critical tasks. However, the lighting of these facilities can also effect civic pride. Accenting community art, well controlled luminances, orderly layout of lighting equipment, accentuation of spatial form, and well maintained luminaires can all help define a place of pride.

Some of these tasks and applications will require continuous operation for public safety, emergency management, national security, or business continuity and, therefore, critical operations power systems (COPS) will be employed as part of the electrical design [3]. If the lighting designer is someone other than the electrical engineer, then close coordination between the designer and the engineer will be necessary to determine the need for any special control zoning, instant-on lamps, and specific luminaire wiring or ballasting details affecting the lighting layout and specification.

31.2.10.1 City Halls

These facilities primarily house administrative space. See Chapter 22 | LIGHTING FOR COMMON APPLICATIONS for discussion and criteria on administrative spaces. City halls also include council chambers. As the seat of the local government, chambers should have a flexible lighting system to accommodate presentations, deliberations, and forums. Garages are also part of city facilities, though these are typically at some location distant from city hall proper.

31.2.10.2 Emergency Call Centers

Call centers should be carefully programmed and designed accordingly. The visual tasks and the degree of multi-tasking should be used to identify the most common or most critical task and illuminance criteria established accordingly.

31.2.10.3 Fire Stations

Small volunteer stations or those manned with on-call firefighters might include apparatus bays with perimeter gear turnout storage and not much more. Luminaire layouts and optics should accommodate the large equipment. See Figure 31.4. Larger stations can include living quarters, a kitchen, a hose tower, and other spaces necessary for self-sufficiency.

Exterior maintenance and staging areas may be part of a station's site. If lighting is deemed necessary for these areas for nighttime operation, then see 26 | LIGHTING FOR EXTERIORS. The designer may also need to determine illuminance criteria based on the programmed activities and the categories in Table 4.1 | Recommended Illuminance Targets.

31.2.10.4 Police Stations

Police stations may be small precinct stations consisting of a community desk and some offices and support spaces to large central facilities. Larger facilities may include holding cells. The secure movement of detainees is facilitated by a sally port where secure vehicles have access to secure entries. Sally ports are usually fully enclosed porte cocheres or garages. Lighting serves both an adaptation function as vehicles move from exterior to interior and vice versa and as a security function. Although daylighting can be used to limit energy use, its application must be made with great care. Daylight media must itself be secure of breach by people or gunfire and must prevent direct-view situations from any vantage point outside the sally port to limit identification and tracking of those inside.

31.2.11 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS. In secure parking situations, lighting must accommodate camera and surveillance requirements.

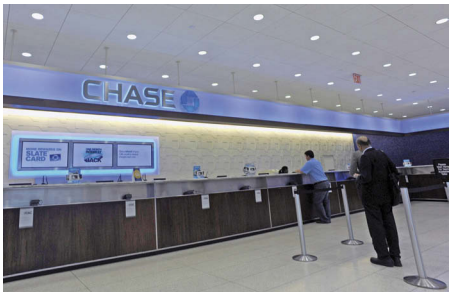

Figure 31.2 | Retail Bank Lobby
A regular array of downlights provides uniform horizontal and vertical illuminance throughout the lobby space. The uniformity is important to visual assessment of faces throughout the space.

Accenting the wall behind the teller stations introduces a sense of spaciousness (see Table 12.2 | Subjective Impressions) and contributes to spatial definition (see Table 12.1b | Spatial Factors: Part Two). The regular array of downlights and the single linear wall slot contribute to pleasantness (see Table 12.1a | Spatial Factors: Part One).

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

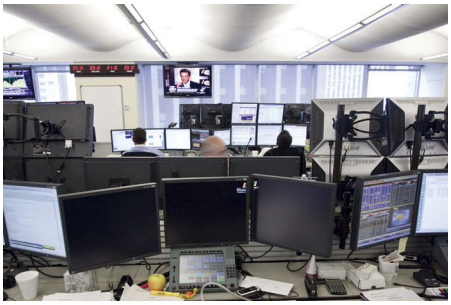

Figure 31.3 | Trading Floor
Indirect/direct linear pendant luminaires provide general lighting throughout this trading floor to accommodate the tasks of paperwork, computer work, and facial modeling. The relative softness of the indirect lighting yields no veiling reflections on CSA/ISO Type I and II monitors in positive or negative polarity in the near vertical orientation. However, screens in the near horizontal orientation exhibit veiling reflections.
» Image ©James Leynse/Corbis

31.2.12 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS. In secure pedestrian-way situations, lighting must accommodate camera and surveillance requirements.

31.2.13 Post Offices

Depending on the size and type of the postal facility, applications might include a consumer lobby, P.O. boxes for mail pickup, a processing center, and shipping/receiving. The consumer lobby may consist of one or several postal windows and writing tables. P.O. boxes might be lined on one or several walls of the lobby or in larger facilities may require separate room or rooms. Lighting must address the vertical face of the wall or walls of boxes.

The processing center involves, reading, encoding, and sorting. A security area might include scanning equipment with video imaging. Visual inspection should also be accommodated. In larger facilities, automated equipment is used to read envelope addresses and sort mail accordingly.

31.2.14 Support Spaces

Lighting for support spaces is briefly addressed in 22 | LIGHTING FOR COMMON APPLICATIONS.

Coat rooms and copy centers are considered support spaces, though these may be decentralized depending on the type of facility. For example, a judge's chamber might need both a coat room and a copy center to address the volume of use and security requirements afforded by in-suite facilities.

Mail rooms in financial and municipal facilities may be relatively small, but there is likely need for an area and lighting to address sorting and to address security inspection. If inspection is an inherent part of sorting, then the security inspection criteria should be applied at all mail room work areas.

31.2.15 Toilets/Locker Rooms

Restrooms are best addressed by highlighting specific task areas. This offers energy efficiency while meeting the different illuminance criteria involved. Highlighting toilets, urinals, and vanities offers a more clean, crisp appearance than the haze of general diffuse lighting. Vanity positions require vertical illuminance on an imaginary facial plane (roughly a zone of sufficient size to encompass faces at standing or seated height) in front of the mirror. See Figure 22.7 for several methods of vanity lighting for non secure toilet facilities. Color of light is important for grooming. Lamps exhibiting 2700 K to 3500 K CCT and CRI ≥82, using triphosphor CFLs as benchmark, are appropriate.

31.2.16 Transition Spaces

How front-of-house transition spaces in many applications are designed and lighted defines the place and welcomes employees and guests. These spaces are transitions from exterior to interior and vice versa or from one kind of interior space to another. Illuminance criteria and accents are an important aspect of making comfortable and safe transitions.

Public spaces in some financial and municipal facilities may be of a particular sequence of passage, ceremonial in nature, or of special importance. To appropriately serve these roles, subjective impressions outlined in Table 12.2 should guide the application of lighting effects. Illuminances associated with artwork and features that assist with these subjective impressions are outlined in Table 31.2.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Security screening areas in public spaces such as lobbies require some additional horizontal and vertical illuminance relative to the background lighting necessary for the normal space function. See Figure 25.1. Where special security procedures demand private screening, horizontal and vertical illuminance criteria should accommodate the situation. Illuminances and lighting hardware locations and light distributions must be coordinated with security cameras. Controls for these rooms may be purposely centralized or limited to motion sensors. The designer must coordinate requirements with the security consultant.

For purposes of visual consistency and of maintenance convenience, lamp types and color qualities should match those used elsewhere.

Figure 31.4 | Apparatus Bays
Linear recessed luminaires are arranged so that some rows are positioned between vehicles to best illuminate the sides of vehicles and into the vehicle compartments. Depending on garage door type, this arrangement also minimizes shadowing by overhead doors.
» Image ©Ocean/Corbis

31.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 31.2.

31.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 31.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 36.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

31.3.2 Notes

The notes in Table 31.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

31.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 31.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for perimeter display walls in a trial jury suite, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on at least one plane of a task. A 0 indicates no light or zero light is recommended for the task or application.

31.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." Note the implication for observers' visual ages. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

31.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. It may be determined that illuminance criteria for an age group other than that representing the majority of the intended observers is appropriate. However, this may result in overlighting, underlighting, harsh lighting, visual displeasure, or visual discomfort for many of the observers. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance. In some situations, such as front projection AV presentations, lighting must meet the requirements of the screen technology to maximize visibility for all age groups and, therefore, is not tied to ages of observers.

31.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 31.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

31.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

31.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h).

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

31.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

31.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

31.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

31.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. However, this may not be practical or appropriate in council chambers or trading floors unless continuous dimming is used on slow response rates. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities.

31.3.6 Veiling Reflections

IESH/10e CSA/ISO

> 12.5 Task Factors

- for information on CSA/ISO computer screen qualities

Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

31.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Tasks and Applications and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 31.2.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 31.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

31.4 Designing

Information provided here is specific to the miscellaneous facilities cited and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. Equipment selection and location strategies may need to address the possibility of lighting equipment abuse. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers of significance intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production, holding, and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic, abuse, and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers of significance is the paramount design tenet and must be kept in perspective during all aspects of design. Here, the designer

must establish the significant observers and their related lighting requirements. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

32 | LIGHTING FOR OFFICES

The best vision is insight.
Malcolm S. Forbes, 20th Century Publisher

Contents

32.1 Project Type and Status. . . 32.2
32.2 Application Types 32.2
32.3 Illuminance Criteria 32.17
32.4 Designing. 32.23
32.5 References 32.24

Lighting is most efficient and sustainable when it is recognized for what it can accomplish and then leveraged for maximum benefit. Figure 32.1 shows typical annual lighting costs that are but a small fraction of the costs of the people and real estate necessary for office operations [1]. The real bottom line is not in securing quick and cheap commodity lighting during the relatively brief project construction period, but rather in leveraging the lighting equipment and their effects and energy value to maximize worker comfort, productivity, and retention over the life of the system. Visually effective and appealing, high quality lighting provides the best employee, environmental, and operating value.

Electric lighting accounts for about 39% of the electricity used in offices [2]. Figure 32.2 shows the breakdown of office electricity use. This amounts to 82 TWh for lighting, which is about a 5% reduction since 1995 while total electricity use in offices increased by more than 25%. The need to design and specify well-controlled efficient lighting remains important, if not a priority. However, it makes little sense to design and specify lighting that is so power-starved and so confoundingly controlled (or not at all) that occupants cannot see well or lighting quality is so poor that few people are willing and/or able to adapt to the prescribed setting. Daylighting and views are integral to simultaneously reducing energy consumption and attracting and retaining a productive workforce. What follows is a discussion of the key aspects affecting lighting: project status; space types; activities; application-specific design goals, and illuminance criteria in office facilities.

Comprehensive design efforts rely on material in this chapter combined with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses specifics related to lighting for offices which should influence luminaire optical selections, lamping, and final layouts based on previously developed thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous and current IES related documents serve as archival and reference sources [3] [4].

Deliberate thought must be given to details beyond the recommended illuminances in this chapter. For example, periodic visual rest from many of the usual reading and writing tasks is appropriate and cannot generally be achieved simply on the basis of task or application illuminance criteria. Accenting artworks or architectural features or providing exterior views are in order. Such situations must be studied carefully before solutions are recommended, particularly those solutions that seem obvious. These kinds of specific details are not enumerated for most tasks. Table 32.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

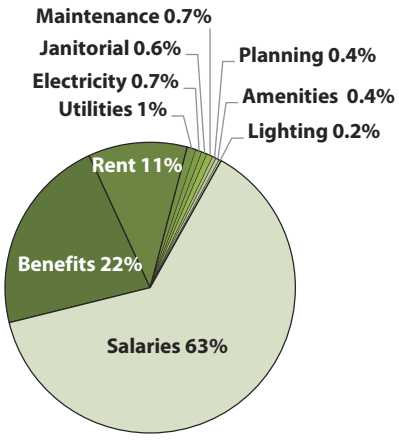

Figure 32.1 | Office Costs

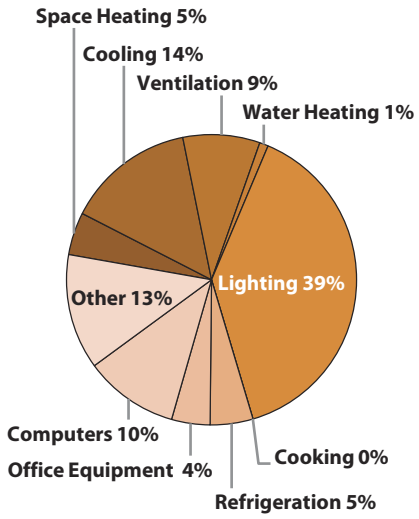

Figure 32.2 | Office Electricity Use
Based on 2003 data from the US DOE's Energy Information Administration, lighting accounts for 39% of electricity use in office buildings (electricity use for Cooking rounds to 0%). Office buildings themselves account for about 20% of electricity use by all commercial and institutional buildings.

32.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. This will establish the extent to which daylighting can address most or many or some of the lighting goals. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. Given hours of operation of many office facilities, daylighting can be a primary light source. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands determined attention to moderate or eliminate glare and balance visible and thermal energy.

32.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the office space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names and department names in large open areas from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 32.2 | Office Facilities Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 32.2.

The following sections are keyed to the major application and task headings in Table 32.2. These discussions, those highlighted in Table 32.1, and material in Table 32.2 offer comprehensive qualitative and quantitative criteria.

32.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction and wayfinding. Default accent lighting criteria are discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Also see 15.1.1.3 Accent Lighting.

32.2.2 Administration

Administrative functions on many projects typically include circulation, conferencing, counseling, lounges, filing or records, interviewing, lobbies, mail sorting, and officing. These functions constitute most office facilities. Each of these functions in turn may involve a number of specifics including some form or degree of acknowledgment, conversation, reading, periods of respite or relaxation, and writing. Acknowledgement of other people and conversation, for example, require some vertical illuminance at face height (seating or standing depending on the nature of the application). Vertical illuminance criteria are cited for such applications.

The architectural scheme and even task specifics will vary based on the associated facility function and type, from insurance to banking to manufacturing to advertising to electronic software or hardware development, and so on. These variations should affect the lighting design—from kinds of lighting effects to lighting equipment styling to luminances and illuminances.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

The administrative areas may be dispersed throughout a facility or complex or may be centralized into a single area, wing, or building. Depending on client wishes and architectural desires, this centralization or decentralization may affect the degree to which the lighting design in administrative areas is sympathetic to or different from that of other applications.

See also 32.2.8 Offices.

32.2.3 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. For building entries of office facilities several distinct variables are time of need, anticipated levels of activity, and the nighttime outdoor lighting zone. Nighttime activity levels may vary by type of office facility, such as a call center with several night shift changes, and by size. This may be best served by a control system capable of addressing various settings at various times of the night through manual intervention, automated time clock, and photocell functions.

The nighttime outdoor lighting zone within which the facility is located establishes the categories of illuminance for outdoor tasks. Nighttime outdoor lighting zones vary by local ordinance, sustainability guides, or the team's own definition of place.

After-hours security needs, such as on-site or remote monitoring or recording, may require that some luminaires at building entries remain energized through the night or placed on motion sensors or interconnected with camera operations. Control zones and time clock functions must be designed accordingly. Where remote monitoring is done with infrared cameras, lighting may be unnecessary.

32.2.4 Conferencing

Conferencing runs the gamut from very simple single-purpose functionality (for example, meet to discuss) to rather complex multipurpose tasks (for example, meet to discuss, present, strategize, and learn, or video conference with others). The lighting is influenced accordingly and also by the formality of the setting. Where presentations are common, such as a board room or a meeting room, and where the participants might number two dozen, the lighting should help define the formality and procedural aspects of the meeting. Accenting on presenter positions is appropriate. Some conference settings strike a balance. In these situations, presentations are common, but intended as a group-think-discuss learning situation. Here, although presentation surfaces are still accented, presenters might not be illuminated. In larger spaces, lighting presets are used to respond to room setups and functions. Figure 32.3 illustrates a training room. Figure 32.4 illustrates a traditional conference room. Figure 32.5 illustrates meeting rooms. Although illuminances are quite similar in the examples, the resolutions vary based on ceiling conditions, architectural styles, and programming requirements and priorities such as flexibility, efficiency, hardware and installation costs. See also Figures 15.5d, 15.16, and 22.5.

Video conferencing criteria are directly related to camera technology and user expectations. Vertical illuminances and uniformity criteria at faces and background wall surfaces are most important. Coordinate illuminance criteria with latest camera requirements. Telepresence is a variation on video conferencing. Portable all-in-one camera and monitor setups, from single to multiple monitors, offer video conferencing in non-dedicated settings. Preset controls should be used for convenient and consistent toggling between typical conferencing functions and video conferencing.

32.2.5 Drafting and Design

Drafting and design tasks typically involve reading computer screens, writing to computer screens, and periodically referencing a keyboard or other interactive device and, in some situations, paper documents. Programming should identify the kinds of computer screens

Notes for Table 32.2

The table column headings are discussed in detail in 32.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 32.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 32.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 32.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, or conference table a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

j. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

k. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 32.2

The table column headings are discussed in detail in 32.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 32.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 32.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 32.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, or conference table a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

j. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

k. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 32.2

The table column headings are discussed in detail in 32.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 32.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 32.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 32.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, or conference table a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

j. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

k. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 32.2

The table column headings are discussed in detail in 32.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 32.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 32.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 32.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. For applications where task position is indefinite, such as some types of flexible meeting rooms, the typical area of coverage is "Room or Designated Area." For applications where task position is known, such as an office desk or a reading chair, or conference table a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area."

j. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

k. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Table 32.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

IESH/10e CSA/ISO

> 12.5 Task Factors
- for information on CSA/ISO computer screen qualities

and the nature of the computer aided design (CAD) task. The designer must review the various reading and writing tasks identified in Table 32.2 and establish which are appropriate to the project at hand. In some situations, one set of illuminance criteria might appropriately address a task. For example, where little reference, if any, is made to paper documents, this is considered an exclusive CAD task. The type of computer screen and its contrast settings determine the degree of sensitivity to light and the need for light. See Figure 12.16 | CSA/ISO Computer Screen Qualities.

Where paper documents are part of the work task, a review of the types of paper tasks is necessary. If these tasks are quite varied and require very different illuminance criteria, it may be necessary to consider a dimmable task lighting system to illuminate just the paper document reference area. An ambient lighting system may be appropriate to address the illuminance criteria of the VDT screen and keyboard. If the paper document reference area is fixed in location and size, then portable or architectural task lighting may be appropriate. For flexible locations and variable sizes of paper document reference areas, dimmable portable task lighting may be most appropriate. Regardless, the optical control of the task lighting solution must be evaluated for its effect on the computer screens. Light spill on CSA/ISO negative polarity Type III monitors may be intolerable by veiling graphic details. Alternatively, CSA/ISO positive polarity Type I monitors may be sufficiently visible even with an ambient lighting system that addresses the paper tasks. Mockups are appropriate to test proposed lighting solutions.

Drafting and design may be housed in a dedicated space or may be one of several tasks performed as part of an office setting. The designer must confirm early in programming the intended application in order to develop appropriate illuminance criteria recommendations and lighting system solutions.

32.2.6 Food Service

Lighting for food service is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Figure 32.6 illustrates a dining room setup in a multi-functional space (top image) and a lunch room or canteen (bottom image). Many times multi-functional spaces must be capable of accommodating any number of applications from meetings to dining to project room or work room. As the design team explores architectural and furnishing

Figure 32.3 | Training Room
Conferencing and meetings are accommodated here with six dimmable fluorescent control zones: ❶ is a wall slot at the white board and AV screen; ❷ is a wall slot at the buffet; ❸ is two wall slots running the length of the room; ❹ is two downlights near the AV screen; ❺ is the remainder of the downlights; and ❻ is the four-sided cove. Preset scenes available are HIGH, LOW, BREAK, AV, and ALL OFF.

Perimeter accenting is used liberally contributing to: spatial definition; preference; and spaciousness. See Table 12.1b | Spatial Factors: Part Two and Table 12.2 | Subjective Impressions. The indirect lighting and surface washes contribute to vertical surface lighting and facial lighting.

layouts, lighting criteria for the various applications and potential approaches are also reviewed so that a lighting solution most capable of meeting various illuminance criteria and the architectural style requirements of the project can be proposed. Controls play a significant role in meeting the challenge of multiple functions.

32.2.7 IT

Lighting for IT tasks is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

32.2.8 Offices

Illuminance criteria for offices revolves around reading and writing and intermittent oral communication. Accenting serves multiple purposes in office situations where users are relatively sedentary and need periodic visual relief from tasks and need relatively consistent visual backgrounds against which to work without visual fatigue. Accenting can help improve the overall environment when subjective impressions are addressed (see Table 12.2 | Subjective Impressions. In any event, accenting need not consume much energy and is typically more efficient and visually interesting than using high-output general lighting.

Illuminance criteria and areas of coverage for office tasks must be carefully established to meet energy requirements, sustainability goals, visual comfort, and task appropriateness. Overlighting leads to energy waste and overly bright tasks which, after several hours of viewing, can lead to visual fatigue. The challenge is establishing which reading and writing tasks should be addressed and determining how to meet the recommended illuminance criteria. See 12.5 Task Factors and Table 12.3 | Sample Visual Task Survey for guidance.

If a number of tasks are involved, prioritize by importance and select criteria accordingly. Alternatively, normalize to tasks with common illuminance criteria, providing this addresses the majority, if not all, of the tasks involved. Another method is to address divergent illuminance criteria using both task and ambient lighting systems. Use an ambient lighting system to meet the lower illuminance criteria for one set of tasks and use a task lighting system to supplement the ambient lighting to address the greater illuminance criteria of a second set of tasks. This solution of task and ambient systems can be more energy effective and visually interesting than that of an ambient system alone to meet illuminance criteria. See 15.1.1.1 Ambient Lighting, and 15.1.1.2 Task Lighting.

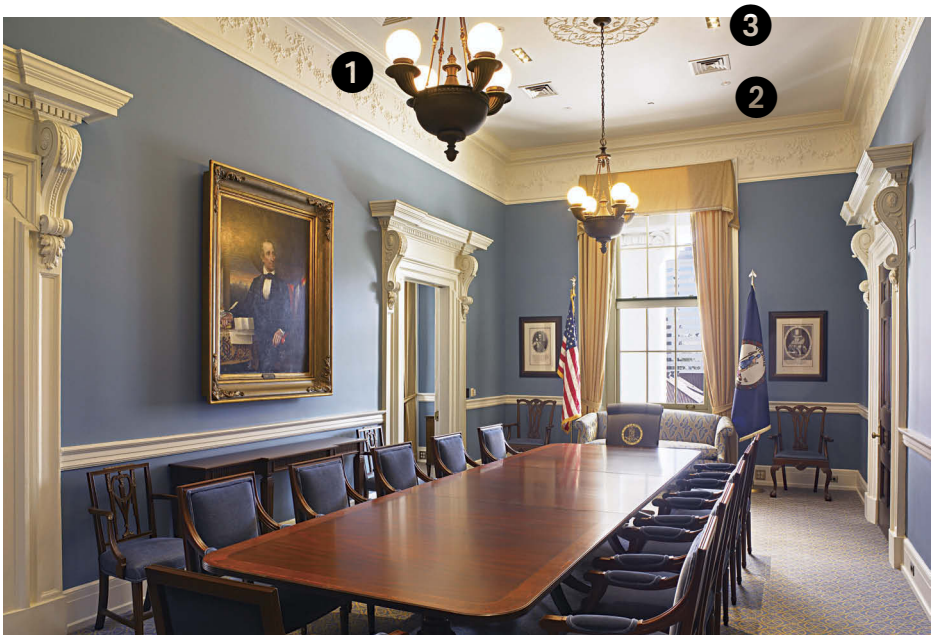

Figure 32.4 | Conference Room
The Governor's Conference Room in the Virginia Capitol is lighted by: ❶ historic reproduction pendant luminaires lamped with 2700 K CFLs; ❷ recessed trimless adjustable pinhole luminaires lamped with halogenIR_{LV} MR16 lamps (not to be confused with the more readily visible air diffusers); and ❸ recessed trimless adjustable multi-lamp linear luminaires also lamped with halogenIR_{LV} MR16 lamps.

Recessed trimless luminaires for drywall or plaster ceilings exhibit no visible trim flange. Plaster or a skim coat is finished to the aperture of the luminaire. Trimless luminaires are less noticeable and improve the monolithic appearance of drywall ceilings. On decorative plaster ceilings, the simplicity of trimless luminaires results in greater visual attraction to the decorative plaster work.

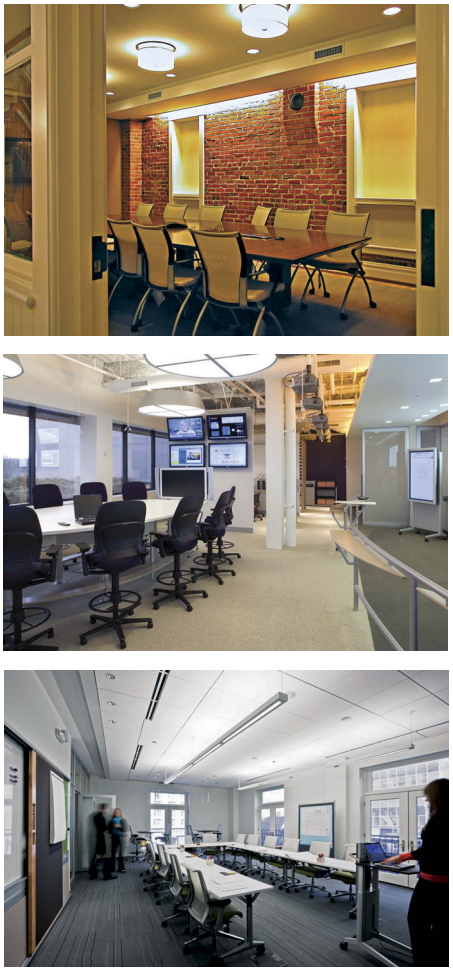

Figure 32.5 | Meeting Rooms
The means to the end of IES illuminance criteria compliance can vary considerably. Surface luminances and both surface color and color of light greatly contribute to the overall appearance. Daylight and view have marked effects.

The majority of the lamps in these three examples are fluorescent varieties exhibiting CCT of 3000 K and CRI ≥82. In the middle image, red and gold fluorescent lamps are used in a cove detail along the upper right. In the bottom image, halogenIR$_{LV}$ MR16 adjustable accent luminaires highlight the left wall and LED decorative pendants are used at break tables near the far end of the room.

The painted-out white plenum condition in the middle image greatly improves overall lighting efficiency.

Linear pendant luminaires with both indirect and direct lighting components such as those shown in the bottom image can offer very efficient approaches.

» Top Image ©Gary Steffy Lighting Design Inc.
» Middle Image ©Steelcase Inc.
» Bottom Image ©Workspring

There are no definitive rules on the ratio of ambient to task illuminance. However, ambient, task, and accent lighting systems and room surface reflectances should be designed such that the resulting luminances are in accordance with Table 12.5 | Default Luminance Ratio Recommendations and the resulting illuminance ratios are in accordance with Table 12.6 | Default Illuminance Ratio Recommendations. Since illuminance is additive, any combination of ambient, task, and accent lighting can be used to meet the illuminance target criteria identified in Table 32.2 for any given task. In an open office, for example, and depending on the photometric properties of the task and ambient lighting systems and the layout and density of the furnishings, it is possible and reasonable for the ambient lighting system to contribute between one-third to two-thirds of the total illuminance required. A task lighting system provides the balance of the illuminance necessary to meet the target criteria. Ambient illuminance is typically applied throughout an entire room. Task illuminance is typically applied to a task proper or task area (see Figure 12.22 | Task Coverage Example).

Figures 32.7, 32.8, and 32.9 illustrate a variety of office situations. In each situation, an ambient lighting system provides a general illuminance throughout the office space that is between one-third and two-thirds of the IES recommended illuminance criteria. In each situation, task lighting is localized to the task proper or task area and contributes the remainder of the illuminance necessary to meet IES criteria. Accenting is used in Figures 32.7 and 32.9 while extensive daylighting fulfills the accenting role in Figure 32.8.

Accent lighting affects brightness perceptions and may also contribute to spatial definition and subjective impressions. See 15.1.1.3 Accent Lighting, Table 12.1b | Spatial Factors: Part Two, and Table 12.2 | Subjective Impressions. To maintain an efficient lighting solution, the contributions to illuminance criteria from the ambient, task, and accent systems must be analyzed and adjusted accordingly. For example, the lighting of the wall to the right in Figure 32.9 sufficiently contributes illuminance in the vicinity of the extemporaneous meeting area that a row of recessed indirect ambient luminaires was unnecessary.

Daylighting success is facilitated by seamless operation of electric lighting and daylighting mechanisms, such as shades. See 14 | DESIGNING DAYLIGHTING for more information. To minimize disruption, maintain comfort, and maximize energy savings, these aspects deserve particular attention:

1. Automate dimming and educate client on functionality
2. Design any east- and west-elevation daylighting with great care relative to glare and hours of operation
3. Automate window treatment or educate client of manual operation and expected time of use
4. Maintain some degree of exterior view
5. Avoid daylight designs requiring near-continual or complete manual shade deployment
6. Perform daylight simulations to limit areas of overlighting and assist with glazing transmittance and shading treatment selections
7. Address luminance ratios (see Table 12.5)
8. Coordinate daylighting with mechanical engineer to assure thermal comfort

Control systems are key to providing seamless operation and daylight integration.

32.2.9 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS.

32.2.10 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

32.2.11 Reading and Writing

Reading and writing tasks occur within various applications. Familiarity with these tasks will aid with assessment of specific application tasks and activities. Additionally, familiarity with client requirements will help the design team tailor lighting criteria and lighting solutions to best meet client needs. This is a departure from some long-held practices of blanketing rooms and, therefore, buildings with an illuminance level intended to accommodate most any reading task, but which typically resulted in less efficient, less comfortable, and bland lighting.

32.2.12 Support Spaces

These relatively back-of-house citations are self-explanatory. For purposes of maintenance convenience, lamp types and color qualities should match those used elsewhere.

32.2.13 Toilets/Locker Rooms

Lighting for toilets and locker rooms is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

32.2.14 Transition Spaces

Although most of these spaces are self-explanatory, a few deserve discussion in the context of office facilities.

Adjacency passageways refer to a condition where circulation areas are encompassed by larger work or task areas. An example is shown in Figure 32.7 where the adjacency passageway is between the workstations and the architectural wall on the right (marked with ❸). Given their adjacency to the open and visually accessible work or task areas, their illuminances, confined to the passageway proper, should be ratios of the nearby task illuminances. This avoids annoying contrasts within the work setting. In Figure 32.7, however, the task of filing also occurs in this zone and must be accommodated with criteria cited in Table 32.2 under ADMINISTRATION/Filing. The wallwash lighting accomplishes three lighting goals: accenting; circulation; and filing.

Lobbies, reception and waiting areas, and breakout passageways should relate stylistically to the office facility. These spaces should take advantage of the efficiencies and visual variety associated with using task, ambient, and accent lighting systems. See Figure 32.10. Programmatically, these areas sometimes serve multiple functions. For example, the reception/waiting area in the middle image of Figure 32.10 was programmed as potential work or meeting space for future expansion. If controls are planned for the work or meeting area, these can be used to adjust illuminances to address criteria for a reception and waiting area. The design team must track space names and functions in these situations to properly document energy allowances and compliance.

For purposes of maintenance convenience, lamp types and color qualities should match those used elsewhere unless distinct differences are an intentional design feature.

Figure 32.6 | Food Service
Food service in office facilities might consist of traditional dining rooms (top image) or lunch rooms (bottom image). Dining rooms in multi-tenant office facilities may be dedicated to a single client or might be available to all tenants. Dining rooms may be multifunctional spaces where meetings and conferences are accommodated through controls.

The lighting criteria need to be established according to anticipated use: conferencing; dining; and project room, for example. Conferencing tasks, if any, must be determined and criteria established. Dining tasks must also be determined from citations in Table 22.2 at FOOD SERVICE/Dining Areas or from the citation in Table 32.2 at SUPPORT SPACES/Break Rooms/Lunch Rooms. Project rooms might be used like private offices for short, but dedicated work efforts on assignments. Alternatively, these might be work spaces for teams involved in long-term projects. In any event, task needs must be defined and lighting criteria assigned accordingly.

32.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various aspects outlined in Table 32.2.

Figure 32.7 | Recessed Direct Low-brightness Ambient
Single-lamp parabolic luminaires with semi-specular large-cell baffles ❶ provide 300 lx of ambient horizontal illuminance on work surfaces in this low-ceiling open office. Task lighting under binder bins ❷ light the reference area and limit shadows. Uniform wall washing from low wattage fluorescent wallwashers ❸ brightens what would be a dark space with the parabolic luminaires (note the comparatively low luminance of the ceiling). Uniform wall lighting also affects a sense of spaciousness. The diffuse wall lighting along with the relatively soft uniform downlighting from the parabolic luminaires generate consistent vertical illuminances for facial recognition. Note how the luminance of the CSA/ISO positive polarity and Type III (glossy) screen is balanced with paper tasks and surrounding surfaces. The ambient lighting luminaires address the candlepower and luminaire luminance criteria in Table 12.4.
» Image ©Robert Eovaldi

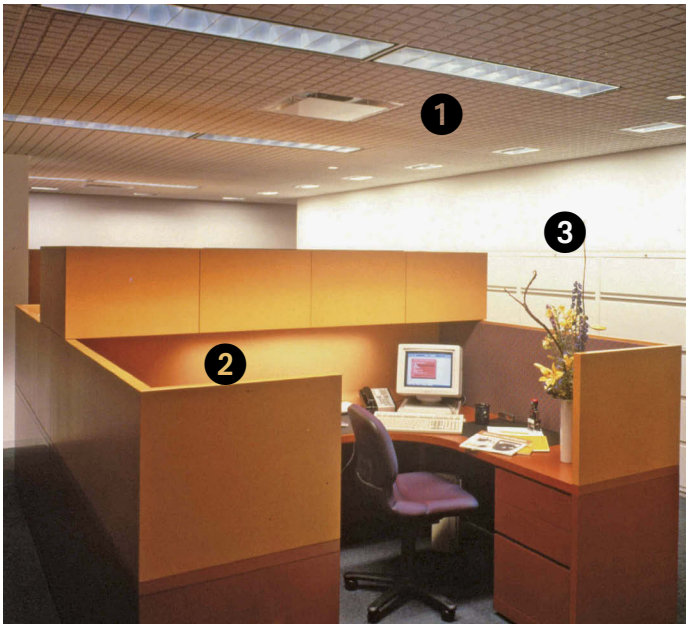

Figure 32.8 | Linear Pendant Indirect Ambient
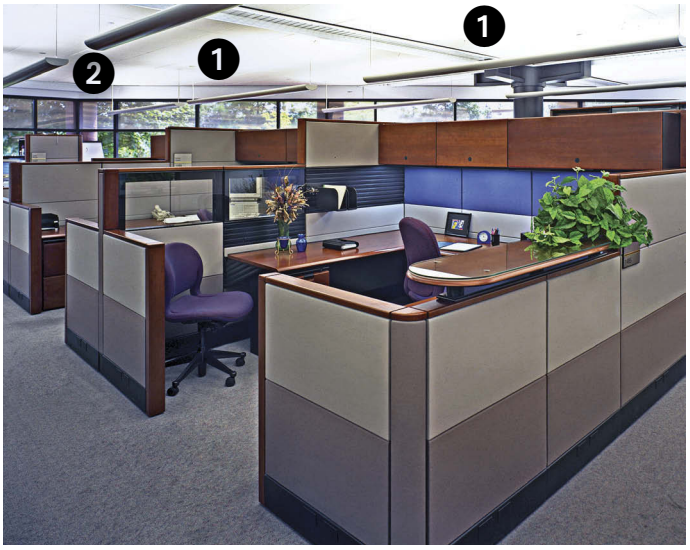
Linear pendant uplights with widespread distribution optics uniformly illuminate the ceiling ❶. The luminance ratio from the brightest portion of the ceiling ❶ to the dimmest ❷ is 3-to-1. This diffuse light reflects to the workplane and provides 300 lx of ambient horizontal illuminance on work surfaces. Task lighting under binder bins light the paperwork area, limit shadows, and help brightness impressions.
» Image ©Robert Eovaldi



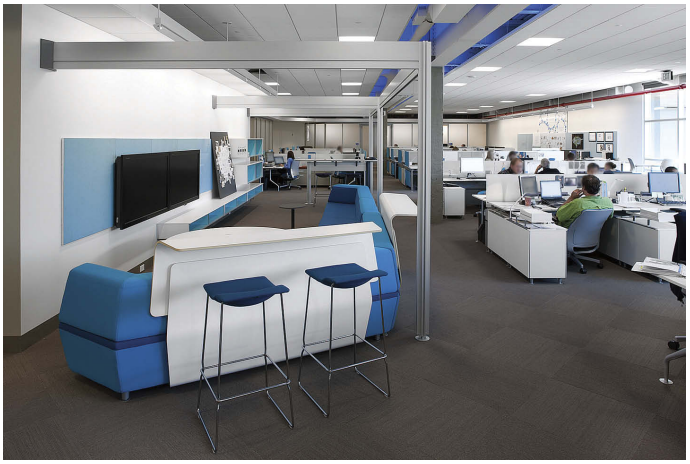


Figure 32.9 | Recessed Direct Architecturally-dimensional Ambient
2' by 2' recessed direct architecturally-dimensional luminaires may be appropriate where a mix of paperwork and computer tasks occur. This family of luminaires is typically less glary than traditional prismatic lensed counterparts. Several varieties are available from "basket" types where lamps are housed in a basket-like compartment with most or all light directed to a reflector at the top of the luminaire for redirection into the room. See Figure 12.19. Another variety consists of an arrangement of high-efficiency lenses and directional optics to limit direct glare. Both varieties exhibit dimensional detailing and intentional brightness variations that diminish the dominant visual mass of previous generations of monolithic-lensed recessed luminaires (effects that are not fully conveyed in photographs). Where computer screens are CSA/ISO positive polarity Type I, some versions of these luminaires may be acceptable. However, with other computer screen types or negative polarity settings, or luminaires with high output lamping, these may not address criteria outlined in Table 12.4. Mockups are recommended to determine suitability and acceptance by clients.

32.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 32.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 32.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

32.3.2 Notes

The notes in Table 32.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

32.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and deemed appropriate for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 32.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Figure 32.10 | Transition Spaces
A breakout passageway is shown in the top image. In situations where the breakout area is clearly defined and unlikely to be reconfigured, illuminance criteria for "breakout passageway" can be applied just to the breakout area while illuminance criteria for circulation can be applied to the zone which is clearly for circulation. The designer must determine areas of coverage which affect lighting power and energy and equipment costs.

In the middle image, a waiting and reception area is also setup to accommodate future expansion when this area will be a workstation or two or a meeting area. Controls can be used to adjust lighting accordingly.

A lobby in a multi-tenant office building, in the bottom image, serves as the "front door" and first impression for the tenants' visitors and is used as an amenity when marketing to potential tenants.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for white board, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

32.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. Additionally, most tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). Where these illuminance components are intended at differing planar elevations, such is indicated under "Notes." For example, for conferencing meetings, horizontal illuminances apply to the table top while vertical illuminances apply to seated-face-plane height of 4' AFF oriented in which may be in the direction or directions facing the primary viewer or viewers.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. In some applications, like conventional conference rooms accommodating a variety of presentation media, horizontal- and vertical-plane illuminances of the various media tasks address the typical situation where simultaneously some work or some portion of the work is on horizontal planes while other work or portion is on vertical planes.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." Tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes" where the directional orientation of the plane is straightforward and easily identified. However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented a number of directions and the designer must determine which are most appropriate for the situation. For example, in a meeting room, the furnishing layout of the space might suggest the number of directions. If the room is to be flexible in its furniture arrangement, then it might be determined that the orientation directions are satisfactorily addressed by assigning vertical criteria at face plane to the four cardinal directions. In a meeting room with a linear table and chairs on the long sides each facing the other side, it may be determined that one orientation direction for each side suffices.

32.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. An efficient, productive, and comfortable workplace can only be achieved if illuminance levels are targeted for the intended audience. Illuminance criteria are presented based on age groupings associated with at least half the observers in a particular application. The designer is always at liberty to reselect criteria based on his own experience or on client direction. In closed offices, age requirements can be readily accommodated. However, the designer should review implications of turnover. In open offices, age differences and turnover may present significant challenges that require the design team and client to review office planning.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Controls can be employed on discrete zones of ambient lighting to allow adjustment of these zones to greater or lesser illuminances. Additionally, task lighting can be specified or also controlled to provide greater or lesser illuminances. All of this demands a concerted design effort and, after completion, dedicated monitoring by the client.

32.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 32.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

32.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, “Avg” is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is “Min” or “Max” respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

32.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h).

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

32.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

32.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

32.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

32.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and continuous dimming or stepped-dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

32.3.6 Veiling Reflections

IESH/10e CSA/ISO

> 12.5 Task Factors
- for information on CSA/ISO computer screen qualities

Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

32.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Tasks and Applications and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 32.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 32.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

32.4 Designing

Information provided here is specific to office facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on those respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

33 | LIGHTING FOR RESIDENCES

Every moment of light and dark is a miracle.
Walt Whitman, 19th Century American Poet

Many homes are refuge. Lighting sets the scene for senses of comfort and protection. However, some activities in a residence are quite demanding visually. Occupants' ages may vary significantly. Some members of the household may use the residence primarily during dark hours for at least four or five days of the week. The majority of use by other occupants may occur during daylight hours. Tasks and activities within the same space may require very different lighting conditions. Yet, as convenient as it may have been long ago, using a limited number of luminaires that accommodate universal-base lamps up to very high wattages has never been the best way to address all of these variables. Electric lighting accounts for about 15% of the electricity used in residences (see Figure 33.1). [1] Efficient lighting and its careful application are appropriate and important. Inventive use of daylighting is a necessity. What follows is a discussion of the key aspects affecting lighting: project status; space types; activities; application-specific design goals, and illuminance criteria for normal-sighted people of all ages in *residential facilities*.

Comprehensive design efforts involve synthesizing the information in this chapter with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance specifics related to lighting for residential applications which should influence luminaire optical selections, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous IES related documents provide archival reference [2] [3].

Careful thought must be given to details beyond the illuminance citations in this chapter. For example, in Table 33.2 the citation RESIDENTIAL INTERIORS/Circulation Corridors/Independent Passageways identifies illuminance for residential hallways in a more conventional, closed plan situation. The uniformity ratio is broad and, therefore, non-uniform lighting quite appropriate. However, at the cited illuminances, such a hallway will appear dark. To some people, this is appealing, but for others this is undesirable. To address the subjective impressions of preference and relaxation in Table 12.2, a wall sconce or two, a table light or two, an art accent or two, some subtle wallwashing or any combination of these techniques will brighten the hallway. These techniques alone may meet the illuminance criteria for the passageway. Such specific details are not enumerated for all tasks. Table 33.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

33.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. This will establish the extent to which daylighting can address most or many or some of the lighting goals. Every opportunity should be given to daylight as a light source. For some applications and tasks, daylighting can be the primary if not sole light source. To be a success, daylighting must address the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

Exterior residential lighting criteria discussed here apply to normal-sighted individuals living in single-family homes. Interior residential lighting criteria discussed here apply to those normal-sighted individuals living in single-family detached homes, duplexes, apartments, condominiums or other residential complexes. Individuals with specific vision impairments may require more or less light depending on the visual condition and tasks. These impairments should be identified in programming and require that the lighting be designed accordingly [4].

33.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational aspects, the residential application space types under consideration and consequently the anticipated occupants, functions, and tasks are inventoried (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 33.2 | Residential Facilities Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 33.2.

Unlike most other project types, residential applications are quite personal and involve one or two stakeholders. It is possible that criteria cited here may not align with programmed applications and functions or with a homeowner's expressed desires, which may range from "I want it to be moody" to "It has to be bright." The designer must interpret these and assess what, if any, illuminance criteria fill the need in the context of a specific project's architecture and finish scheme and then seek the homeowner's approval. A review of Table 4.1 | Recommended Illuminance Targets may be in order to establish criteria suited to the personal specifics of the homeowner. Accenting will greatly assist in brightness perceptions. Dark and high contrast can be beneficial in creating mood in a residence providing these do not compromise safety and sense of security or the homeowner's preferences. In the absence of a homeowner, such as speculative projects, a developer is the client. Here, the designer must project the needs and desires of the anticipated homeowner.

To an end of visual variety expected of residential settings and because residential activities are not encumbered with commercial-like productivity, many uniformity ratios are broader here than in commercial and institutional applications. Where homeowner

direction is for more uniform and consistent lighting throughout, ratios should be narrowed as the designer determines. This may be achieved with more luminaires, though not necessarily much, if any, more wattage or broader-beam optics and will result in a more homogenous look.

The following discussion is keyed to major application headings in Table 33.2. Couple this with topics in Table 33.1 for comprehensive qualitative and quantitative criteria.

33.2.1 Residential Exteriors

For this discussion on exteriors, residents of single-family properties and duplexes are considered during nighttime hours. For larger operations, see relevant applications in 22 | LIGHTING FOR COMMON APPLICATIONS and 26 | LIGHTING FOR EXTERIORS. An overriding dictum is to use exterior lighting only if, when, and where needed. For residential exteriors several conditions influence lighting:

- Number and types of house entry points
- Number of outdoor settings and paths connecting those settings
- Anticipated nighttime activity levels and likely ages of users
- Nighttime outdoor lighting zone for the project under consideration
- Security needs perceived or real

Lighting key entries, site circulation routes and intersections, and elevation changes in between are important to navigating residential sites where nighttime activity is anticipated. For small, simple or pre-existing sites with a straightforward front entry to the home it may be determined that only lighting at the front door is sufficient. For large or new sites with complicated geometry and extensive landscaping it may be determined that lighting at multiple locations may be best to assist in safe navigation and offer a sense of security.

The architectural and landscape schemes will vary based on pre-existing conditions or the homeowner's desires and the architect's and landscape architect's interpretations. These variations should affect the lighting design—from kinds of lighting effects to lighting equipment styling to luminances and illuminances.

The kinds and number of outdoor activities and the homeowner's age affect illuminance criteria and where it is applied. For economy, efficiency, and sustainability, this requires careful and detailed planning rather than uniform single-level-illuminance lighting.

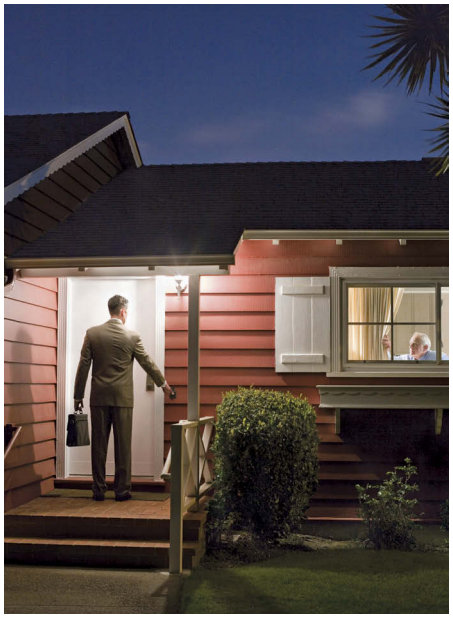

Figure 33.2 | Residential Entries
Both entries are lighted to address functional needs of defining the main entry, identifying visitors, and minimizing light spill. In the image on the far left, the porch roof and elevation of the luminaire work together to limit light spill in one direction, but still illuminate the leading edges of the treads. In the image at the near left, downlights grazing a near-white wall provide diffuse light for rendering visitors' full frontal body for easy identification of faces and clothing. Surface reflectances are important to the success of this approach.

Notes for Table 33.2

The table column headings are discussed in detail in 33.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 33.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 33.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 33.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Identifying elevation changes can be achieved with lighting over the area of interest or by introducing contrast lighting at the change in elevation, such as can be achieved with steplights, in-tread uplights, linear tread nose lights, or other luminaires that accentuate the risers or treads or the edges that define elevation change. Figure 15.13 illustrates one example.

l. For applications where task position is indefinite, the typical area of coverage is "Room or Designated Area." For applications where task position is known, target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

Notes for Table 33.2

The table column headings are discussed in detail in 33.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 33.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 33.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 33.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ↘ signals high likelihood; gray and white ↘ signals moderate likelihood; pale gray and white ↘ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Identifying elevation changes can be achieved with lighting over the area of interest or by introducing contrast lighting at the change in elevation, such as can be achieved with steplights, in-tread uplights, linear tread nose lights, or other luminaires that accentuate the risers or treads or the edges that define elevation change. Figure 15.13 illustrates one example.

l. For applications where task position is indefinite, the typical area of coverage is "Room or Designated Area." For applications where task position is known, target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

Notes for Table 33.2

The table column headings are discussed in detail in 33.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 33.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 33.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 33.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ↑ signals high likelihood; gray and white ↑ signals moderate likelihood; pale gray and white ↑ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

j. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

k. Identifying elevation changes can be achieved with lighting over the area of interest or by introducing contrast lighting at the change in elevation, such as can be achieved with steplights, in-tread uplights, linear tread nose lights, or other luminaires that accentuate the risers or treads or the edges that define elevation change. Figure 15.13 illustrates one example.

l. For applications where task position is indefinite, the typical area of coverage is "Room or Designated Area." For applications where task position is known, target illuminance is applied to the "Task Proper or Task Area."

m. E_h and E_v elevations are based on conventional worksurface and seated eye height. Where other elevations are programmed, designer must adjust illuminance-criteria planes of interest accordingly.

Table 33.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

With exterior lighting, the use of optically-appropriate luminaires and automated controls greatly improves energy conservation and the condition of the night environment. Automatically dimming back or switching off lighting at a predetermined curfew is good practice, if not mandated. Lighting can be switched off entirely at curfew and operation transferred to motion sensors or timed switches. Optics can be used to minimize light spill to adjacent sites or skyward. However, as Figure 33.2 illustrates, simple architectural geometries and luminaire positioning can also limit light spill. On skyward spill, uplights should be limited in use and their reflectors designed to direct light onto vertical surfaces or objects. This usually requires careful aiming, use of louvers, baffles, snoots, and lamp-cap accessories.

The nighttime outdoor lighting zone within which the home is located or to which the design team and homeowner elect to design establishes the categories of illuminance for outdoor tasks. Nighttime outdoor lighting zones vary by local ordinance, sustainability guides, or the team's own definition of place.

Security lighting above and beyond recommendations cited in Table 33.2 should be implemented with great deliberation and care. Without monitoring programs and other security measures, additional lighting may be pointless as well as an energy waste and a source of irritation to neighbors.

33.2.1.1 Building Entries

Table 33.2 outlines illuminance criteria for residential primary and secondary entries. Illuminances at building entries are defined at the immediate exterior with respect to horizontal illuminance at the threshold (for the width of the door) and vertical illuminance within a 3-foot zone of the entry. Vertical illuminance may drive the horizontal illuminance higher than criteria depending on the lighting equipment and layout used. The vertical illuminance on an approaching visitor's face and body is important. Clothing colors and skin tones are best rendered when lamp CRI is ≥82. Where a warm color of light is desired, CCT should be 2700 K to 3000 K.

It may be determined secondary entries are to be unlighted except for purposes of security. Security lighting should be on timed switches and motion sensors to limit their use to time of need. Soft, diffuse light is best to limit annoying glare to distant property owners. Alternatively, well-controlled optics and snoots can be used for greater light throw on larger properties while limiting light trespass. Where electronic surveillance is planned, close coordination with the security consultant is necessary. Cameras sensitive to infrared radiation can pick up visitors or intruders and display on video monitors. This avoids the need for continuous operation of electric lighting.

33.2.1.2 Entry Walks

Some portion of the entry walk, typically a short section near the main sidewalk or street if both are not publicly lighted, and any elevation changes along the walk are lighted to a lesser degree than the entry for sake of efficiency and preserving the night environment while still meeting vision requirements for movement. This lighting is not intended to be uniformly applied to the entire walking path and is meant to help the visitor navigate by lighting key points of interest.

33.2.1.3 Pool Decks

Pools are presumed to be internally lighted. This defines the pool and deck edge and provides some low-level vertical illuminance at the deck in close proximity to the pool. This is sufficient to softly light faces of guests. For navigating the pool deck, low illuminances are used in predetermined circulation areas and at access points to the deck. This might occur at the pool deck perimeter and establishes a social area between the lighted pool and this lighted perimeter. Like entry walks, light is used here for purposes of navigating from one area to another and not applied uniformly throughout. As with all applications, adhere to all code requirements.

Figure 33.3 | Ramada Activity Area
A sitting area is lighted with a total of eight surface mounted downlights. Each downlight exhibits a slightly angled fixed optic lamped with one 40W/PAR20/WFL halogenIR lamp. The downlights are fitted with a linear spread lens to further spread light and reduce direct glare. Two planters are accented with single 20W/MR16/NSP halogen$_{LV}$ lamps in deep-snooted adjustable accent luminaires. This perimeter accenting acts in conjunction with the linear fire pit on the far left and the pool on the near right to address the perimeter lighting modes identified in Table 12.2 for preference and relaxation. Pool lighting is accomplished with RGB LED in-pool luminaires (set here to saturated blue). All luminaires are on preset scene control and can be addressed by handheld wireless devices.
» Image ©Gary Steffy Lighting Design Inc.

33.2.1.4 Social Areas

Gazebos or ramadas or other semi-protected areas establish gathering points for socializing. If these are programmed for use as barbecue, game, or reading areas, illuminances supporting those activities are necessary. However, homeowners should be advised these illuminances are low compared to indoor counterparts for several reasons: the casual nature of the exterior setting and the impracticality of providing interior illuminances in such a setting. Lighting should address the task area only and uniformities within that area may be broad. Figure 33.3 illustrates lighting for a reading and card-playing area at a ramada.

33.2.1.5 Site Paths, Ramps, Stairs, and Steps

Site paths can be addressed similar to entry walks with lighting helping to identify key points along the path to allow for navigation without uniformly lighting the entire path. Very low illuminances and broad uniformity ratios will create this effect. Where paths exhibit switchbacks or are set on irregular terrain, more uniform application of light may be warranted. The designer is challenged with proposing the path of most prominence and, therefore, the path that is deserving of light. Otherwise an entire site may be lighted unwittingly. Ramps, stairs, and the occasional step should be marked with light.

33.2.1.5 Landscapes

There are no illuminance criteria for landscapes cited in Table 33.2. Landscape lighting can provide peripheral accenting and some degree of security by limiting dark areas of cover and silhouetting foreground movement. In residential applications, lamps typically at 20 W or less with beam spreads typically tighter than 25° in luminaires with louvers or snoots suffice for softly accenting key landscape elements while limiting the effects of light trespass and light pollution. Adjustable equipment should exhibit locking tilt and rotation to maintain proper aiming. Automated time clocks should extinguish tree uplighting at a reasonable curfew to better accommodate stargazing. See Figure 33.4. Landscapes can benefit from high color temperature lamps or luminaires fitted with blue-green gels. Since colorful effects may elicit a harsh reaction, these effects should be reviewed with the homeowner. Mockups are an excellent way to explore the use of color or even lamps exhibiting CCTs ≥4100 K.

Figure 33.4 | Landscape Lighting
A mesquite tree is uplighted with three luminaires each lamped with 20W/MR16/NSP halogen$_{LV}$ lamps in deep-snooted accents. Luminaires are aimed into the central branch structure of the canopy. Using such low-wattage, well-controlled equipment is an appropriate way to provide lighting sufficient for outdoor close-view and enjoyment. This tree is located at one end of a barbecue terrace and helps define the boundary and serves as back drop to seated conversation. Time clocks should be used to extinguish lights at a reasonable curfew.

33.2.2 Residential Interiors

For this discussion on interiors, lighting needs of residents in single-family detached and attached homes and in the living quarters of duplexes, apartments, condominiums or other similar complexes are considered during day- and night-time hours. For public areas in the larger operations, see relevant applications in 22 | LIGHTING FOR COMMON APPLICATIONS and 26 | LIGHTING FOR EXTERIORS. See Figure 33.5. For assisted-living situations, reference relevant applications in 27 | LIGHTING FOR HEALTH CARE. For residential interiors several conditions influence lighting:

- Architectural and interiors styles
- Number and ages of occupants
- Primary hours of use
- Life activities
- Sustainability

Unlike commercial, civic, and institutional projects, residential architectural and interior designs are usually strong reflections of the homeowner's own sense of style. Lighting should respond to traditional, transitional, contemporary, or eclectic styles through luminaire styles and the types of lighting effects. Reviewing luminaire selections and lighting effects with the homeowner is a key component of the design process.

The number of occupants and their ages may influence the diversity of lighting techniques and illuminances available throughout the residence. Lighting for bedrooms and game rooms for people under 25 years of age may establish a convenient means of addressing the likely aesthetic and illuminance differences. Where a large family is involved with young and elder members, the design must review respective spaces and tasks and discuss with the homeowner the options for addressing the age differences. Controls can assist in meeting varying needs based on occupancy, tasks, and time of day. However, for these to be successful, their operation must be quite straightforward.

Some residences require near 24-hour operation while others are primarily used during dark hours on weekdays and daylight hours on weekends. The use patterns may well influence lighting decisions and controls. Daylighting strategies may not have the sustainability benefits if they contribute little to reduced use of electric lights during weekday peak utility demand and may even contribute unfavorably to weekday cooling load. On the other hand, value to future homeowners must be considered. These are aspects that must be explored with the homeowner.

Life activities will influence the kinds of applications and tasks to be performed, will affect design priorities, and will affect the kinds and number of defined areas in the house. Some homeowners are quite active and will have indoor and outdoor areas and equipment to support sports or exercising activities. Some homeowners dedicate life to raising children and, later, grandchildren. Other homeowners are hobbyists and may be involved in such activities as knitting or collecting dolls, stamps, or coins. Still, others cook. Some are movie buffs. Some enjoy entertaining. Some households encompass all of these activities. A good program will detail the life activities, outline space and area requirements, and can serve as an outline of lighting needs.

Energy use and maintenance are sustainability aspects that should weigh on the designer's and homeowner's design selections. Efficient, long-life lamps can result in low connected loads. Dedicated-socket luminaires can assure this low-load over time. Controls can have a positive influence on energy use. Simple vacancy sensors can switch lights off in unoccupied rooms thereby reducing energy use and extending in-service life of lamps and ballasts, drivers, and transformers.

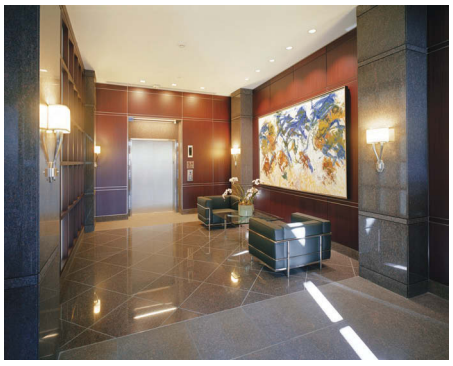

Figure 33.5 | Common Application: Condominium Lobby
Illuminance criteria for lobbies and circulation corridors for apartments and condominium complexes are addressed in Table 22.2 | Common Applications Illuminance Recommendations/Transition Spaces.

Here, fabric-shade wall sconces lamped with 13 W CFLs contribute to a residential atmosphere. Adjustable accents lamped with 20W/PAR20/CMH 25°-beam flood lamps highlight the artwork. The wood surround at the elevator wall is lighted with 26 W CFL wallwashers. A recessed linear, continuous, lensed luminaire of 2½" width and 4' length at the elevator header illuminates the threshold. All lamps exhibit CCT of 3000 K and CRI ≥82.

Daylight in combination with electric light is used to address daytime illuminance criteria.

The applications and tasks outlined in Table 33.2 are extensive, if not exhaustive, and many are self-explanatory. However, as is the case with nearly all lighting design efforts, the devil is in the details. Identifying applications or tasks, selecting an illuminance target, and laying out lighting equipment to address that target is a gross foreshortening of the design process. The design components outlined in Chapters 12, 14, and 15 should not be dismissed. Even within the more analytic aspect of laying out equipment to meet illuminances, the reasons for introducing light must be understood. For example, why light a garage? Many answers come to mind, but perhaps not loading or unloading the car. For such common activities, daylighting and electric lighting should be designed to illuminate the sides of the vehicle, thereby allowing some light to enter side windows and doors, preferably from both sides, and assist with the visual requirements of loading and unloading. This sidelight approach also reduces shadowing common when opening hoods, trunks, and hatches.

What follows are brief annotations on lighting of some interior residential applications and tasks.

33.2.2.1 Accenting

Accenting is used to address subjective impressions identified in Chapter 12. Accenting may take several forms, including: art; feature wall; perimeter; and significant focal point. Figures 33.6, 33.7, and 33.8 identify a few techniques for achieving some forms of accenting. Particularly in single-family residences, access to skylight and clerestory techniques can lead to effective daylight accenting solutions. In any event, accenting need not consume much energy and is typically more efficient and visually interesting than using high-output general lighting.

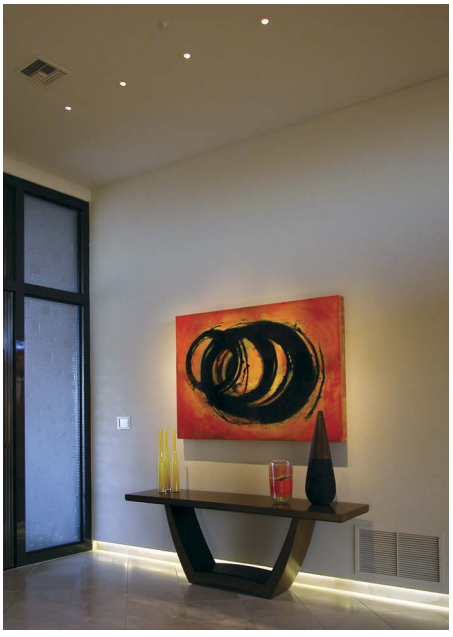

Figure 33.6 | Accenting Art
Although illuminance target and uniformity are important, other design criteria include: scale of luminaire aperture; ceiling height; and the artwork media. Here, four pinhole adjustable accents are used, each lamped with a 20W/MR16/VNSP halogen$_{LV}$ lamp and fitted with soft diffusion and UV filters.
» Image ©Gary Steffy Lighting Design Inc.

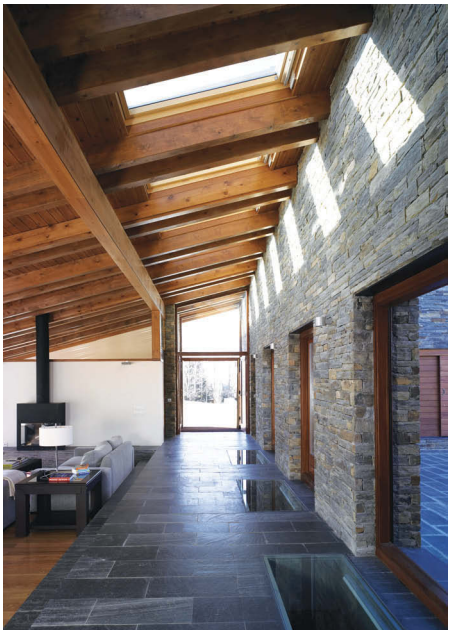

Figure 33.7 | Accenting Perimeter
Daylight apertures are strategically placed to wash the stone wall and balance the brightnesses from other daylight media. In this location and at this angle, the skylights are less likely to create glare for people in the living area than would skylights located directly over the living area.
» Image ©Eugeni Pons/Arcaid/Corbis

Figure 33.8 | Accenting Feature Wall
A skylight is positioned to graze this tile wall with daylight and introduce general light in the vicinity of the bathtub. Skylight geometry can be designed to limit direct glare during the more relaxed function of bathing. Electric lighting must also address direct glare in these situations.

Figure 33.9 | Vanities
Mirror-integrated lighting addresses criteria for grooming at the vanities in the modern master bath in the top image. The dimmable long compact fluorescent lamps exhibit CCT of 3000 K and CRI of 82.

Wall sconces achieve a similar result in a more traditional setting in the middle image.

Middle and bottom images clearly show the effect of vertical illuminance on the face generated by well-placed luminaires.

» Top image ©Glen Calvin Moon
» Middle image ©Felix Wirth/Corbis
» Bottom image ©Trinette Reed Blend Images Getty

33.2.2.2 Bathrooms

In an effort to address all task requirements, general lighting alone addresses none very well in bathrooms. Task-functional lighting can be appropriate without the glare and shadows common with one or two high-output ceiling luminaires or a field of downlights. The targeted use of lighting energy is more efficient with a task-functional approach. Grooming is an especially significant task, both in time consumption and in esteem-value and lighting plays a valuable role, and demands frontal lighting of the face. The designer must determine the extent and priority of bathroom tasks for a given homeowner. In some situations, grooming may take place at sit-down vanities and the E_v values cited in Table 33.2 should then be applied to a seated eye-height position corresponding to chair- or stool-height sitting position. Reading in the bathroom may be a homeowner's desire or requirement for which a review of reading tasks is undertaken, such as 12 pt. font under READING AND WRITING in Table 33.2. Figure 33.9 illustrates several lighting approaches to a master bathroom. Although downlights alone might be deemed expeditious, glare and shadows are serious side effects unless great care is taken in selection of optics and lamping. Downlights are used for top lighting the head, thereby addressing the Table 33.2 citation of RESIDENTIAL INTERIORS/Bathrooms/Vanities/Top-of-head.

33.2.2.3 Bedrooms

Bedrooms may be the most multi-functional spaces in a home. Reading for pleasure, watching television, surfing the Internet, dressing, amorous activities, and studying or working at a desk are some of the functions. In addition to a variety of lighting effects, controls are usually employed to address the desired variability. Reading for pleasure in bed may involve separate controls for each side of the bed. If there is a programmed need for reading light for one party independent of the other party, optically well-controlled table luminaires, gooseneck wall luminaires, or even ceiling pinholes may be warranted. Care should be taken by the design team to accommodate a sleep cycle with no light. Where nightlights are deemed appropriate, strategic placement of one or several architecturally-integrated steplights may be in order. To limit sleep disturbance these should be tied to occupancy sensors on timers or photocells. To best limit the disturbance to the circadian rhythm during the sleep cycle, long wavelength sources such as LEDs producing spectra between 600 and 620 nm are appropriate. However, there should be no direct view of the source or optical media and illuminances should be extremely low.

33.2.2.4 Circulation

Where circulation lighting and general lighting throughout a residence are deemed necessary, these need not and usually are not achieved with a complete and distinctly separate lighting system. After developing design strategies to address accents and the host of other application and task requirements in a home, calculation checks are made. Where illuminance results are below design targets for circulation, then additional design work is necessary. This might involve additional accent lighting, additional decorative lighting, or the introduction of lighting for purposes of meeting the circulation illuminance target. This might be daylighting or electric lighting or both to accommodate day and night situations.

In open layouts, circulation zones might be obvious, but no designated or walled-off corridor exists. Here, lighting criteria are quite directly related to the lighting of the adjoining area.

33.2.2.5 Closets

Closet space is always at a premium. Closets are usually small and potentially fitted-out with ceiling-high closet-wide shelving, drawers, hanger rods, or some combination. The very nature of clothing and most stored items, other than linens, make for a low-reflectance room. Code requirements on types of luminaires and their proximity to clothing and storage shelving result in little flexibility for luminaire sizes and locations in small closets. In some situations, the closet is so small that a code-compliant lighting layout cannot be accommodated and it may be necessary to mount the lighting equipment outside of the closet. In these situations, the designer must more carefully consider several items in the context of the adjacent space:

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

- luminaire placement and orientation to limit effects of body shadow from users
- luminaire styling and scale
- controls such as keypad or switch, door-activated switch or occupancy sensor

In walk-in closets, needs may be multiple and perhaps for different users. Preset controls can help establish appropriate lighting for each function and user. For dressing room situations, frontal lighting for users standing in front of a mirror is necessary (see Figure 33.10). Where makeup and grooming are accommodated with mirror(s) at perhaps a sitting area, facial lighting at the appropriate elevation is necessary. Criteria for these various tasks from Table 33.2 can be used to set various scenes.

Color discrimination, between navy, black, and dark brown for example, may be best accommodated with the introduction of some accent lighting aimed to a dresser or sorting surface. Daylighting is extremely helpful, but has obvious availability limitations. Lamps should exhibit CRI ≥85. To avoid the effects of spectral deficiencies of any one light source, mixing lamp technologies is beneficial. A combination of some fluorescent with some LED or halogenIR lighting offers good color discrimination and matching when all lighting is used simultaneously.

Figure 33.10 | Dressing Mirror
Full length mirrors work well when diffuse frontal lighting is available across the face of the standing body. Opal-lensed surface mounted or semi-recessed luminaires, electric skylights, and wall sconces are all effective options. Narrow or even wide-beam downlights are typically unsuccessful as these create harsh shadows across the face of the body sometimes creating unflattering views.
» Image ©Adrian Wilson/Corbis

33.2.2.6 Family Rooms and Living Rooms

Family rooms and living rooms have evolved with technology and lifestyle. Televisions have moved to rooms dedicated to their use, like media lounges or home theaters. Family and living rooms are one-in-the-same in many residences and function as conversation areas and places for pleasure reading and entertaining. Figure 33.11 illustrates a room that functions as family room and living room and the lighting employed to address respective architectural cues, subjective impressions, and luminance and illuminance criteria.

33.2.2.7 Kitchens

Lighting for working kitchens is most successful when surface finishes are matte and of high reflectance. Dark cabinetry, counter tops, backs plashes, and floors contribute to an overall dark, though highly-dramatic appearance and exacerbate shadowing. Black, polished stone counter tops exhibit annoying veiling reflections if not discomfort glare caused by luminaire reflections. Lighting can be efficient and pleasant and yet meet what appear to be demanding illuminance criteria. See Figure 33.12.

33.2.2.8 Media Lounges

Home theaters are evolving into media lounges to accommodate the growing variety of media entertainment. Where home theaters are programmed, seating might be tiered, such as in a movie theater, and the experience is intended to be much like that of a theater. Controls play a role in allowing for slow fades from relatively bright settings to theater-dark settings. Vertical illuminance at the video screen are expected to be very low for best picture contrast. Finishes affect the overall light quality, even in the theater-dark scene, as the screen emits enough light to illuminate room surfaces and, consequently, lighter surfaces may make for an undesirably bright experience. On the other hand, as the video screen technologies advance, screen luminance improves to the point where some background luminance is desirable. Soft background lighting and lighter-toned surfaces will minimize screen glare and visual fatigue. The designer must assess the homeowner's intended use of the media lounge and the luminance of the screen to determine appropriate illuminance criteria.

In some situations media lounges replace the traditional TV-watching room where reading for pleasure, conversation, and entertainment occurred. Accommodations should be made for reading and conversation tasks to occur in conjunction with TV-watching. Here, vertical illuminance at the video screen isn't as important as that for the theater experience, but is important for facial recognition for conversation and accommodating varying positions of the reading material.

Figure 33.11 | Family and Living Rooms
The architectural cues of the cathedral ceiling and the massive fireplace wall helped establish lighting design strategies. Spatial definition and preference suggested wall-washing and art accenting techniques (from Table 12.1b | Spatial Factors: Part Two and Table 12.2 | Subjective Impressions respectively). Illuminance criteria for Family Room/Living Room and for Reading/Writing/Casual Chair were used to finalize lamping in the cove uplight and the number, positioning, and wattage of downlights.
» Image ©Glen Calvin Moon

Where gaming activities are involved, the floor is not tiered and the lighting system and lighting controls must be designed to accommodate the theater experience and the gaming experiences, of which there may be several. Gaming might be an immersive interactive experience or might be a shared, active-sport experience. Each of these should be lighted to address the desired mood and function. Immersive gaming is typically a darker setting with full attention on the video screen while active-sport gaming is typically a lighter setting where visual attention periodically alternates from screen to participants. As these technologies of video and gaming evolve, lighting solutions should as well. Figure 33.13 illustrates variations on a theme for the theater experience.

33.2.2.9 Offices

In the home, the office may take many forms and serve many functions. An office where work from "the office" is performed on a regular and perhaps even full-time basis, should be lighted to support such continuous, fast-paced, productively-accurate, and long-term work. However, where an office at home is used infrequently for the household tasks of paying bills, making weekly or monthly family schedules, reviewing and filing financial statements, and surfing the Internet, which can be done at a less demanding pace and degree of accounting, lighting should be designed accordingly.

33.2.2.10 Reading and Writing

Reading and writing tasks occur within various applications. Familiarity with these tasks will aid with assessment of specific application tasks and activities. This may result in the recommendation of illuminance criteria different than that proposed in Table 33.2 for a particular application. For example, if the homeowner is inclined or required to read documents printed in small typeface such as 6 point font, then illuminance criteria at areas where this reading is to take place should reflect this.

Electronic readers may revolutionize the reading task. The technologies employed in various versions of these readers determine the illuminance criteria. As these technologies evolve, the designer needs to periodically assess lighting requirements and adjust designs accordingly.

33.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 33.2.

33.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 33.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 33.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

33.3.2 Notes

The notes in Table 33.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

33.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, an accounting must be made of anticipated light losses through the point in time at which lamps will be changed. For residential applications, this may not occur until the lamp fails. Accounting for lamp lumen depreciation (LLD) through end of life may wildly throw off initial costs, energy and sustainability efforts, and illuminances for much of the life of the lamp. Ultimately this is unsustainable and is unacceptable to most homeowners. In most situations, homeowners will understand the consequences of poor LLDs resulting from spot relamping at time of lamp failure. Most homeowners accept the gradual reduction in illuminance over time of operation where illuminance is not tied to safety or the degrees of accuracy and speed required in commercial and institutional settings. Therefore, a default design strategy bases LLDs on group-relamping to avoid what otherwise will be the shock of still-greater initial and operating costs and subpar energy and sustainability performance. This condition of illuminances ultimately falling below criteria, but the ramifications of the alternative should be reviewed with the homeowner. Luminaire dirt depreciation (LDD) can be maintained at an efficient level with periodic cleaning, a concept appreciated by many homeowners.

Targets cited are consensus and recommended for respective functional activity. Footcandle conversions of any values cited in Table 33.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple

Figure 33.12 | Kitchens
Architectural style and personal taste influence design and operation. The top image illustrates a kitchen and dining area where small downlights concentrate light at the island. Undercabinet task lighting, a mainstay in many kitchens, meets illuminance criteria a the counters. A unique pendant luminaire at the dining table is combined with a wallslot detail with closed shades as the reflecting surface for a dramatic look and spacious effect.

The middle image illustrates undercabinet lighting with traditional-style short-stem pendants to provide general diffuse light.

In the lower image, a simple layout of linear indirect pendants complement the modern architecture and illuminate the work area with no glare. The dimmable T5HO fluorescent lamps exhibit CCT of 3000 K and CRI of 85.

citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions.

A lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for lighting white boards, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on at least one plane of a task. A 0 indicates no light or zero light is recommended for the task or application.

33.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. Additionally, most tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). Where these illuminance components are intended at differing planar elevations, such is indicated under "Notes." For example, for bathroom vanities, horizontal illuminances apply to the counter top while vertical illuminances apply to standing-face-plane height of 5' AFF oriented in the direction facing the mirror. In situations where a sit-down vanity is designed the height of the counter top or table and of the seated face must be established and criteria applied to the respective planes of interest.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation. For example, in a kitchen, E_v at preparation surfaces (RESIDENTIAL INTERIORS/Kitchen/Preparation Counters), the number and orientation of vertical planar points assessed depends on the preparation surface. On a counter against a full-height wall, the vertical planes of most interest are the one facing the preparer and the two planes perpendicular to the preparer (one oriented toward the right and one toward the left). The criteria apply to these three planes. On an island or peninsula which may be used from more than one side, there are four planes of interest.

33.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the homeowner. It may be determined that in a residence where perhaps two people constitute a majority the "design age" is for a different age group to address an elderly relative or accommodate the homeowner's own desire to remain a resident of the house for a long time. However, this may result in over lighting, under lighting, harsh lighting, visual displeasure, or visual discomfort for some residents some of the time. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance.

33.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 33.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

33.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

33.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio. Ratios in many residential applications are relatively broad reflecting the greater diversity in illuminances that are tolerated, even enjoyed, in a residential setting.

33.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

33.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

33.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

33.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Where users are willing to cede to automation, photocells and stepped-dimming or continuous dimming can be used to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

33.3.6 Veiling Reflections

Tasks with specular components, like some televisions or computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

IESH/10e CSA/ISO

> 12.5 Task Factors
- for information on CSA/ISO computer screen qualities

33.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Tasks and Applications and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 33.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or homeowner. The area-of-coverage citations in Table 33.2 are based on traditional notions.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

33.4 Designing

Information provided here is specific to residential dwelling units and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 22 | LIGHTING FOR COMMON APPLICATIONS and 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects, particularly as it relates to common areas in residential complexes.

Unlike most other application types, a residence is usually inhabited by a small number of occupants. One or two of these occupants, the homeowner, is typically in charge of voicing needs and desires of the family and of making decisions. Design must accommodate these very specific needs and desires.

Programming should include personal lifestyle information if lighting is to be successful. Which occupants will use which rooms exclusively, mostly, seldom, or collectively may help define or refine tasks and visual age of the user or users. An appreciation of homeowner preferences on color, light levels, brightnesses, manual and automated technologies, and style and design is a must. An understanding of homeowner priorities such as initial and operating costs, leadtime, comfort, sustainability, and project life cycle is also necessary. Details on living range from entertainment needs to how much time and what times are spent at home. Lighting can only be appropriately tailored to an individual's or family's lifestyle where lifestyle detail has been investigated.

Also unlike most other applications, some homeowners have a penchant for leading style or technology movements. Opportunities may exist for unique, even untried techniques, to be implemented. These include siting and building configuration and orientation to optimize daylight and introduction of novel power generation and distribution systems for lighting which may be too exotic or costly for larger-scale commercial applications.

Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth

resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

34 | LIGHTING FOR RETAIL

I take the family shopping round. The markets of the world.
Edgar A. Guest, 20th Century Poet

Contents

34.1 Project Type and Status. . . . 34.2
34.2 Application Types 34.2
34.3 Illuminance Criteria 34.43
34.4 Designing. 34.47
34.5 References 34.48

Shopping may be a past time for some, but a necessity for many. From food to clothing to electronics to paper and pens to vehicles and their servicing and fueling many purchases are an integral, if not essential, part of people's lives. Most shopping occurs in traditional brick-and-mortar settings where the shoppers' experiences of store, mall, and center affects brand perceptions and loyalty. Exciting store design has been cited as a contributor to brand [1]. Lighting influences, if not creates excitement. This does not diminish lighting's other long-standing retail attributes of rendering goods for visual attraction and inspection. Just like most other applications, the real bottom line should not be in securing quick and cheap commodity lighting at the time of project construction for what amounts to a fleeting gain of perhaps a tenth of a percentage point, if that, in construction costs. Rather, the long-term value is leveraging lighting for its contribution to branding and to overtly or subliminally sell merchandise.

Even online or e-commerce shopping demands attention to lighting. In these situations, retailers rely on employees in stocked warehouses and distribution centers to make accurate selections, careful packing, and timely shipments.

Electric lighting accounts for about 42% of the electricity used in retailing [2]. Figure 34.1 shows the breakdown of electricity use in retail facilities. Proper use of daylight and efficient electric light is unquestionable. What follows is a discussion of the key aspects affecting lighting for people in retail facilities: project status; space types; activities; application-specific design goals, and illuminance criteria.

Comprehensive design efforts must also rely on material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. The designer should have a thorough understanding of the design tenets outlined in those chapters, must identify those deemed appropriate and develop lighting goals and strategies accordingly. This chapter primarily addresses specifics related to lighting for retail which should influence luminaire optical selections, lamping, and final layouts based on previously developed thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous and current IES related documents serve as archival and reference sources [3] [4].

Deliberate thought should be given to details beyond the recommended illuminances in this chapter. For example, in a department store setting where daylighting is introduced, the control system to operate electric lighting and any shade treatments could be used for other purposes. The control system could also be used to vary the illuminances on feature displays over time, thereby providing a dynamic visual rotation of feature displays. This is one means of contributing to an exciting store design. These and other techniques can only come from contemplation of the design problem while addressing design priorities outlined in the project's program. Table 34.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

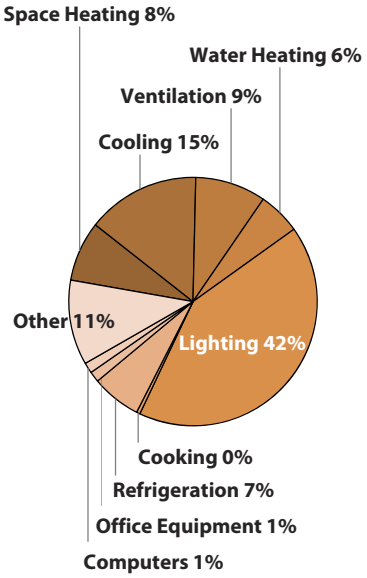

Figure 34.1 | Electricity Use of Retail Facilities
Based on 2003 data from the US DOE's Energy Information Administration, lighting accounts for 42% of electricity use in retail buildings (electricity use for Cooking rounds to 0%). Retail buildings themselves account for about 21% of electricity use by all commercial and institutional buildings.

34.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. A clear understanding of the project type and scope will help establish the extent to which daylighting can address most or many or some of the lighting goals. At every opportunity the lighting designer should consider daylighting as a light source. A host of lighting design factors is identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands determined attention to address glare and balance visible and thermal energy. Since many retail establishments operate during dark hours, electric lighting and controls must be well-integrated.

34.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the retail space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room and store department names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 34.2 | Retail Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room and department names, and the available application and task citations in Table 34.2.

The following sections are keyed to the major application and task headings in Table 34.2. These discussions, those identified in Table 34.1, and the material in Table 34.2 offer comprehensive qualitative and quantitative criteria.

34.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction and wayfinding. Default accent lighting criteria are discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Also see 15.1.1.3 Accent Lighting.

34.2.2 Administration

Lighting for administrative areas is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The architectural scheme and even task specifics may vary based on the associated type of retail facility.

34.2.3 Atria and Courtyards

Lighting for atria and courtyards is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The design for the store, mall, or retail center may include one or several multi-story covered or open daylighted spaces considered atria or courtyards. The designer must coordinate with the team and the client to determine if programmed activities and style are best served by illuminance criteria for malls or atria and courtyards. Criteria for live plants are outlined in 22 | LIGHTING FOR COMMON APPLICATIONS.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

34.2.4 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. For building entries, variables affecting recommended illuminance criteria include anticipated levels of activity and the nighttime outdoor lighting zone. Nighttime activity levels may vary by type of retail facility, such as automotive dealership versus a mall versus shopping district, by specific schedules, such as which night of the week, and by other events or activities, such as sports. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions. All of this may demand a control system capable of addressing various settings on various evenings through manual intervention, automated time clock, and photocell functions.

The nighttime outdoor lighting zone within which the facility is located establishes the categories of illuminance for outdoor tasks. Nighttime outdoor lighting zones vary by local ordinance, sustainability guides, or the team's own definition of place. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions.

Business- and after-hours security needs, such as on-site or remote monitoring or recording, may require specific luminaire placement and specific illuminances coordinated with security cameras, and, after hours, may require that some luminaires at building entries remain energized through the night or placed on motion sensors or interconnected with camera operations. Control zones and time clock functions must be designed accordingly. Where remote monitoring is done with infrared cameras, lighting may be unnecessary.

Entry lighting must transition between the indoor and outdoor lighting conditions. Entries should be inviting and reflect the indoor setting. Lamp CCTs and CRIs should be based on indoor lamping color criteria rather than on parking or roadway selections.

34.2.5 Centers, Outdoor

Outdoor shopping centers, districts, and malls served by mass transit and where vehicles are restricted to distant parking and service areas should be designed strictly for pedestrian shopping and social experiences. Vertical illuminances are relatively low and uniformity ratios are relatively broad. Attention to lighting of show windows, store fronts, art features, sidewalk cafes, and beverage oases is important. Curbs, ramps, and stairs must be addressed. If curfew occurs after business hours, lighting should be extinguished except as needed for security. Security lighting can be motion-sensor controlled for improved sustainability and detection and deterrence. If curfew occurs prior to businesses closing, lighting should be controlled to allow a set-back to reduce illuminances and broaden uniformities as outlined in Table 34.2. Regardless, all non-commercial accent lighting on plazas, promenades, and town squares, such as that for sculpture and fountains, should be extinguished at curfew. A control system of photocells and astronomical time clock functions can automate much of the lighting. For special events, manual or programmed overrides are appropriate.

As illustrated in Figure 34.2, one approach to lighting large promenades or other pedestrian areas is to transition lighting from peripheral brighter zones (store fronts and their immediately-adjacent pavement) to darker central zones (center of the promenades between opposing store fronts). Vertical and horizontal illuminances drop toward the central zones while meeting uniformity ratios and overall averages. This approach better enables shoppers to adapt as they move between store interiors and central areas of promenades. Finally, a darker central promenade establishes a backdrop for better contrast of accented features such as sculpture or fountains.

The designer must work with team members and the client to define an appropriate level of activity. Although seasonal activity levels might be higher than those expected at other times, this should not necessarily establish the norm for year-round operations. Additionally, seasonal activity is itself identified with seasonal decorations, many with lighting. Overlighting the pedestrian areas will diminish the visual effects of the lighted decorations.

Figure 34.2 | Shopping Promenades
Open air shopping districts and centers offer promenades, plazas and town squares exclusive to shoppers on foot. Lighting is not burdened with interaction between pedestrians and vehicles and should be designed to enhance the retail and social experiences. Lighting of show windows and store fronts is introduced primarily for attention. Decorative lighting effects are introduced secondarily for visual interest. All of these lighting techniques also address subjective impressions of preference and relaxation and mix to create an exciting experience.

Notes for Table 34.2

The table column headings are discussed in detail in 34.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 34.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 34.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 34.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some general retail sales, the typical area of coverage is "Room or Designated Area" at the planar elevations noted. For applications where task position is known, such as fixed displays or specific gondola layouts, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area" and which may involve different planar elevations that the designer must accommodate.

Notes for Table 34.2

The table column headings are discussed in detail in 34.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 34.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 34.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 34.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some general retail sales, the typical area of coverage is "Room or Designated Area" at the planar elevations noted. For applications where task position is known, such as fixed displays or specific gondola layouts, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area" and which may involve different planar elevations that the designer must accommodate.

Notes for Table 34.2

The table column headings are discussed in detail in 34.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 34.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 34.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 34.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◆ signals high likelihood; gray and white ◆ signals moderate likelihood; pale gray and white ◆ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some general retail sales, the typical area of coverage is "Room or Designated Area" at the planar elevations noted. For applications where task position is known, such as fixed displays or specific gondola layouts, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area" and which may involve different planar elevations that the designer must accommodate.

Notes for Table 34.2

The table column headings are discussed in detail in 34.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 34.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 34.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 34.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◥ signals high likelihood; gray and white ◥ signals moderate likelihood; pale gray and white ◥ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some general retail sales, the typical area of coverage is "Room or Designated Area" at the planar elevations noted. For applications where task position is known, such as fixed displays or specific gondola layouts, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area" and which may involve different planar elevations that the designer must accommodate.

Notes for Table 34.2

The table column headings are discussed in detail in 34.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 34.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 34.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 34.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some general retail sales, the typical area of coverage is "Room or Designated Area" at the planar elevations noted. For applications where task position is known, such as fixed displays or specific gondola layouts, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area" and which may involve different planar elevations that the designer must accommodate.

Notes for Table 34.2

The table column headings are discussed in detail in 34.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 34.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 34.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 34.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some general retail sales, the typical area of coverage is "Room or Designated Area" at the planar elevations noted. For applications where task position is known, such as fixed displays or specific gondola layouts, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area" and which may involve different planar elevations that the designer must accommodate.

Notes for Table 34.2

The table column headings are discussed in detail in 34.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 34.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 34.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 34.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some general retail sales, the typical area of coverage is "Room or Designated Area" at the planar elevations noted. For applications where task position is known, such as fixed displays or specific gondola layouts, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area" and which may involve different planar elevations that the designer must accommodate.

Notes for Table 34.2

The table column headings are discussed in detail in 34.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 34.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 34.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 34.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◥ signals high likelihood; gray and white ◥ signals moderate likelihood; pale gray and white ◥ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

l. For applications where task position is indefinite, such as some general retail sales, the typical area of coverage is "Room or Designated Area" at the planar elevations noted. For applications where task position is known, such as fixed displays or specific gondola layouts, a more efficient approach is likely achieved when target illuminance is applied to the "Task Proper or Task Area" and which may involve different planar elevations that the designer must accommodate.

Table 34.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

Where nighttime outdoor lighting zones are not defined by local ordinance, their determination must then be addressed with team members and client. Selecting a higher-than-appropriate nighttime outdoor lighting zone only serves to ratchet illuminances unnecessarily high and will likely result in too much light and glare for the shopper. This can negatively affect the experience and reduce the sense of excitement. Overlighting pedestrian areas may encourage overlighting of stores and show windows as these "compete" for attention relative to the lighting of pedestrian areas. For these same reasons, where nighttime outdoor lighting zones are established by ordinance, it makes little sense to insert higher- or lower-zoned projects, as such variances only serve to encourage others to seek similar exemptions and perpetuate the problem.

34.2.6 Food Service

Lighting for food service is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Food service lighting can be categorized as that for food preparation and handling, food consumption, and cleanup. These illuminance criteria address the safety of those handling and preparing the food, the safety of the food for consumption, which involves inspection, the presentation of the food for consumption, and cleanliness of food stuffs and facilities. In the U.S., lighting for commercial and institutional food preparation must meet FDA Food Code requirements for minimum illuminance which have basis in the IES guidelines. Apparently due to metrication, code requirements are within 10% of IES recommendations. Regardless, a lighting design must meet code.

To avoid the consequences of violent lamp failure and therefore food contamination, lamps used over food preparation areas must be shielded. New technologies, including LEDs and OLEDs, have not been vetted for this aspect. Consult with current codes or code officials if any question exists.

34.2.7 IT

Lighting for IT tasks is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Many retail establishments may have few IT tasks. Some establishments, however, rely on computers to operate, track, and perform functions.

34.2.8 Malls, Indoor

Malls are covered facilities. The introduction of daylighting is considered a great benefit to the shopping experience and should be pursued. See Figure 34.3.

Accenting in malls should enhance shopping, not compete with it, and therefore careful application is necessary. Where important art features are planned, accenting can help establish these as iconic references to aid wayfinding. Where architectural feature walls form backdrops or where store fronts consist of limited glazing and impressions of spaciousness and preference are desired, wall lighting is recommended. Accenting of important service areas or concierge stations helps shoppers identify these upon arrival or departure. Services might include coat check, stroller and electric wheelchair pickup, wrapping, and valet.

Concourses typically serve as neutral background for circulation against the visually exciting store fronts, show windows, displays, and features. If malls accommodate kiosks, market stalls, or carts, then lighting should be specific to the task area defined by each kiosk rather than increasing lighting throughout the concourse.

For lighting of relatively straightforward entertainment events, see AUDITORIA/ Performance citations in Table 24.2 | Education Facilities Illuminance Recommendations. For professional theatrical events with lighting cues sequenced to the show, consult with a professional theater lighting designer.

See Food Service citations in Table 22.2 | Common Applications Illuminance Recommendations for lighting criteria related to food courts. For food court dining areas, lighting should relate to the type of eating establishments and the mall's architectural style.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Maintenance challenges in malls are a result of large-volume and usually high-ceiling architecture and the hours during which maintenance may be performed without affecting the shopping experience. Lighting equipment that can be accessed from above is appropriate, but the cost of access ways and catwalks must be considered. Long-life lamps and disciplined use of controls are helpful to extending in-service life. Reliable and warranted LEDs may be appropriate, depending on throw distances and areas of coverage. Regardless, access to lighting equipment must be coordinated with the design team and client.

34.2.9 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS.

34.2.10 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS.

34.2.11 Retailing, Indoor

Indoor retailing involves lighting of the shopping area, the sales transaction area, show windows, and wrapping and packaging. Depending on the retailer, some of these aspects are set apart in distinctly different areas or even rooms. The shopping area itself consists of circulation, feature displays, general retail areas, and perimeters. Nevertheless, color qualities of light, equipment styles, and even lighting effects are coordinated for harmony.

Fitting Rooms
In clothing stores and where alterations are a part of the selling strategy, dressing rooms and fitting areas are used. If alterations are not a part of the strategy, then dressing rooms suffice. Both dressing rooms and fitting areas should be lighted to feature the shopper. Vertical illuminance is important. In upscale situations and in the fitting rooms for tailoring, higher vertical illuminances are appropriate. The plane of application is that of the shopper's body oriented toward the mirror. In fitting areas, vertical illuminance may be needed for the plane oriented in the direction opposite the mirror depending on tailoring requirements. These vertical illuminances are best achieved with diffuse frontal lighting, such as wall sconces at the mirror combined with diffuse overhead light to provide some top lighting.

Retailing: Circulation; Feature Displays; General Retail Areas; Perimeters
Retail lighting should be tailored to the type of merchandise and consequently the classification of retailer. There are 16 retail classifications cited in Table 34.2. Each classification includes criteria for circulation, feature displays, general retail areas, and store perimeters. A detailed store plan is necessary so that the designer may best:

- Establish appropriate contrasts between merchandise, displays, and backgrounds
- Use available lighting energy
- Establish accent luminaire locations with optimal aiming angles

If store plans cannot be resolved by time of lighting design or if design direction is for "maximum flexibility," then the resulting lighting layouts may compromise lighting effects and the shopping experience.

Circulation lighting establishes a base condition of uniform and relatively low horizontal and vertical illuminances where circulation is designated. Spill light from feature displays, general retail areas, and perimeters may result in circulation illuminances greater than IES recommendations once these components are designed and their effects included. When general retail and perimeter lighting are achieved from fixed architecturally-integrated lighting systems, their spill light can be calculated and considered as part or all of the circulation lighting system. Figures 34.4 and 34.5 illustrate such an approach.

Feature displays can and should be significant focal points to lead shoppers into and through the store. Typically, these are best illuminated with lighting directed to the surface or surfaces which are most visible from key viewing directions. These usually are

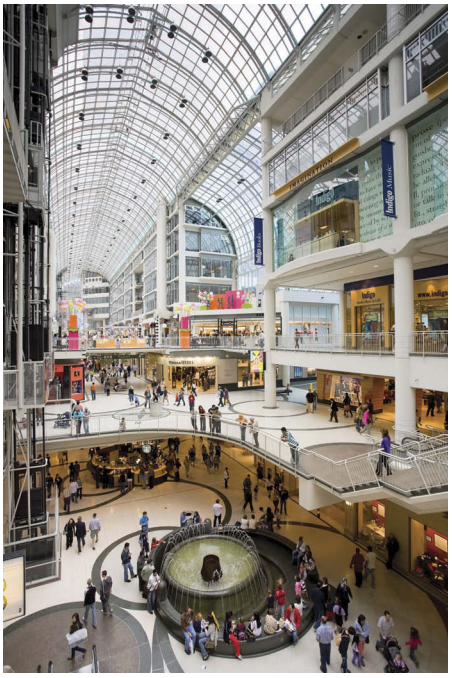

Figure 34.3 | Malls
Even in relatively narrow and tall structures, toplighting daylight strategies can provide sufficient illuminance for circulation and lounge areas.

Figure 34.4 | Feature Displays
Feature displays are used to attract shoppers through visual intrigue and excitement. Lighting is a necessary means to that end. Here, a series of mannequins and feature display lighting effects appear to suggest a fashion runway and collectively provide a significant focal feature. A feature display in the middle left background draws attention to that area inviting further exploration.

Perimeter lighting is used here to accentuate an architectural backdrop of wood. Rather than a continuous uniform wash across a large area of the ceiling or the walls, lighting details are used to enhance the juxtaposition of planes (see Table 12.1b | Spatial Factors: Part Two).

Spill light from perimeter architectural lighting can address some or all of the circulation illuminance.

» Image ©WWD/Condé Nast/Corbis

vertical surfaces, but may be horizontal or some combination of vertical and horizontal. In the life of a store, all may be possibilities and the designer should develop a solution accordingly. Primary viewing direction is typically the main approach into a department or area and, if the store area is large, a secondary approach direction may exist. The total display should be lighted to a base illuminance identified in Table 34.2 as "General retail" citation under the various retail classifications of RETAILING, INDOOR. Then, 25% of the feature display should be highlighted to five times the base illuminance. For additional emphasis and visual variety, another 10% of the display can be dazzled to ten times the base illuminance. The dazzle effect may be particularly appropriate on displays of low reflectance. See Figure 34.4. Using such an arrangement creates dramatic contrast across the display, introduces visual intrigue, and avoids washout and sameness of feature displays throughout the store. Nevertheless, to maintain an appropriate degree of intrigue, interest, and attention, feature displays must be limited in number. The general retail illuminance is used to light merchandise for sale. If too much of the merchandise is feature lighted, then no merchandise has the visual interest and excitement that results from a selective approach and an over lighted sales space results. With respect to highlight and dazzle, see discussion below on Merchandise Fading and Bleaching.

Lighting of the general retail area is more dramatic if it can target the merchandise displays, whether they be tables, gondolas, racks, or shelves. This can be accomplished by strategically positioning optically appropriate lighting equipment. This may take a number of trials and errors in virtual modeling for a given situation to balance lighting effects, illuminances, and energy. However, where a high degree of flexibility is necessary or where merchandise displays are tightly arranged or regularly changing significantly in size and position, such as appliances, general uniform layouts of lighting equipment may be appropriate. Figure 34.6 illustrates an approach where merchandise is purposefully targeted.

Perimeter areas should be lighted to attract attention into the store. Although consistent and uniform perimeter lighting can make a small boutique feel more spacious, such an approach in large stores or departments may result in visual monotony unless graphics, signage or color are used, such as illustrated in Figure 34.8. The designer must establish which perimeter surfaces are worthy of lighting. That is, which perimeter surfaces, when lighted, will best attract the eye and shopper to explore. Sometimes this involves illuminating interesting wall or ceiling treatments along the perimeter, such as those in Figure 34.4. At other times, depending on the display of merchandise, this involves lighting merchandise to "general retail" illuminances with some intermittent feature display lighting, such as illustrated in Figures 34.5 and 34.7. With perimeter lighting, visual order is important. Since perimeter surfaces are most often well-organized architectural surfaces, randomly positioned and sized brightness patterns can be disconcerting in a retail setting, though this depends on the merchandising strategy and the architecture.

Sales Transaction Areas

Sales transaction areas should be lighted to meet the demands of shoppers and sales staff visually scanning invoices or credit slips and checking merchandise. Depending on the type and size of store or department, accenting of signage, ceiling elements, backdrops or specific transaction features or surfaces may be employed to attract attention.

Show Windows

A form of advertising, show windows are used to help destination shoppers identify their destination or to attract the impulse shopper. Show window lighting criteria depend on the application of the window: interior facing or exterior facing. Interior facing windows are usually employed in enclosed malls or within a store where little or no daylight is present.

Similar to in-store feature displays, illuminance recommendations for show window displays involve total display lighting, highlighting, and dazzle lighting. During daylight hours for exterior facing window displays, dazzle lighting is necessary. During dark hours of operation or for interior facing windows especially where no daylight is available, the

Figure 34.5 | Perimeter Lighting
Perimeter lighting here illuminates merchandise and promotes a sense of spaciousness (see Table 12.2 | Subjective Impressions). Sufficient spill light from the perimeter lighting can address circulation illuminance. Centrally positioned slot luminaires house adjustable accent fittings on various control zones to allow for selective feature lighting.
» Image ©Giuseppe Cacace/Getty Images

Figure 34.6 | Retail Display Lighting
Some of the general retail area in a grocery store typically consists of shelving. In addition to ambient lighting, a system of localized accent lighting directed specifically at the retail display can provide more visual interest and offer better glare control and subsequently a more comfortable shopping experience. Here, a valance-like detail at the top of the shelving localizes lighting to the merchandise. Total illuminance on the display results from contribution from the ambient system and from the display accent system. The designer should explore luminaire optics and mounting geometry to maximize illuminances with limited energy use.
» Image ©Chuck Savage/CORBIS

Figure 34.7 | Perimeter Lighting and Feature Displays
Perimeter lighting is used to direct shoppers' attention. In the process of circulating to the brighter perimeter zone, shoppers are encouraged to explore merchandise.

Perimeter lighting in the upper middle is part of a seating zone. In the area to the upper right, feature display lighting and perimeter lighting are one in the same.

A secondary benefit of perimeter lighting when applied uniformly as here, is its promotion of a sense of spaciousness (see Table 12.2 | Subjective Impressions).

Depending on the architectural style or the brand image, portable or decorative lighting is used. For portable lighting, provisions for power and controls must be made. For chandeliers, pendants, and wall sconces, locations must be established that work with the store plan and do not conflict with merchandise or feature display lighting.
» Image ©Todd Williamson/Getty Images

Figure 34.8 | Perimeter Lighting
Perimeter lighting is used here to direct shoppers to deeper interior zones of the store and highlight signage. In mass-merchandise situations, more continuous perimeter lighting can define entire departments and serve as backdrop against which large appliances and televisions are displayed, for example.

dazzle effect may be unnecessary on all but one or a few window displays. With respect to highlight and dazzle, see discussion below on Merchandise Fading and Bleaching.

During daylight hours, very high illuminances must be used on at least some portion of exterior facing window displays. Accenting is most effective when canopies, awnings, or neighboring architecture limit the available daylight. A confounding element is the glazing T_{vis}. Glass with T_{vis} less than 70% is likely to exhibit veiling reflections severe enough to preclude or greatly limit view of these exterior facing displays (see Figure 12.24). Glazing is available that exhibits a low-glare or non-reflective quality and a T_{vis} of at least 98%.

Lighting of exterior facing show window displays during dark hours of operation relates to the activity level and nighttime outdoor lighting zone of the area. Lighting should be extinguished at curfew or time of business closing, whichever is later. When curfew occurs prior to closing, lighting should be dimmed back according to recommended criteria in Table 34.2.

Wrapping and Packaging
Lighting at wrapping and packaging stations or rooms must accommodate the process of inspecting the merchandise package, selecting wrapping materials, positioning the merchandise and packing materials in a box or other container, sealing, wrapping, and, if necessary, addressing the package. These areas may function much like merchandising spaces, with accent lighting employed on wrapping paper and container displays.

Service
Where stores offer repair services, notably automotive retailers and service stations, lighting must address the respective work areas. Ambient lighting is typically used in combination with architectural and portable task lighting. Figure 34.9 illustrates these concepts and the importance of wall and ceiling surface reflectances in achieving an efficient operation as well as an appearance of cleanliness.

Color Qualities of Light
Color temperature and color rendering qualities of lighting should be carefully reviewed and documented during the design process. Color temperature can be rationalized on many levels: classification of retailer; quality of merchandise; client preference; and designer preference. The whiteness of the light arguably contributes to the overall atmosphere and mood. Where a more residential or less institutional appearance is desired, 2700 K to 3200 K CCTs may be appropriate. Where a neutral-white color of light is desired, 3300 K to 4100 K CCTs should be considered. Where a crisp-white color of light is desired, 4200 K to 6500 K CCTs should be considered. Mockups or at least sample reviews of operable lamps are appropriate prior to final specification.

Color rendering affects visual discrimination of color tones and contrast. Where colorful merchandise and architectural finishes are used a rich, vivid scene results with high color rendering light. For many retail applications, a CRI of 80 should be considered a minimum. Lamps with lower CRIs will render many colors as muted or dulled. Mockups or sample reviews of operable lamps exhibiting the proposed CRIs are appropriate prior to final specification.

Matching CCTs and CRIs for electric lamps is desirable, but often impractical if not impossible. Nevertheless, to limit harsh and readily obvious differences, unless these are desired for effect, attempt should be made to match CCTs and CRIs from one electric source to another. Daylight exhibits a wide range of color temperatures based on time of day and sky condition and the daylight aperture glazing. Matching electric light CCTs to daylighting is usually unwarranted, if not futile, given the fleeting nature of daylight. Daylight exhibits CRI of 100 during most daylight conditions. Many shoppers appreciate access to daylight to review color of many products since these are likely to be seen outdoors or under interior daylight conditions.

Merchandise Fading and Bleaching

Display lighting, particularly highlight and dazzle, and uncontrolled daylighting can fade and bleach merchandise. The degree of susceptibility is merchandise dependent. Some materials are susceptible to UV, or IR, or visible radiation or some combination. Where the merchandise is a consistent product and universally susceptible to specific radiation, such as chocolate to IR, lamp selection or lamp and glazing filters on daylight media and on display cases can be employed. Where merchandise is moved periodically or simply changes seasonally, it may be impractical to select lamping to address both IR and UV and still provide appropriate illuminance and color quality. Several techniques can be used to limit exposure to fading and bleaching:

- Rotate merchandise
- Display sacrificial items
- Automate controls

Rotating merchandise requires staff intervention to rotate merchandise out of the high-illuminance condition on a 7- to 10-day cycle. Sacrificing items for display purposes and not for resale requires retailer staff concurrence and intervention. Automated controls can incorporate photocell and time clock functions to adjust light levels and simply extinguish lights on a regular basis to minimize exposure. Where merchandise has a high turnover rate or where its packaging is opaque or the merchandise consists of durable materials and finishes, no measures to limit fading and bleaching may be necessary. Programming information or interviews with store owner or merchandise display designers should reveal any need for IR or UV control. Natural fabrics and dyes may be especially susceptible. Table 21.3 | Light Sensitivity Categories identifies some materials and their relative sensitivity to UV. Section 21.2.7.2 Objects discusses UV control for preservation-worthy objects. Packaging or merchandise that is considered more sustainable may be more vulnerable to IR and UV.

34.2.12 Retailing, Outdoor

Outdoor retail lighting involves lighting of the shopping and transaction areas. Unlike indoor retailing, the shoppers' states of adaptation are much lower outdoors. Lighting should be designed for this outdoor seeing condition rather than attempting to impose indoor illuminances. Outdoor retailing has few walls and ceilings to contain and reflect light. Lighting must be designed and controlled to specifically address tasks and surfaces rather than attempting to uniformly floodlight a setting. The night environment is greatly affected by electric lighting. Lighting should be optically appropriate and electrically controlled to place light only where and when needed in the recommended illuminances cited in Table 34.2. In general, illuminance criteria are much lower than for interior situations. Color contrast, typically enhanced with lamps exhibiting CRIs ≥80, can help, to a point, compensate for low illuminances in outdoor situations.

See 26 | LIGHTING FOR EXTERIORS for additional information related to outdoor sensitivities involving light trespass and light pollution.

Automotive Sales

In addition to an indoor showroom and service facility, an automotive sales property is usually comprised of outdoor circulation drives, featured vehicle, parking, preparation and storage, and sales or retail area. Tailor lighting of these properties to the anticipated levels of activity and the nighttime outdoor lighting zones within which they are located.

Outdoor automotive sales generally involve destination shoppers viewing models and buyers taking delivery of vehicles at times of convenience. Visual tasks include gross inspections of vehicle forms, components, trims, and finishes and window stickers. Perhaps the easiest of these tasks is reading window stickers. Standardized simple-style black-ink fonts, with bold and large typefaces outlining key information on generous label sizes offer inherent advantages. Coupled with no real penalties on speed and accuracy of visual performance, this task requires relatively low illuminance.

Figure 34.10 | Automotive Sales
Vehicle luminance is starkly illustrated in the top image. Even under low outdoor illuminances lighter-colored vehicles will elicit significant visual attention.

Straightforward cutoff pole luminaires can provide appropriate illuminances at the retail areas for casual nighttime viewing. Relatively low-wattage luminaires with highly-controlled optics will limit light trespass and upward light. Lamps should be recessed entirely into the luminaire housing with no dropped lens for best glare control of general lighting. LEDs may offer dazzle and glitter reflections from vehicles, but must be well-controlled optically to limit direct glare. Lamps with CRIs ≥80 are appropriate.

Showroom general lighting consists of three techniques: diffuse indirect; linear accent; and direct. The combined effect of these on form, contours, and finish are evident in the bottom image. The auto placed immediately outside the showroom also benefits from the luminances of the indirect and linear accent lighting.

» Images ©Jim R. Bounds/Bloomberg via Getty Images

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Vehicle forms, components, and trims can be tentatively assessed in relatively low illuminances as seen in Figure 34.10. However, complete and detailed assessments are best performed under very high illuminances and luminances, daylight being preferred, or in the indoor showroom conditions where some amount of diffuse indirect lighting, linear accenting, and highlighting should be made available for appraisal of the sheet metal and other formed materials, their contours, surface qualities, gauges, and fit as seen in the bottom image of Figure 34.10.

Vehicle finishes can only be tentatively assessed under relatively low illuminances. Appraising quality of application of the finish, including consistency, depth, coverage, flake content or iridescence, if any, and color is best done in daylight or showroom conditions. Color aspects include appraising color matching, where applicable, between various substrates such as metal, plastic, fiberglass, and composites. Color reviews under electric lighting in mesopic and photopic states are arguably reasonable when lamps exhibit CRIs ≥80.

Controls are used to dim or step-dim lighting at closing or curfew. For best energy savings, extended in-service life, and environmental benefit, lights might be extinguished except as may be necessary for security. Where instant-on lamps are used, motion sensors are appropriate means of control after hours.

Seasonal Open-air

Open-air markets usually consist of produce stands or designated selling zones where seasonal merchandise is displayed for sale. Lighting must be tailored to the anticipated level of activity and the nighttime outdoor lighting zone in which the market is located. General retail lighting must be well-controlled optically to limit light trespass, light pollution, and glare. Traditional *RLM* luminaires using deep reflectors with lamps recessed above the bottom of the reflector can be effective. Contemporary luminaires with optics appropriate to outdoor sensitivities are also available for general and feature display lighting.

Service Stations

Outdoor lighting for service station retailing should, like other outdoor and indoor retailing, target visual tasks with little extraneous light. This minimizes glare and efficiently directs lighting energy for best visual effect and performance. Illuminance criteria are based on level of anticipated activity and the nighttime outdoor lighting zone in which the service station is located. This coordinates with drivers' adaptation states. See Figure 34.12. Dispensing equipment is evolving from gasoline and diesel to alternative fuels, including electricity. At publishing time, standards for two levels of charging equipment have been adopted by the Society of Automotive Engineers (SAE) and a third is under consideration [6]. The Level 2 and Level 3 charging stations are likely to be accessible at parking lots and service stations. Their formats and locations and the nature of the charging task should be monitored as these aspects may require illuminances other than those recommended in Table 34.2.

34.2.13 Support Spaces

These relatively back-of-house citations are self-explanatory.

34.2.14 Toilets/Locker Rooms

Lighting for toilets and locker rooms is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Addressing the fixture functional areas, such as toilets, urinals, vanities, will provide sufficient light where needed without overlighting the entire toilet room. Vanities are problematic when little or no vertical illuminance is designed to illuminate an imaginary facial plane (roughly a zone of sufficient size to encompass faces) in front of the mirrors. Design treatments vary based on retail classification.

Vertical light on the faces of lockers will assist with locker use.

RLM was originally an acronym for Reflector and Lamp Manufacturers, an association formed by GE and Electrical Testing Laboratories in the early 20th century to develop and promote standards for luminaire reflectors. Some vintage models survive or have been revived today with modern lamping options. Their simple construction and appearance make these arguably timeless [5]. See Figure 34.11.

Figure 34.11 | RLM Luminaires
The series of luminaires in the foreground top are variations of RLMs used to light these market displays.

34.2.15 Transition Spaces

Most of these spaces are self-explanatory. Codes may demand different illuminances in some circulation areas, including elevators, escalators, and stairs which the designer must address.

Typically, for visual consistency and total store branding as well as for purposes of maintenance convenience, lamp types and color qualities should match those used elsewhere.

34.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various aspects outlined in Table 34.2.

34.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 34.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 34.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

34.3.2 Notes

Notes may refer to other application and task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

34.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 34.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for perimeter lighting in indoor retailing situations, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on one or both planes of a task. A dash indicates no light or zero light is recommended for the task or application, such as exterior facing show windows at night after curfew in LZ1 locales.

34.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane. For example, if a home/bath/bedding store general retail area consists primarily of vertically oriented product displays, then a more exciting rendering of those general retail areas will take place if the horizontal illuminance criteria from Table 34.2 are actually assigned as the vertical illuminance criteria and vice versa. This, however, pressures the designer to attend to glare issues associated with higher vertical illuminances.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. In many retail applications accommodating a variety of merchandise displays, horizontal- and vertical-plane illuminances address the common situation where simultaneously some merchandise or some portion of the merchandise is on horizontal planes while other merchandise or portion is on vertical planes.

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." For example, for outdoor general merchandise displays (RETAILING, OUTDOOR/Seasonal Open-air/Merchandise), E_h illuminance targets are intended for 2' 6" above finished grade while E_v illuminance targets are intended for 4' 0". Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes" where the directional orientation of the plane is believed straightforward and easily identified. However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation. For example, feature displays may have a single direction of view or may have multiple directions of view. Lighting three or four sides where only a single-direction-view is possible for shoppers is a waste of resources. Lighting one or two sides of a display with a 360-degree-view may be a lost opportunity in drawing the attention of a significant number of shoppers. The designer must analyze the situation and determine what best meets the needs of the retailer.

34.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. The designer must coordinate with the design team and retailer to establish the age group of the intended observers. The target market may differ from those making the actual purchase, such as parents of shopping children, or from the sales staff. Perhaps transaction areas are illuminated to one age group's criteria while retail areas and feature displays are lighted to another's. The aspects of observers' ages, task sets for age groups, and illuminance targets should be resolved during programming with the client. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance.

34.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 34.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

34.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

34.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

34.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

34.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

34.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

34.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views.

Daylight must be controlled to provide illuminances appropriate to the task. Overlighting with daylight can accelerate fading and bleaching of merchandise.

34.3.6 Veiling Reflections

Tasks with specular components, which in retail includes most anything behind glass, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. In situations where merchandise is behind glass, veiling reflections are minimized by carefully analyzing geometry of luminaire-to-glass-plane-to-shopper. Placing lighting equipment outside the typical viewing orientations can help as can the use of anti-reflective glass for the case. Using lighting within the display case is generally superior, though LEDs or fiber optics are best to avoid excessive heating of the display case and limit UV and IR (see Figure 34.13).

34.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Tasks and Applications and Figure 12.22 | Task Coverage Example. In some situations, such as accenting, the "task" area may consist of the entire wall when "feature wall" or "perimeter" accenting is desired. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 34.2. With outdoor retail areas it is most effective to target light to task proper or task area. General lighting, unless extremely low level over the important shopper-occupied zones, is inappropriate over large areas of the merchandising property.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the department or retail layout, for example, but should be scrutinized by the design team and retailer. If, however, the task will be confined to one portion of the department area or if the room or area in which the task is located is itself relatively small, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then a strategy of refining area or areas of coverage to the task proper or task area has merit. This can result in reduced energy use, more significant visual emphasis of the merchandise, and a more visually interesting and exciting shopping experience.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

Figure 34.13 | Display Cases
Veiling reflections can be avoided with displays behind glass by using lighting internal to the case. LED or fiber optic luminaires limit heat in the cases and limit UV and IR.

34.4 Designing

Information provided here is specific to retail facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria

- for more on energy
- for more on life cycle analyses
- for more on lighting design
- for more on recycling

- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

35 | LIGHTING FOR SPORTS AND RECREATION

Do you what my favorite part of the game is? The opportunity to play.
Mike Singletary

Sport has always been a part of civilization, but it is only general economic growth and prosperity that provide leisure time sufficient for recreation and sport. A consequence of this has been growth in the demand for facilities to accommodate the large numbers of people who want to participate in sporting events, seeking desirable leisure time activities that are healthy and fun. Sports have also become an important form of entertainment. Venues for spectators of amateur, collegiate, and professional sports are complex facilities that must provide not only for the spectators, but also the equipment used in modern sports broadcasting. Sports are also an important part of education, with gymnasia, ball fields, and other sports facilities commonly being part of schools and municipal recreation centers.

Comprehensive design efforts involve the information in this chapter combined with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance criteria for sports applications which should influence luminaire optical selections, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. 21 The IESNA Recommended Practice for Sports and Recreational Area Lighting shows the best locations for luminaires to be placed, and is an invaluable source of information for designing sports facilities [1][2].

Deliberate thought must be given to details beyond the recommended illuminances in this chapter. For example, From Table 35.3, for BASEBALL/Infield, the vertical illuminance citation does not necessarily reveal the demand for light from multiple directions required to minimize shadows and provide good modeling of ball and players. Though a target illuminance can achieved, the manner of bringing it about can be as important as the value itself. Such specific details are not enumerated for all tasks. Table 35.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

35.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. This will establish the extent to which daylighting can address most or many or some of the lighting goals. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. For some applications and tasks, daylighting can be the primary light source. Critically, this means addressing the host of lighting factors identified in 12 | COMPONENTS OF

LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

In general, as the skill level is elevated, players and spectators require a better and more sophisticated luminous environment. A correlation exists between the size of a facility and the level of play, for example, a higher skill level attracts a greater number of spectators. As the number of spectators increases their distance from the playing surface increases and their need for increased illuminance to see players and tasks requires the values to increase. Accordingly, facilities should be designed to satisfy the most talented players and accommodate the greatest potential spectator capacity. It is important to note that in large facilities which seat over 10,000 spectators the lighting criteria are usually governed by the needs of television. Recommendations for such facilities are not included in this chapter. To determine illumination criteria, this chapter groups facilities into four classes based on the skill levels of the players and the anticipated number of spectators. See Table 35.2.

- Class I - Competition play before a large group (5000 or more spectators). However, for the purpose of this Practice, illumination criteria for individual sports are limited to a spectator capacity of 10,000 or less. Lighting criteria for major stadiums and arenas require special design considerations such as vertical and horizontal illuminance values not covered by this Practice, which may be defined by individual sports and/or broadcasting organizations.
- Class II - Competition play with facilities for up to 5000 spectators.
- Class III - Competition play with some spectator facilities.
- Class IV - Competition or recreational play only (no provision for spectators).

To develop lighting solutions that meet quality, quantity, and operational criteria, an assessment must be made of the sport or sports that will be played, the level of play, and the requirements of spectators that the facility to be lighted must accommodate. Sports may be considered either aerial sports or ground level sports. Within each of these two groups, all activities can be further divided into multi-directional sports and unidirectional sports.

35.1.1 Aerial Sports

These sports involve playing with an object (such as a ball) that is in the air at least part of the time. The major subcategories are multi- and uni-directional.

35.1.1.1 Multi-directional

Multi-directional aerial sports are sports where the players and spectators view the playing object from multiple positions and viewing angles. These sports demand critical vertical illuminance over the height of the entire playing area as well as horizontal illuminance at ground level. It is important to control direct glare by locating the luminaires away from the most frequent viewing directions of players and spectators. Typical multi-directional aerial sports include badminton, baseball, basketball, football, handball, jai alai, ski jumping, soccer, squash, tennis, and volleyball.

35.1.1.2 Uni-directional

Uni-directional aerial sports are sports where the playing object is viewed in the air from a fixed position on the ground. General horizontal illuminance is required where the playing object is launched (start) and vertical illuminance is required where the playing object lands or is intercepted (finish). This is normally achieved by aiming some luminaires downward at the start and aiming other luminaires at high angles toward the finish. All luminaires must be shielded from the player's field of view. Typical unidirectional sports include golf at a driving range, skeet shooting, and trap shooting.

35.1.2 Ground Level Sports

These sports are played on the ground or a short distance above the ground. In the normal course of play, players and spectators do not look upward. The major subcategories are muti- and uni-directional.

High Schools		x	x	x
Training Facilities			x	x
Elementary Schools				x
Recreational Events				x
Social Events				x
Spectator Capacity	Over 5000	Under 5000	some	none

35.1.2.1 Multi-directional

Multi-directional ground level sports where the players and spectators view playing objects from multiple positions, normally looking downward, horizontally, and occasionally upward. These sports require well-distributed horizontal illuminance, although vertical illuminance should be considered. Typical multi-directional ground level sports include boxing, curling, field hockey, ice hockey, skating, swimming (excluding high board diving), and wrestling.

35.1.2.2 Uni-directional

Uni-directional ground level sports where the playing object is aimed at a fixed target near ground level (usually the target is in a vertical position). Vertical illuminance is critical at the target. It is normally provided by aiming luminaires (shielded from the players and spectators field of view) toward the target. Typical uni-directional ground level sports include archery, bowling, skiing, and target shooting.

35.1.3 Television Broadcasting

In larger facilities, sports events are broadcast or recorded for television. Higher illuminances allow the use of high speed shutters and small apertures that increase image sharpness and depth of field. More light also favors stop action, slow motion, and special effects created with telephoto/zoom lenses. Even simple panned shots of the playing field and spectator stands will show improved quality with higher luminances. : As high definition television (HDTV) replaces standard color television, it is recommended that lighting systems address the lamp's stroboscopic effect associated with low frequency ballasts on HID systems. This can be minimized by ensuring the illumination is provided by multiples of three luminaires, with overlapping beams which are balanced across three electrical phases. It should be noted that the recommended values in Table 35.3 do not necessarily provide sufficient illuminance for broadcast equipment. Many TV broadcast companies and sports leagues have recommended lighting specifications available and should be consulted to determine the appropriate illumination levels. Several aspects of the equipment used for television broadcasting can help define the type of project and lighting system required since they have an effect on illuminance requirements.

35.1.3.1 Position and Distance of the Camera Relative to the Playing Field

Telephoto lenses usually have a smaller optical aperture, and thus, require higher illuminance.

35.1.3.2 Apparent Speed and Size of the Object in Play

The speed of the object in play appears faster for movement across rather than along the direction of view. Smaller objects, such as baseballs or tennis balls, require higher illuminance than larger objects such as basketballs or footballs.

Notes for Table 35.3

The table column headings are discussed in detail in 35.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 35.4 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 35.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 35.3 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Minimum illuminance shall be set according to the following table:

Recommended Uniformity Ratio	Percentage of Average that Defines Mimimum
1.5:1	80%
1.7:1	74%
2:1	66%
2.5:1	57%
3:1	50%
4:1	40%

f. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

g. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

h. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

i. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

Notes for Table 35.3

The table column headings are discussed in detail in 35.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 35.4 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 35.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 35.3 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Minimum illuminance shall be set according to the following table:

Recommended Uniformity Ratio	Percentage of Average that Defines Mimimum
1.5:1	80%
1.7:1	74%
2:1	66%
2.5:1	57%
3:1	50%
4:1	40%

f. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

g. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

h. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

i. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

Notes for Table 35.3

The table column headings are discussed in detail in 35.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 35.4 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 35.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 35.3 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Minimum illuminance shall be set according to the following table:

Recommended Uniformity Ratio	Percentage of Average that Defines Mimimum
1.5:1	80%
1.7:1	74%
2:1	66%
2.5:1	57%
3:1	50%
4:1	40%

f. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

g. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

h. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

i. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

Uniformity Targets[f] Over Area of Coverage		[g] [h]	Typical Area of Coverage[i]	
CV_{max}	Max:Min		Task Proper or Task Area	Room or Designated Area
0.3	4:1			
0.3	4:1			
0.25	3:1			
0.3	4:1			
0.3	4:1			

Notes for Table 35.3

The table column headings are discussed in detail in 35.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 35.4 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 35.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 35.3 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Minimum illuminance shall be set according to the following table:

Recommended Uniformity Ratio	Percentage of Average that Defines Mimimum
1.5:1	80%
1.7:1	74%
2:1	66%
2.5:1	57%
3:1	50%
4:1	40%

f. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

g. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

h. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

i. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

Figure 35.1 | Multiple Luminaires on a Single Pole
Athletic field lighting involves determining the minimum number of poles and their height and placement, the correct choice of luminaire optics, and careful luminaire aiming in the field. All these aspects can produce an illuminated playing field with the necessary horizontal and vertical illuminances, control of spill and light trespass, and good visibility for players and spectators.

35.1.3.3 Color Temperature of Light Sources

One of the most difficult effects to overcome in television broadcasting is differences in color temperature and color rendering in an installation from imperfect mixing of light sources. The television camera can be balanced for a wide range of light source color temperatures (typically 3000 K to 6000 K). Abrupt color changes should be avoided (abrupt change can come from optical systems projecting beams that include source color separation or from non-uniform coverage of the facility by two different sources). Similarly, in facilities where daylight is present (from windows, skylights, clerestories) or in outdoor facilities with roof shadows, any abrupt color change at a shadow line produces poor picture quality. Daylight color light sources should be chosen to supplement the available daylighting to minimize these problems. Daylight sources also improve the transition from daylight to dark in outdoor facilities. No lighting system, however, will overcome the "shadow edge" problem where direct sunlight produces shadows on playing surfaces.

35.1.3.4 Viewing Direction

From the perspective of players, spectators, or television and film cameras there are a large number of vertical planes. Lighting software permits calculation of the illuminance normal to the camera's or spectator's plane of view. These values should be identified and calculated whenever possible to ensure that the lighting installation will meet all specified requirements.

35.1.3.5 Elevation

Elevations will vary with the sport and the skill level of play. Generally, if only one elevation is selected, it should coincide with that of the horizontal plane to be measured. Horizontal illuminance values are normally in a plane one meter (3 ft) above a playing surface. Vertical illuminance values, except when on a specific object such as an archery target or a bowling pin are also in a plane one meter (3 ft) above the playing surface.

35.1.3.6 Vertical Luminance

Although horizontal illuminance is important for television and film cameras, the average luminance in the direction of the camera establishes the f-stop criteria of a camera lens and the resultant depth of field of the picture. Generally, the greater the camera-to-subject distance, the more luminance is needed to obtain satisfactory pictures.

Objects seen by individuals or cameras are not cubes with only four values of illuminance on four vertical surfaces. Television and film have a contrast latitude (black to white) that is limited, especially when compared to the visual system. The greatest amount of light reaching a plane that is perpendicular to the axis of the viewing direction of a camera (that is, within 90 degrees of the incident camera axis) establishes the white value or most intense area seen by the camera. The axis of primary illumination onto the object, therefore, need not be along the camera, player, or spectator viewing axis.

35.1.3.7 Color and Color Quality

The method used to specify light source color quality is the General Color Rendering Index (CRI). For acceptable color rendering, the CRI should not be less than 65. See 6.3 Color Rendition.

35.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the sports or recreation activities that will be performed in the spaces under consideration, the anticipated players and spectators, and broadcast media requirements. Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

These definitions are required early in project design in order to track design efforts that include inventorying project knowns, anticipated sports and recreation functions, and calculating lighting, power, and energy compliance. Sports and recreation functions cited in Table 35.3 | Sports and Recreation Illuminance Recommendations should be reviewed against the project knowns and correlated with the sports and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information and the available application and task citations in Table 35.3.

High reflectance ceilings, walls, and floors increase the amount of light delivered to the playing surface. However, if they exhibit a high component of specular reflectance they may also cause reflected glare and may exhibit poor contrast for visual targets as, for example, when the polished finish basketball floor of an arena reflects an image of the bright luminaires to spectators on the opposite side. This issue can be minimized with the use of matte playing surfaces, however to properly address the issue, the luminaires must be carefully located. For new construction it is important that catwalks where the luminaires are located be in the proper position to optimize the sports lighting design.

The following sections describe identifiable facilities in which sports and recreation functions are commonly found. These discussions, those identified in Table 35.1, and the available sports and recreation functions identified in Table 35.3 offer comprehensive qualitative and quantitative criteria.

35.2.1 Arenas

Typically large, multipurpose facilities, arena floors often include playing areas for basketball, hockey and indoor soccer, and are capable of handling rodeos, circuses, animal shows, concert events, and trade shows. Portable seating is often used to make full use of the facility. Lighting installations should be flexible to accommodate this variety of uses.

The size, height, and use of general purpose sports facilities vary widely. Table 35.3 provides recommendations to meet the horizontal, vertical and uniformity illuminance requirements of such facilities, depending on the sports involved. In addition, direct and reflected glare control, direction of light, and modeling must be considered. Electric lighting systems are often capable of a wide area of coverage and usually controlled to provide for illuminance requirements of different sports and activities.

The use of daylight can conserve energy and provide visual attraction. However, it also creates glare and presents blackout control difficulty for visual presentations. In all indoor

Table 35.4 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

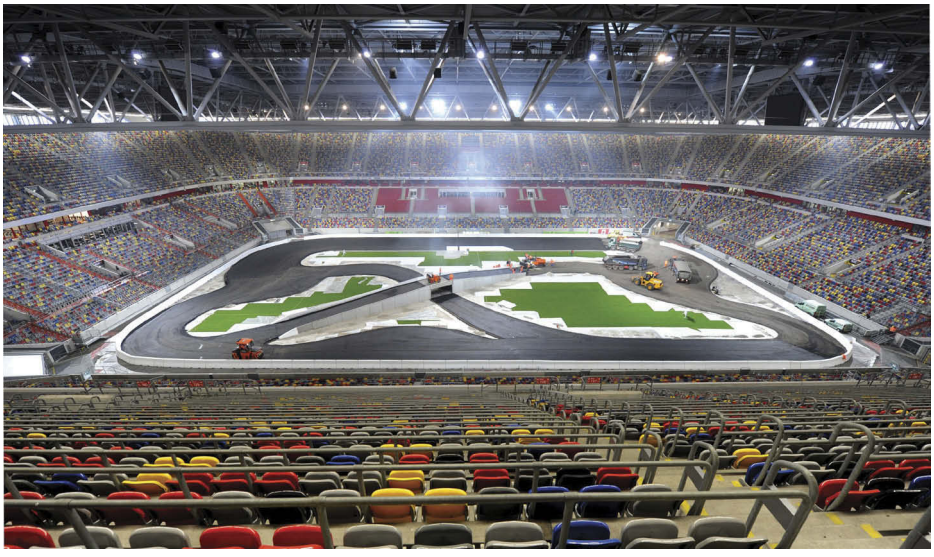

Figure 35.2 | General Arena Lighting
Arenas usually require the ability to light many types of sports and recreational functions. Arena structure provides opportunities for luminaire mounting. Overhead to produce the necessary horizontal illumance and at the sides to augment the vertical illuminance. Controls are usually required to provide the flexibility required to light different events.

Figure 35.6 | Gymnasium
Ceiling-mounted wide-spread luminaires produce sufficient horizontal and vertial illuminance on the playing floor. The same luminaires adequatley light the basketball backstops. If HID sources are used, provision must usually be made for instant restrike or supplemental lighting to provide for power outage or emergency situations.
» Image ©John Connell/Corbis

sports facilities, windows and skylights should be evaluated for their impact on construction cost, energy savings, and visual comfort for players and spectators. See 14 | DESIGNING DAYLIGHTING.

Also, many arenas with professional sports teams require the HID lighting to have shutters so the illumination on the floor can be reduced for introductions and other theatrical events without extinguishing the lamps.

35.2.2 Athletic Fields

Athletic fields for high schools and colleges typically serve several different sports. Lighting of such a multipurpose or combination field may not be as satisfactory as when the field lighting can be dedicated to an individual sport. Lighting a multipurpose field requires special attention to the lighting requirements of several sports. The final design is affected by the relative location of the various fields and the limits which each specific arrangement may impose upon lighting equipment locations. Pole mounting height should account for luminaire beam spread and location limitations. Ideally, most of the beam is directed onto the playing field while minimizing light trespass. Also there are locations where luminaires should not be located to eliminate glare for players such as behind the end zone of a sports field or behind home plate in ball fields.

The uncontrolled direct component from luminaires shining beyond the sports facility is called spill light. Sometimes referred to as light trespass, spill light may cause annoyance to the adjacent property or neighborhood. Spill light may be controlled by a number of design considerations:

- Selecting a luminaire with an optical system (and proper orientation) such that the defined beam does not extend beyond the sports facility.
- Checking to ensure that proper mounting heights have been selected. Low luminaire mounting heights increase glare and negatively impact the illumination on the sports field. Occasionally it is possible to add landscaping materials (shrubs, trees) that will partially shield adjacent properties from direct glare.
- Using internal and external shielding louvers or baffles on the luminaires. Note, however that these devices may not be effective and they may reduce optical system efficiency. If shields or baffles are employed, then photometric data that includes the shielding devices must be utilized in the computer calculations to obtain accurate results.

Figure 35.7 | Daylighting a Gymnasium
Daylighting and dimmable/switchable fluroescent electric lighting can effectively and efficinetly light a general purpose gymnasium and multi-function recreation room.

Figure 352.8 | Underwater Pool Lighting
Underwater luminaires can addequately light a pool and augment daylighting. Luminaire placement is to the sides of the principal swimming lanes, if they are present..
» Image ©cultura/Corbis

- Using low reflectance colors on critical surfaces so that reflected light from surrounding surfaces within the facility can be minimized.
- The hours of use are often an issue for spill light and it is good practice to install a timer to automatically turn off the playing field lights at a designated closure or curfew hour.

This combination of design factors must be evaluated as a whole to control spill light or reduce light trespass. Issues related to spill light, like glare, frequently create emotional and political tempests. Review of local ordinances, proper documentation, and early public input to the design process can help minimize this problem.

35.2.3 Field Houses

Many uses are common to both field houses and gymnasiums. However, field houses are generally larger and serve a wider range of sports, including indoor track and field events. Field houses can also accommodate outdoor sports brought indoors during inclement weather. Portable floors and ceiling facilities are commonly used to increase flexibility. Consideration should be given to versatile control schemes, individual lighting systems for aerial and ground level sports, and the needs of participants and spectators. See 35.2.1 Arenas.

35.2.4 Gymnasiums

Generally implemented as part of an educational facility, gymnasiums frequently host school programs during the day and community functions at night. A wide choice of lighting levels may be desirable because diverse visual tasks can be encountered. General lighting control can be achieved through dimming or split switching. See 35.2.1 Arenas.

35.2.5 Pools

Swimming pools come in a wide variety of shapes and sizes and may be used day or night. However, competitive events occurring after dark are generally held at indoor facilities. Swimming is a multi-directional ground level sport. It is a popular recreational activity as well as a competitive sport. Lighting design criteria are similar for both indoor and

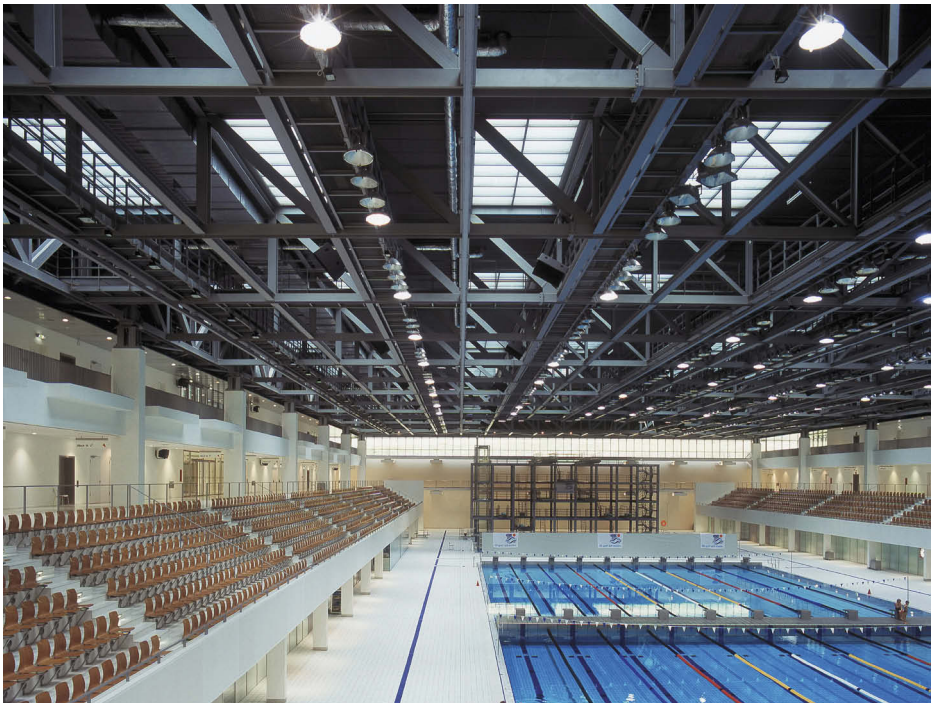

Figure 35.9 | Daylighting a Pool
Daylighting can provide much of the general lighting required for indoor pools. Overhead luminaires provide addition light and illuminate areas adjacent to the pool. Switching allows electric lighting levels to chance with the use and functions in the pool.
» Image ©Construction Photography/Corbis

outdoor swimming pools. The illumination criteria cited in Table 35.3 are for both indoor and outdoor facilities with the emphasis placed on commercial, public, and institutional swimming pools. However, the illumination criteria are also applicable to private and recreational pools.

Water is a good transmitter and diffuser of light. However, the surface of water also acts as a reflector of incident light. The degree of reflection depends on the angle of incidence. Moreover, swimming action causes surface turbulence which produces scattered reflections. In practice, at any one moment, a major part of the water surface is not disturbed by more than 20 degrees from the horizontal.

35.2.5.1 Luminaire locations

As the light strikes the water at shallower angles, the reflected component increases until virtually no light penetrates the water surface. This reflection of light causes veiling reflections, making it difficult to see into the water to observe swimmers and divers. It is, therefore, necessary to control reflections from luminaires or daylight through windows on the water surface to ensure a good penetration of light into the water. As a general rule, it is desirable to locate all overhead light sources so the angle of incidence of the main light beam is less than 50 degrees from vertical. Light from above is required to illuminate pool deck areas, diving platforms, sport action occurring above the water surface (for example, water polo), and to provide light penetration into the water basin.

For improved safety and observation of swimmers in water, illuminances within the pool basin should exceed the luminance of reflected light from the water surface. Underwater luminaires are used to minimize veiling reflections on the surface of the water and enhance visibility for swimmers in the water. For maximum effectiveness, pool basin finishes below the water line preferably should be white or a color with a reflectance of not less than 50 percent.

Luminaires should be placed at locations that permit an adequate portion of the incident light to penetrate the water and not be reflected into the eyes of observers. Luminaires located near the pool edges are easy to maintain and can still provide good light penetration. Luminaires should not be placed inside a 20-degree cone extending above the diving platform.

Figure 35.10 | Soccer Stadium
Highly-controlled optics and aiming produce illuminances on the field with little glare and spill light.
» Image ©2010 LatinContent/Getty Images

35.2.5.2 Daylight

Daylight presents problems in terms of glare and reflection control. Daylight admitted from directly above the pool is desirable. But light from windows along the sides or ends of the pool can cause excess glare. The total intensity of the viewed scene (including reflections on the water) should be less than the illuminance in the pool basins. The illuminance from skylights can be calculated using any of the generally accepted algorithms. The skylights should be diffuse with splayed matte finished wells to prevent shafts of direct sunlight from entering the pool area. See 14 | DESIGNING DAYLIGHTING.

35.2.5.3 Underwater Luminaires

There are two types of underwater lighting: dry and wet niche mounting. For wet niches, special watertight luminaires are recessed into the pool walls. For dry niches, the luminaires are placed behind watertight portholes or windows. Wet niche designs, if defective, can produce electric shock. Thus the hardware, wiring installation, and ground fault detection methods used must strictly conform to the National Electric Code.

Underwater lights should be placed about 0.61 to 0.91 meters (2.0 to 3.0 feet) below the water surface on the long sides of the pool with another row of luminaires at the 2.4- to 3.0-meter (8.0- to 10.0-foot) level for deep pools. Aiming should be approximately ten degrees above the horizontal so that light from the underwater luminaires reflects off the water surface and back into the pool.

Underwater luminaires should not face swimmers competing in parallel lanes. If the pool is too wide for luminaires with the recommended spacing on the long sides of the pool to provide proper coverage, narrow beam distribution and closer luminaire spacing should be considered.

35.2.5.4 Luminance Requirements

Some of the recommendations in Table 35.3 involve water sports and give required water surface luminances. For design purposes, the following empirical equation can be used to determine the number of total lumens required on a pool surface:

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

$$\Phi_{required} = \frac{A \pi L_{required}}{0.8 \rho}$$

Where

$\Phi_{required}$ = Lumens required to achieve required luminance
A = Area of water surface in m^2
$L_{required}$ = Required water surface luminance in cd/m^2
0.8 = Water turbity factor
ρ = Reflectance of pool basin surfaces

35.2.6 Stadiums, Indoor

Large arenas for major league baseball and football that accommodate up to 100,000 spectators are called stadiums. Stadium lighting design should be similar to that for arenas. Some stadiums feature translucent air- or cable-supported soft roofs. During the day these roofs can have the appearance of an overcast sky. This causes direct glare for players looking up and poor contrast between the roof and the visual target (white base ball). To mitigate this problem, the translucent roof and other interior surfaces should have a color and/or finish that increases contrast with the visual target. See 35.2.1 Arenas.

35.2.7 Stadiums, Outdoor

Stadiums are facilities with large seating capacities used for individual or multiple sports and public events. Stadium lighting should be specially designed with proper orientations, locations, illuminances, and controls that will satisfy the needs of any contingency. Typical designs are not recommended here because of the wide variation in stadium configurations. See 35.2.2 Athletic Fields.

35.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Following are notes related to various topics outlined in Table 35.3.

35.3.1 Applications and Tasks

Sports encountered on any given project may be different from those identified in Table 35.3 and may warrant different illuminance criteria. Cross referencing closely associated sports is appropriate. Failing this technique, reviewing the list in Table 35.3 may be in order to determine if any sports exhibit a similar visual component to the unique application's sport. This involves similar aerial or ground sports having similar objects, speed of play, and important surfaces. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the sport characteristics most closely associated with the unique sports of the application. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

35.3.2 Notes

The notes in Table 35.3 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

35.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice and for purposes of sustainability can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 35.3 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for lighting driving range distance markers, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

35.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane. In sports facilities, this is sometimes the case for vertical illuminance. For example, the principal axis of play of a uni-directional sport in an arena may not align with the main axes of the arena.

Nearly all tasks have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Where illuminance targets are intended at differing planar elevations, this is indicated under "Notes." For example, in some cases the illuminance requirement is on the competitive surface, while it others it is 3' AFF. The height at which vertical illuminances are recommended may not be the same as that for horizontal illuminance recommendations.

Note the implication for observers' visual ages. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer must determine the orientation of multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation. Unless otherwise noted, vertical illuminances should be calculated or measured in four cardinal or perpendicular vertical planes at each point of interest. The average of the values at all points in at least one of these planes should meet or exceed the specified vertical illuminance.

35.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. It may be determined that illuminance criteria for an age group other than that representing the majority of the intended observers is appropriate. However, this may result in overlighting, underlighting, harsh lighting, visual displeasure, or visual discomfort for many of the observers. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance. In some situations, such as video conferencing, lighting must meet the requirements of the camera technology and, therefore, is not tied to ages of observers.

35.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in Table 35.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

35.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

35.3.3.4 Defining the Minimum Illuminance

For personal safety of the players, a minimum illuminance over the entire playing surface must be maintained. It is recommended that this minimum be a fraction of the average illuminance, where the fraction is a function of the uniformity target. See the values of fractions listed in note e in Table 35.3 | Sports and Recreation Illuminance Recommendations. For example, a sports application with a recommended illuminance of 300 lux and maximum--to-minimum uniformity target of 2:1, 66% of the average recommended illuminance defines the recommended minimum illuminance to be 200 lux.

35.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. The uniformity ratios listed in the table are for the horizontal illuminance only. Generally, the more important speed and accuracy are, and the more demanding the visual task, the tighter the ratio should be.

35.3.4.1 Coefficient of Variance

This method (commonly used in statistics) is a measure of the weighted average of all relevant illuminance values, where the variance of a set of values (CV) is calculated as the ratio of the standard deviation for all illuminance values to the mean illuminance value. CV has been shown to be related to the uniformity ratios common in the lighting industry. It does not consider just 2 points within an array, but includes in the formula every reading point. It is the preferred method for use when referring to uniformity of a sports lighting installation. See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

35.3.4.2 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

35.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold.

35.3.6 Veiling Reflections

Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

35.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified in RP-6 [2]. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. Examples are the head pin in bowling, or the target on an archery course.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to an entire area of play and is usually of fairly substantive size representing the zone in which the sport is played. The designated area is typically established by the games rules or the practical limits of a playing field. The area-of-coverage citations in Table 35.3 are based on standard playing fields defined for individual sports and are described in [2].

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project. This is particularly true when multiple sports are to be accommodated on a single field and by a single lighting system.

35.4 Designing

Information provided here is specific to sports and recreation facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria

- for more on lighting design
- for more on recycling

- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical timeclocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the players and spectators is the paramount design tenet and must be kept in perspective during all aspects of design. If the players' and spectators' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

36 | LIGHTING FOR TRANSPORT

Travel is fatal to prejudice, bigotry, and narrow-mindedness, and many of our people need it sorely on these accounts. Broad, wholesome, charitable views of men and things cannot be acquired by vegetating in one little corner of the earth all one's lifetime.
Mark Twain

Contents

36.1 Project Type and Status. . . 36.1
36.2 Application Types 36.2
36.3 Illuminance Criteria 36.13
36.4 Designing. 36.18
36.5 References 36.19

General economic growth and prosperity are both provided for and based on modern transportation. Communication and cargo, trade and tourism, all depend on modern transportation systems. This chapter gives recommendations for the ground-based facilities used by air, rail, and bus travelers. They are often complex environments that must accommodate large numbers of people, queues for checking in and security, food service and retail, and waiting areas that are comfortable and provide for a certain amount of visual work. A consequence of this is typically very large spaces that must provide lighting for a variety of tasks and functions. Urban areas of even modest size have airports and bus terminals that are important for local trade, transportation, and economic growth. Major cities have large airports with multiple terminals. These complexes must provide for not only the practical mechanics of traveling for thousands of travelers, such as checking in, security, baggage handing, and waiting, but also venues for food service, retail, and comfortable and attractive spaces for business travelers and tourists.

Comprehensive design efforts involve the information in this chapter combined with material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Design tenets deemed appropriate from those chapters must be identified and lighting goals and strategies developed accordingly. This chapter primarily addresses illuminance criteria for applications in transportation facilities which should influence luminaire optical selections, lampings, and final layouts based on design thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous IES related documents serve as archival reference sources [1].

Deliberate thought must be given to details beyond the recommended illuminances in this chapter. For example, in Table 36.2 for FLIGHT INFORMATION SCREENS, the illuminance citations alone do not guarantee successful lighting of this important task. The precise nature of the digital displays, wide and multiple angle of view, potential veiling reflections, and glare from distant but visually adjacent sources must be considered. Such specific details are not enumerated for all tasks. Table 36.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

36.1 Project Type and Status

Before any design work, an understanding of the project type and scope is necessary. This will establish the extent to which daylighting can address most or many or some of the lighting goals. New, renovation, and restoration projects each offer varying opportunities.

12.5.1 Visual Tasks
Table 12.3 | Sample Visual Task Survey

See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. At every opportunity the lighting designer should give every consideration to daylighting as a light source. For some applications and tasks, daylighting can be the primary light source. Critically, this means addressing the host of lighting factors identified in 12 | COMPONENTS OF LIGHTING DESIGN. Daylight demands attention to moderate or eliminate glare and balance visible and thermal energy.

36.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the common applications space types, under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 36.2 | Transport Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 36.2.

The following discussion is keyed to major application headings in Table 36.2. Couple this with topics in Table 36.1 for comprehensive qualitative and quantitative criteria.

36.2.1 Administration

Most transportation facilities must provide for administrative functions and typically include circulation, conferencing, lounges, filing or records, and officing. Each of these in turn may involve a number of specifics including some form or degree of acknowledgment, conversation, reading, periods of respite or relaxation, and writing—all tasks within applications. Acknowledgement of other people and conversation, for example, require some vertical illuminance at face height (seating or standing depending on the nature of the application). Vertical illuminance criteria are cited for such applications.

Administrative areas may be dispersed throughout a facility or complex or may be centralized into a single area or building. Depending on client wishes and architectural desires, this centralization or decentralization may affect the degree to which the lighting design in administrative areas is sympathetic to or different from that of other applications.

See also 32 | LIGHTING FOR OFFICES.

36.2.2 Baggage Claim and Service Office

Baggage claim areas house equipment that moves baggage in front of waiting passengers. Carousels with slanted moving surfaces present inclined surfaces for reading and identification. Horizontal belt carousels present more arbitrarily oriented surfaces. In both cases, passengers are usually crowded close the moving surfaces, so illumination must come from above and in front to avoid shadows. Baggage is usually recognized, in part, by its color or the color of an attached tag or flag; good color rendering is therefore a requirement. See Figures 36.1 and 36.2.

In addition to baggage recognition and retrieval, baggage claim areas at airports are places where arriving passengers are met. Vertical illuminance and modeling for good facial

recognition are important. For this reason, baggage claim areas also are transition spaces to outdoor walkways, platforms, waiting areas such as taxi stands, and other exterior functions. See 22 | LIGHTING FOR COMMON APPLICATIONS.

For Baggage Claim Service Offices, see also 32 | LIGHTING FOR OFFICES.

36.2.3 Bus and Shuttle Pick-up and Drop-off

Buses and shuttle vans to rental car areas, parking, and other areas of an airport are usually waited for at curb-side areas just outside a terminal or at islands separated from the terminal building by walkways. Several conditions in these areas influence lighting:

- Degree to which they are covered from the elements
- Proximity of vehicular traffic to pedestrian traffic
- Anticipated nighttime activity levels

Notes for Table 36.2

The table column headings are discussed in detail in 36.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 36.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 36.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 36.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

Notes for Table 36.2

The table column headings are discussed in detail in 36.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 36.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 36.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria. Outdoor tasks are so noted.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 36.2 should be made at 1 fc to 10 lx. Regardless, codes, ordinances, or mandates may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

j. See Table 26.4 | Nighttime Outdoor Lighting Zone Definitions. Nighttime illuminance targets are intended for application during dark hours of operation where lighting is deemed necessary or desirable. At curfew (client- or jurisdiction-defined), if lighting is still deemed necessary or desirable, then reduce lighting as indicated. See Table 26.5 | Recommended Light Trespass Illuminance Limits for recommended light trespass illuminance limits.

k. Use motion-sensing control to toggle lighting from on/off/dimmed state to recommended curfew state or from recommended curfew state to pre-curfew state as designer and client deem necessary to meet functional needs. Use instant-on lighting equipment.

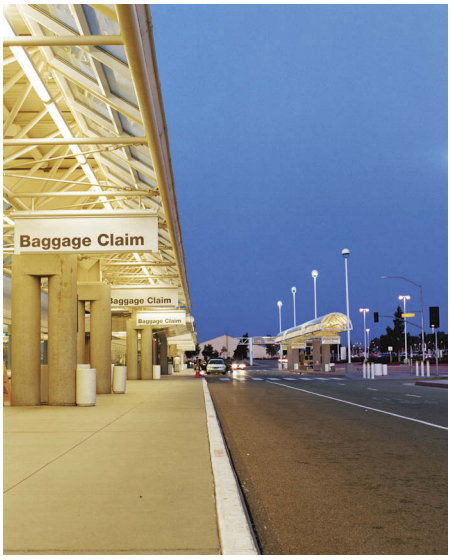

Figure 36.3 | Airport Pick-up/Drop-off
Pick-up and drop-off areas outside of transportation terminals are typically covered to the curb, providing mounting locations for luminaires. Lighting must provide for the safe interaction of pedestrian and vehicular traffic. Here, diffuse light addresses horizontal and vertical illuminances.
» Image ©Mike Powell/Getty Images

Table 36.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

Table 22.2 in 22 | LIGHTING FOR COMMON APPLICATIONS outlines an extensive list of entry types and situations that give recommendations for these areas where vehicular and pedestrian traffic mix. See Figure 36.3.

These bus and shuttle pick-up and drop-off areas are can be uncovered or canopied. The canopied areas are covered either as an extension of the terminal building, or separately in the case of islands. For such areas under cover where there is expectation for some passing conversation and acknowledgement and for a larger crowd of people, somewhat higher illuminances are appropriate than those for open or uncovered waiting areas, such as out in parking lots. Covered waiting areas near curbside by their nature involve a mix of vehicular and pedestrian traffic and in these situations, still higher illuminances are appropriate.

36.2.4 Concourses

Concourses are usually the largest spaces at airports and provide seating areas for travelers waiting for flights. They also usually contain or are connected by moving and fixed walkways, and house not only gate areas but adjacent retail and food service areas and often areas for temporary or permanent display of art.

Lighting in waiting and seating areas must support conversation, face recognition, and some tasks usually associated with offices, such as reading and working on a laptop computer. As such, vertical illuminance is as important as horizontal.

If the architecture permits, daylighting can be the principal source of illuminance in concourses, particularly in areas with high ceilings. Control of surface finishes and the use of some supplemental electric lighting may be necessary to balance luminances in large spaces. See Figures 36.4 and 36.5.

See 34 | LIGHTING FOR RETAIL, 21 | lighting FOR ART, and 22 | LIGHTING FOR COMMON APPLICATIONS.

36.2.5 Gate Areas

Gate areas provide seating and waiting areas for travelers about to board aircraft and a service counter for gate agents. Work at this counter involves not only printed tasks, but also computer work, ID and document checking, and facial recognition. For these reasons, illuminance in gate areas is usually higher than in other areas of a concourse.

See also 36.2.4 Concourses

36.2.6 Flight Information Screens

Flight information screens are a critical component of the system that delivers flight status information to travelers. They are usually mounted at or above head-height, tipped down, in large open areas to permit access by a large number of travelers, and are self-illuminated. They must be visible from a wide range of viewing positions and angles, and care must be taken to prevent veiling reflections. The designer needs to know the type of VDTs that are used, where they mounted, and their orientation. Electric lighting and daylighting must not generate veiling glare, and surfaces in the passenger's field of view that immediately surround the VDTs, should not produce high luminance ratios with them.

36.2.6 Passenger Pick-up and Drop-off

See 36.2.3 Bus and Shuttle Pick-up and Drop-off

36.2.7 Security

Security at most of the world's airports now includes passenger screening. This involves ID and document checking, X-ray of baggage, and visual observation of all passengers en-

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

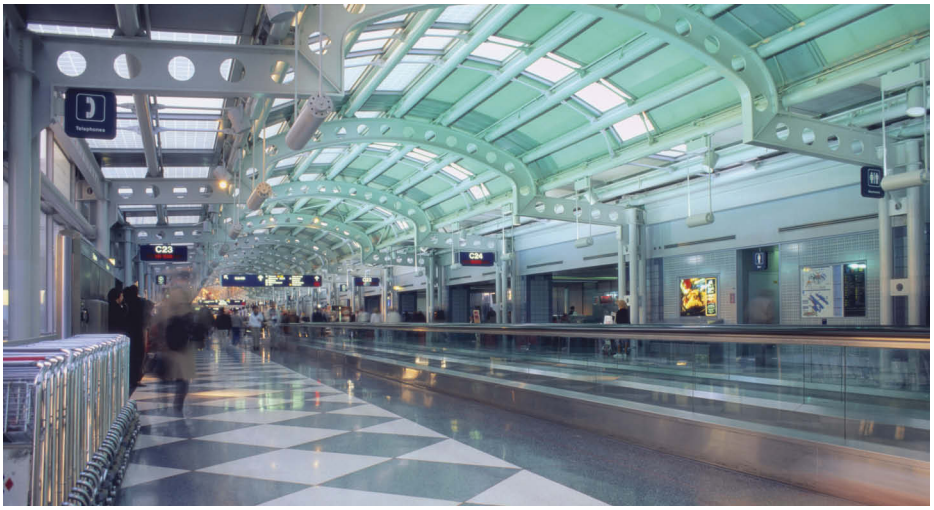

Figure 36.4 | Concourse Walkways
Fixed and moving walkways move passengers between gates and concourses. Integrated daylighting and electric lighting can provide the necessary general illumination. Fritted glass, louvers, and screens may be necessary to control direct sunlight.

Retail and food service areas may need additional lighting to highlight their position along long walkways.

» Image ©Mark E. Gibson/CORBIS

tering an airport's secured areas. Document check stands must provide for reading printed text in both horizontal and vertical orientations. Passenger face recognition by the security officer must be provided by sufficient vertical illuminance on and modeling of faces of passengers standing at the document check stand. See Figure 36.5

36.2.8 Ticketing

Ticket counters at airports and bus and train stations present a wide range of visual tasks that must be performed efficiently and quickly.. These include

- ID and document checking
- VDT reading and keyboard work
- Baggage claim check printing and reading
- Face recognition

Self-service check-in kiosks are located near ticket counters and adjacent to baggage checking stations. These kiosks present VDT tasks that must be viewed from a wide range of viewing angles and are subject to veiling reflections.

Since the task planes are many and varied, illumination at ticket counters should come from multiple directions. See Figure 36.6.

36.2.9 Waiting Shelters

Waiting shelters are popular along routes of mass transit. Lighting responding to photocells and motion sensors minimizes energy use while assuring electric light is available when these facilities are occupied.

36.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various topics outlined in Table 36.2.

Figure 36.5 | Document Check Stand
General, multidirectional lighting is required at security document check stands in order to provide sufficient horizontal and vertical illuminance.
» Image ©Joshua Sudock/ZUMA Press/Corbis

36.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 36.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or functions change to conform to current practice, client programming, or architectural conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 36.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Otherwise, reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique applications or tasks. These exercises as well as any deviations from recommendations the designer intends to make should be carefully documented for the record.

36.3.2 Notes

The notes in Table 36.2 may refer to other task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

36.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice and for purposes of sustainability can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Ratcheting initial illuminances higher is poor practice and not recommended. Maintenance procedures may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with

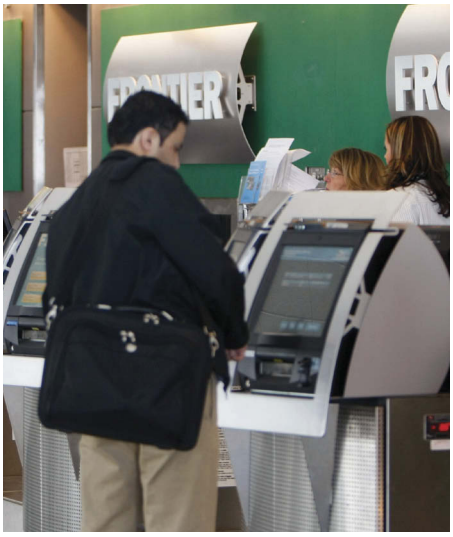

Figure 36.6 | Ticket Counter and Kiosk
The several tasks performed at ticket and customer service counters (left) usually require additional lighting beyond what is provided in the concourse. Walls behind counters are opportunities for wallwahing, highlighting the area and providing additional vertical illuminance on passenger faces.

Self-service ticketing and baggage check-in kiosks (right) can be subject to veiling reflections.

» Left image © DreamPictures/Blend Images/Corbis
» Right image ©RICK WILKING/Reuters/Corbis

the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Targets cited are consensus and recommended for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 36.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for lighting white boards, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

In some situations, no light is anticipated on at least one plane of a task. A 0 indicates no light or zero light is recommended for the task or application.

36.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane. For example, if ID and document checking at a security stand involves vertically-held documents, then the illuminance target cited in Table 36.2 (SECURITY/ID Check Stand/ID reading), which is for a dominant horizontal orientation, must be applied to the vertical plane at eye-height above the check stand.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. Where illuminance targets are intended at differing planar elevations, this is indicated under “Notes.”

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

Note the implication for observers' visual ages. Establishing and tracking task orientations and addressing both horizontal and vertical illuminance is necessary. If orientations in the project under consideration are programmed to be flipped from what might be considered normal-viewing, then criteria must be adjusted accordingly. If a task is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under "Notes." However, the designer may elect to use alternate or multiple vertical planes. In some situations the vertical planes could be oriented in a number of directions and the designer must determine which are most appropriate for the situation.

36.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. This aspect should be resolved during programming with the client. It may be determined that illuminance criteria for an age group other than that representing the majority of the intended observers is appropriate. However, this may result in overlighting, underlighting, harsh lighting, visual displeasure, or visual discomfort for many of the observers. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance. In some situations, such as video conferencing, lighting must meet the requirements of the camera technology and, therefore, is not tied to ages of observers.

36.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are shown in the table for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

36.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

36.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h). In some situations, notably those with regard to exterior illuminances, two uniformity values are cited. The first value addresses the primary cited application or task. The parenthetical value references the parenthetical application or task, such as a curfew situation associated with nighttime outdoor lighting.

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

36.3.4.1 Maximum-to-average

This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

36.3.4.2 Average-to-minimum

This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

36.3.4.3 Maximum-to-minimum

This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

36.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold.

36.3.6 Veiling Reflections

Tasks with specular components, like computers with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a “reflected light” icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Addressing luminance recommendations (see Table 12.4 | Default Luminance and Luminaire

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.

Intensity Recommendations for VDT Applications) minimizes veiling reflections. Changing the task will reduce or eliminate veiling reflections, such as use of CSA/ISO Type I or II computer screens and matte paper versus their specular counterparts.

36.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Applications and Tasks and Figure 12.22 | Task Coverage Example.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the furniture layout, for example, or might be established by the design team or client. The area-of-coverage citations in Table 36.2 are based on traditional notions. So, for example, it may be determined that a "task proper or task area" coverage would result in some amount of LPD reduction when compared to "room or designated area" coverage. If the task can be confined to one area rather then multiple areas, if the room or area in which the task is located is itself relatively small, such as a single-occupant office, and if the other design goals and criteria outlined in 12 | COMPONENTS OF LIGHTING DESIGN are addressed, then this strategy of redefining area of coverage has merit.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

36.4 Designing

Information provided here is specific to transportation facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. Equipment selection and location strategies may need to address the possibility of lighting equipment abuse. For outdoor applications, lamps and ballasts, transformers, and drivers must be selected for ambient temperature conditions, some of which are extremely hot and others extremely cold. Dimming response to daylight may be impractical. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects. Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the comfort and convenience of travelers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production, holding, and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic, abuse, and luminance criteria
- using accenting to provide luminance balancing
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical timeclocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria

- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the comfort and convenience of travelers is the paramount design tenet and must be kept in perspective during all aspects of design. If the workers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

37.5 References 37.24

Worship is an intensely personal endeavor that may or may not involve a community of participants. Lighting should acknowledge and enhance this deeply personal act, regardless of the setting or number of participants. Focal elements play a significant if not profound role in developing a visual scene conducive to ceremony or meditative state or both. Whether these focal elements are icons relating to a particular ceremony of worship or are visually-arresting elements that evoke introspection and ethereal contemplation, their lighting should create dramatic attention or soothing backdrop. Tasks that involve reading or acknowledgement or interaction require appropriate amounts of light. Appropriate lighting solutions will address occupants' needs within the context of the architecture and not preconceived notions of worship lighting hardware and architecture. Electric lighting accounts for about 28% of the electricity used in worship facilities (see Figure 37.1) [1] What follows is a discussion of the key aspects affecting lighting for people in settings for worship: project status; space types; activities; application-specific design goals, and illuminance criteria.

Comprehensive design efforts must also rely on material in 12 | COMPONENTS OF LIGHTING DESIGN, 13 | LIGHT SOURCES: APPLICATION CONSIDERATIONS, 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. The designer should have a thorough understanding of the design tenets outlined in those chapters, must identify those deemed appropriate and develop lighting goals and strategies accordingly. This chapter primarily addresses specifics related to lighting for worship which should influence luminaire optical selections, lamping, and final layouts based on previously developed thought-starters (see 15.2 A Lighting Scheme). Use of the material in this chapter to the exclusion of material in Chapters 12, 13, 14, and 15 will likely lead to unsatisfactory results. Previous IES related documentation serves as archival and reference source [2].

Deliberate thought must be given to details beyond the citations in this chapter. For example, in monumental cathedrals with unattended access, automated controls responding to occupancy are critical to minimizing energy use and maximizing in-service system life. See 16.3.4 Occupancy/Vacancy Sensors. Challenges include determining areas of coverage and equipment appropriate to the scale of the spaces involved. Such specific details are not enumerated for all applications and tasks. Table 37.1 offers a checklist of IES lighting topics and criteria. The design team is responsible for determining and addressing indoor and outdoor lighting and energy criteria set forth by authorities having jurisdiction (AHJ) which may be different from and supersede IES criteria. See also 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY.

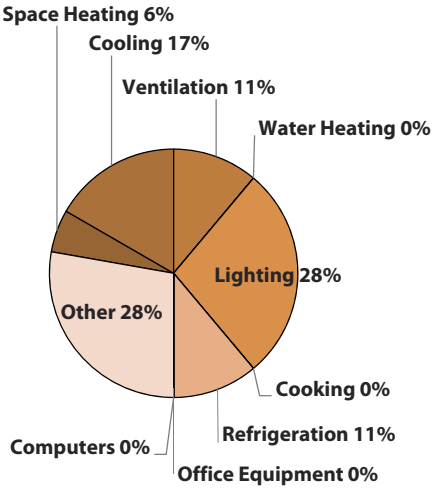

Figure 37.1 | Worship Electricity Use
Based on 2003 data from the US DOE's Energy Information Administration, lighting accounts for 28% of electricity use in worship buildings (electricity use for Computers, Cooking, Office Equipment, and Water Heating rounds to 0%). Worship buildings themselves account for about 2% of electricity use by all commercial and institutional buildings.

37.1 Project Type and Status

An understanding of the project type and scope is necessary before any design work commences. New, renovation, and restoration projects each offer varying opportunities. See 11.2 Planning, 11.3.1 Pre-design, and 11.3.2 Schematic Design. A clear understanding

of the project type and scope helps establish the extent to which daylighting will address most or many or some of the lighting goals. At every opportunity daylighting should be considered as a light source. Dappled and colored light through stained glass is a tried-and-true application of daylighting for worship. However this generally yields relatively low illuminances that are only appropriate for certain aspects of worship ceremonies in the traditional sense. Attempts have been made to introduce daylight harvesting into the worship environment. If daylight harvesting is not carefully designed, then discomfort glare and sometimes disability glare result. Daylighting requires attention to address glare and manage visible and thermal energy. Critically, this means addressing the host of lighting design factors identified in 12 | COMPONENTS OF LIGHTING DESIGN and in 14 | DESIGNING DAYLIGHTING.

37.2 Application Types

To develop lighting solutions that meet quality, quantity, and operational criteria, an inventory is made of the worship space types under consideration and the anticipated occupants, functions, and tasks (see Table 11.2 | Programming: Inventory Scope and Specific Examples and Table 12.3 | Sample Visual Task Survey). Otherwise, lighting cannot be best targeted to the users, their expectations, functions and tasks.

Space type definitions are required early in the project design in order to track design efforts that include inventorying the project knowns, anticipated functions, and tasks and calculating lighting, power, and energy compliance. Room names and celebratory or liturgical areas, from which functions can be deduced, and numbers for tracking should be clearly marked on architectural backgrounds. The applications and tasks cited in Table 37.2 | Worship Facilities Illuminance Recommendations should be reviewed against the project knowns and correlated with the named space types and functions to establish recommended illuminance criteria. Seek clarification with the client where discrepancies occur between programming information, the list of room names, and the available application and task citations in Table 37.2.

Some worship facilities are relatively diverse activity or cultural centers with a need to accommodate functions other than conventional worship in the main worship space. These other activities should be outlined in the program or might become obvious during a task survey, but might include communal suppers, socializing and learning in the form of prayer and study groups, lectures, music performances, and skits, and movie and book reviews. To accommodate these additional activities, lighting different from that necessary to achieve the goals of worship will be necessary along with controls offering a greater range of flexibility. Some criteria related to performance lighting is cited at CONTEMPORARY FORM/Performance in Table 37.2. The designer should reference other application chapters for further guidance and illuminance criteria depending on the additional tasks involved. This might include referencing 22 | LIGHTING FOR COMMON APPLICATIONS, 24 | LIGHTING FOR EDUCATION, and 28 | LIGHTING FOR HOSPITALITY AND ENTERTAINMENT.

Worship applications are quite personal. The client might be a religious leader, a committee of worshipers, or both. It is possible that criteria cited here may not align with programmed applications and functions or with a client's expressed desires, which may range from "I want it to be mysterious" to "I want my parishioners to be able to read the hymnal." The designer must be interpreter and assess what illuminance criteria are appropriate to meet the needs in the context of a specific project's architecture and finish scheme and the prioritized lighting criteria discussed in 12 | COMPONENTS OF LIGHTING DESIGN. A review of Table 4.1 | Recommended Target Illuminances may be in order to establish criteria suited to the specifics of the client. Accenting greatly assists in brightness perceptions. Dark and high contrast help create a sense of mystery. Design

reviews, including criteria implications, and design resolution and agreement between the designer and client are important.

The following sections are keyed to the major application and task headings in Table 37.2. These discussions, those highlighted in Table 37.1, and material in Table 37.2 offer comprehensive qualitative and quantitative criteria.

37.2.1 Accenting

Accenting affects people's brightness perceptions and provides visual relief. Accenting is also used for visual attraction and wayfinding. Default accent lighting criteria are discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Also see 15.1.1.3 Accent Lighting.

37.2.2 Administration

Lighting for administrative areas is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. The architectural scheme and even task specifics may vary based on the associated worship facility and its size and outreach programs, if any. These distinctions may affect lighting design—from kinds of lighting effects to lighting equipment styling to luminances and illuminances.

The administrative areas may be dispersed throughout a worship facility or complex or may be centralized into a single area, wing, or building. Depending on client wishes and architectural desires, this centralization or decentralization may affect the degree to which the lighting design in administrative areas is sympathetic to or different from that of the other applications and tasks at the worship facility in question.

37.2.3 Building Entries

Lighting for building entries is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. For building entries of worship facilities two distinct variables are time and duration of need. Other variables demanding attention prior to recommending illuminance criteria include anticipated levels of activity and the nighttime outdoor lighting zone. Nighttime activity levels may vary by type of worship facility and the extent and type of outreach programs. Worship may be primarily a day-time activity, a nighttime activity, or both and may fluctuate seasonally. Outreach programs may include community-activity centers, soup kitchens, bible schools, and fund-rasing activities, to name a few. All of this may demand a control system capable of addressing various settings on various evenings through manual intervention, automated time clock, and photocell functions.

The nighttime outdoor lighting zone within which the facility is located establishes the illuminance categories for outdoor tasks. Nighttime outdoor lighting zones vary by local ordinance, sustainability guides, or the team's own definition of place.

After-hours security needs, such as on-site or remote monitoring or recording, may require that some luminaires at building entries remain energized through the night or placed on motion sensors or interconnected with camera operations. Control zones and time clock functions must be designed accordingly. Where remote monitoring is done with infrared cameras, lighting may be unnecessary.

37.2.4 Classrooms

Lighting for classrooms is discussed in 24 | LIGHTING FOR EDUCATION. Relatively simple lighting and controls may be appropriate for religious education classes that occur once a week and for an hour or so and where no multi-technology-presentation is used frequently, if at all. However, where worship facilities encompass faith-based education, lighting needs to address the demands of a pedagogy, formal schedule, testing, and curriculum, including various presentation technologies.

Notes for Table 37.2

The table column headings are discussed in detail in 37.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 37.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 37.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 37.2 should be made at 1 fc to 10 lx. Regardless, codes and ordinances may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers or video display screens with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 37.2

The table column headings are discussed in detail in 37.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 37.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 37.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 37.2 should be made at 1 fc to 10 lx. Regardless, codes and ordinances may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers or video display screens with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Notes for Table 37.2

The table column headings are discussed in detail in 37.3 Illuminance Criteria. See 12.5.5 Illuminance for discussion on procedures for establishing illuminance targets for a project. See Table 37.3 | SI Dimensional Conversions.

a. Applications, tasks, or viewing specifics encountered on any given project may be different from these and may warrant different criteria. See 37.3.1 Applications and Tasks. The designer is responsible for making final determinations of applications, tasks, and illuminance criteria.

b. Values cited are to be maintained over time on the area of coverage.

c. Values cited are consensus and deemed appropriate for respective functional activity. In a few situations, code requirements are within 10% of IES recommendations. This is apparently an artifact of metrication. Footcandle conversions of any values cited in Table 37.2 should be made at 1 fc to 10 lx. Regardless, codes and ordinances may supersede any of the IES criteria for any of the applications and tasks and the designer must design accordingly.

d. Targets are intended to apply to the respective plane or planes of the task.

e. Illuminance uniformity targets offer best results when planned in conjunction with luminance ratios and surface reflectances. Any parenthetical uniformity values reference respective parenthetical applications or tasks, such as a curfew situation associated with nighttime outdoor lighting.

f. Applications and tasks cited with sunburst icon ☀ are candidates for strategies employing any combination of daylighting and electric lighting to achieve target values during daylight hours. Daylighting may require unconventional approaches.

g. Tasks with specular components, like computers or video display screens with CSA/ISO Type III screens or printed tasks with glossy ink or glossy paper, are prone to veiling reflections. The likelihood of an application's or task's predisposition to veiling reflections is indicated by the reflected-light icon: black and white ◪ signals high likelihood; gray and white ◪ signals moderate likelihood; pale gray and white ◪ signals some likelihood; and all-white signals little-to-no likelihood.

h. The designer must establish areas of coverage to which targets apply. Green ■ highlight identifies task proper or task area as the typical area of coverage for respective cited targets. Amber ■ highlight identifies room or designated area as the typical area of coverage for respective cited targets.

i. See Table 22.4 | Indoor and Nighttime Outdoor Activity Level Definitions.

Table 37.3 | SI Dimensional Conversions

US Customary	SI
General	**Hard Conversion**
inches	mm [inches × 25.40]
feet	m [feet × 0.30]
Specific	**Convenient Conversions[a]**
2'	610 mm or 0.6 m
2' 6"	760 mm or 0.75 m
3'	915 mm or 0.9 m
3' 6"	1065 mm or 1.1 m
4'	1220 mm or 1.2 m
5'	1525 mm or 1.5 m

a. Hard conversions rounded for reporting convenience. Not to be confused with metric-sized luminaires or other building materials. Not for precision construction.

37.2.5 Worship Needs

The need to fully program worship facilities such as cathedrals, churches, mosques, shrines, synagogues, temples or other houses of worship cannot be overstated. The religious sect, its kind of worship, and the congregants of a facility steer lighting among other design and planning decisions. Organized religion is categorized here as that taking a contemporary form, or traditional form, or a transitional form. These are cited in Table 37.2 in alphabetical order amongst the other applications and tasks. The designer must consult with the client to establish the appropriate form of worship, which may relate to the intended tone and dynamics of the ceremonies or liturgy, to the architecture, or to both. For personal meditation by one individual or an intimate group, see Table 34.2 | Residential Illuminance Recommendations/Residential Interiors/Meditation Rooms. Horizontal illuminance criteria for a task should not be the sole driver behind lighting solutions. Vertical illuminances, peripheral lighting, and accenting play a significant role in lighting for worship. See Figure 37.2. In addition to some discussion on the various forms of worship, controls, maintenance, and broadcast requirements are discussed below.

37.2.5.1 Contemporary, Traditional, and Transitional Forms of Worship

For contemporary forms of worship, illuminance criteria are cited in Table 37.2 for tasks and applications that are related to contemporary ambience or of exuberant worship. The illuminance criteria for traditional forms of worship are related to traditional ambience or formal worship. Illuminance criteria for transitional forms of worship are related to transitional ambience or an informal worship style. Generally, illuminances are highest for exuberant worship, lowest for formal worship, and moderate for informal worship. See Figures 37.3 and 37.4.

Criteria for each form of worship is available to address the following common applications and tasks: choir; congregation; music; narthex; reverent focal areas; and sacristy. The congregation may also be referenced as nave, prayer hall, or assembly depending on the religion. For the body of congregants, criteria are cited for circulation, collective meditation, participatory action, personal meditation, and sermon. The designer must determine which of these applications and tasks are relevant to the worship project at hand. A basic lighting situation for the congregation area should include lighting for participatory action and sermon.

Conventional church architecture may be laid out with traditional worship spaces and areas such as a chancel, nave, sanctuary, side aisles, and transept. Rather than light these areas to predetermined illuminances, they should be lighted according to applications and tasks and to the visual hierarchies the designer and client deem appropriate for the liturgy.

Contemporary form is most likely to have a need for lighting to address a broad array of AV and performance functions as part of the liturgy.

37.2.5.2 Reverent Focal Areas

Reverent focal areas might include those furnishings that support liturgy or are a significant artifact or feature, such as the altar, ambo, chair, ark, lectern, minbar, pulpit, raredos, reliquary, and tabernacle. These might be accented in a hierarchy relating to the worship activity or might be statically lighted for the duration of a service. The designer must coordinate such lighting schemes with the needs of the particular client. Reverent focal areas that are determined appropriate to the liturgy are lighted based on their reflectance, their relative importance, and the worship activity setting. Where icons or art are of some visual importance, but not of primary or secondary stature, Table 15.2 | Accent Illuminance Ratios is a useful reference. See Figures 37.4, 37.5, and 37.6.

37.2.5.3 Choirs and Music

Areas of music performance and choirs are considered secondary focal elements for purposes of illuminance criteria. These are dimensional focals, much like altars and lecterns, where horizontal and vertical illuminance are equal in value. This assures celebrants can

Copyright ©2011 by the Illuminating Engineering Society of North America (IES). The purchaser is licensed to this publication according to the purchased number of concurrent users.
No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

perform the reading tasks and simultaneously be sufficiently lighted vertically to appear as a focal element to the congregants.

37.2.5.4 Narthex

A traditional term, narthex defines a foyer or lobby area that is a transition from outdoor to indoor assembly space. Many times the narthex serves as a greeting space. To assist with adaptation, daytime illuminances are higher than nighttime values. With respect to adaptation and circulation to the congregation area, the transition is best if floor surface reflectance values between the narthex and congregation circulation area are nearly identical. Otherwise illuminance at the congregation circulation floor should be adjusted by the ratio of the narthex floor reflectance to the congregation circulation floor reflectance.

37.2.5.5 Sacristy

Sacristy is a traditional term associated with the room where sacred objects may be stored or items associated with the liturgy, including robes, communion cups, and linens.

37.2.5.6 Controls

In even a modest place of worship where a number of ceremonies or functions are to be accommodated and where light will play a role in sequencing through the various ceremonies and functions, controls are necessary. Usually standard wallbox dimmers and switches are insufficient unless dedicated staff is consistently available and capable of punctual operation of the various lighting zones in a predetermined sequence. Typically preset control systems are employed for consistent settings and timely operation of all luminaires. Close coordination with the client is necessary to determine the number and location of control stations and which preset scenes are available at each location. In liturgies where performance is a significant component, a sound and light director may need access to a lighting control board for dynamic lighting effects tailored to a service or performance. The type of lighting control depends on the degree to which clergy requires or desires lighting operation and by whom. Where daylighting has an integral role, automated controls are necessary. Figure 37.7 illustrates just a few of many preprogrammed liturgical scenes which can be made available on a preset system.

37.2.5.7 Maintenance

Some architecture for worship poses two significant challenges: spatial volume; and accessibility to lighting equipment. A further challenge is one of budget which typically precludes extensive catwalks, motorized man lifts, or lowering lifts for luminaires. Spaces with tall ceilings and where recessed luminaires are a preference demand luminaires with precision optics. Any shift in the optical mechanisms during maintenance will result in ineffective and possibly glary lighting and essentially a waste of energy. Accessibility to lighting equipment complicates the process of cleaning and servicing luminaires. Lamping, type of luminaire, and luminaire layout are all influenced by accessibility. A review of maintenance options versus quality and quantity of light and dimming must be made with the client and might include discussion of man lifts, lowering lifts, top access and attic or catwalk requirements, or periodic use of riggers. Automated controls can greatly assist maintenance. Occupancy sensors or time clock controls for some or all of the lighting can lengthen in-service life of lamp and ballast, drivers, and transformers. Some facilities only require much or all of the lighting to be energized for perhaps ten hours a week. Automated controls can help achieve such a low use rate by scheduling when certain lights are available.

37.2.5.8 Broadcast Lighting

Some congregations broadcast services usually over local cable channels. Depending on camera technology and positions, architectural lighting may meet the needs of broadcast. However, some situations will require additional lighting for those services that are broadcast. The illuminance and contrast requirements of the cameras must be accommodated. Separate architectural lighting or theatrical lighting instruments can address these requirements and require separate control.

Figure 37.2 | Personal Meditation
This small hospital chapel is available 24/7. A personal meditation lighting scene offers lighting to an intimate group in the foreground. For intensely private situations, refuge exists beyond the lattice where only a tabernacle is accented. Lighting of the lattice offers spatial definition to both areas and serves as a meditative backdrop or focal element.
» Image ©INAI Studio

Figure 37.3 | Transitional Worship
The designer and client may determine that transitional worship lighting is appropriate to the liturgy, regardless of the architecture. Here, wood furnishings and a historic interpretation of the original ceiling introduce an informal quality. Therefore, the worship lighting criteria could arguably be based on transitional worship for both liturgy and architecture.

With a Sunday outreach of live broadcast to the home-bound and those in nursing homes, hospitals, and prisons, lighting was coordinated with camera requirements for both illuminance and contrast ratios.
» Image ©carr cialdella

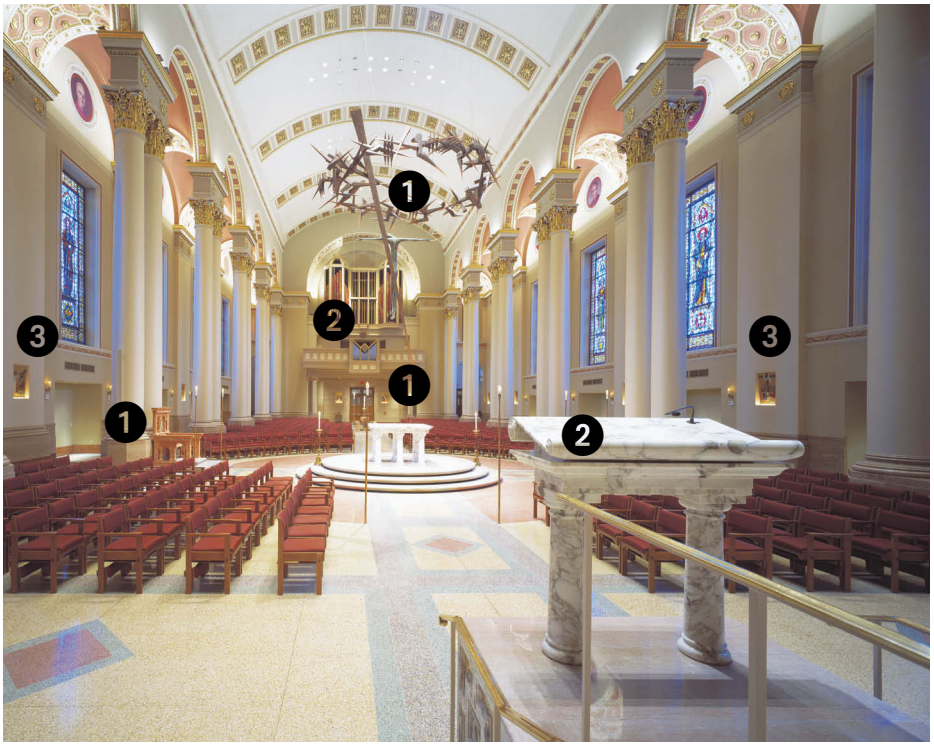

Figure 37.4 | Pre/Post Worship
The lighting in this restored cathedral consists of a variety of zones and presets coordinated with the liturgy. For pre/post worship and for participatory action, an "all-on" and "full-bright" arrangement can be used. The chair, altar, and sculpture above it are primary focal elements ❶ in this scene. Secondary focal elements ❷ are the lectern (also known as ambo or pulpit) and the organ pipes. Stations of the cross ❸ are lighted as art to "Subtle" in accordance with Table 15.2 (see detail in Figure 37.5, below). Indirect lighting accentuates roundel portraits in side-aisle arches and softly washes the barrel vault of the nave which improves overall brightness and accentuates architectural detailing and softly lights congregants faces.

Preset controls choreograph emphasis of various focal elements as outlined in Table 37.2 to accommodate the liturgy. The "sermon" scene prominently features the lectern while dimming the altar. Other scenes can be developed by dimming or extinguishing the indirect lighting or by dimming downlights and selected accents.

» Image ©John J. Korom Photography

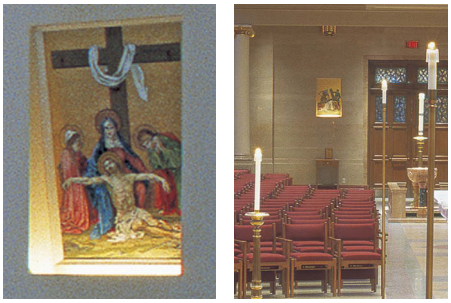

Figure 37.5 | Improved Coverage
To improve the coverage of light over the stations of the cross visible at ❸ in Figure 37.4, and in blow-up to the left, without using picture lights or other obvious luminaires with accent optics, a wall-niche was created at each station. The depth of the niche was sufficient to allow for a lighting detail at the bottom. The artwork was then tipped out to the face of the wall at the top of the niche. The gilt work is more uniformly bright when viewed head-on as seen in the detail on the right.

» Images ©John J. Korom Photography

37.2.6 Food Service

Food service lighting is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS.

37.2.7 Parking

Lighting for parking facilities is discussed in 26 | LIGHTING FOR EXTERIORS.

37.2.8 Pedestrian Ways

Lighting for pedestrian ways is discussed in 26 | LIGHTING FOR EXTERIORS.

37.2.9 Support Spaces

These relatively back-of-house citations are self-explanatory. For purposes of maintenance convenience, lamp types and color qualities should match those used elsewhere.

37.2.10 Toilets/Locker Rooms

Lighting for toilets and locker rooms is discussed in 22 | LIGHTING FOR COMMON APPLICATIONS. Addressing the fixture functional areas, such as toilets, urinals, vanities, will provide sufficient light where needed without overlighting the entire toilet room. Vanities are problematic when little or no vertical illuminance is designed to illuminate an imaginary facial plane (roughly a zone of sufficient size to encompass faces) in front of the mirrors. For purposes of maintenance convenience, lamp types and color qualities should match those used elsewhere.

37.2.11 Transition Spaces

Most of these spaces are self-explanatory. Many apply to very large facilities or a complex or compound. For purposes of maintenance convenience, lamp types and color qualities should match those used elsewhere.

37.3 Illuminance Criteria

Illuminance criteria, when fully deployed, are a robust set of quantitative values that influence visibility, visual performance, and visual comfort and attention. Short-circuiting the criteria selection or designing to a single criterion value, such as horizontal illuminance, to address worst-case tasks will surely result in dissatisfaction. Even if clients accept the visual results, not getting the most from the energy expended or, worse, energy waste is a likely result. Following are notes related to various aspects outlined in Table 37.2.

37.3.1 Applications and Tasks

Applications and tasks encountered on any given project may be different from those identified in Table 37.2 and may warrant different illuminance criteria. Cross-referencing closely-associated applications or tasks is appropriate. Sometimes naming trends or conventions for space types or liturgical areas and functions change to conform to current practice, client programming, or architectural or liturgical conventions, but the actual activities and tasks remain the same and this cross-referencing works. Failing this technique, reviewing the list in Table 37.2 may be in order to determine if any applications or tasks exhibit a similar visual-component to the unique applications or tasks. Additionally, reviewing the tasks of other applications sometimes yields insight. For example, a lounge or game room for teens is addressed by criteria cited in Table 28.2 | Hospitality and Entertainment Facilities Illuminance Recommendations/TRANSITION SPACES/Lounges/Clubs and Game Rooms. Where no similar-in-nature tasks can be found, then reviewing 4.12 An Illuminance Determination System and Table 4.1 is necessary to establish a task category based on the task characteristics or visual performance descriptions most closely associated with the unique tasks.

37.3.2 Notes

Notes may refer to other application and task headings in the table or to other handbook chapters as appropriate. Where some degree of clarification is warranted, notes are made.

37.3.3 Recommended Maintained Illuminance Targets

Values cited are maintained on the area of coverage for the task under consideration. Illuminance is additive. Where practical and without negatively affecting the intended application of light, target values are achieved with any combination of daylighting and/or electric lighting in whatever mix of ambient, task, and accent lighting is deemed appropriate to meet these and the other lighting goals established during design. See 12 | COMPONENTS OF LIGHTING DESIGN and see 10.7.1 Light Loss Factors.

With respect to light loss factors, account for anticipated losses through the point in time at which group relamping and cleaning should occur. Group relamping and cleaning should be standard practice, though these need not occur at the same frequency. Periodic cleaning and group relamping essentially maintain the illuminance at criteria and make the most efficient use of the installed equipment. For purposes of sustainability, cleaning and group relamping can no longer be presumed to be infrequent or unlikely. Maintenance procedures must be part of the design discussions with the client. See the IES document IESNA/NALMCO RP-36 Recommended Practice for Planned Indoor Lighting Maintenance for additional information. Where maintenance is deferred or practiced poorly or not at all, the actual illuminance values will fall below criteria targets. This is inefficient, unsustainable, and may be unsafe while adversely affecting users' quality of life or work. Maintenance may be especially problematic with LEDs where promises of extraordinarily long life may be offered, but usually with the caveat that lamp lumen depreciation (LLD) at that rated life is 70% or perhaps even as low as 50% of initial rating. If replacement cycles are presumed to be rated life, then LLD alone must be 0.7 or 0.5 or whatever lumen rating is certified by the LED vendor. See 13.3 Life and Lumen Maintenance.

Figure 37.6 | Focal Areas and AV
House lighting and focal lighting control zones are carefully discretized to achieve best effect. Well-designed optically-controlled downlights and theatrical instruments are used. All of these attributes contribute to distinctly rendered focal areas and provide good contrast at AV screens while providing sufficient house lighting.

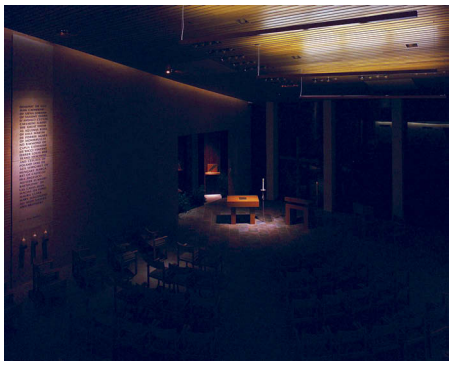

Figure 37.7 | Liturgical Presets
For sustainability, all accent lighting here is achieved with 39W/T6/CMH lamps exhibiting 3000 K CCT and 80CRI. Careful sequencing of presets throughout worship is necessary to avoid the unacceptable delays involved when CMH lamps are extinguished and immediately recalled for operation. By switching off various zones of CMH accents and dimming various zones of fluorescent luminaires, available scenes include (from top):

1. CELEBRATION OF MASS;
2. MUSICAL EVENT (focusing on a music area on the left although altar and tabernacle remain accented);
3. NIGHT MEDITATION.

» Images ©2005 Gene Meadows

A detail involving LEDs and maintenance that is especially relevant to places of worship involves difficulty of access in large-volume high-ceiling spaces. At this writing, LEDs remain untested over long periods of time. It has not been unheard of that LEDs designed into nearly inaccessible areas have failed prematurely. The mechanics and labor involved to service these luminaires and their auxiliary components, including, but not limited to drivers, transformers, and control interfaces has proved difficult and costly. Regardless of the promise of longevity, the designer should confirm warranty coverage for the cost of equipment and labor, preferably for a period of at least 5 years. Detailing and access with design team members and clients prior to layout and specification.

Targets cited are consensus and deemed appropriate for respective functional activity. For some applications, IES recommendations are within 10% of code requirements. This apparently is an artifact of metrication. Footcandle conversions of any values cited in Table 37.2 should be made at 1 fc to 10 lx. This soft conversion avoids a redundant diminishing of illuminance values after multiple citations and conversions over time. This also eliminates a false sense of accuracy advanced by an ever-increasing number of decimal places and a false sense of urgency advanced by eccentric fractional values introduced by hard conversions. Nevertheless, a lighting design must meet code and the mechanics of which must be coordinated amongst the design team. The IES recommendations should not, do not, and cannot reflect all of the various code requirements in force in all jurisdictions at any given time.

Targets are intended to apply to the dominant plane of the task, typically, but not always, horizontal or vertical. In some situations, illuminance criteria are cited for one plane, such as the vertical plane for a front projection screen, while the other plane is blank. The blank signifies that illuminance on that plane is unimportant and may be a consequence of the illuminance of other tasks within the vicinity or by whatever illuminance results from meeting the target illuminance for the prescribed plane of interest.

37.3.3.1 Target Planes

Many, though certainly not all, tasks are performed with the task in roughly a horizontal orientation or vertical orientation. A dominant orientation must be assigned and the illuminance target determined accordingly. There may be situations where the IES recommended target relating to the typical planar mode of a task must be applied to a different plane.

Nearly all tasks are expected to have both a horizontal illuminance component (E_h) and a vertical illuminance component (E_v). This allows some degree of task flexibility for off-plane viewing and accommodates various aspects of the task. In some applications, like participatory action where hymn singing might occur, horizontal- and vertical-plane illuminances address the common situation where reading takes place on near-horizontal to half-way between horizontal and vertical planes.

Where illuminance targets are intended at differing planar elevations, this is indicated under “Notes.” For example, for some congregation areas, horizontal illuminances apply to the lap plane or standing-hymnal plane. Depending on the form of worship and the religion, the designer may elect to set the lap-plane elevation to the floor plane if congregants are seated on floors or floor cushions. Tracking task plane locations and their orientations and addressing both horizontal and vertical illuminance is necessary. If a single focal element is scheduled to be oriented on some plane off axis from horizontal or vertical by more than 10°, say, then the illuminance criteria must be applied to that off-axis orientation. This is an important distinction for luminaire optical selection and aiming capabilities and for layout, calculations, and field measurements.

For planes related to vertical illuminance targets, some guidance is indicated under “Notes” where the directional orientation of the plane is straightforward and easily identified. However, the designer must establish orientations based on project conditions. For example, in a sermon-in-the-round situation, and especially where reconfigurable loose seating is used, the designer must determine if vertical illuminances apply to one plane or multiple

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

planes. Additionally, the resolution of a "one-plane" approach must be assessed with respect to the other congregants located at 90° and, most critically, at 180° to the design area in question as luminaire orientation and optics to achieve the desired illuminance outcome may inadvertently create discomfort glare for these other congregants.

37.3.3.2 Visual Ages of Observers

Illuminance criteria are based on the visual ages of more than half the intended observers. In some worship settings, this must be applied to each application or task item. For example, the sermon may be made by clergy over 65 years old, yet the illuminance of the pulpit task plane is likely driven by the focal area illuminance criteria necessary for congregants to appreciate of the significance of the focal element. The focal area illuminance is most often well in excess of the illuminance required for reading by the clergy at an ambo or lectern, for example. The designer can confirm this by reviewing samples of typically sermon texts for font size, paper, and ink quality, and then comparing this to tasks identified in Table 22.2 | Common Applications Illuminance Recommendations/READING AND WRITING and their respective illuminance criteria. The greater issue for clergy over 65 years of age is sensitivity to the glare created by the focal area lighting. The designer should take action to limit glare, which may involve lamp and luminaire optics, off-axis luminaire positions to either side of the focal element (to avoid "straight-in-the-face" aiming), and somewhat more grazing aiming angles of 25° to 30° from nadir rather than the more flattering 35° to 40° from nadir. All deserve modeling in computer or mockups, but certainly require review with client. In any event, the observers' ages, task sets for age groups, and illuminance targets should be resolved during programming with the client. See 12.5.5 Illuminance and 4.12 An Illuminance Determination System for additional information and guidance.

37.3.3.3 Illuminance Categories

Illuminance categories are designated by letters A through Y. These are listed in Table 37.2 for more convenient reference to Table 4.1 | Recommended Illuminance Targets should the designer wish to explore other criteria targets or if applications or tasks on a specific project are not readily correlated to the table citations.

37.3.3.4 Gauge

The common gauge for determining illuminance target compliance is cited for each application. All gauges presume that point-by-point techniques are used for predictive calculations and presume that uniformity criteria are closely monitored. Where an average illuminance value over the area of coverage can satisfy target compliance, "Avg" is cited. In applications or tasks where a minimum or maximum target is necessary, the gauge for compliance is "Min" or "Max" respectively.

The designer may elect to use other methods to evaluate target compliance, such as criterion rating (CR) or coefficient of variation (C_v). See 4.12.4.5 Tasks at Uncertain Locations Over a Large Area.

In any event, once illuminance targets and uniformities are established, then any calculated deviation from them should be limited. Standard engineering allowance of ±10% might be acceptable for targets gauged as average unless contractual or code obligations demand otherwise. Minima and maxima must be achieved as intended.

Designs should be adjusted until predictions are within allowance for averages and meet minima and maxima. For additional information, see 4.12.4.1 Recommended Illuminances at Design Time, 4.12.5 Illuminance Ratios, 9.15.1.1 Average Illuminance, and 10.8 Assessing Computed Results.

37.3.4 Uniformity Targets

Illuminance uniformity targets work in conjunction with luminance uniformities and surface reflectances all of which must be addressed as part of the design to avoid visual

Figure 37.8 | Progressive Daylighting
Siting, orientation, and appropriately configured architecture and daylight-aperture geometry can yield settings where electric light is only necessary during dark hours, depending on liturgical needs. Here, north daylight is distributed onto and then softly and efficiently reflects from the white architectural form of Alvar Aalto's Riola Parish Church, Riola, Italy. See 11.2.1 Progressive Planning for more information on lighting planning techniques.
» Image ©Richard Einzig/Arcaid/Corbis

discomfort, glare, and strain. Uniformity ratios are targets that define the widest recommended ranges. In many situations, uniformity ratio criteria are those between average values of an array of points and the minimum value in the same array of points. Uniformity targets apply to both horizontal and vertical illuminances over the area of coverage. Where horizontal uniformity criterion is different from vertical uniformity criterion, two ratios are reported with the first value for horizontal illuminance (E_h).

Generally the more important speed and accuracy and the more demanding the visual task, the tighter the ratio.

37.3.4.1 Maximum-to-average
This is the recommended ratio of maximum illuminance to the average illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations sensitive to even a relatively small degree of overlighting.

37.3.4.2 Average-to-minimum
This is the recommended ratio of average illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where illuminance too far below average conditions is noticeable and detrimental to task performance or inconsistent with normal expectations.

37.3.4.3 Maximum-to-minimum
This is the recommended ratio of maximum illuminance to the minimum illuminance found on the area of coverage of interest. This ratio is typically ascribed to situations where too much variation in illuminance is considered undesirable and untenable from a performance or safety perspective.

37.3.5 Daylighting Advancement

Generally, design strategies should embrace any combination of daylighting and electric lighting to achieve target values during daylight hours. The preference is for daylighting to provide all or most of the recommended illuminance presuming that all aspects of daylighting are properly addressed. A sunburst icon depicts those applications and tasks where daylighting is considered a strategic candidate. Use photocells and stepped-dimming or continuous dimming to reduce or eliminate electric lighting during daylight hours. See 14 | DESIGNING DAYLIGHTING and 15 | DESIGNING ELECTRIC LIGHTING. Even for those applications where daylighting is not traditionally a strategic candidate, it may be determined that very careful and coordinated design will offer great sustainability opportunities along with positive influences associated with daylight and views. Figure 37.8 illustrates progressive daylighting for worship and Figure 37.9 illustrates conventional daylighting for worship.

Daylight must be controlled to provide illuminances appropriate to the task. Overlighting with daylight can accelerate fading and bleaching and the ultimate demise of sacred or historic artifacts.

37.3.6 Veiling Reflections

Tasks with specular components, like printed tasks with glossy ink or glossy paper or, worse, both, are prone to veiling reflections. The likelihood of particular applications and tasks predisposed to veiling reflections is indicated by a "reflected light" icon: black and white signals high likelihood; gray and white signals moderate likelihood; pale gray and white signals some likelihood; and all-white signals little-to-no likelihood. Veiling reflections are minimized by controlling the overall amount and direction of light with respect to the task locations and orientations. Alternatively, tasks sensitive to veiling reflections can be screened or isolated. Effective strategies include employing some amount of indirect soft, diffuse electric lighting or direct electric lighting with multiple low-output luminaires, or positioning tasks and luminaires and luminance patterns to avoid harsh reflections from tasks. Where clergy or celebrants are likely to be reading text, such as part of participatory

No part of this publication may be reproduced in any form without prior written permission of the IES. For inquiries, please contact ies@ies.org.

action or a sermon from an altar, ambo, lectern, pulpit, or minbar, the accent lighting on these focal areas is sufficient to cause veiling reflections. Using multiple lights positioned off axis from the main direction of the reader's view will help minimize veiling reflections.

In situations where sacred or historic documents and objects are behind glass, veiling reflections are minimized by carefully analyzing geometry of luminaire-to-glass-plane-to-viewer. Placing lighting equipment outside the typical viewing orientations can help as can the use of anti-reflective glass for the case. Using lighting within the display case is generally superior, though LEDs or fiber optics are best to avoid excessive heating of the display case and limit UV and IR.

37.3.7 Defining Areas of Coverage

In addition to establishing planes of task orientation, the areas of coverage to which targets apply must be determined. Typical areas of task illuminance coverage are identified here, but these may not be appropriate to specific project situations. One area of coverage is "task proper or task area." Here, the illuminance criteria are applied to the task itself or to a relatively small area to which the task is confined. See 12.5.5.1 Applications and Tasks and Figure 12.22 | Task Coverage Example. It is important to remember that illuminance is additive, that is, task illuminance can be achieved with some combination of ambient lighting, task lighting, and/or accent lighting, providing that the total illuminance on the task proper or task area meets the illuminance criteria outlined in Table 37.2.

Another area of coverage is "room or designated area." In this situation, illuminance criteria are applied to the room or an area of fairly substantive size representing the zone in which the applications and tasks are expected to occur. The designated area is typically established by the layout of furnishings.

In worship settings, areas of coverage for some focal elements such as ambo, altar and chair might be collectively configured on a platform or a broadly defined area such as a chancel. To light celebrants' actions in this area, illuminance may apply to the entire defined area. This is especially important for video recording where cameras focused on and panning with celebrants' movements cannot tolerate contrast ranges that would be achieved with the more dramatic look of distinctly lighted individual focal elements.

An assessment and determination must be made on which area of coverage best satisfies the lighting goals on a particular project.

37.4 Designing

Information provided here is specific to worship facilities and should be used as part of the design and documentation processes outlined in Chapters 12, 15, and 20. See 25 | LIGHTING FOR EMERGENCY, SAFETY, AND SECURITY for additional information on respective aspects.

As noted in 37.2 Application Types, worship facilities are unlike most other application types. Design must accommodate very specific needs and desires of a client or client team. Programming should include worship rituals and procedures if lighting is to be successful. An appreciation of client preferences on color, light levels, brightnesses, manual and automated technologies, and style and design is a must. An understanding of client priorities such as initial and operating costs, leadtime, comfort, sustainability, and project life cycle is also necessary. Details on worship range from entertainment needs to how much time and what times are spent at worship. Some congregations express beliefs through music and performance. For lighting of relatively straightforward entertainment events, see AUDITORIA/Performance citations in Table 24.2 | Educational Facilities Illuminance Recommendations. For professional stage situations, stage lighting should be designed by

Figure 37.9 | Conventional Daylighting
Where siting, orientation, and architectural configuration offer conventional daylighting approaches, T_{vis} of glazing and shading must combine to provide appropriate conditions. Here, west sky at late-afternoon mass would be problematic without glazing T_{vis} of 18% and additional shading available with T_{vis} of 5% for an aggregate T_{vis} of about 1%. Top image is without shades deployed. Surfaces adjacent and opposite the daylight apertures are lighted to balance luminances and limit harsh contrasts. Focal areas are electrically lighted to overcome silhouetting of celebrants and focal elements. Liturgical presets could be used to automate and combine electric light and shading control for various liturgical functions. However, in this situation it was determined that automated shade control would disrupt services at various times of the year and sky conditions.

theater lighting designers. See IES DG-20 | Stage Lighting A Guide to the Planning of Theatres and Auditoriums for guidance on architectural and electrical infrastructure

Lighting can only be appropriately tailored to a congregation's needs if a high degree of familiarity with the ceremony is known. Similar to the programming steps on other application types, visits and reviews of existing situations, including observing at least one worship service is recommended if the designer is not familiar with the liturgy.

Addressing all code requirements is a must. Energy efficient and sustainable practices are an integral part of all IES recommendations. Key design tenets include, but are not limited to:

- designing for the satisfaction of the observers intended to use the project
- using baseline reflectances of 90-60-20 (percentage light reflectance values [LRVs] of ceilings, walls, and floors respectively) in interior production and work-oriented spaces
- using daylighting that meets luminance and illuminance criteria
- using highest-efficacy lamps that meet color, optical and electrical control, and output criteria
- using highest-efficiency luminaires that meet aesthetic and luminance criteria
- using accenting to provide luminance balancing or improve brightness perceptions where necessary
- using controls liberally, preferably automated varieties such as presets, occupancy and vacancy sensors, astronomical time clocks, and photocells
- establishing IES-recommended illuminance criteria to meet programmed tasks
- establishing layouts that just meet IES-recommended illuminance criteria
- addressing outdoor environmental needs
- using calculations, photometrically-realistic renderings, and operational samples and mockups to prove concepts
- identifying and designing to code-specific requirements, if any, for ambient, task, and accent lighting
- documenting all code-, energy-, sustainability-, and IES-criteria compliance
- documenting criteria and design deviations and rationale and subsequent disposition by team, client, or AHJ
- documenting clearly the layouts, controls, and luminaire and lamp selections

Designing for the satisfaction of the observers is the paramount design tenet and must be kept in perspective during all aspects of design. If the observers' expectations are not fulfilled, then how much energy could be saved is moot, as is how many fewer earth resources were spared, as is how much the whole affair cost or how much value engineering saved or the photogenic qualities of the project. See sidebar references for additional guidance on the key tenets. The design effort must be undertaken with coordinated and realistic expectations by all involved on initial and life cycle costs. Budgeting should include designer input and dialogue with the team and client at project commencement and design milestones. In other words, and paraphrasing Thomas Edison, genius is, indeed, just 1% inspiration and 99% perspiration.

INDEX

This index serves the usual function for a user who has a particular word or narrow topic in minde and needs pointing to a particular page. All references are given as chapter and page number. The material presented here also functions as a synopticon: giving a general view, summary, or snyopsis of the principal parts of a subject. A word or phrase for a general topic is followed by an outline of its most important aspects covered in this handbook. Indenting is used to group related material and to indicate the level of detail of the entry. These short outlines can be used as checklists of the design tasks.

Parameters Important to Suprathreshold Visual Performance 4.20
Speed and Accuracy 4.20
Suprathreshold Response 4.20
Target Luminance Contrast 4.20
Target Size 4.20
Task Contrast and Size 4.20
Viewing Time, Search, and Task Eccentricity 4.21
Motor Components 4.19
Performance of Visual Tasks 4.19
Productivity 4.19
Relative Visual Performance 4.22
Adaptation Luminance 4.22
Escarpment 4.22
Light Distribution 4.22
Light Polarization 4.22
Luminance Contrast 4.22
Nonvisual Components of Performance. 4.22
Realistic Tasks Performed At Suprathreshold Visibility 4.22
Relative Visual Performance (RVP) Model 4.22
Visual Size 4.22
Task Performance 4.19
Visual Components 4.19
Visual Performance 4.19
Visual Photometry 9.3
Brightness Matching 9.3
Individual Observers 9.3
Visual Appraisal 9.3
Size, Parameters of Perception 4.4
Tasks, Lighting Design Task Factors 12.12
Visual System Above the Eye 2.10
Channels 2.10
Geniculate Nucleus 2.10
Geniculate Nuclei 2.10
Geniculate Nucleus 2.10
Magnocellular 2.10
Parvocelluar and Magnocellular Channels 2.10
Parvocellular 2.10
Layers of the Visual System 2.10
Optic Nerve 2.10
Lateral Geniculate Nucleus 2.10
Optic Chiasm 2.10
Optic Tracts 2.10
Perceptions and Performance 2.12
Brightness 2.12
Chromatic Channels 2.12
Color 2.12
Depth 2.12
Lightness 2.12
Receptive Fields 2.12
Spatial Channels 2.12
Temporal Channels 2.12
