Foreword

Coping with Global Environmental Change, Disasters and Security – Threats, Challenges, Vulnerabilities and Risks is the fifth volume in the *Hexagon Series on Human and Environmental Security* and Peace and it completes the *Global Environmental and Human Security Handbook for the Anthropocene*.

This handbook addresses scientific issues of utmost importance for UNEP. In calling for a 'Fourth Green Revolution' the concluding chapter endorses the Global Green New Deal/Green Economy Initiative (GEI) launched during the unfolding financial and economic crisis of late 2008: At the time, few may have thought that it would gain such rapid traction.

However, it is estimated that around 15 per cent of more than $3 trillion-worth of stimulus funds are green in nature, with that rising to around 80 per cent in the Republic of Korea. Within a relatively short space of time, terms such as Green Economy and Green Growth have become common parlance in many capital cities and at key international gatherings, including G8 and G20 summits and ministerial sessions of the OECD.

The urgency of the challenges facing all economies, from climate change to ecological losses, allied to the need to deliver growth, overcome poverty and generate employment, are more apparent with every passing year and every new decade. The Green Economy is taking root in diverse economies and geographical locations, all allied by a common need.

More than two dozen governments have requested the UN Environment Programme's (UNEP) assistance and advice how best to tailor a transition to a low carbon, resource efficient Green Economy within national development strategies and economic planning. In China, UNEP is collaborating with the Ministry of the Environment and relevant institutions to produce a series of sectoral green economy studies, which will feed into the country's five year development plan.

A Green Economy Initiative for Africa is in preparation and studies are underway in Eastern Europe, the Caucasus and Central Asia looking at the prospects for promoting organic agriculture. In West Asia, priority sectors for catalyzing a Green Economy have emerged following discussions in countries including Bahrain, Dubai and Jordan to Kuwait, Lebanon and Saudi Arabia.

These exciting opportunities dovetail with the acceleration of Technology Needs Assessments under the framework of the UN Framework Convention on Climate Change (UNFCCC). The assessments are being supported by the Global Environment Facility. Up to 45 countries are to be assisted in prioritizing technologies for both mitigation and adaptation to climate change, as well as investigating and overcoming potential legal, financial, policy and other barriers to their uptake.

The first wave of 15 countries have been selected ranging from Cote D'Ivoire and Mali in Africa; Bangladesh, Cambodia and Indonesia in Asia to Argentina and Guatemala in Latin America and Georgia in Europe. With more carbon dioxide in the atmosphere now than at any time in the past 650,000 years, it's evident that these types of measures are imperative to deal with the growing climate crisis.

The Green Economy could be the biggest innovation project in history breaching the divide as the economic models of the 20th century look less and less able to serve a planet of six billion, rising to nine billion by 2050.

This book, looking at global environmental change, details threats to our future wellbeing and our security. We live in a rapidly evolving world. Sixty per cent of the world's largest urban areas, with a population of over 5 million, are located within 100 km of the coast. The current climate footprint from buildings is equivalent to 8.6 billion tons of CO_2 a year, and predicted to almost double to 15.6 billion tons of CO_2 by 2030. Every year an estimated $2 to $5 trillion is lost-almost without notice or comment from the global economy, as a result of the degradation and destruction of the planet's nature-based resources.

The public is looking to its leaders and its policy-makers for solutions. It's time to combine policy choices that work long-term, combined with supportive market mechanisms to "green" our economies, lifestyles and jobs. Together we can perhaps provide a route to sustainable development that to date has eluded human-kind. In investment terms, it a low risk, high and sustainable growth investment portfolio for the planet.

So I welcome this volume on *Coping with Global Environmental Change, Disasters and Security – Threats, Challenges, Vulnerabilities and Risks* and its 95 peer-reviewed chapters as an eye-opener to both the challenges but also the opportunities of our age. I hope that private foundations and donors can ensure that its important ideas, debates and essential reading find their way equally onto the library book shelves of the South as well as the nations of the North.

Nairobi, in June 2010

Achim Steiner
UN Under-Secretary General and
Executive Director,
UN Environment Programme (UNEP)

Foreword

This 5th volume of the Hexagon Series on Human and Environmental Security and Peace on *Coping with Global Environmental Change, Disasters and Security – Threats, Challenges, Vulnerabilities and Risks contributes to the task* of the United Nations University to advance knowledge for human security, peace, and development. Written by over 100 experts, it addresses the conceptual linkages between the four key goals of the United Nations system of security, peace, development and the environment.

It also completes the embedded three volumes on *Global Environmental and Human Security Handbook for the Anthropocene* (GEHSHA) within the Hexagon Series.

This book addresses in 95 chapters key environmental and human security issues from the perspective of many disciplines, cultures and world regions. It reviews the ongoing conceptual debate on security threats, challenges, vulnerabilities and risks. It analyses military and political hard and soft security dangers and concerns and assesses economic, social, environmental and human security issues especially in the Middle East, North Africa and Asia. It also includes selected results of a summer academy organized by the Munich Re Foundation and the Institute for Environment and Human Security of the United Nations University (UNU-EHS) on urban centres and agglomerations as vulnerability hot spots. Senior UNU-EHS scientists write on strategies for coping with social vulnerability and resilience building during and after the occurrence of hazard events.

Altogether 28 chapters deal with adaptation to and coping with Global Environmental Change focusing on climate change, soil degradation and desertification, water management and food and health security issues. An additional 16 chapters address scientific, international, regional and national political coping strategies, policies and measures. Finally, the remaining seven chapters deal with remote sensing, vulnerability mapping and indicators of environmental security challenges and risks, with improved early warning of conflicts and hazards and propose a 'political geoecology' for the Anthropocene and a new 'Fourth Green Revolution'.

Of the eight editors of this major scientific reference book, two women from Mexico and Kenya and six men from Europe and North Africa, three have been or are associated with UNU-EHS. This book contributes to the mission of the United Nations University system "to resolve the pressing global problems of human survival, development and welfare that are the concern of the United Nations, its Peoples and Member States" by relying on the knowledge generated by the social sciences and humanities as well as natural sciences based on a "holistic approach to the complex problems that affect human security and development".

This unique compilation of global scholarship is thought provoking, analytical and very comprehensive. It deserves many readers from all walks of life. It, like the other issues of the Hexagon Series, should be available for those seeking in depth knowledge of the complexities and security implications of the linked social-environmental system we live in.

Tokyo, May 2010

Konrad Osterwalder
Rector, United Nations University
Under-Secretary-General of the
United Nations

Foreword

"Coping with Global Environmental Change, Disasters and Security Threats, Challenges, Vulnerabilities and Risks" is a burning issue today.

Climate change is a threat to vital resources and can provoke major social, economic and political problems. As such, it has major security dimensions and could act as a "threat multiplier" by increasing conflict and instability in several regions.

This was already the subject of a workshop that was co-sponsored in 2005 by NATO's Public Diplomacy Division. The book collates the results and recommendations of this workshop and constitutes a reference to security issues in this field. It raises awareness on global environmental change and its impact on security not only among high-level officials, scientists, but also among citizens. The topics of concern include: environmental security concepts and debates; climate change and security; energy; water; food and health security for the 21st century.

In addition, it will help to identify a roadmap for future multi-disciplinary research to better understand the vulnerability and instability driven by global environmental change.

NATO is looking at the work and discussion related to climate change with great interest. Hence, global climate change is mentioned as a global threat to security in NATO's long-term study on Future Security Environment conducted by Allied Command Transformation.

As an integral part of public diplomacy activities, NATO's Science for Peace and Security (SPS) Programme contributes to security, stability and solidarity among NATO and partner countries, including Mediterranean Dialogue countries, by facilitating cooperation, networking and capacity-building. The main objectives of NATO's SPS Programme are to promote the application of the best technical expertise to problem-solving.

Environmental security has been identified as a key priority for NATO's Partner and Mediterranean Dialogue countries and, in 2008, NATO members agreed that the Science Security Forum would address this issue in-depth by bringing together internationally-recognized experts. The Forum clearly demonstrated the close link between global security concerns and environmental issues related to climate change, management of shared water resources and energy security.

Indeed, public diplomacy has an important role to play in taking the end results of these deliberations to the public in order to explain how these threats impact on human security.

Brussels, January 2010

Jean-François Bureau
NATO Assistant Secretary General for Public Diplomacy
Chairman, Science for Peace and Security (SPS) Committee

Foreword

Coping with Global Environmental Change, Disasters and Security – Threats, Challenges, Vulnerabilities and Risks is the fifth volume in the *Hexagon Series on Human and Environmental Security* and Peace. It completes the *Global Environmental and Human Security Handbook for the Anthropocene*. I am pleased that one of the coeditors is a Kenyan and 16 contributors to the volume are from various parts of Africa, including Egypt, Tunisia, and Mauritania (North Africa), and Nigeria, Ghana, Niger, and Burkina Faso (West Africa). This situation ensures that the diverse security challenges in Africa and how they have been confronted are adequately addressed in the book.

This scientific peer-reviewed volume contributes to crucial global dialogue and learning, based on topical new evidence from several disciplines. In the 20th century, Africa has suffered severely from the effects of global environmental change resulting from desertification, drought, famine, floods and heat waves. Millions of Africans have either been killed or forced to flee their homes.

The fourth IPCC Assessment Report of 2007 estimates that climate change will have several negative impacts on Africa, especially regarding access to clean water, sufficient food, stable health conditions, ecosystem resources, and security of settlements. It further estimates that many semi-arid areas in North and Southern Africa, will become severely water-stressed, and by 2020, between 75 and 250 million people are projected to experience increased water stress. During the same period, yields from rain-fed agriculture in some African countries could be reduced by up to 50 per cent, thus affecting food security and exacerbating malnutrition. Indeed, several African mega-deltas, due to large populations and high exposure to sea level rise, storm surges, and river flooding, will suffer from the impacts of global environmental and climate change. Although Africa has historically contributed little to climate change, the limited adaptive capacity of the countries on the continent has increased the impact of climate change on the continent.

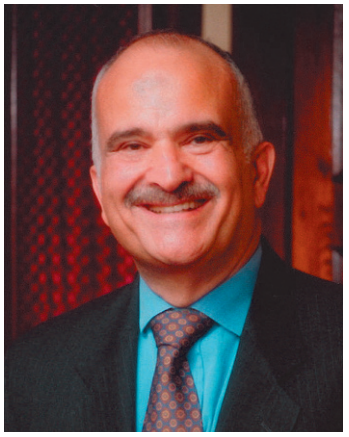
This book, with 95 chapters, reviews the conceptual debate on security threats, challenges, vulnerabilities and risks. It analyses military and political hard and soft security dangers and concerns in West Africa and assesses environmental and human security issues in North Africa. The main parts deal with the challenges of coping with Global Environmental Change, focusing on climate change, soil degradation and desertification, water management, food and health security issues. It also deals with scientific, international, regional and national political remediation strategies, policies and measures. One chapter discusses early warning systems for conflicts in East Africa and two chapters propose a 'political geoecology' for the Anthropocene and a new 'Fourth Green Revolution'.

This huge volume of excellent scholarship from all parts of the world helps to sensitize, not only policy makers but also enable the young generation of professors and students globally but specifically, in the most affected countries in the South. It calls for proactive and concerted action and for a global science partnership to reduce the most debilitating

impact of the projected trends in ëbusiness as usualí strategies. This book deserves many readers in all parts of the world, even in the countries where university and research libraries are unable to afford such books. It is my sincere hope that this high-quality, multidisciplinary study and reference book, and its key messages will be made available to university and research libraries through the support of private foundations and public donors. The young generation in the South that must cope with these challenges to their security in the 21st century must be availed of this book. I wish the book-aid project success for the benefit of university libraries and research institutes and their readers in Africa, Asia and Latin America.

New York, May 2010

Ambassador Prof. Dr. Joy Ogwu
Permanent Representative of the
Federal Republic of Nigeria to the
United Nations



Foreword

Environmentally induced population displacement resulting from climate change is now indisputable. Simultaneously, as noted by the UN High Commissioner for Refugees, António Guterres, it is becoming increasingly difficult to categorize people as displaced by any single cause: conflict, economic marginalization, environmental degradation, climate change, or any other factor, since their fate may be the result of a combination of all or any of the above. The statistics in the report that follow are alarming: 300,000 deaths and 300 million severely affected each year by climate impacts today; currently, 100 billion US dollars of economic losses annually and over 20 million persons displaced; and as so often is the case, it is the poor that are worst affected, with 99 per cent of climate change casualties taking place in developing countries (Global Humanitarian Forum, 2009).

This is a human tragedy on a massive scale. It is also a major threat to global security and could result in global catastrophe costing millions of lives in climate induced wars and natural disasters. Yet governments procrastinate. This is frustrating for the many of us who know that solutions are available – now. But it requires a move away from the failed unilateral strategies of the past.

The world is facing what amounts to an existential crisis in which we are all wholly interconnected – in everything but policy. The West Asia-North Africa region, the intermediary meeting point of Eurasia, home to the greatest concentration of energy reserves, and one of the most populous, poorest, and arguably, most volatile regions of the world, is at the centre of this global crisis. Yet, with approaches inspired by vision and integrity, which place people at the centre, it can also offer solutions.

The international community has a vital role here. Rather than seek to balance power and influence in the region, global security would be better served by fostering collaboration and inclusion in policy and attitude at every level.

In practical terms, this means forging partnerships which bind the region together while looking outwards across the 'energy ellipse' (from the Caucasus to the Straits of Hormuz) and beyond to enable regional stabilization.

It has been universally agreed that we cannot remain dependant on finite fossil fuels, and that the development of alternative energy applications via multilateral consent and cooperation is a way forward.

A regional community employing modern technology could use the region's deserts to develop clean energy. The jobs created in the fields of water desalination and solar energy, together with their service industries, would go some way towards meeting growing demands for employment – estimated by the World Bank as some 100 million new job opportunities required by 2020. Sustainable governance of shared resources would enable us to replace fossil fuels, help in solving ours and

Europe's energy crisis, reduce carbon emissions, slow climate change, and maximize the carrying capacity of the trans-border area.

Our composite security needs can only be addressed by humanizing globalization. The ambitious trans-regional cooperation, envisaged in the DESERTEC project's high tension grid network that would connect European national grids with the WANA region, would foster a new chapter in terms of international energy trade for 'clean, renewable energy'; could secure international energy stability between the EU-Mediterranean countries and hopefully reinvigorate the Barcelona Process. It could provide the impetus for the establishment of not only a much needed community for energy, water, and climate security for the Mediterranean riparian regions of Europe, the Middle East and North Africa, but in due course for a water and energy authority to oversee both the oil rich countries and those of the hinterland. Resource scarcity, resource wealth, and human resource wealth could thus be transformed from a source of conflict into points of cooperation.

It is with this vision of stabilizing the region on the basis of a thematic and integrated approach that puts people, human dignity, and preventive security at the forefront that I recommend this volume of work on *Coping with Global Environmental Change* and hope it will galvanize decision makers into addressing the challenges we face right now.

Amman, January 2010

The Hashemite Kingdom of Jordan

Dedication by the AFES-PRESS Board

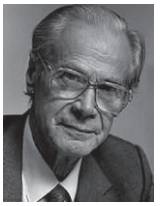
This book is dedicated to a founding mother and two founding fathers
of the first generation of international peace research

Prof. Dr. Elise Boulding

*6 July 1920 in Oslo (Norway) + 24 June 2010 in Needham, MA (USA)

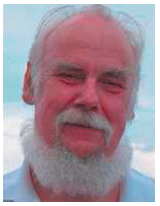
Prof. of Sociology, Dartmouth College, NH (USA)
Secretary General of IPRA (1988–1990)

Prof. Dr. John W. Burton



*2 March 1915 in Melbourne +23 June 2010 in Canberra

Signer of the UN Charter in June 1945 San Francisco
Civil Servant, international relations specialist and academic teacher



Prof. Dr. Håkan Wiberg

*12 June 1942 in where in Sweden + 3 July 2010 in Copenhagen

Professor of Sociology, University of Lund (1981–2007)
Director, Copenhagen Peace Research Institute (COPRI, 1988–2001)

And as a representative for the women of the world who experienced the horror of war in the 20th century and who conveyed the values of a more peaceful world to their children, we wish to honour here

Irma Brauch

*27 December 1920 in Neuhausen/Erzg. + 21 August 2010 in Mosbach

A mother who inspired her son to become a peace researcher and who created an atmosphere that facilitated the emergence of this handbook

While the three scientists inspired us by their intellectual contributions to peace research Irma Brauch conveyed her devotion to a world without war, human humiliation and injustice and thus to the values and goals of peace research by hosting in her home the AFES-PRESS board, several receptions during international workshops as well as peace researchers, colleagues and friends from all parts of the world with her own homemade cooking and especially with her special cheese cake.

The Board of
Peace Research and European Security Studies (AFES-PRESS) e.V.

Acknowledgements

This volume is the third and final volume of the *Global Environmental and Human Security Handbook for the Anthropocene* (GEHSHA). This handbook in three volumes includes a total of 270 peer reviewed book chapters by some 300 authors from about 100 countries. Early versions of several chapters were presented at a series of workshops that were held in the framework of international scientific conferences between 2004 and 2010 organized by the

- *International Studies Association* (ISA) in Montreal (2004), San Francisco (2008), New York (2009) and New Orleans (2010);
- first and second *World International Studies Conference* (WISC) in Istanbul, Turkey (2005) and Ljubljana, Slovenia (2008);
- *International Peace Research Association* (IPRA) in Sopron, Hungary (2004), in Vancouver, Canada (2006) and in Leuven, Belgium (2008);
- fifth *Pan-European Conference on International Relations* in The Hague, the Netherlands (2004);
- by the fifth and sixth Open Meeting of the *International Human Dimensions Programme* (IHDP) on Global Change in Bonn (2006, 2009);
- during the fourth and fifth *World Water Forum* (WWF) in Mexico City, Mexico (2006) and in Istanbul, Turkey (2009)
- at the *International Scientific Conference on Climate Change* in Copenhagen (2009);
- and at many other conferences, workshops, symposia and expert meetings in the context of scientific and policy-oriented events in many parts of the world.

Financial contributions for these workshops and for the preparation and production of this book were made by the following donors: the Berghof Foundation for Conflict Research in Berlin, the European Commission and NATO in Brussels, the *Netherlands Organisation for Scientific Research* (NOW) in The Hague and by Springer-Verlag in Heidelberg. However, most chapters were commissioned by the editors based on conference appearances of authors or their known published expertise on specific issues.

Hans Günter Brauch is grateful to the Berghof Foundation for Conflict Studies, a private foundation based in Germany. A foundation grant covered a part of the editorial and production costs of this book. He is especially grateful to the founder of the Berghof Foundation, Prof. Dr. rer. nat. Georg Zundel, a former Professor at the University of Munich. For more than three decades, the Berghof Foundation has funded often unconventional, trans- and multidisciplinary and goal-oriented international research and scientific cooperation.

- AFES-PRESS received financial support under grant SNE-3-CT-1003-503699 from the DG Aerospace and Industry, European Commission to cover the costs of an AFES-PRESS research team consisting of three AFES-PRESS board members from Germany, the Netherlands and Poland, of two associated colleagues from Tunisia and Egypt and four Ph.D. candidates from Germany, France and Italy to participate at three workshops during 2004:
  - at the 45th ISA Convention in Montreal Canada, 17–20 March 2004;
  - at the 20th IPRA Conference in Sopron, Hungary, 5–9 July 2004;
  - at the 5th Pan-European Conference on International Relations, 8–11 September 2004.
- AFES-PRESS appreciates a subsidy from NATO contributing to the workshop in The Hague (2005) and in Istanbul (2005) enabling the participation of colleagues from NATO Mediterranean dialogue countries (Algeria, Egypt, Israel, Jordan, Morocco, Tunisia, Turkey) and from Palestine.

The editors of this book would like to thank their institutions for permitting the use of part of their time and their infrastructure for this project:

- *PD Dr. Hans Günter Brauch* would like to thank Úrsula Oswald Spring for her good cooperation, scientific advice, friendship, encouragement and support, Czeslaw Mesjasz and John Grin for their good advice, friendship and support and all co-editors for their devotion and hard work as reviewers and contributors. Without this global team this volume would not have been possible.
- *Prof. Dr. Úrsula Oswald Spring* is grateful to the *Centre for Regional Multidisciplinary Studies* (CRIM) and the *National University of Mexico* (UNAM), for permitting her to allocate a part of her research time to this project. She is also thankful to the *National Network for Water Research* (RETAC) from the *National Council of Sciences and Technology* (CONACYT) for their financial support to attend some conferences. As the first MunichRE chair on Social Vulnerability at UNU-EHS she appreciates the support of UNU-EHS in Bonn and of the MunichRe Foundation. Finally, she wants to thank AFES-PRESS for permitting her to use its research library and office facilities during her stay in Europe in the summers of 2005, 2006 and 2007 and for the intellectually stimulating professional discussions with Hans Günter Brauch.
- *Prof. Dr. Czeslaw Mesjasz* would like to thank Lidia for her patience and support and Hans Günter Brauch for his compassion, hard work, inspiration and friendship.
- *Prof. Dr. John Grin* wishes to thank his fellow editors, especially Hans Günter Brauch, who pairs incredible energy to patience and understanding. He owes his assistant Amy-Jane Gielen for relieving him of many other duties, thus being able to spend time on this volume, and his family for adding the sort of duties which keep one in healthy balance.
- *Prof. Dr. Patricia Kameri-Mbote* would like to thank her husband John Mbote for his unwavering support, patience and friendship. Hans Günter for spurring team spirit and getting work done.
- *Prof. Dr. Béhir Chourou* would like to thank the team of editors for their *esprit d'équipe*, especially Hans Günter Brauch for his particular efforts on behalf of the MENA region. Special thanks go to his wife Zeineb and his daughter Hela for putting up with his peculiar modus operandi when he is working under stress – which seems to be the only work method he knows.
- *Dr. Pál Dunay* would like to thank his spouse and children who have been very patient while he was reviewing chapters and writing his own contributions.
- *PD. Dr-Ing. Jörn Birkmann* likes to express a very special thanks and appreciation to his wife and his daughter for the support while working on the chapter and the various reviews. Furthermore, he would also like to acknowledge his deep gratitude to the UNU Rector, to the former Vice Rector and to the UNU-EHS director as well as to the team of the Vulnerability Assessment Section of UNU-EHS for the continuous support and important comments during the development of the chapter. In this regard he would also like to thank the reviewers and Prof. Heike Egner for important remarks on his own manuscript.
- All eight co-editors are grateful to all anonymous reviewers from all parts of the world and from many disciplines for their devotion and many recommendations to improve the quality of the texts in this *Global Environmental and Human Security Handbook for the Anthropocene* (GEHSHA).
- Last but not least, the 11 co-editors of this *Global Environmental and Human Security Handbook for the Anthropocene* from 10 countries would like to thank the ca. 300 authors from 100 countries on all five continents for their contributions and their reflection of the reviewers' comments in the revised printed versions.

Hans Günter Brauch would like to thank Dr. Christian Witschel, Editorial Director, Earth Sciences, Geosciences Editorial, Springer-Verlag for his support of this project and his patience with an international team and Ms. Almas Schimmel, the producer of this book within Springer-Verlag, for her efficient coordination and implementation of this project, as well as the many other unnamed persons within Springer-Verlag for their devotion to this publication.

All editorial decisions were made by the editors in their personal capacity only. The funders had no influence on the themes of this book and on the views expressed by its authors. None of the authors and editors receives any personal remuneration from this collaborative research project. Any income will be used by AFES-PRESS, a non-profit scientific society under German law, for future projects to further global scientific cooperation including the book-aid project for Third World Libraries.[1]

All editors are grateful to Thomas Bast, who in his quiet and efficient way, acted as the webmaster and produced several versions of the proofs, the whole layout, as well as the index. The editors and the producer would like to thank Ms. Patrizia Kummer, director of D.T.u.L. GmbH in Fellbach near Stuttgart, for permitting the producer to use the infrastructure of her company for this book selflessly. This support has greatly facilitated the work of the producer.

The editors are grateful to Ronald Lappin, the International Programme Director of GBA Ships International e.V., in Mosbach (Germany), for his extremely careful language editing. He speaks many languages and thus he could often anticipate what the non-native speakers intended to express, and adapt the language of most non-native speakers to proper British English.

Last but not least, the editors are grateful to the 164 authors and editors, coming from 48 countries and many scientific disciplines for their contributions to this book and for their readiness to reflect the critiques and suggestions of the anonymous reviewers trying to look beyond the boundaries of their respective discipline and expertise.

The editors are grateful for the contribution of forewords to *Mr. Achim Steiner*, UN Under Secretary General and Executive Director, UN Environment Programme (UNEP); *Prof. Dr. Konrad Osterwalder*, Under Secretary General of the United Nations, Rector, United Nations University; *M. Jean-Francois Bureau*, Assistant Secretary General for Science and Public Diplomacy of NATO; *Her Excellency Ambassador Prof. Dr. Joy Ogwu*, Permanent Representative of the Federal Republic of Nigeria to the United Nations; and to *His Royal Highness, Prince Hassan Bin Talal of Jordan*.

The editors appreciate the preface essays written by distinguished scientists and global policy-makers: *Prof. Dr. Paul C. Crutzen*, Nobel Laureate in Chemistry, Mainz; *His Excellency Amb. Jayantha Dhanapala*, President, Pugwash Conferences on Science and World Affairs, recipient of the Nobel Peace Prize 1995; *Prof. Dr. Ulrich Beck*, University of Munich and LSE; *Dr. Hania Zlotnik*, Director, UN Populations Division, United Nations, New York; *Dr. Christoph Müller, Dr. Hermann Lotze-Campen, Dr. Veronika Huber, Dr. Alexander*

Popp, Dr. Anastasia Svirejeva-Hopkins, Mr. Michael Krause and Prof. Dr. Hans Joachim Schellnhuber, Director, Potsdam Institute for Climate Impact Research.

Finally, the editors would like to thank the photographers of the photos on the book cover that was the result of an intensive discussion among the co-editors on the proper image to reduce the complex messages of the book that address the environmental challenges affecting the human security of affected people in Africa. The Canadian photographer *Finbarr O'Reilly* contributed the image of children in Rwanda who are coping with water scarcity, our author *Ismail Galil Ab del Hussein* of Egypt contributed the photo of the tree surviving in the Sinai while the photo by the French photographer *Pascal Meunier* of El Oued in Algeria addresses the progressing Sahara Desert and human responses in coping with global environmental change, especially with water scarcity, sole erosion and food challenges during this century.

Permissions and Credits

The editors and authors are grateful to the following copyright holders, publishers, authors and photographers who granted permission to use copy-righted material.

The copyright for the photos of the book cover was granted by
- *Prof. Dr. Ismail Abd El Galil Hussein* (Egypt), former chairman of the *Desert Research Center* (DRC) in Egypt for a photo of a tree surviving in the Sinai;
- *M. Pascal Meunier* (France) for a photo on agriculture in the Sahara at El Oued in Algeria;
- *Mr. Finbarr O'Reilly* for the photo of children in Rwanda coping with water scarcity.

The staff of the authors of the forewords supplied the photos and obtained the permission from the photographers and copyright holders to use them:
- The photo of *Mr. Achim Steiner*, Under-Secretary General of the United Nations, Executive Director of UNEP, was provided by the UNEP Secretariat, Nairobi.
- The photo of *Prof. Dr. Konrad Osterwalder*, Under-Secretary General of the United Nations, Rector, United Nations University, Tokyo was provided by UNU, Tokyo.
- The photo of *M. Jean-François Bureau*, Assistant Secretary General for Science and Public Diplomacy of NATO, Brussels was provided by his office, Brussels.
- The photo of *Her Excellency Amb. Prof. Dr. Joy Ogwu*, Permanent Representative of Nigeria to the United Nations, New York was provided by the Nigerian Embassy in New York.
- The photo of *His Royal Highness Prince Hassan Bin Talal* of Jordan, Amman was provided by his staff in the Palace, Amman.

The authors of the preface essays supplied the photos and obtained the permission from the photographers and copyright holders to use them.
- *Prof. Dr. Paul C. Crutzen*, Nobel laureate in Chemistry, Mainz, Germany;
- *His Excellency Amb. Jayantha Dhanapala*, President, Pugwash Conferences on Science and World Affairs, Colombo, Sri Lanka;
- *Prof. Dr. Ulrich Beck*, University of Munich and LSE, Munich, Germany;
- *Dr. Hania Zlotnik*, Director, UN Populations Division, United Nations, New York, USA;
- *Dr. Christoph Müller*, Senior Researcher, and *Prof. Dr. Hans Joachim Schellnhuber*, Director of Potsdam Institute for Climate Impact Research, Potsdam, Germany.

In the preface essay by *Hania Zlotnik* two figures were provided by the author that are in the public domain:
- *Figure PE 4.1*: World population according to different scenarios, 2000-2300. *Source*: UN (2004).
- *Figure PE 4.2*: The world's cities above 1 million inhabitants. *Source*: UN: "World Urbanization Prospects: The 2009 Revision", Press Release, New York, 25 March 2010.

In the preface essay by *Christoph Müller, Hermann Lotze-Campen, Veronika Huber, Alexander Popp, Anastasia Svirejeva-Hopkins, Michael Krause and Hans Joachim Schellnhuber* the two figures were developed by the authors for which permission was obtained:
- *Figure PE 5.1*: Global map showing current dominant land-use types: agriculture (including cropland, managed pasture land and rangeland), forestry, infrastructure and settlement, unused land, and nature conservation based on data that were provided by Erb, Gaube, Krausmann, Plutzar, Bondeau and Haberl (2007).

- *Figure PE 5.2*: Observed global agricultural land-use pattern of 1995 versus globally optimized pattern that would allow feeding 12 billion people with 1995 dietary habits. Figures were taken without modifications from Müller, Bondeau, Lotze-Campen, Cramer and Lucht (2006).

In chapter *2*, *Hans Günter Brauch* is grateful to UNISDR for supplying detailed definitions of disaster risk reduction related terms that are in the public domain and summarized in

- *Table* 2.1: Selected UNISDR key terminology on *Disaster Risk Reduction*. *Source:* UNISDR; at: <http://www.unisdr.org/eng/terminology/terminology-2009-eng.html>.

In chapter 12, *Hans Günter Brauch* appreciates the permission of the authors to reproduce the following two tables:

2 *Table 12.1:* Key Postulates of Neo-Kantian and Neo-Hobbesian world views on the US role in global security. *Source:* Binnendijk and Kugler (2006: 11). Permission for reproduction was granted by the authors.

- *Table 12.2*: Premises of philosophies on national security strategy. *Source:* Binnendijk and Kugler (2006: 164). Permission for reproduction was granted by the authors.

In chapter 20, *Béchir Chourou* has reproduced adapted versions of several figures and tables originally developed in publications by UNU-EHS (tables 20.1, 20.3), of the Millennium Project (table 20.2); the Millennium Ecosystem Assessment (figure 20.1), based on FAO (tables 20.4, 20.5, 20.6, 20.8; figure 20.3), UNECA (table 20.7), AOCRS (figure 20.4), the WRI (figure 20.2) and additional tables were compiled based on EM-DAT of OFDA/CRED (table 20.9) and on the Global Resource Information Database (GRID)/UNEP (figures 20.5, 20.6, 20.7, 20.8, 20.9; tables 20.10, 20.11, 20.12) and UNEP/MAP/Blue Plan (figure 20.11) that are all fully acknowledged and are in the public domain.

In chapter *21, Bassam Ossama Hayek* and *Nisreen Daifallah Al Hmoud* acknowledge the reproduction of

- *Figure 21.1*: Map of Jordan. *Source*: University of Texas at Austin, Perry-Castañeda Library Map Collection; at: <http://www.lib.utexas.edu/maps/middle_east_and_asia/jordan_rel_2004.jpg>. This map is in the public domain.

In chapter *22*, *Marwan Haddad* has used the following figures that are either in the public domain (figure 22.1) or for which permission by the copyright holder (figure 22.2) has been granted:

- *Figure 22.1*: General location Map. *Source*: Amnesty International (2009).
- *Figure 22.2*: The map of the groundwater vulnerability to contamination for the West Bank. *Source*: Qamhieh (2006).

In chapter 23, Hilmi Salem acknowledges the permissions of the copyright holders for the reproduction of the following figures:

- *Figure 23.1*: Historical Palestine within the Current Regional Context. *Source*: ARIJ (2009).
- *Figure 23.2*: The *Israeli Segregation Wall* (ISW) and Segregation Zones in the West Bank. *Source*: ARIJ (2008).
- *Figure 23.3*: The Gaza Strip Surrounded by Three Israeli Buffer Zones. *Source*: ARIJ (2008).
- *Figure 23.4*: The Aquifer Systems in Historical Palestine (including Israel and the OPT). *Source*: Salem and Isaac (2007).
- *Figure 23.5*: The Aquifer Systems in the Occupied West Bank and Gaza Strip. *Source*: Salem and Isaac (2007).

- *Figure 23.6*: The Proposed Red Sea-Dead Sea Conveyance (RSDSC). *Source*: El-Atrash, Salem and Isaac (2008).
- *Figure 23.7*: The Israeli Settlement of Jabal Abu Ghneim (Har Homa) in the West Bank, as developed in a 10-year period (1997-2007): *Source*: ARIJ (2007, 2008).

The tables were compiled by the author based on UN data (table 23.1), of the IPCC chairman (23.5), and on his own data (table 23.2, 23.4) that are in the public domain. For the following table permission was obtained from the copyright holder:

- *Table* 23.3: Changes in the Route of the Israeli Segregation Wall (ISW) between June 2004 and December 2008. *Source*: ARIJ (2008).

In chapter *24*, *Arie S. Issar* is grateful for the permission of the copyright holders to reproduce the following two figures:

- *Figure 24.1*: Precipitation map of Israel and Palestine. *Source*: Based on the map in the Israel Atlas (1995: 27).
- *Figure 24.2*: National Water Carrier, Israel. *Source*: Based on Mekorot's Major Water Plants Map, Mekorot, Israel National Water Co.

In chapter 25, *Mohammed S. Dajani Daoudi* and *Ashraf M. Dajani* appreciate the permission of the copyright holders to use the following maps and photographic reproductions.

- *Figure 25.1*: Map of Jerusalem. *Source*: Hartmann Schedel (1440-1514); Hierosolima (Jerusalem) Liber cronicarum, Nuremberg/Nürnberg 1493 Woodcut, 19.0 x 22.3 cm - Kyram Collection; at: <http://commons.wikimedia.org/wiki/File:Hartmann-schedel-hierosolima-1493_2-BW-1147x965.jpg>. This map is in the public domain.

- *Figure 25.13*: Dome of the Rock, Christian churches, and Jewish cemetery outside the wall. Holy Sites of Muslims, Jews and Christians in Jerusalem. *Source*: Photo by Úrsula Oswald Spring (Mexico). Printed with permission.
- *Figure 25.14*: Al-Haram Sharif and Wall of Mourning: Holy Sites of Jews and Muslims in Jerusalem. *Source*: Photo by Úrsula Oswald Spring (Mexico). Printed with permission.

In chapter 26, *Hans Günter Brauch* appreciates the permission of the copyright holders to reproduce the following four figures:

- *Figure 26.1*: Member Countries of the Union for the Mediterranean (November 2009). *Source:* Brauch (2010: 21) that was provided by the IE in Barcelona.
- *Figure 26.2:* Climate change and food security in the Mediterranean space and changes in agricultural yields until 2020, 2050 and 2080. *Source:* WBGU (2006a).
- *Figure 26.3*: Framework for a causal analysis of migration dynamics. *Source*: Brauch (2000/2001: 111).
- *Figure 26.4*: The best regions for *Concentrated Solar Power* (CSP). *Source:* Jonathan Walters, World Bank: "MENA Concentrated Solar Power", presentation for the Conference on the Mediterranean Solar Plan, Valencia, 11-12 May 2010; at: <http://www.mediterraneansolarplan-conference.es/uploads/documentos/documentos_Jonathan_Walters_World _Bank_9769228b.pdf>. This talk is in the public domain.

The following tables (26.1, 26.2, 26.3, 26.4, 26.5, 266, 26.7, 26.8) were compiled by the author based on publicly available data. For these tables (26.10, 26.11, 26.12) the sources are in the public domain, while for the remaining tables permission was obtained from the copyright holders or are available for scientific purposes.

- *Table 26.9*: Impact of climate change on water availability, drought and flood occurrence in Europe for various time slices and under various scenarios based on the ECHAM4 and HadCM3 models. *Source*: IPCC (2007a: 550).
- *Table 26.13*: Cereal balance for MENA countries. *Source*: Bruinsma (2003). The copyright holder is FAO.
- *Table 26.14*: Increase in number of migrants in Spain (1975-2005). *Source*: Population Division of the DESA of the United Nations: *Trends in Total Migrant Stock. The* 2005 *Revision*; at: <http://esa.un.org/ migration> (16 October 2006).
- *Table 26.15*: Migrants from five North African countries to five South European EU states. *Source*: Fargues (2006: 24-25) based on Fargues (2005).

The references in box 26.1 were taken from a public document of the European Commission that is in the public domain.

In chapter 27, *Jenniver Sehring and Ernst Giese* reproduced a figure that is in the public domain:

- *Figure 27.2:* Impact of climate change on environmental risks in the Fergana valley, Uzbekistan. *Source*: Philippe Rekacewicz (UNEP/GRID/Arenal 2005); at: <http://maps.grida.no/go/graphic/climate_change_and_natural_disaster_impacts_in_the_ferghana_valley>. Printed with permission.

In chapter 29, *Mark Pelling* has developed a table he co-authored with colleagues further in

- *Table 29.3*: Six aspects of human vulnerability to climate change. *Source*: Based on Satterthwaite, Huq, Pelling, Reid and Lankao (2008).

In chapter 31, *Mabel C. Marulanda, Omar D. Cardona* and *Alex H. Barbat* used for the compilation of their tables data of the *DesInventar* database of IDEA, ERN-Colombia and of the World Bank that are either in the public domain and do not require permission:

- *Table 31.1*: Number of small and medium disasters in Colombia (1971-2002). *Source*: *DesInventar* database, La RED (2004).
- *Table 31.2*: Gross figures of effects as a result of small and moderate disasters. *Source*: *DesInventar* database, La RED (2004).
- *Table 31.3*: Effects per local event on average. *Source*: DesInventar database, La RED (2004).
- *Table 31.4*: Comparison between the effects due to small and extreme disasters. *Sources*: *DesInventar* database, La RED (2004), and report on small disasters for National Department of Planning, ERN-Colombia (2005).
- *Table* 31.5: Estimated cost of losses and damage caused by small disasters, in 1,000 US$. *Source*: Based on the methodology of the IDB-IDEA Programme of Indicators, IDEA (2005a/b).
- *Table 31.6*: Losses of extreme hazard events, in current million dollars and in percentage of GDP. *Source*: Extreme events, report on small disasters for National Department of Planning, ERN-Colombia (2005).
- *Table 31.7*: Accumulated losses of small disasters in million US$ and percentage of the agricultural GDP. *Source*: For the estimate the GDP of the last year of each period was taken using data by the Word Bank (2003).
- *Table 31.8*: Accumulated losses from small disasters in million US$ and percentage of construction GDP. *Source*: For estimates, the GDP was taken of the last year of each period using data of the Word Bank (2003).
- *Table 31.9*: Accumulated losses of small disasters in million US$ and percentage of GDP of Colombia. *Source*: For estimates, the GDP was taken of the last year of each period using data of the Word Bank (2003).

In chapter 32, *Carmen Lacambra* and *Kaveh Zahedi* developed several figures (32.1, 32.2) and compiled several tables based on data that are in the public domain or on their previous publications. They appreciate the permission of the copyright holder to use the following photos from the archives of the newspaper *El Universal*:

- *Figure 32.3*: Occurrence of natural disaster events in Latin America and the Caribbean by decade (1900-99). *Source*: Chaveriat (2000: 29, chart 1.3).
- *Figure 32.5*: Claiming land in a mangrove swamp in Cartagena (Colombia). *Source*: Photo: Correa, *El Universal* (14 November 2008); at: <http://www.eluniversal.com.co/>.
- *Figure 32.6*: Deteriorated mangrove in Cartagena (Colombia). *Source*: Archive, *El Universal* (September 2008).

They also compiled several tables (32.2, 32.3) based on data from the Desinventar database and on other cited sources that do not require permission.

- *Table 32.5*: Status of coral reefs in Central and South America. *Source*: Modified from Wilkinson (2004).
- *Table 32.6*: 20 indicators more frequently reported to be used in vulnerability analyses. Indicators are presented in order and according to frequency of use. *Sources*: Brooks/Adger/Kelly (2005); Blaikie/Cannon/Davis/Wisner (1994); Mancilla (1996); Cardona (2003); Adrianto/Matsuda (2002); Alcantara-Ayalam (2002); Briguglio (2003); UNEP (2005); Chang (2004); Bush/Neal/Young/Pilkey (1999); FAO (2001).
- *Table 32.8*: Characteristics of the region's coastal areas. *Sources*: Alonso/Ramirez/Diaz/Segura/Castillo/Chatwin (2007: 31); Chatwin (2007); CIA Factbooka; CIEb;

DANE (2005)c INE (2001)d; INEC-Costa Rica (2000)e; INEC-Ecuador (2001)f; INEC-Nicaragua (2005)g; Ministerio de Economia – El Salvador (2007)h; PNUMA (2003); Restrepo/Kjerfve (2004); Rodriguez/Windevoxhel (1998:11); WRI (2003).

In chapter 33, *Monalisa Chatterjee* compiled five tables that are based on the author's own field research in Mumbai.

In chapter 34, *Reena Singh* designed two figures based on her own household survey and adapted a third figure of UN Habitat that is in the public domain:

- *Figure 34.1*: Causes and Implications of Inadequate Water and Sewerage in Urban Areas *Source*: Designed by the author, adapted from UN Habitat (2003: 103).

Furthermore, she compiled three tables based on her own survey data and on information that is in the public domain:

- *Table 34.1*: Trends in population growth, water, and sewerage in Delhi. *Source*: CPCB (2004: 14).

In chapter 35, *Nanda Kishor* used a map of Hyderabad that is in the public domain:

- *Figure 35.2*: The three sites of displacement in the mega city of Hyderabad: 1) MMTS station Lakdikapool; 2) Cyberabad Info Tech park; and 3) the International Airport. *Source:* Corporate Infobase Ltd. and Municipal Corporation of Hyderabad; at: <http://www.ghmc.gov.in/hyd/hydmap.asp>.

He also compiled a table based on data of the World Bank (35.1) that are in the public domain and he reproduced a table for which permission was obtained from the copyright holder.

- *Table 35.2*: Presence of resettlement and rehabilitation policies in India. *Source*: Cernea (1996).

In chapter 36, *Xiaomeng Shen*, reproduced two figures and compiled one table that are either in the public domain and for which she obtained permission from the copyright holder:

- *Figure 36.1:* Gross domestic product of the Changjiang River Basin (2000). *Source*: Shi (2003: 108).
- *Figure 36.2*: Retention areas in Wuhan. *Source*: Wuhan Chengshi Guihuaju (2003).
- *Table 36.1*: Overview of the ten flood events with most people killed. *Source*: Université Catholique de Louvain, Brussels, Belgium, EM-DAT: The OFDA/CRED International Disaster Database; Created on: 2 June 2009. Data version: v12.07; at: <www.em-dat.net>.

Three tables (36.1, 36.2, 36.3) are based on EM-DAT, the OFDA/CRED International Disaster Database; Created on: 2 June 2009 that is maintained by CRED of the Université Catholique de Louvain, Brussels, Belgium and for the fourth she obtained permission of the copyright holder.

- *Table 36.4*: Overview of the five freshwater flood events with most people killed. *Source*: Jonkman (2005: 158).

In chapter 38, *Ebru A. Gencer* acknowledges that this chapter relies on her Ph.D. thesis that was published as: Gencer, Ebru, 2008: *Natural Disasters, Vulnerability, and Sustainable Development: Examining the Interplay, Global Trends and Local Practices in Istanbul* (Saarbrücken: Vdm Verlag Dr. Müller, 2008).

She illustrated her chapter with her own photographs (figure 38.8, 38.10) and of a previous paper (38.9). Several figures (38.1, 38.2, 39.3, 39.4, 39.6, 39.7) are in the public domain and for the remaining two figures and one table she obtained permission from the copyright holder:

- *Figure 38.5*: Distribution of intensities after a Mw=7.5 Earthquake. *Source*: Erdik, Durukal, Biro, Siyahi and Akman (2001).
- *Figure 38.9*: Selected districts in project. *Source*: Author's adaptation of *Expected Earthquake Shaking Map of the Istanbul Metropolitan Area*, in: *International Urban Planning Studio: Disaster Resistant Istanbul.* Final Report (New York: Columbia University, Graduate School of Architecture, Planning and Preservation, Urban Planning Program). *Source*: NEHRP Soil Classification Map for Istanbul 1997.
- *Table 38.1*: Selected demographic data of Istanbul and of the three project districts. *Sources*: Data from the State Institute of Statistics (SIS) Census Results (TCBDE 2002); IMM Statistics for Istanbul (BB); SIS News Bulletin (TCBDE 1997); Bekar (2002); Yapi (2006a); and IEMP (Gülersoy/Eyidoğan/Gülkan/Türkoğlu/Erkut/Tezer 2003): 119; Ökten/Şengezer/ Dinçer/Batuk/Koç/Gül/Evren/Seçkin/Çekiç/Emem (2003): 276).

In chapter 39, *Adeniyi Sulaiman Gbadegesin, Felix Bayode Olorunfemi* and *Usman Adebimpe Raheem* have reproduced two maps that are in the public domain (39.1, 39.3). The written permission to reproduce two photos by David Simon was granted on 9 October 2009:

- *Figure 39.2*: Inappropriate construction of residential buildings on urban wetlands, Bariga, Lagos. *Source*: Photo by D. Simon (2007: 22).
- *Figure 39.3*: Houses in Bariga on stilts over Lagos Lagoon. *Source*: Photo by D. Simon (2007: 26).

The authors compiled ten tables that are based on data that are either in the public domain (39.1, 39.2, 39.3, 39.4, 39.5, 39.8, 39.9) or based on their own research (39.6, 39.7, 39,10). In three boxes they reproduced excerpts from newspaper and journal articles within the fair use:

- *Box 39.1*: People under siege: "We are Dying". *Source*: TELL Magazine (19 April 2004: 49).
- *Box 39.2*: Panic as Toxic Smoke Covers Lagos. *Source*: Vanguard (13 October 2005: 46).
- *Box 39.3*: Climate Change Risks and Response in the megacity of Lagos. *Source*: Mehrotra, Natenzon, Omojola, Folorunsho, Rosenzweig and Rosenzweig (2009).

In chapter 40, *Debarati Guha-Sapir* and *Femke Vos*, have used 16 figures, 13 tables and 1 box that are all based on the EMDAT developed and maintained by CRED at the Université Catholique de Louvain, Brussels, Belgium, EM-DAT.

In chapter 41, *Steffen Bauer* reproduced two figures from the WBGU's (2007, 2008) report on *Security Risk Climate Chang*e to which he was actively contributing. These figures are in the public domain.

In chapter 42, Jürgen Scheffran modified a figure he previously published with a colleague:

- *Figure 42.6*: Conflicting and cooperative relationships between two actors making efforts to achieve value goals according to given action rules. *Source*: Modified from Scheffran/Hannon 2007: 82.

In chapter 44, *Carlo Buontempo, Jens Kristian Lørup, Michael Sanderson, Michael Butts, Erika Palin, Rachel McCarthy, Richard Jones, Richard Betts* and *Mamdouh Antar* used a NASA satellite image (44.1) that is in the public domain and other figures of the Met Office Hadley Centre (44.2, 44.3, 44.4, 44.5, 44.6) under the terms of the British Crown Copyright.

- *Figure 44.1*: This satellite image shows the northern portion of the Nile which is being modelled as part of the case study. At the apex of the delta is the Egyptian capital city

of Cairo. *Source*: Courtesy NASA/JPL-Caltech; at: <http://www.jpl.nasa.gov/imagepolicy/>.
- *Figure 44.2*: The rainfall comparison between the regional climate model output and the driving GCM. *Source*: Met Office Hadley Centre. ©British Crown Copyright.
- *Figure 44.3*: Schematic layout of the project. *Source*: Met Office Hadley Centre. ©British Crown Copyright.
- *Figure 44.4*: Comparison between one of the five regional climate model simulations (left) and the climatology (CRU) for June, July and August. *Source*: Met Office Hadley Centre © British Crown copyright.
- *Figure 44.5*: Monthly temperature and precipitation for different ensemble members. *Source*: Met Office Hadley Centre. ©British Crown Copyright.
- *Figure 44.6*: Rainfall percentage difference (blue +100 per cent and above red -100 per cent) between two different projections. *Source*: Met Office Hadley Centre. ©British Crown Copyright.

In chapter 45, *Mohamed El Raey* reproduced several satellite images by NASA (45.1, 45.2), figures of the US Mapping Agency (45.4) and of Egyptian government institutions (45.8, 45.9) that are in the public domain and figures of his co-authored publications (46.6, 45.7) and of his colleagues (46.5, 45.13) with their permission. For the following remaining figures written permission was obtained:
- *Figure 45.3*: Contour map of the Nile delta region indicating areas of the delta below sea-level (in red), the 2m contour and below in yellow. *Source*: Sestini (1991) with modifications by El Raey.
- *Figure 45.8*: A map of Alexandria districts and Lake Maryut. The water surface of the lake is kept at 2.8m below sea-level by a set of pumping stations at El Mex. *Source*: This official map is in the public domain.
- *Figure 45.9*: The main topographic features of Alexandria City indicating major ridges or hills (in dark black) and tunnels in between. *Source*: Abdel Hakim, Sobhy (1958); *Alexandria City* (Alexandria Library 1958).
- *Figure 45.10*: Land cover and land use of Alexandria City as observed based on an analysis of satellite images. *Source*: Al Hosaini (2006).
- *Figure 45.11*: Percentage land-use to be affected by scenarios of sea-level rise in Alexandria. *Source*: Al Hosaini (2006).
- *Figure 45.12*: Loss of employment in each district of Alexandria City by various scenarios of sea-level rise. *Source*: Al Hosaini (2006).
- *Figure 45.14*: The location of the city of Port Said on the tip of Suez Canal, surrounded by water bodies and indicating high vulnerability of the city to potential impacts of sea-level rise. *Source*: Sestini (1991: 547).
- *Figure 45.15*: Distribution of groundwater salinity in ppm in the Nile delta region in the year 2000. *Source*: Gaamea (2000) cited in Frihy (2003).

The data used in table 45.1 rely on (UNDP 2005) and in table 45.2 on a co-authored previous publication (El Raey/Fouda/Nasr 1997).

In chapter 46, *Hans Juergen Boehmer* included four photographs that were taken by himself (46.2) and his colleagues Jutta Pscherer (46.1, 46.3b), Dieter Mueller-Dombois (46.3a) and Manfred Denich who gave their written permission.
- *Figure 46.1*: Montane rain forest on the island of Hawaii, Kilauea area, ca. 1200 m above sea level. *Source*: Photograph by Jutta Pscherer (2002).
- *Figure 46.3*: Dieback of the foundation species *Metrosideros polymorpha*, montane rain forest, Mauna Kea, island of Hawaii. *Sources*: a) aerial photograph by Dieter Mueller-Dombois (1972); b) Jutta Pscherer (2002).

- *Figure 46.4*: Managed montane rain forest with indigenous coffee shrubs (*Coffea arabica)*, Kayakela Forest, Kafa zone, south-west Ethiopia. *Source*: Photograph by Manfred Denich (2004).

In chapter 47, *Hans Günter Brauch* and *Úrsula Oswald Spring* have reproduced two figures (47.1, 47.2) of their publication for UNCCD (Brauch/Oswald Spring 2009) and they obtained permission to use the following three maps:

- *Figure 47.3*: Country progress in reducing the global hunger index (percentage decrease in 2009 GHI compared with 1990 GHI. *Source*: IFPRI (2009: 12). Reproduced with permission from the International Food Policy Research Institute.
- *Figure 47.4*: Armed conflicts (1989-2008). *Source*: UCDP/PRIO Armed Conflict Dataset v5-2009; at: <http://www. prio.no/CSCW/Datasets/Armed-Conflict/UCDP-PRIO/>.
- *Figure 47.5*: World map of Environmental Conflicts (1980-2006). *Source*: WBGU (2008: 32). This map is in the public domain.

Furthermore, they compiled table 47.1 based on information of EM-DAT: The OFDA/CRED International Disaster Database developed and maintained by the Université Catholique de Louvain - Brussels – Belgium and in table 47.2 they referred to four scenarios for combating desertification from the Millennium Ecosystem assessment (MA 2005a: 11).

In chapter 48, *Uri Safriel*, acknowledges that this chapter is partly based on a lecture delivered at the conference "Desertificacion y Seguridad Ambiental: consecuencias y prevención", 9–11 March 2006 in Madrid that was published as: "Alternative livelihoods for attaining dryland sustainability", in: Rubio, Jose L.; Andrew, Vincent (Eds.): *Human and socioeconomic consequences of desertification* (Las Palmas: Universidad de Las Palmas de Gran Canaria, Servicio de Publicaciones y Difusion Cientifica de la ULPGC, 2009): 161 – 190. Figures 48.1, 48.4 and 48.10 are in the public domain and in figure 48.7 the author used his own photo. He is grateful to the copyright holders for permission to use the following figures or to adapt them for this chapter. Figures 48.8 and 48.9 were adapted from figures under the fair use provision:

- *Figure 48.8*: Scheme of aquaculture-agriculture hybrid. *Source*: Adapted from Rothbard/Peretz (2002); permission was granted by the copyright holder.
- *Figure 48.9*: Aquaculture sites in Egypt. *Source*: Adapted from Salem (2006); at: <http://www.fao.org/figis/servlet/static?dom=countrysector&xml=naso_egypt.xml>.

The author appreciates the permission of the copyright holder to use these two photos:

- *Figure 48.5*: Landscape manipulation for water harvesting supporting afforestation in an arid dryland (Negev Desert, Israel). *Source*: Photo by Keren Kayemet Le'Israel (JNF).
- *Figure 48.6*: Commercially provided colonies of bumblebees for pollination within a greenhouse in Israel's semi-arid region. *Source*: BioBee (2006); at: <http://www.bchothouse.com/greenhouse-3.html>.

In chapter 49, *Zafar Adeel* acknowledges the permission to use this copyrighted material in

- *Figure 49.1*: Sand dune encroachment, like this example in an Algerian village, is misconceived to be the only type of desertification, ignoring the broader examples of persistent declining natural resource provisioning. *Source*: Photo by © Photo by Houcine Khatteli. The author never replied to the request for permission.
- *Table 49.1*: The number of migrants in selected countries, shown also as a fraction of the global number of migrants and national population. *Source*: Adapted from Renaud, Bogardi, Dun and Warner (2007).

In the following figures and tables the author adapted material from previous publications of which he is a either co-author or that is in the public domain:

- *Figure 49.2*: Key statistics for dryland countries (excluding OECD or developed countries). Drylands are classified according to the climatic conditions as *dry sub-humid*,

semi-arid, *arid* or *hyper-arid*; this classification is based on the values of the Aridity Index, which is the long-term mean of the ratio of an area's mean annual precipitation to its mean annual potential evapotranspiration. *Source*: Safriel and Adeel (2005).
- *Table 49.2*: Comparison of economic and social indicators in developing dryland countries. *Source*: Column 2: Adeel/Safriel/Niemeijer/White/de Kalbermatten/Glantz/Salem/Scholes/Niamir-Fuller/Ehui/Yapi-Gnaore (2005); column 3-5: UNDP (2007).
- *Box 49.1*: WTO's Agreement on Agriculture. *Source*: Adapted from the Millennium Ecosystem Assessment (Hassan/Scholes/Ash 2005).

In chapter 50, *Ismail Abd El Galil Hussein* used the following figures and tables based on material by the government of Egypt or the UN that is in the public domain:
- *Figure 50.1*: Map with the aridity index of Egypt. *Source*: Ministry of Agriculture and Land Reclamation. Desert Research Center (DRC), RS & GIS Unit, Mataria, Cairo.
- *Figure 50.2*: Agro-ecological zones of Egypt.
- *Figure 50.3*: Egyptian population (1897-2017). *Source*: Ministry of Water Resources and Irrigation.
- *Figure 50.4*: Water share in Egypt per capita/m3 (1897-2010). *Source*: Ministry of Water Resources and Irrigation.
- *Table 50.2:* Population density in several governorates of Egypt in 2009. *Source*: Annual Report 2009 (Cairo: Central Agency for Public Mobilization and Statistics).
- *Table 50.3*: Changes of the population size (in thousands) and of the urban population in Egypt (1950-2050) for the medium variant. *Source*: UN (2009, 2008); at: <http://esa.un.org/unpp/p2kodata.asp>.

Figure 50.5 is a photo by Ismail Abd El Galil Hussein and for table 50.1 the copyright holder could not be traced:
- *Table 50.1*: Percentage of hyper-arid, arid, semi-arid, and humid drylands in the Arab world. *Source:* Meigs (1953: 203- 209).

In chapter 51, *Tulio Arredondo Moreno* and *Elisabeth Huber-Sannwald* used the following figures, tables and boxes that are either in the public domain or were drafted or compiled by the authors for which no permission is needed:
- *Figure 51.1*: Administrative Districts in Mexico, 1990. *Source*: OECD (1998: 38).
- *Table 51.2*: Total human population growth between 1910 and 2004 in the arid lands of Northern Mexico. *Source*: INEGI (2004).
- *Table 51.3:* Hydrologic regions with corresponding total concessioned volume of water, average availability, pressure on the watershed (percentage of water used in relation to disponibility) and degree of pressure (above 40 per cent corresponds to strong pressure). *Source*: CNA (2007).
- *Table 51.4*: Area and percentage of land belonging to ejidos in each of the states from Northern Mexico for the year 2001. *Source*: INEGI VIII censo ejidal (2004: <http://www.inegi.org.mx/inegi/default.aspx?s=est&c=15688&pred=1>).
- *Table 51.6*: Population growth in Mexico under rural and urban conditions for the past 50 years and projections to the year 2030. *Source*: INEGI (2000) and CNA (2007).
- *Box 51.1*: Drought periods in Mexico associated with social phenomena. *Source*: The text was written by the authors.

Permission was obtained from the copyright holders to use the following material:
- *Figure 51.2*: Map of Mexico's Arid Zones and Deserts of Northern Mexico. Arid and semi-arid regions are enclosed within zone 1. *Source*: Flores-Villela (1993: 264).
- *Figure 51.3*: Four characteristic arid ecosystem types in the Chihuahua Desert.
- *Figure 51.4*: Estimated changes in yield and the stage of grain filling in corn during El Niño years. *Source*: Conde/Ferrer/Araujo/Gay/Magaña/Pérez/Morales/Saturnino (1999).

- *Figure 51.5*: Distribution of areas suitable for corn production in Mexico. *Source:* Flores/Araujo/Betancourt (2003).
- *Figure 51.6*: Image showing the 'water boxes' of the 'entarquinamiento' system, during the process of being flooded and emptied. *Source*: Photo was taken by Jacinta Pelerm Viqueira/Martin Ssanchez Rodriguez/Elvia Lopez Pacheco/Jose Luis Pimentel Equihua/Herb Eling.
- *Table 51.1*: Area dominant land cover types in Northern Mexico in 2000. *Source*: INEGI (2004); Palacio/Bocco/Velásquez/Mas/Takaki-Takaki/Victoria/Luna-González/Gómez-Rodríguez/López-García/Palma-Muñoz/Trejo-Vázquez/Peralta-Higuera/Prado-Molina/Rodríguez-Aguilar/Mayorga-Saucedo/González-Medrano (2001).
- *Table 51.5*: Years of observed and recorded droughts for the Northern States of Mexico. *Source*: Carrillo-Arronte cited by Contreras-Servín (2005: 123).
- *Table 51.7*: Proportional land surface of Northern Mexico affected by drought and projections under future scenarios of climate change (CCC and GFDL-R30 models). *Source*: Hernández-Cerda/Torres-Tapia/Váldez-Madero (2003).
- *Table 51.8*: Collapse of corn prices in relation to costs of agriculture inputs between 1981 and 1994. Estimated to corn prices of 1994. *Source*: Becerra-Moreno (1998).
- *Box 51.2*: Water boxes in La Comarca Lagunera. *Source*: Eling/López-Pacheco/Palerm-Viqueira/Pimentel-Equi-hua/Sánchez-Rodríguez (2001); Palerm-Viqueira/Sánchez-Rodríguez (2002).
- *Box 51.3*: The GGAVATT (*Grupo Ganadero para la Validación y Transferencia de Tecnología*) model to implement sustainable farming technology in the aridlands of Northern Mexico. *Source*: Sánchez-Arroyo (2000).
- *Box 51.4*: Dryland Development Paradigm. *Source*: Reynolds/Stafford-Smith/Lambin/Turner II/Mortimore/Batterbury/Downing/Dowlatabadi/Fernández/Herrick/Huber-Sannwald/Jiang/Leemans/Lynam/Maestre/Ayarza/Walker (2007).

In chapter 52, *Pietro Laureano* acknowledges the use of figure 52.1 from his previous publication (Laureano 2001: 372) that is in the public domain:

- *Table 52.1*: Characteristics of modern and traditional knowledge. *Source*: Laureano (2005).

In chapter 53, *Monique Mainguet, Frédéric Dumay, Lahcen Kabiri* and *Boualem Rémini* have reproduced in the following 11 figures (53.3 to 53.13) photos that were taken by Monique Mainguet and Frédéric Dumay. They acknowledge the use of the following material that is in the public domain:

- *Figure 53.1:* Map of Morocco with location of the Study Area. *Source:* <http://www.voyages-tourisme.com/maroc/grande-carte-maroc.jpg>.

For the following figures permission has been obtained from the copyright holders.

- *Figure 53.2:* Map of the Location of the Oases of Tafilalet in the Moroccan Sahara. *Source:* Michelin 959: Morocco 1: 1 000 000. Reproduced with permission of the copyright holder.

In chapter 54, *Andres Miguel Garcia Lorca* drafted seven of the 12 figures himself and he also compiled table 54.1. The remaining five figures are based on sources that are in the public domain (figure 54.8) for which no permission is needed.

- *Figure 54.8*: Increase of foreigners in Almeria. *Source*: Census-Foreign Yearbook.
- *Figure 54.9*: Demographic growth in Almeria. *Source*: National Institute of Statistics of Spain.
- *Figure 54.10*: Increase of registered foreigners in Spain, Andalusia and in Almeria. *Source*: Census 2006.
- *Figure 54.11*: Increase of resident foreigners. *Source*: Ministry of Interior.

- *Figure 54.12*: Cluster of the agricultural model of Almeria. *Source*: Cajamar Foundation (2004: 25).

In chapter 55, *Jorge García Gómez, Francisco López-Bermúdez* and *Juan Manuel Quiñonero Rubio* drafted four figures based on Spanish official sources that are in the public domain.

- *Figure 55.1*: Average rainfall in the Region of Murcia, by decade (1863-2008) in mm. *Source*: *Regional Statistics* (Murcia: Regional Ministry of Economy and Treasury, 2008).
- *Figure 55.2*: Desertification risk in Spain. *Source*: National Ministry of Rural and Marine Environment (MARM).
- *Figure 55.3*: Evolution of the Population in the Region of Murcia (1900-2008). *Source*: National Institute of Statistics (INE) of Spain (1900-2008).
- *Figure 55.4*: Evolution of the GVA at market prices for the agricultural sector in the Region of Murcia. *Source*: National Institute of Statistics (INE) of Spain (2009).

Permission was obtained to use the following satellite images:

- *Figure 55.5*: New urban settlements in traditional farming or forest areas. *Sources*: The 1956 aerial photo, taken from a USAF flight, is the property of the Instituto Geográfico Nacional de España; the photo of 1997 is from the Ministry of Environment and Rural and Marine Affairs. Olive GIS mapping; and the photo of 2007 is from Ministry of Development (Ministerio de Fomento) PNOA (National Plan of Aerial Ortophotography).
- *Figure 55.6*: The images (1956, 1997 and 2007) are located in the coastal area near the city of Cartagena. *Sources*: The 1956 aerial photo is from a USAF flight and is the property of the Instituto Geográfico Nacional de España; the photo of 1997 is from the Ministry of Environment and Rural and Marine Affairs. Olive GIS mapping; and the photo of 2007 is from Ministry of Development (Ministerio de Fomento) PNOA (National Plan of Aerial Ortophotography).
- *Figure 55.7*: Intensification of farming activities in traditional dry-farming areas. In this sequence (1956, 1997 and 2007), located near the town of Fuente Álamo, the change to more intensive farming activities is shown. *Sources*: The 1956 aerial photo is from a USAF flight and is the property of the Instituto Geográfico Nacional de España; the photo of 1997 is from the Ministry of Environment and Rural and Marine Affairs. Olive GIS mapping (SIG oleicola); and the photo of 2007 is from Ministry of Development (Ministerio de Fomento) PNOA (National Plan of Aerial Ortophotography).
- *Figure 55.8*: Irrigation development. Development of irrigation farming in Rambla de *Las Moreras*, Murcia (1956, 1987, 2003). *Sources*: The 1956 aerial photo is from a USAF flight and is the property of the Instituto Geográfico Nacional de España; the photo of 1987 is from the Ministry of Environment and Rural and Marine Affairs. Olive GIS mapping (SIG oleicola); and the photo of 2003 is from Regional Ministry for Agriculture and Water based on Quickbird satellite images.

In chapter 56, *Jacob Granit* reproduced in box 56.1 text of the *Nile Basin Initiative* (NBI) that is in the public domain and the text in box 56.2 was written by the author.

- *Box 56.1*: The Nile Basin Initiative (NBI): Management and development efforts in a transboundary basin. *Source:* See at: <http://www.nilebasin.org/> (23 March 2009).
- *Box 56.2*: The Baltic Sea - the ecosystem that 'flipped'. *Source:* The author.

In chapter 57, *Zhanyi Gao and Yaqiong Hu* designed the following figures and compiled the following tables based on their own research:

- *Figure 57.3*: Framework for grain production and the analysis of the development of irrigation. *Source*: Developed by the authors.

For the following graphics they used official material and documents that are in the public domain and for which no permissions are needed:

- *Figure 57.2*: Growth of grain production with the increase of the irrigated area in China. *Source*: MWR *Statistic Bulletin on China's Water Activities* (2000-2008).
- *Table 57.1*: Changes of the population size (in thousand), population density and of the urban population in China (1950-2050) for the medium variant. *Source*: UN (2009, 2008); at: <http://esa.un.org/unpp/p2kodata.asp>.
- *Table 57.2*: Achievement in the Agricultural Production of the People's Republic of China from 1950 to 2008. *Source*: UN (2009, 2008); at: <http://esa.un.org/unpp/p2kodata.asp>; National Bureau of Statistics of China (2001, 2008) at: <http://www.stats.gov.cn/tjgb/> and <http://www.cpirc.org.cn/tjsj/tjsj_cy_detail.asp?id=304>.
- *Table 57.3*: Population Projection in China (unit: billion people) for 2010 and 2020. *Sources*: UN (2001, 2009); China Population and Development Research Center (2000).
- *Table 57.8*: Flood and drought affected areas in China. *Source*: PRC (2009).
- *Box 57.1*: Modifications of the Chinese water law. *Source:* PRC (1 October 2002).
- *Box 57.2*: References to irrigation in the law on agriculture. *Source*: PRC (1 March 2003).

For the following figures they obtained the permission of the copyright holder:

- *Figure 57.1*: Rivers of China. *Source*: © Heilig, G.K. (1999): *ChinaFood. Can China Feed Itself?* (Laxenburg: IIASA, 1999) [CD-ROM Vers. 1.1].
- *Figure 57.4:* Evolution of world grain production (1950-1995). *Source*: Philippe Rekacewicz, UNEP/GRID-Arendal based on data from the Worldwatch Institute (1996); at: <http://maps.grida.no/go/graphic/evolution_of_the_world_grain_production_comparison_world_europe_china_africa> and at: <http://maps.grida.no/go/graphic/evolution_of_the_world_grain_production_comparision_with_china_and_united_states>.
- *Figure 57.5*: Precipitation distribution and irrigation zones. *Source*: Gao (2006).
- *Figure 57.6*: Structure of the irrigation management system. *Source*: Li Daixin (2002).
- Table *57.4*: Grain demands at target years. *Source*: Gao and Wang (2008).
- Table *57.5*: Required grain under different grain selfsufficiency rates. *Source*: Gao and Wang (2008).
- Table *57.6*: Requirement for the irrigation area in 2010. *Source*: Gao and Wang (2008)
- Table *57.7*: Requirement for the irrigation area in 2020. *Source*: Gao and Wang (2008).

In chapter 58, *Mohammed Rahman Zillur* and *Kuntala Lahiri-Dutt* designed the following figures (58.6, 58.7, 58.8) based on their own research findings. For the following graphics they used official material and documents that are in the public domain and for which no permissions are needed:

- *Figure 58.1*: Possible Climate Change Related Impacts in Tropical Asia. *Source*: IPCC (1998: 392). Reprinted with permission of the IPCC.
- *Table 58.1*: Socio-economic impacts of sea-level rise (IPCC 1996a: 306). *Source*: Reprinted with permission of the IPCC.
- *Table 58.2*: Synthesized results of case studies on Bangladesh and Egypt on 1-m sea-level rise in 1990 US$. *Source*: IPCC (1996a: 308).
- *Table 58.3*: Potential land loss and population exposed in Asian countries to sea-level rise. *Source*: IPCC (2001a: 569).

For these figures they obtained the permission of the copyright holder:

- *Figure 58.2*: Flood types in Bangladesh. *Source*: Ahmad, Warrick, Ericksen and Mirza (1996: 13). With kind permission of Springer Science and Business Media.
- *Figure 58.3*: Five main types of climate-related natural events for Bangladesh. *Source:* Ericksen, Ahmad and Chowdhury (1996: 264). With kind permission of Springer Science and Business Media.

- *Figure 58.4*: Urbanization in Bangladesh. *Source*: Ericksen, Ahmad and Chowdhury (1996: 239). With kind permission of Springer Science and Business Media.
- *Figure 58.5*: Migration in Bangladesh. *Source*: Ericksen, Ahmad and Chowdhury (1996: 245). With kind permission of Springer Science and Business Media.

Chapter 59 by *Kanupriya Harish* and *Mathews Mullackal* was illustrated in figures (59.1-59.6, 59.8-59.26) with 25 photos taken by *Kanupriya Harish* and with a map produced by the Jal Bhagirathi Foundation (59.27) that also provided the text for Box 59.1 to 59.3. For one figure permission was obtained from the copyright holder:

- *Figure 59.7*: Growth of human population. *Source*: Dhir, R.P. 2004: "Ecological fluxes in the Thar Desert", in: Narain, Pratap; Kathju, S.; Kar, Amal; Singh, M.P.; Praveen-Kumar Eds.): *Human Impact on Desert Environment* (Jodhpur, India: Arid Zone Research Association of India and Scientific Publishers): 1-11.

In chapter 60, *Abdelkader Dodo, Mohamedou Ould Bab Sy* and *Jihad Channem* included eight figures and one table of which all but one was produced by OSS, the organizations for which these three authors work. For the remaining figure the copyright was obtained:

- *Figure 60.2*: Isohyets glide between the two periods before and after 1968. *Source*: Centre Regional AGRHYMET (Niamey, Niger).

Úrsula Oswald Spring documented chapter 62 with box 62.2 based on her own research and she based figure 62.4 and tables 62.4 to 62.8 on sources that are in the public domain:

- *Table 62.4*: GM seed market of cotton in the USA in 2005. *Source*: USDA (2005).
- *Table 62.5*: Summary of the status and trends in major bioprospecting industries. *Source*: Millennium Ecosystem Assessment (2005: 109).
- *Table 62.6*: Compounds of natural products and semi-synthetic modifications approved in the USA. *Source*: Millennium Ecosystem Assessment (2005: 110).
- *Table 62.7*: Minimal obligations to import, customs on imported maize and imports. *Source*: Banco de Comercio Exterior (Foreign Trade) for the years 2000 to 2008.
- *Table 62.8*: World inventory of maize stock (million tons). *Source*: USDA (2007).
- *Table 62.9*: International maize prices in Mexico. *Source*: INEGI (January 2007).

For the following graphics permissions were obtained from the copyright holder:

- *Figure 62.1*: Genetically modified plants (in Mha). *Source*: GMO Compass of Genius GmbH, Darmstadt (Germany); at: <http://www.gmo-compass.org/eng/news/> (15 February 2008).
- *Figure 62.2*: Global areas of GM crops in million hectares (1996-2004). *Source*: ISAAA (2007); at: <http://www.isaaa.org/resources/publications/briefs/37/executivesummary/ default. html>.
- *Figure 62.3*: Countries with GM-crops in 2006. *Source*: ISAAA (2006).
- *Figure 62.4*: GM Pollution, accidents, and collateral effects of GM in the world. *Sources:* GeneWatch, UK; Greenpeace International (2006: 35).
- *Table 62.1*: Evolution of agricultural development. *Source*: Adapted from van der Walt (2000) and FAO (2002; 2005: 6- 7).
- *Table 62.2*: Areas and types of GM seeds worldwide. *Source*: ISAAA (2007), Brief No. 37; at: <http:// www.isaaa.org/resources/publications/briefs/37/executivesummary/default.html>.
- *Table 62.3*: Frequency of gene flow from out-crossing. *Source*: Eastham and Sweet (2002: 9).
- *Table 62.10*: Global and regional risks and benefits from transgenic food crops for Africa, Latin America, and Asia. *Source*: Adapted from a study by the University of Michigan (2006).

- *Box 62.1*: Most common biological threats posed by GM crops. *Source*: IUCN Programme (2000: 17-19).

Issa Martin Bikienga illustrated chapter 63 with a figure (63.6: Locust Invasion affecting the Sahel Countries. *Source*: FAO; at: <http://www.fao.org/DOCREP/006/J2517E/J2517E00. HTM# bkf>) and a table (63.1: Population Change and Projection for the Sahel Countries (1950-2050). *Source:* UN, Populations Division, 2006 Revision; at: <http://esa.un.org/ unpp/>) that are in the public domain and with figures for which permission was granted by EM-DAT, The OFDA/CRED International Disaster Database, Université Catholique de Louvain, Brussels, Belgium:

- *Figure 63.1*: Number and Occurrence of Drought/Famine Disasters by Country (1974-2003).
- *Figure 63.2*: Number and Occurrence of Flood Disasters by Country (1974-2003).
- *Figure 63.3*: Worldwide Epidemic Occurrence (1974-2003). *Source*: EM-DAT, The OFDA/CRED International Disaster Database; at: <www.em-dat.net>, Université Catholique de Louvain, Brussels, Belgium.
- *Figure 63.4*: Total Number of Deaths and of People Affected by Natural Disasters per 100,000 inhabitants (1974-2003).
- *Figure 63.5*: Disaster Type Proportions by UN Sub-Regions (1974-2003).

In chapter 64, *Sreeja Nair* used five figures for which copyright was obtained:

- *Figure 64.1*: Mode of interaction in anarchy, hierarchy and heterarchy. *Source*: Eoyang/Berkas (1999: 5); at: <www.chaos-limited.com/EvalinCAS.pdf>.
- *Figure 64.2*: Conceptual linkages between vulnerability, resilience and adaptive capacity. *Source*: Cutter/Barnes/Berry/Burton/Evans/Tate/Webb (2008: 600).
- *Figure 64.3*: Co-management: fostering linkages between stakeholders at all levels. *Source*: Adger/Arnell/Tompkins (2005: 6); at: <http://www.ecologyandsociety.org/vol10/iss2/art9/>.
- *Figure 64.4*: Cross-scale interaction between institutions. Circles indicate potential points of entry for cooperating individuals or institutions. Black arrows and open arrows indicate hypothetical pathways. *Source*: Cash/Moser (2000: 115).
- *Figure 64.5*: Structure of multi-level government in India. *Source:* Rao, G. (2000: 11); at: <http://www.imf.org/external/pubs/ft/seminar/2000/fiscal/rao.pdf>.

Cecilia Conde illustrated chapter 65 with eight figures of which several figures were based on her research and on her previous co-authored publications and photographs by her colleague:

- *Figure 65.2*: Map of the two study areas in Tlaxcala and Veracruz, Mexico. *Source*: Elaborated by the geographer Raquel Araujo, postgraduate student (unpublished).
- *Figure 65.3*: Focus Group in Coatepec, Veracruz. Presentation on climate impacts. *Source*: Photo by Beatriz Palma (2008).
- *Figure 65.4*: Focus Group in Coatepec, Veracruz. Review of the map of natural resources and land use. *Source*: Photo by Beatriz Palma (2008).
- *Figure 65.5*: Example of the base scenario for mean temperature (in July). *Source*: See at: <http://www.atmosfera.unam.mx/gcclimatico/index.php?option=com_content&view=article&id=77 &Itemid=74> (1 September 2009).
- *Figure 65.6*: Example of climate change scenario, EHCAM5 model, A2 emission scenario, and horizon 205. Mean temperature (in July). *Source*: <http://www.atmosfera.unam.mx/gcclimatico/index.php?option=com_content&view=article&id=77&Itemid=74> (1 September 2009).

- Figure *65.7*: Projected changes in temperature (A) and precipitation (B), for Tlaxcala (2020 and 2050), using 3 GCM (G: GFDL; H: Hadley; E: ECHAM) outputs and two SRES scenarios (A2 and B2). *Source*: Conde, Ferrer and Orozco (2006).
- Figure *65.8*: Projected changes in temperature (A) and precipitation (B), for Veracruz (2020 and 2050), using 3 GCM (G: GFDL; H: Hadley; E: ECHAM) outputs and two SRES scenarios (A2 and B2). *Source*: Conde, Vinocur, Gay, Seiler and Estrada (2008).

One map is in the public domain:

- *Figure 65.1*: Federal states of Mexico and the study area in Tlaxcala (No. 29 in the list of states) and Veracruz (No. 30 in the list of states). *Source*: OECD (1998: 3).

Tanja Wolf, Glenn McGregor and *Anna Paldy* illustrated chapter 67 with three figures and two tables based on data by the Central Statistical Office in Budapest (figure 67.1; table 67.2), on own maps by Tanja Wolf (figure 67.2, 67.3) and one table based on a previous co-authored publication by Anna Paldy (table 67.1) for which no permissions were needed.

In chapter 68, *Jörn Birkmann* reproduced eight figures for which permissions were obtained:

- *Figure 68.1*: The basic concept of human ecology and the relationship between Society, Man and Environment (nature) through the lens of a differential theory perspective. *Source*: Egner (2008: 135) based on Luhmann (1988).
- *Figure 68.2*: The Sahel-Syndrome. *Source*: WBGU (1996: 141).
- *Figure 68.3*: Linkages between Ecosystem Services and Human Well-Being. *Source*: MA (2005: VI) and Leemans (2009: 56).
- *Figure 68.4*: The Disaster Risk Cycle. *Source:* Cutter/Gall (2008: 356) based on FEMA (2007).
- *Figure 68.5*: The hunger-famine process or chain. *Source*: Watts and Bohle (1993: 43ff.).
- *Figure 68.6*: Coping and adaptation as well as impact and change. *Source*: Own figure based on Birkmann, Buckle, Jäger, Pelling, Setiadi, Garschagen, Fernando and Kropp (2009: i.p.).
- *Figure 68.7*: The actual inundation in Galle and the 100 metre buffer-zone. The proposed 100 Meter Buffer Zone (red line) based on own calculations. *Source*: Naßl/Voigt (2006) and actual inundation due to the tsunami in Galle, Sri Lanka (Hettiarachchi/Wijeratne 2006).
- *Figure 68.8*: Key stakeholders and their structure in the post-tsunami process. *Source*: Own figure based on Amarasinghe (2005) and Hettige (2007).

In chapter 69, *Katherina Marre* and *Fabrice Renaud* summarized their field research in 22 tables based on the Statistical Office of Sri Lanca (tables 69.1-69.16) and the authors own field research (tables 69.17-69.22). They included four figures of which three were produced by the authors based on their own research and on public sources while the images in figure 69.1 are in the public domain:

- *Figure 69.1*: Landsat DEM (resolution 90 m) showing the topography in both districts. *Source*: The data for this digital elevation model (DEM) was provided by the International Water Management Institute; at: <http://www.iwmidsp.org> and processed by the authors with ArcGIS. The DEM data stem from the United States Geological Survey (USGS) that are in the public domain.

In chapter 70, *Juan Carlos de Villagran* adapted two figures based on sources that are in the public domain (70.1, 70.2) and added one designed by the author (70.3). He also compiled five tables based on scientific data of OFTA/CRED (70.1, 70.3) and official resources (70.2, 70.4) that are in the public domain and obtained permission for:

- *Table 70.5*: Main results of the evaluation of the Quinquennium for the Reduction of Vulnerability (2000-2004). *Source*: Novelo/Smith (2004: 3-6).

Finally he wrote the text for boxes 70.1 and 70.2, the latter based on data by the IPCC (1998, 2007: 892-896, 2007a: 583-607).

In chapter 71, *Koko Warner* reproduced two figures based on a previous co-authored publication and a third on Hurricane Katrina for which permission was obtained:

- *Figure 71.1*: Shocks disrupt economic performance over time. *Source*: Freeman/Warner (2001: 27), reprinted with permission.
- *Figure 71.2*: The number of people in poverty increases if the poor suffer disproportionately from catastrophic events. *Source*: Freeman/Warner (2001: 32). Reprinted with permission.
- *Figure 71.3*: Places of displacement following Hurricane Katrina. *Source*: Epodunk website, 2007: "Places of Displacement Following Hurricane Katrina"; at: <http://www. epodunk.com/top10/diaspora/destination-map.html> (21 March 2007). Reprinted with permission.

In chapter 72, *Úrsula Oswald Spring* used two figures (72.1, 72.2) that are based on official Mexican sources that are in the public domain and obtained permission for three figures:

- *Figure 72.3*: World population, international migrants, and refugees (1960-2005). *Source*: Designed by Guillermo Peimberg of UNAM/CRIM based on data of UN Population Division (2007); at: <http://esa.un.org/ unmigration/>.
- *Figure 72.4*: Native Mexican residents in the USA. *Source*: Estimations by CONAPO based on *Current Population Survey* 1994-2007, elaborated by F. Lozano, CRIM, 2009.
- *Figure 72.5*: Long-term trend in the global number of natural disasters (1975-2005). *Source*: EM-DAT: The OFDA/CRED International Disaster Database, Université de Louvain, Brussels, Belgium; at: <http://www.em-dat.net>.

Further, three tables were compiled by the author based on public sources (72.1, 72.2) and she summarized three alternative visions to understand and combat discrimination (70.3).

In chapter 74, *Rik Leemans, Martin Rice, Ann Henderson-Sellers* and *Kevin Noone* compiled one table (74.1) and developed and designed six figures based on the scientific literature (74.1) and projects (74.5, 74.6) and obtained permission for:

- *Figure 74.4*: Schematic representation of the structure and activities of the Challenge Program on Climate Change, Agriculture and Food Security (CCAFS). *Source*: CGIAR Alliance/ESSP (2008).

In chapter 75, *Louise von Falkenhayn, Andreas Rechkemmer* and *Oran R. Young* in sections 75.4.1 to 75.5. rely on Rechkemmer, A.; von Falkenhayn, L. 2009: "The human dimensions of global environmental change: Ecosystem services, resilience and governance", in: *European Physical Journal. Special Topics,* 167, 3-17. The permission to reuse this material was granted by Springer Rights and Permissions; Springer-Verlag Heidelberg, 3 May 2010. Figures 75.1 and 75.2 were designed by IHDP and figure 75.3 is in the public domain.

- *Figure 75.3*: Dynamics and Stability in Ecosystem Services. *Source*: Millennium Ecosystem Assessment (2005).

In chapter 78, *John A. Church, Ghassem R. Asrar, Antonio J. Busalacchi* and *Carolin E. Arndt* compiled five figures based on photos, figures and images that are in the public domain.

- *Figure 78.1*: Human well-being and local economies are severely affected by droughts and floods. *Sources*: Photos clockwise from top left: J. Isaac: <FAO/13702/J.Isaac>; NASA: <www.travelblog.org/Rich>; SanSan Samuel: <www.freedigitalphotos.net/>, J.

Barker Free Digital Photo; Texas Forest Service by Jan Amen. These photos are in the public domain.

- *Figure 78.2*: Illustrative examples of WCRP accomplishments. Clockwise from top left: Projection of global averaged temperature for the 21st century as prepared for the IPCC (IPCC 2007); WCRP *World Ocean Circulation Experiment* (figure prepared by the WCRP-GEWEX Global Precipitation Climatology Project); Schematic observed and predicted evolution of global ozone (UNEP/WMO Scientific Assessment of Ozone Depletion: WMO 2006). These figures are in the public domain.
- *Figure 78.3*: Satellite observations and in situ measurements. *Sources*: ESA; Argo; www.ISRIC.org/V. van EngelenSOTER; JAMSTEC Earth Simulator Center. These satellite images are in the public domain.
- *Figure 78.4*: A schematic of the flow of the climate information system. *Source*: This figure was developed by K. Trenberth (2008: 18) and slightly modified by G. Asrar.
- *Figure 78.5*: Climate adaptation solutions. *Sources*: <Treehuggerwww.PlayPumps.org>; International Federation of Red Cross and Red Crescent Societies (IFRC); UK Environment Agency; at: <www.WIKIMEDIA.org> by J. Gao. These images are in the public domain.

In chapter 79, *Martin Parry, Osvaldo Canziani, Jean Palutikof* and *Clair Hanson* included five figures with graphics and images produced by Working Group II of the IPCC that are all in the public domain:

- *Figure 79.1*: Change in glacier extent on Mt. Kilimanjaro (1912-2003). *Source*: IPCC (2007a: 440; modified from Cullen/Mölg/Kaser/Hussein/Steffen/Hardy 2006).
- *Figure 79.2*: Global impacts projected for changes in climate (and sea level and atmospheric carbon dioxide where relevant) associated with different amounts of global average surface temperature change in the 21st century. *Source*: IPCC (2007a: 66, Technical Summary).
- *Figure 79.3*: Regional impacts projected for changes in climate (and sea level and atmospheric carbon dioxide where relevant) associated with different amounts of global average surface temperature change in the 21st century. *Source*: IPCC (2007a: 67, Technical Summary).
- *Figure 79.4*: Sensitivity of wheat yield in mid- to high latitudes. Responses indicate cases without adaptation (light grey dots) and with adaptation (dark grey dots). The studies analysed here include a range of precipitation changes and CO2 concentrations (from IPCC 2007a: 286).
- *Figure 79.5*: Estimated millions of people per annum at risk globally from coastal flooding. Light grey bars: numbers at risk without sea-level rise; dark grey bars: numbers at risk with sea-level rise (from IPCC 2007a: 75; Technical Summary).

In chapter 80, *Peter Bosch* and *Bert Metz* included four figures with graphics and one table produced by Working Group III of the IPCC that are all in the public domain:

- *Figure 80.1*: Stabilization scenario categories and their relationship to equilibrium global mean temperature change above pre-industrial temperatures in °C. *Source*: IPCC (2007b: 228).
- *Figure 80.2*: Emission pathways of mitigation scenarios for alternative categories of stabilization levels (category I to VI defined in table 80.1). *Source*: IPCC (2007b: 199).
- *Figure 80.3*: Comparison between global economic mitigation potential and projected emissions increase in 2030. *Source*: IPCC (2007b: 625-635).
- *Figure 80.4*: Estimated sectoral economic potential for global mitigation for different regions as a function of carbon price in 2030 from bottom-up studies, compared to the respective baselines assumed in the sector assessments. *Source*: IPCC (2007b: 632).

- *Table* 80.1: Characteristics of stabilization scenarios published after 2000. *Source*: IPCC (2007b: 198).

In chapter 82, *Veerle Vandeweerd, Yannick Glemarec* and *Vivienne Caballero* included ten figures and eight boxes produced by UNDP that are all in the public domain:

- *Figure 82.1*: Delivery of UNDP Environmental Finance Services. *Source*: UNDP (2009a: 8).
- *Figure 82.2*: Support Levels for Global Environmental Change Responses. *Source*: UNDP (2008: 27).
- *Figure 82.3*: UNDP-GEF Adaptation portfolio. UNDP has leveraged over $800 million for climate change resilient development in 75 countries. *Source*: Data generated from UNDP 2010 <http://ccmap.undp.org>.
- *Figure 82.4*: Six dimensions for scaling up climate change. *Source*: Adapted from UNDP (2008: 17).
- *Figure 82.5*: Methodologies and processes for developing an ITCP. *Source*: Glemarec (UNDP 2009: 60).
- *Figure 82.6*: Key Steps in Assessing Adaptation Options. *Source*: Kurukulasuriya/Mendelsohn (2008). Kurukulasuriya/Glemarec/Retiere (UNDP 2009: 103).
- *Figure 82.7*: Key Data for Vulnerability Analysis. *Source*: Kurukulasuriya/Mendelsohn (2006). Kurukulasuriya/Glemarec/ Retiere (UNDP 2009: 106).
- *Figure 82.8*: Climate Analogues. *Source*: Kurukulasuriya/Mendelsohn (2006); Kurukulasuriya/Glemarec/Retiere (UNDP 2009: 107).
- *Figure 82.9*: Adaptation Profiles. *Source*: Kurukulasuriya/Mendelsohn (2006); Kurukulasuriya/Glemarec/Retiere (UNDP 2009: 108).
- *Figure 82.10*: Sequencing public finance and carbon finance. *Source*: Glemarec (UNDP 2009: 112).
- *Box 82.1*: UNDP. *Source*: <www.undp.org>.

The Anthropocene: Geology by Mankind

Paul Crutzen, Nobel Laureate for Chemistry
Max Planck Institute for Chemistry
Department Atmospheric Chemistry

During 4,5 billion years of Earth history, after a long string of biological processes, only a million years ago, a single species 'homo sapiens' evolved, which grew increasingly capable of influencing the geology of our planet. That species is unique in the solar system and maybe beyond. A species, us, was created with a brain size of only some 1,300 g, which is capable of using and manipulating the Earth's environment in major ways from generation to generation in a catalytic fashion. Especially over the past hundred years, the human impact has become increasingly clear. Supported by great technological and medical advances and access to plentiful natural resources, the expansion of humankind, both in numbers and exploitation of the Earth's resources is astounding. Let us give a few examples.

- During the past 3 centuries human population increased tenfold to more than 6,000 million.
- This expansion was accompanied by a growth in cattle population to 1,400 million (about one cow per average size family). They produce methane gas.
- Urbanization has increased more than tenfold in the past century. About half of the human population lives in cities and megacities.
- Similarly large or larger were the increases in several other factors, such as world economy, of industries (40 times) and of energy use (16 times).
- More than half of all accessible fresh water is used by mankind.
- Fish catch increased 40 times.
- In a few generations humankind is exhausting the fossil fuels that were generated over hundreds of million of years.
- The release of sulphur dioxide, about hundred million tonnes per year, at least two times larger than the sum of all natural emissions, has led to acidification of precipitation, causing forest damage and fish death in biologically sensitive regions, such as Scandinavia and the north-east of North America. The situation in these regions has improved. However, in the meanwhile, the problem has got worse in East Asia.
- 30–50 per cent of the world's land surface has been transformed by humans; land under cropping has doubled during the past century at the expense of forests.
- More nitrogen is applied as synthetic fertilizer in agriculture than fixed naturally. Oversupply of nitrogen fertilizers have led to eutrophication of surface waters.
- Human activity has already increased species extinction rates by orders of magnitude.
- As a result of increasing fossil fuel burning, agricultural activities, deforestation, and intensive animal husbandry, several climatically important 'greenhouse' gases have substantially increased in the atmosphere over the past two centuries: CO_2 by more than 30 per cent and CH_4 by more than 100 per cent, causing the observed global average temperature increase by about 0.6 °C that has been observed during the past century.
- According to IPCC's 'business as usual scenario', global average temperatures are projected to rise by 2.0–4.5 °C during the current century and sea level is expected to rise by 9–88 cm, up to 50–140 cm.
- Humankind also releases many detrimental substances in the environment and even some, the chlorofluorocarbon gases ($CFCl_3$ and CF_2Cl_2), which are not directly toxic, but which destroy stratospheric O_3 and have led to the Antarctic 'ozone hole'. A global catastrophe has been averted through the Montreal Protocol and suc-

cessive amendments. Nevertheless, it will take more than half a century before the ozone layer may have recovered.

- Considering these and many other major and still growing impacts of human activities on earth and atmosphere, and at all scales, it thus is more than appropriate to emphasize the central role of humankind in the environment by using the term 'Anthropocene' for the current geological epoch. The impact of current human activities is projected to last and even expand over long periods. According to M. Loutre and A. Berger (2000), because of past and future anthropogenic emissions of CO_2, climate will depart significantly from natural behaviour over the next 50,000 years (no ice ages).
- To assign a more specific date to the onset of the 'Anthropocene' we propose the latter part of the 18^{th} century, when the global effects of human activities became clearly noticeable, by data retrieved from ice cores, which show the beginning of a growth in the atmospheric concentrations of several 'greenhouse gases', in particular CO_2 and CH_4. Such a starting date also coincides with James Watt's invention of the steam engine in 1784.
- Humankind will remain a major geological force for many millennia, maybe millions of years. To develop a worldwide accepted strategy leading to sustainability of ecosystems against human-induced stresses is one of the great challenges of humankind, requiring intensive research efforts and wise application of the knowledge thus acquired.

Hopefully, in the future, the 'Anthropocene' will not only be characterized by continued human plundering of the Earth's resources and dumping of excessive amounts of waste products in the environment, but also by vastly improved technology and management, wise use of the Earth's resources, and control of human and domestic animal population. For example, building on the success of the Montreal Protocol, we need something similar for climate, starting with COP 15 at Copenhagen. But maybe we run out of elements, such as phosphorus, and will experience a short Anthropocene.

Connecting Inconvenient Truths: Urgency of Nuclear Disarmament in a World of Pressing Problems[1]

Amb. Jayantha Dhanapala,
Former UN Under-Secretary General for Disarmament,
President, Pugwash Conferences on Science and World Affairs[2]

The fall of the Berlin Wall symbolized the end of the Cold War, a toxic legacy of which is the nuclear weapon. In 1989, Francis Fukuyama proclaimed the "the end of history" arguing "What we may be witnessing is not just the end of the Cold War or the passing of a particular period of post-war history, but the end of history as such: that is, the end point of mankind's ideological evolution and the universalization of Western liberal democracy as the final form of human government."

This neo-conservative dogma has propelled the world into a succession of calamities. The invasion of Afghanistan and Iraq, the bombing of its civilians, escalating global military expenditure of which the US share in 2008 was 41.5 per cent, the gulag of Guantánamo and the practice of torture and rendition, casino capitalism on Wall Street causing the greatest financial meltdown since the Great Depression of 1929, and the general rejection of multilateral cooperation as a means of finding durable global solutions to global problems are some of them.

With President Obama's policies a unique opportunity exists to reaffirm multilateralism. The 58th Pugwash Council statement of April 2009 stated that:

> the new international climate makes it possible for multilateral co-operative solutions to be negotiated for the critical issues affecting the global community. On nuclear disarmament and non-proliferation, weapons of mass destruction, terrorism, the international economic crisis, the urgent problem of climate change, the achievement of the *Millennium Development Goals* (MDGs), the strengthening of the rule of law, human rights, and other issues, the moment has arrived and we must seize the opportunity.[3]

But the international community is missing this opportunity. In November 2009, a FAO food security summit held to face the challenge of one billion hungry people in our world today declined to commit to the $ 44 billion needed as agricultural aid and failed to set a target date for the eradication of hunger. Underinvestment in agriculture – the source of livelihood for 70 per cent of the poor – will mean that in 2050 when the world's population reaches an estimated 9.1 billion, we will be in a worse situation than today.

The UN Climate Change Conference in Copenhagen failed to reach a binding agreement on greenhouse gas emissions between developed and developing countries with pledges of financial aid. In April 2010, the Obama Administration convened a World Nuclear Security Summit to ensure the safeguarding of the nuclear materials in the world and counter efforts of terrorist groups and the black market to exploit existing loopholes and weaknesses in the systems in place. In May 2010 the parties to the *Treaty for the Non-proliferation of Nuclear Weapons* (NPT) met in New York for its Eighth Review Conference forty years after the global non-proliferation regime entered into force.

Global interdependence has long been established, as the findings of the *Intergovernmental Panel on Climate Change* (IPCC 2007, 2007a, 2007b, 2007c) have shown. No state however powerful and wealthy can solve the problems facing its citizens without global cooperation that must be based in this cen-

1 This text is based on a speech at the Royal Society, London, 1 December 2009.

2 Pugwash Conferences and Joseph Rotblat were jointly awarded the Nobel Peace Prize in 1995 for their efforts to diminish the part played by nuclear arms in international politics and in the longer run to eliminate such arms.

3 See at: <http://www.pugwash.org/reports/pic/58/council-statement.htm>.

tury on the fundamental values of freedom, equality, solidarity, tolerance, and respect for nature and shared responsibility as lessons gleaned from the pages of history. The holistic approach to international peace and security that has now evolved compels us to recognize that there can be "no security without development; no development without security and no security or development without human rights" (Kofi Annan 2005). A convergence of national and human security (Ogata/Sen 2003) is also needed. We observe the interconnection among the problems facing our global community from nuclear weapon possession and proliferation, the risks of the peaceful uses of nuclear energy, the problems of climate change, the escalation of world military expenditure to levels exceeding those of the Cold War and the conflicts they fuel, the poverty of the 'bottom billion' (Collier 2007), international terrorism and the danger of non-state actors acquiring weapons of mass destruction, the widespread violation of human rights and other issues. The global chain connecting us all is as strong as its weakest link.

With the end of the Cold War we hope to end ideological or civilizational confrontation. New challenges facing the global community are terrorism, nationalism, and consumerism. Without global responses we are likely to endanger the future of our planet through nuclear annihilation or disastrous climate change or both.

The global reach of modern international terrorism with its complex network of funding, arms purchases and supplies, training and planning, is new, and 9/11 represents its epitome. It has resulted in a global consensus condemning terrorism in all its forms and manifestations, and a recognition that no cause justifies the use of terrorism. Thirteen international conventions were adopted to counter terrorism. Evidence of terrorist groups seeking weapons of mass destruction has emerged, and the network of clandestine nuclear proliferation activities of Dr. A. Q. Khan enhances the danger of nuclear terrorism. International cooperation is the key to combating terrorism.

That cooperation is undermined by nationalism. With supranational economic entities like the European Union and other regional and global international organizations, nation states were prematurely regarded as historical relics of the 1648 Treaty of Westphalia. Nationalist competition over territory and resources dominated international politics until World War II when the United Nations was established with the hope of eliminating "the scourge of war" and ushering in global cooperation for freedom, peace, development, and human rights. In the post-Cold War phase, nationalism is alive with multiple ethno-nationalist groups, all seeking to achieve statehood. It is also evident in the actions of large countries defending their national security interests. This trend cannot be underestimated. Dangers arise from the covert support for terrorism by some countries to groups elsewhere in support of irredentist claims or international rivalries. Encouragement of groups who have used or continue to use terrorist means by the grant of recognition or by arms supplies violates the global strategy against terrorism. It can also be self-destructive as terrorist groups created for one purpose mutate horribly to strike back even at their own creators.

Thus the Taliban, financed and run by the CIA against the Soviet invaders in Afghanistan, transformed themselves into the extremist force that harboured Bin Laden and incubated global terrorism against the USA and others. Within South Asia, Indira Gandhi's short-sighted policy of encouraging Bhindranwale as a counter to the Akali Dal's dominance in the Punjab led to Sikh terrorism and her own assassination. Examples abound but the lessons are not learned as surreptitious means are found to finance, arm, and otherwise support groups to destabilize neighbours or opponents in the perceived national interest. And so the unbridled nationalism of some countries is in conflict with the common interest of stamping out terrorism in terms of the UN strategy of 2006. We have to ensure that the legitimate pursuit of national security interests meshes with common and cooperative security and a norm-based structure that serves our interests.

Nationalism spurs nuclear weapon possession that is identified as an insurance policy for national security and as a symbol of global power status. But nuclear deterrence cannot be good for some and bad for others. Hence the clandestine WMD programmes of Saddam Hussein's Iraq which were discovered and destroyed by the UN and the IAEA acting under the authority of the Security Council; and North Korea's withdrawal from the NPT and subsequent nuclear tests. There was also popular jubilation when India and Pakistan conducted their nuclear tests in 1998 and became nuclear weapon states. Similarly, there were also strong nationalistic reactions of Iran over its enrichment of uranium at its Natanz and Fordo facilities belatedly reported to the IAEA.

Finally, consumerism has become an important driver of the global economy. With mass production,

consumerism is now a global phenomenon that lubricates markets and creates a demand for commodities and brands. The recent emergence of large economies in the South, particularly in China, India and Brazil, has led to a demand for energy and other commodities, entailing a rise in prices already distorted by agricultural subsidies in the USA, the European Union, and other developed countries. Economic nationalism drives protectionism, obstructing free and fair trade. Despite the stalemate over the Doha Round of the World Trade Organization, we need to move rapidly for equality in terms of trade, so allowing developing countries access to markets and to commodities that their people seek in an increasingly interdependent world. We cannot continue the use of fossil fuels to satisfy the consumer demands of the world. The reports of the IPCC (1990, 1995, 2001, 2007) argued that case. To ignore them would be a supreme, self-destructive folly.

The case against hydrocarbon has resulted in a 'nuclear renaissance'. Although Article IV of the NPT guarantees that non-nuclear weapon state parties will have an 'inalienable right' to the peaceful uses of nuclear energy, the world has suddenly woken up to the perils of this. It is less the threat of massive radiation leaks or accidents, like in Chernobyl (1986) and Three Mile Island (1979), to human lives and the environment but more the lack of credible firewalls between peaceful uses of nuclear energy and the development of nuclear weapons. The signing of the voluntary Additional Protocol of the *International Atomic Energy Agency* (IAEA) is no longer the confidence building measure. Many proposals for the multilateralization of the fuel cycle have been made. While some states will opt not to have their own enrichment facilities others will not want to be dependent on foreign supplies of nuclear fuel for their development needs. The dilemma could be resolved through innovative technology with proliferation-resistant reactors and the elimination of highly-enriched uranium. The discovery of other cheaper and safer sources of energy and greater investment in wind and solar power could also lower the demand for nuclear power.

The interconnectedness of these 'isms' is self evident. So also is their link with prevailing crises and the solutions. The first crisis is the possible use of the 8,392 nuclear weapons deployed by the nine nuclear weapon states (of their combined 23,300 warheads) either by accident or in accordance with their nuclear doctrines (SIPRI 2009: 16). President Obama (2009) said in Prague that

> one nuclear weapon exploded in one city – be it New York or Moscow, Islamabad or Mumbai, Tokyo or Tel Aviv, Paris or Prague – could kill hundreds of thousands of people. And no matter where it happens, there is no end to what the consequences might be – for our global safety, our security, our society, our economy, to our ultimate survival.[4]

Building on studies of a 'nuclear winter' (Crutzen/Birks 1982) caused by the use of nuclear weapons, more recent research has concluded[5] that even a minor nuclear war with 0.03 per cent of the current global arsenals will produce catastrophic climate change.

- Nuclear weapon proliferation arises largely from the strong demand for national security in a world of competing nationalisms where some nations are permitted to have these weapons and others are not. Neither the NPT nor the Nuclear Terrorism Convention together with UN Security Council Resolution 1540 which seeks to prevent terrorist groups acquiring weapons of mass destruction, can hold this demand in check as long as nuclear weapons are held by some states and vast amounts of enriched uranium and separated plutonium lie around.
- The second crisis confronting us is climate change caused by our global consumption patterns, the prevailing structure of international trade and our failure to invest in and cooperate in the search for new environmentally friendly sources of energy.

Both crises have the best chance of being resolved through a nuclear weapon free world – consistently espoused by Pugwash and more recently endorsed by George Schultz, Henry Kissinger, Sam Nunn, and Bill Perry.[6] This vision is being pursued by President

Obama. Any delay in implementing nuclear disarmament and nuclear non-proliferation policies can be dangerous even though Obama himself hedges on a timetable for achieving his vision. The Obama-Medvedev Joint Statement of 1 April 2009[7] and Obama's Prague speech of 5 April 2009 set the goals[8] that are being implemented through

- the resumption of bilateral US-Russian negotiations for a follow-up to the *Strategic Arms Reduction Treaty* (START) that expired on 5 December 2009 with significant nuclear weapon reductions in both countries that own 95 per cent of nuclear weapons;
- the lifting of US impediments to the negotiation of a *Fissile Material Cut-off Treaty* (FMCT) in the Conference on Disarmament permitting other countries to reciprocate;
- the message by Obama to the parties to the NPT at their Preparatory Committee meeting in New York in May 2009 stressing the US commitment to the NPT;
- the statement of Secretary of State Hillary Clinton at the Article XIV Conference of the *Comprehensive Nuclear Test Ban Treaty* (CTBT) in New York, 24 September 2009;
- President Obama's statement on 24 September 2009 and the unanimous adoption of Resolution 1887 (2009) stressing more non-proliferation than nuclear disarmament;
- and the return to diplomacy resulting in fresh negotiations with Iran on the basis of IAEA proposals and the prospect of direct US-North Korean talks.

But obstructionist tactics are evident in the nuclear disarmament area both within the USA and with some NATO allies. As a confidence building measure President Obama has reversed the US ballistic missile defence plans in the Czech Republic and Poland. But the unfulfilled agenda is huge as is the task of setting the right conditions for a successful NPT Review Conference in May 2010. A new US Nuclear Posture Review must reflect the Obama vision accurately by abandoning nuclear first use and launch-on-warning capabilities deemphasizing the role of nuclear weapons in US defence strategy. The US senate must 'advise and consent' to both treaties: the new START and the CTBT. A well-organized campaign is needed and compromises must be reached to maintain his domestic and international support. The Nobel Peace Prize Committee has referred to Obama's "vision of a world free from nuclear arms (which) has powerfully stimulated disarmament and arms control negotiations".

West European leaders, especially within NATO, and of countries enjoying the shelter of the US nuclear umbrella must help persuade US Senators of the global importance of ratifying the new START and the CTBT. There is an international responsibility to protect the vision of Obama. In autumn 2009, the new German government has called for the elimination of US nuclear weapons from its soil. In the UK, Douglas Hurd, Malcolm Rifkind, David Owen, and George Robertson[9] supported this goal on 30 June 2008, as did the June 2009 report of the House of Commons Foreign Affairs Committee on "Global Security: Non-proliferation"[10] and the launch of the Top Level Group of UK Parliamentarians for Multilateral Nuclear Disarmament and Non-proliferation on 29 October 2009 who share the vision of a nuclear weapon free world.

However, until the UK government and the governments of other nuclear weapon states take more practical steps towards realizing this vision, a credibility gap will remain between the nuclear weapon states and non-nuclear weapon states within the NPT. Over six decades after Hiroshima and Nagasaki incremental steps towards a nuclear weapon free world makes the goal seem a mirage. The Global Zero group has set a target of 2030 for the completion of its phased verified programme for the total elimination of nuclear weapons. Reports of the *International Commis-*

9 Douglas Hurd, Malcolm Rifkind, David Owen and George Robertson: "Start worrying and learn to ditch the bomb. It won't be easy, but a world free of nuclear weapons is possible", in: *The Times*, 30 June 2008; at: <http://www.timesonline.co.uk/tol/comment/columnists/guest_contributors/article4237387.ece >.

10 UK, House of Commons Foreign Affairs Committee: "Global Security: Non-Proliferation – Foreign Affairs Committee"; at: <http://www.publications.parliament.uk/pa/cm200809/cmselect/cmfaff/222/22210.htm>.

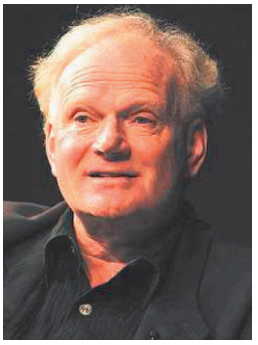
sion for Nuclear Non-proliferation and Disarmament (ICNND), co-chaired by the former Foreign Ministers of Australia and Japan, point to advocacy of a 'minimization' point of over 1,000 nuclear warheads by 2025, while President Obama says "perhaps not in my lifetime".

The simplest and most direct route would be to negotiate a verifiable Nuclear Weapon Convention to outlaw nuclear weapons as the world outlawed biological and chemical weapons. A draft Convention is before the UN, proposed by Malaysia and Costa Rica, and recommended by the Secretary-General in his 5-point plan of October 2008. It will contribute towards easing global tensions and resolving the burning issues of our times – nuclear weapons, climate change, terrorism, poverty, international finance, and human rights which intersect. With the elimination of nuclear weapons we have, in the words of UN Secretary-General Ban Ki-moon, "a global good of the highest public".

There is no greater task than achieving peace and security through disarmament. Einstein (1879–1955), the co-author of the Manifesto that continues to inspire Pugwash, once said,

> concern for man himself and his fate must always be the chief interest of all technical endeavours...in order that the creations of our minds shall be a blessing and not a curse to mankind. Never forget this in the midst of your diagrams and equations.

Scientists remain at the centre of weapon laboratories, the military industrial complexes, and energy consuming industries in all countries. National loyalties and protectionist pressures are strong in such situations and I can only quote the Russian playwright Anton Chekhov (1860–1904) who said, "Science cannot be national, in the same way that a multiplication table cannot be national. If a science becomes national it ceases to be a science." The common humanity of all scientists should act as a code of ethics to ensure nuclear disarmament and to arrest and reverse climate change. The Russell-Einstein Manifesto of 9 July 1955 said, "We appeal, as human beings, to human beings: Remember your humanity, and forget the rest." It is time to follow this advice before it is too late.



Living in and Coping with World Risk Society

Ulrich Beck

The narrative of global risk is a narrative of irony. This narrative deals with the involuntary satire, the optimistic futility, with which the highly developed institutions of modern society – science, state, business and military - attempt to anticipate what cannot be anticipated. Socrates has left us to make sense of the puzzling sentence: I know that I know nothing. The fatal irony, into which scientific-technical society plunges us, is, as a consequence of its perfection, much more radical: We don't know what it is we don't know - but from these dangers arise, which threaten mankind! The perfect example here is provided by the debate about the cooling agent CFC. About 45 years after the discovery of the CFC, the chemists Rowland and Molina (1974) put forward the hypothesis, that CFCs destroy the ozone layer of the stratosphere and as a result increased ultraviolet radiation would reach the earth. The chain of unforeseen secondary effects would lead to a significant increase of cancer all over the world. When coolants were invented no one could know or even suspect, that they would create such a danger.

The irony of risk is that rationality, that is, the experience of the past, encourages anticipation of the wrong kind of risk, the one we believe we can calculate and control, whereas the disaster arises from what we don't know and cannot calculate. The bitter varieties of this risk irony are virtually endless: climate change, mad cow decease, 9/11 terror attacks, global financial crises, swine flue virus and latest but not last, volcano ash clouds disrupting air traffic in Europe and elsewhere.

To the extent that risk is experienced as omnipresent, there are only three possible reactions: *Denial*, *apathy*, or *transformation*. The first is largely inscribed in modern culture, the second resembles postmodern nihilism, and the third is the 'cosmopolitan moment' of world risk society (Beck 1986, 1992, 2006, 2007, 2009). I would like to demonstrate that here in three steps (drawing on empirical research findings of the Munich Research Centre on 'Reflexive Modernization'):

1. Old dangers - new risks: What is new about world risk society?
2. Ruse of history: To what extent are global risks a global force in present and future world history, controllable by no one, but which also open up new opportunities of action for states, civil society actors etc.?
3. Consequences and perspectives: In order to understand the manufactured uncertainty, lack of safety and insecurity of world risk society is there a need for a paradigm shift in the social sciences?

Old Dangers - New Risks: What is New About World Risk Society?

Modern society has become a risk society in the sense that it is increasingly occupied with debating, preventing and managing risks that it itself has produced. That may well be, many will object, but it is indicative rather of a hysteria and politics of fear instigated and aggravated by the mass media. On the contrary, would not someone, looking at European societies from outside have to acknowledge that the risks which get us worked up, are luxury risks, more than anything else? After all, our world appears a lot safer than that, say, of the war-torn regions of Africa, Afghanistan or the Middle East. Are modern societies not distinguished precisely by the fact that to a large extent they have succeeded in bringing under control contingencies and uncertainties, for example with respect to accidents, violence and sickness?

As true as all such observations may be, they miss the most obvious point about risk: that is, the key distinction between risk and catastrophe. Risk does *not* mean catastrophe. Risk means the *anticipation* of catastrophe. Risks exist in a permanent state of virtuality, and only become 'topical' to the extent that they are anticipated. Without techniques of visualization, without symbolic forms, without mass media etc. risks are nothing at all. In other words, it is irrelevant, whether we live in a world which is in fact or in some sense 'objectively' safer than all other worlds; if destruction and disasters are anticipated, then that produces a compulsion to act.

The theory of 'world risk society' maintains that modern societies are shaped by new kinds of risks, that their foundations are shaken by the global anticipation of global catastrophes. Such perceptions of global risk are characterized by three features:

1. *De-localization*: Its causes and consequences are not limited to one geographical location or space, they are in principle omnipresent.
2. *Incalculableness*: Its consequences are in principle incalculable; at bottom it's a matter of 'hypothetical' risks, which, not least, are based on science-induced not-knowing and normative dissent.
3. *Non-compensatibility*: The security dream of first modernity was based on the scientific utopia of making the unsafe consequences and dangers of decisions ever more controllable; accidents could occur, as long and because they were considered compensatible. If the climate has changed irreversibly, if progress in human genetics makes irreversible interventions in human existence possible, if terrorist groups already have weapons of mass destruction available to them, then it's too late. Given this new quality of 'threats to humanity' – argues Francois Ewald (2002: 275) – the logic of compensation breaks down and is replaced by the principle of *precaution through prevention*. Not only is prevention taking precedence over compensation, we are also trying to anticipate and prevent risks whose existence has not been proven. Let me explain these points - de-localization, incalculableness, non-compensatibility – in greater detail.

The de-localization of incalculable interdependency risks takes place at three levels:

1. *spatial*: The new risks (e.g. climate change) do not respect nation state or any other borders;
2. *temporal*: The new risks have a long latency period (e.g. nuclear waste), so that their effect over time cannot be reliably determined and limited.
3. *Social*: Thanks to the complexity of the problems and the length of chains of effect, assignment of causes and consequences is no longer possible with any degree of reliability (e.g. financial crises).

The discovery of the incalculability of risk is closely connected to the discovery of the importance of not-knowing to risk calculation, and it's part of another kind of irony, that surprisingly this discovery of not-knowing occurred in a scholarly discipline, which today no longer wants to have anything to do with it: economics. It was Knight and Keynes, who early on insisted on a distinction between predictable and non-predictable or calculable and non-calculable forms of contingency. In a famous article in *The Quarterly Journal of Economics* Keynes (1937: 213–14) writes: "...by 'uncertain knowledge', let me explain, I do not mean merely to distinguish what is known from what is merely probable. The sense in which I am using the term is that in which the price of copper and the rate of interest twenty years hence, all the obsolescence of a new invention are uncertain. About these matters there is no scientific basis on which to form any calculable probability whatever. We simply do not know..." However, Keynes' admonition to open up the field of economic decision-making to the unknown unknowns was entirely neglected in the subsequent development of mainstream economics (including mainstream Keynesian economics); and this denial of non-knowing has become a causal condition for the emergence of the global financial crisis in 2009.

The crucial point, however, is not only the discovery of the importance of non-knowing, but that simultaneously the knowledge, control and security claim of state and society was, indeed had to be, renewed, deepened, and expanded. The irony lies in the institutionalized security claim, to have to control something, even if one does not know, whether it exists! It are precisely unknown unknowns which provoke far-reaching conflicts over the definition and construction of political rules and responsibilities with the aim of preventing the worst. For the time being the last and most striking example of that are the volcano ash clouds in spring 2010: flights are back – ash is too!

If catastrophes are anticipated whose potential for destruction ultimately threatens everyone, then a risk calculation based on experience and rationality breaks down. Now all possible, more or less improbable scenarios have to be taken into consideration; to knowledge, therefore, drawn from experience and science there now also has to be added imagination, suspicion, fiction, fear (Ewald 2002: 273–301). The boundary between rationality and hysteria becomes blurred.

Given the right invested in them to avert dangers politicians, in particular, may easily be forced to proclaim a security, which they cannot honour. Because the *political* costs of omission are much higher than the political costs of overreaction. In future, therefore, it is not going to be easy, in the context of state promises of security and a mass media hungry for catastrophes, to actively limit and prevent a diabolical power game with the hysteria of not-knowing. I don't even dare think about deliberate attempts to instrumentalize this situation.

The Ruse of Risk: Global Risk is an Unpredictable and Impersonal Force in the Contemporary World

There is no better way than to start with an example: in 2005 Hurricane Katrina destroyed New Orleans. This was a horrifying act of nature, but one which simultaneously, as a global media event, involuntarily and unexpectedly developed an enlightenment function which broke all resistance. What no social movement, no political party, and certainly no sociological analysis (no matter how well grounded and brilliantly written) would have been able to achieve, happened within a few days: America and the world were confronted by global media pictures of the repressed *other* America, the largely racialized face of poverty. How can this relationship between risk and the creation of a global public be understood? In his 1927 book *The Public and its Problems*, John Dewey explained that not actions but *consequences* lie at the heart of politics. Although Dewey was certainly not thinking of global warming, BSE or terrorist attacks, his idea is perfectly applicable to world risk society. A global public discourse does *not* grow out of a consensus on decisions, but out of *dissent* over the *consequences* of decisions. Modern risk crises are constituted by just such controversies over consequences. Where some may see an overreaction to risk, it is also possible to see grounds for hope. Because such risk conflicts do indeed have an enlightenment function. They destabilize the existing order, but the same events can also look like a vital step towards the building of new institutions. Global risk has the power to tear away the facades of organized irresponsibility.

Egoism, autonomy, autopoesis, self-isolation, improbability of translation – these are key terms which, in sociological theory, but also in public and political debates, distinguish modern society. The communicative logic of global risk can be understood as the exact opposite principle. Risk is *the* involuntary, unintended compulsory medium of communication in a world of irreconcilable differences, in which everyone revolves around themselves. Hence a publicly perceived risk compels communication between those, who do not want to have anything to do with one another. It assigns obligations and costs to those who refuse them - and who often even have current law on their side. In other words: Risks cut through the self-absorption of cultures, languages, religions and systems as well as the national and international agenda of politics, they overturn their priorities and create contexts for action between camps, parties and quarrelling nations, which ignore and oppose one another.

I propose that a clear distinction be made between the philosophical and normative ideas of cosmopolitanism on the one hand and the 'impure' actual cosmopolitanization in the sociological sense on the other. The crucial point about this distinction is that cosmopolitanism cannot, for example, only become real deductively in a translation of the sublime principles of philosophy, but also and above all through the back doors of global risks, unseen, unintended, enforced. Down through history cosmopolitanism bore the taint of being elitist, idealistic, imperialist, capitalist; today, however, we see, that reality itself has become cosmopolitan. Cosmopolitanism does not mean - as it did for Immanuel Kant – an asset, a task, that is to order the world. Cosmopolitanism in world risk society opens our eyes to the uncontrollable liabilities, to something that happens to us, befalls us, but at the same time stimulates us to make border-transcending new beginnings. The insight, that in the dynamic of world risk society we are dealing with a cosmopolitanization under duress, robs 'impure' cosmopolitanism of much of its ethical attractiveness. If the cosmopolitan moment of world risk society is both at once: deformed and inevitable, then seemingly it is not an appropriate object for sociological and political reflections. But precisely that would be a serious mistake.

As important as all these arguments are, the decisive question is a different one: To what extent does the threat and shock of world risk society open up the horizon to *historic alternatives of political action*? For an answer see *Power in the Global Age* (Beck 2005). Here I can only outline the basic idea.

Two premises: (1) World risk society brings a new, historic key logic to the fore: No nation can cope with its problems alone. (2) A realistic political alternative in the global age is possible, which counteracts the loss to globalized capital of the commanding power

of state politics. The condition is, that globalization must be decoded not as economic fate, but as a strategic game for world power. A new global domestic politics that is already at work here and now, beyond the national-international distinction, has become a meta-power game, whose outcome is completely open-ended. It is a game in which boundaries, basic rules and basic distinctions are renegotiated - not only those between the national and the international spheres, but also those between global business and the state, transnational civil society movements, supranational organizations and national governments and societies.

The strategies of action, which global risks open up, overthrow the order of power, which has formed in the neo-liberal capital-state coalition: global risks *empower* states and civil society movements, because they reveal new sources of legitimation and options for action for these groups of actors; they *disempower* globalized capital on the other hand, because the consequences of investment decisions and externalizing risks in financial markets contribute to creating global risks, destabilizing markets, globally operating banks, and activating the power of the state as well as of that sleeping giant the consumer. Conversely, the goal of global civil society and its actors is to achieve a connection between civil society and the state, that is, to bring about a *cosmopolitan form of statehood*. The forms of alliances entered into by the neo-liberal state instrumentalize the state (and state-theory) in order to optimize and legitimize the interests of capital world wide. Conversely the idea of a cosmopolitan state in civil society form aims at imagining and realizing a robust diversity and a post-national order. The neo-liberal agenda surrounds itself with an aura of self-regulation and self-legitimation. Civil society's agenda, on the other hand, surrounds itself with the aura of human rights, global justice and struggles for a new grand narrative of radical-democratic globalization.

Why is this not wishful thinking, why is it an expression of a *cosmopolitan realpolitik*? The cosmopolitan perspective suggests that there is a hidden link between global risk and Immanuel Kant. It is precisely the stark realism of the *cosmopolitan imperative: either Kant or catastrophe! either cooperate or fail!* which is also cause for hope.

Consequences and Perspectives

It is evident, that the taken-for-granted nation-state frame of reference – what I call 'methodological nationalism' – prevents the social and political science from understanding and analyzing the dynamics and conflicts, ambivalences and ironies of world risk society. This is also true - at least in part - of the two major theoretical approaches and empirical schools of research, which deal with risk, on the one hand in the tradition of Mary Douglas, on the other in that of Michel Foucault. These traditions of thought and research have undoubtedly raised key questions and produced extremely interesting detailed results as far as understanding definitions of risk and risk policies is concerned, work which no one can dispense with and which will always remain an essential component of social science risk research. Their achievement and their evidence are to open up risk as a battle for the redefinition of state and scientific power.

An initial defect lies in regarding risk more or less or even exclusively as an ally, but failing to perceive it as an *unreliable* ally and not at all as a potential antagonist, as a force hostile both to nation state power as well as to global capital. Surprisingly the research traditions of Douglas and Foucault define their problem in such a way, that the battle over risk always comes down to the reproduction of the social and state order of power. Because the nation state, which attempts to deal with global risks in isolation, resembles a drunk man, who on a dark night is trying to find his lost wallet in the cone of light of a street lamp. To the question: Did you actually lose your wallet here, he replies, no, but in the light of the street lamp I can at least look for it.

In other words, global risks are producing 'failed or bankrupt states' - even in the West (last example Greece, but maybe in the near future also Italy or Great Britain or even the USA). The state-structure evolving under the conditions of world risk society could be characterized in terms of both inefficiency *and* post-democratic authority. A clear distinction, therefore, has to be made between rule and inefficiency. It is quite possible, that the end result could be the gloomy perspective, that we have totally ineffective and authoritarian state regimes (even in the context of the Western democracies). The irony here is this: manufactured uncertainty (knowledge), insecurity (welfare state) and lack of safety (violence) undermine *and* reaffirm state power beyond democratic legitimacy. Given the maddening conditions of world risk society, the older critical theory of Foucault is in

danger of becoming simultaneously affirmative and antiquated, along with large areas of sociology, which have concentrated on class dynamics in the welfare state. It underestimates and castrates the communicative cosmopolitan logic and irony of global risks; consequently the historic question, where politics has lost its wallet, that is, the question of an alternative modernity, is analytically excluded by the vain searching in the cone of light of the nation state street light.

Cosmopolitan social sciences, which face up to the challenges of global risks, must also, however, shed its political quietism: Society and its institutions are incapable of adequately conceptualizing risks, because they are caught up in the concepts of first nation state modernity, believing in scientific certainty and linear progress, which by now have become inappropriate. And it has to face the question: How can non-Western risk societies be understood by a sociology, which so far has taken it for granted, that its object - Western modernity - is at once both historically unique and universally valid?[1] How is it possible to decipher the internal link between risk and race, risk and enemy image, risk and exclusion?

Population Prospects and the Challenges of Sustainability

Hania Zlotnik[1]

As the world prepares to cope with the challenges posed by environmental change, the implications of the rapid population growth that started almost a century ago and of future population trends cannot be ignored. Between the late 1920's and today, the population of the world has more than tripled, passing from 2 billion to nearly 7 billion. Except for a short hiatus caused by the Second World War, the growth rate of the world population accelerated between the 1920's and the late 1960's, passing from 0.5 per cent per year to 2.0 per cent per year. Such acceleration was the result of reductions in mortality, particularly among children. Starting in the 1970's, declining fertility in developing countries began to counteract the reduction of mortality to produce a declining global rate of population growth. Yet, despite the major reductions in fertility that the majority of countries have recorded, population growth still averages 1.2 per cent per year globally and is a high 2.4 per cent per year in sub-Saharan Africa and 2.3 per cent in the least developed countries (about two thirds of which are in sub-Saharan Africa).

Because of population momentum, even if the fertility of each country were to reach replacement[2] level tomorrow, the world population would still increase to 9 billion by 2050 and, in a scenario without further change in fertility and mortality, it would attain 10.1 billion by mid-century and still have a large potential for continued growth.

These population outcomes need to be borne in mind when considering the medium variant projection (UN 2009) produced by the United Nations Population Division, whose results are the most often used to indicate the likely size of the world population by mid-century. In the medium variant, mortality is projected to decrease in all countries and fertility levels in developing countries are projected to fall below replacement level, whereas the fertility of developed countries is expected to recuperate somewhat from the very low levels reached over the past decade. The result is a population of 9.1 billion in 2050, whose annual rate of change would have dropped to 0.3 per cent by then and would therefore be well on the way to stabilization. Nevertheless, this low growth rate is not equally shared by all development groups. Developed countries as a whole are projected to have a declining population in 2050. In sharp contrast, the population of the least developed countries will still be growing at a rate of 1.1 per cent annually and the rest of the developing world will have a population that is nearing the end of population growth, rising annually at a low rate of just 0.2 per cent.

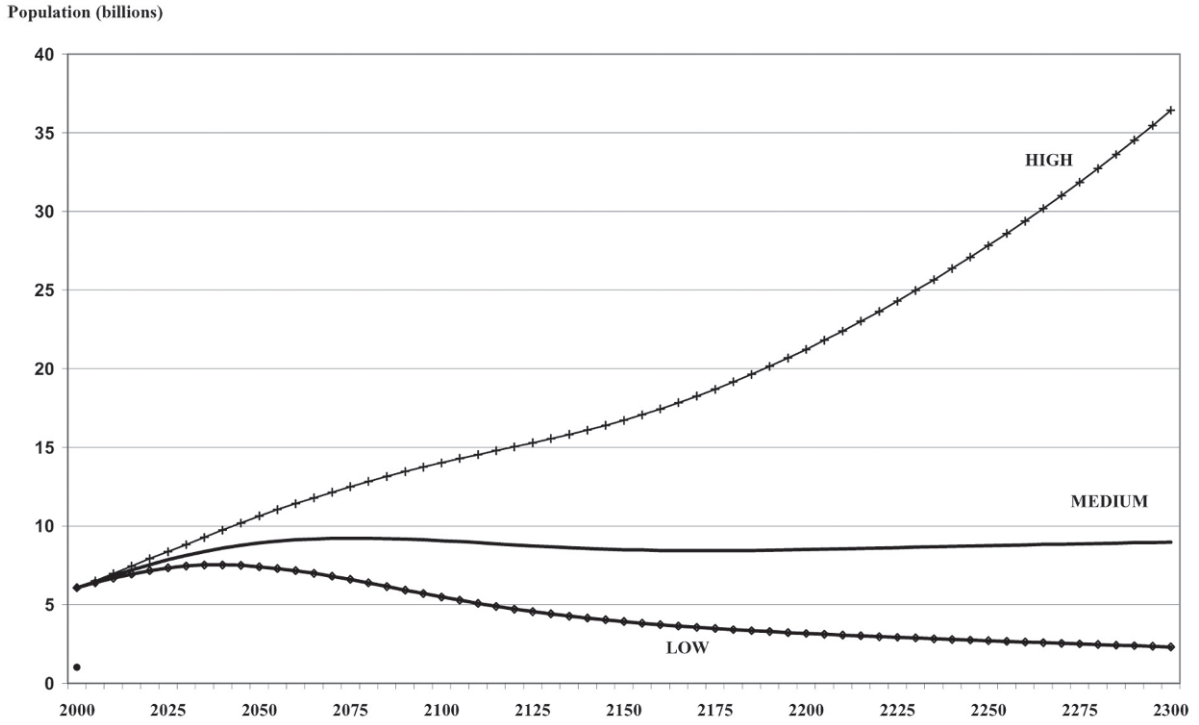
According to the medium variant, nearly all the increases in population expected from now to 2050 will occur in developing countries. Out of the additional 2.2 billion people expected to live on Earth by 2050, 48 per cent will be added to the population of Asia and 43 per cent to that of Africa. The least developed countries, which account for just 12 per cent of the world population today, are projected to account for 36 per cent of the population growth expected from now to 2050 under the medium variant.

---

1 The views and opinions expressed in this essay are those of the author and do not necessarily represent those of the United Nations.

2 Replacement-level fertility is the number of children women should have on average to ensure that every woman is replaced by a daughter. Because some women die before they reach the age when they can reproduce and more boys are born than girls, replacement-level fertility is always above 2 children per woman and can be much higher in high-mortality countries. In the scenario whose results are cited here, replacement-level fertility is calculated exactly for each country according to its level of mortality.

Figure PE 4.1: World population according to different scenarios, 2000-2300. **Source:** UN (2004).



These trends present opportunities and challenges. The population reductions expected in developed countries as a whole can help moderate the impact that high standards of living have on the environment. Similarly, slowing population growth in the majority of developing countries can assist in counterbalancing the impact that accelerated economic growth will likely have on the forces leading to environmental change. Yet, even with slowing population growth, India alone will account for nearly 18 per cent of future population increases and, together with China, Indonesia and Brazil, in order of importance, will add 541 million inhabitants to Earth by 2050 or a quarter of the overall projected population increase.

In the least developed countries, the rapid population growth still expected to occur is likely to present more challenges than opportunities. Precisely the populations that are already most vulnerable to environmental change because of the limited capacity and resources they have to adapt are those most likely to see their numbers double over the next forty years. An Africa of 1 billion people today is very likely to become the home of 2 billion by 2050. The least developed countries, whose current population is 0.9 billion, are projected to have 1.7 billion inhabitants by mid-century.

The Sensitivity of Long-term Population Trends to Deviations from Zero Population Growth

In 2004, the United Nations Population Division produced long-range projections to 2300 to explore the impact that deviations from replacement-level fertility would have on the eventual size and distribution of populations (UN 2004). The medium scenario in that set of projections produced a world population of 8.9 billion in 2050 and a population that peaked at 9.2 billion in 2075, declined to 8.3 billion in 2175 and then increased slowly to reach again 9.0 billion in 2300. Underlying those changes in population size was a fertility path that kept every country at below replacement level for about 100 years and then returned fertility to replacement level[3] and maintained it there until 2300. The population did not quite stabilize over the projection period because mortality was projected to keep on declining, producing therefore a sustained but very slow population increase.

3 Replacement-level fertility for each country was calculated according to its level of mortality. If mortality is constant and net migration is nil, maintaining fertility at replacement level yields eventually an unchanging population with zero population growth.

Two different scenarios were produced to test the sensitivity of future population size to small but sustained deviations of fertility from replacement level. Thus, a low scenario, where fertility remained a quarter of a child below that in the medium scenario, yielded a 2300 population of just 2.3 billion, similar in size to the global population in 1950. In contrast, a high scenario where fertility remained a quarter of a child higher than in the medium scenario produced a 2300 population of 36.4 billion.

Even more telling was the scenario where fertility was maintained constant at the level it had in 1995–2000. Under that assumption, world population soared to 244 billion by 2150 and 134 trillion in 2300, indicating the unsustainable character of current fertility levels. Furthermore, all the projected population increase occurred in the developing world, whose population rose from 4.9 billion in 2000 to 134 trillion in 2300. Africa's population alone was projected to rise from 0.8 billion in 2000 to 115 trillion in 2300. In contrast, the population of developed countries as a whole was projected to be cut in half, from 1.2 billion in 2000 to 0.6 billion in 2300. This unlikely scenario served to highlight the stark regional differences that exist today in population trends and their implications for the future.

Although none of the scenarios produced as part of the long-term projections may actually come to pass, their implications are clear: positive deviations from zero population growth maintained over the long run are unlikely to be sustainable. So far, the major cause of the global deceleration of population growth has been the reduction of fertility, which dropped from nearly 5 children per woman in 1950–1955 to 2.6 in 2005–2010. The medium variant produced in 2008 projected that global fertility would be slightly below replacement level by 2045–2050, at 2.0 children per woman. To attain that level, fertility still needs to decline in many countries, including in the least developed countries, where fertility averages 4.4 children per woman, and in a number of other developing countries, especially those in South-central Asia, Western Asia and Northern Africa, where fertility still averages just under 3 children per woman, and in Central America, where it averages close to 2.5 children per woman. A number of measures can be taken to promote and facilitate the further reduction of fertility, including improving information and access to contraceptive methods (UN 2009a) and supporting the empowerment of women through education, equality of rights with men and women's increased participation in economic and social life.

The Increasing World Urbanization

With 50.5 per cent or 3.5 billion of the people on Earth living in cities in 2010 and urban populations growing, often at the expense of rural areas, the global population as a whole has become more urban than rural.[4] Yet, there are major disparities in the levels of urbanization among regions. Northern America, Latin America and the Caribbean, Europe and Oceania are highly urbanized, with proportions urban ranging from 70 per cent in Oceania to 82 per cent in Northern America. In sharp contrast, Africa and Asia remain mostly rural, with just 40 per cent and 42 per cent of their respective populations living in urban settlements in 2010.

A third of all urban inhabitants (1.1 billion) live in small urban localities with populations below 100,000. Another 0.6 billion live in urban centres with populations ranging between 100,000 and 500,000 inhabitants. In all, 52 per cent of the urban population lives in urban centres with fewer than half a million inhabitants. The rest live in 958 cities having more than half a million inhabitants each in 2010, only 53 of which have populations surpassing 5 million. These larger cities include 21 megacities, that is, cities with at least 10 million inhabitants, which altogether account for 9 per cent of the world urban population (324 million).

According to current projections, the level of urbanization of the highly-urbanized regions is expected to increase slowly, but a relatively rapid urbanization is projected in both Africa and Asia. Nevertheless, by 2050 both Africa and Asia are expected to be significantly less urbanized than the other regions, with 60 per cent and 65 per cent of their respective populations living in urban areas. All other regions, except Oceania, are projected to be more than 84 per cent urban in 2050.

In 2009, 140 out of the 230 countries or areas constituting the world were already more than half urban. Over the next four decades, 66 countries or areas are expected to reach that threshold for the first time. In 2050, only 24 countries or areas are expected to fall

4 This section draws heavily on the following United Nations publications: UN (2009b, 2010); and on "World Urbanization Prospects: The 2009 Revision", Press Release, New York, 25 March 2010; at: <http://esa.un.org/unpd/wup/Documents/WUP2009_Press-Release_Final_Rev1.pdf>. All UNPD documents are accessible at: <http://www.un.org/esa/population/>.

short from being half urban, including eight countries in Africa, another eight in Oceania and five in Asia.

Globally, the rural population is projected to start decreasing around 2020 and 0.56 billion fewer rural inhabitants are expected in 2050 than today, with the rural population projected to decline from 3.4 billion in 2010 to 2.9 billion in 2050. Asia, having the largest number of rural inhabitants, is expected to experience the most sizable reduction: from 2.4 billion in 2010 to 1.8 billion in 2050. In contrast, the rural population of Africa is expected to gain 147 million and to keep on rising until 2040. By 2050, Africa is expected to have 0.8 billion rural inhabitants.

The slowing pace of growth and outright decline of the rural population and the rising levels of urbanization are two sides of the same coin. Urbanization results from the restructuring of economies to become more productive and is an intrinsic part of the development process. Agriculture, the major economic activity in rural areas, is subject to diminishing returns if, over long periods, the number of agricultural workers grows more rapidly than the land available for production. When the urban productive sector can absorb the excess labour force in rural areas, both sectors benefit. Successful economies have all experienced an acceleration of urbanization. Today, countries having large proportions of the population living in rural areas are more likely to be among the least developed countries and to have lower levels of national income per capita. Conversely, higher levels of urbanization are associated with higher income levels.

Because the rural population is projected to decrease, the urban areas of the world are expected to absorb all the population growth expected over the next four decades while at the same time drawing in some of the rural population. Between 2010 and 2050, the world population is expected to increase by 2.2 billion, passing from 6.9 billion to 9.1 billion. At the same time, the population living in urban areas is projected to gain 2.8 billion, passing from 3.5 billion in 2010 to 6.3 billion 2050. Asia, which is home to the largest number of urban dwellers in the world (1.8 billion in 2010) is expected to see its urban population increase by 1.6 billion, to reach 3.4 billion. Africa, whose urban population is the fourth largest in the world in 2010, following those of Europe and Latin America and the Caribbean, is expected to see it rise by 0.8 billion, to reach 1.2 billion in 2050, when it will be the second largest after that of Asia.

The expected redistribution of the world's population between urban and rural settlements has important implications for both economic growth and environmental change. It is estimated that the 3.5 billion people living in cities today occupy 3 per cent of the Earth's land area, while the livelihoods of today's 3.4 billion rural dwellers depend mainly on cropland, which accounts for 12 per cent of the world's land area (UN 2009c). Burdening agricultural areas with the additional 2.2 billion people expected to live on Earth by 2050 would be unsustainable. Cities, where wealth, infrastructure and know-how are already concentrated, are in a better position to adapt to growing populations but to do so authorities at both the local

and the national levels must address the ills that often affect urban settlements, especially environmental contamination stemming from traffic congestion, the concentration of industry and inadequate waste disposal systems, as well as inequities arising from the persistent disparities among city dwellers, which mean that poor people bear the brunt of the negative aspects of urbanization. The expected rapid urbanization of low-income countries, particularly those in Africa and Asia, pose special challenges. Providing urban populations with access to services, including water and sanitation, transport and adequate housing, is necessary if their vulnerability to the extreme weather events associated with climate change is to be reduced. The concentration of population in cities generates the economies of scale that can justify improving planning for the provision of services in ways that are consistent with better protection of the environment.

As the world becomes increasingly urban, decisions taken today in cities across the world will shape the economic, social and environmental future of humankind. Properly managed, urbanization can help in combating poverty, inequality and environmental degradation, but action to capitalize on the opportunities it presents and to address the challenges it raises must be prompt and sustained (UN 2009c: 46–47).

Towards a Great Land-Use Transformation?

Christoph Müller, Hermann Lotze-Campen, Veronika Huber, Alexander Popp, Anastasia Svirejeva-Hopkins, Michael Krause and Hans Joachim Schellnhuber

The Climate Change Challenge and Land-use Mitigation Options

Climate change poses great threats to many compartments of the Earth System and, as a consequence, to human societies. There is growing scientific evidence that a rise of the global mean temperature by more than 2 °C (as compared to pre-industrial levels) would irreversibly harm many ecosystems and most likely exceed the adaptive capacities of many societies. In order to confine global warming to maximally 2 °C, major efforts to reduce emissions of greenhouse gases are required. These may even include 'negative emissions' of carbon dioxide to be achieved by the second half of this century: carbon dioxide may have to be actively removed from the atmosphere and deposited on land for many decades, centuries, or even millennia.

The transformation of the energy system, steering away from fossil fuels, will have to contribute the lion's share of emission reductions. However, land-use changes are currently responsible for one third of total greenhouse gas emissions, so improved land management and productivity increases on land under cultivation could significantly contribute to climate change mitigation since soils and forests store large amounts of carbon.

Several techniques that would allow for negative emissions are currently discussed: afforestation and the restoration of peat and wetlands would be the most easily accessible options. Other options such as technologies for *carbon capture and storage* (CCS) in the energy sector involve sequestration of carbon dioxide in geological formations underground. Carbon dioxide could be directly extracted from the atmosphere making use of chemical reactions turning the greenhouse gas into solid carbonates. The large-scale application of these technologies is however still in its infancy. The most promising mechanism to achieve negative emissions is to fuel power plants with biomass, extract carbon dioxide from the exhaust and sequester it underground. However, in order to draw down a really significant amount of carbon dioxide, enormous quantities of biomass would have to be processed this way.

Increasing Demands on Land and the Need for Adaptation

In many regions, most of the available resources of fresh water and fertile land are already being used excessively, either directly for the production of food, fibre, and timber, or indirectly as carbon sinks, for water and air purification, nature conservation, and many other ecosystem services. This scarcity of basic resources is amplified by a non-sustainable use, causing degradation of ecosystems and production potentials. Fifteen per cent of the global land surface (about 2 billion hectares) are currently considered as being degraded – due to overgrazing, deforestation, over-exploitation and non-sustainable agricultural practices.

Since the year 2000, global agricultural supply has not kept pace with an increasing demand for food and bioenergy. The food price spike in 2007–2008 and related food riots in more than 60 countries had many underlying causes, but increasing demand in large emerging economies and dwindling stocks were certainly part of them. High oil prices and subsidies for biofuels in rich countries urged farmers around the world to allocate land and other factor inputs to energy crops, thus reducing the production of staple food crops. Continuous droughts, e.g. in Australia, added more pressure on food markets. Finally, an underlying cause of stagnating productivity increase in

agriculture is a lack of funds for research and development.

In most countries, land prices insufficiently reflect the growing imbalance between demand and supply of fertile land. However, first conspicuous signs of land shortages have emerged. Large companies and even countries are already trying to stake their claims globally, a process known as 'land-grabbing'. In addition to buying food on the world market, several governments and large companies lease or buy land abroad, and ship the products back home. Advocates of these deals emphasize that poor countries may gain from access to new seeds and advanced farming practices. However, leasing land to financially powerful investors has also sparked conflict in the recent past. In Madagascar, public hostility to a deal that would have leased 1.3 million hectares to a South Korean company – half of the country's arable land – contributed to the overthrowing of the government. While foreign investors mostly secure land to improve food security in their home countries, an increasing number of projects involve growing biomass for fuel production. China has recently succeeded in leasing 2.8 million hectares in the Congo to construct the world's largest palm oil plantation.

Climate change is expected to increase these pressures and further reduce land productivity in many regions (chap. 1 by Brauch/Oswald Spring). The need for climate change adaptation is evident – already today. Most developing countries are located in the lower latitudes, they are dependent on agriculture, they will be strongly affected by climate impacts, and they have lower adaptive capacity (chap. 49 by Adeel; chap. 50 by Galil Hussein; chap. 51 by Arredondo/Huber-Sannwald; chap. 63 by Bikienga). People migrate from degraded to more fertile areas, from the countryside to cities, from regions that cannot provide sufficient resources to sustain people's livelihoods to more fortunate places. The war in Sudan, for example, has partly been blamed on the competition for water supplies and grazing lands. About 155 million people worldwide are known to be currently displaced by environmental conflicts and natural disasters (chap. 40 Guha-Sapir/Vos). This number could significantly grow under climate change as more people are expected to be affected by water shortages, sea level rise, deteriorating pasture land, and crop shortage.

Negative climate impacts on agriculture may be reduced through a range of adaptation measures. Adjustments in production technology and soil management, crop insurance schemes, modified agricultural policies, and diversified international trade flows can improve regional food availability and security of farm incomes. Creating more options for climate change adaptation and improving the adaptive capacity in the agricultural sector will be crucial for improving food security and rural development, and for preventing an increase in global inequality in living standards in the future (chap. 48 by Safriel; chap. 54 by García Lorca). However, at present, these improvements are often blocked by the lack of information, financial resources and good governance in the developing world.

The Earth's Carrying Capacity Conundrum

Mismatches between the demand and supply of land and its services already exist today. They could increase in the future not only due to climate change but also due to human population growth. Until the year 2100, human population is projected by the UN to grow up to 9–12 billion people, while already today about 1 billion people are undernourished. Changing lifestyles will further accelerate demand growth as people start to consume more goods that are produced with large amounts of energy, land, and water (such as meat) as soon as they can afford it.

The increasing competition for land and water resources between production sectors, ecosystem services, and regions raises the question of the Earth's carrying capacity for humans.[1] The first known attempt to answer the question of how many people the Earth can support was undertaken in the late 17th century. By extrapolating the population density of the Netherlands at that time to the global scale, Antonie van Leeuwenhoek in 1679 calculated a maximum human population of 13.4 billion people, which is astonishingly close to current UN projections of maximum world population.

Estimates of the human carrying capacities since then have varied substantially in a range of below 1 billion to more than 1 trillion people. Magnitudes reflect surprisingly well optimistic or pessimistic contemporary beliefs on the pace of technological progress and future development of energy supply. The broad range of possible lifestyles and accompanying usage

1 Ecologists define 'carrying capacity' as the population of a given species that can be supported indefinitely in a defined habitat without permanently damaging the ecosystem upon which it is dependent.

patterns of energy, land, and water complicate a direct assessment of the human carrying capacity. Estimating the human carrying capacity in any serious manner therefore requires first of all answers to a set of crucial sub-questions:

- Solar energy is theoretically infinitely abundant and could be harvested to fulfil all global energy needs. However, is it feasible given the current state of technology?
- It has been shown during the past 'Green Revolution' that agricultural productivity can be increased by 2 per cent per year for some time, but can this be sustained for another half a century into the future?
- How much land will be available for food production, while other land-use types for forestry, energy, infrastructure and settlements, and nature conservation also have to be taken into account?
- Agriculture accounts for 70 per cent of global freshwater use. How can agricultural water use be reduced in the future, in order to meet increasing demands from households and industry?

Defining a realistic set of assumptions on limits to technological change, energy generation, and the availability of land and water is a most difficult task. Consequently, it is more promising to undertake the *inverse* exercise and, instead of aiming at an estimate of the human carrying capacity, to ask the question: How much land, water, agricultural productivity increase, and financial resources are required to feed 9–12 billion people in a sustainable manner, i.e. without exhausting the planetary regeneration capacities?

With the given competition for the scarce resources of fertile land and water, higher production on currently used areas is a necessity. Assessments show, however, that average productivity of current cropland needs to be increased by 70 per cent by 2050 if only population growth and changing diets with rising income are considered. If further climate change impacts and increasing demand for bioenergy are taken into account, agricultural productivity may need to be increased by 150 per cent by 2050. This would be equivalent to an average annual growth rate of 2.3 per cent in land productivity over the next 40 years.

The historic development of agricultural productivity puts this challenge into perspective: The overall increase over the period 1961–2005 was approximately 1.4 per cent per year. These growth rates could be achieved because of large-scale application of artificially synthesized nitrogen (Haber-Bosch process) and chemical pest control, but also improvements in cropping methods, mechanization, and breeding. These technological advances allowed for agricultural production to keep pace with past population growth and diet changes, including rising consumption of animal products, which require higher inputs of nitrogen, water, and land per calorie produced than vegetal products. It is, however, questionable whether technological innovation and further intensification of agriculture will bring about the productivity rise needed to feed 9–12 billion people on a planet suffering from climate change and land degradation.

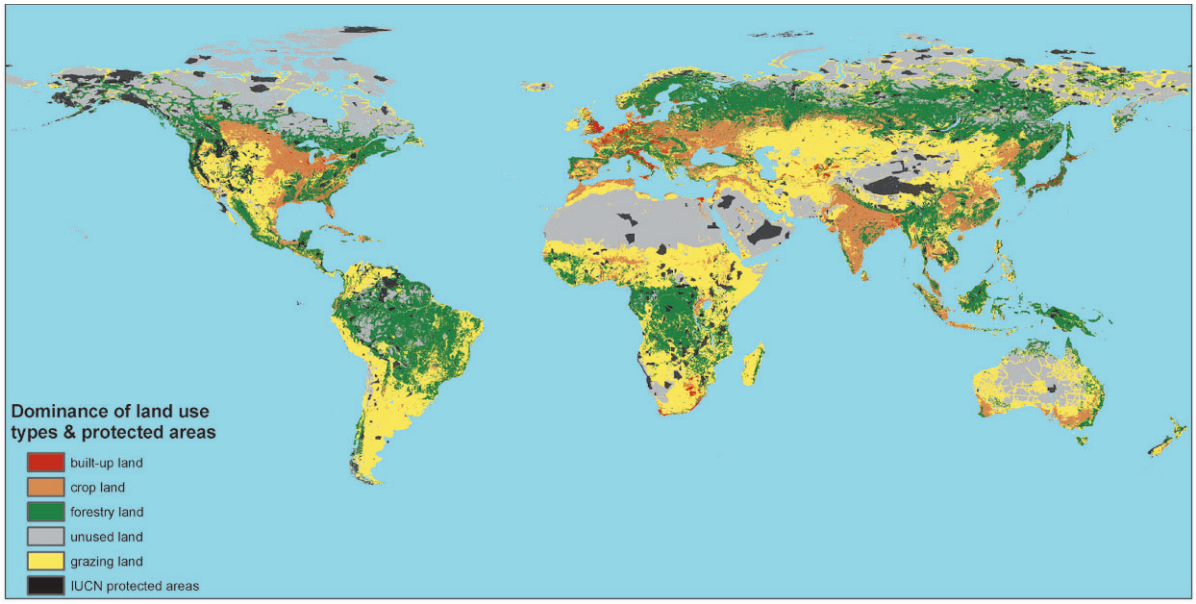
Water scarcity may be technically overcome by improved desalination. However, this depends on the availability of clean energy as well as on future cost reductions for desalination technologies. Aquaculture has the potential to provide an increasing share of world food supplies, but it is not without its own sustainability challenges regarding feed and nutrient management. In other words: It seems unlikely that improved management and technological change alone will suffice to counterbalance the increasing pressure on land and water resources.

The Great Land-use Transformation

Climate change and the scarcity of land and water resources are global-scale challenges to humankind and therefore require global-scale transformations in the energy and food systems. However, initiating and managing major socio-economic transitions is often impeded by path dependencies – or so-called "QWERTY phenomena": Q-W-E-R-T-Y are the first six letters on the upper left part of an English typing keyboard. As a matter of fact, this arrangement of symbols has become an iconic constituent of our technical culture. Interestingly, the arrangement of letters on modern computer keyboards is by no means optimized with respect to the frequencies of use defined by the language. Instead, the key configuration probably originates from some mechanical requirements for the first typewriters built in the 19th century. Similarly, societal processes are often locked, through historic pathways, into certain patterns, which are defined by past knowledge and technologies and which can only be changed through major investments and/or behavioural changes. New and potentially radical ideas and actions are needed to overcome these lock-in phenomena.

Current land-use patterns have developed over hundreds of years, largely reflecting heterogeneous

Figure PE 5.1: Global map showing current dominant land-use types: agriculture (including cropland, managed pasture land and rangeland), forestry, infrastructure and settlement, unused land, and nature conservation (protected areas as listed by the International Union for the Conservation of Nature, IUCN). Areas that are used for renewable energy generation are either included in the cropland category (in the case of bioenergy) or are not represented in the map (in the case of e.g. solar thermal power in the deserts and onshore/offshore wind energy production). **Source:** Data sets on global land-use types, i.e. built-up land, cropland, forestry land, unused land, and grazing land were provided by Erb, Gaube, Krausmann, Plutzar, Bondeau and Haberl (2007).[a]

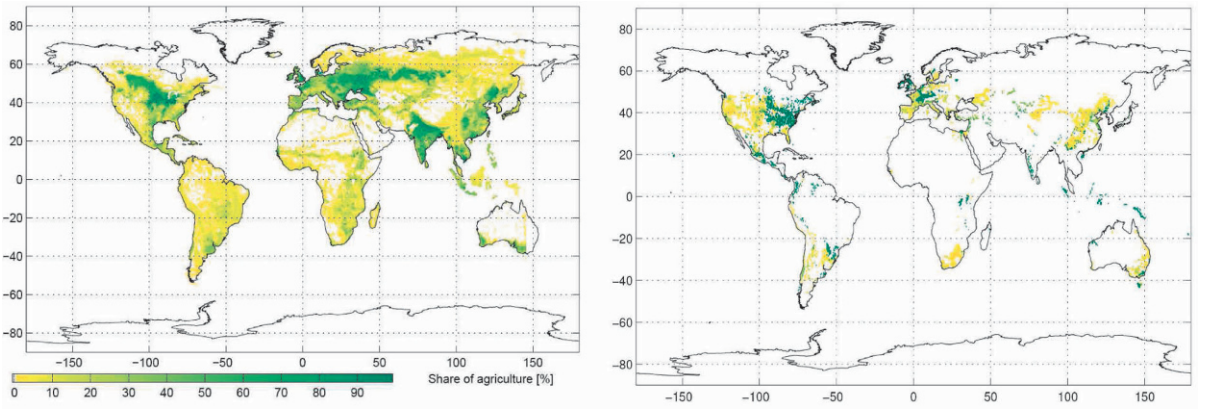


a. Currently protected areas and restricted management areas were captured by overlaying data sets on IUCN protected areas category I to VI, i.e. nature reserves and wilderness areas, national parks, natural monuments, habitat/species management areas, protected landscapes, and protected areas sustainable use of natural resources (UNEP-WCMC 2007). Data sets were integrated at a spatial resolution of 5 arc minutes, i.e. 8.3 km times 8.3 km at the equator. By rule, the land-use type bearing the maximum fraction per grid cell was defined as dominant. Built-up land which covers 10 per cent of the grid cell at a minimum was intuitively added in order to emphasize the presence of rural and urban built-up areas, industrial and transport facilities, as well as other urban areas. The IUCN protected area cover entered as a separate layer independent of the underlying land-use types. The map was produced by means of ArcGIS v. 9.2 and R v. 2.8.1.

distribution and growth of population density and productivity of the land. From a local perspective, land-use patterns have been well adapted and optimized given local resource and market conditions and constraints. However, the globalization of trade has made some parts of these local multi-purpose land-use mosaics obsolete. About 10 per cent of the total raw production of food, fibre, and forest products is traded around the world, and a much higher percentage could be allocated reasonably by the global market. Still, land-use patterns determined by history are largely persistent. This lock-in situation can be partly explained by transportation costs and the inertia of land-use patterns due to large investments required for land conversion. However, another factor is societies' and countries' desire to remain largely autonomous with respect to their most fundamental resources: food and water.

If humankind wants to manage the climate change challenge through a cooperative global strategy, such heterogeneous land-use patterns for agriculture, forestry, energy, infrastructure, and nature conservation (figure 1) may have to be questioned. If productivity cannot be increased to similar levels across the globe, due to a variety of bio-physical, social, institutional, and economic reasons, a larger share of production may have to be concentrated in the most productive areas instead. Studies show that optimal spatial allocation and specialization can, in theory, strongly reduce the area needed for agricultural production, literally leaving room for other purposes such as bioenergy production, afforestation for carbon storage, or nature conservation (figure 2).

Figure PE 5.2: Observed global agricultural land-use pattern of 1995 (left panel) versus globally optimized pattern that would allow feeding 12 billion people with 1995 dietary habits (right panel). Agricultural areas shown in right panel correspond to roughly one third of the area currently used for crop growing. **Source:** Figures were taken without modifications from Müller, Bondeau, Lotze-Campen, Cramer and Lucht (2006).[a]



a. Details on data used, underlying assumptions and optimization algorithm can be found in the publication.

The world's regions have heterogeneous potentials and different land-use categories also have very heterogeneous demands. Climate change will certainly require reallocating some of the land-use types on the planetary map simply for ensuring their functionality. There is an ongoing debate about advantages and disadvantages of segregating versus integrating nature conservation and agricultural production at the local scale. But the climate change challenge requires lifting this discussion also to the global scale. In the future, specific migration corridors may be needed which allow species to move with changing climate patterns. Agricultural areas will be abandoned if they are degraded or fall dry. Settlements may also have to be moved if droughts, heat waves, hurricanes, and floods occur more frequently, or if sea level rise threatens to inundate them.

As global land-use patterns will have to adapt to climate change, the potential for optimizing these patterns by matching the different land-use categories to the needs of heterogeneous potentials have to be considered. There are and will be regions that are especially appropriate for certain land-use types, e.g. because of their favourable climatic conditions or fertile soils. Urban areas, for example, often spread on fertile land even though they do not require them, outcompeting agricultural or forestry systems that do depend on fertile soils. The Sahara region, on the other hand, is of little use for agriculture, but is suitable for solar power harvesting, potentially combined with desalination of water along the coastlines. This, however, requires large investments to install the infrastructure for power generation and for electricity transport to the regions with high energy demand – such as Europe. Joint international efforts, like the recently launched DESERTEC project, could lead the way to the benefit of all. In the interest of climate mitigation, adaptation, and development, international efforts are needed to harmonize the spatial patterns of land use with the spatial patterns of potentials, beyond national boundaries and interests.

Global Agricultural Commons: A Proposal

'Global Agricultural Commons' may provide a way to overcome the inefficient use of land resources. Under such a scheme the most fertile areas of the planet would be declared a global public good (albeit still part of the national territories) and reserved for agricultural production. Wealthier regions increasingly expect countries like Brazil, Indonesia, and the Congo to refrain from large-scale deforestation or timber harvest and protect the global public goods and services that tropical rainforests provide to humankind. Could these countries in return expect other countries to put their productive agricultural systems to the most valuable and yet sustainable use to feed the world? Declaring the fertile soils of the Earth a common agricultural good would help to frame the supranational obligation to use them efficiently and sustainably.

The idea of conserving areas of international interest is not new: the UNESCO's 'Convention concerning the Protection of the World Cultural and Natural Heritage' and its *International Union for Nature*

Conservation (IUCN) already provide frameworks for the protection of areas of universal value. Intensive but sustainable exploitation of the agricultural production potential is, however, not yet considered a value that deserves internationally coordinated protection.

There are of course several restrictions to the idea of globally optimized land-use patterns and agricultural commons. First of all, the ecological side effects will have to be carefully evaluated. Land conversion often triggers undesired secondary effects, such as carbon emissions, degradation, or increased vulnerability to climate variability. Intensive agricultural management often comprises non-sustainable treatment of soils and water as well as spillover of nutrients and pesticides to neighbouring ecosystems and also causes emissions of nitrous oxide and methane, both being very potent greenhouse gases. These systems have high energy requirements for providing production inputs, like fertilizers, pesticides, and machinery. An optimized global land-use pattern will require more trade and transportation between the producing and the consuming regions.

There are, certainly, also many political obstacles, the most important being the lack of international trust. The supply of fundamental resources to sustain human livelihoods, like water, food, and energy, is usually considered a question of national autonomy. Not surprisingly, the most protectionist policies are prevalent in the agricultural and energy sectors. Relying on international trade for providing a larger share of domestic food supplies would require the development of strong and competitive non-agricultural sectors, which is an obstacle for many food-insecure countries.

Yet, in a world that faces the risk of dangerous climate change and the enormous challenge to guarantee a decent life for 9–12 billion people these political obstacles may have to be overcome. Planet Earth, a number of degrees Celsius warmer than today, is unlikely – if not by all means incapable – of carrying such a big human population. Rising up to the double challenge of climate change and population growth seems impossible without calling into question the current land-use pattern, which has emerged from a history that was more or less blind to considerations of global sustainability.

1 Introduction: Coping with Global Environmental Change in the Anthropocene

Hans Günter Brauch and Úrsula Oswald Spring

1.1 Introduction and Objectives of the Book

This third volume of the *Global Environmental and Human Security Handbook for the Anthropocene* (GEHSHA) focuses on issues of *Coping with Global Environmental Change* that are contributing to a *reconceptualization of security* in the 21st century that has evolved since the end of the Cold War and has significantly been influenced by the globalization process.

1.1.1 Contextual Change from the Holocene to the Anthropocene

While the end of the Cold War marked the first peaceful global transition of the structure, strategies and policies of international politics since the French Revolution (1789) and the Congress of Vienna (1815) and of the Westphalian sovereignty-based system of nation states, the transition from the Holocene period of Earth history to the 'Anthropocene' is more profound (preface essay by Crutzen). The Holocene started with the end of the glacial period about 12,000 years ago what marked the onset of major human progress and the development of high civilizations in the Mediterranean, in China, India and in Mesoamerica. In earth and human history a fundamental change has occurred since the Industrial Revolution (1750) from the '*Holocene*' to the '*Anthropocene*' due to increasing human interventions, especially through the burning of fossil energy that has resulted in an anthropogenic period of climate change. The 'Anthropocene' concept was introduced by Crutzen (2002) as "a new geologic epoch in which [hu]mankind has emerged as a globally significant – and potentially intelligent – force capable of reshaping the face of the planet" (Clark/Crutzen/Schellnhuber 2004: 1; Ehlers/Krafft 2006; Ehlers 2008).

The 'Holocene' is a period of geological transition with a dramatic environmental change with a major sea-level rise due to the melting of the huge ice sheets that covered large areas in the northern hemisphere. Bond, Kromer, Beer, Nuscheler, Evans, Showers, Hoffmann, Lotti-Bond, Hajdas and Bonani (2001) postulated a 1,500 year cycle throughout the Holocene with an important contrast in hydrological circulation patterns. These changes in climate had a major influence on the development and collapse of high civilizations (Fagan 2004; Diamond 2005; Bluemel 2009: 104). The Roman Empire coincided with the 'Roman optimum' while its collapse occurred during a cooler period when massive people's migration occurred from Central Asia to Europe and from Northern Europe to the Mediterranean (Issar/Zohar 2004: 14, 2007: 12; 2009: 125). The second climatic downturn led to the "little ice age" (Fagan 2000, 2002) that coincided with bad harvests, famines, pandemics (pest), and the Thirty Years War (1618–1648).

The role of climate for the decline and fall of civilizations has been disputed between climate determinists and climate sceptics (Brown 2001). Since the 1930's the anthropogenic model placed all blame on human malpractice (Issar/Zohar 2003, 2007). The neo-deterministic paradigm "emphasizes the dynamic interaction between the natural environment ... and the human society" (Issar/Zohar 2009: 110–120). Many neo-determinists have argued that during the Holocene cold periods, precipitation changes and long periods of drought triggered massive people's movements.[1] Due to natural climate variability, longer periods of drought and famine resulted in the sudden collapse of several high civilizations (Diamond 2005).[2]

1 For an overview on the old people's migration see: Curta (2001), Heather (1998), Kulikowski (2007), Todd (1996), Noble and Goffart (2006), Fouracre (2005) and Halsall (2007).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_1, © Springer-Verlag Berlin Heidelberg 2011

Since the late 19th century several authors have referred to the human intervention into nature (Marsh 1864, 1965; Stoppani 1873; Vernadsky 1926, 1998) and the earth system that were facilitated by major population growth (Malthus 1798; preface essay by Zlotnik) due to technological and medical advances and the availability of cheap fossil energy sources (Mc Neill 2000, 2009). Crutzen (2006: 13–17) pointed to the chemical impacts of human activities during the Anthropocene resulting in increasing air pollution, acidification of precipitation, major changes in land-use.[3] Crutzen (2006: 16) concluded that the "still growing impacts of human activities on earth and atmosphere" make it "appropriate to emphasize the central role of [hu]mankind in geology and ecology by using the term 'Anthropocene' for the current ecological epoch".

In response to the gradual understanding of the anthropogenic contribution to *global environmental change* (GEC) and climate change in the Anthropocene the 'sustainable development' (Brundtland 1987) concept was adopted in Rio de Janeiro (1992) at the *United Nations Conference on the Environment and Development* (UNCED) and became a key policy goal of UN Secretary-General Kofi Annan's *Millennium Report* (2000), and at the *World Summit on Sustainable Development* (WSSD) in Johannesburg (2002) where "the need for harnessing science and technology in support of efforts to achieve the goal of environmentally sustainable human development in the Anthropocene was generally recognized" (Clark/Crutzen/Schellnhuber 2004: 3).

Crutzen (2006: 17) argues that as humankind "will remain a major geological force for many millennia" it is necessary "to develop a world-wide accepted strategy leading to sustainability of ecosystems against human induced stresses" what will be "one of the greatest tasks of [hu]mankind, requiring intensive research efforts and wise application of the knowledge".

This fundamental change in earth and human history provides the third causal chain for a reconceptualization of the security. The societal and political impacts of this far more severe global change than the end of the Cold War is gradually being understood by policy-makers and international relations and security specialists who have launched a process of the securitization of the causes, effects, impacts and societal outcomes of global environmental change (Brauch 2009_4; Brauch/Oswald Spring 2009; Oswald Spring/Brauch 2009, 2009a).

During the 21st century, the causal relationship between the causes and severe societal outcomes of GEC and climate change may result in environmentally-induced massive and forced people's movements, hunger- and famine-induced protests and small-scale societal violence, and possibly also in violent conflicts within and between countries that may pose multiple security dangers that have increasingly been addressed by governments and international organizations. The causal linkages and possible extreme and sometimes fatal societal outcomes have been discussed from four perspectives:

1. *Determinists* have claimed that climate change will lead to wars during the twenty-first century. This argument has been made by scientists (e.g. Welzer 2008; Leggewie/Welzer 2009; Lee 2009), humanitarian organizations, and NGOs and a few governments.
2. *Empiricists* have stressed (Dalby/Brauch/Oswald 2009; Oswald/Brauch/Dalby, 2009) that environmental stress and climate change have contributed to forced migration and small scale violence (Kahl 2003, 2006). They analysed the securitization of climate change impacts (Brauch 2009; Scheffran 2010, chap. 42; Scheffran/Brozska/Brauch/Link/Schilling forthcoming) and reviewed conflict constellations triggered by climate change (WBGU 2008).
3. *Sceptics* have pointed to a lack of evidence in the peer-reviewed, quantitative literature on the linkage between climate change and wars (Gleditsch/Nordas 2009; Breitmeir 2009).
4 *Deniers* have challenged both the anthropogenic climate change (Lomborg [2]2009, 2004) and the linkages between climate change and possible conflicts posing security threats. For different reasons many governments expressed this view within the UN context.

2 The urban Late Uruk society in Mesopotamia that suddenly collapsed at about 5200–5000 BP due to a short but severe drought (Weiss/Bradley 2001). The collapse of the Mycenaean Kingdom, the Hittite Empire in Anatolia and of the Egyptian Empire (3206–3150 BP) were due to a persisting drought (Drew 1977; Weiss 1982). Between 810 and 910 AD, several mega-droughts occurred in the Yucatán Peninsula and in the Petén Basin that resulted in land degradation (Coe 1999: 26–27; Braswell 1990) and the collapse of the Mayan civilization (Demarest 2004; Sabloff 1990; Gill 2000). In China, the decline of the Tang (850–940), the Yuan (1340–1360); and late Ming period (1580–1640) were all related to a reduction of the monsoon and to severe droughts.

3 Vitousek/Dantonio/Loope/Westbrooks 1996; preface essay by Müller/Lotze-Campen/Huber/Popp/Svirejeva-Hopkins/Krause/Schellnhuber

While future climatic scenarios can be simulated and socio-economic trends can be projected, specific events (Gaddis 1992–1993), such as climate conflicts and wars as the outcome of decisions of future policy-makers cannot be predicted, rather several 'conflict constellations' can be foreseen (WBGU 2007, 2008; Bauer 2009, chap. 41) that may possibly escalate into violence.

1.1.2 Structure of the Environmental Security Handbook

A key goal of this multidisciplinary and international '*Global Environmental and Human Security Handbook for the Anthropocene*' (GEHSHA) is to conceptually map the manifold reconceptualizations of security that have been observed, analysed, assessed and interpreted by scientists from different disciplines primarily since 1990.

While many dangers that were influenced or triggered by the human-nature interface have affected humankind for millennia, only during the past two decades have they been socially constructed as posing severe security dangers and concerns for the livelihoods and survival of billions of people and, if business as usual trends continue unabated, in the very worst case even for the human species. Since 2007 they have increasingly emerged in the social discourse as new security concerns that may pose multiple soft security issues during the 21st century.

While the impacts of a large nuclear war or the result of a possible 'nuclear winter' (Crutzen/Birks 1982; Turco/Toon/Ackerman/Pollack/Sagan 1983; Robock/Oman/Stenchikov 2007) have been discussed by natural scientists and strategic security analysts during the Cold War as major threats to the lives of millions of people, the new security threats posed by GEC are fundamentally different. These threats are not posed by 'them', the other social system, the competing military alliance or political and economic bloc, nor is it posed by an 'axis of evil' and by 'rogue states', but by us, by our lifestyle, especially by the adored and imitated 'American way of life' of consumerism – that has since World War II been pursued as a goal by the middle and upper classes around the globe – without taking the environmental externalities into account. If 'we' are the threat causing the multiple global environmental changes, then the military strategies, policies and means based on the mindsets of the Cold War have become totally obsolete for coping with this new threat in the Anthropocene.

Of the two previous volumes of the GEHSHA the first on *Globalization and Environmental Challenges* analysed the conceptual response primarily to the first two causes of the end of the Cold War and of globalization, while the second on *Facing Global Environmental Change: Environmental, Human, Energy, Food, Health and Water Security Concepts* reviewed the third cause and several of the new sectoral security concepts that have been used by international organizations to legitimate their activities in terms of different referents, i.e. of human, national and international security. This third volume on *Coping with Global Environmental Change, Disasters and Security – Threats, Challenges, Vulnerabilities and Risks* moves a step further by addressing strategies, policies and measures, as well as goals and means for dealing with these manifold new security 'threats, challenges, vulnerabilities and risks' (chap. 2 by Brauch) in a proactive manner what requires forward-looking and policy-relevant research, anticipatory learning and policy-makers with a vision, a sense of responsibility and courage to implement many of the unpopular measures that challenge fundamental features of our lifestyles and ways of life.

These three volumes of the GEHSHA aim to achieve these three scientific goals: a) to map the *North-South scientific debate* on *reconceptualizing security*; b) to document a *multidisciplinary debate* and learning; and c) to offer a *dialogue between academia and policy-makers* in international organizations, national governments and *between academia and* non-governmental actors in civil society and in social movements on security concepts. These three volumes focus on the conceptual thinking on a wide notion of security in all parts of the world that has often been used to legitimate the allocation of public and private resources and to justify the use of force both to 'protect' and to 'kill' people in the realization of a major value.

1.1.3 Three Stages of Addressing Global Environmental Change

Three stages of addressing *Global Environmental Change* (GEC) can be distinguished:

1. The emergence as a new interdisciplinary scientific field of study since the 1970's and 1980's that has focused on climate change, desertification, water and biodiversity. Since the 1990's global change scientific networks, programmes (IGBP, IHDP, DIVERSITAS, WCRP), and projects as well as policy-focused scientific "epistemic communi-

ties" (Haas 1989, 1990, 1992, 1993) as the IPCC (Bolin 2007) have evolved that assess and interpret scientific research results, and explain them to the global policy community and via the media to a global attentive public (*scientific agenda setting* or *scientization*).

2. The development of a new major policy field of international (environment) policy since the Earth Summit in Rio de Janeiro in 1992 has resulted in new forms of international governance (climate change, biodiversity, desertification, water regimes) that have moved to the centre of political concerns (*politicization)*[4] through major global governmental conferences in the framework of the annual *conference of parties* (COPs) of UNFCCC,[5] CBD,[6] UNCCD,[7] and the triennial World Water Fora.[8]

3 Since the early 21st century this process of *politicization* has been complemented by a process of declaring selected global challenges (especially climate change) as political issues of 'utmost importance' that 'require extraordinary means' (Wæver 1995, 2008), and by addressing these global dangers and concerns as key security issues (*securitization*).

The year 2007 has been a turning point in this process of *securitization* of questions of global environmental change, and especially of climate change (Brauch 2009a) when the highest national policy-makers (G-8, European Council) and high-level fora (UN Security Council) and officials of international organizations (UN Secretary-General 2009) addressed global warming (in relationship with desertification and water scarcity) as key political and security issues that may lead to internal displacements, forced distress migration, as well as crises and conflicts. This emerging *securitization* of GEC focuses on the environmental dimension of security and on the complex interaction between human beings and humankind as causes, triggers, and victims of the societal consequences of this process.

On 11 June 2009, the UN General Assembly adopted the first resolution on "Climate change and its possible security implications" (A63/281) that invited the organs of the UN "to intensify their efforts in considering and addressing climate change, including its possible security implications" requesting "the Secretary-General to submit a comprehensive report ... on the possible security implications of climate change". In his report (A/64/350 of 11 September 2009) Secretary-General Ban-Ki Moon identified five channels through which climate change could affect security:

a) *Vulnerability*: Climate change threatens food security and human health, and increases human exposure to extreme events.
b) *Development*: If climate change results in slowing down or reversing the development process, this will exacerbate vulnerability and could undermine the capacity of states to maintain stability.
c) *Coping and security*: Migration, competition over natural resources and other coping responses of households and communities faced with climate-related threats could increase the risk of domestic conflict as well as have international repercussions.
d) *Statelessness*: There are implications for rights, security, and sovereignty of the loss of statehood because of the disappearance of territory.
e.) *International conflict*: There may be implications for international cooperation from climate change's impact on shared or undemarcated international resources (A/64/350: 1).[9]

4 An extensive scientific and political literature is available on these issues that have contributed to the process of politicization especially of climate change issues (Dessler/Parson 2006, 2008).

5 The *UN Framework Convention on Climate Change* (UNFCCC) was signed in 1992 at the Earth Summit and entered into force on 21 March 1994; its Kyoto Protocol (1997) entered into force on 16 February 2005 with the ratification by Russia and it will expire in 2012. Until April 2008 the USA and Turkey did not ratify the Kyoto Protocol. See the documentation at: <http://unfccc.int/essential_background/items/2877.php>.

6 The *Convention on Biological Diversity* (CBD) was signed in 1992 at the Earth Summit and until April 2008 it was ratified by 187 countries. Its Cartagena Protocol on Biosafety was adopted in 2000 and entered into force in 2003, and by April 2008 147 countries had deposited their ratification. The USA did so far neither sign nor ratify this protocol. See the documentation at: <http://www.cbd.int/>.

7 The UNCCD was signed in 1994 and entered into force on 26 December 1996. As of March 2002 over 179 countries were parties. See the documentation at: <http://www.unccd.int/>.

8 The first five world water fora occurred in Marrakesh (I: 1997), The Hague (II: 2000), Kyoto (III: 2003), Mexico City (IV: 2006) and Istanbul (V: 2009); the sixth is scheduled for 2012 in Marseilles.

9 See at: <http://daccess-dds-ny.un.org/doc/UNDOC/GEN/N09/509/46/PDF/N0950946.pdf?OpenElement>.

The report points to views interpreting climate change as a 'threat multiplier' and identifies several 'threat minimizers', such as "conditions or actions that are desirable in their own right but also help lower the risk of climate-related insecurity", which "include climate mitigation and adaptation, economic development, democratic governance and strong local and national institutions, international cooperation, preventive diplomacy and mediation, timely availability of information and increased support for research and analysis to improve the understanding of linkages between climate change and security". With the goal "to bolster these threat minimizers", the report also "identifies a set of emerging climate change related threats ... that appear highly likely, are large in magnitude, may unfold relatively swiftly, and are unprecedented in nature, including: loss of territory, statelessness and increased numbers of displaced persons; stress on shared international water resources, e.g. with the melting of glaciers; and disputes surrounding the opening of the Arctic region to resource exploitation and trade".

The report which focuses on "the mutual interdependence between the security of individuals and communities and the security of nation states" is based on the response of governments and regional organizations[10] and a literature review that distinguishes among five groups of threats to a) human well-being, b) to economic development, c) from uncoordinated coping, d) of loss of territory and statelessness, and e) to international cooperation in managing shared resources. A UNEP study (2007)[11] emphasized "that the potential consequences of climate change for water availability, food security, prevalence of disease, coastal boundaries, and population distribution may aggravate existing tensions and generate new conflicts" (cited in UN-SG, A/64/350: 20).

With regard to responding and preventing climate change-induced emerging security threats the report referred to the following policy responses: a) mitigation, b) adaptation, c) economic growth and sustainable development, d) effective governance mechanisms and institutions, e) information for decision-making and risk management, and f) reinforcing international cooperation. The report pointed also to the need for the international capacity "to anticipate and prepare itself to address a number of largely unprecedented challenges posed by climate change for which existing mechanisms may be inadequate", by pointing specifically to climate-induced displaced persons and migrants, to the "statelessness of citizens of submerged island nations", water-scarcity and the increased competition "over newly accessible Arctic natural resources and trade routes". Among the states' responses only those of the present two major contributors, of the United States and the People's Republic of China, as well as the primary victims, the small islands developing countries, will be briefly referred to.

While the previous US administration of George W. Bush (2001–2009) doubted the existence of an anthropogenic climate change, this position changed prior to the Obama Administration when the U.S. National Intelligence Estimate on Security and Climate Change (2008)[12] claimed "that no country will be immune to the effects of climate change" and that most "developing states that will potentially suffer from adverse impacts to economic security are in Sub-Saharan Africa, the Middle East, and Central and Southeast Asia", and that the possible "spillover – from potentially increased migration and water-related disputes – could have a harmful global impact".[13] In 2008, Thomas Fingar, Deputy Director of National Intelligence for Analysis and Chairman of the National Intelligence Council of the United States, summarized the key findings of the secret report

> We judge global climate change will have wide-ranging implications for US national security interests over the next 20 years. Although the United States will be less affected and is better equipped than most nations to deal with climate change, and may even see a benefit owing to increases in agriculture productivity, infrastructure repair and replacement will be costly. We judge that the most significant impact for the United States will be indirect and result from climate-driven effects on many other countries and their potential to seriously affect US national security interests. We assess that climate change alone is unlikely to trigger state failure in any state out to 2030, but the impacts will worsen existing problems – such as poverty, social tensions, environmental degradation, ineffectual leadership, and weak political institutions. Climate change could threaten domestic stability in some states, potentially contributing to intra- or, less likely, interstate conflict, particularly over access to increasingly scarce water resources. We judge that economic migrants will perceive additional reasons to

11 UNEP, 2007: Sudan: *Post-Conflict Environmental Assessment* (Geneva: UNEP).

> migrate because of harsh climates, both within nations and from disadvantaged to richer countries.

The US submission to the above report of the UNSG (A/64/350) pointed to many security dangers due to i) agricultural production at risk, and ii) international migration that will also have severe implications for the US due to an increase of humanitarian emergencies. The US report specifically pointed to a lack of resolution to analyse the security implications at the country level and it pointed to a need for "better information on physical, agricultural, economic, social, and political impacts from climate change at country and regional levels", what may "also facilitate adaptation efforts". It argued that

> the security elements of climate change are best understood and addressed in the context of pre-existing social, political, and environmental conditions. ... Additional analysis is required to determine the world-wide potential vulnerability to storm tracks and severe weather. ... In addition, detailed agriculture vulnerability should be studied; this would include anticipated changes in temperature, precipitation levels and patterns (US-CCIS 2009: 8–9).[14]

The most recent issue of the CIA's: *Global Trends 2025: A Transformed World* (20 November 2008) argued that "Climate Change is expected to exacerbate resource scarcity" (NIC 2008: viii) and in one of its four scenarios on *October Surprise* it illustrated the potential impact of inattention to climate change (NIC 2008: 57–59). This report concluded on climate change:

> *Climate change* is unlikely to trigger interstate war, but it could lead to increasingly heated interstate recriminations and possibly to low-level armed conflicts. With water becoming scarcer in several regions, cooperation over changing water resources is likely to be increasingly difficult within and between states, straining regional relations. Such regions include the Himalayan region, which feeds the major rivers of China, Pakistan, India, and Bangladesh; Israel-Palestinian Territories; along the Jordan River (Israel-Jordan) and the Fergana Valley of Central Asia. Such dire scenarios are not inevitable even with worse-than-anticipated climate change impacts, however. Economic development, the spread of new technologies, and robust new mechanisms for multilateral cooperation to deal with climate change may foster greater global collaboration (NIC 2008: 66, 68).

In contrast, the *People's Republic of China* (PRC) referred to the fundamental differences between climate change and security, treating climate change as an issue of sustainable development where developed countries should take the primary responsibility while developing countries "should improve their capacity to address climate change", and address it in the "framework of sustainable development".[15] However, this claim ignores that the PRC has in 2007/2008

12 United States House Permanent Select Committee Intelligence, House Select Committee on Energy Independence and Global Warming, 25 June 2008; National Intelligence Assessment on the National Security Implications of Global Climate Change to 2030 Statement for the Record of Dr. Thomas Fingar, Deputy Director of National Intelligence for Analysis and Chairman of the National Intelligence Council of the United States; see at: <http://www.dni.gov/testimonies/20080625_testimony.pdf>. While this report is 'secret', Mr. Fingar described the process as follows: "We began our effort following a National Intelligence Priorities Framework review in 2006. ... Following draft Congressional language in the spring of 2007, we elevated the level of our effort to a *National Intelligence Assessment* (NIA), developed terms of reference, and initiated the study (emphasis added, the authors)." He noted the "fundamentally different kind of analytical methodology" and that the NIC "depended upon open sources and greatly leveraged outside expertise. Since the Intelligence Community does not conduct climate research, we began our effort by looking for other US government entities that were experts in this area". Its primary sources was the IPCC's (2007, 2007a, 2007b, 2007c) Fourth Assessment Report and "other peer-reviewed analyses and contracted research". Its referent object was a broad definition of US national security, especially its impacts on "US homeland, a US economic partner, or a US ally. We also focused on the potential for humanitarian disaster, such that the response would consume US resources. We then considered if the result would degrade or enhance one of the elements of national power (Geopolitical, Military, Economic, or Social Cohesion), and if the degradation or enhancement, even if temporary, would be significant. In the end, we reported on key effects that we judged would meet this threshold."

13 After the publication in 2008 of the National Intelligence Assessment on the National Security Implications of Global Climate Change to 2030 the US *National Intelligence Council* (NIC) explored in greater detail the national security implications of climate change in six countries or regions of the world: India, China, Russia, North Africa, Mexico and the Caribbean, and Southeast Asia and the Pacific Island States. On each of these six countries or regions detailed research and conference reports have been published. All these reports may be accessed at: <http://www.dni.gov/nic/special_climate 2030.html>.

14 US Department of State, 2009: "Submission of the United States of America on the Security Implications of Climate Change"; at: <http://www.un.org/esa/dsd/resources/res_docugaecos_64.shtml>.

overtaken the USA as the major producer of CO_2, even though its per capita contribution to global warning is still less than ¼ of each American consumer.

In contrast, in their submission the *Pacific Small Island Developing States* (PSIDS) pointed to the biophysical factors (rising sea levels, changing weather patterns and natural disasters, soil erosion, loss of coral reefs) that could have security implications for food (fisheries, agriculture) and water security, public health, physical and social infrastructure, the loss of lives and livelihoods, migration (internal, external), loss of islands, territorial integrity, sovereignty, legal rights, conflict and unrest, as well as for socio-cultural impacts. The PSDIS concluded that the above factors

> either already have security implications or are likely to become threats to national security as well as to international peace and security. ... While the[se] factors ... can cause conflict directly, the combination of the threats stemming from climate change impacts ... will create risks to national and regional security as well as to international peace and security. ... Climate change ... has the potential to cause multiple problems simultaneously and erode already fragile conditions. ... The combination of increased disease ... and migration will continue to escalate into humanitarian crises that will strain government resources around the globe and especially within the Pacific. In the Solomon Islands, the combination of various adverse impacts of climate change led to armed conflict. ... These elements all lead to increased humanitarian crises.[16]

The PSIDS see the effects of climate change as a direct threat to their national security and survival. In their assessment "the security threats posed by climate changes are ... no longer a *possibility* but a reality". They call on the UN "to keep track of the growing security implications of climate change", and to consider urgently the "immediate actions which can reduce security implications of climate change, including long-term security issues" (PSIDS 2009: 14).

A study of the European Commission and the Council on "Climate Change and International Security" (14 March 2008) suggested detailed policy recommendations especially for the US, China and India and on the implications of its long-term relations with Russia. The paper recommended regarding an improvement of the analytical capabilities of the EU:

> A first step to address the impact of climate change on international security should be to *build up knowledge and assess the EU's own capacities*, followed by an improvement in the *prevention of, and preparedness for early responses to, disasters and conflicts*. Financial implications for such responses should be identified and also be considered in the EU's budget review.

On the international level the EU plans to take over a multilateral leadership role with regard to furthering climate security.[17] The Report on the "Implementation of the European Security Strategy - Providing Security in a Changing World" of 11 December 2008 noted that the *EU's European Security Strategy - A Secure Europe in a Better World* approved in December 2003: already identified the security implications of climate change.

> Five years on, this has taken on a new urgency. ... Natural disasters, environmental degradation and competition for resources exacerbate conflict, especially in situations of poverty and population growth, with humanitarian, health, political and security consequences, including greater migration. Climate change can also lead to disputes over trade routes, maritime zones and resources previously inaccessible. We have enhanced our conflict prevention and crisis management, but need to improve analysis and early warning capabilities. The EU cannot do this alone. We must step up our work with countries most at risk by strengthening their capacity to cope. International co-operation, with the UN and regional organisations, will be essential.

For the EU Presidency, the Swedish Foreign Ministry submitted many specific proposals for dealing with climate change as a security issue at the UN.[18] At the request of the DG External Relations of the European Commission, as part of the EU Roadmap process on climate change and international security, a survey of studies on the regional security implications of climate change was prepared which summarizes the recommendations on awareness raising, further research, stakeholder dialogue, capacity building, policy priorities, priority regions and international system

development (Maas/Tänzler 2009). Several regional scenarios focusing on sub-regions in Central America, in Southwest and Southeast Asia as well as in the Indian-Pacific region were completed by December 2009. On 8 December 2009 the Council of the European Union adopted conclusions on "climate change and security" (box 1.1).

Box 1.1: Excerpts from the Council conclusions on climate change and security adopted at its 2985th Foreign Affairs Council meeting, Brussels, 8 December 2009. **Source**: Council of the European Union; Press Release 17218/09 (Presse 371; at: <http://www.consilium. europa.eu/uedocs/cms_data/docs/pressdata/EN/foraff/111833.pdf>.

1. The Council endorsed the *Joint Progress Report and Follow-up Recommendations on Climate Change and International Security* (CCIS) as a follow-up to the Joint Paper in March 2008 ..., the report of the implementation of the *European Security Strategy* (ESS) ..., and the report on the implementation of the Joint Paper presented to the Council in December 2008.
2. The Council stated that climate change and its international security implications are part of EU's wider agenda for climate, energy and the Common Foreign and Security Policy ... This adds an incentive to strengthen EU's comprehensive efforts to reduce emissions and to increase its energy security.
3. The Council underlined the possible international security implications of climate change, and the potential risk for increased natural disasters and conflicts over scarcer resources, its effect on migration and state and regional instability, which will add additional stress on the increasingly interdependent global system and structures. ...
4. The Council concluded that more vulnerable parts of human society in developing countries and emerging economies will be adversely affected, and will need our support, but developed countries will also suffer. Adaptation to climate change, sound policies on displacement, migration and conflict prevention are the most effective ways of dealing with the international security implications of climate change. We will address these issues in a spirit of partnership between developed and developing countries and confirm our commitment to take bold action on climate change mitigation in order to limit temperature increases to below a threshold of 2°C ... An ambitious and comprehensive international agreement (UNFCCC) will be an important factor in preventing and reducing the security implications of climate change.
5. The Council welcomed that the UN has taken a leading role on CCIS demonstrated by the UN General Assembly resolution A/63/281 of June 2009, ... followed by the Secretary-General's report A/64/350 on Climate Change and its possible Security Implications of September which was discussed in the UN General Assembly in November this year. The Council ... looked forward to further debates in the UN Security Council ... The EU stands ready to support this global endeavour. ...
6. The Council noted ... that considerable progress has been made to enhance EU capacities for early warning, analysis and response to climate-induced international security implications and to foster international cooperation with the aim to create dialogue, common awareness, share analysis and cooperatively address the challenges in all relevant existing fora, including the UN.
7. The Council supported the recommendations in the Progress Report; to promote EU multilateral leadership in cooperation with the UN and third parties, reinforce the EU's institutional capacity to deal with CCIS in the implementation of the Lisbon Treaty, include security aspects in climate change in EU development assistance, build knowledge, hone and sharpen the EU's crisis management capabilities relevant to dealing with CCIS and to follow-up the implementation through a report to the Council during the latter part of 2010.

But also other regions, besides the most severely affected *small developing island states* (SIDS) have addressed the security relevance and impacts of climate Change. On 21 February 2010, the Government of Mexico and the Member States of the Caribbean (CARICOM), in a summit at Riviera Maya, Quintana Roo also addressed the danger of climate change in their "Climate Change Declaration" (box 1.2).

Since 2007, this emerging UN debate and the considerations of the European Union as well as many other regional bodies, such as the PSIDS and of CARICOM, offer a political context for the securitization of climate change, even though the latter did not refer specifically to the 'security' threat posed by climate change.

1.2 Three Debates on GEC, Security and Disasters

This book goes a step further by analysing the synergies and linkages between three scientific 'epistemic communities' focusing on global environmental change (1.2.1), security (1.2.2), natural hazards and

Box 1.2: Excerpts from the *Climate Change Declaration* adapted by the Heads of State and Government of Mexico and the Member States of the Caribbean (CARICOM), Riviera Maya, Quintana Roo on 21 February 2010. **Source:** at: <http://www.presidencia.gob.mx/en/ press/?contenido=53294>.

1. We, the Heads of State and Government of Mexico and the Member States of the Caribbean (CARICOM)... confirm our commitment to reinforcing cooperation to deal with the threat of climate change through joint efforts by our nations.
2. We express our concern over the scientific evidence showing that climate change induced by humans is worse than predicted and that the impacts of climate change we are already experiencing in our region will intensify.
3. Since the Caribbean is a highly vulnerable region to the harmful effects of climate change, we are determined to strengthen our mitigation and adaptation policies with the support of the international community to cope with this serious threat. We call for an increase in cooperation in our region to achieve understanding and adapt to the adverse impacts of climate change and in this respect, we will ask for the establishment of collaboration links between the Caribbean Community's Center for Climate Change (CCCCC) and the Government of Mexico.
4. Our region widely acknowledges the fact that the development of mitigation actions will reduce the long-term costs and effects of the climate phenomenon. In this respect, we have been concerned to note that ever year, the continuous increase in global emissions reduces the possibilities of stabilizing the average global temperature and at the same time, increases the costs associated with this stabilization.
5. We stress the need to continue negotiations within the United Nations Framework Agreement on Climate Change and the Bali Action Plan and we urge all the states to become constructively involved in the negotiations and to build on the results achieved in Copenhagen.
6. We regard the Copenhagen Agreement as a significant step towards the implementation of the Bali Action Plan and express our interest in ensuring that the understanding reached over certain crucial elements will facilitate the negotiations underway at the Convention.
7. We also welcome the fact that our region will host the 16th Conference of the Parties to the Convention (COP 16) and the 6th Meeting of the Parties to the Kyoto Protocol (CMP 6) and we pledge to collaborate and support the Mexican Government to ensure the adoption of a broad, ambitious, effective agreement that will meet the challenges and needs of mankind, particularly the most vulnerable sectors. CARICOM and Mexico agree over the importance of ensuring that the COP 16 results are legally binding.

societal disasters (1.2.3) that are pursued by different scientific disciplines, as well as by different national and international institutions.

1.2.1 Focus on GEC: Approaches from the Natural Sciences

In the introduction to the previous volume the evolution of GEC research has been reviewed in detail (Brauch 2009a) that encompass "a full range of globally significant issues relating to both natural and human-induced changes in the Earth's environment, as well as their socio-economic drivers". According to Munn (2002: xi) "changes greater than humankind has experienced in its history are in progress and are likely to accelerate". Dealing with future environmental trajectories requires more than a prediction of a single future path. It requires to "map a broad range of future environmental trajectories" that may confirm "that the changes of the 21st century could be far greater than experienced in the last several millennia" (Munn 2002: xii). Scientists, but also decision-makers and administrators are challenged to think the unthinkable; to minimize 'surprise' should nature manifest itself.

Since the 1990's this evolving research field has been advanced and coordinated by the *International Geosphere-Biosphere Programme* (IGBP, chap. 77 by Noone/Nobre/Seitzinger), the *International Human Dimensions Programme* (IHDP, chap. 75 by von Falkenhayn/Rechkemmer/Young), the *World Climate Research Programme* (WCRP, chap. 78 by Church/Asrar/Busalacchi/Arndt), *DIVERSITAS* (chap. 76 by Walther/Larigauderie/Loreau) and by the *Earth Systems Science Partnership* (ESSP, chap. 74 by Leemans/Rice/Henderson-Sellers/Noone) that will be addressed in this book.[19] However, in the rapidly growing multidisciplinary research programmes on *Earth System Science* (ESA) the security dimension that has been addressed by the UN Security Council, the General Assembly, the Secretary-General and on a regional level by the European Commission and the European Council as well as by many countries, has

19 The early activities of these four programmes until 2001 are covered in the *Encyclopedia of Global Environmental Change* (Munn 2002); Diversitas (Prance 2002: 268–271); IGBP (McCarthy 2002: 350–351; Steffen 2002: 351–357); IHDP (IV: Shaw 2002: 245); Perry (2002: 753–754).

so far only been addressed by the *Global Environmental Change and Human Security* (GECHS) project within IHDP (Barnett/Matthew/O'Brien 2008) that has come to an end with the synthesis conference in June 2009.[20]

1.2.2 Focus on Security: Approaches of the Social Sciences

The narrow classical security approach inspired by a Hobbesian obsession is bound to fail in addressing these new security dangers, as are the security strategies, policies and measures that are guided by the power-centred worldviews of policy analysts and advisers and the mindsets of policy-makers that have been influenced by the Cold War experience. The multiple new security dangers posed by the implications of GEC, especially by incremental or linear climate change projections and possible nonlinear tipping points (Lenton/Held/Kriegler/Hall/Lucht/Ramstorf/Schellnhuber 2008) in the climate system, have increasingly been perceived and socially constructed as security concerns since the turn of the millennium.

While the debate on the reconceptualization of security was initially focused backward by addressing the security consequences of the Cold War and the impacts of globalization adding new non-state actors (terrorists and organized crime), the new security agenda of the Anthropocene (Dalby 2009; Brauch/Oswald Spring 2009a) addresses fundamentally different objective security dangers that threaten first the lives, livelihoods and survival of human beings in small islands states, in coastal regions and river deltas, but also those that are seriously affected by the increasing intensity of climate-induced natural hazards (heatwaves, droughts, forest fires as well as by storms, floods and landslides).

Thus, the focus of the new environmental security studies will have to shift from environmental scarcity, degradation and stress during the first three research stages both to the complex causes and the manifold natural implications and the societal outcomes posed by GEC during the Anthropocene era of earth and human history. Wæver's theory (1995, 2008a) of securitization as well as Beck's (2007, 2008, preface essay) theory of international risk society offer two different perspectives for dealing with the security impacts of GEC.

While Wæver's theory offers an approach for analysing policy declarations by policy-makers and representatives of international organizations that have declared climate change as well as water, soil, food and health as issues of 'utmost importance', Beck's (1986, 1992, 1999, 2007, 2007a) international risk society points to a new quality of risk against which traditional insurance efforts do not apply any longer.

1.2.3 Focus on Natural Hazards and Societal Disasters

Natural hazards and human-induced societal disasters existed throughout earth and human history due to the natural variability in climate and extreme weather events, causing in the past mass migrations, multiple conflicts and even the declines of civilizations due to the natural variations of the climate during the Holocene age of earth history (see 1.1.1). The new challenges in the Anthropocene have been an increase in the number and especially in the intensity of natural hazards (chap. 40 by Guha-Sapir/Vos) that have affected more people due to the rapid increase in populations often living in urban conglomerates. Many of these natural hazards and societal disasters have further increased the social vulnerability of the affected people and thus posed dangers for human, national and international security.

The hazard impact depends on the degree of social vulnerability of the affected people and on the coping capacities of the states. Therefore the societal impacts are the most severe in the poorest countries with limited financial and administrative capabilities and resilience. Some developing countries (e.g. Cuba) have often been more effective in coping with the societal impacts of hurricanes, as the case of Hurricane Katrina has illustrated for the United States.

1.3 Coping with GEC and Hazards with Adaptation, Mitigation and Resilience Building

Three different modes for 'coping' with the causes of GEC, including global climate change and desertification and land degradation, and with the societal impacts of hazards, e.g. of droughts and subsequent storms and flooding, have been distinguished in the GEC and hazard communities to adapt to, to mitigate against, and to build resilience. The 'coping' con-

20 On GECHS, see at: <http://www.gechs.org/>; on its synthesis conference in 2009, at: <http://www.gechs.org/synthesis-conference/>.

cept[21] has been widely used in psychology.[22] It has later been taken up by the global change community (including climate change)[23] and hazards (Mitchell 1995; Ammann/Dannenmann/Vulliet 2006) and also applied by the security community.[24] In this book the concept of 'coping' embraces the three concepts of adaptation[25], mitigation[26] and resilience building.[27]

> Mitigation strategies can reduce ecosystem vulnerability, and adaptation strategies can increase ecological resilience to climate and landscape change. Mitigation strategies are actions to prevent, reduce, or slow climate and/or landscape change. Adaptation strategies are actions to counteract the adverse consequences of climate and landscape change. Natural resource managers can use both strategies to reduce adverse ecosystem effects of climate and landscape change.[28]

An early IPCC (1995) glossary did not offer any definition for coping, adaptation, mitigation and resilience.[29] But later IPCC assessment reports, and especially the fourth of 2007, gave detailed definitions of adaptation and mitigation that differed among the working groups. The term 'coping' was not defined by the IPCC (2007, 2007a, 2007b).

The IPCC's second working group (2007a: 869) used adaptation as: "adjustment in natural or *human systems* in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities. Various types of adaptation can be distinguished, including anticipatory, autonomous and planned adaptation". It referred to *anticipatory adaptation* as "adaptation that takes place before impacts of *climate change* are observed" that is also "referred to as proactive adaptation". In contrast, *autonomous adaptation* "does not constitute a conscious response to climatic stimuli but is triggered by ecological changes in natural systems and by market or *welfare* changes in *human systems*, also referred to as spontaneous adaptation". Finally, *planned adaptation* "is the result of a deliberate policy decision, based on an awareness that conditions have changed or are about to change and that action is required to return to, maintain, or achieve a desired state".

The IPCC's third working group (2007b: 809) defined adaptation: as "Initiatives and measures to reduce the vulnerability of natural and human systems against actual or expected climate change effects." This working group also distinguished among "anticipatory and reactive, private and public, and autonomous and planned" adaptation by referring to "raising river or coastal dikes, the substitution of more temperature shock resistant plants for sensitive ones, etc". According to the IPCC adaptive capacity refers to

21 According to the *Oxford Dictionary and Thesaurus* (2001: 160) the verb cope (coping) refers to: manage, deal effectively or contend, get by, survive, win through, endure. The *Chambers Dictionary* (2001) refers i.a. to these meanings: to contend, deal with successfully, to encounter, meet, to match.

22 In psychology, according to Ray, Lindop and Gibson 1982): "Coping is action directed at the resolution or mitigation of a problematic situation. There are a number of ways in which this may be attempted, and a number of ways of classifying coping strategies. This paper presents a simple schema of six coping themes, ordered in terms of their defensiveness and the degree of attempted personal control which they imply. They comprise rejection, control, resignation, dependency, avoidance and minimization, and characterize the meaning or qualitative 'style' of the individual's response, rather than the formal characteristics of the strategies employed." Alan, Lazarus and Reevy (2007) in five chapters introduce the coping concept as used in psychology and offer four more chapters with examples of coping with stress and disease.

23 Easterling, William E.; Hurd, Brian H.; Smith, Joel B., 2004: "Coping with global climate change: the role of adaptation in the United States", in: *Pew Center on Global Climate Change* (June); at: <http://www.pewtrusts.org/uploadedFiles/wwwpewtrustsorg/Reports/Global_warming/pew_climate_0704.pdf >.

24 In May 2009 the 8th Security Forum held in Geneva addressed as the conference theme: "Coping with global change"; see at: <http://www.8isf.ethz.ch/index.cfm>.

25 According to the *Oxford Dictionary and Thesaurus* (2001: 9) the verb 'adapt' refers to: "fit, adjust, alter, make suitable, modify, adjust to new conditions". The *Chambers Dictionary* (2001: 17) refers to 'adaptation' as: "the fact, act, process, or result of adapting".

26 According to the *Oxford Dictionary and Thesaurus* (2001: 479) the verb 'mitigate' means: "make less intense or severe". The *Chambers Dictionary* (2001: 1032) refers to 'mitigate' as: "to mollify, appease; to make more easily borne, to lessen the severity, violence or evil of; temper".

27 According to the *Oxford Dictionary and Thesaurus* (2001: 645) the adjective 'resilient' means: "resuming original form after compression etc., readily recovering from setback". The *Chambers Dictionary* (2001) refers i.a. to 'resilient' as: "recoiling, rebounding, able to recover form and position elastically, able to withstand shock, suffering, disappointment, etc."

28 Tony Prato and Dan Fagre: "Coping with Climate Change – An ActionBioscience.org original article"; at: <http://www.actionbioscience.org/environment/prato_fagre.html>.

29 IPCC, 1995; at: <http://www1.ipcc.ch/pdf/glossary/ipcc-glossary.pdf>.

"the whole of capabilities, resources and institutions of a country or region to implement effective adaptation measures".

The IPCC's first working group (2007: 949) referred to mitigation as "a human intervention to reduce the *sources* or enhance the *sinks* of *greenhouse gases*". Its second working group (IPCC 2007a: 878) defined mitigation as: "an *anthropogenic* intervention to reduce the anthropogenic forcing of the *climate system*; it includes strategies to reduce *greenhouse gas sources* and emissions and enhancing *greenhouse gas sinks*". Its third working group (IPCC 2007b: 818) understood mitigation as: "technological change and substitution that reduce resource inputs and emissions per unit of output. Although several social, economic and technological policies would produce an emission reduction, with respect to climate change, mitigation means implementing policies to reduce GHG emissions and enhance sinks". In the IPCC's understanding, mitigative capacity "is a country's ability to reduce anthropogenic GHG emissions or to enhance natural sinks, where ability refers to skills, competencies, fitness and proficiencies that a country has attained and depends on technology, institutions, wealth, equity, infrastructure and information. Mitigative capacity is rooted in a country's sustainable development path".

But only the IPCC's second working group (2007a: 880) defined resilience as: "The ability of a social or ecological system to absorb disturbances while retaining the same basic structure and ways of functioning, the capacity for self-organization, and the capacity to adapt to stress and change."

1.3.1 Phases of Scientization, Politicization and Securitization

Three phases of dealing with environmental and GEC issues may be distinguished of scientization, politicization and securitization.

1.3.1.1 Scientization

During the *first phase* the scientific issues related to GEC are gradually being addressed, framed, explained, and understood and communicated to the public at large via the media and perceived as issues of public importance that require a policy response. Although environmental (Thoreau 1854; Vernadsky 1926; Carson 1962), ecological (Haeckel 1866, 1870) and climate issues (Baron Jean-Baptiste Fourier in 1823; John Tyndall in 1860; Svante Arrhenius 1896; Roger Revelle and Hans Suess in the 1950's and 1960's)[30] have been addressed by a few natural scientists already in the late 18th century (Malthus 1798), a wider scientization of environmental problems and the emergence of environmental science (Chauhan 2008), of university departments and research institutes primarily in the natural sciences evolved since the 1960's and in the social sciences one or two decades later. Issues of global environmental change and climate change were increasingly addressed since the early 1970's.

Major scientific centres on climate change research have emerged since the late 1980's (besides many university centres, e.g. the Tyndall Centre, UK; Potsdam Institute on Climate Change Impact Research (PIK), Germany; Cicero Institute, Norway) and international scientific programmes on GEC evolved since the 1980's that were coordinated by the *World Climate Research Programme* (WCRP) and the establishment of the IPCC (1988). During this first stage of this *scientization* of global environmental and climate issues scientists put new scientific questions and political issues on the national and international scientific and political agendas humankind has been facing in the Anthropocene, especially since the late 1950's.

1.3.1.2 Politicization

While nature conservation organizations emerged since the 19th century focusing on wildlife management, water, soil conservation and sustainable forestry, major environmental NGOs were founded since the 1960's (e.g. WWF, 1961; Greenpeace, 1969), the first national environmental agencies (US-EPA, 1970) and ministries were established since the 1970's. The first global environmental conference of states took place in 1972 in Stockholm that established UNEP as the key agency within the UN system. In 1987 the World Commission on Environment and Development introduced the sustainability concept as a guiding scientific and political goal. The Rio Summit (1992) of the *United Nations Conference on Environment and Development* (UNCED) adopted the *biodiversity* (CBD) and *climate change* (UNFCCC) conventions and a mandate for the negotiation of a *convention to combat desertification* (UNCCD) that was adopted in 1994.

The Berlin Mandate (1995) that was approved at the first *conference of parties* (COP 1) launched a negotiation process that resulted in 1997 at COP 3 in

30 These historical references were brought to our attention by Sarina Keller, in a term paper at the Free University of Berlin (2010) based on Alfsen/Skodvin (1989), Bolin (2007); Luhmann (2009).

the adoption of the Kyoto Protocol that will expire in 2012. As COP 15 in Copenhagen (2009) failed to accept a new legally binding accord, in January 2010 the future of the climate change regime has become uncertain and it is uncertain whether and when a new legally binding regime will be adopted. During this second phase of the gradual *politicization* of GEC and global climate change issues many political initiatives were launched for 'responding' to and 'coping' with the causes and societal impacts of GEC and natural hazards.

Within this global climate change regime multiple declaratory and legally binding initiatives were approved by international organizations and partly implemented by nation states for coping with the anthropogenic causes, physical effects and societal impacts and outcomes by adapting to and mitigating against climate change. The third working group of the IPCC (1990, 1995, 2001, 2007) has assessed the state of the knowledge and of government plans and implementing activities. However, since UNFCC (1995) and the Kyoto Protocol (16 February 2005) entered into force only few governments have so far fully complied with their declaratory aims and their legally binding commitments under the Kyoto Protocol.[31]

1.3.1.3 Securitization

During the third stage – referred to above – some scientists, governments and international organizations have declared climate change as an existential political issue of utmost importance that require extraordinary political measures. The *securitization* of GEC by policy-makers and the relationship of climate change, desertification and water scarcity and degradation for human, national and international security are addressed in this book.

1.3.2 Coping with GEC

In the global environmental and climate change community three mayor schools or approaches prevail:

1. The *climate change community* focuses on physical outcomes and characteristics of vulnerability. Their vision of vulnerability "is the degree to which a system is susceptible to, and unable to cope with, adverse effects of climate change, including climate variability and extremes. Vulnerability is a function of the character, magnitude, and rate of climate change and variation to which a system is exposed, its sensitivity, and its adaptive capacity" (IPCC 2007a: 883).
2. The *disaster risk reduction* (DRR) and hazard-related research approach deals with human responses. The DRR distinguishes different physical, social, cultural and psychological vulnerability features. Cutter (1996) identified three distinct sources of vulnerability: (a) as risk of exposure to hazards (e.g. for settlements in flood plains and river basins), (b) as a capability for social response (e.g. exit road systems or insurance), and (c) as an attribute of places (e.g. vulnerability of coastlines or river basins to floods). Vulnerability is related to one or several hazards, while climate change results in multiple hazards that may trigger societal outcomes.
3. The *sustainable development research community* centres on societal characteristics that make people vulnerable. These scholars examine poverty and capacity-building and for them vulnerability is a lack of capabilities or 'capitals' (Sen 2000) preventing them to cope with, to mitigate against or to adapt to climate change processes. Kofi Annan (2005) included in this approach elements of governance, institution-building and a legal framework. This community points to a vicious circle of vulnerability, where poverty creates the inability of people to cope with or to recover from hazards or situations that disrupt their life (e.g. through illness). Any of these processes represent an immediate threat for their livelihood and survival that are beyond their control. Besides by rapid onset hazards and the increase of food prices or the alteration of market structures, the most vulnerable

31 For an overview of the compliance with the Kyoto Protocol see at: <http://unfccc.int/kyoto_protocol/compliance/items/2875.php>. See also: UNFCC, 2009: "National greenhouse gas inventory data for the period 1990–2007", FCCC/SBI/2009/12 (12 October 2009); at: <http://unfccc.int/resource/docs/2009/sbi/eng/12.pdf>. Among the 41 annex I countries with reduction obligations under the UNFCCC between 1990 and 2007 without land-use changes and forestry 23 countries should have decreases in emission reductions by more than 1 per cent, while 18 countries showed increases above 1 per cent. Russia reduced its emissions by 35.9 per cent, the 27 EU countries by 4.3 percent (among them Germany by 21.3 per cent, the UK by 17.3 per cent, France by 5.3 per cent) while Japan increased its GHG emissions by 8.2 per cent; the USA by 16.8 per cent, Canada by 26.2 per cent and Australia by 30.0 per cent and Spain by 53.5 per cent and Turkey by 119.1 per cent (UNFCCC 2009: 16). These data slightly differ if land-use changes and forestry are included (UNFCCC 2009: 17).

people are further affected by middle-range processes such as land degradation, desertification, lower precipitation and sea-level rise. Indirect processes of climate change are related to lower ecosystem services, economic crises and unemployment in developed countries. This often leads to rural-urban migration where these people find some social protection (subsidies, food support) or to international migration to OECD countries. Strahm and Oswald Spring (1990) and Richards (2000, 2001) and others have argued that vulnerability is caused by industrialization and its polluting activities along with the present consumption model that have harmed poor countries.

1.3.3 Mitigation Against GEC

These three approaches create different concepts of mitigation:

1. In the climate change and natural hazard communities mitigation involves the reduction of the concentration of greenhouse gases, either by reducing their sources (by geo-engineering, solar radiation management, seeding oceans with iron, etc.) or by increasing their sinks (by carbon capture and storage, bio-sequestration, elimination of waste methane). These processes are technologically specific (e.g. fluorescent light bulbs, geothermal and pollution reduction), industry-related (e.g. public private partnerships in the oil or petrochemical industry, bus and public transportation) and system-wide (such as the reduction of GHG in urban areas, recycling of waste, public transport systems, district heating systems, etc.).
2. The hazard and DRR community emphasizes three simultaneous mitigation processes: a) infrastructure for protective measures (sea walls, levees, dams for water regulation and irrigation, restoration of damaged ecosystems such as mangroves, coral reefs, seagrass and forests). City planners are modelling the risks in cooperation with citizens from megacities and urban agencies to develop a coordinated approach for protecting vulnerable people, roads, tunnels, water supplies, energy and transportation systems, sewage and water treatment plants and industries with hazardous materials.
   a) insurance and micro-insurance and the establishment of escape routes to reduce human harm and permit a fast recovery after an extreme event;
   b) early warning, preventive evacuation, urban and landscape planning, civil protection laws, disaster funds, etc.;
   c) education and training on DRR and disaster management.
3. The sustainable development research community integrates the socio-economic processes with network building, reinforcement of capacities and the combined use of different capitals (natural, economic, societal and cultural), to create circles of virtuous development processes. This community has proposed carbon emissions trading, sustainable land and forest management, carbon taxes, financial and technological transfer from industrialized to affected poor countries. They have combined the preventive disaster management with proactive development processes to enhance the capability of the people for resisting extreme events and dealing with multiple socio-natural hazards. They have promoted population control, healthcare for children and mothers, preventive health services (by vaccination and campaigns against HIV-AIDS) and food supply for the hungry. Their interest has focused on sustainable consumption patterns, small-scale and self-sufficient agriculture and micro-credits for livelihood improvements in the framework of an economy of solidarity (Cadena 2009) or informal economic activities. This community has supported education from the kindergarten onward (Van Dijk 2009), survival strategies adapted to scarce resources, and fair trade to reduce the negative impacts of a collapse or a sudden increase of prices.

1.3.4 Adaptation to GEC

On adaptation these three schools propose different ways to deal with GEC:

1. For many researchers in the climate change community the adaptation concept had a traitorous connotation. They initially believed that this concept would undermine the urgency to mitigate against the threat of global warming by significantly reducing GHG emissions. Therefore, adaptation was for quitters. Based on systematic measurements of GHG and their significant increase during the past decade, this school argued that mitigation alone would not resolve climate related threats. Therefore, the climate change and natural hazard communities have suggested different processes of adaptation to climate change with regard to data collection and scenario development.

Despite improved meteorological data and mid-term weather forecasts it is still impossible to predict for farmers, the people, and insurance companies which regions will become wetter or drier. So far there is little agreement how these trends will affect the annual or seasonal rainfall patterns and the growing season to determine yield productivity. Furthermore, glaciers are retreating what will lead to increased temporal floods but throughout the year to a decline in water resources for rain-fed agriculture and urban development. This will affect large populations in China, in South and East Asia but also in the Andes in South America and the land around Kilimanjaro in Africa. Thus, scientists must develop and share knowledge on land-use, forestry and agriculture (by developing drought- and saline-resistant crops) and develop scenarios for dealing not only with linear, but also with chaotic impacts of climate change. Adaptation should also address negative societal outcomes. More intensive floods from storm surges require complex and expensive solutions for protecting home, people, sanitation, communication and transportation infrastructures.[32]

2. According to the DRR and hazard community adaptation requires: a) assessing risk and reducing vulnerability of the affected people; b) adaptation planning at the national and regional level to reduce the impacts of climate change; c) a more resilient infrastructure; d) broader disaster relief and preparedness measures; e) new agricultural technologies and practices of land management and productive processes to counter the increased climate risks; f) conservation and restoration processes to maintain the environmental services. Adaptation planning at the local, state, and national levels may reduce the damage caused by climate change, as well as the long-term costs of responding to climate-related impacts. It is estimated that by 2030 about 60 per cent of the world's population will live in flood-prone coastal areas. This requires conserving and restoring mangroves to counter the flooding of agricultural land and human settlements. This will also protect deltas from washing away. Bangladesh and other highly affected countries are also reforesting in the upland to prevent downstream erosion. Low lying islands are creating natural buffer zones for human settlements to adapt to rising seas.
3. The sustainable development community argues that strategies for coping with the impacts of a warmer world will be complex and expensive. Adaptation strategies must:
   a) Deal simultaneously with poverty alleviation, high population growth and job creation for young people. This is further reinforced by natural events in countries with low human development, few trained people and the lowest capacity to cope with the high impact of climate-related disasters.
   b) The expected increase of diseases due to climate change, above all in the sensitive regions due to flooding and sea-level rise, may also contaminate water supplies and intensify the vicious circle of poverty, diseases, ignorance and disasters.
   c) Biodiversity and recovery of affected ecosystems is a local adaptation strategy that creates for most marginal people a potential to charge for environmental services, thus reducing the negative impacts of extreme events.
   d) Early adjustment to increasing climate threats permits a better adaptation, making people resilient to possible changes and new threats, taking cultural, economic, and political differences into account.
   e) Traditional societies with a greater integration with nature adapt more easily to a warmer environment (e.g. Myanmar) than cultures driven by the extraction of oil and minerals (e.g. Peru), thus adaptation strategies must be carbon neutral.
   f) Oxfam (2009) pointed to "three major challenges that climate change brings to bear on rural communities: undermined sustainability of current livelihood strategies; increased pressure on already depleted natural resource bases; and increased disaster risk from climate hazards. Effective adaptation must therefore bring together sustainable livelihoods, natural resource management, and disaster risk reduction approaches to secure and enhance assets within the analysis of climate change", including the reduction of social vulnerability and DRR.
   g) Sustainable energy and energy efficiency are crucial for the adaptation process to climate change including incentives for the private sec-

32 New York City, Mumbai, Calcutta, Lagos, Buenos Aires, Bangkok and other megacities are only a few metres above sea level and they must develop adaptation plans for sea-level rises and for increased tidal and storm surges.

tor, the elimination of counterproductive subsidies (e.g. in water-intensive crops), and the protection of land-use, ownership and guarantee of the social security for the most vulnerable people.

1.3.5 Protection, Empowerment and Resilience Building

The concept of resilience has been used differently by authors and scientific communities. It was critiqued for emphasizing systems stability over change and thus reducing DRR with preventive measures. Wisner, Blaikie, Cannon and Davis (2004) use resilience as a continuous learning process to improve the capacity for handling hazards and to reduce risk by empowering communities to make better decisions on dealing with hazards. Resilience may also be linked to vulnerability (Manyena 2006) and adaptation capacity. Resilience is understood to have inherent functions in normal times and to be adaptive during extreme events and disasters. This is related to infrastructure, institutions and social, cultural or economic systems.

1. Climate experts defined resilience as the "ability of a social or ecological system to absorb disturbances while retaining the same basic structure and ways of functioning, the capacity for self-organization, and the capacity to adapt to stress and change" (IPCC 2007a: 880).
2. "Determining whether resilience is an outcome or a process is an important step toward its application to disaster reduction. When compared to the global change perspective, hazards researchers often embed adaptive capacity or mitigation within resilience" (Cutter/Barnes/Berry/Burton 2008: 600). According to researchers working on hazards, resilience focuses on technical and social systems, where preventive DRR helps to cope with and minimize the potential disaster impacts through early warning, evacuation and post-event processes (Bruneau 2006; Tierney/Bruneau 2007). The Hyogo Framework for Action stressed the need to build resilient communities through integrated disaster prevention, mitigation, preparedness and vulnerability reduction, where the local capacity is increased for dealing better with hazards. In this framework DRR is integrated into early warning, the response, recovery, and reconstruction process in case of a disaster.
3 The research community dealing with resilience and sustainable development goals includes human rights and basic human needs. The human security approach (UNDP 1994) was the starting point for combining human capitals (social, economic, political and cultural) with protection and empowerment (Ogata/Sen 2003) and resilience-building in regions threatened by climate impacts (UNEP, FAO, Oxfam, Greenpeace, etc.). This community defined the resilience process as the ability to "tolerate – and overcome – damage, diminished productivity, and reduced quality of life from an extreme event without significant outside assistance" (Mileti/Mileti 1999: 4). Within the context of natural disasters, this community redefined the sustainability approach as the necessity of a systems' change, including risk factors not only from natural extreme events, but also from the complex interrelationship with human factors, such as chaotic urbanization, livelihood loss, economic crises, environmentally forced migration, unstable governments and the linkage among several factors. Particularly a high exposure is related to the distribution and access to land, water and productive means that are crucial to reinforce the livelihood at the local level or to expel people when their survival is at risk.
Social safety networks are crucial to prevent, support, and recover from extreme hydro-meteorological events. In facing climate change the sustainable research and action community emphasizes to conserve and restore the natural capital, while the cultural, economic and political capitals are oriented at resilience-building, sustainable agriculture and dignified livelihood. Social movements have analysed the inefficiency of agribusiness, pollution and agricultural subsidies that have increased hunger worldwide due to speculation with food prices and the use of basic grains for biofuel. Their adaptation strategies start at the local level with the recovery of environmentally damaged ecosystems and the improvement of environmental services. FAO (2009) adopted the food sovereignty concept of Vía Campesina as a holistic approach for increasingly insecure situations. In this approach hazard-prone countries in the South that are exposed to risk are concentrating their technical, economic and human capitals on efficient DRR and CCA processes, where bottom-up initiatives, disaster organizations and international bodies collaborate. The reduction of social vulnerability requires democratic structures, norms and laws, disaster funds, but also bottom-up resilience-building.

The three research communities agree that the greater the level of risk of a country or community and the

greater the resilience is, the better the DRR and the lower the negative impact of an extreme event will be. This permits a more rapid recovery, but also a better preparedness and rebuilding processes. As global environmental change is an increasing risk and not only a hazard but also a vulnerable and exposure component, the combined economic, energy and food crises may threaten sustainability in a larger and in the extreme case at global scale (see the present financial crisis).

Thus, significant financial resources are required, and until new sources are available, most of them must be diverted from existing development programmes what again affects the highly vulnerable regions and social groups. Oxfam (2009) estimates that sustainable climate change programmes with resilience-building require about 40 billion/year, while the World Bank estimates that financial needs would be four times higher if adaptation and mitigation processes are included.

This also requires institutional arrangements, above all in the water, agriculture and productive structure, with an increasing coordination among different sectors and levels for DRM with participatory community involvement in decision-making and educational programmes. Safety nets for disaster-stricken households and strengthened disaster preparedness may substantially reduce the disaster costs with early warning, improved hydro-meteorological services, and weather prediction. These safety nets also develop self-sustaining bodies of expertise in remote and marginalized regions. Women are not only the world's poorest and most vulnerable persons, but their social representations are also able to consolidate and support countries and communities prior, during, and after a disaster (Oswald 2006). Building on existing and past experiences of a proactive and constructive dynamics among top-down and bottom-up efforts may open a potential to reduce human and economic costs in a world increasingly threatened by GEC.

1.4 Dialogue Among Three Scientific Epistemic Communities on Global Change, Security and Disaster

The 95 chapters in this book bring together authors from these three research communities (1.3.2–1.3.4) and from three distinct scientific research areas and many different scientific disciplines in the natural and social sciences, including teams of authors reflecting multi- and interdisciplinary approaches (table 1.1).

1.4.1 Security Community

Of these three scientific communities the security research community has evolved since the end of the Second World War as two competing research programmes: on the one hand as war, national, international and global security or strategic studies, and on the other as peace science, studies or research. Since the late 19th century, issues of external and internal security, and the activities of the military, diplomacy and of the police have been reviewed by historians and lawyers, the state sciences and especially since the late 1940's by international relations scholars, and as a response to the Cold War, since the late 1950's by peace researchers.

In 1958, the *International Institute for Strategic Studies* (IISS) was set up in London, and in 1959 the *International Peace Research Institute in Oslo* (PRIO), and in 1966 the *Stockholm International Peace Research Institute* (SIPRI) were established. Since then numerous security policy think tanks and scientific research institutes as well as peace research institutes and programmes and scientific journals have emerged and several controversial methodological and policy-focused controversies have taken place between the traditional and the critical wings of the security community (Albrecht/Brauch 2008, 2009). This wide-ranging security community pursued different tasks to analyse, assess, critique or legitimize specific security policies and decisions.

With the reconceptualization of security since 1990 the scope of analysis has widened from the classic policy and military dimensions to include the economic, societal and environmental dimensions and the range of referent objects or actors have deepened from state-centred perspectives of national, international and global security to human- or people-centred approaches of human and gender security. This widening and deepening of the security concept since 1990 has been conceptually mapped in the previous two volumes of this GEHSHA. Furthermore, many international organizations have sectorialized the security concept by linking it to their key mission of energy (IEA), food (FAO, WFP), health (WHO), water (UNEP, UNU) and more recently to climate (UNSC, UNGA, UNSG, EU, PSIDS)

The security repercussions of GEC, especially of climate change and of natural hazards as well as of societal disasters are gradually being addressed since

Table 1.1: Three epistemic communities focusing on global environmental change, natural hazards and security. **Source:** Developed by the authors.

Epistemic community (research area)	Security	Natural hazards	Global environmental and climate change
Primary discipline (policy, politics, polity)	• Political science • international relations • policy studies	• Geography and geo-sciences • hydrology • soil sciences • geophysics (earthquakes, volcanism, tsunamis)	• Meteorology • climatology • soil sciences • hydrology • biology • ecology
Secondary disciplines	• History, law, economics, ecology • natural sciences, engineering, IT • communication science (C_3I problems)	• Sociology • human geography • political science (international humanitarian policy) • psychology	• Physics • chemistry • oceanography • agriculture • medicine • anthropology
Research programmes	• War, security or strategic studies • peace studies, science or research	• Natural hazard research (drought, (tropical) storms, floods)	• Global environmental change • ESS or ESA • geoecology
Scientific Institutes (no university departments, institutes)	• RAND, IISS • PRIO, SIPRI, ISFH, PRIF	• Natural Hazards Centre (UC, Boulder) • UCL Hazard Research Centre • Centre for Natural Hazard Research	• Tyndall Centre • MPI for Climatology • PIK • Cicero • Pew Centre on Global Climate Change

the early 21st century (chap. 42 by Scheffran; chap. 41 by Bauer) by security specialists from both security studies (Schwartz/Randall 2003; Campbell/Lennon/Smith 2007) and peace research (Gleditsch/Nordas 2009; Brauch 2009a). Besides, the social sciences, policy think tanks[33], NGOs (Brown/Crawford 2008) and the US intelligence and military community have addressed the climate change and security linkage.[34]

Climate change impacts on international, national and human security have also increasingly been addressed by think tanks, NGOs and scholars in Asia[35] (chap. 87 by Yu/Smith; chap. 88 by Ohta; chap. 89 by Kanie), Africa[36], Latin America[37] and in the Middle East[38].

1.4.2 Natural Hazard and Disaster Community

The natural hazard community is much older and goes back to the early high civilizations when various water saving technologies were developed to cope with the effects of drought and to reduce the impacts of floods and inundation. Since the 1930's, hazards were not any longer perceived as pure engineering problems but increasingly analysed as societal issues that were influenced by societal preferences and resource allocations. The practical applications of this community comprises three main activities of emergency management: a) of civil defence,[39] b) disaster relief,[40] and c) disaster risk reduction (DRR).[41]

Within the UN System, the *International Strategy for Disaster Reduction* (UN/ISDR)[42] has been a major coordinator of the many stakeholders involved in DRR, besides the ProVention Consortium[43] that is coordinated by the Red Cross and Red Crescent Society in Geneva. In the European Union, the DG Environment has been responsible for the coordination within the EU[44], while within the DG Development its *European Humanitarian Aid Office* (ECHO)[45] has become a key actor and source of financial support for UNOCHA. Besides, the World Bank, UNDP and UNEP, the International Red Cross as well as humanitarian organizations have become major actors in

33 Since mid 2008, US security think tanks published reports on climate change and security; e.g. Congressional Budget Office (2009); U.S. Global Change Research Program (2009); Carnegie Endowment for International Peace (2009); Strategic Studies Institute (Parsons 2009); Pew Center on Global Climate Change (2009); and the American Security Project (2009); for web links see at: <http://www.hsdl.org/hslog/?q=node/5093>.

34 In September 2009, the CIA set up a "Climate Change and National Security Center"; at: <https://www.cia.gov/news-information/press-releases-statements/center-on-climate-change-and-national-security.html>.

35 There are many reports on the impact of climate change on national, food and energy security in India, see: IDSA Working Group on Security Implications of Climate Change (2009); Nitin Desai, an adviser to the Prime Minister of India: "When Things Hot Up", in: *Times of India*, 29 September 2009, at: <http://timesofindia.Indiatimes.com/opinion/edit-page/Top-Article-When-Things-Hot-Up/articleshow/5065540.cms>; see: The RSIS Centre for NTS Studies Conference on Climate Insecurities, Human Security and Social Resilience, 27–28 August 2009, Four Seasons Hotel, Singapore; at: <http://www.rsis.edu.sg/nts/Events/Climate_change_conf. html>; Zhang, Zhang, Lee and He (2007); Zhan, Brecke, Lee, He and Zhan (2007).

36 See: Oli and Crawford (March 2009); Leonie Joubert: "Africa: Climate Change 'Is a Security Issue'", in: *allAfrica.com* (28 August 2009); at: <http://allafrica.com/stories/200908310376.html>; IRIN: "AFRICA: Climate change and conflicts" (23 February 2009); at: <http://www.irinnews.org/Report.aspx? Report Id=83096>; Brown, Crawford (24 March 2008); Brown, Hammil and McLeman (2008); Brown, Hammil and Crawford (2007); Hendrix, Glaser (2007): Swatuk (2007).

37 There are a few reports on the impact of climate change on food, energy and national security in Latin America: e.g. by the Centro Mario Molina; Fetzek (October 2009), at: <http://www.rusi.org/downloads/assets/Mexico_CC_Text_-_English.pdf>; "Investigadores británicos hablan sobre cambio climático y seguridad", in: *Excélsior* (13 July 2009), at: <http://ukinmexico.fco.gov.uk/es/newsroom/?view=News&id=20563860>; Emilio Sempris: "Climate Change and Freshwater in Latin America and the Caribbean", in: *UN Chronicle*, at: <http://www.un.org/wcm/content/site/chronicle/cache/bypass/lang/en/home/archive/Issues2009/pid/5075?ctnscroll_articleContainerList=1_0&ctnlistpagination_articleContainerList=true>; DFID: *Climate Change in Latin America*, at: <http://www.dfid.gov.uk/Documents/publications/climatechange/12LatinAmerica.pdf>.

38 Freimuth, Bromberg, Mehyar and al Khateeb (2007); Brauch (2007); Brown and Crawford (2009).

39 In most countries the ministries for interior are responsible for civil defence functions. In the USA, the civil defence function was developed in the 1950's to cope with the threat of a nuclear war; in the 1980's the new *Federal Emergency Management Agency* (FEMA) focused "almost exclusively on nuclear attack and continuity of government planning"; in the 1990's "FEMA adopted an all-hazards approach to disaster man-agement ... for natural hazards preparedness and mitigation programs". During the administration of G.W. Bush "at the federal level, funding for traditional natural and technological hazard programs at FEMA have been cut significantly, and funding for hazard mitigation programs such as Project Impact have been cut completely", (see: George Haddow: "The Challenges of Emergency Management Planning in 2005"; at: <http://www.disaster-resource.com/articles/05p_056.shtml>.

40 Primarily international organizations and humanitarian NGOs are responsible for the implementation of the disaster relief programmes.

political efforts of disaster relief and disaster risk reduction.

The impacts of hazards have been intensively discussed and analysed in many scientific contributions and UN reports in the context of food, water, health and human security (Seck 2007).[46] While in the USA hazards were addressed in the context of homeland security, since the mid 2000's climate change impacts were discussed in a security context (BMU 2002; WBGU 2008). The security impacts of natural hazards within the EU context have been interpreted as "functional security" (Ekengren 2009). From the perspective of many analysts and third world countries hazards pose major threats to their national security and for the human security of their citizens.

1.4.3 Global Change Community

The origins of the scientific global change community can be traced back to the 1970's in the aftermath of the Stockholm Conference (1972) on the *Environment and Development* that put the environment on the international institutional agenda with the establishment of UNEP, but it took another two decades until the four international global change programmes gradually evolved after the Rio Earth Summit. Increasingly climate change institutes with a primary focus on the natural sciences address security implications of climate change (Tyndall Centre[47]; Hamburg ClimateCampus[48]).

1.4.4 Towards a New Interdisciplinary Epistemic Community

These three distinct scientific communities have for many decades coexisted in parallel with a limited intellectual contact, debate and exchange. The disciplinary boundaries of these three scientific communities are gradually eroding but the emergence of an inter-, multi- and transdisciplinary epistemic community (Oswald Spring/Brauch 2008) has so far remained an ambitious scientific goal as – besides the initiatives referred to above – both the GEC and the hazard community have so far resisted to consider their issue areas in terms of theoretical approaches of security and peace studies.

In chap. 94 Brauch, Dalby and Oswald Spring suggest a new multi- and interdisciplinary scientific approach of a 'political geoecology' that fundamentally

41 The DDR term refers to techniques for preventing or minimizing the effects of disasters and has been adopted by the United Nations <http://www.unisdr.org/>. In the political realm, within the framework of UN/ISDR a Global Platform for DRR was set up that held so far two sessions. For the proceedings of the second session see at: <http://www.prevention-web.net/files/section/193_GPProceedingsFINAL. pdf>. Its list of participants offers a good overview of the many stakeholders involved in DRR activities.

42 On UN/ISDR's mission, see at: <http://www.unisdr.org/eng/un-isdr/secre-functions-responsibilities-eng.htm>. It is a system of partnerships with the overall objective to generate and support a global disaster risk reduction movement to implement HFA. Its Inter-Agency Group is to enhance "joint work programming among ... FAO, IFRC, ILO, OCHA, UNDP, UNEP, UNESCO, UNICEF, WFP, WHO, WMO and the World Bank ... and to improve coherence."

43 For details at: <http://www.proventionconsortium.org>.

44 Within the DG Environment, in the Directorate A: Legal Affairs & Civil Protection, two units deal with natural hazards: A3. Civil Protection - disaster response and A4. Civil Protection - prevention and preparedness¸ see at: <http://ec.europa.eu/dgs/environment/directory. htm>.

45 ECHO is made up of two directorates. The first is operations-oriented, organized geographically and thematically, and the second is dedicated to operational support; at: <http://ec.europa.eu/echo/index_en.htm> and on disaster response at: <http://ec.europa.eu/echo/aid/dipecho_en.htm>. From 2005 to 2008 the total funding of ECHO has increased from €631 to €884 million. In 2009, €571 million were spent for humanitarian aid, €280 million for food aid, €34 million for disaster preparedness and €9 million for support expenditure.

46 Papa Seck: "Links between Natural Disasters, Humanitarian Assistance and Disaster Risk Reduction: A Critical Perspective", in: UNDP, Human Development Report Office, Occasional paper on: *Human Development Report 2007/2008 - Fighting climate change: Human solidarity in a divided world* (New York: UNDP); at: <http://www.sarpn.org.za/documents/d0002903/Natural_disasters_HDR_UNDP_2007.pdf>.

47 In January 2010, the Tyndall Centre for Climate Change Research has focused on 'securities' as one of four research areas besides resilience, transitions and CIAS (A Community Integrated Assessment System). Within the context of securities these research topics are being analysed: "a) Food, water and human security, b) Biofuels: food security, energy, and equity implications, c) Food security, agriculture, fisheries and nutrition, d) Human security in the face of climate change and other stresses: health, migration and conflict, e) Implications of climate change extreme events for individual resilience and behavioural responses, f) Water security: Adaptation strategies for river basins and water infrastructure." See the overview and details at: <http://www.tyndall.ac.uk/research/transition-period/securities>.

48 See for details at: <http://clisec.zmaw.de/Contact.850.0.html>.

differs from 'old geopolitics' and that suggests to introduce the political and especially the security dimension into this new research agenda building on the 'theory or securitization' (Wæver 1995, 2008; Buzan/Wæver/de Wilde 1998, 2004) that focuses on issues of 'utmost importance' that require 'extraordinary means'. This new research approach suggests introducing both the environmental dimension and especially global environmental change issues into spatial policy and strategic considerations and a political dimension and a security perspective into earth system analysis and science in the natural sciences.

1.5 Horizontal Cooperation Among Ministries and International Organizations on GEC, Security and Disasters

While multi-, inter- and transdisciplinary cooperation among scientists has not been easy, the cooperation has often been difficult between organized civil society and the state, as well as the vertical cooperation between local, state and federal governments and the horizontal cooperation among different units within a ministry, and even more difficult is the collaboration among ministries and on the international level among international organizations.

Issues of GEC, security and disasters are not only an object of intensive scientific analysis by and among the three communities reviewed above by many government agencies and international organizations, but they have also become key issues of debate and controversy between organized civil society, including business organizations and the states on the national level as well as among transnational state-centred and non-governmental organizations. In the realm of international environment policy, several regimes – most prominently the climate regime – have evolved where these three key actors, the representatives of international society, and of the business community are continuously focusing their activities to influence the positions of their respective governments and to support or oppose the outcome of international negotiation processes, most recently at COP 15 of the UNFCCC in Copenhagen in December 2009. Thus, the activities of the state negotiators always focus simultaneously on the international but also on the national level to reflect the competing and often opposite interests of the business community, of social movements and social organizations, as well as of the specific interests of powerful lobby groups and international NGOs.

Global environmental change and especially climate change issues have not only been the exclusive interest of the nation state at the national level, but also of the state, municipal and local governments. They have played a crucial role in the process of agenda setting and policy formulation and implementation. The specific role and influence of the states and municipalities depends on the governmental system and whether a centralized or a federal system of government exists where certain competences are shared between the federal government and the states. But any impact of extreme weather events and natural hazards must first be addressed at the local and municipal level.

Horizontal cooperation among national or state ministries among the DGs of the European Union with shared competences with national ministries and implementation agencies as well as international organizations and agencies have often been suboptimal due to competing and conflicting competencies and 'turf conflicts'. Nevertheless, reactive and proactive policies as well as decisions on issues of global environmental change and in particular on climate change require multi-sectoral approaches that always involve many ministries, DGs, or international organizations (table 1.2).

1.6 Key Questions and Structure of the Book

In the five preface essays above the Nobel Laureate in atmospheric chemistry, *Paul C. Crutzen* (the Netherlands), introduces the 'Anthropocene' as the new era in the geology of humankind that is influenced by the direct and increasing human interventions into the processes of the Earth system. *Jayantha Dhanapala* (President, Pugwash Conferences on Science and World Affairs, former UN Under Secretary General for Disarmament) in the second essay suggests: "Connecting Inconvenient Truths: Urgency of Nuclear Disarmament in a World of Pressing Problems". In the next essay *Ulrich Beck* (Professor em. University of Munich and LSE) reflects on "Living in and coping with the world risk society". *Hania Zlotnik* (Director, UN Populations Division, UN, New York from Mexico) gives an overview on global "trends of population growth, urbanization and migration until 2050". In a co-authored essay eight authors from the *Potsdam Institute of Climate Change Research* (PIK), *Christoph*

Table 1.2: Different competencies and responsibilities of state and international bodies on security, natural hazards and global environmental change issues. **Source:** Developed by the authors.

	Security	Natural hazards	Global environmental change
Policy field (issue areas)	• Internal (police) • External (diplomacy and the military)	• Civil defence, protection and infrastructure • Humanitarian search and rescue, reconstruction, disaster relief • disaster risk reduction	• Climate change • Soil • Water • Biodiversity
Local community and municipality	• Police • Municipal guards, • Militia	• Local and municipal government • NGOs: firefighters, catastrophe protection, Red Cross and other humanitarian NGOs • Social movements	• Local government units and officials • Units of municipalities: implementation level of state and federal laws NGOs • Social movements • Professionals checking the implementation of legal norms
Nation state (federal or central government)	• Ministry of Interior (national, federal police, intelligence)	• -Subsidiary units of ministries of interior responsible for civil protection	
	• Ministry of Justice • Ministry of Foreign Affairs • Ministry of Defence	• Ministry of Interior or • Ministry of Defence	• Ministries of environment, development, agriculture, energy, economics, foreign affairs,
Supranational and intergovernmental (European Union)	• EU Council • DG External affairs	• DG Environment • DG Development (ECHO) • DG External Relations	• DG Development • DG Environment • DG External Relations • DG for Climate Policy
International/ regional	• OSCE, AU, OAS,AL • NATO and other military alliances	• UN-OCHA, UNDP, UNEP, World Bank • UN/ISDR • International Federation of Red Cross and Red Crescent • Humanitarian NGOs	• OSCE, basket II • OAS, • NAFTA (CEC, BECC)[a)] • AL (Council of Arab Environmental Affairs Ministers) • AU (African Ministerial Conference on the Environment)
International/ global	• UN (SC, MSC), GA • UN SG • NATO	• UN/ISDR, UN-OCHA	• UN (SC, GA, GS, ECOSOC) • UNFCCC Secretariat in Bonn, Germany • UNCCD Secretariat in Bonn, Germany • CBD Secretariat in Montreal, Canada
International, national and state polity (legal norms)	• UN-SC decisions • NATO decisions • EU decisions and recommendations • National implementation laws	• Hyogo Framework of Action (recommen-dations) • EU (directives, regulations, decisions and recommendations on civil protection) • UN/ISDR guidelines and recommendations	• International environmental law: treaties & conventions (UNCBD, UNFCCC, with legally binding Kyoto Protocol and successor regime)

a) CEC = Commission for Environmental Cooperation; BECC = Border Environment Cooperation Commission of NAFTA

Müller, Hermann Lotze-Campen, Veronika Huber, Alexander Popp (all from Germany), *Anastasia Svirejeva-Hopkins* (from Canada and Russia), *Michael Krause and Hans Joachim Schellnhuber* (Professor and Director of PIK, both from Germany), raise the issue of steps "Towards a great land-use transformation?"

The book is structured in ten parts, of which the first develops the key concepts of security threats, challenges, vulnerabilities and risks (1.6.1), while the second reviews the more narrow military and political hard and soft security dangers and concerns (1.6.2). The third assesses economic, social, environmental security and human threats, challenges, vulnerabilities and risks in the Mediterranean, in Central Asia and China (1.6.3) and the fourth focuses on the threats, challenges, vulnerabilities and risks for urban centres in hazards and disasters (1.6.4). The fifth part addresses different approaches to coping with global environmental change: climate change, soil and desertification as well as with water management, food and health issues (1.6.5). The sixth part shifts the analytical focus to coping with hazards and strategies for addressing social vulnerability and resilience building (1.6.6), while the seventh reviews different modes for coping with GEC as well as scientific and international and regional political strategies, policies and measures (1.6.7). The remaining three parts focus on vulnerability mapping and indicators of environmental security issues (1.6.8.), discuss moves towards an improved early warning of conflicts and hazards (1.6.9) and offer both conceptual and policy oriented conclusions for moving from knowledge to action (1.6.10).

1.6.1 Concepts of Security Threats, Challenges, Vulnerabilities and Risks

Of the next four chapters three offer a conceptualization of the four key concepts of threats, challenges, vulnerabilities and risks. From a political science perspective in chapter 2 *Hans Günter Brauch* (Adj. Professor (PD), Free University of Berlin, Germany) reviews the conceptual evolution and use by different scientific communities and in the areas of security, global environmental change and natural hazards of the four key "Concepts of Security Threats, Challenges, Vulnerabilities and Risks." In chapter 3, *Omar Darío Cardona A.* (Professor, Centre of Studies on Disasters and Risks, University of Los Andes, Colombia) analyses "Disaster Risk and Vulnerability: Concepts and Measurement of Human and Environmental Insecurity" from the vantage point of a civil engineer, while *Czeslaw Mesjasz* (Assoc. Professor, Economic University Cracow, Poland) develops the linkages between "Economic Vulnerability and Economic Security" in chapter 4. Finally, in chapter 5: *Lidia Mesjasz* (Assistant Professor, Economic University Cracow, Poland) discusses in an economic case study problems of "Debt Relief, Economic Growth and Poverty Reduction in Low-Income Countries".

1.6.2 Military and Political Security Threats, Challenges, Vulnerabilities and Risks

In the second part, fifteen chapters offer a conceptual mapping of the four key terms used in this book for the military and political security realm. The first six chapters address security conceptualizations in Europe or specific European security issues and of NATO, this is followed by four chapters focusing on Russia, the United States and China, two on the Middle East and two on Africa.

Chapter 6 starts with an analysis by Ambassador *Alyson J.K. Bailes* (Visiting professor, University of Iceland, Reykjavik from the United Kingdom) and the former director, of the *Stockholm International Peace Research Institute* (SIPRI) on "Security threats, challenges, vulnerabilities and risks in the evolution and implementation of the European Security Strategy" from 2003 up to the adoption of the implementation paper in December 2008. In chapter 7, *Pál Dunay* (Faculty member, Geneva Centre for Security Policy, Geneva from Hungary) reviews the "NATO's traditional security problems". In chapter 8, *Eduard Soler i Lecha* (Coordinador del Programa Mediterráneo, Fundación CIDOB, Barcelona, Spain) focuses on "European Responses to Security Threats in the Mediterranean in the Early 21st Century". In chapter 9, *Mustafa Aydin* (Rector, Kadir Has University, Istanbul, Turkey) and *Asli Toksabay Esen* (research associate, *Economic Policy Research Institute of Turkey* (TEPAV), Ankara, Turkey) discuss "Inside/outside: Turkey's security dilemmas and priorities in the early 21st century". In chapter 10, *Omar Serrano* (Ph.D. candidate, Graduate Institute of International and Development Studies, Geneva from Mexico and Switzerland) provides a quantitative analysis of "Promoting democracy as a security goal. The inward/outward paradox of the EU's foreign policy"; and in chapter 11, *Vilho Harle* (Professor, University of Tampere, Finland) and *Sami Moisi* (Docent at the Academy of Finland; senior research fellow, University of Turku, Fin-

land) offer a critical assessment of the "Rhetoric of military and other security challenges in Finland".

In chapter 12 *Alexander Sergunin* (Professor, St. Petersburg State University, Russia) assesses the "Changes in the Perception of Military Threats, Challenges, Vulnerabilities and Risks in Russia (1991–2008)", while *Pál Dunay* reviews in chapter 13 from the outside "Russian security policy in the 21st century based on the experiences of its first decade". This is followed in chapter 14 by a critical review by *Hans Günter Brauch* of the: "Security Threats, Challenges, Vulnerabilities and Risks in US National Security Documents (1990–2010)" that covers the two decades since the end of the Cold War of the US administrations of George Bush (1989–1993), William J. Clinton (1993–2001), George W. Bush (2001–2009) and Barack Obama (since 2009). This section concludes in chapter 15 with an essay by *Zhongqin Zhao* (Brig. General, Associate Professor, Military Academy, Shijiazhuang, China) on the "Non-traditional security and the new concept of security of China".

The third section shifts the focus on the Middle East and on West Africa. In chapter 16, *Gamal Selim* (PhD candidate, University of Calgary, Canada from Egypt) assesses the "Perceptions of hard security issues in the Arab world", while in chapter 17, *Mohamed El-Sayed Selim* (Professor, Kuwait University from Egypt) analyses the: "Arab perceptions of soft security issues".

In the last two chapters on West Africa, *Kwesi Aning* (Head, Conflict Prevention Department, Kofi Annan Center, Accra, Ghana) and *Andrews Atta-Asamoah* (Researcher, *Institute for Security Studies* (ISS), Nairobi, Kenya from Ghana) analyse in chapter 18: "Military challenges and threats in West Africa", while *John Emeka Akude* (Lecturer, Research Fellow, University of Cologne, Germany from Nigeria) gives in chapter 19 a theoretically-based empirical analysis on "Weak sates and security threats in West Africa".

1.6.3 Environmental and Human Security Dangers in the Near East and Three Regional Prospects until 2020 and 2050

This third part consists of nine chapters that are organized in two sections, whereof in the first part authors from Tunisia, Palestine and Israel address environmental and human security dangers in the Middle East and North Africa, and in the second section three chapters deal with regional environmental security prospects until 2020 and 2050 and potential impacts that may create instability and conflicts.

In chapter 20, *Bechir Chourou* (Director, University of Tunis-Carthage, and Professor of International Relations from Tunisia who taught in the United States, Europe and Tunisia) discusses multiple "Environmental challenges and risks in North Africa"; in chapter 21: *Bassam Ossama Hayek* (Director, Ecotech Park, *Royal Scientific Society* (RSS)., *Royal Scientific Society*, Amman, Jordan) and *Nisreen Daifallah Al Hmoud* (Researcher, Environmental Research Centre (RSS), Jordan) analyse: "Water degradation as a human security challenge in Jordan"; and in chapter 22: *Marwan Haddad* (Professor, Nablus University, Palestine) assesses: "Water scarcity and degradation in Palestine as challenges, vulnerabilities and risks for environmental security".

The next two chapters provide two distinct analyses on climate change impacts from a Palestinian and Israeli perspective. In chapter 23, *Hilmi S. Salem* (Research Professor and Director General, Applied Sciences and Engineering Research Centers, Palestine Technical University Kadoorie, Palestine) discusses "Social, environmental, and security impacts of climate change on the Eastern Mediterranean"; while in chapter 24 *Arie Issar* (Professor em., Ben Gurion University, Beer Sheva, Israel) develops his own concept of "Progressive development of the water resources of Israel and Palestine to mitigate the negative impact of global warming". This section concludes with chapter 25 by *Mohamed Dajani Daoudi* (Professor and director of America Institute, Al Quds University, Jerusalem) and *Ashraf M. Dajani* (Ph. D. Candidate, European University Institute, Florence, Italy from Palestine) on: "Jerusalem: Where To? In search for hidden opportunities", in which both authors discuss proposals by Christians, Jews and Muslims and develop their own concept of a sustainable conflict resolution for solving the highly disputed Jerusalem question.

In chapter 26, *Hans Günter Brauch*, discusses "Human and Environmental Security Challenges Posed by Global Environmental and Climate Change for the Mediterranean", while *Ernst Giese* (Professor emeritus, University of Giessen, Germany) and *Jennifer Sehring* (Assistant professor, University of Würzburg, Germany) assess in chapter 27 the impacts of "Global environmental change and conflict potential in Central Asia" and in chapter 28: *Thomas Heberer* (Professor, University Duisburg-Essen, Germany) and *Anja Senz* (Lecturer, University of Duisburg-Essen) analyse the "Impact of environmental change on stability and conflict potentials in China".

1.6.4 Threats, Challenges, Vulnerabilities and Risks for Urban Centres in Hazards and Disasters

In part IV the introductory chapter 29 by *Mark Pelling* (Reader, King's College, London, UK) offers a conceptual introduction on "The vulnerability of cities to disasters and climate change: A conceptual framework". In chapter 30 *Fabien Nathan* (Project Manager at Sogreah Consultants in Echirolles, France), discusses "Vulnerability to natural hazards: case study on landslide risks in La Paz". In chapter 31: *Mabel-Cristina Marulanda* (*Technical University of Catalonia* (UPC), Barcelona, Spain from Colombia), Omar Darío Cardona A. (Colombia) and *Alex H. Barbat* (Professor, UPC, Barcelona, Spain) in a case study on Latin America are "Revealing the impact of small disasters to the economic and social development"; while in chapter 32: *Carmen Lacambra* (PhD candidate, University of Cambridge, UK from Colombia) and *Kaveh Zahedi* (Climate Change Coordinator at UNEP from the UK) analyse: "Climate change, natural hazards and coastal ecosystems in Latin America: A framework for analysis".

In chapter 33 *Monalisa Chatterjee*, (PhD candidate, Rutgers University, USA from India) addresses the: "Flood loss redistribution in a Third World megacity: The case of Mumbai"; while in chapter 34: *Reena Singh* (Research associate, University of Cologne, Germany from India) focuses on: "Coping with water- and wastewater-related risks in the megacity Delhi"; and in chapter 35: *Nanda Kishor* (Doctoral Fellow, University of Hyderabad, India) offers a critical discussion on: "Politics of displacement and vulnerability".

In chapter 36 by *Xiaomeng Shen* (Associate academic officer, United Nations University Institute for Environment and Human Security (UNU-EHS) Bonn, Germany from China) focuses on "Linking Oriental and Western thinking to mitigate flood risk comparing risk perceptions of floods: The cases of Beijing and Bonn". In the next two chapters on hazards in Istanbul, *Sidika Tekeli-Yesil* (Research assistant, Institute of Social and Preventive Medicine, Swiss Tropical Institute in Basel, Switzerland from Turkey) analyses in chapter 37 the "Preparation for an Earthquake in the megacity Istanbul"; while in chapter 38 *Ebru Gencer* (Consultant at ARC and a member of the ISOCARP Urban Planning Advisory Team for Haiti and Chile) reviews: "Risk management strategies for the predicted earthquake hazard in Istanbul". Finally, in chapter 39: Adeniyi Sulaiman Gbadegesin (Professor, University of Ibadan, Nigeria); *Felix Olorunfemi* (Research Fellow, *Nigerian Institute of Social and Economic Research* (NISER), Ibadan, Nigeria) and *Usman Adebimpe Raheem* (Lecturer, University of Ilorin, Nigeria) assess the "Urban vulnerability to climate change and natural hazards in Nigeria".

1.6.5 Coping with Global Environmental Change: Climate Change, Desertification, Water Management, Food and Health

This part is organized in five sections and includes 28 chapters. First, in chapter 40 *Debarati Guha-Sapir* (Director, WHO *Collaborating Centre for Research on the Epidemiology of Disasters* (CRED) and Professor, University of Louvain, Brussels, Belgium) and *Femke Vos* (Researcher, CRED, University of Louvain, Brussels from the Netherlands and Belgium) offer a statistical overview on "Quantifying global environmental change impacts: methods, criteria and definitions for compiling data on hydro-meteorological disasters". The following five sections deal with the coping activities and efforts with regard to climate change (section A with chapters 41 to 46), to soil and desertification (section B with chapters 47 to 55), water management (section C with chapters 56–60), food (section D with chapters 61 to 65) and health (section E with chapters 66 to 67).

In section A on climate change, *Stefan Bauer* (Senior researcher, German Development Institute, Bonn; research assistant, German Advisory Council on Global Change (WBGU), Berlin, Germany) in chapter 41 addresses "Stormy weather: International security in the shadow of climate change". In chapter 42 *Jürgen Scheffran* (Professor, Hamburg University, Germany) offers a theoretical analysis on: "Security risks of climate change: vulnerabilities, threats, conflicts and strategies", while *Anders Jägersköp* (Programme Director, Stockholm International Water Institute (SIWI), Stockholm, Sweden) in chapter 43 discusses: "New threats? Risk and securitization theory on climate change and water".

The next two chapters focus on the Nile River and the Nile Basin. In chapter 44 a team of nine authors consisting of *Carlo Buontempo* (Senior scientist, Met Office Hadley Centre, UK from Italy), *Jens Kristian Lørup* (DHI, Denmark), *Mamdouh A. Antar* (Manager, Nile Forecast Centre, Ministry of Water Resources and Irrigation, Planning Sector, Cairo, Egypt), *Michael Sanderso* (Senior climate consultant, Met Office Hadley Centre, UK), *Michael Butts* (Head, Inno-

vation for Water Resources and Environmental Management, DHI, Denmark from New Zealand), *Erika Palin* (Climate change consultant, Met Office Hadley Centre, UK), *Rachel McCarthy* (Climate change consultant, Met Office Hadley Centre, UK), *Richard Jones* (Manager, regional climate predictions, Met Office Hadley Centre, UK) and *Richard Betts* (Head, climate impacts, Met Office Hadley Centre, UK) are "Dealing with uncertainties in climate change impacts assessments: A case study on the Nile Basin", *Mohammed El Raey* (Professor em., University of Alexandria, Egypt) in chapter 45 gives an empirical analysis of: "Mapping areas affected by sea-level rise due to climate change in the Nile Delta until 2100". Finally, in chapter 46 *Hans Jürgen Boehmer* (Senior research scientist and managing director, *Interdisciplinary Latin America Center* (ILZ), University of Bonn, Germany) analyses the "Vulnerability of tropical montane rain forest ecosystems due to climate change".

In section B on issues of soil degradation, drought and desertification in drylands nine chapters address a wide area of themes that are related to environmental security issues. In chapter 47, *Hans Guenter Brauch* and *Úrsula Oswald Spring* introduce into the theme of "Securitizing land degradation and desertification: A proactive soil security concept". In chapter 48 *Uri Safriel* (Professor, Hebrew Universty, Jerusalem, Israel) analyses: "Alternative livelihoods for attaining sustainability and security in drylands", while in chapter 49 *Adeel Zafer* (Director, UNU's Institute on Water, Environment and Health, Hamilton, Canada from Pakistan): addresses "Societal vulnerability to desertification and policy response options". In chapter 50, *Ismail Abd El Galil Hussein* (Chairman, Desert Research Centre, Cairo, Egypt): provides an overview of the "Desertification process in Egypt". In chapter 51, *Tulio Arredondo Moreno* (Researcher, Division Ciencias Ambientales (IPICYT), San Luís Potosí, Mexico) and *Elisabeth Huber-Sannwald* (Researcher, IPICYT, San Luís Potosí, Mexico from Austria) discuss the "Impacts of drought on agriculture in Northern Mexico". In chapter 52 *Pietro Laureano* (President, *Research Centre on Local and Traditional Knowledge* (IPOGEA), Florence, Italy) reviews the "Traditional knowledge in coping with desertification".

The next three chapters address problems of desertification in drylands in the Sahara, of agriculture in drylands in Almería and of impacts of climate change on desertification in Murcia in Spain. Chapter 53 that is co-authored by *Monique Mainguet* (Professor em., University of Reims Champagne Ardenne, France), *Frederic Dumay* (Research engineer, University of Reims Champagne Ardenne, France), *Lahcen Kabiri* (Professor, Moulay Ismaïl University, Meknes, Morocco) and *Boualem Rémini* (Professor, Blida University, Algeria) offer an analysis of "Prodromes of desertification in the Oasis of Tafilalet (Morocco) and specific local solutions". In chapter 54 *Andrés Miguel García Lorca* (Professor, University of Almería, Spain) reviews the "Agriculture in drylands: Experience in Almería"; while in chapter 55 *Francisco López-Bermúdez* (Professor, University of Murcia, Spain), *Jorge García Gómez* (Agronomic engineer, Eurovertice Consultants S.L., Murcia, Spain), *Juan Manuel Quiñonero Rubio* (Ph.D. candidate, University of Murcia, Spain) analyse "Land-use changes, desertification, and climate change impacts in Southeastern Spain".

In section C in five chapters authors from Sweden, China, India, Bangladesh, Niger, Mauritania and Tunisia analyse issues of water management with a specific focus on drylands. In chapter 56 *Jacob Granit* (Project Director, Stockholm International Water Institute (SIWI), Sweden) introduces into the topic by "Reconsidering integrated water resources management: Promoting economic growth and tackling environmental stress". In chapter 57: *Zhanyi Gao* (Director, Department of Irrigation and Drainage, *Institute of Water Resources and Hydropower Research* (IWHR), and Director, National Centre for Efficient Irrigation Technology Research, Beijing, PR China) and *Yaqiong Hu* (Senior Engineer, IWHR and National Centre for Efficient Irrigation Technology Research, Beijing, PR China) focus on "Coping with population growth, climate change, water scarcity and growing food demand in China in the 21st century".

In chapter 58 *Mohammed Rahman Zillur* (PhD candidate, The Australian National University (ANU) from Bangladesh) and *Kuntala Lahiri-Dutt* (Fellow, Australian National University, College of Asia and the Pacific from India) offer an analysis on "Ensuring water security in rural areas of Bangladesh under climate change and non-climatic drivers of change", while in chapter 59 *Kanupria Harish* (Project Director, Jal Bhagirathi Foundation, Jodhpur, India) and *Mathews Mullackal* (Head, Programme Development Group, JBF, Jodhpur, India): discuss "Applying bottom-up participatory strategies and traditional methods of water harvesting in the Desert Thar, Rajasthan". Finally, in chapter 60: Abdelkader Dodo (Hydrogeologist and manager, Iullemeden Aquifer System (IAS) project, Sahara and Sahel Observatory (OSS) Tunis from Niger), *Mohamedou Ould Bab Sy*

(Hydrogeologist, OSS, Tunis from Mauritania) and *Jihad Channem* (Special assistant to Executive Secretary and communications officer, OSS, Tunis from Tunisia) offer an overview on "Coping with water scarcity in the Sahel: Assessing ground water resources in the Western Sahel".

Section D on coping with food security issues combines five chapters. In chapter 61 *John Grin* (Professor, University of Amsterdam and until December 2009 scientific director, Amsterdam School for Social Science Research, the Netherlands) and *Esther Marijnen* (BSC student, University of Amsterdam) discuss "Global threats, Global changes and connected communities in the global agrofood system" and in chapter 62 *Úrsula Oswald Spring* deals with "Genetically modified organisms: A threat for food security and a risk for food sovereignty and survival".

In chapter 63 *Issa Martin Bikienga* (Deputy Executive Secretary, *Comité Permanent inter Etats de Lutte Contre Secheresse dans le Sahel* (CILSS) from Burkina Faso) gives an overview on "Natural disasters and major challenges towards achieving food security in the Sahel: The experience of CILSS", while in chapter 64 *Sreeja Nair* (Research associate, Center for Global Environment Research, TERI, New Delhi, India) focuses on "Responding to climate variability and change under a multi-level governance framework". Finally, in chapter 65 *Cecilia Conde* (Senior Researcher, Centro de Ciencias de la Atmósfera, UNAM, Mexico City, Mexico) addresses "Coping with climate change impacts on coffee and maize for peasants in Mexico."

In section E on coping with health security issues in chapter 66: *Fátima Flores Palacios* (Research Professor, UNAM, Cuernavaca, Mexico) and *Wolfgang Wagner* (Professor, University of Linz, Austria) address "The Impact of AIDS on women's social life in a Mexican rural community", while in chapter 67: Tanja Wolf (WHO Regional Office Europe, Rome, Italy from Germany), Glenn McGregor (Director, School of Environment, University of Auckland, New Zealand from UK) and Anna Paldy (Deputy director, National Institute of Environmental Health, Budapest, Hungary) offer an "Integrated assessment of vulnerability to heat stress in urban areas".

1.6.6 Coping with Hazards and Strategies for Social Vulnerability and Resilience Building

This part combines five chapters by authors from Germany, France, Guatemala, the United States and Mexico that are or were recently working for or connected to the *United Nations University's Institute on the Environment and Human Security* (UNU-EHS) in Bonn (Germany). In chapter 68 *Jörn Birkmann* (Academic officer, head, vulnerability assessment section, UNU-EHS from Germany) offers a theory-guided analysis on: "Regulation and coupling of society and nature in the context of natural hazards". In chapter 69: *K. Marre* (Former academic officer, UNU-EHS) and *Fabrice Renaud* (Acting director, head, environmental assessment and resource vulnerability section, UNU-EHS from France) provide an empirical analysis of "Differentials in impacts and recovery in the aftermath of the 2004 Indian Ocean Tsunami: local examples at different scales in Sri Lanka". *Juan Carlos de Villagrán* (Programme officer, UN-SPIDER Programme, UNOOSA, United Nations Office Vienna, Austria; former academic officer and head, risk management section, UNU-EHS, Bonn, Germany from Guatemala) in chapter 70 addresses: "Risks in Central America: Bringing them under control"; while in chapter 71 *Koko Warner* (Academic officer, head, environmental migration, social vulnerability and adaptation section, UNU-EHS from the USA), discusses "Economics and social vulnerability: Dynamics of entitlement and access". Finally, in chapter 72 *Úrsula Oswald Spring* (first chair holder, MRF chair on social vulnerability, UNU-EHS from Mexico) offers a critical discussion on "Social vulnerability, discrimination and resilience-building in disaster risk reduction".

1.6.7 Coping with Global Environmental Change: Scientific International and Regional Political Strategies, Policies and Measures

This part includes 16 chapters that address in three sections the scientific research goals (section A, chapters 73 to 78) and strategies for coping with GEC, especially the global (section B, chapters 79 to 82) and regional (section C, chapters 83 to 86) and national (section C, chapters 87 to 89) strategies, policies and measures for coping with climate change.

Section A on scientific research goals and strategies for coping with GEC starts with chapter 73 by *Gordon McBean* (Professor and director of policy studies, Institute for Catastrophic Loss Reduction, University of Western Ontario, London, Canada) on "Coping with global environmental change – Need for an interdisciplinary, integrated approach".

The next five chapters provide an overview on the international GEC scientific programmes. In chapter 74 *Rik Leemans* (Professor, Wageningen University;

director, WIMEK graduate school; chair, *Earth System Science Partnership* (ESSP), the Netherlands), *Martin Rice* (ESSP, Paris from UK, PhD Student at Sydney University, Australia), *Ann Henderson-Sellers* (Professor, Macquarie University, ARC Professorial Research Fellow, Climate Risk Concentration of Research; former director, *World Climate Research Programme* (WCRP), Australia) and *Kevin Noone* (Professor, Department of Applied Environmental Science and Stockholm Resilience Centre, Stockholm University; Director, Global Environmental Change Secretariat, Royal Swedish Academy of Sciences, Stockholm, Sweden from the USA) summarize and assess the "Research agenda and policy input of the Earth System Science Partnership for coping with global environmental change".

In chapter 75 *Louise von Falkenhayn* (former Academic Officer, *International Human Dimensions Programme on Global Environmental Change* (IHDP) from Australia), *Andreas Rechkemmer* (Lecturer, University of Cologne and Guest professor Beijing Normal University; former Executive Director, IHDP, from Germany) and *Oran R. Young* (Professor, Bren School of Environmental Science and Management, University of California, Santa Barbara, USA; chair, Scientific Committee, IHDP) give an overview on the activities of "The International Human Dimensions Programme on Global Environmental Change: Taking stock and moving forward".

In chapter 76 *Bruno A. Walther* (Visiting assistant professor, Taipei Medical University Taipei, Taiwan; former science officer, Diversitas from Germany), *Anne Larigauderie* (Executive director, Diversitas, Paris from France) *and Michel Loreau* (Professor, McGill University, Montreal, Canada; chairman, Scientific Steering Committee, Diversitas from Canada) review the activities of "DIVERSITAS: Biodiversity science integrating research and policy for human wellbeing".

In chapter 77 *Kevin J. Noone* (Professor, Department of Applied Environmental Science and Stockholm Resilience Centre, Stockholm University; Director, Global Environmental Change Secretariat, Royal Swedish Academy of Sciences), *Carlos Nobre* (Director, Centro de Previsão de Tempo e Estudos Climáticos – CPTEC, Brazil; chairman, Scientific Steering Committee, IGBP from Brazil) and *Sybil Seitzinger* (Executive Director of the International Geosphere-Biosphere Programme from the USA) assess the "Scientific research agenda of the International Geosphere-Biosphere Programme: Coping with global environmental change".

Finally, in chapter 78: *John A. Church* (Professor, CSIRO, Centre for Australian Weather and Climate Research, Antarctic Climate and Ecosystems Cooperative Research Centre; director, *World Climate Research Programme* (WCRP) from Australia), *Ghassem R. Asrar* (Director, WCRP's Joint Planning Staff from the USA), *Antonio J. Busalacchi* (Professor and director *Earth System Science Interdisciplinary Center* (ESSIC), University of Maryland, USA; Chair, Joint Scientific Committee, WCRP from the USA) and *Carolin E. Arndt* (Programme officer, IPCC Secretariat; scientific consultant, WCRP's Joint Planning Staff from Germany) analyse the "Climate information for coping with environmental change: Contributions of the World Climate Research Programme".

In section B four chapters (79 to 82) review global strategies, policies and measures for coping with climate change focusing on the activities of the IPCC, of UNESCO and UNDP. In chapter 79: *Martin Parry* (Professor, Imperial College, University of London; former Co-Chair, Working Group II, IPCC, FAR from the UK), *Osvaldo Canziani* (Professor, University of Buenos Aires, University of Asunción and La Molina; former Co-Chair, Working Group II, IPCC, FAR from Argentina), *Jean Palutikof* (Professor, Griffith University, Queensland, Australia; former staff director, Working Group II, IPCC, FAR from the UK) and *Clair Hanson* (Senior research associate, University of East Anglia, UK; former deputy head, IPCC Technical Support Unit, UK Met Office, Working Group II, IPCC, FAR from the UK) summarize the "Key IPCC conclusions on climate change impacts and adaptations". In chapter 80 *Peter Bosch* (Former coordinator and editor, Working Group III, IPCC, AR4 from the Netherlands) and *Bert Metz* (Former co-chairman (1997–2008), Working Group III, IPCC, AR4 from the Netherlands) offer an overview on the "Options for mitigating climate change results of IPCC working group III of the Fourth Assessment Report of the IPCC".

In chapter 81 *Walter Erdelen* (Assistant Director-General for Natural Sciences, UNESCO since 2001 from Germany) and *Badaoui Rouhban* (Director, Section, Disaster Reduction, Natural Sciences Sector, UNESCO from Lebanon) review and analyse "Global climate change, natural hazards and the environment: an overview of UNESCO's activities". Finally, in chapter 82 *Yannick Glemarec* (Executive coordinator, UNDP's Global Environment Facility from France), *Veerle Vandeweerd* (Director, Environment and Energy Group, UNDP from Belgium) and *Vivienne Caballero* (Programme officer, UNDP-UNEP Poverty

and Environment Initiative, Regional Office for Latin America and the Caribbean; former climate change programme specialist, Environment and Energy Group, Bureau for Development Policy, UNDP from Colombia) give an overview on the "Climate Change and Development: UNDP's Approach to Helping Countries Build a New Paradigm".

In section C four chapters (83 to 86) discuss regional strategies, policies and measures for coping with climate change. In chapter 83: *Christian Egenhofer* (Senior Fellow, *Centre for European Policy Studies* (CEPS) from Germany), *Arno Behrens* (Research Fellow, CEPS from Germany) and *Anton Georgiev* (Researcher, CEPS from Bulgaria) review "EU strategies for coping with global environmental change: Perspective beyond 2012". In chapter 84 *Paul Harris* (Lingnan University, Hong Kong) assesses efforts for "Coping with climate change in East Asia: Vulnerabilities and responsibilities". In chapter 85 *Ricardo Zapata-Marti* (CEPAL from Chile) reviews and discusses "Strategies for coping with climate change in Latin America: Perspective beyond 2012". In chapter 86 Ariel Macaspac Penetrante (a coordinator of the programme of international negotiation processes at IISA from Germany) discusses "Politics of Equity and Justice in Climate Change Negotiations in North-South Relations".

In section D three chapters (87 to 89) review different national perspectives of the USA, China and Japan. In chapter 87 *Yu Hongyuan* (Assoc. Professor, Shanghai Institutes for International Studies, PR China) and *Paul J. Smith* (Assoc. Professor, US Naval War College, Newport, Rhode Island) analyse the policies of "Climate change: Long-term security implications for China and the international community". In chapter 88 *Hiroshi Ohta* (Professor, Waseda University, Japan) offers an overview on the "Japanese climate change policy: Moving beyond the Kyoto Process". Finally, in chapter 89 *Narichika Kanie* (Assoc. Professor, Tokyo Institute of Technology, Department of Value and Decision Science, Graduate School of Decision Science and Technology) *Hiromi Nishimoto* (Ph.D. student, Graduate School of Global Environmental Studies, Kyoto University), *Yasuaki Hijioka* (Senior Researcher of the National Institute of Environmental Studies in Japan), and *Yasuko Kameyama* (Senior Researcher, National Institute for Environmental Studies) analyse the evolution "Implications of Equity Consideration and Emission Reduction Targets: Lessons from the Case of Japan's Mid-Term Target".

1.6.8 Vulnerability Mapping and Environmental Security Indicators

The following two chapters introduce two technical tools into the environmental security analysis, remote sensing and indicators. In chapter 90 *Juan M. Quiñonero-Rubio* (PhD candidate, University of Murcia; researcher, Technical University of Cartagena, Spain), *Francisco López-Bermúdez* (Professor, University of Murcia), *Francisco Alonso-Sarría* (Research associate, *Institute of Water and Environment* (INUAMA), University of Murcia) and *Francisco J. Gomariz-Castillo* (Lecturer, University of Murcia; subdirector, INUAMA) offer an empirical analysis on: "Land use and flood risk changes in coastal areas in South-eastern Spain". From an economic perspective in chapter 91 *Jochen Jesinghaus* (Economist and engineer, European Commission, Joint Research Centre (JRC), Ispra, Italy from Germany) suggests in a conceptual analysis "Monitoring conflict risk: The contribution of globally used indicator systems".

1.6.9 Improved Early Warning of Conflicts and Hazards

These two chapters address improved early warning of conflicts and hazards that represent different research communities that have so far hardly interacted although in many so-called 'complex emergencies' natural hazards have impacted on conflict prone regions, as the case of the December 2004 tsunami has shown for Sri Lanka where the conflict intensified after the tsunami while it was resolved in the case of the Aceh province in Sumatra (Indonesia) with the assistance of an outside mediator.[49] In chapter 92 *Patrick Meier* (Doctoral research fellow, *Harvard Humanitarian Initiative* (HHI), Harvard University; PhD candidate, Fletcher School, Tufts University, USA) analyses "Networking disaster and conflict early warning in responses to climate change" in a case study on CEWARN in East Africa, while in chapter 93 *Juan Carlos Villagrán de León* offers a "Vulnerability assessment in Sri Lanka and the context of tsunami early warning".

---

49 See the poster by Úrsula Oswald Spring and Hans Günter Brauch: "Mainstreaming Early Warning of Hazards and Conflicts", presented at the Third International Conference on Early Warning (EWC III): From Concept to Action, Bonn, Germany, 27–29 March 2006; at: <http://www.afes-press.de/pdf/Brauch_Oswald,%20final. pdf>.

1.6.10 Summary and Conclusions

In chapter 94 *Hans Günter Brauch, Simon Dalby* (Professor, Carleton University, Ottawa, Canada) and *Úrsula Oswald Spring* develop a new policy-focused "Political geoecology for the Anthropocene" and finally in chapter 95 *Hans Günter Brauch* and *Úrsula Oswald Spring* suggest in the concluding chapter for "Coping with global environmental change: Sustainability revolution towards a sustainable peace".

1.7 Concluding Remark

These three volumes of this *Global Environmental and Human Security Handbook for the Anthropocene* (GEHSHA) offer a global mapping of the manifold and diverse reconceptualizations of security that have been triggered by the end of the Cold War, the impact of the globalization process and by the new dangers and concerns posed by multiple issues of GEC for the security and survival of humankind, less for the 'top billion' of the people in OECD countries but especially for the rest of the world, most particularly for those that were excluded from economic growth since the end of World War II. The rethinking of their political and ecological spokespersons matters and should not be ignored any longer during the 21st century.

2 Concepts of Security Threats, Challenges, Vulnerabilities and Risks

Hans Günter Brauch

2.1 Introduction[1]

The reconceptualization of security has been triggered by the end of the Cold War, by the process of globalization, and by the gradual transition from the Holocene to the Anthropocene phase of earth history (Brauch 2008, 2009, chap. 1 by Brauch/Oswald Spring above). From a philosophical perspective, in the contemporary security discussion the "dual moment of prevention and compensation of genuinely social and technical uncertainties" (Makropoulos 1995: 745–750) becomes decisive. These new uncertainties are no manifest or latent dangers emerging from individuals and societal groups that can be prevented by police and political measures but 'societal risks'. This implies that security is no longer a situation free of dangers, but rather an 'insurance' as a 'technology of risks' becomes a disposition of the social steering of modern societies. With the shift of focus from protection against concrete dangers towards insurance in the context of abstract risks, security has become "a general 'societal idea of value' (*Wertidee*) and a universally employed 'normative concept', that is used with different meanings in an affirmative manner" (Makropoulos 1995: 749).

Today 'security' as a political value, at least in Western thinking, has no independent meaning and is related to individual or societal value systems. As a social science concept, "*security* is ambiguous and elastic in its meaning" (Art 1993: 820–22). Wolfers (1962) pointed to two sides of the security concept: "Security, in an *objective* sense, measures the absence of threats to acquired values, in a *subjective* sense, the absence of fear that such values will be attacked". From the perspective of social constructivist approaches in international relations (Adler 1997; Fearon/Wendt 2002; Risse 2003; Wendt 1992, 1999) 'security' is conceived as an outcome of a process of social and political interaction where social values and norms, collective identities and cultural traditions are essential. From this perspective, security is always *intersubjective* or "security is what actors make of it" (Wendt 1992).

For Wolfers security refers to an *absence of objective dangers*, i.e. of security 'threats', 'challenges', 'vulnerabilities' and 'risks', and of *subjective fears or concerns*, and to the *perception thereof*. From a realist perspective, *objective* security is achieved when the dangers posed by manifold threats, challenges, vulnerabilities and risks are avoided, prevented, managed, coped with, mitigated and adapted to by individuals, societal groups, the state or regional or global international organizations. From a social constructivist approach, security is achieved once the perception and fears of security 'threats', 'challenges', 'vulnerabilities' and 'risks' are allayed and overcome. While objective factors in the security perception are necessary, they are not sufficient. Subjective factors influence security perceptions. The *perception* of security dangers depends on the worldviews or traditions of the analyst (Bull 1977, Wight 1991) and on the mind-set of policymakers (Booth 1979, 1987: 39–66) that have often distorted the assessment of 'new challenges' and that "freeze international relations into crude images, portray its processes as mechanistic responses of power and characterize other nations as stereotypes" (Booth 1987: 44; 1998: 28). Influenced by these worldviews and mind-sets, security is a concept of *s* (Buzan/Hansen 2009) and of *peace and conflict research* (Albrecht/Brauch 2008, 2009).

Since 1990 new debates have emerged between traditional approaches, critical security studies, and

1 This chapter is based on several earlier papers of the author most particularly on two reports he wrote for UNU-EHS (Brauch 2005, 2005a), several chapters he wrote for volume 39 of *UNESCO's Encyclopaedia of Life Support Systems* (Brauch 2007, 2007a, 2007b, 2007c), as well as on a contract report he wrote for UNESCO (Brauch 2006, 2008a). The permission of these institutions to use the previous material is kindly acknowledged. The author appreciates the very useful comments of three reviewers.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_2, © Springer-Verlag Berlin Heidelberg 2011

constructivist approaches. While *national security* has the state as the major referent, *human security* has human beings and humankind as the referent. The answers to the questions of security for whom, from whom, by whom, of what values, from what threats and by what means differ fundamentally between both concepts.

On the background of the observed widening, deepening and sectorialization of the security concept, this chapter reviews four *objective security dangers* and *subjective security concerns* often referred to as security 'threats' (2.2.), 'challenges' (2.3), 'vulnerabilities' (2.4) and 'risks' (2.5), and the use of these basic concepts in different scientific research communities, especially those working on global environmental change, climate change, as well as hazards and disasters. It discusses the relevance of these four concepts for the 'environmental' security dimension (2.6) and for 'human security' (2.7) approaches. The goal of this chapter is to enhance synergies and to mainstream related efforts to strengthen proactive policy initiatives (2.8).

2.2 Reconceptualizing 'Security Threats'

2.2.1 'Threat' as a Political Term

The English term 'threat', or 'menace' (Latin: 'trudere' or to push, thrust; French: 'menace'; Italian: 'minaccia'; Spanish: 'amenaza' or: 'conminación'; Portuguese: 'ameaça'; German: 'Drohung' or 'Bedrohung') refers to "a communication of a disagreeable alternative to an individual or group by one in authority or who pretends to be" (Koschnik 1992: 210). According to *Webster's Dictionary* a 'threat' is "1. a statement or expression of intention to hurt, destroy, punish, etc. in retaliation or intimidation", and 2. "an indication of imminent danger, harm, evil etc.; as, the threat of war" (McKechnie 1979: 1901). Langenscheidt-Longman (1995) defines 'threat' as: "1. a statement that you will cause someone pain, unhappiness, or trouble...; 2. the possibility that something very bad will happen (famine, attack etc.)...; 3. someone or something that is regarded as a possible danger". For the *Compact Oxford English Dictionary* threat means: "1. a stated intention to inflict injury, damage, or other hostile action on someone; 2. a person or thing likely to cause damage or danger; 3. the possibility of trouble or danger" (Soanes 2000: 1199). For the *Shorter Oxford English Dictionary* threat refers to "1. A throng or crowd of people; a troop, a band. ... 2. Oppression, compulsion; torment; distress, misery; danger. ... 3. A declaration of an intention to make some hostile action, esp. a declaration of an intention to inflict pain, injury, damage, or other punishment in retribution for something done or not done. ... An indication of the approach of something unwelcome or undesirable; a person or thing regarded as a likely cause of harm etc." (Oxford ^{5}2002: 3251). Thus, in the common use of the term in contemporary British and American English the word 'threat' has multiple meanings.

2.2.2 'Threat' as a Scientific Concept

In security policy and studies 'threat' is used as a 'political term' and as a 'scientific concept' that remains undefined in many social science dictionaries. Robertson (1987: 304–305) used the concept 'threat assessment' as an analysis of "the reasons behind an opponent's armament programmes" that was often made during the Cold War "on a worst case basis", where "besides personnel and hardware totals" the opponent's strategic doctrine had also to be taken into account.

During the Cold War, within the framework of *national security*, Buzan (1983: 57) pointed to a dual threat to state institutions by force (capabilities) and ideas (ideology). The state's territory "can be threatened by seizure or damage, and the threats can come from within and outside of the state". For Buzan different components of the state are vulnerable to different types of threats where strong states are primarily threatened by outside forces while weak states may be challenged both from within and outside. From a national security perspective, Buzan (1983: 75–83) distinguished between *military threats* (seizure of territory, invasion, occupation, change of government, manipulation of policy), *economic threats* (export practices, import restrictions, price manipulations, default on debt, currency controls etc., and those to domestic stability), and *ecological threats* (damaging the physical base of the state). These threats, Buzan (1983: 88) argued, "define [the state's] insecurity, and set the agenda for national security as a security problem". These threats require to understand the state's vulnerabilities. Weapons development as a combination of capabilities and intentions has been semi-independent from threats. Dealing with specific threats, an international security strategy focuses on "the sources and causes of threats, the purpose being not to block or offset the threats, but to reduce

or eliminate them by political action" (Buzan 1983: 218).

This type of 'threat' has disappeared in Europe with the end of the East-West conflict in 1990, and thus the threat perception has fundamentally changed. Already during the first (1969–1975) and second détente (1986–1989) the classic threat concept lost in importance. Since 1990, threat is also defined as referring to the dangers the planet earth is confronted with due to the manifold destructive potentials of the environment and its global and societal consequences. Steiner (2001) pointed to the fundamental change in the risks, dangers and threats since 1990, which has increased the dangers of violent domestic wars and has reduced the effectiveness of arms control regimes. But outside Europe, e.g. in the Middle East, in South Asia or on the Korean Peninsula, many of the old threats have not been overcome.

However, the increase in asymmetric forms of warfare (Kaldor 1999; Kaldor/Vashee 1997; Münkler 2002, 2005), and of the increasing role of more sophisticated and brutal non-state actors (or terrorist networks) but also the negative global impacts of uncontrolled financial activities (by greedy speculators and hedge funds as a kind of 'structural terrorism'[2] with non-violent means provoking new forms of personal and structural violence) have made the security dangers more complex and the security risks less calculable and predictable.

2.2.3 Redefining the Concept of 'Threat' to Security since 1990

Two decades after the end of the Cold War, Buzan and Hansen (2009: 11–12) referred to four key questions that structure *international security studies* (ISS) focusing on the state as the key referent object, on including internal and external threats that have been increasingly blurred by globalization, on the widening beyond the military dimension and the use of force and its close link to "a dynamic of threats, dangers and urgency". While during the Cold War a majority of ISS focused on external threats, since its end "ethnic conflict and civil wars came to the fore, so did questions of domestic stability and cohesion (Posen 1993; Van Evera 1994; Kaufmann 1996)" (Buzan/Hansen 2009: 29) that were discussed in the concept of 'societal security' introduced by the Copenhagen School (Wæver/Buzan/Kelstrup/Lemaitre 2003; Buzan/Wæver/de Wilde 1998; Wæver 2008a).

The threat concept as the basis for military planning and legitimating military programmes – at least among many NATO countries – has fundamentally changed after 1990. With the widening of the security concept from the traditional military and diplomatic security, to the new economic, societal and environmental dimensions, the threat concept has also widened and been applied to a series of new threats not only to the 'state' but also to the other referents of new security concepts, from human beings to global security.

The early proponents of environmental security have extended 'threats' from the military to the environmental realm. Ullman (1983: 133) defined a national security *threat* as "an action or sequence of events that: 1) threatens drastically and over a relatively brief span of time to degrade the quality of life for the inhabitants of a state; or 2) threatens significantly to narrow the range of policy choices available to the government of a state or to private non-governmental entities (persons, groups, corporations) within the state". For Mathews (1989) and Myers (1989, 1989a) the *new security threats* of the future included population growth, resource scarcity, and environmental degradation.

The Brundtland Commission (1987) also referred to two great threats facing humankind: "The first is that of nuclear exchange. ... The second is that of environmental ruin worldwide". In 1988 President Gorbachev stressed: "The relationship between man and the environment has become menacing. ... The threat from the sky is no longer missiles but global warm-

2 The term 'structural terrorism' has been inspired by Galtung's (1969, 1975) differentiation between personal and structural violence. This term has been used by Kapitan (2004) for states: "States, in particular, accomplish such *structural terrorism* by forcibly implementing or impeding institutions, laws, policies, and practices that result in harm to noncombatants." F.H. Knelman: "Who Are the Terrorists" (October 2001), in: Nuclear Peace Foundation; at: <http://www.wagingpeace.org/articles/2001/10/00_knelman_who.htm> (16 May 2010) referred to "internal or structural terrorism derived from poverty, disease, murder, hunger and deprivation of all kinds". The term 'structural terrorism' is used here in a different meaning by pointing to non-state economic actors and processes that have contributed to the worst global financial crisis since 1929 and that have added with speculation on food commodities to price hikes in basic food staples and the resulting food riots causing many casualties from protests and more who died of hunger.

ing". Brundtland (1993: 189–194) pointed to the new 'threats' to security that "may be caused by social unrest caused by poverty and inequality, by environmental degradation, by internal conflicts leading to new flows of refugees". She noted that "the pressure on the environment from a rapidly growing world population will increase the likelihood of such conflicts. Climate change, desertification, deforestation, massive loss of species and biological diversity, depletion of freshwater resources and soil erosion are global trends that are not sustainable". As most serious she saw "the threats to the world's atmosphere".

In 1992, Senator Al Gore referred to several environmental threats from the local (tactical) to the global (strategic) level such as global warming and ozone depletion. In 1997, Eilen Claussen defined as global environmental threats those "which are human-caused and have, or can be expected to have serious economic, health, environmental, and quality of life implications for the United States". Irrespective of the application of this concept to environmental problems, this author suggested to limit the threat concept to hardware related military problems, and to describe dangers posed by the environment as "environmental security challenges, vulnerabilities and risks" (Brauch 2005a, 2008a). However, in political practice, e.g. in the US national security strategy papers (see chap. 12 by Brauch below); this suggestion could not be observed.

2.2.4 Application of a Widened Concept of Security Threats

Several countries reacted in their national defence white papers and national strategic documents to the fundamental change in the nature of threats with an extended security concept that included many new non-military soft security threats such as: economic vulnerabilities, environmental challenges, political and societal instabilities (e.g. German Defence White Paper; BMVg 1994: 25–26) pointing to a "multitude of risk factors of a different nature with widely varying regional manifestations". The official German document suggested that "risk analysis of future developments must be based on a broad concept of security ... They must include social economic and ecological trends and view them in relation to the security of Germany and its allies."[3]

In the United States, several national security strategy papers of the Clinton administration have pointed to the fundamental change in security threats (Matthew/Mc Donald 2009). The administration of George W. Bush in its *Quadrennial Defense Review Report (*QDR) of 30 September 2001 announced: "to shift the basis of defence planning from a 'threat-based' model that has dominated thinking in the past to a 'capabilities-based' model in the future [that] ... focuses more on how an adversary might fight rather than specifically who the adversary might be or where a war might occur" (Brauch 2003b, chap. 12 by Brauch). The first QDR of the Obama Administration of 1 February 2010 referred to "Climate change and energy [as] two key issues ... in shaping the future security environment". It further acknowledged that

> climate change could have significant geopolitical impacts around the world, contributing to poverty, environmental degradation, and the further weakening of fragile governments. Climate change will contribute to food and water scarcity, will increase the spread of disease, and may spur or exacerbate mass migration. While climate change alone does not cause conflict, it may act as an accelerant of instability or conflict, placing a burden to respond on civilian institutions and militaries around the world. In addition, extreme weather events may lead to increased demands for defense support to civil authorities for humanitarian assistance or disaster response both within the United States and overseas. ... DoD has undertaken environmental security cooperative initiatives with foreign militaries that represent a nonthreatening way of building trust, sharing best practices on installations management and operations, and developing response capacity (DoD 2010: 85).

The Pentagon now considers climate change as a "legitimate national security concern" (Parthermore/Rogers 2010), even though not yet specifically as a 'national security threat'. This is also reflected in the first *National Security Strategy* of the Obama Administration (chap. 12 by Brauch).

The guarantee of "international peace and international security" was emphasized in the Covenant of the League of Nations (28 April 1919) and in the United Nations Charter (26 June 1945) "to maintain international peace and security". But in 1919 and in 1945, "development" and "environment" were not yet political concepts.

---

3 The most recent German Defence White Paper refers to new opportunities as well as risks and threats posed by globalization and it notes among the strategic framework conditions "global challenges, opportunities, risks and dangers" (BMVg 2006: 20–23) and lists among them: globalization, terrorism, proliferation and armament tendencies, regional conflicts, illegal arms trade, impediments for development and fragile statehood, transportation routes, resources, communication, energy security, migration and pandemics.

The UN Charter distinguished among three security systems: a universal system of *collective security* (Chap. VI: Art. 33–38; Chap. VII: Art. 39–50); "*regional arrangements or agencies*" (Chap. VIII: Art. 52 to 54); and a right of "*individual or collective self-defence*" (WEU, NATO; WTO) in Art. 51. While the first two systems deal with "threats to peace and international security" from within, among member states, the third is oriented against an outside threat. They perform three functions: peaceful settlement of disputes, peace enforcement and peacekeeping. Art. 1.1 of the UN Charter calls on its members "to take effective collective measures for the prevention and removal of threats to the peace, and for the suppression of acts of aggression or other breaches of the peace", "to develop friendly relations among nations" and "to achieve international co-operation in solving international problems of an economic, social, cultural, or humanitarian nature". The UN Charter relies on a narrow 'nation'-centred concept of 'international security' and on a concept of 'negative peace', although Art. 1.1, 1.2, and Art. 1.3 "indicate that peace is more than the absence of war" (Wolfrum 1994: 50).

During the Cold War, collective self-defence prevailed while collective security was paralysed (Brauch/Mesjasz/Møller 1998). After 1990, collective security was temporarily strengthened, but with the failure to solve the Gulf War (1990–1991) and to cope with the post-Yugoslav conflicts (1991–1999) within the framework of the UN, NATO and the EU emerged as key security institutions. Since 1990 the UN Security Council decisions on humanitarian interventions and the debate on 'environmental' and 'human' security have moved beyond these constraints and also the meaning of peace and security has significantly changed (Bothe 2008).

The Report of the Secretary-General's High-level Panel on Threats, Challenges and Change (2 December 2004) reflects this widening of the 'security' concept pointing to new tasks for the UN system in the 21st century. In the new emerging security consensus, collective security rests on three basic pillars (Synopsis of the Report):

> Today's threats recognize no national boundaries, are connected, and must be addressed at the global and regional as well as the national levels. No State, no matter how powerful, can by its own efforts alone make itself invulnerable to today's threats. And it cannot be assumed that every State will always be able, or willing, to meet its responsibility to protect its own peoples and not to harm its neighbours. ... Differences of power, wealth and geography do determine what we perceive as the gravest threats to our survival and well-being. ... Without mutual recognition of threats there can be no collective security. ... What is needed is nothing less than a new consensus. ... The essence of that consensus is simple: we all share responsibility for each other's security.[4]

The High-level Panel distinguished among six clusters of threats, ranging from economic and social threats (including poverty, infectious disease and *environmental degradation*, interstate and internal conflict, weapons of mass destruction, terrorism and transnational organized crime. Thus, for the first time "environmental degradation" is listed among the threats confronting the UN that require preventive action "which addresses all these threats". Development "helps combat the poverty, infectious disease and environmental degradation that kill millions and threaten human security". The High-level Panel (§ 53) claims:

> Environmental degradation has enhanced the destructive potential of natural disasters and in some cases hastened their occurrence. The dramatic increase in major disasters witnessed in the last 50 years provides worrying evidence of this trend. More than two billion people were affected by such disasters in the last decade, and in the same period, the economic toll surpassed that of the previous four decades combined. If climate change produces more flooding, heat waves, droughts and storms, this pace may accelerate.

The High-level Panel notes that "rarely are environmental concerns factored into security, development or humanitarian strategies" and it points to the lack of effective governance structures to deal with climate change, deforestation and desertification, as well as to the inadequate "implementation and enforcement" of regional and global treaties. In the discussion of the legitimacy of the use of military force, the High-level Panel distinguishes between "harm to state or human security". Two of the 101 recommendations of the High-level Panel deal with environmental issues, with renewable energy sources and with the Kyoto Protocol. The High-level Panel mentioned 'human security' several times, but its main focus remained on the 'state' as the cause and as a key actor in dealing primarily with military and societal threats.[5]

---

4 See for download of the complete report and press releases at: <http://www.un.org/secureworld/>.

5 For an assessment of the High-level Panel see von Einsiedel, Nitzschke and Chhabra (2008); on the 'security development' nexus see Sending (2008), Katseli (2008), Klingebiel and Roehder (2008) and most recently see Tschirgi, Lund and Mancini (2010).

On 21 March 2005, in his own report: "*In larger freedom: towards development, security and human rights for all*", Kofi Annan (2005) drew both on the High-level panel and on the assessment of the *Millennium project*. He analysed the three key goals of development as 'freedom from want', of security as 'freedom from fear', and human rights as 'freedom to live in dignity'. With regard to security, Annan (2005: 24) noted a lack of consensus on the assessment of the threat. He has listed among the present threats to peace and security:

> international war and conflict ..., civil violence, organized crime, terrorism and weapons of mass destruction. They also include poverty, deadly infectious disease and environmental degradation since these can have equally catastrophic consequences. All of these threats can cause death or lessen life chances on a large scale. All of them can undermine States as the basic unit of the international system. ... In our globalized world, the threats we face are interconnected. The rich are vulnerable to the threats that attack the poor and the strong are vulnerable to the weak, as well as vice versa. A nuclear terrorist attack on the United States or Europe would have devastating effects on the whole world.

Following his High-level Panel, Annan discussed four threats in detail: a) preventing catastrophic terrorism; b) organized crime; c) nuclear, biological and chemical weapons; and d) reducing the risk and prevalence of war.

The *European Union Security Strategy* (European Council 2003) also referred to five key threats: "terrorism, weapons of mass destruction, regional conflicts, state failure, and organized crime". But this strategy also pointed to new global challenges and vulnerabilities confronting the European Union. Since 2007, both the UN and the EU have repeatedly stated that climate change poses new threats to international security (chap. 1 by Brauch/Oswald Spring).

2.3 Reconceptualizing 'Security Challenges' .

2.3.1 The Political Term of 'Challenges' for Security

For 'challenge' (Lat.: 'calumnia', false accusation; Fr.: 'defi'; Sp.: 'desafío', 'reto'; Port.: 'desafio'; It.: 'sfida'; Ger.: 'Herausforderung') the synonyms are "confrontation, defiance, interrogation, provocation, question, summons to contest, test, trial, ultimatum", as well as "questioning, dispute, stand opposition; difficult task, test trial". *British* English dictionaries offered these meanings of the term challenge: "1. something difficult ... that tests strength, skill, or ability...; 2. questioning rightness: a refusal to accept that something is right and legal; 3. invitation to compete: a suggestion to someone that they should try to defeat you in a fight, game etc.; 4. a demand to stop: a demand from someone such as a guard to stop and give proof who you are, and an explanation of what you are doing"; or: "a demanding task or situation"; as well as: "call to try one's skill or strength; demand to respond or identify oneself; formal objection"; or: "a call to engage in a fight, argument or contest; a questioning of a statement or fact; a demanding or stimulating situation, career, etc."

2.3.2 The Political and Scientific Concept of 'Security Challenges'

The term 'challenge' has often been used for security and global issues but it has hardly been defined, and in many cases it is used synonymously with 'threat' (chap. 12 by Brauch).[6] Dodds and Schnabel (2001: 42–43) pointed to 'new' and 'non-traditional' security challenges as a major concern in the post-cold war security environment. They argued "that the general public's conception of the security environment has altered so dramatically as we enter the new millennium is an indicator of how significantly this environment may have actually changed". They see as major forces for the reconceptualization of security "the increasing level of globalization" that "has engendered a growing sense of vulnerability to ... remote threats, such as distant conflicts, contagions, crop failures and currency fluctuations".

2.3.3 Application of the Concept of 'Security Challenges'

Van Ginkel and Velásquez (2001: 58–70) pointed to these environmental challenges: a) ozone depletion; b) impact of toxic chemicals on the global ecosystem; and c) increasing greenhouse emissions and their negative reinforcements as well as to "uncertainty about

6 *Security Challenges* is the name of Australia's leading peer-reviewed journal on future security issues that "reaches a wide audience of established military, government, commercial and academic experts as well as up-and-coming younger players in the security field" that aims for "innovative thinking about future challenges to the security (broadly defined) of Australia and other countries in the Asia Pacific region. See at: <http://www.securitychallenges.org.au/index.html>.

the future and an element of surprise", especially if associated with natural and man-made environmental disasters. They stressed eight sub-themes: "global environmental governance, water, urbanization, industry and sustainability, global food security, energy requirements for the next millennium, global governance of biological diversity, land degradation, and the atmosphere".

In a report of the Trilateral Commission, Slaughter, Bildt and Ogura (2004) tried "to integrate traditional understandings of state security ... with an appreciation of the magnitude and importance of 'global security issues': terrorism, environmental degradation, international crime, infectious diseases and refugees". They organized the many ideas and proposals in five basic dichotomies: "State security versus human security; hard versus soft interventions; legality versus legitimacy; pre-emption versus prevention; and states versus non-state actors" (Slaughter 2004).

The former director of the Stockholm International Peace Research Institute (SIPRI), Amb. Alyson J.K. Bailes (2003; also chap. 6 below), in a talk on "New Security Challenges for the EU" noted several human security challenges confronting Europe: "such as the collapse of the environment, pollution of food and natural resources, human and animal disease and genetic manipulation, employment, health care and social security in general". These are not just subjective but also scientific perceptions. She referred to many non-military, non-intentional threats, such as:

> greenhouse effect, depletion of ozone, badly-handled migration, ageing of the population, and an energy crisis as well as the ... case of a nuclear accident. ...The lesson is that many aspects of life in the EU which do fall within the Union's competence but are not normally thought of as security matters are indeed highly relevant to the survival and welfare of our populations, and the more so precisely because of the high level of development and interdependence we have attained. The ... harmonized approaches ... should ... be extended ... to deal e.g. with climatic damage (drought, heat, storm and flood), major cases of pollution, and the interruption of any type of energy supplies.

This comprehensive list of security challenges for the EU in the post-Cold War period indicates a basic shift since 1990 away from primarily military threats from the rival superpower to a broad range of manifold challenges from all dimensions of a widened security concept. Security challenges may refer to less urgent and sometimes non-violent *soft security* problems, such as migration, human and drug trafficking. These issues are less on the external and primarily on the internal security agenda, and thus a topic for the home and justice ministries and agencies, such as national and international police organizations and of the courts but also of non-governmental societal groups. Migration may be a consequence of domestic conflicts emerging from environmental degradation and resource depletion but it will remain difficult to distinguish *push* and *pull* factors.

2.4 Reconceptualizing 'Security Vulnerabilities'

While the concepts of threats and challenges are often used synonymously for hard and soft security dangers, the vulnerability concept has been utilized more widely by many different policy and scientific communities with different meanings.

2.4.1 The Political and Societal Term of 'Vulnerability'

English dictionaries refer to these synonyms 'vulnerability' (Lat.: 'vulnus' or: 'vulnerabilis'; Fr.: 'vulnérabilité'; It.: 'vulnerabile'; Sp.: 'vulnerabilidad'; Port.: 'vulnerável'; Ger.: 'Verwundbarkeit') or 'vulnerable' as: "accessible, assailable, defenceless, exposed, open to attack, sensitive, susceptible, tender, thin-skinned, unprotected, weak, wide open"; and: "1. in danger: in peril, in jeopardy, at risk, endangered, unsafe, unprotected, unguarded; wide open; undefended, unfortified, unarmed, helpless, pregnable; 2. exposed to: open to, liable to, prone to, prey to, susceptible to, subject to, an easy target for; as well as: "non-immunity, susceptibility, danger of, insecurity, exposure, nakedness, helplessness".

According to *Webster's* 'vulnerability' is "the state or property of being vulnerable" where vulnerable refers to: "1. capable of being wounded or physically injured...; 2. open to criticism or attack...; 3. open to attack or assault by armed forces. ...; 4. in contract bridge, liable to increase penalties and entitled to increased bonuses"; or "the quality or state of being vulnerable". *British* dictionaries offer additional meanings: "someone who is vulnerable is easily harmed or hurt emotionally, or morally"; "susceptible to injury, exposed to damage by weapon, criticism, etc."; as well as: "open to temptation, censure etc."; as "unprotected against attack; liable to be hurt or damaged".

2.4.2 Vulnerability as a Scientific Concept

The vulnerability concept is defined in encyclopaedias in the geosciences where the referent object of 'vulnerability' are both human beings, especially children, and the environment. The vulnerability concept is used in the global change literature (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004), on climate change impacts (IPCC 2001a, 2007a) and in the disaster community (ISDR 2004). Vulnerability results from "poverty, exclusion, marginalization and inequities in material consumption", and it is generated by "social, economic and political processes" (Barnett 2001: 132–133). In the context of the precautionary principle O'Riordan (2002: 369) defined vulnerability at the societal level as: "the incapacity to avoid danger, or to be uninformed of impending threat, or to be so politically powerless and poor as to be forced to live in conditions of danger".

For Oliver-Smith (2004: 10) "vulnerability is fundamentally a political ecological concept". As a theoretical framework "vulnerability can become a key concept in translating that multi-disciplinarity into the concrete circumstances of life that account for a disaster". He argues that disasters "are channelled and distributed in the form of risk within society to political, social and economic practices and institutions". Wilches-Chaux (1989: 20–41, 1993) identified 11 types of vulnerability, "natural, physical, economic, social, political, technical, ideological, cultural, educational, ecological and institutional vulnerability". For Oliver-Smith (2004: 11) "vulnerability is conceptually located at the interaction of nature and culture" that also links "social and economic structures, cultural norms and values and environmental hazards". He discussed four questions: 1) the "general contributions of the cultural construction of nature to the social production of disaster"; 2) "how the political and economic forms and conditions that characterize vulnerability are inscribed in an environment"; 3) "the relationship between cultural interpretation and the material world of risk, threat and impact of disasters"; and 4) "how do we theorize the linkages among these three issues, particularly in the context of current patterns of globalization". Nathan (2009: 1125) pointed to a dual vulnerability:

> on the one side ... a tendency to undergo damages, i.e. a state of fragility, or a set of conditions, that raise the susceptibility of a community to the impact of a damaging phenomenon. On the other side, vulnerability is an incapacity to anticipate, cope with, resist to, adapt to and recover from hazards. Vulnerable units are either not resistant, i.e. not capable to withstand the shock (without adapting); and/or not resilient, i.e. not capable to absorb the shock and adapt to come back to an acceptable state.

Nathan (2009: 1125) characterized vulnerability "as a *complex* process encompassing multiple intricate dimensions" that is constantly changing. In his view vulnerability is:

> often *cumulative*, causing disasters that in turn aggravate it, or adding to vulnerabilities to other risks (such as socio-economical risks, etc.). Furthermore, vulnerability is both *hazard-related* ... and *subject-related*. ... Therefore, one has to specify which vulnerability one is talking about, and at which level of analysis (individual, group, society). ... Vulnerability is also highly *differentiated*: different subjects, even at the same 'level', have different vulnerabilities. ... Generally, the most miserable and isolated suffer most, as well as the less organized. ... Vulnerability is *context-dependent*, be it an individual exposed to natural hazards at the household level, or mankind at a global level. These 'transversal' features of global vulnerability apply to each component of vulnerability (Nathan 2009: 1125).

Nathan (2009: 1126) distinguished among two features of vulnerability: *exposure* and *insufficient capacities*.

> a) *physical exposure*: presence and density of the people, habitat, networks, goods and services in risk zones, defining potential losses or damages, both human and non-human (stakes); and b) *socio-ecological*: human-induced ecosystemic perturbations aggravating the natural hazard – such as deforestation, land degradation, street pavement, some engineering practices, climate change, etc.

Furthermore, he pointed to "insufficient capacities to prevent, prepare for, face and cope with hazards and disasters" he separated as:

- *physical weakness*: physical incapacity to resist or recover from a hazard's impact;
- *legal vulnerability*: weak state of the legislative and judiciary regulations to prevent, mitigate, prepare for, face and recover from disasters;
- *organizational vulnerability*: weak state of the organizational disposals, at all levels, to prevent, mitigate, prepare for, face and recover from disasters;
- *technical vulnerability*: inadequate knowledge and/or use of risk management techniques;
- *political vulnerability*: weakness of the political powers, their legitimacy and control. Inadequacy of the control schemes, policies and planning, or broad political conditions;

- *socio-economical vulnerability*: socio-spatial segregation, large inequalities of wealth and of access to the security disposals, misery, anomie and social disorganization, poor social position and social isolation of exposed people, existence of higher social risks undergone by people;
- *psychological and cultural vulnerability*: inadequate security paradigm or risk perceptions; cultural anomie or weakness; attachment to risk zones or risky behaviour, non-willingness or incapacity to protect oneself (Nathan 2009: 1126).

Nathan (2009: 1126; see chap. 30 below) concluded that "the overall vulnerability of an element (or stake) to one or several hazards is a mix of these particular vulnerabilities".

Cardona (2004: 37–51; see also chap. 3 below) proposed to rethink vulnerability and risk from a holistic perspective arguing that in developing countries often social, economical, cultural and educational aspects are "the cause of the potential physical damage". For Cardona "vulnerability of human settlements is intrinsically tied to different social processes. It is related to fragility, susceptibility or lack of resilience of the exposed elements. On the other hand, vulnerability is closely linked to natural and human environmental degradation at urban and rural levels". Cardona (2004: 49) argued that from a social view "vulnerability signifies a lack or a deficiency of development" that often contribute to "disaster vulnerability". He pointed out that population growth, rapid urbanization, environmental degradation, global warming, international financial pressures and war have all increased vulnerability. Cardona argued that vulnerability originates in:

- *Physical fragility* or *exposure*: the susceptibility of a human settlement to be affected by a dangerous phenomenon due to its location in the area of influence of the phenomenon and a lack of physical resistance;
- *Socio-economic fragility*; the predisposition to suffer harm from the levels of marginality and social segregation of human settlements, and the disadvantageous conditions and relative weakness related to social and economic factors; and
- *Lack of resilience*: an expression of the limitations of access and mobilization of the resources of human settlement, and its incapacity to respond when it comes to absorbing the impact.

He pointed to the closely interrelated nature of efforts reducing hazard or vulnerability, thus contributing to risk reduction, and the possibility of future disaster (chap. 3 by Cardona).

According to Heijmans (2004: 115–127) disaster agencies have often focused on physical and economic vulnerability. Based on the literature she distinguished three strategies to address vulnerability:

1. *Nature as cause* → technological, scientific solutions: Reduce vulnerability by early warning systems, technologies to withstand negative impacts (monitor seismic activity, weather forecasting, remote sensing for drought, fire, water control systems, building codes, etc.).
2. *Cost as cause* → economic and financial solutions: Costly prediction and mitigation technologies; reduction of vulnerability by national safety nets, insurance and calamity funds.
3. *Social structure as cause* → political solutions: Socio-economic factors that generate vulnerability, require political and development solutions that transform the social and political structures breeding poverty.

Heijmans (2004: 117ff.) discussed the conceptual relationship between vulnerability and empowerment, argued that the people's perspectives are missing in all three strategies, and also in the perception of vulnerability by the aid agencies. According to Wisner (2004: 183–193) vulnerability is used in the hazard community as:

- Structural engineering vulnerability;
- Lifeline infrastructural vulnerability;
- Communications systems vulnerability;
- Macro-economic vulnerability;
- Regional economic vulnerability;
- Commercial vulnerability; and
- Social vulnerability.

Wisner distinguished four approaches on social vulnerability: a) demographic; b) taxonomic; c) situational; and d) contextual or proactive approach. He criticized that many studies on social vulnerability have devalued local knowledge and coping capacities and he supported efforts to empower people to reclaim their local knowledge (chap. 52 by Laureano). Frerks and Bender (2004: 194–205) argued that the societal focus on vulnerability has shifted from disasters as a natural event to exposure and a complex socially constructed process.

Pelling (2003: 5; also in chap. 29) analysed the vulnerability of cities to natural disasters and the role of social resilience. He defined vulnerability as "exposure to risks and an inability to avoid or absorb poten-

tial harm", *physical* vulnerability as that "in the built environment", *social* vulnerability as that "experienced by people and their social, economic and political systems", and *human* vulnerability as the combination of "physical and social vulnerability".

The 'vulnerability' concept has been widely used, often with different meanings, by the global change research (2.4.3), by the climate change (2.4.4), by the natural hazard (2.4.5) and by the environment, development and early warning community (2.4.6), while the concept of 'social vulnerability' is intensively employed both in the hazard and development research and policy communities (2.4.7). The 'vulnerability' concept was also widely used in the security and strategic community (2.4.8) while the concepts of 'economic' (Crawford 1992, 1993, 1995) and 'financial' vulnerability have become crucial research and policy objects for the economic and policy communities (see chap. 5 and 6 by Czeslaw and Lidia Mesjasz).

2.4.3 Vulnerability as a Scientific Concept in the Global Change Research Community

Steffen, Sanderson, Tyson, Jäger, Matson, Moore III, Oldfield, Richardson, Schellnhuber, Turner and Wasson (2004) address the consequences of changes in the Earth System due to human activities for human well-being. The vulnerability concept offers a useful framework for the study of consequences of global change on human societies. Using a scenario-driven approach they discuss linear projections and non-linear surprises resulting from an integrated assessment approach: "Scenario-driven approaches to impact assessment, even the most sophisticated of the integrated assessment methods, do not allow the vulnerability or resilience of the impacted systems to be assessed directly" (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004: 204).

While impact assessment selects one specific environmental stress and seeks to identify the most important consequences for social and ecosystem properties on environmental stress, vulnerability assessment tries to assess the risk of diverse outcomes for a unit of concern (e.g. landless farmers) "in the face of a variety of stresses and identifies a range of factors that may reduce response capacity and adaptation to stressors" (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004: 205). While impact assessment offers little guidance among the many environmental stresses,

> vulnerability assessment offers a maturing strategy to provide such guidance. Vulnerability to global environmental change has been conceptualized as the risk of adverse outcomes to receptors or exposure units (human groups, ecosystems and communities) in the face of relevant changes in climate, other environmental variables, and social conditions. ... Vulnerability is emerging as a multi-dimensional concept involving at least *exposure* – the degree to which a human group or ecosystem comes into contact with particular stresses; *sensitivity* – the degree to which an exposure unit is affected by exposure to any set of stresses; and *resilience* – the ability of the exposure unit to resist or recover from the damage associated with the convergence of multiple stresses. ... Vulnerability can increase through cumulative events or when multiple stresses weaken the ability of a human group or ecosystem to buffer itself against future adverse events, often through the reduction in coping resources and adaptive capacities (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004: 205).

Steffen et al. (2004) point to the scale- and space-dependent property of systems and thus differ on the local, regional and global level. Complex vulnerability analyses can address "multiple causes of critical outcomes rather than only the multiple outcomes of a single event". Thus, scenario development becomes a crucial element of vulnerability analysis. An important precondition for the quantification of vulnerability parameters could be vulnerability indicators. Along these lines, Comfort, Wisner, Cutter, Pulwarty, Hewitt, Oliver-Smith, Wiener, Fordham, Peacock and Krimgold (1999) developed a "standardized all-hazards vulnerability index". Others have suggested an Index of Human Insecurity (Lonergan/Gustavson/Carter 2000). Steffen et al. (2004: 209) admit that the current status of vulnerability research and assessment "exhibit both a potential for substantial synergy in addressing global environmental risks ... as well as significant weaknesses which undermine the potential". A major driver of GEC has been climate change where the 'vulnerability' concept has been extensively discussed.

Brklacich, Chazan and Bohle (2010: 36–37) developed "a conceptual framework for understanding human vulnerability to GEC and other stressors" by combining existing frameworks into a "comprehensive human vulnerability-security model". While human vulnerability has been extensively researched (Burton/Kates/White 1993; Mitchell 1989, 1990; Emel/Peer 1989; Watts/Bohle 1993; Adger 1999) they proposed to move "from a state of human vulnerability to one of human security" (Bohle 2001; Twigg/

Bhatt 1998; O'Brien/Vogel 2004). Earlier Bohle (2001) had pointed to the "double structure of vulnerability" linking external or environmental with internal or social vulnerability. While the external side (structure) of vulnerability refers to exposure to social and environmental stressors, the internal side (agency) points to the policy response or the capacity to mitigate, cope with, recover from, and adapt to stressors with the goal to achieve human security. While the 'structure' is influenced by the ecological and geographic context, the 'agency' depends on the institutional context and both rely on the distribution of rights and resources as well as on the control over and access to assets. For the analysis of the linkages between human vulnerability and security they suggest research on four interrelated drivers "control of and access to assets, institutional factors, distribution of rights and resources, and ecological and geographic conditions" (Brklacich/Chazan/Bohle 2010: 42). These drivers are influenced by *environmental change* (change in type, frequency, and scale of environmental threats) and by *societal change* (change in economic, political, social and demographic conditions). They concluded arguing that

> Movement along the continuum from vulnerability to security is most likely influenced by context-specific, local interactions between multi-scale stressors, exposure to threats, capacity for response, and socio-environmental drivers. This contextual nature of vulnerability supports trends towards micro-level approaches to vulnerability assessment (Brklacich/Chazan/Bohle 2010: 49).

In analysing the linkages between environmental change and violent conflict, Barnett and Adger (2010: 120) listed among the factors affecting violent conflicts besides poverty, migration, and weak states also 'vulnerable livelihoods' that directly influence water, agricultural productivity, the frequency and intensity of extreme events and the distribution of diseases. "These affect livelihoods by exposing people to risks, thereby increasing their vulnerability. The impacts are more significant in sectors of the population with high resource-dependency, and located in more environmentally and socially marginalized areas."

Barnett, Matthew and O'Brien (2010a: 308ff.) pointed to several areas of future research on GEC, vulnerability and human security, such as 1) social causes of vulnerability (including gender differentiations) to environmental change; 2) the mediating role of perceptions between GEC and policy responses and the roles of values, beliefs and worldviews, 3) the interface of GEC and human health, 4) shift to peaceful responses to the linkage of GEC and human security (e.g. environmental peacemaking), 5) the impacts of violent conflict on human security and vulnerability to environmental change, 6) need for more consideration to linkages among human rights, human security and GEC, and 7) to reflect on the coping capabilities and resilience of the affected people.

2.4.4 Vulnerability as a Political and Scientific Concept in the Climate Research Community

Climate change impacts, adaptation and *vulnerability* have been analysed by the second IPCC working group (1990, 1996a, 2001a, 2007a) whose mandate is "to assess the vulnerability of ecological systems, socio-economic sectors, and human health to climate change". The IPCC also distinguishes between *sensitivity*, *adaptive capacity* and *vulnerability* ("the degree to which a system is susceptible to, or unable to cope with, adverse effects of climate change, including climate variability and extremes").

In *The Regional Impacts of Climate Change: An Assessment of Vulnerability*, the IPCC (1998) explores potential consequences of climate change for ten regions based on "assessing sensitivities and vulnerabilities of each region, rather than attempting to provide quantitative predictions of the impacts of climate change", i.e. to assess "the extent to which climate change may damage or harm a system" taking into account the sensitivity of the region to climate and the adaptive ability. The report tries to explain: "how projected changes in climate could interact with other environmental changes (e.g. biodiversity loss, land degradation, stratospheric ozone depletion, and degradation of water resources) and social trends (e.g. population growth, economic development and technological progress" (IPCC 1998: ix). It calls for more research on "interlinkages among environmental issues". This IPCC report assessed the vulnerability of natural and social systems of major regions to climate change with qualitative methods. These regional assessments focus on: a) ecosystems, b) hydrology and water resources, c) food and fibre production, d) coastal systems, human settlements, human health, and other sectors or systems including the climate system of relevance for the 10 regions analysed.

In the *Third Assessment Report* (TAR), the WG II examines "climate change impacts, adaptations and vulnerabilities of systems and regions" with the goal "to provide a global synthesis of cross-system and cross-regional issues", and "in the context of sustaina-

ble development and equity" (IPCC 2001a: 22–25). In its regional assessment, the IPCC (1998) explores potential consequences of climate change by "assessing sensitivities and vulnerabilities of each region, rather than attempting to provide quantitative predictions of the impacts of climate change". The IPCC cautions: "The estimates ... serve as indicators of sensitivities and possible vulnerabilities" (IPCC 1998: 4). The report suggests an "anticipatory adaptation in the context of current policies and conditions" and so-called "win-win" or "no-regrets" options by adding that: "adaptation will require anticipation and planning. ... Additional analysis of current vulnerability to today's climate fluctuations and existing coping mechanisms is needed." As has been argued, the vulnerability concepts in the GEC and in the climate change communities have differed significantly from those concepts that have been employed in the hazard research community, but even within this research community conceptual differences have existed.[7]

In the *Fourth Assessment Report* (AR4), the WG II has extensively used the concepts of 'vulnerabilities', 'vulnerability assessment' and 'vulnerability hotspot' (IPCC 2007a: 974–975) with regard to Africa, Amazonia, Asia, Australia and New Zealand, Latin America, coastal systems and mega-deltas. For the AR4:

> Vulnerability to climate change is the degree to which geophysical, biological and socio-economic systems are susceptible to, and unable to cope with, adverse impacts of climate change. The term 'vulnerability' may therefore refer to the vulnerable system itself (e.g. low-lying islands or coastal cities), the impacts to this system (e.g. flooding of coastal cities and agricultural lands or forced migration), or the mechanisms causing these impacts (e.g. disintegration of the West Antarctic ice sheet). Based on a number of criteria in the literature (i.e., magnitude, timing, persistence/reversibility, potential for adaptation, distributional aspects, likelihood and 'importance' of the impacts, some of these vulnerabilities might be identified as 'key'. Key impacts and resultant key vulnerabilities are found in many social, economic, biological and geophysical systems (IPCC 2007a: 73).

These potential key vulnerabilities are to help decision-makers to identify "levels and rates of climate change that may be associated with '*dangerous anthropogenic interference*' (DAI) with the climate system". The Technical Summary of the AR4 also points to the link with "systemic thresholds where non-linear processes cause a system to shift from one major state to another". Besides these potential 'tipping points' of the climate system (Lenton/Held/Kriegler/Hall/Lucht/Ramstorf/Schellnhuber 2008) key vulnerabilities may be linked to "'normative thresholds' defined by stakeholders or decision-makers (e.g. a magnitude of sea-level rise no longer considered acceptable by low-lying coastal dwellers" (IPCC 2007a: 73). AR4 argues that "some key vulnerabilities have been associated with observed climate change", such as "increases in human mortality during extreme weather events, and increasing problems associated with permafrost melting, glacier retreat and sea-level rise". AR4 distinguished among three different climate change regimes associated with a global mean temperature increase of up to 2°C, between 2 to 4°C, and above 4°C until the end of the 21st century.[8]

With regard to security risks posed by climate change, the WBGU (2008: 242) defined vulnerability as "the susceptibility of a social group or (environmental) system to →crises and pressures" by distinguishing between social and biophysical vulnerability. The report of the UN Secretary-General on "Climate change and its possible security implications" (UN-SG 2009: 1) approached this linkage "from a perspective of interdependence between human vulnerability and national security" and it identified 'vulnerability' among the five channels through which climate change could affect security, arguing that "Climate change threatens food security and human health, and increases human exposure to extreme events," especially for the poor countries that "are among the most vulnerable, and the best way to reduce their vulnerability is to help lift them out of poverty". The use of the vulnerability concept by the climate community

7 There is an extensive literature on the vulnerability concept as used by the climate change community, see e.g. Füssel (2007); O'Brien, Eriksen, Nygaard and Schjolden (2007); Roberts and Parks (2007); Adger (2006); Kates and Millman (1990); Kates and Millman (1990); Füssel and Klein (2006); Watts and Bohle (1993); Bohle (2001); Bohle, Downing, Watts (1994); Ribot (1995); Turner II, Matson, McCarthy, Corell, Christensen, Eckley, Hovelsrud-Broda, Kasperson, Luers, Martello, Mathiesen, Naylor, Polsky, Pulsipher, Schiller, Selin and Tyler (2003).

8 Table TS.8 in the Technical Summary of WG II of the Fourth Assessment Report of the IPCC (2007a: 74) offers an overview of the key vulnerabilities of the global social, regional, biological and geophysical systems as well as of the risks from extreme events for global average temperature changes from 0°C up to 5°C above 1990.

partly overlaps with its employment by the natural hazard community.

2.4.5 Vulnerability as a Political and Scientific Concept in the Hazard Research Community

From the perspective of the hazard research community, Blaikie, Cannon, Davis and Wisner (1994) redefined vulnerability commonly used as "being prone to or susceptible to damage or injury". Their working definition is:

> By 'vulnerability' we mean the characteristics of a person or group in terms of their capacity to anticipate, cope with, resist, and recover from the impact of a natural hazard. It involves a combination of factors that determine the degree to which someone's life and livelihood is put at risk by a discrete and identifiable event in nature or in society. ... We use the term to mean those who are more vulnerable. When used in this sense, the implied opposite of vulnerable is sometimes indicated by our use of the term *secure*. ... Our definition of vulnerability has a time dimension built into it. Since it is damage to livelihood and not just life and property that is at issue, the more vulnerable groups are those that also find it hardest to reconstruct their livelihoods following disasters. ... Our focus on vulnerable people leads to give secondary consideration to natural events as determinants of disasters. Normally, vulnerability is closely correlated with socio-economic position.

In the context of the research on hazards the concept of *vulnerability assessment* was used to refer to an: "evaluation of the sensitivity of a particular ecosystem, resource or activity to a broad range of environmental and socio-economic stresses" (Bass 2002: 346–347). According to Hewitt (2002: 299) a vulnerability perspective "considers especially how communities are exposed to dangers, the ways in which they are readily harmed, and the protection that they lack". Vulnerability to a hazard is to a large extent created by the respective social order on the division of labour, cultural values and on legal rights. Thus, according to Hewitt (2002: 300), vulnerability is a "relative condition, and can only be defined and assessed in relation to the safety which others actually enjoy".[9]

The *International Strategy on Disaster Reduction* (ISDR 2002: 24, 342) defined *vulnerability* "as a set of conditions and processes resulting from physical, social, economical, and environmental factors, which increase the susceptibility of a community to the impact of hazards". These conditions are shaped "continually by attitudinal, behavioural, cultural, socio-economic and political influences at the individuals, families, communities, and countries". Vulnerability is closely linked to development.

Physical factors include the location and susceptibility of the built environment and are often influenced by the "density levels, remoteness of a settlement, its sitting design and materials used for critical infrastructure and for housing". Among the *social factors*, at the level of individuals, communities and society, ISDR (2002: 47) listed "levels of literacy and education, the existence of peace and security, access to basic human rights, systems of good governance, social equity, positive traditional values, knowledge structures, customs and ideological beliefs, and over all collective organizational systems". Vulnerability highly depends on *economic factors*, including poverty, "individual, community and national economic reserves, levels of debt and the degree of access to credit and loans as well as insurance", but also access to communication networks and socio-economic infrastructure. Finally, among the *ecological factors*, ISDR (2002: 47, 60) referred to the "very broad range of issues in the inter-acting social, economic and ecological aspects of sustainable development as it relates to disaster risk reduction" and distinguished among: "1) the extent of natural resource depletion; 2) the state of resource degradation; 3) loss of resilience of the ecological systems; 4) loss of biodiversity; and 5) exposure to toxic and hazardous pollutants."

Efforts to increase the ability of people "to cope effectively with hazards, and that increase their resilience, or that otherwise reduce their susceptibility, are considered as *capacities*" (ISDR 2002: 23–24). Vulnerability to hazards is higher in many developing countries, where they are "exacerbated by socio-economic and environmental conditions", including "the occupation of hazard-prone areas, the concentration of industrial infrastructure and critical facilities" (ISDR 2002: 62–64).

For disaster reduction, vulnerability and capacity assessment is essential (ISDR 2002: 69–78) which was addressed initially by the ISDR Interagency Task Force Working Group 3 on Risk, Vulnerability and Impact Assessment which has become the Global Platform for Disaster Reduction.[10] A lot of work has been

9 See for more recent literature on vulnerability and disasters: Cannon (2000); Downing (1991); Kasperson, Dow, Archer, Caceres, Downing, Elmqvist, Eriksen, Folke, Han, Iyengar, Vogel, Wilson and Ziervogel (2005); Smucker and Wisner (2008); Cannon, Twigg and Rowell (N.d.. 2003?); Wisner, Blaikie, Cannon and Davis (^{2}2004).

done on methodologies and instruments for *Vulnerability and Capacity Assessment* (VCA) and in the framework of a *Capabilities and Vulnerability Analysis* (CVA), together with the International Federation of the Red Cross (IFRC 2002) as a major proactive promoter. The ISDR (2002: 78) considered hazard, vulnerability and capacity as "the operational basis for a culture of prevention" with four priority areas:

- Risk assessment for decision-making;
- Terminology, data and methodology;
- Higher visibility and priority to reduce vulnerability and strengthen capacities; and
- Addressing new trends in hazard and vulnerability.

ISDR (2002) defined vulnerability as: "a set of conditions and processes resulting from physical, social, economical and environmental factors, which increase the susceptibility of a community to the impact of hazards", while UNDP (2004) stressed "a human condition or process resulting from physical, social, economic and environmental factors, which determine the likelihood and scale of damage from the impact of a given hazard". The ISDR (2002) definition juxtaposed vulnerability with its complementary component capacity, which is defined as "a combination of all strengths and resources available within a community or organization that can reduce the level of risk or the effects of a disaster".

Bohle (2001, 2002) distinguished between *external* (environmental) and *internal* (human) vulnerability,

> thus clearly identifying vulnerability as a potentially detrimental social response to environmental events and changes. Vulnerability can cover susceptibilities to a broad range of possible harms and consequences; it implies a relatively long time period, certainly exceeding that of the extreme event itself, which might have triggered its exposure. This interpretation of vulnerability is unavoidably related to resilience, the ability to return to a state similar to the one prevailing prior to the disaster. Thus, vulnerability is not only ill-defined, but its manifestation and magnitude depend on many partially unknown factors and their coincidence.

Plate (2002) recommended a critical index of vulnerability measured as the distance between the part of the GNP per person needed for maintaining minimum social standards and the available GNP per person. This index would focus on the financial resources available within a society or a community, or even an individual household that can reduce the effect of a disaster. This vulnerability measure would cover only some problems, while the environmental dimension cannot adequately be expressed in monetary terms.

Bogardi and Birkmann (2004) analysed the potential of vulnerability assessment for sustainable risk reduction, given the uncertainty of the vulnerability concept that was defined by Wisner (2002) as the "likelihood of injury, death, loss, disruption of livelihood or other harm in an extreme event, and/or unusual difficulties in recovering from such effects". They call for more direct indicators of national and regional scale which could be linked to strategic goals and instruments of vulnerability assessment. For them "an interdisciplinary approach will be essential to take into account economic, social and environmental consequences as well as different objects of protection (individual, community features). While the potential economic losses caused by floods can often be quantified and estimated, methods and data to measure social, cultural, institutional and environmental features of vulnerability and coping capacity are still not sufficiently developed". The vulnerability concept has also been used by those researchers who have worked on early warning of hazards while other concepts have been used by those who work on early warning of conflicts.

With regard to cities, for Satterthwaite, Huq, Reid, Pelling and Romero Lankao (2009: 19):

> vulnerability to climate change is understood to mean the potential of people to be killed, injured or otherwise harmed by the direct or indirect impacts of climate change. This is most obvious with regard to risk from extreme events (such as storms or floods); but it includes risk from direct impacts – for instance, declining freshwater availability or livelihoods dependent upon climate sensitive resources.

Sherbinin, Schiller and Pulsipher (2009: 131) framed vulnerability of global cities to climate hazards as "the degree to which a system or unit is likely to experience harm due to exposure to perturbations or stresses". They argued that by using this concept it became clear

> that the ability of a system to attenuate stresses or cope with the consequences through various strategies or

10 See at: <http://www.preventionweb.net/english/hyogo/GP/>. The Global Platform is the main global forum for representatives of governments and other stakeholders ... to: 1. Assess progress made in implementation of the Hyogo Framework for Action. 2. Enhance global awareness of disaster risk reduction. 3. Share experiences among countries and learn from good practice. 4. Identify remaining gaps and actions needed to accelerate national and local implementation of the Hyogo Framework.

> mechanisms constituted a key determinant of system response, and ultimately, of system impact. ... Vulnerability in the social sciences is typically identified in terms of three elements: systems exposure to crises, stresses and shocks; inadequate system capacity to cope; and consequences of attendant risks of slow (or poor) system recovery. ... The most vulnerable individuals, groups, classes and regions or places are those that experience the most exposure to perturbations or stresses; are the most sensitive to perturbations or stresses (i.e. most likely to suffer from exposure), and have the weakest capacity to respond and ability to recover.

They aimed at 'gap analysis' of areas of exposure and vulnerability pointing "to areas of greatest need for strengthened adaptive capacity and risk management" (Sherbinin/Schiller/Pulsipher 2009: 132). By linking a scenario-based 'top-down' approach with 'bottom-up' assessments using vulnerability mapping techniques they reached a better understanding "of likely future climate impacts while assessing the resilience of the current socio-ecological system in the face of bundles of stresses that are partly related to climate impacts and partly to fragilities in the system itself" (Sherbinin/Schiller/Pulsipher 2009: 152).

In an extensive review of the vulnerability concept in disaster management, environmental change and development research, Birkmann (2006: 16) stated that "the concept is still somewhat fuzzy and often used with different connotations" and that it would be "misleading to try to establish a universal definition". In his review of the literature, Birkmann (2006: 17–39) distinguished among five key spheres of the vulnerability concept: a) vulnerability as an internal risk factor (intrinsic vulnerability); b) vulnerability as the likelihood to experience harm (human centred); c) vulnerability as a dualistic approach of susceptibility and coping capacity; d) vulnerability as a multiple structure: susceptibility, coping capacity, exposure, adaptive capacity; and e) multi-dimensional vulnerability encompassing physical, social, economic, environmental and institutional features. After a review of the different conceptual and analytical frameworks pertaining to vulnerability Birkmann (2006: 39–40) distinguished among at least six different schools:

- the school of the double structure of vulnerability (Bohle 2001, 2002);
- the analytical framework for vulnerability assessment of the disaster risk community (Davidson 1997; Bollin/Cárdenas/Hahn/Vatsa 2003);
- the analytical framework for vulnerability assessment in the global change community (Turner/Kasperson/Matson/McCarthy/Corell/Christensen/Eckley/Kasperson/Luers/Martello/Polsky/Pulsipher/Schiller 2003);
- the school of political economy, which addresses the root causes, dynamic pressures and unsafe conditions that determine vulnerability (Wisner/Blaikie/Cannon/Davis 2004);
- the holistic approach to risk and vunerability assessment (Cardona 1999a, 2001, chap. 3 below; Cardona/Barbat 2000; Carreño/Cardona/Barbat 2004, 2005a, 2005b);
- the BBC conceptual framework, which places vulnerability within a feedback loop system and links it to the sustainable development discourse (Bogardi/Birkmann 2004; Cardona 1999, 2001).

However, the use of the 'vulnerability concept' has not been limited to these six schools but it was also in the broader environment, development and early warning community (2.4.6) and in peace research and security studies (Albrecht/Brauch 2008, 2009; Buzan/Hansen 2009) and in security policy both during the Cold War period and less in the post-Cold War US national security strategy documents (chap. 12 by Brauch).

2.4.6 Vulnerability in the Environment, Development and Early Warning Community

The vulnerability concept has also been widely used in the broader environment, in the development (Naudé/Santos-Paulina/Mc Gillivray 2009) and also in the two early warning communities with regard to natural hazards and conflicts and by officials in the respective offices of international organizations (UNDP, UNEP, UNISDR et al.).

Pascal Peduzzi (2000: 2), head of the Early Warning Unit at UNEP/DEWA/GRID-Europe and of a team of authors have contributed together with UNEP to the development of key indicators for 'global vulnerability and risk mapping'. Initially he defined *risk* as "a measure of the expected losses due to hazard event of a particular magnitude occurring in a given area over a specific time period" (Tobin/Montz 1997) and *vulnerability* as "the degree of loss to each element should a hazard of a given severity occur" (Coburn/Spence/Pomonis 1991: 49) and as the "expected percentage of population loss due to socio-politico-economical context".

In their feasibility study report on "*G*lobal *R*isk *a*nd *V*ulnerability *I*ndex", Peduzzi, Dao, Herold, Rochette and Sanahuja (2001) and their 'GRAVITY-Team' defined vulnerability as: "the extent to which a

community, structure, service or geographic area is likely to be damaged or disrupted by the impact of a particular hazard" (Tobin/Montz 1997). They separated vulnerability into *geophysical* (low evaluation along the sea, high vulnerability to Tsunami), *socio-economical* parameters (cultural, technical, economic factors using indicators as: GDP, literacy, life expectancy, corruption, population density, and (urban population growth), and *mitigation capacities*.

Vulnerability cannot be directly measured but estimated "by a set of socio-economic variables and compared to actual disaster losses as reported by CRED" (*Centre for Research on Epidemiology of Disasters* in Louvain, Belgium). It "measures how easily the exposed people, physical objects and activities may be affected in the short or long-term". Vulnerability can be defined as "what turns a hazard into a disaster" (Peduzzi/Dao/Herold/Rochette/Sanahuja 2001: 45). They distinguish between *economic* (impact of a disaster on the economy), *human* (human losses and injuries) and *social vulnerability* (social structure influences the impact of a hazard, e.g. on women, families etc.). Vulnerability is specific to a hazard and a region. To measure vulnerability they used disaster data (especially on observed damages) from the CRED database and socio-economic indicators.

In their report on "Phase II: Development, analysis and results" Peduzzi, Dao, Herold (2002: 4–5) and the GRAVITY-Team noted that the vulnerability concept "is perhaps the most difficult to approach" (Coburn/Spence/Pomonis 1991: 49) and "depends on socio-politico-economical context of this population" where vulnerability factors are "socio-economic factors having an influence on the level of losses for a given hazard type".

In their report on "Phase III: Drought analysis", Peduzzi, Dao, Herold and Muton (2003: 4–5) and the GRAVITY-Team focused both on the natural and human induced (conflicts, bad governance) causes of this complex hazard and developed indicators for drought and food insecurity. They distinguished among eight vulnerability indicators, which they grouped as a) *economic* (GDP, HDI); b) *type of economic activities* (percentage of agriculture's dependency for GDP, of labour force in agricultural sector); c) *dependency and quality of the environment* (human induced soil degradation: GLASOD); d) *development* (HDI); and e) *health and sanitation* (percentage of people with access to safe water, mortality rate of under five-year-olds).

In their report on "Phase IV: Annex to WVR and Multi Risk Integration", Dao and Peducci (2003: 1) described the "concepts, data and methods applied to achieve the Disaster Risk Index (DRI)". They offered two definitions of vulnerability. The first is reflecting "the range of potentially damaging events and their statistical variability at a particular location" (Smith 1996), and the second is pointing to "the degree of loss to each element should a hazard of a given severity occur" (Coburn/Spence/Pomonis 1991: 49). As a specificity of their research they noted "the discrepancies of casualties induced by different vulnerabilities are used to identify socio-economical indicators reflecting such vulnerabilities".

They also broadened the scope of their *vulnerability indicators* and distinguished them for two types of hazards: drought, and floods, cyclones and earthquakes; and nine categories of vulnerability: 1) *economic* (GDP, HDI, debt, inflation, unemployment); 2) *type of economic activities* (arable land, urban population, percentage of agriculture's dependency for GDP, of labour force in the agricultural sector); 3) *dependency and quality of the environment* (forests, woodlands, per cent of irrigated land, human induced soil degradation: GLASOD); 4) *demography* (population growth, urban growth, population density, age dependency ratio); 5) *health and sanitation* (calorie supply per person, access to sanitation, safe water, physicians, hospital beds, life expectancy, mortality rate of under five year of age); 6) *politics* (corruption); 7) *early warning capacity* (number of radios); 8) *education* (illiteracy, school enrolment, secondary, labour force with primary, secondary or tertiary education); and 9) *development* (HDI).

The UNDP (2004) report on *Reducing Disaster Risk – A Challenge for Development* includes a *Disaster Risk Index* (DRI) – developed by the GRAVITY-Team – which provides decision-makers with an overview of risk and vulnerability levels in different countries. This risk is measured in terms of the number of deaths during disasters. The Report has defined 'human vulnerability' as a

> human condition process resulting from physical, social, economic and environmental factors, which determine the likelihood and scale of damage from the impact of a given hazard. In the DRI, human vulnerability refers to the different variables that make people more or less able to absorb the impact and recover from a hazard event. The way vulnerability is used in the DRI means that it *also* includes anthropogenic variables that may increase the severity, frequency, extension and unpredictability of a hazard (UNDP 2004: 98).

Based on their previous work, Dao and Peducci (2004) discussed methodological aspects of the *Disaster Risk Index* (DRI) in the UNDP (2004) report on

Reducing Disaster Risk. The report is based on the assumption "that differences in risk levels faced by countries with similar exposures to natural hazards are explained by socio-economic factors, i.e. by the population's vulnerability" with a special focus on "socio-economical indicators reflecting human vulnerability to hazards". They used a total of 38 variables dealing with economic features, dependency on environment quality, demography, health and sanitation, politics, infrastructure, early warning and capacity of response, education and development, and they discussed the global risk and vulnerability patterns for four hazards: cyclones, droughts, earthquakes, and floods. The concept 'social vulnerability' has been extensively used both in the development and in the hazard community.

2.4.7 'Social Vulnerability' in the Hazard and Development Research and Policy Community

'Social vulnerability' has been used in many definitions in the hazard research community to distinguish the social and societal factors from the manifold physical, economic, political and human aspects (Adger 1999; Cutter/Boruff/Shirley 2003; Downing/Patwardhan 2005; Warner 2007). In the development policy community in the UK, a DFID (Department for International Development) White Paper (1997) and a policy paper (1999: 4) focused on socio-economic factors that made people vulnerable to disasters. It listed among its humanitarian policy goals "to save lives and relieve suffering, hasten recovery, and protect and rebuild livelihoods and communities, and reduce risks and vulnerability to future crises" thus stressing the link between "the sustainability approach and vulnerability reduction". Cannon, Twigg and Rowell (2003: 4) argue that vulnerability analysis can "become an integral part of humanitarian work ... [and] enable [this] work to be more closely integrated with the SL [sustainable livelihood] approach, by using vulnerability analysis in both the operation of emergency preparedness and reducing poverty". In their view:

> *[V]ulnerability* should involve a *predictive* quality: it is supposedly a way of conceptualizing what may happen to an identifiable population under conditions of particular risks and hazards. ... VA should be capable of directing development aid interventions, seeking ways to protect and enhance peoples' livelihoods, assist vulnerable people in their own self-protection, and support institutions in their role of disaster prevention (Cannon/Twigg/Rowell 2003: 4).

Disasters occur when a natural hazard affects a population unprepared to recover without assistance. The impacts of hazards differ for people at different levels of preparedness, resilience, and with varying capacities for recovery.

> *Vulnerability* ... involves much more than the likelihood of their being injured or killed by a particular hazard, and includes the type of livelihoods people engage in, and the impact of different hazards on them. ... Social vulnerability is the complex set of characteristics that include a person's
>
> - *initial well-being* (nutritional status, physical and mental health, morale);
> - *livelihood and resilience* (asset pattern and capitals, income and exchange options, qualifications);
> - *self-protection* (the degree of protection afforded by capability and willingness to build safe home, use safe site);
> - *social protection* (forms of hazard preparedness provided by society more generally, e.g. building codes, mitigation measures, shelters, preparedness); and
> - *social and political networks and institutions* (social capital, but also role of institutional environment in setting good conditions for hazard precautions, peoples' rights to express needs and of access to preparedness) (Cannon/Twigg/Rowell 2003: 5).

According to the DFID study, the vulnerability conditions are distant from the impact of a hazard. Vulnerability variables are connected with peoples' livelihoods and poverty. Thus, development work should reduce disaster vulnerability and make people become more resilient to hazards by

- the strengthening of peoples' 'base-line' conditions (nutrition, health, morale ...);
- reinforcement of their livelihood and its resilience to possible hazard impacts;
- peoples' own efforts ... to reinforce their home and workplace against particular hazards;
- or by access to proper support ... by institutions of government or civil society (Cannon/Twigg/ Rowell 2003: 6).

Livelihoods are influenced by *social and political networks* that may have varying levels of cohesion and resilience in the face of hazards. When disasters occur, relief and recovery is tied with the restoration of livelihoods, and the strengthening of self-protection. Vulnerability can be seen as a term that encompasses all levels of exposure to risk. There are two separate approaches to vulnerability and capacity. The first conceives people who have a high degree of vulnerability and are low in capacity. The second perceives them as two distinct sets of factors. A capacity

might include institutional membership, group cohesion or literacy. Vulnerability can include poverty, house quality, or illiteracy. Some capacities are not the opposite of vulnerabilities, and some low-level vulnerability characteristics are not amenable to being considered capacities.

The concept of 'capabilities' (Sen 1981, 1999; Comin/Qizilbash/Alkire 2008) emerged in response to the term 'vulnerability'. It was suggested that speaking of people as being vulnerable ignored many capacities which make them competent to resist hazards. Some characteristics may be considered capacities when they score well, and vulnerabilities when they score badly, even when they are in fact opposite ends of a scale. There can be high and low levels of vulnerability without implying victimhood.

One of the reasons why capacities seem to be often separated from vulnerability is that capacities are regarded as dependent on groups or some form of social organization, while vulnerabilities are socially-determined. One way around the problem is simply to acknowledge that high capacities likely reduce the vulnerability. If we accept that measuring vulnerability includes any factor or process that can alter the exposure of a person or household to risk, then capacities can also be considered as scaled factors leading to greater danger (vulnerability) when they are low, and reduced danger when they are high.

Vulnerability analysis offers DFID the opportunity to integrate development work with disaster preparedness, prevention and recovery. By adopting a *vulnerability assessment* (VA) approach, disaster prevention, preparedness and recovery work should be integrated with development work. With VA as a means of integrating its development and disaster work, DFID may also be able to foster a better integration and convergence of the wide range of vulnerability and capacity methods what can assist in its work of creating partnerships.

Since 2005, the MunichRe Chairs on Social Vulnerability of UNU-EHS have made significant contributions to the theoretical and conceptual development of social vulnerability, in relation to *Gender and Disasters* (Oswald Spring 2008, 2001), on *Livelihoods and Human Security in Risky Environments* (Bohle 2007), and on *Sea Level Rise and the Vulnerability of Coastal Peoples* (Oliver-Smith 2009) and on *Nature, Society, and Population Displacement* (Oliver-Smith 2009a). In the first three summer academies of UNU-EHS, PhD candidates from many disciplines and all parts of the globe provided theoretical and empirical inputs to the debate on social vulnerability with a focus on *Perspectives on Social Vulnerability* (Warner 2007); on *Megacities - Resilience and Social Vulnerability* (Bohle/Warner 2008) and on *Linking Environmental Change, Migration & Social Vulnerability* (Oliver-Smith/Shen 2009).[11]

From the review of many scientific vulnerability concepts used in the global change, climate change, hazard, environment, development and early warning communities no consensus has emerged on a definition, on criteria and indicators for the measurement of vulnerability. For the hazard community, vulnerability is the combination of additional contributing factors causing a hazard due to natural variability or human inducement to a disaster. The selection and inclusion of these contributing factors is configured by the worldview, mind-set, perception, the theories and models of the analyst. Thus, vulnerability is always socially constructed. 'Vulnerability' is how the analyst or policy-maker has defined it, and which definition has become accepted by a consensus within the respective research community.'

2.4.8 The Vulnerability Concept in Strategic and Security Studies

During the Cold War period, the concept of vulnerability was widely used for technical systems (e.g. of the land based strategic deterrent with regard to both intercontinental bombers and fixed land-based ICBMs), critical military and command, control and communication infrastructure but also of urban centres and the highly sensitive industrial and transportation systems. Since the global turn of 1990, at least in US national security guidance papers this concept has been used much less and with a specific meaning (chap. 12 by Brauch).

2.5 Reconceptualizing 'Security Risks'

2.5.1 The Term 'Risk'

For the term 'risk' (Lat.: 'risicare' navigate around cliffs; Fr.: 'risque'; It.: 'risico, risco'; Sp.: 'riesgo'; Port.:

11 Selected contributions by participants are included in part IV of this book (see chap. 30–38 by Fabien Nathan (France); Mabel-Cristina Marulanda and Carmen Lacambra (Colombia); Monalisa Chatterjee, Reena Singh and Nanda Kishor (India) Xiaomeng Shen (China); Sidika Tekeli-Yesil, and Ebru Gencer (Turkey).

'risco'; Ger.: 'Risiko') many synonyms are used: danger, peril, jeopardy, hazard; chance, gamble, possibility, speculation, uncertainty, venture; unpredictability, precariousness, instability, insecurity, perilousness, riskiness, probability, likelihood, threat, menace, fear, prospect.

For *Webster's Third International Dictionary* 'risk' means "1. the possibility of loss, injury, disadvantage, or destruction: contingency, danger, peril, threat ...; 2. someone or something that creates or suggests a hazard or adverse chance: a dangerous element or factor ...; 3. the chance of loss or the perils to the subject matter or insurance covered by the contract; the degree of probability of such loss; amount at risk; a person or thing judged as a specified hazard to an insurer; an insurance hazard from a cause or source (war, disaster); 4. the product of the amount that may be lost and the probability of losing it" (Gove 2002: 1961). Langenscheidt-Longman (1995) defines 'risk' as: "1. possibility of bad result: the possibility that something bad, unpleasant, or dangerous may happen ...; 2. take a risk: to decide to do something even though you know it may have bad results; 3. at risk: be in a situation where you may be harmed ...; 4. run a risk: to be in a situation where there is a risk of something bad happening to you ...; 5. at the risk of doing something: used when you think that what you are going to say or do may have a bad result, may offend or annoy people etc.; 6. at your own risk: if you do something at your own risk, you do it even though you understand the possible dangers and have been warned about them; 7. cause of dangers: something or someone that is likely to cause harm or danger...; 8. insurance/business: a person or business judged according the danger involved in giving them insurance or lending them money" (Langenscheidt-Longman 1995). *The Oxford Guide to the English Language* gives this concise definition: "possibility of meeting danger or suffering harm; person or thing representing a source of risk" (Weiner/Hawkins 1985).

Besides these many meanings of this term in contemporary American and British English, the 'risk' concept has been employed in many natural and social science disciplines as a concept that is also widely used by policy-makers to justify specific policy goals and programmes.

2.5.2 Risk as a Political and Scientific Concept in Encyclopaedias

As a scientific concept, risk is defined in major encyclopaedias and scientific dictionaries in many disciplines, including philosophy, political science, sociology, psychology, economics and in the geosciences. The *Brockhaus Enzyklopädie* ([19]1992, XVIII: 440–444) offers a detailed assessment of the different meanings of the term 'risk', of its historic development, as well as 'risk measures', 'risk assessment', 'risk factors' and 'risk indicators', 'risk society', 'risk capital, 'risk policy and management' and 'risk premiums'. The *Brockhaus* distinguishes among these meanings of risk": 1. a possibility that an action or activity causes damage or loss of material or persons; and 2. risk is used when the consequences are uncertain. The *Brockhaus* differentiates among *pure* (crash of an airplane), *speculative* (stock market), *insured* and *technical risks* (of equipment).

For the quantitative measurement of risks, often simple risk indicators are used: 'Risk estimates' always involve a prospective estimate based on the probability, frequency and intensity of damages that are often based on specific 'risk analyses'. 'Risk assessment' is used in the daily practice in many disciplines and it is often influenced by the personal risk acceptance. The risk assessment e.g. of nuclear technologies differs among groups and countries. The concept 'risk factors' is used in social medicine, public health and epidemiology to point to factors which may increase the probability to get affected by a disease, while risk indicators may also be indirect contributing factors (e.g. social conditions for the breakout of a disease). Beck's (1986, 1992, 1999, 2007, preface essay by Beck) concept of an (international) 'risk society' initiated a global debate in the social sciences that impacts on security risks. 'Risk policy and politics' as well as 'risk management' comprise all measures of an enterprise to improve its financial performance.

2.5.3 Risk as a Political and as a Scientific Concept in Scientific Dictionaries

The term 'risk' evolved since the 15th century referring to the financial danger associated with trade. This concept was primarily used with reference to insurance in economic activities. The term is widely employed in the *probability theory* (Bernoulli 1738, Laplace 1816), in *economics* (A. Smith 1776, Ricardo 1821, J.S. Mills 1848, Knight 1921), in *existential philosophy* (Kierkegaard 1844, Heidegger, Jaspers 1932, 1956, Sartre 1948, Camus 1958) and in *decision-making theory* (Neumann/von Morgenstern 1944). The risk concept is used as a political term in nuclear technology for estimating how much security of technology is needed and how much insecurity is acceptable

for society. Here risk is equated with the expectation of security contributing to risk acceptance. Since the 1970's the concept has been intensively discussed in economics, psychology, sociology and political science (Rammstedt VIII, 1992: 1049). Koschnick (1993: 1325) refers to 'risk' in the context of decision-making theory where

> risk is defined as imperfect information, leading to a situation in which one is forced to take chances that certain outcomes or events will occur. Risk can range from risk that is close to perfect uncertainty to risk that approaches perfect uncertainty. ... In face of risk, one may proceed in three stages. First, one evaluates the various possible consequences of alternative policies on their merits. Second, one specifies the probability relationships between given policies and these evaluated outcomes. And finally, one tries to rank policies by the probabilistically weighted values of the consequences to which they may lead.

As complete certainty is hardly possible, Llewllyn (1996: 744–746) argues that "risk and uncertainty are an integral part of most human behaviour", especially in economics and finance: "*Uncertainty* arises when the future is unknown but no actual probabilities (objective or subjective) are attached to alternative outcomes. *Risk* arises when specific numerical probabilities are attached to alternative outcomes." *Risk analysis* relies on probability theory.

> Behaviour is ... influenced both by the risk of an event to occur or outcome and the potential seriousness if it occurs. This ... gives rise to the concept of *disaster* myopia. ... Risk analysis is applied to situations which have multiple, uncertain outcomes. .... Risk analysis and management for a bank involves five key processes: first, identification and measurement of risk...; second, what can be done to lower the probability of default; third, measures to limit the damage in the event that the risk materializes...; fourth, action to shift risk to others, that is, risk-sharing, and fifth, how the residual risk is absorbed. ... The same principles apply in all risk analysis. ... Risk analysis is inseparable from risk management.

An economic dictionary (Grüske/Recktenwald 1995: 528–529) includes 'risk', 'risk premium', 'risk theory' and 'risk management' where 'risk' is defined

> as an economic and social danger of loss in reputation, position, wealth resulting from the market dependence of the entrepreneur and the financier. In the economy it is closely linked with responsibility. Knight distinguishes between risk, where the probable distribution of results of possible actions is known and insecurity where this is not the case. Thus, insecurity cannot be measured and cannot be insured against, while risks may be insured against. In the literature the risk concept is manifold: 1) the danger to make a loss, or the distance between possible profit and loss; 2) risk expresses the positive and negative deviation from the expected value, or 3) risk as the difference between the planned data and the facts. ... The risk policy of companies tries to remove unnecessary risks, ... as a result of careful market analyses and to secure it legally. ... Decision theory has developed ... procedures, to constrain risks (Grüske/Schneider 2003: 456).

Grüske and Schneider (2003: 456) defined risk management as: "The analysis of risks as well as the implementation of measures to manage risks". This covers insurance contracts of households, strategies of companies to differentiate production, and speculation in money markets as part of risk management. A major task of risk management is risk limitation.

In psychology 'risk' (Städtler 2003: 937–938) is used in decision-making theories, especially for decision situations taken under risk, synonymously for decision and decision behaviour. Risk implies that individuals show in decisions variance preferences that do not always follow the principle of maximizing benefits, but also reflect the relationship between maximum gain and loss. The portfolio theory of risks by Coombs (1975) implies a preference function for risks where the optimal value of risk is to find a balance between greed, challenge and fear. Some theories try to explain the risk-taking behaviour of humans given possible cognition of dangers.

The risk concept was gradually introduced in sociology, with a reference to environmental issues. In a German dictionary of sociology (Endruweit/Trommsdorff 1989) the term 'risk' was still missing, while in a sociological lexicon (Fuchs/Klima/Lautmann/Rammstedt/Wienold 1978, 1988) 'risk' was included as "readiness to take risks" (*Risikobereitschaft*), as "risk population" and as "risky shift". In the dictionary of sociology (Hillmann 1994: 740–741) risk is defined as a decision situation with incomplete information. In game and decision-making theory risk is distinguished from uncertainty. Subjective risk perceptions have often differed from the objective level of risk (Nathan 2010; chap. 30 in this vol.).

2.5.4 The Debate on 'Risk' and 'Risk Society' in the Social Sciences

The concept of risks has been used in the social sciences and especially in sociology, with a special reference to environmental issues.[12] Löfstedt and Frewer (1998, 2004: 3–27) reviewed the debates on 'risk management' tracing the origin of risk analysis to the response of psychologists to an engineer's work on

technological risks, and to the Chicago school of geography and argued that the people's response to hazards depended on their experience and knowledge. The debate on risk perception was provoked by Starr who pointed to the importance of contextual factors in risk perception pertaining to natural and technological hazards.

In the 1990's, a new school doubted the existence of objective risks pointing to the social construction of risk that influenced risk perceptions and risk-taking behaviour. Others have criticized risk comparisons because they ignored the societal risk context. A cultural theory of risks emerged in the UK but the empirical results in other countries were mixed. In the 1980's and 1990's research moved from 'risk perception' to 'risk communication' including the role of the media and of the social amplification of risk. In analysing the failure of risk communication initiatives, research increasingly has focused on the lack of trust towards policy-makers with regard to hazardous industrial plants and installations.

One reason for distrust has been the growing relevance of globalization (Giddens 1990, 1994).[13] The concept 'risk society' was introduced by Ulrich Beck (1986, preface essay above) and has widely influenced the debate in the social sciences.[14] Beck (1986, 1992) has argued that risk is increasing with the complexity of technology. Regaining trust requires competence and credibility of policy-makers. Research on mental models gained in importance focusing on misperceptions regarding different kinds of risks. Others have focused on the optimistic bias or the unreal optimism that has become a major barrier to effective risk communication. Due to the crisis of confidence, the requests on social scientists have increased to contribute to an improved risk management. Löfstedt and Frewer (1998, 2004: 19–20) argue on the future of risk research that the model of social amplification of risk should be developed further, as well as the research on risk perception and risk communication, and on public responses to transboundary risks.

In his book *On Risk*, Bonß (1995) reviewed the development of the 'sociology of risk' that has gradually emerged since the late 1960's in response to the disasters of Seveso, Harrisburg, Bhopal or Chernobyl which Luhmann (1990: 138) has described as an "articulated displeasure". With his theory of a 'risk society', Beck tried to place the problem of risk in the context of a theory of modernity focusing primarily on technical dangers and less on social action. Bonß (1995: 18–19) suggested to broaden the sociological risk debates in two respects: 1) the linkage between risk and technology must be dissolved and it should be analysed as a problem of insecurity; and 2) from a historical perspective the treatment of uncertainty should be reconstructed. He offered a systematic history of the discourse on the risk concept as a social and cultural construct with a special focus on the transition from a reactive towards an active orientation of insecurity. Among several classifications of risk concepts Bonß pointed to two alternatives to analyse risk as a social phenomenon from an action (*ex ante*) or systems (*ex post*) perspective. From an action perspective, risks are reduced to risk decisions, while from a systems perspective risks are treated as threats or danger of loss. Bonß suggests analysing risks in the context of the social construction of uncertainties. While uncertainties due to dangers exist irrespective of human actions, uncertainties as risks include both the intentions and implementation of action. Thus, risks are often the result of decisions made under uncertainty.

12 Keith Smith (^{3}2001: 6) noted that risk is sometimes used synonymously with hazards whereby "risk has the additional implication of the chance of a particular hazard actually occurring. ... *Risk* is the actual exposure of something of human value to a hazard and is often regarded as the product of probability and loss".

13 Tester (1996: 747) noted that risk is a major theme in Giddens's works who "distinguishes pre-modern (traditional) and modern environments of risk: 'The risk environment of traditional cultures was dominated by hazards of the physical world' while the modern risk environment is 'structured mainly by humanly created risks' (Giddens 1990). Giddens stresses the importance of the environment, war and personal relationships in modern experiences and construction of risk. In so doing, Giddens makes plain that 'risk is not just a major individual action. There are environments of risk that collectively affect masses of individuals'".

14 Tester (1996: 747) summarized and interpreted Beck's key concept of risk' and risk society': "In a risk society the future has become uncertain. Possible events which technology unintentionally generates cannot be insured against because they have unimaginable implications. ..... *The residual risk society has become an uninsured society* (Beck 1992a: 101). Instead of belief in progress and the future, risk society is experienced in terms of short-term calculations of danger: 'In this sense, one could say that the calculus of risk exemplifies a type of ethics without morality, the mathematical ethics of the technological age (Beck 1992a: 99). ... He has faith in the potential of a self-critical technological enterprise to solve risk problems. Secondly, Beck emphasizes the sociological significance of the environment and ecology".

Jaeger, Renn, Rosa and Webler (2001: 9) reviewed the thinking of risk, uncertainty and rational action. In their view "risk developed over the past several decades as the key analytical lens for attempting to anticipate the consequences of our purposive actions on the environment and ourselves". Risk has always been constitutive of the *conditio humana*. However, the nature of risks has changed, while they were originally local in impact, today many risks are eco-centric (i.e. they are linked to environmental problems or related to environmental conditions), and global. They are increasingly perceived as common risks, be it as systematic cumulative environmental risks, often affecting the globe as a whole (e.g. climate change), and the increasing risk consciousness of high technology. With the adoption of 'risk' as the imprimatur of our age, as suggested by Beck and Giddens, the direction of Western thought has shifted from "the expectation of progress, of continued improvement in the social world" to an epoch "in which the dark sides of progress increasingly come to dominate social debate", shifting from the 'goods' of modernization to the often unintended 'bads' (Jaeger/Renn/Rosa/Webler 2001: 15).

In Giddens' terminology (1984, 1991) social fabric produces "ontological security"[15], he specified as "the confidence that most human beings have in the continuity of their self-identity and the constancy of the surrounding social and material environments of action" (1991: 92). Today they often "take the form of uncertainties, and risks associated with them", i.e. increasing these risks results from human choice threatening both environmental conditions and individual identity.

For Jaeger, Renn, Rosa and Webler (2001: 16) "reducing uncertainties in order to maintain ontological security is clearly a task worthy of sociological investigation". With a special focus on risks, they discuss first rational action, as the dominant worldview "for understanding and managing risk", and then shift to alternative approaches: "reflexive modernization, critical theory, systems theory, and postmodernism". While there are many meanings of risk, they argue that "all conceptions of risk presuppose a distinction between *predetermination* and *possibility*" (Jaeger/Renn/Rosa/Webler 2001: 17).

Risk implies uncertainty, an indispensable element of risk. Risk "is present only to the extent that uncertainty involves some feature of the world, stemming from natural events or human activities that impacts human reality. Risk, in human terms, exists only when humans have a *stake in outcomes*". Jaeger, Renn, Rosa and Webler (2001: 17) defined risk as "a situation or event in which something of human value (including humans themselves) has been put at stake and where the outcome is uncertain".

In the late 20th century, for industrialized societies the new risks have reached a level that could endanger human life and survival on the planet. Technological and industrial developments have created new dangers that could endanger life in all its forms. These new risks for survival cannot be geographically limited nor can they be insured against. The competition on the division of resources has partly been replaced by the management of these global risks of survival. They require a reflexive modernization where prevailing views, values, norms, conventions and behavioural patterns are an object of sociological reflection (Hillmann 1994). Ulrich Beck (1999: 3–4) defined 'risk' as

> the modern approach to foresee and control the future consequences of human action, the various unintended consequences of radicalized modernization. It is an (institutionalized) attempt, a cognitive map, to colonize the future. Every society has ... experienced dangers. But the risk regime is a function of a new order: it is not national, but global. ... Risks presuppose decision. These decisions were previously undertaken with fixed norms of calculability, connecting means and ends or causes and effects. These norms are precisely what 'world risk society' has rendered invalid. ... What has given rise to the prominence of risk? The concept of risk and risk society combines what once was mutually exclusive – society and nature, social sciences and material sciences, the discursive construction of risk and the materiality of threats.

15 Giddens (1991) calls the need for stable expectations, e.g. of states, 'ontological security'. According to Mitzen (2005: 3) this refers to a "need to secure one's identity. Actors do this through cognitive and behavioural routines; and because the resulting routines stabilize the self, actors become attached to them". Based on Huymans (1998) and Mc Sweeney (1999), Mitzen (2005) argues that states also need ontological security and she proposes "that states achieve ontological security by routinizing relations with other states and apply that argument to entrenched interstate conflict. This reveals another, second 'security dilemma' in international politics: ontological security can impede physical security". If states try to break out of security dilemmas, Mitzen (2005: 3–4) argues that this could "generate ontological insecurity". Thus, "parties may prefer to remain in security dilemmas, even if offered credible opportunities for escape. In short, ontological security turns security dilemma logic on its head, suggesting that the persistence of conflict is rooted not in uncertainty but in the certainty such dilemmas offer their participants".

Beck (1999: 55–57) distinguished between predictable *risks* and unpredictable *threats* and offered a typology of three types of global threats: 1) *wealth-driven* ecological destruction and technological-industrial dangers (ozone hole, global warming, regional water shortage) and the unpredictable risk of genetic engineering; 2) risks related to *poverty* (environmental destruction); and 3) *weapons of mass destruction*.

Zürn (1995: 51) saw an essential difference between environmental destruction as a result of well-being and poverty: "Whereas many wealth-driven ecological threats stem from the externalization of production costs, in the case of the poverty-driven ecological destruction it is the poor who destroy themselves with side-effects for the rich." Thus, wealth-driven environmental destruction becomes international only through side-effects in the medium term.

Beck (1999: 36) argued that ecological destruction may promote war either as an outgrowth of resource scarcity (water) or because Western eco-fundamentalists use force to stop ongoing destruction. Such ecological destruction may trigger mass emigration which may lead to war. This may result in a spiral of destruction where different crisis phenomena converge. In the world risk society, these

> 'global threats' have together led to a world where the basis of established risk-logic has whittled away, and where hard to manage dangers prevail instead of quantifiable risks. The new dangers are removing the conventional pillars of safety calculation. Damage loses its spatio-temporal limits and becomes global and lasting. It is hardly possible any more to blame definite individuals for such damage. ... Often, too, financial compensation cannot be awarded for the damage done; it has no meaning to insure oneself against the worst-case effects of spiralling global threats (Beck 1999: 36).

The analysis of risk has become an objective of many disciplines. While the calculation of risk as a function of the probability that an event becomes real is a task of the natural science, of medicine and applied mathematics, the response of human beings to risky situations is an area for psychology, anthropology and the social sciences and how organizations and whole societies regulate risks is being analysed by political science, sociology and of law departments (Renn/Schweizer/Dreyer/Klinke 2007: 13).

These authors distinguished among seven scientific risk concepts of: 1) of the expected risk (tool: statistics; application: insurance companies); 2) risk assessment (tool: modelled risk expectance in toxicology and epidemiology; application: health, environmental protection); 3) probabilistic risk assessment (tool: event, error tree analysis; application: security analysis); 4) economic risks (tool: portfolio analysis; application: preparation of decisions); 5) risk perception (tool: psychometric experiments); 6) social risk assessment (tool: group surveys, structural analysis); 7) culture and risk assessment (tool: network analysis). The likely application of the last three risk concepts is as risk policy and regulation, conflict management, risk communication (Renn/Schweizer/Dreyer/Klinke 2007: 25; Renn 2008: 15). Renn (2008: 24–40) further distinguished among seven "social science-based theoretical approaches to risk":

1. the *rational choice approach* (Renn/Schrimpf/Büttner/Carius/Köberle/Oppermann/Schneider/Zöller 1999; Renn/Sirling/Müller-Herold/Fisher/Dreyer/Losert/Klinke/Morisini/van Zwanenberg 2003; Jaeger/Renn/Rosa/Webler 2001);
2. the *reflexive modernization approach* by Beck (1986, 1992) and Giddens (1991, 2000);
3. the *systems theory approach* of Luhmann (1986, 1989, 1993);
4. the *critical theory approach* based on Habermas (1984, 1987);
5. the *post-modern perspective* introduced by Foucault (1982) and further developed by Ewald (1986), Burchell, Gordon, Miller (1991) and Dean (1999);
6. a *cultural theory* approach, originally introduced by Douglas (1966, 1985) and Douglas and Wildavsky (1982), recently re-presented by Adams (1995) and Lupton and Tulloch (2002);
7. the framework of the *social amplification of risk* as an example of an integrative framework that promises to link psychological, social and cultural risk theories (Kasperson/Renn/Slovic/Kasperson/Emani 1988; Kasperson/Kasperson/Pidgeon/Slovic 2003; Renn/Webler 1992; Breakwell 2007).

Since the mid 1990's, the concept of 'risk society' (Beck 1986, 1992) and 'world risk society' (Beck 1999, 2007, preface essay) also became a new concept in political science and in international relations (M.G. Schmidt 1995, 2004). Beck's concept of risk society has also triggered a debate on 'risk policy' in political science.

2.5.5 From Security and Defence Policy to the Management of Political Risks

In security policy (Brauch chap. 12) and in national and *international security studies* (ISS) in the post-Cold War era the management of global risks has become a major security task arguing "that risk rather

than security captured the nature of the post-Cold War era (Rasmussen 2001b, 2004; Beck 2002; Coker 2002; Griner 2002; Heng 2002, 2006; M.J. Williams 2008)" (Buzan/Hansen 2009: 250). By focusing both on 'every day risk management' and on catastrophic risks, Buzan and Hansen (2009: 205–251) argued that risk analysis was a topic of ISS before the events of 11 September 2001, but since then many risk theorists argued that risk analysis was better suited for dealing with issues of terrorism and migration.

Furio Cerutti (2007: 27) raised the question whether the two major global challenges of nuclear war and global warming are risks whereby he defined risk "as a function, that is, the product of the probability and size of loss", where risk is understood as risk-taking and where the selection of damage is culturally determined. Facing risks implies two kinds of uncertainty: "one regards the probability of a loss, the other our evaluation of its size and significance" (Cerutti 2007: 28).

Cass R. Sunstein (2007: 9) pointed to uncertainties in specifying the probabilities of a worst-case scenario of a dangerous climate change. In comparing the two major security dangers posed by terrorism and climate change, Sunstein (2007: 53) pointed to a specific risk perception of many Americans, for whom "the idea of terrorism conjures up intense images of disaster, as the idea of climate change does not". For Kahan and Braman (2006) and Slovic (2000) these different risk-related judgements are a product of a 'cultural cognition' or of cultural orientations that may help to explain "public reactions to numerous risks, including those associated with climate change" (Sunstein 2007: 66–67).

Henry N. Pollack (2003: 6) addressed the ambivalence between uncertainty in science and risk-taking that is referred to in "many cultures as an attribute of a successful person. But risk arises precisely because of uncertainty. The willingness and the ability to formulate and take action and accept risk in the face of uncertainty is considered a character strength. ... An unwillingness to be motivated by uncertainty is indeed a real barrier to progress." But he also noted that "science can never produce absolute certainty, and definitely not on a schedule" (Pollack 2003: 213). With regard to the tipping points in the climate system, Pollack (2003: 232) acknowledged that "climate scientists do not yet know how to identify the thresholds for such events, and the uncertainties remain formidable".

The *Millennium Ecosystem Assessment* (MA 2005: 193–195) noted the problems in dealing with risk and uncertainties that are inherent in all human activity and cannot totally be eliminated. Ecological risk assessment has many tools and a large "potential for informing the decision process" by providing 1) analysis and a knowledge base for supporting sound decisions; 2) deliberation based on a consultation process and stakeholder involvement; 3) and relying increasingly on the precautionary principle.

A group of German scholars at the Free University of Berlin developed a new concept of 'international risk policy' for dealing with the new dangers in international relations, such as nuclear proliferation and terrorism, as well as the soft security challenges of migration, climate change, computer crime, drug trafficking and dealing with financial markets. Daase (2002: 9–35) argued that these new dangers require a paradigmatic change in security policy from defence against threats to crisis prevention. He distinguished between risks due to transformation and globalization and new political and international risks. Since 1990, the traditional threat triangle of an actor, his intentions and capabilities, has been replaced with different dangers that are often indirect, non-intended and uncertain. The fundamental difference between security threats and risks, in his view, has been that the certainty of expectation has disappeared with the departure of a clearly defined threat. Instead of reacting to perceived security threats, a proactive security policy should focus on the prevention of the causes and effects of risks. This would lead to four ideal-type strategies of international risk policy that may be described as cooperation, intervention, compensation and preparation to contain risks.

The goal of the first strategy is to reduce the probability of risks becoming reality by reducing misperceptions and by fostering a cooperative risk management;[16] the second intends reducing the probability of a future damage occurring by using political and military coercion; the third aims at a cooperative reduction of the level of the probable future damage by risk sharing strategies; and finally, the fourth strategy aims at a repressive reduction of the level of probable future damage by an efficient use of political, economic, legal and military measures that try to prevent

16 Such a strategy may lead to the creation of new institutions, e.g. of the crisis prevention centre of the OSCE, or to the adaptation of existing institutions to new tasks, e.g. of NATO. The task of scientific efforts is to review the methods and procedures of risk assessment (e.g. of prognoses, projections, estimates of probabilities) to point to shortcomings and to proposed alternative procedures (Daase 2002: 19).

follow-on damages. He distinguished economic, psychological, technical, and sociological approaches for dealing with risks. This paradigm was applied in several case studies on non-proliferation, migration, climate change, terrorism, drug trafficking, computer crimes and financial markets – but none on hazards. These studies focused on risk perception, risk policy, and a risk paradox.

Daase, Feske and Peters (2002: 267–276) concluded on risk perception that while material factors played a role in the perception of dangers, socio-cultural factors determined the different risk perceptions of states. Risk perception is not stable and it may change during a political process or as a result of scientific discourses. Risk perception is a process. It is an important but not the only factor for the explanation of risk policy. To justify proactive political action the danger is often oversold, a threat is being created and several risks are combined.

2.5.6 'Reflexive Security' and 'Risk Society' as Key Concepts of Security Studies

The sociologists Giddens and Beck have stimulated in parts of the international relations research community a debate on 'ontological security' (Giddens 1991; Huymans 1998; Mc Sweeney 1999; Mitzen 2005) as well as an emerging debate on 'reflexive security'. Rasmussen (2004: 381–395) outlined a research programme on 'reflexive security' by applying Beck's 'risk society' to security studies. While during the Cold War the balance of power and deterrence theory constituted an expert system with its own rationality and bureaucracy, since 1990 and especially 2001 they were challenged by new non-state actors, new military technologies and terrorists who "fight for values other than those of national interests". Rasmussen asks whether the transatlantic debate focuses more on different means than on goals, or on the scale, degrees and urgency of risks.

> 'Risk society' is one way to explain what is missing in the debate between soft and hard security. The point is not on how to apply the concept of security, but that the concept of security itself is changing. Surveying the history of the concept of security from the Romans to the present, Ole Wæver (2002) thus argues that today's considerations of safety are increasingly about managing risks rather than achieving perfect security. The focus on risk society turns the 'broad conception of security' inside out. It is not only the case that security policy needs to take many more issues into consideration, it is argued, but along with the many other policy areas, the way security issues are being handled politically is being transformed (Rasmussen 2004: 388–389).

Rasmussen (2004: 389–395) proposes to apply the sociological theories of reflexive modernity to "reflexive security studies"[17] and to translate the empirical findings back to sociological theory.[18] However, the social science debate on the concepts of 'risk' and 'risk society' was largely detached from the specific issues addressed in the environment and hazard communities to which we turn next. While some authors of international security studies argued that

> risk rather than security captured the nature of the post-Cold War era (Rasmussen [2001a, 2001b, 2002], 2004, [2006]; Beck 2002; Coker 2002; Griner 2002; Heng 2002, 2006; M.J. Williams 2008). ... Risk analysis had been brought into ISS prior to 9/11, but the surprise attack on 9/11 as well as the utility of 'everyday risk management' to identify the enactment of anti-terrorism and anti-migration policies made risk theorists hold that they offered a better account of security and terrorism (Buzan/Hansen 2009: 250).

Buzan and Hansen argued that the risk literature is an inherent part of ISS while many traditional American reviews of security studies have ignored the discourse

17 Rasmussen (2004) has mapped "the current achievements and future challenges of this emerging research programme on risk arguing that it offers a way to overcome the debate about whether to apply a 'broad' or 'narrow' concept of security; a debate which is stifling the discipline's ability to appreciate the 'war on terrorism' as an example of a new security practice. Discussing the nature of strategy in a risk environment, the paper outlines the consequences for applying the concept of reflexive rationality to strategy". See also: Shlomo Griner (2002).

18 Rasmussen (2004: 389–395) identified three research themes on: 1. globalization; 2. region and individual level of non-sate actors; and 3. study of specific strategies. He argues that reflexive security studies that make conceptual change an empirical matter "offer one possibility for taking account of the transformation of practice". This requires a clear definition of this scope: "Are reflexive security studies about certain 'risky' policy areas or has it something to say about the entire security agenda?" He argues that the polarized debate on the policy response to 9/11 illustrates "one of the basic facts of life in reflexive modernity: that the way by which we try to solve problems ... become a 'theme and a problem itself'." He points to a need "to develop a shared discourse on how to manage risks that takes account of strategic necessities, as well as concerns of world order, legitimacy and human rights. ... It highlights the need for security studies to catch up with the present practices of security policy and help develop a vocabulary that enables a reflexive debate on security priorities in the future".

provoked by Beck. In *The Politics of Climate Change* Anthony Giddens (2009: 7) argued that "climate change politics is all about risk and how to manage it" and that "the long-term thinking needed to counter climate change has to operate against the backdrop of uncertainty". To develop such a forward looking politics of climate change, Giddens (2009: 8) suggested several new concepts that of the "*ensuring state*" that acts as a "facilitator, an enabler" and "*political* and *economic convergence*".

> The first refers to how far climate change policy overlaps in a positive way with other values and political goals. Political convergence is crucial to how far climate change policy becomes innovative and energetic, but also to whether it receives widespread support. ... In the developed countries, we can no longer equate progress with economic growth. ... Economic convergence concerns how far economic and technological innovations that are developed to combat global warming also generate competitive advantage to those who deploy them (Giddens 2009: 8–9).

Giddens calls for "a positive model for a low-carbon future" that requires a transition strategy towards sustainable development (Grin/Rotmanns/Schot 2010) that should aim at a "Fourth Green Revolution" (chap. 95 by Oswald Spring/Brauch). In moving towards that end, Gidden's (2009: 12–13) advice to policy-makers is:

1. Promote political and economic convergence wherever possible and do so in an active way. ...
2. Look first and foremost to embed a concern with climate change to people's everyday lives, while recognizing the formidable problems involved in doing so. ...
3. Avoid making political capital out of global warming. ...
4. Set up detailed risk assessment procedures, stretching into the long run, since the implications of climate change policy are complex. We have to construct a future in which renewable sources will comprise the bulk of energy use. It will be a far-reaching transition indeed, with a whole raft of complex social and economic effects.

In conclusion, Giddens (2009: 229–230) argues that "coping with climate change could be a springboard for creating a more cooperative world. It might be a means of reinvigorating the UN and other institutions of global governance". But he cautioned that "all governments face deep dilemmas in reconciling climate change with energy policy with sustaining popular support, especially in times of economic difficulty". However, "technological innovation is one of the several major jokers in the pack", where a quantum leap is needed to move humankind towards a new enlightenment and to avoid new Dark Ages.

This requires from the social sciences conceptual contributions to develop strategies for an ecological transition (Grin/Rotmanns/Schot 2010) to cope with the projected impacts of climate change during the 21st century with a complex set of adaptation and mitigation measures. Toward that end, Nair, Tanner and Bhadwal (2009: 399ff.) in a study by TERI, IISD and CICERO suggested a "climate risk screening" with an "evaluation of adaptation to climate change" that includes a portfolio screening using the ORCHID (*Opportunities and Risks of Climate Change and Disaster*s process) methodology (chap. 64 by Nair).

Finally, from an economic perspective, Nicholas Stern (2009: 12) suggested to include ethical considerations in the long-term thinking on "how to reduce risks for future generations". Given the lack of knowledge, "policy on climate change involve decision-making under risk and uncertainty" (Stern 2009: 16–19), where 'risk' refers to an estimated probability and 'uncertainty' to the impossibility to make educated guesses on the probability. But besides risks, Stern (2009: 135) refers to the many economic opportunities due to the "transformation of energy systems from high- to low-carbon" that creates "new, multibillion-dollar markets, which are now attracting significant capital".

2.5.7 Global and Regional Environmental Risk as a Scientific Concept

In security and environment policy, the risk concept is sometimes used without a clear delineation from the other concepts of threats and challenges. From an environmental perspective, Kasperson and Kasperson (2001: 1) tried to combine all four basic concepts: "global environmental *risk* is about *threat*; it is also about opportunity". The goal of their book is to take stock of "distinctive *challenges* posed by global environmental *risks*, the ability of the knowledge system to identify and characterize such *threats*, and the capability of societies to address the management of *challenges*" (emphasis added).

They distinguish between *systemic* risks (e.g. of global warming) and *cumulative environmental change* that may cause both short- and long-term consequences. They used risk synonymously with hazard, referring to "human beings and what they value". For them, *global environmental risk* "refers to threats ... resulting from human-induced environmental change, either systemic or cumulative, on the global scale".

They focus on five themes: 1) Global environment *risk* is the ultimate *threat*. 2) *Uncertainty* is a persistent feature both of understanding process and causation as well as predicting outcomes. 3) Global environment risk manifests itself in different ways at different spatial scale. 4) *Vulnerability* is a function of variability and distribution in physical and socio-economic systems, the limited human ability to cope with additional and sometimes accumulating hazard, and the social and economic constraints that limit these abilities. 5) Futures are not given, they must be negotiated.

The authors claim that global environmental risks "threaten international security and peaceful relations among states" contributing to differentiation of wealth and "increasing competition, tensions, and conflict". They refer to five risk sources: a) disputes arising from human-induced local environmental degradation; b) ethnic clashes arising from population migration and deepened social cleavage due to environmental scarcity; c) civil strife caused by environmental scarcity that affects economic productivity and, in turn, people's livelihoods, elite groups, and the ability of states to meet changing demands; d) scarcity-induced interstate war over, for example, water[19]; and e) North-South conflicts over mitigation of, adaptation to, and compensation for global environmental problems (Homer-Dixon 1999: 5). On the environmental security debate they admit "that such frameworks and models remain very limited in providing satisfactory interpretations" and that "causal linkages between environmental change and attributes of environmental security are yet poorly defined and understood".

Kasperson, Kasperson, Turner, Dow and Meyer (1995: 5–8) distinguished between *geocentric* and *anthropocentric* approaches to the study of environmental criticality which they defined as "a state of both environmental degradation and associated socio-economic deterioration". A *critical region* refers to "an area that has reached such a state of interactive degradation". The *geocentric* approach defines criticality "in terms of changes in physical attributes or social dimensions" due to human-induced perturbations that have altered the biophysical system. While the *geocentric* approach focuses purely on the physical environment, the *anthropocentric perspective* focuses solely on human inhabitants. Therefore, the authors suggest an integrative, holistic approach to the criticality of environmental threats which they describe with the conflicting terms – sensitivity, resistance, resilience, marginality, fragility, and vulnerability. Any analysis of criticality requires an assessment of what and who is threatened by environmental degradation. From the literature and their discussion they drew several lessons for the study of 'environmental criticality' of relevance for a regional approach:

> Human-environment trajectories appear particularly likely to lead to criticality in situations that have some combination of:
>
> - economies of high sensitivity and low resilience to environmental change;
> - human societies with high social and economic vulnerability;
> - economies strongly dependent upon local environmental resources;
> - frontier areas exposed to new forms of use; and
> - close linkage with, and dependent position *vis-à-vis*, global markets or distant political authority (Kasperson/Kasperson/Turner/Dow/Meyer 1995: 22–23).

Non-linear environmental change may exacerbate societal diagnosis and delay responses. Criticality refers to situations where emerging environmental degradation may lead to a loss of a capability to survive. The 'critical region' concept does not adequately capture the identifiable situations, rather additional categories are needed. A lot of the change inflicted by human pressures on the environment may impose costs on future generations that must be included in approaches to endangerment and criticality. But many of the currently perceived environmental threats may disappear in the near future. These authors differentiate "criticality" from lesser degrees of environmental threats such as environmental endangerment and impoverishment. The 'critical regions' are characterized by *environmental degradation* (water, air, soil, biomass productivity), *wealth* (GNP, income, savings), *well-being* (longevity, mortality, infant mortality, nutrition, environmentally induced disease) and *economic and technological substitutability* (cash-crop dependency, technological monocultures, innovation, economic diversity). Before a region reaches a status of environmental criticality, many warning signals alert experts and the society to impending or recurring damage. The degree of response depends largely on the political and societal sensitivity but also on the resources available to cope with these challenges.

19 While both international officials and national policymakers, journalists and defence officials have used the water war argument, this hypothesis has been disputed by many recent scientific publications in the social sciences (e.g. Wolf 2002; WWAP 2003; Kipping/Lindemann 2005).

Based on nine case studies they concluded that a) external factors were more important than internal ones; and b) state policy and institutions were key factors of change while the I = PAT formula (*Impact = population – affluence – technology*) was criticized for overstressing affluence and neglecting poverty. In most third world cases "poverty rather than affluence has driven unsustainable resource use". On the regional level, they pointed to "three aspects of environmental and socio-economic conditions [that] suggest an increasing potential for higher or catastrophic losses: 1. *Vulnerability and overshoot* ... 2. *market conditions and overcapitalization*... [and] 3. *loss of options and safety nets*" (Turner/Kasperson/Kasperson/ Dow/Meyer 1995: 560). They discussed different societal responses, symptoms of emerging criticality, spatial and temporal categories. Contrary to global environmental change, the trajectories of change

> in these threatened areas provide a warning, ... that supplements those recent discoveries ... at the global scale. In nearly all these regions, trajectories of change are proceeding to greater endangerment, ... while societal efforts to stabilize these trajectories and to avert further environmental deterioration are lagging and are generally only ameliorating the damage rather than intercepting the basic human driving forces of change. ... The trajectories of change in most ... regions are rapidly outstripping societal responses. ... The future populations ... are being environmentally impoverished by these trends. ... The trajectories suggest growing long-term costs of regional substitution, adaptation, and remedial measures. ... In the future, these trends will also eclipse regional societal capabilities to respond (Turner/Kasperson/Kasperson/Dow/Meyer 1995: 580).

They noted a rich variety of human causation and they argued that no single dominant human driving force can explain "the historical emergence of environmental degradation", nor could the *grand theories* offer satisfying interpretations. They conclude that "the regional dynamics of change – the interplay among the trends of environmental change, vulnerabilities and fragility, human driving forces, and societal responses – must be examined within their cultural, economic, and ecological contexts". For them "the most satisfying interpretations ... recognize the shifting complexes of driving forces and responses over time, tap diverse social science theory, and are firmly grounded in ... empirical work". The regional trajectories of change and associated regional dynamics must be analysed in the broader framework of extra-regional linkages, such as processes of economic globalization, including trade policies in the WTO framework that have a major environmental impact.

In conclusion, Turner, Kasperson, Kasperson, Dow and Meyer (1995: 582–583) suggest a regional tailoring of global initiatives:

> The regional dynamics of change ... reveal a recurring disjuncture between the fast rate of environmental change and the slow pace of societal response. ... The global scale reveals a much more mixed picture where societal responses to such changes as stratospheric ozone depletion, global warming, and industrial accidents have often been quite rapid, if less than totally effective. Still, signals of environmental threat have been processed with considerable speed and coping actions undertaken. But the trajectories of change ... provide considerable confirmation of the argument of overshoot ... by Donella Meadows and her colleagues (1972, 1992).

This debate on risk in the environmental research community has been developed further with a slightly different focus in the international scientific and political hazard community.

2.5.8 Risk as a Scientific Concept in the Hazard Community

A major area of the debate on risks in many scientific disciplines have been natural, human-induced natural, man-made hazards, technical calamities and manifold disasters or catastrophes that have focused on problems of 'risk perception', 'risk analysis', 'risk assessment' and 'risk management'. Slovic (2000) summarized the results of a research team that examined "the gap between expert views of risk and public perceptions", how these perceptions have evolved and changed over time, increasingly recognizing "the importance and legitimacy of equity, trust, power and other value-laden issues underlying public concern". They described "new methods for assessing perceptions of risk" and they discussed "the implications for regulation and public policy". In a follow-up study Pidgeon, Kasperson and Slovic (2003) analysed "how both social and individual factors act to amplify or dampen perceptions of risk and through this created secondary effects such as stigmatization of technologies, economic losses, or regulatory impacts". They focus on "risk perception and communication" and draw lessons "for public policy, risk management, and risk communication practice".

Posner (2004) offers an interdisciplinary perspective that combines the insights of a lawyer, a social and physical scientist in weighing risks and possible responses to a major catastrophe such as global warming, bioterrorism or a major accident. He argues that the risks of global catastrophe have grown due to the

technological advance and industrial applications, the growth of the world economy and population, and the rise of apocalyptic global terrorism that are often underestimated due to low probability that they may happen in the near future. However, there is a difference in public attention and response between creeping natural disasters (climate change) and intended catastrophes, such as nuclear attacks, bioterrorism, and cyber terrorism that have become an objective of the military and of criminal justice. Posner calls for a mutual rethinking of the liberals "in the face of technological terrorism" and of the conservatives on global warming, many of them deny that these global challenges and risks require a global response based on international cooperation.

Blaikie, Cannon, Davis and Wisner (1994) as well as Wisner, Blaikie, Cannon and Davis (2004)[20] offered a comprehensive theoretical framework on the challenges of disasters, on disaster pressure and release models, and access to resources and coping in adversity as well as an empirical analysis of famine and natural hazards, biological hazards, floods, coastal storms, earthquakes, volcanoes and landslides and on action for disaster reduction. They look for "the connections between the risks people face and the reasons for their *vulnerability* to hazards". For them disasters "are not only natural events that cause them. They are also the product of the social, political, and economic environment ... because of the way it structures the lives of different groups of people". Many disasters are a complex mix "of natural hazards and human action". In their definition:

> A disaster occurs when a significant number of vulnerable people experience a hazard and suffer severe damage and/or disruption of their livelihood system in such a way that recovery is unlikely without external aid. By recovery we mean the psychological and physical recovery of the victims, the replacement of physical resources and the social relations required to use them (Blaikie/Cannon/Davis/Wisner 1994: 21).

To understand risk in terms of their vulnerability analysis, they use two models of disaster: a) a *pressure and release* model (PAR), and b) an access model that relates to both *human vulnerability* and *exposure* to physical hazard. In the PAR model they distinguish three stages of vulnerability: a) the *root causes* (access to power, structure, resources; ideologies, political and economic systems); b) *dynamic pressures* (lack of local institutions, training, skills, local investment and markets, press freedom; macro forces: population growth, urbanization, arms expenditure, debt repayment, deforestation, decline in soil productivity); and c) *unsafe conditions* (fragile physical environment: dangerous location, unprotected buildings, infrastructures; fragile local economy: livelihoods at risk, low income levels; vulnerable society: special groups at risk, lack of local institutions; public actions: lack of disaster preparedness, prevalence of endemic disease). They refer to hazards of a *biological* (virus, pest), *geophysical* (earthquake, volcano) or *hydro-meteorological* (storms, floods, drought) nature. They defined risk as hazard + vulnerability (R=H+V). Thus, vulnerability refers to "unsafe conditions".

Wisner, Blaikie, Cannon and Davis (2004: 10) differed from the conventional approach to disasters that in their view stressed "the 'trigger' role of geo-tectonics, climate or biological factors arising in nature (... Bryant 1991; Alexander 1993; Tobin/Montz 1997; K. Smith 2001)". They argued that other authors "focus on the human response, psychosocial and physical trauma, economic, legal and political consequences (Dynes/DeMarchi/Pelanda 1987; Lindell/Perry 1992; Oliver-Smith 1996; Platt 1999)". Both approaches from the natural and from the social sciences "assume that disasters are departures from 'normal' social functioning, and that recovery means a return to normal". Wisner, Blaikie, Cannon and Davis (2004: 10) do

> not deny the significance of natural hazards as trigger events, but [their book] puts the main emphasis on the various ways in which social systems operate to generate disasters by making people vulnerable. In the 1970's and early 1980's, the vulnerability approach to disasters began with a rejection of the assumption that disasters are 'caused' in any simple way by external natural events, and a revision of the assumption that disasters are 'normal'. Emel and Peet (1989), Oliver-Smith (1986) and Hewitt (1983a) review these reflections on causality and 'normality'. A competing vulnerability framework arose from the experience of research in situations where 'normal' daily life was itself difficult to distinguish from disaster. This work related to earlier notions of 'marginality'.

To overcome the separation of the hazard from the social system (figure 2.1), they have developed a second access model that focuses on "the way unsafe conditions arise in relation to the economic and polit-

20 Parts of the revised second edition are available at: <http://www.unisdr.org/eng/library/Literature/7235.pdf>. In the introduction the authors discuss more recent literature on the basic idea and some variations, on Beck's theory of risk society, on various deconstruction approaches as well as on vulnerability and normal, daily life. Wisner, Blaikie, Cannon and Davis (2004: 8) outlined their approach in a figure on the social causation of disasters.

ical process that allocates the assets, income, and other resources in a society" (Blaikie/Cannon/Davis/Wisner 1994: 46) and to include "nature in the explanation of hazard impacts". For them vulnerability is a hypothetical term "which can only be 'proved' by observing the impact of the event when, and if, it occurs. By constructing the household access model for the affected people we can understand the causes and symptoms of vulnerability" (Blaikie/Cannon/Davis/Wisner 1994: 58).

In the second edition, Wisner, Blaikie, Cannon and Davis (2004: 13-) referred to four new streams of thought on vulnerability (e.g. by Wilches-Chaux 1992; Jeggle/Stephenson 1994; Davis 1994; Buckle 1998/99; Buckle/Marsh/Smale 2000; Currey 2002) since the early 1990's: a) emphasizing the people's 'capacity' to protect themselves rather than just the 'vulnerability' that limits them (Hewitt 1997: 167); b) quantifying vulnerability as a tool of planning and policy-making (Gupta/Kakhandiki/Davidson 1996; Davidson/Gupta/Kakhan-diki/Shah 1997; Davidson/Villacis/Cardona/Tucker 2000; Hill/Cutter 2001; UNDP 2003; Gheorghe 2003); c) pointing to the cultural, psychosocial and subjective impacts of disasters (Rosa 1998; Perry/Mushkatel 1986; Oliver-Smith/Hoffman 1999; Johns 1999; Tuan 1979); and d) shifting from 'vulnerable groups' to a concern with 'vulnerable situations' (Harding 2001).

In the first edition they distinguish several types of coping strategies: a) preventive strategies; b) impact-minimizing strategies; c) creation and maintenance of labour power; d) building up stores of food and saleable assets; e) diversification of the production strategy; f) diversification of income sources; g) development of social support networks; and h) post-event coping strategies.

To release the pressures contributing to vulnerability and thus to reduce disasters, Blaikie, Cannon, Davis and Wisner (1994) suggest to address the root causes, to reduce pressure, and to achieve safe conditions aiming at: no loss of life, no casualties, restricted damage and food security, and to reduce hazards by improved flood control, shelter breaks, etc. The management of vulnerability reduction should follow 12 principles: 1. vigorously manage mitigation; 2. integrate the elements of mitigation; 3. capitalize on a disaster to initiate or develop mitigation; 4. monitor and modify to suit new conditions; 5. focus attention on protection of the most vulnerable; and 6. on lives and livelihoods of the vulnerable; 7. on active rather than passive approaches; and 8. on protecting priority sectors; 9. measures must be sustainable over time; 10. assimilate mitigation into normal practices; 11. incorporate mitigation into specific development projects; and 12. maintain political commitment. They propose efforts "towards sustainable reduction of disasters".

In the second edition, Wisner, Blaikie, Cannon and Davis (2004: 20–35) pointed to new developments in disaster research reflecting the theoretical, practical and institutional work in the framework of the United Nations' *International Decade for Natural Disaster Reduction* (IDNDR, 1990–1999), with a special focus on: a) urban growth and urban concerns; b) changes in earth care, of the climate change negotiations and lessons learned from wildfires, tropical storms, floods and landslides; c) the emergence of the 'precautionary principle'; d) critiques of globalization; e) changes in human development and well-being; f) war and humanitarian relief; g) media and policy selectivity.

In Chinese, the word risk combines the characters meaning 'opportunity' and 'danger' what implies that risks cannot be eliminated but only managed. From a hazard perspective, Smith ([3]2001: 14) defined risk as:

> the actual exposure of something of human value to a hazard and is often regarded as the product of probability and loss. Thus we may define hazard (or cause) as 'a potential threat to humans and their welfare' and risk (or consequences) as 'the probability of a hazard occurring and creating loss'. ... An earthquake hazard can exist in an uninhabited region but an earthquake risk can occur only in an area where people and their possessions exist. Clearly, both hazard and risk can be increased and reduced by human actions.

For Smith (2001: 55) *risk management* "means reducing the threats posed by known hazards, whilst simultaneously accepting unmanageable risks, and maximizing any related benefits". *Risk assessment* "involves evaluating the significance of a risk, either quantitatively or qualitatively". He conceptualizes: *risk = hazard (probability) x loss (expected) : preparedness (loss mitigation).* Both risk assessment and management depend on value judgments that are conditioned by beliefs and circumstances. Perceived risks are often distinguished as 1. *involuntary risks* (in a hazard prone environment); and 2. *voluntary risks* (more susceptible to control). Based on Kates and Kasperson (1983) for Smith (2001: 59) risk assessment comprises three steps:

1 The identification of local hazards likely to result in disasters, what hazardous events may occur?
2 The estimation of the risks of such events, that is, what is the probability of each event?

3 The evaluation of the social consequences of the derived risk, that is, what is the likely loss created by each event?

Risk is thus defined as the product of probability and loss: R = p x L. While risk assessment depends on expert assessments, risk perception depends on an individual's intuition, estimation and evaluation. It may be determinate, dissonant or probabilistic.

From a natural hazard perspective Tobin and Montz (1997: 281–283) defined risks as a part of hazard but both are not synonymous.

> Risk is an important component of hazard analysis and risk analysis forms an important subdivision of the study of natural hazards. ... Frequently risk is seen as the product of some probability of occurrence and expected loss. ... To get a better assessment of hazard risk, details of vulnerability must be incorporated in the analysis. Statistically, this relationship can be expressed as:
>
> *Risk = probability of occurrence x vulnerability.*
>
> This formula ... fails to incorporate geographic differences in population size and density (or ... exposure) as well as communal adjustments undertaken to minimize loss. Mitchell (1990) conceptualizes hazards as a multiplicative function of risk, exposure, vulnerability, and response:
>
> Hazard = f (risk x exposure x vulnerability x response) where
>
> risk = the probability of an adverse effect
>
> exposure = the size and characteristics of the at-risk population
>
> vulnerability = the potential for loss
>
> response = the extent to which mitigation measures are in place.
>
> Just as risk is only one component of hazards.... It comprises two elements that must be considered separately and together. These are (1) a choice of action and (2) an outcome, which includes a probability of occurrence and a consequence (or magnitude).

For Tobin and Montz (1997: 331–332) a combination of physical characteristics and political factors defines risks. "By contrast, vulnerability is determined by all the elements in various combinations; this suggests that if we alter one of the elements, we have altered vulnerability. ... Risk and vulnerability are a part of the context, and they are changed when any one element in any of the three categories is changed." This is crucial for hazard mitigation efforts that focus on reducing exposure, risk, economic losses and death as well as stress. Structural changes in society can reduce vulnerability and thus impact on reducing economic losses, death and stress. The above quotes indicate that within the natural hazard community no consensus exists on the definition of the risk concept. This definition has been used in several studies by the 'GRAVITY team' of UNEP/DEW/GRID and by the UNDP/BCPR Report on *Reducing Disaster Risk* (2004).

2.5.9 Risk as a Practical Concept in the Hazard Research Community

For the practical and policy-oriented hazard community 'risk' has been the key operative concept. In July 1979, a UN expert meeting suggested a framework for the analysis of risks and natural disasters (UNDRO 1980) and in 2009, the *International Standardization Organization* (ISO) published ISO 31000 (2009) on principle and guidelines of risk management.

From an American perspective, the American Society of Civil Engineers (Haimes/Stakhiv 1989) reviewed 'risk analyses', 'risk communication decision-making', 'environmental risk analysis' and health hazards, global warming and climate change, as well as 'risk management strategies' for natural and technological hazards.[21] The US *National Research Council* (NRC 2000) analysed the application of 'risk analysis' techniques for US institutions, especially for the US Army's Corps of Engineers, and the U*S Federal Emergency Management Agency* (FEMA).[22] Risk analysis should deal with temporal and spatial natural variability, knowledge uncertainty (parameters, models), and decision model uncertainty (time preferences, values, objectives). Based on a review of global disaster reduction initiatives, UN-ISDR (2002: 24) defined 'risk' as:

> The probability of harmful consequences, or expected loss (of lives, people injured, property, livelihoods, economic activity disrupted or environment damaged) resulting from interactions between natural or human induced hazards and vulnerable/capable conditions.

21 In the introductory chapter, W.D. Rowe (1989: 1–2) defined risk as "the downside of a gamble" [that] "implies a probability of outcome, and the gamble may be involuntary or voluntary, avoidable or unavoidable, controllable or uncontrollable. The total gamble in which risk is imbedded must be addressed if the risk is to be analyzed, both the upside (benefits) and downside."

22 The NRC Study (2000: 179) defined "risk as the probability of failure during a flood event. For reaches without levees, failure means exceeding a target stage. For reaches with levees, it means a levee failure." And residual risk as: "the portion of the flood risk that still exists with the flood damage reduction project implemented".

> Conditionally risk is expressed by the equation Risk = Hazards x Vulnerability/Capacity.

In the second edition (ISDR 2004, II: 6) a slightly different definition of 'risk' is offered:

> Conventionally risk is expressed by the notation: Risk = Hazards x Vulnerability. Some disciplines also include the concept of exposure to refer particularly to the physical aspects of vulnerability. Beyond expressing a possibility of physical harm, it is crucial to recognize that risks are inherent or can be created or exist within social systems. It is important to consider the social contexts in which risks occur and that people therefore do not necessarily share the same perceptions of risk and their underlying causes.

ISDR (2004: II: 6) described 'risk assessment and analysis' as:

> A methodology to determine the nature and extent of risk by analysing potential hazards and evaluating existing conditions of vulnerability that could pose a potential threat or harm to people, property, livelihoods and the environment on which they depend. The process of conducting a risk assessment is based on a review of both the technical features of hazards such as their location, intensity, frequency and probability, and also the analysis of the physical, social, economic and environmental dimensions of vulnerability and exposure, while taking particular account of the coping capacities pertinent to the risk scenarios.

However, the social contexts are crucial in which risks occur, and thus often the perceptions of risks and of their causes differ (Nathan 2001). Accordingly, the process of risk assessment relies on a review of both technical features of hazards and of the physical, social and economic dimensions of vulnerability, reflecting the different coping capabilities. ISDR (2002: 24) defined 'risk assessment and analysis' as: "A process to determine the nature and extent of risk by analysing conditions of vulnerability/capacity that could pose a potential threat or harm to people, property, livelihoods and the environment on which they depend."

Based on Tobin and Montz (1997), Peduzzi, Dao, Herold, Rochette and Sanahuja (2001: 9–10) defined risk as "a measure of the expected losses due to hazard event of a particular magnitude occurring in a given area over a specific time period" – The GRAVITY--team focused on risks "faced by population, in terms of wounded and killed while confronted to natural disasters". This risk definition includes: "the probability of occurrence and severity of a specific hazard for a given area and length of time, the vulnerability of the population and the capacity of mitigation, this last could be introduced in the vulnerability or taken separately, depending on authors". They offer this formula of risk:

$$Risk_i = (Hazard_i - Prevention_i) \times [Population \times (Vulnerability_i - Mitigation_i)]$$

As no data were available on both preparedness and mitigation, they proposed a simplified model:

$$Risk_i = Hazard_i \times Population \times Vulnerability_i$$

Where the hazard multiplied by the population represents the physical exposure, risk is also:

$$Risk = Physical\ exposure \times Vulnerability\ or$$
$$Risk/Physical\ exposure = Vulnerability$$

In their second report, Peduzzi, Dao and Herold (2002: 3) used the term 'risk': "to describe potential losses resulting from expected future hazard". Their research focused on human aspects (i.e. persons killed) from natural hazards, and they relied on the database of *the Centre for Research on Epidemiology of Disasters* (CRED) in Louvain, Belgium for 'killed', 'wounded', 'homeless', 'affected' and 'total affected', but due to a high variation they only used the number of persons killed as risk indicators. Based on a definition by the *United Nations Disaster Relief Coordinator* (UNDRO 1979) for them risk results from three components: "*hazard occurrence probability*, defined as the probability of occurrence of a specified natural hazard as a specified severity level in a specified future time period, *elements at risk*, an inventory of those people or artefacts which are exposed to the hazard and *vulnerability*, the degree of loss to each element should a hazard of a given severity occur" (Coburn/Spence/Pomonis 1991: 49). Peduzzi, Dao and Herold (2002: 3) proposed for modelling risk to multiply the three factors explaining risk: *Risk = Hazard x Population x Vulnerability.* Thus, there is no risk if no hazard exists or nobody lives in the affected area, or if the vulnerability is reduced by preparedness and mitigation measures.

In the fourth report of the GRAVITY-Team, Dao and Peduzzi (2003: 3) repeated their previous definitions and they used as risk indicators the "number of killed, percentage of killed, percentage of killed as compared to the exposed population with their respective advantages and inconveniences". The *Disaster Risk Index* (DRI) is based on a combination of the first two indicators. In a brief article, Dao and Peduzzi (2004: 2) relied on the definition of risk by UNDRO (1979) that "refers to the expected losses from a particular hazard to a specified element of risk in a particular future time period" that may occur in

terms of "human lives, or building destroyed or in financial terms". Thus, if risk represents the losses, then "hazard can be defined as a potential threat to humans and their welfare" (Smith 1996). As extreme events, hazards "may create risk and potentially turn into disasters if the exposed elements are vulnerable".

The UNDP Report (2004: 2): *Reducing Disaster Risk – A Challenge for Development* has applied the methodology and the DRI developed by the GRAVITY-Team of UNEP. In responding to the *Millennium Development Goals* (MDGs), the UNDP report tried to mainstream disaster reduction and developing concerns by a) a collection of basic data on disaster risk and the development of planning tools; b) collection and dissemination of best practice in development planning; and c) galvanizing of political will to reorient both the development and disaster management sectors. The initial *Disaster Risk Index* (DRI) points to three limitations by a) focusing only on the risk of death; b) examining only risks associated with large- and medium-scale disasters; and c) representing risks associated with earthquakes, tropical cyclones and floods.

2.5.10 From Yokohama to Kobe: Global Policy Goals for Natural Disaster Prevention, Preparedness, and Mitigation

Since the adoption of the *Yokohama Strategy for a Safer World: Guidelines for Natural Disaster Prevention, Preparedness and Mitigation and its Plan of Action* in 1994 significant conceptual and practical policy progress has been made. The *Review of the Yokohama Strategy* (A/Conf.206/L.1) listed five major accomplishments and remaining challenges, dealing with governance, risk identification, knowledge management, reducing underlying risk factors and preparedness for effective response and recovery. Under risk identification they referred to assessment, monitoring and early warning. The review stressed a need for "greater awareness of the social and economic dimensions of vulnerability", for improved data and analytical tools, it pointed to *emerging risks* (urban risks and exposure of complex infrastructure, greater attention to the interaction between natural and human-induced hazards (technological risks), including climate change impacts. With regard to *reducing underlying risk factors*, the review addressed (i) environmental and natural resource management; (ii) social and economic development practices; (iii) land-use planning and other technical measures; and (iv) advanced technologies (including remote sensing).

The *World Conference on Disaster Reduction* (WCDR) in Kobe (18 to 22 January 2005), in its *Hyogo Framework for Action 2005–2015* promoted "a strategic and systematic approach to reducing vulnerabilities and risks to hazards" by underscoring "the need for ... building the resilience of nations and communities to disasters" (A/Conf.206/L.2/Rev.1: 3). The final document maintained:

> Disaster risk arises when hazards interact with physical, social, economic and environmental vulnerabilities. Events of hydro-meteorological origin constitute the large majority of disasters. Despite the growing understanding and acceptance of the importance of disaster risk reduction and increased disaster response capacities, disasters and in particular the management and reduction of risk continue to pose a global challenge.

At the Kobe conference, among the five main areas where gaps for action for 2005 to 2015 were identified, two dealt with "risk identification, assessment, monitoring and early warning" and with "reducing underlying risk factors". To achieve these aims, the conference adopted three strategic goals of which the third called for "the systematic incorporation of risk reduction approaches into the design and implementation of emergency preparedness, response, recovery programmes for disaster affected communities". The *Hyogo Framework for Action 2005–2015* proposed enhanced international cooperation and assistance in the field of disaster risk reduction, including knowledge transfer, sharing of research results, enhance governance, financial assistance to reduce existing risks and setting-up of governance systems that "can avoid the generation of new risk". The strategy called for preventive and proactive measures (early warning efforts and systems).

In order to identify, assess and monitor disaster risk and enhance early warning, the Kobe strategy listed among the key activities: i) *National and local risk assessments* (risk maps, indicators of disaster risk and vulnerability); ii) *early warning* (people-centred, information systems, institutional capacities, better cooperation); iii) *capacity* (support for infrastructures, databases, support for methods and capacities); and iv) *regional and emerging risks* (cooperation, early warning, research on long-term changes: climate trends, diseases, land-use, environmental hotspots, slope deforestation, demographic changes and density, rapid urbanization, relevant trade factors). For reducing underlying risk factors, the document has referred to: i) *environmental and natural resource management*; ii) *social and economic development*

practices; and iii) *land-use planning and other technical measures*.

On a regional European level, the Commission of the European Communities, in its "Strategic Objectives 2005–2009 – Europe 2010: A Partnership for European Renewal: Prosperity, Solidarity and Security" (26 January 2005) stated that the security of the citizen "can be put at risk by natural disasters, environmental or health crises and transport and energy threats". The President of the Commission stated that "the Union has a role to play at all stages: risk prevention, early warning, crisis management, and acting in solidarity with the victims of disasters". One of the five key security themes will be: "managing risk in the modern world". The Commission documents as the first of three tasks:

> Environmental and health risks such as the increased threats of floods or droughts following climate change, the fallout from potential biological, chemical or radiological attacks of serious outbreaks of disease have immediate EU-wide implications. They must be tackled in two ways: by the ability to offer early warning and immediate response to a particular crisis, and by long-term prevention. Information and surveillance networks need to be effective if they are to cope adequately with cross-border threats.

With regard to "Europe as a world partner", the strategic objectives of the European Commission called for: 1) a stronger actor in the world economy; 2) global solidarity; and 3) making security work worldwide to enable Europe "to tackle stability and security issues at their root by strongly promoting sustainable development through both multilateral and bilateral channels".

The security part of the EU Commission's "Strategic Objectives" reflected the debate on reconceptualization of security by shifting the focus from narrow military threats to: a) non-military security challenges for justice and home affairs (to counter crime, terrorism, human and drug trafficking); b) natural disasters, environmental and health risks; c) energy supply crises and vulnerability of traffic and energy infrastructure; and d) promoting global solidarity with sustainable development.

These declaratory policy goals of the UN's *Hyogo Declaration* and the EU's *Strategic Objective*s reflect both a reconceptualization and a redefinition of security 'threats', 'challenges', 'vulnerabilities' and 'risks' with an application to natural hazards. In 2005, the Hyogo Framework for Action 2005–2015 requested the UNISDR secretariat to "update and widely disseminate international standard terminology related to disaster risk reduction". In the 2009 version, the terms were revised and are now defined by a single sentence (table 2.1).[23]

These adopted definitions apply to the risk related activities of many international organizations and they are also used by many governments for guidance.

2.6 Environmental Security Threats, Challenges, Vulnerabilities and Risks

The contextual change since 1990 and the scientific changes in several disciplines have contributed to a widening and a deepening of 'security' and accordingly the related concepts of security threats, challenges, vulnerabilities and risks have also changed. Since 1989 a debate has evolved on the 'environmental security dimension' and on 'environmental' or 'ecological' threats, challenges, vulnerabilities and risks for national, international and human security.

2.6.1 The Environment as New 'Threats' to National Security

The scientific debate on environmental security started at the end of the Cold War. Westing (1988: 257–264) pointed to both the military impact on the environment and to environmental factors of security, such as territorial, shared or extra-territorial resources that require mechanisms for the non-violent resolution of resource conflicts. The former Norwegian Foreign Minister Holst (1989: 123–128) saw a triple relationship between conflict and environment: a) *environmental deterioration* (space, atmosphere, lithosphere, hydrosphere, biosphere) as a consequence of armed conflict; b) *environmental degradation* (due to poverty, injustice, population growth) as a *cause* of conflict; and c) *self-reinforcing environmental degradation* (refugees, food riots, urban violence) as a *contribution* to armed conflict. Both environmental impacts of military activities and of wars, and the environment as a cause or contributing factor to hazards, migration, crises and in the extreme case also to conflicts have posed 'threats', 'challenges', 'vulnerabilities' and 'risks' that have been conceptualized since the late 1980's in the context of US 'na-

23 See the complete list of UNISDR key terminology on *Disaster Risk Reduction* at: < http://www.unisdr.org/eng/terminology/terminology-2009-eng.html> that reflects the ISO guide on risk management.

Table 2.1: Selected UNISDR key terminology on *Disaster Risk Reduction*. **Source:** UNISDR; at: <http://www.unisdr.org/eng/terminology/terminology-2009-eng.html>.

Term	Definition	Comment
Acceptable risk	The level of potential losses that a society or community considers acceptable given existing social, economic, political, cultural, technical and environmental conditions.	In engineering terms, acceptable risk is also used to assess and define the structural and non-structural measures that are needed in order to reduce possible harm to people, property, services and systems to a chosen tolerated level, according to codes or 'accepted practice' which are based on known probabilities of hazards and other factors.
Corrective disaster risk management	Management activities that address and seek to correct or reduce disaster risks which are already present.	This concept aims to distinguish between the risks that are already present, and which need to be managed and reduced now, and the prospective risks that may develop in future if risk reduction policies are not put in place. See also Prospective risk management.
Disaster risk	The potential disaster losses, in lives, health status, livelihoods, assets and services, which could occur to a particular community or a society over some specified future time period.	The definition of disaster risk reflects the concept of disasters as the outcome of continuously present conditions of risk. Disaster risk comprises different types of potential losses which are often difficult to quantify. Nevertheless, with knowledge of the prevailing hazards and the patterns of population and socio-economic development, disaster risks can be assessed and mapped, in broad terms at least.
Disaster risk management	The systematic process of using administrative directives, organizations, and operational skills and capacities to implement strategies, policies and improved coping capacities in order to lessen the adverse impacts of hazards and the possibility of disaster.	This term is an extension of the more general term 'risk management' to address the specific issue of disaster risks. Disaster risk management aims to avoid, lessen or transfer the adverse effects of hazards through activities and measures for prevention, mitigation and preparedness.
Disaster risk reduction	The concept and practice of reducing disaster risks through systematic efforts to analyse and manage the causal factors of disasters, including through reduced exposure to hazards, lessened vulnerability of people and property, wise management of land and the environment, and improved preparedness for adverse events.	A comprehensive approach to reduce disaster risks is set out in the United Nations-endorsed Hyogo Framework for Action, adopted in 2005, whose expected outcome is "The substantial reduction of disaster losses, in lives and the social, economic and environmental assets of communities and countries." The International Strategy for Disaster Reduction (ISDR) system provides a vehicle for cooperation among Governments, organizations and civil society actors to assist in the implementation of the Framework. Note that while the term 'disaster reduction' is sometimes used, the term 'disaster risk reduction' provides a better recognition of the ongoing nature of disaster risks and the ongoing potential to reduce these risks.
Disaster risk reduction plan	A document prepared by an authority, sector, organization or enterprise that sets out goals and specific objectives for reducing disaster risks together with related actions to accomplish these objectives.	Disaster risk reduction plans should be guided by the Hyogo Framework and considered and coordinated within relevant development plans, resource allocations and programme activities. National level plans need to be specific to each level of administrative responsibility and adapted to the different social and geographical circumstances that are present. The time frame and responsibilities for implementation and the sources of funding should be specified in the plan. Linkages to climate change adaptation plans should be made where possible.
Extensive risk	The widespread risk associated with the exposure of dispersed populations to repeated or persistent hazard conditions of low or moderate intensity, often of a highly localized nature, which can lead to debilitating cumulative disaster impacts.	Extensive risk is mainly a characteristic of rural areas and urban margins where communities are exposed to, and vulnerable to, recurring localized floods, landslides storms or drought. Extensive risk is often associated with poverty, urbanization and environmental degradation. See also 'Intensive risk'.

Term	Definition	Comment
Intensive risk	The risk associated with the exposure of large concentrations of people and economic activities to intense hazard events, which can lead to potentially catastrophic disaster impacts involving high mortality and asset loss.	Intensive risk is mainly a characteristic of large cities or densely populated areas that are not only exposed to intense hazards such as strong earthquakes, active volcanoes, heavy floods, tsunamis, or major storms but also have high levels of vulnerability to these hazards. See also 'Extensive risk'.
National platform for disaster risk reduction	A generic term for national mechanisms for coordination and policy guidance on disaster risk reduction that are multi-sectoral and inter-disciplinary in nature, with public, private and civil society participation involving all concerned entities within a country.	This definition is derived from footnote 10 of the Hyogo Framework. Disaster risk reduction requires the knowledge, capacities and inputs of a wide range of sectors and organizations, including United Nations agencies present at the national level, as appropriate. Most sectors are affected directly or indirectly by disasters and many have specific responsibilities that impinge upon disaster risks. National platforms provide a means to enhance national action to reduce disaster risks, and they represent the national mechanism for the ISDR.
Prospective disaster risk management	Management activities that address and seek to avoid the development of new or increased disaster risks.	This concept focuses on addressing risks that may develop in future if risk reduction policies are not put in place, rather than on the risks that are already present and which can be managed and reduced now. See also Corrective disaster risk management
Residual risk	The risk that remains in unmanaged form, even when effective disaster risk reduction measures are in place, and for which emergency response and recovery capacities must be maintained.	The presence of residual risk implies a continuing need to develop and support effective capacities for emergency services, preparedness, response and recovery together with socio-economic policies such as safety nets and risk transfer mechanisms.
Risk	The combination of the probability of an event and its negative consequences.	This definition closely follows the definition of the ISO/IEC Guide 73. The word 'risk' has two distinctive connotations: in popular usage the emphasis is usually placed on the concept of chance or possibility, such as in 'the risk of an accident'; whereas in technical settings the emphasis is usually placed on the consequences, in terms of 'potential losses' for some particular cause, place and period. It can be noted that people do not necessarily share the same perceptions of the significance and underlying causes of different risks.
Risk assessment	A methodology to determine the nature and extent of risk by analysing potential hazards and evaluating existing conditions of vulnerability that together could potentially harm exposed people, property, services, livelihoods and the environment on which they depend.	Risk assessments (and associated risk mapping) include: a review of the technical characteristics of hazards such as their location, intensity, frequency and probability; the analysis of exposure and vulnerability including the physical social, health, economic and environmental dimensions; and the evaluation of the effectiveness of prevailing and alternative coping capacities in respect to likely risk scenarios. This series of activities is sometimes known as a risk analysis process.
Risk management	The systematic approach and practice of managing uncertainty to minimize potential harm and loss.	Risk management comprises risk assessment and analysis, and the implementation of strategies and specific actions to control, reduce and transfer risks. It is widely practised by organizations to minimize risk in investment decisions and to address operational risks such as those of business disruption, production failure, environmental damage, social impacts and damage from fire and natural hazards. Risk management is a core issue for sectors such as water supply, energy and agriculture whose production is directly affected by extremes of weather and climate.

Term	Definition	Comment
Risk transfer	The process of formally or informally shifting the financial consequences of particular risks from one party to another whereby a household, community, enterprise or state authority will obtain resources from the other party after a disaster occurs, in exchange for ongoing or compensatory social or financial benefits provided to that other party.	Insurance is a well-known form of risk transfer, where coverage of a risk is obtained from an insurer in exchange for ongoing premiums paid to the insurer. Risk transfer can occur informally within family and community networks where there are reciprocal expectations of mutual aid by means of gifts or credit, as well as formally where governments, insurers, multilateral banks and other large risk-bearing entities establish mechanisms to help cope with losses in major events. Such mechanisms include insurance and re-insurance contracts, catastrophe bonds, contingent credit facilities and reserve funds, where the costs are covered by premiums, investor contributions, interest rates and past savings, respectively.

tional security' and since the 1990's increasingly also as dangers to 'human security'.

Within the framework of national security Mathews (1989) and Myers (1989, 1989a) argued: "First there was a need to redefine security and to include a new range of threats. ... Second, there was an acceptance that the object of security was no longer simply the state, but ranges to levels above and below the level of the state" (Lonergan 2002: 270–271). Mathews (1989: 162) proposed a "broadening definition of national security to include resource, environmental and demographic issues". She warned that global changes "in the chemical composition of the atmosphere, in the genetic diversity of species inhabiting the planet, and in the cycling of vital chemicals through the oceans, atmosphere, biosphere and geosphere" could lead to irreversible damage. Myers (1989: 23–41) pointed to several environmental factors (soil erosion, ozone layer, climate change) as legitimate causes for international concern that may have repercussions for US security policy. Myers (1993, 1994, 1996: 12) also claimed that the "principal threat to security and peace stems from environmental breakdown" and that environmental problems can "figure as causes of conflict", such as water in the Middle East, desertification in the Sahel, water diversion or flooding in Bangladesh. Myers (1993: 20–21) equated security with "human well-being; not only from harm and injury but access to water, food, shelter, health, employment, and other basic requisites". He warned if the environmental foundations are depleted:

> the nation's economy will eventually decline, its social fabric will deteriorate, and its political structure will become destabilized. The outcome is all too likely to be conflict, whether in the form of disorder and insurrection within a nation or tensions and hostilities with other nations. ... National security is no longer about fighting forces and weaponry alone. It relates to watersheds, croplands, forests, genetic resources, climate, and other factors rarely considered by military experts and political leaders, but that taken together deserve to be viewed as equally crucial to a nation's security as military prowess.

Myers (1996: 22) analysed as environmental factors contributing to conflict: population growth, ozone layer depletion and global warming, mass extinction of species and as a direct consequence: environmental refugees. These 'Neo-Malthusian' (Malthus 1789 [1993]) and 'realist' concerns that focused on the 'state' as the major referent object had a conceptual impact on the US defence and security policy during the Clinton administration but they were discontinued by his successor (Matthew/McDonald 2009).

2.6.2 'Environmental Security Agenda' as an Object of Securitization

Simultaneously the Copenhagen school has widened the scope of security from a 'constructivist perspective'. According to Buzan, Kelstrup, Lemaitre, Tomer and Wæver (1990) "*Environmental security* concerns the maintenance of the local and the planetary biosphere as the essential support system on which all human enterprises depend." Later, Buzan, Wæver and de Wilde (1998: 71–93) noted a scientific and a political agenda on how to analyse and deal with these concerns.

> The scientific agenda underpins securitizing moves, whereas the political agenda is about three areas: (1) state and public awareness of issues on the scientific agenda ...; (2) the acceptance of political responsibility for dealing with these issues; and (3) the political management questions that arise: problems of international cooperation and institutionalization – in particular regime formation, the effectiveness of unilateral national initiatives, distribution of costs and benefits, free-rider dilemmas, problems of enforcement, and so forth (Buzan/Wæver/de Wilde 1998: 72).

On the scientific environmental agenda the following issues are often included (Buzan/Wæver/de Wilde

1998: 74–75): a) *Disruption of ecosystems* (climate change; biodiversity loss, deforestation, desertification, soil erosion; ozone layer depletion; pollution); b) *energy problems* (natural resource depletion, pollution, disaster depletion, nuclear energy, oil transportation, chemical industries, scarcities, uneven distribution); c) *population problems* (population growth, consumption beyond carrying capacity, epidemics, poor health conditions, declining literacy rates, uncontrollable migrations, unmanageable urbanization); d) *food problems (*poverty, famines, overconsumption, diseases related to extremes; loss of fertile soils and water resources; epidemics and poor health conditions; scarcities, uneven distribution); e) *economic problems* (protection of unsustainable production, societal instability leading to cyclical and hegemonic breakdowns, structural asymmetries and inequality); and f) *civil strife* (war-related environmental damage and violence related to environmental degradation). Securitization efforts were made at all levels but the most effective were on the local level. For Buzan (2004), the 'state' and the 'society' remained major referents of securitization, and he was sceptical to the human security concept. More recently, Buzan and Hansen (2009) reviewed the gradual development of environmental security in a broader and systematic context of the evolution of international security studies.

2.6.3 'Environmental Security Issues' as New Causes of Conflicts

So far four phases of research on environmental security issues have been distinguished. Dalby, Brauch and Oswald Spring (2009) have recently reviewed the first three phases of environmental security research and Oswald Spring, Brauch and Dalby (2009; Brauch 2003, 2003a) have suggested to include in the research agenda for the fourth research phase, a human security perspective and to address gender issues and natural hazards. In this volume, Brauch, Dalby and Oswald Spring (chap. 94) suggest a new multidisciplinary approach of a 'political geoecology' and to introduce the 'political' dimension into Earth Systems Science as well as knowledge from the natural sciences into the discourses on environmental and human security.

In the centre of the second empirical phase of the debate on environmental security have been many case studies conducted by two research teams in Toronto (Homer Dixon 1991, 1994, 1999, 2000), and in Zurich and Berne (Bächler/Spillmann 1996, 1996a, 1996b; Bächler 1999; Bächler/Spillmann/Suliman 2002). They focused on the linkages between environmental stress and extreme outcomes: societal crises, domestic or international conflicts and cooperation.

While these case studies focused primarily on environmental scarcity ('*grievance*') other more recent studies have argued that resource abundance (diamonds, coltan et cetera) or 'greed' has been a major cause for the new wars by local war lords (Gleditsch 2001, 2003; Conca/Dabelko 2002; Collier 2000, Bannon/Collier 2003; Collier/Elliott/Hegre/ Hoeffler/ Reynal Querol/Sambanis 2003). A recent study by Kipping (2009) has shown that water scarcity in the Senegal River basin has been the reason for cooperation between Senegal and Mauritania. But after the building of dams and introduction of irrigated agriculture water abundance had became a cause of violent conflict.

John Gerard Ruggie (1998: 155–171) argued on the eco-demographic contexts of emerging new conflicts in developing countries that a part of the populations may experience "institutional barriers long before they encounter absolute physical scarcity" which may result in a spillover of population pressures into international conflict behaviour. On rapid urbanization, Ruggie (1998: 163) emphasized that social turmoil may result from the "insufficient capacity on the part of the cities to service such large increments of population in so short a time. A social turmoil in turn may provide targets of opportunity, either for domestic forces to internationalize the problem or for foreign forces to meddle in domestic affairs". Ruggie concluded that in contrast to the past, the "interplay between socio-economic forces and biophysical factors have reached a planetary scale".

Paul Kennedy (2000: 239–245) stated that environmental pressures "could produce threats to human well-being and social stability" and that, if the projected effects of climate change are accurate, "then mankind will face atmospheric turbulences and environmental hazards in the future that will cause distress: melting of the polar ice caps, rise in sea levels, more extreme weather conditions, greater storm damage, crop displacement, and habitat changes", challenges that could be addressed with regular means, at least in the US. But on the regional and local level these environmental damages could result in unrest and migration often combined with violence. He argued that the new global challenges, including global warming and migration pressure, which are further intensified by demographic and environmental stress, bring some societies to worrying thresholds and thus

could become threats to national and international stability.

Since 2007, climate change has been added to the political and scientific agenda as an object of securitization and as a potential cause of international, national and human security as well as a trigger or force multiplier resulting in different forms of primarily small-scale conflict.[24] At least five different approaches may be distinguished of policy analysis, causal analysis, scenario analysis, discourse analysis (of securitization moves by policy-makers and international organizations) and quantitative correlation analyses.

2.6.4 Environmental Security 'Threats', 'Challenges', 'Vulnerabilities', and 'Risks'

Security with its dual focus is achieved if there is an absence of objective threats and subjective fears to basic values. The ecosystem was introduced as the reference object of '*environmental security*'. Its values at risk are sustainability and the sources of dangers are humankind and global environmental change. The environment is considered both as a cause and an object of specific threats, challenges, vulnerabilities, and risks posed by GEC, by environmental pollution and by natural hazards to the 'objective' and 'subjective' security of human beings and humankind (*human security*), of societal groups (*societal security*), of nation states (*national security*), and of association of states (*European security*) from the impacts in the most affected states outside of the EU, for macro regions (*regional security*), and in a few extreme cases, such as 'abrupt climate change' (NRC 2002) also for the Earth (*global security*). While most securitization efforts have focused on the 'state' or on the 'society' as major referent objects, Westing (1989, 1989a: 129–134) introduced the environment into a 'comprehensive human security' concept that requires both a *protection* (quality of the environment) and a *utilization* requirement (human welfare). In this concept renewable natural resources must be used in a sustainable way.

Table 2.2 provides a heuristic compilation of possible linkages between environmental causes, stressors, impacts or outcomes that may pose security threats, challenges, vulnerabilities, and risks for human beings or humankind within their respective natural environment. Natural and human-induced hazards are rapid onset events also influenced by long-term, creeping or structural factors or processes.

Hazards and hazard-induced distress or forced migration may trigger socio-political consequences beyond the traditional scope of the hazard community, such as societal crises among residents and migrants competing for scarce soil and water for food security and survival.[25] These socio-political consequences have become an object of securitization in the context of a human security approach with the affected human beings as referent objects.

2.6.5 Environmental Factors as Security Threats, Challenges, Vulnerabilities, and Risks

Contrary to the 'state-centred national security' concepts of the realist school, global environmental change, as well as hydro-meteorological hazards, affect primarily the individual or humankind whose perception of 'insecurity' therefore change. Environmental factors, both *rapid-onset* hydro-meteorological hazards and *creeping* challenges posed by global environmental change have increased 'human insecurity' by confronting the highly vulnerable and poor people with a 'survival dilemma' (Brauch 2008b): either to stay at home in their village continuing their traditional livelihood, or to move first to the next major urban centre. The young and those who can afford it have of course a third possibility: to move to a country or a region that offers them better economic conditions and future prospects for survival of their family.

Hazard-induced or environmentally triggered distress migration has become a major 'human' and 'societal' security challenge for the 21st century. In Europe, in the US, but also in India, the counter strategies have been similar in tightening border controls. However, these measures could neither stop nor prevent immigration, they rather increased the number of illegal immigrants from Mexico to the US (Oswald

24 There is rapidly growing political, consultancy and scientific literature on the 'climate change-security-conflict' nexus: BMU 2002; WBGU 2007, 2008; EU 2008; UNSG 2009; Maas/Tänzler 2009; Bushby 2009; Breitmeier 2009; Gleditsch/Nordas 2009; Brauch 2009a; chap. 1 by Brauch/Oswald Spring and 95 by Oswald Spring/Brauch; chap. 41 by Bauer; chap. 42 by Scheffran.

Environmental causes, stressors, effects and natural hazards that pose	**Natural and economic factors**		**Societal impact factors (exposure)**	
	Substantial threats for	**Challenges affecting**	**Vulnerabilities for**	**Risks for**
	Security objects (for what or whom?)			
Climate change • temperature increase (creeping, long-term)	• Human health • agriculture (yield decline) • biodiversity • desertification	• tourism • food security • fisheries • government action • economic action	• infectious disease • damage to crops • natural systems • water scarcity • forest fire	• human populations • the poor, old people and children due to heatwaves
Climate change • sea level rise (creeping, long-term)	• Small island states • marine ecosystem, • indigenous communities, • industry, energy	• deltas • coastal zones • marine, freshwater ecosystems	• coastal cities, habitats, infrastructure, jobs • cities, homes, jobs	• livelihood • poor people, • insurance, • financial services
Climate change • -Extreme weather events: • storms (hurricanes, cyclones, winter storms)	• Habitat, technical infrastructure, transportation, etc	• forests (health of trees) • food security	• coastal ecosystems • forests, settlements • electricity transmission	• human life & property • insurance, • financial services
Climate change • Extreme weather events: floods	• Habitat, technical infrastructure and people	• vulnerable, flood-prone areas	• persons living in flood-prone areas	• human life & property
Climate change • Extreme weather events: drought	• Availability of water and food, survival of people	• decreased crop yield and water quality & quantity	• arid and semi-arid zones, agriculture • forests (tree health)	• human life & animals, property
Tipping points in the climate system (crossing thresholds due to linear climate change impacts)[a)]	• unforeseeable consequences • for water, soil, food and livelihood security	• agriculture, • tourism • urban habitats	• damage to crops • natural systems • water scarcity • forest fire	• human populations • the poor, old people and children due to heatwaves
Abrupt climate change (shutoff of the Gulf Stream in the North Atlantic) • e.g. cooling in Central and Northern Europe, in North America (USA)	• Countries and people in Northern Europe, benefiting from Gulf Stream	• livelihood • survival	• agriculture • habitat • people	• human life & animals, property • forced migration of people
Geophysical hazards • earthquakes, • volcanic eruptions • tsunamis	Hazard prone areas • regional and local affected areas • coastal areas (in Indian Ocean)	• habitat, • technical & economic infrastructure • people	• poor living in hazard prone areas and in vulnerable housing	• poor people with little resilience & disaster preparedness, no insurance
Soil erosion, desertification, drought	• water scarcity • agriculture • habitats	• food security • human livelihood (forced migration)	• livelihoods • rural areas • specific crops	• people & livestock in rural areas • people in slums

Table 2.2: Compilation of environmental threats, challenges, vulnerabilities, and risks. **Source:** Compiled by the author.

Deforestation	• Landscape, cities, habitat	• water availability	• landslides	• informal housing (slums)
Water scarcity and degradation	• Agriculture, food security, people	• econ. behaviour • human health	• poor in slums	• old people, children, poor
Forced Migration	• Resident population, clash on water and food	• overgrazing on marginal soils, • environment	• fragile ecosystems • people on the move	• migrants and their animals

a) Lenton, Held, Kriegler, Hall, Lucht, Ramsdorf, and Schellnhuber (2008: 1186) argued that the term 'tipping point' has been used in discussions of global change "to describe a variety of phenomena, including the appearance of a positive feedback, reversible phase transitions, phase transitions with hysteresis effects, and bifurcations where the transition is smooth but the future path of the system depends on the noise at a critical point". They offered "a formal definition, introducing the term 'tipping element' to describe subsystems of the Earth system that are at least subcontinental in scale and can be switched – under certain circumstances – into a qualitatively different state by small perturbations. The tipping point is the corresponding critical point – in forcing and a feature of the system – at which the future state of the system is qualitatively altered". They pointed to the melting of the Arctic sea-ice, rapid changes in the Greenland and in the West Antarctic ice sheet, a shutoff of the Gulf Stream (Atlantic Thermohaline Circulation), changes in the El Niño-Southern Oscillation (ENSO), in the Indian summer monsoon, in the Sahara/Sahel and West African monsoon, a drying of the Amazon basin and changes in boreal forests. The potential political and security consequences of these non-linear or chaotic perturbations in the climate system once unknown thresholds have been crossed have not yet been analysed and may only be discussed in the context of worst-case impact scenarios.

Spring/Brauch 2005; Verduzco/de Lozano 2010; chap. 26 by Brauch and chap. 47 by Brauch/Oswald Spring).

2.6.6 Proactive Security Response Strategies

Addressing the environmental dangers to security (table 2.2) requires a complex combination of strategic instruments and policies to reduce the vulnerability to natural hazards and the related risks for human beings and affected societal groups. Thus a dual strategy is needed for dealing with: *short-term situational* impacts of extreme weather events and natural hazards; and *longer-term structural impacts* of global environmental change. While the global environmental change, the climate change and the hazard research communities have used different concepts of environmental, social and economic vulnerabilities and risks, a conceptual and a policy-oriented mainstreaming is needed to address both impacts. Three groups of vulnerability and risk indicators are needed: for both climate change and hydro-meteorological hazards; for specific hazards (storms, floods, drought), and for temperature increase and sea-level rise.

Thus, effective climate policies with legally binding obligations may be the most cost-effective solutions to counter the projected increase in extreme weather events. To respond to these complex and manifold environmental security threats, challenges, vulnerabilities, and risks as well as to those posed by manifold hazards, it is primarily *proactive* non-military policies and measures (table 2.3) which are needed. More conceptual work on the linkages between 'environmental' and 'human' security is necessary, but also between economic production and ecosystems (N. Georgescu-Roegen 1971). Mainstreaming efforts are required on the scientific and political tracks with regard to the environmental dimension of human security (conceptualization in the scientific community); and a 'paradigm shift' in the UN system from 'national' towards 'human security' perspectives.

With regard to the work of international organizations, a dual mainstreaming may be needed:

- to incorporate a 'human security perspective' into environmental security initiatives, such as ENVSEC of OSCE, UNEP, UNDP[26] and NATO (Cheterian 2009) into the green diplomacy of the European Union launched at the European Council in Thessaloniki in June 2003; and
- to include an 'environmental security dimension' into the work of the *Human Security Network*

26 See the joint initiative of OSCE, UNEP and UNDP on: *An Environment Agenda for Security and Cooperation in South Eastern Europe and Central Asia*; at: <http://www.iisd.org/natres/security/envsec/>; <www.osce.org/documents/sg/2003/01/324_en.pdf>; and at: <http://www.oecd.org/dataoecd/53/3/33687392.pdf>.

Table 2.3: Human security policies and measures for coping with environmental threats, challenges, vulnerabilities, and risks for ecosystems and sustainability. **Source:** Compiled by the author.

Strategies and means for coping with	Threats of	Challenges for	Vulnerabilities of	Risks of
	Environmental Security for			
Sustainable development policy goals	• Air (climate), soil, water	• agriculture and food security	• vulnerable people (old, children, women, indigenous groups)	
Environment policy (implementation of environmental treaties, regimes)	• Climate change, • soil erosion, • water scarcity and degradation	• economy • agriculture • tourism • health	• rural livelihood • urban habitat • transport & econo- • mic infrastructure	• reducing exposure of people with low resilience
Early recognition (research, education, training, agenda-setting)	• Extreme weather events (storm, flood, drought)	• agriculture (shift in crops)	• city planning • building standards	• enhancing knowledge of these people
Early warning of hazards and disasters	• Hydro-meteorological (storms, floods, drought) and geophysical (earthquake, volcano, tsunami) hazards	• agriculture (specific crops) • public health	• vulnerability mapping of hazard prone areas and housing	• enhancing training of these people
Effective disaster preparedness and rapid disaster response		• (inter)national organizations and resources	• vulnerability mapping of hazard prone areas and housing	• enhancing protection of these people
Humanitarian aid	• Hazards and conflicts	• access to affected areas	• spread of infectious disease	• reducing low recognition
Refugee assistance	• Distress migration	• environment • food supply	• refugees (in times of conflict)	• old, weak and poor

(HSN) focusing primarily on 'freedom from fear', elaborating it further also in the context of the report of the *Commission on Human Security* (CHS 2003) focusing on 'freedom from want' by adding a new pillar of 'freedom from hazard impact' (Brauch 2009b; Fuentes Julio/Brauch 2009);
- to launch a Mediterranean Environmental and Human Security Initiative (MEH-SEC) within the Union for the Mediterranean (Brauch 2010).

Including vulnerability concerns into the human security concept and in their environmental management plans requires the active involvement of other UN agencies and programmes.

2.7 Human Security Threats, Challenges, Vulnerabilities, and Risks

Parallel to the academic debate on environmental security that influenced the policy agenda of several international organizations, the human security concept used by UNDP (1994) triggered a global and ongoing political and scientific debate. UN Secretary-General Kofi Annan (2001) has referred to the need for a human-centred approach to security that must encompass "economic development, social justice, environmental protection, democratization, disarmament, and respect for human rights and the rule of law".

UNESCO (1997, 1998, 1998a, 2001, 2001a, 2003) has been instrumental for initiating and supporting the scientific debate on 'human security' especially in developing countries, by organizing regional conferences in all parts of the world (UNESCO 2008; Goucha/Crowley 2008). These regional conceptual efforts have linked the debate with pertinent security concerns. An intensive debate is continuing in OECD countries and there is a growing debate in developing countries focusing on specific 'human security' (HS) threats, challenges vulnerabilities, and risks (Brauch 2009b).

2.7.1 Towards a Human-centred Environmental Security Concept

What poses a threat, challenge, vulnerability or risk to human security, both to the individual human being

or to humankind, depends on whether a 'wide' or a 'narrow' HS concept is chosen focusing on 'freedom from want' (Japanese concept, CHS 2003), 'freedom from fear' (Norwegian and Canadian concept), 'freedom to live in dignity' (Annan 2005) or 'freedom from hazard impact' (Bogardi/Brauch 2005). GECHS (1999) argued that the following types of environmental change affect *human security*: a) natural disasters, b) cumulative changes or slow-onset changes, c) accidental disruptions or industrial accidents, d) development projects, and e) conflict and warfare.

Barnett (2001: 127) considered a "human-centred environmental security concept" as justified on moral and pragmatic grounds "because addressing the welfare of the most disadvantaged means addressing many of the future sources of environmental degradation" by protecting the rights of the most vulnerable members of society and by enhancing "welfare, peace and justice" on which legitimate institutions should be built which are required "for human and environmental security" (Conca 1994, 1994a). Najam (2003: 1–24) proposed an environment and security discussion around two sources of insecurity (violent conflict and social eruption), and to focus the analysis on state centred and society centred activities. This leads him to four outcomes: 1) *interstate war* (state centred violent conflict); 2) *civil strife* (society centred violent conflict); 3) *institutional failure* (state centred social disruption); and 4) *human insecurity* (as a society centred social disruption).

Barnett, Matthew and O'Brien (2008) and Matthew, Barnett, Mc Donald and O'Brien (2010, 2010a) offered a glimpse on the work the *Global Environmental Change and Human Security* (GECHS) project within the *International Human Dimensions Programme* (IHDP) that has been pursued from 1996 to June 2009 when the project ended with a synthesis conference. Barnett, Matthew and O'Brien (2010: 4) argued that "global environmental change poses new and in some cases unprecedented threats to human security ... that transcend the North-South binary and the 'rich-poor' dichotomy" and they discussed "how a human security orientation to environmental change can contribute to initiatives such as the Millennium Development Goals (MDGs)". In contrast to national or state security, human security "securitizes ...what individuals themselves see as their paramount concerns, and so pluralizes the meaning of security and opens up space for alternative security practices. It adds to the concept of human development ... by focusing on immediate concerns such as basic needs and peace, and by directing attention toward the most vulnerable (Gasper/Truong 2005)" (Barnett/Matthew/O'Brien 2010: 9). They concluded that "global environmental change is adding impetus to the realization that traditional understandings of security are limited and are an inadequate basis for making policy" and that GEC "is raising new and unavoidable question to equity and sustainability, which already underlie every aspect of human security". Finally they called "for greater integration of the security, development, and sustainable development research and policy communities, which have for too long been too distinct".

2.7.2 Human Security Threats, Challenges, Vulnerability, and Risks

From a human security perspective many threats, challenges, vulnerabilities, and risks exist for the major referent: the individual human being or humankind in contrast to the state in prevailing national security concepts. From a human security perspective all five security dimensions and also sectoral security concepts may be analysed. Human security is infringed by underdevelopment ('want'), conflicts and human rights violations ('fear'), by hazards and disasters ('hazard impact') and by the violation of human rights ('to live in dignity'). These four pillars of human insecurity pose threats, challenges, vulnerabilities, and risks to different aspects of human security and call for three different but interrelated strategies for coping and overcoming human insecurity for which different national and international organizations and means are needed.

All four pillars of human insecurity (want, fear, hazard impact, indignity) also impact on health insecurity. Chen and Narasimhan (2003: 3–12) in their human security agenda for global health argued that three factors: 1) conflicts and humanitarian emergencies; 2) infectious crisis (HIV/AIDS); and 3) impoverishment impact on illness, injury, disability, death posing critical pervasive threats to the vital core of human security: human survival and flourishing; livelihood; and dignity. For Leaning, Arie, Holleufer and Bruderlein (2003: 13–30) measuring human security focuses on the fulfilment of basic needs, and home, community and future.

Table 2.4: Compilation of human security threats, challenges, vulnerabilities, and risks**. Source:** Compiled by the author.

Dangers for Human Security Posed by	Human Security			
	Threats to	**Challenges for**	**Vulnerabilities to**	**Risks for**
Underdevelopment ('freedom of want')	• Human well- being, • human health • life expectancy	• social safety nets • human development • food security	• economic crisis and shocks • communicable diseases	those most vulnerable (socially, economically) and exposed to underdevelopment, violence and hazards: • peasants, • poor • women, • children, • old people • indigenous people • minorities.
Conflicts and human rights violations ('freedom from fear')	• Human life and personal safety (from wars) • identity, values	• feeling secure in a community • human rights • democracy	• warlords, criminals • corrupt regime, ruler • human rights abuses, violations	
Hazards and disasters ('freedom from hazard impact')	• Livelihood • survival • settlements, urban slums	• sustainable development • food security	• exposed population • livelihoods, habitat • disease (cholera, dengue, malaria, etc.)	
Violation of basic laws, lack of good governance ('freedom to live in dignity')	• human dignity, • human rights, • basic human needs	• rule of law, • democratic system of rule • peaceful conflict resolution	• corruption and organized crime	• rights of the citizens • human well-being

2.8 Conclusions for Research and Policy Suggestions

This survey reviewed the many political and scientific concepts dealing with four basic dangers undermining security, namely 'threats', 'challenges', 'vulnerabilities', and 'risks'. These concepts have been used in several scientific disciplines (political science, economics, psychology, sociology, international law) and research communities focusing on global environmental change, sustainable development, climate change as well as on hazards and disasters both in policy discourses and declarations.

This survey of scientific concepts has been a part of a scientific effort to reconceptualize security, its five dimensions, its levels of analyses since the global turn of 1989 and 1990 (global security order), since the terrorist attack on the United States of 11 September 2001 resulting in 'personal violence' and wars (Afghanistan, Iraq) and since the global financial crisis of 2008 resulting in 'structural violence' where millions of people lost their homes (e.g. in the United States), their income (rise in global unemployment, loss of pensions), their right to food (price hikes in basic food staples with resulting food riots during 2008 and major increase in hunger in the poor countries and among the poorest people in many countries since 2008 and 2009).

Due to globalization, trade flows, foreign investments and the exchange of information based on new forms of communication have not only increased, but non-state actors and processes beyond the control of the nation states and international organizations have also posed multiple new security threats, challenges, vulnerabilities, and risks that have resulted in new forms of 'invisible' antipersonnel and structural terrorism. While the instigators of the antipersonnel terrorism have become the object of a 'war on terror', those who caused and are responsible for the new 'structural terrorism' that deprived millions of people of their livelihood, income, economic well-being, and that threatened the common European currency have so far remained a part of the system that determined the rules that made this form of structural terrorism possible, and it is unclear whether the rules will or can be changed to permit that they can be brought to justice for violating national laws.

Since 1990 in many countries a widening of security has occurred away from the narrow military, political and economic security of the Cold War towards a

wider scope that has also included societal and environmental dimensions, but also a temporary return to a narrow Hobbesian (1651, [1965], 1658) primarily military security concept. In the 21st century, with regard to the thinking on security and sovereignty, three different contexts have coexisted:

- the *pre-modern* world where state sovereignty and the ability to rule the whole state territory has ceased to exist in so-called 'failing', or 'failed states', many of them having fallen victim to internal conflicts or civil wars where warlords control part of the country and major resources;
- the *modern* world where the defence of the Westphalian state and of its population and territory against undue outside intervention and intrusion is a major goal of 'national security' policies;
- the *postmodern* world where a progressive internal de-borderization (e.g. within the EU) combined with a tightening of external borders has occurred and both integration and globalization processes have reduced the classical *domaine réservé* of the nation state.

In addition, since the early 1990's, influenced by the concerns for 'human development' (UNDP 1994), a shift in the referent object of the security concept has taken place from an exclusive focus on the 'nation state' to 'human beings and humankind' or from the prevailing 'national security' to 'human security'. Since the late 1990's two parallel debates have taken place on 'environmental security' and on 'human security' both in the social sciences and within international organizations that have also been stimulated by several international commissions and high-level expert panels.

Within the UN system, UNU-EHS has started to advance the development of the 'environmental dimension of human security' (Bogardi/Brauch 2005; Brauch 2003, 2005, 2005a, 2008a) trying to bring both scientific and political communities together, and to develop the conceptual ideas of those further (Barnett 2001) who have called for a 'human centred environmental security' concept. Conceptualizing the 'environmental dimension of human security' implies that the victims (human beings and humankind), their social, economic, environmental and political vulnerabilities and risks become the central object of analysis and not only the state, its institutions and governance structures, strategies, policies, and measures.

Since the early 1990's, the scientific and conceptual debate on security concepts has proliferated from the OECD countries to other regions and to developing countries that have been major victims of the interaction between humankind and global environmental change, and where the need to overcome 'want' (development) and 'fear' (cooperation, disarmament, human rights) as well as to reduce the 'impact of hazards' is most severe and where the right to live in dignity and under good governance must still be realized. This survey of the conceptual thinking on *security threats, challenges, vulnerabilities, and risks* has stressed a dual need for:

- *more precise definitions* to reach a consensus on these concepts especially with regard to practical political measures to achieve the agreed goals; and
- *a systematization of the threats, challenges, vulnerabilities, and risks* for military, diplomatic, economic, societal, environmental as well as human, food, health, energy, livelihood, and gender security (Brauch/Oswald Spring/Grin/Mesjasz/Kameri-Mbote/Chadha Behera/ Chourou/Krummenacher 2009).

However, the latter is influenced by the political mindset of policy-makers and by the scientific worldview (chap. 95 by Oswald Spring/Brauch), disciplinary and theoretical approaches and models, as well as by the economic status and by the geographic location of the country concerned but also by the systems of rule and the level of participation of civil society in local, provincial and national decision-making.

For the hazard community, the concepts of vulnerability and risk have been crucial in a wider context that moves from the purely physical aspects of natural hazards to an assessment and ranking of vulnerability through indicators where the *environmental* (air, soil, water, ecosystems, natural resources), the *economic* (development, resources), the *social* (coping capacities), but also the *political* (governance, participation) contexts are fully taken into account.

A major conceptual and policy task could be to develop the new pillar of human security as 'freedom from hazard impact', and to contribute to the implementation of this goal through capacity-building for early warning, developing vulnerability indicators (Birkmann 2006), and vulnerability mapping (Bankoff/Frerks/Hilhorst 2004). While human-induced and natural hazards cannot be prevented, the impact of tragic events, like the Tsunami of 26 December 2004 in the Indian Ocean, Hurricane Katrina in 2005, or the earthquakes in Haiti and Chile in January and February 2010, can be reduced primarily by measures of early warning and better disaster preparedness that address the 'social vulnerability' of those

most exposed to both hydro-meteorological and geophysical hazards. The fourth pillar of human security aiming at 'freedom from hazard impact' would imply that people are empowered to mobilize and use their resources to address sustainable development goals rather than remain in the vicious cycle of a 'survival dilemma' (Brauch 2008b).

Human security as 'freedom from hazard impact' is achieved when people who are vulnerable to these manifold environmental hazards and disasters (floods, landslides, and drought) often intensified by other associated societal threats (poverty), challenges (food insecurity), vulnerabilities and risks (improper housing in highly vulnerable flood-prone and coastal areas) are better warned of impending hazards, prepared, and protected against these impacts and are empowered to prepare themselves effectively to avoid and to cope with the 'survival dilemma' that often occurs during conflicts, natural hazards, and in complex emergencies where both coincide.

3 Disaster Risk and Vulnerability: Concepts and Measurement of Human and Environmental Insecurity

Omar D. Cardona

3.1 Introduction

Disaster risk management is a development strategy that is notably attracting the increasing concern of policymakers and the general public due to the current emphasis on various components of human and environmental security. From the scientific perspective, comprehension of disaster risk is often manifested by compartmentalization of knowledge; in contrast, from the political and social point of view, this situation leads to a fragmented concept of management. The result is decreased effectiveness in terms of disaster risk reduction and, thus, an integrative framework seems essential.

This chapter provides conceptual and methodological contributions as a general guide to a comprehensive risk management base regarding a holistic approach of disaster risk, given a special relevance to the concept and the different dimensions or components of vulnerability. They can be better understood within the notion of human and environmental security. The integration of an appropriate measurement of these individual and collective vulnerability dimensions enables a grasp of the risk complexity while demanding an interdisciplinary approach for the effectiveness of risk management.

The issues are treated below in four parts. First, a state-of-the-art discussion of risk and its theories from different disciplines is summarized to indicate certain difficulties encountered in the conceptualization of the notion of risk (3.2). Second, a conceptual framework of disaster risk is developed from an integrated approach (3.3). The third part focuses the discussion on the vulnerability concept and on its relevance on risk measurement to favour the awareness and the effectiveness of decision-making (3.4). The fourth session presents the territorial safety as the objective of disaster risk management; i.e. security for the society and for the ecosystem in the space of configurations based on their compatibility and the balance of their interactions (3.5).

3.2 Theories of Risk

Theoretical contributions on risk from different disciplinary perspectives may be classified in various categories including: a) *process*, *analogue* or *systemic* models; b) *structural* and *cognitive* explanations; c) *interpretative* representations; d) *quantitative* methods; and e) *taxonomic* frameworks.

The *process model* proposed by Rowe (1977) is widely used in the field of technological risk and toxicology. This approach suggests the existence of four stages: hazard identification, risk estimation, risk evaluation, and risk management. An example of an *analogue model* is provided by Covello, von Winterfeldt, and Slovic (1987) in an attempt to explain risk communication using signal theory. Palmlund (1992) proposed an analogue model with the classic structure of a Greek tragedy (with actors, scenario, drama, and roles) in order to explain the environmental tragedy from a political and social perspective. An example of a *systemic model* is provided by Kates (1971) from the human ecology school of thought. He describes the notion of *adjustment* to natural hazards considering the interactions between nature, humans, and technology. This model attempts to explain the dynamics of the interaction between the components, but does not necessarily provide information on the underlying causes of the process.

A classic *contextual* or *structural explanation*, where risk is seen as an attribute of social structures, is that proposed by Douglas and Wildavsky (1982). A cultural theory of risk is proposed by Rayner (1992). In this category, we may also include those approaches proposed by the *political economy school*, which may be considered constructivist. This is the case in the work of Westgate and O'Keefe (1976), Wi-

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_3, © Springer-Verlag Berlin Heidelberg 2011

jkman and Timberlake (1984), Susman, O'Keefe and Wisner (1983) and Chambers (1989). These socio-economic approaches defend the idea that risk is socially constructed. The contributions of Wisner (1993), Cannon (1994), Blaikie, Cannon, Davis and Wisner (1996) and those of different members of the Network for the Social Study of Disaster Prevention in Latin America (Maskrey 1994; Lavell 1996; Cardona 1996; Mansilla 1996) may also be considered constructivist, taking a neo-Marxist approach and emphasizing the social construction of vulnerability and, therefore, risk.

A *cognitive explanation* which has been called 'psychometric theory of risk' is provided by Fischhoff, Slovic and Lichtenstein (1979) and Slovic (1992). This theory proposes the existence of *mental models* and *cognitive architecture*. A case of quantitative laws is provided by Starr (1969), who uses three quantitative laws to explain behaviour when faced with risk. His ideas were not well accepted by social scientists but continue to be a necessary point of reference when one talks of the acceptability of risk, and of security norms and codes.

Systematic classifications (*taxonomies*) have also been used to provide order and structure for a range of phenomena and circumstances. Examples may be found in the classification of natural hazards proposed by Burton and Kates (1964), the classification of dangerous materials proposed by Slovic, Fischhoff and Lichtenstein (1985) and the vulnerability classifications developed by Wilches-Chaux (1989) and Aysan (1993). Many of these conceptual proposals have been published in the *Journal of the Society of Risk Analysis*, founded in 1980. This journal was inspired by concerns for technological risk in particular. However, many of the ideas put forward may be extrapolated to the field of risk associated with natural and socio-natural phenomena.

Finally, mention must be made of the *postmodernist* ideas put forward towards the end of the 20th century by social scientists such as Ulrich Beck, Niklas Luhmann, and Anthony Giddens. For these authors, risk is intimately linked to societal development and is influenced by the decision-making and communication processes that occur under the influence of current power relations (Muñoz-Carmona 1997). A theoretical proposal that attempts to integrate all of these categories can be found, for example, in the *theory of the social amplification of risk* proposed by Kasperson, Renn, Slovic, Brown, Emel, Goble, Kasperson and Ratick (1988). This attempts to lay out a causal process integrating the technical, social, cultural, and psychological dimensions of risk.

On a historical note, the first specialized research centre to be established on the topic of disaster was *the Disaster Research Centre* at Ohio State University, which built on the pioneering geographical research of Gilbert White and his collaborators at the University of Chicago. This centre was founded by sociologists, Enrico Quarantelli and Russell Dynes in 1963, and was later moved to the University of Delaware in 1985. Research here was concentrated on the social response to disaster and on post disaster recovery, following, in the first instance, analogies with response in case of nuclear attacks. However, the first centre to really study risk was the *Centre for Technology, Environment, and Development* (CENTED) at Clarke University. This centre was established by geographers Robert Kates and Roger Kasperson, and physicist, Christopher Hohenemser, in 1972. The centre concentrates on both natural and nuclear risks. Since then, at least six research centres were established in the USA in the 1970's, and at least seven more during the 1980's (Golding 1992). During the 1990's, stimulated by the *International Decade for Natural Disaster Reduction* (IDNDR), innumerable centres and programmes dealing with risks and disasters were founded around the world. The topic gained popularity since then and it was increasingly recognized that the terms hazard, vulnerability, and risk have different meanings and implications from both the methodological and practical angles.

For many years the term risk was used to refer to what is today called hazard, and still currently many references are made to the word vulnerability as if it were the same thing as risk. Notwithstanding, on the whole, the enunciation of a risk notably implies a potential for loss; and when a hazard event occurs and the loss is substantial – as a result of the vulnerability degree of the exposed elements – the term normally used is *disaster*. In the vocabulary of the United Nations, a disaster is "a serious disruption of the functioning of society, causing widespread human, material or environmental losses which exceed the ability of affected society to cope using only its own resources" (UNDHA 1992). Nowadays, the risk of a major disaster is also termed a *major risk*, (Harding/Romerio/Rossiaud/Wagner/Bertrand/Frischknecht/Laporte 2001).

3.2.1 Conceptual Approaches

The different approaches to risk concepts and evaluation are based, in general, on different disciplinary foundations. One can distinguish between two major approaches, namely the socio-technical approach which may be considered as having been derived from the applied sciences and economics, and the socio-cultural approaches derived from sociology, psychology, anthropology, and culture studies.

The socio-technical approach includes contributions by the natural and engineering sciences and is based on probabilistic estimation of risk. This approach is adopted in toxicology and epidemiology, the actuarial[1] sciences and economics where cost-benefit comparisons are made. All these approaches are based on statistical prediction and on probability analysis. With reference to the socio-cultural vision, diverse social theories of risk may be identified and, as Ortwin Renn (1992) points out, there may be as many perspectives in sociology as there are sociologists. Renn classifies the theories in two categories, namely objectivist and constructivist. Moreover, the socio-cultural vision also covers psychological approaches which include psychometric analysis and the cultural school that bases its work on the analysis of groups and organizations. Unlike the socio-technical methods, socio-cultural approaches do not offer a common denominator for measuring the social and cultural acceptability of risk (Douglas 1985).

3.2.2 Objectivism and Constructivism

Probabilistic estimates of risk attempt to predict failures in the security of complicated technology systems, even where insufficient data are available on the system being analysed. Failure and event trees are used for the analysis, and the probability of failure of each component of the system is evaluated in a systematic fashion linking these to the structure of the system. This approach is useful for detecting deficiencies and for improving security levels in complex systems. The actuarial approach represents a classic example of *objectivist* approaches to the analysis of risk, where the base unit is an expected value that corresponds to the relative frequency of an average event in time.

Undesirable events are understood in terms of physical damage to persons and ecosystems. This may be observed and objectively measured with appropriate scientific methods. An application of this approach can be found in the case of predictions of road accidents for some future year. Results may be extrapolated from data on fatal accidents in previous years. The estimation of risk is reduced to a single dimension and is represented by an average in time, space, and context. Estimations of health and environmental risks basically use the same types of method.

The approach taken by economics transforms physical damage or other undesirable effects into subjective benefits. The base unit of these benefits describes the level of satisfaction associated with a possible action or transaction. An attempt is made to compare risks with benefits (Camerer/Kunreuther 1989). Since risks represent possible and not real costs it is necessary to relate them to the probability of occurrence of an event. Ultimately, what is sought is the use of resources in order to maximize benefits for society. Economic risk comprises a logical and coherent framework for situations where decisions have to be made by individuals and where decisions on loss are confined to the decision-maker's immediate environment. Although the economic perspective permits a uni-dimensional measure of risk that supposes that the benefits and risks are commensurable, there are many factors that impede its use in risk management policies. These include: the problem of aggregating individual gains, the existence of variations between individual preferences, the problem of taking appropriate action to reduce future negative consequences, the impacts on third parties, and the notions of rationality and ethical considerations that the model is based on.

In general, such *technical analysis* provides society with a limited and narrow definition of desirable effects, reducing the possibilities to numeric probabilities based on relative frequencies. Unfortunately, the objectivity that is associated with such calculations, which may be seen as a virtue, can also lead to the serious problem of oversimplifying a complex phenomenon.

On the other hand, the *psychological approach* suggests that individuals respond according to their perception of risk and not according to objective risk levels and scientific evaluations of this. Such estimations are only taken into account by individuals to the extent that they are considered in the light of individual perceptions. This approach assigns importance to the beliefs people have regarding the possibility of the

1 Field of mathematics that is directly related to risk evaluation using probabilistic (analytic) and statistical (data) models. The insurance industry has been based on actuarial studies since many years ago.

occurrence of an undesirable event. In this regard, the question arises as to whether perceptions are based on adequate information or rather, on biases and ignorance, which would make them very inadequate if they are to be used as criteria for decisions on risk reduction. From the point of view of many anthropologists and cultural sociologists, social responses to risk are determined by prototypes and cultural mores i.e. clusters of convictions related to different perceptions of reality. Seen from this perspective, environmental risks are considered to be purely social constructions.

3.2.3 Individualism and Structuralism

Individual and *contextual models* have been proposed by social scientists to explain social responses to risk. The individual model is largely based on psychology, whereas the contextual one is sociologically oriented. In the case of the individualist paradigm an attempt to understand group behaviour is made by studying individuals. An example of such models can be found in the "theory of knowledge and personality" (Wildavsky/Dake 1990). This offers an explanation of the cognitive response to risk, which is based on the knowledge, information, aversion or tolerance of risk that is characteristic of different personality types. Psychometric and risk perception theories are based on this type of paradigm, as are some economic models of risk based on the theory of expected gains to which Camerer and Kunreuther make reference (1989).

Theoretical development of risk perception commenced with the research of Tversky and Kahneman (1973, 1974). These authors were interested in the identification of factors that influence the probability estimations of persons. They concluded that when people face complex problems that involve probability and event frequency, they apply certain rules of judgment and heuristics in order to simplify the problem. These often lead to biases and value judgments. Later contributions by Slovic, Fischhoff, and Lichtenstein (1981) led to the psychometric and cognitive theory of risk perception, based on prediction of individual responses to certain activities, particularly those of a technological nature.

Through the contributions of cultural theory and structuralism an attempt has been made to advance the understanding of the ontological aspects of risk and of the connection between sociological variables and individual attitudes to risk. The ontology of risk refers to its metaphysical status as a property and quality of the physical world. This is a common supposition amongst those who promote the technical evaluation of risk. In the case of contextual approaches, the context is taken as a starting point. These models take into account the social structure, institutional forms, and culture. This approach has many variations, including those proposed by Rayner, Renn, Palmlund, Wynne, and Kasperson, although the latter author avoids providing social factors with an ontological character (Krimsky/Golding 1992).

Structuralists and *contextualists* defend the position that risk is subjective and varies according to the context, criticizing attempts to give it an objective and measurable character. Cultural theorists have even gone as far as to criticize the psychometric paradigm indicating that risk is inevitably the result of a social process, even though it has some roots in nature. That is to say, they defend the position that the most appropriate approach to risk analysis is sociological and not psychological, given that risk is a social product (Thompson/Wildavsky 1982). The debate between individualism and contextualism can only be resolved if we find a reply to the difficult question as to whether personality precedes context or vice versa.

All concepts of risk have a common element: a distinction between reality and possibility. If the future were predetermined or independent of present human activities, the term risk would have no significance. If the distinction between reality and possibility is accepted, then the term risk could be defined as "the possibility that an undesirable state of reality (adverse effects) will occur as a result of natural events or human activities" (Luhmann 1990a). This definition means that humans can and do make causal connections between actions (or events) and effects, and that undesirable effects can be avoided or reduced if the causal events or actions are avoided or modified. According to this definition, risk is a descriptive concept (a representation) and, at the same time, takes a normative dimension. The definition of risk involves three elements: undesirable results, the possibility of occurrence, and a state of reality. All approaches to risk provide different conceptualizations of these three elements. These may be paraphrased in the following three questions: How may we specify and measure uncertainty? What are the undesirable results? What is the concept of reality we hold to? This helps us to distinguish between the different perspectives (Renn 1992).

The distinction between risk evaluation and risk reduction is of interest in this regard, since it has implications regarding the distinctions between science and political decision-making. If risk is seen as being

objectively associated with an activity or a phenomenon and as something measurable in probabilistic terms in order to identify well-defined adverse effects, one can order the risks according to *objective* measures of the probability and magnitude of damage, and resources would be allocated in order to deal with the greatest risks. However, if risk is seen as a social or cultural construction, then intervention would have to be based on different criteria and priorities, and should reflect *social values* and *preferences* for different life styles. These two positions represent the extremes of a spectrum of different positions regarding risk, and both could possibly be biased versions of reality (Renn 1992). Experience shows us that risk is multidimensional, and that differences in culture and social values call for different approaches. Experience shows us that there is no society in which a single criterion has been held to as regards all types of risk. However, the relativist position derived from social constructivism is difficult to justify in terms of its practical consequences when we observe that in many countries similar reduction standards and priorities have been established, despite notable differences in culture and society.

In summary, the conceptual frameworks used to understand and interpret disaster risk and the associated terminologies have not only varied over time, but also differ according to the disciplinary perspective considered. Despite the refinement with which disaster risk is considered in the different fields of knowledge, there is, in reality, no singular concept that unifies the different approaches, or that brings them together in a consistent and coherent manner. Although researchers and professionals working in the disaster areas may believe that they are talking about the same concept, serious differences exist that impede the decision-making effectiveness; i.e. successful, efficient, and effective risk reduction implementation. The conceptual framework proposed herein searches to present a consistent and coherent holistic theory of disaster risk contributing to the effective risk management by policy planners and stakeholders at all levels.

3.3 Conceptual Framework for Decision-making Effectiveness

Risk management is a crucial issue at both the scientific and political contexts, but the concept of risk is a polysemous notion. Psychologists, sociologists, and historians generally consider risk as a social phenomenon. This approach may be termed as *constructivist*. From this perspective, understanding of risk requires knowledge of individual perceptions and social representations, and of the interactions between the different social actors. On the other hand, engineers, geologists, geographers, economists, and epidemiologists generally adopt an approach that may be described as *realist* or *objective*, based on the hypothesis that risk can be quantified or objectively assessed. The same dichotomy of subjective vs. objective features has been inherent to the security concept.

In addition, the enunciation of risk, like security and insecurity, is performative; a situation is described as *safe*, or on the contrary *risky*, to attribute a positive or negative value to it and to begin to act. It is precisely in this respect that risk, security, and insecurity can be considered performative – or normative – notions. Furthermore, with regard to the notion of environmental and human security, to speak of insecurity is also to suggest a *threat* to security – always potentially menaced by crisis or disaster – and the risk one takes in according or refusing trust to the systems that organize the social context. The relationship between environmental and human security and risk involves the idea of threat. A hazard is only considered a risk when there is a threat to exposed elements. Thus the components of security provide a framework for analysis of the vulnerability – and of the resilience – of each element at risk in a hazard prone territory, (Harding/Romerio/Rossiaud/Wagner/Bertrand/Frischknecht/Laporte 2001).

Therefore, the antagonism between the *objectivist* and *constructivist* paradigms must be transcended, and more confidence must be placed in both qualitative and quantitative methods. Action and decision, implicit in the definition of risk, require a compromise between subjective risk perception and the scientific need for objective measurement. While the objective approach lacks the social dimension, which is an important consideration when assessing disasters, subjective definitions are equally unsatisfactory, since they imply that risk is a matter of personal interpretation only. This position is totally inoperable when intervention in risk becomes a must from the public policy angle. That is the reason why there is a need for a common language and a *holistic theory* of risk from an interdisciplinary perspective and based on the approach of the complex dynamic systems (Cardona 2004).

3.3.1 Differences between Risk and Disaster

Risk is not synonymous of catastrophe (Beck 2007, 2008); risk means the possibility of future disaster. The term *disaster risk* suggests that there is a possibility that a dangerous phenomenon or event will occur and that there are exposed elements predisposed or susceptible to being affected. The reduction of risk, therefore, means the reduction of the possibility of future disaster. Hence, *disaster* is a social context or process, triggered by a natural, technological or anthropogenic phenomenon, which in interaction with a susceptible medium causes intense alterations in the normal functioning of the community. These alterations may be expressed, amongst other things, as loss of life, serious health problems, damage or destruction of individual and collective goods, or severe damage to the environment. For this reason, rapid response is required in order to restore the well-being of affected persons or ecosystems and to re-establish adequate levels of normalcy. Disaster implies loss and damage, and consequential impacts that the affected community is unable to absorb or to cushion the effects and recover using its own resources and reserves. This suggests that there are levels and types of loss and damage that do not signify disaster for society. Disaster is a given situation, a product that is tangible and measurable.

Disaster supposes the prior existence of determined risk conditions. That is to say, disaster is the materialization of pre-existing risk. On the other hand, when defined as the probability of future loss, a disaster can be explained by the prior existence of a latent threat and certain intrinsic or constructed characteristics of society that predispose it to suffer determined levels of damage. Disaster risk may be considered a collective or public risk. It is the type of risk which signifies a threat to all members of the prone community. Once this risk is recognized as such by the community something must be done about it. Commitment by public and private institutions and the community itself becomes a must. But, collective risk supposes a series of interdependent, dynamic, and uncertain problems that require collective action in order to solve them. Unfortunately, it is not uncommon for communities that are exposed to and aware of dangerous phenomena to do nothing about it due to resource restrictions, or because perception of the danger is insufficient to stimulate collective action. On occasions, some community members are conscious of the danger and carry out individual actions to reduce it, but the community as a whole still remains vulnerable. The risk level of a society is related to its development level and the ability to modify the risk factors that affect it. In this sense, disasters may be considered unmanaged risks. Risk is constructed socially, even where the physical phenomenon is natural.

Definitions and concepts may hide many different aspects and vary notoriously with scientific discipline, ideology, and ontological viewpoint. As with almost all conceptual processes, the epistemological foundations and context are crucial for understanding the way a topic is dealt with. For example, 'the reduction [or mitigation] of natural disasters' has been a useful slogan for mobilizing support in general, but from a conceptual viewpoint this terminology is imprecise and confusing. What is it precisely we search to reduce or mitigate? Although it may seem to be a subtlety, it is a very different thing to talk of 'disaster risk reduction' as opposed to 'natural disaster reduction or mitigation'. From a decision-making viewpoint or from the point of view of the public in general, different ways of defining the same term will elicit different responses. Moreover, the risk *of* disaster used to refer to a probability is different to risk *from* disaster, which refers to feasible consequences. Concentrating on *risk* clearly allows us to discriminate between activities *ex ante* and *ex post*, and between the needs and activities relevant to one or another of these situations. Here, it is clear that the management approach has been long dominated by consequences (interest in humanitarian response) and not by an interest in the probability that these will occur (interest in prevention-mitigation). Although these approaches have common objectives, they signify different things in terms of funding, methods, functions, interests and expertise. In other words, it is not the same to visualize the problem from a social and economic development perspective, for example, as it is to look at it from the perspective of preparedness for humanitarian emergencies.

3.3.2 Disaster Risk as Potential of Crisis

The formulations of the problem owe a lot to the original ideas of the so-called *human ecology* school of thought first proposed by geographers at the University of Chicago during the second decade of the 20th century and further developed by White (1942, 1964, 1973), Kates (1971, 1978) and Burton (1962), by Burton and Kates (1964), as well as by Burton, Kates and White (1968, 1978) in their studies on hazards and disasters. On the other hand, the convolution of the

frequency of hazard events with the severity of its feasible consequences has been the traditional approach for risk assessment from the techno-hazards point of view.

Prompted by these ideas, the Office of the United Nations Disaster Relief Coordinator (UNDRO) and UNESCO organized an expert meeting in July 1979 with the objective of proposing a unification of disaster related definitions. The report from that meeting, *Natural Disasters and Vulnerability Analysis* (UNDRO 1980), included the definitions of natural *hazard* (H), *vulnerability* (V), *elements* at risk (E), *specific risk* (S), and *risk* (R). From this perspective, risk may be defined as

$$R = E \cdot S = E \cdot H \cdot V \text{(given that } S = H \cdot V \text{)} \quad (1)$$

Whilst essentially maintaining this conceptual framework, during the Institute for Earthquake Engineering and Engineering Seismology meeting, held in 1985 in Skopje (Former Yugoslav Republic of Macedonia), this author proposed the suppression of the variable related to the exposure, because it is implicit in the notion of vulnerability. In other words, one cannot be 'vulnerable' unless one is 'exposed'. Originally, this formulation was presented by Fournier d'Albe (1985), Petrovsky and Milutinoviç (1986) and later by Coburn and Spence (1992). The expression of risk as a function of hazard and vulnerability that is now widely accepted in the technical and scientific fields, and increasingly in the social and environmental sciences, was formulated as follows[2]:

$$R_{ie} \mid_t = f\left(H_i, V_e\right) \mid_t \quad (2)$$

This signifies that once the *hazard* or *threat* (H_i), is known (expressed as the probability that an event with an intensity greater or equal to *i* will appear during a period of *exposition t*), and the *vulnerability* (V_e), is also known (understood as the intrinsic predisposition of an element *e*, to be affected or to be susceptible to damage with the occurrence of an event with an *intensity i*), the *risk* (R_{ie}), is expressed as the probability of loss to the element as a result of the occurrence of an event with an intensity greater or equal to *i*. That is to say, risk in general may be understood as the probability of loss during a given period of *time t* (Cardona 1985, 1986).

Now, if C_p expresses a *crisis potential*, T_a represents the possibility of occurrence of a *trigger agent*, and I_c are the *instability conditions* of a system, from the perspective of the complex systems, it is possible to posit the following meta concept:

$$C_p \mid_t = f\left(T_a, I_c\right) \mid_t \quad (3)$$

This expression is more general and contains the abovementioned equation of risk, which is a particular case of behaviour of a specific non-linear dynamic system, at the border of chaos, in which it is important to consider the triggering agent or perturbation – i.e. the hazard – but also the dynamic conditions of instability – i.e. the vulnerability – (Cardona 1995, 1999, 1999a). The possibility that a crisis can appear must always be considered in a lapse or a 'window' of time, which would mean to express each factor in probability terms.

The evolution of the complex systems cannot be represented in an adequate way by linear functions or soft and continuous curves, except in the case of approximations over short segments of time. Equation (3) is appropriate to describe the potential bifurcations or inherent unpredictable development of the system. In the case of risk, the instability conditions are the weaknesses or the deficiencies that may be of environmental or ecological character; demographic, social or cultural; economic, institutional or political, among others. The concepts of *vulnerability*, or predisposition to be affected, and *resilience*, or capacity of recovery and adaptive behaviour, play an important role due to their important relation with the possible occurrence of discontinuities. One system may pass from an almost constant state to another one if it is altered by a sufficiently impacting perturbation, which does not only depend on the intensity of the event but also on possible instabilities that are not easily perceptible of the system. Lastly, a few words about the potentiality of the trigger event or agent are needed. This potentiality undoubtedly contributes to knowledge of one main component of risk: the *hazard*; the latent danger or probability of occurrence of a damaging event. It is necessary to have in mind that without hazard, without a trigger phenomenon, there would be no risk and no possible future disaster.

2 This equation is a definitional circle as the well-known Newton's *F=ma* – the force equals to the mass plus acceleration – where acceleration can be definable by itself by independent concepts, whereas force and mass are co-defined; i.e. one depends on another. Hazard and vulnerability are also co-defined: one cannot be vulnerable if one is not threatened by hazard, and one can not be threatened if one is not exposed and vulnerable. However, Wittgenstein pointed out that in any level of description the concepts form typically definitional circles.

3.4 Vulnerability as a Key Concept

Vulnerability of human settlements and ecosystems is intrinsically tied to different socio-cultural and environmental processes, but it is also related to the fragility, the susceptibility, or the lack of resilience of the exposed elements, both from society and environment. It is also closely tied to natural and built environmental degradation at the urban and rural levels. Thus, degradation, poverty, and disasters are all expressions of environmental problems and their materialization is a result of the social construction of risk, brought about through the construction of vulnerability or hazard, or both simultaneously. Therefore, when seen from a social viewpoint, vulnerability signifies a lack or deficit of development. In this regard, risk is constructed socially, even though it has a relationship to physical and natural space. In many places, increases in vulnerability are likely to be related to factors such as rapid and uncontrollable urban growth and environmental deterioration. These lead to losses in the quality of life, the destruction of natural resources and landscape, and loss of genetic and cultural diversity. In order to analyse vulnerability as part of wider societal patterns it is necessary to identify the deep rooted and underlying causes of disaster vulnerability and the mechanisms and dynamic processes that transform these into *insecure conditions*. All this leads to the conclusion that the underlying causes of vulnerability are economic, environmental, demographic, and political processes that affect the distribution of resources among different groups, which in turn reflect the distribution of power in society. Some global processes require more attention than others. These include population growth, rapid urban development, international financial pressures, degradation of the earth, global warming, and environmental change and war. To take but a limited number of examples, urbanization processes have been an important factor in damage caused by earthquakes in urban areas; population increase helps to explain increases in the numbers of persons affected by floods and prolonged droughts; and deforestation increases the chances of flooding and landslides (Blaikie/Cannon/Davis/Wisner 1994). Adhering to the hypothesis that the lack of development and vulnerability are correlated and considering that the lack of capacity to cope, recover, and adapt is also a factor of vulnerability, particularly taking into account the climate variability and change, this author has suggested that vulnerability originates in:

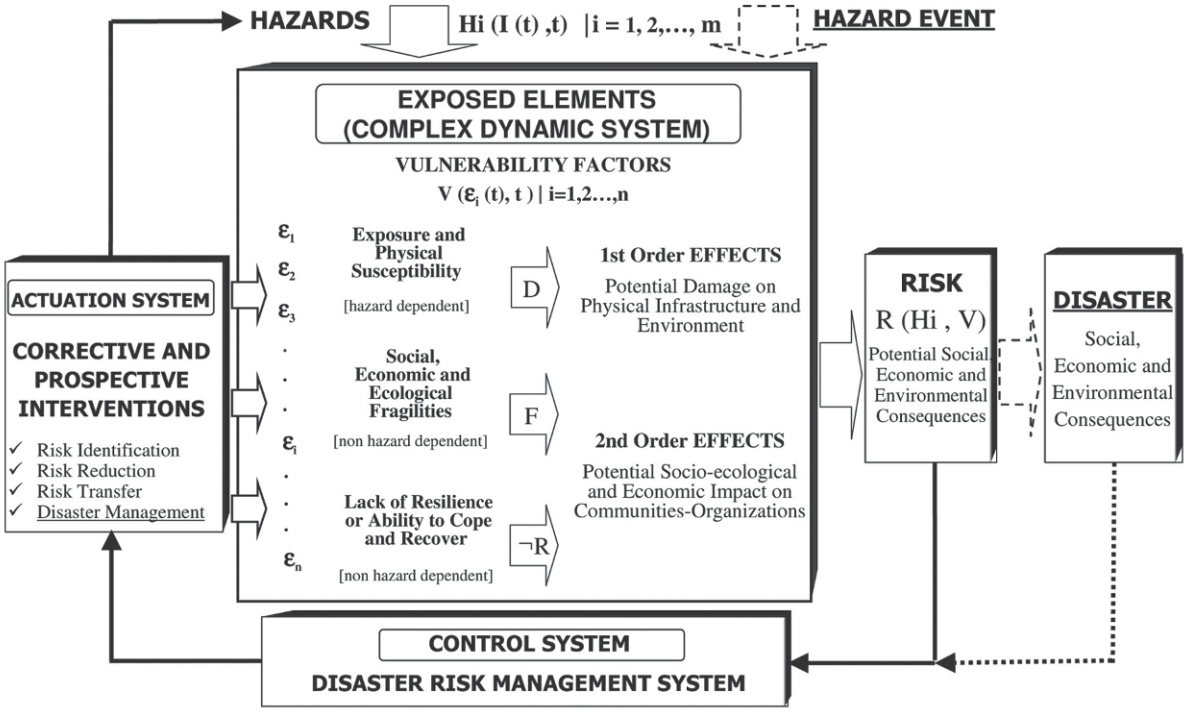
a.) *Physical fragility or exposure* (D): the susceptibility of human settlements and environment to be affected by a dangerous phenomenon due to its location in the area of influence of the phenomenon and to a lack of physical resistance.
b.) *Social, economic, and ecological fragility* (F): predisposition of society and ecosystems to suffer harm resulting from the levels of marginality and social segregation of human settlements and disadvantageous conditions and relative weaknesses related to social, economic, and environmental factors.
c.) *Lack of resilience or ability to cope and recover* (¬R): limitations in access to and mobilization of the resources of the human settlement, and incapacity to adapt and respond in absorbing the socio-ecological and economic impact.

According to this model (figure 3.1), vulnerability conditions in disaster prone areas depend on *exposure* and susceptibility of physical elements (human settlements, infrastructure, and environment), the *socio-economic and ecological fragility* and the *lack of resilience* or *ability to cope* with the context. These factors provide a measure of direct as well as indirect and intangible impacts of hazard events. Vulnerability, and therefore, risk are the result of inadequate economic growth, on the one hand, and of deficiencies that may be corrected by means of adequate development processes, on the other hand.

Indicators or indices could be proposed to measure vulnerability from a comprehensive and multidisciplinary perspective (Birkmann 2006). Their use intend to capture favourable conditions for direct physical impacts (*exposure* and *susceptibility*), as well as indirect and, at times, intangible impacts (*socio-ecological fragility* and *lack of resilience*) of hazard events. Therefore, according to this approach, exposure and susceptibility are necessarily *hard* conditions for the existence of physical risk, or first order effects, and these are hazard dependent. The propensity to suffer negative impacts as a result of the socio-ecological fragilities and not being able to adequately face disasters, are circumstances of the context that can be considered *soft* conditions, related to second order effects that aggravate the impact and usually are non-hazard dependent.

Using the meta concepts of the theory of control and complex system dynamics, to reduce risk it is necessary to intervene in a corrective and prospective way

Figure 3.1: Theoretical Framework and Model for a Holistic Approach to Disaster Risk Assessment and Management. **Source:** Adapted from Cardona (1999: 65), Cardona and Barbat (2000), IDEA (2005a/b) and Carreño, Cardona and Barbat (2007a).



the vulnerability factors and, when it is possible, the hazards directly. Then risk management requires a system of control (institutional structure) and an actuation system (public policies and actions) to implement the changes needed on the exposed elements or complex system where risk is a socio-environmental process.

This kind of thinking attempts to integrate in a holistic way the contributions of the physical and social sciences with the idea of obtaining a more complete vision of the factors that create or exacerbate vulnerability (Cardona/Hurtado 2000a, 2000b, 2000c; Cardona/Barbat 2000; Cardona 2001[3]). The conceptual framework and model for a holistic approach to evaluate disaster risk consider several dimensions or aspects of vulnerability proposed by Wilches-Chaux (1989), which are characterized by the above mentioned three categories or vulnerability factors. These dimensions are correlated to human security components and briefly described as follows:

a.) *Physical (habitat) dimension*: This depicts locations in susceptible areas and deficiencies in the resistance of the exposed elements. The latter affects the capacity to absorb the shocks associated with dangerous phenomena. Examples of the physical dimensions of vulnerability from habitat perspective can be found in the inadequate levels of seismic resistance of buildings located in earthquake prone areas, the location of a community in a landslide or flood prone area, etc.

b.) *Environmental dimension*: There is an increase in vulnerability when the development model is not based on an adequate relationship with the environment and promotes or fosters the exploitation and destruction of natural resources. These circumstances inevitably lead to deterioration in ecosystems and an increase in vulnerability. Self-adjustment in order to compensate the direct and indirect impacts of human activity or of natural events may become very difficult.

c.) *Economic dimension*: More economically depressed sectors are more vulnerable in general. Poverty can increase vulnerability. At the local and individual levels this is expressed in unemployment, lack of income, and difficulties in gaining access to services. At the national level, this is expressed in terms of excessive economic dependency and lack of control over external factors, lack

3 Available at: <http://www.desenredando.org/public/varios/2001/ehrisusd/index.html>.

of diversification of the economic base, restrictions on international commerce, and the imposition of retrograde monetary policies.

d.) *Social dimension*: The higher the levels of social integration of the community, the easier it will be for the community to absorb the consequences of a disaster and react more rapidly. Societies may be less vulnerable when they react as an organized group or according to group interests, and more vulnerable where individual or circumstantial interests prevail.

e.) *Political dimension*: This may be expressed in terms of the level of autonomy of a community in the use of resources and decision-making. The community is more vulnerable under centralist schemes of decision-making and government. Lower levels of regional and local autonomy impede actions that respond to the felt needs of the population at these levels. Participation in decision-making that affects the community will help reduce vulnerability.

f.) *Institutional dimension*: This relates to the difficulties faced in undertaking risk management. The lack of preparedness or of efficient and effective mitigation actions when collective risk is known to exist are sources of vulnerability. Institutional vulnerability is also expressed in the lack of flexibility and in excessive bureaucracy, and in the fact that political decisions and the desire for protagonism prevail over more rational ways of dealing with problems.

g.) *Educational dimension*: The lack of knowledge of causal factors and effects of disasters, the lack of a sense of the community history and the lack of preparation and understanding of individual and group responses to disaster are all aspects that make a community more vulnerable. Deficient education or lack of educational coverage in a susceptible community and the lack of socialization of information also increase vulnerability.

h.) *Cultural dimension*: This relates to the way individuals see or perceive themselves and the groups or collective units they belong to. This may at times negatively influence the behaviour given the existence of pernicious stereotypes that are neither questioned nor changed. The communication media play a crucial role in this, given that they contribute to the slighted use of images and the transmission of imprecise or inconsequent information related to the environment, society, and disaster.

i.) *Ideological dimension*: This relates to the ideas and beliefs that exist as regards the world, its existence and future. It is at times expressed in passive and fatalistic attitudes and religious beliefs that limit action under certain circumstances. Dogmatic perceptions may generate confusion as regards purpose and a lack of reaction or loss of motivation that limits the undertaking of transforming actions.

This deconstructive approach helps us visualize vulnerability from different angles and perspectives that involve also technological, anthropological, and psychological aspects. The proposal facilitates an understanding of vulnerability as a dynamic and changing circumstance or condition. Moreover, we can also see it as an accumulative process of permanent fragilities, deficiencies, and limitations that play a role in the existence of higher or lower levels of vulnerability.

The Holistic Approach is compatible to the 'Pressure and Release' model and to the 'Access' model; both related to the progression of vulnerability – chain of explanation – and to the analysis of the principal factors of human vulnerability (Wisner/Blaikie/Cannon/Davis 1994, 2004). From the perspective of these models vulnerability is related to the situation or the characteristics of a person or group that influence the impact of hazard event or process on them. This situation or characteristics of people depend on their unsafe conditions that are product of a set of dynamic pressures whose explanation is due to another set of root causes. The main subtle conceptual differences between these models and the Holistic Approach are that in the latter human and environmental insecurities are the result of a set of vulnerability dimensions and factors in each level of the chain or hierarchy of the explanation. Vulnerability is not only referring to the people but also to the contexts and to the complex interactions of society and environment; particularly, interactions not only from the global to the local but also from the local to the global. This is important for the exacerbation of socio-natural hazards and disaster risk understanding in the framework of climate change and environmental degradation, and to improve the resilience-building processes where a top-down political decision approach has to be combined with a bottom-up of awareness and social practices of environmental protection and disaster risk reduction.

3.4.1 Quantifying and Applying the Model

The Holistic Approach was used to evaluate disaster risk in countries[4] of Latin America and the Caribbean

in the framework of the *Disaster Risk Management Indicators Program for the Americas*, led by the Institute of Environmental Studies (IDEA), of the National University of Colombia for the Inter-American Development Bank (IDB) (Cardona 2006, IDEA 2005a, 2005b, ERN 2009). In addition, it has been applied in Italy at the regional level in Lombardy (Prevenzione Lombardia 2007).

The methodology applied for the calculation of *Urban Seismic Risk index*, USRi, proposed by Carreño, Cardona, and Barbat (2007a) is useful to illustrate the quantifying and application of the holistic approach described above. The model was developed to guide the risk management decision-making, helping to identify the critical zones of a city and their vulnerability from an interdisciplinary perspective. This approach contributes to the effectiveness of risk management, inviting to the action or intervention by identifying the hard and soft weakness, reflected by distinct type of indicators of the different units of analysis (districts or areas, for example) of an urban centre. The total urban disaster risk is measured not only in terms of the direct impact of expected physical damage but also considers indirect impact factors that account for the socio-economic fragility and coping capabilities of the city's population and its institutions. In this application, the USRi is the total risk R_T obtained from the potential direct impact of earthquakes denoted as physical risk R_F, and on the indirect effects given by and impact factor $(1+F)$ based on the aggravating coefficient, F. Thus, it is expressed as follows:

$$USRi = R_T = R_F(1+F) \tag{4}$$

where

$$R_F = \sum_{i=1}^{p} F_{FRi} \cdot w_{FRi} \tag{5}$$

and

$$F = \sum_{i=1}^{m} F_{SFi} \cdot w_{SFi} + \sum_{j=1}^{m} F_{LRj} \cdot w_{LRj} \tag{6}$$

The factors of the physical risk are based on the gross values of the physical risk descriptors such as the number of potential deaths, injured, or the destroyed area, among others. The factors of the aggravating coefficient are based on socio-economic conditions (social fragilities) and coping capacity descriptors (lack of resilience) such as area of slums, social disparity, population density, awareness level, public space available, hospital beds, physicians, firemen, etc. They are calculated using transformation functions that standardize the gross values of the descriptors, transforming them in commensurable factors which take values between 0 and 1; w are the weights or influences of each factor of physical risk, social fragility and lack of resilience, respectively. They represent the relative importance of each factor and are calculated by means of the Analytic Hierarchy Process (Saaty 1980). Figure 3.2 presents the summary of the USRi results for the all cities of Metro Manila.

Once the results have been obtained for each locality or district, it is easy to identify the most relevant aspects of the total risk index. The results can be verified and the mitigation priorities can be established as regards the prevention and planning actions to modify those conditions (sub-indicators) having a greater influence on risk. In addition, this technique allows comparing risk among different megacities, therefore this methodology allows using a common rule of measurement to compare and benchmark the results. It is a comprehensive technique where the concept underlying is one of controlling risk rather than obtaining a precise evaluation of it. This methodology has been applied at the urban level to Bogotá, Metro Manila, Barcelona, Manizales, and currently to Istanbul (Cardona 2001; Cardona/Hurtado 2000a/b; Carreño/Cardona/Barbat 2007a, Fernandez/Mattingly/Bendimerad/Cardona 2006, Suarez 2007, Khasai 2007; Marulanda/Cardona/Barbat 2009; Carreño/Cardona/Marulanda/Barbat 2009).

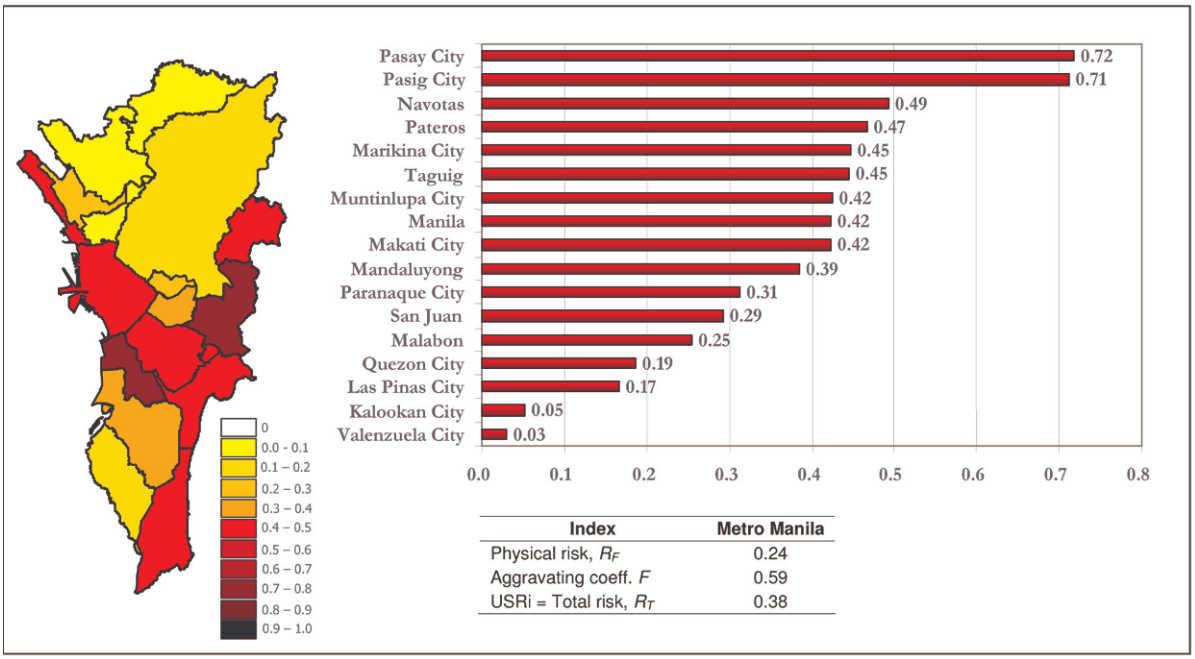
3.5 Territorial Safety as an Object of Risk Management

One of the objectives of *risk management* and of *sustainable human development* is to guarantee to human communities the *territorial safety*[5] that they require in order to develop their lives with quality and dignity. This is, in fact, an attribute that is beneficial for communities and for nature. Territorial safety is the result of the interaction between a set of factors that allow a territory, as space of policymaking and management (Agudelo 2005), to offer *stability* to

4 14 countries in 2005 and 18 countries in 2009.

5 Territory as space of mutual interactions between society and nature is understood as a space of management not only as an area or surface.

Figure 3.2: USRi results for the holistic seismic risk evaluation of Metro Manila. **Source:** (Fernandez/Mattingly/Bendimerad/Cardona (2006) and Marulanda/Cardona/Barbat (2009).



those who inhabit it; that is to say, they provide permanence of the conditions that make life in space and time possible. These conditions or factors – some are natural and others anthropogenic – on which the capacity of the territory depends to offer stability and security for their inhabitants, are mainly *food security*, *ecological security*, *social security*, *economic security*, and *institutional and legal security* (Cardona/Wilches-Chaux 2006). In general, the responsibility of the state is to generate the conditions that permit *territorial safety* in its different dimensions, as much for the people as for the ecosystems that comprise the territory. For that reason the security is an attribute both for the society (human) and for the ecosystems (environment) on which sustainable development depends; understanding sustainable development as that form of development which allows that the dynamics of nature neither become a threat to human communities and their processes of production, nor that the dynamics of human communities become a threat to ecosystems.

Risk management may be understood as a set of elements, measures, and tools directed towards intervention in hazards and vulnerabilities with the objective of reducing *existing* – by corrective interventions – or controlling *future* possible risks – by prospective interventions (Lavell 2000). This concept of prevention and mitigation can be differentiated from another group of tools whose objective has been the improvement of intervention in disasters once these occur: preparedness activities, response, and reconstruction. Risk management aims to articulate different types of actions, assigning a central role for prevention and mitigation, but without abandoning disaster response, in an attempt to develop preventive policies that significantly reduce the need for intervening in disasters once these occur.

This type of management should not be seen as a purely government-led process, but a participatory exercise, involving governmental and non-governmental actors with the idea of dealing with risk and disaster. In this sense, risk management policy must be based on the involvement of the diverse social, institutional, public, and private forces and groups that exist, on a broad and inclusive *territorial* basis; i.e. a national, regional or local system for disaster risk management. A part of the improvement in human living conditions consists in the achievement of greater levels of *security* and survival in relation to the actions and reactions of the environment. This calls for a better understanding of the forms of interaction between our immediate social environment and the natural environment (Duque 1990). It follows, therefore, that risk management is a fundamental strategy for sustainable human development given that it attempts to establish an equilibrium between natural ecosystems and the societies which oc-

cupy and utilize them, guiding human actions and activities that affect the environment and vice versa.

It should be realized that disasters are to a great extent an expression of an inadequate relationship between the development model and the environment within which the model is supposed to operate. Conflicts between economic, social, political, and cultural objectives and mores may lead to inconsistencies in this regard, possibly ending up in a disaster. Because of this, risk management should be an explicit objective and component of development planning where development is understood not only as an improvement in living conditions but also in the quality of life and *well-being*. Independently of ideological discussions, development should guarantee the needs of humans and their environment, and promote quality growth. *Territorial security* is in general a fundamental component of sustainable human development and, for this reason risk reduction is also a fundamental strategy in the search for equilibrium between human settlements and nature.

3.5.1 Risk as a Measure of Human and Environmental Insecurity

It is necessary to make risk *manifest* for decision-making. Risk must be recognized and it thus becomes a preoccupation for somebody. However, risk is a complex and at the same time, curious concept; its existence is consubstantial for human beings. It is an abstraction of a transformation process that denotes simultaneously a possibility and a reality. It represents something unreal, related to uncertainty. It reflects an undesirable state of reality which has not yet materialized. It is imaginary, difficult to grasp, and does not exist in the present but only in the future. According to Ulrich Beck (2000: 213) "risks, then 'are' a type of *virtual reality*, real virtuality." Beck cites Van Loon (2000: 176) who writes: "Only by thinking of risk in terms of reality, or better, *a becoming-real* (a virtuality) its social materialization can be understood. Only by thinking risk in terms of a construction can we understand its indefinitely deferred essence." Risks are necessarily constructed but they are not constructed on the basis of imagination; that is, we are not free to *construct* risk as we please (Adam/Van Loon 2000). In risk analysis, the context – management capacity and related actors – determines the limits, reasons, purpose, and interactions to be considered, which reveals its normative character. Analysis has to be congruent with context and this must be taken into account when analysing the sum of the contributing factors. If not, analysis would be totally irrelevant or useless.

Vulnerability is the state of reality that underlies the concept of risk. It is the causal reality that determines the selective character of the severity of damage when a hazard event appears (Cardona 2001). Vulnerability reflects susceptibility, the intrinsic predisposition to being affected; the conditions that favour or facilitate damage. The measurement of vulnerability is a challenge; many believe it is not feasible. However, it is fundamentally important to understand how vulnerability is generated, how it increases, and how it builds up. The evaluation and follow-up of vulnerability and risk is needed to make sure that all those who might be affected, as well as those responsible for risk management, are made aware of it and can identify its causes. To this end, evaluation and follow-up must be undertaken using methods that facilitate an understanding of the problem and that can help guide the decision-making process.

It is important to mention that research in and the development of the concept of risk in the applied and physical sciences commenced with the modern development of probability theory. In this context, the concept of *probability* had quasi-deterministic overtones, where probability scores were influenced by an epistemic lack of knowledge or, in other words, *uncertainty*. This can, in principle, be overcome by more experimentation and learning exercise. But the need to formulate statistical physics in order to study certain complex phenomenon has introduced a component of irreducible uncertainty, which has been called *randomness*. These two types of uncertainty reflect the duality that underlies the concept of probability, and therefore of risk.[6] At present some other analytical theories are related to the uncertainty: the theory of fuzzy sets, the theory of possibility, and the theory of evidence (Kikuchi/Pursula 1998). According to Max Weber (1991) the sociology of risk is a science of potentialities and of *Möglichkeitsurteile*; i.e. of judgments about possibilities.

There are a wide range of approaches for integrating data and modelling risk and vulnerability. *Inductive* approaches model risk through weighting and combining different hazard, vulnerability, and risk reduction variables. *Deductive* approaches are based on the modelling of historical patterns of materialized risk (i.e. disasters, or damage and loss that have already occurred). Other approaches combine the re-

6 Such as it is defined in a platform for disaster risk modeling like CAPRA (ERN 2009a). See <www.ecapra.org>.

sults of inductive and deductive modelling. An obstacle to inductive modelling is the lack of accepted procedures for assigning values and weights to the different vulnerability and hazard factors that contribute to risk. Deductive modelling will not accurately reflect risk in contexts where disasters occur infrequently or where historical data are not available. In spite of this weakness, deductive modelling offers a short cut to risk indexing in many contexts and can be used to validate the results from inductive models. There are no standard procedures for measuring or weighting the effectiveness of risk reduction, given the large number of stakeholders and the wide variety of activities involved.

Risk *indicators* or *indices* are feasible techniques for risk monitoring and may take into account both the harder aspects of risk as well as its softer aspects (Cardona/Hurtado/Duque/Moreno/Chardon/Velásquez/Prieto 2003; Cardona 2006; IDEA 2005a, 2005b[7]). The usefulness of indicators depends on how they are employed. The way in which indicators are used to produce a diagnosis has various implications. The first relates to the structuring of the theoretical model. The second refers to the way risk management objectives and goals are decided on. This aspect is important given that it is preferable to promote an understanding of reality not in strict terms of the ends to be pursued, but, rather, in terms of the identification of a range of possibilities, information on which is critical to organize and orientate the praxis of effective intervention (Zemelman 1989). An appropriate technique based on indicators can be a rational benchmark or a *common metric* to rule the risk variables from a *control* point of view (Carreño/Cardona/Barbat 2007b). The goal is not to *reveal the truth*, but rather to provide information and analyses that can improve decisions.

It is important to recognize that complex systems[8] involve multiple facets (physical, social, cultural, economic, and environmental) that are not likely to be measured in the same manner. Physical or material reality have a *harder* topology that allows the use of quantitative measurement, whilst collective and historical reality have a *softer* topology where the majority of the qualities are described in qualitative terms (Munda 2000). These aspects indicate that a weighing or measurement of risk involves the integration of diverse disciplinary perspectives and this may usher in problems of comparability. In other words, in order to measure risk and its management we need a holistic focus (Cardona 2001, 2004, 2006). This type of integral and interdisciplinary focus can more consistently take into account the non-linear relations of the parameters, the context, complexity, and dynamics of social and environmental systems, and contribute to more effective risk management by the different stakeholders involved in risk reduction decision-making. It permits the follow-up of the risk situation and the effectiveness of the prevention and mitigation measures can be easily achieved. Results can be verified and the mitigation priorities can be established with regard to the prevention and planning actions to modify those conditions having a greater influence on risk (Carreño/Cardona/Barbat 2007a).

3.5.2 Politics and the Decision-making Process

It is important to stress that the concept of risk is linked to decision-making and, therefore, it has a time dimension relating to the feasibility and convenience of taking action. Risk is directly related to its mediation; be it scientific, political, economic or popular. Once one knows that there is a possible consequence, one faces a responsibility. This responsibility takes the form of a *decision*, although not to decide is by itself a decision. From a risk management perspective, actions that reduce the vulnerabilities and stimulate the strengths and capabilities of exposed communities must be the main objective of risk management planning and actions; i.e. the *decision science* from the perspective of disasters.

Political decisions on risk are taken under conditions of uncertainty and are based on data of variables and, at times, of undetermined quality. This may be complicated by the political manipulation of uncertainty in order to speed up or slow down a decision and action. Quality, understood as the ability of a product to satisfy determined requisites, is the concept that underlies the determination of its attributes and criteria that allows an analysis of the decision-making process (Funtowicz/Ravetz 1990, 1992). Hence, the key question is: what is the role of the information in decision-making? Once the problem of

7 Available at: <http://idea.unalmzl.edu.co>.

8 This representation is based on a constructive rationality that allows the consideration of uncertain, incommensurable, multidimensional, and conflicting aspects and effects. It departs from the recognition that risk is a condition or state of the dynamics of a socio-ecological, non-linear, and dissipative system as a framework for interactions and for making integrated multi-criteria evaluations (macro and micro) and for decision-making in multiple variable environments.

designing criteria has been resolved, the following question arises: who will determine the criteria to be used? (Corral 2000) Uncertainty with regard to risk and the fact that the scientific community can not possibly resolve and characterize these problems totally ('given that no expert can provide certainty for political decisions') has led to a request for the inclusion of more actors, including the community, into the decision-making process. This permits a plurality of perspectives which, whilst not denying the competence of experts, permits the inclusion of a wide range of stakeholders in decision-making. It provides a combination of skills that permit all those involved in the problem to enrich the collective vision. Thus, the determination of criteria must be arrived at by dialogue and cooperation between experts, decision-makers, and other relevant actors, using the notion of *quality* as a baseline.

The models that are applied in the design of public policies such as risk management may influence the quality of the decision process. Opting for one type of modelling over another (for instance, mono- as opposed to multi-criteria models) may lead to different results which then push public policy objectives in a determined direction. Therefore, despite what many believe, the design of a public policy like risk management is very much related to the evaluation technique used to orient that policy. The quality of the evaluation technique, called by some as its scientific pedigree, has unsuspected influence on policy formulation. If the diagnosis invites action it is much more effective than where the results are limited to identifying the simple existence of weaknesses or failures.

The quality attributes of a model are represented by its *applicability*, *transparency*, *presentation*, and *legitimacy*. Respect for these attributes determines the *scientific pedigree* of a particular technique. Applicability refers to the way a model is adjusted to the evaluation problem at hand, to its reach and comprehensiveness, and the accessibility, aptitude, and level of confidence of the information required. Transparency is related to the way the problem is structured, facility of use, flexibility and adaptability, and to the level of intelligibility and comprehensiveness of the algorithm or model. Presentation relates to the transformation of the information, visualization, and understanding of the results. Finally, legitimacy is linked to the role of the analyst, control, comparison, the possibility of verification, and acceptance and consensus on the part of the evaluators and decision-makers.

In conclusion, the development of techniques that permit a permanent monitoring of territorial and social accumulation of vulnerability or the evolution of physical trigger processes is conducive to the application of realistic and dynamic planning techniques. This should be flexible enough to adjust to continuous or abrupt changes in the natural, economic, and social environment. This type of corrective and prospective approach is more appropriate than the uni-dimensional approaches, given the levels of uncertainty and instability that characterize existing processes of change and which render long term plans almost impossible to realize. In many places economic, social, and cultural factors are becoming increasingly relevant for the dynamics of growth and progress. In view of this, we need to develop less rigid planning models that allow us to more adequately incorporate uncertainty, instability and surprise, using diagnostic and follow-up techniques that permit the monitoring of the social and environmental context and possible perturbing agents.

The holistic approach to disaster risk and management herein described, based on a consistent conceptual framework, has been used to develop evaluation methods to measure vulnerability and risk with the purpose to favour decision-making, implementation, and action. They have been developed taking into account the attributes of the scientific pedigree of modelling. Nowadays, there are examples worldwide of how this model has been used by distinct kind of stakeholders in different territorial levels. The methods based on composite indicators and indices developed and adapted using this model have proven useful in identifying relevant issues of vulnerability, in guiding risk reduction from an interdisciplinary perspective, and taking in mind as objective of these metrics a preventive vision of development.

4 Economic Vulnerability and Economic Security

Czeslaw Mesjasz

4.1 Introduction

Over the last two decades 'vulnerability' has become a topical issue in multidisciplinary studies concerning a broad variety of overlapping domains – agriculture, climate, development and poverty studies, disaster and risk management, economic geography, engineering, finance, information technology, military theory and policy, public health, security studies and sociological studies of disasters. Vulnerability is also applied both in a traditional, narrow approach and in a broadened interpretation of security.

Due to its multiple applications, vulnerability must have different meanings depending on the area (narrow interpretation of security, economy, environment) and on the level of socio-economic hierarchy. Similarly as in the case of security, which has also a multitude of meanings, a question must be asked whether a common systemic interpretation of the vulnerability concept is achievable.

In the literature four security 'dangers' and 'concerns' are distinguished: threats, challenges, vulnerabilities and risks (Brauch 2005: 7; chap. 2 above). A closer look at these concepts allows concluding that their meanings are overlapping and that they are logically interdependent. It has important consequences for security theory since it shows that those terms are redundant and it is necessary either to resign from some of them or to study their meaning more precisely. It has a fundamental importance for the proponents and critics of securitization of environmental issues and for advocates and adversaries of the concept of human security.

Similarly as in 'adjective' domains of security in its broadened meaning, several overlapping domains (sectors, areas) of vulnerability can be distinguished – economic, environmental, military, social and political although in most cases a separation of these areas is impossible.

As in other cases of fuzzily defined normative concepts, vulnerability can be seen both as a 'buzzword' in the language of politics and as a term used for more or less precise descriptions and analyses in research and policy-making. It is then necessary to investigate whether structural invariants of vulnerability exist in various contexts or whether it is just another term used in theory as a dead metaphor with different and incongruent meanings. Such a situation exists in security theory where it is sometimes difficult to find a systemic resemblance between broadly defined human security and military security. It is especially visible when a securitization approach is applied.

For more precise considerations, vulnerability needs to be interpreted in a multiple way as "vulnerability of what", "vulnerability to what" at "what scale", to mention only the most important aspects (Bogardi 2006: 5).

In the broadened security concept, vulnerability was treated as the other side of the coin with threats in all security sectors (Buzan/Wæver/de Wilde 1998). In the discussion on vulnerability it is commonly agreed that vulnerability is a two-sided phenomenon. Thus in the security discourse threats and vulnerabilities are two sides of the coupling state of an object with its environment.

A review of writings on the theory of development and environment concludes that vulnerability has become their key descriptive and analytical concept, in some way competing with the use of security in a broadened sense. In consequence, the use of the concept of security in non-traditional sectors, e.g. in environment studies, is decreasing, and subsequently, considerations on securitization in the sense proposed by the Copenhagen School (Buzan/ Wæver/de Wilde 1998) are also given less attention.

This process reflects a specific 'desecuritization' of environmental issues. A question is however arising what are the consequences of a replacement of security with vulnerability in various areas of extended security theory and policy – environmental, economic, development, and last but not least, in human security.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_4, © Springer-Verlag Berlin Heidelberg 2011

This is not only a theoretical problem. The process of replacement of security considerations with vulnerability means a shift of attention from the context of an object where threats (dangers, disturbances) and reactions to them are scrutinized in relation to the object, to inherent characteristics of that object considered in relations to its surrounding.[1] As far as the emotional or normative meaning of those two terms is concerned they both have the same appeal of uncertainty and negative emotions on the present status and about the future of the object and its surrounding. The dilemma emerging in the theory of broadened security requires separate considerations, especially for environmental studies, development problems and human security issues.

A similar phenomenon can be also observed in the discussions on economic security. In this case interactions between security and vulnerability seem particularly interesting due to difficulties in defining economic security under market conditions and for market actors – companies and areas – finance (Buzan/Wæver/de Wilde 1998; Mesjasz 2008a).

There are other impulses to broaden and deepen the studies of economic vulnerability and economic security. The ongoing turmoil on financial markets (2007–2010) has shown that studies of economic vulnerability should be extended from the traditional area of poor and small states to more developed indebted countries, e.g. to Greece, Portugal, Spain, some of the new emerging market economies, e.g. Latvia and Lithuania or perhaps, even to most developed countries affected by financial problems, such as the United Kingdom or the United States.

Trouble on financial markets is caused and at the same time is stimulated by inefficient governance and control of financial institutions and of corporate governance. Therefore it is inevitable to expand reflections on economic vulnerability and economic security to market-oriented organizations as well as other institutions.

In continuation of earlier studies on economic security, several questions can be raised. What is economic vulnerability? What are the relations between security and vulnerability in all security sectors? And subsequently, what is the specificity of the links between economic security and economic vulnerability for all economic actors? Can the term economic security be applied to all economic actors?

In systemic terms, security and vulnerability can be regarded as two sides of the same coin since each of them enables defining the other one. The same relationship exists between vulnerability and threat, danger and disturbance. Thus, additional questions may be raised. Are those ideas absolutely symmetrical? If so then in purely logical terms their definitions would be redundant and only one of them should remain. If not, then what makes a difference between them?

This chapter offers partial answers to these questions on the relations between economic security and economic vulnerability. The broadened security concept of the Copenhagen School (Buzan 1991; Buzan/Wæver/de Wilde 1998) and ideas developed in previous volumes of the Hexagon series constitute a conceptual framework. A detailed analysis of the meanings of the above utterances is not possible here but a deeper explanation of economic vulnerability and economic security as well as of their linkages is proposed.

A further objective is to extend the discussion on vulnerability beyond environmental issues and development theory to broader economic issues and to include other market and non-market actors. A survey of definitions of vulnerability is treated as a point for departure for a deepened analysis of the meaning of economic vulnerability. The chapter was prepared between 2008 and May 2010 when new phenomena relating to economic and financial vulnerability were in *statu nascendi*. Thus, any far-reaching conclusions are impossible.

Given the multitude of definitions, interpretations, measures and indices of vulnerability (chap. 2 by Brauch), and economic vulnerability in particular, it is impossible to refer to all of them. The selection is based on the need to answer the research questions. This also applies to the discussion of relations between economic vulnerability and sustainability. The many definitions of vulnerability make it impossible to study the links between the levels of hierarchy of socio-economic systems and economic vulnerability.

Section 4.2 offers a survey of definitions and interpretations of vulnerability, including environmental and social vulnerability, and proposes a systemic interpretation of vulnerability, security and securitization. The next part focuses on economic vulnerability (4.3.) discussing the meaning of the term 'economic' in the discussion on vulnerability (4.3.1) and interpreting economic vulnerability of various social entities, of states (4.3.2), non-state actors (4.3.3), households and individuals (4.3.4). Then the links between economic

1 Due to the variety of definitions of such terms as hazard, risk, threat, etc. the terms 'disturbance' and 'disruption' will be used for describing external or internal influence on the functioning of a system under scrutiny.

vulnerability, economic security and securitization are studied (4.4). Finally, a new approach and an extension of applications of the concept of economic security are proposed (4.5).

4.2 Vulnerability in the Security-related Discourse

4.2.1 Definitions and Interpretations of Vulnerability

The concept of vulnerability is used in many areas,[2] why vulnerability research covers a complex, multidisciplinary field that is of particular importance for organizations trying to reduce vulnerability, especially regarding poverty and other Millennium Development Goals. Researchers are currently working to refine definitions of 'vulnerability', measurement and assessment methods, and effective communication of research to decision-makers.

Given the many applications of vulnerability and its multiple interpretations, in the social sciences it is neither necessary nor possible to strive for a unique definition of vulnerability. Multidimensional interpretations that include only a common 'core meaning' are sufficient for studying various characteristics of objects taken together and labelled as vulnerability. The Vulnerability Network and Observatory[3] collected 30 definitions of vulnerability and are discussed below (Brauch 2005; Perry/Quarantelli 2005; Thywissen 2006; Villagrán de León 2006; Warner 2007; Nathan 2009).

For Brauch (2005: 7; chap. 2 above) 'vulnerability' is one of four security features besides 'threats', 'challenges' and 'risks', but the redundancy of the meaning and of the political use of these terms makes this typology rather superficial (chap. 12 by Brauch). In a universal sense, vulnerability has two basic meanings. First, as a set of characteristics of uncertainty about the future of any object – technical (military equipment, IT systems), biological (human beings, animals, species) and social (from individuals to global society). In this meaning vulnerability is usually associated with danger, disaster, hazard, resilience, risk, stress, threat, etc. Relations between vulnerability of social entities will be discussed below. In a general sense vulnerability refers to expectations towards negative external and internal contingencies of a system.

The second meaning of vulnerability in development theory and policy and in associated areas points to 'vulnerable groups', such as the elderly, orphans, widows or even more general, such as the landless or low-paid workers (Dercon 2006). Vulnerability refers to a more general 'weakness' or a meaning of 'defencelessness' and to a lack of means to cope without damaging loss. The loss can take many forms, becoming or being physically weaker, economically impoverished, socially dependent, humiliated or psychologically harmed.

In one of the first definitions, vulnerability is treated as an opposite to security and described as exposure to contingencies and stress, and difficulty in coping with them. It has two sides: an external side of risks, shocks, and stress to which an individual or household is subject; and an internal side which is defencelessness. Although vulnerable is used simply as a synonym for poor, vulnerability is no synonym for poverty (Chambers 1989: 1). The weak social groups may also face uncertainty-related vulnerability, but their defining characteristic is unrelated to uncertainty or risk, but linked to their general inability to take advantage of profitable opportunities. Without substantial support they may end up in severe and persistent poverty.

The two-sided interpretation of vulnerability proposed by Chambers (1989) has been extended by Bohle (2001). In this structured approach, the external side of vulnerability basically refers to the exposure to stresses and is influenced by these factors (Bohle 2001; Villagrán de León 2006: 12):

- *human-ecological perspectives*, which target population dynamics and capacities to manage the environment;
- *entitlement theory*, which relates vulnerability to the incapacity of people to obtain or manage assets via legitimate economic means;
- *political economy* approaches, which relate vulnerability to the exposure of some groups to social inequalities and to the control of assets by some upper classes, leading to struggles, including struggles between government and some groups of people.

The internal (coping) side of vulnerability is determined by:

- *action theory* approaches, which span the means and ways used by the people to act, either by free

2 Deepened linguistic considerations on vulnerability are presented in Brauch (2005: 31) and chap. 2 above.

3 Vulnerability Network & Observatory: *Definitions of Vulnerability*; at <http://www.vulnerabilitynet.org/> (15 March 2010).

will or as a result of societal, governmental, or economic constraints;
- *models of access to assets*, which allow people to mitigate their vulnerability via access to assets of different nature;
- *crisis and conflict theory*, which focuses on the control of resources and assets, the capacity to manage crisis situations, and the resolution of conflicts.

Definitions quoted herein reflect most important features of vulnerability in a universal sense. In a framework of the *International Strategy on Disaster Reduction* (ISDR 2002: 24, 342) vulnerability has been defined "as a set of conditions and processes resulting from physical, social, economical, and environmental factors, which increase the susceptibility of a community to the impact of hazards". These conditions are shaped "continually by attitudinal, behavioural, cultural, socio-economic and political influences at the individuals, families, communities, and countries". Vulnerability is closely linked to development.

From the perspective of the hazard research community, Blaikie, Cannon, Davis and Wisner (1994, 2000) redefined vulnerability commonly used as "being prone to or susceptible to damage or injury". Their working definition is:

> By 'vulnerability' we mean the characteristics of a person or group in terms of their capacity to anticipate, cope with, resist, and recover from the impact of a natural hazard. It involves a combination of factors that determine the degree to which someone's life and livelihood is put at risk by a discrete and identifiable event in nature or in society. ... We use the term to mean those who are more vulnerable. When used in this sense, the implied opposite of vulnerable is sometimes indicated by our use of the term secure. ... Our definition of vulnerability has a time dimension built into it. Since it is damage to livelihood and not just life and property that is at issue, the more vulnerable groups are those that also find it hardest to reconstruct their livelihoods following disasters. ... Our focus on vulnerable people leads to give secondary consideration to natural events as determinants of disasters. Normally, vulnerability is closely correlated with socio-economic position (cited and summarized by Brauch 2005: 36).

According to Villagrán de León (2006: 8), vulnerability is generally perceived as the predisposition of societies to be affected and the incapacity to cope with disasters; and hazard, as the probability or possibility that an external event manifests itself in a certain geographical area within a certain interval of time. Hazards can be classified as natural: earthquakes, volcanic eruptions or hurricanes; technological in the case of explosions, spills, and release of toxic chemicals, and as social or human-induced in the case of civil riots, or terrorist attacks.

The list of hazards can also include a new emerging class, denoted as socio-natural, which are created or enhanced as a result of human action: climate change as a result of agricultural fires, burns and gaseous industrial emissions; landslides due to deforestation of mountains and high-sloped hills, and salinization as a result of poorly designed irrigation of soils are typical examples.

In a general sense, although relating to country's economy, vulnerability may be defined as the risk of being negatively affected by shocks. Shocks can be caused by nature – for example, a cyclone, earthquake, drought or locust invasion. Such shocks can perhaps be anticipated but often cannot be prevented. However, countries can also be adversely affected by economic shocks that are outside their control, such as a rapid decline in the price of their major export, changes in interest rates on international capital markets or reduced access to credit (UN CDP 1999: 10).

The impacts of climate change, adaptation and vulnerability have also been scrutinized by the second IPCC working group (1990, 1996a, 2001a, 2007a; Brauch 2005: 35; chap. 2 above), whose mandate is "to assess the vulnerability of ecological systems, socio-economic sectors, and human health to climate change". The IPCC also distinguishes between sensitivity, adaptive capacity and vulnerability ("the degree to which a system is susceptible to, or unable to cope with, adverse effects of climate change, including climate variability and extremes").

It is also necessary to underline narrow and broad interpretations of vulnerability. For Oliver-Smith (2004: 10) "vulnerability is fundamentally a political ecological concept", while, according to Brauch (2005: 31), Wilches-Chaux (1989: 20–41) identifies 11 types of vulnerability, "natural, physical, economic, social, political, technical, ideological, cultural, educational, ecological and institutional vulnerability". Villagrán de León (2006) distinguishes three independent categories (dimensions) of description and analysis of vulnerability – sectors, components and scale of consideration. For the purpose of studying economic vulnerability the last dimension should also include another level of companies and social organizations.

According to Wisner (2004: 183–193), vulnerability is used in the hazard community as:

- structural engineering vulnerability;
- lifeline infrastructural vulnerability;
- communications systems vulnerability;

Table 4.1: Dimensions of description and analysis of vulnerability. **Source:** The author's own research based on Villagrán de León (2006: 22).

Sectors	Components of vulnerability	Scale of consideration
Agriculture	Administrative	Global
Basic lifelines	Economic	Regional (Transnational)
Commerce	Environmental	National
Education	Functional	State or Province
Energy	Gender	District or Municipal
Finance	Physical	Local or Community
Health		Company or Social Organization
Housing		Household (Livelihood)
Industry		Human beings
Infrastructure		
Telecommunications		

- macro-economic vulnerability;
- regional economic vulnerability;
- commercial vulnerability;
- social vulnerability.

Cardona (2004: 37–51; chap. 3 above) proposed a holistic approach to vulnerability and risk arguing that in developing countries social, economic cultural and educational aspects are frequently "the cause of the potential physical damage". For Cardona "vulnerability of human settlements is intrinsically tied to different social processes. It is related to fragility, susceptibility or lack of resilience of the exposed elements. On the other hand, vulnerability is closely linked to natural and human environmental degradation at urban and rural levels".

In his process-based interpretation, Cardona (2004: 49) argues that from a social view "vulnerability signifies a lack or a deficiency of development" that often contribute to "disaster vulnerability". He pointed out that population growth, rapid urbanization, environmental degradation, global warming, international financial pressures and war have all increased vulnerability resulting from:

- physical fragility or exposure: the susceptibility of a human settlement to be affected by a dangerous phenomenon due to its location in the area of influence of the phenomenon and a lack of physical resistance;
- socio-economic fragility; the predisposition to suffer harm from the levels of marginality and social segregation of human settlements, and the disadvantageous conditions and relative weakness related to social and economic factors; and
- lack of resilience: an expression of the limitations of access and mobilization of the resources of human settlement, and its incapacity to respond when it comes to absorbing the impact.

To expose the links between vulnerability and social change, Birkmann (2005: 5) proposes that vulnerability must be understood as a process embedded in a larger development process. In this processual interpretation vulnerability does not involve merely active and passive factors, but rather dynamic objects and subjects in continuous motion. It could be described with the indicators which should allow identifying goals more precisely and providing guidance for strategies of vulnerability reduction. Due to the intricate character of vulnerability it is not surprising that it is often associated with ideas derived from complex systems studies (Warner 2007: 16).

These definitions of vulnerability and adaptation have implications for normative assessments. In the first case, vulnerability depends on the adaptation that has taken place; in the other, vulnerability is defined as a capacity to adapt, and the capacity to respond to stress is a starting point for impact analysis.

Nathan (2009: 1126) distinguished two features of vulnerability: exposure and insufficient capacities. a) physical exposure: presence and density of the people, habitat, networks, goods and services in risk zones, defining potential losses or damages, both human and non-human (stakes); and b) socio-ecological: human-induced ecosystemic perturbations aggravating the natural hazard (deforestation, land degradation, street pavement, some engineering practices, climate change, etc.) Insufficient capacities to prevent, prepare for, face and cope with hazards and disasters can be separated in:

- physical weakness: physical incapacity to resist or recover from a hazard's impact;
- legal vulnerability: weak state of the legislative and judiciary regulations to prevent, mitigate, prepare for, face and recover from disasters;
- organizational vulnerability: weak state of the organizational disposals, at all levels, to prevent, mitigate, prepare for, face and recover from disasters;
- technical vulnerability: inadequate knowledge and/or use of risk management techniques;
- political vulnerability: weakness of the political powers, their legitimacy and control. Inadequacy

of the control schemes, policies and planning, or broad political conditions;
- socio-economical vulnerability: socio-spatial segregation, large inequalities of wealth and of access to the security disposals, misery, anomie and social disorganization, poor social position and social isolation of exposed people, existence of higher social risks undergone by people;
- psychological and cultural vulnerability: inadequate security paradigm or risk perceptions;
- cultural anomie or weakness; attachment to risk zones or risky behaviour, non-willingness or incapacity to protect oneself.

Scholars from UNU-EHS have developed two different vulnerability models: the 'BBC-model' by Bogardi and Birkmann (2004) based on the concept of Cardona (2004) and the 'onion model'. The latter model analyses the impacts of a hazard (based on processes of climate change, globalization and innovation) both on a reality (certainty) and an opportunity (probability) axis on a natural events sphere (as a flood event or hazard) that impact on the economic sphere (as flood damage or risk) and on the social (disutility) sphere (as flood disaster or vulnerability) whose intensity or degree will be modified by the coping capacity. Social vulnerability should include the economic dimension but also confidence, trust, fear, apathy as potential consequences of a specific hazard (Brauch 2005: 54).

The 'BBC-model' defines 'vulnerability' and 'risk' as key components in the hazard-vulnerability-risk chain. A hazard impacts on a multidimensional concept of vulnerability that is influenced by the environmental, the social and the economic sphere, where the degree of exposure is reduced by the specific coping capacity in the specific region or country. 'Risk' is the product of these complex determinants and can be measured and observed as environmental, social and economic risk. While the 'onion model' excludes environmental vulnerability, the 'BBC-model' takes social, economic and environmental vulnerabilities into account (Brauch 2005: 54–55).

Villagrán de León (2006: 18) distinguishes two discerning facts regarding views on vulnerabilities with respect to their dependency on the type of hazard. According to one view, vulnerability does not depend on the type of hazard in question and can be related to issues associated with underdevelopment (poverty, power relations, access and control of assets, societal structures, insecurity, etc.), and in the opposite point of view it does.

Models proposed by Chambers (1989), Bohle (2001), Briguglio (1995, 1997) and Pelling (2003) are examples associated with the first perspective. Models by UNDP-BCPR (2004) and Villagrán de León (2006) point to the second. Among the examples associated with the second view are the vulnerability of infrastructure to earthquakes and droughts. The impact of drought on infrastructure is negligible compared to earthquakes. However, the impact of droughts on agriculture is vast and can be minimal in the case of earthquakes.

In addition to the above selective list of definitions and interpretations of vulnerability there are attempts to elaborate more precise definitions of vulnerability. The most advanced model was proposed by Luers (2005) that defined vulnerability as the susceptibility to damage, and is often characterized in terms of one or more of the following: the sensitivity to or exposure of a system (people or place) to shocks, stresses or disturbances, the state of the system relative to a threshold of damage, and the system's ability to adapt to changing conditions (IPCC 2001; Luers/Lobell/Sklar/Addams/Matson 2003). The terms 'shocks', 'disturbances', 'stresses' and 'perturbations' are often used to refer to exogenous forces that have the potential of creating an adverse impact, e.g. (Kelly/Adger 2000; Chambers 1989; Bohle/Downing/Watts 1994). A force is seen to be 'exogenous' if its occurrence is beyond the power of the unit of analysis such as the individual or household (Kelly/Adger 2000). These forces include phenomena such as climate variability and change, floods, hurricanes and market fluctuations.

Research on all kinds of vulnerability often deals with characteristics that are difficult to measure, either because data are unavailable or because the factor of interest is difficult to quantify with features which could be described with objective scales, a ratio scale or at least a cardinal scale. Therefore, as for many other features of social systems, debates evolved on how to measure the 'unmeasurable' in ways that are meaningful to policy-makers and institutions in the realm of sustainable development, environment policy and economy, or in a broader sense, in governance in all those areas (Birkmann 2006, chap. 69 below; Warner 2007, chap. 71 below).

The quantification of vulnerability is accomplished in two ways. The most dominant approach is based on defining various sets of indices which reflect characteristics of vulnerability of social entities and individuals. Less frequent are comprehensive mathemati-

cal models reflecting functional relationships between components of vulnerability.

Among numerous more or less descriptive qualitative or quantitative models of vulnerability, the concept of operationalization proposed by Luers (2005) is among the most rigorous. According to this model, vulnerability is conceptualized as a vector, and relative vulnerability is represented by a position on a three-dimensional surface. Definition of the surface is based on a generic vulnerability function, which is derived by translating a general definition of vulnerability, the susceptibility to damage, into a mathematical expression (Luers/Lobell/Sklar/Addams/Matson 2003). To do this, first a threshold of damage is defined and then susceptibility is represented in terms of its sensitivity and exposure to exogenous disturbing forces and its state relative to a threshold of damage:

$$Vulnerability = f\left[\frac{(Sensitivity, Exposure)}{State/Threshold}\right]$$

Vulnerability expressed in this form can be treated as a surface in a three dimensional space and is proportional to sensitivity and exposure and inversely proportional to the state of the system relative to a threshold of damage. While the specific functional form will vary by context and location, the general relationship between the components of the equation is likely to characterize vulnerability broadly. The goal is not to simply define a quantifiable measure, but rather to represent a relationship in a standard form that can be used as a tool to help sort through the complexity of vulnerability analysis (Luers 2005: 216).

4.2.2 Vulnerability and Related Concepts

Difficulties with defining vulnerability are in some way deriving from the many proposals of its determinants and components. Vulnerability is usually defined with the use of two groups of terms. The first group embodies external factors influencing an object (system, element) under scrutiny – risk, challenge, disaster, hazard, shock, stressor, threat, security challenge. The other one includes characteristics of the object (system, element) – coping, coping capacity, adaptive capacity, exposure, resilience.

A special significance in the discussions on economic vulnerability and economic security is given to sustainability in numerous areas – environmental, social economic and at all levels, beginning from the global one and ending with the level of elementary market units (company) and non-market units – institutions of self-government, households, etc. Due to its complexity and lack of an unequivocal definition it may be only stated that vulnerability is rather a short-term characteristic of any social entity while sustainability reflects a long time tendency. In numerous cases vulnerability is referred to as a factor undermining sustainability. Although the authors of definitions of vulnerability aim at putting in order relations among meanings of those terms, it will most likely not be possible. In consequence, more advanced discussions on vulnerability are hampered by an insufficient clarity of the notions applied.

In order to achieve a sufficient level of conceptual precision for analysing economic vulnerability, economic security and the sense of securitization in the discourse on economic vulnerability, a review of building blocks of definitions of vulnerability is presented below. It does not provide systematic typologies of interpretations but only shows the main discrepancies and similarities in defining vulnerability both in a universal sense as well as in specific domains.

It is somehow puzzling to observe that definitions of vulnerability and of other above terms are often illustrated with specific formulae and expressions, which sometimes are labelled as the 'mathematical' ones. However, they cannot be treated like that, e.g. as algebraic formulae but solely as a kind of conceptual framework in which various fuzzily defined linguistic variables are presented in quasi mathematical (arithmetic) operations applied as a point of departure for further operationalizations. Some of those formulae are described below.

4.2.2.1 Risk

Risk is the first notion that is used in defining vulnerability. It has become especially important since the ideas of 'risk society' (Beck 1986, 1992, 1999, 2007, preface essay above) have become dominant in theoretical discussions as a reaction to the increasing role of human-driven change in a modern society. Beck (1999: 3–4) defines 'risk'

> as the modern approach to foresee and control the future consequences of human action, the various unintended consequences of radicalized modernization. It is an (institutionalized) attempt, a cognitive map, to colonize the future. Every society has ... experienced dangers. But the risk regime is a function of a new order: it is not national, but global. ... Risks presuppose decision. These decisions were previously undertaken with fixed norms of calculability, connecting means and ends or causes and effects. These norms are precisely what 'world risk society' has rendered invalid. ... What has given rise to the prominence of risk? The concept of

risk and risk society combines what once was mutually exclusive – society and nature, social sciences and material sciences, the discursive construction of risk and the materiality of threats.

In more 'technical' considerations risk can be depicted in a threefold way:

- definition from classical decision theory and economics – "risk as a measurable uncertainty" (Knight 1921; Luce/Raiffa 1957).
- risk as missing the goal (in negative and in a positive sense) – definition applied in risk management,
- functional definitions of risk in which it is treated as a function, usually product and/or sum of specific components.

The concept of risk applied in the discourse on vulnerability is usually reduced to the third group of definitions. Bearing in mind a subjective character of risk, such an approach imposes significant limits on a deepened understanding and analysis of vulnerability, not only in economics but also in other areas (Mesjasz 2008b). The basic formula of risk found in numerous writings in risk studies (Villagrán de León 2006: 9) reflects the abovementioned 'mathematical' interpretations:

$$\text{Risk} = \text{Hazard} \,¤\, \text{Vulnerability}$$

where ¤ represents the function that describes the combination between the hazard and the vulnerability. The simplest example of such a function is a product, as proposed by UNISDR (2004: 16)

$$\text{Risk} = \text{Hazard} \times \text{Vulnerability}$$

Alexander (2000: 10) defines risk as "the likelihood, or more formally the probability, that a particular level of loss will be sustained by a given series of elements as a result of a given level of hazard". Total risk would then consist of the sum of predictable casualties, damages and losses, represented via the equation:

$$\text{Total Risk} = (\text{Elements at Risk}) \times \text{Hazard} \times \text{Vulnerability}$$

Relations between vulnerability and other related concepts are not always exposed by product. Other formulae are accommodated as well. Recent publications define risk incorporating such terms as 'coping capacity', 'exposure', and 'deficiencies in preparedness'. For example, one typical relation employed by many agencies is (Villagrán de León 2006: 9):

$$Risk = \frac{\text{Hazard x Vulnerability}}{\text{Coping Capacity}}$$

In this context, coping capacities refer to the means by which people or organizations use available resources and capacities to face adverse consequences related to a disaster. In general, such capacities involve management of resources before, during, and after the disaster.

Another formula of vulnerability has been proposed by the *Disaster Reduction Institute* (DRI) in a report to the *Department for International Development* (DFID) of the UK (Villagrán de León 2006: 9). Vulnerability itself is seen as a combination of exposure, susceptibility, and coping capacity:

$$\text{Vulnerability} = \frac{\text{Exposure x Susceptibility}}{\text{Coping Capacity}}$$

Villagrán de León (2006: 10) proposes another equation:

$$\text{Risk} = \text{Hazard} \times \text{Vulnerability} \times \text{Deficiencies in Preparedness}$$

More similar formulae can be found in the studies by Brauch (2005) and Villagrán de León (2006: 10) that concluded that no commonly accepted definition of risk exists. Despite multiple interpretations, risk remains a relatively clearly defined concept used in describing or defining vulnerability. Other ideas associated with vulnerability are defined in a more fuzzy way and their scope of meaning is often overlapping.

4.2.2.2 Hazard

Hazard is relatively clearly defined in the literature on natural disasters. From a variety of definitions the following ones are representative. According to UNISDR (2004: 16) hazard is a potentially damaging physical event, phenomenon or human activity that may cause the loss of life or injury, property damage, social and economic disruption or environmental degradation. Hazards can include latent conditions that may represent future threats and can have different origins: natural (geological, hydro-meteorological and biological) or induced by human processes (environmental degradation and technological hazards). Hazards can be single, sequential or combined in their origin and effects. Each hazard is characterized by its location, intensity, frequency and probability.

Other attempts tried to define hazards with 'mathematical' formulae. Mitchell (1990) conceptualizes

hazards as a multiplicative function of risk, exposure, vulnerability, and response:

Hazard = f (risk x exposure x vulnerability x response)

where
risk = the probability of an adverse effect
exposure = the size and characteristics of the at-risk population
vulnerability = the potential for loss
response = the extent to which mitigation measures are in place.

4.2.2.3 Disaster

Disasters are an object of analysis in anthropology, development studies, engineering, geography, geophysical science, sociology, social psychology, and in health sciences. This list is not complete and can be supplemented with other domains, e.g. environment studies or international relations. From many definitions the following can be viewed as representative.[4]

According to the UNISDR (2004: 17), disaster is a serious disruption of the functioning of a community or a society causing widespread human, material, economic or environmental losses which exceed the ability of the affected community or society to cope using its own resources. A disaster is a function of the risk process. It results from the combination of hazards, conditions of vulnerability and insufficient capacity or measures to reduce the potential negative consequences of risk.

Blaikie, Cannon, Davis and Wisner (1994) offered a comprehensive theoretical framework on the challenges of disasters. According to their definition: A disaster occurs when a significant number of vulnerable people experience a hazard and suffer severe damage and/or disruption of their livelihood system in such a way that recovery is unlikely without external aid. By recovery we mean the psychological and physical recovery of the victims, the replacement of physical resources and the social relations required to use them (Blaikie/Cannon/Davis/Wisner 1994: 21).

An attempt to develop a precise mathematical definition of disaster based in political economy of war and foreign aid was made by Cohen and Werker (2007). As a point of departure of the model the following distinction is proposed. 'Shock' refers to the natural act itself – the volcanic eruption, earthquake, drought, etc. – and 'disaster' refers to the net impact of the shock on the population.

4.2.2.4 Stress (Stressor)

While disturbances (perturbations) usually emerge unexpectedly and are major alterations in the system deriving from external surroundings and generating exceeding effects with which the system can cope while stress is a continuous increasing pressure on the system. Stressors are components of the stress, means of exerting a negative influence on that system.

4.2.2.5 Threat

In security theory and policy the term 'threat' is commonly applied usually without any deepened reflections on its meaning. According to the Merriam-Webster Online Dictionary the term threat has the following etymology: Middle English *thret* coercion, threat, from Old English *thrat* coercion; akin to Middle High German *drz* annoyance, Latin *trudere* to push, thrust. It has three meanings: "a) an expression of the intention to inflict evil, injury, or damage; b) one that threatens, and c) an indication of something impending <the sky held a threat of rain>" (chap. 2 by Brauch).

A more thorough analysis concerns the sense of the term 'existential threat', which constitutes the key concept of securitization theory proposed by the Copenhagen School. Assigning a meaning of existential threat to an issue is the foundation of securitization (Buzan/Wæver/de Wilde 1998). Threat without any measures of intensity and such normative interpretations as the above 'existential' characteristic is often used as a concept applied in describing or defining vulnerability in development or environment studies. A closer look at the literature on vulnerability leads to the conclusion that the difference between threat and hazard is of a purely discretionary character and would require a more deepened analysis.

While the above definitions considered the environment as an object under scrutiny, other concepts, such as exposure (Nathan 2009, see above), coping, coping capacity, adaptive capacity and resilience reflect characteristics of the object itself.

4.2.2.6 Coping and Coping Capacity

Following the definition by UNISDR (2004: 16), 'capacity' is a combination of all the strengths and resources available within a community, society or organization that can reduce the level of risk, or the effects of a disaster. Capacity may include physical, in-

4 A broad survey of interpretations of vulnerability can be also found in (Perry/Quarantelli 2005).

stitutional, social or economic means as well as skilled personal or collective attributes such as leadership and management. Capacity may also be described as capability.

'Coping capacity' refers to the means by which people or organizations use available resources and abilities to face adverse consequences that could lead to a disaster. In general, this involves managing resources, both in normal times as well as during crises or adverse conditions. The strengthening of coping capacities usually builds resilience to withstand the effects of natural and human-induced hazards. Sometimes coping capacity is reduced to the ability of adaptation, i.e. an ability of a unit to gradually transform its structure, functioning or organization to survive under hazards threatening its existence (Kelly/Adger 2000; Saldaña-Zorrilla 2006: 16).

4.2.2.7 Resilience

The meaning of resilience is close to the meaning of coping capacity (chap. 1 by Brauch/Oswald Spring). Resilience can be interpreted as an antonym of vulnerability. Similarly as with other vulnerability-related terms, there are numerous attempts to define resilience. According to UNISDR (2004: 16–17), resilience is the capacity of a system, community or society potentially exposed to hazards to adapt, by resisting or changing in order to reach and maintain an acceptable level of functioning and structure. This is determined by the degree to which the social system is capable of organizing itself to increase its capacity for learning from past disasters for better future protection and to improve risk reduction measures.

Resilience is becoming a notion with an autonomous meaning applied as sufficient for establishing a new domain of environmental and social research. The Stockholm Resilience Centre, established in 2007, aims to advance transdisciplinary research for governance of social-ecological systems with a special emphasis on resilience – the ability to deal with change and continue to develop. It is a joint initiative among Stockholm University, the Stockholm Environment Institute and the Beijer International Institute of Ecological Economics at The Royal Swedish Academy of Sciences. The centre is funded by the Foundation for Strategic Environmental Research (Mistra). According to this Centre, resilience refers to the capacity of a social-ecological system both to withstand perturbations from, for instance climate or economic shocks, and to rebuild and renew itself afterwards. Loss of resilience can cause loss of valuable ecosystem services, and may even lead to rapid transitions or shifts into qualitatively different situations and configurations, evident in, for instance, people, ecosystems, knowledge systems, or whole cultures.[5]

4.2.2.8 Security Challenge

In the literature on a wider security and human security (Brauch 2009: 74) the concept of 'security challenge' has been widely and increasingly applied. Similarly as in other cases, there are no deepened analyses on the links between the challenge and similar ideas such as risk, threat and vulnerability. The concept 'security challenge' is either treated as synonymous to 'threat' or implies a broader, softer character or new (non-classical) present and potential disturbances of functioning of a social or natural system (Brauch 2005: 29: chap. 2 above). It is also frequently used in the language of politics both at international (interstate) and national levels when precision is not necessary and the appeal is more of emotional character (see below chap. 12 by Brauch on the discussion in US national strategy papers).

As can be seen from the above preliminary survey of definitions and formulae, characteristics depicting the vulnerability possess a very broad spectre of interpretations. Sometimes they are even included in the definitions in a contradicting sense, as for example risk and hazard. In one case risk is used to define hazard and in another hazard is used to define risk. In purely formal terms it seems correct but when verbal definitions are taken into account such symmetry can be rarely achieved. Similarly, disaster research is a separate domain of scientific inquiry and it is not too easy to distinguish it from, say, risk analysis. The above survey shows that definitions of all those terms are fuzzy and overlapping. Thus, the discussions on vulnerability and related terms in various areas are incompatible and communication about their meaning is of a very limited effectiveness.

4.2.3 Vulnerability, Security and Securitization: A Systemic Interpretation

In security theory and policy and in the studies on vulnerability the relations between vulnerability and security are not always clearly delineated and in the literature there are a few studies addressing their direct links. Usually their relations are treated as indirect.

5 See on the Stockholm Resilience Centre; at <http://www.stockholmresilience.org/>.

The studies of direct links between vulnerability and security are focused on these topics:

- security and vulnerability in classic security considerations,
- vulnerability in all sectors of a broadened security concept,
- environmental (ecological) vulnerability and environmental (ecological) security,
- vulnerability and human security (including food security and livelihood security).

The indirect relations between those two concepts are commonly described but it must be underlined that it is not always possible to identify precisely the indirect links between universal or specific definitions of vulnerability and specific sectors of security. It is especially difficult in all areas of security except for military and environmental security. While military threats and vulnerabilities are relatively simple to identify, some environmental threats or hazards are undisputable, e.g. natural disasters, other examples of environmental threats may seem to be more disputable, e.g. long-term consequences of global warming.

In the narrow approach, security of the state or country is viewed as supplementary and in some way mirrors the category of vulnerability (Buzan 1991: 112–116; Crawford 1992: 4). A threat to the security of an object (a social entity or individual) may occur in consequence of existence of its vulnerability and vice versa. This symmetry and coupling constitute the key element in any discussions on the sense of vulnerability and security taken together. It concerns all security sectors and the only distinguishing factor is to what extent threat and vulnerability are objective or subjective and how easily this relationship can be identified.

In a classical definition proposed by Chambers (1989) vulnerability of social actors is also treated as opposite (inverse) to their security and described as exposure to contingencies and stress, and difficulty in coping with them. Villagrán de León (2006) indirectly refers to vulnerability as a concept opposite to security although he makes no direct reference to classical security concepts. Brauch (2005) treats discussions on vulnerability as a part of analysis of broadened security although he focuses primarily on environmental and human security. He also indirectly refers to securitization of environmental issues but does not propose any specific approach for the role of vulnerability in the processes of securitization.

Vulnerability of individuals is usually more often linked to security in a general sense, and to human security. In the World Bank's campaign vulnerability and risk associated with poverty are treated as opposites to security. Enhancing security is equivalent to reducing poor people's vulnerability to ill health, economic shocks, crop failure, policy-induced dislocations, natural disasters, and violence, as well as helping them cope with adverse shocks when they occur. A big part of this is ensuring that effective safety nets are in place to mitigate the impact of personal and national calamities (World Bank 2001: vi).

The links between vulnerability and security can be described with the idea of securitization developed by the Copenhagen School (Buzan/Wæver/de Wilde 1998). In the original approach of the Copenhagen School security is regarded as an act of speech which assigns an extraordinary significance to disruptions called threats, dangers, etc. but no direct reference is made to the role of vulnerability in securitization.

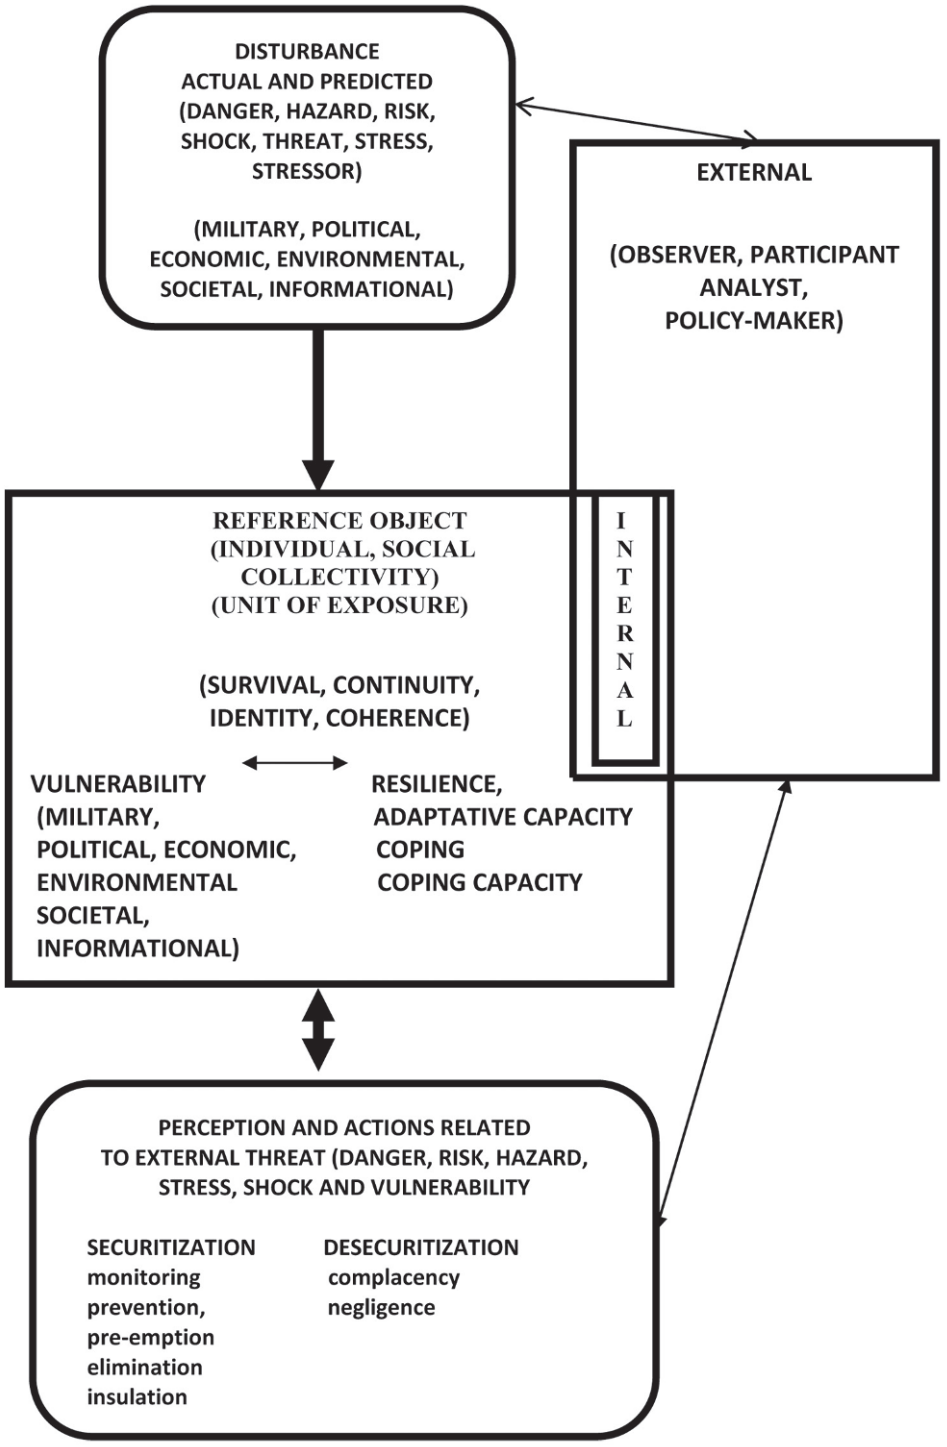
A question is how vulnerability can be included into the securitization process. First and foremost it must be concluded that vulnerability is associated with all kinds of external disturbances. It means that if an object is vulnerable beyond certain limits, or threat is perceived as something extraordinary, then the securitization is taking place. Subsequently, it may be concluded that calling a set of characteristics vulnerability can be perceived as an act of speech. Therefore a deeper reflection is needed whether in securitization the identification of external threats is equivalent to identification of vulnerability.

The following situations are hypothetically possible:

- identification of threats is directly linked to exposing vulnerabilities,
- external threats are exposed without a relevant reference to vulnerabilities,
- vulnerability is exposed to explicit relations to threats in the securitization process,
- vulnerability is exposed without direct relations to securitization,
- vulnerability is treated as dominant and security in a traditional and in a broadened sense is not considered.

The concept of vulnerability has been applied in theory and practice in a broad variety of areas that can be described in universal systemic terms as a feature of relations between an object (unit of exposure) and its environment. When recalling a systemic interpretation of a broadened concept of security, vulnerability is always linked to external disturbance. Taking into account the broadened security concepts and the impact of the Copenhagen School (Buzan/Wæver/de

Figure 4.1: Systemic framework of security, vulnerability and securitization. **Source:** The author's own research.



Wilde 1998; Brauch/Oswald Spring/Mesjasz/Grin/Dunay/Behera Chadha/Chourou/Kameri-Mbote/Liotta 2008), it can be also added that both threats (danger, disturbance, risk) and vulnerability are interconnected in the process of securitization. They can be seen as two sides of the same coin although it seems that they are different and not purely symmetrical. The asymmetry of those two ideas will be discussed below. As was observed in some studies (Luers/Lobell/Sklar/Addams/Matson 2003: 255),

> a new emphasis on vulnerability marks a shift away from traditional scientific assessments, which limit analysis to the stressors (e.g. climate change, hurricanes) and the corresponding impacts, towards an examination of the system being stressed and its ability to respond. By focusing on the mechanisms that facilitate or constrain a system's ability to cope, adapt or recover from various disturbing forces, vulnerability assessments aim to not only identify which systems are most at risk but also to understand why. This information is critical for decision-makers who often must prioritize limited resources in the design of vulnerability-reducing interventions.

In a simplified form interdependence between security and vulnerability can be illustrated with a scheme deriving from a systemic interpretation of security (Mesjasz 2008: 51). It can be treated as an extension and supplementary to the above considerations on relationships between various characteristics of vulnerability, its context, and relations to security and securitization. The above systemic or structural scheme (figure 4.1) allows for identification of characteristics of vulnerability and security that are applied in the process of securitization. It requires some additional explanations of the character of disruptions, their character (external/internal) and their consequences (risk and disaster), their measures and explanation of the links between vulnerability and security.

As to grasp the complexity of the double analysis of vulnerability and security, the initial scheme of a systemic interpretation of security should be extended by a rank of element. While in the discourse on security, the disturbances (disruptions) were predominantly associated with threat, danger, shock, they should be extended to other categories of risk, hazard, stress, stressors. In addition, characteristics of the second side of vulnerability of resilience, coping, coping capacity, adaptive capacity should also be taken into account.

The extension of categories of disturbances brings about two questions. First, in the concept of a broadened security, it is not clearly defined in a universal way whether 'existential threats' may have an external or internal character, in the discourse on vulnerability, threats, risks, hazards, etc. are only external. The internal side of vulnerability is characterized by susceptibility, resilience, coping capacity, adaptive capacity, etc. Second, the concepts of hazard, risk, threat and danger implicitly assume discontinuity, surprise and unpredictability. In the discussions on vulnerability they are supplemented with such ideas as stress and stressors which may be continuous and their impact can be to a large extent predictable.

Measurability of vulnerability is associated with predictability and unpredictability. In most of the attempts of building indices of vulnerability (social, environmental, economic) an implicit assumption of possibility of identification of threats, hazards and risks is embedded (Warner 2007). In the discourse on security dominance of uncertainty of existential threats is emphasized (Buzan/Wæver/de Wilde 1998). The role of uncertainty and limits of predictability is taken into consideration in all cases when a processual understanding of vulnerability is assumed (Cardona 2004).

Relations between vulnerability and security have to be analysed for both objective narrow and broadened security and subjective broadened security. In the case of objective, 'classical' security for which a threat is an objective category, vulnerability characterizes the state of a system exposed to the disturbances – risk or threats, etc. All barriers resulting from limitations of definitions of state (international security) or internal security and vulnerability are relevant, e.g. an unclear meaning of hazard, risk, threat and related terms – resilience, coping capacity, etc. remain valid. Security and vulnerability are interrelated with the latter being equivalent to insecurity.

Although in vulnerability-related studies objectivity is one of the core issues, there are some attempts to introduce subjective elements into the discourse. Alexander (2000: 12) defines vulnerability as "the potential for casualty, destruction, damage, disruption or other forms of loss with respect to a particular element". He also recognizes that vulnerability can be enhanced or reduced depending on the type of action taken with respect to it, and its perception is an important factor to consider. Such an approach relating to the role of the observer in the second-order cybernetics makes an explicit connection between vulnerability and the research conducted to assess it. Deprived vulnerability arises when research results are not disseminated nor used, while wilful vulnerability arises when such knowledge on vulnerability is deliberately ignored. In this respect, he comments that pristine vulnerability arises as a result of the lack of experience regarding hazards. These views would lead to a proposal of vulnerability reflecting the lack of use of research information.

In contrast, he points to the notion of primary vulnerability in relation to the high susceptibility to catastrophic damage, while secondary vulnerability is related to the lack of appropriate capacities and resources which can lead to a poor or deficient response in case of a disaster. In this case vulnerability

relates to susceptibilities or incapacities, rather than the lack of use of knowledge (Villagrán de León 2006: 12).

However, the interdependence between the meaning of vulnerability and a broadened subjective security is much more complex. In the concept of securitization, a disturbance called 'existential threat' emerging outside or inside the reference object (system) exposes its vulnerability and is identified as the first one. Vulnerability is even not mentioned directly in the initial concept of securitization. It means that a specific asymmetry is assumed between disturbances and vulnerability. All kinds of external and internal disturbances are given a subjective priority in securitization although in an objective sense they are connected and equal.

In the case when vulnerability is given priority in the discourse, characteristics of the system (reference object) are considered together solely with external disturbances since internal disturbances are included in resilience (coping ability, coping capacity). In such situations the objective symmetry between disturbances and system vulnerability is reflected in a better way. It may then be concluded that securitization extended to the sectors where disturbances (existential threats) are more difficult to define, e.g. the environment, economy or social life in general, the approach based on the dominance of vulnerability seems to be more relevant. It also means that securitization in those sectors is more difficult both in theoretical and empirical terms. It also proves the increasing role of vulnerability in theoretical and policy discourse which is even reflected in a growing number of publications concerning vulnerability in those sectors.

4.2.4 Vulnerability and Security of the State: The Classical Approach

Origins of discussions on vulnerability in a broadened security theory deriving from classical security ideas can be traced already in the early 1990's. In his first work on broadening the meaning of security, when discussing national security, Buzan (1991: 12) regarded the concepts of threats and vulnerabilities as "a key divide in security policy". The early discussions were predominantly focused on state security and vulnerability understood in a classical military-political-economic sense.

Because in numerous considerations no difference is made between vulnerability of the state understood as an institution and vulnerability of a country (embodying state apparatus, which in many cases can be acting against the population and society), no distinction between both terms is made in this chapter. This lack of distinction is probably caused by the fact that some definitions are proposed by UN agencies, which are determined by the opinions of the member states.

Focusing on state security, it can be observed that the source of vulnerability lies in one's capabilities in relation to the capabilities of others. The source of threats can be found in one's intentions toward others. In order to reduce threats, states attempt to affect the intentions of others; traditional means include the negotiation of treaties, like arms control or trade agreements. As to reduce relative vulnerabilities, states must implement policies that expand their own military and industrial power, reduce the military and industrial power of others, and reduce their dependence on others (Buzan 1991: 112–116; Crawford 1992: 4).

The links between both security and vulnerability of the state were analysed by Crawford with the use of examples taken from the Cold War era and from the post-Cold War period. Focusing on the last years of the Cold War, Crawford (1993) used East-West economic relations as to show how trade relations contributed to the vulnerability of both parties. She examined the impact on the Soviet economy of imports of technology-laden products and joint ventures with Western firms, the vulnerability of Europe arising from imports of Soviet gas, and the impact on both borrowers and lenders of the substantial build-up of hard currency debt, especially in Eastern Europe. The concept of vulnerability allowed for showing to what extent economic and financial relations and vulnerability of parties involved exerted an impact of their security posture.

In addition to conclusions about a limited impact of trade on security of both parts, Crawford showed that vulnerability deriving from economic relations could be applied in the analysis of international security. Crawford analysed also the impact of international economic interdependence on debates over the redefinition and reconstruction of 'national security' after the end of the Cold War. She explored how the forces of interdependence influence those debates by reducing military threats in the view of analysts (called economic 'doves') and increasing military vulnerabilities in the view of others (called economic 'hawks') (Crawford 1995). The arguments by both sides can be simply stated: Interdependence reduces threats because it weakens incentives for military conquest.

But at the same time, interdependence increases vulnerabilities, and threatens to weaken the state, because potential military resources – especially high-technology ones – are increasingly found in global commercial markets over which states have little control. Policy responses are, in some countries, at least, focused on reducing vulnerabilities and strengthening the state through strategies of market control, indicating that 'hawks' have come to dominate the discourse of economic security. In examining these debates and policy strategies, this essay is both an exploration of the interaction between material and cognitive factors that shape the political elite's new definitions of security and an assessment of their policy responses.

The distinction between threats and vulnerabilities in state security allows to distinguish the following approaches (Crawford 1992: 4–5): Structural realists tend to focus on vulnerability and vulnerability reduction as the central security concern. They believe that states will enhance their capabilities to reduce vulnerabilities, and that they are constantly in the process of measuring the capabilities of others. They further argue that states care more about relative than absolute gains of interaction, because the state who gains more will be the more powerful.

Liberals look to a set of processes and institutions that shape intentions to reduce the threat of war, despite a potential lack of clarity about power positions or vast differences in power. Finally, those who study the domestic causes of war and peace also address the sources of threat rather than vulnerability. They argue that the nature of states and societies will determine the intensity of the military threat. These theoretical approaches provide a new framework for studying vulnerability, resulting from economic interdependence and contributing to states insecurity in the post-Cold War era.

According to Crawford (1992), relative gains from interdependent economic relationships matter for national security for two reasons. The first is the increasing importance of industrial strength to military power. A superior economy can be rapidly converted into a stronger war machine. No modern state has been able to maintain a first-rate military capability with a declining industrial base. Economic power, in turn, depends on technological excellence. And technological strength developed in commercial competition can quickly be adapted to bolster military capabilities to counter potential new threats.

Secondly, just as states have come to rely increasingly on industrial strength and commercial technology for military power, the factors of production have become increasingly mobile: corporations can easily move their bases of operation to lower-cost production areas; technology and information diffuse almost instantly across national boundaries; raw materials are rapidly transported from their source to production sites thousands of miles away.

What this means is that military power has increasingly come to rely on goods and services allocated by global commercial markets. Not only will the market increasingly allocate goods necessary for national security but those goods cannot necessarily be confined to home markets which states can control. Market forces create a specialization of production meaning that different firms around the globe occupy niches in the markets which supply the defence industrial base of any particular nation.

In such a way interdependence increases vulnerabilities and threatens to weaken the state, because potential military resources, especially high-technology ones, are increasingly found in global commercial markets over which states have little control (Crawford 1992). The above description exposing a kind of mirror relation expressed by the external character of threats and the internal character of vulnerabilities shows only as an example of the sense of both ideas in state security without specifying how they can be defined and how they are interrelated.

4.2.5 Social Vulnerability

Among a large number of definitions and approaches to vulnerability, a group of broader concepts can be distinguished. They can be placed between specific types of vulnerability to economic and natural disturbances and security and political vulnerability. These concepts and measures of vulnerability can be treated as another category called 'social vulnerability' (chap. 68 by Birkmann; chap. 69 by Marre/Renaud; chap. 70 by Villagrán; chap. 71 by Warner; chap. 72 by Oswald Spring).

It is described with several definitions of the meaning of 'social' (Gall 2007). Similarly as in other cases of vulnerability studies, the term social is also ambiguous. On the one hand it is used in defining social vulnerability as: "the characteristics of a person or group and their situation that influence their capacity to anticipate, cope with, resist and recover from the impact of a natural hazard" (Wisner/Blaikie/Cannon/Davis 2004: 11). On the other hand, the adjective 'social' means that attention is paid to broader categories however always focusing on the weaker groups of society: "...vulnerability to disasters refers to the ina-

bility of people, organizations, and societies to withstand adverse impacts from multiple stressors to which they are exposed" (Warner 2007: 9).

In spite of a broad variety of definitions of social vulnerability some common characteristics, or the sources of adjectives, 'social' can be identified. In definitions of social vulnerability its collective character is emphasized since it can be seen as the inability of people, organizations, and societies to withstand adverse impacts from multiple disturbances to which they are exposed. These impacts are stemming from characteristics inherent in social interactions, institutions, and systems of cultural values. In other words, social vulnerability is a structural feature since it can be eliminated or diminished solely and resolved through social (as opposed to individual) means.

Research on social vulnerability can be based upon the 5 W's reflecting the following questions of what, who, where, when and why? (Warner 2007: 14–15):

- What is social vulnerability?
- Who are those most affected by social vulnerability?
- Where is social vulnerability the biggest problem?
- When is social vulnerability most apparent?
- Why does social vulnerability persist?

Answers to these questions are to various extents given in all definitions and studies of social vulnerability. Pizarro (2001: 11) of the *Economic Committee for Latin America and Caribbean* (ECLAC) defines social vulnerability in terms of two components: "the insecurity and defencelessness experimented by communities, families, and individuals in their livelihoods as a consequence of the impact of a socio-economic event of traumatic character; and the second component is the management of resources and strategies which are utilized by these communities, families, and individuals to cope with the effects of this event". In addition to social vulnerability, political and institutional vulnerabilities have also been addressed by ECLAC and the *Inter-American Development Bank* (IADB). In this context, vulnerability is defined in general terms as "the probability of a community, exposed to a natural hazard, given the degree of fragility of its elements (infrastructure, housing, productive activities, degree of organization, warning systems, political and institutional development), to suffer human and material damages" (Villagrán de León 2006: 15).

As an illustration of the idea of social vulnerability and its links with economic vulnerability, the following concepts can be taken: Prevalent Vulnerability Index, Predictive Indicators of Vulnerability, and Index of Social Vulnerability to Climate Change for Africa.

The *Prevalent Vulnerability Index* (PVI) is part of a much broader, comparative analysis of risk management in Latin America developed by the Institute of Environmental Studies of the University of Colombia in Manizales, the Economic Committee for Latin America and the Caribbean, and the Inter-American Development Bank. It focuses on social, economic, institutional, and infrastructural capacity to recover from natural hazards or the lack thereof (Cardona 2007; chap. 3 above). This index depicts predominant vulnerability conditions by measuring exposure and susceptibility in prone areas, socio-economic fragility and lack of social resilience. These items provide a measure of direct as well as indirect and intangible impacts of hazard events. The index is a composite indicator that provides a comparative measure of a country's pattern or situation. Inherent vulnerability conditions underscore the relationship between risk and development. Vulnerability, and therefore risk, are the result of inadequate economic growth, on the one hand, and deficiencies that may be corrected by means of adequate development processes. The PVI recognizes 24 indicators ranging from the percentage of population that lives in poverty to the amount of insured infrastructure and built environment expressed as a percentage of the GDP (Cardona 2007).

The index of *Social Vulnerability to Climate Change for Africa* (SVA) can be treated as an explicit social vulnerability index although its spatial coverage is limited to Africa (Adger/Vincent 2005). The SVA concentrates on social vulnerability to climate change and in particular water availability. This causes the index to be inherently biased towards events such as droughts and does not accomplish an all-hazards representation. The index includes five indicators which are aggregated with weights: institutional capacity, economics, rural population, demographics, and trade balance. In its current version, the SVA describes the social vulnerability of 49 African nations based on eight (Version A) or nine (Version B) indicators. The two index versions differ in their in-/exclusion of a corruption indicator (Gall 2007: 51). Leaving apart assessment of the validity of the SVA, it can be added that it is just another illustration of variety of interpretations of the term 'social' and of the links between that interpretation and economic factors of vulnerability.

Another example of the links between climate and social vulnerability is reflected in the *Predictive Indicators of Vulnerability* (PIV) that is focused on vulnerability to climate variability and climate change and excludes geophysical events in its assessment

(Brooks/Adger/Kelly 2005; Gall 2007). The PIV rests on the conceptual framework that risk (outcome) is a function of biophysical and social vulnerability, which is similar to the DRI's approach (Brooks/Adger/Kelly 2005). The PIV includes the following partial indicators: literacy (15–24 yrs.), sanitation, voice and accountability, literacy (> 15 yrs.), calorie intake, civil liberties, male to female literacy ratio, life expectancy, political rights, maternal mortality and governance. It should be stressed that the SVA represents a framework-driven approach whereas the PIV is outcome-driven. The PIV consults hazard fatalities to conclude on driving vulnerability (Gall 2007: 57–58).

In addition to more or less precisely defined concepts, estimates and measures of social vulnerability, there are some ideas which have been elaborated in the studies of broadened security, outside the traditional areas of vulnerability studies. A proposal that not all security issues involve threats and that the notion vulnerability should be used for 'soft' (non-military) security was put before by Liotta and Miskel (2008: 879–880). Coming out from that assumption they regard threat as identifiable, often immediate, and requiring an understandable response. A threat is clearly visible or commonly acknowledged. Vulnerability is often only an indicator perhaps not completely understood and not always suggestive.

In human and environmental security a condition of extreme vulnerability can arise from living under conditions of severe economic deprivation, to victims of natural hazards and to those who are caught in the midst of war and internal conflicts. Long-term vulnerabilities requiring strategic planning can be called *creeping vulnerabilities*. They may include (Liotta/Miskel 2008: 880–881):

- disproportional population growth and urbanization;[6]
- the outbreak and the rapid spread of diseases such as HIV/AIDS; SARS;[7]
- significant climate change;
- the scarcity of water and other natural resources;
- the decline in food production; access and availability;
- progressing soil erosion and desertification;
- increased urbanization and pollution in 'megacities';
- the lack of warning systems for ecological disasters.

4.2.6 Environmental Vulnerability: Definitions and Measures

In addition to poverty, it was predominantly environmental concerns which led to the development and implementation of the concept of vulnerability. Environment-related concepts of vulnerability have been widely described in the literature on security, development, and in related areas, and are an important factor in policy-making at various levels of socio-political hierarchy. Although environmental (ecological) concerns are taken into account in most concepts of vulnerability, they play the key role in the following areas: global change, climate research, hazard research, environment, development and early warning studies (Brauch 2005, chap. 2 above). Definitions of environmental vulnerability include economic and social attributes, thus in result separation of definitions and measures does not seem achievable. They have been surveyed and presented in a synthetic way by Brauch (2005), Gall (2007), Nathan (2009) and below (chap. 20–28),

In the studies of economic vulnerability attention should be paid to attempts of measuring 'environmental vulnerability' since it usually embodies economic and social attributes. Although it is impossible to measure vulnerability in an objective way and only estimates are feasible, there have been several attempts to define and measure characteristics describing variously defined environmental vulnerability (Luers/Lobella/Sklar/Addams/Matson 2003). They were designed either to grasp all aspects of environmental vulnerability or only specific types of disasters, such as hurricanes, floods or earthquakes.

A comprehensive index allowing for analyses of environmental vulnerability was elaborated by the *South Pacific Applied Geoscience Commission* (SOPAC) in cooperation with the *United Nations Environment Programme* (UNEP) and their partners (Kaly/Pratt/Mitchell 2005). The *Environmental Vulnerability Index* (EVI) was stemming from the efforts of the *Small Island Developing States* (SIDS) of the Pacific to promote sustainable development across the world and cooperation on issues relating to our natural life-support ecosystems.

The logic of the *Environmental Vulnerability Index* (EVI)[8] can be described as follows. Vulnerability

6 It may also include changing demographic structure, which in the future will make developed societies more vulnerable.

7 The list of diseases may be extended with the avian flu and H1N1 influenza (swine flu) which have become a cause of fear and controversy during 2008 and 2009.

can be defined as the potential for attributes of any system, human or natural, to respond adversely to events. Hazardous events are those that can lead to a loss of diversity, extent, quality and function of ecosystems. These changes are often described as damage to the biological integrity or health of ecosystems, and therefore their ability to keep supporting humans. These may include natural hazards as well as human pressures.

Vulnerability to damage arises from a combination of the inherent characteristics of a country, the forces of nature and human use, including the special case of climate change. The EVI simultaneously examines levels of present risk and conditions, predicting how the environment is likely to cope with future events.

For example, environments that have been damaged in the past, particularly more recently, are likely to be more at risk of damage from events in the future. The EVI focuses on feedback and interactions, being more proactive than measures of the state of the environment, though it includes them. A result indicating high vulnerability speaks of a high risk of damage from future conditions, some of which may be related to damage in the past, and may therefore be a more appropriate measure for adaptive management, particularly at the scale of countries.

The EVI does not address the vulnerability of the social, cultural or economic environment, nor the environment that has become dominated by those same human systems (such as cities and farms) because these are included in the economic and social vulnerability indices which are needed separately to identify trade-offs. Therefore, the natural environment includes those biophysical systems that can be sustained without direct and/or continuing human support. The environment at risk includes ecosystems, habitats, populations and communities of organisms, physical and biological processes (such as beach building and reproduction), productivity and energy flows, diversity at all levels, and interactions among them all.

A rank of other indices aiming at capturing vulnerability and environmental issues was surveyed by Simpson and Katirai (2006: 19):

- *Urban Earthquake Disaster Risk Index* (EDRI);
- *Environmental Vulnerability Index* (EVI);
- *Disaster Risk Index* (DRI) - United Nations;
- *Hurricane Disaster Risk Index* (HDRI);
- Indicators of Disaster Risk and Risk Management;
- Measuring Improvements in the Disaster Resilience of Communities;
- Social Flood Vulnerability Index;
- *Social Vulnerability to Environmental Hazards* (SoVI);
- Natural Hazard Index for Megacities.

4.3 Survey of Definitions and Measures of Economic Vulnerability

4.3.1 What Is 'Economic' in Economic Vulnerability?

Although a semantic reflection on the adjective 'economic' was offered earlier (Mesjasz 2008a), it is necessary to extend them to economic vulnerability and in consequence, to add new elements to theoretical considerations on economic security. The notion 'economic' refers to a) a type of activity (economic); b) a conceptual approach (associated with economics as part of scientific reasoning); and c) an economic component of any kind of social activity.

In the first, general sense 'economic' refers to the human activities related to the production, distribution, exchange, and consumption of goods and services. All those activities are accomplished at different levels constituting a hierarchy of aggregation: global, regional (supra-national), international, state (4.3.2), non-state actors, e.g. of the market (companies) and non-market (4.3.3), and individuals (4.3.4).

Subsequently, economic may mean any aspect of those activities accomplished by those actors at those levels. In such a case external threatening circumstances refer to threats or risks, etc. and subsequently, to economic security, while susceptibility to potential harm caused by those external and internal factors to activities in all those areas and coping capacities (resilience) can be referred to as economic vulnerability (table 4.2).

As it is stressed in studies of economic security, all the above 'economic' processes, perhaps with the exception of consumption, depend on different external threats. Therefore economic vulnerability must have different interpretations for production, exchange, distribution and for consumption. It also has another sense in finance where risk and vulnerabilities associated with it are viewed as an indispensable component.

8 See: *Environmental Vulnerability Index. The Official Global EVI Website*; at: <http://www.vulnerability-index.net/index.htm> (26 November 2009).

Table 4.2: Framework of analysis of economic security and vulnerability. **Source:** The author's own research.

	Production	Distribution	Exchange	Consumption
Global	ECONOMIC SECURITY (Threat (disturbance, hazard, risk), securitization)			
Regional (supra-national)				
International				
State	ECONOMIC VULNERABILITY (Threat (disturbance, hazard, risk), susceptibility, resilience) (Securitization?)			
Non-state actors				
Individual				

The second meaning of the adjective 'economic' is deriving from the sciences of economy and economics. In a historic perspective it was initially Political Economy and later International Political Economy which linked security issues with economic activities at the state and international levels.

The term 'economics' was proposed to reflect a more scientific understanding of the discipline. In such an approach economics is commonly understood as the scientific study of the choices made by individuals and societies in regard to the alternative uses of scarce resources which are employed to satisfy wants. From the point of view of normative security-related considerations the divide into positive economics ('what is?') and normative economics ('what ought to be?') is of a special importance.

If economics as science is involved in the discourse on security and vulnerability, two situations should be borne in mind. The first, when general normative economic considerations are taken into account with such categories as utility, rationality, efficiency, optimization, etc. In this case, security threats and subsequent vulnerabilities may emerge when some of those criteria are not fulfilled. In the second situation, economic mathematical models are applied in solving specific problems which can be associated directly with security, conflicts, threats, etc. (Hirshleifer 1997, 2001). Indirectly, they can also relate to vulnerability, not necessarily only in the economic sphere.

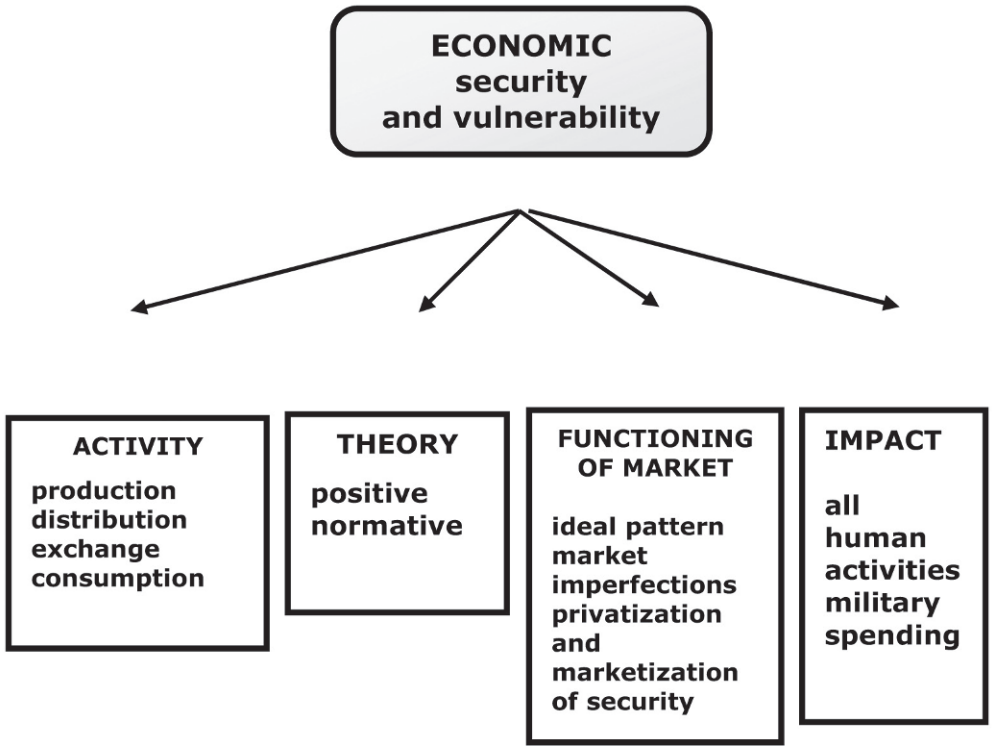
The third meaning of economic in reflections on security and vulnerability is associated with the normative approach and with the functioning of the market. In such a case, two options can be considered. Firstly, assuming that the market is an ideal pattern for all economic activities – 'ideal market', any deviation from market rules can be viewed as a source of vulnerability, and subsequently, insecurity. Secondly, all theoretical and real market imperfections – externalities, non-competitive markets and public goods can also be seen as causes of vulnerability and insecurity. This assumption is likely too far-reaching but it is resulting from a purely formal reasoning in which a normative system is treated as an 'ideal pattern'. In economics treated as a normative science the 'ideal market' is an absolute reference point. In this case the scope and form of the external intervention by the state or other institutions can be viewed either as a source of additional vulnerability or, on the contrary, as a method of strengthening resilience, diminishing vulnerability and increasing economic security.

In a present era of enlarging the scope of influence of market mechanisms, security traditionally treated as a public good is more often economized and marketized. It concerns both the individual levels – private security guards and ends with state security – 'outsourcing' of some military operations as in the case of Blackwater (a private US military company in Iraq). This phenomenon can be included into the third meaning of economic in security and vulnerability analysis.

Fourth, similarly as economic security, economic vulnerability is strongly interlinked with all human activities, and subsequently, with vulnerability and security in other sectors. Disruption of economic activities of any state and non-state actor may contribute to increased vulnerability of those sectors. Opposite relations also seem plausible, although not necessary. In this case a special significance is given to economic foundations of military strength and the impact of military spending on economics.

Obstacles in defining economic vulnerability are to some extent similar to the barriers in defining vulnerability in a universal sense in other areas. The term 'economic' in the definitions is associated with various characteristics and activities, and no systematic attempt to study links between economic theory and policy, and differently interpreted economic vulnerability have been made.

Figure 4.2: Interpretations of the meaning of 'economic' in the discourses on security and vulnerability. **Source:** The author's own research.



The typology proposed by Villagrán de León (2006: 22), including the following levels (subjects) – global, regional (transnational), national, state or province, district or municipal local or community, company/social organization, household (livelihood), human being along with various interpretations of the term 'economic', can be used as a point of departure for a preliminary ordering of ideas how to define, assess and measure economic vulnerability. In addition, it must also be taken into account that economic aspects of vulnerability are included in numerous attempts to define vulnerability in other areas.

The hierarchy of economic vulnerabilities leads to many questions on disturbances influencing economic activities at all those levels. The origins of those disturbances, shocks and threats, etc. can be natural or man-made. The first group of disturbances influencing economic activities is associated with environmental disturbances, irrespective of their character. The second includes all categories resulting from purposive human economic, social, political, military activities. In the case of economic and social disturbances influencing economic vulnerability two categories can be distinguished – policy-induced and market-induced. Thus, two kinds of economic vulnerability can be distinguished.

The hierarchy of economic vulnerabilities is associated with a hierarchy of economic disturbances. It may be observed that in the case of economic vulnerability the hierarchy of disturbances is isomorphic with the hierarchy of disturbances although their interdependence is very complex. While in the case of an individual or a household it is difficult to distinguish ecological disturbance affecting only their level, in the case of economic vulnerability each actor or object is exposed to disturbances emerging at all levels and at its specific level, e.g. sources of poverty of an individual or household may refer only to their specific level.

4.3.2 Economic Vulnerability of the Country or State

4.3.2.1 General Definitions of Economic Vulnerability

Analysis of the meaning of 'economic' in the studies of vulnerability allows to conclude that in the simplest sense this term may be associated with a disturbance (natural and/or man-made, including an economic one) affecting any form of economic activity (production, distribution, exchange, consumption) and resil-

ience in any of those forms of activity. In defining economic vulnerability it is necessary to include structural factors allowing for linking processes and phenomena at all levels of social entities or units, beginning from the global one and ending with the individuals.[9] These interdependences are not yet clearly explained due to their inherent systemic complexity.

It is worth mentioning that studies of vulnerability are not a new research area in economic theory. As one leading specialist in the theory and practice of vulnerability stated: "Vulnerability is not really a new concept in economics, but it has recently become a fashioned one, noticeably because of the concern of several political bodies and the 'turmoil' of international economy" (Guillaumont 1999: 2). In a universal sense economic vulnerability is determined by the following factors (Benson/Clay 2004): natural hazards, economic structure, stage of development, prevailing socio-economic conditions, macroeconomic conditions.

An attempt to define economic vulnerability as an instrument of studies of a developing country (Mexico) was suggested by Saldaña-Zorrilla (2006) who proposes a comprehensive interpretation of economic vulnerability, which in addition to external factors – disturbances and shocks, includes the following components:

- coping capacity achieved thanks to entitlements and assets;
- adaptive capacity achieved thanks to structural changes and embodying risk management and protection.

Saldaña-Zorrilla (2006: 20) defines economic vulnerability as the susceptibility of an economic agent to absorb external shocks (hazards) negatively, given its possession of assets and entitlements system (coping capacity), as well as its implemented risk management and protection measures (adaptive capacity). Following this definition, reducing economic vulnerability consists basically of implementing necessary changes in time to minimize negative effects from exogenous shocks upon economic agents' assets by strengthening contractual elements in the society (entitlements and assets) and/or improving the risk management and protection strategies.

Despite all definitional efforts, similarly as in other areas, there are not any universal definitions of economic vulnerability reflecting specific invariant structural properties. Considerations of economic vulnerability are to a large extent focused on specific groups of states – less developed ones and poor regions, and individuals living in those states or regions.

Two groups of countries have been subject to special interest with respect to vulnerability: the *Small Island Developing States* (SIDS) and the *Least Developed Countries* (LDCs).

4.3.2.2 Economic Vulnerability and Resilience of Small States

Poverty and vulnerability of states or countries are predominantly a topic of concern in human security. However, most ideas on the vulnerability of a state or country originated in theory and policy-making for a very specific group of the *Small Island Developing States* (SIDS), and more generally of small states. The first group comprises fifty-one small island developing states and territories that are listed by the United Nations Department of Economic and Social Affairs in monitoring their sustainable development. These countries are often categorized by their three regions of Africa, Indian Ocean, Mediterranean and South China Sea (AIMS) as well as the Caribbean and the Pacific.

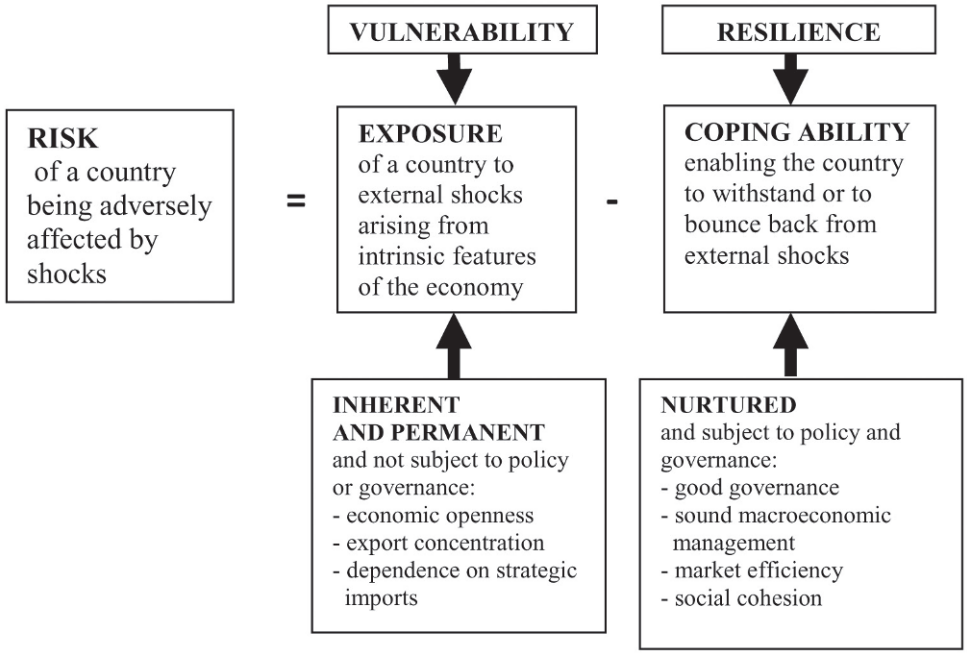
The second is more difficult to describe since there is no generally agreed definition as to which variable should be used to measure the size of countries and as to what should be the cut-off point between a small country and other countries. Generally speaking, population is used as an indicator of size (Briguglio/Cordina/Farrugia/Vella 2008).

SIDS and LDCs constitute two different, although overlapping, groups of countries. In mid-2007, among the 50 LDCs, twelve are SIDS that represent more than 35 per cent of the 37 independent SIDS. Most SIDS countries do not qualify as low income and some have very high income. Among the LDCs, the majority or 58 per cent (39 countries) are fairly small countries (with population sizes smaller than those of the larger SIDS; e.g. Cuba has a population of 11 million people). In brief, the two categories refer to countries that differ significantly in other characteristics but which face, to a large extent, problems associated with small size and in particular high economic vulnerability (Guillamont 2009).

Despite the generalization of the idea of an economic vulnerability index for small states, it is more focused on the small island ones, which tend to be

9 As was declared in the beginning of the chapter, no difference is made between vulnerability of the state understood as an institution and vulnerability of a country (embodying state apparatus).

Figure 4.3: Risk associated with being adversely affected by external shocks. **Source:** Briguglio, Cordina, Farrugia and Vella (2008: 3).



characterized by high degrees of economic openness and export concentration. It leads to exposure to exogenous shocks, that is, economic vulnerability, which could constitute a disadvantage for economic development by magnifying the element of risk in the growth process, without necessarily compromising the overall viability.

Although they are vulnerable in an economic sense, many small states manage to generate a relatively high GDP per capita, when compared with other developing countries. This has been called the 'Singapore Paradox'. There are a number of SIDS – Singapore, Cyprus and Malta are prime examples – that are very economically vulnerable, but have managed to generate high income per capita in spite of this condition. The reason for this is that it is possible for SIDS to build up their own resilience to improve their ability to cope with vulnerability (Briguglio 1995, 2004; Briguglio/Cordina/Farrugia/Vella 2008).

The definition and measurement of economic vulnerability and resilience of small states were among the first focuses of studies in that field. According to researchers specializing in SIDS, economic vulnerability is defined as "the exposure of an economy to exogenous shocks, arising out of economic openness, while economic resilience is defined as the policy-induced ability of an economy to withstand or recover from the effects of such shocks" (Briguglio/Cordina/Farrugia/Vella 2008). In this approach, economic vulnerability is assigned to inherent conditions affecting a country's exposure to exogenous shocks, while economic resilience is associated with actions undertaken by policy-makers and private economic agents which enable a country to withstand or recover from the negative effects of shocks. Actions which enable a country to better benefit from positive shocks are also considered to be conducive to economic resilience.

Using a simplified formula of risk, it is shown that the risk of a country has two elements. The first one is associated with the inherent conditions of the country that is exposed to external shocks and the second is associated with conditions developed to absorb, cope with or bounce back from adverse shocks. The risk of being adversely affected by external shocks is therefore the combination of the two elements (figure 4.3).

The above scheme was used for developing economic vulnerability and resilience indices of the SIDS (Briguglio 1995, 2004; Briguglio/Cordina/Farrugia/Vella 2008).

An *economic vulnerability index* is often based on the premise that a country's proneness to exogenous shocks stems from a number of inherent economic features, including high degrees of economic openness, export concentration and dependence on strategic imports. According to the scheme, economic resil-

ience refers to the policy-induced ability of an economy to recover from or adjust to the negative impacts of adverse exogenous shocks and to benefit from positive shocks. The term is used here in a double meaning referring to the ability to recover quickly from a shock, and to withstand the effect of a shock.

The *resilience index* is intended to measure the effect of shock absorption or shock counteraction policies across countries. It can be assumed that the variables capturing these effects are the following: macroeconomic stability, microeconomic market efficiency; good governance and social development. According to its authors, the resilience index developed by Briguglio and his co-authors can be applied to support decision-making, especially for setting directions and justifying choice of priorities for resilience building (Briguglio/Cordina/Farrugia/Vella 2008):

- disseminate information on and draw attention to the issue of resilience building;
- focus the discussion on essential resilience-building issues;
- promote the idea of integrated action.

Since their onset perception of both indices has been evolved. While the economic vulnerability index is more relevant for small island states and is distinguished from a similar index for poor countries, the resilience index is applied to a wider group of countries.

4.3.2.3 Economic Vulnerability of Least Developed Countries (LDC) – Economic Vulnerability Index

In one of the first studies on economic development, Todaro (1982) considers vulnerability as a situation in which *least developed countries* (LDC) find themselves in a dominance and dependence relationship vis-à-vis developed countries. The same view was expressed by the UN General Assembly (2001: 43). LDCs are structurally more exposed to external economic shocks than most other developing countries, and they also suffer the consequences of major global and regional economic and financial disturbances and increases in the prices of critical imports such as energy products. The typical export dominance of a single commodity or service sector makes their economies particularly vulnerable to adverse physical or economic shocks. Therefore it is not incidental that measures and indices of economic vulnerability were developed as an instrument of analysis of the situations of those countries.

The vulnerability index that was developed for SIDS was not the only attempt to define and measure economic vulnerability. The economic vulnerability of a country can also be defined by the risk of a (poor) country seeing its development hampered by the natural or external shocks it faces. Two main kinds of exogenous shocks or sources of vulnerability can be considered:

- *environmental or 'natural' shocks*, namely natural disasters such as earthquakes or volcanic eruptions, and the more frequent climatic shocks such as typhoons and hurricanes, droughts, floods, etc.;
- *external (trade- and exchange-related) shocks*, such as slumps in external demand, instability of world commodity prices (and correlated instability of terms of trade), international fluctuations of interest rates, etc. Other domestic shocks may also be generated by political instability or, more generally, by unforeseen political changes.

Vulnerability can be perceived as the result of three components (Guillaumont 2008: 2–3)

- the size and frequency of the exogenous shocks, either observed (ex-post vulnerability) or anticipated (ex-ante vulnerability);
- exposure to shocks;
- the capacity to react to shocks, or resilience.

Resilience depends more on current policy, is more easily reversed, and is less structural. But there may also be a structural element in the resilience component of vulnerability. Therefore in considering economic vulnerability, an important distinction should be made between structural vulnerability, which results from factors that are relatively impervious to national policies, and the vulnerability deriving from economic policy, which results from choices made in the recent past, and is therefore conjunctural. For example, export instability (as a result of heavy dependence on a limited number of exports) is a structural factor of vulnerability. However, the capacity to manage instability of the revenue received from such exports depends on the economic policies pursued (UNCDP 1999: 29; Guillaumont 2008, 2009).

Structural economic vulnerability should be distinguished from state fragility. Fragile states are defined as the *Low-Income Countries under Stress* (LICUS) according to policy indicators, essentially the World Bank's *Country Policy and Institutional Assessment* (CPIA) (IEG 2006). Many countries may meet both criteria of structural vulnerability as well as state fragility due to the likely influence of the former on the lat-

ter, but the two concepts are founded on opposite grounds, structural versus policy factors.

Another distinction should be made between economic vulnerability and ecological fragility. The UN's initial concern over vulnerability included both economic vulnerability and ecological fragility, but The Committee for Development Planning at its 32nd session agreed that two concepts should be analysed separately. For instance, losses in biodiversity reflect ecological fragility and are not necessarily major elements of economic vulnerability. Therefore, environmentally-induced economic vulnerability can be considered either as economic vulnerability or ecological vulnerability (UNCDP 1999: 29; Guillaumont 2008: 3).

With resolution 1998/39 of 30 July 1998, the Economic and Social Council requested the *Committee for Development Planning* (CDP) to report on the usefulness of a vulnerability index as a criterion to designate least developed countries. It suggested as the best way of addressing economic vulnerability of least developed countries the replacement of the current *Economic Diversification Index* (EDI) with a composite *Economic Vulnerability Index* (EVI).

In the proposed EVI five indicators of export concentration, the instability of export earnings and of agricultural production, the share of manufacturing and modern services in *Gross Domestic Product* (GDP), and population size were given equal weight. The Committee considered that, since the EVI could give only a partial and approximate measure of the relative level of vulnerability of a country, a country vulnerability profile should be prepared, for some countries to provide a more detailed assessment of the impact of external economic and natural shocks on their economic performance and structure (UNCDP 1999: 5–6). At its triennial review of the LDCs list in 2000 CDP implemented the EVI index as an identification criterion and with some revisions also in 2003 and 2006 (Guillaumont 2008: 2).

The present version of the EVI composite index includes two groups of indicators of exposure to shocks and shocks. They are supported with methodological explanations relating to measures, determinants and weights (Guillaumont 2008). As in all cases of a quantification of qualitative criteria on phenomena in a macro scale they can be criticized for simplifications and arbitrariness. However, they provide at least more or less objective arguments regarding the theory of development and poverty alleviation as well as in policy-making that are targeted at decreasing vulnerability and increasing resilience. In the case of the latter, the EVI allows for a more reliable assistance policy/decision-making. The EVI index can be treated as a universal measure applied also for the SIDS although the division of areas of applications can be seen in the studies of their proponents (Briguglio 1995, 2004; Briguglio/Cordina/Farrugia/Vella 2008; Guillaumont 2008, 2009).

In the studies on poverty not only the country level has become a topic of interest but also the regions within countries where the aim was to develop a concept and measure of the 'vulnerability of place'. It was designed as being due to vulnerability in various areas, such as economic and environmental vulnerability, of governance, demographic and health fragilities. The studies at the subnational level allow for constructing a *Local Vulnerability Index* (LVI) for various districts (Naudé/McGillivray/Rossouw 2008).

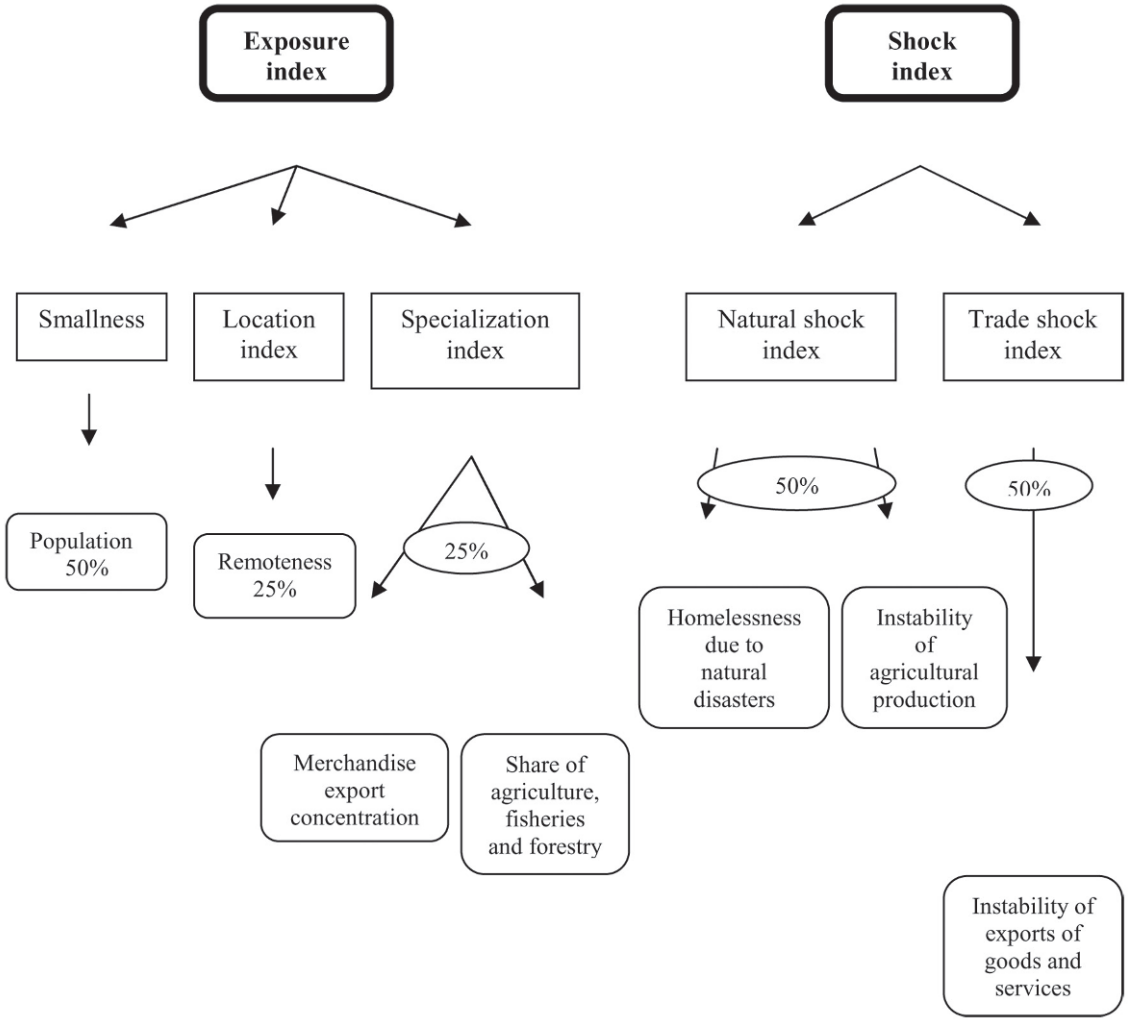
4.3.2.4 Financial Vulnerability

Financial vulnerability constitutes an important component of economic vulnerability. Similarly as in the case of various interpretations of the adjective 'economic', the term 'financial' in the context of vulnerability studies also requires further elucidation. Financial in such a case can refer to vulnerability of broadly defined financial activities under the impact of various natural and man-made disturbances or vulnerability in other sectors caused by financial disturbances. This twofold meaning of financial vulnerability should be kept in mind in the discussion on all kinds of vulnerability. It is visible in different approaches to finance in the discussions on disasters in which either financial vulnerability is viewed in the context of consequences of disasters (Benson/Clay 2004) or financial vulnerability is viewed as a consequence of the overall economic stance of a country as in the studies of poverty.

Finance at the global, international and national level is undoubtedly an area where various forms of vulnerability can also emerge and can expand to other domains. Natural disturbances and financial disturbances, such as shocks, crises and hazards influence the value at risk of assets and if their value is decreasing, the shocks and vulnerability are influencing all areas of socio-economic life in complex ways.

The very character of the international system implies that the basic unit of analysis of financial vulnerability is a state or country. Due to globalization, definitions of vulnerability may also include transnational regions and the global scale. It does not exclude the necessity to consider the financial vulnerability of other units, e.g. banks, companies, households but all of them to a large extent are deriving from the financial vulnerability of the state. As economic vulnerabil-

Figure 4.4: Structure of Economic Vulnerability Index (EVI). **Source**: Based on Guillaumont (2008: 13)



ity, financial vulnerability can also be caused by external and internal shocks and disturbances. It may be a result of structural and policy causes and of a combination of both. Since it is impossible to elaborate a unique definition of financial vulnerability, several types of financial vulnerability can be distinguished:

- vulnerability of the countries with limited access to private financing;
- vulnerability of the countries with access to market-related financing; and
- vulnerability of developed countries.

While the first two categories of vulnerability have been analysed in development studies, the third category should be included in the discussion, especially since the beginning of the turmoil on financial markets affecting the United States and the European Union since 2007. Financial vulnerability is a result of external shocks and domestic policy errors and it may occur in several forms as a component of economic vulnerability of less developed and economically vulnerable countries but if they may also fall in the category of the 'Singapore Paradox' that has more in common with the financial vulnerability of developed states.

Financial activities are also included in the definitions of vulnerability in all areas as a part of the preparedness for hazards and the elimination of the consequences of disasters. The framework of financial mechanisms refers to identification, measuring, and comparing vulnerability to natural hazards (using case studies in different countries) outlining initiated schemes of the federal and local governments, NGOs and micro finance initiated schemes. Those schemes include the expected rise in disaster losses related to

climate change, the public and private insurance system, and an international reinsurance pool.

- natural hazard and financial vulnerability affect how natural disasters interact with the economy;
- financial vulnerability of a government is defined by ex-ante and ex-post decisions where the benefits depend on policy objectives of a maximization of returns, instability and variability;
- tools available to identify, measure, and compare financial vulnerability and to plan.

From the standpoint of macroeconomic policy, the key question is how much and how rapidly can the government afford to borrow to finance the reconstruction costs, while keeping fiscal policy on a sustainable path (Hossini 2008: 22–23). Financial vulnerability caused by financial activities may stem from an unpredictability or a limited predictability of financial disturbances, which are usually identified with the absence of an early warning system. According to some authors such an early warning system should be developed to prevent various crisis situations on financial markets, which may affect entire economic systems at the national and international levels through contagion. Several attempts were made to develop such early warning systems (Goldstein/Kaminski/Reinhart 2000). The aim of that model is to identify key empirical regularities prior to the banking and currency crises that would enable officials and private market participants to recognize the vulnerability to financial crises at an earlier stage. This should facilitate corrective policy actions to prevent such crises from occurring.

Financial vulnerability is sometimes viewed as a mirror concept of financial stability and financial sustainability referring to states, transnational regions and the global financial system. Since no unequivocal definitions of financial stability and sustainability exist, and the definitions are very diverse, then financial stability can be viewed as just another example of a normative term in the discourse on finance (Mesjasz/Rogowski 2005; Schinasi 2006).

4.3.3 Economic Vulnerability of Non-state Actors

The attention focused on economic vulnerability at the household and individual levels that has emerged in connection with environment studies and poverty-related research has also reinforced an interest in other areas and reference objects. Economic vulnerability of households and individuals results to a large extent from disturbances in the entire socio-economic system. It seems that the vulnerability of other market and non-market economic actors, and not only individuals and households, should be treated in a more universal way, not necessarily always in the context of poverty and/or environmental disasters. Thus, considerations of economic vulnerability should be extended to all countries and institutions and the following issues should be taken into account when discussing vulnerability of non-state actors, such as a) market organizations, b) non-market institutions, c) globalization and vulnerability in a universal sense, and d) globalization and economic vulnerability.

4.3.3.1 Market Organizations

In the discussion on economic vulnerability attention is focused on less developed countries and economic causes and consequences of disasters (Benson/Clay 2004). Disturbances on the world market observed since 2007 and earlier events, e.g. the Asian Crisis of the late 1990's or various market 'bubbles' stir the necessity to extend the studies of economic vulnerability beyond traditional areas of poor and developing and/or fragile countries and individuals to organizations operating on the markets in any country at any level of economic development.

Defining economic vulnerability of organizations functioning under market rules, such as non financial (manufacturing and service enterprises), financial (banks, insurance companies, etc.) and others is no easy task since risk and hazards are indispensable factors of their activities.[10] They are exposed to external disturbances which are not depending on their decisions but a large part of those disturbances must be included in their strategic and current planning.

What may external and internal factors contribute to the vulnerability of such organizations? Their external risks and hazards derive from 'natural' risks due to the functioning of an 'ideal' market without market imperfections, what is rather hypothetical if not irrelevant. If deviations from the 'ideal market' are treated as sources of economic vulnerability and threats to economic security, then it is necessary to ask what kind of deviations from that ideal are to be regarded as sources of risks, hazards and limited defensive capacities, such as resilience, coping capacities, etc. In this case the dilemma of an ideally self-regulating market vs. any form of intervention comes to the fore as

10 Due to different interpretations of companies and enterprises in various legal systems, only the divide non-financial and financial market organizations is used herein.

in previous discussions on economic security (Mesjasz 2008a). Answering this question is not simple since when a company (corporation) is taken as a reference object, it is not possible to state whether the absence of any external intervention is unconditionally positive or whether such an intervention is essential for the survival of market-oriented organizations in the competitive environment.

The third source of economic vulnerability of market organizations is the same as for other types of vulnerability, such as environmental, economic (including financial), social and military. In this case a market organization is exposed to the same disturbances as the rest of the society. Resilience to such threats, hazards, etc. is not necessarily connected to its ability to cope with market adversities but with those threats which equally affect other actors during natural disasters, deep economic shocks, etc. Obviously the overall standing of a market organization and its location, be it a developed or developing country, has also a significant impact on its vulnerability.

The economic vulnerability of market organizations should be studied in all areas of modern economic science, beginning from political economy and macroeconomics and ending with the microeconomic level, including analyses of market mechanisms and theories of the firm. From numerous issues which should be analysed, the following ones seem most urgent at the macroeconomic level:

- increasing vulnerability of the world economic system in a global scale (Beck 1999, 2007);
- increasing complexity of economic mechanisms and especially finance;
- governance dilemma: free market vs. external intervention and its impact on economic vulnerability of the market at the global (international) level;
- the impact of environmental factors on economic activities worldwide;
- identification of the limits to growth and a deeper understanding of sustainable development, which too often remains but a void utterance;
- positive and negative impacts of economic globalization on vulnerability in a general sense and on economic vulnerability of all social actors.

At the microeconomic level, the following factors should be taken into account in extending the scope of the concept of economic vulnerability onto market-oriented organizations:

- better understanding of market uncertainty and risk;
- studies of the role of information and knowledge in changing the role of risk management in the environment with increased uncertainty;
- better understanding of the consequences of imperfections of market mechanisms, especially information asymmetry and its consequences (adverse selection, moral hazard) for market organizations and at the global scale (Stiglitz 2002, 2006);
- emphasis of ethical aspects of modern economic activities;
- the impact of environmental factors on the functioning of market organizations under the conditions of disasters.

The list of potential areas of investigation is obviously not complete. For example, a growing role of the impact of the vulnerability of IT systems on the functioning of all organizations should also be noticed (Sutton/Nagle 2006, chap. 12 by Brauch).

4.3.3.2 Non-market Institutions

The term non-market institutions relates to those areas of social life where fundamental economic characteristics are not directly associated with market mechanisms. Non-market patterns of functioning, including political interventions into economic processes are also taken into account. The divide may seem to some extent artificial and fuzzy but it allows defining the vulnerability of non-state actors. The collection of reference objects may include – broadly defined public institutions, public administration, self-government institutions, intra- and inter-state regions, non-market services, e.g. health care and infrastructure.

The economic vulnerability of non-market institutions may have several interpretations resulting from disturbances of all economic activities of those institutions during natural disasters and human-made political, economic or financial disruptions. Such institutions are usually created for providing public goods both under the normal conditions and especially in the time of a disaster, thus any disruptions in delivering those goods may cause a specific threat to those who rely on those goods.

Considerations on vulnerability of non-state institutions cannot focus solely on developing countries. Vulnerability as a new idea is transferred to other areas of economic life only partly relying on market mechanisms. The examples given below do not exhaust all possibilities but may be treated as representative for many entities.

Economic vulnerability may affect regions as in the case of a *Local Vulnerability Index* (LVI) for various districts (Naudé/McGillivray/Rossouw 2008). Economic vulnerability plays an important role in *Critical Infrastructure* (CI) for a wide variety of areas and institutions, including public institutions, health care, civil protection, etc. It is also affected by the disturbances where infrastructure and economic vulnerability of the market organizations and non-state institutions may undermine the functioning of infrastructure.

Another example shows how the idea of vulnerability is extended to areas where market mechanisms coincide with non-market institutions. The Centre of Full Employment and Equity in conjunction with the Urban Research Programme (Griffith University, Brisbane) have developed the *Employment Vulnerability Index* (EVI) for suburbs across Australia, which is an indicator that identifies those suburbs that have higher proportions of the types of jobs considered as being most at risk in the current economic climate (Baum/Mitchell 2009). Similar theoretical and policy efforts are undertaken on the macro level by the UN, where economic vulnerability is linked to unemployment (UNCDP 2006).

It is not possible here to discuss globalization as a factor contributing to economic vulnerability at all levels of the social hierarchy and where simultaneously macro-scale economic and financial vulnerability may occur. While in some cases broadly defined globalization contributes to limiting different types of vulnerability in other cases of social and economic vulnerability it does not.

4.3.3.3 Economic Vulnerability of Individuals, Households, Livelihoods and Human Security

Economic vulnerability of individuals is interrelated with various types of vulnerability at all levels of societal hierarchy. It is also a composition of the following overlapping and interrelated domains of vulnerability of livelihood and households and food security (FAO 2009a). In recent years gender vulnerability is also taken into account (UNCTAD 2004; Warner 2007: 17; Oswald Spring 2008). In a natural way, vulnerability of individuals is thus directly or indirectly included in the discourse on human security, although due to the vagueness of both concepts it is usually done in a descriptive way.

The vagueness of the human security concept is due to the fact that although it has become an indispensable part of security theory and practice, its applications as an analytical and political instrument are still unclear (Burgess/Owen 2004). Summarizing the discussion on human security Bogardi and Brauch (2005) as well as Brauch (2005) argue that it should rely on three conceptual pillars:

- 'freedom from want' by reducing societal vulnerability through poverty eradication programmes (UNDP 1994; CHS 2003);
- 'freedom from hazard impact' by reducing vulnerability and enhancing coping capabilities of societies confronted with natural and human-induced hazards (UNU-EHS 2004);
- 'freedom from fear' by reducing the probability that hazards may pose a 'survival dilemma' for the people most affected by extreme weather events (UNESCO, HSN).

The links between all three 'freedoms' and economic vulnerability of individuals, households and livelihoods cannot be identified due to the multiple meanings and fuzziness of both terms. Therefore, it is only possible to show some basic relationships between those two categories. Economic vulnerability at the level of individuals, households and livelihoods is always analysed with reference to poverty. Vulnerability can be interpreted in such a case as the existence and the extent of a threat of poverty and destitution; the danger that a socially unacceptable level of well-being may materialize (Dercon 2006).

In this approach, vulnerability may be defined as the magnitude of the threat of poverty, measured *ex ante*, before the veil of uncertainty has been lifted. This may be compared to poverty, which points to the magnitude of low welfare outcomes, as observed without uncertainty and whereby low welfare is defined as the outcome levels below some accepted poverty line. The focus is on exposure to the threat or the danger of low welfare outcomes, i.e. downside risk, not just risk in general. Following this definition, vulnerability may be defined or measured by the formula:

$$Vi^*=V(z,y,p)$$

where z is the poverty line, y is a vector of outcomes across n states of the world, and a vector p of corresponding probabilities. It may be easiest to take these outcomes as consumption levels, but it is more suitable to take other well-being dimensions into account. Vulnerability is then a function of outcomes, a norm and the probabilities linked to each outcome. Many functions could be imagined. To narrow this down for a measure, it is possible to define a number of desirable properties of a vulnerability measure. Subse-

quently methods of measurement and forecasting can be elaborated (Dercon 2006: 21).

In discussions of the vulnerability of individuals, livelihood, households and social groups, additional explanations of the entitlements approach developed by Sen (1981) as a concept of famine analysis are needed. Entitlements have been defined by Sen (1984: 497) as "the set of alternative commodity bundles that a person can command in a society using the totality of rights and opportunities that he or she faces". Devereux (2005: 246) notes that entitlements are a descriptive rather than a normative concept and that they derive from legal rights rather than the morality or human rights.

One of the most valuable contributions of the entitlement approach to famine theorizing is the shift of the analytical focus away from concentrating on food supplies – the Malthusian logic of "too many people, too little food" – and onto the inability of groups of people to acquire food. Food insecurity affects people who cannot access adequate food (e.g. because of poverty) irrespective of food availability – a famine can occur even if food supplies are adequate and markets are functioning well. This is a crucial insight. As Sen emphasized, there is no technical reason for markets to meet subsistence needs – and no moral or legal reason why they should. An equally important insight – and one that has generated much confusion and controversy in the literature – is that famine can be caused by an "exchange entitlement decline" (adverse shifts in the exchange value of endowments for food, e.g. falling wages or livestock prices, rising food prices) as well as by "direct entitlement decline", for instance loss of food crops due to drought. The entitlement approach does not exclude the latter possibility.

In his elaboration of the entitlement approach, Sen (1981) chooses the individual, the household, or an "economic class" of people (sharecroppers, pastoralists) as his unit of analysis, and he shifts seamlessly between these levels of aggregation as if they are interchangeable. A person's "entitlement set" is the full range of goods and services that he or she can acquire by converting his or her "endowments" (assets and resources, including labour power) through "exchange entitlement mappings". In the context of poverty and famine, the entitlement approach aims comprehensively to describe all legal sources of food, which Sen (1981: 2) reduces to four categories: "production-based entitlement" (growing food), "trade-based entitlement" (buying food), "own-labour entitlement" (working for food) and "inheritance and transfer entitlement" (being given food by others).

Entitlements can be treated as essentially the system of legal and customary rights defining the access to the society's resources. Individuals face starvation if their full entitlement set does not provide them with adequate food for subsistence. The entitlement approach focuses on starvation, which has to be distinguished from famine mortality, since many of the famine deaths – in some cases most of them – are caused by epidemics, which have patterns of their own. The epidemics are, of course, partly induced by starvation but also by other famine characteristics, e.g. population movement, breakdown of sanitary facilities (Sen 1981: 50). The entitlements approach allows for linking theoretical economic considerations with vulnerability and food insecurity or security although it also has limitations already recognized by Sen (1981: 48–50) and is criticized for several weaknesses, e.g. failure to recognize individuals as socially embedded members of households, communities and states, and second, a failure to recognize that famines are political crises as much as they are economic shocks or natural disasters (Devereux 2001: 259).

In a generalized sense entitlements can be applied as an instrument of deepened understanding of various areas of vulnerability. Adger and Kelly (1999) have proposed to use the entitlements approach in analyses of vulnerability of individuals, households and social groups. As Ribot (1995) argues, this approach introduces a household perspective on vulnerability, one that replaces 'ecocentric' approaches to environmental change. The main contribution of this approach lies in its focus on the vulnerability of individuals and social groups. Within this framework, vulnerability is understood as being determined by access to resources – specifically by individuals' "entitlement" to call on these resources (Adger/Kelly 1999).

Continuing this line of reasoning, it may be stated that vulnerability does not involve merely active and passive factors, but rather dynamic objects and subjects in continuous motion. As pointed out in Turner et al (2003), systems have different sensitivities to perturbations and stressors strongly linked to entitlements in the case of social units. Entitlements are essentially the system of legal and customary rights defining the access to the society's resources (Saldaña-Zorrilla 2006: 16).

Vulnerability of countries and individuals is linked with security in the FAO approach to food security in the Report prepared by the Interdepartmental Programme on *Food Insecurity and Vulnerability Information and Mapping Systems* (FIVIMS) (FAO 2009). In addition to individuals' food vulnerability or secu-

rity vulnerability of household, livelihood and gender are usually linked with human security.

As far as household vulnerability to poverty is concerned, alternative definitions exist. They were surveyed by Zhang and Wan (2008). In addition to 'typical' interpretations of vulnerability to poverty as the propensity of a household to suffer a significant shock that brings its welfare below a socially accepted level. Some of the definitions include references to the probability that a household would experience at least one episode of poverty in the near future or over a given number of time periods or that vulnerability to poverty at time t as the probability that a household becomes or remains poor at time $t+1$. It is worth noting the key difference between poverty and vulnerability to poverty. The latter involves future risks, is a forward-looking concept, and cannot be observed. One can, however, estimate the probability that a household may remain or become poor in the future due to various risks (Zhang/Wan 2008: 1).

Corresponding to different definitions of vulnerability, alternative measurement methods exist. They include using various differences and proportions between expected consumption and the poverty line and the probability to fall into poverty. Other measures are based on the use of average income and its standard deviation to measure vulnerability or as the difference between the expected value of poverty in the future and its current value. However, as demonstrated in Zhang and Wan (2008), most researchers prefer to define vulnerability to poverty as the probability of a household or individual falling into poverty in the future.

There are also other measures of household vulnerability. Dercon (2006) simply takes the degree of risks faced by individuals or households as a measure of vulnerability. Leaving apart other definitions of vulnerability to poverty, it may be concluded that as the household is a major economic actor studied with a more advanced economic apparatus, the studies of household vulnerability to poverty are deeply rooted in economic considerations.

Links between human security and vulnerability, both in a universal sense and narrowed to economic factors are also exposed in gender vulnerability. Traditional division of labour, more limited access to education and health care, lack of empowerment and entitlement, all put women at the forefront of socially vulnerable groups. They care for children and the elderly. The home-bound status of many women often makes them the first victims of a variety of stressors (Warner 2007: 18). Economic vulnerability is also directly related to more comprehensive ideas associated with human security can be quoted (see the *Human, Gender and Environmental Security* (HUGE) concept by Oswald Spring 2009). An integrated approach of HUGE focuses on overcoming the consolidated gender discrimination by reorienting human security. Economic vulnerability of women is explicitly and implicitly embedded into that concept (Oswald Spring 2008, 2009). This survey shows that vulnerability in a universal sense and economic vulnerability are closely linked to human security at a declaratory level.

4.4 A New Approach to Economic Vulnerability

4.4.1 Conceptual Limitations of Economic Vulnerability and Economic Security

In any attempts to deepen the understanding of economic vulnerability and economic security, the multitude of definitions of both terms, which sometimes do not correspond to each other, should be viewed as a fundamental obstacle. What is even more pessimistic, those linguistic barriers are insurmountable and it is in vain to try to overcome them. Of course, a total conceptual chaos is unacceptable and putting some order into the discourse is necessary.

In the search for better understanding of economic vulnerability, economic security and their relations the following barriers must be considered. A deeper explanation of the meaning of the term 'economic' is lacking in security-related considerations. Usually this adjective is applied without any attempt to explain its specificity although even the basic question whether vulnerability results from economic factors or whether vulnerability concerns economic activities usually remains unanswered.

Second, there are even different structural interpretations of vulnerability in a general sense. Chambers (1989) and other authors distinguish two sides of vulnerability: an external side of risks, shocks, and stress, and an internal side which is defencelessness. Briguglio, Cordina, Farrugia and Vella (2008) and other authors distinguish between vulnerability solely as an exposure to external threats, risks and hazards, and resilience (coping capacity) as an internal feature of the entity (system/individual). In this case relations between defencelessness and resilience would require additional explanations.

Third, it is impossible to separate various types of vulnerability. In attempts to define social, environmen-

tal and economic vulnerability the same characteristics are given mutually excluding significance in various types of vulnerability. For example, in the definition and measures of social vulnerability and economic vulnerability, economic factors are in different places of typological hierarchy like in the definition of *Prevalent Vulnerability Index* (Cardona 2007) and the vulnerability and resilience indices of the *Small Island Developing States* (SIDS) (Briguglio/Cordina/Farrugia/Vella 2008). Numerous similarities and dissimi-larities as well as subjective approaches of that kind can be easily found in deepened studies of other measures and indices of vulnerability (Gall 2007).

Fourth, only with a few exceptions, in most ideas discussed above economic vulnerability was used in a descriptive way. The indices were predominantly designed as descriptive parameters reflecting threats and resilience in a static manner. No attempts could be found to give them a predictive character. Therefore it is necessary to develop the concepts of economic vulnerability and economic security with a broader reference to economic theory – macroeconomics – development theory and microeconomics – risk, decision-making, rational choice, limitations of rationality, public choice, information asymmetry and its consequences, etc. A comment is necessary whether risk, hazard, etc. can be treated as dynamic and uncertain and vulnerability as static. A deeper reflection on vulnerability concludes that it also has a dynamic character. Any external disturbance which can be named as risk or hazard is always coupled with properties of the entity under study. It is prediction of disturbances – risks, hazards, threats, etc. which is contributing to the emergence of vulnerability.

Fifth, as shown above where general definitions of vulnerability and of related terms were surveyed, there exists a significant lack of logical coherence in defining relations between risk, hazards, vulnerabilities that are illustrated with various mathematical formulae, which are sometimes contradictory.

Sixth, since 2007 economic vulnerability of entities at all levels of socio-political hierarchy has increased due to the disturbances on the financial markets worldwide. Thus, it is necessary to include financial dimensions in the discussion on economic vulnerability and economic security. A special role in the discourse on economic vulnerability and economic security must be assigned to limitations of prediction of social phenomena (Mesjasz 2008b). Although most are already well-known in econometrics, yet in economics and in finance special attention is given recently to various 'rare events' labelled with such metaphors as the famous "Black Swan" (Taleb 2007) or less famous but equally rare mysterious "Dragon-Kings" running away from the Zipf's Law (Power Law) ruling (Sornette 2009). Barriers of prediction are part of the limitations of economic vulnerability. Despite many interpretations, economic security is still lacking a deepened theoretical background drawn from economic theory.

4.4.2 Economic Vulnerability, Economic Security and Securitization

While many definitions and interpretations of vulnerability, economic vulnerability and economic security exist, an elaboration of their new preliminary framework interpretations may help to facilitate the discourse. It will never be possible to develop universal definitions of those terms so only a more detailed specification of their meaning is possible. The proposed framework interpretations are stemming from the following assumptions and ideas:

- fuzziness of definitions of economic vulnerability and economic security,
- unclear interpretations of the term 'economic' in the discussions on economic vulnerability and economic security,
- systemic interpretations of the concepts of security, vulnerability and securitization (Mesjasz 2008) having their roots in cybernetics and systems thinking,
- economic vulnerability embodies also all financial activities,
- existence of a typical 'disordered' discourse in which the absence of definitions leads to a strive for political dominance of concepts caused by individual or institutional authority and power.

Two fundamental interpretations of economic vulnerability can help in solidifying the conceptual background of studies on economic vulnerability.

1. Economic vulnerability is a dynamic relationship between a socio-economic entity (system, individual) and its broadly defined environment where any external sudden (predicted, predictable or unpredictable) disturbance and/or any constant external negative stressors undermine accomplishment of its basic economic functions (production, distribution, exchange and consumption) of the system or unit due to its limited capabilities to respond to that external impact, i.e. its capacity to

compensate the impact, eliminate the impact or protect itself from that impact.

2. Economic vulnerability is a dynamic relationship between a system (individual) and its broadly defined environment where external economic (emerging anywhere in production, distribution, exchange and consumption), sudden (predicted, predictable or unpredictable) disturbance and/or any constant economic external negative stressors undermine the accomplishment of any basic function of the system or unit due to its limited capabilities to respond to that external impact due to its capacity to compensate the impact, eliminate the impact or protect itself from that impact.

Based on these two interpretations of economic vulnerability, two mirror interpretations of economic security may be proposed. First, economic security is understood as absence of any kind of threats influencing fundamental economic processes of a socio-economic entity (system or individual). Second, economic security is understood as the absence of economic threats to all areas of the functioning of any area of a socio-economic entity (system or individual).

The above interpretations require additional comments. While the interpretations of 'economic vulnerability' represent all possible situations, the interpretations of 'economic security' do not include all possible contingencies. This especially concerns those cases when economic aspects of defence are considered – defence spending, links between the economic potential of a country and its military potential.

The interpretations proposed above may also be criticized for their universality, which is an absolute purposive feature. It is not the aim of this chapter to propose any comprehensive definitions of economic vulnerability and economic security. The framework interpretations can be used solely as a point of departure for more rigorous studies of economic vulnerability and economic security allowing to put the discourse on those topics in order and preventing applications of those terms in a superficial manner. It is not the only attempt to treat economic vulnerability in a more cautious and logical way instead of just labelling various phenomena with such terms as risk, hazard, challenge, etc. without reflecting on their meaning and without any reference to their earlier interpretations. Therefore in the framework interpretation of economic vulnerability, no discussion on risks and hazards is proposed. Economic risk and hazards are defined in a more precise way and the framework concepts of economic vulnerability and economic security can be treated solely as points of departure for better specified definitions of risk, threats, hazards, challenges, etc. These framework interpretations can be treated as a point of departure for an interpretation of securitization in the economic sector. Two questions should be asked: What is the sense of securitization in the economic sector? What are the links between securitization and vulnerability?

Securitization in the economic domain is very intricate and cannot be achieved in an unequivocal way. Given the multiple meaning of 'economic' in the security-related discourse, securitization may also have a dual meaning: 1) Securitization concerns the threats affecting economic activities; and 2) securitization addresses economic threats affecting all security domains, including also the economic domain. This line of reasoning proves that security and securitization are in some way cyclical and self-referential processes.

The next explanation concerns the relationship between securitization in the economic domain and economic vulnerability. Securitization allows us to identify existential threats and due to the fact that both types of economic security are interrelated with both types of economic vulnerability it may be concluded that securitization allows us to identify vulnerability only indirectly. This pattern of relationships between economic security and economic vulnerability is common for all domains of security and vulnerability. It is only becoming more intricate for the economic security sector (domain).

The literature on economic vulnerability and economic security, similarly as in the environment and social domains of security, shows that since several years the former concept has been applied more frequently than the latter one. It is especially surprising after the period of popularity and frequent applications of securitization in security theory in the 1990's and in the first decade of the 21st century.

The best explanation for that phenomenon arises from a deeper understanding of vulnerability and security and from the specificity of economic vulnerability and economic security, where double asymmetry can be observed. Firstly, economic vulnerability is easier to identify and analyse due to the difficulties with identifying existential threats and a relative simpler identification of characteristics describing a social entity or individual. Secondly, specific barriers of identification of risks, hazards and existential threats in all kinds of economic and financial activities only add to the easiness of shifting from securitizing moves in that domain to identification of characteristics of vulnerability. As was mentioned in the systemic interpretation of the links between vulnerability and security, al-

though they are both closely interlinked in all domains, in search for characteristics of vulnerability, existential threats are identified indirectly. This has a significant theoretical impact – it is easier to study directly the features of the system or individual and indirectly predicting external threats than trying to predict them in a direct way. Once again it refers to finance where an unclearly defined stability concept dominates the discourse in theory and policy, and the use of concepts of the global systemic financial risk is rare (Mesjasz/Rogowski 2005).

4.5 Conclusions

The above considerations on definitions and interpretations of vulnerability used both in a universal sense as well as in various social, environmental and economic contexts are by their very nature limited. They may be treated as to some extent representative, and as such, they allow to conclude on the general interpretations and applications of that term in reference to economic processes. They also identify the links between vulnerability and security both in a universal sense and in the economic domain. Relations between vulnerability, security and securitization can also be studied thanks to a more comprehensive understanding of all terms.

The main conclusion concerning universal and specific definitions of vulnerability is that terminological disorder in that field has become almost uncontrollable and in many instances the basic terms are used in a completely uncoordinated manner. A deepened study of applications of various concepts of vulnerability, including the economic one, leaves the reader with an impression of an 'overflow' of definitions and interpretations, scores of institutions and people dealing with that utterance in various circumstances. Inevitably reflections on the role of fashion in science come to mind. Except for a few works cited above, the definitions and interpretations are sometimes contradictory in a logical sense, e.g. confusions of *definiendum* and *definiens* in describing risk and hazard, and many similar examples. Such a terminological disorder has several theoretical and practical consequences.

In many cases the links between vulnerability and security and the economy in environmental and development studies may not be identified. A systemic framework interpretation of vulnerability and security can thus be treated as a point of departure of identifying the relations between vulnerability and security in a universal sense and in specific domains. Although vulnerability and security are logically symmetrical, in the recent discourse on environment, development and economy the dominance of a vulnerability-based over a security-based approach may be observed. Such a shift is caused by a relative simpler, and in consequence, less costly study of properties of a system or individual than studies of the necessary surrounding in the security discourse in which, especially in securitization, external and internal existential disturbances have to be predicted and securitized as threats.

The survey of definitions and interpretations of vulnerability leads also to a conclusion on a specific conceptual and institutional consequence of the definitional disorder. The lack of unequivocally dominating ideas, except for very general ones, creates a situation where a specific game of words is emerging in the discourse. It is not always necessary to provide a coherent set of ideas but just naming some concepts and then using them for institutional purposes. What could be a difference between 'resilience studies' and 'vulnerability studies' if such names are assigned to research teams and institutions? The situation is similar with the use of the term 'risk' in the names of more or less institutionalized research. Fuzziness of terms used in the 'game of words' allows an uncontrollable 'power game' on the knowledge wherever vulnerability and associated terms are applied in development and environmental studies and in economics.

Similar conclusions are also relevant for definitions and interpretations of economic vulnerability and economic security. Here the conceptual disorder can be somehow structured if a deepened interpretation of the meanings of the term 'economic' in considerations on vulnerability and security is borne in mind. The links between economic vulnerability and economic security also remain asymmetric with a dominance of the former. In addition, economic vulnerability better corresponds with theory and policy in those areas where the term human security is applied (food, gender, household and livelihood). For the following reasons, it is proposed to extend the use of the term economic vulnerability:

- simpler defining economic vulnerability,
- difficulties of securitization in the economic sector,
- autonomization of economic vulnerability from other forms of vulnerability where it was treated only as a component,
- increasing economic threats to developed and developing countries arising from the economic and financial turmoil on modern markets and also

from natural disasters. Many disturbances may create a kind of negative synergy unbearable even for the rich countries at the state level and for market and non-market institutions.

An extension of the applications of the concept of economic vulnerability should then include:

- recognition of the role of economic vulnerability outside the studies of environmental considerations and studies of poor countries,
- inclusion of developed countries into the research area of the studies of vulnerability, and of economic vulnerability in particular,
- studies of vulnerability of market institutions – manufacturing and service companies including the financial ones as well as broadly defined non-market institutions.

On the basis of the conclusions, further studies on the links between economic vulnerability and economic security should be focused on the following issues.

- First and foremost it is necessary to elaborate a more coherent terminology of theory and policy-making concerning economic vulnerability, even in a minimal degree. Perhaps, similarly as is done in management, some standards could be helpful, e.g. (ISO 31000 2009) or similar concepts proposed in risk management in market organizations and non-market institutions. Obviously, it will not be possible to elaborate a unique standard but the present chaos leads to confusion and a waste of resources.
- Second, ordering of terminology should be accompanied by the studies on the links between hierarchy of economic systems or actors and systemic aspects of economic vulnerability. It should include all levels of hierarchy – beginning at the global one and ending with the individual.
- Third, more attention should be given to sound theoretical economic foundations of the studies of economic vulnerability. Rigorous economic thinking is often used in the studies of economic vulnerability but still in too many instances the terms vulnerability and economic vulnerability are used as void labels ('Leerformel').

5 Debt Relief, Economic Growth and Poverty Reduction in Low-Income Countries

Lidia Mesjasz

5.1 Introduction

The debt problem of poor countries has attracted considerable public attention in the 1990's through the Jubillee 2000 campaign for debt cancellation. The United Nations' Millennium Declaration and the associated *Millennium Development Goals* (MDGs) have played an important role in the recognition of debt as a global issue by focusing the world's attention on the plight of the poorest, and making debt relief one of the development goals. In Monterrey in March 2002 the international community agreed that external debt relief could play an important role in financing development and accelerating progress toward the MDGs.

Unlike the earlier debt crisis of the 1980's that broke out suddenly in middle-income countries in Latin America and was largely resolved by the early 1990's, the *low-income countries* (LICs) debt crisis has developed gradually, and arguably worsened to this day. It primarily involves the poorest of the poor nations, especially those of sub-Saharan Africa.[1] LICs' debt crisis can perhaps be best described as a chronic syndrome. Much of the debt of poor countries is owed to official lenders, including individual governments, and multilateral institutions, such as the World Bank and the *International Monetary Fund* (IMF). Low-income countries – unlike the middle-income countries – had to rely on official loans, since their access to private capital markets was very limited. By the early 1990's, debt service was taking a large and rising share of the public budget in poor countries, and donors came under mounting pressure to resolve the issue. The Paris Club[2] creditors provided repeated debt reschedulings on increasingly more concessional terms that involved debt reduction. But this only postponed the resolution of the growing problem of unsustainable debt burdens that could not have been serviced without seriously compromising the poor countries economic growth. Gradually it became clear that a more far reaching programme of debt relief was needed. In 1996, the *Heavily Indebted Poor Countries* (HIPC) Initiative was launched with the aim of cutting debt to sustainable levels, and thereby releasing resources for development spending, including poverty reduction. After further public pressure, this was followed by the *Enhanced HIPC Initiative* of late 1999 which raised the amount of debt relief, accelerated the process and tightened the link between debt relief and the objective of poverty reduction.

The analysis of the HIPC Initiative presented in this chapter addresses directly and indirectly the links between broadly defined security and debt relief of the poor countries. Often a high level of indebtedness of developing countries is either a consequence or a cause of main security threats emerging in all sectors in those countries that undermine international security at the regional, and even at the global level.

The HIPC Initiative has been the most sweeping debt relief programme so far developed by official creditors for low-income countries. However, the HIPC Initiative raises many issues:

1. Can the debt relief Initiative reduce debt burdens of HIPCs to sustainable levels?
2. Will debt relief stimulate economic growth and development spending, including pro-poor spending, contributing to poverty reduction in HIPCs?

1 Low-income countries according to the World Bank classification are those whose gross national income (GNI) per capita in 2008 was 935 US dollars or less. This group consisted of 43 countries in 2008.

2 An informal group of official creditors from currently 19 of the world's richest countries, which provide financial services such as: debt restructuring, debt relief, and debt cancellation to indebted countries and their official creditors.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_5, © Springer-Verlag Berlin Heidelberg 2011

3. Is debt relief a viable solution to broader economic development problems?
4. What could be a potential impact of debt relief on economic and human security in low-income countries?
5. What will be the likely impact of the current global financial and economic crisis on achieving the goals of the HIPC Initiative?

These are crucial questions this chapter seeks to answer. There has been little rigorous analysis on the development effects of debt in low-income countries (as opposed to the work done on middle-income countries), and the likely impact of debt relief under the HIPC Initiative. Accordingly, this chapter aims to improve our understanding of the economics of debt relief, including its potential for accelerating growth and reducing poverty in low-income countries. This is especially important for an assessment of how much the HIPC Initiative did contribute to achieving the Millennium Development Goals. The current global economic crisis seriously challenges these goals.

With its initial overview of history, methods and results of debt relief policy of the poor countries by the creditor governments and international financial institutions, the chapter offers a point of departure for further, more advanced considerations on the links between debt of the poor countries and its impact on their broadly defined security. Economic considerations can also be applied as an instrument or methodology for studying the impact of poverty and debt reduction on security, with special attention on human security.

After a preliminary assessment of the links between debt relief and economic and human security in poor countries (5.2), theoretical arguments for debt relief are presented (5.3), and a brief history of the debt crisis and of debt relief initiatives for low-income countries are described (5.4). This is followed by a survey of empirical evidence on the debt and growth relationship (5.5), an analysis whether the HIPC Initiative has met its objectives (5.6), a preliminary evaluation of the likely impact of the current economic crisis on achieving these objectives (5.7), and by concluding remarks (5.8).

5.2 An Economic and Financial Security Context for the Analysis of Debt Relief

There is little doubt that the debt burden of a majority of the least developed countries constitutes a significant factor of broadly defined security of those countries as well as of their neighbours. It also affects directly and indirectly security at regional and even at global levels. Similarly as in most examples of the discussion on economic security a specific dichotomy can be observed. On the one hand self-evident links between official sovereign debt and security in all sectors are easy to identify. At the same time, however, direct links between indebtedness and the broadened concept of security have not yet been studied thoroughly.

Economic security remains probably the most difficult idea of the discourse on broadened security. Referring to various ideas of economic security developed in the literature (Cable 1995; Buzan/Wæver/de Wilde 1998; Kahler 2003; Nesadurai 2005; Mesjasz 2008a), it must be stated that the studies on the links between indebtedness of the poor countries and broadly defined security should be focused on the following issues:

- theoretical considerations on the role of external indebtedness as an element of economic security,
- direct and indirect impact of indebtedness as a determinant of security in all sectors,
- official debt as a determinant of a country's development, and of economic and human security in particular,
- securitization of threats stemming from official and commercial debts of poor countries,[3]
- debt relief as an element of security policy of the rich countries in relation with poor countries.

When studying the role of sovereign debt as an element of broadly defined economic security, it should firstly be answered whether a special role of financial security should be exposed. It is especially an important question which is becoming more urgent under the impact of the turmoil on the financial markets. With regard to economic and financial security, the latter may be seen as a part of the former and the specification of financial security, especially at the state level, should be left for further theoretical considerations.

Financial security is usually well-defined at the micro level as protection against poverty and safety of income of individuals and households and prospects of the future financial guarantees of welfare in case of sickness and retirement. Financial security of interme-

3 Securitization is understood herein in the sense proposed by Copenhagen School (Buzan/Wæver/de Wilde 1998) and not as in financial risk management.

diate actors, e.g. companies is most difficult to define. At the national or international level financial security can be associated either with vaguely defined financial stability (Schinasi 2006; Mesjasz 2008a) or with the impact of the overall financial stance on other security sectors.

Sovereign debt plays a decisive role in all sectors of security in the poor countries. Several examples show that unpaid debt of the state can be both the cause and effect of the situation in the failed states and their consequences, e.g. terrorism and piracy, a cause of local conflicts and of an internationalization of local conflicts, and due to vulnerability to natural disasters. Frequently all those factors occur in parallel as in the case of Somalia or Sudan. Therefore debt relief offered by the creditor country governments and international financial institutions can be viewed as a significant element of the security policy of the affected countries.

Although debt relief is addressed by states and governments, it should also be considered that individuals are the main indirect addressees of that relief. Therefore it should be emphasized that an improvement of human security, and not only of poverty alleviation and eradication, can be also seen as an ultimate goal of this assistance for poor countries.

If debt relief works, it can be argued that it could reduce security risks by making a population more satisfied. But the majority of debt relief efforts have failed; in fact, in many cases relief itself has created worse conditions. Without an effective use of funds that may be made available through a reduced debt service there will be no improvement. Improving conditions in the least developed and usually highly indebted countries could lead to a limitation of security threats but the question is arising whether this form of assistance is effective.

Securitization of indebtedness of developing countries, not in terms of financial risk management, but as understood by the Copenhagen School appears as another important element of the security discourse. Although securitization of economic threats is still a major obstacle, in the case of debts of developing countries the situation seems easier to analyse. A high level of indebtedness is always a threat influencing other security sectors and threatens human security. However, such securitizing moves, due to their complexity, must be preceded by deepened financial and economic analyses of indebtedness and debt relief programmes.

Finally, debt relief is obviously an important instrument of direct policy-making of rich towards poor countries.[4] It can also be used (and abused) as a narrowly defined instrument of foreign policy and influence. In another framework, as exposed by the United Nations, debt relief can also be perceived as an important instrument of security policy of rich countries –viewed in social, economic, political and ethical terms – due to its impact on development of poor countries, on the elimination of poverty and on other threats to human security.

The above survey of potential links between debt relief of poor countries and broadly defined security shows that any deepened security considerations relating to this form of assistance should be accomplished based on thorough economic, financial, institutional and political analyses. A discussion on debt relief can be viewed as a first step into that direction.

5.3 Theoretical Arguments for Debt Relief

In economic discussions four basic arguments for providing debt relief to low-income countries are noted: a) the moral, b) the 'overlending', c) the 'additional financing', and d) the 'debt overhang' argument (Varma 2006).

- The *moral argument* is that it is unjust for rich countries to try to collect the debts owed to them by countries that are desperately poor. This line of argument that was strongly promoted by civil society organizations, religious groups, and some other advocates is exemplified by Jeffrey Sachs' statement: "No civilized country should try to collect the debts of people that are dying of hunger and disease and poverty."[5] The second rationale within the same moral line of reasoning is that some debts were 'llegitimate' in the first place as they were contracted by dictators supported by foreign governments (such as Mobutu Sese Seko in Zaire, now the Congo), and used for their personal and nefarious purposes. Thus, the country should not be responsible for paying such debts; they are solely the liability of the creditor who has made improper loans (Adams 1991; Hanlon 2006). Although the moral argument resonates

4 Commercial debt can be managed by the states only indirectly and therefore should be a topic for separate studies.

5 The statement made at the UN conference on hunger in Africa in July 2004 is quoted by Andrew England, in: *Financial Times Syndication Service*, 7 October 2004 (England 2004).

strongly with anyone who feels compassion for the plight of the world's poor, it would essentially mean no further lending to poor countries, which would then be limited to accessing grant resources to finance their development. This would imply a shrinking of the total resources available to help poor countries invest and grow.

- In the second argument of 'overlending' debt relief is an efficient way of cleaning up the balance sheet in the event that lenders have overlent, partly in an effort to ensure positive net flows to poor countries. If provided in this context, however, debt relief might create a moral hazard: if the 'overlending' argument was valid last time, why should it not be valid again next time? Such reasoning might lead developing countries – possibly the same ones as before – to borrow heavily and recklessly in the future, in the expectation that they will once again receive debt relief should the perception again arise that creditors have overlent.
- The third, and perhaps the most reasonable argument for debt relief in low-income countries, is that of 'additional financing'. It states that debt relief can be an important alternative source of financial flows to the poorest countries that desperately need financing to meet their basic needs. Debt relief offers a vehicle for the international community to provide the additional resources needed to meet the MDGs in a predictable and easily accessible form. But this argument also has its shortcomings. *First*, the additionality of debt relief cannot be taken for granted. Debt relief can only generate a limited amount of resources, especially for HIPCs, much of whose debt has already been forgiven, and most of whose remaining debt is at very low interest rates. *Second*, there may be better ways to provide MDG financing, as debt relief is allocated based on past lending decisions and is small relative to new development assistance.
- The fourth, most popular, argument in support of debt relief initiatives refers to 'debt overhang' (Krugman 1988; Sachs 1989). It has been stated that highly indebted countries benefit very little, if ever, from the returns on any additional investment because of the debt service obligation. Large debt obligations can be seen as a high tax on investment, policy reforms and development, because a significant part of the gains from economic adjustment would go to foreign creditors and not to the country itself. Creditors should therefore offer debt relief to countries with large stocks of external debt in order to reduce future debt obligations. This would increase the share of any marginal gains from economic adjustments that goes to the debtor country and create incentives to make these adjustments. This strategy could end up in a win-win-situation by not only easing the debt burden of debtors but also increasing future repayments to the creditors (Dijkstra/Hermes 2001).

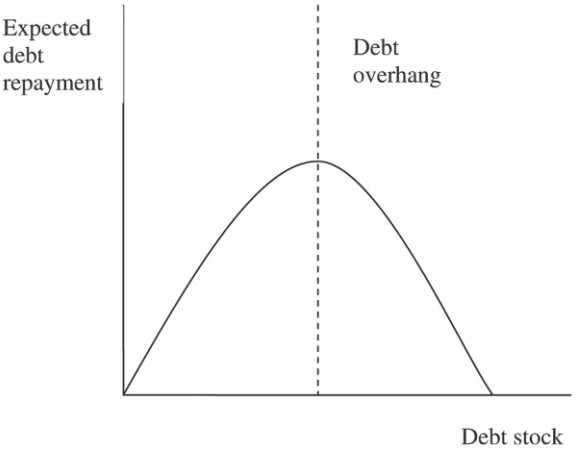
The disincentives for the government to carry out economic reforms caused by excessive external debt are of special concern in low-income countries, where an acceleration of structural reforms is needed to sustain higher growth to meet the Millennium Development Goals. Similarly important is private investment that is discouraged by increasing uncertainty stemming from high indebtedness. As the size of the public debt increases, there is growing uncertainty about actions and policies that the government will resort to in order to meet its debt servicing obligations. In particular, private investors may expect that the government may resort to inflationary finance or future tax increases that could be required to service public debt (Agénor/Montiel 1996). The extensive literature on uncertainty and investment suggests that in highly uncertain and unstable environments, even if the fundamentals are improving, potential private investors wait and see before taking new investment decisions (Serven 1997). Moreover, investment may be misallocated to activities with quick returns, rather than long-term, higher-risk irreversible projects which would be more conducive to long-run productivity growth. Misallocated resources and less efficient investment projects could thus contribute to slower productivity growth.

Since debt acts as a tax on debtors' resources that deters profitable investment opportunities, the debt overhang argument is usually illustrated in a 'debt Laffer curve' (figure 5.1). The concave curve traces the value of expected repayment as a function of outstanding debt: as outstanding debt increases beyond the threshold level, the expected repayment begins to fall as a consequence of the adverse effects mentioned above (Cohen 1993). On the upward-sloping or 'good' section of the curve, increases in the face value of debt are associated with increases in expected debt repayment, while on the downward-sloping or 'bad' section of the curve increases in the face value of debt reducing expected payments. Thus, debt relief becomes a rational choice for both creditors and debtors, when a debtor is said to be on the 'wrong side' of the Laffer curve. Although the debt overhang theories have not

explicitly traced the effect on growth, it may be possible to extend and translate the 'debt Laffer curve' posited by these models into a Laffer curve for the effect of debt on growth. Since the peak of the debt Laffer curve shows the point at which rising debt stocks begin acting as a tax on investment and policy reforms (that is where debt overhang begins), the peak may relate to the point at which debt begins to have a negative marginal impact on growth (Pattillo/Poirson/Ricci 2002).

Not only high debt stocks but also excessive burden of *debt service* actually paid can negatively affect growth. Its adverse effect on growth is by crowding out private investment (Cohen 1993) or altering the composition of public spending. Higher external interest payments can increase a country's budget deficit, thereby reducing public savings. This, in turn, may either raise interest rates or crowd out the credit available for private investment, depressing economic growth. Larger debt-service payments can also inhibit growth by squeezing the public resources available for investment in infrastructure and human capital. Even if HIPCs borrow at high concessional terms, so that the debt service is lower than in middle-income countries, their revenues are much lower because of weak tax systems and scarce enforcements. As a consequence, even if external debt service is not always large as a share of GDP, it is nonetheless a relevant fraction of revenues, so that it could really be a constraint to the government budget. On the other hand, as HIPCs are usually net recipients of resource transfers from external creditors and donors, the adverse effects of debt service on real economic activity are mitigated.

Figure 5.1: Debt Laffer Curve. **Source:** Pattillo, Poirson and Ricci (2002).



In addition, the *uncertainty* about the future debt service burdens may also have negative effects on economic growth because it may hamper much needed government policies, which in turn reduce the incentives to private investors (Dijkstra/Hermes 2001). High instability of annual debt service payments increases the uncertainty with respect to the implementation of government policies. If governments do not have a clear picture of the annual debt service payments, they do not know either how much money will be available for carrying out economic reforms, investments in infrastructure and spending on social programmes. The uncertainty reduces the effectiveness of government policies. This in turn will adversely affect private investment and may even stimulate capital flight. Both the erratic government policies and lower private investments will contribute to lower (and perhaps even negative) rates of economic growth.

Heavily indebted poor countries are particularly confronted with unstable payment patterns. This instability may come from several sources. Firstly, most HIPCs are regularly negotiating with bilateral and multilateral donors about the terms of debt service repayments. The outcomes of these negotiations are difficult to predict, contributing to the uncertainty about the annual debt service payments due. Secondly, the uncertainty about debt payments can be partly explained by the way the debt servicing system is organized. In most cases, these countries only pay part of the debt service due; the rest is postponed. A substantial part of the debt service payments actually made is paid for by new concessional loans and grants. Yet, for governments of HIPCs it remains highly uncertain how much is exactly available to pay debt service from own and external sources. Moreover, a part of the grants are earmarked for special purposes, since the donors do not want their aid money to be used for payment of debt service. These characteristics of the debt servicing system in turn contribute to erratic patterns of debt service payments actually made.

The HIPC Initiative can lower the uncertainty of debt service payments by cutting the number and/or frequency of negotiations on the terms of debt payments as well as on new loans and grants. In addition, the irrevocable nature of the HIPC debt relief upon reaching the completion point may reduce the uncertainty faced by recipient countries about their ability to use grants to service debt, by providing a credible multiyear commitment. This may help the governments of debtor countries to plan more carefully revenues and expenditures, making them more predicta-

ble, which in turn may stimulate private investment and economic growth.

When seen from a broader perspective the above arguments to a large extent coincide with security reasons, which particularly concern economic and human security. Economic analysis extended to ethics can thus be treated as an initial step in studying the impact of debt relief on all security sectors in poor countries.

5.4 Brief History of the Debt Crisis and Debt Relief Initiatives of Low-income Countries

The low-income countries' debt crisis – unlike the middle-income Latin American countries' debt crisis that broke out suddenly in 1982 and was largely resolved by the early 1990's – has gradually developed, largely invisibly, and worsened to this day. It originated from an inadequate use of large volumes of borrowed funds that were not put in growth-enhancing projects and policies that would enable to attain higher growth and poverty alleviation. Several factors were responsible for the poor link between borrowing and growth in most crisis countries. Perhaps the foremost of these were severe shocks such as droughts or prolonged declines in prices of primary commodities – the predominant export category for many low-income countries. Commodity prices fell sharply in the early 1980's and remained low for many years. Other factors included, depending on the country, waste of resources due to policy deficiencies, poor governance, or weak institutions, inadequate debt management, lack of adjustment to an evolving economic environment, as well as political and security factors such as civil wars and social unrest, which often had devastating economic consequences (Brooks/Cortes/Fornasari/Ketchekmen/Metzgen 1998). Some borrowed resources were simply embezzled by corrupt governments and never used for the purposes for which they were intended (Adams 1991).

During the 1970's and 1980's external borrowing to low-income countries increased significantly when creditor governments provided official export credits in order to stimulate their own exports, and export credit guarantees as a complement to direct grants and concessional *Official Development Assistance* (ODA) loans in their overall development cooperation policy (Daseking/Powell 1999).[6] The debt burden of low-income countries rose steadily. By the early 1980's many low-income countries were brought to the point of economic collapse by the years of economic mismanagement. It led to severe security consequences in all traditional sectors but undoubtedly it was human security which was affected the most. Therefore any debt relief for those countries had become an important instrument of improvement of economic security of individuals and, in a broader sense, as an instrument of amelioration of human security.

The international financial community's reaction to the unfolding debt crisis in the 1980's differed for middle-income and low-income countries. In the early 1980's, the prevalent paradigm was that the debt crisis was a problem of illiquidity, and that countries could 'grow out of debt', given temporary debt servicing relief. The Baker Plan launched in 1985 was mainly directed at middle-income Latin American countries whose commercial debt was so high that if they defaulted this could have created a threat to the international banking system's stability.[7] Under the Baker Plan it was assumed that a 'flow rescheduling' of debt without any reduction in its *net present value* (NPV),[8] together with provisions of new lending by commercial banks and creditor governments, conditional on the implementation of an IMF-approved structural adjustment programme, would bring about a solution.[9] New lending would lead to increased investment, which would eventually lead to greater economic growth.

---

6 ODA comprises loans or grants to developing countries and territories provided by donor governments and their agencies for the purpose of promoting economic development and welfare. If it is a loan it must be extended on concessional financial terms that are, with a grant element of 25 per cent or more, calculated as the *net present value* (NPV) of the future payment stream discounted at 10 per cent.

7 The plan was named after the then U.S. Secretary of the Treasury, James Baker.

8 The NPV of debt is defined as the sum of all future debt-service obligations (interest and principal) on existing debt, discounted at market interest rates. Whenever the interest rate on a loan is lower than the market rate the resulting NPV of debt is smaller than its face value, with the difference reflecting the grant element (expressed as a fraction of the debt stock). Given the concessionality in loans extended to LICs, the NPV of debt is a more relevant metric for evaluation than the face value of debt as it takes into account the degree of concessionality present in the stock of debt.

9 A 'flow rescheduling' of debt means that interest and principal payments are postponed for some period in the hope that economic growth in the meantime will make it easier for the debtor to repay the debt.

Unfortunately, net new lending was too modest to spur economic growth and adjustment programmes generally failed to boost borrowers' ability to repay loans. The typical austerity programmes included spending cuts, tighter monetary policy to control inflation and liberalization of foreign-exchange regulation in order to make imports more expensive and exports more competitive. In countries that practiced austerity programmes, private and public investment usually fell, unemployment climbed, poverty spread, and the improvement in the balance of payments was at most modest (Killick 1998). Between 1980 and 1990, the *gross domestic product* (GDP) per capita fell 7 per cent in both Latin America and Africa (Maddison 1995: 21–22). But external debt continued to grow both in nominal and in relative terms.

In the meantime, commercial banks started setting aside loan-loss reserves, that eventually allowed them to accept losses in face value of debt by writing down outstanding obligations in the late 1980's. Debt was traded on secondary markets at a substantial discount to face value, confirming the market's scepticism that debt would ever be repaid in full. In the late 1980's the paradigm shifted from one of a liquidity problem to a 'debt overhang problem'. This shift led to the Brady Plan in 1989, which used market-oriented debt reduction schemes, such as debt buybacks and equity swaps, to solve the debt crisis.[10] Again, mainly Latin American countries were involved. Commercial banks used this opportunity to leave the market by making use of their previously accumulated loan-loss reserves. From 1989 to 1995, 13 countries with US$191 billion in commercial bank debt completed debt and debt service reduction operations, which provided for the reduction of nearly 20 per cent in the nominal value of commercial bank debt (World Bank 2003: 60). The overall debt situation of those countries improved, which allowed them to regain access to international capital markets till the mid 1990's. By that time Latin America's debt crisis was over.

But the low-income countries debt problem remained unresolved. Official creditors, which dominated lending to LICs were slower to compromise and more willing to take risks than commercial creditors. While commercial creditors typically reduced their exposure and cut their losses in response to LICs liquidity crisis, official creditors continued to provide comprehensive non-concessional 'flow rescheduling' in the Paris Club, new lending from several multilateral agencies, as well as some additional export credits from creditor governments. By doing so official lenders were able to put pressure on borrowers' governments to implement harsh economic reforms advised by the IMF as well as conceal their imprudent past lending. One reason why the process was able to continue for so long was that in practice the rescheduling approach worked for both creditors and debtors, at least in the short run. Flow rescheduling reduced pressure on official donors to find other – potentially more costly – approaches to ensuring fully financed adjustment programmes in LICs. The industrial country governments had no desire to provide additional direct finance to low-income countries. All in all, the approach allowed for substantial cash flow financing continuing to be made available to LICs during the 1980's. Unfortunately, much of the money provided was not used effectively, and the debt stocks continued to grow. Consequently, a severe debt overhang had arrived by the late 1980's. The nominal stock of HIPCs debt increased from US$55 billion in 1980 to US$183 billion in 1990 (World Bank 1997: 42). On average the net present value of debt as a ratio to exports for HIPCs rose from below 150 per cent in the early 1980s to some 800 per cent by the mid-1990s (Varma 2006).

A 'flow rescheduling' in the Paris Club involved simply a delay in repayments during the IMF-supported economic programme. As the 1980's progressed, the LICs rescheduling increasingly involved all or most principal and interest payments that were rescheduled over a longer period of time. From 1976 to 1988 the Paris Club approved 81 non-concessional flows rescheduling with 27 of the countries now identified as HIPCs. They allowed for payments equivalent to about US$23 billion to be delayed into the future. Nevertheless, the debt service paid by HIPCs increased from about 17 per cent of exports on average in 1980 to a peak of about 30 per cent of exports on average in 1986, although this was less than the scheduled debt service ratios (Daseking/Powell 1999: 5–7).

In the late 1980's the notion of debt overhang gained prominence among policy makers dealing with debt of low-income countries. Krugman (1988) and Sachs (1989) argued that highly indebted poor countries were on the 'wrong side' of a 'debt Laffer curve', and suggested that writing down a debt overhang would raise countries' incentives to invest domestically and therefore increase the available surplus used for debt repayment. Official creditors were forced to accept rescheduling on concessional terms that in-

10 The plan was named after then US treasury secretary Nicolas Brady.

volved reduction in the present value of the debt outstanding. The first initiative by the Paris Club creditors that included an element of forgiveness in non-concessional debt rescheduling, was taken at the Toronto G-7 summit in 1988. G-7 leaders agreed that non-concessional debt of African countries that are eligible to borrow only from the *International Development Association* (IDA), could be reduced by up to 33 per cent in net present value terms. In 1990, these terms were extended to non-African countries. From 1988 to 1991, 20 LICs received rescheduling on Toronto terms, with about $6 billion of declining payments due to either being partially cancelled or rescheduled on a concessional basis (Daseking/Powell 1999: 9).

Although the Toronto terms had some beneficial effect, the international community realized before long that a deeper reduction in the stock of debt was needed to achieve sustained improvement in the debt situation of LICs. The Paris Club creditors accordingly increased the reduction to 50 per cent in 1991 (London or Enhanced Toronto terms) and to 67 per cent in 1994 (Naples terms). In the period since 1991, 26 rescheduling agreements were signed under the London terms, and a further 34 under the Naples terms – seven of which covered the full stock of eligible debt – with a total of about US$25 billion of payments being either partially forgiven or rescheduled at low interest rates over the medium or long term (Daseking/Powell 1999: 10).

Among other fundamental changes of the Paris Club creditors' approach three are worth mentioning. *First*, the Paris Club creditors adopted a flexible two-step approach to debt restructuring combining the restructuring of the debt service during a limited consolidation period[11] with the possibility of a later reduction in debt stock. *Second*, they allowed the possibility of rescheduling, under the Naples terms, of debts previously rescheduled under the Toronto or London terms. *Third*, some Paris Club creditors took important complementary measures, namely the forgiveness of the ODA loans by members of the *Development Assistance Committee* (DAC) of the *Organization for Economic Cooperation and Development* (OECD), and debt conversion arrangements under the Paris Club auspices and through special initiatives such as the U.S. Enterprise for the Americas Initiative and the Swiss Debt Reduction Facility.

The LICs have also benefited from debt relief from commercial creditors. The bulk of it was provided through debt buybacks supported by the *Debt Reduction Facility* (DRF) for IDA-countries only.[12] The DRF-supported operations typically involve a government buying back its public and publicly-guaranteed debts from external commercial creditors for cash at a deep discount, thereby extinguishing such debts from the books of the public sector. Since its creation in 1989, the DRF has supported 24 completed buy-back operations in 21 low-income countries, resulting in the extinguishing of some US$9 billion of debt. In 2008, its policies and practices were modified to enhance the speed and effectiveness of its support for commercial debt reduction operations. The DRF's current mandate expires on 31 July 2012 (IDA/IMF 2008: 24–25; World Bank 2008a).

Since 1990 the stock of HIPCs debt has grown more slowly, though by the end of 1995 it had reached US$215 billion. The slowdown reflected concessional rescheduling of loans, a shift towards greater provision of grants, commercial bank debt reduction, and widespread forgiveness of official development assistance loans (World Bank 1997: 42). The increasingly concessional rescheduling allowed bringing debt service payments of HIPCs down from 30 per cent of exports in 1986 to about 17 per cent in 1997, and below the aggregate level for LICs more generally. Moreover, the debt service paid by HIPCs has typically remained in the range of about 25–35 per cent of total gross external financing (including official grants) for most of the period since 1980. Rescheduling, therefore, has helped to ensure that after other official support was taken into account, overall official transfer (grants and loans minus debt service paid) to LICs remained highly positive throughout the period, averaging 13 per cent of GDP for the average borrowing country over 1984–1996 (Varma 2006). The present value of debt-to-exports ratios started to fall after 1992, reflecting increasingly concessional rescheduling terms, stock-of-debt operations, and more concessional new finance (Daseking/Powell 1999: 11–12).

Nevertheless, several LICs continued to be affected by unsustainable debt burdens, the situation in which they were no longer able to fully service their

11 Consolidation period in a debt restructuring agreement is the period of time during which debt service payments are to be consolidated and rescheduled or deferred.

12 IDA-only countries are those which only receive loans from International Development Association (the concessional lending arm of the World Bank) and usually have no access to international capital markets.

future debt obligations without seriously compromising economic growth. Debt workouts initiated by the Paris Club creditors since the late 1980's were far from effective in offering a permanent solution. The rescheduling and forgiven debt stock was only marginal compared to the accumulated debt stocks. By the mid 1990's, with an increasing share of debt owed to multilateral creditors, a new debt relief initiative was called for at the June 1996 G-7 summit in Lyon. The Paris Club creditors agreed to increase the level of debt reduction up to 80 per cent on net present value basis (Lyon terms). In response, the World Bank and the International Monetary Fund launched the *Heavily Indebted Poor Countries* (HIPC) Initiative in September 1996 to promote growth in the poorest, most heavily indebted countries by removing the debt overhang, provided that they adopted and carried out programmes of macroeconomic adjustment and structural reform. In contrast with earlier proposals for debt relief (also called 'traditional debt relief mechanisms'[13]), the HIPC Initiative also includes the relief of debt to multilateral institutions like the IMF, World Bank and the regional development banks.

After much criticism that the Initiative was too limited and too slow, the Enhanced HIPC Initiative was launched in September 1999 in line with the suggestions endorsed in the June 1999 G-7 summit in Cologne, where the Paris Club creditors agreed to provide up to 90 per cent reduction in debt on net present value basis. The Initiative's framework was enhanced to provide deeper, broader, and faster debt relief, and to strengthen the links between debt relief and poverty reduction. The external debt thresholds for eligibility were lowered, which enabled a broader group of countries to qualify for larger volumes of debt relief. A country becomes classified as a HIPC once the net present value of debt-to-exports ratio exceeds 150 per cent (previously 200–250 per cent on a case-by-case basis[14]) or the NPV debt-to-revenue ratio exceeds 250 per cent (previously 280 per cent). Other low-income countries that have smaller debt burden are not included in a heavily indebted poor countries' group. For example, in 2004 other LICs comprised of 18 countries whose NPV of debt relative to exports was on average 99.5 per cent (the ratio very similar to that of middle-income countries: 98 per cent; World Bank 2006a: 94).

The link between debt relief and poverty reduction was strengthened by requiring that resources released by debt relief were to be used to support poverty reduction strategies through *Poverty Reduction Strategy Papers* (PRSPs), which are developed by national governments in consultation with civil society. The new framework permitted countries to reach decision and completion points faster. A country reaches a decision point and receives interim debt relief just after implementing key reforms (a 3-year track record of good performance is no longer required). If it maintains macroeconomic stability, carries out key structural, and social reforms, and implements satisfactorily a Poverty Reduction Strategy for one year, enhancing human security, it then reaches the completion point, at which time the full amount of debt relief committed at the decision point is irrevocably provided by its creditors.[15]

In 2006, following the 2005 Gleneagles summit of the G-8, the HIPC Initiative was supplemented by the *Multilateral Debt Relief Initiative* (MDRI) providing additional support to HIPCs to help them reach the United Nations *Millennium Development Goals* (MDGs). The MDRI allows for 100 per cent relief on eligible debts by the IDA, the IMF, and the African Development Fund, for countries completing the HIPC process. In 2007, the Inter-American Development Bank also decided to provide similar debt relief to the five HIPCs in the Western Hemisphere.

The debt relief provided to LICs during 1988–2008 has significantly lowered their debt burden. By July 2008, the overall debt relief provided under the HIPC Initiative and MDRI as well as traditional mechanisms, and additional relief from some other creditors to the 33 post-decision-point HIPCs, amounted to US$76 in end-2007 net present value terms. As a result, the debt stocks of these countries have been reduced by about 90 per cent. Most of this reduction (76 per cent) has been delivered in the context of the HIPC Initiative and the MDRI. (IDA/IMF 2008: 29). The debt relief received by countries currently considered as HIPC from the Paris Club creditors through agreements signed between 1988 and 1998 is estimated at US$30 billion in end-1997 NPV terms. Over

13 The term 'traditional debt relief mechanisms' refers to debt relief initiatives by the Paris Club previous to the HIPC Initiative. Traditional debt relief generally allowed for debt reduction of up to 67 per cent in net present value terms.

14 These thresholds were based on early work, by Cohen (1996), among others, who found that the likelihood of debt default climbed rapidly after a country's NPV of debt-to-export ratio climbed above the 200–250 per cent range.

15 See Boorman and Ahmed (1999) for a discussion of the contents of the HIPC Initiative.

the same period, most OECD countries cancelled their ODA loans and LICs were able to extinguish about US$5 billion of commercial external debt through DRF-supported operations (Gamarra/Pollock/Primo Braga 2008).

5.5 Empirical Evidence of the Debt/Growth Relationship

The empirical literature analysing the debt/growth relationship has focused on testing the 'debt overhang' hypothesis. Despite extensive studies on this issue, we still have only a partial understanding of fundamental questions, such as:

- Beyond what level does external debt impair economic performance?
- What is the quantitative effect of debt on economic growth for the typical developing country?
- Is the effect of debt on growth nonlinear – in other words, does the effect on growth of additional debt vary, depending on the level of the debt stock?
- What are the channels through which debt affects growth?
- What effect on growth can we expect from the debt reduction associated with the HIPC Initiative?

The vast majority of the literature on debt overhang was developed in response to the Latin American debt crisis of the 1980's, and thus must be interpreted with caution in assessing the debt/growth relationship in a low-income country context. The channels through which debt affects growth varies between low and middle-income countries, due to the differences in their access to international capital markets, the development of the private sector, the presence of basic infrastructure and their macroeconomic environment. In addition, the aid that donors provide to low-income countries could mitigate any negative effects debt service obligations might have on their economic activity.

The empirical evidence on the existence of the debt overhang hypothesis has been rather mixed. For example, Cohen (1993) using data for a sample of 81 less developed countries finds no evidence for the general existence of a debt overhang. Yet, for the Latin American countries he shows that high debt had a negative impact on their growth performance. In a similar vein, Greene and Villanueva (1991), Serven and Solimano (1993), Elbadawi, Ndulu, and Ndung'u (1997), Deshpande (1997) and Chowdhury (2001) find evidence in support of the debt overhang hypothesis in middle-income countries. In contrast, Warner (1992) concludes that the debt crisis in middle-income countries did not depress investment.

Similar inconclusiveness can be found in the empirical studies on low-income countries. Cohen (1997) explicitly states that for African countries high debt was not a major cause for the low levels of economic growth in the 1980's and 1990's. In a similar vein, Birdsall, Claessens and Diwan (2004) argue that debt overhang argument is not relevant to HIPCs as net transfers to most HIPCs are positive (averaging 12 per cent of gross domestic product in Africa) and consequently there is no fear of a 'debt tax' – unlike in Latin America in the 1980's when net transfers turned sharply negative. Consequently, in their view the HIPC Initiative does not provide positive incentives for better policies. Also Arslanalp and Blair Henry (2004) reject the debt overhang hypothesis in LICs on the ground of positive net resource transfers they face. The authors find that debt relief provided under the HIPC Initiative had little impact on either investment or growth, contrary to countries benefiting from debt relief under the Brady Plan. They argue that the key constraint to investment in HIPCs is not tax uncertainty but an absence of functional economic institutions that provide the foundation for a profitable private sector. Hepp (2005) has found no significant effect of debt relief on growth rates in HIPCs, but argues that non-HIPCs have benefited significantly from debt service relief in the 1990's (a one per cent increase in debt service relief leads to a 0.2 per cent increase in the GDP growth rates). Depetris Chauvin and Kraay (2005) found practically no evidence that debt relief has raised economic growth, investment rates or public spending in low-income countries.

In contrast, Fosu (1999), Cohen (2000), and Clements, Bhattacharya, and Quoc Nguyen (2005) find evidence for the debt overhang effect in HIPCs. Clements and his co-authors conclude that debt appears to affect growth via its effect on the efficiency of resource use, rather than through its depressing effect on private investment. Presbitero (2005) finds the negative relation between external debt and growth in LICs, but her findings suggest that external debt does not reduce the level of investment in physical capital (because the continuous mechanism of new concessional borrowing, debt relief and rescheduling reduces the implicit tax perceived by the investor), but works in terms of misallocation of capital, lack of structural

reforms, and subsequent lower efficiency. Cassimon and Van Compenhout (2007) found a positive effect of debt relief on overall investment spending in African HIPCs, using vector autoregressive techniques. Clements, Bhattacharya, and Quoc Nguyen (2005) suggest that debt relief has significant indirect effect on growth in LICs through higher public investment. Berthélemy (2004) argues that the HIPC Initiative does increase incentives to policy reform (i.e. the debt overhang effect exists) in countries with good economic governance but not in HIPCs with bad economic governance. In the latter group, debt relief will at best act as a multi-year programme of aid flows targeted to poverty reduction.

Few studies have been able to determine how large the stock of external debt has to be for the debt overhang to have an effect. Clements Bhattacharya, and Quoc Nguyen (2005), using data for 1970–1999 for 55 low income countries, found that external debt slows growth only after its net present value reaches a threshold level of 20–25 per cent of GDP or 100–105 per cent of exports. These findings imply that the projected decline in external debt for the countries participating in the HIPC Initiative would directly add 0.8–1.1 per cent to their per capita GDP growth rates. Pattillo, Poirson, and Ricci (2002), in their study of 93 developing countries between 1969 and 1998, found that external debt began to have a negative impact on growth when its net present value exceeded 160–170 per cent of exports and 35–40 per cent of GDP. High debt appears to reduce growth mainly by lowering the efficiency of investment rather than its volume. It should be noted that the target debt level in the HIPC Initiative (150 per cent of exports in NPV terms) remains close to the estimated threshold above which the impact of debt on growth is likely to be negative. In other words, the HIPC Initiative might reduce the level of indebtedness just to a level where a new increase in debt would have a negative impact on growth.

In a follow up study Pattillo, Poirson and Ricci (2004) estimated that halving the 2000 level of debt in the HIPCs is likely to increase the annual average growth rate by 0.5 to 1 per centage point. In the next study (Pattillo/Poirson/Ricci 2004a) the same authors applied a growth-accounting framework to a group of 61 developing countries over 1969–1998 and found that doubling their average external debt level reduces growth of both per capita physical capital and total factor productivity by almost 1 per centage point. In other words, large debt stocks negatively affect growth by dampening both physical capital accumulation and total factor productivity growth.

Relatively few empirical studies have tested the hypothesis of debt service effects on economic growth, and the available evidence is mixed. Elbadawi, Ndulu, and Ndung'u (1997), for example, find a statistically significant relationship between debt service (as a share of exports) and growth in Sub-Saharan Africa, while Fosu (1999) finds no such relationship for countries of that region. Using a broader set of countries, Pattillo, Poirson, and Ricci (2002) also find no statistically significant relationship between debt service and growth. However, Greene and Villanueva (1991) find that external debt service dampens private investment, while Serieux and Samy (2001) find a similar link between debt service and total investment. Hansen (2004) finds that debt service relief in HIPCs can boost economic growth provided that it is additional to other resource transfers. He estimated that 1.3 per centage points decline in the annual debt-service to GDP during 2001–2005, would increase the average annual growth rate of about 0.2 per centage points, if this reduction was additional. For a large sample of developing countries, including some HIPCs, Savvides (1992) finds that debt service crowds out public investment spending. The same effect was observed in low-income countries by Clements, Bhattacharya, and Quoc Nguyen (2005), who found that the crowing-out effect intensifies as the ratio of debt service to GDP rises. On average, every per centage point increase in debt service as a share of GDP reduces public investment by about 0.2 per centage point, implying that reducing debt service by about 6 per centage points of GDP would raise public investment by 0.75–1.0 per centage point of GDP, which in turn result in an increase of about 0.2 per centage points in growth. These findings suggest that one way for country authorities to raise growth and combat poverty would be to allocate a substantial share of debt relief to public investment.

Also Presbitero (2005) finds a very strong crowding out effect of total investment in low-income countries, while there is no evidence of liquidity constraints in middle-income countries. On average, a one per cent increase in the debt service to GDP ratio reduces the total investment rate by almost 0.4 per centage point in low income countries. Presbitero also notices a very high sensitivity on investment to economic policies, but only in LICs, where a one point upward shift in the *Country Policy and Institutional Assessment* (CPIA)[16] add about 2 per centage points to the investment rate. In middle-income coun-

tries, the institutional indicator is not significant, suggesting that, probably, over a certain threshold, institutions and policies are no more likely to boost investment. This result underlines the relevance that should be given to economic and structural reforms in the poorest countries, in order to grant a minimum level of economic management to trigger investment and economic growth.

Very few studies have empirically analysed the relationship between the uncertainty of debt service payments and economic growth. Oks and Van Wijnbergen (1995) find that instability of debt service payments did matter for Mexico in 1988–1990. In particular, they show that the Brady initiative led to a smoothening of external resource transfers, which reduced the uncertainty about future exchange rate crises. This, they argue, stimulated private investment, which contributed to regaining growth in Mexico in the early 1990's. Dijkstra and Hermes (2001) find supportive evidence for the relationship between the uncertainty of debt service payments and economic performance for HIPCs. They conclude that debt relief may contribute to regaining growth by reducing uncertainty with respect to the debt service payments, which in turn may increase the effectiveness of government policies and consequently provide the private sector with positive signals about the future profitability of their investment.

In sum, the existing empirical literature provides diverging conclusions on the debt/growth relationship. The reasons for that might be different samples in terms of countries and time span, as well as different operationalizations of variables. There is limited evidence on how the stock of external debt and debt service affect growth, particularly in low-income countries. There is scope for additional work to clarify the size of these effects, especially for low-income countries that are benefiting from debt relief. Furthermore, more work is needed to explore the channels through which debt affects growth.

5.6 Growth and Poverty Effects of the HIPC Initiative

This section seeks to answer the question whether debt relief granted to low-income countries under the HIPC Initiative has positive effects on their growth performance and poverty reduction. The Enhanced HIPC Initiative has three objectives:

- to help countries achieve debt sustainability by reducing the excessive debt burden and providing a permanent exit from debt rescheduling;
- to promote growth by removing the debt overhang;
- to reduce poverty by freeing up resources for higher social spending.

By end of July 2008, 33 out of 41 HIPCs had passed the decision point and qualified for the HIPC Initiative assistance. Of those, 23 countries reached the completion point and qualified for irrevocable debt relief under the HIPC Initiative and the MDRI. The debt relief committed to the 33 post-decision-point HIPCs amounts to US$76.5 billion (in end-2007 net present value terms), including US$25.4 billion under the MDRI (table 5.1). On average this debt relief represents about 50 per cent of these countries' 2007 GDP. The debt relief accorded to 10 decision-point countries will not become irrevocable until they pass the completion point. A further 8 countries, referred to as pre-decision-point countries, are potentially eligible for the HIPC Initiative debt relief (having met the income and indebtedness criteria), pending the agreement of macroeconomic reforms, poverty reduction strategies, and/or arrears clearance plans[17]. The main obstacles to the other eight countries' progress under the Initiative are of a political or security nature. Many of them have been beset by civil wars and cross-border armed conflicts. Thus a kind of vicious circle emerges. Security cannot be improved without debt reduction, which, in turn, cannot be implemented without ameliorating security conditions. Looking from that point of view it may be worthwhile to reconsider the debt relief programmes as to make them less prone to the impact of that bootstrap effects.

16 CPIA, developed by the World Bank, assesses the quality of a country's policy and institutions in the sense of creating a good environment for sustainable growth and poverty reduction (World Bank 2007).

17 Completion-point countries include: Benin, Bolivia, Burkina Faso, Cameroon, Ethiopia, the Gambia, Ghana, Guyana, Honduras, Madagascar, Malawi, Mali, Mauritania, Mozambique, Nicaragua, Niger, Rwanda, Sao Tome and Principe, Senegal, Sierra Leone, Tanzania, Uganda, and Zambia. Decision-point countries include: Afghanistan, Burundi, Central African Republic, Chad, the Democratic Republic of the Congo, Liberia, the Republic of Congo, Guinea, Guinea-Bissau, and Haiti. Pre-decision-point countries include: Comoros, Côte d'Ivoire, Eritrea, the Kyrgyz Republic, Nepal, Somalia, Sudan, and Togo.

Table 5.1: HIPC and MDRI: Estimates of Debt Relief (end of 2007 NPV terms, in billions of US$). **Source:** World Bank: *HIPC-At-A-Glance-Guide* (Fall 2008); at: <http://siteresources.worldbank.org/INTDEBTDEPT/Resources/Debt_PocketBroch_Fall08.pdf> (3 of 6).

	HIPC	MDRI	HIPC and MDRI
All HIPCs	71.2	28.1	99.3
23 Post-Completion-Point HIPCs	34.9	22.6	57.5
10 Interim HIPCs	16.1	2.8	19.0
8 Pre-Decision-Point HIPCs	20.1	2.7	22.8

Table 5.2: Debt Indicators of 33 Post-Decision-Point-HIPCs in 1999 and 2007 (in per cent). **Source**: World Bank 2008: *HIPC-At-A-Glance-Guide* (Fall 2008); at: <http://siteresources.world-bank.org/INTDEBTDEPT/Resources/Debt_Pocket Broch_Fall08.pdf>: (4 of 6).

	1999	2007
NPV of debt-to-exports	440	128
NPV of debt-to-GDP	102	31
Debt service-to-exports	19	7
NPV of debt-to-revenue	556	171
Debt service-to-revenue	22	8

As a result of debt reduction, the debt burden of the 33 HIPCs is expected to be reduced on average by about 90 per cent in end of 2007 NPV terms compared to their pre-decision-point debt stock. Debt stocks in the 10 interim HIPCs are expected to decline by a similar factor (World Bank 2008; IDA/IMF 2008: 29). Also in relative terms the debt burdens of the 33 HIPCs have substantially declined (table 5.2). At the end of 2007, the NPV of the debt-to-export-ratio averaged 128 per cent (below the Initiative's target: 150 per cent) in contrast to 440 per cent in 1999. During the same period the NPV of debt-to-GDP ratio declined from 102 per cent to 31 per cent on average. Both ratios reached the levels that are broadly consistent with the estimated thresholds at which debt overhang should be eliminated (Clements/Bhattacharya/Quoc Nguyen 2005; Patillo/Poirson/Ricci 2002).[18] Other debt indicators also improved. The NPV of the debt-to-revenue-ratio declined from 556 per cent to 171 per cent on average (well below the Initiative's target of 250 per cent of revenues). Debt service-to-exports and debt service-to-revenue dropped almost three times at that time.

Despite the significant decline of debt burdens due to this debt relief, long-term debt sustainability of many HIPCs remains a concern even for the 23 post-completion-point countries according to the most recent *debt sustainability analyses* (DSAs) performed jointly by the World Bank and the IMF (World Bank/IMF 2008). As of end of June 2008 post-completion-point HIPCs are in a better debt situation than other HIPCs (at end of 2007, the NPV of the debt-to-export ratio for post-completion-point HIPCs averaged 63 per cent whilst for pre-completion-point HIPCs 200 per cent), and also other low-income non-HIPCs. But only about 40 per cent of them (nine countries) have been assessed as having a low risk of debt distress. More importantly, reflecting structural weaknesses in their economies or weak macroeconomic management, four of these countries have been assessed as having a high risk of debt distress. In addition, the analyses show that the debt outlook in post-completion-point countries is very sensitive to export shocks and the terms of new financing.

These results highlight the need for implementing sound borrowing policies and strengthening the countries' capacity in public debt management. Meeting the MDGs by the target date of 2015 will require substantial financial flows to developing countries. These resources need to be provided on sufficiently concessional terms to avoid a renewed risk of debt distress. Finally, a country's debt sustainability depends also on implementing growth-enhancing policies that would boost its repayment capacity. This is particularly relevant for post-completion-point HIPCs given their increased attractiveness for private and non-traditional official creditors. Thus, it is critical for LICs to reflect upon the middle income countries' experience regarding the links between debt sustainability and growth (IDA/IMF 2008: 30–34).

A second objective of the HIPC Initiative it to stimulate economic growth by removing the debt overhang. This is important for two reasons. First, the growth rates of HIPCs have been extremely low, and as a result, the tax base has stagnated or declined in many cases, and low or declining public revenues have contributed to the under-funding of development spending, including pro-poor spending. Second, growth can reduce income poverty by enhancing the living standard of the poor, although its effectiveness in doing so depends on complementary action to enhance the human capital and productive assets of the

18 For details see above.

poor which are key determinants of their participation in growth.

Removing the debt overhang is a necessary but not a sufficient condition for achieving sustainable growth, reduce poverty, and as a consequence, to improve human security conditions. To encourage countries to implement significant economic and social reforms, the HIPC Initiative provides debt relief only after a country has developed a track record of a satisfactory reform programme. Then the benefits from debt relief may be felt in longer term institutional development and growth. The World Bank's *Country Policy and Institutional Assessment* (CPIA) is used to assess a country's policy and institutional performance. Post-completion point countries have the best policies as compared to both interim and non-HIPC countries, and have seen significant improvements in their policy performance over the past few years as measured by their aggregate CPIA score (IEG 2006a: 25–27). That progress is consistent with the requirement that they implement a satisfactory programme of reform.

Answering the question of whether debt relief boosts growth is very difficult by the fact that growth is effected by many factors. Looking at growth over time of those countries receiving debt relief does not give an accurate portrayal. Table 5.3 shows average real growth rates from a sample of decision-point HIPCs, pre-decision point HIPCs, other low-income countries and middle-income countries. Growth in all groups of countries has risen recently. Real GDP growth in decision-point HIPCs averaged 4.6 per cent over the period 2000–2005, up considerably from an average rate of 2.6 per cent in the 1990's and just 1.8 per cent in the 1980's. Moreover, the average increase in real GDP growth in decision-point countries over the periods 1990–1999 versus 2000–2005 (1.9 percentage points) was the same as in 'other low-income countries' (countries that currently are not eligible for the HIPC Initiative) and in middle-income countries. Furthermore, the increase in growth also reflects the fact that HIPCs are required to establish a track record of macroeconomic stability in order to reach the decision point. In the pre-decision HIPCs real GDP growth increased by only half of a percentage point during this period. It is still too early to tell whether and to what extent higher growth is a result of the debt-stock reduction.

A third goal of the HIPC Initiative is to reduce poverty, by freeing up resources for *poverty-reducing expenditures* (PRE). In general, debt relief could contribute to higher PRE in two ways. First, debt relief

Table 5.3: Average Real GDP Growth Rates in Low Income Countries, 1980–2005 (in per cent). **Source:** World Bank (2006a: 97).

	1980-1989	1990-1999	2000-2005
27 Decision-point HIPCs	1.8	2.6	4.6
11 Pre-decision point HIPCs	2.6	1.7	2.2
19 Other low income countries	4.7	2.7	4.6
77 Middle income countries	3.5	2.8	4.8

creates fiscal space that may be used for PRE. The Initiative has encouraged countries to increase their social expenditures by requiring to develop and implement a country-owned poverty-reduction strategy that specifies exactly how resources that are released by the Initiative are to be used, and by tracking public expenditures deemed to be 'poverty reducing'. Largely as a result of the Initiative, an increasing number of HIPCs are now reporting poverty-reducing spending: in 2005, 19 countries reported such spending, compared with only four in 2002 (IEG 2006: 30). Debt service relief should positively affect the growth rate: directly by increasing public investment activity, and indirectly by increasing human capital (at least in the long term). Second, a reduction in the debt stock eases the government's intertemporal budget constraints, and may facilitates borrowing to raise PRE. The first effect would be limited if debt relief is provided in the form of arrears clearance, which would not reduce debt service due. The second channel may not work in countries which are still credit constrained, like HIPCs in the interim period.

If debt relief is to increase fiscal space for poverty-reducing expenditures it must be additional to other resource transfers. The goal of additionality was explicitly incorporated in the Enhanced HIPC Initiative in 1999. *Additionality* means that debt relief should supplement, not replace, the flow of development aid to the poorest countries. Hansen (2004) stresses that additionality of debt relief resources is necessary for debt relief to have positive impact on economic growth. By joint analysis of aid flows and debt service payments, Hansen concludes that non-additional debt relief will in all likelihood not lead to increased growth rates in the HIPCs. He also finds that if decreases in debt service payments are accompanied by falling grant levels, there may even be a negative impact on growth.

Assessing additionality of HIPC debt relief is extremely difficult. One way to do that is to look at changes in net development aid to eligible countries

Table 5.4: Debt Service and Poverty Reducing Expenditure in 33 Post-Decision-Point HIPCs, 1999-2007 (in millions of U.S. dollars, unless otherwise indicated). **Source** IDA/IMF (2008: 65).

a) Excludes CAR, Haiti, and Liberia for which data are not available.

in response to debt relief. Debt relief is *additional* if it leads to additional resources made available to the *individual* debtor receiving debt relief. The empirical studies on debt relief additionality have brought about mixed results. For instance, Birdsall and Williamson (2002) show that from 1990 to 1999, as debt relief programmes intensified, total ODA declined. Birdsall, Claessens, and Diwan (2004) find that debt reduction in the 1990's crowded out other forms of disbursements. However, Powell (2003), looking at data for 60 'IDA-only' countries from 1996 to 2000, finds that neither the level of official development assistance nor official net transfers received is affected by debt relief provided by official and multilateral creditors. Hence, there seems to be additionality (in the sense the term is used here). Also Hepp (2005a), focusing on 66 low income countries (fourty of them are classified as HIPC) over the period 1989 to 2002, finds that debt relief did not affect aid inflows significantly for low-income countries, neither positively nor negatively. Hence, debt relief provides additional resources since donors did not cut aid flows by the amount of debt relief provided.

The additionality of the HIPC Initiative was also found by the *Independent Evaluation Group* (IEG) of the World Bank (IEG 2006: 9–10). In its 2006 evaluation report, the IEG stated that debt relief has been significantly additional to other net resource transfers since 2000. Net annual transfers to the 28 decision-point HIPCs have doubled from $7.3 billion in 2000 to $15.8 billion in 2004, while transfers to other developing countries grew by only one third. As a result HIPCs' share of net transfers to all developing countries has increased substantially. On average, the 28 decision-point HIPCs received 47 per cent of transfers to all developing countries since 1999, compared with 33 per cent from 1990 to 1999. Commensurately, the share of non-HIPC developing countries declined from 60 per cent between 1990 and 1999 to 48 per cent, on average, since 1999. The increased share of resources to HIPCs suggests that debt relief has become a significant vehicle of resource transfer to this set of countries.

The effect of debt relief on poverty-reducing expenditures has been difficult to establish empirically, given data limitations and the multiplicity of channels at play. Empirical work has instead focused on the link between debt relief and poverty reducing expenditures, which is easier to measure than social outcomes. For HIPCs, there appears to be a strong positive correlation between the reduction in debt service and the increase in poverty-reducing spending. As a result of the HIPC initiative the average debt-service payment relative to GDP for 33 post-decision-point countries has declined by about 2 per cent - falling from 3.9 per cent of GDP in 1999 to 1.5 per cent of GDP in 2007 (table 5.4). At the same time poverty-reducing expenditures (in areas including health, rural infrastructure, and education) have been increased by about the same amount – rising from 7 per cent of GDP to 8.8 per cent of GDP. In relation to government revenue poverty-reducing expenditures have risen on average from 34.7 to 47.2 per cent of GDP. In nominal terms, total poverty-reducing expenditures amounted to about US$21 billion in 2007, which represents an increase of almost US$15 billion since 1999 (IDA/IMF 2008: 65).

5.7 Impact of the Current Global Crisis on the LICs

The global financial crisis that grew into an economic crisis, now risks becoming a human and social crisis with political implications. In many instances, already dire human security conditions will likely deteriorate in the poorest countries, and probably not only there. Developing countries will be hit by global recession and declining world trade. The poor countries are particularly vulnerable as they have much less cushion

to withstand the events. They will be affected through reductions in export volumes, commodity prices, remittances, tourism, foreign direct investment, and possibly even foreign aid. These shocks in turn will hurt public revenues, adding to the sizable negative fiscal impact of the food and fuel crises, and putting further pressure on public expenditure programmes (World Bank 2009: 2–21).

The impact of the global financial crisis on developing countries is reflected in sharp reductions in their projected GDP growth. For developing countries as a whole, growth is now projected to fall to 1.6 per cent in 2009, from an average of 8.1 per cent in 2006–07. Growth in Sub-Saharan Africa is projected to slow to 1.7 per cent in 2009, from 6.7 per cent in 2006–07. The sharp slowdown in growth can seriously set back progress on poverty reduction and other Millennium Development Goals.

Strong economic growth in developing countries in the past decade had put the MDG for poverty reduction (halving the proportion of the extreme poor in the population between 1990 and 2015) within reach at the global level. But the triple jeopardy of the food, fuel, and financial crises adds new challenges. The rise in food prices between 2005 and 2008 pushed an estimated 160 million to 200 million more people into extreme poverty. The growth slowdown resulting from the financial crisis will add to the poverty impact of high food prices. Past trends show that a decline in the average GDP growth rate in developing countries by one percentage point can trap as many as 20 million more people in poverty. Estimates of the poverty impact of the growth slowdown in developing countries as a result of the financial crisis range from 55 million to 90 million more poor people in 2009 than anticipated before the crisis. At current growth projections, overall poverty rates in the developing world are still expected to fall in 2009 but at a much slower pace than before the crisis.

The impact of the crisis upon poverty, or put in other words, on human security, and other security sectors as well, will vary across regions and countries. In Sub-Saharan Africa and South Asia (except India), the growth slowdown essentially eliminates the prospect of continued reductions in the poverty count in 2009. Within these regions, which already have high poverty rates, rising poverty can be expected in some of the more fragile and low-growth economies, which may experience declines in the per capita incomes as a result of the growth slowdown.

Progress in reducing hunger and malnutrition, i.e. improvement of food security, has also been affected. Although the proportion of people who suffer from hunger has fallen since 1990, there are serious shortfalls in achieving the goal of halving the incidence of hunger and malnutrition. The recent food crisis is eroding some of the hard-won past gains in fighting hunger and malnutrition. High prices have increased the number of people without sufficient access to food. Before the onset of the food crisis in 2007, there were about 850 million chronically hungry people in the developing world. This number rose to 960 million people in 2008 and is expected to climb past 1 billion in 2009. The financial crisis and the resulting fall in economic growth are likely to exacerbate this impact.

Of greatest concern are the overall human security and development goals. With the world already off track on most of these goals, the financial crisis threatens to further set back progress. In the face of the economic crises, both household and public investments in human capital tend to suffer. With falling employment, wages, and asset values, and with weak social insurance systems, poor households in developing countries may not be able to cope with the economic shocks without cutting investments in human capital. Faced with declining revenues and limited financing options, government social sector spending is also likely to come under pressure. Experience suggests that growth collapses from financial crises are costly for human development outcomes. Countries that suffered economic contractions of 10 per cent or more between 1980 and 2004 experienced more than 1 million additional infant deaths. Human security and development outcomes tend to deteriorate more quickly during growth decelerations than they improve during growth accelerations. The projected slowdown in growth in developing countries is likely to sharply slow progress in reducing infant mortality. Based on current projections of lower growth, preliminary analysis shows that infant deaths in developing countries may be 200,000 to 400,000 per year higher on average between 2009 and the MDG target year of 2015 than they would have been in the absence of the crisis; that translates into an additional 1.4 million to 2.8 million infant deaths during the period. In poor developing countries, education outcomes such as school enrolment also tend to deteriorate during economic crises. Evidence indicates that fluctuations in income have a larger impact on survival and school enrolment among girls than among boys.

The long-run implications of the crisis for human development/human security outcomes may be more severe than those observed in the short run. When

poor households withdraw their children from school, there is a significant risk that they will not return once the crisis is over or that they will be unable to fill the learning gaps resulting from the lack of attendance. And the decline in nutritional and health status among children who suffer from reduced (or lower-quality) food consumption can be irreversible, retarding their growth and cognitive and learning abilities.

Even though the global economic crisis will slow progress, the target for reducing income poverty remains within reach at the global level based on current growth projections, which envisage a recovery in growth starting in 2010. The goals for gender parity in primary and secondary education and for access to safe water have also seen relatively good progress and are expected to be met at the global level by 2015, although prospects for gender parity in tertiary education and other targets about empowerment of women are less promising. Of greatest concern are the no income human development goals. Based on current trends, most human development MDGs – especially for child and maternal mortality, but also for primary school completion, nutrition, and sanitation – are unlikely to be met at the global level.

Within this global picture, considerable variation occurs across regions and countries. At the regional level, Sub-Saharan Africa lags on all MDGs, including the goal for poverty education, which on current trends will be achieved or nearly achieved in all other regions. Thanks to rapid growth, especially in China, the East Asia region has already succeeded in halving extreme poverty. South Asia is on track to achieve the poverty reduction goal, but it is seriously off track on most human development goals. On the goals relating to health, most regions are off track, though the rate of progress varies substantially across regions, with East Asia, Europe and Central Asia, and Latin America in general doing better than the other regions.

Middle-income countries have made the most rapid progress toward the MDGs. These countries as a group are on track to achieve the target for poverty reduction. Many of these countries, however, continue to have large concentrations of poverty, in part reflecting high levels of income inequality. This factor, together with the large population size of some middle-income countries, means that these countries remain home to a majority of the world's poor in absolute numbers. Many of these countries also continue to face major challenges in achieving the no income human development goals.

Overall progress toward the MDGs has been weaker in low-income countries, although here too performance varies considerably across countries within the group. Progress toward the MDGs has been slowest in fragile and conflict-affected states. Wracked by conflict and hampered by weak capacities, these states – more than half of which are in Sub-Saharan Africa – present difficult political and governance contexts for effective delivery of development finance and services. Fragile states account for close to one fifth of the population of low-income countries but more than one third of their poor people. Looking ahead, the challenge to achieve the MDGs will increasingly be concentrated in low-income countries, especially fragile states.

The deepening human and development crisis in poor countries leading in some cases to extreme security threats, e.g. in the Sudan, calls for urgent actions of the international community to assist these countries to lay the ground for a recovery of strong growth and accelerated progress toward the MDGs. Additional development assistance is essential to lessen the impact of the global crisis on these countries. At the recently concluded London summit of the *Group of Twenty* (G-20), held on 2 April 2009, donors reiterated their commitment to meeting ODA pledges made at Gleneagles.[19] The prospects of reaching the Gleneagles targets remain uncertain as some donors may cut their aid budgets. Indeed, there is a risk that aid flows could decline (World Bank 2009: 113–134).

5.8 Conclusions

The main aim of the chapter was to enhance the understanding of the economics of debt relief in low-income countries, and to evaluate the *Heavily Indebted Poor Countries* (HIPC) Initiative's potential for accelerating growth and reducing poverty. In addition, a preliminary survey of the links between debt relief and economic security of individuals and of human security in poor countries has been developed.

The main conclusions of this chapter are:

19 At the Gleneagles G-8 meeting donors promised, with other donors, to double their aid to Africa by 2010 – an increase of $25 billion a year compared to 2004 amounts – and to increase overall aid by $50 billion a year by 2010. However, in real terms, aid in 2008 was US$29 billon short of the Gleneagles target of the US$130 billion per year by 2010. Aid do Africa was about US$20 billion short of the 2010 target of US$50 billion per year.

1. The HIPC Initiative combined with the *Multilateral Debt Relief Initiative* (MDRI) has substantially lowered the debt burdens of poor countries. However, the evidence on post-HIPC debt sustainability is not encouraging. Debt relief itself cannot guarantee to maintain debt sustainability, which in the long run will depend on prudential borrowing policies, strengthening public debt management, lowering the structural weaknesses and high sensitivity to export shocks as well as implementing growth-enhancing policies to boost the repayment capacity.
2. The empirical work on the growth effect of debt relief in heavily indebted low-income countries is mostly positive. Although the predicted impact is rather small (a growth increase between 0.2–1.1 percentage points), the cumulative effect should not be neglected. The HIPC Initiative has created a potential for accelerating economic growth and reducing poverty in HIPCs, but in order to realize its potential HIPCs must sufficiently reduce macroeconomic and structural distortions, as well as high economic and political risks that might otherwise constrain growth. Moreover, debt relief must be additional to existing aid flows, not a substitute for aid, in order to have a positive impact on growth and poverty reduction. The evidence suggests that debt relief provided under the HIPC Initiative after 2000 has been significantly additional to other net resource transfers, which means that debt relief has brought more resource for poverty reduction. But serious questions remain. *First*, whether poor countries, with still weak institutions, will be able to effectively use the resources freed up by debt relief for the benefit of the poor. Much depends on the quality of the fiscal system (not only public expenditure management but also the ability of revenue institutions to mobilize the necessary additional domestic resources through taxation). Extensive analytical work is needed to assess the distribution of public spending and the changes in their composition induced by the HIPC Initiative, as well as to track the additional resources to their final destination. *Second*, if the HIPC Initiative raises growth, it should reduce income poverty, but it is not clear whether the growth reaches the poorest regions. An analysis must be undertaken to determine the poverty impact of growth, and whether the PRSP has been effective in raising a country's poverty elasticity of growth.
3. For accomplishing the broader objectives of growth, sustainable development, and poverty reduction, debt relief is a limited tool, in several ways. *First*, the resources that can be generated from debt relief are limited by the existing stock of debt. The potential gains from debt relief are modest compared with those from trade liberalization and increased access to markets. *Second*, the benefits of debt relief can quickly be erased if relief is not accompanied by sustained improvement in policies and a prudent new strategy for future borrowing. The history of debt relief is filled with countries that failed to reform their policies and began once again to build up debt after having their debts forgiven. *Third*, if donors provide debt relief by reallocating resources already earmarked for aid (as it was a case before 2000), the recipient countries will see no net increase in resources. In the future a necessary condition should be that the donor community increase its overall aid resources, and not reduce other aid flows to finance the debt relief.
4. The current global financial crisis resulting in the sharp slowdown in growth in low-income countries, can seriously set back progress that has been achieved in all areas which determine overall security and human security, i.e. economic growth, debt sustainability, and poverty reduction. Without increasing foreign aid many HIPCs will not be able to maintain debt sustainability nor achieve the MDGs by 2015.
5. High level of indebtedness of low-income countries should be viewed as a source of security threats in all sectors in those countries. It concerns especially economic security at the grassroot level and has a direct impact on human security. Therefore in any-security oriented discourse debt relief should be treated as a part of an improvement of human security. Due to the fact that in too many instances the discourse on human security is hampered by too general considerations, the example of economic and financial analysis of the impact of debt relief on the situation of the poor countries should be treated as an introduction to more rigorous economic security and human security-oriented research.

Further research on growth and poverty effects of debt relief and its links with a broadly defined security should consider the following issues:

1. The channels through which debt relief affects key development variables.

2. The poverty impact of growth and the poverty reduction elasticity of growth.
3. The distribution of public spending and the changes in their composition induced by the HIPC Initiative.
4. Elaboration of a policy-oriented theoretical framework of studies on how the debt of low-income countries influences their security in all sectors with a special attention given to economic security at the grassroots level and subsequently, to human security. In such a case, detailed economic and financial analyses of the debt reduction policy of the poor countries and of its effectiveness, may become a methodological instrument of security studies.
5. Since the debt usually affects the poorest countries, which in turn, are also affected by multiple other threats, beginning from environmental insecurity and ending with a lack of gender security, it may be worthwhile to put these studies into a broader framework of research on the Anthropocene, on HUGE (Human, Gender and Environmental Security) and HESP (Human and Environmental Security and Peace) as was suggested by Oswald Spring, Brauch and Dalby (2009).

6 Security Threats, Challenges, Vulnerabilities and Risks in the Evolution and Implementation of the European Security Strategy

Alyson J.K. Bailes

6.1 Introduction

On 12 December 2003, the heads of state and government of European Union (EU) member states attending the European Council meeting at Brussels adopted the EU's first ever European Security Strategy (ESS) – a 14-page paper with the title "A Secure Europe in a Better World".[1] The document had taken just seven months to produce since May 2003, when EU foreign ministers meeting at Kastellorizo on Rhodes asked the Union's High Representative for CFSP, Javier Solana, to produce a first draft. The version emerging from his staff was welcomed by the Thessaloniki European Council on 20 June, and was subjected to debate both at public seminars and among member states (through the Political and Security Committee[2] at Brussels) before a somewhat adapted version got the final seal of approval in December.

If the nature of the document and also the process of creating it were novel, the circumstances behind its emergence were also special and in some ways unprecedented. In early May 2003 the wounds were still raw from one of the worst political crises in EU history. The rift that had been widening since mid-2002 between EU member states who were sympathetic to, or opposed to, the USA's tough stand on Iraq became an open break when the UK, Italy, Spain and others accompanied the US invasion of that country in March 2003. France and Germany not only condemned the action but adopted a common stance against it with the Russian Federation – until recently, Western Europe's arch-enemy. Almost as the first shots were being fired in Iraq, however – on the morning of 17 March, 2003 – a special "seminar" session of the Political and Security Committee was held to launch work on an EU strategy for the specific issue of proliferation of Weapons of Mass Destruction (WMD)[3], implicitly seeking a way of tackling further challenges in that field that would be both less divisive and less costly for the Europeans than Iraq had already revealed itself to be. By the time the Foreign Ministers at Kastellorizo requested a more comprehensive draft strategy from Solana, there was an even clearer recognition throughout the enlarging Europe[4] that the EU nations must demonstrate, both to themselves and the world, their determination to retrieve their unity for external action on a firm conceptual as well as operational basis.

This background is essential to bear in mind when judging the ESS as a whole and, more specifically, the way it deals with risks, challenges and threats to European security. The select group of Solana's advisers who first drafted it were more than familiar with the intellectual and policy trends that had been transforming the whole notion of "security" for the Western democratic community since 1989/90. Robert Cooper, one of the most influential drafters, had himself written more than one classic work[5] on the way that nations' grip of security processes was being challenged by the growing power both of supranational

1 European Council, 12 December 2003, "A Secure Europe in a Better World", text at URL http://www.consilium.europa.eu/cms3_fo/showPage.ASP?id=266&lang=EN&mode=g, 25 September 2007.

2 The PSC was created in 2000 as part of the new structures of the *European Security and Defence Policy* (ESDP), and consists of Ambassador-level representatives from all member states.

3 Interim documents on this subject were adopted in June and the complete WMD strategy at the 12 Dec. 2003 European Council: see the latter text at <www.consilium.europa.eu/uedocs/cmsUpload/st15708.en03.pdf>, 25 September 2007.

4 The ten Central European and Mediterranean nations to join the EU in Spring 2004 had already been selected by 2003: they were invited to join in the process of finalizing the ESS, and to associate themselves with it.

5 See especially Cooper (2003).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_6, © Springer-Verlag Berlin Heidelberg 2011

organizations and of sub-state, non-state and transnational actors ranging from terrorists to multinational corporations and non-governmental activists. The whole story of the EU's gradual emergence as a security power underlined that traditional, military defence was no longer the sole or even the determinant field for international power-play: the fortunes of developed nations and their peoples would now also be decisively affected by success in handling internal security challenges, "functional" security (energy, environment, infrastructure etc), and challenges to "human security" including low-level violence and disorder, disease, natural disasters, economic and social malfunction and denial of basic rights.[6] In the military operational sphere, the various phases of the Western Balkan wars since the early 1990s – as well as a series of non-European conflicts that called for European action often because of post-colonial ties – had kept Europe's defence planners tightly focussed on the demands of voluntary crisis management operations, and were also deepening understanding of the need to combine military with political, economic and other civilian tools of intervention. (This was also, of course, the field in which EU leaders decided at the Helsinki European Council of December 1999 to give the Union a collective military role in the shape of the new European Security and Defence Policy (ESDP).[7]) Last but not least, the great gain in relative safety for "core Europe" following the collapse of the Soviet empire had not only allowed the EU and NATO to extend their respective security communities to practically the whole European continent through enlargement, but had raised the relative priority of extra-European concerns and of fully global security issues for both institutions. By 2003 the EU had not only adopted two successive Russia strategies, but also its first China strategy.[8]

All this said, however, the primary explanations of the ground covered by the ESS and of its language, priorities and recommendations should not be looked for in the general evolution of European (official or academic) security thinking, and still less in the objective balance of European security conditions between May and December 2003. The Iraq conflict was the midwife of this particular brainchild and, for the ESS's drafters, Iraq stood as the ultimate manifestation of a security analysis and strategic response developed by the *United States* after the massive terrorist attacks it suffered on 11 September 2001. The resultant US strategy focussed on "new", "asymmetric"[9] threats from the worldwide forces of terrorism and the risks of WMD diffusion and misuse, and it called for robust – even "pre-emptive"[10] – responses making use notably of the USA's unique superiority in military force. Some European countries (most obviously, but not only, the UK) found that this ruthless, geographically unlimited reaction against unconventional enemies chimed with elements in their own security traditions and national interests. For many others, the very idea of using such force against non-state opponents and of using conflict as a conscious tool of change – especially in the name of "democracy" as defined by the current US Administration – was ethically as well as intellectually suspect. Washington's new strategic vocabulary thus became also the language of an internal European rift; and the main preoccupation of European drafters as they started work on the ESS was how to

6 A study on a "human security" doctrine for Europe was commissioned by Solana in 2003 and finally published in September 2004 as "A Human Security Doctrine for Europe: the Barcelona report of the study group on Europe's security capabilities¨ (text at <http://www.lse.ac.uk/Depts/global/Publications/HumanSecurityDoctrine.pdf>, 24 September 2007). This document's focus is, however, on EU intervention missions rather than on global problem analysis or the overall impact of EU policies; its key recommendation is for a standing EU civil-military force.

7 For the founding documents of ESDP see the Presidency Conclusions of the Helsinki European Council, 10–11 Dec. 1999, Part II and Annex IV, URL http://ue.eu.int/ueDocs/cms_Data/docs/pressData/en/ec/ACFA4C.htm, 25 September 2007.

8 EU strategy towards China, presented by the European Commission as COM(2001) 26 Final of 15 May 2001 and repeatedly updated, most recently in 2007 (all references available online at http://ec.europa.int/external_rekations/china/intro/index.htm, 25 September 2007). The "strategy" as a type of EU policy document was formally introduced in the 1997 Treaty of Amsterdam, but the Council had adopted "strategies" on Central European accession, Russia, and the Baltic Sea before that date and adopted three more before 2003 (Russia again in 1999, Ukraine 1999, Mediterranean region 2000). The Amsterdam provisions placed the process for generating strategies clearly in the Council domain whereas the Commission had previously drafted most such documents (and continued to do so after 1997, but with different titles).

9 An asymmetric threat was defined in this context as one involving major or existential damage by a smaller and weaker actor against a powerful one.

10 The case for pre-emption of imminent major threats was set out in *The National Security Strategy of the United States of America* published on 17 Sep.2002; see at: <http://www.whitehouse.gov/nsc/nss.pdf>, 25 September 2007.

absorb what should and must be absorbed from the US analysis while moderating and transmuting it into something all Europeans could recognize as their own. To put it another way, they were not writing on an empty sheet but seeking to deconstruct and then re-compose an existing body of strategic analysis, for which the most obvious source was the USA's own National Security Strategy (NSS) of September 2002.

While most of the ESS's eventual features can be explained by this single thesis, there were other reasons, too, why it would have been unrealistic to look to such a document in 2003 for a reasoned *tous azimuths* threat analysis and situation assessment of the sort familiar from national (and NATO) military documents. Not only were the drafters themselves civilians, but the EU had in 2003 no real organ of risk assessment, no experience of evaluating "harder" military threats, and only the most rudimentary intelligence exchanges.[11] The best European capacities of those kinds were still lodged in NATO, and a deep reluctance among many EU members to stray into NATO's analytical or policy territory will have played a large part, even if only unconsciously, in determining the conceptual space that the ESS eventually occupied.

With these explanations as a starting point, the present chapter will start by surveying the treatment of risks, challenges, threats and vulnerabilities in the ESS document of December 2003 and seeking to relate both the process and vocabulary used, and the document's substantive judgements, to the particular circumstances of its creation (6.2). The following section will outline relevant developments in the first three years following the adoption of the ESS (i.e., up to late 2006/early 2007), asking what new internal and external factors modified or should have modified the EU vision of security challenges over that period (6.3). There follows a necessarily brief discussion of how far the process of follow-up to the ESS as such was helpful to the EU in tackling both the original, and the newer, revised, threat constellations (6.4). The concluding section addresses the relevance of the ESS to handling Europe's further strategic challenges from 2007 onwards, in the light inter alia of the EU's own formal review process carried out in 2008 (6.5).

6.2 The ESS as a Risk- or Challenge-based Document[12]

Given the points made above about the EU's limited capacities for threat or risk assessment, it may seem surprising to note that as many as 5 of the ESS's 14 pages (in the final version) are devoted to problem analysis. The USA's National Security Strategy (NSS) of September 2002 (White House 2002) – the document against which the ESS was in many ways matching itself – launches straight into a statement of the Administration's intent with little initial scene-setting. However, the US connection is the key to understanding this aspect of the ESS as well. Its drafters wanted at the same time (a) to show that the EU took the USA's new security vision seriously and shared the underlying concerns; (b) to nuance the treatment of the major "new threats" in line with different European perceptions; and (c) to highlight other threats and challenges that the EU saw as equally serious with – and/or causally linked with – terrorism, proliferation and dysfunctional or deviant states. Purpose (a) mattered for EU governments precisely because they had not worked together on such an assessment before. Purposes (b) and (c) were linked with the need to justify strategic prescriptions in which the EU nations

11 A "SITCEN" was set up for ESDP purposes but developed only slowly after 2000 and was shaped by the fact that ESDP missions were limited to essentially altruistic, extra-European crisis management. It was given more powers, and intelligence exchange was stepped up, by decisions taken after the Madrid terrorist bombings of March 2004.

12 A great deal could be written about the relative meaning, and merits, of the expressions "risk", "challenge" and "threat" to express the substance of contemporary European security concerns. "Threat" was the standard expression for the starting point of security analysis and response in cold war times, but today is most properly reserved for cases where there is a conscious human intent to harm. "Risk" is potentially the widest term since it can include hazards not usually thought of as belonging to the security policy sphere such as traffic accidents or financial collapse. (For the author's own views on this see Bailes, 2007.). However, this author has found no evidence that the varied use of these terms in the ESS - on which see details in the main text, below - is based on consistent theoretical differentiation or, indeed, on anything much more than familiarity, euphony and ease of translation. (It is telling that the non-specific "problem" is the second most frequently used word in the ESS after "threat", see note 15 below.) It would be strange anyway to expect much depth of conceptual refinement and consistency in a text produced by months of inter-governmental bargaining.

would more openly signal an alternative 'European way' of tackling shared Euro-Atlantic problems.[13]

Common elements of analysis between the ESS and the 2002 NSS are both generic and specific. Both documents agree that the interests of the Euro-Atlantic community are threatened, in twenty-first century conditions, by non-state actors and transnational movements as much as – or even more than – by traditional military opponents. Both give credit for the easing of more traditional strategic concerns in Europe: the EU paper's opening line is that "Europe has never been so prosperous, so secure or so free". Both accordingly treat Russia as a potential partner rather than an adversary, while at the same time signalling that the West has not made a "new Yalta" agreement and must be free to continue spreading its own influence Eastward. The ESS states: "Our task is to promote a ring of well-governed countries to the East of the European Union....with whom we can enjoy close and cooperative relations". Both documents stress that new risks and challenges arise increasingly from *global* phenomena and both argue that the West's responses must be both proactive and potentially equally global. A much-quoted sentence from the ESS is that "with the new threats, the first line of defence will often be abroad." In practical terms, both strategies prescribe the use of a mixture of traditional and non-traditional, military and non-military instruments; and last but not least, both link the promotion of western countries' national and collective security interests with the promotion of democratic values, human rights and good governance worldwide.

As to specific risks and threats, the ESS follows the NSS in discussing at greatest length those from international terrorism and the proliferation of WMD. It describes the combination of these – the risk that terrorists will use WMD for their attacks – as "the most frightening scenario" of all. Already here, however, we can see the first signs of the EU drafters' nuancing their approach in order to embed these threats in a European world-view that paints motivation and identities in shades of grey rather than black and white, and that seeks to understand, transform and embrace hostile actors rather than to stigmatize and destroy them. While the NSS detects threats only outside the USA's own shores, the ESS acknowledges that "this phenomenon [alienation as a root cause of terrorism] is also part of our own society." The ESS also presents terrorism as a symptom rather than a cause of other security abnormalities (conflict, weak states, bad governance and social ills), and sees the desire of countries to acquire WMD as reflecting something more generally amiss in their and/or their region's security environment. Significantly, the EU document never uses the world "enemy" which is liberally scattered through the NSS,[14] while it does use "threat(s)" 24 times.[15] European "vulnerability" is mentioned only once, in connection with dependence on external energy supplies.

Perhaps most significantly in terms of analysis, the final version of the ESS contains several paragraphs – much increased from Solana's earlier draft – on the phenomenon of conflict as a problem in itself (for human values and international order as well as European interests) and as a powerful contributory cause for the "new threats" as well as for state weakness and human suffering.[16] This conflict-averseness reflects a strong strand in both the EU's philosophy and its members' experience – open fighting over Kosovo was still a recent memory in 2003! – and it helps to explain why the ESS deliberately distances itself from the NSS's famous or notorious doctrine of forceful "pre-emption" when it comes to the prescriptions.[17] Even if the UK, Spain, Denmark and others were willing to join the USA in deliberately starting a conflict (in Iraq) to stop another perceived threat, the EU at 25 could never endorse such a position. Finally, the ESS sketches out more fully than the NSS (in proportional terms) the importance for Europe's security of

13 The ESS's prescriptions are not fully analysed in this chapter; for details see Bailes (2005).

14 Similarly, the ESS avoids using US-type terminology about "rogue states": the nearest it gets is "countries (that) have placed themselves outside the bounds of international society," adding that "It is desirable that such countries should rejoin the international community."

15 And "challenge" twice, "risk" just once, "danger" twice and "problem(s)" (in the security sense) eight times.

16 Conflict is actually the very first "threat and challenge" mentioned in the document.

17 The word "pre-emptive" was actually used in the Solana draft, but in a paragraph (p. 10) calling for "pre-emptive *engagement*" when necessary to assure development and justice for all citizens (a context far removed from the US version of military pre-emption *á la* Iraq). During the inter-governmental debate on the text this wording was dropped under pressure from Germany and others, and the idea of "preventive engagement" was used instead when discussing failing states, proliferation and humanitarian emergencies. More generally, the ESS distances itself from the US doctrine by stressing the need to respect international organizations and defend their rules.

global *economic* cooperation and the correct handling of *social* challenges especially in poorer countries: and this greater focus on the "softest" security problems–which can neither be tackled militarily, nor unilaterally–helps to explain why the ESS's supreme prescription is "effective multilateralism".

In all these respects, it can be shown that the drafters of the ESS were sensitive to empirical differences between the risk/threat perceptions of the wider European population and those of the US popular mainstream. A "Transatlantic Trends" opinion poll published in autumn 2003[18] showed that 70 per cent of both US and European respondents thought the threat from terrorism extremely important", but significantly fewer Europeans than Americans were similarly concerned about the North Korean and Iranian WMD challenges or Islamic fundamentalism. Only on the Arab-Israel conflict was European opinion more concerned than US respondents (46 per cent compared with 39 per cent).

A Eurobarometer poll taken around the same time also showed that the top five concerns of EU citizens included fighting organized crime, and – with even higher scores – "fighting unemployment" and "fighting poverty".[19] This last finding is also interesting because the percentages of those expressing concern were much higher than the numbers of the actual unemployed and poor: and it goes to reinforce the conclusion that the European conception of threat and challenge (at least at this time) was significantly *internalized* as compared with the USA's persistent inclination to *externalize* – and often personify! – evil influences.

To revert to the point made above about the ESS's incompleteness as a "360 degree" threat assessment, it is worth briefly noting what was *not* covered in the EU document. In retrospect, the treatment of challenges to human and state security in the domains of energy, the environment and epidemic disease was pretty perfunctory, and human migration (with its consequence, growing multiculturalism) was touched on only obliquely. Challenges from individual states were almost absent: thus, not only was the continuing ambiguity of strategic relations with Russia not discussed - which, as argued above, could have been construed as NATO's business - but China and India received only the briefest of (positive) references as "strategic partners" (Bailes 2006). Finally, it was perhaps not surprising that the Iraq issue itself was shrouded in silence, but slightly more surprising that no specific analysis was offered of the operation ongoing since end-2001 in Afghanistan where Europeans of all shades of opinion were contributing (most of them through the UN-mandated *International Security Assistance Force* (ISAF). The only conflict locations receiving detailed comment in the ESS were the Israel/Palestinians conflict and the Western Balkans.

6.3 Five Years Later: (i) The Changing Scene

Contemporary history moves fast. In less than half a decade since the adoption of the ESS, both the EU's own circumstances and the outside influences on its security vision have been in many ways transformed. Internally, the planned "big bang" enlargement was completed on schedule when 10 new member states joined the Union in May 2004,[20] but the EU's new draft Constitution (bringing governance changes that were supposed to safeguard the larger Union's efficiency) was rejected by voters in national referendums in France and the Netherlands just twelve months later.[21] The somewhat watered-down Reform Treaty ("Lisbon Treaty") that was drafted in 2007 to replace the Constitution, after a rather lengthy pause for reflection, likewise ran into a roadblock when an Irish referendum on it failed in Spring 2008.[22] Contrary to all previous orthodoxy, the EU has therefore been obliged – at least in the short run– to "widen" itself radically without any institutional "deepening". At the time of writing, the Lisbon Treaty remains the focus of reform ambitions and has been ratified by a major-

19 Eurobarometer poll taken in May 2003, quoted in: *Financial Times*, 17 September 2003.

20 Estonia, Cyprus, the Czech Republic, Hungary, Latvia, Malta, Poland, Slovakia and Slovenia became EU members on 1 May 2004. NATO admitted 9 new members in March the same year.

21 In referendums on 29 May and 1 June 2005 respectively. For the text of the draft constitutional treaty see at: <http://europa.eu.int/scadplus/constitution/index_en.htm>.

22 Treaty of Lisbon, 13 Dec. 2007: for information and text see <http://europa.eu/lisbon_treaty/index_en.htm>. The European Council in December 2008 adopted a game-plan to try to change Ireland's position through a new referendum, allowing the Treaty to come into force by end-2009.

ity of member states, but how and when the Irish blockage can be overcome remains moot.

The delay in constitutional reform has disappointed hopes, among other things, of a stronger central apparatus for managing EU foreign and security policy. Both the Constitution and the Lisbon Treaty would have given the European Council a long-term Presidency, and elevated Solana to the status of a European "Foreign Minister" sitting simultaneously in the European Commission and supervising all existing external-affairs staffs and funds.[23] The first set of failed referendums also triggered, however, a more general crisis of confidence in and among the European leadership. The symptoms included a growing popular backlash against enlargement (also a motive for the French and Dutch peoples' "No" votes on the constitution), and a hardening of resistance in certain countries—again, especially France – against the idea of according full membership to Turkey which began its formal accession talks in October 2005. These popular attitudes were linked with a more general reaction against the "dilution" of European societies by immigration, and against the opening of European industries and markets to competition that might threaten "national economic treasures" and employment. The resulting "enlargement fatigue" did not stop the planned accessions of Bulgaria and Romania in January 2007, but did render very remote any idea of accommodating the next "tier" of countries like Georgia and Ukraine. The leaders installed in these last two nations by the "rose" and "orange" democratic revolutions of 2003 and 2004–2005 respectively suffered serious policy setbacks and eroding personal images as their governments had to grapple with harsh realities, reinforcing the message of pessimism and caution among Western observers. By 2006 a number of the newly integrated Central European states had also run into domestic turbulence characterized by a surge of nationalist, Euro-sceptical sentiment at popular or government level or both.[24] Many pundits had forecast that seeking unity on tricky strategic issues would be difficult in an EU of 25 (now 27) members, but most assumed that the new states would act – as in the 2003 Iraq debate – as a fairly coherent, militarily robust pro-Atlantic bloc. Few could have guessed either how far the ten Central European capitals would themselves become split on key European issues, nor how far Poland in particular would be prepared to go in blocking majority decisions. The final shock in this Eastern context came, of course, with the Russia-Georgia conflict of August 2008 and resulting Russian part-occupation of Georgia: an episode that called in question not just Russia's strategic intent, but also Georgian judgement and the whole credibility of Western policies beyond the EU (and NATO) border.

It was, thus, a *politically, mentally and institutionally vulnerable* Europe that had to cope with the fast-evolving threat picture of the years 2004–2008.[25] The main changes impacting upon it will be addressed here first in terms of the ESS template, and then of what the ESS did *not* (directly or adequately) cover. First, the threats of terrorism and WMD proliferation became if anything more real for Europe after 2003 than they appeared to most people in that year. The mass-casualty attacks of 11 March 2004 in Spain and 7 July 2005 in the UK not only drove the general lesson home but shook national self-confidence in different ways: the Spanish attack because it was *not* carried out by the "familiar enemy" of Basque terrorism, the British attacks because they *did* come from "home-bred" terrorists. Nuclear proliferation took a tangible step forward with North Korea's nuclear test of October 2006, while Iran's progress towards potential nuclear weapon capability was not halted either by the EU's mediation efforts (Bailes 2006a) or by the USA's tougher stance. Opinion poll figures from mid-2006 showed that 52 per cent of European respondents now thought the threat of Islamic fundamentalism "extremely important" (as against 47 per cent in 2003 and 41 per cent in 2005), although general terrorism-related concerns were somewhat lower than in 2003; and extreme concern about Iran had gone up from 46 per cent in 2003 to 58 per cent in 2006 (even higher in Germany and Poland).[26] Over the same period, however, the main counter-stroke by the US-led coalition against such "new threats" – the invasion and oc-

23 For the specific impact of the Lisbon Treaty on ESDP see Biscop and Algieri (2008).

24 Best known examples during 2006 were the confrontational policies adopted by the Kaczynski brothers in Poland and the violent protests against the government led by Prime Minister Ferenc Gyurcsány in Hungary.

25 The West's sense of *economic* vulnerability was also sharply increased in 2007-8 by an extreme surge in oil prices, a parallel global shortage in some foodstuffs, and a protracted credit/financial crisis that spread from the US to affect all European to some degree (incidentally making the management of the Euro even more difficult). These problems should be borne in mind as deepening European policy-makers' sense of instability and inadequacy, but it is not possible to analyse them in any further detail in this text.

cupation of Iraq – came to be seen overwhelmingly in Europe (and by a majority of the US population) as a mistake of tragic proportions, likely only to strengthen the forces of terrorism (and more indirectly, the temptation to proliferation) and to further destabilize the greater Middle East. The "Transatlantic Trends" poll in 2006 found that 45 per cent of Europeans considered the violent and divided state of Iraq an extremely important threat in itself, with an even higher figure in the UK – the EU member with the largest remaining military investment there.[27] According to the Pew global organization,[28] in Spring 2006 41 per cent of UK respondents (and 56 per cent in Spain, 40 per cent in Germany and 36 per cent in France) saw the US presence in Iraq as "a danger to world peace" and 45 per cent were equally concerned about the unsolved Israel/Palestinians conflict, while just 34 per cent saw Iran, and 19 per cent saw North Korea, as a comparable danger.[29] Overall, the number of European respondents considering US leadership in the world "desirable" had fallen from 64 per cent in 2002 and 45 per cent in 2003 to just 37 per cent in 2006.[30]

To sum up, in the first five years after 2003 the common security challenges facing the USA and European did not ease and if anything became more clear, but the passing of time brought even greater disagreement and confusion over how to prioritize them and on the USA's way of tackling them. This meant an unhealed, or even deepening, crisis of confidence in Atlantic relations just at the time when EU leaders were abnormally un-confident about their own grip of the Union's affairs. Paradoxically, however, the trans-Atlantic debate at political level was fairly muted in 2005–2008 as European leaders (such as Germany's new Chancellor Angela Merkel) tried to build common ground on the less controversial, generic anti-terrorist and anti-proliferation measures or the shared Afghanistan mission, and the US Administration eased up on some of its more extreme prescriptions. Parallel weaknesses made each side reluctant to shake popular trust further by a mutually damaging war of words. Overlaid on this situation, however, came a surge from early 2005 onwards in two further, new or renewed sets of security concerns each with its own divisive overtones.

First was the sharpened European concern about a set of "functional" security concerns: the security of energy supply (starting from an episode in January 2006 when a temporary stoppage of gas supplies from Russia to Ukraine also hit European consumers); the likely impact of climate change and associated environmental damage; and the fear of a new (post-SARS) killer epidemic evolving out of avian influenza. If the last of these was not inherently divisive, the energy issue impacted US and European opinion differently – President Bush vowing to cut down dependence on Arab sources of oil and gas while Europe was both obsessed with and divided by the question of Russia's reliability[31] – and on climate change, it was easy for Europeans to see the USA as the "bad guy" given its refusal either to join the Kyoto Protocol or (at federal level) adopt strict measures of economy and self-restraint. The Pew poll of mid-2006 already quoted showed that 51 per cent of Spaniards, 46 per cent of the French and 30 per cent of Germans were "very worried" about global warming while the US figure was as low as 19 per cent.[32] As for policy solutions, EU leaders did manage on 9 March 2007 to unite on a new policy to deal with climate change including unprecedentedly low voluntary limits on certain emissions.[33] They could reasonably feel vindicated when Senator Barack Obama, the winning candidate in the USA's November 2008 Presidential elections, committed himself explicitly to move US policy in a more 'European' direction. However, European agreement on a common energy policy as such

31 The effect was intensified by a further Russian stoppage (of deliveries through Belarus) in January 2007 and by Russian-German plans to open a new direct pipeline, bypassing Poland, the Baltic and Nordic countries who feared Russia might then be able to cut off supplies to them while still cooperating with Berlin.

32 Interestingly also for revealing the mechanics of divergence in US and European concerns, 99 per cent of Spaniards had *heard about* bird 'flu but only 74 per cent about Iran's nuclear ambitions: 90 per cent about Abu Ghraib prison (a location of US atrocities in Iraq) and Guantanamo Bay, but only 68 per cent about Hamas's gains of power in the Palestinian elections

33 See para 29–38 on "Climate protection" and "Energy policy" of the Presidency Conclusions of the European Council of 8 and 9 March 2007; at: <www.consilium.europa.eu/ueDocs/cms_Data/docs/pressData/en/ec/93135.pdf>.

proved more elusive, given conflicting interests over freeing up the intra-EU market, but also because of concerns in Central Europe over the burden on industry. If the Georgia shock of 2008 showed more nakedly than ever the destabilizing and divisive cost of EU members' energy dependence on Russia, the 2008 economic crisis threatened to sap both the will and time-pressure for finding better alternatives. The December 2008 European Council did reach agreement on continued European leadership in climate change restraints, but independent campaigners criticized the small print of its decisions for backsliding.

The second set of concerns related to the general challenge of Russia's increasingly high-handed behaviour both at home and abroad from late 2005 onwards. Fuelled by gains from high oil prices, President Putin used the "energy weapon" without compunction even against his closest post-Soviet neighbours; was clearly implicated in political manipulation of some major corporate relationships where foreign firms came off worst; embarked upon major increases in defence spending and the armed forces' equipment, and was widely suspected of complicity in a number of ruthless actions (including as-yet-unsolved murders) against political opponents at home. Institutional relations became affected when work on a Russia-EU partnership agreement broke down in December 2006, ultimately because of a unilateral ban by Moscow on Polish meat exports. In principle this resurgence of challenge from the East should have led (and at earlier points in history would have led) to a reinforcement of US-European solidarity in NATO. However, by 2006 NATO had almost completely shifted its focus away from Europe's own security to the pursuit of overseas deployments like the one in Afghanistan: all Western Balkans peace missions except KFOR (in Kosovo) had been transferred under the EU's authority. Two new "expansionist" US initiatives launched in 2006 – a "global partnership" with like-minded non-European states and the opening of membership prospects for Ukraine and Georgia – proved too much for the Europeans to stomach and failed to be adopted at NATO's Riga Summit in November. Opinion polls showed that only 55 per cent of Europeans in 2006 considered NATO "essential" for their interests in 2006 as against 69 per cent in 2002: although by mid-2008 the figures had improved again slightly.[34]

A further setback with more directly military overtones came in February 2007 when Putin used the platform of the annual Wehrkunde conference in Germany[35] to attack the West over the USA's plans to set up missile defence bases – positioned to cover a possible Iranian threat – in Poland and the Czech Republic.[36] Putin argued that these not only violated repeated assurances given by NATO since 1990 that it would not station foreign forces on its new members' territory, but also the terms of the US/Soviet INF Treaty signed in December 1987 which banned intermediate-range missiles on both sides in Europe – and which Russia itself might now not wish to respect.[37] A few months later he declared that Russia would "freeze" its implementation of the Conventional Forces in Europe (CFE) treaty, of which Western countries had in any case declined to ratify the latest version. While the USA robustly rejected all Putin's criticisms and claimed to have consulted and reassured Moscow, European reactions gradually revealed (a) that the programme for the USA's new European bases had not been debated and pre-approved by NATO as a whole and (b) that many Allies were actually unsure of their rationale. Throughout 2007–8, NATO in particular had to devote more energy to reconstructing some element of Western consensus than to trying to convince the Russians, who in any case showed more and more plainly that they relished the quarrel. Still more fuel was added to the flames by the EU and US decision to endorse Kosovo's unilateral declaration of independence in February 2008 (and provide for continued Western deployments there) while Moscow rejected it. The Georgian crisis against this background was only the last straw that broke the camel's back of Russia-West "partnership", leading to the suspension of most NATO/Russia cooperation and a further delay in negotiating the new Russia-EU agreement.

36 The USA was also planning to create transfer and storage bases in Poland, Bulgaria and Romania for future conventional-force deployments in the Middle East "arc of crisis".

37 The *Treaty on the Elimination of Intermediate-range and Shorter-range Missiles* (INF Treaty), entered into force on 1 June 1988.

6.4 Five Years Later: (ii) The Fate of the ESS

As stressed by many analysts, the ESS was never a "strategy" in the sense of providing a detailed action programme on a rigorous defined set of strategic challenges, and/or a framework that could directly guide military actions.[38] Its status as a political document, generated in the EU's Council of Ministers framework, did not allow it either to create new EU law nor to create and allocate new EU funds.[39] It could only impact on day-to-day EU policies by being translated into more detailed "sub"-strategies or corresponding documents, making clear who should do what under them and from what sources any expenses would be met. In fact, the European Council that adopted the ESS in December 2003 also adopted an initial follow-up programme calling for further policy development in four areas: EU-UN relations, anti-terrorism, the Western Balkans and the Middle East.[40] (WMD issues were not mentioned because a strategy on those was already prepared, and a number of specific advances in ESDP mechanisms and operations were made by separate decisions in 2003–2004.) In the event, progress in anti-terrorist cooperation was boosted unexpectedly by the Madrid incidents of 11 March 2004. The European Council that met two weeks later adopted an ambitious package of measures including a declaration of mutual "solidarity" against all such attacks and the decision to draft a full anti-terrorist "strategy".[41] A document laying out a "comprehensive policy" for future EU actions in and responsibilities to Bosnia-Herzegovina was endorsed by the European Council in June 2004 and a whole raft of documents about EU-UN cooperation in the spirit of "effective multilateralism" were approved from September 2003 to May 2004.[42] Only on the Middle East did the EU fail to make any clear breakthroughs, conceptual or operational, in the first years after the ESS's adoption – constrained as it was by a lack of influence and resources, and its commitment to work within the international Quartet with the USA, UN, and Russia.[43]

In its own terms and by the EU's usual standards, this stands out as a coherent and reasonably creditable follow-up. However, caveats can be expressed both about the final *output* and impact of the EU policies covered, and about what the follow-up programme did *not* address. On the first point, the anti-terrorism field probably shows the best harvests of results both within the EU, and in EU–US cooperation (e.g. on aviation security and travel documentation, judicial measures, vulnerability mapping and emergency response): but even here the results may be seen as too little from one viewpoint – still too much national divergence and too little coordinating power in Brussels[44] – or too much from the standpoint of EU citizens' rights and liberties.[45] In the Western Balkans, the EU has assumed fuller responsibility for post-con-

38 See Heisbourg (2004), Freedman (2004); and European Institute for Security Studies (2004). It may be added that the ESDP missions launched since 2003 have not clearly fitted the ESS's prescriptions and priorities.

39 For further discussion of these procedural points against the background of evolving notions of "strategy" within EU governance see Bailes (2005), esp. pp. 7-8, 22, 25 and 27.

40 See European Council, "Presidency Conclusions of the meeting at Brussels on 12–13 December 2003"; at: < http: //ue.eu.int/ueDocs/cms_Data/docs/pressData/en/ec/78364.pdf >.

41 European Council, "Declaration on Combating Terrorism", 25 March 2004; at: <http://ue.eu.int/ueDocs/cmsUpload/79635.pdf.

42 For details on these topics see Bailes (2005: 31).

43 Since the end of 2004 when the first cycle of ESS follow-up was complete, no new "package" of sub-strategies has been commissioned but some important specific ones have been tabled, e.g. by the European Commission on Africa: "The EU Strategy for Africa: Towards a Euro-African Pact to accelerate Africa's Development", published on 12 October 2007 and adopted by the General Affairs and External Relations Council on 12 December 2007; for a summary of the security implications see at: <www.isis-europe.org/ ftp/Download/ARTICLE%203.pdf>, 18 August 2007 and a "Strategy to combat illicit accumulation and trafficking of SALW and their ammunition", adopted by the European Council on 15–16 December 2005; at: <http://register.consilium.europa.eu/pdf/en/06/st05/st05319.en06.pdf>, 18 August 2007. The 21–22 June 2007 European Council adopted "The EU and Central Asia: Strategy for a New Partnership" (Council of the European Union document 10113/07 of 31 May), see para. 47 of Presidency conclusions at <www.consilium,europa.eu/ueDocs/cms_Data/docs/pressData/en/ec/94932.pdf>, 15 September 2007. There are intriguing signs of the Commission re-gaining ground in long-range policy formulation generally, as a function of the more "economic" nature of new preoccupations (see below) and/or political exhaustion in Solana's team and some key national regimes.

44 A central "terrorism coordinator" post (first held by Gijs de Vries) was created under Solana in 2004 but at a modest level, with no power e.g. to command relevant resources in the EU's first and third "pillars", while states have blocked the Commission from acquiring new relevant competence .

flict transformation in Bosnia-Herzegovina (BiH) and for coordinating its different inputs there, but little progress has been made in "re-centralizing" the country's security structures and policies, while the EU's "enlargement fatigue" makes it harder to wield the stick-and-carrots of conditions for eventual accession against the BiH élites themselves. This last point perhaps even more seriously affected the EU leverage for gaining Serbia's acquiescence for the managed independence of Kosovo – a far greater and still unresolved test of the EU's credibility in the sub-region. As regards global security challenges, the EU could neither convert the UN's 50th anniversary summit declaration in September into more than a very partial success for "effective multilateralism", nor rein in the disorder and violence that marked the Middle East in 2004–2007 (including an open attack by Israel on Lebanon).

With all this, the most serious change against the ESS and its follow-up process is probably still what they failed to address. When the concern over energy security reached its first peak in January 2004, the Europeans had to start virtually from scratch in devising a common policy, with the mixed results that have already been noted. Work to prepare common responses to avian 'flu or other epidemics centred from early 2005 on a new European Centre for Disease Control (at Stockholm),[46] not even envisaged at the time of the ESS's drafting. The frenzied work in 2006–2007 to prepare and agree a policy that would place the EU in the lead in mitigating global warming was led by the European Commission rather than by Solana's team. Here lies a retrospective clue to some of the ESS's key limitations: bold as the document was in shaping new lines for external security policy, it studiously avoided trespassing (at least in terms of prescription) on functional areas at the intersection between security and economics or trade, if they belonged formally or presumptively to the Commission's competence in the Union's "first pillar". The ESS did make the obvious point about the need to combine tools from all parts of the Union's structure to implement strategic aims, but dodged the details of coordination or hierarchy between them. Conversely, as already noted, the long-standing EU/NATO role division – perhaps combined with several member states' concern not to "militarize" EU policy – prevented the ESS from either anticipating or offering solutions for the new directions taken by Russian misbehaviour from 2004 and the splits it was to re-open in European ranks. (As one result, the task of preserving any kind of momentum in European nuclear or conventional *arms control* was left dangerously in limbo between the institutions, contrasting with the new push to control the global arms trade through an EU-backed Arms Trade Treaty (ATT).) Last but not least, the whole US-European strategic relationship that provided the spur for creation of the ESS – and which explains the choices made in almost every single sentence of the document – was just too large and painful a challenge for the Union's leaders to address frontally and frankly in any open political statement in 2003. For the most part it still is.

6.5 The Future History of the ESS

None of these lacunae in the ESS's legacy should detract from its historic importance in symbolic, inspirational, and even lasting philosophical terms. It said what it needed to say, and was silent where it needed to be, to succeed in rallying European nations at a particularly dangerous moment in Spring 2003 and in inspiring concrete advances in several security-related fields. Considering the period of internal weakness and division that was to follow over the draft Constitution, with several key European leaders entering their lame-duck periods in parallel, the swift repair-work carried out by the ESS looks even more crucial in retrospect for allowing at least some minimum of common European strategic purpose to survive through to the potential renaissance of 2007. Indeed, a striking feature of EU activity in 2004–8 was precisely the way that external strategic affairs – including the burgeoning set of ESDP missions – provided a rare zone of steadily progressing achievement and relative "good behaviour" among the contributing states. The Central European regimes who caused such difficulties for EU internal and functional security decisions did not after all appear to be a brake on the development of ESDP as such.

On this showing alone, there would be no case for the EU to disavow its formulations of 2003 when considering how to take its strategic development forward from 2008 onwards, under a new set of leaders in Britain, France and Germany and with a radical change imminent in the White House. Moreover, sev-

45 The new common European Arrest Warrant (EAW) ran into particular difficulties, with constitutional courts in Germany and some other member states finding that insufficient safeguards for the rights of citizens facing extradition had been incorporated in national implementing legislation.

46 More information at: <http://www.ecdc.europa.eu>.

eral of the substantial judgements and guidelines within the 2003 text are also looking even better today than they did originally, in the light of the now-mounting costs of the Bush Administration's hard-line alternatives. In particular, the doctrine of "effective multilateralism" has won reinforcement as the USA has found itself obliged to tone down its advocacy of *ad hoc* coalitions, to accept new elaborations of the UN machinery[47] and to work harder once again for the renewal of NATO as an institution, as well as accepting or even engineering multilateral solutions for some other regions' security problems.[48] Latest experiences of conflict management and peacebuilding, not least in Iraq and Afghanistan themselves, have further underlined the limitations of the military instrument and the importance of local will and "ownership" in securing real transformations. Even if latest events have shown the huge difficulties of making Russia into a "partner", and many of the doubts about China's ultimate acceptance of that role remain, the USA's experimentation with harsher and more rejectionist approaches to such non-Western powers has only aggravated Western divisions as well as Western exposure and highlighted the urgent need for more imaginative and constructive approaches. Overall, it could be concluded that any security strategy based too much on "threat" and on assumed existential confrontations is liable to be an impoverished as well as a high-risk one: and the ESS's way of softening, of qualifying, and even of deliberately leaving things out from the "threat" picture may hold a kind of modest wisdom of its own.

Nonetheless, today's clearer appreciation of the gaps in the ESS's coverage – and the sketchiness of many of its prescriptions – is bound to raise the question of whether the EU needs to revise or even replace the document as it moves into a new and possibly more effective stage of its strategic maturation. Such a revisiting of the ESS became official policy in December 2007 when – under particular pressure from France which was in parallel overhauling its national defence strategy – the European Council agreed to give Solana twelve months to examine implementation of the Strategy and suggest elements that might both improve its implementation and "complement" the document itself.[49] As with the original draft, discussions proceeded in parallel during 2008 among governments and in academic seminars (coordinated by the EU Institute of Security Studies)[50] on what could and should come out of this exercise.

The Strategy review process was timely and the related intra-elite debates useful in themselves, given the coincidence with an impending change of US leadership – which European countries realized they would need to match with robust ideas of their own – and the obvious need to re-think all Russia-related and former Soviet Union-related policies. However, there were other ways in which the context did not favour any major, *a priori* re-imagining of EU strategy in late 2008. The trouble was not only that the issues themselves – Russia but also Iraq, Afghanistan, energy security, immigration, the financial crisis and more – needed more time and work to be digested before a proactive EU consensus (not a mere papering-over of rifts) could emerge. The whole governance context was also out of joint because of the postponement of the Lisbon reforms meant that Solana's team were still operating in an essentially inter-governmental, 'foreign affairs' context, rather than having one foot also in the Commission and being able to debate the strategic relevance, and use, of all the Union's mighty economic and functional capacities.

The December 2007 mandate implicitly recognized this by noting that the current review should take note in particular of the experience of ESDP missions, on which Solana's team are the experts but which play only a limited and perhaps unrepresentative role in the emergence of "Europe as a power".[51] It is relevant also that the EU has adopted another French idea for an independent wise persons' study on the 'horizon' for Europe's development by 2020–

47 The UN Summit of September 2005 reached agreement on the creation of a Peacebuilding Commission and a new form of Human Rights Council, both of which were in place by mid-2007.

48 The most obvious case is the agreement on handling the North Korean nuclear problem reached at the Six-Party Talks hosted by China in February 2007, but the USA has also been obliged to agree to the start of talks with and among Iraq's neighbours on handing border security problems there. Some passages confirming the USA's conceptual acknowledgement of the uses of multilateralism (eg in regions with many weak states) will be found in the new version of the NSS published in March 2006, text at <http://www.whitehouse.gov/nsc/nss/2006/>, 25 September 2007.

49 Presidency Conclusions of the European Council 13–14 Dec. 2007, para. 90, Council document 16616/1/07/REV1, available at http://consilium.europa.eu/cms3_fo/showPage.asp?id=432&lang=EN&mode=g.

50 See the information and papers at http://www.iss.europa.eu/index.php?id=247.

51 See Bailes (2008) and other articles in International Affairs Vol 84 No 1 of Jan. 2008.

2030, and it is arguably in that exercise – to be undertaken as and when forward motion is resumed on the Lisbon Treaty – that any major re-thinking of the EU's strategic identity should find its place. Last and not least, at a time when European populations were facing serious pain from the economic turndown, it would have been suicidal for European politicians either to give the impression that they were wasting major energies on lofty long-term visions, or, indeed, to attempt a new strategic breakthrough that might have alienated as many citizens as it inspired.[52]

Sensibly enough, Solana's drafters adopted - and the European Council on December 11–12 2008 accepted - a prudent and workmanlike approach. The European Council "endorsed the analysis" in a 12-page report made to the Council of Ministers "on the implementation of the European Security Strategy",[53] but did not itself adopt the paper for publication – making clear it was not replacing the original Strategy. The paper replicated the approach of the first ESS in stating general desiderata for EU policy rather than conveying new decisions (or mentioning money); thus, such concrete steps as were ripe for adoption in the defence/security field – notably a new Declaration on ESDP goals,[54] a package of decisions on global WMD issues and changes in the European Neighbourhood Policy's Eastern and Mediterranean dimensions – were announced in separate declarations by the Council and European Council.

The report itself made a fair attempt to remedy some of the generic imbalances of the ESS e.g. by saying more on economic and energy problems (and the connection between security and development); acknowledging the newly fashionable topics of cyber-sabotage and piracy; playing up the issues and needs created for the EU's own territory by the risks of terrorism, crime and migration; and in general, taking a more holistic approach to the internal and external dimensions of European security. In terms of institutional partnership it stressed UN supremacy more clearly than before – perhaps hoping to strike a chord with President-elect Obama! – but also echoed recent shifts in French national policy by expanding on the need and scope for cooperation with NATO.

It seems unlikely that this new text will attract more than a fraction of the academic attention lavished on the original. Even a first reading confirms, however, that the drafters did not manage – or perhaps even try – to overcome some of the ESS's more basic omissions. The challenge of Russia for Europe's own security is again dodged to an extraordinary extent, with the bland statement appearing on page 10 that "Our relations with Russia have deteriorated over the conflict with Georgia." Even less are the conundrums of the USA's role in European and global security, or the rise of China, addressed; and the discussions of the Western Balkans, EU neighbour regions and Iraq are superficial and complacent. Those who criticized the first ESS for lack of true 'strategic' thinking[55] will find no greater satisfaction here; nor is it easy to imagine ordinary European citizens finding much that would resonate with their own day-to day anxieties. At least, the 2008 report includes one concluding paragraph acknowledging that "Maintaining public support for our global engagement is fundamental."

How much do these continuing inadequacies matter? Arguably, the EU is more likely to define active and correct responses to today's security changes through separate sectoral decisions ('sub-strategies' adopted by the Council, or Commission-led policy developments) than it could ever be expected to do in a conceptual paper covering so many great issues so thinly. Moreover, the EU's future weight in the global system and the way it changes global practice for good or ill depends in almost every field on how it relates to other great powers – the USA, Russia and increasingly China – than on any policy it can formulate in full independence. For managing those tricky but vital relationships, Europe's leaders are unlikely to refer to any single documentary road-map even if the ESS had been able to offer them a good one. In the last analysis, strategies are created for men and not men for strategies. What the EU needs in order to confront the more multiform threat and risk environment of 2008 onwards is, not so much to re-imagine the document that first emerged in June 2003, as to recapture the spirit of resolve and unity in which Europe's leaders first endorsed it.

52 Research during 2008 into reasons for the failure of the Irish Lisbon Treaty referendum suggested some voters had been scared off by the belief that a common 'European army' was being planned.

7 NATO's Traditional Security Problems

Pál Dunay

7.1 Introduction

Whenever attention has been paid to alliances during the last two decades reference is exclusively or nearly exclusively made to the *North Atlantic Treaty Organization* (NATO). Consequently, except for historical works, NATO serves as the ideal type of alliance (Walt 1990). This presents a variety of problems. First of all, NATO "was always intended to be both more and less than a military alliance" (Howard 1999: 164). More in the sense that NATO has always been the most important avenue of transatlantic security dialogue and less in the sense that NATO is not a fighting alliance. During its entire duration it never had to use force for the defence of the member states' territory. This may well be its greatest achievement. If this is true, it is not entirely convincing to draw conclusions from this alliance for alliances generally (Howard 1999). Given the very few recent alliances, it is unconvincing to base alliance theory exclusively on NATO. It would be just as unconvincing to base any theory of alliances on NATO and the Warsaw Treaty, two very dissimilar entities of Cold War history. Methodologically, it is furthermore questionable to base the thinking on alliances exclusively on NATO as a full extrapolation one would thus apply is scientifically unsound.

When NATO's success is mentioned reference is regularly made to the Alliance's age. In spring 2010 the organization was 61 years old. It has certainly achieved a lot beyond its survival for such a long time. It is, however, again problematic to attribute some of the successes frequently mentioned to NATO. The success of deterrence during the Cold War, the success to end the East-West confrontation, the successful management of several post-Cold War conflicts, rallying support to counter terrorism, the collective attention attributed to cyber warfare, and the danger of proliferation are all cases in point. NATO has certainly been present at all these junctures since its inception in 1949 and at least has contributed to manage many of them. A closer look would not attest NATO's prime role, rather its contribution to the change of European, Euro-Atlantic and, since the end of the Cold War, of global security.

This chapter attempts to discuss a narrow and specific though certainly crucial matter on NATO's agenda: Its role in addressing traditional security problems. Although such a matter could be narrowed down to the application of the collective defence article of the Washington Treaty of 1949, it is necessary to broaden the subject further. The question has to be raised, which are the contingencies that would invoke the collective defence commitment of the Alliance. This leads to the question of what could be identified as traditional 'hard' and new 'soft' security threats (chap. 2 by Brauch). This chapter will not address other, however, important matters of the Alliance (Dunay 2008: 713–725).

7.2 Security Threats, Risks, and Challenges

The history of NATO's existence can be divided into two phases. During the Cold War it functioned as a classical military-political alliance. It was its main task to deter a well-identified adversary, the Warsaw Treaty under the leadership of the Soviet Union (Schwartz 1983; Simon 1988). With the end of the Cold War and the advent of a new era the situation has changed fundamentally. The classical function to provide for protection and defence against another group of states, 'against whom' became irrelevant, interestingly at a time when the so-called 'long peace' (Gaddis 1989) of the Cold War came to an end and force was used again on the old continent. It gave way to a far less clearly identified threat. This was a threat originating from the emergence of certain phenomena and not associated with any country or coalition of states, i.e. NATO's activity was moved to providing protection

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_7, © Springer-Verlag Berlin Heidelberg 2011

'against what?' Since then NATO has found it difficult to present a clear view of the prime threats it is facing.

Departing from the Cold War threat perception, the search for new threats occurred during a long transitory period. During that time NATO had difficulties to adapt to the changed security environment. In want of a classical threat the member states had two reactions: 1. There were attempts to portray the protraction of the residues of the old threat. 2. The Atlantic Alliance went 'out of area'.

During the last phase of the decline and near collapse of the Soviet Union and in the first publicized strategic concept of the Atlantic Alliance the 'old' Soviet threat was assessed to exist based on the size of the Soviet, among others, nuclear arsenal (NATO 1991: para. 10).[1] The approach based on net capabilities combined with political uncertainty was excessive, although NATO lost its traditional adversary not much later, since Russia was sliding into chaos (chap. 13 by Sergunin; chap. 14 by Dunay). Russia's weakness was far more significant than Russian strength for most of the 1990's. Analysts nevertheless contemplated Russia's potential to reappear as a threat to Europe (Glaser 1993: 19–21). The doubts that surrounded the credibility of such an approach were mounting and hence it was difficult to conceive that NATO could form cohesion on that basis. The Russian threat was simply not credible and intensive enough to underline NATO policy.

The situation has changed since the early 21st century. Russia has since appeared more prominent on NATO's and its member states' agenda for at least three reasons:

1. The Russian Federation under the leadership of Vladimir Putin has reconsolidated its statehood and allocated more resources to the military than in the 1990's. Furthermore, in the second half of the decade the Russian Federation has embarked upon a defence reform. Although it has remained inconclusive (Fedorov 2009) it carried the promise that Russia will one day have a more effective military.[2] Furthermore, in the last years of the century's first decade Russia returned to the long overdue modernization of its nuclear arsenal.[3]
2. The number of those NATO member states conditioned by history, which have lively concerns about Russia, has increased through enlargement. Estonia, Latvia, Lithuania, and Poland are preconditioned by history to feel strongly about developments in Russia and to interpret them as worrying.
3. The actions of Russia in the second half of the first decade of the 21st century to assert her dominance in the post-Soviet space and curtail the freedom of choice of countries as far as their international alignment underlined the concerns of some NATO member states, if not the alliance as a whole. This has been exacerbated in 2008 when the Russian Federation used military force in an interstate contingency against Georgia, although the former did not initiate it. Even though the changes of Russia may affect the security perception of the Atlantic Alliance, they could be hardly sufficient to influence the entire alliance and shape its security agenda. With this in mind there is no security threat in Europe that could live up to the threshold of response of the Alliance as such.

There was very little to do to defend the sovereign territory of the then 16 NATO member states from external powers or their emerging alliance throughout the 1990's. As it did not seem to change any time soon, NATO had to consider other security functions. It was not only a matter of survival for the organization as also one to retain continuing relevance. For the first half of the 1990's it was not particularly difficult to find the new wherewithal of NATO. The war in the former Yugoslavia that Europe hoped to be able to manage on its own landed on the agenda of NATO. It happened in spite of the fact that the Strategic Concept of 1991 did not envisage participating in any crisis management or peacekeeping operations. This was the first geographical extension of the activity of the alliance. NATO decided to be Europe's military crisis manager irrespective of the effect of the given crisis on the alliance or its member states. Yugoslavia was clearly not a contingency for the collective self-defence of the Alliance. NATO as an all-European institution retained its security relevance at a price of departing from its sound treaty base and thus arriving at an ambiguous situation. That was not positively greeted by states that opposed the expansion of NATO as an all-European institution.

1 See: "The Alliance's New Strategic Concept agreed by the Heads of State and Government Participating in the Meeting of the North Atlantic Council", 7–8 November 1991; at: <http://www.nato.int/cps/en/natolive/official_texts_23847.htm>.

2 The new Russian military doctrine was approved on 5 February 2010 (Voyennaya 2010).

3 The document on the Russian state policy on nuclear deterrence was also approved on 5 February 2010.

Fostering the resolution of the war in the former Yugoslavia broadened the scope of NATO's activity as a crisis manager to Europe as a whole. The next step, although still carried out in Europe, and hence was no further geographic broadening compared to the previous one, represented a fundamental change in NATO's approach to the security of the continent. The 1999 war against Yugoslavia was a humanitarian intervention or a collective coercion verging on aggression. This was a fundamental turn as the 78 days of bombardment, even if it according to many served a noble purpose, could not be legitimized as a defensive action, nor did it have the endorsement of the UN Security Council.

There could be convincing arguments to conclude that the circumstances of the NATO operation were unique, that Yugoslavia (Serbia) under the leadership of Slobodan Milosevic had had a long history of confrontation with NATO. These facts could reassure non-NATO member states that it was not a new era that started in NATO's history characterized by moving from collective defence to collective offence. For anybody who watched the unfolding series of events from outside, in particular those who focused on narrowly defined legality of the spring 1999 operation, there could be hardly any doubt that this was a watershed in NATO's development.[4]

NATO adopted its Strategic Concept at the 50th anniversary summit of the Alliance in 1999 while the operation was going on in Yugoslavia. This has been the first Strategic Concept adopted after the collapse of the Soviet Union and in reflection on the strategic-political change of the 1990's. Regarding the security challenges and risks, the Alliance should respond to, the concept has remained quite abrupt. The five paragraphs (20–24) that list the challenges includes "uncertainty and instability" (para. 20), "powerful nuclear forces outside the Alliance" (para. 21), "proliferation of NBC and their means of delivery", the illicit trade of materials and knowhow (para. 22), and "non-state adversaries" (para. 23). Acts of terrorism and organized crime were mentioned in passing (para. 24). The reference to uncertainty and instability was a clear indication that NATO had not agreed on a concept about its primary future threats. The cursory reference to terrorism demonstrated the absence of a consensus as far as the most important potential emerging threats. Hence, the Strategic Concept illustrated the constraints of prediction.

After having moved from 'against whom' to 'against what', and 'against what type of security phenomena' instead of what enemy, it was difficult to interpret which geographical region has priority on the agenda of the Alliance. For some time, it seemed the greater Middle East would be an area where the future of NATO should be decided (Asmus 2003), but probably in a traditional sense the ambiguity will have to be retained for the cohesion of the member states. It can be taken for granted that NATO's acceptance in the greater Middle East must be built up by years of tedious work, if not that of decades. It must include soft security measures, which are already on the agenda.

The 9/11 terrorist attack against the World Trade Center in New York and the Pentagon near Washington fundamentally rearranged the threat perception of the Atlantic Alliance. Terrorism has become the primary threat and will continue to remain on the top of the list of threats for the foreseeable future. This means that on the list of threats one that originates from non-state actors is on the top. States matter as much as they cannot control their territory fully and hence serve as platforms for terrorists (or others who present transnational threats). Since then terrorism, particularly in combination with the aspiration to acquire weapons of mass destruction and states, which do not control their territory effectively, and hence carry the risk to be exploited by groups carrying transnational security risks are the primary threats. It is necessary to fight against those states which may be hijacked by terrorists or which live in symbiosis with them. Somalia could be an example of the former, Afghanistan of the latter.

If NATO may well be threatened from (and not by) countries, which are inherently weak, unable to fully control their territory or, eventually, their statehood tends to move from fragile to failing or failed, it reconfirms the policy of the Alliance that conflict management and support for post-conflict recovery are essential elements of guaranteeing security of the allies and the broader community of democracies. That has resulted in the reconfirmation of two major trends in NATO policy: It has contributed to the further extension of the activity of NATO beyond collective defence to collective security, further eroding the boundaries between the two. It has also contributed to the confirmation of the thinking of NATO that the security of the North Atlantic area in the era of globalization cannot be confined geographically to the

4 During the Kosovo operation of 1999 some members of the Russian security establishment spoke about the 'loss of NATO's innocence', i.e. the vanishing of the moral superiority of the West.

territory of the member states, not even to Europe more broadly.

There was a full consensus in NATO and in the international community generally that Afghanistan carried the danger of the proliferation of terrorism unless the regime would change in that country. That's how Afghanistan not much after the September 2001 terrorist attacks has become the shared responsibility of NATO and of like-minded countries. It has to be emphasized, however, that not every member of NATO participated in the operation that resulted in the removal of the Taliban government, and it was not an operation of the Alliance. ISAF, a NATO operation only started later. In light of the preceding high intensity operation it would be difficult to regard it as a collective defence action although imagination may help get beyond it.

The fact that terrorism has been the highest ranked shared threat of the Alliance for a decade has challenged the frontiers of collective defence. The Alliance faced a delicate choice: It could stay with a narrow definition, i.e. focus on a classical interstate challenge against a member state's territory and due to the minimum likelihood of such a scenario lose its residual relevance. Or it could adapt to the strategic change flexibly, reflect actively on the changed strategic situation and regain some of its relevance. It is clear the Alliance practically had no choice. Moreover the choice was made long before 9/11. According to this author's assessment it happened when NATO refocused its attention to security threats ('of what?') and no longer had a state-identified threat perception ('by whom?'). Since then in a cautious and reactive manner the Alliance has been reacting to emerging security concerns. It has done so irrespective of whether the foundations of the Alliance have supported it or not.

As the policy of NATO has reflected upon and reacted to the emergence of new threats and risks, terrorism and organized crime could not remain the only transnational phenomena. When Estonia faced a cyber security challenge the Alliance demonstrated political solidarity and also established a small cyber security centre in the country, strengthening key Alliance information systems against cyber attacks. NATO declared, and in light of the increasingly frequent cyber attacks rightly and in time:

> We have recently adopted a Policy on Cyber Defence, and are developing the structures and authorities to carry it out. Our Policy on Cyber Defence emphasizes the need for NATO and nations to protect key information systems in accordance with their respective responsibilities; share best practices; and provide a capability to assist Allied nations, upon request, to counter a cyber attack (para. 47).

As energy security has emerged on the agenda for many NATO members the organization was also pulled into taking a position on it. Certainly, it was a divisive matter as member states were affected differently by hydrocarbon dependence. Hence, understandably the text agreed upon had to remain ambiguous and programmatic. It promised the

> formation and intelligence fusion and sharing; projecting stability; advancing international and regional cooperation; supporting consequence management; and supporting the protection of critical energy infrastructure (para. 48).

It certainly presents a problem for the Alliance that these new risks or threats although they do not qualify as armed attack, still they require reaction from NATO: "attacks against computer networks (cyber attacks), the release of hazardous material or the cut-off of energy supplies can hardly be seen as armed attacks but we still require solidarity and common action" (Kamp 2009). This fact notwithstanding, various circles ranging from U.S. Senators to the NATO Council have contemplated how solidarity could extend to such contingencies, which are definitely more likely than a classical article 5 based scenario.

7.3 What Would Collective Defence Mean for NATO?

The legal foundations of NATO are extremely solid. The basis of the Atlantic Alliance is the Washington Treaty. In article 5 the parties agreed

> ... that an armed attack against one or more of them in Europe or North America shall be considered an attack against them all and consequently they agree that, if such an armed attack occurs, each of them, in exercise of the right of individual or collective self-defence recognized by Article 51 of the Charter of the United Nations, will assist the Party or Parties so attacked by taking forthwith, individually and in concert with the other Parties, such action as it deems necessary, including the use of armed force, to restore and maintain the security of the North Atlantic area.[5]

Since the inception of NATO this article has been the core commitment enshrined in the Treaty. When the

5 See: "The North Atlantic Treaty, Washington D.C. – 4 April 1949", at: <http://www.nato.int/cps/en/natolive/official_texts_17120.htm>.

Treaty was drafted and agreed the 12 signatories had different preferences. For most West Europeans which faced a determined adversary victorious in World War II with huge conventional armed forces and a large area of forward deployment, collective defence, including the involvement of the United States in European security was the most important. For the USA it was much more article 2 of the Treaty that spoke about the objective of strengthening free institutions, by bringing about a better understanding of the principles upon which these institutions are founded that mattered. This could mean the consolidation of democracy in Europe for the coming historical era. Last, but not least, article 4 with its soft commitment to initiate consultation by any one member state could also be important as it could guarantee that no member of the Alliance would remain isolated with its security concern, founded or not.

If one takes a close look at article 5 the following can be stated: The article is a clear expression of the core of an alliance based on "collective self-defence" (Art. 51 of the UN Charter). The commitment, taken somewhat hesitantly by the USA at the time, is confined geographically. It extends to Europe and North America only. This was due primarily to the territories that first of all the UK and France controlled overseas as their colonies. It was also an important constraint that collective defence could only be invoked when an "armed attack" occurs. As this part of article 5 in fact refers back to the same expression in the UN Charter there is little room left for interpretation. That formulation excludes anticipatory self-defence or pre-emption as in those cases no armed attack actually occurs. International lawyers who pay no attention to strategic considerations would probably go down that road (Haines 2009; Cassesse 1999; Simma 1999; Frowein 1999). This could make this essential treaty article detached from reality and strategically irrelevant (Daalder 1999).

The most important ambiguity of article 5, however, is the definition of action that may follow. First of all it is necessary to identify that an "armed attack" has actually occurred. The states parties may conclude that it is impossible to define, whether the non-NATO member state has launched the armed attack or the member state itself. This could serve as ground for inaction. If NATO concludes that an external armed attack has actually occurred the Alliance is still not obliged to defend the member state. It may take such action as the Alliance and the member states deem necessary. This can range from virtual inactivity to forceful collective defence using massive force. It is at the discretion of NATO members to decide what follows. This may not be particularly reassuring for a member state that is under the impression of its facing a classical interstate security challenge. Even if a state under article 5 of the Washington Treaty does not get massive military support on the basis of collective defence it would not be left alone. It could share its security concerns with all the other member states under article 4. This may matter more than one could imagine on the basis of the text. Namely, if the concerns of the member state present a *prima facie* case for collective defence it would be difficult for others to ignore it without severely undermining the core commitment[6] inherent in NATO.

This may very well be behind the impression that NATO is hesitant, if not outright reluctant, to offer membership to countries with outstanding individual defence deficit that may end up becoming a collective defence problem. On the one hand this is fully understandable as NATO should not, irresponsibly, import security problems. But on the other hand it has to be taken into consideration that it is thus possible for states outside the Alliance to block the advancement of countries which aspire for NATO membership. They have to demonstrate resolve to oppose accession and present a picture whereby the aspirant country is pulled into a security quagmire. It requires extreme care from the Alliance on how to react to this. Whether to put the advancement of the aspirant on halt and thus in fact provide a veto right upon its choice by a third party or to continue with the approach to membership and import a potential collective defence problem. Although several factors make the matter far more complex this lies at the heart of the accession aspiration of Georgia and the opposition of Russia to it.

It may be found reassuring that no NATO member state has been attacked by a non-member since the inception of NATO.[7] During the Cold War this

6 In 1995 when Hungary was an aspirant for NATO membership this author asked a ranking U.S. official why there was so much fuss about Article 5 when the obligation of the member states to massively back the country claiming collective defence. His answer was succint: "Because we mean it."

7 On the contrary, a NATO member state has already attacked a non-member when Turkey launched an attack against Cyprus. Two NATO members, Greece and Turkey had a long series of lower intensity military exchanges. A non-NATO member, Libya, attacked Italy when it launched a rocket on the Italian island of Lampedusa that actually missed its target.

could have been due to the success of collective deterrence symbolized by the existence of NATO. Since the end of the East-West conflict, it cannot be attributed to that. Either one remains agnostic and concludes it is not known why there was no large-scale military confrontation in Europe or one realizes that intentions have been absent to use force in Europe to achieving political goals. Therefore article 5 of the Washington Treaty never had to be used during the Cold War. Deterrence worked and prevented the organization from facing the test of what it would mean in practice.

Article 5 of the Washington Treaty was invoked only once since the end of the East-West conflict. On 12 September 2001, the day after the deadly terrorist attack on the USA.

> The Council agreed that if it is determined that this attack was directed from abroad against the United States, it shall be regarded as an action covered by Article 5 of the Washington Treaty, which states that an armed attack against one or more of the Allies in Europe or North America shall be considered an attack against them all.[8]

It is clear that the day after the event it was difficult for the North Atlantic Council to draw the conclusion on legal grounds that the case fell under article 5 of the Washington Treaty. It was the explicit reason to which reference was actually made in the statement whether the case had an international element at all or it was fully domestic, confined to the USA. There the conclusion could be drawn easily that the matter was partly international. Some perpetrators lived in Europe and used their European residence to prepare the terrorist act. There was, however, a tacit issue as well. Namely, whether the terrorist attack could be regarded as an armed attack at all. In the end, the terrorists did not use arms; they used civilian aircraft and flew them into buildings. Irrespective of the legal ambiguity it is clear that not demonstrating solidarity with the victim of the attack, the USA could have given a very strange political signal. The United States' NATO allies with the statement expressed their readiness to "stand ready to provide the assistance that may be required as a consequence of these acts of barbarism".[9] NATO demonstrated political solidarity with the USA during those historical days and gave credit to collective defence even though the USA needed very little actual military support.

When during the period that led to operation 'Iraqi Freedom' Turkey wanted to get extra reassurance for contributing to the operation as a major springboard, it did not get a satisfying counter-offer to its request. Namely, Turkey basically wanted to get a guarantee that would have made article 5 of the Washington Treaty automatically applicable to mean defending Turkey in turn for an eventual Iraqi countermeasure for its helping the Iraq operation of the USA and its allies.

There were several problems with this proposition. First, this operation was not carried out by the Alliance. Second, it would have given a blank cheque to Turkey and could have been regarded as a very shaky precedent. For these reasons Turkey had to live with less (Gilmore 2003) and NATO could retain the ambiguity that has surrounded the content of article 5.

7.4 Dilemmas of a New Strategic Concept

The Atlantic Alliance decided in April 2009 to prepare and publish a new strategic concept. This will be the third post-Cold War concept of NATO. In light of the changes in international security since the adoption of the previous Strategic Concept in 1999 there is no reason to argue for the need of a new one. The Alliance invented a framework in which the preparation of the text will be somewhat non-traditional. Rather than letting the member states have a classical politico-diplomatic drafting exercise, member states have set up a three stage process where a 12-member expert group headed by former U.S. Secretary of State Madeleine Albright, the NATO Secretary-General Anders Fogh Rasmussen, and the member states equally play a role (IISS 2009). It seems the process is geared to avoid that member states, in an endless drafting exercise, would ground the new Strategic Concept and arrive at the lowest common denominator. Bearing in mind the objective difference in the position and interests of the member states and their preferences this may well be the best solution. However, member states have already noticed it and started to produce national position papers where they have outlined the minimum content acceptable for them.

The expert group tried its best to find an adequate balance between the Scylla and the Charybdis of different national interests of NATO's 28 member states and the strong opinion of the NATO secretary gen-

8 See: "Statement by the North Atlantic Council", Press Release (2001)124, 12 September 2001; at: <http://www.nato.int/docu/pr/2001/p01-124e.htm>.

9 See: "Statement by the North Atlantic Council", Press Release (2001)124, 12 September 2001.

eral in its analysis (NATO 2010). However, this could only partially be successful. On the one hand, the group of experts found it crucial to reaffirm "NATO's Core Commitment: Collective Defence" while they also broadened the scope to extend the protection to unconventional threats (NATO 2020: 8–9) arguing

> the Alliance must maintain the ability to deter and defend member states against any threat of aggression. This commitment ... should be reaffirmed in unmistakable terms. At the same time, NATO ... must recognise that the potential sources of Article 5 threats have broadened and now include dangers that could arise either inside or outside the Euro-Atlantic region" (NATO 2010: 19).

This approach may balance the matters important to varying extent for different members. Furthermore, it advocated establishing "Guidelines for Operations outside Alliance Borders" generally, while separating, and thus emphasizing the crucial importance of one operation outside the territory of the Alliance: Afghanistan (NATO 2020: 9). It remains to be seen in what form these delicate balances will be preserved in the forthcoming Strategic Concept of 2010. The recommendations of the Group of Experts have indicated a realistic approach.

All the current ambiguities of NATO's orientation ('against whom' vs. 'against what', 'global' vs. 'regional', 'collective defence' vs. other tasks of the Alliance) have appeared in the national position papers. A kind of compromise will be achieved certainly at the NATO Lisbon Summit of November 2010. It will require finding the right balance between states, which represent one view or the other in the three matters outlined above as a minimum.

For the purposes of this chapter it will be the most delicate to find the balance between non-article 5 activities of the Alliance, which dominate the agenda ranging from stabilization operations, like in Afghanistan, to broader conflict management tasks on the one hand and the reconfirmation of article 5 guarantees on the other. For Estonia, Latvia and Lithuania, and maybe also for Poland, a strong and credible verbal reassurance of article 5 is essential. This is particularly the case when Russia has put (the continuation of) NATO enlargement high among the threats in its military doctrine.[10]

On the other hand, those countries, first of all the United States, which sacrifice the most in international operations should also gain reassurance that the Alliance may add to global international security beyond political reassurance. This requires some commitment from the other member states to "include the narrowing of the investment and capabilities gap among the Allies, improving the usability, interoperability, deployability and sustainability of the Allied forces, conducting the missions in Afghanistan, the Balkans, and Iraq" (Necas/Terem/Kelemen 2009).

It is fortunate that article 5 did not have to be invoked more frequently, and thus the Alliance could refocus its attention on other matters and hence in the strategic concept the balance is to be established between the 'alliance in being' and the 'alliance in doing'.

7.5 Conclusions

NATO has never been a classical defence alliance. During the Cold War it still more resembled one than it has since 1990. Since then it has been continuously adapting to changing circumstances, first and foremost to the globalization of international security both functionally and geographically. The move from 'defence against whom?' to 'defence against what?' adequately reflecting strategic uncertainty and ambiguity logically led to the erosion of boundaries of traditional security. The most important change that stems from it is the blurring of collective defence and collective security on the Alliance's agenda. NATO has become an institution with a broad security agenda ranging from defence against terrorism to conflict management to guaranteeing cyber security and contributing to energy security. It is difficult to imagine how the Alliance could deliver on the many often ambiguous promises in spite of the vague formulation. The other broadening of Alliance activity is geographical from the territory of the member states to conflict management in Europe (former Yugoslavia) and then more broadly. These changes have eroded the strategic cohesion once shared in the Alliance.

The main dilemma that has resulted from the changes mentioned above could not be resolved. In an environment where the strategic interests of the

10 The text of the Russian military doctrine formulates it in a complex manner. It mentions "the attribution of global function to the force potential of the *North Atlantic Alliance* (NATO) in violation of international law, the approach of the military infrastructure of NATO member-states to the borders of the Russian Federation, including through enlargement" (Voyennaya Doktrina Rossiyskoy Federatsii 5 fevralya 2010-ogo goda" [Military Doctrine of the Russian Federation of 5 February 2010]: point 8, para. a; at: <http://www.kremlin.ru/ref_notes/461>).

allies are not held together by sharing the existential threat where they are by far not identical and where their security perceptions vary, the alliance is held together by constantly seeking and finding compromise. The fact that one member of the Alliance has preponderance may also help overcome the differences. Consequently, it is a matter of constant balancing first and foremost in NATO documents and often also in reality that has been necessary to maintain the balance of interests. This can be overshadowed by diplomacy as well as by the prominent role and leadership of one member state that helps find reconciliation in the Alliance; however, it cannot be taken off the agenda. Short of a fundamental change in European security the muddling through will have to continue.

8 European Responses to Security Threats in the Mediterranean in the Early 21st Century

Eduard Soler i Lecha

8.1 Introduction[1]

According to the *European Security Strategy* (ESS 2003) European security cannot be tackled without considering the security of neighbouring countries (chap. 6 by Bailes). Threats to the security in countries in the Southern and Eastern Mediterranean can rapidly become security threats for the *European Union* (EU) as a whole, and can particularly affect countries of Southern Europe. In this context, the Euro-Mediterranean area has been described as a single security complex (Biscop 2003: 191) or as a system of security complexes (Bremberg Heijl 2007: 2). Similar considerations were also made from a sub-regional perspective for the Western Mediterranean (Haddadi 1999). Moving beyond this debate, this chapter attempts to highlight the threats affecting the Euro-Mediterranean area, or some countries that comprise it. It examines to what extent the European Union has succeeded in providing sufficient cooperation mechanisms for improving security conditions in the region.

While there are numerous security doctrines in security studies, this chapter uses the 'human security doctrine'.[2] It emphasizes threats undermining the security of citizens on both rims of the Mediterranean. Among various definitions of the human security concept (UNDP 1994), the 'freedom from fear' approach will be used here. That is, a narrower concept which focuses on threats to physical security of individuals.[3] However, the chapter acknowledges that a wider definition embracing socio-economic needs ('freedom from want') could offer relevant insights. It also takes threats to state security (e.g. classical territorial disputes) into account as long as they affect, directly or indirectly, the personal security of citizens.

If states' security would be the exclusive focus of this chapter, an ideal scenario for the EU and Mediterranean countries would be to agree on a collective security system to eradicate violence or the threat of violence among them and to defend collectively the interests of each state. This ideal scenario would turn the Euro-Mediterranean area into a security community (Deutsch/Burrell/Kann/Lee/Lichterman/Lindgren/Loewenheim/Van Wagenen 1957). From a human security approach the concerns of citizens' security is crucial. A collective security framework should be accompanied by measures guaranteeing the respect for the individual and for fundamental freedoms as well as fighting against crime.

How can these goals be reached? Which stages are needed for this framework? Is the Barcelona Process (and since 2008 the Union for the Mediterranean) a suitable framework for the implementation of these goals, or should other cooperation frameworks be adopted? This chapter is divided into five different sections. The first part outlines the discussion on the existence of old and new threats (8.2), the second differentiates between intra-states and domestic threats in the region (8.3), the third identifies some of the most relevant threats for the physical integrity of citizens (8.4), the fourth deals with the existent cooperation initiatives relevant to the security realm (8.5) and in the conclusion, this chapter outlines alternatives that may lead in the medium term to a situation where the citizens of the Mediterranean, together with all Europeans, will live in security.

The Mediterranean is one of the greatest challenge for Europe's security, besides being a region where the EU must become more involved in security

1 The author thanks Fadela Hilali, assistant of the Mediterranean Programme at CIDOB Foundation, as well as for the comments of the three anonymous reviewers which improved this text.

2 The report: *A Human Security Doctrine for Europe, The Barcelona Report of the Study Group on Europe's Security Capabilities* applied this doctrine to the European external and its security policy.

3 For a similar focus see Serra Serra (2008, 2009); Chourou (2005, 2009); Soler i Lecha (2007); Morillas and Soler i Lecha (2006).

issues (Serra Serra 2008: 24; 2009). This is a key task for the EU in the 21st century.

8.2 The Mediterranean Under Threat

In security debates 'new' and 'old' wars (Kaldor 1999) are distinguished, as are new and old victims or new and old threats. On Mediterranean security, rather than speaking of new and old phenomena, these phenomena have attracted more attention over time and their effects have always been visible. Many of the 'new' threats in the early 21st century – e.g. natural disasters or new forms of terrorism – have affected the Mediterranean for many years. However, now their effects are more acute and more attention is being paid to them.

Regardless of being 'old' or 'new', 'hard' or 'soft', 'classic' or 'modern', some of these threats produce a climate of insecurity that Mediterranean states and citizens experience now. These threats are: 1) regional conflicts, including situations of occupation and the perceived threat of attack by neighbouring countries or their allies; 2) domestic political conflicts that may lead to outbreaks of violence; 3) international terrorist acts; 4) threats to personal safety deriving from various criminal groups or other threats that are combated ineffectively by the security forces; 5) threats to personal safety from the abuse of their own citizens by governments and police forces; and (6) effects of natural disasters.

These threats cannot be viewed as isolated phenomena, as many of them are interlinked. There are links between international terrorism, persistent regional conflicts, and organized crime networks. Some states notoriously oppose measures to foster democracy or human rights, and they justify this stance with a need to safeguard their states from other states or terrorist actions. Finally, the effects of natural disasters are much greater where the state lacks preventive mechanisms, or sufficient ability to react to such emergencies.

8.3 Regional and Internal Conflicts

The key regional conflict is the Arab-Israeli conflict that is a system of conflicts comprising the occupation of the Palestine Territories, the occupation of the Golan Heights, and the repercussions of these acts on relations between Syria and Israel besides the tense relations between Israel and Lebanon, which erupted in armed conflicts. In all these cases, escalation or even maintenance of conflict do not only affect states' security but harms the daily life and the survival of this region's citizens. Its geographical range has widened due to the links between Syria, Hezbollah, and Hamas. Iran has become a key actor and the declarations by certain Iranian leaders seriously threatening Israel and the fears over its nuclear programme have widened the scope of conflict and its possible consequences for regional stability.

Besides these Arab-Israeli conflicts, the Mediterranean has experienced other confrontations among neighbouring states, although the possibility of an escalation into violence varies. In the Eastern Mediterranean, Greece and Turkey still have open disputes despite the *rapprochement* since 1999. For instance, the behaviour of the countries' armed forces (e.g. aerial chases among aircraft) illustrate that relations are not yet normal. The partition of Cyprus and the deployment of Turkish troops in the north show that there is much work ahead (Pfetsch 2003).

The destabilization potential of the ongoing United States occupation of Iraq is significant. The situation in Iraqi Kurdistan and Turkey's reaction may unleash spiralling tensions in the Middle East. The Western Balkans is also vulnerable in security terms. The future of Kosovo, Serbia's nationalism, and the delicate balances in Macedonia, point to an uncertain future.

In the Western Mediterranean, the situation is more stable, being completely stable in the North but less so in the South. The still unresolved Western Sahara issue, where sovereignty is disputed between Morocco and the Polisario Front, has ramifications throughout the region. Morocco's involvement in the conflict implies considerable resources are allocated for the military instead of being used for the basic needs of its population.[4] For the past three decades, the Saharaui people have been forced to live in terrible conditions in refugee camps. For the Maghreb, this conflict prevents progress towards integration beyond the Union of the Arab Maghreb, a formal structure with limited leverage.

Relations between Spain and Morocco worsened in 2002 with the confrontation over the sovereignty of

4 According to *El País*, Morocco's defence budget in 2009 will almost double, reaching 34,625 millions dirhams (3.2 billion €), This represents 16 per cent of the state's budget and 4 per cent of its GDP; at: <http://www.elpais.com/articulo/internacional/Marruecos/duplica/2009/presupuesto/militar/elpepuint/20081214elpepuint_9/Tes> (23 December 2008).

the tiny island of Perejil (Parsley) in the Strait of Gibraltar. This resulted in the occupation of this tiny patch of land by both countries' security forces (Cembrero 2006; Gillespie 2006; Bremberg Heijl 2007). The incident showed armed confrontation can arise even between countries from the north and south of the Mediterranean. Since 2002, great efforts were made in Spanish-Moroccan relations to avoid such situations.

Besides these conflicts between two or more states, there are internal conflicts that have threatened to spread into neighbouring countries. Among them is Algeria's bloody undeclared civil war in the 1990's, for which definitive figures of the dead, disappeared, and otherwise affected people were never released. This episode shows how these threats to security interact, as the Algerian government referred to a 'terrorist threat' to justify violations against fundamental freedoms.

The danger of confrontation in Lebanon is still urgent. The growing polarization of Lebanese society, the use of terrorist methods to eliminate political rivals, the persistent fracturing of communities, and the existence of new dividing lines all represent bad omens. Equally dramatic are the divisions within the Palestine Territories after the collapse of the government of national unity that was formed in February 2007, when tensions increased between supporters of Hamas and Fatah and both territories became virtually separated into two political entities: 'Hamastan' in Gaza and 'Fathia' in the West Bank.

This case clearly demonstrates the extent to which the action and inaction of international actors, such as the European Union and the United States, can inflame such conflicts. Following the victory of Hamas, both the EU and USA marginalized this movement instead of backing Fatah and the Presidency of the Palestine National Authority. The international community ignored the fact that an agreement among all parties is needed for peace in Palestine and for a lasting peace agreement between Palestine and Israel.

8.4 New or Old Threats?

One may categorize those linked to international terrorism or the consequences of climate change as 'new threats', although the violation of fundamental political freedoms and the access to basic resources for survival are phenomena that have a long history in the region. Beyond the debate over whether these threats are 'new' or 'old', there is a growing fear from a new kind of international terrorism that justifies its actions using religious pretexts. Al-Qaeda has become one of the highest profile threats throughout the world, specifically in the Mediterranean, that furthered regional cooperation (Reinares 2005; Bicchi/Martin 2006). After the 9/11 attacks, there were many attacks in this region, 14 German tourists died in Djerba (Tunisia) in 2002, 46 people died in a suicide bombing in Casablanca in May 2003, 57 civilians died in Istanbul from a similar attack in November 2003, while on 11 March 2004 Madrid experienced the worst bombing in its history with a death toll of 191 people. In 2005, 60 people died in Amman from a similar attack.

There is a growing number of terrorist groups in the Maghreb (Al-Qaeda in the Islamic Maghreb) which claim to be the heir of the *Salafist Group for Preaching and Combat* (GSPC). In 2007, Algeria was particularly affected by these terrorist groups, which caused fears of a return of the nightmare of the 1990's. Furthermore, other countries that previously succeeded in eradicating this phenomenon (Mauritania, Libya) became a theatre of operations for these violent movements (Echeverría 2007; Steinberg/Werenfels 2007). There were jihadist threats in the Sahel and growing fears that the porous borders in the Sahara may result in more terrorist threats in North Africa (Gregorian 2007).

Without minimizing the importance of international terrorism, other phenomena threaten personal safety, such as criminal activities and transnational organized crime. Trafficking in arms, people, and drugs generates insecurity and weakens state structures. Mafia-type structures in certain areas have become a joint concern in both North and South. There are links between such phenomena and terrorist activities.

Some arses in the Southern Mediterranean are threatened by anti-personnel mines (Sánchez Mateos 2000), some dating back to the Second World War (Kadry Said 2003). Algeria, Libya, and Egypt are most affected by this problem and have called on the EU and its members for assistance in mine clearing, but so far, their pleas were not successful.[5]

International terrorism has not only diverted attention from these problems, it has also been used by some regimes to justify human rights violations in their countries. To increase the efficiency in fighting problems (e.g. terrorism) that affect both, violations

5 The Barcelona Euro-Mediterranean Summit (2005) agreed that "the EU is also prepared to examine appropriate technical assistance in the field of clearing areas affected by land mines."

of fundamental freedoms and human rights were often ignored, what contributed to a perpetuation of authoritarian regimes in the Southern and Eastern Mediterranean. While the EU and its members have continually debated whether to promote stability or democratic reform, the threat of terrorism has strengthened the arguments of those championing the former. In addition, since 11 September migration flows have increasingly been securitized (Joffè 2008).

The effects of natural disasters pose another threat to the Mediterranean (Brauch 2003c) due to its climate and geography. The region frequently experiences forest fires and flooding, and is also regularly hit by oil spills and slicks. Several Mediterranean countries, including Algeria, Morocco, Greece and Turkey, are also at severe risk of earthquakes. Desertification affects the lives of the region's inhabitants (Nasr 2003; Brauch/Oswald Spring 2009).

In the Mediterranean many threats converge, some clearly affecting the security of states and indirectly hamper citizen's security, while others solely affect the security of citizens and do not compromise state's survival. Similarly, some threats only affect countries in the Southern and Eastern Mediterranean, while others exist throughout the region (Brauch 2001, 2003). The Mediterranean is highly vulnerable to multiple security challenges that require suitable responses that must be sufficiently flexible to deal with the range of threats described above, and should be adaptable to the particular circumstances of each place.

8.5 Catalogue of Cooperation Initiatives

There are many cooperation frameworks in the Mediterranean basin to turn the region into an area of peace and security and to guarantee that its states embrace cooperation where the EU and its member states have played a fundamental role.

8.5.1 Barcelona Process and Union for the Mediterranean

The Barcelona Process (since 1995) emerged from the Italian-Spanish proposal for a *Conference on Security and Cooperation in the Mediterranean* (CSCM). It is structured along three baskets (political, economic and cultural).[6] At the first Euro-Mediterranean conference, the Barcelona Declaration (1995) was approved with the goal to turn the Mediterranean into an area of peace and stability (Brauch/Marquina/Biad 2000). Fourteen years later, the Euro-Mediterranean cooperation was not promising in the security realm. Rather, the old threats persist and are often reinforced, while new ones have appeared.

During the first years various efforts were made to develop confidence building measures, and work on a Euro-Mediterranean Charter for Peace and Stability started (Aliboni 1999). After several years of negotiations efforts failed to approve it during the French EU presidency in the year 2000. This document would have been an important step towards a concept of shared security, and for turning the Mediterranean into 'a security community'. After the Al-Aqsa Intifada in 2000, diplomatic efforts linked with security have failed.

However, in three areas progress was made: a) the fight against terrorism, b) civil protection, and c) bilateral cooperation in the framework of the *European Security and Defence Policy* (ESDP). During the Euro-Mediterranean summit (2005) a 'code of conduct for fighting terrorism' was adopted,[7] in an area that had provoked most controversy since the inception of the Barcelona Process (Barbé 1996). There were strong disagreements on how to define a terrorist action (Bicchi/Martin 2006). The code lacks a definition of terrorism and thus made its practical application impossible.[8] The only agreement the parties reached was to complete the 'General Convention on International Terrorism' before the 60th session of the United Nations General Assembly in 2005 that contains a legal definition of terrorist acts.[9]

Some observers (especially Spanish diplomats) insisted that the code's added value was not the definition but other aspects of the text. The code expresses a unanimous condemnation of terrorism in all its forms and manifestations, as well as a determination

6 Since 2005 it incorporated a Justice and Human Affairs basket which mainly dealt with migration issues.

7 "Euro-Mediterranean Code of Conduct on Countering Terrorism", Brussels, 28 November 2005, press release 328 (15075/05).

8 Jesús Núñez: "Las Carencias de la Cumbre de Barcelona" in: *El Mundo*, 1 December, 2005, claimed that "the failure to agree on a definition of terrorism and the general vagueness of the document, which is stuffed with well-intentioned declarations that are open to multiple interpretations and calls for cooperation to be voluntary, hardly manages to conceal its ineffectiveness."

9 As is commonly known, a wide gulf exists between Israel's standpoint and those of Lebanon and Syria that argue for a differentiation between terrorist acts and acts of resistance to occupation.

to eradicate it and to fight all those supporting it. The document contains a commitment to refuse political asylum to terrorists, condemns terrorism, and to not associate terrorism with any religion or culture. Equally important is the document emphasizing that cooperation in this field must not be carried out at the expense of citizens' fundamental rights, and that victims of terrorist actions should be given priority attention (Soler i Lecha, 2007).

On civil protection advances have been made here in a discreet but effective manner. These activities emerged from an initiative launched by Egypt and Italy in 1996 for cooperation on the effects of natural disasters (Courela 2004). Subsequently, Algeria, France, the European Commission, and the Council joined this initiative, known as the Bridge project.[10] The next step was to turn it into a regional framework with a Euro-Mediterranean scope, or to move towards a Euro-Mediterranean system of civil protection.[11]

Such a system is entirely in harmony with the Work Programme adopted at the Barcelona summit in 2005 for the following five years. This document specified that the signatories would collaborate in "crisis management and activities as well as in the areas of civil protection and the prevention of natural disasters."[12] At a meeting in Porto on 24 October 2007, the chief executives for civil protection of the EuroMed programme and their European counterparts agreed on steps in this direction with the aim to develop such a fully-integrated Euro-Mediterranean system. The Euro-Mediterranean conference in Lisbon in November 2007 made further progress.[13] But in this specific field the Euro-Mediterranean cooperation faces a major obstacle: the lack of a real EU system on civil protection.

Finally, the third area where some progress has been made is the bilateral cooperation within the ESDP, most particularly with Morocco. This country is attempting to strengthen its ties with the EU, opening up new areas of cooperation between both, including on security. Based on a mutually agreed Advanced Statute, Morocco will be granted a wider role in ESDP mechanisms and missions. Morocco has already participated in the ALTHEA mission in Bosnia-Herzegovina, and was the first country to designate a contact point in the Council. Morocco is also interested in strengthening the cooperation with the *Political and Security Committee* (PSC).

During the French EU Presidency on 13 July 2008 a "Union for the Mediterranean" was established. This proposal, which initially envisaged the participation of all countries bordering the Mediterranean, was enlarged to include all EU members. This new body formally adheres to the Barcelona *acquis*, launches new multilateral projects, and is to raise private funds and, above all, it implies significant changes in the institutional dimension of the process (including a co-presidency, secretariat). However, in the initial steps of this new initiative, security cooperation was rather marginal, except for the proposal to foster greater cooperation on civil protection (Bremberg/Driss/Horst/Soler i Lecha/Werenfels 2009). Thus, despite the changes introduced in 2008, continuity prevails in dealing with security issues in Euro-Mediterranean relations.

8.5.2 European Neighbourhood Policy

The negotiation of Morocco's Advanced Statute coincided with, and was in line with the development of the new *European Neighbourhood Policy* (ENP) that was initially devised for East European countries, but later extended to all Mediterranean countries. Being strictly bilateral, the ENP intends to promote reforms more effectively and through specific action plans which, adapted to the needs and capacities of each country, also consider how to offer member countries suitable incentives to carry out these reforms (Johanson-Nogués 2004; Attinà/Rossi, 2004; Del Sarto/Schumacher 2005; Kelley 2006; Danreuther 2006).

A few years after its launch, the ENP shows its weak points. In December 2006 the European Commission declared that the policy needed to be revised, and called for a *Strengthened European Neighbourhood Policy*.[14] The contributions of the ENP in the field of security are very limited, and especially regard-

10 The actions carried out in this project are detailed on: <http://euromed-protection-civile.eu/>

11 "Communication from the Commission to the Council and the European Parliament on the preparation of the Lisbon Euro-Mediterranean Foreign Affairs Conference (5–6 November 2007)", [SEC(2007) 1309], Brussels, 17/10/2007, COM(2007) 598 final, p. 6.

12 *Five-Year Work Programme*, Brussels, 28 November 2005, 15074/05 (Press release 327).

13 The participants supported the setting up of a new stage of the Bridge project, the "Euro-Med Programme of Prevention, Reduction and Management of Natural and Man-made Disasters", for the period 2008–2010.

14 *Communication from the Commission to the Council and the European Parliament on Strengthening the European Neighbourhood Policy*, Brussels, 4 December 2006, COM(2006)726 final.

ing conflict resolution. References to such issues in ENP action plans are rather vague because the EU cannot offer many incentives in this area.[15].

In these action plans, when it comes to security issues, regardless of the usual lack of thoroughness, there is a bias towards European preoccupations: control of borders, fighting organized crime, etc. Concerns that are fundamental for the security of these countries' citizens (prison reform, fighting torture and ill-treatment, reforming security bodies, etc.) are dealt with casually and, in some cases, they are not even included on the agenda.

Due to its tailored approach and sophisticated political conditionality, the ENP should be able to promote political changes in neighbouring countries and thus contribute to the respect for fundamental freedoms and human rights of the citizens of those countries. But in this area the effects of this new policy are still to be proven.

8.5.3 Besides the EU: 5+5 and NATO's Mediterranean Dialogue

Beyond the EU framework, other security cooperation frameworks exist where EU member states and some Mediterranean partners participate. Two examples are the defence initiative 5+5 and NATO's Mediterranean Dialogue. The 5+5 process is an intergovernmental cooperation framework of Western Mediterranean countries, which can be traced back to the early 1980's. Countries participating include Portugal, Spain, France, Italy, Malta, Mauritania, Morocco, Algeria, Tunisia and Libya.

In 2005, a security dimension was added (as a French initiative), and the 5+5 began organizing meetings of defence ministers. This is known as the "5+5 initiative in the area of defence". This framework has an informal nature and a light architecture, and its main areas of action are maritime surveillance, civil protection, and aerial security. Thus, it does not represent a catalogue of ambitious objectives able to guarantee regional security in the short term; instead, it is a modest step forward which, in the medium and long term, could increase trust between the armed forces of the countries concerned (Coustillière 2007).

Meanwhile, NATO's Mediterranean Dialogue is a framework launched in 1994, with the participation of the members of the alliance, Egypt, Israel, Jordan, Mauritania, Morocco and Tunisia and, since 2000, also Algeria. While NATO's interest for the Mediterranean surged after the Cold War, the tragic events of 11 September have helped clarify its functions and objectives (Bin 2002). The aim of this framework is to strengthen political dialogue, fight terrorism, modernize the armed forces, and improve the interoperability between military forces of different countries. In spite of the efforts made by these countries, the initiative's influence was undermined by several factors, including the non-participation of some states in the region, the aversion some states feel towards American policy in the region, and its neglect of conflict resolution.

8.6 Concluding Remarks

So far the balance sheet of all these Euro-Mediterranean initiatives is mixed. On the positive side, there have been political efforts to formulate and reformulate cooperation frameworks that were based on a bottom-up approach to create conditions for greater cooperation in the area of security which, in the medium or long term, could lead to the establishment of a collective security mechanism. A somewhat preferential attention has been given to natural disasters, and as far as terrorism is concerned, Euro-Mediterranean partners have started to pay more attention to the victims of such attacks.

On the negative side, the EU and the Euro-Mediterranean countries in general have failed to tackle regional conflicts. This has paralysed other spheres of cooperation. This strategy is equals of the Arabic saying of "unrolling the carpets before having built the mosque" (Chourou 2001: 64). Unless these conflicts are resolved, it will be very hard to achieve positive results in any dialogue on security issues.

Some recent EU documents seem to reflect this criticism. The European Security Strategy stipulates that "the resolution of the Arab-Israeli conflict is a strategic priority for Europe, because without it, there is little chance of solving other problems in the Near East. The European Union should carry on intervening, and be prepared to promise resources until the conflict is resolved" (ESS 2003). The document "A Strategic Partnership with the Mediterranean and the Middle East" also stresses that the resolution of this conflict is a strategic priority, and that "it is obvious that an area of peace, prosperity and progress cannot be attained until a lasting resolution to the conflict is achieved."[16]

This remark may be extended to a lacking consideration of inter-state conflicts in cooperation frameworks. A climate of conflict has an impact on democ-

15 Fraser Cameron and Rosa Balfour (2006) have made specific proposals for improvement in this field.

ratization processes and on the respect for human rights (Barbé 1999: 220). Specifically in these two areas progress has been the weakest. Therefore, human rights violations and authoritarian regimes are a blot on the integrity of the Euro-Mediterranen project. And what is even more serious, as a consequence of Europe's reaction to the Hamas victory in the Palestinian elections in 2006, the EU has lost much credibility among democrats in the Arab world. The dilemma between promoting democracy and the need to maintain stability is still an issue, especially when it comes to dealing with terrorism.

Five conclusions may be drawn. *First*, given the many cooperation initiatives and potential overlaps, there must be a rationalization and more efficient distribution of resources. *Second*, although some progress has been made, the measures undertaken in the different cooperation and dialogue initiatives had a limited impact on the improvement of security conditions for states and citizens of the Mediterranean. *Third*, the resolution of regional and domestic conflicts and the promotion of fundamental freedoms (personal safety, political freedom, etc.) are still unresolved in Euro-Mediterranean cooperation. *Fourth*, a more comprehensive view of security requires that the fight against specific threats does not create additional harmful effects which could strengthen other threats. Thus, it must be highlighted that the fight against terrorism and organized crime should not be carried out at the expense of citizens' freedom and rights. Consequently, cooperation must be continued by reinforcing current instruments and incorporating new mechanisms which pay further attention to the security needs of citizens. And *finally*, the EU and its member states have a particular responsibility in this region, and – given their geographical proximity and the strength of their links with all Mediterranean countries – the EU should play a more important role. But in many fields, it has to seek the support of third countries such as the United States, Russia and China or, at least, guarantee that the actions of these countries will not counter or weaken European efforts.

9 Inside/Outside: Turkey's Security Dilemmas and Priorities in the Early 21st Century

Mustafa Aydin and Asli Toksabay Esen

9.1 Introduction

Turkey has undergone major transformations and a number of ups and downs during the past two decades. At the end of the Cold War, Turkey was an outdated flank country, whose 'strategic value' to its Western allies was at best diminished. Yet, its location suddenly opened up new windows of opportunity to exploit in the newly emerging world (dis)order, although these, more often than not, also entailed risks and challenges. Turkey's economic, social, and political transformations during the late 1980's from a mixed economy to a more liberal approach, from a military tutelage to a multi party representation once again, and from an intensely secluded country to one that is ever increasingly interconnected with the world at large, had prompted it to try and play an influential role in its neighbourhood (Aydin 2003a). Thus, in the post-Cold War era, Turkey launched a number of new initiatives in the Caucasus, Central Asia, Middle East, the Balkans, and the Black Sea; areas where the Turkish government believed that Turkey would have inbuilt comparative advantages because of its historical, ethnic, linguistic, and political affinities with local populations. Yet, most of the 1990's saw a Turkey that 'wasted' opportunities through contradicting initiatives, overblown expectations, misused resources, inefficient coalition governments, infighting between ethnic, religious, and political cleavages, political mismanagement, and coordination weaknesses at the top of the state, etc. (Barkey/Taspinar 2006: 2). Thus, the end of the 1990's found Turkey woeful for its diminished strategic significance of the Cold War *temps perdus*, resentful of its alienation from successive waves of European Union enlargement, and bitter for failing to achieve the ambitious targets it had set for itself at the end of the Cold War.

Yet today, Turkey is a country negotiating for accession to the European Union, an emerging regional power, a member of the only surviving global military alliance, an active participant in international peacekeeping or peacemaking efforts, a mediator in its region, an aspiring energy hub, and an elected member of the UN Security Council for 2009–10. All these do not preclude the fact that Turkey today continues to face several challenges, both in domestic politics and regarding its regional and global role. As domestic cleavages persist on both ethnic and religious grounds, thus the continuing salience of perennial identity discussion, the EU negotiation process has come close to stalling (ICG 2007: 32). Turkey faces dilemmas in defining a position for itself in the post-9/11 world before it could even put its post-Cold War role into perspective. The US intervention in Iraq and pressure on Iran and Syria, the re-emergence of Russia with a renewed claim to international supremacy, and a confused EU about the role it should play in the wider Eurasia all contribute to the delicacy of the various balances that Turkey has to maintain in terms of its regional and global alliances.

While the world's geopolitical balances are constantly changing, Turkey's regional and international security concerns have become somewhat less visible in the domestic domain in recent years. Almost overwhelmed by the unceasing series of political crises and power struggles within its governing elite, the public in general, and to a large extent the intelligentsia, have lost their appetite for a discussion on international issues. Although this apathy stems primarily from the salience of domestic political complexities, the EU-fatigue and the dominant focus on external threats coming especially from the spiral of constant Iraqi crises since the early 1990's have also contributed to the weariness in the Turkish public opinion.

The Turkish domestic political scene has since the 2002 elections been characterized by a division between the government (a religiously and socially conservative but economically globalist single-party government) and the state (or rather, the establishment, which includes secular republicans, left and right wing

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_9, © Springer-Verlag Berlin Heidelberg 2011

nationalists, the military, and part of the civilian bureaucracy), which have had different conceptions of security, perceptions of insecurity, and priorities in policy-making, including the foreign policy realm. This, and the mutual animosity and mistrust between the two sides of the equation, has led to a shift of attention to domestic woes and clashes. Recently however, the schism between the government and the state appears to have withered away to a certain extent, to the advantage of the governing party. The repeated successes of the AKP at the ballot box, the accomplishment of having seated a party member at the presidential palace, and certain requirements of the European Union accession process, have been effective in somewhat alleviating the stand-off. Nevertheless, the societal polarization and animosity prevails. For instance, the *Ergenekon* legal case appears to onlookers as a major achievement that should boost the sense of security and safety for the Turkish public, for its avowed mission is to eliminate clandestine paramilitary groups, organized within 'the deep state', plotting to cause social chaos through terrorist acts and ultimately undermine or overthrow the government. However, the case causes concern for a large segment of the society as they perceive the prosecution as a hotchpotch that brings a large number of diverse people whose only common denominator appears as their opposition to the AKP together under the shadow of a single allegation, and hence a counterplot by the government to eliminate its critics. Indeed, Turkey's major security challenges today seem to stem from identity problems and disputes within, while the government chooses to pursue a "zero-problem-with-neighbours" policy (Davutoglu 2008: 80). As the balance of power between the government and state elite shifts to the benefit of the former, the latter finds itself to have lesser say in policy-making, and its concerns resonate less among the people. This signals a reversal of traditional policy-making and of the conventional threat perceptions that have hitherto been conceived as quite static (Aydin 2003b; Bilgin 2005).

One immediate impact of the shift in attention to domestic affairs and the growing indifference towards international concerns is a decrease in the perception of immediate security risks (in the traditional sense) and a greater confidence that the country is better equipped to tackle them, which probably also partly explains the lesser sense of insecurity for the masses. Nevertheless, not only are Turkey's external woes interconnected with internal ones and becoming more so within the context of the EU accession process (Aybet 2006), but they also exacerbate the domestic divide across policy-making stakeholders when concerns are not shared and acted on jointly.[1] Besides, several international and regional issues and problems spill over into Turkey, irrespective of how hard Turkey may try to avoid them. Developments in connection to Iraq since 1991 are just one glaring case in point (Aydin/Özcan/Kaptanoglu 2007).

Meanwhile, it is worth noting that the official understanding of security in Turkey has come to include issues other than traditional ones, following the popular mood that had entered a similar phase of transformation much earlier (Aydin 2003b).[2] Hence, climate change, energy and hydropolitics as well as human security issues have become mainstream in Turkey's security concerns. Accordingly, this chapter provides an overview of the salient domestic (9.3) and international (9.4) issues for today's Turkey, as well as the wider security concerns (9.5), and will try to demonstrate the ways in which these categories overlap, interact, and exacerbate one another, affecting Turkey's security conceptualization and prioritization (9.6).

9.2 Conceptual Framework

The conceptual framework for the following overview of the Turkish scene addresses a familiar one that has been subject to controversy for decades. The interaction between domestic and international realms has been the subject matter of numerous theoretical and practical explorations in the international relations literature. The debate that ensued Waltz's introduction of the three images into international relations analysis in his quest for an explanation for war has been lively (Waltz 1959). The interdependence school led by Robert Keohane and Joseph Nye (1977) and the classic article by Gourevitch (1978) where he 'reversed' the second image have been notable and influential contenders to Waltz. With the advent of globalization, the controversy over the question of interconnectedness between the domestic sphere and the international realm has become all the more vivid. A signifi-

1 Although Robins (2007) disagrees, the time differential might matter: the latter part of 2007 and 2008 have helped the differences in both domestic and foreign politics in Turkey surface and become much more ostensible.

2 See also other contributions by this author to previous volumes of the Hexagon book series: Aydin and Acikmese (2008a); Aydin and Kaptanoglu (2008); and Aydin and Ereker (2009).

cant contribution, or rather, intervention, to this debate came from R.B.J. Walker, who advocated in his *Inside/Outside* (1992) the arbitrariness of the division separating the two realms and disputes the territoriality and sovereignty that is defined, demarcated and reified by the act of drawing boundaries. Walker then moves on to suggest the ephemeral quality of this particular spatial/temporal construct that is called the nation-state, the basic premise that underlies international relations, and the challenge posed against it by globalization.

While we feel that the process that blurs boundaries is far from complete and the nation-state still an object of analysis, this chapter feeds on the sentiment that both hard and soft security issues are increasingly creating further interconnections between the domestic, the regional, and the global scenes, and Turkey obviously is not immune from this process. With the trend of globalization, be it economic, political or criminal; and with the pervasiveness of certain problems (health, environment, finance, etc.), hard or soft security issues transcend boundaries and build a dense network of bridges between the 'domestic' and the 'foreign'.

Several authors, some of which are cited below, have already pointed to the shift of Turkish foreign and security policy priorities in the last decade; thus the primary purpose of this chapter is to offer an overview of the issues at stake. The discussion rests on a combination of factual data and discourse analysis, with the nebula of perceptions and representations of security issues at the background. The highlighted cases and issues below, chosen among several possible alternatives, are arbitrary to an extend that reflect the authors' preferences and understanding that they can satisfactorily demonstrate the complexities of policy-making and changes in Turkey's security understanding.

9.3 Domestic Politics

Turkey's domestic concerns today, as indicated by the military and civilian security bureaucracy most ostensibly in the National Security Documents and the proceedings of National Security Council meetings, stem mainly from ethnic insurgency and Islamic or Islamist resurgence. In fact, neither question is new to Turkey, having inherited them from its Ottoman predecessor and struggled to tackle them since its inception. The two issues were intertwined in the early stages of the Republic, they parted ways with the rise of an avowedly Marxist and Leninist Kurdish movement in the late 1970's, but are coming full circle to unison again.

9.3.1 The Rise of Political Islam as a Threat

A secular Turkey has sensed the threat of Islamist activism ever since its genesis and rising religious fundamentalism has been one of Turkey's major concerns throughout the 1990's. The activity of Islamists groups like the *Hizb-ut Tahrir* and *Hizballah*[3] and the rise of political Islam in Turkey have deeply troubled the Turkish establishment, so much so that the military forced the coalition government of the Welfare Party (RP) with True Path Party (DYP) to resign in 1997 through a well organized and orchestrated public campaign following tensions over its prime minister's ostentatiously 'Islamic' moves both in domestic and foreign policy areas. This was a critical juncture in Turkish republican history, one which came to be termed as 'the post-modern coup' of 28 February 1997. The same supposedly 'Islamic' behaviour of the then prime minister Necmeddin Erbakan, especially in the foreign policy domain, has also led an intra-party group (the so-called 'youngsters') to first criticize him within the party for causing trouble with the military and leading the country into humiliating positions in the international arena,[4] and then to break away from the tradition to set up their own party (*Adalet ve Kalkinma Partisi*), the Justice and Development Party (AKP).

The rise of the AKP to power in 2002 with the first general elections it contested in stirred up a similar alarm among the secular establishment and the secularized, modernized segments of the society that an 'Islamist' party was now in office with a powerful stronghold based on a parliamentary majority and a single-party government.[5] The AKP, however, tried to alleviate these concerns by an assertion that party officials had undergone a profound transformation, an

3 Turkey's Hizballah is different and independent from the various groups operating under the same name in the Middle East.

4 While visiting Libya in 1996, Prime Minister Erbakan stood listening to the ranting of Muammar Al-Gathafi on Turkey's supposed human rights abuses, democracy deficit, and its treatment of Kurds, while being referred to as 'my commander'. The Libya incident was the final straw in the long list of controversial foreign visits and led to severe criticism of Erbakan within his own party, notably by the Minister of State Abdulah Gul, who later lead the way of intra-party opposition, thus contributing to the emergence of AKP.

avowal that the party identity was one of 'conservative democrat' rather than 'Islamist', as well as via a fervent pursuit of Turkey's EU vocation. However, the secular establishment and the opposition retained their sceptical outlook on the AKP amidst concerns that the latter has a hidden agenda of Islamicizing the society and ultimately the state.

The division appears unbridgeable despite brief periods of détente and rapprochement between the two sides (Baran 2008). Although issues deemed vital to Turkey's national interests can be sources of cooperation, they easily become sources of confrontation due to diversions in outlook and action. While the European Union reform process had united the government, the opposition and the Turkish civilian and military bureaucracy throughout a period of euphoria in the early 2000's, it has become a source of contention in the last few years following the onset of the (now stalled) negotiations due to what has come to be seen as 'unnecessary and futile concessions' to the EU on behalf of the government (Toksabay Esen/Bölükbasi 2008: 192–195). The Cyprus issue and the shift of the official policy on this by the AKP government has been a source of covert conflict, as well as other issues considered central to the Turkish official line and national security, the chief one being the struggle against Kurdish terrorism. It is worth noting at this point that the resistance in these issues stems mainly from the loss of the EU membership perspective and the widespread sentiment that the AKP government is compromising Turkey's interests for no good reason.

The domestic cleavage in Turkey in this sense has several manifestations in the tension between the civil and the military; the new versus the old elite; the conservative versus the progressive[6] segments of the society and finally, the state versus the government, ascribing therefore a complex outlook to the picture. Whatever the context may be, however, the common thread is the deep lack of mutual confidence across the two sides of a fault line that divides both the popular masses and the ruling elite in Turkey. The divisions, the power struggle, and the striking schism between the state and the government, in the final analysis, shape and are in turn shaped by Turkey's foreign policy and security questions.

9.3.2 Threat to Territorial Integrity of the State: Ethnic Separatism

Turkey's long-term inability to come to terms with its Kurdish population has been exacerbated in the last few decades following the foundation of the terrorist *Partiya Karkerên Kurdistan* (Kurdistan Workers' Party [PKK]). Turkey's initial reflex to underestimate the PKK in the late 1970's was followed by a tendency to respond to the violence induced by the PKK through military means. An attempt to make political processes work failed in the early 1990's when the newly elected MPs of Kurdish origin from *Halkin Emek Partisi* (People's Labour Party [HEP]) saw their inauguration ceremony as an opportunity to make a scene at the Parliament.[7] The 1990's witnessed the climax of PKK terrorism which claimed more than 40,000 lives to date, and poisoned Turkey's relations with its neighbours, as well as the EU that condemned harsh Turkish measures in its struggle with terrorism, and some European countries that alleg-

5 The use of the term 'Islamist' in referring to the AKP is disputed by both its leaders and many Turkish political scientists. The latter, complaining about the tendency to lump such unlikely groups as AKP, *Gamaa Islamiyya* of Egypt, *Al-Qaeda* and others together under the banner of Islam, point out the differences in both rhetoric and action of AKP from others. The AKP leadership on the other hand variously defines their party as 'conservative democrat', 'Muslim democrat' and recently 'centrist', but never as 'Islamist' or 'Islamic'. For further discussion from both flanks see Akdogan (2004); Balci (2008); Fuller (2002); Özbudun (2006).

6 The categories of progressive and conservative, as well as the distinctions between them, seem to have become quite blurred in the case of contemporary Turkey. For example, a supposedly progressive left wing *Cumhuriyet Halk Partisi* (Republican Peoples Party [CHP]) easily defends a limitation on the freedom of speech through its support for the infamous article 301 of the Turkish Penal Code that penalizes 'insulting Turkishness', while clearly conservative AKP can become the agent of change (see Onar 2007).

7 The parliamentary immunities of four HEP MPs were swiftly lifted by a unanimous vote of the Parliament and the State Security Court of the time sentenced them to 7.5 years in prison (Ergil 2000). HEP was consecutively replaced by the *Demokrasi Partisi* (Democracy Party [DEP]), *Halkin Demokrasi Partisi* (People's Democracy Party [HADEP]), *Demokratik Halk Partisi* (Democratic People's Party [DEHAP]) and *Demokratik Toplum Partisi* (Democratic Society Party [DTP]). All of the former three were banned by the Constitutional Court on the grounds of being the focus for secessionist activities against the state and the integrity of the territory and the nation, while the fourth dissolved itself when a similar case was pending. A closure case against DTP is also pending today. The parties cited above are generally considered to be the legal political wing of the PKK (Uslu 2008: 99).

edly offered sympathy and support to the PKK's cause (Aydinli 2002: 213–217).

For a while, the organization struggled to recover from the shock and disorientation following the capture of its leader Abdullah Öcalan in Kenya in 1999, declared a unilateral ceasefire and withdrew from Turkey to its hideouts in the mountainous terrain of northern Iraq. Although Öcalan's pleading and appeasing performance during his trial was quite a disappointment to separatist Kurdish groups, he nevertheless managed to revive his leadership eventually, and the PKK resumed its terrorist activity in the countryside of the southeast as well as in urban centres in western Turkey. Although the PKK has become less visible on the public agenda from the mid-2000's onwards compared to the 1990's except for some urban bombings and few large-scale hot clashes with security forces, the figures indicating the scope of its activity remain quite striking: within the first nine months of 2008, more than 100 soldiers and civilian village guards (*korucu*) died in the struggle, while the PKK lost some 1,000 members, including those that died, surrendered, or were captured.[8]

Although the Turkish Parliament is once again hosting a party (DTP), which represents a segment of the Kurdish population that also supports the PKK, a political solution is yet to come. Kurds find the reforms inadequate and pretentious (Uslu 2007), while DTP refuses to condemn the PKK violence and fails to disprove the common understanding that it endorses terrorism. Meanwhile, the nationalist hardliners, both Turkish and Kurdish, do not believe in the possibility of a resolution through democratic reforms or wider liberties. In addition, Turkish nationalists insist that the reform process will divide Turkey for good (Avci 2003: 164). The ongoing violence also hampers the popular support for a peaceful resolution.

The struggle against terrorism is a significant point of division between the state establishment (particularly the military bureaucracy) and the AKP government, which has a Kurdish faction among party ranks and therefore has until recently given more weight to political and cultural solutions in its discourse, much to the dismay of hardliners.[9] The state establishment implicitly blamed the government for failing to live up to the terrorism challenge. The detrimental impact of the Kurdish problem on relations with neighbours and the EU today is not comparable to the 1990's, but the issue continues to mould Turkish foreign policy; so much so that it has had its toll on the relations with the United States following the latter's intervention in Iraq. Segments of Turkish society feel that the USA (as well as the EU) decline to cooperate in the struggle against terrorism and tacitly support the formation of an independent Kurdish state. This latter possibility is one of Turkey's nightmares due to the belief that this will fuel separatist aspirations among Turkey's Kurds (Gordon/Taspinar 2006). Thus, despite fluctuations, the Kurdish problem persists both as a political issue and as a source of threat to security.

9.4 Global and Regional Politics

For the past few years, numerous authors and observers have commented about Turkey's frustration and alienation with the West, and some have asked whether Turkey may be turning to the East (Önis/Yilmaz 2005; Gordon/Taspinar 2006; Menon/Wimbush 2007; Oguzlu 2008; Baran 2008). Regardless of the sense of confidence stated above, Turks do not feel any more sympathetic to foreign countries. Despite a recent dose of amelioration, public surveys repeatedly indicate that the Turkish population disfavours the USA, Israel, and the EU as well as a majority of its immediate neighbours (GMFUS 2007, 2008). While Turkey is evidently experiencing disappointment with its traditional Western allies and a trend of diversification in Turkish foreign policy is ostensible, it is premature to say that Turkey is turning away from the West. Even when we leave civilizational aspirations aside and think in *realpolitik* terms, this stickiness in orientation hardly stems from the fact that Turkey appreciates the USA and the EU as reliable allies and part-

8 The figures are compiled from the website of the Office of the Chief of General Staff of Turkey; at: <http://www.tsk.mil.tr> (25 October 2008).

9 One implication here is that the DTP (or from another perspective the PKK) is no longer the only player standing for the population of Kurdish origin Turkish citizens in the political arena. Indeed, recent elections indicate that the support for DTP is on the wane in the Southeast of Turkey where the PKK is most active, while AKP is expanding its influence in the region. In the 2007 elections, the DTP received 17 per cent of the votes in Eastern and 25 per cent in Southeastern Anatolia, while the AKP raised its votes from 33 per cent in 2002 to 56 per cent to 2007 in Eastern Turkey and from 26 per cent in 2002 to 52 per cent in 2007 in Southeastern Turkey. See the analysis by Oflazoglu and Benli in: *Radikal Daily* (8 November 2007); at: <http://www.radikal.com.tr/haber.php?haberno=238214>.

ners, but merely indicates that it finds the alternatives no more palatable (Aydin/Erhan 2006) despite the cold shoulder that it insistently, in fact increasingly, receives from the EU.

9.4.1 Western Connection Questioned

The greatest uncertainty that Turkey is facing today in its foreign policy emerges from the fact that Turkey and the United States, which deemed one another as 'strategic allies' during the Cold War and 'strategic partners' since the end of it, have found it difficult to readjust their relationship to the changing parameters of the post-Cold War and post-9/11 era (Baynham 2003; Lesser 2006; Aydin 2007 & 2008; Larrabee 2007; Menon/Wimbush 2007; Oguzlu 2008). While the fallout between Turkey and the US over the refusal of the Turkish parliament to open a second front via Turkey in the 2003 Iraq War has left its scars (Park 2004), problems have remained on the horizon as Turkey has maintained several points of disagreement with the United States in its Middle Eastern policy, has been troubled by developments in Iraq, and found it difficult to offer support to US pressure on Iran and Syria (Oguzlu 2008).

Although definitive judgements would be premature, the ascendance of Barack Obama to the US presidency and his attempts to remedy the havoc wrought by the Bush administration and to mend fences with the Islamic world, as well as the apparent change of values in his global outlook, are issues that should be taken into consideration in order to discuss the prospects of Turkey-US relations. While Turkey still requires and seeks US cooperation to take action in its neighbourhood (Olson 2007; Aydin 2007) and maintains a collaborative stance towards it, there is a likelihood that Obama's government will try to make sure that this positive trend in relations and cooperation is wrought with more consent than coercion, at least on the discourse level. Obama's global agenda is also likely to alter the security definitions and priorities somewhat, with soft security possibly taking the lead over hard security. In turn, collaboration with the US in regional affairs will probably be more readily received and digested by the Turkish public opinion.

Turkey's relations with the EU on the other hand are not on a good track, even though there appears to be very little disparity in Turkey's foreign policy with that of the EU's *Common Foreign and Security Policy* (CFSP) (Aydin/Acikmese 2007). The discontent in Turkey-EU relations is mainly a result of second-guessing in some EU countries of Turkey's 'Europeanness'. The persistent unfavourable mood in some EU countries about Turkish membership despite the 1999 Helsinki Summit decision to start negotiations aiming at full membership, and the emerging discourse on arrangements that fall short of full membership have had a dramatic impact in undermining the morale in Turkey and brought the reform process close to a stall (Patton 2007; Narbone/Tocci 2007; Toksabay Esen/Bölükbasi 2008). The discourse on Turkey's 'non-Europeanness', the limits of the EU's 'absorption capacity', 'privileged partnership' alternative, and the 'Union of the Mediterranean' have had a massive toll on an already delicate relationship.

This was not always the case: after two major letdowns in 1987 and 1997, the EU had given Turkey a green light at the Helsinki Summit. This then led Turkey to strive, quite successfully and surprisingly to outside observers, to handle major reform packages under the two unlikely governments of the DSP-MHP-ANAP coalition[10] and the AKP single party government.[11] However, it appears that Turkey has been the follower rather than the leader and the determinant of the dynamics in the cyclical pattern that Turkey-EU relations have followed (Narbone/Tocci 2007) and as the mood towards Turkey in the EU member states soured, Turkey found little motivation to try and push relations forward. The impasse also hampers the transformation of Turkish politics by diminishing incentives for reform and arousing scepticism on the part of the establishment about the 'security during transformation', i.e. the control over domestic threats *during* the reform process and *prior to* actual membership (Toksabay Esen/Bölükbasi 2008). The current scheme with a tilted balance of power against a back-

10 *Demokratik Sol Parti* (Democratic Left Party [DSP]) is a left-wing nationalist party with affinities to the structuralist arguments of the 1970's, whose late leader Bülent Ecevit was known for his hawkish attitude on Cyprus; while *Milliyetci Hareket Partisi* (Nationalist Action Party [MHP]) is a right-wing nationalist party with a hard-line approach to many issues, including the Kurdish problem, Cyprus and even the EU itself. *Anavatan Partisi* (Motherland Party [ANAP]) was a central-right party that was considered the only likely champion of the EU within the coalition, and has indeed been an engine in the process. Ultimately, the government passed many significant reforms, including controversial ones like the abolition of the death penalty.

11 As outlined above, the AKP's pursuit of the EU goal was most unexpected due to its origins in the anti-Western political Islamist movement. See Toksabay Esen/Bölükbasi (2008) for a detailed account of the possible rationale and the reversal of their favourable approach.

drop of poor rule of law makes domestic affairs more fragile. As an additional factor, the EU's interventions in Turkey's domestic struggles, which have at times indicated minimal understanding or empathy of the country's dynamics or problems, have always left a certain segment in Turkey disenchanted and enraged (Baran 2008), deepening domestic divisions and casting a shadow on the EU perspective.

The downturn in the Turkey-EU connection also slowed down Turkey's rapprochement with Greece to an extent and adversely affected the political environment in Cyprus (Aydin/Acikmese 2008b, 8–10). Despite the recent amelioration in the Turkish-Greek relations following the advent of 'seismic diplomacy' in the aftermath of the 1999 earthquakes (Aydin/Ifantis 2004) and the apparent – albeit conditional – support that Greece offers for Turkey's EU membership (Tarifa/Adams 2007; Ifantis 2007), Turks feel that Greece (and Cyprus) chose to use the EU as a platform to engage rather than alienate Turkey for the resolution of long-standing disputes by imposing demands in the form of conditionality on the latter. Against an appearance of congruence, the sense of insecurity prevails. The Greek/Cypriot perception of threat from Turkey remains high. Turks meanwhile sense no guarantee that Greece and Cyprus will not use their veto power once all the concessions they demand are met, but at the same time see that Cyprus is one of the biggest stumbling blocks on the road to EU accession (Tarifa/Adams 2007: 69). In fact, Turkey feels a sense of betrayal vis-à-vis the EU over the Cyprus issue (Gordon/Taspinar 2006): The twist of politics on the part of Turkey in 2004 to make room for a UN-inspired resolution in Cyprus was thwarted by the Greek Cypriots in a referendum, only to be followed by the full membership of Cyprus (in effect only the Greek Cypriot part as the *acquis* adoption is suspended in the north of the Island) to the EU, the EU's turn away from its promises to Turkish Cypriots as a result of Greek Cypriot veto threat, and finally the suspension of eight chapters in Turkey's accession negotiations when Turkey refused to open its ports to Greek Cypriot vessels. The issue has had domestic ramifications as well: the AKP's willingness to compromise over Cyprus (Barkey/Taspinar 2006), which has yet to produce tangible results, has become another breeding ground for the suspicions of the establishment over the government's standing in national interests, since the Turkish establishment views Cyprus as an indispensable, vital, unalienable matter of national security (Bilgin 2007).

All these then led to a questioning among the Turkish elite of the value of Turkey's alignment with the West in its external relations, and brought forward suggestions for alternative connections or for going-alone. Turkey's western orientation, seen from the Turkish perspective not simply as a question of alliances and/or affiliation, but as a matter of civilizational belonging, that it has boasted for more than a century, fails to deliver and comes under scrutiny as a romanticized ideal that has only helped hurt Turkey's interests in the wider framework. This sense of frustration and alienation is further fuelled by the mounting nationalism of both left- and right-wing politics and paralleled with an overarching emotion that Turkey is being abused and bullied in the process as the West "takes what it can, gives nothing back" (Toksabay Esen/Bölükbasi 2008). Depending on the political orientation of the speaker, questions as to why Turkey has distanced itself from the Muslim world which "promises religious fraternity and wealth;" why Turkey does not opt for a Russia-China-Iran axis that has supposedly been in the making and on the rise; or why South-South cooperation, integration with the Turkic world, or a lone-goer that relies on day-to-day alliances rather than a long-standing orientation have come to be voiced among the elite as well as the masses. These discussions inflame questions about Turkey's identity and belonging, for disassociation from the West implies a void, which is supposed to be filled through different means and with different attachments in the perspectives of different stakeholders in Turkey. This, in turn, taps into the domestic cleavages, feeds into an uncertainty that surrounds the country and hence leads to a feeling of insecurity in general.

9.4.2 Regional Environment

Turkey has for decades tried to detach and/or isolate itself from its surrounding regions mainly as a result of the early republican founding philosophy as well as constraints of the Cold War era, and was able to look at 'its region' with a positive view only at the end of the Cold War, when Turkey found itself in a power vacuum that it considered itself opportune to fill (Aydin 2005). Turkish foreign policy during the Cold War was meant to distance itself from the Middle East primarily due to the perceived incompatibility between a Middle Eastern orientation and the country's civilizational aspirations, as touched upon above. Recent developments, however, suggest that Turkey comes to see the Middle East as an important pillar of its effort

to diversify its foreign policy options both in a political and economic sense. Part of this has been by compulsion: the sudden focus on the Middle East after 9/11 has rendered it impossible for Turkey to ignore the region, and made it imperative that it is involved in the new configurations of power in the region (Aras 2005; Aydin/Özcan/Kaptanoglu 2007; Olson 2008). Besides, the rising significance of energy has been another compelling factor to do so. The other part has been shaped by conviction: many observers note that the AKP government feels more comfortable dealing with its Muslim counterparts than, say, the EU. Moreover, the wealth accumulated in the Gulf from the early 1980's onwards and the recent inflow of funds due to rising oil prices on the one hand and Turkey's dynamic economic performance and an FDI-seeking government on the other, made Turkey and the Gulf countries likely partners (Olson 2008). There is a strong likelihood that Gulf countries as well as the other Middle Eastern governments see Turkey in a different light now that a 'moderate Islamic' government is in office, which has the potential to make Turkey a better-suited role model for a combination of democracy and Islam compared to what was before.

The non-Gulf Middle East is no longer perceived by the Turkish government as a source of immediate threat either, with avenues of communication and cooperation sought with the hitherto unseemly partners in the region. But neither the region nor the relations promise any stability. Turkey has mended fences with Syria in the aftermath of the 1999 crisis, developing its relations to a point of becoming a trusted facilitator in the roundabout negotiations between Israel and Syria. However, the relationship still remains precarious given the US opposition to de-isolate Syria and the latter's connection to various terror organizations in the Middle East. Turkey also feels no immediate threat from Iran and cooperates with it on energy issues as well as against the PKK. However, this picture too can change rather suddenly should the latter's alleged efforts towards nuclear armament prove fruitful. The developments in Iraq and the possibility of an independent Kurdish state emerging from a divided Iraq are matters that still trouble the Turkish establishment, due to its connections with the domestic Kurdish issue. Although there are serious obstacles to the Middle East's becoming the primary orientation in Turkish foreign policy, global developments and the ongoing US interest in the region makes it likely that the region will be on Turkey's radar for a while.

Turkey's connections to the Black Sea, Caucasus, Central Asia, and the Russian Federation make up another cluster of regional politics (one may call it the Eurasian dimension) that has developed since the end of the Cold War. Russia and Turkey have a long history of friction and clashes, and Turkey has been wary of 'Russian intentions' since the Ottoman era, exacerbated by the Soviet threat during the Cold War. After the fall of the Soviet Union, as Turkey aspired to assume a leadership position in what it chose to call the 'Turkic world', i.e. the Central Asian countries and Azerbaijan (Aydin 2004a, 2004b), Turkish-Russian relations entered a period of influence competition. Despite allegations of pan-Turkism and in addition to a dose of sentimental affinity, concerns over *realpolitik* with Turkey trying to gain a renewed strategic significance following the 'fall of the wall', the efforts towards the diversification of foreign policy amidst another tense period with the European Union (Aras 2008), the profit potential of the new markets and a growing awareness on the vitality of energy resources were strong rationales for Turkey's activity in the region. Turkey stressed ethnic and cultural ties and tried to develop strong economic and political relations with Azerbaijan, Kazakhstan, Kyrgyzstan, Turkmenistan and Uzbekistan, but failed to deliver, not least because of Turkey's preoccupation with domestic woes. Although these countries still matter to Turkey due to various reasons, including their vitality as sources of energy, the web of relationships have become all the more intricate as Turkey's 'kin' chose to ally with others (ICG 2007).

As a result of the disappointment experienced about its policies towards Central Asia, Turkey has, since 1995, increasingly focused its attention to the Caucasus, where energy and various conflicts threatened to spill over into Turkey (Aydin 2004b). This focus, while accelerating Turkish-Russian competition briefly, resulted in building the Baku-Tbilisi-Ceyhan oil and Baku-Tbilisi-Erzurum gas pipelines providing alternative routes to Caspian energy resources to reach European markets (Winrow 2009). The process also made Turkey the main trading, political, and security partner of both Azerbaijan and Georgia.

Turkey's relations with Armenia, on the other hand, have not followed this pattern, as the latter quickly signed a security treaty with Russia in 1997, allowing its borders with Turkey to be guarded by Russian soldiers once again. Turkey's troubles with Armenia stem from a number of problems, including the reluctance of Armenia to unequivocally recognize the border between the two countries, allegations of Ar-

menia's support for challenges against Turkey's integrity, Turkey's solidarity with Azerbaijan over Nagorno-Karabakh, and Armenia's insistence to call the 1915 events as 'genocide' (Barkey/Taspinar 2006; Tocci 2007). Turks view the 1915 events as "the deportation of a large Armenian population who tragically perished due to adverse conditions during the war" and insist that the losses were reciprocal; while Armenians claim that their ancestors were subjected to a systematic and planned mass murder. Turkey has reacted harshly to several national legislations around the world that recognize the 1915 events as 'genocide', and Turks see the Armenians, whether those in Armenia or in the Diaspora, as the perpetrators of this defamatory campaign. The issue, while a challenge for Turkey in terms of global prestige, in effect pales in comparison to Turkey's concerns over Iraq and/or Cyprus. Nevertheless, under pressure from the recent developments in the Caucasus and with a realization that Turkey's claim for regional leadership would be lame while its land border with a neighbouring country remains closed, the Turkish government has recently been engaged in a rapprochement process with Armenia, initiated through what has come to be known as the football diplomacy. However, not only has the move drawn yet again the ire of nationalists who view the move as outright treason, but it has also profoundly upset Azerbaijan, which has retaliated against Turkey via its grip on energy resources and forced Turkey to take heed of its concerns. The rapprochement process therefore seems to come to an impasse.

All these developments of course reflected immediately on the Turkish-Russian relations, which are not exactly built on amicable foundations, but are not openly antagonistic either. The degree of perceived threat compared to the Soviet period is lower and the two countries have strong commercial ties; but a sense of rivalry and of mutual mistrust ensues. The recent developments in the Caucasus, Russia's attempt to return to the global arena as an aspiring major power, and the pressure by its Western allies on Turkey "to side with themselves" on the one hand; and its kinship ties, affinities and/or strategic interests that compels it to approach the Caucasian and Central Asian states differently on the other, forces Turkey to seek and maintain a delicate balance in its relations with its Eurasian neighbours and the wider set of international actors, including its long-standing allies. The recent Russia-Georgia crisis has been indicative in terms of the potential dilemmas that await Turkey in its choices.

9.5 Soft(er) Security Issues Also Matter

Although the security understanding in Turkey heavily favours the traditional definition of security (Aydin 2003b), relatively new areas of security such as economic challenges, demographic and social trends, as well as environmental problems and energy dependency have increasingly come to appear in the discussions around security.

9.5.1 Global Economic Integration and Energy Dependency

Curiously, even though Turkey has been rapidly integrating with the global economy since the reforms of the early 1980's, a considerable portion of the population has failed to make peace with the idea of globalization. Indeed, there exists a large segment among the opinion-shaping elites who see globalization as a source of security threat; even a threat to Turkish territorial integrity. It is the political side of globalization with its weakening affects on the idea of the nation state that is considered as a threat among Turkey's top brass and decision-makers.

Economically, on the other hand, Turkey clearly benefits from the globalization process. Its significant industrial base, albeit less prominent than that of the BRIC countries,[12] allows it to be dominant in export markets in its region as well as making it increasingly attractive for *foreign direct investments* (FDI). Nevertheless, the very level of integration makes Turkey more vulnerable to international developments in economic terms. Economic and financial crises have troubled Turkey for decades, with the 1994, 2000, and particularly 2001 crises being the most severe ones. The economy has been open to contagion effect by meltdowns in other emerging markets, and has had vulnerabilities and volatilities of its own (Chibber 2004). Economic instability often went hand in hand with political instability, exemplified by the 2001 crisis triggered by a row among the top brass of the state apparatus. However, Turkey, having signed a stand-by agreement with the IMF has undertaken a sizeable transformation programme[13] that was pretty successful in reining in inflation, cutting back budgetary deficits, rationalizing the financial markets, and consolidating a banking system that had gone off the rails.

12 BRIC is the name given to the four leading emerging markets, namely Brazil, Russia, India and China.

The EU accession process has meanwhile served as an anchor for stability along with the IMF.

The 2008 financial crisis gives a patchy picture concerning Turkey's performance. Data[14] reveal that Turkey has in fact suffered severe damage, with exports down by some 33.3 per cent and imports by 43.4 per cent between April 2008 and April 2009. Capacity utilization dropped by some 10 per cent points throughout the same period in the overall economy, and almost 40 per cent in the public sector. These figures are indicative of a serious recession underway in Turkey. The biggest cause for concern, however, is the unemployment rate, which rose from 11.9 to 16.1 per cent between February 2008 and February 2009, and more significantly, youth unemployment, rose from 21.5 to 28.6 per cent in the same period. This can be compared to the United States[15] (9.4 per cent; up from 4.5 per cent) and the United Kingdom (7.1 per cent, up by 1.8 per cent),[16] which are considered to be among the countries that have suffered grave blows from the global crisis. Considering that Turkey still suffers from an overvalued lira, massive current deficits and foreign debt, and moreover that the crisis has clearly proved that there is no immunity from meltdown for any country, there is still room for concern for the economic security of Turkey.

Nevertheless, the psychological impact has been considerably milder. While newspapers report on the effects of the recession and businessmen call on the government to take action, the sentiment of 'insecurity' is not comparable to that experienced by citizens of advanced countries. It appears that there are at least three reasons for this: Firstly, Turkey has been through two major crises in one generation (1994 and 2001/2002) whose impact has been sudden and 'lethal'. The spillover of the 2008 crisis has been relatively gradual, and the Turkish public, which has already 'been there', has a relatively impervious attitude towards the crisis. Secondly, the banking sector, which the crisis in the world had started from and concentrated in since then, was reformed and reshaped substantially in Turkey after the 2001 crisis. As a result, Turkey was saved from the adverse affects of the initial phase of the crisis. Thirdly, the cogent and quite denialist approach adopted by the government vis-à-vis the crisis, epitomized by Erdoğan's now infamous statement, "The crisis will go tangent to Turkey," appears to have proved effective over the public opinion, although the relative inertia of the government in terms of taking measures will probably imply a deeper recession for Turkey as well.

In the same vein, energy has long been a delicate concern for Turkey considering the country's dependence on imports from its neighbours, and at the same time a trump card in the making particularly vis-à-vis Europe due to the country's role in transit (Barysch 2007). While Turkey aspires to be a major energy hub in the region, the prospects for this role are hampered by a series of issues. For one, Turkey is a latecomer to the issue, whereby existing contracts and alignments have already gained path-dependency. Moreover, technology and financial resources to be devoted to energy suffer severe constraints in the Turkish context. Turkey also faces grave difficulty in finding reliable partners: Iran and Iraq have proven volatile as trade partners given the sensitive political relations, while Kazakhstan and Turkmenistan choose to align themselves with Russia, partly due to path-dependency mentioned above. This left mainly Azerbaijan to tap for Turkey's energy needs as well as create alternative transit routes towards Europe. The competition between Turkey and Russia on regional influence is a major disincentive for Russia to cooperate with Turkey on energy and share the benefits of a scarce resource while it has the upper hand by a large margin. Developments in recent years in the context of Russian pressures and energy cuts towards Georgia and the Ukraine have raised concern that Russia may use the energy dependency of its trade partners towards political ends, which is also a challenge for Turkey due to its dependence on Russia for its natural gas, amounting to 65 per cent of its consumption. However, the energy race in Turkey's immediate neighbourhood is still ongoing with deals made and broken every other day.

Beyond energy dependency, vulnerability of pipelines passing through the country has also become an important security issue for Turkey in recent years with occasional ruptures on existing lines due to terrorist attacks, accidents or natural causes. Should Tur-

13 The economic reform programme in the aftermath of 2001 did not simply involve an IMF scheme but benefited largely from the experiences and the expertise of the Turkish bureaucracy that found the opportunity to channel its awareness about the problems in the economy to a list of maladies and remedies.

14 All data concerning Turkey's economic performance are retrieved from *Türkiye Istatistik Kurumu* (Turkish Statistics Institute [TUIK]); at: <http://www.tuik.gov.tr>.

15 May 2009 data; increase rate since December 2007, onset of recession. http://www.bls.gov/news.release/empsit.nr0.htm

16 Data belong to the first quarters of 2008 and 2009; at: <http://www.statistics.gov.uk/cci/nugget.asp?ID=12>.

key be able to expand its pipeline systems and truly become an energy transit country (even if not an energy hub), this issue will get even more attention both inside Turkey and also from the countries that depend on the continuous flow of oil and gas through pipelines. All in all, the area of energy is full of potentials for Turkey, as well as a great number of challenges en route.

9.5.2 Social, Demographic and Environmental Trends

Turkey has a young population, with a share of those under 25 standing at 53 per cent in 2007,[17] posing significant challenges concerning the education and health services to be provided to the population, employment opportunities to be created to absorb the new work force and the social unrest that will ensue if economic growth trends are reversed or decelerated. The demographic portrait, on the other hand, bears the potential to open up a window of opportunity in terms of Turkey's prospects, if these challenges can be met.

Turkey's economic transformation particularly in the aftermath of the 2001 crisis has been accompanied by a premature shift towards a sectoral redistribution typical of post-industrial economies: a shrinking agricultural sector and a growing services sector, both in terms of the size of the work force and the share in the national output. This has meant, however, massive migratory inflows from the rural areas to urban centres, with ensuing pressures in terms of employment creation, services provision, housing, social security, and urban safety, as well as fuelling cleavages. Despite creating new jobs thanks to a period of economic boom, Turkey has failed to bring unemployment figures down due to migratory and demographic pressures. The entire picture has resulted in considerable urban and rural unemployment, an unruly urbanization pattern, social unrest, and hostility against newcomers (at times matched with ethnic and religious tensions among the old and the new settlers) as well as poverty and deprivation among the uprooted population, all of which have also had significant political ramifications in electoral politics.

Immigration has not remained solely an internal concern. Turkey in recent years has become a transit route for flows of refugees and illegal immigrants from east to west (Emerson/Tocci 2004), but now also is evolving towards being a centre of attraction and a destination point itself. Men and women from the former Soviet republics, the Middle East, the Balkans, and Africa either come to Turkey in search of asylum or jobs, or are trafficked for illicit purposes. With a prospective change to its asylum policy,[18] Turkey is bound to face more migratory pressures from outside, particularly in periods of regional instability due to wars and political strife.

Turkey's awareness of environmental problems and their detrimental impacts is also quite recent, and the environmental sensitivity of policy-makers remains shallow to date. Turkey has signed the Kyoto protocol in February 2009, but its compliance with the EU *acquis* on the environment is far from satisfactory. The primary concerns for which the civil society strives to draw attention are air, water and sea pollution, deforestation, land erosion and desertification, as well as air and waterborne diseases (SPO 1998). Moreover, the impacts of climate change became obvious in Turkey primarily through the volatility in rainfall, drought and/or floods; water scarcity and the impact of the former on agriculture and food security, all of which has made the environment a growing security concern (Aydin/Ereker 2009). Turkey, being in an arid region where water can be a *casus belli*, has begun to include environmental concerns in its political agenda. The global food crisis, despite a rise in prices, has yet to have a comparable effect on Turkey, but it is widely acknowledged that the trend indicates more difficult times ahead for Turkish agriculture (Eraktan 2008). For the well-being of future generations, Turkey's adoption of a sustainable development framework appears to have become a matter of security.

9.6 Conclusion

Turkey finds itself in an ongoing phase of transformation as far as its domestic dynamics is concerned, the directions and the implications of which vary along with the transformation in its immediate neighbourhood and the wider global context. Major issues haunting Turkey today primarily derive from the lega-

17 TUIK (28 October 2008) on: "Population Trends Statistics"; at: <http://tuikapp.tuik.gov.tr/adnksdagitimapp/adnks.zul>.

18 Turkey has a reserve clause against the 1951 Geneva Convention that imposes a geographical restriction to preclude the right to asylum to persons coming from countries to its east and therefore only serves as a transit point for these asylum seekers. Turkey's asylum regime is undergoing transformation for conformity to EU practices and standards.

cies of its distant and recent past. This implies shortcomings on the part of the Republican nation-building scheme which resolved to break with the past and create a secular, democratic state of law and a monolithic society devoid of divisions along the lines of ethnicity, religion, and class. As the European Union which Turkey aspires to join is evolving towards a post-national, post-modern state of being, Turkey is, in a way, still struggling with the modernist project of nation-building 85 years after the foundation of the Republic.[19]

The EU accession process, in the face of the current impasse, fails to fulfil its role as an anchor. The moment of optimism at one point where major reforms were considered possible and the accession prospect promised remedy to Turkey's woes has failed to deliver, and worse still, left Turkey 'half-done'. What replaced the optimism is an anxiety for the state establishment that the political space opened up by reforms will endanger what remains of the integrity of the nation and the territory. To sum up, the blurring of the membership prospect has made Turkey's transformation thorny and contentious, lowered incentives for undertaking politically risky reforms and rendered domestic divisions more vivid. This left the country in between the Devil and the deep blue sea, where the national leadership finds itself unable to either push for further reforms or able to go back to 'good old days' when ruling an isolated, introverted, un-integrated country was much more manageable. The acute sentiment of an unsatisfactory position and the inability to move further or back away defines the current understanding of (in)security in Turkey.

Many challenges that Turkey faces in the regional and the broader international arena have also ostensible historical backgrounds, but what is more striking is their immediate relation to domestic concerns. Turkey today appears to view international relations through domestic political lenses: different actors perceive, define, and prioritize international challenges, threats or tendencies through different prisms of their respective fears and desires of the domestic sphere; which, in turn, translate into different preferences and tendencies in the regional and international sense, as well as securitization of different areas. On the other hand, actors view one another's foreign policy choices as means to gauge and judge one another's true colours. The overall picture indicates that not only do internal and external matters interact and/or coincide, but the domestic divisions and mistrust are nurtured by different conceptions of security, different orientations and expectations in the realm of global politics. This then creates in Turkey a much more pathological mood where every issue easily translates into a perceived new security threat or a cleavage over the fundamentals of, the state, nation, unity, territorial integrity or Turkish identity.

19 Barkey and Taspinar (2006: 3) seem to disagree, stating that the Kemalist nation-building project has accomplished its goals and is now struggling to "preserve and protect what has already been achieved."

10 Promoting Democracy as a Security Goal. The 'inward-outward' Paradox of the EU's Foreign Policy

Omar Serrano

10.1 Introduction[1]

This chapter looks at the influence of domestic political processes and public opinion in the framing of EU foreign policy. In doing so, policies which have been aimed at achieving regional security by means of promoting internal reforms are evaluated. The chapter emphasizes a mismatch between security concerns amongst policy-makers[2] and public opinion.[3] An increased concern on foreign policy-related issues (from domestic constituencies) it seems follows a similar pattern to the erosion of the 'permissive consensus' (Lindberg/Scheingold 1971) in the past decade.[4] There is strong opposition in many *member states* (MS) towards the effects of policies which comprise the extension of the 'four freedoms' (of capital, labour, goods, and services). The latter are the main incentives offered by both enlargement and New Neighbourhood strategies. This is relevant inasmuch as it suffices for public opinion to constrain a few MS for *European foreign policy* (EFP) as a whole to be affected. Since most areas in EFP are intergovernmental, a single member can in principle block or alter a common position.[5] Thus, the influence of domestic pressures should not be overlooked.

The paradox of the internal-external dimension suggests that a certain mismatch exists amongst the security perceptions (and security goals) of policy-makers and voters. European voters have stressed social (job insecurity) or societal (fear of immigration) dimensions of security, whilst policy-makers have emphasized external or political ones. Regional democratization strategies are particularly affected by this happening.

That the Eastern enlargement (whilst extremely successful in promoting democratic consolidation of the new member states) has heightened public concerns on EFP, has to do with the aforementioned paradox. In particular, given the strong opposition towards extending membership to some of the countries included in the 2004 enlargement (10.3). Although current voters' concerns have (so far) mainly affected some of the EU's democratization policies,[6] it is not the only foreign policy area where domestic

1 The author would like to thank Jonas Hagmann, Thorsten Wetzling, and four anonymous reviewers for helpful comments on previous versions of this chapter. He is also grateful to policy-makers from various MS permanent representations in Brussels, and at the Commission, who kindly provided their time and hindsight and whose interviews greatly enhanced this research.

2 By policy-makers, ideal types are considered. The aim is to capture the EU policy-making process as a whole, and not any individual cases. There was much divergence amongst the different representatives of *member states* (MS) in the run-up to the 2004 enlargement (O'Brennan 2006).

3 When measuring public opinion the study relies on Eurobarometer surveys. Aggregate EU-15 data are used for the 2004 enlargement, and in more recent cases the data are aggregated for the EU-25 or EU-27. In some particularly relevant cases, public opinion of individual MS is also examined.

4 Several authors (e.g. Norris 1997) have argued that this consensus began to disappear by 1989 and became clear with the opposition to the Maastricht referendum. Whilst this is the case for overall support to European integration (both from an affective and a utilitarian perspective) this does not seem to have directly translated into the realm of foreign policy. After all, this was one of the fastest growing areas of integration throughout the decade of the 1990's. The Eastern enlargement appears to have changed this 'benign neglect' as further enlargement policies given immigration or economic liberalization fears have met strong opposition.

5 In practice this works through coalition-building, as peer pressure can be strong and it is unlikely for a single MS to defend a position alone.

6 Chiefly the enlargements towards Turkey and the West Balkans, but possibly also to the New Neighbourhood policy if it were to be fully implemented (i.e. the extension of the four freedoms).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_10, © Springer-Verlag Berlin Heidelberg 2011

politics might be of relevance. Somewhat ironically, through the promotion of democratization, the EU has brought on itself increasing calls for a more democratic foreign policy. Whether and how this has happened is a relevant topic for further research (in areas such as trade, defence, and justice and home affairs). This does not mean that all MS have been equally affected. There seem to be relevant differences as to the degree to which domestic politics influences behaviour of the 27 MS. Indeed, there might be groups of MS (e.g. old and new members or small and big MS) that behave in similar ways. This could have significant effects in the coalitions that are formed when formulating European foreign policy.

The chapter is divided as follows. A first part evaluates (from a theoretical and empirical perspective) the mismatch in security concerns of policy-makers and voters (10.2). This is followed by an empirical appraisal on the achievements of the EU in its diverse strategies for promoting democratization (10.3). A third section evaluates public preferences vis-à-vis the 2004 enlargement (10.4). A fourth part suggests a framework of analysis for the influence of domestic politics in European foreign policy-making (10.5).

10.2 Security and Democracy: An Inward-Outward Paradox

The aim of promoting democracy through enlargement was made explicit in article 49 of the Maastricht Treaty and following the incorporation of the so-called Copenhagen criteria (adopted as central components of the enlargement process during the European Council in the summer of 1993).[7] It must be noted that enlargement is only one of the various instruments the EU has implemented for promoting democracy. This objective has not been limited to regional policies as the promotion of democracy has been an integral component of EU relations with third countries.[8] This said, it is precisely regional policies (and in particular enlargement) where the effects of democracy promotion have been most successful (i.e. have achieved substantial reforms). It is also towards them that public opinion in the European Union has been most divergent.

Both the New Neighbourhood strategy and Enlargement can be seen to reflect a 'narrow' notion of security contained in the *European Security Strategy* (ESS).[9] This key document (a doctrine for European foreign and security policy) underlines the importance of enlargement as a foreign policy tool.[10] The ESS identifies terrorism, proliferation of weapons of mass destruction, regional conflicts, state failure, and organized crime as key threats (chap. 6 by Bailes). Under this optic, neighbourhood policies are directed towards "promoting a ring of well governed countries to the East of the European Union and on the borders of the Mediterranean" (ESS 2003: 13). The aims are the promotion of good governance in the Balkans and the Mediterranean rim; the main (although not exclusive) areas of concern for enlargement and neighbourhood policies.

Finding whether a mismatch amongst security concerns of voters and policy-makers exists, requires a careful examination of the concept of security. Buzan's (1991) widely shared typology conceives security threats as 'military', 'political', 'economic', 'environmental', or 'societal'. In this view, *military security* is centred along offensive and defensive capacities of states; *political security* on the organizational stability of states; *economic security* on access to resources to sustain welfare and state power; *environmental security* on the maintenance of the local and planetary biosphere; and *societal security* comprises sustainability of traditional patterns of language, culture, and religious and national identities and customs (Buzan 1991: 19–20; Brauch 2008, 2009).

This framework is useful when examining the objectives of the ESS as they fall in the external or political security typology. At the same time, both enlargement and neighbourhood policies touch upon

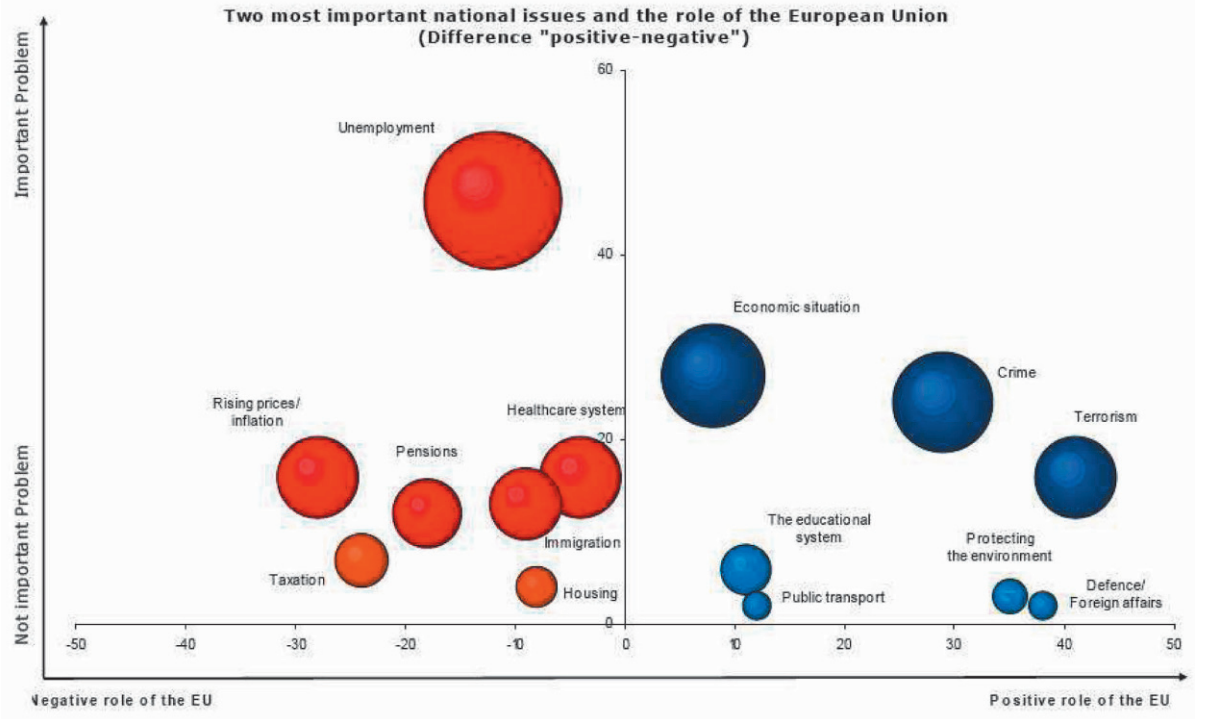
7 See European Council, 21–22 June 1993: Conclusions of the Presidency; at: <http://ue.eu.int/ueDocs/cms_Data/docs/pressdata/en/ec/72921.pdf>.

8 This aspect is not covered in this chapter. However, a recent conference organized by Annette Jünemann and Michèle Knodt deals extensively with the subject. In an ensuing publication (Jünnemann/Knodt 2007) diverse authors look at EU democracy promotion in Africa, Latin America and the Caribbean, Asia, Russia, East and Central Europe; as well as the Mediterranean and the Arab world. Their analysis is centred along dimensions such as the degree of interaction, economic potential, security advantages, internal security situation, and changes in the overall security environment.

9 See European Council, European Security Strategy 2003; at: < http://www.consilium.europa.eu/ cms3_fo/showPage.ASP?id=266&lang=EN&mode=g>.

10 "[T]he progressive spread of the rule of law and democracy has seen authoritarian regimes change into secure, stable, and dynamic democracies. Successive enlargements are making a reality of the vision of a united and peaceful continent" (ESS 2003: 3).

Figure 10.1: Important issues and role of the European Union in them. **Source:** Eurobarometer no. 62 (autumn 2004).



social and societal aspects which seem to be relevant security concerns for voters within member states. Thus, it is argued, there is a certain mismatch. It must be noted, however, that these categorizations are ideal types; a more careful analysis is thus required.

An assessment of possible differences amongst public opinion and policy-makers requires decorticating different meanings of security, as they are themselves contested. Baldwin (1997) proposes a useful framework for doing this through seven axes: referent objects (security for whom?); values (which values are to be secured?); amount (how much security is needed?); threats (what threats are to be conceived?); costs (at what cost?); time (for how long?); and means (by what means are they to be secured?). Some of these axes, used as analytical tools, seem helpful in clarifying where the aforementioned differences might exist (Hintermeier 2008).

By using these different axes and evaluating public opinion responses in Eurobarometer surveys, we may compare these preferences with the positions stated by the ESS. There is one caveat in following this methodology. As Cautrès and Monceau (2007) argue, Eurobarometer questions are subject to one dimension or to a simple contrast amongst two possibilities (e.g. tend to agree, tend to disagree). Public opinion dynamics, however, are likely to be more complex than this. The Eurobarometer surveys, nevertheless, provide us with a wide range of interrelated questions, which combined with the appropriate tools (such as factor analysis) may help us in gaining a more accurate picture. According to the research of the above-mentioned authors (in which the authors apply factor analysis to French Eurobarometer responses), they find similar results as the ones which shall be portrayed below. Nevertheless, in the present research sets of interrelated questions have been evaluated to minimize the above-mentioned biases.

The ESS aims at securing states or the EU as a whole. At the same time the most important concerns for voters according to Eurobarometer surveys have been unemployment, crime, and the economic situation.[11] These pertain either to individuals or to society as referent objects. European citizens, it seems, conceive threats along two different dimensions. A first one refers to the aforesaid fears of unemployment, crime, and the economic situation. A second relies on traditional (or external) threats such as terrorism – largely in line with those threats identified by the ESS. Societal concerns, however, are more present than external ones. They become more salient, given that in

11 This can be found in different Eurobarometer surveys. See for example the latest *Eurobarometer* (Spring 2007, no. 67); at: <http://ec.europa.eu/public_opinion/archives/eb/eb67/eb_67_first_en.pdf>.

relation to unemployment – the main concern for European public opinion – the EU's role is considered to be a negative one. Figure 10.1 taken from the Eurobarometer 62 (autumn 2004)[12] shows that threat perception (and the role of the EU in confronting threats) is dual; as there is an internal and an external dimension. The Y axis represents the concerns of a particular issue in public opinion. The X axis comprises the impact (positive in blue and negative in red) of the EU on these concerns. Time series of different Eurobarometer surveys show these responses to be stable over time.

The EU's role is seen as positive in areas such as the economy, crime, terrorism, and foreign affairs. At the same time, it is negatively perceived in fighting unemployment, inflation, and immigration. Said otherwise, the EU is perceived to play a relevant role in generating external security but a negative one when it comes to societal security. That said, EU involvement is favoured in both dimensions: fighting unemployment (44 per cent); poverty and social exclusion (40 per cent); keeping peace and stability in Europe (34 per cent); fighting organized crime and drug trafficking (30 per cent); terrorism (27 per cent).[13] These responses also indicate that societal security concerns are seen to be more acute than those relevant to external security. Considering that European unification has produced significant stability, these results seem understandable.

In themselves, these findings should not be problematic. Tensions arise, however, when external aims touch upon societal issues. This is the case of external democratization policies. When the means by which these objectives are furthered touch the societal dimension, they are (not surprisingly) strongly opposed. This, concerning not only enlargement, but also the wider neighbourhood policy which is perceived to be costly and even as a possible threat to the EU's prosperity and stability (in the case of the promotion of internal reforms).[14]

To avoid biases from issue-framing, it is useful to look at related questions (alternatively, quantitative methods such as factor analysis could be applied). A special Eurobarometer survey[15] on relations with neighbouring countries suggests European citizens consider the most important areas of cooperation to be: terrorism (90 per cent) and crime (90 per cent); followed by economic development (88 per cent); energy (87 per cent); the environment (87 per cent); and democracy (87 per cent). All of them are in line with the aims of the ESS. However, when asked on whether promoting reforms in those neighbouring countries would endanger the EU's own prosperity and stability, a high number of respondents agree. This is the prevailing opinion in fourteen member states (Portugal, Denmark, Italy, the UK, Latvia, Malta, Austria, Estonia, Slovenia, Luxembourg, the Czech Republic, Hungary, Ireland, and Slovakia). For the EU-25, nearly half of the respondents consider furthering reforms in neighbouring countries as a potential threat. This goes against policies aimed at democratization, which have been developed by the EU towards neighbouring countries. It also suggests scepticism as to the costs of such policies.

A further way of looking at these public concerns is by evaluating public opinion positions on the consequences of enlargement. The main stated consequences are: increased mobility within Europe (82 per cent of responses), increase of job transfers to cheaper locations (75 per cent), and increased settlements of workers from future members into old member states (73 per cent).[16] Respondents also consider that enlargement increases the risks of criminal activities (62 per cent); even if they also think it reinforces the capabilities of the Union to fight criminality and terrorism. The same pattern identified with earlier responses is confirmed.

So far, only enlargement has been mentioned. However, neighbourhood policies are affected by the very same concerns. What makes the *New Neighbourhood Strategy* so similar to enlargement is the proposed extension of the 'four freedoms'. As a consequence, the *New Neighbourhood Policy* has similar distributional consequences as enlargement (and can be expected to cause analogous opposition). Resistance is predictable on issues such as immigration or

the re-allocation of firms to countries or regions with cheaper labour, lower taxes, and laxer regulatory frameworks.

There is a caveat to the previous results. The issue of timing seems to be important. When a temporal dimension is added, opposition to enlargement drops.[17] This suggests that a slower enlargement (or liberalization) process is desired; which is understandable in light of the societal concerns expressed on public opinion surveys. Nevertheless, this poses a problem when confronted with external and political aims. It would have been extremely hard to include only a few countries in the 2004 enlargement (say Poland, Hungary and the Czech Republic) whilst leaving other candidate countries waiting for accession. It would also have weakened the incentives offered by the EU, which are central to the success of enlargement and New Neighbourhood policies (10.3). Moreover, the 'road map' of the Copenhagen criteria (even with its clause on absorption capacity), makes it extremely hard to delay accession once chapters are being closed. Recent developments related to the Turkish accession process (in which the French government has without much success sought to slow down the pace), underline the difficulties when the Commission faces attempts to delay the process.

In sum, European voters seem to support cooperation with neighbouring countries (along the lines stated in the ESS) as long as it does not touch upon social issues (in particular immigration and unemployment). These phenomena underline an external-internal paradox. External goals which affect societal issues will be opposed. Moreover, there is significant scepticism towards promoting internal reforms in neighbouring countries. As a consequence, the mismatch is not so much on the objectives, but on the policies or instruments by which these objectives are furthered. To provide a more detailed explanation of these objectives, the next section evaluates the way in which enlargement and neighbourhood policies have been implemented.

10.3 Promoting Democracy as a Security Goal: Enlargement and Neighbourhood Strategies

The 2004 enlargement is to be seen as part of a wider effort to integrate Eastern Europe into the West's political and military institutions. The political imperative to do so has been enormous, given both the desire from candidate countries and the historical determinants of the long-lasting division of Europe during the Cold War. This has posed enormous pressure on EU policy-makers to act. At the same time, for candidate countries, enlargement criteria have entailed significant restructuring of domestic institutions and public policies (Schimmelfennig/Sedelmeier 2004). The strategy has proven extremely successful in consolidating democratization processes, but also in the protection of minorities and the relations amongst governments and the military. The most pertinent examples of these effects are the Baltic States, the Balkans, and Turkey.

The Baltic States were reluctant to integrate sizable ethnic minorities.[18] The cases of Moldova and Georgia, where the OSCE had established *long term missions* (LTMs) after bloody infighting, warned of the potential dangers of such a situation.[19] An OSCE mission was proposed in both Estonia and Latvia to prevent similar developments. However, both Baltic countries were reluctant, in part given that it could divert foreign direct investment. The aim of joining the EU (and NATO) proved a strong element in persuading both of these countries to accept the involvement of the OSCE (and in complying with the requirements of the Commission on the protection of minorities).

In the Balkans, after a long series of policy setbacks throughout the conflict in Yugoslavia, the prospect of membership has been a relevant factor in ensuring the post-war stability of the region. In this sense, the incorporation of Slovenia to the Union has sent a powerful message to other former Yugoslav countries. The incorporation of Bulgaria and Roma-

17 Special issue of: *Eurobarometer*, no. 253 (July 2006) on enlargement; at: <http://ec.europa.eu/public_opinion/archives/ebs/ebs_255_en.pdf>.

18 In particular Estonia and Latvia. Estonia hosts a population of about 400,000 Russian-speaking 'non-citizens' and Latvia nearly 700,000 – approximately 30 and 40 per cent of their respective total populations (Ghebali 2004).

19 The conflict involved minorities in both Trasniestria and South Ossetia, to large extent holders of Russian passports, as is the case with Russian-speaking minorities in the Baltic States.

nia has reinforced this appeal; Croatia is likely to join in the near future. Gänzle and Sens (2007) argue that after the war in Bosnia (in 1995); the Kosovo War (of 1999); and the resulting Stability Pact, the EU has played a central role as an economic, political, and security actor.

These two cases had particular importance given the risks of violent conflict erupting or re-emerging. Furthermore, the incentive of joining the EU is likely to have helped opposition parties to consolidate and the mobilization of societies against authoritarianism. This could well have been the case in Slovakia under the Meiar government; Romania in the early 1990's; Croatia under Tudjman; and Serbia under Milosevic (Schimmelfennig/Sedelmeier 2004).

Current accession candidates have also engaged in wide-ranging democratic reforms. Turkey has reduced the involvement of its military in the country's political life. This has made possible the rise to power of the moderate Islamist government of Recep Tayyip Erdogan, less than a decade after the military overthrew the government of Necmettin Erbakan, due to its Islamic credentials (chap. 9 by Aydin/Esen). The reduction of the military's involvement in Turkish politics, its allowance of the rise and continuation of a moderate Islamist government, mark a watershed in this country's modern history. This might also have helped easing tensions towards Cyprus. The enlargement of Cyprus itself raised expectations of achieving a solution to the long-lasting division of the island. Even if these expectations proved premature, the possibility of joining the Union encouraged Turkish Cypriots to largely support a UN plan for reunification, which has opened new opportunities for a conflict settlement.

Overall, as Schimmelfennig (2007) argues, the transformative effect of the EU and other regional organizations (such as NATO or the OSCE), has occurred in two main directions. Either by creating a virtuous circle which reinforces and stabilizes norm conformance; or by assuring compliance with particular rules – as was the case of minority rights in the Baltic countries. In authoritarian or autocratic countries, such as Serbia and the Ukraine, domestic revolutions might have been encouraged by the prospect of membership in these regional organizations. Hence, the success in bringing about democratization and democratic consolidation depends on the pre-existence of conditions favourable to democratization, and on a credible conditional perspective of admission.

It is hard to find any counterfactual which would allow measuring the degree to which EU membership explains these developments by itself. However, given the important incentives provided by the EU; the 'road map' of the Copenhagen criteria; and the monitoring of the Commission, it seems unlikely that enlargement has not been important – if not essential – in bringing about these internal reforms.

The *European Neighbourhood Policy* (ENP) has been less successful. There have been a number of explanations for its much studied shortcomings.[20] A major element has been the lack of a clear policy. An example of this is the strategy towards the countries which were to join the 'Barcelona Process'. Until 1995, the strategy focused on promoting stability rather than democracy (e.g. the support to the Algerian coup in 1991). However, the aim for a more coherent foreign policy and a reassessment of European interests[21] brought about the *Euro-Mediterranean Partnership* (EMP) in November 1995 (Youngs 2002).

According to Schimmelfennig and Sedelmeier (2004), the shortcomings of the ENP vis-à-vis enlargement are to be found mainly as a consequence of the lack of a mechanism of conditionality – through which the EU has been able to transfer rules. Essentially, conditionality entails a 'bargaining strategy of reinforcement by reward' (Schimmelfennig/Sedelmeier 2004: 662). The lure of the neighbourhood strategy has not proven successful in bringing about significant democratization and reform, since it does not offer membership as an end goal. Moreover, beyond the EMP, the *Partnership and Cooperation Agreements* (PCAs) that are in force with Russia, Ukraine, and Moldova do not include preferential trade. Thus, a timetable for regulatory approximation does not exist. This limits even more the influence of the EU in bringing about institutional change in these countries. Pridham (2002) suggests that given the complexity and the length of democratic consolidation, long-term incentives and political conditionality (as required by the EU through the Copenhagen criteria) are essential.

Perhaps, not surprisingly then, the Commission's more recent approach towards ENP aims to reinforce the neighbourhood strategy through what it defines as a differentiated, progressive, and benchmarked approach.[22] This essentially means achieving reform through conditionality (in a similar way enlargement

20 For a full overview see: Jünnemann and Knodt (2007).

21 The belief that good governance and democracy were by themselves better ways of bringing about long-term stability in the region and containing radical Islam instead of supporting repressive governments.

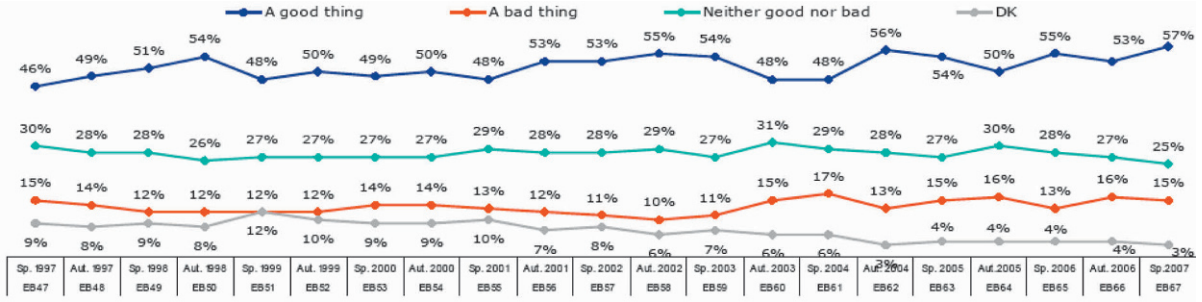

Figure 10.3: In favour of the EU enlargement with regard to the Eastern enlargement candidate countries in per cent. **Source:** Author's elaboration based on Eurobarometer (1996 to 2002) data.

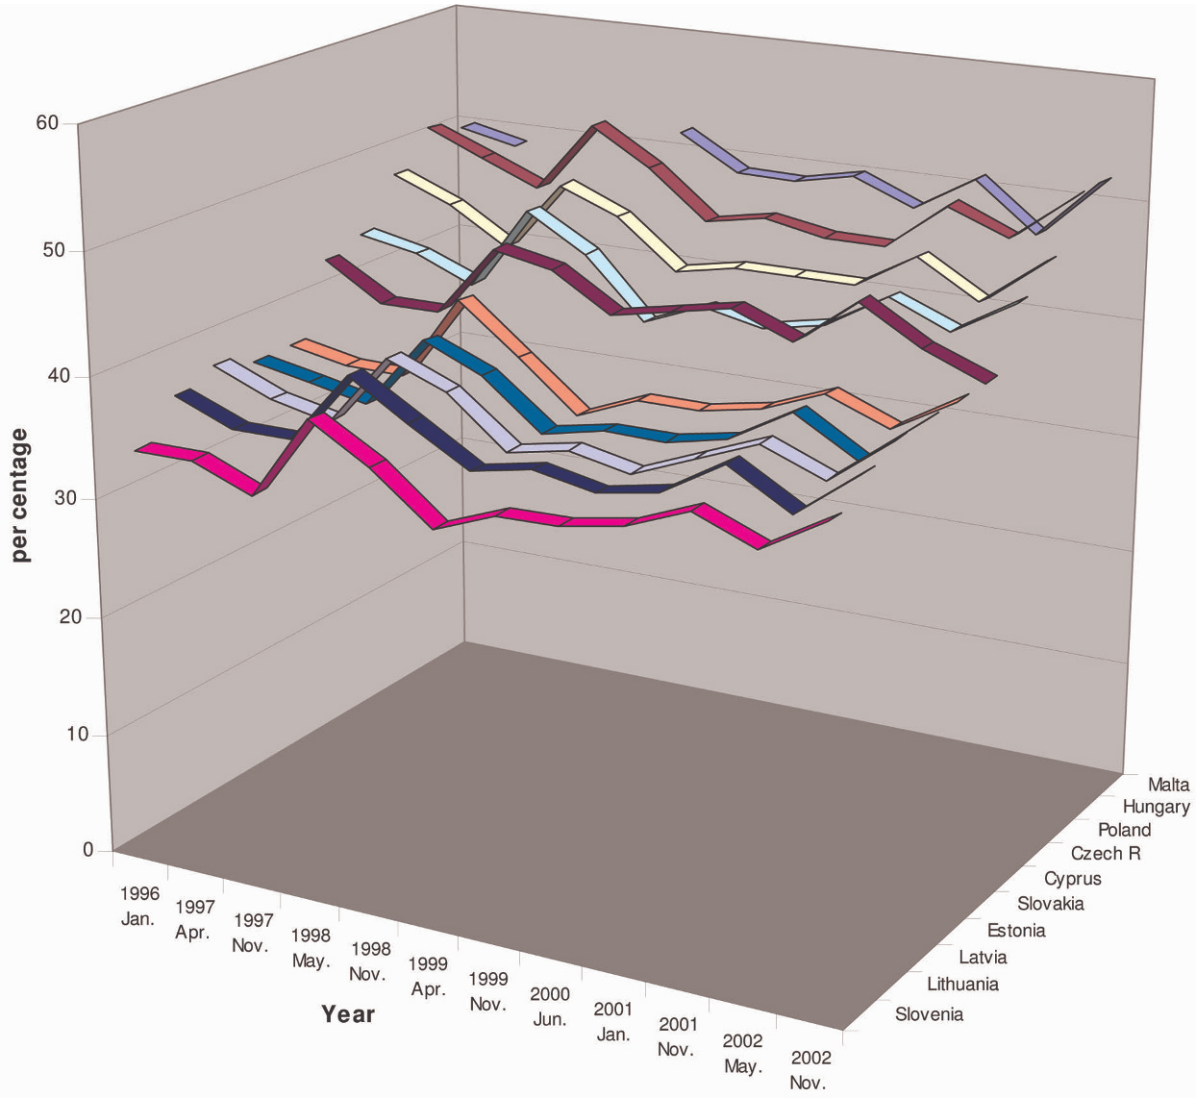

has worked), while offering the 'four freedoms' (of capital, labour, goods, and services) as a reward.[23] This is to be achieved through negotiated consensual bilateral 'Action Plans' with each target state (Biscop 2008). As with enlargement, the success of this policy ultimately depends on the credibility of the reward

(that is on the extension of the four freedoms). However, the extension of the free movement of people risks facing strong opposition from domestic constituents. This might weaken the credibility, and thus the effectiveness, of the Union's policy – a similar dynamic to that which currently occurs with the enlargement process.

10.4 Public Support, the Eastern Enlargement and its Consequences for European Foreign Policy

There is plenty of evidence that public orientations can influence the European integration process, as can be seen in the outcomes of Maastricht, the failed constitutional referendums, and the impact of public opinion in policies such as the common agricultural policy, the implementation of the Euro, and the debates on enlargement (Laumen/Maurer 2006). At the same time, it is less clear to which extent they influence European foreign policy. A traditional view is that foreign policy (and in particular security policy) is the domain of the executive and that only in exceptional cases it affects policy decisions. In this sense foreign policy is seen to be an area shielded from public debate and as such little influenced by public orientations (10.5). Whilst this may be true in an important number of European countries (as seems to be the case for most of the new member states and perhaps even older members such as Germany),[24] this is certainly not what happens in MS such as France, the Netherlands, the UK, Ireland, and more recently Italy.[25] It is thus relevant to look at public perceptions on enlargement. Before that, however, it is pertinent to emphasize that throughout the period following Maastricht support for European integration has remained stable and overall high (figure 10.2). Thus, lack of support to enlargement cannot be directly attributed to a lack of support to the EU.

Support to enlargement has been low (and continues to be so). Moreover, it has been selective, with some candidate countries enjoying stronger backing than others. What is the more surprising is that (with

22 See European Commission, 2003: *Communication from the Commission to the Council and the European Parliament*: *Wider Europe – Neighbourhood: A New Framework for Relations with our Eastern and Southern Neighbours* (Brussels: European Commission, 11 March, 2003); at: <http://ec.europa.eu/world/enp/pdf/com03_104_en.pdf>.

23 'In return for concrete progress demonstrating shared values and effective implementation of political, economic and institutional reforms, including in aligning legislation with the acquis, the EU's neighbourhood should benefit from the prospect of closer economic integration with the EU. To this end, *Russia, the countries of the Western NIS and the Southern Mediterranean should be offered the prospect of a stake in the EU's Internal Market and further integration and liberalization to promote the free movement of – persons, goods, services and capital (four freedoms).*' (emphasis in original), in: *Communication from the Commission to the Council and the European Parliament*: *Wider Europe – Neighbourhood: A New Framework for Relations with our Eastern and Southern Neighbours* (Brussels: European Commission, 11 March, 2003: 4); at: <http://ec.europa.eu/world/enp/pdf/com03_104_en.pdf>.

24 The case of Germany is puzzling as on the one hand there seems to be an elite consensus on foreign policy and little public debate on foreign policy decisions. A case in point is the strong involvement of Germany in the Eufor-Congo mission which was strongly opposed by public opinion and the parliament. On the other hand, there are cases where policy does seem to be constrained by public opinion. The reluctance of the Merkel administration to increase the participation of German troops in the NATO mission in Afghanistan suggests so. At the same time, on enlargement, the CDU/CSU position on a privileged partnership as an alternative to Turkish membership has been much publicized.

25 France changed its constitution to require a referendum to any further enlargement and French President Sarkozy made his opposition to Turkey a central element of his election campaign. The UK imposed labour restrictions towards Romania and Bulgaria, in large part as a reaction to the huge influx of immigrants from the 2004 enlargement, Ireland followed suit. The British Conservatives have profited from the immigration issue, they made it a central (if at best partially successful) component in the run-up to the 2005 election. More recently Gordon Brown has also included the immigration issue in Labour's agenda. The Dutch have significantly altered their position towards enlargement and the EU, as the economic consequences of enlargement and immigration fears have spurred a vocal domestic debate. The rejection of the Constitutional Treaty by both Dutch and French voters has been attributed in part to the unease of voters towards further enlargement. More recently, Italy has challenged the free movement of people within the Union on security concerns and has repatriated Romanian citizens on these grounds. Radical right parties have increased their presence in parliaments throughout Europe, leading to right-wing shifts in political parties on issues such as immigration.

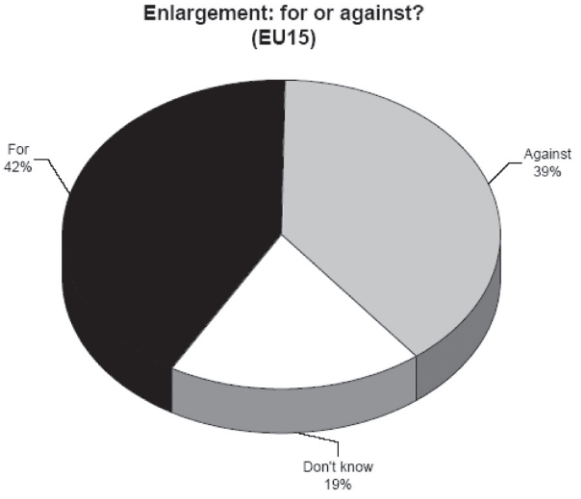
the exception of Cyprus[26]) this approval (or lack of it) is remarkably stable and has remained so over time. This is shown in figure (10.3) and table (10.1). Separate data for each candidate country is only available until 2002.

Figure 10.3 shows that support towards particular countries in the years preceding the 2004 enlargement was remarkably stable both in absolute and relative terms (the exact figures are shown in table 10.1). Thus, variations in overall support have affected all countries equally (with the aforementioned exception of Cyprus). [27]

While the data for each one of the candidate countries was not published in the Eurobarometer reports after November 2002, the Eurobarometer 61 of spring 2004 (the last before enlargement took place) recorded a loss of support for enlargement. Overall support fell to 42 per cent (figure 10.4). See also figure (10.6) which looks at the support in each of the EU-15 MS.

Figure 10.4: In favour of or against EU enlargement. **Source:** Eurobarometer, no 61, Fieldwork (February-March 2004).

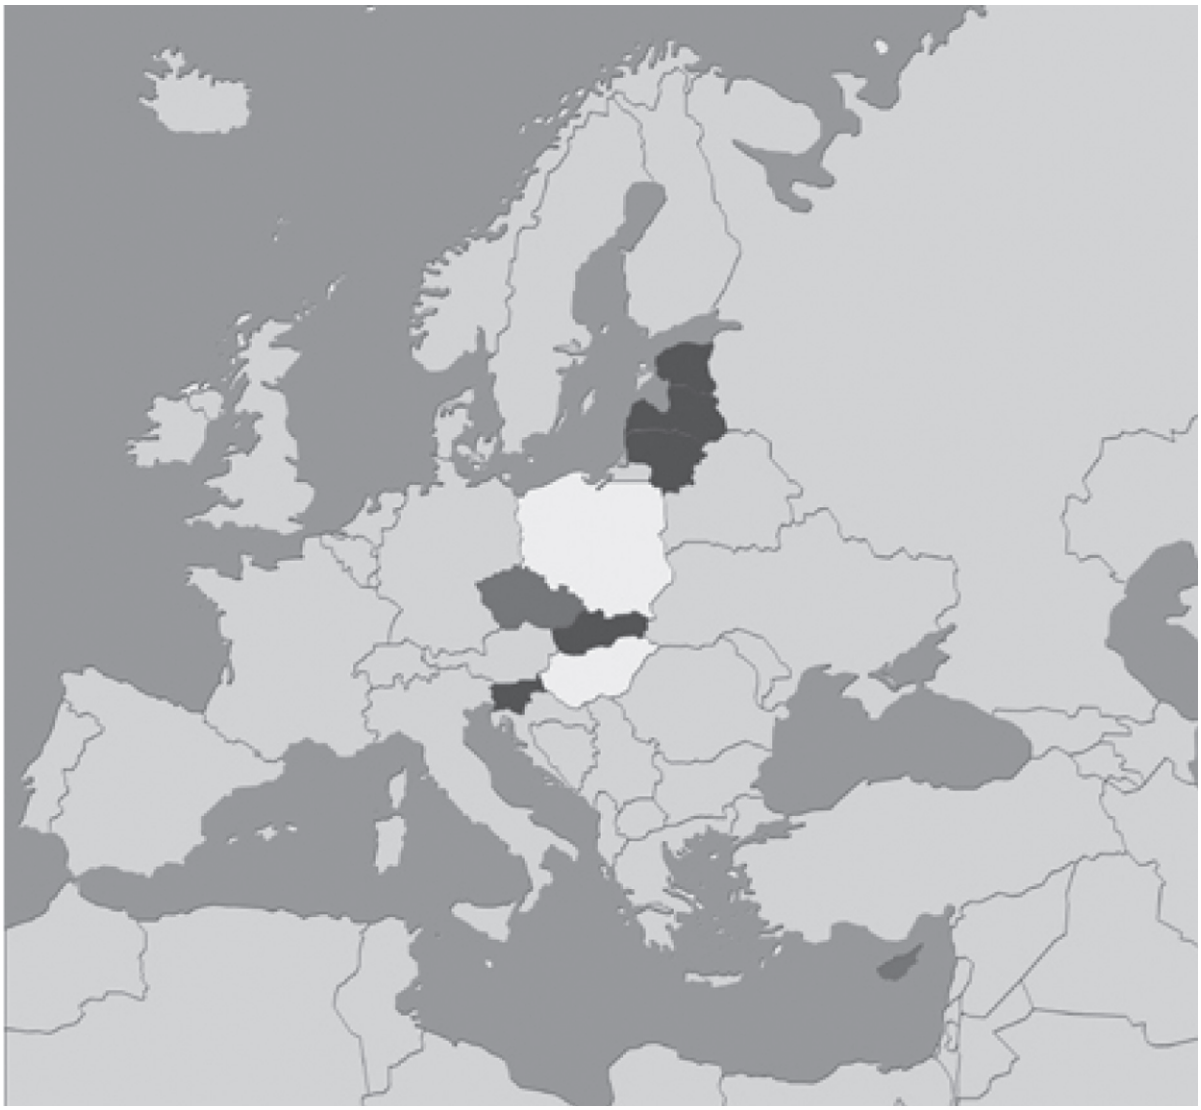


As table 10.1 showed, and this is also reflected in figure 10.5, the states where the lure of enlargement was most important in achieving democratic consolidation – or regional stabilization – were also the countries towards which public support was at its lowest.

26 Its public support decreased as the 2004 enlargement approached. This, nevertheless, seems explainable considering the position taken by the Greek-Cypriot government towards the 'Annan Referendum' supported by the EU and aimed at the island's re-unification. Turkish-Cypriots strongly supported this plan, but it was rejected by the Greek-Cypriots to a large extend given the vocal opposition of its government to the plan. This suggests that public preferences react in a rational way, which goes against one of the main claims of the 'Almond-Lippmann Consensus' (see next section) which is that public opinion is volatile and irrational.

27 It could be conceived that the wider support for some countries was a result of their earlier engagement in the accession process. After all, Helmut Kohl had early on promised and set a date for Polish accession, and with it Hungarian and Czech as well (O'Brennan 2006). However, if this were the case one would expect relative changes in public support over time. That support was overall stable and that the differences in support among the different candidate countries were remarkably constant suggests otherwise.

Figure 10.5: In favour of the enlargement towards Eastern European countries 2004. **Source:** Author's elaboration based on Eurobarometer data (1996 to 2002).



Schimmelfennig and Sedelmeier (2004: 669) argue that the effectiveness of the EU's strategy depended crucially on initial conditions. Thus, both for completely undemocratic countries or for the 'democratic frontrunners' (e.g. Czech Republic, Hungary, and Poland where conditionality was *unnecessary* for democratization and democratic consolidation) EU external governance was ineffective. The democratic frontrunners are amongst those who enjoyed the strongest support in public preferences. On the other hand, public support was at its furthest for those countries which were particularly relevant in the EU's security aims and where success was most evident (i.e. Slovenia, Lithuania, Latvia, Estonia, and Slovakia).[28] Public attitudes towards these countries tended to oppose membership. That the differences in support were stable throughout the whole period covered (both in absolute and relative terms) repeats for the next wave of prospective or new member states (table 10.2).

28 As was mentioned in part 10.2, the Baltic countries had important minority issues to resolve, whereas EU accession was relevant in bringing about the democratic consolidation in Slovakia. Slovenia was the first country in the Balkans to be admitted and consequently a first step in the EU's aim of eventually integrating and ensuring the democratization and stability of other former Yugoslav states.

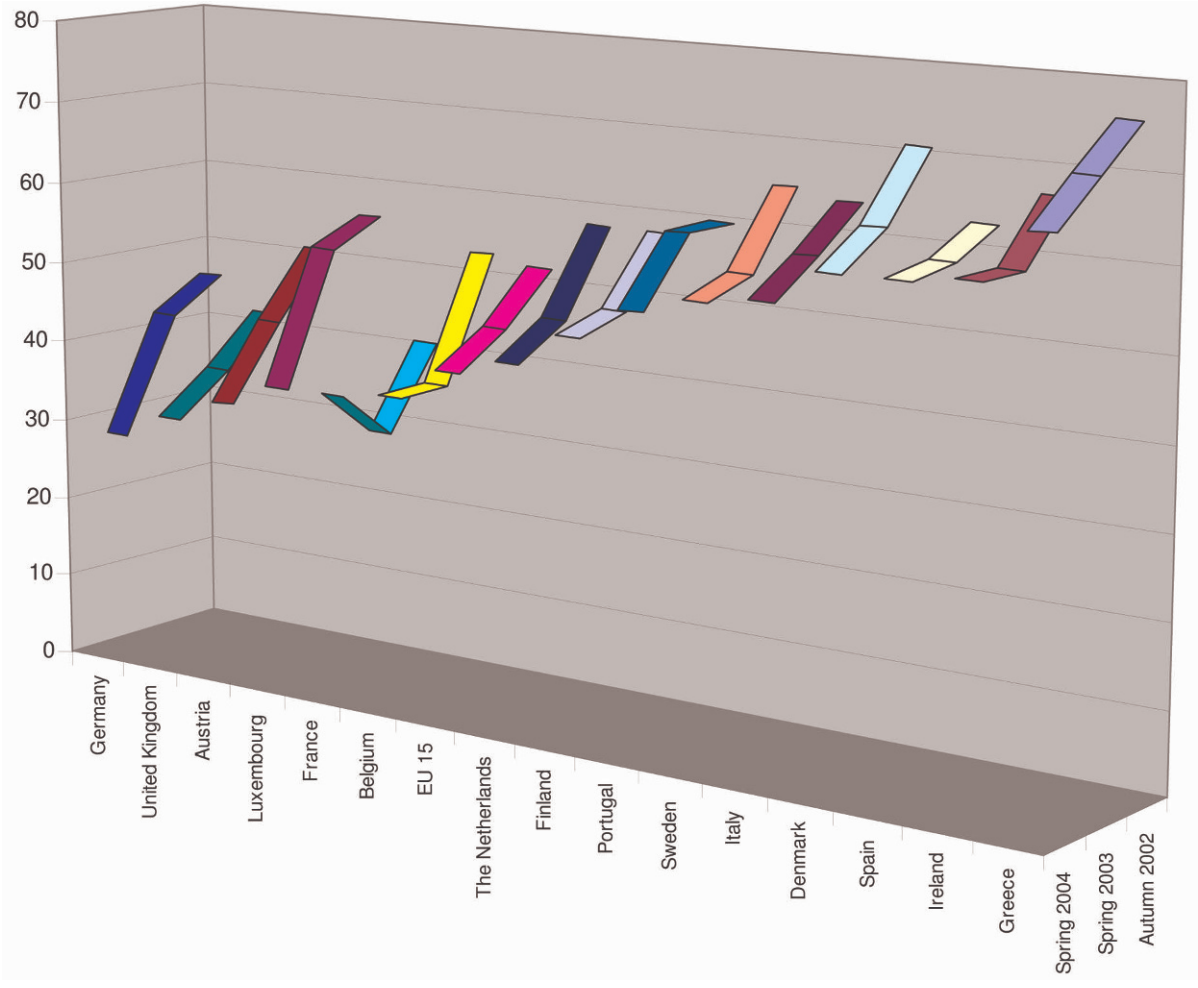
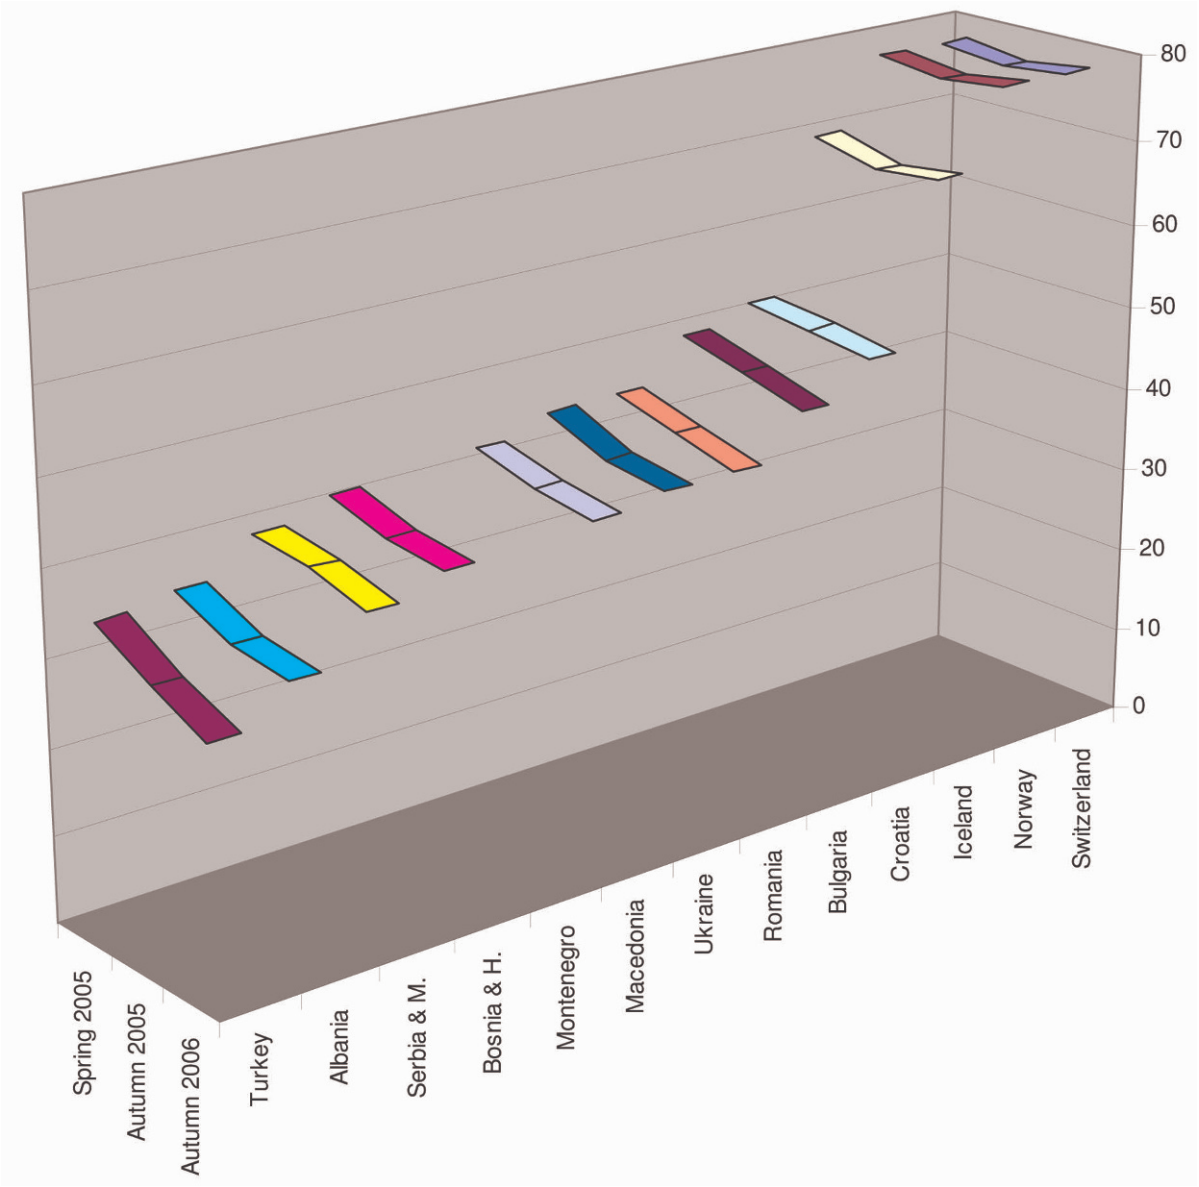
Figure 10.6: In favour of the Eastern enlargement (EU-15 countries). **Source:** Author's elaboration based on Eurobarometer data (2002 to 2004).



There is another important aspect to be considered, namely the existing differences amongst EU members themselves towards enlargement. Figure 10.6 looks at these differences before the 2004 enlargement. What the figure shows is that, even when these differences

Figure 10.7: In favour of the enlargement towards possible new member states. **Source:** Author's elaboration based on Eurobarometer data (2005 to 2006).

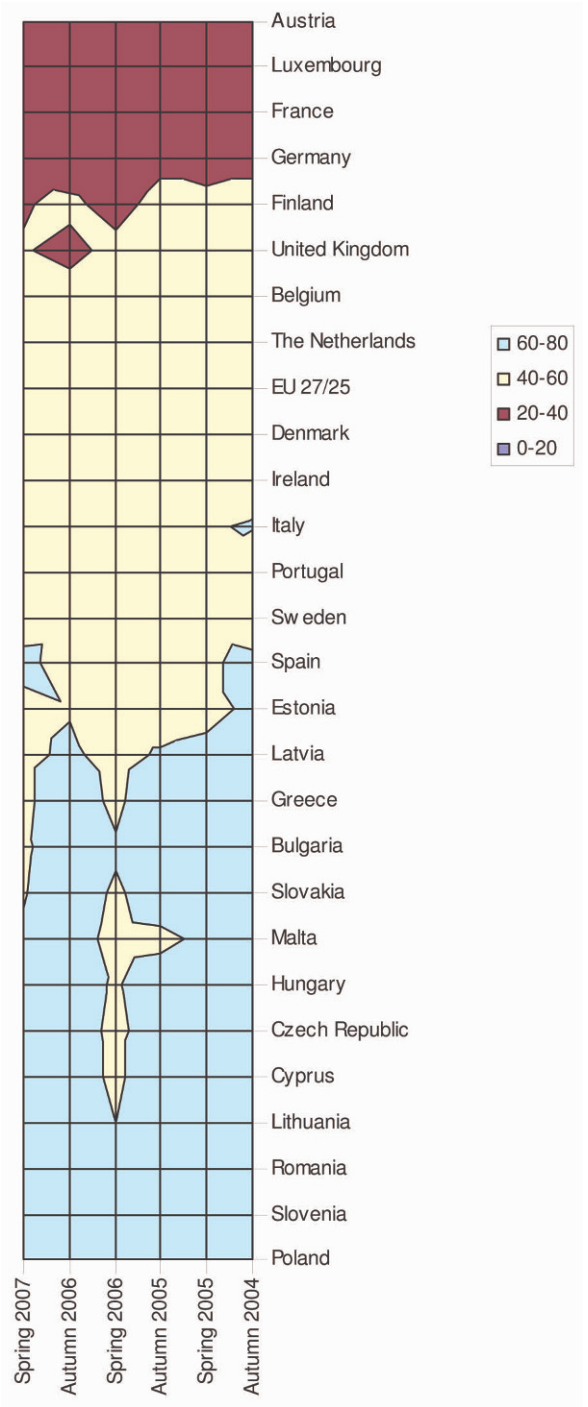


exist, they tend to follow similar patterns (with the exception of France).

The analysis of the current candidate countries (and of Bulgaria and Romania which joined in 2007) shows another big difference amongst on the one hand Croatia and on the other the rest of the West Balkans and Turkey. Figure 10.7 follows patterns similar to the 2004 enlargement.

As with the 2004 enlargement, important differences exist amongst existing MS. In the EU-25 (or EU-27), however, these differences have become more pronounced. It is interesting to note (figures 10.8, 10.9) that there are groups of countries where public opinion towards enlargement reacts in similar ways; particularly in some of the new MS (Lithuania, Cyprus, Czech Republic, Hungary, and Malta). Moreover, there is a clear difference amongst older and newer MS. Public opinion in the former is much more reticent to further enlargement. There is, however, an overall tendency towards opposing enlargement as can be seen by the evolution from 2004 to 2007 (figure 10.8).

Figure 10.8: In favour of further enlargement (EU-25 and EU-27). **Source:** Author's elaboration based on Eurobarometer data (2004 to 2007).



How can one account for the effects of such differences? The next section proposes a framework for doing so.

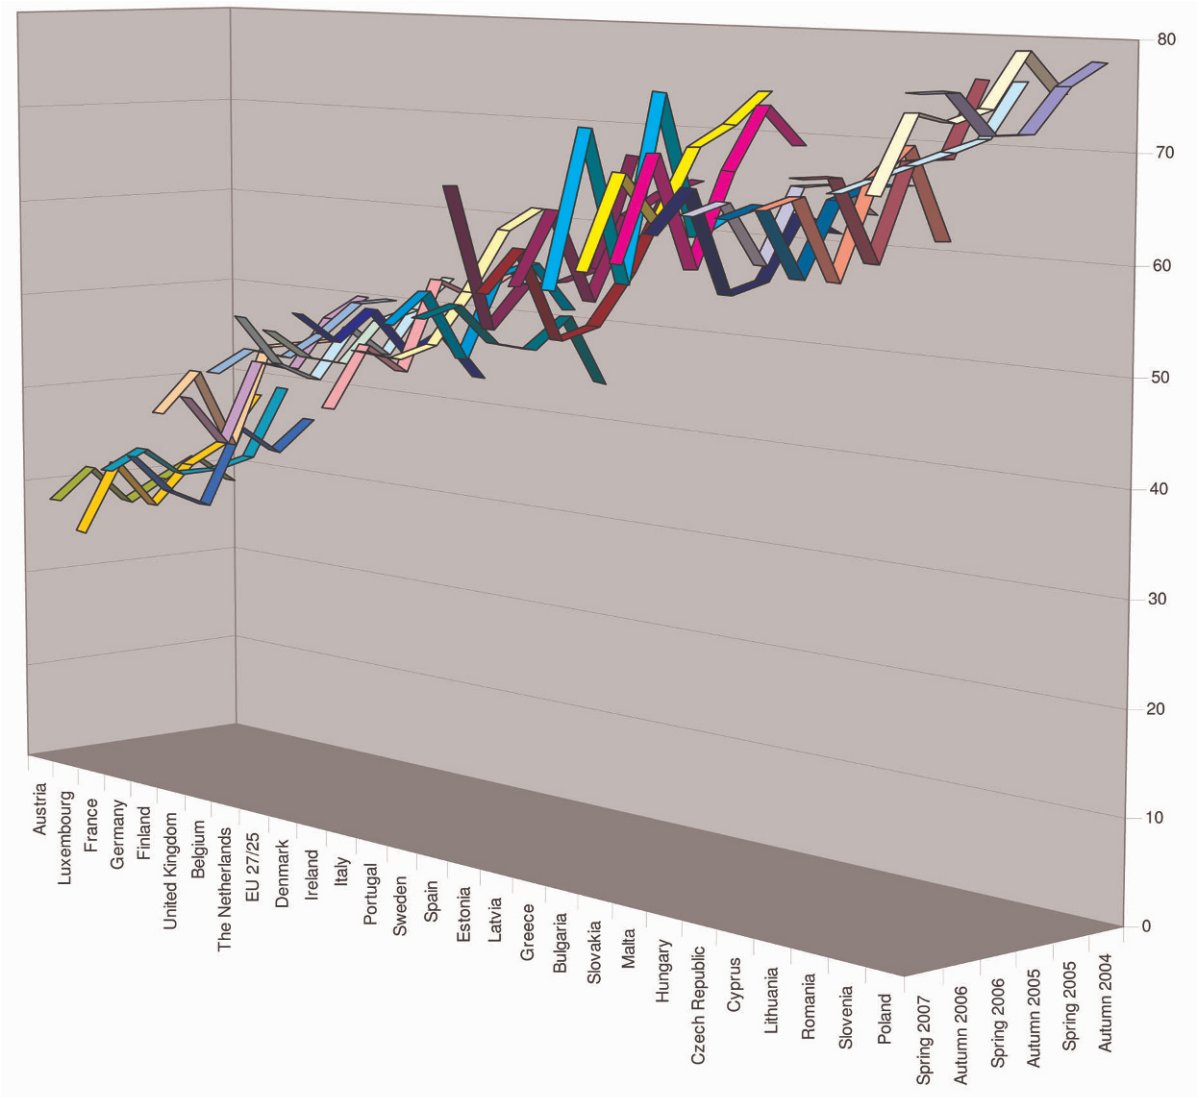
10.5 Domestic Pressures and EFP: A Framework for Analysis

The alleged mismatch amongst policy-makers and public opinion is only relevant inasmuch as domestic political processes have an impact on shaping foreign policy. There is growing interest in the literature on the importance of public opinion in foreign policy-making. These studies have proliferated on American foreign policy, but its insights are equally applicable to the European case. Given its steady evolution (of which the Lisbon Treaty is the most recent example) EFP is subject to increased attention. When developing an analytical framework that captures the influence of domestic politics in European foreign policy it is useful to consider previous studies on the field of IR and comparative politics.

On the wider question of state-society relations a significant body of literature exists. It has been mainly developed by the comparative politics school, the political economy field, and more broadly by the liberal tradition of international relations. A main concern in some of these contributions has been dismissing earlier claims that denied the existence of a link between public opinion, domestic politics, and foreign policy. Holsti (1992) has made a scrupulous revision and critique of the so-called 'Almond-Lippmann consensus'.[29] He does so through an evaluation of academic publications over the last two decades, finding strong evidence against the idea that public opinion exerts little influence on foreign policy and that it is unstructured and volatile.[30] Moreover, when assessing the complexity of the issues involved in foreign policy, which has been argued is a reason for the lack of interest and influence of public opinion; Holsti contends that 'even in the absence of much factual knowledge, members of the public use simple – perhaps even simplistic – heuristics in order to make sense of an increasingly complex world' (Holsti 1992: 450). The Eurobarometer data (parts of which have been examined in the previous section) supports the claims made against the 'Almond-Lippmann consensus'. Preferences have been stable, and where changes occurred (as with Cyprus) these respond to explicable and rational phenomena.

29 A main source for scholars claiming the lack of influence of domestic pressures in foreign policy, its main assumptions are: the volatility of public opinion, the lack in structure of public attitudes, and the limited impact of the later on foreign policy.

Figure 10.9: In favour of further enlargement (EU-25 and EU-27). **Source:** Author's elaboration based on Eurobarometer data (2004 to 2007).



In order to gain insight into the precise mechanism whereby domestic preferences translate into policies, both structure and agency ought to be considered. In this sense, the comparative politics school has long abandoned the strict constitutional and institutional approaches, and has adopted broader conceptions of politics and the political processes (Peters/Doughtie/McCulloch 1977). These look at the input side of the political system: political parties, pressure groups, electoral behaviour, and mass attitudinal configurations. This already suggests the kind of variables which might be useful to consider. Anderson (1998), for example, argues that political parties are the ones who give cues to citizens in their attitudes towards European integration. He finds that the most powerful determinants for support of membership in the EU are system and establishment party support. Hobolt (2006) when looking at integration referendums found a similar result, arguing that parties are in a privileged position to influence voters. Political parties are not, however, the only actors likely to influence public opinion. The development and generation of public opinion as Glyn, Herbst, O'Keefe, and Shapiro (1999) argue, requires active communication processes that involve mass and interpersonal communications as well as third-person effects from the media. These entail complex psychological processes. The media plays a relevant role in this process through agenda-setting and its effects in the informed public.

Institutional factors are also relevant. That is, the output side (or the conversion functions of the political system) which consists of governmental and institutional configurations (Peters/Doughtie/McCulloch 1977). Tsebelis (1995) develops a useful typology to include existing institutional approaches. These approaches comprise three dimensions: presidentialism vs. parliamentarism, bicameralism vs. unicameralism, and two-party vs. multi-party systems.[31] These pairwise structures are compared on the basis of their capacity for policy change (or what Tsebelis calls the presence and number of veto players). His main finding is that as the number of veto players increases, their congruence decreases, their cohesion increases, and so does policy stability. Evaluating the number of veto players can be a useful way of accounting for institutional variation.

Another structural element that seems to be of relevance is the degree of autonomy of the executive. As Klaus Dieter Wolf (1999) argues in his collusive delegation thesis, some institutional configurations offer policy-makers incentives to seek integration in supranational organizations. The main reason for this is to escape from domestic parliamentary control. This occurs, for example, by selling an unpopular policy as part of a package deal which cannot be modified. Enlargement is clearly the case of such a policy.

Koenig-Archibugi (2004) has tested this collusive delegation thesis in the European case. His approach rests on the three main propositions. The first is that initiative (agenda-setting), domestic institutions, information and ideas (ideological justifications) shift due to international cooperation. The second argues that this redistribution of domestic political resources generally favours national executives who are central players in foreign policy. Finally, the third proposition contends that since this cooperation takes the form of intergovernmental bargaining, this increases the incentives for governments to reach an agreement. Thus, weak executives have incentives to promote supranational integration. When testing this thesis on the positions taken by MS in treaty negotiations related to CFSP; Koenig-Archibugi finds that the balance of power between parliaments and executives affects the preferences of executives as to the depth of institutional cooperation in CFSP. Weaker executives are as expected more favourable to integration.

In political economy explanations, on the other hand, a major emphasis has been on the balance amongst domestic and external sectors of the economy (or importers and exporters). For example, it is assumed that individuals who are employed or who invest in export industries are the ones who benefit most from trade whilst those related to import-competing industries are most disadvantaged. This is known as the 'specific factors model' (Hiscox 2005). Given that enlargement has relevant distributional consequences, it is likely to bring about the opposition from those sectors affected.[32] Furthermore, firm advocacy (lobbying) is well documented (Dagger/Kambeck 2007). Firm advocacy occurs both at the national and supranational level to reap the gains of economic integration through enlargement. This is yet another domestic influence which needs to be considered.

Political parties, the national media, decision-makers, public opinion, lobby-groups, and relevant structural elements (both economic and institutional) have been suggested. These are examples of variables which might play a relevant role in determining national preferences. Thence, they might be pertinent

30 Mueller (cited in Holsti 1992: 446) analyses changes in public opinion towards both the Korean and Vietnam Wars and finds these occurred in ways that seemed explicable and rational, rather than random and mindless. Page and Shapiro (cited in Holsti 1992: 446) develop a massive data-set on questions posed by major polling organizations since the 1930's to find that mass opinion was characterized by a great deal of stability. They also find that changes in PO were neither random nor abrupt and that they move in directions which make sense in terms of events. Furthermore, they find that even if the general public is rather poorly informed about foreign affairs, its attitudes are structured in at least moderately coherent ways; and that a single isolationist-internationalist dimension inadequately describes the main dimensions of public opinion on international affairs.

31 Arguments on presidentialism contend that the latter has advantages over parliamentarism because it secures the accountability of elected officials, the identifiably of likely winners, provides checks and balances, and an arbiter. However, presidentialism suffers from temporal rigidities, majoritarian tendencies, and dual democratic legitimacies. Arguments on bicameralism as opposed to unicameralism follow similar lines to those of presidentialism/parliamentarism. Bicameralism is seen as providing more checks and balances. Finally, the debate on two-party and multi-party systems contends that two-party systems provide moderation of the parties, stable executives, and clear majorities, which Lijphart (cited in Tsebelis 1995) has systematically discarded.

32 Debates on the negative consequences on employment due to a relocation of firms towards Eastern Europe abound in most 'old' EU MS.

when considering a domestic perspective, how they interact, and hence their exact relevance in constraining or furthering European foreign policies is suggested as an area for further research.

At the same time it is important to understand how the enlargement process works. There is a complex relationship between the national governments, their permanent representations in Brussels, and the Commission. Thus, whilst domestic political processes determine a particular agenda for national governments, this agenda needs to be discussed and negotiated with the other MS and the Commission in various fora such as the Enlargement Working Group. This interaction also spurs socialization processes (which is the main reason for policy-makers in the permanent representations to be rotated). This has been covered extensively in the Europeanization literature and hence has not been emphasized here. A domestic approach does not deny the relevance of these forces. It merely suggests more attention is to be paid to the formation of preferences within MS themselves.

10.6 Conclusion

The tension amongst policy-makers and voters concerning EU integration (of which foreign policy is an integral part) has been much touted. In what has essentially been an elite project, largely dependent on leadership, public opinion has come to play a relevant role. The end of the 'permissive consensus' and the political earthquake caused by the rejection of the Constitutional treaty highlight the influence of domestic concerns. As Europe moves towards the ratification of the Lisbon Treaty (without national referendums to avoid the risk of derailing a decade-long sought institutional reform) voter sensitivities remain all too present.[33] The more important since some of the most crucial reforms in the treaty are related to foreign policy (a de facto EU foreign minister and the creation of an EU diplomatic service).

This chapter has aimed at showing how enlargement (but also neighbourhood policies) are affected by public concerns and domestic political processes. These domestic dynamics have so far hardly been studied and might have a significant effect on the shaping of future European foreign policies. As the situation in Kosovo threatens to renew instability in the Balkans, and Turkish membership continues to be a crucial geopolitical aim for many MS, EU leaders and policy-makers will have to carefully balance external and domestic aims. Indeed, this seems to be happening already as the EU pays more emphasis on societal concerns such as unemployment and immigration. A better understanding of domestic political debates – alongside the negotiation processes amongst the 27 MS – will go a long way in helping to clarify the workings and direction of EU foreign policies in the near future.

33 The Irish rejection of the Lisbon Treaty in the only referendum that has taken place has caused much consternation and delayed the implementation of crucial reforms in the foreign policy field. This is a further example of the relevance of domestic politics for the overall European foreign policy.

11 Language Games on Security in Finland: Towards Changing Concepts of the State and National Survival

Vilho Harle and Sami Moisio

11.1 Introduction

'Security' is a contested concept covering an expanding area through conceptual widening (up to climate change, unemployment, poverty, etc.), conceptual deepening (from state-centred to common international and human security), and conceptual expansion to various sectors of social and economic life (energy, water, health, food, etc.). The so-called Copenhagen School opened up the concept of security by introducing ideas such as 'societal security' and 'securitization' as a particular type of 'speech act' (Austin 1975), suggesting that the logic of security may be introduced and accepted in many issue areas beyond military matters (Buzan 1991; Buzan/Wæver/de Wilde 1998; Williams 2003). A conventional approach following these lines in the case of Finland would describe this widening, deepening and sectorialization of security by rejecting state-centric discussions of traditional military security connected to state sovereignty and giving key attention to human security or 'societal security' in its stead. We are not, however, following such a line in our case study of Finland.[1]

Instead, our message is that the traditional, official documents of Finnish defence and security policy have expanded 'security' to a meaningless *word* encompassing all unpleasant things, from natural disasters to large-scale accidents. Scholars, especially those interested in critical security studies, have contributed to this process by suggesting alternatives to the traditional military, state-centric security (e.g. Kaski 1981; Laitinen 2007; Nokkala 2001). While the latter group has been critical towards the traditionalists' attempts to militarize human security, the problem is that issues of human security have further expanded the scope of 'security' and indirectly supported the traditionalists' arguments. In spite of opposing motivations, the expansion of 'security' to new problems and risks relocates them above political deliberation and, in the worst case, to a matter for security organizations of the state (Buzan/Wæver/de Wilde 1998).

In this chapter, we consider what *consequences* the expanding conception of security may have through the growing fear experienced by human beings in the *securitized* life world and their consequent need for a strong state (Rosenau 1990: 449–451). We suggest that, in the case of Finland, one of the major consequences has been the growing power and role of the state over civil society. Therefore, politics of security must be discussed in the context of the transformation of the state as a political community (Cerny 2003; Sørensen 2003). This does not imply a 'state-centric analysis' but rather criticism of the role of the state in security and society in general. We suggest that in the case of Finland, both the traditional military version of security conceptions and those put forward by critical security scholars have increased the power of the state. In other words, the employment of various conceptions of security has contributed to the transformation of Finland towards an 'insecurity state'. This transformation has not been caused, in the case of Finland, by external changes in the security environment or the 'war on terror', but rather by internal factors including the politics of security specialists (military and administrative), scholars and activists; by their power games through securitization of all potential issues. This has not served the security interests of citizens but rather the interests of security institutions and complexes ranging from the military to the private and economic – as well as the interests of scholars working in security studies (see e.g. Tunander 2008; Salonius-Pasternak 2007).

In order to document our claims in the case of Finland, we wish to turn attention from the concept of security to politics (of security). Our thesis is that three major factors contribute – both independently

1 The first paragraph is adapted from a referee statement on this chapter; we thank for making us think through and clarify what we were attempting to do and why.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_11, © Springer-Verlag Berlin Heidelberg 2011

and inherently interwoven – to the increasing role of defence experts and institutions in expanding security affairs and to the transformation of the state and the concept of national competitiveness and even of national survival. These factors are the political application of: a) a 'Russian (military) threat'; b) a comprehensive list of new security threats; and c) an economic understanding of national survival.

By the suggested 'political application' we refer to politics of security: rhetorical campaigns and manoeuvres where the term 'security' is applied as the major asset to 'win the game' of power. Our conception of politics and the political is thus aspectual (the political can be found in any instance of social activity) not sectoral (where politics is what politicians do in traditional political institutions). Our conceptualization of the 'political use of security' thus includes activities of politicians, security experts and planners, but also critical security scholars and peace and environmental activists, journalists and the like. Of course, a comprehensive analysis of all potential data is impossible here. We therefore restrict our attention to a few documents most relevant in the politics of security. This inevitably leads us to concentrate on documents and statements that openly participate in the relevant political 'struggle for security/power'. Unfortunately, in rejecting 'state-centric' approaches, 'non-state-centric' scholars often locate themselves outside the political campaign, thereby contributing to the increasing power of defence experts and state institutions operating with state-centric conceptualizations.

Even though we share the idea of speech acts (Austin 1975) and securitization in the sense of the Copenhagen School (Wæver 1995), we nonetheless maintain that one can not capture the real role and meaning of such speech acts only through conceptual academic analyses. We are especially interested in what a 'political' actor does in arguing with the help of a security conception.[2] This requires a detailed study of cases, here the case of Finland. We apply the new rhetoric (Perelman 1982) to read the selected texts politically (Palonen 2003: 11; see also Palonen 1988, 1993 and 2006). In order to avoid technical and detailed application of the new rhetoric, we apply the concept of 'language game'[3] as a shorthand for the full rhetorical analysis.

We also share a critical and emancipatory approach typical to the Wales' school of security studies (Wyn Jones 1999). However, we suggest that critical security scholars also contribute and are partly responsible for the increasing power of defence experts and the state. We claim that critical security scholars and activists often act against their own deep needs and will submitting themselves to the power of the state by contributing[4] to the transformation of the state towards the insecurity state by de-politicizing security and reinventing the state as the key actor in security issues, and so removing 'security' outside or above 'normal politics'. One may argue that the increasing application of the concept of security in political argumentation has been an integral part of the current transformation of the state from a civic organization into an enterprise organization (Cerny 2003).

Our argument proceeds in four sections. *First*, we will scrutinize the representation and use of the *Russian threat* in the language games of Finnish security politics. We shall point out that the Russian threat still forms a notable part of Finnish security reasoning among the political elites (and even more likely among the majority of the population). We therefore regard the Russian threat as a latent security element, an ontological condition of possibility for the Finnish security debate concerning military affairs and military security (11.2).

Second, we will claim that the *comprehensive estimation of security challenges,* based on extended conceptions of security does not change the suggested picture (11.2), but instead both directly and indirectly strengthens the threat images implied by the case of

2 Just like anything can be politicized (Schmitt 1976: 26–28, 37), anything can be securitized, too. But while 'politicization' moves something into politics, 'securitization' puts the securitized above and outside politics, securitization is a de-politicising move, an instance of 'politicking' (Palonen 2003).

3 Wittgenstein's idea of 'language game' is here adapted from Aaltola (2003, 2002). In our use (following Kari Palonen 1993: 13–14, 101, 130–135), 'language game' implies an analogy between team games (e.g. soccer) and politics. In a game (e.g. soccer) where rules are given and strictly followed, in politics players try to win each other by politicizing and de-politicizing issues according to their political strategies in winning support for their policies. That is, in politics, players try to change both the field and the rules in order to maximize their influence and minimize that of their opponents; yet still, success in politics demands an ability to 'read the game' as it does, for example, in soccer.

4 Our criticism of 'critical' security studies is based on Brian Fay's (1987: 120) idea of critical social science and his argument that "power must involve the activity of those being led or commanded as much as those leading or commanding."

the Russian threat. We claim that the comprehensive approach is a way of discussing the Russian threat indirectly, through silence. Furthermore, even if 'comprehensive' lists of new security threats really are unconnected to the Russian threat, they only add an important strengthening element to the risks demanding 'help' from the state and its security institutions, thereby strengthening their role (11.3).

Third, we will maintain that both the language games of the Russian threat and the comprehensive approach to security have contributed to the increasing and unique role of a *security political mindset* (Laitinen 2005) in Finnish foreign and security politics and in Finnish society in general. In this process, the issue of the 'survival of the Finnish state' has been changing from the old conception of the military understanding of survival towards a reasoning where economic competitiveness is becoming increasingly visible. We propose that this process concerns a fundamental transformation in the meanings of both the survival of and the state itself. Furthermore, we argue that the current transformation of the state towards a competitive economic unit makes it important to go beyond perceptions and rhetoric security challenges to a more fundamental discussion concerning the nature of the agency that 'constitutes' official perceptions and rhetoric. Our conclusion is that the uniqueness of the Finnish case stands in the shift of foreign political power, within the strong administrative state of Finland, from the Ministry of Foreign Affairs to the Ministry of Defence. (11.4).

Finally, we will discuss if the suggested picture[5] ignores elements and features that deviate from it; if our approach exclusively pays all attention to the dominant, traditional, military discourse of security and ignores its challengers. We will find that there are alternatives. However, their existence does not prove our approach biased in its 'state-centrism', but indicates that resistance to the present power of insecurity and the strong administrative state must arise from within the 'system' where 'security' is made a political issue and an element of power games (11.5).

11.2 The 'Russian Threat' in the Language Game of Finnish Security Politics

Finland is a weak state in military capabilities, and has remained outside wars since 1944. Finland experienced three crises in its relations with the *Soviet Union* (SU) between 1948 and 1961 (Väyrynen 1972), and the SU had a campaign against Finnish neutrality from the end of the 1960's up until the mid-1980's. However, since the collapse of the SU in 1991 and Finland's EU membership in 1995, Russia has become a minor issue in Finnish foreign and security politics (Rytövuori-Apunen 2007: 32). Finland has emphasized EU-Russian relations instead of its bilateral dialogue with Russia. This change has been coupled with the fact that Finland has become a rather marginal area in Russian foreign policy. The other neighbours of Finland, from the Baltic States through Germany to the Nordic States, are politically and culturally close to Finland and do not represent any type of security challenges to Finland. Neither does Finland have any serious domestic sources of conflicts.

On this basis, one might expect that 'security' has disappeared from the Finnish political vocabulary. That Finland is removing economic resources from the military sector to human security, including developmental aid to the poor of the world and to the Finnish health sector, education, and welfare of old people.

Such an implication and expectation is totally incorrect. According to a widely shared reasoning[6], Finland still needs a strong army, and must take care of its defence and be prepared for a major military attack against its integrity. The majority of Finns are unanimous that the defence efforts should not be decreased, rather on the contrary: for instance, those who reject NATO membership are willing to allocate increasing resources to the defence forces in order to maintain a credible national defence.

Indeed, what makes the Finnish case unique is that there are contending public perceptions of security challenges. For instance, in September 2007 Prime Minister Matti Vanhanen declared "There are *no* threats towards Finland from any direction" (Vanhanen 2007a). But no later than in December of the same year the Ministry of Foreign Affairs published its memorandum on "potential NATO membership" de-

5 While this is a case study attempting to delineate unique features in Finnish language and power games of 'security', our contribution also represents theory (of the role of the security discourse in the transformation of the Finnish state) in the sense of the grounded theory (Glaser 2001; Seale/Gobo/Gubrium/Silverman 2007).

6 Concerning the public opinion, we refer to regular surveys by The *Advisory Board for Defence Information* (ABDI); at: <http://www.defmin.fi/index.phtml?l=en&s=179>; and e.g. ABDI Survey (2008).

claring that "NATO membership may have an important pre-emptive influence on threats towards Finland" (Sierla 2007; Salonius-Pasternak 2007; Tiilikainen 2008). We argue in this section that these opposing 'perceptions' of threat are not in conflict with each other but rather represent the unique language game, whereby both the speakers and the audience know what the speaker is speaking about and why. This section aims to open up this complex logic of security rhetoric in the Finnish political discourse.

In reading the official White Books of Finnish Security and Defence Policy[7] it appears that official Finnish perceptions of external security challenges are based on the (neo)realist theory of an anarchic international system (Waltz 1979) and Schmitt's (1996) concept of the political as a distinction between the friend and the enemy, or a Hobbesian anarchy between states (Wendt 1999: 259–60). In this interpretation of the nature of inter-state relations, state survival is about excluding the enemy; maintaining territorial integrity and the boundaries of the state; increasing the homogeneity of a nation; and increasing military capability (Moisio 2008a). In such a view, states are potential enemies to each other, and the enemy represents the issue of life and death. In this image, the threat exists, whatever the states do and say. Therefore this existential threat always represents a fundamental danger to the life of the state and its people. It is maintained that states can live in peace, but it is always possible that some of them will attack another state(s). In the Hobbesian anarchy, therefore, survival of the state demands the capacity and willingness to struggle at any time as required for the very existence of the political community, its people and its way of life. Finland, too, must prepare itself for the case of such an attack. The lesson of history is, according to this view, that it will be too late to do something when an attack actually takes place.[8]

Obviously, this reasoning is articulated as a *general theory* of potential enmity between *all states*. Our point is, however, that the Finnish security political rhetoric applies the suggested general theory rather *selectively*. Not all states, but *Russia* exclusively, are concerned. For Finns, Russia is the only state that represents any potential threat: Russia can remain peaceful for a while but it never looses its basic expansionist nature. The Finnish version of Hobbesian realism considers the potentiality of Russian expansionism as an unquestionable universal truth. However, the point is that this is not usually presented in open terms but concealed in the rhetoric of security debates.

In the first White Book of Finnish Defence Policy in 1926 (PR 1926), the SU was openly represented as the single threat to Finland. After the Winter War (1939–40) and the Continuation War (1941–44), the second White Book (PRK 1949) did not mention any hostile states that would have posed a direct security challenge against Finland. The Soviet-dominated Allied Control Commission in Helsinki, and the Soviet military base in Porkkala close to Helsinki, did not allow an explicit discussion of external threats. The Finns, therefore, began to apply a unique language game, where the potential threat of the SU was explicitly denied but simultaneously implicitly considered within the same texts. In other words, the SU became an ontological condition of possibility for the Finnish security rhetoric, a sort of latent factor that was widely shared among political circles. In official foreign policy, the language game was carried out by Presidents Paasikivi and Kekkonen through the ideas of friendship and neutrality. In defence policy, the language game of security was hidden in complex threat estimations. The Committee of 1949 and the Finnish Defence Ministry had to find indirect and undeclared justifications for the existence and improvement of the Finnish armed forces.[9]

7 Puolustusrevisioni 1923–26 (hereafter PR 1923–26; Puolustusrevisionikomitea 1949 (PRK 1949); Parlamentaarisen puolustuskomitean mietintö 1971 (PPK 1971); Kolmannen parlamentaarisen puolustuskomitean mietintö 1981 (KPPK 1981); Puolustus- ja turvallisuuspoliittnen selonteko (PTPS 2004).

8 This is a typical pro-NATO membership argument often presented in the current debate.

9 This section, especially parts related to political history before the White Book (PTPS 2004), does not make detailed references to 'sources' for two reasons. First, it is based on shared knowledge, not demanding detailed references, expressed in easily accessible text-books of Finnish political history since the war (e.g. Häikiö 1992; Singleton 1998). Second, the section presents an original interpretation by the authors based on personal experience of the senior author, for instance, on the *Advisory Board for Defence Information* (ABDI) during 1976–1984 and in researching and writing two books on various aspects of Finnish defence affairs (Harle/Joenniemi 1977; Harle 1978), as well as the exchange of opinions between the two authors for over a decade on issues of Finnish identity politics. The scientific value of experience is usually rejected by (as feminists put it) 'malestream' scholars, but in this case experience and intuition are invaluable. The reader can compare our interpretation with Raumolin (1978), Nokkala (2004; 2008; 2009), and Raitasalo (2008), which are all based on interviews and systematic documentation.

This justification was found in the Finnish-Soviet treaty on friendship, cooperation, and mutual assistance of 1948. The justification was derived from the Treaty's article concerning military cooperation in the case of threat of military attack by Germany and its allies towards the SU through Finland. More precisely, the Treaty ordered Finland to defend its area against such an attack either alone or in cooperation with the SU. In the case that there would be an imminent threat (defined and perceived as such by the SU), Finland had to start consultations about the need of military cooperation between Finland the SU (Singleton 1998: Appendix C; Raumolin 1978). In Finland, it was received wisdom that such consultations and cooperation had to be prevented at all costs.[10]

Finnish political elites did not believe in the attack by Germany or any other Western power against the SU through Finland. The real threat, as suggested above, consisted of the possibility of Russian demands for military cooperation with, and even occupation of, Finland. The task, therefore, was to make such Russian rhetoric invalid by suggesting that the Finnish army is, or should be, strong enough to prevent any attack alone or at least to fight against it long enough to make last resort assistance from the SU possible. In other words, the military vacuum of Finland was represented as a threat to the SU; it was implied that such a vacuum was likely to pull Western powers to attack the SU through Finland. Finland was successful in finally getting permission to maintain and develop military forces. As a great practical achievement, the first Russian Mig fighters and French earth-to-air missiles were bought by Finland at the end of the 1950's (Raumolin 1978; Harle 1978; Harle/Joenniemi 1977).

The SU accepted the rules of the language game due to its respect for the Finnish earlier survival campaigns; and even more importantly, the SU chose to soften its pressures towards Finland also due to its strategy to maintain political influence within Finland. Its supporters – the Communist Party and partly also the Agrarian League – might have lost their power if the SU had broken the rules of the game.

The language game developed to its highest stage during three crises in Finnish-Soviet relations during 1949–1961. It was later (around 1968–1984) tested when the SU suggested common military exercises and attempted to downgrade the Finnish neutrality in many other ways too. The peculiar language game has not disappeared after the Cold War or following EU membership in 1995. Indeed, it can still be perceived in the conflicting statements quoted earlier in this section.

According to the rules of the game, to be called in general terms the culture of silence, the Russian threat is not usually referred to in security policy rhetoric. Rather the idea that Russia represents a potential military threat is often implicitly expressed in political argumentation which seeks to point out that the future of Russian politics is full of uncertainties concerning the development of democracy, power structures, and society in general (PTPS 2004: 27, 65–66). In other words, it is not the enmity of Russia as such but rather the uncertainty of Russian politics and development that is perceived to pose security challenges for Finland.

In Finland, the political development of Russia is seen as proceeding in vicious cycles: a positive development is always followed by a negative one. This point also helps us to understand the ongoing need of the Finns to constantly make diagnoses about Russian political development. Today, a commonly accepted understanding that Russia is in a process of transition is in fact a major stimulus behind such diagnoses. More often than not, these diagnoses evaluate whether Russia is becoming a 'normal state' which accepts the basic rules of 'Western' free democracy, human rights and a free market economy – and which refuses autocratic political culture, the use of political force against its neighbours and a state-controlled economy. Signs of the latter option are usually taken seriously in Finland as they are understood to authenticate the historical fact that Russia is again selecting its own track which may cause harm to its neighbours.

Certainly, Finnish business and political circles often perceive Russia as a possibility, especially in economic terms. However, it is among these very same circles in which Russia is also considered as posing a security challenge towards Finland, be the Russian state weak or strong. If Russia is perceived as a weak state, its domestic crises are argued to have some 'reflections' in Finland. For example, weaknesses in economy, politics and technology may cause accidents in nuclear power plants or enable the expansion of Russian criminal gangs into Finland. In the case

10 In autumn 1939, Finland rejected Stalin's proposals which, in the final analysis, demanded Finland to make an unpopular identity political choice of joining the SU against Germany (the 'West'). Such proposals cause a sort of panic in Finland, and even still at the end of 2008 Russian proposals (Serdjukov 2008: 19) to have 'common exercises' for potential common crisis management and anti-terrorist operations were ignored by total silence.

where Russia becomes stronger, it is perceived to use, for example, energy exports into Finland as political weapons in the case of political disagreements. Therefore, it is often argued that Finland should not become too dependent on Russian oil, natural gas, or nuclear fuel.[11]

Concerning more explicit references to the traditional Russian threat, Finnish politicians are usually rather clever in using indirect, non-provocative vocabulary. This flexible rhetoric is sufficient exactly because of the strong discursive structures of Finnish security politics: the Finnish audience is capable of understanding the specific position of Russia in Finnish security reasoning. For example, Johannes Virolainen – the then Speaker of Parliament – explained in 1978 that the National Coalition Party was not taken into the Government due to 'general reasons'. The general reasons – indirectly and silently – referred to the SU's influence on Finnish politics and President Kekkonen as the major vehicle of this influence. A more recent Speaker of Parliament and former Prime Minister of two successive governments, Paavo Lipponen, once rationalized NATO-membership by referring to the "historical reasons known to all Finns."[12]

Applying the complex logic of the language game, the pro-EU political decision-makers did not usually mention military security issues at all during the heated debate preceding the EU referendum in 1994. Instead, they often denied the interpretation of EU membership in security political terms. However, afterwards President Koivisto (1995) claimed that he had considered the membership primarily as a security political issue; he even made the membership his greatest achievement in Finnish *security* politics. This can be understood in the context of cultural-geographical imagination and identity politics (Harle/Moisio 2000).

One crucial element of Finnish security politics – and its language game – is that Finland is understood to represent a Western cultural-political tradition which the country inherited already under Swedish rule (Lipponen 2008). Indeed, the logic of cultural-geographical belonging was at the core of the pro-EU campaigning, especially when the decisive moments of the EU struggle took place (Moisio 2006). More precisely, the pro-EU elites wholeheartedly argued that EU membership was a tool to relocate Finland within the political map of Europe. They suggested that the relocation would mean two interrelated things. First, it would bring Finland back into a group of Western states to which Finland naturally belonged even though it had practiced the politics of friendship with the Soviets for the past fifty years. Second, they proclaimed that EU membership would distance Finland from the sphere of Russia as it would demonstrate to both Russians and Western Europeans that Finland belongs to the Western world. In other words, the security of the state was in EU campaigning connected to the question of the political recognition of Finland as a state that does not belong to the Russian sphere of culture and political power. Similar logic of cultural-geographical belonging is also present in the NATO debates. The recent comments by the chairperson of the Finnish Business and Policy Forum, Risto E.J. Penttilä, nicely reveal that logic. According to Penttilä (2008), by joining NATO Finland would finally assert that it is an integral part of 'Europe' and the 'Western camp', not a 'geopolitical exception'.

In the White Book of Finnish Security and Defence policy 2004 (PTPS 2004)[13], the estimations of the Russian threats are made by applying general, universal truths in neutral words. When Russian military power is mentioned, it is often emphasized that it is not directed towards Finland. It remains up to the reader to understand the message. According to the White Book (PTPS 2004: 102; official translation; italics added; see also pp. 68, 66) the evaluation of the security environment is based on three scenarios:

> The Defence Forces must be prepared to prevent and, if necessary, to repel any use of military force against Finland. The crisis and threat scenarios used in defence planning are: a *regional crisis* that may have effects on Finland; political, economic and military pressure, which may include a threat of using military force and its restricted use; and *use of military force* in the form of a strategic strike or an attack beginning with a strategic strike aimed at seizing territory.

By reading the text carefully one might suggest that the first scenario touches upon the global environ-

11 E.g. by the Green Party during the Parliamentary election campaign in 2007.

12 The 'Bomb of Mid-Summer's Day', i.e. Kekkonen's strong hostile attack on Virolainen's statement, soon became a widely used idiom in the Finnish political vocabulary. An item on Lipponen's statement, given passingly in a TV interview, is included in the archives of the senior author without a date.

13 The While Book '2008' was to be published in July 2008; however, publication was postponed first to October 2008, and later until February 2009 and it was not yet available in January 2009 when this chapter was finalized.

ment but the two other scenarios can refer to Russia only. Looking more carefully, all three references are made to Russia. Regional crises, it is argued, "can emerge far away from Finland, but they may have repercussions in Finland either gradually or sometimes very rapidly" (Vanhanen 2007b; PTPS 2004: 99). It is obvious that regional crises, while originally perhaps taking place outside Russia, can escalate and draw Russia along. Therefore, it is again the Russian threat, not 'regional crises' as such, which counts in the first scenario too.

The security political language game, the culture of silence, was the dominating trend in Finnish foreign and security political rhetoric until September 2007. Then the Minister of Defence, Jyri Häkämies (2007), gave his speech at the Center for Strategic and International Studies (CSIS) in Washington. Häkämies told his audience that Finland has "three main security challenges: Russia, Russia and Russia!"

This unique speech act seems to be a path-breaking deviance from the suggested language game. In the final analysis, however, it is not. The speech represents nothing more than a different type of case in the continuing tradition of the complexity of Finnish security political rhetoric, its pervasiveness and its continuity.

Häkämies argued that Finland's security interests form three concentric circles. The first circle consists of "common [Western] values." Finland pursues cooperation with those states that support the common values. Cooperation takes place, especially, in UN peace-keeping and humanitarian operations. The second circle, Häkämies goes on, consists of security threats "affecting [Western] Europe." In order to struggle against such threats, Finland participates both in EU and NATO-led operations.

According to Häkämies, within the third circle, "our national interest reigns supreme." In the case of Finnish security and territory, the question is not about abstract security challenges: "such core issues as national independence, security and well-being of the Finnish citizens, and, ultimately, even the very survival of the nation, are at stake." In Häkämies' speech, this is further explicated by references to the Finnish regional defence system, the conscription army, and large reserves of manpower consisting of 350,000 soldiers at the moment of the speech, and 250,000 still in the coming decade.

Häkämies emphasized that Finland cannot participate in extensive NATO operations far away from its own geographical area: Finland must take care of its defence in the Finnish and neighbouring areas. In other words, Finland must be able to struggle against any Russian attack at least so long as other (Western) countries will come to assist the Finnish troops. Indeed, Häkämies suggests that the Russian triple-challenge concerns not only Finland but "all of us" – most likely the EU and NATO countries. In other words, Häkämies not only expects the others to understand the Finnish position but he also expects the others to give support to Finnish efforts to cope with the Russian challenges within the innermost circle.

Häkämies argued that Finland is, in many ways, willing and ready to cooperate with NATO, but Finland must keep its 'powder dry' within its own security area. That is, according to Häkämies, "a country like mine might produce the necessary tools in a different way from the others, but the end result is similar" to "all of us: ... We are ready to stand up to protect our common values, to produce security and stability, and even to defend our national territory, whenever and wherever such threats emerge."

In his speech, Häkämies explicitly applies a geopolitical approach and analysis. More precisely, his rhetoric is partly connected to the post-war security vocabulary in which it was often highlighted that Finland cannot escape 'history and geopolitics': it is a historical and geopolitical fact that Russia is Finland's Eastern neighbour. According to Häkämies, it is exactly the geopolitical location of Finland which produces the suggested three security political 'challenges' for Finland. Indeed, as he reminds us, "geopolitics is back, and it is back with force." It is important to notice that in Häkämies's language the term 'geopolitics' replaces the term 'threat'.

Public comments from the President and the Prime Minister were slightly critical about the connection between the forum of the speech and its content. The speech was declared a 'private' opinion of the Defence Minister, and the President[14] emphasized that the Defence Minister is not among the key figures in Finnish foreign policy. The Prime Minister, for his part, declared that Finland prefers a "comprehensive approach" in speaking of security challenges (Vanhanen 2007a). But neither of them actually suggested that Häkämies was wrong in his analysis of the Finnish security environment.

As for newspaper editorials, almost all important newspapers[15] shared the view that Russia is the only potential threat to Finland. On many occasions, it was maintained that the Russian military threat towards

14 In a TV interview, a note in the archives of the senior author without a date.

Finland is the only reason for the existence of Finnish military forces. Häkämies was represented as the figure who boldly expressed the undeniable historical truth of the Russian threat. Many editorials, however, were also sceptical about the wisdom of speaking the truth; the old traditional language game of the culture of silence was preferred instead. One editor-in-chief demanded Häkämies to resign, not because of the content of the speech, but because of its openness!

One may claim that Häkämies' speech represented the end to the culture of silence. However, this positively was not the case. The language game soon returned to its original form whereby the Russian threat is still disguised in complex indirect rhetoric of security. Häkämies himself contributed to that 'correcting move' already in his very speech.

Häkämies actually continued the old language game where Russian enmity is denied in explicit terms. After shouting his 'triple-challenge' Häkämies added in the terms of the old language game: "It would be [a] foolish – and mistaken – conclusion to draw that the new Russia will threaten Finland's security." Furthermore, Häkämies suggested a conceptual distinction between 'challenge' and 'threat'; this terminological 'clarification' was shared by other important speakers and soon accepted in public debates. All the revealing elements of his speech – words like 'dry powder', 'geopolitics' and 'regional defence needs', and 'Finnish military reserve forces' – were pushed under the carpet of the traditional culture of silence.

11.3 The Language Game of the Comprehensive Approach to Threat Estimations

Instead of 'silenced' Russian military security challenges, a comprehensive survey of all types of threats is given the open key role in security estimations in contemporary Finland. The military dimension is still the basic issue of these security perceptions; the comprehensive approach is introduced in order to strengthen the truth and continuity of military, especially Russian, security threats in an indirect way. The comprehensible list does not replace the military threat challenges but adds new causes of fears concerning the threatening world, justifying the increasing role of the state as the exclusive security agent and of military-oriented measures to manage the dangers.

The list of comprehensive threats also includes military ones: "The threat of weapons of mass destruction, threats targeted at information systems, information warfare and terrorism are challenges for which the defence establishment is prepared" (PTPS 2004: 9; official translation). Surely, weapons of mass destruction are a 'universal' category of threats, but one cannot read the quoted text fully ignoring the specific case of Russia. Threats against information systems and information war in general can, and actually must, be understood with Russia in mind.

The White Book 2004 (PTPS 2004) speaks of terrorism in general and universal terms. It does not suggest that Finland might be a target for terrorists, but that Finland may become a potential sanctuary for terrorists when they prepare for new attacks against their real targets (PTPS 2004: 22). No distinctions are officially made between various terrorists. However, 'terrorism' actually refers exclusively to the Islamist al-Qaida version of it (PTPS 2004: 21). The White Book is silent in the case of terrorists, who struggle against the Russian state and its political leadership.

Less official sources are more explicit by distinguishing between anti-American and anti-Russian terrorism. The Chechnyan terrorist attacks are often suggested to be justified as part of the Chechnyan campaign for independency. For example, a systematic analysis (Normio 2007; see also Pietiläinen 2005) of two large newspapers (*Helsingin Sanomat*; *Aamulehti)* documented this convincingly. The newspapers were somewhat critical of both the American and Russian leadership and the foreign policies of the two countries but the two major terrorists attacks were represented in opposite ways in the newspapers. The September 2001 attack was strongly judged as a planned and unjustified attack against innocent people by al-Qaida. The Beslan school massacre in 2004 was suggested as being caused by Russia and Putin; that is, the badly planned and executed Russian operation was condemned, but the terrorists' attack on the school was not.

Concerning 'non-military' new threats, those delineated by the comprehensive approach are still perceived in the context of the state and its territory. The official representation of threats does not list any country as the source of a military threat towards Finland: neither Russia nor rogue states. But revealingly, most new threats are located outside the Finnish ter-

15 All leading national and regional newspapers were checked for two days after the speech, all of them publishing at least one editor's comment. Only one of the newspapers, *Hämeen Sanomat*, did not share the reality of the Russian threat.

ritory in Russia and the near-by area (PTPS 2004: 28–29, 137).

It must be noted that not the comprehensive but rather the selective approach is typical to this current, post-Cold War, rhetoric. However, this is not easy to recognize; the comprehensive approach to security seems to produce a long list of threats ranging from military to environmental, and from external to domestic. Instead, the White Book lists all threatening or unpleasant things from terrorism to local crises and natural disasters and climate turbulence (PTPS 2004: 5, 27, 138). In short, the world has turned into a completely dangerous place: "In the modern world there are more and more possibilities to get involved in unexpected crisis situations caused by new threats" (Vanhanen 2007b). But, looking more carefully, the estimation of threats is much less comprehensive than the name suggests. Some security challenges and risks are ignored altogether.

The Finnish White Books purposefully never discuss threats for which Finnish military resources are insufficient. For example, neither limited nor full-scale nuclear wars are taken into consideration. Another case of the selective approach can be found in the case of non-military disasters. Climate change is given much attention, and even tsunamis and tornadoes are predicted to hit Finnish soil (Vanhanen 2008). This is a rather imaginary prediction attempting to conceal the fact that more likely domestic disasters are not discussed at all. Not a single word is given to the risk of disasters in Finnish nuclear power plants, which are all located in the most populated Southern area of the country. According to a rather general wisdom such disasters, however, can take place in Russia and in the Baltic.

11.4 The Transformation of the State on the Basis of New National Survival

Considering the insecurity state (Chernus 2006), we can find some signs of it, for example, in the White Book (PTPS 2004) where terrorism is increasingly connected to immigrants and non-Finnish foreign minorities dwelling in Finland or, in some cases, where the state restricts or controls the movement or the freedom of expression of citizens. However, it must be claimed that it is not issues concerning US-like homeland security but instead more traditional military threats that are key factors in the Finnish case. Military security and willingness to defend the country in the case of attack are typical Finnish ways of speaking about security (e.g. ABDI Survey 2008). An extended security conception is not replacing but rather supporting this traditional mode of security thinking.

Still, we might speak of the insecurity state also in the case of Finland, but in a peculiar sense only. Both the traditional way of thinking of state security and the more critical orientation of security studies have contributed to the same goal of making security the key term in the current discourse. Both the traditional thinking and the critical school share the view that this is all about nothing else than security. There is no alternative thinking or approaches that would suggest that the long lists of security threats and challenges include issues that should be called other names. Things like unemployment, and health or environmental problems, are spoken in terms of security challenges. In listing such fears a journalist suggested, rather 'logically', that Finland cannot stay alone in front of such 'threats' as poverty, unemployment and climate change; "Finland must enter into an *alliance*!" (Vasama 2007).

However, this is not just a simple securitization process in which more and more issues are given a (military) security meaning. We would alternatively like to argue that the key issue here is that the very idea of national survival is currently getting a fundamentally social and economic meaning. Consequently, the traditional Weberian state monopoly of violence is changing towards a more fundamental state monopoly of social and economic development. In other words, the state's security function is extending from military security to daily, social and economic activities. The state decides upon not only the use of military force but the development and use of all social energy throughout civil society.

This particular security logic has been very visible in the current debate on the 'international competitiveness' of Finland. In this ongoing debate, issues such as national survival, national success and national security are discussed in market terms, and political actors increasingly conceptualize national interests in terms of the market rather than in terms of political community. In this debate nations are understood to compete with one another in the same way as corporations compete with one another. We may therefore ask whether the fact that in political action the 'national interests' are increasingly expressed in terms of market metaphors, reflects a significant paradigm shift in Finnish security culture. The practice of referring to nations and states as companies is in fact

typical to this security rhetoric whereby the issues of world and domestic politics are articulated with recourse to market metaphors (Moisio 2008b; Kettunen 2008).

The new security monopoly of the Finnish state can be explained by three factors. First, it is based on the perceptions of external (Russian) military threats. The public opinion both sustains official security and defence policy and demands the careful consideration of the Russian dimension, so demanding strong national, independent defence arrangements. Second, the comprehensive approach and extended security conceptions lead to an increasing support for the role of the state in all types of threat/security issues including natural catastrophes, terrorism, immigrants, and the like. Third, the state's increasing role is justified by the need to make the Finnish nation more competitive in the globalizing world markets.

Our point is that in the Finnish case the security political mindset has found its major application, in addition to the traditional defence sector, within the economic sector. In Finland the Hobbesian notion of anarchy has given space to the Lockean conception of anarchy (Wendt 1999: 279), according to which the relationships between states and their very survival are based on economic not military competition. One may, therefore, argue that this partly leads to the securitization of economic issues, for example in the case of Nokia. Discourse concerning Nokia became (in the 1990's and up to recent years) rather security political, with terminology of family resemblance with that related to external and internal security challenges (Salomäki 2004, 2007).

This economic competitiveness is not just a simple *security* issue: it is currently argued as the key to and basis of national *survival* and the future of the nation.[16] If the question of national survival was earlier defined in military terms, as the ability and willingness to defend the country's territory, societal order and independence, now the basic independence and survival struggle is carried out within the economic sector as a question of competitiveness. The earlier national survival was something for foreign and security policy to take care of, now this responsibility belongs to private firms and the state supporting their competitiveness. Surely, the old conception of national survival (Apunen/Rytövuori 1982) and the new one do not exclude but rather complement each other, yet even so, the new conception is taking the upper hand in processes of the reasoning of national survival and national security.

This step towards a competition state and the consequent increase in the role of the state has not taken long. The earlier welfare state was based much on the central role of the state. The state was a powerful actor because only the state was able to maintain the distribution of incomes demanded for the maintenance of the welfare systems throughout the territory. Therefore, the role of the state is not the basic issue here: it is rather the content of the state's policy that counts. In the welfare state the leading ideas were based on equality, social (re)distribution, social compromise and humanity – the importance of giving equal opportunities to all to develop themselves as members of the Finnish society – that is, a sort of 'human security'. Of course, these welfare state principles sought to increase the power of the state apparatus and the legitimacy of its power throughout the territory and across social classes. In the welfare state, security was defined in social terms and especially in the terms of mutual solidarity. In the competition state, individualism, competition and material values are increasingly becoming the measure of happiness.

The politics of competitiveness means especially the development of practices (typical to the global market-place model) through which the Finnish state tries to attract transnational footloose capital as well as the international 'creative class'. Moreover, when the state is required to build the basis for national competitiveness in order to maintain the survival of the nation, the state's policy in all sectors, from the economy to education and culture, becomes a new type of security policy. Security and insecurity obtain a totally new meaning, whereby the welfare state takes its last step towards the insecurity state in this new sense.

This chapter has claimed that traditional perceptions of military security challenges, with emphasis on the Russia threat, still govern the Finnish security political discourse. Related to this, the comprehensive approach in the estimation of old and new security challenges led to the situation where security and security challenges govern the Finnish mindset more than ever before. As the last step, the insecurity state has obtained the meaning of the competition state where the question of national survival has received a strongly economic connotation. In other words, the ways through which the relations between states are currently perceived in Finland include both the Hobbesian and Lockean understanding of anarchy.

16 The step from 'security' to 'survival' represents a unique 'deepening' of security in the Finnish case.

One key factor or consequence of making security a national issue that controls the behaviour of all serious politicians and excludes all non-military alternatives and ways of thinking, can be found in the fact that security political debate and opinion formation has become a sort of monopoly of the Defence Ministry. Earlier, up to the end of the 1980's, 'foreign policy' was the leading sector in Finland's external relations. This was challenged already in the 1970's by the military establishment and also politicians and individuals emphasising the traditional Finnish duty to defend the Motherland against the external enemy (Russia). They introduced the concept of 'foreign and security policy'. Originally, the concept implied that foreign policy and defence policy are equals in the foreign affairs of the country. Later on, the Ministry of Defence won the struggle, and emphasis went towards 'security policy', suggesting that foreign policy was included as its *sub-section*. For several years now, it seems that 'security and defence policy' has replaced the earlier terms. Indeed, the White Book to which we have referred to above (PTPS 2004) is a four-year plan for *security and defence policy* – and arms procurement. However, it is presented under the auspices of the Government, and also otherwise reads as a sort of White Book of *Finnish Foreign Policy*.

Originally, the parliamentary defence committees, of which the first one presented its report in 1971 (PPK 1971; see also KPPK 1981) as the modern successor of the defence revisions of 1926 (PR 1926) and 1949 (PRK 1949), aimed at raising defence issues above or outside party politics. The idea was to avoid 'political' passions in the matter vitally important to the country. The debates of the committee were carried out behind closed doors, where the representatives of the defence establishment were able to negotiate with responsible politicians. In practice, both parties and the Parliament gave their power in defence planning to the parliamentary committee. The committee suggested its report as a sort of agreement, and therefore it was followed without long debates, at least as far as defence funding was concerned.

This open aim to close or prevent political debates on security and defence issues made the estimations of security challenges rather narrow and technical. Through this process, the defence administration has taken the major role. Planning staff are located in the Ministry of Defence, and also the representatives of the military establishment have a strong influence on the committee. The representatives of the political parties have been selected, by definition, from those politicians who are interested in the defence of the country and are openly in favour of the Finnish military forces and military defence. Furthermore, the role and influence of the Ministry of Foreign Affairs is excluded from the committee by its very name. Formally, the White Book on Security and Defence Policy does not appear to deal with the foreign policy of the country. In practice, it certainly does.

The process was made easier by the culture of silence typical to Finnish foreign politics. Open debate did not belong to post-war foreign politics: power was purposefully given to the President, who according to the Constitution was alone responsible for foreign policy. Foreign political discussion was allowed as an educational process, where the President took the role of educator. His task was to make the citizens learn what the correct truth was. The Ministry of Foreign Affairs supported the President in this effort, always willing to point out what was wise and unwise. As suggested above, the culture of silence in Finnish foreign politics became the dominating art of wisdom, leading to rhetoric that was accessible to the 'high priests' of foreign politics only. This culture of silence has strongly favoured the (re)militarization of security. Gradual steps towards military 'crisis management' are sold as continuity rather than change in Finnish foreign policy. The more the foreign policy changes, the more loudly it is presented as continuity. For example, when Finland decided to join the NATO Response Forces in March 2008, it was emphasized loud and clear that this participation was limited and that the decision did not constitute a step towards NATO membership.

The increasing role of the Ministry of Defence and the emphasis given to technical issues of security and defence politics is not a single case where political debate and political decision making is put aside in Finnish politics. Finland can be called a strong administrative state, where administration, not politics, is leading the country.[17] This can be found, for example, in issues like nuclear power. Nuclear power is defined in technical and legal, not political terms. This has increased the role of the administrative staff of

17 The term 'strong administrative state' is adapted from Säynässalo (2009) who speaks of the case of nuclear power. However, the role and power of administrative staff and experts is typical to all areas of Finnish politics and public administration, including security and defence affairs. In our case, what is interesting is the movement of administrative power from the Ministry of Foreign Affairs to the Ministry of Defence in the case of 'security threats'.

the Ministry of Trade and Industry, which has recently become (partly removing the Ministry of Finance side) the most powerful political agency of the country, not only in nuclear power but in the economy in general. Indeed, due to its role in the area of the competitiveness of the national economy, this ministry is having increasing power in Finnish security policy as well.

11.5 Discussion

The suggested picture – the impact of the perceptions of a Russian threat; the comprehensive estimation of threats; and the changing conception of national survival with the increasing power and transformation of the state – obviously looks rather 'state-centric'. We have, however, discussed the reasons behind this orientation. It is not our choice of academic preference, but is fully dependent on the phenomenon under investigation. Therefore, our orientation is critical towards the observed development. We tend to think that the more broad and comprehensive 'security' is made, the greater the power that is given to the state.

Certainly, the story here is written as a sort of dominant discourse. This may look unfair to those who seriously work in favour of human security, and who wish to oppose the development towards an insecurity/strong administrative state. We do not wish to nullify such efforts; we only call attention to the fact that those efforts must not be based on expanding 'security' to all possible issues. Instead, 'security' should be returned back to where it has come from. Only then, as the traditional military threat, can it be estimated realistically both at the regional (Russian) and global level. And only then can alternatives to military efforts to build security be discussed and developed in open political deliberations.

We suggest that Finnish public opinion (against NATO membership) reveals that Finns are able to estimate military threats and to avoid measures that would increase, not decrease, such threats (ABDI Survey 2008; Rahkonen 2004), and that they are able to discuss such issues as poverty, unemployment and healthcare problems as normal social – not security – problems in the society. Both the security political elite and (critical) security scholars would win by taking this public opinion seriously. Not fear towards all imaginable threats but instead pragmatic measures to deal with practical problems are demanded.

While we have not discussed rivalling discourses as alternatives to the dominant one, we must say that there have been and still are alternatives to the suggested development. The question is: where and how to find them? Considering that this is an issue of the role of and power over the state ('who moves the strong administrative state?'), one must look at the alternative discourse(s) not in the margins but in the foreign and security political elites of the country. Indeed, one might claim that we have introduced not the 'dominant' discourse but rather a minority discourse of security political elites; and even that of its minority. We confess that this point is correct at least partly. We have concentrated on the issues and problems of expanding 'security' and the consequences of this expansion on the growing power of the state apparatus. This development does not serve the interests of the majority of the population or the elite, but the interests of those who wish to raise (military) security above democratic deliberations. Similarly, as economic issues are increasingly represented as national security issues, this type of action potentially increases the power of the economic circles within the state.

The history of Finnish *foreign policy* after the Continuation War (1944) is not based on the language game suggested above, only perceptions of and dealing with the Russian and new comprehensive threats are. President Kekkonen (1956–81) spoke for good relations between the former arch-enemies (Finland and the SU), and maintained that "security implies not building fences but opening doors."[18] Furthermore, the use of expanding, non-military and non-state centric security conceptions did not, originally, serve only military interests. For example, President Koivisto (1982–1994) declared in 1985 that:

> The UN has taught all nations to understand that there cannot be national security without international security. The understanding of this dependency is not limited just to nuclear weapons and military threats. Security implies more than the prevention of war and the abolishment of fear of military attack. Security is needed in everyday life in order to guarantee the satisfaction of the needs of all human beings and fulfilment of human rights. This demands continuous and increasing efforts to support and advance universal justice (Koivisto 1992: 51).

This line of argumentation has found comprehensive applications in President Halonen's (2000-) thinking and speeches (Halonen 2000-).[19] Indeed, her under-

18 Quoted in Koivisto (1992: 48); references to Koivisto's statements are to Koivisto (1992: 7–12, 15–22); and for Halonen see her home page at: <http://www.tpk.fi>.

standing of international cooperation, common security and human well-being and principles of equality and human (including women's) rights are widely supported by the population. Halonen (e.g. 2005) is sceptical towards NATO membership, as is the majority of the population (where pro-membership share has remained around 25 per cent for several years).

While the president is still the most powerful political institution in Finland, and while the current Prime Minister (Vanhanen, holding his second term since 2007) shares the fundamental ideas of the president, the current political struggle in the field of security perceptions and politics of security takes place between the pro-NATO fraction of the elite and the president. The president has a sort of idealist reputation, but the media does not pay much attention to her views. The two most favoured candidates[20] to become her successor come from the party that strongly supports NATO-membership, and those candidates declare their preferences in open terms. Martti Ahtisaari (President 1994–1999 and Nobel Peace Prize laureate of 2008) joins the pro-NATO orientation on the basis of identity policy; Ahtisaari maintains that Finland should join its friends who represent the same values as Finland does, so symbolizing the alliance between the traditional military understanding of security and that of security of identity (e.g. Ahtisaari 2005, 2008), a basic feature in the perception of the Russian threat (see 11.2).

So, in this constellation, 'security' is not the essence of 'security challenges': the political struggle for power is.

19 See Harle (1995) on Koivisto's and Harle (2000) on Ahtisaari's rhetoric. A study on Halonen's rhetoric is under progress, but it can be claimed that Halonen is a unique case among the Finnish presidents in emphasizing the positive values of human security and the related values and norms.

20 The Speaker of Parliament, Sauli Niinistö, and the current Minister of Foreign Affairs, Alexander Stubb.

12 Security Threats, Challenges, Vulnerabilities and Risks in US National Security Documents (1990–2010)

Hans Günter Brauch

12.1 Introduction

Since the end of WWII and since the adoption of the US National Security Act of 1947 (Czempiel 1966; Brauch 1976; Yergin 1977) issues of defence were framed, formulated and legitimated as issues of US national security. Thus, issues of international and regional (hemispheric, European, Asian and Middle East) security were perceived through the perspective of United States national security reflecting US national military, political and economic interests. In most official documents the specific meaning of 'national security' remains undefined or was defined to serve the specific purposes of the respective organization. During the Cold War, the former US Secretary of Defense Harald Brown suggested this definition:

> National security ... is the ability to preserve the nation's physical integrity and territory; to maintain its economic relations with the rest of the world on reasonable terms; to protect its nature, institutions and governance from disruption from outside, and to control its borders (Brown 1983: 4).

Ernest R. May (1992: 94) in his review of "national security in American history", defined national security as "preserving the United States as a free nation, with its fundamental institutions and values intact", where the values and institutions have changed significantly. In their annual messages to the Congress, the US presidents since George Washington used instead of the 'new concept of national security', terms of 'safety', 'tranquillity', 'insecurity', 'danger', 'threat' or 'peril'. May argued that "American ideas about national security evolved in four stages" referring to: 1) the safety of borders and the preservation of the union of states (from the 1790's to the 1870's), 2) to hemispheric independence (Monroe doctrine, 1823) and social order (from the 1880's to WWII), 3) to a free world independence with prosperity at home (from WWII to the 1960's), and 4) to stability and economic growth (from the 1960's to the 1980's). May (1992: 104-) concluded from his analysis that 1) US national security interests always combined external and domestic components, 2) that it "identified its security with the security of other states" including their traditional interests.

This narrow definition of national security that referred to the three features of national sovereignty (of the territory, people, and system of rule) has been gradually widened, deepened and increasingly also sectorialized in official national policy declarations of many countries and in the pronouncements of international organizations since the end of the Cold War in 1989.

After a brief overview of the different perspectives and worldviews of strategic thinkers and foreign policy specialists on the role of the United States in the post-Cold War world (12.2) this chapter reviews the 'speech acts' (Wæver 1995, 1997, 2008) of key US institutions as 'securitizing actors' that are responsible for defining the policy goals, developing policy guidance with a set of policy documents (quadrennial defence review, national security strategy, as well as military and defence strategy and nuclear defence posture statements) and overseeing and controlling their implementation. Thus, this chapter addresses these questions:

- How have the concepts of security, and especially the references to key security dangers and concerns as *threats*, *challenges*, *vulnerabilities* and *risks* been defined in the major US national security documents in the US Administrations from George Bush (1989–1993) to William J. Clinton (1993–2001), George W. Bush (2001–2009) and Barack Obama (since 2009)?
- How has the perception of US national security threats, challenges, vulnerabilities and risks changed since the end of the Cold War (1989), in the aftermath of 11 September 2001 and since the Administration of Barack Obama?

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_12, © Springer-Verlag Berlin Heidelberg 2011

- Did international factors or internal interests (technological impetus, strategic rationales) contribute to a change in the perception and definition of the security dangers and concerns?
- Did the dominant 'worldview' of the civilian and military strategists and the 'mindset' of the national security policy-makers prevent a redefinition of the security dangers and concerns facing the USA since the end of the Cold War?

The basis of the empirical analysis will be a) the *National Security Strategies* (1991, 1994, 1996, 1998, 2000, 2002, 2006) of the US President, b) the *Quadrennial Defence Review* (1997, 2001, 2006, 2010), and c) the *Nuclear Posture Reviews* (1994, 2001, 2010) of the Secretary of Defense, as well as d) selected other documents such as the US National Military Strategy (1995, 1997, 2004) of the Joint Chiefs of Staff, and the National Defense Strategy of the US Department of Defense (2005, 2008).

It will first introduce the legal basis and the specific political objective of these documents that are addressed both to the domestic audience to 'assure' the people and to 'guide' the national security establishment but also to the international audience both to 'reassure' its allies and to 'warn' and to 'deter' its opponents (12.3.). It will then analyse and assess as to how the four key concepts of security threats, challenges, vulnerabilities and risks for the *US National Security Strategy* (12.4), the *Quadrennial Defence Review* (12.5), c) the *Nuclear Posture Reviews* (12.6.) and other key military and defence documents (12.7.).

In the conclusions this chapter will discuss the above research questions both with regard to the 'worldviews' of academic writers and policy analysts and the 'mindsets', roles and interests of the representatives of major institutions that formulate and implement US national security policies with a specific focus on elements of change and continuity in these major official US documents. However, the chapter will not assess how these policy goals have been implemented in the framework of US global diplomacy and its national and international defence policy.

12.2 Contrasting Worldviews and Mindsets

This survey of the major official pronouncements of the US national security strategy since the Cold War by the major 'securitizing actors' (President, Secretary of Defense) refer to different 'mindsets' on the US global role represented by the conservative realists of the Administration of George Bush (1989–1993), the multilateral liberal vision of the Clinton Administration (1993–2001), the self-centred neo-conservative perspective of the Administration of George W. Bush (2001–2009), as well as the pragmatic internationalist vision of the Obama Administration.

Binnendijk and Kugler (2006: 6) distinguished between two different ideal type worldviews in the policy-oriented US literature on "the US role in global security" (between 1990 and 2005) they categorized as Neo-Kantian and Neo-Hobbessian "each offering different interpretations of contemporary trends" that referred to two different political philosophies "whereas Hobbes sought solutions through state power, Kant sought them through moral conduct and law" (table 12.1).[1]

In discussing "US national security goals and constraints" Binnendijk and Kugler (2006: 161–216) distinguished with regard to the motivation and preferred instruments of power among: a) assertive interventionists (Mead 2004; Ferguson 2004; Lieber 2005); b) progressive multilateralists (Brzezinski 1997, 2004; Nye 2004); c) traditional conservatives (Kissinger 1994; Haass 2005); and d) offshore balancers

1 These dichotomic categorizations of basic trends in thinking on world affairs have been widely used in the major US dominated debates among international relations specialists since the end of World War II that started in the 1940's with the attack of the so-called 'realists', many of them being refugees from Europe (Morgenthau 1948, 1951; Herz 1959, Kissinger 1994) on the Wilsonian 'idealists' (Maghroory/Ramberg 1982). The so-called British school of Martin Wight (1991) and Hedley Bull (1977) distinguished among three schools of thought represented by the adherents of Machiavelli and Hobbes (realists), of Kant (revolutionists) and Grotius (rationalists or pragmatists). During the George W. Bush Administration, Kagan (2003) contrasted the US thinking with Mars and the European thought with that of Venus. Following this tradition, in a book addressed to students of America's war colleges, Binnendijk and Kugler (2006) contrasted the foreign and defence thinking by civilian specialists during the Administrations of Clinton (1993–2001) and George W. Bush (since 2001) in the context of the two opposite intellectual traditions of Hobbes and Kant. Since the early 1990's, this author has used the trilogy of the English school and has contextualized his own thinking on security in the tradition of the Grotian or rationalist school (Brauch 1995, 2002, 2005, 2005a), where cooperation matters, and with regard to the environment as that of an equity-oriented pragmatist where multilateral cooperation will be able to solve most of the environmental security dangers and concerns.

Table 12.1: Key Postulates of Neo-Kantian and Neo-Hobbesian worldviews on the US role in global security. **Source:** Binnendijk and Kugler (2006: 11). Permission for reproduction was granted by the authors.

	Neo-Kantian[a)]	Neo-Hobbesian[b)]
Modern world affairs are driven mainly by:	Democratization and economic growth	Stressful security affairs
The primary instrument is:	Democratic institutions and economic instruments	Military power
The geographic focus is on:	Europe, Asia, Latin America	Greater Middle East
The main goals of foreign policy should be:	Democracy and economic growth	Stable security affairs
The future is:	Optimistic	Pessimistic
Treaties, alliances, and inter-national institutions merit:	Strong support	Less faith
Interdependence creates	Opportunities for cooperation	Vulnerabilities
Best chance of success in world affairs comes from:	Liberal democracies working together multilaterally	United States often acting unilaterally as a Leviathan

a) Binnendijk and Kugler (2006: 15-57) attributed the label 'Neokantian' to the following authors and books: Fukuyama (1992); Huntington (1991); Lipson (2003); Friedman (1999); Garten (1992); Asmus (2002); Kegley/Raymond (1994), Yergin/Stanislaw (1998); Gilpin (2000); Keohane (2002); Slaughter (2004).
b) Binnendijk and Kugler (2006: 59-104) labelled the following authors and books as 'Neohobbessian': Brzezinski (1993); Huntington (1996); Mearsheimer (2001); Terrill (2003); Greenfeld (1992); Moynihan (1993); Pfaff (1993); Kaplan (2000); Power (2002); Lewis (2003); Pollack (2004).

(Kennedy 1987; Daalder/Lindsay 2003, 2005; Huntington 2004; Kagan 2003, 2004; Walt 2005; Zakaria 2004).

In their reading of the US literature on the American role in the post-Cold War world Binnendijk and Kugler (2006: 164) synthesized the premises of the different philosophies and 'worldviews' on national security strategy that were partly reflected in the 'mindsets' of policy-makers and their advisers that drafted the *national security strategy* documents and the military strategy papers of the Pentagon (table 12.2).

This categorization of the different 'worldviews' (Krell 2000)[2] of strategic thinkers is only partially reflected in the 'mindsets' (Booth 1979, 1987, 1991, 1998, 2007) of policy-makers and the roles and interests of big institutions that interpret world trends, developments and events in light of their past experience, their often crude images of the world, but also reflecting their present role and the specific interests of their organization (White House, National Security Council, Department of Defense, Department of State, etc.). By securitizing policy topics, the 'securitizing actors' have stressed that these objects are of 'utmost importance' and 'require extraordinary measures' (Wæver 1995, 1997, 2008) and also substantial financial resources to address these new security dangers, concerns and issues. Thus, in the USA 'securitizing moves' have become major policy instruments for legitimating political preferences and for the allocation of resources.

Thus, key strategic policy documents represent 'speech acts' that aim to convince both the audience at home whose support must be maintained and regained, and the international audience that must be deterred, persuaded and reassured. Thus, these 'speech acts' as reflected in the political notions associated with security threats, challenges, vulnerabilities and risks perform multiple political functions beyond the effort to describe and assess aspects of political reality. While strategic thinkers and policy analysts may be influenced by or promote different 'political philosophies' (macro theories) or develop and test their 'academic theories', institutions have strong bureaucratic or institutional interests which are reflected in the specific roles policy-makers play as representatives of these institutions. Thus, the 'terms' they use may not be interpreted as 'concepts' as they have been developed by different scientific communities to frame specific scientific issue areas (Brauch chap. 2).

2 See the definitions of the concepts of 'worldview' and 'mindset' and their use in international relations in chap. 95 by Oswald Spring and Brauch.

Table 12.2: Premises of philosophies on U.S. national security strategy. **Source:** Binnendijk and Kugler (2006: 164). Permission for reproduction was granted by the authors.

	Traditional Conservatives	Progressive Multilaterialism	Assertive Interventionism	Offshore Balancers
Kant vs. Hobbes	Mostly Hobbes	Mostly Kant, some Hobbes	Mostly Hobbes, some Kant	Mostly Hobbes, some Kant
Nature of major threat	Unstable big power relations	Chaotic southern arc, terrorism	Chaotic southern arc, terrorism	American Overstretch
Role of alliances	Important	Very Important	Less Important	Very Important
Instruments of power	Hard military power and diplomacy	Soft power and diplomacy	Hard military and economic power	Soft power and diplomacy
Mechanisms of success	Power balancing and major-power equilibrium	Persuasion and coalition building	Suppression of threats and promotion of democratization	Balancing and using regional powers
US leadership style	Architect of big power concert	Consensual leader of multilateral alliances	Path-setting leader of ad hoc coalitions	Less engagement
Attention to Limits of US Power	Moderate emphasis	Major emphasis	Little emphasis	Strongest emphasis
Also called	Realists	Liberals, idealists	Neoconservatives	Neoisolationists

12.3 National Security Strategy, Quadrennial Defence Reviews and Nuclear Posture Statements

The selected official documents of the *national security strategies*, *quadrennial defence reviews*, *nuclear posture statements* and other *national military* and *defence strategies* are the most representative official and public pronouncements of American national interests in its diplomacy and military policy (table 12.3).

12.3.1 National Security Strategy Documents

The *National Security Strategy* (NSS) *of the United States of America* (USA) has been prepared since 1986 by the executive branch and released by the US President for the US Congress. It outlines the major US national security dangers and concerns and how the Administration plans to deal with them (Kugler 2000; Newman 2003; Korb 2003; Flanagan/Schear 2008). In contrast with the *National Military Strategy* (NMS) its implementation relies on elaborating guidance in supporting documents. Since the end of the Cold War nine national security strategy documents were released by President George Bush (1991), William J. Clinton (1994, 1996, 1998, 2000), George W. Bush (2002 and 2006) and by Barack H. Obama in May 2010.

During the Cold War the milestone US strategic documents have been the Truman Doctrine and the Marshall Plan (1947); NSC-68 (1950) that outlined the military component of the US Grand Strategy of Containment, NSC 162/2 with the New Look of the Eisenhower Administration (1953) and its implementation in NATO's MC 48 and its strategy of flexible response (1957) that resulted in NATO's MC 14/3 (1967) with its dual diplomatic and military goals. President Kennedy's nuclear strategy of *Mutual Assured Destruction* (MAD) of 1963 was complemented by the Nixon Doctrine (1969) and developed further by the Reagan Doctrine (1982).

Since the end of the Cold War, Richard Betts (2004) referred to the *Draft Defense Planning Guidance* (1992) calling for a strategy for primacy, President Clinton's first NSS (1994) that proposed "Engagement and Enlargement" aiming at primacy and world order and the first NSS (17 September 2002) of George W. Bush as major strategic milestones that called after 11 September 2001 for a strategy of 'preemption' with the goal of a strategic primacy. This NSS (2002) contains the notion of 'military preeminence' that was first suggested in the *Draft Defense Planning Guidance* (1992) by its two principal authors, Paul Wolfowitz and I. Lewis Libby, who were working for then Secretary of Defense Richard Cheney. The Bush doctrine (NSS 2002) had moved from the doctrine of deterrence to a proactive attempt to adjust policy to the realities of the current

Table 12.3: Overview of major US strategic documents (1989-2010). **Source:** The author.

Administration	US Quadrennial Defense Reviews (DoD)	US National Security Strategy (President)	US Nuclear Posture Review (DoD)	National Military/ Defense Strategy (JCS, DoD)
George Bush (1989-1993)		NSS (1991)		*Draft Defense Planning Guidance* (1992)
William J. Clinton (1993-1997)		NSS (1994) NSS (1996)	NPR (1994)	*National Military Strategy* (1995)
William J. Clinton (1997-2001)	1997 (William C. Cohen)	NSS (1997) NSS (1998) NSS (2000)		*National Military Strategy* (1997)
George W. Bush (2001-2005)	30 September 2001 (Donald Rumsfeld)	NSS (2002)		*National Military Strategy* (2004)
George W. Bush (2001-2005)	February 2006 (Donald Rumsfeld)	NSS (2006)	NPR (2001)	*National Defense Strategy* (2005) *National Defense Strategy* (2008)
Barack H. Obama (2009-	1 February 2010 (Robert Gates)	NSS (2010)	NPR (April 2010)	*Quadrennial Homeland Security Review Report* (2010)

situation where the threat was coming both from terrorist groups and from nation states. However, his second NSS of 16 March 2006 returned to a more multilateral approach by restating America's commitment to support democracies and defeat terrorism by discussing the challenges of globalization.

12.3.2 Quadrennial Defence Reviews

In 1996, the US Congress requested that "the Secretary of Defense, in consultation with the Chairman of the Joint Chiefs of Staff, shall complete in 1997 a review of the defense program of the United States intended to satisfy the requirements for a Quadrennial Defense Review" that should "include a comprehensive examination of the defense strategy, force structure, force modernization plans, infrastructure, budget plan, and other elements of the defense program and policies with a view toward determining and expressing the defense strategy of the United States and establishing a revised defense program through the year 2005". So far four such documents have been released by the Clinton (1997), the George W. Bush (2001, 2006) and the Obama (1 February 2010) Administrations.

12.3.3 US Nuclear Posture Reviews

Since the end of the Cold War, the US Department of Defense (DoD) completed three *Nuclear Posture Reviews* (NPRs)[3] in 1994, 2001, and in April 2010 that offer

> the framework for US nuclear policy for the following five to 10 years. The purpose of the reviews is to determine the role of nuclear weapons in the broader context of US security policy. In order to determine this role, the DoD and several appointed commissions assess nuclear policy in light of the global strategic environment, and then provide a collective recommendation to senior DoD staff, the president, and Congress. The NPR then becomes a guide for the operation and budget of the nuclear weapons community.

In the post-Cold War era the primary US concern was to downsize and to legitimate its large nuclear forces in its strategic arsenal trying to incorporate nuclear forces into a new geostrategic situation. The 1994 NPR of the Clinton Administration "reaffirmed the centrality and legitimacy of strategic deterrence, which is based on the threat of retaliation with nuclear weapons in the event that the United States is attacked by another state with nuclear weapons". It

3 This section relies on an analysis on "Nuclear Posture Reviews" by the Monterey Institute's James Martin Center for Nonproliferation Studies; at: <http://www.nti.org/f_wmd411/f2c.html> (17 April 2010).

focused on Russia as the primary nuclear threat to the US and called for maintaining the existing nuclear triad of bombers, submarines, and land-based ballistic missiles. This NPR affirmed US commitments to arms control agreements (*Non-Proliferation Treaty* (NPT), *Cooperative Threat Reduction* (CTR) Program, START I) and emphasized US commitments to the *Comprehensive Test Ban Treaty* (CTBT). The NPR of 2001 by the Administration of George W. Bush

> underscored the importance of nuclear weapons in war fighting. It also reiterated the importance of the US-Russian relationship and noted that Russia retained the ability to destroy the United States with its immense nuclear arsenal. In addition to Russia, the United States named six countries that could present a threat and therefore might warrant a nuclear strike: North Korea, Iran, Iraq, Syria, Libya, and China. Finally, the 2001 NPR asserted the need for military flexibility through a 'capabilities-based' defense system as opposed to a 'threat-based' system.

The NPR 2001 downgraded arms control by withdrawing from the ABM and opposing the CTBT and called for "a new strategic nuclear triad that incorporated conventional weapons as well as a stronger role for missile defense". It supported "the development and deployment of ... bunker busters and low-yield nuclear weapons ..., which would serve the primary role of destroying underground nuclear facilities".

The NPR of 6 April 2010 by the Obama Administration reflected recommendations of the *Congressional Commission on the Strategic Posture of the United States* made in its Final Report (May 2009) that had recommended "that a step-by-step approach should be taken with Russia to establish a follow-on agreement to START I" but it also stressed the "need to improve nuclear infrastructure; pursue missile defense, so long as it does not cause heightened threats from Russia and China; and increase the safety, security and reliability of warheads permissible" (Perry 2009). The release of NPR 2010 was delayed because President Obama opposed draft versions "resembling too closely the status quo" and the nuclear policy of his predecessor. Its five key objectives include: "1) preventing nuclear proliferation and nuclear terrorism; 2) reducing the role of US nuclear weapons in US national security strategy; 3) maintaining strategic deterrence and stability at lower nuclear force levels; 4) strengthening regional deterrence and reassuring US allies and partners; and 5) sustaining a safe, secure, and effective nuclear arsenal". NPR 2010 stressed

> that the security environment is significantly different since the Cold War ended, which requires an alteration in the US nuclear posture. The report states that ... the reduction of nuclear arms will help to persuade other NPT members to collaborate in the fight against nuclear proliferation and terrorism. The NPR also indicates that any state, terrorist organization or non-state actor pursuing the use of WMD will be held fully accountable. Additionally, the review also advocates for the successful negotiation of a *Fissile Material Cut-off Treaty*.

While most Democrats in the US Congress support the measured approach of NPR 2010, several Republicans were concerned "over a few key provisions, among them being uncertainty over the extent of reliance on conventional capabilities and further reductions to the US nuclear arsenal".

12.3.4 Other US National Security Documents

Many other official US documents have specified the very general policy guidelines in the NSS documents of the American President and in the QDRs and the NPRs by the US Department of Defense. Among them is the US *National Military Strategy* (NMS) by the *Chairman of the Joint Chiefs of Staff* that outlines the strategic aims of the armed forces, which the JCS must submit each second year to the *Senate* and the *House Committee on Armed Services* with "a comprehensive examination of the national military strategy". The NMS

> must provide a description of the strategic environment and the opportunities and challenges that affect United States national interests and United States national security. The Report must describe the most significant regional threats to US national interests and security as well as the international threats posed by terrorism, weapons of mass destruction, and asymmetric challenges.

In February 2010, the Obama Administration also released its *Quadrennial Homeland Security Review Report* that reviewed its assessment and guidance for domestic security.

12.4 Threats, Challenges, Vulnerabilities and Risks in US National Security Strategy Documents (1991-2010)

Between 1991 and 2010, nine *National Security Strategy* (NSS) documents were released by President Georg Bush (1991), William J. Clinton (1994/1995, 1996, 1997, 1998, 2000), George W. Bush (2002,

2006), and by Barack Obama in May 2010. Have there been any clear differences in the use of the four terms of security threats, challenges, vulnerabilities and risks or have they been used as synonyms for describing major security dangers and concerns for the USA in the post-Cold War era?

12.4.1 References to US National Security 'Threats'

The nine NSS documents have offered many different definitions and references to US national security threats since the end of the Cold War.

12.4.1.1 Threats in the NSS of the Administration of George Bush

The first NSS document of August 1991 pointed to the key goal of "the survival of the United States as a free and independent nation, with its fundamental values intact and its institutions and people secure". It referred to a "reduced *Soviet threat*" [emphasis added by the author also in the citations below] but also claimed that the SU's "conventional forces west of the Urals ... could still pose a *potent threat* to a single flank or region". NSS 1991 noted "*threats of power vacuums* and regional instabilities", and the *threats of drug trafficking, of international terrorism*, to combat "*threats to democratic institutions* from aggression, coercion, insurgencies, subversion, terrorism and illicit drug trafficking". In the context of economic and security assistance NSS 1991 added to the list of threats "AIDS and environmental degradation". The security concerns include besides illicit drugs, protection of the oil supplies, *varied threats to stability, ballistic missile proliferation and weapons of mass destruction*, and it claimed "regional crises are the *predominant military threat* we will face in the future". Thus, the term 'threat' was widened from military to non-military security dangers and also the referent object (security for whom?) was deepened by the Bush Administration.

12.4.1.2 Threats in the NSS of the Clinton Administration

The first NSS 1994/1995 of the Clinton Administration on "Engagement and Enlargement" used the term 'threat' 25 times with a wide range of connotations. It stated with regard to the US historical experience: "After World War II, ... in the face of a new *totalitarian threat* this great nation did not walk away from the *challenge* of the moment" and it noted that "the *threat of communist expansion* – is gone" and that "the *threat of a war* among great powers and the specter of nuclear annihilation have receded dramatically" and that the US support "market reforms in Russia (and the other newly independent states)" and thus "help turn a *former threat* into a region of *valued diplomatic and economic partners*". NSS 1994/1995 claimed that "the unitary threat that dominated our engagement during the Cold War has been replaced by a complex set of challenges".

NSS 1994/1995 pointed to several remaining military threats, such as another "*Iraqi threat* to Kuwait", and that "the continuing *tensions on the Korean Peninsula* remain the principal *threat* to the peace and stability of the Asian region". But it also considered it "essential that *China not become a security threat to the region*", and that "in Southwest Asia, the United States remains focused on *deterring threats to regional stability*, particularly from *Iraq and Iran* as long as those states *pose a threat* to US interests, to other states in the region, and to their own citizens". The object of the threat is not only 'US interests' but also 'other states in the region' and 'their citizens'.

With regard to the conflict in the post Yugoslav space NSS 1994/1995 claimed that "the *threat of NATO air power* was judged real", but it was clear that "allied or friendly governments" should "ultimately, defeat aggression should it occur, we must prepare our forces to *confront this scale of threat*, preferably in concert with our allies and friends, but unilaterally if necessary", acknowledging that this "does not pose a *direct threat* to our security or warrant unilateral US involvement".

The Clinton Administration used the term 'threat' for various non-military dangers such as "the *threat of intrusions to our military and commercial information systems*", and that the US has "the political will to confront the *narcotics threat*" and that it will "address the *growing threat from high-purity heroin* entering this country" as well as "seek to eliminate the scourge of drug trafficking, which poses a *serious threat to democracy and security*". NSS 1994/1995 goes beyond the state as the sole source and points to dangers posed by non-state actors: "*Terrorism* involving weapons of mass destruction represents a particularly *dangerous potential threat* that must be countered." With regard to the "Nunn-Lugar *Cooperative Threat Reduction* effort and other denuclearization initiatives", the NSS 1994/1995 stated that the USA "are working with our Allies to develop a policy framework to consider how to reinforce ongoing prevention efforts and to reduce the *proliferation threat*

and protect against it", and it announced to "develop security countermeasures based on *sound threat analysis* and risk management practices".

The Clinton Administration's second *National Security Strategy of Engagement and Enlargement* (February 1996) used the term 'threat' and 'threaten' more than 100 times both with regard to military and non-military security problems, many of them were also cited in the previous document. It refers to a key scientific debate that "democratic states are less likely to *threaten* our interests and more likely to cooperate with the United States to meet security *threats* and promote free trade and sustainable development". It also notes that "the boundaries between *threats* that start outside our borders and the *challenges* from within are diminishing". NSS 1996 uses the term 'threat' both for military and non-military dangers but nearly exclusively with regard to the USA and its allies but also to "US enterprises" and "threats to democracy", posed by states and transnational threats (drugs, organized crime), thus reflecting a widening with a limited deepening.

In May 1997 in the early second Clinton Administration *A National Security Strategy for A New Century* was released that refers 89 times to the term 'threat' noting in the preface that

> the dangers we face are unprecedented in their complexity. Ethnic conflict and outlaw states *threaten* regional stability; terrorism, drugs, organized crime and proliferation of weapons of mass destruction are global concerns that transcend national borders; and environmental damage and rapid population growth undermine economic prosperity and political stability in many countries.

These new dangers require to "increase cooperation in confronting *new security threats* that defy borders and unilateral solutions". It specifically lists as "*threats to US interests* ... [that] are generally grouped into three, often intertwined, categories:

- *Regional or State-centered Threats*: A number of states still have the capabilities and the desire to *threaten* our vital interests, through either coercion or cross border aggression. In many cases, these states are also actively improving their offensive capabilities, including efforts to obtain nuclear, biological or chemical weapons. In other cases, unstable nations, internal conflicts or failed states may threaten to further destabilize regions where we have clear interests.
- *Transnational Threats*: Some *threats transcend national borders*. These *transnational threats*, such as terrorism, the illegal drug trade, illicit arms trafficking, international organized crime, uncontrolled refugee migrations, and environmental damage threaten American interests and citizens, both directly and indirectly. *Not all of these are new threats*, but advances in technology have, in some cases, made these threats more potent.
- *Threats from Weapons of Mass Destruction*: Weapons of mass destruction pose the *greatest potential threat to global security*. We must continue to reduce the *threat* posed by existing arsenals of such weaponry as well as work to stop the proliferation of advanced technologies that place these destructive capabilities in the hands of parties hostile to US and global security interests. Danger exists from outlaw states opposed to regional and global security efforts and transnational actors, such as terrorists or international crime organizations, potentially employing nuclear, chemical or biological weapons against unprotected peoples and governments.

NSS 1997 contains a clear commitment to multilateralism when it states that "No one nation can defeat these threats alone. Accordingly, a central thrust of our strategy is to adapt our security relationships with key nations around the world to *combat these threats* to *common interests*" by using diplomacy, international assistance, and military activities as major tools and it notes with regard to "*transnational threats*" that

> Today, American diplomats, law enforcement officials, military personnel and others are called upon to respond to *assorted transnational threats* that have moved to center stage with the Cold War's end. Combating these dangers which range from terrorism, international crime, and trafficking in drugs and illegal arms, to environmental damage and intrusions in our critical information infrastructures requires far-reaching cooperation among the agencies of our government as well as with other nations.

Among the transnational threats NSS 1997 refers besides drug trafficking and organized crime also to "environmental and security concerns" by stating:

> *Environmental threats* do not heed national borders and can pose long-term dangers to our security and well-being. Natural resource scarcities often trigger and exacerbate conflict. *Environmental threats* such as climate change, ozone depletion and the transnational movement of dangerous chemicals directly *threaten the health of US citizens*. We must work closely with other countries to respond aggressively to *these and other environmental threats*.
>
> Decisions today regarding the environment and natural resources can affect our security for generations; consequently, our national security planning is incorporating environmental analyses as never before. In addition, we have a full diplomatic agenda, working unilaterally, regionally and multilaterally to forge agreements to protect the global environment.

This statement clearly reflects the arguments of the first two phases of the policy and scientific debates on environmental security (Brauch 2008, 2009; chap. 1 in this vol.). NSS 1997 pointed to "promoting sustainable development abroad" as a key US national security goal:

> Sustainable development improves the prospects for democracy in developing countries and expands the demand for US exports. It alleviates pressure on the global environment, reduces the attraction of the illegal drug trade and improves health and economic productivity. ... New diseases, such as AIDS, and other epidemics that can spread through environmental damage, *threaten* to overwhelm the health facilities of developing countries, disrupt societies and stop economic growth. ... The Global Environmental Facility provides a source of financial assistance to the developing world for climate change, biodiversity and oceans initiatives that will benefit all the world's citizens.
>
> Environmental and natural resource issues can impede sustainable development efforts and promote regional instability. ... Environmental damage in countries of the NIS and Central and Eastern Europe continues to impede their ability to emerge as prosperous, independent countries. In addition, the effects of climate change and ozone depletion know no borders and can pose grave dangers to our nation and the world. We seek to accomplish the following:
>
> - forge an international consensus to address the challenge of global climate change, as evidenced by *threats such as rising sea levels*, the spread of tropical disease and more frequent and severe storms;
> - achieve increased compliance with the Montreal Protocol through domestic and multilateral efforts aimed at curbing illegal trade in ozone depleting substances;
> - implement the UN Straddling Stocks Agreement, ratify the Law of the Sea Convention and help to promote sustainable management of fisheries worldwide;
> - implement the Program of Action on population growth developed at the 1994 Cairo Conference;
> - expand bilateral forest assistance programs and promote sustainable management of tropical forests;
> - focus technical assistance and encourage non-governmental environmental groups to provide expertise to the NIS and Central and Eastern European nations ...;
> - achieve Senate ratification of the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes;
> - lead a renewed global effort to address population problems and promote international consensus for stabilizing world population growth; and
> - achieve Senate ratification of the Biodiversity Convention and take steps to slow or stop biodiversity loss. ...

Thus, with NSS 1997 the Clinton Administration clearly responded to the emerging policy (Mathews 1989, Myers 1989) and scientific (Homer-Dixon 1991, 1994, 1995) debate on environmental security that had started in the USA in 1989 and illustrates the progressing official securitization of the environmental dimension of US national security.

NSS 1998 used the term 'threat' 32 times by referring to the threat to US national security, to global instability, posed by existing weapons and from foreign intelligence services and by "traditional human, technical and signals intelligence activities". It pointed to Clinton's Presidential Decision Directive 62 of May 1998 that "creates a new and more systematic approach to fighting the *terrorist threat* of the next century". NSS 1998 mentions the "*serious and potent threat to the American people at home and abroad*" posed by international crime, where this "*growing threat* to our security from *transnational crime* makes international law enforcement cooperation vital".

The Clinton Administration submitted its last *National Security Strategy For A Global Age* in December 2000 just before leaving office, where the term 'threat' was employed 34 times referring to new international health security issues, where the US "leadership in the international fight against infectious diseases, especially HIV/AIDS, is critical to defeat a *threat that kills massively*, crosses frontiers and destabilizes whole regions", because such international cooperation on health issues "*reduces the threat of diseases to Americans*, and because global international economic development, democratization, and political stability are predicated in part on the health of populations worldwide". The threat concept is widely used with regard to BMD and WMD but also for the drug issue and international crime. However, the indication to go it alone was a tendency that became more pronounced during the Administration of George W. Bush.

12.4.1.3 Threats in the NSS of the Administration of George W. Bush

In the first *National Security Strategy* (NSS 2002) of President George W. Bush of September 2002 there were 18 references to the term 'threat' that pointed to a shift from states to non-state actors as the cause of insecurity: "Enemies in the past needed great armies and great industrial capabilities to endanger America. Now, shadowy networks of individuals can bring great chaos and suffering to our shores for less than it costs to purchase a single tank. Terrorists are organized to penetrate open societies and to turn the power

of modern technologies against us." NSS 2002 notes that once this threat is localized the USA "will help ensure the state has the military, law enforcement, political, and financial tools necessary to finish the task". It stressed the task of "defending the United States, the American people, and our interests at home and abroad by *identifying and destroying the threat* before it reaches our borders". With regard to the danger of proliferation of WMD the US "comprehensive strategy to combat WMD includes: a) Proactive counterproliferation efforts. We must deter and defend against the threat before it is unleashed". Against this new threat posed by

> rogue states and terrorists, the United States can no longer solely rely on a reactive posture as we have in the past. The inability to deter a potential attacker, the immediacy of *today's threats*, and the magnitude of potential harm that could be caused by our adversaries' choice of weapons, do not permit that option. We cannot let our enemies strike first. ... But deterrence based only upon the *threat of retaliation* is less likely to work against leaders of rogue states more willing to take risks, gambling with the lives of their people, and the wealth of their nations. ... For centuries, international law recognized that nations need not suffer an attack before they can lawfully take action to defend themselves against forces that present an imminent danger of attack. Legal scholars and international jurists often conditioned the legitimacy of pre-emption on the existence of an *imminent threat* – most often a visible mobilization of armies, navies, and air forces preparing to attack.

The NSS 2002 of the Administration of George W. Bush proposed to "adapt the concept of *imminent threat* to the capabilities and objectives of today's adversaries" and it legitimated pre-emptive action: "to counter a *sufficient threat to our national security*. The *greater the threat*, the greater is the risk of inaction – and the more compelling the case for taking anticipatory action to defend ourselves, even if uncertainty remains as to the time and place of the enemy's attack. To forestall or prevent such hostile acts by our adversaries, the United States will, if necessary, act pre-emptively". NSS 2002 suggested to "strengthen intelligence warning and analysis to provide *integrated threat assessments for national and homeland security*. Since the *threats inspired by foreign governments and groups* may be conducted inside the United States, we must also ensure the proper fusion of information between intelligence and law enforcement". This use of the threat concept is limited to military but also domestic security dangers posed by so-called 'rogue states' and 'terrorists' where all references to non-military soft security dangers and concerns had disappeared.

The second *National Security Strategy* (NSS 2006) of President George W. Bush of March 2006 used the term 'threat' 14 times, noting that "some conflicts pose such a *grave threat to our broader interests and values* that conflict intervention may be needed to restore peace and stability" and that "the *proliferation of nuclear weapons* poses the *greatest threat* to our national security". NSS 2006 focused primarily to threats posed by biological, chemical and nuclear weapons with a special reference to the claimed threats of the WMD of Iraq that were later rejected by the Silverman Commission set up by President George W. Bush. However, it also applied the threat concept as well to a new non-military danger to human health: "To confront the *threat of a possible pandemic*, the Administration took the lead in creating the International Partnership on Avian and Pandemic Influenza, a new global partnership of states committed to effective surveillance and preparedness that will help to detect and respond quickly to any outbreaks of the disease." Contrary to the Clinton Administration the 'threat' concept of George W. Bush stressed nearly exclusively hard security dangers and concerns and there was no more reference to 'environmental threats'.

12.4.1.4 Threats in the NSS of the Administration of Barack H. Obama

The first *National Security Strategy* of the Obama Administration of May 2010 (NSS 2010) has significantly changed the foreign and security strategy of the United States. President Barak H. Obama stressed in his introduction that the national security strategy "begins with the steps we take at home". As goals he lists economic growth, reduction of the deficit, education "of our children to compete in an age where knowledge is capital". The US Armed Forces as the cornerstone of US national security must be complemented by the diplomats. He argued that "America's greatest asset is its people" and he believed that the USA "must foster even deeper connections among Americans and peoples around the globe". While NSS 2010 does not use the concept of 'human security', it acknowledges however that "The freedom that America stands for includes freedom from want."

NSS 2010 is structured in four parts referring (I.) to an Overview of National Security Strategy; (II.) providing an outline of the Strategic Approach referring to "the world we seek" that builds on the foundations of the USA, pursues a comprehensive engagement

and promotes a just and sustainable international order; (III.) a strategy for advancing US interests of security, prosperity, values and international order; and a brief concluding section.

The strategic shift of the declared NSS from the Administration of George W. Bush can be described from a 'capability-based' towards a value oriented strategy. Among the key security goals NSS 2010 lists: "strengthen security and resilience at home", "disrupt, dismantle and defeat Al Qa'ida and its violent extremist affiliates in Afghanistan, Pakistan, and around the world", ... "revise the spread of nuclear and biological weapons and secure nuclear materials", "advance peace, security, and opportunity in the Greater Middle East", "invest in the capacity of strong and capable partners", and to "secure cyberspace".

With regard to the value basis, NSS 2010 emphasizes to "strengthen the power of our example", "promote democracy and human rights abroad" and to "promote dignity by meeting basic needs". On international order, NSS 2010 stresses to "ensure strong alliances", to "build cooperation with other 21st century centers of influence", to "strengthen institutions and mechanisms for cooperation" and to "sustain broad cooperation on key global challenges".

NSS 2010 used the term 'security' 251 times, with the qualifiers of *national, state, homeland, internal, regional, European, African, international, global, transnational, mutual, common, collective, broader, shared, nuclear, proliferation, maritime, positive and negative, food, energy, cyber, aviation, physical, health, transition, lasting, true, responsible, civilian, border, future, America's, Israel's, Afghanistan's and Iraqi* security but it did not use the terms of 'human', 'environmental', 'ecological' and 'social' or 'societal security'.

NSS 2010 used 17 and 55 times the term threat(s), 8 times challenge(s), 3 times vulnerability(ies) and 13 times risk(s). Besides the "immediate threat" in the aftermath of the events of 11 September 2001, NSS 2010 pointed to the American engagement

> on strengthening international institutions and galvanizing the collective action that can serve common interests such as combating violent extremism; stopping the spread of nuclear weapons and securing nuclear materials; achieving balanced and sustainable economic growth; and forging cooperative solutions to the *threat of climate change, armed conflict, and pandemic disease*.

NSS 2010 notes that there "is *no greater threat to the American people than weapons of mass destruction*, particularly the danger posed by the pursuit of nuclear weapons by violent extremists and their proliferation to additional states". Instead of the "*ideological, economic, and military threat* from communism" during the Cold War, now "we must once again position the United States to champion mutual interests among nations and peoples". With regard to homeland security the new US approach "relies on our *shared efforts to identify and interdict threat*s; deny hostile actors the ability to operate within our borders; maintain effective control of our physical borders; safeguard lawful trade and travel into and out of the United States; disrupt and dismantle transnational terrorist, and criminal organizations; and ensure our national resilience in the face of the threat and hazards". But NSS 2010 also notes that it will not be able "to *deter or prevent every single threat*" but that the USA is "committed to fighting here and abroad have *underscored the threat* to the United States and our interests *posed by individuals radicalized at home*" but also that the "best *defenses against this threat* are well informed and equipped families, local communities, and institutions" and that "the Federal Government will invest in intelligence to understand this threat and expand community engagement and development programs to empower local communities".

Internationally, NSS 2010 refers to "Al Qa'ida's core in Pakistan" and the "*growing threat from the group's allies* worldwide" and that the USA is working with the government of Pakistan "to address the *local, regional, and global threat from violent extremists*". NSS 2010 also discusses "global *financial threats*" resulting from globalization. NSS 2010 points specifically to non-state actors "that *pose a threat to our national security* – terrorists, proliferators, narcotics traffickers, corrupt officials, and others". Therefore the USA should expedite "the lawful and legitimate flow of people and goods while *interdicting transnational threat that threaten our open societies*".

Besides environmental security dangers, NSS 2010 argues that "the *threat of contagious disease* transcends political boundaries, and the ability to prevent, quickly detect and contain outbreaks with pandemic potential has never been so important". Thus, "addressing these transnational risks requires advance preparation, extensive collaboration with the global community, and the development of a resilient population at home". This requires to "improve global surveillance and early warning capabilities and quickly enact control and containment measures against the next pandemic threat" and "to mitigate other problem areas, including limited global vaccine production capacity, and the threat of emergent and reemergent dis-

ease in poorly governed states". The 55 references to 'threats' are linked to 'new', 'evolving' and 'asymmetric' threats as well as vital, military, intelligence, transnational, terrorist, biological, external, cybersecurity, financial, health, criminal and maritime threats. From the Administration of George W. Bush to that of Barak H. Obama, the scope of the threat has widened and become increasingly of a non-military nature against which non-military counter strategies, policies, measures and means are needed.

12.4.2 Changing Perceptions of US National Security Challenges

12.4.2.1 Challenges in the NSS of the George Bush Administration

The NSS 1991 used the term 'challenge' much less than 'threat', primarily with a non-military or 'soft security' meaning in the following contexts [emphasis added by the author]: "We face *new challenges* not only to our security, but to our ways of thinking about security;" or by referring to "a new agenda of *political challenges*", or "the *security challenges* of a new era" or to "The upheavals of this era are also giving rise to human migrations on an unprecedented scale, raising a host of *social, economic, political and moral challenges* to the world's nations." NSS 1991 listed among its goals, to "achieve cooperative international solutions to key *environmental challenges*, assuring the sustainability and environmental security of the planet as well as growth and opportunity for all". Migration and refugees are also described as "an unprecedented *challenge* to the new Europe". But it also referred to China and the Soviet Union as posing "a complex *challenge* as it proceeds inexorably toward major systemic change", and it listed as top issues "for international cooperation ... the *global challenges* posed by illegal drugs, terrorism and degradation of the environment". NSS 1991 also stated:

> We will focus our efforts and resources on five *major challenges*:
>
> - Promoting and consolidating democratic values ....
> - Promoting market principles: ...
> - Promoting peace: ...
> - Protecting against transnational threats: International terrorism, narcotics, AIDS and environmental degradation threaten all peaceful nations....
> - Meeting urgent human needs. We will respond quickly and substantially to the suffering caused by natural or man-made disasters.

The term challenges was also used as "*economic challenges*" by referring to "the ability and willingness of all countries to rise to the *challenges of a new world order* and will require compromise on all sides" and as "*environmental challenges*" that are "already contributing to political conflict". But it also notes that "the *specific challenges facing our military* in the 1990's and beyond will be different from those that have dominated our thinking for the past 40 years", and it argues that the new US strategy will "also guide our restructuring so that our remaining forces are appropriate to the *challenges of a new era*" and that with regard to crisis response the USA "must be prepared for our interests to be challenged with force, often with little or no warning". But with regard to the solution NSS 1991 reflects a technological imperative when it argues "we must *challenge our technology* to develop forces that are lethal but more readily deployable" and "another *challenge* will be to maintain our edge in defense technology, even as we reduce our forces" following this principle of "reducing our defense burden as appropriate, while restructuring our *forces for new challenges*". The concept of 'security challenges' was extensively used in the NSS 1991 by the Bush Administration reflecting a wider meaning of security including the economic, environmental and technological dimensions where the state remains the primary reference object.

12.4.2.2 Challenges in the NSS of the Clinton Administration

NSS 1994/1995 of the Clinton Administration used the term 'challenge' seven times sometimes as a synonym for threat but mostly with regard to new non-military security dangers. For Haiti after the coup, "our *challenge* now is to help the Haitian people consolidate their hard-won democracy and rebuild their country" and it noted on the financial crisis in Mexico in December 1994 that "the United States took the lead in marshaling international support to assist the country in meeting this *challenge*". For the "Middle East and elsewhere" the USA shared its concerns "for the *enormous challenge* of stemming the proliferation of such weapons".

The Clinton Administration's second *National Security Strategy of Engagement and Enlargement* (February 1996) used the term 'challenge' 36 times for both hard and soft security issues, arguing that with the end of the past primary security imperative of "containing communist expansion while preventing nuclear war", the US is now "confronted [with] a complex array of *new and old security challenges*". It points to the new dangers posed by globalization that "makes possible for the violence of terrorism, organ-

ized crime and drug trafficking to challenge the security of *our borders* and that of our *citizens* in new ways". With regard to Africa, different security dimensions are linked as "*economic, political, social, ethnic and environmental challenges*" that could lead to "Afro-pessimism" but if the USA "can simultaneously *address these challenges*, we create a synergy that can stimulate development, resurrect societies and build hope". NSS 1996 has often combined threats and challenges in the same sentence and often contrasted challenges and opportunities.

NSS 1997 referred 48 times to the term 'challenge' with the connotations of the previous strategy statements of the Clinton Administration. It refers to "joint action on *common security challenges*" in Europe contributing "to a democratic Russia's active participation in the post-Cold War European security system" and to various environmental goals "to close the hole in the ozone layer, reducing the greenhouse gases that challenge our health as they change our climate". However, NSS 1997 used the term challenge more for military and regional security issues than for environmental dangers.

NSS 1998 employed the term 'challenge' 15 times pointing to globalization that "enables other states, terrorists, criminals, drug traffickers and others to challenge the safety of our citizens and the security of our borders in new ways". A special focus was on macroeconomic issues, such as the Asian financial crisis.

NSS 2000 referred to the term 'challenge' six times in connotation with "international drug syndicates based abroad *challenge* us", but also with "*ethnic conflict [that] represents a great challenge to our values and our security*" and democracy and human rights where the USA announced to "promote responsible indigenous moves toward increasing political participation and enhancing the quality of governance, and we will continue to *challenge governments* in the region to improve their human rights records". These five national security strategy papers of the Clinton Administration have used the term 'challenge' with a wide variety of referents with both a wider and a more constrained meaning (widening), with both the states but also the American and other peoples as referent objects (deepening) but only a few pointed to sectorialized security concepts. However, there have been no clear borderlines between the use of the terms 'threat' and challenge'.

12.4.2.3 Challenges in the NSS of the Administration of George W. Bush

NSS 2002 by George W. Bush employed the term 'challenge' 13 times referring to the other non-military dimensions of security for which it would "deliver greater development assistance through the *New Millennium Challenge Account* to nations that govern justly, invest in their people, and encourage economic freedom" and that the USA "will also continue to lead the world in efforts to reduce the terrible toll of HIV/AIDS and other infectious diseases". It also announced "*to challenge Israeli leaders* to take concrete steps to support the emergence of a viable, credible Palestinian state" and with regard to Colombia, the US "recognize the link between terrorist and extremist groups that *challenge the security of the state* and drug trafficking activities that help finance the operations of such groups". It emphasized that the US would only "aid countries that have *met the challenge of national reform*" and that its "*Millennium Challenge Account* will reward countries that have demonstrated real policy change and *challenge those that have not* to implement reforms." Both "share health and environmental threats, such as the spread of HIV/AIDS, *challenge us to promote jointly the welfare of our citizens*" but also "addressing these transnational threats will *challenge China* to become more open with information, promote the development of civil society, and enhance individual human rights".

NSS 2006 employed the term 'challenge' six times by referring with regard to terrorism to "sub-cultures of conspiracy and misinformation" that "keep alive grievances and filter out facts that would *challenge popular prejudices* and self-serving propaganda". NSS 2006 also points to the great "challenge" the USA is facing from Iran and to the "serious *nuclear proliferation challenge*" from the North Korean regime. The two NSS documents of the Administration of G.W. Bush used the term 'challenge' for both hard and soft security problems.

12.4.2.4 Challenges in the NSS of the Administration of Barack H. Obama

NSS 2010 used the term 'challenge' 8 times, three times as a noun and five times as a verb. The plural of 'challenges' was used 64 times, most particularly in connotation with 'new', 'emerging', 'shared', 'major', 'tough', 'difficult', 'enormous', 'global', 'common', 'civilian', 'transnational', 'economic' and 'development' issues. Under the heading of "sustain broad cooperation on key global challenges", NSS 2010 returns to a

broad global multilateral and cooperative approach of the Clinton Administration as being "necessary to meet 21st century challenges".

Among the key new challenges "requiring broad global cooperation", NSS 2010 refers to climate change, peacekeeping and armed conflict, pandemics and infectious disease, transnational criminal threats and threats to governance and safeguarding the global commons. With regard to climate change, NSS 2010 stated:

> The danger from climate change is real, urgent, and severe. The change wrought by a warming planet will lead to new conflicts over refugees and resources; new suffering from drought and famine; catastrophic natural disasters; and the degradation of land across the globe. The United States will therefore confront climate change based upon clear guidance from the science, and in cooperation with all nations—for there is no effective solution to climate change that does not depend upon all nations taking responsibility for their own actions and for the planet we will leave behind.
>
> *Home*: Our effort begins with the steps that we are taking at home. We will stimulate our energy economy at home, reinvigorate the U.S. domestic nuclear industry, increase our efficiency standards, invest in renewable energy, and provide the incentives that make clean energy the profitable kind of energy. This will allow us to make deep cuts in emissions—in the range of 17 percent by 2020 and more than 80 percent by 2050. This will depend in part upon comprehensive legislation and its effective implementation.
>
> *Abroad*: Regionally, we will build on efforts in Asia, the Americas, and Africa to forge new clean energy partnerships. Globally, we will seek to implement and build on the Copenhagen Accord, and ensure a response to climate change that draws upon decisive action by all nations. Our goal is an effective, international effort in which all major economies commit to ambitious national action to reduce their emissions, nations meet their commitments in a transparent manner, and the necessary financing is mobilized so that developing countries can adapt to climate change, mitigate its impacts, conserve forests, and invest in clean energy technologies. We will pursue this global cooperation through multiple avenues, with a focus on advancing cooperation that works. We accept the principle of common but differentiated responses and respective capabilities, but will insist that any approach draws upon each nation taking responsibility for its own actions.

With regard to peacekeeping and armed conflict, NSS 2010 calls for preventing genocide and mass atrocities and international justice. For pandemics and infectious disease, NSS 2010 states that "addressing these transnational risks requires advance preparation, extensive collaboration with the global community, and the development of a resilient population at home". Internationally, the USA "are enhancing international collaboration and strengthening multilateral institutions in order to improve global surveillance and early warning capabilities and quickly enact control and containment measures against the next pandemic threat". With regard to "transnational criminal threats" NSS 2010 supports a "multidimensional strategy that safeguards citizens, breaks the financial strength of criminal and terrorist networks, disrupts illicit trafficking networks, defeats transnational criminal organizations, fights government corruption, strengthens the rule of law, bolsters judicial systems, and improves transparency". Finally for safeguarding the global commons, NSS 2010 stresses that the US "must work in concert with allies and partners to optimize the use of shared sea, air, and space domains", and it notes that "these efforts require strong multilateral cooperation, enhanced domain awareness and monitoring, and the strengthening of international norms and standards". Whether these new value-based goals will be implemented in the years ahead also partly depends on the rather interest-driven and short-time focused U.S. Congress.

12.4.3 US National Security Vulnerabilities

In the NSS statement of 1991 there is only one reference to the term 'vulnerability' that is used solely in the context of *energy security*: "Our use of oil is the key source of our *vulnerability* to world oil supply disruption. To reduce this *vulnerability*, we must work to both reduce oil consumption and to use oil more efficiently."

In NSS 1994/1995 of the Clinton Administration there was again only one reference to 'vulnerability' that referred to the goal "to minimize the *vulnerability of our forces* abroad to weapons of mass destruction". The single reference to 'vulnerability' in NSS 1996 is used for protecting US "forces abroad to weapons of mass destruction" why the USA "are placing a high priority on improving our ability to locate, identify and disable arsenals of weapons of mass destruction, production and storage facilities for such weapons and their delivery systems".

NSS 1997 used the term 'vulnerability' twice with regard to the *information infrastructure* and major theatre warfare. While for the first "concepts and technologies are being developed and employed to protect and defend against these *vulnerabilities*; we must fully implement them to ensure the future secu-

rity of not only our national information infrastructures, but our nation as well", for the second it concludes that the US "must plan and prepare to fight and win under conditions where an adversary may use asymmetric means against us, unconventional approaches that avoid or undermine our strengths while exploiting our *vulnerabilities*". NSS 1998 and NSS 2000 did not use the vulnerability term at all, nor did NSS 2002 of the Administration of George W. Bush. The NSS 2006 has one reference to 'vulnerability' with regard to the "Department of Homeland Security" that "is focused on three national security priorities: preventing terrorist attacks within the United States; reducing America's *vulnerability* to terrorism; and minimizing the damage and facilitating the recovery from attacks that do occur". However, contrary to the use of 'vulnerability' during the Cold War referring to its nuclear forces no similar solely technical use could be documented for the post-Cold War period.

12.4.3.1 Vulnerabilities in the NSS of the Administration of Barack H. Obama

NSS 2010 has used the term 'vulnerability' only once in the context of natural hazards for improving "resilience through increased public-private partnerships" where the private sector as the owner and operator of the critical infrastructure "lays a vital role in preparing for and recovering from disasters". With a strengthened "public-private partnerships" new structures and systems are to be designed

> that can withstand disruptions and mitigate associated consequences, ensure redundant systems where necessary to maintain the ability to operate, decentralize critical operations to reduce our *vulnerability* to single points of disruption, develop and test continuity plans to ensure the ability to restore critical capabilities, and invest in improvements and maintenance of existing infrastructure.

The plural of 'vulnerabilities' was used twice in NSS 2010 in the context of enhancing security at home that "relies on our shared efforts to prevent and deter attacks by identifying and interdicting *threats*, denying hostile actors the ability to operate within our borders, protecting the nation's critical infrastructure and key resources, and securing cyberspace. That is why we are pursuing initiatives to *protect and reduce vulnerabilities in critical infrastructure, at our borders, ports, and airports, and to enhance overall air, maritime, transportation, and space and cyber security*".

Other new security dangers are 'cybersecurity threats' that "represent one of the most serious national security, public safety, and economic challenges we face as a nation". However, the US "public safety depend[s] on power and electric grids, but *potential adversaries could use cyber vulnerabilities* to disrupt them on a massive scale". The term vulnerability is not used any more with a purely military meaning as during the Cold War but with various non-military connotations.

12.4.4 Perceptions of US National Security Risks

12.4.4.1 Risks in the NSS of the George Bush Administration

In NSS 1991 the term 'risk' was used four times in the following political contexts: "American leadership must include mobilizing the world community to share the danger and *risk*." In a different context NSS 1991 stresses that "nonstrategic nuclear weapons remain integral to our strategy of deterrence" and suggests that "as the principal means by which Alliance members share nuclear *risk*s and burdens, these aircraft and their weapons must be based in Europe". It points to the goal "to maintain our edge in defense technology, even as we reduce our forces. Technology has historically been a comparative advantage for American forces, and we have often relied on it to overcome numerical disparities and to reduce the *risk* to American lives". And it notes with regard to resource competition, our "emphasis on technology development ... may mean accepting some continued *risk* in the near term. But accepting such *risk* may well be prudent in a period of reduced East-West tensions".

12.4.4.2 Risks in the NSS of the Clinton Administration

In NSS 1994/1995 of the Clinton Administration the term 'risk' was used eight times arguing that the external and internal "threat of intrusions to our military and commercial information systems poses a significant *risk to national security*". It also noted that regarding the US humanitarian interests that "the *risk to American troops* is minimal". With regard to the conclusions of the NPR 1994, NSS 1994/1995 stated that the USA "will continue to maintain nuclear forces of sufficient size and capability to *hold at risk* a broad range of assets valued by such political and military leaders" and with regard to nuclear arms control it noted that the USA "will also explore strategic confidence building measures and mutual understandings that reduce the *risk of accidental war*". It further an-

nounced that the USA would "develop security countermeasures based on sound threat analysis and *risk management practices*".

With regard to the environment and sustainable development NSS 1994/1995 reflected the concerns of the Clinton Administration with regard to environmental security (Matthew/McDonald 2009) by noting that the "increasing competition for the dwindling reserves of uncontaminated air, arable land, fisheries and other food sources, and water, once considered 'free' goods, is already a very *real risk to regional stability around the world*". And with regard to NATO's involvement in the Balkans, NSS 1994 argues that this would promote US interests "by reducing *the risk of instability or conflict in Europe's eastern half*".

NSS 1996 used the term 'risk' 22 times, referring to the US soldiers that "put their *lives at risk*" and it repeatedly notes that "US security, prosperity and freedom are neither cost- nor *risk-free*", why "resources must be spent and casualties may be incurred", and that the USA faces "*security risks* that are not solely military in nature". It acknowledges the positive cost-benefit analysis of humanitarian missions when "only the military has the ability to jump-start the longer-term response to the disaster; when the response requires resources unique to the military; and when the *risk to American troops is minimal*". NSS 1996 also asks about "the *environment of risk*" the USA is entering. It interprets *limiting risks* also as a major diplomatic task where "the G-7 leaders [are] committed to intensify cooperation among financial authorities to *limit systemic risk* and pledged to develop and enhance safeguards, standards, transparency and systems to reduce *risk*".

NSS 1997 employed the term 'risk' 17 times, by referring to preventive mission of US policy as "an unrelenting force for peace – from the Middle East to Haiti, from Northern Ireland to Central Africa. Taking *reasonable risks for peace* keeps us from being drawn into far more costly conflicts", and it claims that "the more America leads, the more willing others are to share the *risks and responsibilities* of forging our futures". It also stresses

> the requirement to invest in selected research and prototype systems while monitoring trends in likely future threats. These prudent steps provide insurance against the possibility that some of our efforts to shape the international environment in ways favorable to US interests do not succeed. Although such insurance is certainly not free, it is a relatively inexpensive way to *manage risk in an uncertain, resource-constrained environment* – that is, *the risk of being unprepared to meet a new threat*, the *risk of developing the wrong capabilities*, and the *risk of producing a capability too early* and having it become obsolete by the time it is needed.

NSS 1997 employed the term 'risk' 15 times, including with regard to environmental issues: "A deteriorating environment not only threatens public health, it impedes economic growth and can generate tensions that threaten international stability. To the extent that other nations believe they must engage in non-sustainable exploitation of natural resources, *our long-term prosperity and security are at risk*." Such international cooperation could "also help to prevent threats from arising that *place at risk American lives and property at home*". With regard to the potential danger of biological weapons, NSS 1998 noted "we must have the medicines and vaccines needed to treat those who fall sick or prevent *those at risk from falling ill* because of a biological weapons attack".

NSS 2000 employed the term 'risk' nine times by referring to putting "*US forces at risk*" primarily with regard to military contingencies that by failing "to defeat initial enemy advances rapidly ... could undermine US credibility and *increase the risk of conflict* elsewhere", but that the USA must "accept a *degree of risk* associated with withdrawing from contingency operations and engagement activities in order to *reduce the greater risk* incurred if we failed to respond adequately to major theater wars". It further used the risk concept with regard to the war against Yugoslavia that "prevented the *real risk* that violence in Kosovo would create turmoil throughout the region, undermining its new, fragile democracies and reversing our progress in Bosnia and Herzegovina", and for its dialogue to encourage with India and Pakistan "to take steps to prevent further proliferation, *reduce the risk of conflict*, and exercise restraint in their nuclear and missile programs". Again in these five national security statements of the Clinton Administration between 1994/1995 and 2000 there was no consistency in the use of the term risk that was often used synonymously with threats and challenges.

12.4.4.3 Risks in the US NSS of the Administration of G.W. Bush

NSS 2002 used the term 'risk' only three times with different connotations by focusing on international efforts and resources against terrorism "on *areas most at risk*" and that the US faced after the Cuban Missile Crisis (1963) "a generally status quo, *risk-averse adversary*" and in the context of the legitimating pre-emptive action it stressed "The greater the threat, *the greater is the risk of inaction* – and the more compel-

ling the case for taking anticipatory action to defend ourselves, even if uncertainty remains as to the time and place of the enemy's attack."

NSS 2006 used the term risk three times with regard to the "great *personal risk*" of Muslims that are "a target of this ideology of terror" and with regard to international trade where "protectionist impulses in many countries *put at risk* the benefits of open markets and impede the expansion of free and fair trade and economic growth". This use does not reflect any of the suggested definitions in the highly sophisticated scientific debates on risk.

12.4.4.4 Risks in the NSS of the Administration of Barack H. Obama

NSS 2010 used the term 'risk' 9 times and 'risks' four more times in several contexts. With regard to engaging "with communities and citizens" NSS 2010 announces: "We will emphasize individual and community preparedness and resilience through frequent engagement that provides clear and *reliable risk and emergency information* to the public." On the danger of terrorism, NSS 2010 claims to "deny safe havens and strengthen *at-risk states*", ... "pursue sustainable and responsible security systems in *at-risk states*", and that the USA "must improve its capability to strengthen the security of *states at risk* of conflict and violence. We will undertake long-term, sustained efforts to strengthen the capacity of security forces to guarantee internal security, defend against external threats, and promote regional security and respect for human rights and the rule of law". Furthermore, NSS 2010 states that "the *increased risk of terrorism* necessitates a capacity to detain and interrogate suspected violent extremists, but that framework must align with our laws to be effective and sustainable" and that the USA "will place renewed emphasis on deterrence and prevention by mobilizing diplomatic action, and use development and security sector assistance to *build the capacity of at-risk nations and reduce the appeal of violent extremism*".

NSS 2010 sees the USA more threatened "by proliferation that could lead to a nuclear exchange. Indeed, since the end of the Cold War, the *risk of a nuclear attack* has increased." Further, the USA "must continue to work at home with first responders and health officials to reduce the *risk associated with unintentional or deliberate outbreaks of infectious disease* and to strengthen our resilience across the spectrum of high-consequence biological threats". On the prevention of "the emergence of conflict", NSS 2010 notes that the USA "have already begun to reorient and strengthen our development agenda; to take stock of and enhance our capabilities; and to forge new and more effective means of applying the skills of our military, diplomats, and development experts. These kinds of measures will help us *diminish military risk*, act before crises and conflicts erupt, and ensure that governments are better able to serve their people".

With regard to the use of force, NSS 2010 argues that the USA "will exhaust other options before war whenever we can, and carefully weigh the *costs and risks of action* against the *costs and risks of inaction*". On countering biological threats, the USA promotes global health security and aims at "obtaining timely and accurate insight on *current and emerging risks*". Regarding pandemics, NSS 2010 notes that "addressing these *transnational risks* requires advance preparation, extensive collaboration with the global community, and the development of a resilient population at home".

12.5 Threats, Challenges, Vulnerabilities and Risks in the US Quadrennial Defense Reviews

12.5.1 Security Threats in the QDRs

The first *Quadrennial Defense Review* (QDR 1997) was a six-month analysis of the threats, risks and opportunities for US national security which reviewed US defence strategy and programmes, including force structure, infrastructure, readiness, intelligence, modernization and people. Its task was to delineate a national defence strategy consistent with the most recent National Security Strategy by defining force structure, modernization plans, and a budget plan allowing the military to successfully execute the full range of missions within that strategy.

Secretary of Defense William C. Cohen in his preface to the first QDR of May 1997 referred to new "*threats and dangers* - harder to define and more difficult to track" which have made it necessary that "America's policy makers ... *comprehend the nature of these threats* and devise appropriate strategies and programmes to defuse or defeat them" and to "be better able to respond to a variety of smaller-scale contingencies and asymmetric threats ... ranging from nuclear, biological, and chemical weapons to attacks via information warfare and terrorism".

With regard to the "global security environment", the QDR 1997 noted that "the *threat of global war*

has receded" but that *new threats of "coercion and large-scale, cross-border aggression against US allies and friends* in key regions by hostile states with significant military power" remain, and that "both *Iraq and Iran continue to pose threats* to their neighbors and to the free flow of oil from the region", and that in "the Middle East, the potential for conflict will remain until there is a just and lasting peace in the region and security for Israel" while "*North Korea continues to pose a highly unpredictable threat*". QDR 1997 noted that

> US interests will continue to be challenged by a variety of transnational dangers, and the lives of US citizens will often be placed at risk, directly and indirectly. Increasingly capable and violent terrorists will continue to directly *threaten the lives of American citizens* and try to undermine US policies and alliances. The illegal drug trade and international organized crime will continue to ignore our borders, attack our society, and threaten our personal liberty and well-being. Uncontrolled flows of migrants will sporadically destabilize regions of the world and *threaten American interests and citizens*.

Besides the threats posed by WMD, "*information warfare* (attacks on our infrastructure through computer-based information networks) *is a growing threat*". Besides the projected trends of

> continued regional dangers, the proliferation of advanced weapons and technologies, transnational dangers, and the increased danger of asymmetric attacks, there are a number of 'wild card' scenarios that could seriously challenge US interests both at home and abroad. Such scenarios range from the *unanticipated emergence of new technological threats*, to the loss of US access to critical facilities and lines of communication in key regions, to the takeover of friendly regimes by hostile parties. Taken individually, these scenarios are unlikely. But taken together, it is more likely that one or more wild cards *will* occur than it is that *none* will occur. ... while the probability of individual wild cards may be low, their consequences may be disproportionately high. Therefore, the United States must maintain military capabilities sufficient to deal with such events.

QDR 1997 saw "the dominant challenge ... [in] the possible emergence, after 2010–2015, of a regional great power or global peer competitor, as well as more *stressing combinations of asymmetric threats*". QDR 1997 defines as the goal "to ensure the long-term dominance of US forces by preparing now for the emergence of *more challenging threats* in the future while accepting reductions in our capabilities to meet near-term demands". Contrary to the NSS of the Clinton Administration the QDR referred solely to hard security and regional military threats as well as to the uncertainty related to asymmetric threats and 'wild cards'.

The first QDR of the Administration of George W. Bush was released on 30 September 2001 by Secretary of Defense Donald Rumsfeld shortly after the third attack on the US territory of 11 September (after 1812 by Britain and 1941 by Japan). It referred 16 times to the concept of 'threat' that point to a fundamental change in defence planning from

> a '*threat-based*' model that has dominated thinking in the past to a 'capabilities-based' model for the future. This capabilities-based model focuses more on how an adversary might fight rather than specifically whom the adversary might be or where a war might occur. It recognizes that it is not enough to plan for large conventional wars in distant theaters. Instead, the United States must identify the capabilities required to deter and defeat adversaries who will rely on surprise, deception, and asymmetric warfare to achieve their objectives.

The QDR 2001 distinguished between "*threat of major war to the faceless threat of terror*". For the QDR 2001 Russia "does not pose a large-scale *conventional military threat to NATO*" but "It shares some important security concerns with the United States, including the problem of vulnerability to attack by ballistic missiles from regional aggressors, the danger of accidental or unauthorized launches of strategic weapons, and *the threat of international terrorism*." But "in several regions, the inability of some states to govern their societies, safeguard their military armaments, and prevent their territories from serving as sanctuary to terrorists and criminal organizations can also pose a *threat to stability* and place demands on US forces". This was a clear reference to Afghanistan that became an objective of a US led intervention a few weeks later responding to the attack of 11 September 2001.

QDR 2001 identified elements of a new US defence strategy "for deterring conflict and conducting military operations" but it also noted that "*future challenges risk not only addresses possible future threats*, but also the ability to meet critical transformational challenges. For example, the decision not to pursue a new technology due to the lack of a current threat entails risk: introducing it early provides a military advantage for a time, and it may dissuade any potential adversary from pursuing similar capabilities." However, the shift towards a capability-based strategy decouples defence planning from specific 'threats' and legitimates the technological imperative as a major driver of future defence spending on military R&D.

The second QDR of the Administration of G.W. Bush was released on 6 February 2006 and referred 19

times to the term 'threat' in the context of a wider defence transformation from "*threat-based*" to "*capabilities based planning*", whose essence is "to identify capabilities that adversaries could employ and capabilities that could be available to the United States, then evaluate their interaction, rather than over-optimize the joint force for a *limited set of threat scenarios*". Among the specific threats and countermeasures the QDR 2006 announced "to develop broad-spectrum medical countermeasures against the *threat of genetically engineered bio-terror agents*" as part of the DoD's countermeasures against the "*threat of biological terrorism*". It also notes that in many countries "*terrorist networks pose a greater threat than external threats*" but that "the *threat to the US homeland, however, is broader than that posed by terrorists*". While QDR 2006 considered it unlikely that Russia poses "*a military threat to the United States or its allies* on the same scale", it stresses with regard to China the US goal "to encourage China to choose a path of peaceful economic growth and political liberalization, *rather than military threat and intimidation*". While some states "do not pose a *direct military threat to the United States*, these states may *threaten* the United States or its allies indirectly by transferring weapons or expertise to terrorists". It also points to the threat that "nuclear weapons, sophisticated and/or bioengineered biological agents, and non-traditional chemical agents – once the sole purview of large, complex state weapons programs – will be within reach of a growing number of actors in the coming decades". Therefore, "national efforts to counter the *threat posed by weapons of mass destruction* must incorporate both preventive and responsive dimensions" and "the future force will be organized, trained, equipped, and resourced to *deal with all aspects of the threat* posed by weapons of mass destruction" with the goal "to better support the warfighter and [that] are appropriate for the *threat environment*".

The QDR of the Administration of Barack H. Obama of 1 February 2010 referred 21 times to the term of 'threat'. It repeated many threats listed in the earlier QDR of 2001 and 2006 posed by

> the proliferation of weapons of mass destruction (WMD) [that] continues to undermine global security, further complicating efforts to sustain peace and prevent harmful arms races. The instability or collapse of a WMD-armed state is among our most troubling concerns. Such an occurrence could lead to rapid proliferation of WMD material, weapons, and technology, and could quickly become a global crisis posing a direct *physical threat to the United States* and all other nations.

QDR 2010 argued that "if deterrence fails and adversaries challenge our interests with the *threat or use of force*, the United States must be prepared to respond in support of US national interests". It also considered WMD and the *terrorist threat in Afghanistan and Pakistan* "posing an *enduring threat to the security of America and its allies and partners*".

12.5.2 Security Challenges in the QDRs

The first QDR 1997 stressed that "the United States likely will face a number of significant *challenges to its security* between now and 2015" and "will continue to confront a variety of regional dangers" and that "more than one aspiring regional power will have both the desire and the means to *challenge US interests militarily*". Synonymously with its reference to threats posed by WMD it points to challenges by the proliferation of "NBC weapons, materials, and technologies" and to challenges "by a variety of transnational dangers" that will place "the lives of US citizens ... placed at risk, directly and indirectly". Further, "dealing with ... *asymmetric challenges* must be an important element of US defense strategy, from fielding new capabilities to adapting how US forces will operate in future contingencies". The term 'challenge' was in most cases used synonymously for the term 'threat' and both were limited solely to military security dangers and concerns.

The second QDR 2001 used the term 'challenge' 13 times stating that "*uncertainty is a key challenge for US defense planning*, certain features and trends of the security environment define not only today's *geopolitical and military-technical challenges* but also highlight critical *operational challenges* that the Nation's armed forces will need to master in the future". Further, "the pervasiveness of proliferation in an era of globalization has increased the availability of technologies and expertise needed to create the *military means to challenge* directly the United States and its allies and friends". QDR 2001 states that "a *fundamental challenge* confronting DoD is ensuring that US forces have the capabilities they need to carry out the new defense strategy and meet the demands of the 21st century". It further notes that "while the United States cannot predict with confidence which adversaries will pose threats in the future, the types of military capabilities that will be used *to challenge US interests and US military forces* can be identified and understood". QDR 2001 concludes that "*mitigating*

future challenge risks [requires] experimentation, R&D, and Selective Procurement. Achieving DoD's strategic goals mandates embarking on the long-term transformation of US military capabilities".

The third QDR 2006 used the term 'challenge' six times with these connotations referring to the challenge posed by Iraq and the challenges facing the USA that differ from the Cold War, "a *challenge so immense* that it requires major shifts in strategic concepts for national security and the role of military power". In his assessment the chairman of the JCS, emphasized that "any attempt to predict the future security environment of 2025 is inherently difficult. ... Given the dynamics of change over time, we must develop a mix of agile and flexible capabilities to mitigate uncertainty".

The fourth QDR 2010 employed ten times the term 'challenge' arguing that "If deterrence fails and *adversaries challenge our interests with the threat or use of force*, the United States must be prepared to respond in support of US national interests." QDR 2010 referred to this "range of *plausible future challenges*" with which the DoD will be required to deal with:

- Defeating Al Qaeda and its allies;
- Supporting a national response to attacks on, or natural disasters in, the United States;
- Defeating aggression by adversary states, including states armed with advanced anti-access capabilities and/or nuclear weapons;
- Locating, securing, or neutralizing weapons of mass destruction, key materials, and related facilities in the context of a loss of control of such weapons or materials, and thwarting the potential for a non-state adversary to acquire them;
- Supporting and stabilizing fragile states facing threats from terrorist and insurgent groups;
- Protecting American citizens in harm's way overseas;
- Conducting effective operations in cyberspace; and
- Preventing human suffering due to mass atrocities or large-scale natural disasters abroad.

The QDR 2010 also "gives solid direction on developing capabilities that counter the proliferation of anti-access and area-denial threats, which present an *increased challenge to our maritime, air, space, and cyber forces*".

12.5.3 Security Vulnerabilities in the QDRs

The first QDR 1997 argued that "US dominance in the conventional military arena may encourage adversaries to use such asymmetric means to attack our forces and interests overseas and Americans at home. That is, they are likely to seek advantage over the United States by using unconventional approaches to *circumvent* or *undermine* our strengths while *exploiting* our *vulnerabilities*". Further, "areas in which the United States has a significant advantage over potential opponents and increasing capabilities (e.g., space-based assets; command, control, communications, and computers; and intelligence, surveillance, and reconnaissance) could also involve inherent *vulnerabilities* that could be exploited by potential opponents (e.g., attacking our reliance on commercial communications) should we fail to account for such challenges", and to "prevent and deter future terrorism and *reduce US vulnerability to terrorist acts* through DoD efforts to enhance intelligence collection capabilities and protect critical infrastructure". The second (QDR 2001), third (QDR 2006), and fourth *Quadrennial Defence Reviews* (QDR 2010) lacked any reference to the term 'vulnerability'.

12.5.4 US National Security Risks in the QDRs

The first QDR 1997 "examined three alternative paths that differed in where they accepted *risks* and emphasized investment over the near term, midterm, and long term" and it argued that in the early post-Cold War period "US interests will continue to be challenged by a variety of transnational dangers, and the *lives of US citizens will often be placed at risk*, directly and indirectly". For primarily humanitarian missions, QDR suggests that "the military mission should be clearly defined, the *risk to American troops* should be minimal, and substantial US military involvement should be confined to the initial period of providing relief until broader international assistance efforts get underway". Furthermore, "US participation in smaller-scale contingency operations must be selective, depending largely on the interests at stake and the *risk of major aggression* elsewhere." The USA should also "insure or hedge against unlikely, but significant, future threats in order to *manage risk in a resource-constrained environment* and better position the Department to respond in a timely and effective manner to new threats as they emerge".

The second QDR 2001 used the term risk 70 times including a whole section on "managing risks" with "a New Risk Framework" with regard to force management, operational, future challenges, and institutional risks and a section on "*mitigating risks across the spectrum*". The QDR 2001 called for a "culture within the military that embraces innovation and *risk-taking*" and states that the DoD "will pursue new de-

terrence tools that not only *hold at risk an adversary's military forces and other valued assets*, but also extend greater protection to allies and friends in crisis through capabilities such as missile defenses, defensive information operations, and counter-terrorist operations" and it suggested that the "DoD must find ways to encourage and *reward innovation and risk-taking among fighting forces* as well as support personnel". The QDR 2001 suggested that the proposed

> *risk framework* is made up of four related dimensions: a) force management - the ability to recruit, retain, train, and equip sufficient numbers of quality personnel and sustain the readiness of the force while accomplishing its many operational tasks; b) operational - the ability to achieve military objectives in a near term conflict or other contingency; c) future challenges - the ability to invest in new capabilities and develop new operational concepts needed to dissuade or defeat mid- to long-term military challenges; and d) institutional - the ability to develop management practices and controls that use resources efficiently and promote the effective operation of the defense establishment.

With regard to "*mitigating operational risks* ... the QDR has developed a broader approach to *operational risk* that involves assessing the Department's ability to perform the following: i) defend the United States; ii) deter forward in critical areas; iii) swiftly defeat aggression in overlapping major conflicts; and iv) conduct a limited number of small-scale contingencies". This proposed new risk framework for the Pentagon's operations was totally detached from the sophisticated debates on risks in the social sciences.

The third QDR 2006 had 12 references to the term 'risk' including the approach to risk assessment it adopted with the QDR 2001. It noted with concern that "the pace and scope of China's military build-up already *puts regional military balances at risk*". QDR 2006 indicated that the DoD "is considering adopting a *risk-based source selection process* in place of the current cost-based approach".

The fourth QDR 2010 used the term 'risk' 83 times, including again a whole section dealing with "a *defence risk management framework*". DoD suggested to balance "*resources and risk* among four priority objectives: prevail in today's wars, prevent and deter conflict, prepare to defeat adversaries and succeed in a wide range of contingencies, and preserve and enhance the All-Volunteer Force". The QDR widened the focus from the narrow military focus of the first three QDR to include the economic and environmental dimensions of security. It noted with regard to the former that "the US export system itself poses a potential national security risk. Its structure is overly complicated, contains too many redundancies, and tries to protect too much". For the first time, the QDR stressed that the "DoD will need to adjust to the impacts of climate change on our facilities and military capabilities", noting that according to an estimate of the National Intelligence Council

> more than *30 US military installations* were already facing e*levated levels of risk* from rising sea levels. DoD's operational readiness hinges on continued access to land, air, and sea training and test space. Consequently, the Department must complete a comprehensive assessment of all installations to assess the potential impacts of climate change on its missions and adapt as required.

In its risk assessment "for this QDR, the Department used a multidisciplinary approach" that included "updated thinking on best practice" drawing on "quantitative analysis", but also relying "on informed judgments, expert opinions, and the use of scenarios" and DoD "ensured that its *risk assessment was strategy driven*". It also noted that "a failure by the Department to secure its systems in cyberspace would pose a *fundamental risk to our ability to accomplish defense missions* today and in the future", and that "a number of factors related to research and development will, over time, generate *increased risk to America's technological edge*".

Without any reference to the four key terms of security 'threats', 'challenges', 'vulnerabilities' and 'risks', the QDR 2010 referred 19 times to climate change noting that the "rising demand for resources, rapid urbanization of littoral regions, the *effects of climate change*, the emergence of new strains of disease, and profound cultural and demographic tensions in several regions are just some of the trends whose complex interplay may spark or exacerbate future conflicts". The QDR 2010 announced that the DoD would craft "a strategic approach to climate and energy" where "climate change and energy will play significant roles in the future security environment" by "developing policies and plans to manage the effects of climate change on its operating environment, missions, and facilities". The new global challenges of the "rising demand for resources, rapid urbanization of littoral regions, the effects of climate change, the emergence of new strains of disease, and profound cultural and demographic tensions in several regions are just some of the trends whose complex interplay may spark or exacerbate future conflicts". DoD acknowledged that "climate change will shape the operating environment, roles, and missions that we undertake". According to "assessments conducted by the intelligence community indicate that climate change

could have significant geopolitical impacts around the world, contributing to poverty, environmental degradation, and the further weakening of fragile governments. Climate change will contribute to food and water scarcity, will increase the spread of disease, and may spur or exacerbate mass migration". Objecting to any mono-causality, the QDR 2010 stated that

> while climate change alone does not cause conflict, it may act as an accelerant of instability or conflict, placing a burden to respond on civilian institutions and militaries around the world. In addition, extreme weather events may lead to increased demands for defense support to civil authorities for humanitarian assistance or disaster response both within the United States and overseas. In some nations, the military is the only institution with the capacity to respond to a large-scale natural disaster. Proactive engagement with these countries can help build their capability to respond to such events.

Furthermore, "DoD will need to adjust to the impacts of climate change on our facilities and military capabilities". Adaptation to climate change would "pose challenges for civil society and DoD alike, particularly in light of the nation's extensive coastal infrastructure". As 30 US military installations may face "elevated levels of risk from rising sea levels, DoD's operational readiness hinges on continued access to land, air, and sea training and test space. Consequently, the Department must complete a comprehensive assessment of all installations to assess the potential impacts of climate change on its missions and adapt as required". This necessitates that the DoD "must complete a comprehensive assessment of all installations to assess the potential impacts of climate change on its missions and adapt as required". Further, "as climate science advances, the Department will regularly re-evaluate climate change risks and opportunities in order to develop policies and plans to manage its effects on the Department's operating environment, missions, and facilities. Managing the national security effects of climate change will require DoD to work collaboratively, through a whole-of-government approach, with both traditional allies and new partners". And finally, DoD "is increasing its use of renewable energy supplies and reducing energy demand to improve operational effectiveness, reduce greenhouse gas emissions in support of US climate change initiatives, and protect the Department from energy price fluctuations".

12.6 Threats, Challenges, Vulnerabilities and Risks in the US Nuclear Posture Reviews

At the request of President Clinton Secretary of Defense Les Aspin initiated on 29 October 1993 a comprehensive review of America's nuclear posture that was described as "the first DOD study of its kind to incorporate reviews of policy, doctrine, force structure, operations, safety and security, and arms control in one look". This review focused on: "1. The role of nuclear weapons in US security strategy; 2. US nuclear force structure; 3. US nuclear force operations; 4. Nuclear safety and security; 5. The relationship between US nuclear posture and counterproliferation policy; 6. The relationship between US nuclear posture and threat reduction policy with the former Soviet Union."

The goal was to replace two presidential directives: a) *National Security Decision Directive* (NSDD) 13 on nuclear employment policy (Ronald Reagan, 1981); b) *Presidential Decision* (PD) 48 on ballistic missile submarine commitments to NATO (Jimmy Carter, April 1979).[4] President Clinton approved the *Nuclear Posture Review* (NPR) in September 1994 that

> defines and integrates past and present US policies for nuclear deterrence, arms control, and nonproliferation objectives. The NPR ... provides the DoD policy guidance, force structure and stewardship obligations for the enduring nuclear weapons stockpile. This force structure reflects the reduced role nuclear weapons now play in US security strategy.[5]

The second *Nuclear Posture Review* (NPR) was submitted by Secretary of Defense Donald Rumsfeld on 31 December 2001 to the US Congress to "lay out the direction for American nuclear forces over the next five to ten years". Based on the (QDR 2001) the NPR (2002) implemented a major change in the US approach "to the role of nuclear offensive forces in our deterrent strategy and presents the blueprint for transforming our strategic posture".[6]

---

4 This paragraph is based on: The Nautilus Institute, Nuclear Strategy Project: "The 1994 Nuclear Posture Review"; at: <http://www.nautilus.org/archives/nukestrat/USA/Npr/npr94.html> (19 April 2010).

5 See "PDD/NSC-30 Nuclear Posture Review Implementation [September 1994], Text Not Available"; at: <http://www.fas.org/nuke/guide/usa/doctrine/dod/95_npr.htm> (19 April 2010).

6 See "Nuclear Posture Review (Excerpts)"; at: <http://www.globalsecurity.org/wmd/library/policy/dod/npr.htm> (19 April 2010).

The third *Nuclear Posture Review* (NPR) was submitted by Secretary of Defense Robert Gates on 6 April 2010 to the US Congress that "provides a roadmap for President Obama's agenda for reducing nuclear risks to the United States, our allies and partners and the international community".[7] As only the latter review is fully available the use of the four key terms of threats, challenges, vulnerabilities and risks can only be reviewed for the most recent document.

Commenting on the changed international security environment since the end of the Cold War, the NPR 2010, uses 19 times the term 'threat' noting that "The *threat of global nuclear war* has become remote, but the *risk of nuclear attack has increased*", and "Today's other pressing *threat is nuclear proliferation*", but "the *most immediate and extreme threat* today is nuclear terrorism". It claims that "changes in the *nuclear threat environment* have altered the hierarchy of our nuclear concerns and strategic objectives". NPR 2010 announced that the Obama Administration will accelerate "the *Global Threat Reduction Initiative* and the International Nuclear Material Protection and Cooperation Program", and that the US would secure and eliminate WMD "through cooperative *threat reduction programs* at the Departments of Defense, State, and Energy, including the flagship Nunn-Lugar program". It announces with regard to "the catastrophic potential of biological weapons and the rapid pace of bio-technology development" that the USA "reserves the right to make any adjustment in the assurance that may be warranted by the evolution and proliferation of the *biological weapons threat* and US capacities to counter that *threat*". Not surprisingly, in the NPR the use of the term 'threat' has been limited to nuclear issues and to other WMD and their proliferation.

The NPR 2010 refers nine times to the term 'challenge' which was used with these connotations that in facing "increasingly urgent *threats of nuclear terrorism and nuclear proliferation,* the United States must continue to address the more familiar *challenge of ensuring strategic stability with existing nuclear powers* – most notably Russia and China" and that "today, the reassurance mission remains, but the *deterrence challenge is fundamentally different*" as well as that "our most pressing *security challenge* at present is preventing nuclear proliferation and nuclear terrorism, for which a nuclear force of thousands of weapons has little relevance".

With regard to Russia and China NPR 2010 states that "*maintaining strategic stability* with the two countries will be an important *challenge* in the years ahead" and that the USA "must continue to address the more familiar *challenge of ensuring strategic stability* with existing nuclear powers – most notably Russia and China" and that "maintaining strategic stability at reduced force levels will be an *enduring and evolving challenge* for the United States in the years ahead", and "ongoing nuclear and other military modernization efforts by Russia and China compound this *challenge*, making the need for strategic stability dialogues all the more critical", but also "maintaining strategic stability with the two countries will be an *important challenge* in the years ahead". NPR 2010 also states that "the cumulative loss of focus, expertise, and excellence on nuclear matters in the United States remains a *significant challenge*".

The NPR 2010 did not use the term 'vulnerability' but employed the term 'risk' nine times in the following contexts arguing repeatedly that "while *the risk of all-out nuclear war* is much diminished relative to the Cold War" and the "*risk of nuclear attack against NATO* members is at an historic low", nevertheless "the *risk of nuclear attack has increased*", especially as the "nuclear black market, create a serious *risk* that terrorists may acquire what they need to build a nuclear weapon". Therefore, the "verified elimination of all nuclear weapons and minimize risk of cheating and breakout", and new "*technologies will help us manage risk*" with the goal to be "able to detect potential clandestine weapons programs".

In conclusion, in the NPR 2010 – representing a major policy declaration of the Obama Administration or a 'speech act' in the wording of the theory of securitization - the three terms 'threat', 'challenge' and 'risk' that refer to the nature of the 'objective' security dangers, but also 'subjective' security concerns and 'intersubjective' security issues have been used synonymously. However, their use differs significantly from the complex scientific definitions and debates in the security, the global change, the climate change and in the natural hazard communities (chap. 2 by Brauch).

7 See all details on the release of NPR 2010 at: <http://www.defense.gov/npr/>. The full text of the *Nuclear Posture Review Report* (April 2010) is at: <http://www.defense.gov/npr/docs/2010%20Nuclear%20Posture%20Review%20Report.pdf> (19 April 2010).

12.7 Threats, Challenges, Vulnerabilities and Risks in the National Military and Defense Strategy Documents

The moderate *National Security Strategy* of August 1991 by President George Bush was in clear contrast to the *Draft Defense Planning Guidance* of February 1992 under the direction of then Under Secretary of Defense Paul Wolfowitz for the then Secretary of Defense Richard Cheney that "outlined strategy to prevent the rise of 'potential competitors', to discourage advanced countries 'from challenging our leadership', and to extend security commitments to countries that had been Soviet allies only a short time before" (Betts 2004: 24). According to a leaked draft version excerpted by the New York Times this document

> called for massive increases in defense spending, the assertion of lone superpower status, the prevention of the emergence of any regional competitors, the use of preventive—or pre-emptive—force, and the idea of forsaking multilateralism if it did not suit US interests. It called for intervening in disputes throughout the globe, even when the disputes were not directly related to US interests, arguing that the United States should 'retain the preeminent responsibility for addressing selectively those wrongs which threaten not only our interests, but those of our allies or friends, or which could seriously disrupt international relations'. According to the draft DPG, the United States must also 'show the leadership necessary to establish and protect a new order that holds the promise of convincing potential competitors that they need not aspire to a greater role or pursue a more aggressive posture to protect their legitimate interests'.[8]

The *Draft Defense Planning Guidance* further argued,

> Our first objective is to prevent the re-emergence of a new rival. This is a dominant consideration underlying the new regional defense strategy and requires that we endeavor to prevent any hostile power from dominating a region whose resources would, under consolidated control, be sufficient to generate global power. These regions include Western Europe, East Asia, the territory of the former Soviet Union, and Southwest Asia. There are three additional aspects to this objective: First the United States must show the leadership necessary to establish and protect a new order that holds the promise of convincing potential competitors that they need not aspire to a greater role or pursue a more aggressive posture to protect their legitimate interests. Second, in the non-defense areas, we must account sufficiently for the interests of the advanced industrial nations to discourage them from challenging our leadership or seeking to overturn the established political and economic order. Finally, we must maintain the mechanisms for deterring potential competitors from even aspiring to a larger regional or global role."[9]

Thus, the neoconservative defence officials that produced the Guidance wanted to preserve the unique position of American predominance "to protect US territory, citizens, and military forces from attack, to back up security guarantees to allies", and to "preclude any hostile power from dominating a region critical to our interests", and they argued that the USA had to:

- Pursue the 'military-technological revolution' to preserve its superiority in the latest weapons systems (e.g. smart munitions);
- Sustain the 'forward' presence of US ground, air, and naval forces in strategically important areas, to validate commitments, and to provide a capability to respond to crises affecting significant interests, such as freedom of the seas and access to markets and energy supplies;
- Preserve a smaller but diverse 'mix' of survivable nuclear forces to support a global role, validate security guarantees, and deter Russian nuclear forces;
- Field a missile defence system as a shield against accidental missile launches or limited missile strikes by 'international outlaws';
- Maintain a capability to reconstitute military forces in the event that a regional hegemon threatens to become a global threat;
- Find ways to integrate the 'new democracies' of the former Soviet bloc into the US-led system;
- Work with allies in NATO Europe and elsewhere but be ready to act unilaterally or with only a few other nations when multilateral and cooperative action proves too 'sluggish' to protect vital interests.[10]

This draft guidance reflects the 'mindset' of strategists during the Cold War era reflecting a Hobbesian or

8 IPS (Washington, D.C.): "1992 Draft Defense Planning Guidance", at: <http://www.rightweb.irc-online.org/profile/1992_Draft_Defense_Planning_Guidance> [updated 12 March 2008] (16 April 2010).

9 IPS (Washington, D.C.): "1992 Draft Defense Planning Guidance", at: <http://www.rightweb.irc-online.org/profile/1992_Draft_Defense_Planning_Guidance> [updated 12 March 2008] (16 April 2010).

10 For redacted versions of the original draft DPG and supporting documents, see the *National Security Archive*, February 26, 2008: "Declassified Studies from Cheney Pentagon Show Push for US Military Predominance and a Strategy to "Prevent the Reemergence of a New Rival"; at: <http://www.gwu.edu/~nsarchiv/nukevault/ebb245/ index.htm>.

Neohobbesian worldview. It offered a 'rationale' for the policies pursued nine years later by the Administration of George W. Bush, and according to James Mann, the Iraq War "was carried out in pursuit of a larger vision of using America's overwhelming military power to shape the future".[11] An analysis of the threat definitions in this DPG is not possible as the version that was excerpted in the *New York Times* in 7 March 1992 and the version that was declassified in February 2008 differed. But the NSS 1991 prepared by the NSC for President George Bush and the DPG (1992) drafted for the Secretary of Defence Richard Cheney have differed significantly and reflect two different mindsets, of the pragmatic realist and more diplomatic perspective in the White House, the NSC and in the State Department and the Hobbesian worldview of the neoconservatives around Paul Wolfowitz in the US Department of Defense.

During the first Clinton Administration (1993-1997) the perspective of the hawkish neocons was rejected. In the NSS 1994 and NSS 1996, in the NPR 1994 and in the NMS 1995 the term 'threat' was used both for hard and soft security dangers and concerns.

To implement the National Security Strategies of the US presidents and the Quadrennial Defense Reviews as well as the Nuclear Posture Reviews of the US Department of Defense, the Joint Chiefs of Staff have prepared so far three *National Military Strategy* (1995, 1997, 2004) papers and two *National Defense Strategy* (2005, 2008) documents that focus solely on military issues, as do the respective posture papers of the four military services of the US Army, US Navy, US Air Force and of the US National Guard. In addition, the *Quadrennial Homeland Security Review Report* of the Department of Homeland Security (2010) on issues of domestic security as well as the *Diplomatic and Development Reviews* of the Department of State addresses the diplomatic aspects of US national security. These multiple policy reports and declarations all represent additional official 'speech acts' that refer to 'issues of utmost importance' for the well-being and survival of the USA, its territory, people, values and political system that 'require extraordinary measures' to cope with these security dangers, concerns and issues. However, to avoid redundancy and due to space limitations these many additional official documents have not been included in this review.

12.8 A Concluding Assessment

Based on the above review of four qualifiers – threats, challenges, vulnerabilities and risks – of objective security dangers, subjective concerns and intersubjective security issues, this concluding section will return to the four initial questions and offer tentative answers based on the above review of the use of the four key terms of security threats, challenges, vulnerabilities and risks and to which extent their substantial meanings, contexts and connotations have changed in the public utterances but also to which extent a verbal continuity of legitimating efforts could be observed.

With regard to the first question in all documents the US concept of national security has widened with regard to the four qualifiers of *threats*, *challenges*, *vulnerabilities* and *risks* from the narrow political and military dimension of the Cold War, to include the economic and environmental and only marginally also the societal dimension. However, the key referent object has remained the 'nation state' of the USA as well as the other components of US national sovereignty (territory, people, system of rule) and in none of these documents the term or concept of human security was ever mentioned. However, from a US national security perspective many references to global, international and regional security problems were included. Among the sectoral security concepts only energy, health and food security problems were repeatedly discussed while the policy problems of water and soil security were widely ignored.

Environmental security issues were extensively referred to in the NSS 1997 by the Clinton Administration and the nexus between climate change and security was addressed in NSS 2010 of May 2010 and in the QDR document of 1 February 2010 by the Administration of Barack H. Obama. Obviously in both Administrations academic and policy debates were taken up by the NSC and by the DoD while the neoconservative mindset of the policy-makers, advisers and officials of the Administration of George W. Bush ignored these debates (Matthew/McDonald 2009).

While after the end of the Cold War the scope of national security dangers, concerns and issues had significantly widened during the Administrations of George Bush, William J. Clinton and Barack H. Obama, as was documented above with many cita-

11 James Mann: "The True Rationale: It's A Decade Old", in: *The Washington Post*, 7 March 2004; reprinted at: <http://www.gwu.edu/~nsarchiv/nukevault/ebb245/wp_true_rationale.pdf>; see also Mann (2004): 208–215. On the impact of the neocons see: Halper and Clarke (2004), Heilbrunn (2008) and Ehrman (1995).

tions, during the Administration of George W. Bush the main focus was reduced to weapons of mass destruction, so-called rogue states and terrorism.

Thus, both the end of the Cold War and the attack on the USA on 11 September 2001 had a major impact on the framing of national security threats, challenges, vulnerabilities and risks, while only during the Clinton and Obama Administrations policy and scientific debates, e.g. on environmental security and climate change were reflected at least in three of these official 'speech acts' of NSS 1997, NSS 2010 and QDR 2010.

As was reviewed above (12.2) there was no single dominant worldview of the strategists, policy analysts and academic security and foreign policy specialists but a combination of Neokantian and Neohobbesian perspectives, partly influenced by both Wilsonian goals of spreading democracy, and partly stimulated by contemporary conservative philosophers, such as Leo Strauss who had influenced many neoconservative thinkers and whose views had some impact on the mindset of key officials in the Pentagon and NSC during the time of President George W. Bush. As the above official pronouncements of US national strategy goals and means are the outcome of a complex bureaucratic process the result has not been conceptual clarity but rather a reflection of many different political and institutional perspectives and interests.

13 Changes in the Perception of Military Threats, Challenges, Vulnerabilities and Risks in Russia (1991-2009)

Alexander Sergunin

13.1 Introduction

To understand the nature and orientation of Russia's foreign policy it is very important to examine how this state identifies challenges to its security. This is also helpful for explaining how the national security discourse and ideas developed by various foreign policy schools are translated into concrete political initiatives and implemented by practitioners.

In defining its national security doctrine (including threat perceptions) in the 1990's, Russian policy makers and analysts faced numerous problems. One of them was the lack of a point of departure because the old doctrine did not exist (at least in a formal sense). What has been called the Soviet national security doctrine, in reality, was a mixture of ideological dogma and real political considerations, a mixture which had usually been camouflaged by peaceful rhetoric (Kremenyuk 1994: 88). The very notion of 'national interests' or 'national security' was rejected because of the dominance of cosmopolitan ideas. At the same time, the concept of security was interpreted in purely military terms. Other (the so-called 'soft') aspects of security (such as economic, societal, environmental, information and other dimensions) were nearly completely ignored. For the above reasons, the Russian post-Communist theorists and practitioners had to start from scratch.

Drafting of the security concept began in the late Soviet period, but its completion foundered both on rapid changes in the international environment and on the political upheavals - and the related political infighting between competing interest groups - that have been a regular feature of the Russian political scene. The long failure by the country's political elite to reach a consensus on the security concept complicated efforts to draft a series of other documents, including Russia's military and foreign policy doctrines, that in principle needed to follow from the concept.

This chapter examines how Russian military threat perceptions evolved over the last two decades and what factors affected this process. Since elsewhere in this volume some issues of the 'soft' security problematique have been discussed this chapter will examine primarily traditional 'hard' or military aspects of Russian threat perceptions that still play a significant role in Russian strategic thinking. The analysis below focuses primarily on the official Russian documents but informal discussions among Russian strategic experts and academics are also taken into consideration.

The evolution of the Russian post-Soviet military or national security doctrines and strategies evolved in several phases.

- The *first*, formative, period took place in 1991–1993 when the new Russian politico-military elites tried to apprehend new domestic and international realities and formulate the country's national interests and relevant strategies. First national security-related documents were adopted.
- The *second period* (1994–1999) was characterized by attempts to define more precisely Russia's threat perceptions and national security interests (on the one hand) and develop a more coherent and integrative national security strategy (on the other). Particularly, a national security doctrine that integrated previous similar documents was adopted in 1997.
- The *third period* (2000–2006) was related to Russia's efforts to reassess its national security strategy because of the second Chechen war, NATO military intervention in Kosovo, NATO's eastward enlargement and wars in Afghanistan and Iraq. A new set of military and national security doctrines was adopted in 2000 and the military reform that aimed at radical restructuring of the Russian armed forces was speeded up.
- The *fourth period* that started in 2007 and continues so far is famous by Russia's more assertive for-

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_13, © Springer-Verlag Berlin Heidelberg 2011

eign and security policies both in the 'near' and 'far' abroad, Moscow's growing anti-NATO and especially anti-American sentiments and attempts to restore its former military strength (albeit for different purposes and on a different basis).

13.2 Early Concepts

Immediately after the collapse of the Soviet Union the Yeltsin government surprisingly found itself as the only relevant military successor of the USSR. For the period of several months the Russian leadership simply did not have a coherent and clear vision of its future security strategy. The new Russian government was hesitating between the desire to keep a unified control over the military structures of the *Commonwealth of Independent States* (CIS), especially of its nuclear forces that were based not only in Russia but also in Belarus, Ukraine and Kazakhstan, and plans to create national armed forces.[1]

Initially, the new Russian leadership pushed the idea of creating collective armed forces of the CIS with a command centre in Moscow (without national armies). However, this idea very soon failed because for various reasons (civil or inter-state wars, nationalistic/anti-Russian sentiments among the local elites, etc) CIS member states started to form their national armies. By spring 1992 President Yeltsin had to abandon the idea of keeping a unified CIS military structure and decided to create independent Russian armed forces and develop Russia's national security strategy.

13.2.1 Russia's Law on Security of 1992

On 5 March 1992 President Boris Yeltsin signed "*The Law on Security of the Russian Federation*" which the Supreme Soviet (the then Russian Parliament) had initiated. The Law established some legal and institutional frameworks for Russia's security policy. It was a rather interesting document from both the theoretical and practical points of view. First of all, it defined the very notion of security: "Security is freedom from internal and external threats to vital interests of the individual, society and state" (Yeltsin 1992: 5).[2] In line with the foreign political thought the authors of the document singled out not only state and military security but also economic, social, information, and ecological aspects of security. Contrary to the Soviet legislation, which had focused on state or party interests, the above document declared priority of interests of the individual and society. It also established a national security system of the newly born Russian Federation. Along with already existing bodies such as the Ministry of Foreign Affairs, Ministry of Interior, Ministry of Security, Foreign Intelligence Service, Ministry of Environment, the Law recommended to set up the Security Council, the Ministry of Defence, and several committees including the Border Guards Committee and so on.

However, this document was too abstract and vague to design a coherent national security strategy. It mainly focused on domestic issues and lacked proper legal and conceptual grounds for a number of important areas such as foreign policy and military reform. A special section on threat perceptions was lacking as well. Moreover, in adopting this legislation the leadership of the Supreme Soviet was eager to use it as a tool in the power struggle with the President. With the adoption of the new Russian Constitution in December 1993, which has designed a new system of government, some provisions of the Law became outdated.

13.2.2 Russia's Draft Military Doctrine of 1992

Following the recommendations of the *Law on Security* the armed forces of the Russian Federation have been formed in May 1992. In the same month, the General Staff published its draft of the military doctrine in its journal *Voennaya Mysl* (Military Thought). According to some accounts, some civilian experts

1 On this period of Russia's strategic thinking see Blackwill and Karaganov (1994); Dawisha and Parrott (1994); Dunlop (1993); Razuvayev (1993); Sergunin (1998a: 146–148); Shearman (1995).

2 From the linguistic point of view the Russian word 'security' ('*bezopasnost*') literally means 'the lack of danger', i.e. defines this concept in a negative rather than in positive way. That's why some experts see this word as misleading because it does not explain what will be next when the danger is prevented. Some experts suggest the concepts of 'stability' or 'sustainable development' to provide the notion of security with a more positive content (see, e.g. Makarychev 2001: 15–24). Along with the concept of security, Russian specialists use terms such as 'threat' ('*ugroza*': a clear danger to security of an individual or the state or combination of factors that pose such a danger); 'challenge' ('*vyzov*': less threatening factor than danger but it requires preparedness and some kind of response); 'risk' (the same word in Russian: potential threats and challenges). On the Russian security-related terminology see: Sergunin (2003: 65–75).

(including Andrei Kokoshin, the then First Deputy Defence Minister) also took part in its drafting (Kremenyuk 1994: 91).

In the document, the sources of threat were described as purely external, whereas the possibility of internal threats had been ignored (with the exception of reference to potential conflicts between the members (regions) of the Russian Federation). The draft document underlined that Russia does not regard any state as its enemy. However, while not actually naming the USA and NATO as the enemy, there can be no doubt that its authors meant them when it referred to "some states and coalitions" which wished to dominate the world or particular regions and which continued to regard force as a means of resolving disputes. It was also declared that the violations of rights of Russian citizens and of the population in the ex-Soviet republics might be a major source of conflicts. The text described in detail how Russia intended to cope with such a threat. This particular section of the document evoked most negative comments of foreign analysts who immediately accused Russia of imperialist intentions (Sakwa 1993: 317–318; Tsypkin 1994: 197–198; Ra'anan 1995: 20).

In line with the Soviet tradition it was planned to design the armed forces mainly for high intensity conflict. It made a particular emphasis on the use of nuclear weapons as a political deterrent to nuclear or conventional aggression. Remarkably, the famous Brezhnev's 'no-first-use principle' has been reiterated in the draft. At the same time, the paper stated that conventional attacks on nuclear systems, early warning or C^3 (*command, control, communications*) facilities, or on nuclear or other 'dangerous' installations, could provoke a nuclear retaliation. The draft had also been based on the assumption that the CIS would soon become an integrated and cohesive military mechanism, which could be successfully used to meet security challenges. The document emphasized the need for priority to be given to the military's needs in government spending. It also called for the preservation of the defence industry and on the maintenance of a mass mobilization capability (Ministry of Defence of the Russian Federation 1992: 4–7).[3]

There were also some alternative drafts that stemmed from the officer corps and 'national patriotic forces'. For example, in April 1992 Major-General Aleksandr Vladimirov personally presented to Yeltsin a concept of his own. The document had been based on the principle of reasonable defence sufficiency and called for integration of the CIS military structures into a global security system under the auspices of the United Nations (Vladimirov 1992). Contrary to this liberal doctrine, the Russian National Convention, the leading organization of the 'patriotic movement' at that time, proposed a series of documents, which insisted on the preservation and further development of the defence industrial base and an active arms export policy, which in turn could strengthen Russia's military security and international position (Modestov 1992).

These suggestions, however, did not affect the mainstream of Russian security thinking. According to many experts, at this stage the Russian security discourse had been dominated by traditionalists from the military agencies whose views were rather close to the General Staff's draft (Malcolm/Pravda/Allison/Light 1996: 254–256).

13.2.3 Russia's Foreign Policy Concept of 1993

In early 1993, the Foreign Ministry presented a foreign policy concept of the Russian Federation that was consequently approved by the Supreme Soviet (the then Russian Parliament) and President Boris Yeltsin (Ministry of Foreign Affairs of the Russian Federation 1993: 3–23). For the first time post-Soviet Russia has adopted a systemic foreign policy doctrine. Despite numerous inconsistencies and shortcomings this document clearly described Russian national interests and foreign policy priorities. Its basic premise was that Russia's foreign policy must meet fundamental national interests, primarily the need to preserve the sovereignty, independence and territorial integrity of the country, strengthen its security in every respect, revive Russia as a free, democratic country, provide favourable conditions for the formation of an efficient market economy in keeping with the status of a great power and for the entry of the Russian Federation into the world community.

The document suggested greater emphasis on the economic aspect of foreign policy to mobilize international support for Russian economic reforms, integrate the national economy into world economic relations in competitive forms, ease the burden of military spending, solve the problem of foreign debt, support Russian business, carry out conversion projects. The text called for giving priority to the interests of the individual, to human and minority rights.

3 See also discussions on this draft published in *Voennaya Mysl*, Special Issue, July 1992 (in Russian).

According to the concept, Russia was to exercise its responsibility as a great power to maintain global and regional stability, conflict prevention, and promotion of the democratic principles such as rule of law, human and minority rights protection. The document emphasized Russia's commitment to political and diplomatic methods and negotiation rather than to the use of military force, the admissibility of the limited use of force in strict accordance with international law to ensure national and international security and stability.

The aims of the military strategy had been depicted as follows: a) transformation of the international relations system from a bipolar, bloc-based model to a co-operative one; facilitating the arms control and disarmament process; b) bringing the military potential into line with a new pattern of challenges and threats and in accordance with the principle of reasonable defence sufficiency; c) a military reform should be conducted on the basis of a national security concept and it should take into consideration the economic and social potential of the country.

The concept did not see any serious threats to Russia's security. Even the Baltic states that discriminated Russian-speaking minorities and pushed the Russian Federation to withdraw its armed forces from their territory were seen as promising international partners. The only exception was the Third World that had initially been characterized as a main source of threats to regional and global security. However, in the document's sections dealing with regional issues developing countries were depicted as an important resource for Russia's successful global strategy.

In general, the document can be characterized as liberal and pro-Western in its spirit. This did not come as a surprise because the concept was prepared by the team of the so-called 'Atlanticists' – a group of Russian liberal-minded pro-Western politicians and experts (led by the then Foreign Minister Andrei Kozyrev).

13.2.4 Skokov's Foreign Policy Concept (1993)

In April 1993, a group of conservative politicians and experts who were discontent with Kozyrev's doctrine have tried to develop a foreign policy concept of their own. This document was drafted by an anonymous collective of authors called "groups of experts from the Defence Ministry, the Foreign Intelligence Service, the Ministry of Foreign Economic Relations, the Ministry of Foreign Affairs, as well as the staffers of the Directorate for Strategic Security and other structures of the Security Council" (Orlov 1993: 9). Some accounts suggest that the Council's Inter-Agency Foreign Policy Commission organized the final stages of discussion and preparation of this concept (*Diplomaticheskiy Vestnik* 1993, 7–8: 67–68; Malcolm/Pravda/Allison/Light 1996: 114). It has been classified as 'not for press' and never been published, albeit Vladislav Chernov, Deputy Head of the Security Council's Directorate on Strategic Security, quoted extensively from the document in his article in *Nezavisimaya Gazeta* published on 29 April 1993.

The new document, entitled "Guidelines of the Foreign Policy Concept of the Russian Federation", had been prepared under supervision of Yuri Skokov, the Security Council's Secretary. The paper both listed external threats to Russian security and defined Russia's military-related national interests. From the theoretical point of view, it represented a mixture of various approaches. Contrary to some interpretations, it was not extreme, and with some adaptation, it could suit the radical democrats, the national patriots, political scientists and officials from the foreign policy and national security agencies. However, in some respects it was closer to the hard-liners' position than to the liberal one. It used rather strong language regarding the Russian minorities in the Baltic states, the nuclear ambitions of Ukraine and admitted rivalry with the United States (Orlov 1993: 9). The document claimed that Russia should be responsible not only for the creation of a new world order but, in particular, for building a new security system in the post-Soviet space and assume the role of a guarantor of Eurasian stability.

The authors of the document underlined that in contrast with the previous practice, the document had been drafted in co-operation with all interested foreign policy agencies. The new concept had been approved by the heads of all so-called 'power structures' (including the then Defence Minister Pavel Grachev, Security Minister Vadim Barannikov, and Director of the Foreign Intelligence Service Yevgeny Primakov).

The new concept, however, had met a negative reaction from Kozyrev and some foreign countries. Kozyrev was discontent with the document's recommendations on Russian policies towards the CIS and the United States (Orlov 1993: 9). The Baltic states expressed their concerns as to Russia's intention to protect its citizens in the 'near abroad'. In a hard-hitting speech to an audience in Stuttgart, Germany, on 3 May 1993, the then Estonian President Lennart Meri termed the stance a 'Monroe doctrine'. "The change in Russia's foreign policy places the democratic world

before a choice, which has a great deal in common with the fateful pre-Munich days", he said. "I recall, for example, the use of armed forces beyond internationally recognized boundaries under the pretext of 'protecting' the human rights of the Sudeten Germans."[4]

In spite of the adoption of his version of the concept Skokov failed to retain his influence on the President. In May 1993, he was forced to resign due to his questionable loyalty to the President. Kozyrev who for a few months remained outside the 'ring of power' regained his former influential position (Malcolm/Pravda/Allison/Light 1996: 111, 135–136; Baev 1996: 45).

13.3 The Russian Military Doctrine of 1993

By autumn 1993, Yeltsin decided to proceed with the adoption of a new military doctrine. There were several reasons why a military doctrine had to be declared. The military badly needed guidance by the state in organizing, equipping and training the new armed forces. Moreover, the emerging civil society needed such a document for organizing democratic control on and accountability of the armed forces. Russia's international partners also wished to know about Moscow's intentions in the military sphere. Finally, the new doctrine was one of the rewards the military had received from the President for their loyalty in the October 1993 coup de état. The new military doctrine was approved by the Russian Security Council on 2 November 1993 and published. According to the document,

> The Basic Provisions of the Military Doctrine of the Russian Federation are part and parcel of the security concept of the Russian Federation and represent a document covering Russia's transitional period - the period of the establishment of statehood, implementation of democratic reform and formation of a new system of international relations. They represent a system of views officially accepted by the state on the prevention of wars and armed conflicts, on the development of the armed forces, on the country's preparations to defend itself, on the organization of actions to ward off threats to the military security of the state, and on the use of the armed forces and other troops of the Russian Federation to defend the vital interests of Russia (Yeltsin 1994: 6).

In contrast with the earlier versions of the military doctrine and foreign policy concept of 1993, this document clearly defined both external and internal sources of military threats. The doctrine singled out ten major external challenges to Russia's military security:

1. territorial claims of other states on the Russian Federation and its allies;
2. existing and potential seats of local wars and armed conflicts, above all in the direct proximity of the Russian borders (there was a special section on the attitude of Russia to armed conflicts);
3. the potential use (including the unsanctioned use) of nuclear and other mass destruction weapons owned by some states;
4. the proliferation of nuclear and other mass destruction weapons, their delivery vehicles and latest military technologies, coupled with the attempts of certain states, organizations and terrorist groups to achieve their military and political ambitions;
5. the potential undermining of strategic stability by violations of international agreements in the sphere of arms control and reductions and the qualitative and quantitative arms build-up by other countries;
6. attempts to interfere in the internal affairs of and destabilize the internal political situation in Russia;
7. the suppression of the rights, freedoms and legitimate interests of citizens of the Russian Federation in foreign states;
8. attacks on military facilities of the Russian armed forces situated on the territory of foreign states;
9. expansion of military blocs and alliances to the detriment of the interests of Russia's military security; and
10. international terrorism.

In a separate section, the document highlighted five crucial factors facilitating the escalation of a military danger into a direct military threat to the Russian Federation:

1. the build-up of forces on the Russian borders to limits which upset the existing balance of forces;
2. attacks on the facilities and structures on the Russian border and the borders of its allies, border conflicts and armed provocations;
3. the training of armed formations and groups on the territory of other states for dispatch to the territory of the Russian Federation and its allies;
4. the actions of other countries which hinder the operation of the logistics system of the Russian

4 See in: *The Baltic Independent*, 14–20 May 1993: 3.

strategic nuclear forces and of state and military control of, above all, their space components; and
5. the deployment of foreign troops on the territory of states adjacent to the Russian Federation unless this is done to restore or maintain peace, in accordance with the decision of the UN Security Council or a regional agency of collective security, by agreement with Russia.

Along with the external threats the new doctrine identified seven major internal threats against which the armed forces and other services may be used:

1. the illegal activity of nationalist, secessionist and other organizations, designed to destabilize the internal situation in Russia and violate its territorial integrity and carried out with the use of armed force;
2. attempts to overthrow the constitutional regime and disorganize the operation of bodies of state power and administration;
3. attacks on the facilities of nuclear engineering, chemical and biological industries, and other potentially dangerous facilities;
4. the creation of illegal armed formations;
5. the growth of organized crime and smuggling on a scale where they threaten the security of citizens and society;
6. attacks on arsenals, arms depots, enterprises producing weapons, military and specialized equipment, and organizations, establishments and structures which have weapons, with the aim of capturing them; and
7. illegal proliferation of weapons, munitions, explosives and other means used for subversion and terrorist acts on the territory of the Russian Federation, as well as illegal drug trafficking.

The section on threat perceptions had many important implications. Along with the systematic description of these threats it demonstrated rather substantial changes in Russia's strategic thinking. In contrast with the General Staff draft of 1992 the new doctrine did not identify the USA and NATO as a primary source of military danger. Rather, they were warned not to provoke a new confrontation by violating the strategic balance, military build-up in the regions adjacent to Russia, NATO expansion and so on. This implied that Russia also would refrain from any destabilizing actions.

Instead of the traditional threat from the West, other challenges such as armed conflicts, subversive activities and territorial disputes in the post-Soviet space were seen to be a major danger. This was understandable because by the moment of the adoption of the above document all but two FSU (former Soviet Union) inter-state borders were disputed and 164 different territorial-ethnic disputes were identified in this region (Dick 1994: 3). The doctrine, however, did not specify what kinds of territorial claims and local conflicts that really threatened Russia's security and which ones might be potentially dangerous. For example, the Russian-Japanese dispute on the Kuriles originates from the World War II and Russian-Norwegian disputes on economic zones and maritime borders in the Barents and North Seas date back to the 1920's. However, these conflicts do not create an immediate military threat to the Russian Federation. Moreover, most of the countries being in dispute with Russia are simply unable to pose a military threat because they lack a sufficient potential. On the contrary, these countries fear the potential use of military force by Russia pursuing its interests.

The proliferation of weapons of mass destruction and international terrorism, which have been on the periphery of the Russian strategic priorities in the previous doctrines and drafts, were given a rather important status in the new concept. Above all, this brought Russia closer to the major Western countries that also refer to these phenomena as the most dangerous international developments.

The identification of violation of the rights of Russian citizens in foreign states and attacks on Russian military facilities in foreign countries as potential sources of military threat is a rather common stance not only for the Russian but also for other great powers' security doctrines. However, from a legal point of view it was not clear who could be considered as Russian citizens in the FSU countries and what was the status of the Russian military bases in these republics for the time being. The Russian foreign policy concept of 1993 acknowledged that Russia was only in the very beginning of negotiating and concluding corresponding agreements with the former Soviet republics. In fact, the lack of a legal framework for the relations with the FSU countries gave a certain number of excuses for interventions in the 'near abroad' (Ra'anan 1995: 21–22).

The most significant change in the Russian threat perceptions occurred with regard to internal threats. The Law on Security of 1992 only mentioned that some of these might exist. The General Staff draft of the military doctrine (1992) simply ignored the very possibility of internal threats to Russia's security and therefore did not foresee any internal mission for the armed forces. This view was a result of the military

elite's belief that the armed forces should protect the country only from external enemies, not internal ones. The latter should be the business of the Ministry of Interior and of the security services. However, accepting reality, the military doctrine of 1993 acknowledged that there were many dangers stemming from domestic developments. This inevitably led to a commitment of the military to an internal role. As the failed coup of August 1991 and the attack on the White House in October 1993 demonstrated, the armed forces have already been involved in domestic power struggles.

The new reading of military threats has led to the new approaches to military strategy, as well as to an appropriate organization and training of the armed forces.

Since the main threat to stability and peace in the post-Cold War period comes from local wars and armed conflicts, the document called for a re-targeting of the Russian armed forces from large-scale war to low intensity conflicts. The main aim of the use of the armed forces and other services in armed conflicts and local wars, the doctrine said, was "to localize the seat of tensions and stop hostilities at the earliest possible stage, in the interests of creating conditions for a peaceful settlement of the conflict on conditions suiting the interests of the Russian Federation" (Yeltsin 1994: 9). Military operation in armed conflicts and local wars should be carried out by peacetime groups of forces (those which organized for peace-time conditions, i.e. have incomplete personnel and arsenals; in the war-time period they are reorganized to be a full-fledged military units), deployed in the conflict area. In case of need, they might be strengthened by a partial deployment and redeployment of forces from other regions.

According to the document, the priority was to develop the armed forces and other services designed to deter aggression, as well as mobile elements, which can be quickly delivered and deployed in the required area and carry out mobile operations in any region where the security of Russia might be threatened.

When faced with conventional war, the armed forces must act decisively, using both defensive and offensive methods to destroy the enemy. The armed forces should

a.) repel the attacks of the enemy in the air, on land and in the seas;
b.) defeat the enemy and create conditions for ending hostilities at the earliest possible stage and signing a peace treaty on conditions suiting Russia; and
c.) carry out military operations together with the armed forces of allied states, in accordance with international obligations of the Russian Federation.

A number of tasks have been set up by the doctrine for other services:

a.) to ensure a stable operation of intelligence, control and communication systems and to seize and keep the initiative in different spheres;
b.) to isolate the intruding groups of forces of the aggressor;
c.) to flexibly combine firepower and manoeuvre;
d.) to ensure close co-operation of the arms and services, including special services of the armed forces and to co-ordinate the plans of using the armed forces and other services in armed conflicts and wars, and in performing joint tasks;
e.) to hit the facilities of the enemy's troop and weapon control systems.

This combination of defensive and offensive methods was an important distinction from Gorbachev's military concept that had been oriented only at defensive operations.

Some military experts were concerned with the fact that the doctrine said nothing about the country's role in regional security systems; this absence could be interpreted as an intention to ensure Russia's security by unilateral, purely national efforts (Davydov 1996: 267). Despite the focus on local conflicts the military doctrine of 1993, however, said nothing about the need for a different force structuring, equipping and training for low intensity operations. Besides, some military experts noted, the emphasis on mobile forces could be seen as a preparation for an intervention in the 'near abroad' (Dick 1994: 4; Grigoriev 1995: 6).

In the document, the requirement to deploy troops outside the Russian territory is specifically stated. This resulted both from threat perceptions and Russia's international obligations (peacekeeping operations, military bases, joint groups of forces, etc.). It was underlined that irrespective of the terms of deployment, Russian military formations deployed on the territory of other states remain a part of the armed forces and should act in accordance with the procedure established for the Russian armed forces on the basis of bilateral and multilateral treaties and agreements. However, some specialists believed that despite the reference to international agreements and commitments the possibility was left open that such

agreements could be imposed by Russia on weaker states (Davydov 1996: 267).

The doctrine did not exclude the possibility of large-scale war. It was mentioned in the document that under certain conditions, armed conflicts and local wars can develop into an all-out war. Factors which increase the danger of the escalation of conventional war into a nuclear war can be deliberate actions of the aggressor designed to destroy or undermine the operation of strategic nuclear forces, early warning systems, nuclear and chemical facilities. The document also included a provision according to which any, including limited, use of nuclear weapons even by one of the sides can provoke a mass use of nuclear weapons, with catastrophic consequences.

The doctrine clarified Russia's nuclear policy, which had not been updated since the Gorbachev period. It has been declared that the aim of the Russian Federation's nuclear policy is to avert the threat of a nuclear war by deterring aggression against Russia and its allies. Therefore, nuclear weapons were no longer regarded by the Russian strategic planners primarily as war fighting means. Instead, their main use has been seen as a political deterrent to nuclear or conventional aggression. This marked the change in Russian strategic thinking to a Western-like concept of deterrence, compensating for conventional weakness.

The most distinct departure of the new Russian nuclear doctrine from the Soviet one was Russia's abandonment of the principle of no-first-use (introduced by Leoinid Brezhnev in 1982). At the same time, the document promised that Russia would never use its nuclear weapons against any state party to the Non-Proliferation Treaty (1968), which does not possess nuclear weapons, unless:

> (a) such a state, which is connected by an alliance agreement with a nuclear state attacks the Russian Federation, its territory, Armed Forces and other services or its allies; (b) such a state collaborates with a nuclear power in carrying out, or supporting, an invasion or an armed aggression against the Russian Federation, its territory, armed forces and other services or its allies (Yeltsin 1994: 6).

In one way or another all NATO members, China and Japan as nuclear states or the allies of nuclear powers, the Baltic states and Central and Eastern European countries should they join NATO or WEU (Western European Union) come into these categories.

The reaction of Russia's international partners to the repeal of the no-first-use principle was rather contradictory (Davydov 1996: 267). On the one hand, they considered this change to a Western concept of deterrence as evidence of a greater inclination towards openness and frankness in military matters on Russia's part: few in the West took the old Soviet doctrine of 'no-first-use' seriously. They understood that Russia's new nuclear doctrine reflected Moscow's intention to rely mainly upon nuclear deterrence to compensate for its conventional weakness and keep its great power status. On the other hand, they perceived this change as a clear message to them, especially to the Baltic states and the Visegrad countries (Czech Republic, Hungary, Poland and Slovakia) that they would come into the categories of exceptions if they joined NATO or the WEU or supported any Western intervention in Russia or the 'near abroad', for example, by giving rights of passage or providing bases. This had also been a pressure on Ukraine, which delayed the transfer of the nuclear weapons deployed on its territory during Soviet times to Russia (Dick 1994: 2; Lockwood 1994: 648).

Along with these innovations the document confirmed Russia's long-standing interest in (a) a comprehensive nuclear weapon test ban; (b) reduction of nuclear forces to a minimum which would guarantee against a large-scale war and maintain strategic stability, and eventual elimination of nuclear weapons; and (c) strengthening of the non-proliferation regime and making it universal.

Since internal armed conflicts have also been regarded as a considerable threat to the vital interests of the country, the document described the aims of using armed forces and troops in this case as to localize and blockade the conflict zone, suppress armed clashes and disengage the warring sides, take measures to disarm and eliminate illegal armed forces and confiscate weapons from the population in the conflict zone, carry out operational and investigative operations in order to remove the threat to internal security, normalize the situation as soon as possible, restore law and order, ensure social security, render the requisite assistance to the population and create conditions for a political settlement of conflicts. These functions had to be fulfilled mainly by the Interior Troops. However, as the document prescribed, separate elements of the armed forces and other services (the border guards and counter-intelligence) might be used to help the law-enforcement bodies and Interior Ministry troops localize and blockade the conflict zone, preclude armed clashes and disengage the warring sides, and protect strategic facilities. Having in mind antipathy of the military to internal missions General Manilov of the Security Council explained that the armed forces can only be used

> when nationalist or separatist groups are active, using armed violence and posing a threat to Russia and its integrity, or when attempts are made to use force to overthrow the constitutional system, or when nuclear facilities are attacked, and also when illegal armed formations are being created (Dick 1994: 4).

So, the legal foundations for the use of the armed forces in internal conflicts such as Chechnya had been laid by the new doctrine (Davydov 1996: 267). Given that fact that the Interior Troops had been manned and equipped insufficiently, the use of the armed forces in internal operations was inevitable. And the two subsequent Chechen wars have confirmed this suggestion.

13.4 The National Security Concept of the Russian Federation (1997)

On 17 December 1997 President Yeltsin signed the decree No. 1300 thus approving a new Russian national security concept. It outlined Russian national interests, the major threats to the country's security and established a set of domestic and foreign policy goals aimed at strengthening Russia's statehood and geopolitical position. As it was emphasized in the document, the concept was

> a political document reflecting the officially accepted views of the goals and state strategy in ensuring the security of the individual, society and the state against external and internal threats of a political, economic, social, military, technogenic, ecological, information and other character with account of available resources and opportunities (Yeltsin 1997: 4).

Similar to the Law on Security (1992) and the Duma draft of the Law on National Security (1995), the new doctrine departed from the broad understanding of security and focused not only on the interests of the state but also on the interests of the individual and society. According to one of the authors of the concept, Deputy Secretary of the Security Council Leonid Mayorov, this document, which had been developed in the course of several years, comprehensively reflected, for the first time in Russian history, the system of views on the security of the individual, society and the state (Chugayev 1997).

In fact, the concept was a sort of guideline, a theoretical base, which could be used to develop such requisite programme documents as the military doctrine and the economic security doctrine. This was also the base for military reform. At least it made it possible to understand better what armed forces Russia must have and which conflicts they should be prepared for. It was specified in the preamble that "The Concept is the basis for the development of concrete programmes and organizational documents related to the national security of the Russian Federation" (Yeltsin 1997: 4).

The paper described the global situation and Russia's place in the world. Similar to the foreign policy concept of 1993, the paper saw the rise of a multipolar world as the most important characteristics of contemporary world dynamics. According to the doctrine, Russia should find its own 'niche' in this complex world structure and even become one of the 'poles'.

Despite the fact that the document mentioned a couple of times, *en passant*, the need for retaining Russia's great power status it did not insist on Russia's global responsibilities and interests (as some previous doctrines did). On the contrary, the paper acknowledged that Russia's capacity to influence the solution of cardinal issues of international life has greatly diminished.

The document singled out both positive and negative factors affecting the country's position in the world system. Interestingly, the paper pointed to the changing nature of world power in the post-Cold War period. "While military force remains a significant factor in international relations, economic, political, scientific-technical, ecological and information factors play a growing role" (Yeltsin, 1997: 4).

The document noted that some prerequisites have been created for the demilitarization of international relations, strengthening the role of law in conflict resolution, and that the danger of a direct aggression against Russia has diminished. There were some prospects of greater integration of Russia into the world economy, including some Western economic and financial institutions. Russia shared common security interests with many states in areas such as nuclear non-proliferation, conflict resolution, combating international terrorism, environmental problems and so on. At this point, the paper arrived at an important conclusion that Russia's national security may be ensured by non-military means.

At the same time, a number of international and especially domestic processes undermined Russia's international positions. The shift of world power from military-strategic parameters to economic, technological and information ones has intensified international competition for natural, financial, technological and information resources as well as for markets. Some states did not accept a multipolar world model. In some regions, traditions of the 'bloc politics' were

still strong and attempts to isolate Russia could be identified (the document refers to NATO's enlargement and to the Asia Pacific). The document said that the Russian domestic environment was not very helpful for developing an active foreign policy. Russia had yet to develop a unifying national idea that would determine not only the view of the world but also transform the society. The country's economic, scientific and demographic potentials (Lutz 2009) were shrinking. The former defence system has been disrupted and the new one had yet to be created.

However, the concept was quite optimistic with regard to the country's prospects. It stated that Russia had all the prerequisites for maintaining and strengthening its position in the world. Russia possessed a sizeable economic and scientific-technical potential as well as natural resources. It occupied a unique strategic position in Eurasia. The country has created a democratic system of government and a mixed economy. The paper also mentioned Russia's century-old history, culture and traditions which could be an important spiritual resource for rebuilding the country.

The new national security concept asserted that Russia faced no immediate danger of large-scale aggression, and that, because the country was beset with a myriad of debilitating domestic problems, the greatest threat to Russia's security was now an internal one. The document said: "An analysis of the threats to the national security of the Russian Federation shows that the main threats at present and in the foreseeable future will not be military, but predominantly internal in character and will focus on the internal political, economic, social, ecological, information and spiritual spheres" (Yeltsin 1997: 4). This was a distinct departure from previous doctrines. Even the military doctrine of 1993 was based on the assumption that the main threat to Russia's security was posed by external factors such as local conflicts or territorial claims.

As some analysts emphasized, no less important was the fact that for the first time it has been substantiated at such a high official level (the President, Security Council, and Parliament) that there was no external military threat to Russia.[5] The concept clearly suggested that today's relatively benign international climate afforded Russia the opportunity to direct resources away from the defence sector and toward the rebuilding of the Russian economy.

> The development of a qualitatively new pattern of relations with the leading world states and the political absence of the threat of a large-scale aggression against Russia, while it preserves its nuclear deterrent, makes it possible to redistribute the resources of the state and society to address priority internal problems (Yeltsin 1997: 4).

In general, it placed this rebuilding effort in the context of continued democratization and marketization.

The document focused in particular on the dangers posed by Russia's *economic* woes, which were described frankly and at length. It was underlined in the paper that "The state of crisis in the economy is the main cause from which threats to national security of the Russian Federation arise" (Yeltsin 1997: 4). The concept highlighted a number of major threats to economic security such as a substantial drop of production and investments; destruction of the scientific-technical potential; disarray in the financial and monetary systems; shrinkage of the federal revenues; growing national debt; Russia's overdependence on export of raw materials and import of equipment, consumer goods and foodstuff; 'brain drain', and uncontrolled flight of capital.

The document also pointed to internal *social, political, ethnic* and *cultural* tensions that threatened to undermine both the viability and the territorial integrity of the Russian state. Among these social polarization, demographic problems (in particular, the reduction of the birth rate, average life expectancy and population), corruption, organized crime, drug-trade, terrorism, virulent nationalism, separatism, deterioration of the health system, ecological catastrophes and disintegration of the 'common spiritual space' were singled out.

Along with the major internal threats to Russia's security, the document identified a number of dangers stemming from the *international* dynamics. The doctrine highlighted the following sources of external threat: territorial claims; attempts of foreign countries to use Russia's domestic problems for weakening its international positions or challenging its territorial integrity; local conflicts and military build-up in the country's vicinity; mass migration from the troubled CIS countries; proliferation of weapons of mass destruction; international terrorism and drug-trafficking and growing activities of foreign intelligence services. These, however, were of less significance than internal threats.

In general, this shift in Russia's threat perceptions could be assessed positively. Looking at the bright side of the document, three main advantages could be distinguished. First, this was a step to a more realistic

5 See the section on: "Russian National Security: the Concept" of "The Fortnight in Reviewî, in: *The Jamestown Foundation Prism,* 4,1 (9 January 1998).

estimation of Russia's domestic and international problems. Second, given Russia's limited resources this doctrine helped in setting a proper system of political priorities. Finally, it almost dismissed xenophobia regarding to Russia's relations with the West and, thus, laid foundations for more intense international co-operation.

From the critical point of view, two minor comments can be made. First, some threats (environmental, information, spiritual, etc.) have just been mentioned but not substantiated. Some of them, however, were described implicitly in the section on the national security strategy. Second, there were some grounds for concern that 'securitization' of Russian domestic politics, i.e., identification of main security threats inside rather than outside the country, under certain circumstances might result in a sort of 'witch-hunt'. To prevent this, some analysts believed, individuals and civil society should serve as a check on the state and should not allow the state to be the sole agency in national security matters (Chugayev 1997; Sergunin 1998b).

Along with explaining Russia's national interests and threat perceptions, the doctrine determined ways and means of the country's security policy. According to the document,

> The *chief purpose* of ensuring national security of the Russian Federation is to create and maintain such an economic, political, international and military-strategic position of the country which would provide favourable conditions for the development of the individual, society and the state and preclude a danger of weakening the role and significance of the Russian Federation as a subject of international law and of undermining the capability of the state to meet its national interests on the international scene (Yeltsin 1997: 4).

The document set up a number of *particular tasks* to ensure national security of the Russian Federation: a) to develop the country's economy and pursue an independent and socially-oriented economic course; b) to further improve the legislation and strengthen law and order and social-political stability of society, Russian statehood, federalism and local self-administration; c) to shape harmonious inter-ethnic relations; d) to ensure Russia's international security by establishing equal partnership with the major states of the world; e) to strengthen state security in the defence and information spheres; f) to ensure the vital activity of the population in a technogenically safe and environmentally clean world.

With regard to Russia's military policy, the national security concept served as a post-facto justification for the down-sizing of Russia's armed forces that has occurred since the Soviet Union's dissolution, and for the continued restructuring envisioned in the Kremlin's still evolving military reform programme. By emphasizing domestic rather than foreign threats to Russia's security, it seemed also to justify the rapid strengthening of the country's internal security forces relative to the regular army during the past ten years, even if defence reform plans aimed to moderate that policy somewhat. In a related fashion, the document described an alleged threat to Russian economic interests posed by foreign competitors, and underscored the importance of the role played by Russia's intelligence services in countering it.

The document also emphasized the overriding importance of Russia's strategic forces to the country's security and again disavowed the no-first-use principle. With regard to conventional weapons, the concept proclaimed a policy of 'realistic deterrence' in discarding officially any effort to maintain parity with the armed forces of the world's leading states. The concept highlighted the importance of Russian participation in international peacekeeping missions as a means of maintaining Russia's influence abroad.

The document declared that in preventing war and armed conflicts Russia preferred political, economic and other non-military means. However, as far as the "non-use of force" (Art. 2,7 of the UN Charter)[6] has not yet been fully implemented as a norm of international relations, the national interests of the Russian Federation required sufficient military might for its defence. The document said that Russia might use military force for ensuring its national security, proceeding from the following principles:

- Russia reserved the right to use all the forces and systems at its disposal, including nuclear weapons, if the unleashing of armed aggression results in a threat to the actual existence of the Russian Federation as an independent sovereign state.
- The armed forces of the Russian Federation should be used resolutely, consistently up to the point when conditions for making peace which are favourable to the Russian Federation have been created.
- The armed forces should be used on a legal basis and only when all other non-military possibilities of settling a crisis situation have been exhausted or proved to be ineffective.

6 This is referred to in Art. 2,7 of the UN Charter of June 1945 and are binding on all states although this principle has been largely ignored.

- The use of the armed forces against peaceful civilians or for attaining domestic political aims shall not be permitted. However, it was permitted to use individual units of the armed forces for joint operation with other services against illegal armed formations that present a threat to the national interests of Russia.
- The participation of the Russian armed forces in wars and armed conflicts of different intensity and scope shall be aimed at accomplishing the priority military-political and military-strategic tasks meeting Russia's national interests and its allied obligations.

The doctrine underlined that Russia had no intention of entering into confrontation with any state or alliance of states, nor did it pursue hegemonic or expansionist objectives. Russia will maintain relations of partnership with all interested countries of the world community.

The concept reiterated Russia's opposition to NATO enlargement and it called for multilateral collective security organizations such as the UN and the OSCE to play a greater role in ensuring international security. The paper called on the international community to create a new Euro-Atlantic security system on the basis of the OSCE as well as to strengthen (with Russian participation) multilateralism in the Asia Pacific.

The national security concept formally stated what has long been a cornerstone of Russian declared foreign policy: i.e., that the rebuilding of Russia is best served not by a passive diplomatic posture, but rather by an aggressive and multi-faceted diplomacy aimed at winning membership, or increasing Russia's influence, in various international organizations, while simultaneously striving to make Russia an important global player.

13.5 The Putin and Medvedev Era

During the late Yeltsin and early Putin period four major factors have changed Russian threat perceptions – its financial collapse of 1998, NATO's military intervention in Kosovo (1999), NATO's new strategic doctrine (1999) and the second Chechen war that also started in 1999.

Russia's financial crisis of August 1998 undermined to some extent the popularity of liberal concepts (including a positive attitude to globalization) in the country by exposing Russia's vulnerability to the international economy and financial markets. But some specialists believe that the fundamental sources of this crisis were internal policy failures and economic weakness, but it was triggered by the vulnerability of the ruble to speculative international financial markets (Wallander 2000: 2). Moreover, because Russia's economy began to recover in the aftermath of the decision to devalue the ruble and implement limited debt defaults, the crisis reinforced statist arguments that a less Western-dependent, more state-directed policy of economic reform could be Russia's path to stability and eventual prosperity. One of the lessons of the 1998 financial meltdown was that globalization may be a source of threat to Russia's economic security.

As for the Kosovo war of 1999, Russia has again become suspicious about NATO's real character and its future plans. In the Russian view, in this case NATO – contrary to previous declarations on its intentions to be transformed from a military-political to a political-military organization – demonstrated that this alliance still preferred to be a 'hard' security organization and continued to reproduce a Cold War-type logic and policies. Moreover, NATO demonstrated its ambitions to be a major (if not a sole) security provider in Europe trying to sideline other regional organizations, such as OSCE, EU, the Council of Europe, the Council of the Baltic Sea States, etc.

In addition, the Kosovo war coincided with the adoption of a new NATO strategic doctrine that turned out much more expansionist than the previous one (Wallander 1999: 4). In particular, the new doctrine envisaged further enlargements of NATO towards the east, a redeployment of its military infrastructure closer to Russian borders and even military operations beyond its traditional 'zone of responsibility' (in fact, globally). Finally, the Kosovo crisis gave the Russian military much needed arguments to force through their view that a large-scale conventional war is not a nearly remote possibility as stated in the national security concept of 1997 (Ball 1999: 2).

The second Chechen war has affected Russian threat perceptions as well. First of all, it demonstrated that in the modern era international and domestic terrorisms are intertwined and it is impossible to fight them separately. In addition, it turned out that the financial and military-technical basis of terrorism in the North Caucasus was that strong that it was unrealistic to wage the war only by special forces and internal troops (without the help of regular armed forces). As mentioned, Russia's previous military and security doctrines admitted only a limited and short-term involvement of the regular army. It should also be noted that Russia was both disappointed and irritated by

what it called a Western 'policy of double standards' with regard to Chechnya. On the one hand, Western countries called on Russia to join a 'global war on terror' after the events of 11 September 2001 and Russia responded in a positive way. But, on the other hand, the West treated Chechen rebels as 'freedom-fighters' rather than terrorists, provided Chechen leaders with political asylum, allowed Chechen representative missions to wage anti-Russian propaganda in Europe and in the U.S. and heavily criticized Russia for human rights violations in the region. Such a policy contributed to the rise of new mutual suspicions and mistrust in Russia's relations with its Western partners.

In 2000, under the new President Vladimir Putin, a series of new security-related documents was adopted, among them a national security concept, a military doctrine, a foreign policy concept and even an information security concept. The national security concept of 2000 was the most significant document for understanding Russia's new approaches to its security policies.

There were several differences between the concepts of 1997 and 2000. The most important aspect of the 2000 concept was that it elevated the importance and expanded the types of external threats to Russian security. The concept no longer stated that there were no external threats arising from deliberate actions or aggression. It provided a substantial list of external threats, including: the weakening of the OSCE and UN; weakening Russian political, economic, and military influence in the world; the consolidation of military-political blocs and alliances (particularly further eastward expansion of NATO), including the possibility of foreign military bases or deployment of forces on Russian borders; proliferation of weapons of mass destruction and the means of their delivery; weakening of the CIS, and escalation of conflicts on CIS members' borders; and territorial claims against Russia (Putin 2000: 4).

In several places the concept of 2000 emphasized that the natural tendency of international relations after the Cold-War confrontation was toward the development of a multipolar world in which relations should be based on international law and a proper role for Russia. It argued that the United States and its allies, against this tendency, under the guise of multilateralism have sought to establish a unipolar world outside of international law. The document warned that NATO's policy transition to the use of military force outside of its alliance territory without a UN Security Council approval was a major threat to world stability, and that these trends could create the potential for a new era of arms races among the world's great powers. The concept of 2000 links the internal threat of terrorism and separatism (clearly with Chechnya in mind) to external threats: it argues that international terrorism involves efforts to undermine the sovereignty and territorial integrity of Russia, with the possibility of direct military aggression. However, in dealing with the threat the document calls for international cooperation (Putin 2000: 4).

Russia's military doctrine of 2000 enlists almost the same threats to Russia's security. Perhaps there was the only exception: in addition to the threats that were mentioned in the national security concept of 2000 and in the military doctrine of 1993 the new document points to a new threat of an information war against Russia as an important factor of the contemporary security environment in the world.

The military doctrine of 2000 describes in detail the nature of contemporary and future wars distinguishing the following trends:

- The use of high-precision and non-contact weapons (with a minimal involvement of ground forces);
- An emphasis on the predominant use of air/space and mobile forces;
- An aspiration to destroy an enemy's military and administrative command structures; making strikes on military, administrative, economic and infrastructure objects throughout the whole enemy's territory;
- Widespread use of methods of information war – both world-wide and inside the enemy's country;
- Potential technical catastrophes as a result of strikes on nuclear, chemical and industrial installations and communications;
- Involvement of irregular/paramilitary formations in waging war (along with regular armed forces);
- The high risk of escalation of an armed conflict to a large-scale war in terms of a number of participants and the use of weapons of mass destruction (WMD).

Depending on the level of confrontation the doctrine singles out the following types of armed conflicts:

- Armed conflict – intra-state (Chechnya, Trans-Dnistria, Georgia-Abkhazia, Georgia-South Ossetia, the civil war in Tajikistan) or inter-state (Russia-Georgia);
- Local war (Iran-Iraq in the 1980s, Armenia-Azerbajan: Nagorny Karabakh);
- Regional war with the participation of a group of states (Afghanistan, both Iraq wars);

- Large-scale war (both world wars). The possibility of a large-scale war is seen by Russian strategists as purely theoretical.

With a political and economic stabilization and subsequent economic growth in Russia under President Putin Russia's foreign and security policies became more assertive. President Putin's 'Munich speech'[7] of 10 February 2007 exemplified a new Russian stance (Putin 2007). Although there were no radical changes in Russia's basic threat perceptions, President Putin has emphasized some interesting nuances in Russia's approaches to international security. Moscow's security concerns were related to the following recent developments:

- The unilateral use of military force by the U.S. and its allies (in Kosovo, Afghanistan and Iraq). The Russian Federation was also discontent with regular U.S. military threats to Iran, Syria and North Korea.
- The weakening of traditional international security institutions such as the UN (Security Council) and OSCE where Russia is represented on equal footing with other countries. President Putin said that the crisis of these organizations is a result of a deliberate strategy conducted by a small group of states that are interested in creation of a unirather a multi-polar world.
- NATO's eastward extension and the growth of its military infrastructure on the Russian borders.
- The U.S. plans to deploy elements of ABM (anti-ballistic missile) defence system in East and Central Europe (in Poland and in the Czech Republic).
- The lack of progress in arms control and disarmament. In particular, Putin criticized also other nuclear powers who do not want to join existing arms control regimes and reduce their nuclear arsenals. The Russian President also criticized NATO for its unwillingness to ratify the 1999 Adaptation Treaty on Conventional Forces in Europe that aimed at significant force reductions and development of confidence-building and security measures in Europe. Protesting against NATO's position Putin has suspended Russia's participation in the CFE Treaty in 2007.
- The lack of efficient cooperation between Russia and its Western partners on fighting international terrorism. Putin reiterated Russia's famous stance on the Western 'policy of double standards' and proposed to the international community an intensified cooperation in this sphere.

Russian security thinking under Putin was also deeply affected by a series of the so-called colour revolutions (Ukraine, Georgia and Kyrgystan). It has resulted in a certain re-assessment of Russian security perception towards the 'near' abroad, particularly in implementing 'tightening of the screw' policies. The Russian leadership now believes that Russia cannot be a regional great power (and a pole of the world multi-polar system) if it cannot keep its central position in the former Soviet space. Along the same lines, Putin tried to re-animate CIS collective security structures such as the protection of the common CIS borders, a single air defence system and the creation of the collective rapid reaction forces.

The new Russian President Dmitry Medvedev has repeatedly said that his foreign and security policy course will continue the strategy of his predecessor and that there should be no expectations of major changes in Russia's threat perceptions and security policies.

However, the beginning of his presidency was marked by two security challenges that earlier were seen as highly hypothetical – the inter-state military conflict with Russia's participation (South Ossetia) and 'energy wars' (Russian-Ukrainian gas conflict).

When in August 2008 Georgia has attacked South Ossetia and the Russian peace-keepers who were located there, for the first time in its post-Soviet history the Russian government had to execute a full-fledged peace-enforcement operation forcing Georgia to return to a *status-quo* situation. It appeared that the Russian armed forces were ill-prepared for such an operation (although the possibility of a limited armed conflict was foreseen in the Russian military doctrine). It took a long time to re-deploy forces from North to South Ossetia. The mobile forces were almost not engaged in the operation. The air and electronic intelligence were inappropriate and this inevitably led to mistakes in command chain and losses in manpower and military equipment. It was reported that the Russian General Staff has initiated a special investigation to draw lessons from the South Ossetian conflict.

The 'gas war' with Ukraine that had quite serious repercussions for Europe has demonstrated Russia's vulnerability in the energy sector, its dependence on the transition countries and challenged its credibility as a reliable energy supplier.

7 See President Putin's presentation at the Munich Conference on International Security; at: <http:// www.securityconference.de/konferenzen/rede.php?sprache=en&id=179>.

In both cases (South Ossetia and the Ukraine) Russia called for multilateral decisions. To avoid conflicts similar to the Russian-Georgian one President Medvedev proposed a new Trans-Atlantic Security Charter that should lay foundations for a new international security architecture in this huge region. A multilateral mechanism to prevent and solve local conflicts was proposed. Although the US and EU reaction to the Medvedev's proposal was cautious, it was not completely rejected and further discussions were suggested.[8] In addition, at the EU-Russia summit in November 2008 the EU and Russia decided to intensify their cooperation on external security, including conflict management and joint peacekeeping operations throughout the world.[9]

As far as the problem of reliable energy shipments to Europe is concerned President Medvedev has also proposed to create an international control mechanism that could monitor the supply process. It is planned that the issue of energy security will become an important part of a new EU-Russian cooperative agreement that is now under negotiation. In addition, President Medvedev invited European energy companies to actively invest in the construction of alternative gas pipelines that could be independent of transit countries (the so-called projects 'Nord stream' and 'South stream').

Medvedev has continued Putin's course on strengthening the CIS collective security system (i.e. the Tashkent Treaty of 1992). In 2009, he signed an agreement with President Alexander Lukashenko on the creation of a single Russian-Belarussian air defence system and completed the creation of collective rapid reaction forces of the CIS (mainly consisting of the Russian airborne troops).[10]

The new Russian National Security Strategy that was adopted by the presidential decree no. 537 of 12 May 2009 has incorporated these developments into the Russian strategic thinking. The list of military threats remained almost unchanged but they were presented in a slightly different way. For example, it distinguished between threats to the state and society, on the one hand, and to the individual, on the other. The paper is a bit more detailed in the description of the sources of the military threats to Russia than previous documents. And it has a more strategic, forward-looking character (Strategia Natsionalnoi Bezopasnosti Rossiyskoi Federatsii do 2020 goda).

13.6 Conclusions

Six conclusions emerge from the above review of the evolution of Russia's military threat perceptions and national security doctrines:

- *First,* during the past two decades Russia has managed to formulate its national interests, threat perceptions and a more or less coherent national security strategy.
- *Second,* Russian national security doctrines defined both national interests and security threats quite realistically. They are based on the assumption that there are no major external threats to its security and that internal sources of threats should be given more attention. Logically, Russian security concerns have shifted from the 'hard' to the 'soft' security domain.
- *Third,* Russian national security doctrines are based on a broader understanding of the notion of security in which the non-military issues such as the economy, social problems, environment, demography, information, culture and religion are included.
- *Fourth,* in line with the democratic principles, these concepts acknowledged the need for ensuring national security at three levels (the individual, society and the state) albeit the state 'bias' still remains (particularly in the field of implementation of the national security strategy).
- *Fifth,* with the adoption of a non-aggressive military strategy and clarification of Russia's national security interests, Russia becomes a more attractive and predictable international partner.
- *Sixth,* it appears that the national security debate has been a rather effective way of nation-building and constructing a new Russian identity. The national security concepts claim that they are based on national values and traditions and aim at the search for a national consensus and a unifying national idea.

14 Russian Security Policy in the 21st Century Based on the Experiences of Its First Decade

Pál Dunay

14.1 Introduction

Russia's security policy and perception of the 21st century cannot be understood without taking a glance at the preceding fifteen years or so (Sergunin 2008; see chap. 12; Bailes/Baranovsky/Dunay 2007). Although there are certain elements of continuity between the 15 years since the mid-1980's to the end of the 20th century and the first decade of the 21st century, there are also major elements of discontinuity. Therefore historical references may be of limited relevance for the recent past and the near future.

This chapter analyses the security policy of the Russian Federation during the first decade of the 21st century based on official documents, which summarize the country's security perceptions, the actions it has taken from the second Chechnya conflict (1999), to the five-day war with Georgia (2008), and Russia's assertions regarding its future status in the international system.

A key question is whether security is conceived either with a narrow or wider meaning (Brauch 2009). This poses a challenge as the contours of Russian security policy cannot arbitrarily be defined and the author cannot ignore how the state uses the concept. Various Russian security concepts did not follow the same line and they showed a certain discrepancy in their use. Although the narrow security concept is deeply rooted in the Soviet past, it does not reflect current Russian security thinking. Russia's security concerns entail elements of soft security and its security strategy has also integrated elements of a wider concept. The state of health of the Russian population, its declining life expectancy and the overall demographic situation belong to the former (Lutz 2008), energy security issues to the latter. Thus, this chapter must remain eclectic as far as the concept of security is concerned.

Analysing Russian security policy requires a consistent analytical framework. For many, Russia is a model of a realist great power in the early 21st century. Russia pursues its national interests, it is ready to clash for their realization and it uses a full array of available economic, political, and military means. Russia has no permanent allies. Thus, it is impossible to draw a clear conclusion. Russia's realism is mitigated by its integration into the international system and its objections to the interests of Western great powers, rather than their full rejection. Its rejection of Western values has been hesitant and tacit. Furthermore, the domestic foundations of Russian politics do not fully underline either a dictatorial, or even an unambiguously authoritarian regime. Taken together, Russia represents a puzzle for the security analyst.

Beyond the grand theories of international relations, it is clear Russia has changed fundamentally since the end of the Soviet Union. The country has remained semi-authoritarian with a bureaucratic hard core, the result and reflection of a recentralization. It is sometimes described as an authoritarian system with a market economy. In this sense parallels are drawn with China. However, this parallel has been largely missing the point. The authoritarianism of both states is very different as are their economic foundations. Russia had at least some short lived experience with democracy during the 1990's, China does not. Furthermore, the expectation of the West which Russia is supposed to live up to is a set of expectations of a prospective member of a value community. China has faced similar expectations. For more than a decade the human rights related demands against China were concrete complaints without an underlying system of expectation to become Western in its approach. Since the late-1990's they have been expressed in a lukewarm manner and often did not go beyond lip service. However, Russia faced systematic expectations to eventually live up to Western standards. Although both China and Russia experienced impressive economic growth rates, their foundations differ fundamentally. Russia's growth largely

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_14, © Springer-Verlag Berlin Heidelberg 2011

depends on world prices of natural resources, specifically on hydrocarbons. China is the world's production site. Hence it is unfounded to assume that the Russian model is a carbon copy of the Chinese. The Russian model faces the danger of a rentier economy where the taxes of the population play a marginal role and its opinions are disregarded by the establishment. In this regard the prospects of Russian democracy may be in doubt.

14.1.1 Where, Why, and How History Matters?

In the international system adaptation is one of the most painstaking processes. The past imposes itself on the present particularly if states do not face up to reality and partly base their actions on illusions. This is relevant for the Russian Federation during the first decade of the 21st century. From the Soviet legacy there are three elements to mention:

1. The Soviet Union after the end of the Second World War qualified as one of the two superpowers and thus as a centre of the bipolar international order.
2. Among the combined elements of the power base of the Soviet Union, military force, including the possession of the largest arsenal of nuclear weapons, and an ideology spread by force played a central role.
3. The Soviet Union, largely based on Russian conquests in the 18th and 19th centuries, integrated many nations and large territories not inhabited by ethnic Russians that became mixed ethnically during the Tsarist and the Soviet eras.

These elements have influenced Russia's conduct since the end of the Soviet Union. Russia had enormous difficulties to adapt to the changes regarding these three elements:

1. The decline of the Soviet Union prior to its end weakened its position but avoided facing the loss of its status as a superpower. That happened later during the first half of the 1990's. Thus, the Soviet legacy could present a status or a point of reference.
2. The power base of the Soviet Union lost its international appeal with regard to the Marxist-Leninist ideology and its relevance as a symbol of military power, and shifted to other sources of power and influence where its performance was less outstanding.
3. The end of the Soviet Union resulted in the loss of all its territorial gains during the last three centuries and disconnected Moscow from its 'backyard'.

For the first years of the Russian Federation two elements are worthy of mention:

1. Russia could learn that its domestic weakness ranging from its economic output to shortcomings in governance undermines its international performance.
2. The West did not reciprocate the readiness of Russia to accept a junior partner status in the international system by a benign attitude or generosity, and several decisions have been made that Moscow perceived as interfering with its essential interests.

The end of the 1990's reconfirmed the earlier experience that Russia has accumulated. A series of events demonstrated the depth of the problem it faced, including the collapse of its financial system in 1998, the extensive influence of oligarchs on managing state affairs in the second term of the Yeltsin presidency, the outbreak of the second Chechnya War. Internationally this coincided with the first eastern enlargement of the Atlantic Alliance in March 1999, the new NATO strategic concept of April 1999, including the declaration of the continuation of its open door policy and NATO's war against Serbia in 1999. There was no doubt left, if Russia wanted to return to the international scene it had to fix its problems ranging from generating a larger GDP and tax revenues to consolidating its government structures and offering an ideology to the population that could find acceptance. It needed a better performance and more stability. The consolidation started with the arrival of the new leadership and not much later with the new era.

These all happened during the last moments of the 20th century with repercussions for the first years of the 21st century. However, the memories of the Soviet Union were still fresh enough to believe that the better performance of Russia as a national economy, a functioning government, more international respect, particularly in its traditional sphere of influence, could re-establish it as a major world political player. These achievements have given the impression to Russia that it could also reclaim its status.

14.1.2 Economic and Social Foundations

At the turn of the century the Russian Federation had a small GDP, a backward economy with regard to the spread of high technology, and an overall poor population (except for some large cities that have benefited

from the lion's share of the inflow of capital). During the Putin presidency the GDP of Russia rose from US$ 560 billion in 1999 to 1.3 trillion in 2007, which moved the Russian Federation from the 14th largest economy to the 12th largest during those eight years.[1] In 2009 it reached US$ 2.1 billion and was the 8th largest national economy in the world (CIA 2010).[2] Its GDP per capita was US$ 15,200 in 2009, ranked as 73rd in the world, compared to US$ 6,775 in 1999.[3] Its currency reserves rose from US$ 8.5 billion to US$ 540 billion between 1999 and 2008.[4] Between 1998 and 2007 the Russian economy rose at an average annual rate of 7 per cent.[5] The consumption of Russian households grew even faster between 1999 and 2007, at a rate of 10.1 per cent (Petro 2009) and significantly less people were living under the official subsistence minimum in Russia. By 2007 it was down to 14 per cent of the population (Petro 2009). Due to these facts, a domestic political consensus was achieved and maintained. As the renewed centralization and the constraining of democracy were accompanied by economic prosperity, the priority attributed to the economic factor in the process remains unquestioned.

However, more recent developments have shown that although Russia is well integrated in the world economy, it is not a central player. In 2008 more than 70 per cent of the value of companies registered at the Russian stock exchange disappeared within four months from May to September (Herd 2009). Even though political factors, like the war between Georgia and Russia, played a role in this, it had far more to do with the spill-over effect of the world financial crisis and the temporary bursting of the oil (and gas) price bubble. This has highlighted that Russia's economic performance to a large extent depends upon the exploitation and export of a few natural resources, i.e. its economy is not sufficiently diversified, high technology industries play a minor role and the financial sector is not developed enough. In 2007, 64 per cent of Russian export revenues relied on the export of oil and natural gas, and the fuel sector accounted for 20.5 per cent of the GDP.[6] But it would be wrong to attribute all positive features in the Russian economy to oil and gas prices, and all weak spots to an insufficient economic modernization. It is recognized that prudent management of public finances, the accumulation of significant reserves in the stabilization fund certainly contributed to the success. Furthermore, on the basis of a general economic boom, the spillover was significant in other sectors, like construction, trade, services, and also in banking. Russia is divided and top-level politics seldom faces the reality of Russia's economic situation. Since the steady growth of the Russian economy has been interrupted, President Medvedev pointed to the need of economic modernization.[7] This is backed by the expert opinion that the "Russian economy is not diversified and is built on the commodity market".[8] Russia reacts allergically if external political players draw critical conclusions on the state of its economy.[9]

It is not only the economy that gave mixed signals during the last decade. Social security does not excel either. Retirees still often face basic subsistence problems, and depend on the next generation. Unemployment has become more widespread due to the finan-

9 Lynn Berry: "US Vice President Biden hits nerve in Russia", in: *The Washington Post*, 27 July 2009; at: <http://www.washingtonpost.com/wp-dyn/content/article/2009/07/27/AR2009072701154.html>. U.S. Vice President Joseph Biden argued on Russia: "They have a shrinking population base, they have a withering economy, they have a banking sector and structure that is not likely to be able to withstand the next 15 years, they're in a situation where the world is changing before them and they're clinging to something in the past that is not sustainable." An author at a critical Russian website called attention to the fact that the U.S. vice president told the truth and that offended the Kremlin. See Aleksandr Golts: "Biden skazal pravdu, Kreml obidel'sya" [Biden told the truth, the Kremlin was offended], in: *Yezhednevnyi zhurnal*, 27 July 2009; at: <www.ej.ru/?a= note&id=9313>.

cial crisis induced economic contraction. Cities with mono-cultural economies often based on the performance of one company may be hit particularly hard.[10] Alcoholism continues to be widespread, now exacerbated by drug use that changed Russia from a transit state to a destination. A phenomenon closely linked with Russia's economic emergence has been that the life expectation, particularly for men, is short, and population decline is massive. Globally, with 12 years, the difference between the life expectancy of men and women is the biggest in Russia. Although immigration from the former Soviet area has continued, it has not compensated for the loss. Further population decline is beyond doubt, it is only the proportions of the problem that is disputed. These factors present complex problems but more is said than done to alleviate them effectively. Thus, the socio-economic foundations of Russia's security will continue to be in trouble. They pose problems of their own and they also react to other more narrowly defined areas of security.

14.2 Russian Security Documents (2003-2010)

Vladimir Putin's era as President of the Russian Federation began with the adoption of four major documents that outlined the country's thinking on national security: Russia's national security strategy in January 2000, its military doctrine in April 2000, its foreign policy concept in June 2000, and its information security concept in September 2000. The drafting in the first three cases preceded the new President's office term but the new administration certainly left its mark on them. Thus, the country could base its activity in the area of international security on adequate documents. Beyond its start the Putin era has not at all been rich in strategic documents.

The first major addition came in 2003 when the document on "The Topical Tasks of the Development of the Armed Forces of the Russian Federation" was published.[11] It is not surprising that a document which addresses the tasks of the armed forces puts the emphasis on the contribution of military power. It is Russia's most important novelty that it concludes that military power has retained its importance in guaranteeing security if its role has not eventually increased. It is further accentuated when the document states: "It is increasingly impossible to guarantee the security of the Russian Federation exclusively on the basis of relying on political opportunities, membership in international organizations, partnerships and political influence." This is certainly in reaction to the developments of the post-bipolar era and the most important event that had preceded the adoption of the document, the Iraq War of 2003.

As far as the topic of nuclear weapons is concerned, the document does not add much to the position of Russia elaborated above. Earlier documents also recognized the first use of nuclear weapons under strictly defined conditions. However, the argument underlying it has developed further in light of current developments. Accordingly, the use of force without the approval of the UN Security Council increases the probability to use weapons of mass destruction, including nuclear arms. This means that according to Russia the nuclear threshold has lowered. Moscow has reaffirmed the doctrine of nuclear deterrence as part of its security policy.

While Western analysts concluded that Russia became more assertively 'militaristic' with the 2003 document, this position is not supported by facts. The Russian Federation only reacted to the change of the international environment. If the world developed in a direction where military force is employed more freely and where those institutions which provide for the enforcement of global order and universal international law lose ground, Russia would recognize the rules of the game and adjust to them. As Russia regards itself as a global player, such rearrangements of the sources of power and of power relations appear on Russia's security agenda faster and more directly than they will affect smaller states, which are not directly exposed to these changes. It reflected that Russia was sufficiently self-confident to react autonomously when it concluded that the lasting rearrange-

10 It is sufficient to mention the situation of the VAZ factory in Togliatti (in the Samara region) where the Lada passenger car is produced. The same applies to the GAZ factory in Nizhny Novgorod less than 500 kilometres east of Moscow where the well-known Volga cars have been produced. The shrinking market threatens with mass unemployment at both places. This can only be tempered by significant governmental assistance but the problem cannot be resolved due to the fact that Lada is not the favourite passenger car either of the Russian or of the foreign customers.

11 Aktualnye, 2003: "Aktualnyye zadachi razvitiya vooruzhennykh sil RF" [The topical tasks of the development of the armed forces of the Russian Federation], at: <http://www.mil.ru/articles/article5005.shtml>.

ment of international power relations was to its disadvantage.

The documents adopted in 2003 and before reflected a mounting Russian dissatisfaction with global processes. The Russian leadership that maintained certain elements of the Soviet legacy faced further challenges when between late 2003 and early 2005 landslide political changes occurred in three former Soviet republics. In two cases more western leaning leaders came to power. This was perceived more as an existential challenge. Russia was deprived of the integrity of its regional backyard (and its unchallenged leadership in the former Soviet area). It found this unacceptable when its President argued that the dissolution of the Soviet Union was the single biggest catastrophe of the 20th century. Furthermore, it perceived that Russia's position as a pole of the multi-polar international system was, among others, based on its regional dominance in the post-Soviet space.

The growing dissatisfaction and bitterness of Russia was reflected in the address of President Putin at the Munich Security Conference in 2007.[12] Although the speech is often mentioned as a turning point in the relations between Russia and the West, a closer look would leave no doubt that all its elements could be found in earlier pronouncements of the Russian leadership. It was new that President Putin systematically summarized the points of contention and their spread was giving the impression of a turn.

The main points included the unilateral use of force against states ranging from Serbia to Iraq and the threat of force to other countries, like Iran, Syria, and North Korea. In conjunction with this it was mentioned that those organizations where Russia was on equal footing with other states, including Western great powers, were marginalized, ranging from the United Nations and most importantly its Security Council to the OSCE. NATO's ongoing enlargement to the East formed part of the list. This was all the more understandable as it formed part and parcel of the western domination of regional and also some global institutions. The deployment of ballistic missile defence in East-Central Europe and the discontinuation of European arms control, including the non-ratification of the adapted CFE Treaty added to the list of grievances. Last, but not least, Russia was dissatisfied with counter-terrorist cooperation. It is an area where Moscow's attitude was no doubt exemplary with particular reference to the immediate demonstration of solidarity with the USA after 9/11. The Russian President did not add the colour revolutions to the list as they were more ambiguous points of reference. Apparently, local populations practised their right to political self-determination, beyond doubt with some external support. On the other hand, Russia remained mute on human security issues, particularly on Moscow's human rights record. This litany could be regarded as one-sided and biased but certainly not fully unfounded. Its relevance has reached beyond the Bush administration and the Putin presidency.

The inception of office by President Medvedev has not resulted in the adoption of a new series of documents due to the succession of power but much more due to the completion of drafting processes long overdue. The foreign policy concept was adopted in June 2008, the National Security Strategy in May 2009.[13]

The foreign policy concept offers a broad overview of Russia's interests. Strengthening the principles of multilateralism, developing a security architecture based on the indivisibility of security that also recognizes diversity lies at its philosophical foundation. A stable system of international relations is to be based on equality, mutual respect, mutually beneficial cooperation, and the norms of international law. As far as international institutions are concerned, Russia attributes importance to those where it is a member on equal footing, with a strong preference for the United Nations in the management of global affairs. The UN Security Council has a monopoly to sanction the use of force for the purpose of coercion to peace. In the area of international security Russia presents its complaints about the absence of arms control both bilaterally (USA-Russia) and multilaterally in Europe.

In its regional policy Russia clearly puts the priority on the former Soviet area and attributes importance to various multilateral frameworks of cooperation. With regard to NATO, the document takes a reactive view and makes Russia's relations dependent upon the readiness of the Alliance "for equal partner-

13 "The Foreign Policy Concept of the Russian Federation", in: *Maxim News Network*, 31 July; at: <http://www.maximsnews.com/news20080731russiaforeignpolicyconcept10807311601.htm>; "The strategy of national security of the Russian Federation until 2020 approved by the decree of the President of the Russian Federation on 12 May 2009"; at: <www.scrf.gov.ru/documents/99.html>.

ship". It is clearly opposed to further NATO enlargement with specific reference to Georgia and Ukraine, and the bringing of the NATO military infrastructure closer to Russia's borders. Overall, the document marks the Russian view in a fairly non-confrontational manner.

The National Security Strategy starts out from a broad definition of national security similarly to concepts like the one adopted in 1997. This is the prime reason for the caveat above according to which Russia does not have a security conception that would help define its contours. The list of security relevant issues includes the development of democracy and civil society, the raising of the living standards of its citizens, defeating population decline, support for the middle class, shrinking the gap between the poor and rich, improvement of the health care system, economic growth and competitiveness (through transformation to an economy based on innovation), reduction of corruption, scientific and technological progress, environmental protection, and resource conservation. The list gives a clear non-military emphasis to security similar to earlier concepts and also to the preferred approach of President Medvedev. Even though it would be an exaggeration to attribute the strategy of 2009 to the President it can be taken for granted that his priorities were set against those of others. There could be another reason for focusing upon internal issues rather than searching for external adversaries: This timing was passed just a few months after the new US administration of Barack Obama came to office. A confrontational tone would have been counterproductive whereas enthusiasm about a new era of cooperation would have been premature and thus unfounded.

This did not mean that Russia did not put forward a list of external threats. It contains neither new elements nor is it novel in its formulation. NATO's eastern enlargement, or more accurately, the moving of the military infrastructure of the Alliance closer to Russia's borders, is of primary concern. Russia clearly focused more on immediate regional concerns than on global ones. Its aspirations are also clear to end the bloc confrontation, to search for creating a multipolar world, and a multi-vector diplomacy. As a lasting element of its foundation, Russia intends to be a regional power in the former Soviet space. It certainly means leadership without hegemony – the latter, a word thoroughly avoided in this concept. On this basis Russia wants to be an independent centre of power in a multi-polar world.

The drafting of the National Security Strategy went in parallel with the development of a new framework of Russia's European policy. The European Security Treaty initiative associated with President Medvedev's inception to power was a vaguely defined concept. It took the form of a few passing remarks of the President of Russia and the initiative was only made more specific on the insistence of Russia's partners who were willing to seriously consider it. It is important to pay attention to it as it reflects both Russia's perception of the international environment as well as its own influence and possibilities to shape it. Taken together, the initiative aims at reconceptualizing the opposition of Russia to the changes that occurred during the last decade (Dunay/Herd 2010). There could be eight reasons behind it, five on the substance, and three tactical ones.

With regard to the substance of the initiative:

1. It is the single most important element of the initiative to stop the further change of the *political status quo* in Europe, and where it has changed to the disadvantage of the Russian Federation, to reverse it. This is particularly the case with respect to the results of the so-called colour revolutions, the establishment of western oriented regimes in the former Soviet area, which are reluctant to pay sufficient attention to Russia's position and concerns.
2. It is to guarantee the respect for certain principles of universal international law and to suppress some others. States in the Euro-Atlantic area should focus on sovereignty and the prohibition of the threat and the use of force. The right to self-determination should in fact be excluded, particularly regarding the creation of new states.
3. Certain organizations of the post-Soviet space, notably the *Commonwealth of Independent States* (CIS) and the *Collective Security Treaty Organization* (CSTO), should gain international recognition in the West.
4. The Russian dissatisfaction with the long-held asymmetry between various dimensions of the OSCE should be rectified. Namely, more attention should be paid to the politico-military dimension and significantly less to the human dimension, particularly to the democratic transformation and election monitoring.
5. European arms control should be revived.

Furthermore, it referred to three tactical reasons:

1. Test the position of Russia's main European partners and the USA with particular emphasis on the new US administration.

2. Position Russia through conceptualizing its dissatisfaction with the evolution of the European security architecture and the political context during the last ten years, since the late 1990's.
3. Present the new President as a political actor internationally and offer a combination of continuity and discontinuity. The initiative has been composed of elements which were present in Russian policy during the Putin presidency, or emerged during this period. However, the framework in which they were presented was somewhat novel.

The Russian Federation was apparently interested in getting feedback to its concerns to regain the initiative in international security and to establish the process where it has superiority due to the fact that the exchanges would be organized around its initiative. The process thus could have been more important than the outcome. It seems that it was neither urgent nor particularly important for Russia to formulate its position in a draft treaty. Finally, after mounting pressure from its Western partners, Russia put forward a draft treaty that has summarized many elements of the initiative.[14]

According to Article 1 of the draft treaty text, "security measures taken by a Party to the Treaty individually or together with other parties, including in the framework of any international organization, military alliance or coalition, shall be implemented with due regard to security interests of all other Parties". This article faces the problem: What does 'due regard' mean? Does it mean subordination of organizations like the EU, NATO, and the CSTO to a collective body of the states parties? If it does, this may well jeopardize the activity of any such organization/alliance/coalition or may well mean constant violation of the Treaty if the parties decide to act (out of necessity) through their institutions and disregard the objection of the other party(ies). This element of the draft closely resembles the differentiation of the Yeltsin-Kozyrev era on dividing institutions into 'mandating' and 'mandated' ones (the former being the UN and the OSCE, the latter NATO and the EU). As the CSTO has not established itself as an organization of similar weight to NATO, there is no 'tit-for-tat' here. Leaders of NATO member states may not yet see any major advantage in curtailing the freedom of action of the CSTO by the same article that would apparently curtail the freedom of NATO.

According to Article 2 "decisions (...) taken in the framework of (...) alliances, coalitions or organizations do not affect significantly [the] security of any Party or Parties to the Treaty". On this basis there is a wide range of possibilities to interpret practically any action of any organization as 'significantly affecting' the security of other parties. As the EU and NATO have well-established enlargement policies based on membership criteria and a declared open door policy, it is difficult to imagine that member states would be ready to expose it to the mercy of non-members. Furthermore, the text is highly ambiguous. It actually reminds of the text the former Soviet Deputy Foreign Minister Yuliy Kvitsinsky brought to capitals of East-central Europe in the spring of 1991 when the new friendship and cooperation treaties were negotiated with the Soviet Union. There it was Moscow's idea that no party to the (bilateral) treaty would join any alliance directed against the interests of the other party. The question emerged immediately during the talks, who would decide which alliance was 'directed against the interests of the other party'. If the party willing to join an alliance herself would do it, that would be 'auto-interpretative'. If the other party, then it would result in endless dispute as far as the legality of such a step. This idea was then soon taken off the negotiating table and there is no reason to assess the situation differently now.

Some other parts of the draft treaty are more difficult to object to. The prohibition to "use the territory of a state party with the purpose of carrying out an armed attack against any other Party (...)" belongs to this category, as the text goes in parallel with the definition of aggression adopted by the United Nations General Assembly back in 1974 (resolution 3314) that was endorsed by every OSCE member state. It is unclear whether this prohibition would also apply to such measures as hosting elements of a ballistic missile defence system on the territory of another party; a measure that could be regarded as fully defensive by some and offensive by others as it would weaken the second strike capability of a state and thus could undermine deterrence.

According to Article 10 of the draft, the area of application of the Treaty would be "the Euro-Atlantic and Eurasian space from Vancouver to Vladivostok". This is an ambiguous definition as it does not make it clear whether it extends exclusively to the current participating states of the OSCE or whether, for instance, the People's Republic of China could also participate in it. The ambition of the original initiative to extend its purview to several institutions which are active in

14 Dimitry Medvedev: "Treaty on European Security"; at: <http://eng.kremlin.ru/text/docs/2009/11/223072. shtml>.

the Euro-Atlantic area has been retained. One of them is all-European (OSCE), two are 'western', the EU and NATO, and two are 'eastern', the CIS and the CSTO. This reflects the long held ambition of Russia to give similar recognition to organizations which operate in the former Soviet area as to the somewhat better established Western ones. The Council of Europe is missing from the list, what raises the question whether it is not regarded as part of Europe's security architecture. Also the *Shanghai Cooperation Organization* (SCO) does not appear in the same capacity. The absence of the SCO from the draft may offer an indirect answer concerning the participation (or rather the non-participation) of China in the draft treaty.

It remains to be seen whether the draft treaty will generate sufficient support to start exchanges or it will be absorbed by other processes and fora. The first reaction of the US administration that followed the publication of the draft treaty text by two months recognized some merits of the initiative but emphasized its reservations as far as the process is concerned:

> the Russian Government under President Medvedev has put forth proposals for new security treaties in Europe. Indivisibility of security is a key feature of those proposals. And that is a goal we share, along with other ideas in the Russian proposals which reaffirm principles of the Helsinki Final Act and the NATO-Russia Founding Act. However, these common goals are best pursued in the context of existing institutions, such as the OSCE and the NATO-Russia Council, rather than by negotiating new treaties, as Russia has suggested – a very long and cumbersome process.[15]

In early 2010, Russia finally adopted a new military doctrine (Doktrina 2010).[16] With this Russia has recently adopted documents on all major elements of the country's external relations and also on a broad range of its internal security. The military doctrine, compared to the one adopted a decade ago, does not refer to the 'defensive nature' of the doctrine. Those who have drafted similar documents know well that the differences between them are often due to inadvertent mistakes. That may also be the case this time.

Military threats and dangers are characterized as follows: The ideological confrontation declines, the economic, political and military influence of certain states (and group of states) weakens, while the influence of other ones that claim global domination is on the increase. Regional conflicts continue to be resolved by the use of force. The international security architecture does not provide equal security for every state. But the likelihood of a large-scale war against the Russian Federation with a global domination is unlikely.

The doctrine lists 11 external military dangers. Among them "the attribution of global function to the force potential of the North Atlantic Alliance (NATO) in violation of international law, the approach of the military infrastructure of NATO member states to the borders of the Russian Federation, including through enlargement" is mentioned first. The importance thus attributed to the Atlantic Alliance demonstrates that Russia declares its popularized threat perception. The further ones include the following: 1. Attempts to destabilize certain states and regions and undermine strategic stability; 2. Deploying military contingents of foreign states on the territory of countries bordering the Russian Federation; 3. Establishing and deploying strategic anti-missile defence system that undermines global stability and violates the current ratios in the nuclear rocket forces; 4. Territorial claims on the Russian Federation and its allies, interference into their domestic affairs; 5. The proliferation of weapons of mass destruction missiles and missile technology; 6. The violation of international agreements and arms control agreements concluded earlier; 7. The use of military force on the territory of states neighbouring the Russian Federation, the violation of the UN Charter and other norms of international law; 8. The emergence of military conflicts and their escalation on the territory of states neighbouring the Russian Federation and its allies, on the territory of states neighbouring the Russian Federation; 9. Spread of international terrorism; 10. The emergence of inter-ethnic and inter-confessional tension, the activity of radical international armed groups in the vicinity of the borders of the Russian Federation and its allies, territorial conflicts, the growth of separatism and religious extremism. It is clear that the list cannot claim a high level of cohesion.

The list of military threats is less exhaustive, though not particularly accurately defined. It is clear that Russia regards every 'hostile' military presence and activity in its neighbourhood and the neighbourhood of its allies adversarial, as well as the activity of

15 Hillary Rodham Clinton: "Remarks on the Future of European Security", in Paris at L'École Militaire, 29 January 2010; at: <www.state.gov/secretary/rm/2010/01/136273.htm>.

16 "Voyennaya Doktrina Rossiyskoy Federatsii", 5 February 2010; at: <http://www.scrf.gov.ru/documents/33html>; "Russian Military Doctrine"; at: <http://www.globalsecurity.org/military/world/russia/doctrine.htm>.

illegal military formations on the territory of the Russian Federation.

In the framework of strategic deterrence, Russia claims the right to use nuclear weapons in reaction to the use of nuclear weapons or other types of weapons of mass destruction against the Russian Federation and/or its allies. It is a novel addition that Russia is also ready to use nuclear weapons if conventional weapons are used against it, and the existence of the state is endangered. This latter formulation is important as the advisory opinion of the International Court of Justice back in 1996 added a very similar condition to the exceptional, legitimate use of nuclear weapons.

14.3 Russian Security Policy Practice: From the Protection of Sovereignty to the Protection of Influence

The 21st century, as outlined above, started with great troubles for the Russian Federation. The first one was an imminent threat to the state's territorial integrity. The second Chechnya War, irrespective of how ambiguous the circumstances that led to its breaking out, was a conflict Moscow had no choice but to fight. It could not afford not to fight a war that threatened its territorial integrity. There could be two somewhat interrelated reasons:

1. The eventual danger of a spillover to a largely destabilized North Caucasus could be one reason why Russia felt compelled to react in the strongest possible terms to the challenge against its sovereignty.
2. No great power can afford to face a challenge against its territorial integrity as it would indicate that its great power status is in jeopardy. Russia, in a large-scale military confrontation gained superiority and could consolidate its rule over there.

However, it is important to point out that even though Chechnya is still not under the full control of Russia, it is no longer a secessionist territory. This is a major success of Russian security policy even though not of the Russian armed forces. Russia had an enormous concentration of heavy armour and used massive force. Despite it, Russia arrived at military victory painstakingly slowly. Moreover, Russia had to realize that its regular forces based on conscription were of extremely doubtful value. It was not surprising that first it gradually replaced them by contract soldiers and then by interior ministry troops. It is also a difference compared to the aftermath of the first Chechnya War of the mid-1990's that Russia in the early-21st century was much better organized and had more to offer to the North Caucasus than in the mid-1990's when the first Chechnya War was fought. Furthermore, Russia, in difference from the first Chechnya War, also addressed the post-conflict phase and started some peace-building after ending the military operation. This complex approach has already paid off and may also pay off in the long run. The counter-insurgency operation in Chechnya was formally terminated only in 2009. However, the stabilization of Chechnya[17] did not result in a general stabilization of the North Caucasus (Melvin 2007). Security threats emanating from terrorist activities and more broad ranging instability continue to prevail from Dagestan to Ingushetia, North Ossetia, and beyond. One could conclude preliminarily that the reduction of the conflict level in Chechnya went in parallel with the spread of terrorism in the North Caucasus unrelated to events in Chechnya.

Russia was still fighting in order to bring Chechnya into submission when the international environment changed fundamentally due to the 9/11 terrorist attacks against the USA. Having emphasized the importance of cooperation in fighting terrorism, Russia found the moment opportune to reaffirm this by its positive attitude to counter-terrorism and offered its collaboration to the USA. In turn, it was expecting American support to its own counter-terrorist activity, in particular in Chechnya. Reciprocity was hesitant and partial at best. Some were more willing to regard the Chechens fighting for their self-determination rather than Russia fighting terrorists. In the end, throughout the first decade of the 21st century Russia was disillusioned as far as the West's reception of its counter-terrorism policy and the activity in the North Caucasus were concerned. More broadly, a narrow path remained between Islamic radicalism, separatism, and terrorism in the policy of the West, and hence its reaction to Russian behaviour remained varied. Double standards often prevailed. Priority to zero sum games over stability prevailed in the attitude of some Western powers. Right after 9/11 the Russian Federation thought to have brought its entry to a point of reconciliation with the USA, and through it with the West. Having been halfway turned down by

17 The recognition of stability in Chechnya does not mean the approval of the means used by the Kadyrov leadership or its predecessors for stabilization.

the West, the Russian Federation understandably felt disenchanted. That impression fed into a larger list of grievances.

The Putin presidency started after the NATO war against Yugoslavia (Serbia and Montenegro) between March and June 1999. Moscow regarded that war as a 'loss of western innocence'. Russia faced the next large-scale Western war in 2001 when the USA and some of its allies reacted to 9/11 by initiating regime change in Afghanistan. Russia was not in the position to object to it, among others as the underlying case was a *prima facie* case of harbouring terrorists on the country's territory and hence a case of fighting terrorism. Furthermore, Russia had to remain mute for two additional reasons:

1. Its predecessor, the Soviet Union, invaded and occupied a large part of Afghanistan between 1979 and 1989.
2. It has been aware that a failure to eliminate Taliban rule and hence the continuing symbiosis between the Afghan government and al-Qaeda would carry severe risks on Russia due to the vicinity of that country to Russia, as well as neighbouring on three successor states of the former Soviet Union.

Two of the three (Tajikistan and Uzbekistan) are members of the *Collective Security Treaty Organization* (CSTO), a regional grouping addressing security matters. It is clear that the Russian Federation plays a prominent role in that organization. Hence, the spill-over of instability from Afghanistan to its northern neighbours would further undermine security also for Russia. Over the years Tajikistan has also developed a bilateral strategic partnership with Moscow that would result in a direct impact upon Russia if the West cannot contain the further destabilization of Afghanistan.

In post-9/11 Afghanistan Russia took a hesitant, in light of current Russian policy one may say, a pragmatic position. Memorably, back in 2001, Russia itself transferred weapons and ammunition worth US$ 140 million to the so-called Northern Alliance and also helped with military advisers. On the one hand, it has been cooperating with the West, and specifically with NATO, to resupply troops in Afghanistan through Russian territory even if not by weapons proper. This has been a demonstration that Russia was well aware of the importance of its cooperation with the West to keep the situation under control to whatever extent possible and prevent the eventual horizontal escalation of the conflict. On the other hand, however, Russia both bilaterally and multilaterally contributed to appeals that invited 'extra-regional' countries to leave Central Asia as the Afghanistan operation was coming to a close. First, Russia and the People's Republic of China called on the extra-regional member states present in Afghanistan. Just a few days later, the Shanghai Cooperation Organization considered the same necessary.[18] It was certainly not only the perception of the Afghan operation coming to a close that was unfounded and the conclusion wrong. It also served for a purpose to indicate Russia regarded Central Asia as its backyard where it found Western military presence unwelcome.

Contrary to Afghanistan where Russia faced difficulties to establish an unambiguous position, it was much easier in the case of the next military action of the United States and some of its allies. The rhetoric that the Bush administration used before the military intervention against Iraq left no doubt that it was ready to go alone if other major players do not play along. The USA was ready to apply military 'sanctions' irrespective of whether the UN Security Council would support them or not. The events followed that pattern. For Russia this was troubling in multiple senses: First and foremost as the unilateral action of the USA denied the monopoly of the Security Council to decide in such cases. Russia is a very strong advocate of the UNSC, where its position is extremely strong on the basis of the UN Charter. The evidence provided to legitimize the military action was not particularly convincing. However, it was probably most important for Russia that the issue went beyond the concrete case. It was measuring the limits of unilateralism. For Russia it was clearly unacceptable that major international contingencies would, as a rule, be decided unilaterally. This has strengthened the conviction of the Russian leadership that it should put the demand of a multi-polar world order in the centre of its international politics. It has in fact put this claim in the centre and continues to base its policy on it now and for the foreseeable future.

Russia was by far not the only opponent of the US intervention in Iraq. There were many other countries that had strong reservations, including France, Ger-

18 Just a few days later, the summit meeting of the *Shanghai Cooperation Organization* (SCO) issued a very similar appeal according to which: "respective members of the antiterrorist coalition set a final timeline for their temporary use of the above-mentioned objects of infrastructure and stay off their military contingents on the territories of the SCO member states".

many, and China. Russia joined them and believed it formed part of a new multilateral coalition that objected to the intervention. It resulted in even more disenchantment for Russia. The anti-Iraq War coalition was confined to that event and did not result in a lasting rearrangement of allegiances.

Beyond the prominent conflicts, Russia also faced challenges as far as the broad area of arms control. The United States, and in some cases the West more broadly, has been ignorant as far as the arms control *acquis* and ignored Moscow's insistence on the continuation of arms control in those traditional areas where it developed during past decades. Russia wanted to continue arms control for three main reasons:

1. Russia was of the view that arms control may continue to make a useful contribution to strategic relations.
2. Russia, that noticed its declining importance during the 1990's, found this area where it could establish and prove its status and demonstrate its prestige as a major player, later as a pole of the international system.
3. An experienced Russian arms control establishment wanted to regain its political importance inside the national administration. In spite of Russia's efforts, arms control did not regain its once enjoyed status, and not without reason.

For the unipolar power of international security (if not of the whole international system) there was no narrowly defined security reason to pursue arms control any longer.[19] The USA, with a passive acceptance of other Western powers, has taken a pragmatic stance and replaced arms control with non proliferation. This meant moving from Russia as the main partner and refocusing attention on certain Asian countries from North Korea to Iran through India and Pakistan. No negotiations beyond SORT were pursued after the termination of the ABM Treaty and the (re-)launch of ballistic missile defence. Multilateral arms control in Europe was interrupted and taken hostage to an originally legitimate, later increasingly counter-productive US-NATO policy. Overall, Russia felt to have been downgraded and marginalized in its traditional comfort zone. The Western policies taken together, ranging from the management of burning conflicts to armed conflicts overall, gave the impression to Russia of unilateralism of the West and the systematic disregard for Moscow's interests.

In the previous cases Russia's security policy was reflective of actions of other major actors, first and foremost of the United States and the West more broadly. However, there were other areas where Russia took the initiative and shaped the international agenda. The Russian Federation has become a status quo power not long after the dissolution of the Soviet Union. Protecting the territorial and the political status quo was an adequate reflection of the significant weakening of Russia's position compared to its predecessor state. In such a situation any reasonable actor of international politics would follow that line. During its decline it has been a realistic objective to prevent its continuation and stabilize what the state is left with. Already in the second half of the 1990's, during the second term of President Boris Yeltsin, Russia made an effort to consolidate its situation internationally. However, objective reasons were not favourable at that time.

The enrichment of Russia both preceded and was going in parallel with the consolidation of the government and the recentralization of political power. These factors have increased the country's appetite. Russia was also aware that its international influence and status beyond domestic consolidation depended on a sphere of influence that was ready to follow its leadership. For Russia there was only one region that it could count on in such a capacity: the rest of the former Soviet Union. Except for the three Baltic States; Estonia, Latvia and Lithuania, the successor states of the Soviet Union were connected by multiple ties ranging from economic to ethnic and cultural links. The Russian leadership, following its inattention in the second half of the decade, by the turn of the century recognized the strategic importance of its backyard. For a while it seemed Moscow retained its monopoly in the post-Soviet space and no other influential players competed for influence over there. The few exceptions remained strictly limited to matters like building alternative oil transport routes not crossing the territory of the Russian Federation, like the Baku-(Tbilisi)-Ceyhan pipeline. Compared to its predecessor, the more assertive position of the Putin administration and its determination to establish its leadership and control in the former Soviet area collided both with the aspirations of some other great

19 See the "Declaration of Heads of Member States of Shanghai Cooperation Organization", in Astana, 6 July 2005; at: <www.sectsco.org/en/00500.html>. The George W. Bush administration pursued an arms control policy based on a narrow definition of its objectives. It considered exclusively the desired outcome, the agreements to achieve, rather than the process that it could entail for political reasons.

powers and in some sense their coalition, like the EU and the perceived interests of some successor states themselves.

There is some tendency in the world at large, primarily in the West, to be extremely critical of Russia's conduct in the former Soviet area. The criticism is certainly not unfounded. It is necessary, however, to take a fresh look and differentiate between various types of Russian actions. Some did not take the form of action beyond the normal persuasion of partners. Some took the form of economic incentives and coercion, others blackmail and intimidation. Last but not least in one specific case, Russia, in support of secessionist forces, used armed force against a successor state, namely against Georgia in 2008. One could conclude that the relationship of Russia with the Soviet successor states applied the entire spectrum of means of international politics demonstrating the intensity and the complexity of relations. Bearing in mind the level of interdependence among the successor states of the Soviet Union, this is fully understandable. The seventy (and in some cases including the history of Tsarist Russia many more) years that these countries spent together in one multinational (federal) state created economic and cultural interdependence including a national mix. Here, it is necessary to emphasize that Russia, which had the upper hand vis-à-vis each and every other country of the region, certainly demonstrated some level of intolerance and often relied on those traditional means of great power politics that its predecessor often used in the so-called socialist countries throughout the decades between the late 1940's and the mid-1980's. Sometimes Russia has not given indication of its experience with democratic politics in international relations. Overall, the record it has established is very mixed and may result in raising doubts about Russia as a power representing different political culture from the Soviet Union in its international behaviour vis-à-vis weaker states in its region. Contrary to many fields presented earlier where Russian policy was reflective upon the activity of other major players of international politics, the situation was different in Russia's neighbourhood. Although, understandably, the activity of others had influence on Russia there as well, the Russian Federation took a proactive stance based on its desire to return and shape, if not outright determine the international politics of the area.

If one takes a closer look, the Putin era gave demonstration of the reliance on means available to a country that has increased its power base and has become increasingly assertive. The fact that Russia collided with some major players of international politics, first of all with the United States in its neighbourhood, added to its determination. It would be unfounded, however, to draw the conclusion that Russia played a similarly reactive role here as in other fields of international politics. It would be interesting to imagine how Russia would have reacted had some states of the post-Soviet space declared their willingness to pursue a Western-orientated policy without this being condoned by the West. Most probably, Russia may have acted very similarly to its actual behaviour. Due to the importance of its post-Soviet neighbourhood, Russia is of the view that it cannot relinquish its authority. This included claiming the right to curtail the freedom of other post-Soviet states to choose their political course and their international allegiance.

During the first decade of the 21st century the Russian Federation aspired to consolidate its leadership role in the former Soviet area. This seemed possible in the beginning of the century. There was no state in the region which was openly and fundamentally opposed to the course represented by Russia and its leadership. It would be wrong, however, to assume that there were no controversies in the post-Soviet space. They remained fairly easily manageable, however. This was partly due to the fact that not even those states which had aspirations different from the Russian Federation presented a major challenge. First of all because their aspirations, like joining the EU and/or NATO, were not credible and hence were not supported by those Western states and institutions that were the indispensable partners of those countries. The half-hearted attempts of Ukraine to get closer to the EU or the only multilateral cooperation framework of Georgia, Ukraine, (Uzbekistan), Azerbaijan and Moldova (GU(U)AM) that was measured on its distance from Moscow are cases in point. Declaratory Western orientation until the beginning of 2004 was nowhere in the former Soviet area backed by sustainable governmental policy. (Melvin 2007)

The situation has changed when the colour revolutions took place in Georgia and in the Ukraine. It made the alternative thinking of those two states credible and easier to support. Furthermore, the George W. Bush administration very early broke away from the idea of the Clinton administration's 'Russia first' policy. With the colour revolutions the USA (and to lesser extent Western Europe) soon found two post-Soviet states worthy of support in their transformation. The external support to the now fundamentally changed regimes upset the earlier balance.

Russia demonstrated its difficulties to react in a measured and sophisticated manner to those processes. It became apparently part of the domestic policy of Ukraine, openly supporting some political forces against others. Irrespective of the complexity of the situation, including the internal division of Ukraine and Russia's stakes ranging from deep-rooted economic interests to the situation of the Russian ethnic minority through geostrategic considerations, it was certainly unwise to take sides so clearly and carelessly in a neighbour's domestic policy. This could also be regarded as a demonstration that Russia 13 years after the end of the Soviet Union still had difficulties in recognizing the independence of another Soviet successor state.

After the so-called Orange Revolution, Russia continued on an often confrontational path with Ukraine. This took various forms of coercion with particular reference to energy matters. There Russia contributed to a series of crises. They have followed the same pattern. Russia changed the price of gas supplied to Ukraine. Ukraine also had a certain often major role in the matter due to its unreliability as a transit country and as a customer with a not entirely reliable payment record. In the end, Russia did not succeed in demonstrating to the world at large that it did not use its energy wealth as a political tool, not to mention as a weapon.

Russia as well as Ukraine had to remain careful to manage their energy affairs as all this happened in front of an eagerly watching West. Namely, Western European countries wanted to see clearly who was to blame: Russia or Ukraine. If the former, the conclusion could be drawn that Europe has to diversify its gas import and reduce the dependence on Russia. If, however, Ukraine was to blame for sniffing gas out of the pipeline system to satisfy its own consumption needs and for its lack of financial discipline to pay for the gas it has consumed in time, then those Russian and other efforts which aim at the reduction of dependence on the Ukrainian gas transit infrastructure may well be sufficient. Consequently, gas pipelines, like Nordstream and Southstream, based on Russian gas delivery without Ukraine's involvement as a transit state may be the solution. If there is reason to assume that both Moscow and Kiev have contributed to the three crises in the winters of 2005, 2006 and 2009, then it is not only necessary to reduce dependence on Ukrainian transit but also on Russia as a supplier. That is the intention of the planned Nabucco pipeline system. These are technical solutions for a set of larger problems. Namely, Russia will continue to use its rich energy resources in its external relations. Due to the long-term supply-demand asymmetry the world will have to rely on Russia as an energy supplier. As long as the current constraints characterize the gas markets of the world with particular emphasis on Russia (most Russian pipelines head to Europe from Russia, the liquefied natural gas supply infrastructure is underdeveloped and some potential Asian consumers, first of all China, buy gas at a much lower price than Europe), there is no imminent reason to worry. The situation cannot be described as unilateral dependence of Europe on Russian gas, much more as interdependence between Russia and Europe. This may give sufficient leverage to the European customers particularly if they coordinate their stance more closely than in the recent past. In the longer run, however, the global energy balance gives ground for concerns as hydrocarbon suppliers, due to the relative shortage of resources, will have the upper hand. Then it will be decisive whether the West is united and whether it has a strategy to diversify its energy consumption both as far as the source, relying more on other energy resources and also geographically. The Russian activity in the energy field in the first decade of the 21st century has attempted to reassure the West and divide it at the same time while being firm with its partners in the former Soviet area. This attempt could not be fully successful but did not fail entirely either.

The Russian-Ukrainian relationship since the Orange Revolution has remained troubled as Moscow wanted to have the upper hand in various areas that the post-Orange leadership strongly opposed. Nevertheless, Russian firms gained significant influence in the Ukrainian economy. Furthermore, Ukraine could not build a strongly pro-Western policy and downplay Russia's importance as this would not have been supported by a very large part of the population and the political elite. Not to mention that western support for Ukraine could only be reflected in an eventual integration in the very long run if and when the attitude of the population were to change one day. Hence, Russia has succeeded to reassert its influence vis-à-vis a disunited and malfunctioning Ukraine. Thus, it has indirectly demonstrated that the successor states of the Soviet Union should seriously consider its perceived security interest and its position when deciding upon their political orientation and international aspirations. President Medvedev's August 2009 message anticipated that relations would improve between Russia and the Ukraine after the January-February 2010 Ukrainian presidential elections.[20] It is clear that

the Russian vector of Ukraine's international relations will remain of primary importance.[21]

The other troubled relationship that is worth mentioning here is between Georgia and Russia. Georgia was the first country where a colour revolution occurred. The new, Western-educated and Western orientated Georgian President Mikheil Saakashvili put the unification of the country very high on his government's agenda the moment he came to power. This aspiration planted the seeds of a conflict as in three areas of Georgia (Abkhazia, Ajaria and South Ossetia) puppet regimes took control since the first half of the 1990's that existed due to the mercy of Moscow. In the case of Ajaria that was not adjacent to Russia, Georgia soon achieved success. The small area returned to Georgian rule. When Georgia tried to follow its government's promise in 2006 and made an attempt to achieve the return of South Ossetia to Georgian rule, it collided with Russia and came close to a violent conflict. Russia tried to coerce Georgia by applying a variety of sanctions.

What followed after the so-called Rose Revolution was six years of constant clashes between Russia and Georgia. The former wanted to curtail the choice of the latter, in particular its aspiration of an eventual accession to Western institutions, notably to NATO. The more Russia insisted on that, the more the Georgian leadership emphasized the importance of its NATO membership. The Republican administration of the United States strongly supported Georgia and thus fuelled its expectations. The result was two assertive powers, though in highly asymmetrical positions of strength, trying to implement diametrically opposing agendas and both confident that their security can be guaranteed only if the other does not achieve its goal (Fedorov 2008: 2).

The conflict escalated vertically and gained a more clearly military dimension. A Georgian UAV was shot down in the airspace of Abkhazia (Georgia) in April 2008 shortly after the Bucharest NATO summit that in unambiguous terms offered the prospect of eventual NATO membership to Georgia (and Ukraine): "We agreed today that [Ukraine and Georgia] will become members of NATO."[22]

On 7 August 2008 war broke out between Georgia and Russia. The conflict, though intensive in the tactical sense, remained limited. Georgia was not occupied, and the Saakashvili government was not overthrown. It was Georgia's aim to achieve the return of South Ossetia to Georgian rule. There could have been such forces which were of the view that the conflict was worthwhile as Russia suffered a major propaganda defeat and was identified as an aggressor. Those who contemplated such an outcome did not count on subsequent developments. The results of the five-day war were highly detrimental to Georgia. The two territories, which were *de jure* under Georgia's control, Abkhazia and South Ossetia, have been lost irrevocably. Furthermore, their independent statehood was recognized by the Russian Parliament, the Duma, two weeks after the end of military confrontation. The expectation that Russia would be identified as aggressor was also undermined a year later by the independent international fact-finding commission that was tasked to report to the Council of the European Union. It concluded that the "shelling of Tskhinvali by the Georgian armed forces ... marked the beginning of the large-scale armed conflict in Georgia" (IIFFMCG-CEIIG: 11). It is a separate matter that Western public opinion continues to be convinced that Russia was the aggressor. Russia, that had certainly provoked Georgia before the war in various ways, went to war and came out of it with a positive sum result for itself. It created a new territorial status quo in the South Caucasus as a result of the use of force. This carried the message that force continued to be a useful tool of international politics and could be used for the resolution of territorial conflicts. Russia was fortunate to achieve some gains without being identified as the aggressor. A situation to the contrary would have certainly significantly curtailed the freedom of Western states to return to 'business as usual'.

20 Robert Coalson: "Russia's Message to Ukraine Echoes Across Former Soviet Union", RFERL, 12 August 2009; at: <http://www.rferl.org/content/Russias_Message_To_Ukraine_Echoes_Across_Former_Soviet_Union/1798413.html>.

21 The most eloquent demonstration of the major improvement of Russian-Ukrainian relations has been the extension of the Russian lease on the territory of Ukraine for the Black Sea navy for further 25 years beyond 2017 (until 2042) followed by an optional five-year extension after that term expires. Dmitry Medvedev signed Federal Law On Ratification of the Agreement between the Russian Federation and Ukraine on the Presence of the Russian Federation's Black Sea Fleet in Ukrainian Territory, 21 April 2010; at: <http://eng.kremlin.ru/text/news/2010/04/225721.shtml>.

It has demonstrated as well, however, that the Russian armed forces do not excel even against a significantly weaker adversary. Last but not least, it served as a deterring example for the eventual forceful resolution of other territorial disputes, like the pending conflict between Armenia and Azerbaijan concerning Nagorno-Karabakh.

14.4 Conclusions

Following a decade of weakness, internal chaos, and a set of humiliating experiences with the West, first of all with the United States in the 1990's, it was Russia's main aspiration in the first decade of the 21st century to return to the scene of world politics as a great power and a pole of the multi-polar international order. This was the main underlying factor of its international policy. It identified the United States as representing the main challenge against this aspiration since the USA has established a unipolar international security order and since the late-1990's represented it assertively. Russia was generally less anxious about the fact that even if due to the co-existence of various reasons the world would turn to multipolarity, Russia would face difficulties to establish itself as a pole of the system.

Russia's return would require consolidating its situation domestically, modernizing its economy, and reducing its dependence on the export of hydrocarbons and other natural resources. It would also require guaranteeing that it fights effectively against challenges to its territorial and political integrity. It has achieved a lot in this area; its territorial integrity is no longer challenged. It still has not been able to eliminate domestic terrorism, however.

The international security policy of Russia raised some concerns. In some directions it was rather reactive first and foremost with respect to the United States. It has tried to reverse the adverse change of international politics. This started with the 1999 so-called Kosovo War and continued throughout the decade. There were two areas where Russia took a proactive stance and made sustained efforts to determine the course of international security. These two areas have been energy policy with an emphasis on hydrocarbon export and the post-Soviet space. Activity in these two areas has raised doubts about the goodwill of the Russian state. However, Russia was proactive in the former Soviet area where it was Moscow's objective to determine the agenda of the region. Due to the resistance of some states Russia felt it necessary to impose its will on those others which did not follow it voluntarily. In the area of the former Soviet Union it has claimed nearly exclusive right to gain influence on the behaviour of other sovereign states. This is understandable as Russia very well knows that without decisive influence in "its backyard" it cannot present itself as a pole of the international system. Nevertheless, Russia cannot "draw lines in the sand" and curtail the freedom of choice of other countries. It has to revise its current approach and find a more constructive one. The West, among others in light of its recent experience, will no longer push for the rapid political transformation of Eastern European and Central Asian countries in the post-Soviet space. It is certain nevertheless that some parts of the former Soviet area will remain the least settled and most contested part where Russian and Western interests in one form or the other may collide. Unless the post-Soviet area unanimously recognizes Russian leadership without reservation – a highly unlikely scenario – or the West retreats and thus betrays those in the region who seek modernization and democratization and independence from Moscow.

Russia presented itself as a great power in supplying hydrocarbons. This has been accompanied by an offensive energy strategy. There was no doubt left that energy policy has become part and parcel of the country's external relations. That has raised concerns in particular as Russia did not succeed to demonstrate that it would not rely on its rich resources and the dependence of some countries on them at critical moments. It is possible that Russia gave 'too early warning' about its intentions. This might make its European partners consider options that would reduce dependence on Russia as the single most important energy supplier of Europe. Russia's reliance on energy supply as a political tool illustrates the thesis that states tend to stand on their 'strong leg' in their policies.

Russia, in continuation of the best Soviet traditions, regards its armed forces as a national institution and a matter of national pride. Although Russia achieved victory in those two wars (Chechnya, Georgia) which its armed forces fought in the first decade of the 21st century, in neither case has it demonstrated convincing superiority. It has underlined that Russia could regard itself fortunate that it does not face a more formidable adversary. It has also demonstrated the fact that the increased defence expenditures have not resulted in a breakthrough of performance, yet. This illustrates that introducing an adequate, effective

structure is a precondition of the increase in efficiency.

Russia has been at least partly successful in fighting terrorism. It achieved that North Caucasian terrorists moved away from massive hostage taking and re-orientated themselves to other tactics. The fact that terrorists attack hardened targets in the North Caucasus nowadays demonstrates that the Russian authorities continue to face domestic contingencies they do not fully control.

Russia has partly realized its objective. It is recognized as an important player of the international system and a potential pole of a multi-polar order. In spite of its great power traditions, nuclear arsenal, and energy resources, it is not the strongest among those poles which combine market economy with authoritarian politics. For Russia, in spite of the experiences of the eight years of unipolar politics of the George W. Bush administration, it is not the USA that presents the biggest challenge in the multi-polar system. But it may well be that another major actor of international politics that represents similar combination of authoritarian politics and market economy is, the People's Republic of China. If the USA and China were to head in a direction of bilateral cooperative global management, Russia would have a new difficult reality to face. But in the early 21st century this appears unlikely.

15 Non-Traditional Security and the New Concept of Security of China

Zhongqin Zhao

15.1 Introduction

With progressing globalization after the end of the Cold War, the *national security concept* (NSC) has experienced new situations and has faced new challenges. Globalization, as an important variable affecting national behaviour around the world, has deeply influenced the people's understanding of national security to adopt a new perspective in addressing NSC issues, thus initiating relative changes in the NSC. On this background the Chinese government adopted a new security concept based on mutual trust and benefit, on equality and cooperation. Based on this guidance, the Chinese government launched diplomatic moves for a new security environment in the 21st century.

15.2 Towards a Comprehensive Security Concept

During the Cold War period, the security concept was interpreted narrowly to mean territorial security against external aggression and to maintain national independence. Then the attention focused only on military and political security. Since the end of the Cold War, the security problems facing each nation have become more complicated. The definitions of security have changed and gradually a comprehensive security concept emerged. Related notions of 'economic' and 'ecological security' were advocated. The means for realizing security are gradually turning from 'zero-sum' considerations to 'win-win' situations. The thinking shifted from confrontation, contradictions, and conflict among nations to seeking cooperation and common ground to overcome the 'security dilemma' while differences remain. In accordance with changes in security bodies, the security content and the means for realizing security, i.e. 'absolute state sovereignty' has been severely undermined due to globalization, and this has changed the way of safeguarding a nation's sovereignty.

15.3 China's Evolving New Security Concept

Globalization and non-traditional security problems resulted in a new security concept. Non-traditional security issues are increasingly posing new threats. As a consequence, changes have occurred in basic concepts of international and national security. This requires modifications in the theories of security, of the causes of security threats, and regarding the means to safeguard security. Mutual trust, mutual benefit, equality and cooperation have been fundamental for China's new security concept.[1] In dealing with non-traditional security, China's new security concept has been deepened and enriched since the early 1990's by globalization and non-traditional security. 'Comprehensive security'[2] is the key characteristic of present security, and 'common security'[3] is the ultimate goal for safeguarding security while 'cooperative security'[4] is the effective way of its implementation.

Since the end of the Cold War, non-traditional challenges for the security of nations and human beings have increased. The concept of non-traditional security has been widely used in international politics and international relations. Major countries tabled

1 See Jiang Zemin's speech on 1 July 2001 in honor of the 80th anniversary of the foundation of the Communist Party of China

2 On comprehensive security see Zhu Yangming: *On the Asian-Pacific Security Strategy* (Beijing: Long March, 2001): 132–134.

3 On common security see Zhu Yangming: *On the Asian-Pacific Security Strategy* (Beijing: Long March, 2001).

4 Cooperative security is defined as seeking security through cooperation. See Zhu Yangming: *On the Asian-Pacific Security Strategy* (Beijing: Long, March 2001): 134–135; Ren Xiao: *From Collective Security to Cooperative Security* (Beijing); Zai Ren Xiao, *New Horizon Theory of International Relations* (Beijing: Long, March 2001): 182–193. Essentially, the definition of cooperative security takes the concepts of common security and comprehensive security as its basis.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_15, © Springer-Verlag Berlin Heidelberg 2011

new security concepts, such as 'comprehensive', 'common' and 'cooperative security'. Since the Asian financial crisis in 1997, China gradually developed the basic idea of its new security concept where 'comprehensive security' is crucial. 'Common security' is the ultimate goal and 'cooperative security' is the effective way of safeguarding international peace. China has combined its new security concept with the principle of mutual trust, mutual benefit, equality, and cooperation.

15.3.1 Features of China's New Security Concept

China's non-traditional security concept has the following features. *First*, it stresses the diversity of actors. The new non-traditional threats come from non-state actors, such as individuals, organizations and groups, not always from a country. *Second*, many new security threats are transnational with regard to their causes and possible solutions. They refer to no specific problems in a certain country, but to problems that are possibly related with benefits for some countries or human beings. This does not only threaten the security of an individual country but also, to a degree, the national security of other countries. *Third*, China's understanding of non-traditional security stresses the uncertainty and changeable nature of 'soft' security problems. Soft security always has changing elements which are not only interchangeable with traditional security threats but also related to other policy fields. *Fourth*, China's non-traditional security stresses the non-military nature of security, which does not directly threaten the country with military measures but is related to a combination of economic problems, environmental deterioration, cultural acknowledgement, and social system and conventions. These factors may threaten regional stability and the security of human beings. *Fifth*, China wants to resolve these non-traditional security problems through international cooperation and coordination. These non-traditional security threats overcome the so-called 'prisoner dilemma' and the antagonistic 'zero-sum' relationship and promote cooperation among each other. *Sixth*, China's non-traditional security concept stresses the security of human beings and takes the existence and development of humankind as the core of its soft security concerns.

Since the early 1990's the Chinese government has formulated its new non-traditional concept of security. Globalization creates social and environmental problems affecting the existence and development of human beings across the borders and regions. They become a common threat to humankind. These widespread transnational security problems can neither be solved by an individual or a country, nor with military means. The Chinese government maintains that comprehensive measures and cooperation should be pursued by the international community and that a new security concept is needed to solve these global problems.

This new security concept differs from the traditional security concept. *First*, in the traditional concept 'national security' is placed in the centre, being mainly confined to the security of the country. Every country perceives other countries as potential threats to its security and as elements of its reality. However, this new security concept emphasizes that the problems of non-traditional security are related to human beings and to the security of peoples. In addition to pursuing its own security, each country should take the security of other countries and of the international community into account; otherwise there will be no security of its own. The non-traditional security approach creates common benefits based on this new common security concept. The traditional security concept focuses on military security, while the new security concept includes economic, social, environmental, and cultural security dimensions besides the narrow traditional military security, thus making it a comprehensive security concept. *Third*, the traditional concept of security stresses the formation of military blocs based on zero-sum games on issues of life and death, while the new security concept stresses the establishment of new organizations, mechanisms, and new ways of cooperation. *Last but not least*, the traditional security concept addresses how to deal with the threats, while the new security concept stresses how the threats can be prevented from occurring.

Comprehensive security is the basic feature of the present security concept. During the 1980's the security concept gradually widened to include economic and environmental issues. Since the 1990's, comprehensive security expanded from the military to other fields, and in the early 21st century the security concept comprises military, economic, and environmental dimensions. Non-traditional threats and traditional security problems can be easily intertwined and cause tensions in international relations and turmoil in some regions. Whenever the government of a country addresses traditional security, e.g. military defence, it is expected to express concern for other threats to security such as the environment and economy and social problems. Common Security is the ultimate goal

to safeguard international security. Globalization creates more common benefits for each country as countries depend more on each other. The global crises confront each country with common shocks and challenges. Thus, countries are closely related to face these new security dangers. The international community should seek common security where cooperative security offers an effective way to safeguard international security. Non-traditional security is related to a wide range of problems, including security issues of the economy, finance, culture and society, which cannot be easily settled merely by using military measures. In order to deal with these new threats, efforts should rely more on joint multilateral mechanisms and on the involvement of the international community. Thus, to deal with non-traditional security threats in the era of globalization, regional and international cooperation are required as an effective way to cope with these new problems. The security of human beings is the focus of attention of this new security concept. It includes the right of existence by averting starvation, diseases, war and natural disasters, and it also implies the right to seek better living conditions and a healthy environment, which are core values of this new concept of security.**t**

15.3.2 Implementing China's New Security Concept

This new concept of security requires the establishment of mechanisms at three levels of the state, the region, and the globe. From the national perspective each country should improve and optimize the mechanisms to guarantee the comprehensive security of its citizens. It should a) consolidate the construction of legal systems, b) improve its social security system and the mechanism for the allocation of social resources, c) coordinate the benefits of different regions and groups, d) establish the preventive mechanism, and e) propel the society to develop in a comprehensive manner. From the perspective of regional cooperation, the neighbouring countries have a better understanding as they face certain problems of non-traditional security and as it is easier for them to establish the cooperative mechanisms. Therefore, the regional cooperative mechanism is an effective way to solve non-traditional security, as a necessary and fundamental complement. From the perspective of multilateralism, the governments and some NGOs cooperate with each other on some issues of common interest and establish a series of cooperative mechanisms which are good for information exchange, coordination, and for having a sense of common interest. It is also beneficial for creating the basis for cooperation and providing support for each other on some key issues at critical moments. From the global perspective, the UN and other international organizations can solve common issues and conduct international exchanges.

China is an active initiator and promoter of this new concept of security and it was the first country to abandon the Cold War mentality. In the early 1980's, when the Cold War had not yet ended, Deng Xiaoping argued, with keen political insight, that peace and development were the two themes of the time. The thinking on non-traditional security became an important element in China's efforts to foster a new concept of security after the end of the Cold War.

Especially after the financial crisis in Asia in 1997, China began to pay more attention to the security questions pertaining to the economy and finance. After the terrorist attack on 11 September 2001, the Chinese government and academic circles began to better understand several non-traditional security threats, like terrorism. China has repeatedly stressed that traditional and non-traditional security are interwoven in the present world, and it refers to the escalation potential of non-traditional security threats for the security of China and for world peace.

In fact, since the end of the Cold War, the Chinese government has deepened its understanding of international security. It has pointed to the changes in the regional security environment and has concluded that military action cannot thoroughly solve international disputes and contradictions. A security concept that relies only on the use of military force cannot create a lasting peace. Thus, the strategies for seeking security have become diversified. The new security concept requires the strengthening of dialogue and cooperation, which has become an important measure. The purpose for launching this new concept of security is to abandon the Cold War thinking and to actively meet the challenges posed by the threats in the new security environment. All this reflects the comprehensive thinking of the Chinese government on national security and on the principles of international relations.

At the core of the new security concept are mutual trust, mutual benefit, equality, and coordination. All countries should secure their common security through mutual trust and by solving their disputes peacefully through friendly negotiation and consultation. Mutual trust means that each country should go beyond its ideology and social system, and should har-

bour no suspicions of the other or be hostile. The countries should inform each other on relevant issues of security, defence, and on important actions. Mutual benefit means that countries should respect each other and create conditions for others to realize common security when it is defending its own benefits and security. Equality means that each country is a member of the international community. Each country, big or small, strong or weak, should respect and treat all states equally. No country should interfere into the internal affairs of other countries and impede the move towards democracy in international relations. Coordination means that each country should solve disputes through friendly negotiations and consultations and should have deep and broad cooperation on security issues of their common concern to overcome potential perils and prevent wars from happening.

The *Shanghai Cooperation Organization* (SCO) is a successful example for effective ways of carrying out this new security concept. The SCO's predecessor, the Shanghai Five mechanism, originated and developed from a joint endeavour by China, Russia, Kazakhstan, Kyrgyzstan, and Tajikistan to strengthen confidence-building and speed up disarmament in the border regions. In 1996 and 1997, the heads of the five states met in Shanghai and Moscow respectively, and signed the 'Treaty on Deepening Military Trust in Border Regions' and the 'Treaty on the Reduction of Military Forces in Border Regions'. These five countries successfully solved their historical border disputes and agreed to jointly fight against terrorism, separatism, and extremism. After the establishment of the SCO, the 'Shanghai Convention against Terrorism, Separatism and Extremism' was signed, in which those three challenges in its five member states were clearly defined for the first time. Furthermore, an 'Agreement of the SCO Member States on the Regional Structure for Counterterrorism' was signed. The main purposes of the SCO are: a) strengthening mutual trust, good neighbourhood and friendship among member states; b) developing their effective cooperation in political affairs, the economy and trade, science and technology, culture, education, energy, transportation, environmental protection and other fields; c) working together to maintain regional peace, security, and stability; and d) promoting the creation of a new international political and economic order featuring democracy, justice, and rationality.

The *Association of Southeast Asian Nations* (ASEAN) '10+3' (China, Republic of Korea and Japan) and the '10+1' (ASEAN and China) cooperative mechanism were launched after the Asian financial crisis. The fields of cooperation were expanded from the economy and finance to closer cooperation in science, information, environmental protection, and society. Under the framework of ASEAN '10+3', a multilevelled cooperative network has been established, which consists of ministerial meetings and deputy ministerial meetings of foreign affairs, economy, finance, transportation, labour, information and education, and some semiofficial seminars and academic conferences. It is the largest cooperative mechanism among governments in Asia.

The new concept of security is not only beneficial for the solution of the problems of non-traditional security, but also helpful for improving and developing traditional relations among major powers. Several years[5] after the new concept of security was launched, China established new partnership relations with major global powers and formed a new international security environment for China based on this new security concept as its guiding principle.

In addition to strengthening the cooperative mechanism of regional security, China cooperates with the US and EU to fight against international terrorism and other non-traditional security threats. After the events of 11 September 2001, China and the US established long-term and medium-term cooperative mechanisms to fight against international terrorism. So far many departments in both states have been involved and these mechanisms have worked well. China actively participates in concerted actions launched by international organizations. China has worked together with the UN to deal with non-traditional security threats, and it cooperated with the WHO during the SARS period, bringing this severe pandemic effectively under control. Thus, China uses diplomatic opportunities to enhance cooperation with other countries on non-traditional security threats, and China has acquired an international image as a responsible big power.

However, during the process of implementing this new security concept, some countries still adhere to the concept of power politics and use it as an excuse for fighting terrorism to pursue a new form of imperialism. In the present international situation, each country stresses the role played by soft forces and employs different resources and means to improve its in-

5 In March 1997, the Chinese government officially announced the new concept of security at the ASEAN Regional Forum.

ternational image. 'The year of the nation' and 'the culture of the nation' are actively promoted. At the same time, some barriers among different cultures and civilizations are not easily overcome. The disputes over international order, sovereignty, and human rights are endless. The world economy is developing unevenly under the conditions of economic globalization. The prices of key products like crude oil are highly fluctuating and the international competition for energy resources has become increasingly fierce. Trade protectionism and economic nationalism have gained ground. But the coordination among international economic policies and the regional economic cooperation is being strengthened and deepened.

15.4 Conclusion

After the end of the Cold War, with the rapid development of globalization, the concept of 'national security' is undergoing rapid changes both theoretically and practically. Since nations came into being, they have always been the main actor in the international system. In a globalized world, national security is going beyond the main body and category of the 'nation', and expanding its focus to 'human security' and 'international security'. 'Human security' started to become an important subject in the area of national security research. Maintaining the security of civilians and ensuring the realization of their rights has become an essential part of national security. The security content is also expanding horizontally from the previous military and political security to a notion of 'comprehensive security' that includes economic and ecological security.

Globalization and non-traditional security problems brought about the concept of new security. Most challenges to the NSC in the era of globalization were originally addressed in the academic world and by international organizations. Whether the changes of the NSC will be adopted as a national policy greatly depends on whether they are accepted and chosen by a nation.

After absorbing some positive elements of the new security concept from the western academic debate, the Chinese government has formulated its new security concept with 'mutual trust, mutual benefit, equality and cooperation' as its core. To meet the aim of security, the Chinese government calls for constructing a 'harmonious world', seeking 'universal security' of the international community; As to the security content and security means, China emphasizes 'comprehensive security'; and with regard to its implementation, China advocates 'cooperative security' based on mutual trust and mutual benefit. This new security concept reflects the progress of our times by vigorously promoting world peace and development. It has become the guidance for the planning of China's national security policy.

Guided by such a 'comprehensive security concept', humankind should overcome the 'zero-sum' relations among nations, establishing international relations based on coexistence aiming at 'mutual benefit' and 'win-win' situations where interests are shared and risks are countered jointly in order to promote cooperation among countries.

16 Perceptions of Hard Security Issues in the Arab World

Gamal M. Selim

16.1 Introduction

During the last half century, Western literature on International Relations (Haas 1964; Lindberg 1963; Haas/Schmitter 1964; Buzan/Wæver/de Wilde 1998; Keohane/Nye 2001) has developed a number of dichotomies, the most important of which have been the high politics vs. low politics, geopolitics vs. geo-economics, old security threats vs. new security threats, and the hard security vs. soft security dichotomies. These dichotomies are based on the assumption that it is possible to dissect the elements of the dichotomy, at least temporarily, and to focus on its second element, which will eventually influence the first in a positive way. For example, one of the most significant conventional arguments of the functional theory of integration has been that cooperation in the area of low politics may spill over to high politics. In the age of globalization, some theorists have argued that geo-economics has surpassed geo-politics, and that emphasis on the geo-economic issues will facilitate dealing with geo-political ones.

In the same vein, one of the main dichotomies has been between 'hard' and 'soft' security. Whereas hard security refers to the military aspect of security, and deals with issues associated with territorial control, use of military weapons especially those of mass destruction, and terrorism, soft security addresses the non-military dimension of security, and is associated with issues related to the environment, energy, drugs, technology, and population. It is assumed that each type of security entails different priorities, and tools. This distinction between hard and soft security mainly emerged after the end of the Cold War in the context of the end of the Soviet threat to the West. This meant the decline of 'hard security threats' to the West, and the shift of attention towards soft security issues (Brauch 2008, 2009). However, this was not the case in other regional areas where hard security threats became more dominant and acute.

The objective of this chapter is to review Arab perceptions of hard security issues at the governmental and non-governmental levels with a view of comparing them, identifying elements of change and continuity of these perceptions, and assessing their implications for security in the Arab world and the Middle East. This review is based on the assumption that perceptions influence the prospects of regional stability and conflict resolution.

16.2 Arab Views on Hard and Soft Security

By and large, the security dichotomies have not been significantly integrated in the Arab discourse at the academic and policy-oriented levels. This can be attributed to the conceptual underpinnings of Arab political thinking which tends to view issues as interrelated rather than compartmentalized. Issues are mostly seen as part of an overall phenomenon in which all elements lead to each other. There is little distinction between the political and the non-political, politics and ethics, politics and economics, and state and religion. It is mostly argued by Muslim jurists that Islam is 'a system of life' in which the social, moral, economic, and political components are part of the overall system. In his book, *The System of Life in Islam*, Al-Mawdoody (1965), a leading Muslim jurist, asserted that in Islam all elements of life are, and should be inter-related, if the objective is to build a genuine Muslim society. He argued that Islam is a way of life encompassing moral, social, economic, and political sub-systems which are an integral part of an overall Islamic system. Muhammad 'Abid al-Jabiri, one of the most distinguished thinkers in the contemporary Arab world, has also emphasized this element of inter-connectedness in Arab and Muslim political thinking. In his book, *The Structure of the Arab Mind,* Al-Jabiri argues that Muslim thinkers "did not view space and location as independent of their sub-

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_16, © Springer-Verlag Berlin Heidelberg 2011

stance, as they linked the object with its location and space, and viewed them as one entity" (Al-Jabiri 1996: 191). Such a tendency partially explains why a disagreement among Arab countries on one issue spills over to all other issues which may not necessarily be a matter of dispute.

The distinction between hard and soft security issues has not readily been accepted in Arab political discourse due to other factors. The distinction assumes that hard security issues have been controlled and that soft security issues have emerged as the most urgent security threats. This has not been the case in the Arab world. The end of the Cold War did not end hard security threats for the Arabs. On the contrary, some of these threats have deteriorated even further, especially after the events of 11 September 2001. When hard and soft security issues co-exist in a certain domain, as has been the case in the Arab world, it is hardly possible to separate or prioritize them. Further, most Arabs have not been convinced that a focus on soft security issues would help to resolve their hard security challenges, as they see them deteriorating even further. In addition, Western countries have reinforced this trend in Arab political thinking, as they have focused on hard security issues and approaches in securing their own interests in the Middle East. This direction was evident in relationship to Iraq, which was subjected to the most severe system of sanctions in the twentieth century, and which led to the misery of millions of Iraqis. This focus culminated in the Anglo-American invasion of Iraq in 2003 which resulted in the virtual destruction of that Arab country. After 11 September 2001, the Arab world almost returned to the 'Hobbesian' state of nature in which 'hard power' became the main tool of Western actors in achieving their interests in the region. Some Western powers focused on 'the War on Terror', employing mainly military instruments including military invasions. They also focused on eliminating weapons of mass destruction from Arab and Iranian hands, leaving those with Israel intact. In addition, the second Palestinian *Intifada* [Uprising] of 2000 was mostly dealt with through military means, which led to the destruction of the Palestinian infrastructure. After the completion of the Anglo-American invasion of Iraq, the Iranian nuclear issue dominated Middle Eastern politics and as a result, hard security issues gained more momentum.

Under these conditions, it was almost impossible for Arabs to distinguish between hard and soft security issues, and when they made such a distinction they tended to place more emphasis on hard security issues. One of the best illustrations of this trend is the anthology of articles on Arab national security edited by Ayoub (2003), an Egyptian analyst, and written by a number of Arab intellectuals representing different political stances. Seventeen out of twenty-five articles dealt with hard security issues, and when the editor short-listed the main threats to Arab national security, he referred mainly to hard security issues such as unbalanced US policy in the Middle East, Israel's territorial ambitions, and Turkish-Israeli military co-operation.

The West has also reinforced the Arab tendency to think of hard and soft security issues in a single framework in another important way. The Western literature on security questions the validity of the distinction between hard and soft security. For example, Buzan, Wæver, and Wilde (1998: 196) adhere to a 'sectoral' approach to security, according to which they dissect security into five sections (or dimensions): military; environmental; economic; societal; and political. However, they conclude that there is too much overlap and interplay among the sectors, and that "units integrate the sectors both in their policy making processes and in the way they relate to each other. Therefore, in political terms, there is *one* integrated field of security" (italics added, GS). This trend was reinforced after 11 September 2001 as Western scholars contended that in the events of September 11, civilian airliners were used by civilians against civilian targets, and as a result they concluded that "the neat dividing line between hard and soft, civil and military is rapidly dissolving, requiring far more flexibility on the part of Western state security institutions than has been hitherto been the case" (Lindley-French 2004: 2). One may also cite the case of energy, which has been traditionally classified as a soft security issue (Selim/Sahar 2009). Oil pipelines have been exposed to armed attacks which threatened the flow of oil, and turned the issue into a hard security problem.

If Arabs emphasize the inter-relatedness of hard and soft security issues, most of them do not necessarily advocate hard (military or coercive) security strategies to deal with hard security issues. As a result of the American military occupation of an Arab country, and the overwhelming tilt of the balance of power in the region in favour of Israel, it has become obvious that Arabs have no military option, and as a result most of them, with the exception of some militant resistance groups, advocate political means to deal with hard security issues. This includes Syria, the staunchest champion of hard security issues. Numerous Israeli military attacks on Syria have not been recipro-

cated, and Syria is advocating a strategy of negotiation with Israel.

16.3 Levels of Arab Perception of Security Issues

In examining the content of Arab perceptions of hard security issues, it is hardly possible to determine a unified Arab perception of any of the issues under review. In this respect, one can differentiate between two dimensions. The first is the distinction between perceptions of different Arab countries, and the second is the distinction between elites and mass perceptions.

In the first dimension, one can distinguish between perceptions of three categories of Arab countries: i) Arab Maghreb countries (Algeria, Libya, Morocco, Mauritania, and Tunisia); ii) Arab Mashreq countries (Egypt, Iraq, Jordan, Palestine, Lebanon and Syria); and iii) Yemen and *Gulf Cooperation Council Arab States* (GCC), which include Bahrain, Kuwait, Qatar, Oman, Saudi Arabia and the *United Arab Emirates* (UAE). Perceptions of security issues vary as we move from one Arab sub-region to the other. This is because the distances between each Arab country and each issue are not the same. Whereas hard security issues are dominant in the Arab Mashreq and the GCC states, they are of less importance in the Arab Maghreb. In the Arab Mashreq and the GCC, security issues related to the Arab-Israeli conflict and threats emanating from the American invasion of Iraq, the Iranian nuclear issue, and terrorism, are quite central in Arab political thinking. With the exception of the conflict over Western Sahara, most of the dominant issues in the Maghreb are soft security ones.

On the second level, there are wide variations between perceptions of the ruling elites, and civil society on hard security issues.[1] At the level of the ruling elites one may identify three basic elements. The first element is the gap between the actual threats ('objective security') and the perceived ones ('subjective security'). Whereas the Anglo-American military interventions in the region are a hard security threat, the ruling elites in Egypt, Jordan, and the GCC states do not perceive them as such. On the contrary, they facilitated them. This can be accounted for by the American 'existential' pressures on Arab regimes to cooperate with the Anglo-American design in the region, or face assured collapse. In this respect, Arab ruling elites are acting to secure regime survival, as regime collapse is viewed as the most crucial security threat. This has been acutely articulated in the case of Libya, which abandoned its nuclear programmes under these Western threats. This was done despite Libya's continued emphasis on the Israeli nuclear arsenal as a security threat. In this case, regime survival has been perceived as more important than deterring Israel. The second element is that the most central hard security threat articulated by most Arab ruling elites is the threat of domestic terrorism. In fact, dealing with this threat has become the main security concern of most GCC states, as such threats de-legitimize regimes, and put them at loggerheads with the USA when local networks attempt to go to Iraq to fight Western forces. The third element is that Arab ruling elites are also more likely to focus on domestic security issues rather than external ones, as the latter seem to be out of their control. For example, the political platform of the Egyptian President Mubarak during the presidential elections of 2005 hardly dealt with external security issues, and only dealt with them, when it did, in vague terms.

Generally, Arab civil society is more radical than the ruling elites. Civil society radicalism comprises two levels. The first is an emphasis on hard security issues to the detriment of soft security ones. That does not mean that Arab civil society marginalizes soft security issues. In fact, there are numerous civil society groups dealing with issues of the environment, human rights, and energy, among many others. Rather, it means that hard security issues are viewed as more central and urgent. The second level is the subscription of Arab civil society to the most radical views on hard security issues. For example, on the Iraqi question they call for the defeat of the American project in Iraq, and are quite critical of any normalization with

1 Mass perceptions of most hard security issues are hardly articulated, as mass involvement in these issues in most Arab societies is limited. In fact, Arab masses, at the grass root levels, are almost apolitical given the traditional authoritarian character of Arab regimes which tends to penalize involvement in opposition politics, and given the impact of the oil wealth which over the last three decades has oriented the masses towards the quest for wealth accumulation rather than politics or security. This does not mean a lack of interest in security issues, but rather reluctance to articulate that interest in public forums unless at times of acute crises. Arab mass perceptions are best articulated in public opinion polls conducted during the broadcasting of the weekly programme "The Opposite Trend" of the Qatar-based satellite channel Al-Jazeera; one clearly finds that the majority adopt the radical side of each issue being discussed (see at: www.aljazeera.net).

Israel before the full withdrawal of Israeli forces from Palestinian, Syrian, and Lebanese territories. Contrary to the dominant views of the ruling elites, they consider Israel as the main security threat in the Arab-Israeli conflict, and the USA as the main security threat in the Iraqi conflict.

In addition, one may distinguish between two main trends in Arab civil society: the neo-liberals, and the radicals. Whereas the first is a minority, the second represents the majority. The neo-liberals, represented by intellectuals such as Abdel-Monem Sa'id, director of Al-Ahram Center for Political and Strategic Studies in Cairo, and Khalil Haider, a prominent Kuwaiti author, argue that Arabs should focus on geo-economics and soft security issues, fully and unconditionally integrate with all aspects of globalization, and endorse US regional and global projects. In fact, some of them were openly supportive of the Anglo-American invasion of Iraq, did not consider the Arab-Israeli conflict as a security priority, and were critical of the slow pace of privatization and trade liberalization in most Arab countries. They assert that an emphasis on soft security issues will lead eventually to the resolution of hard security threats and geo-political issues (Said 1996; Haider 2006). The radicals, in turn, are a conglomeration of Arab nationalists, Islamists, and leftists. The nationalists are best represented by institutions such as the Center for Arab Unity Studies based in Beirut, and the Arab Nasserite Party based in Egypt and its weekly *Al-Araby* (Al-Araby. com). Among the leading Islamists in the Arab world are Mohammad Emara of Egypt, Sheikh Yussef al-Qaradawy of Qatar, and Prof. Said Hareb of the United Arab Emirates (Mabrouk 1999). One may also add here the *Islamonline.net* website. Finally, the leftists are represented by the ruling party of Syria, al-Ba'ath Party, and the scholars such as Gouda Abdel-Khaleq of Al-Tajammu Party in Egypt. All of them have in common either a rejection of globalization, or advocacy of a cautious and conditional integration with its processes. They also view security issues, such as the Iraqi and Palestinian questions, the Israeli nuclear threat, as the most crucial security issues, and are critical of the Western projects in the Arab world.

Finally, Arab perceptions of security are not restricted to these two main ends of the spectrum. In fact, there are a number of variations of Arab perceptions between these two main extremes, with some political actors subscribing to some elements of the perceptions of each type. For example, although Al-Wafd Party in Egypt is a liberal institution advocating a capitalist mode of development, it adopts views on hard security issues quite similar to those of the leftists.

16.4 Arab Perceptions of Hard Security Issues

Perhaps the main Arab hard security issues are those related to the Arab Israeli conflict, the invasion and occupation of Iraq, Arabian Gulf security, the Iranian nuclear programme, and the hard security issues of the Maghreb countries. The choice of the issues is based on the frequency and intensity of their articulation in the public discourse of governments and civil society institutions. Further, whereas the first, third, and fifth of these issues are legacies of the Cold War era, the others emerged only after the end of that War, which proves that the end of the Cold War has not ended or marginalized hard security issues in the Arab world. A brief review of Arab perceptions of these issues follows below.

16.4.1 The Arab-Israeli Conflict

The Arab-Israeli conflict is the oldest and most acute security threat perceived by most Arabs, especially at the level of civil society. There is a great deal of emphasis in the Arab security discourse on the centrality of resolving the Arab-Israeli conflict as a prerequisite for resolving other hard security issues, although such emphasis has recently declined after the events of 11 September 2001. Most Arabs advocate a two state solution to the Arab-Israeli conflict. They argue that Israeli occupation of Arab territories occupied in June 1967 should end, a Palestinian state should be established on these territories with East Jerusalem as its capital, and the return of Palestinian refugees should be secured according to the UN General Assembly Resolution No. 194, in return for full normalization of relations with Israel by all Arab countries. These views were articulated in the 'Arab Peace Initiative' presented by the Arab Summit, held in Beirut in March 2002. However, Al-Qaddafi of Libya advocates a 'One-State Solution', according to which a new state called 'Isratine' should be established in which Palestinians and Jews would co-exist.[2] This should be achieved through serious negotiations

2 See the text of the "Arab Peace Initiative"; at: <http://en.wikipedia.org/wiki/Arab_Peace_Initiative>; and for the text of the Qaddafi proposal, see: *New York Times*, 21 January 2009.

supervised by great powers. The framework of these negotiations should be the United Nations resolutions on the Arab-Israeli conflict. Ahmad Jebriel, the secretary-general of the *Popular Front for the Liberalization of Palestine* (PFLP), has also come in support of the 'One-State Solution' as the most feasible strategy to resolve the Palestinian-Israeli conflict.[3]

Traditionally, and at least until the American occupation of Iraq, Arabs did not view Confidence-Building Measures (CBMs) as a viable strategy for achieving a Middle East peace. This was so because the conditions that led to their success in Europe in the 1970's do not exist in the Middle East. From an Arab perspective, introducing CBMs requires resolving the territorial conflicts in the Middle East and building arms control regimes. It was in this context that the Arabs were reluctant to accept the CBMs initiatives that were proposed by the Western powers (NATO and EU) during the 1990's in the light of the absence of meaningful progress in the Arab-Israeli peace process. Without the resolution of the Arab-Israeli territorial conflict, the application of CBMs, the Arabs argued, would lead to the legitimization of the territorial *status quo*, and thus 'normalizing' Israeli occupation of Arab territories (Al-Shazli 2000; Biad 2000).

Further, the Arabs used to link their endorsement of any regional or trans-regional project of cooperation in which Israel was involved with the resolution of the Arab-Israeli conflict. Such projects were understood as being introduced after, or parallel with the political resolution of the Arab-Israeli conflict. This explains Arab participation in the first three Middle East and North African conferences after the beginning of the Palestinian-Israeli peace process, and their boycott of the fourth conference which was held in 1997 after the collapse of the peace process following the election of an anti-peace government in Israel led by Netanyahu. The Syrians and Lebanese have been the strongest Arab advocates of this linkage.

The Arabs also perceive arms control and disarmament as crucial strategies for the durable resolution of the Arab-Israeli conflict. The Egyptians and the Syrians were quite attentive to the centrality of that strategy given their perception of the regional imbalance in favour of Israel. In their assessment, a Middle Eastern arms control regime should deal with conventional and non-conventional weapons in the Middle East (Selim 2000; Al-Dessouki 1996; Diyab 1995; Fakhr 1995; Abdel-Salam 1992). From an Egyptian perspective, the arms control regimes should focus on the limitation of all levels of armaments, and the ban of all weapons of mass destruction on a comprehensive and equitable basis. The most crucial element in Egypt's approach to arms control was the element of the comprehensive and simultaneous elimination of all weapons of mass destruction in the Middle East. The Middle East must be declared a zone free from weapons of mass destruction. This meant that Israel had to sign and ratify the *Nuclear Non-proliferation Treaty* (NPT), and that Egypt would link the signing of the Chemical Weapons Convention to Israel's adherence to the NPT. It was in this context that the Arabs did not endorse the global arms control plans in the Middle East during the 1990's, such as the American and French Arms Control Plans, as the plans aimed, through a simultaneous freezing of the nuclear *status-quo* and the eliminating of chemical and biological arsenals, at perpetuating Israel's nuclear monopoly in the region, while disallowing the Arabs their unconventional capabilities.

In fact, Arab views on the question of arms control were expressed within the framework of two regional projects. The first was the Egyptian Proposal on the Ban of Weapons of Mass Destruction, presented by President Mubarak in April 1990. The Egyptian Proposal reiterated that nuclear, chemical, and biological weapons must be banned from the Middle East. All actors must be mutually and equitably committed to this principle, and verification mechanism must be established. In September 1992, the *League of Arab States* (LAS) adopted a draft resolution in support of the Egyptian proposal. The LAS resolution called for freeing the Middle East from all types of WMD (nuclear, chemical, and biological) as the best guarantee for achieving security and stability in the region. In December 1994, the three Arab countries of Egypt, Syria and Saudi Arabia joined forces in support for the elimination of all types of WMD from the Middle East. They issued a tripartite communiqué, which called on the international community, especially the co-sponsors of the peace process, to work seriously toward the realization of a WMD Free Zone in the Middle East, and pressure Israel to adhere to this objective. The second project was the *Arms Control and Regional Security* (ACRS) working group within the framework of the Madrid multi-lateral peace talks. Within the ACRS, two major approaches toward arms control were debated. The first approach, adopted by Israel, advocated the introduction of CBMs between the main regional actors as the

3 "Ahmad Jebriel supports the one-state solution"; at: <http://www.aljazeera.net/NR/exeres/A7AC867D-3DC1-4495-B1D3-B6D03065CC45.htm>.

prelude for any discussion on arms control and WMD. The second approach, adopted by Egypt and backed by the Arab states, contended that arms control negotiations should focus on the limitation of all levels of armaments and the ban of all WMD. The Egyptians gave priority in the ACRS discussions to the Israeli nuclear weapons and the need to eliminate WMD from the Middle East on a comprehensive and equitable basis. In this respect, the Arabs stipulated that Israel must sign the NPT and accept IAEA safeguards over its nuclear facilities as a precondition for a comprehensive peace settlement in the region. Further, they linked the endorsement of the Additional Protocol of the NPT to Israel's endorsement of the NPT itself.

There have been some changes in these perceptions after the events of 11 September 2001, and such changes have been reinforced after the USA emerged in the Arab world, for the first time, as a military occupier of an Arab country in 2003. Between 2002 and 2003, the USA strove to establish an Arab regional understanding against Iraq, which was subsequently turned into an Arab-Israeli tacit understanding against Iran with Egypt, the Palestinian Authority, and the GCC states being the most important Arab actors in these understandings, and Israel being an undeclared member. That has led to a decline in Arab emphasis on the centrality of the Arab-Israeli conflict compared with their emphasis on the Iranian threat. Further, the Arab states that joined the American-led regional understanding have been more willing to enter into normalization initiatives with Israel, even though their conflict with Israel has not been resolved. This has been reflected in their participation in the Annapolis Conference held in 2007, and their endorsement of the participation of the *League of Arab States* (LAS) in the Union for the Mediterranean, in association with Israel. This was the first time the League has taken part in a regional arrangement in which Israel participates. In addition, the Arabs have dropped the linkage between endorsing the Additional Protocol of the NPT and Israel's endorsement of the NPT. Libya and Kuwait have already ratified the Additional Protocol, and Egypt, Jordan, and the GCC states have declared their intention to pursue a peaceful nuclear programme. According to Selim, these programmes are mechanisms to rationalize, for public opinion, their intention to endorse the Protocol, as signing that Protocol is a pre-requisite for proceeding with the nuclear programmes.[4] Hisham Fu'ad, the former chairman of Egypt's Atomic Energy Agency, shared a similar view, arguing that the signing of the Additional Protocol would be a pre-condition for developing an Egyptian nuclear programme.[5] This was the case, for example, with the UAE which signed the Additional Protocol in April 2009. The signing of the Additional Protocol was described by Al-Kaabi, the UAE's ambassador to the IAEA, as "an important step for the UAE and another demonstration of the country's commitment to complete operational transparency and the highest standards of non-proliferation."[6] This is despite the fact that the UAE did not possess any nuclear programmes or activities at that time. Finally, since the Arab Peace Initiate of 2002, and the introduction of the Road Map in 2003, the Arab states have dropped their traditional emphasis on the crucial role of Palestinian armed resistance to Israeli occupation. This explains the Arab boycott of Hamas, a radical Islamist organization advocating armed resistance against Israeli occupation, when it was elected to form the Palestinian government in 2006. With the outbreak of the rift between Mahmud Abbas, the head of the *Palestinian Authority* (PA), and the Hamas-led Government of Ismail Haniya, and the control of the latter of the Gaza Strip in 2007, Egypt and Israel imposed an economic blockade on the Gaza Strip hoping to bring about the downfall of that government. Both of them blocked all cross-points from Egypt and Israel to the Gaza Strip, which also included humanitarian supplies.

The Israeli military offensives against Hizbullah in Lebanon, and Hamas in the Gaza Strip in 2006 and 2008, respectively, helped to clarify new Arab perceptions of the Arab-Israeli conflict. In 2006, some Arab governments, mainly Egypt, Jordan, and Saudi Arabia, accused Hizbullah of provoking the Israeli military onslaught on Lebanon. In a joint statement amidst the Israeli aggression on Lebanon, King Abdullah of Jordan and Egyptian President Mubarak put the blame on Hizbullah for the outbreak of the war by referring to "uncalculated adventures that do not serve the interests of the region." The joint statement also made indirect reference to the need to implement UN Security Council Resolution 1559 which called, among

4 Mohammad Selim: "Revealing the Veiled Reality of Arab Nuclear Programs", in: *Al-Arabi* (Cairo), 20 April 2008).

5 Interview with Mr. Hisham Fu'ad, in: *Al-Masry Al-Youm* (Cairo), 10 April 2009.

6 "UAE, IAEA Sign Additional Protocol to Safeguards Agreement," in: *Khaleej Times Online*, 9 April 2009; at: <http://www.khaleejtimes.com/DisplayArticle.asp?xfile=data/theuae/2009/April/theuae_April219.xml&section=theuae&col=>.

other things, for the disarmament of Hizbullah.[7] The Saudi government also condemned Hizbullah's actions as "irresponsible adventurism". In addition, in 2008 the three Arab countries expressed an 'understanding' of the motives of the Israeli onslaught on the Gaza Strip by blaming Hamas, and used the onslaught to introduce measures which would de-throne Hamas from its rule in Gaza. Some Arab intellectuals also expressed the same position. Sa'id, for example, described Hamas as a source of security risks to the region, and to Egypt in particular, and charged Hamas with smuggling arms into the Sinai Peninsula, planning a 'demographic invasion' of Sinai by three quarters of a million Palestinians in January 2008, and becoming part of a much larger coalition of radical forces that target moderate Arab governments.[8] Al-Hadlaq, a Kuwaiti writer, took an even more extreme position by justifying the Israeli onslaught on the Gaza Strip and describing it as a war against 'Palestinian terrorists'. He went further to call upon the Israelis to 'crush' Hamas in Gaza similar to what they had done before in 2006 with Hezbollah in Lebanon.[9]

These stances were not widely shared in the Arab world, except by the ruling elites in Egypt and some GCC states. They were rejected by the ruling elites of Syria, Libya, the Arab Maghreb countries, and by most civil society institutions and actors. These actors argued that the roots of the Israeli attack on Gaza was inherent in the failure to recognize the results of the 2006 Palestinian elections which brought Hamas to power, the subsequent blockade on the Hamas government, and the numerous Israeli military incursions in Gaza and the West Bank which had resulted in thousands of Palestinian prisoners including the head of the Palestinian parliament and hundreds of assassinated civilians.

16.4.2 The Invasion and Occupation of Iraq

In 2002, the USA and UK launched a world campaign charging Iraq with possessing weapons of mass destruction in violation of Security Council resolutions. As a result, the UN inspection system was re-installed. Inspectors, however, came up with no evidence to corroborate the Anglo-American charges. Nevertheless, the USA and the UK persisted in their charges and mobilized their forces in the Arabian Gulf in preparation for a possible invasion of Iraq. Despite the mistrust of most Arab countries in the Iraqi regime, and the pressures exercised by U.S. Vice President Cheney to convince Arab countries to join the Anglo-American campaign against Iraq, Arab countries, with the exception of Kuwait, did not endorse the Anglo-American plans. On the contrary, the Arab summit, held in Beirut in March 2002, witnessed reconciliation between Iraq and other Arab countries, including Saudi Arabia. The Americans replied by giving Israel a green light to carry out its onslaught against the Palestinian city of Jenine which was almost demolished while the Arab leaders were still in Beirut. The United States also exercised intensive pressure on Arab regimes which finally succumbed, and joined, with the exception of Syria and Arab Maghreb countries, the Anglo-American campaign with varying degrees of publicity. The only country which openly supported the Anglo-American invasion was Kuwait on the grounds of the Iraqi invasion of that country in 1990.

At the level of civil society and public opinion, there was a vigorous opposition to the invasion which was reflected in mass protests in most Arab countries. A disparate collection of opposition and civil society groups across the Arab world joined forces in rejecting both the invasion of Iraq and US interventionist strategies in the region. As the US moved ever closer to attacking Iraq in January 2003, approximately one million persons marched in the Yameni capital, Sanaa, chanting slogans against the United States, Israel, and pro-American Arab regimes. In Bahrain, where the US Navy's Fifth Fleet was anchored, tens of thousands of angry Bahrainis marched to the US embassy in Manama in protest against the invasion. The protests terminated into clashes with the security forces in which two people were injured, and witnessed the throwing of three home-made petrol bombs into the embassy garden. In Egypt, which was the launch pad for the demonstrations that swept the Arab world, around 20,000 Egyptians gathered into a massive anti-war rally in Cairo's Tahrir (Liberation) Square on 20 March 2003 to protest against the US-led invasion of Iraq. The rally witnessed heavy clashes with the police where hundreds were arrested and injured. A larger rally also took place in the coastal city of Alexandria, where around 30,000 Egyptians held an anti-war demonstration and called for opening the door for Jihad in Iraq. Further, Arab opposition and civil society groups, belonging to a broad coalition of Islamists, nationalists, and leftists, called on Arab governments

to discontinue all forms of cooperation with the United States and Britain, organized public rallies in support of the Iraqi people, and staged an economic boycott campaign against American products and companies. The Egyptian Lawyers' Syndicate went a step further when it invited applications for Egyptians wishing to join the resistance groups in Iraq. The Syndicate's move attracted about 17,000 Egyptian volunteers, who protested outside the Syndicate's headquarter after they were informed that the government would not allow them to travel.[10] The rejectionist camp has also included mainstream intellectual trends in the Arab world. In March 2003, 40 Egyptian intellectuals – representing a wide range of the political spectrum – issued a joint declaration in which they outlined their position on the Anglo-American invasion of Iraq. The declaration explained that "they (the signatories) differ with the position presented by President Mubarak, who placed the blame on Iraq for the current war", and that the US war is a "colonial one waged against Iraq and the Arab nation".[11] Among the signatories of the declaration were prominent Egyptian intellectuals Fahmy Howeidy and Galal Amin. The same month, the Egyptian Judges' Club issued another statement in which they called on all Arab and Muslim governments "to declare their hostility to the countries taking part in the aggression, led by the United States, and to use all means to fight against their schemes; to deny them military bases, facilities or to take part in military exercises with them, and to offer all means of assistance to the Iraqi people and their government".[12] Abu-Taleb, the editor of the *Arab Strategic Report*, went further when he described the occupation as "a turning point in the history of the modern Arab world, similar in magnitude to the Nakba of Palestine in 1948 and to other major defeats and crises that the Arab regional system has weathered over the past five decades" (Abu-Taleb 2003: 7).

However, a few Arab intellectuals, who have been known for their traditional pro-American stance, openly supported the invasion. This was clearly reflected in the writings of Sa'id, who, in February 2003, wrote two articles subscribing to the Colin Powell charges in the UN Security Council that Iraq was developing weapons of mass destruction, arguing that in that conflict, the USA had the moral high ground, and attempted to persuade Arab countries to join the projected Anglo-American invasion to extract a part of the Iraqi spoils.[13] Al-Manna', a Kuwaiti scholar, also wrote in the second week of the invasion, expressing support for the Anglo-American invasion of Iraq. Al-Manna' called on the coalition forces to proceed with their military campaign in Iraq until the war's objectives are fully realized, including the removal of Saddam Hussien, the disarmament of Iraq, the formation of a transitional administration, the reconstruction of Iraq, and the drafting of a new Iraqi constitution as a prelude for the establishment of a democratic system in Iraq.[14] On the second day of the invasion, and in a move which reflected an implicit approval of the invasion, the pro-government Egyptian newspaper *Al-Ahram* published an interview with US Vice-President Dick Cheney, conducted by the newspaper's editor-in-chief Ibrahim Nafie. In this interview, Cheney defended the invasion, and outlined the main dimensions of U.S. plans in Iraq afterwards. "The military operation will proceed very quickly, and we do not want to stay in Iraq more than is necessary. ... We will work hard to install a democratic government in Iraq, and to protect the unity and sovereignty of the country," Cheney was quoted.[15] Haider (2006) also wrote during the period of the invasion in support of the Anglo-American invasion.

After the occupation of Iraq, Arab countries began to express concern about the destruction of the Iraqi infrastructure, the rise of sectarian conflict in Iraq, the increasing Iranian influence in Iraq, and possible partition of that country. This was mainly because these developments spilled over to the rest of the neighbouring Arab countries who also began to experience sectarian conflict. In this respect, there were two main approaches. The first was advocated by Syria and Libya, who called for the speedy withdrawal of Anglo-American forces from Iraq. Others, such as Egypt, and the GCC states openly called for these forces to remain in Iraq as their withdrawal would lead to an all-out civil war in Iraq. They also strove to prevent their nationals from joining resistance groups operating in Iraq. However, as the US in-

tensified its pressure on Syria and Libya, these countries began to tone down their opposition to the Anglo-American occupation of Iraq. At the level of civil society, opposition to occupation and to the Bush-Blair policies persisted. One can assess that trend on the occasion of shoe-throwing incident at George Bush during his visit to Iraq in 2008, by the Iraqi journalist Al-Zobaidy. When this event was mentioned in the Egyptian parliament on 15 December 2008 there was a jubilant tremendous applause from all parliamentarians, including those who belong to the ruling party. Moreover, hundreds of Arab attorneys volunteered to defend Al-Zobaidy.[16]

Despite their subscription to major American policies in the Middle East, most Arab countries remain critical of American policies towards Iraq and Israel, though this criticism is largely muted. During the US-Gulf Forum held in January 2009, the Saudi deputy Foreign Minister contended that "the USA has adopted policies full of flaws against the Gulf nations, and the Middle East, while it has been extending all-out support to Israel."[17] Further, criticism of American policies is, however, more acute and well-articulated at the level of civil society and public opinion. The public opinion survey conducted by the Pew Research Centre in 2008 showed that only 19 per cent, 22 per cent, and 51 per cent of the Jordanians, Egyptians, and Lebanese had favourable views of the USA, respectively.[18] Arabs are also unconvinced that the USA has established democracy in Iraq. Rather, they assert, it has established a sectarian system unprecedented in Iraqi history. Al-Jasour (2008), the Dean of the Faculty of Political Science at Al-Mustansiriya University in Baghdad, has argued that what has been built in Iraq is a quota system based on sectarian identities rather than on the merit system. This view was supported by Al-Allawy, the first Prime Minister of Iraq after the fall of the Saddam Hussein regime, who contended that the Americans have installed a false democracy in Iraq based on sectarianism and political chaos.[19] Ismael, a prominent Iraqi scholar, has also asserted that political sectarianism has been encouraged and institutionalized in Iraq since the first day of occupation. This has been done through four main instruments that were employed by US occupation forces, and were intended to de-construct Iraqi national identity. These include i) the formation in July 2003 of the Interim Governing Council (IGC) on the basis of ethnic, sectarian and religious identity; ii) the building up of US-sponsored paramilitary forces along sectarian lines. This began with the formation of the Special Police Commandos and the Public Order Brigades, which came under the control of the Shiite-dominated ministry of interior, and has been associated with a campaign of ethnic cleansing against the Sunni Arab population. This was followed by the formation of parallel US-backed paramilitary Sunni groups in an attempt to protect the Sunni Arabs and balance the Shiite militias; iii) the US drafting of the post-Saddam Iraqi constitution, which provided for the establishment of regional governments, and encouraged the merging of regions into mega-states by conferring constitutional autonomy on such mergers. The constitution thus became "a recipe for transforming political sectarianism, resulting in the Balkanization of Iraq"; and iv) the pre-assignment of ethno-religious quota to cabinet positions (Ismael 2009: 452–455).

Iraq today remains a major security concern for the Arab Mashreq countries. The main concerns are that Iraq could be partitioned, triggering other disintegrationist movements in the region, and promoting sectarian rift which has been clearly echoed in the rest of the Arab world with the control of Iraq by Shiite political parties. Finally, there is the concern that Iran is increasingly dominating Iraqi society and politics.

16.4.3 Arabian Gulf Security

The Arabian Gulf region is plagued by a power asymmetry between the GCC states on the one hand and Iran on the other. Until 1991, Iraq was to be a part of that power asymmetry; however, it is no longer a credible component of the Arabian Gulf power equation. Indeed, power asymmetry of the GCC states with Iran is being further magnified by historical legacies of conflicting territorial ambitions which are manifested in Iran's occupation of three islands claimed by the United Arab Emirates. Moreover, Iraq used to consider Kuwait part of its territory. Power asymmetries and historical legacies led the GCC states to solicit the protection of Western powers in the form of security agreements, military bases, and the presence of Western navies in the Arabian Gulf.

19 For a review of the works of this conference, see: http://corp.gulfinthemedia.com/gulf/view_article_ar_print.php?print=1&id=491432.

In addressing these hard security dilemmas, one can identify three main GCC approaches: i) the power politics approach, ii) the CBMs approach, and iii) the approach which combines a balance of power and CBM elements. Within each approach, there are differences over the bilateral or multi-lateral nature of CBMs to be included. Whereas some approaches advocate a pan regional framework of CBMs, others assert that CBMs can be more effective at the bilateral level. There are also those who restrict CBMs to the regional actors, and those who prefer to bring in extra-regional powers.

Advocates of the first approach argue that Arabian Gulf security can only be maintained through a change in the balance of power, and/or creating new security arrangements in cooperation with great powers. They assume that the elimination of certain elements of power from the Gulf region, or the establishment of new security arrangements with great powers would reinforce security and facilitate conflict resolution. This approach is mainly pursued by virtually all GCC states as they have signed security agreements with various Western powers and host military bases in their own territories as a security insurance against Iran. For example, Kuwait is considered by the USA as an ally outside NATO. In 2004 the Dubai-based *Gulf Research Center* (GRC) launched a proposal to establish a nuclear free zone in the Arabian Gulf region, which would include the GCC states, Iraq, Iran, and Yemen. As all other GCC states and Yemen had no nuclear capabilities, the proposal was targeting Iran. Later this proposal was expanded to include biological and chemical weapons and re-named the *Gulf Weapons of Mass Destruction Free Zone* (GWMDFZ). However, the change of scope seemed only symbolic, as all nine countries, which are supposed to be parties of the projected zone, are already parties to the global chemical and biological conventions regime. However, it was argued by advocates of this project that it would facilitate the development of a multilateral regional security arrangement (Alani 2005, 2006). At the official level, the GCC summits have been subscribing to a wider domain of the zone free of weapons of mass destruction as they argue that such a zone should cover the entire Middle East region. The implication is that it would necessarily include Israel. Egypt subscribed to a modified version of this approach and called for the creation of 'Arab' security arrangements in the Arabian Gulf region, in which Egypt would participate. This approach was vehemently rejected by Iran, and was also received with little interest by the GCC states.

The second approach advocates a CBMs strategy for conflict resolution and peace building in the Arabian Gulf region. There are a number of such CBM projects either advocated by institutions, or by individual intellectuals. In November 1999, the Gulf 2000 Project in cooperation with the Center for Research and Consultancy in Oman held a conference in Salala, the Sultanate of Oman. The conference recommended the introduction of non-military CBMs such as environmental cooperation, tourism, and exchange between academics, clerics and the media. It was also suggested that joint cooperation in the field of economic development, such as the Iran-Qatar exploitation of a common gas field, or the development of the disputed islands, is an important 'economic' CBM.[20] Also, Al-Marhoun (2006), an Arab scholar, advocated establishing a 'Gulf Forum for Regional Security' comprising the GCC states, in addition to Iraq, Iran, Yemen, Egypt, India, and Pakistan. The proposed Forum would act as a consultative mechanism to exchange ideas and form expert groups to study security issues and suggest solutions. Al-Marhoun's proposal was premised on the inter-regional linkages between the Mediterranean, the Arabian Gulf, and South Asia, which justified the inclusion of Egypt, India, and Pakistan. Great powers, however, were excluded from the proposal.

The third approach combines both balance of power and CBM elements. It attempts to place CBMs in their wider context of power relations and conflict issues. At the institutional level, the *Bahrain Center for Studies and Research* suggested the promotion of Gulf security by creating a zone free of weapons of mass destruction in the region, and introducing CBMs in the form of non-aggression treaties and pledges by all powers of non-intervention in the domestic affairs of the Gulf countries (Al-Ghatam/Galal 2007). Two scholars from the GCC states have advocated linking the introduction of CBMs with the territorial issues in the Arabian Gulf region. Al-Mani (2002), a Saudi scholar, suggested establishing an Arabian Gulf model of CBMs, which would include official and non-official measures. At the non-official level this model would include people-to-people contacts, and at the official level, military and economic measures would be taken such as prior notification of military manoeuvres, reducing military formations in border areas, cooperation in the areas combating drug trafficking, and transparency in Iran's nuclear activi-

20 For a review of this debate, see *Al-Sharq Al-Awsat* (London), 21 December 2005.

ties. However, a solution of the issue of the occupation of the islands which the UAE claims from Iran and the end of border conflicts in the region are prerequisites for the introduction of these measures. Al-Shaiji (2000), a Kuwaiti scholar, has also advocated the application of CBMs in the GCC-Iran relationships. His model enumerated measures such as hotlines, regional communications centre, periodic summit meetings, de-militarized zones, prior notification of military manoeuvres, transparency measures in military activities, exchange of information, and onsite inspection. He indicated that these measures were built on other CBM experiences and could be successfully applied in the Arabian Gulf region, arguing that CBMs have "succeeded in the Middle East in creating a clear qualitative shift in the two conflicting parties, the Arabs and Israel, towards tension and conflict avoidance." He went on to argue that a solution to the Iran-Emirates conflict over the three islands would tremendously facilitate the application of CBMs, and assist reaching a solution to other border problems.

16.4.4 The Iranian Nuclear Programme

After the Anglo-American invasion and occupation of Iraq in 2003, the Iranian nuclear programme came to the forefront of the Western agenda in the Middle East and the Arabian Gulf. Western powers have claimed that Iran is enriching uranium, and that such an enrichment programme will enable that country to go nuclear in the near future. The EU Troika (Britain, France, and Germany) took the lead in negotiating with Iran to halt its enrichment programme, and the UN Security Council issued a resolution also requesting Iran to do this. When these efforts failed, sanctions were imposed.

Arab perceptions of the Iranian nuclear programme have been mainly articulated in the context of the Western drive to persuade or coerce Iran to halt its programme, and in fact as a result of the Western attempt to isolate Iran by mobilizing Arabs against its nuclear programme. Before the launching of the Western anti-Iranian drive, virtually no Arab country voiced a concern over the Iranian nuclear programme. The Western strategy has been to create a coalition between Israel and pro-Western Arab countries, namely the GCC states, Jordan, the Palestinian Authority, and Egypt against Iran and its allies in the Middle East, namely, Syria, and non-state actors such as Hezbollah, and Hamas. Arab perceptions of the Iranian nuclear programme have been also molded by the dominant role of Iran in Iraq and its drive to promote Shi'ism in the Arab world, and reflected a concern that Iran was attempting to control the Arab world.

In addition, pro-American Arab actors have perceived the Iranian nuclear programme to be a threat, and demanded that Iran comply with the requests of the Security Council and the International Atomic Energy Agency. Perhaps this can be illustrated with reference to the criticism voiced by the GCC states to Amr Moussa, the Secretary-General of the LAS. Moussa sent a message to the GCC summit in Abu-Dhabi in December 2005 focusing mainly on the Israeli nuclear capability. Al-Atiya, the Secretary-General of the GCC, and Abdullah Al-Neamey, the Foreign Minister of the UAE, criticized Moussa publicly on grounds of ignoring the security concerns of the GCC states. Al-Neamey argued that the GCC states are also concerned about the Iranian nuclear programme because of their geographical proximity, and Iran's non-membership in the early warning system in case of any nuclear leakage from the Bousher reactor.[21] In March 2009, the Saudi foreign minister, Saud al-Faisal, reiterated the same position at an Arab League Council meeting. He called on his Arab counterparts to forge a common vision to deal with what he called the 'Iranian challenge', arguing that resolving problems among Arabs would depend on the creation of a joint position regarding Iran's stance on Gulf security and its nuclear programme.[22]

Meanwhile, the GCC states have voiced concern over the possibility of a Western-Iranian military showdown which they perceive will be quite detrimental to their security, given the Iranian threat to retaliate against the GCC states which allow the West to use military bases in the GCC states to attack Iran. In December 2007, Al-Atiya clearly expressed the GCC opposition to the military option against Iraq. "We want the military factor to be eliminated...What we care for in the GCC is finding solutions that enhance security and stability...and [we] believe in dialogue as a way to solve the crisis," he told a conference on regional security that was held in the Bahraini capital, Manama, and attended by US Defense Secretary Robert Gates.[23] On the same occasion, Sheikh Hamad

21 "GCC Calls for Nuclear-Free Middle East," in: *Arab News,* 20 December 2005; at: http://www.arabnews.com/?page=4&section=0&article=74971&d=20&m=12&y=2005. See also: *Al-Sharq al-Awsat* (London), 21 December 2005.

22 *Al-Ahram Weekly* (Cairo), Issue No. 938, 12–18 March 2009.

Bin Jassim Al-Thani, the Qatari Prime Minister, called on Washington to engage Teheran directly in a dialogue to reach a solution to the nuclear crisis. Sheikh Hamad went further when he countered a comparison drawn by Gates between an ambitious nuclear Iran and a responsible nuclear Israel. "We cannot really compare Iran with Israel. Iran is our neighbour, and we should not really look at it as an enemy. ... Israel for 50 years has taken land, is expelling the Palestinians, and interferes under the guise of security, blaming the other party," he told the conference.[24] The comments of the GCC leaders were delivered in response to Gates's remarks in which he stressed the danger of Iran's nuclear programme, and pointed to Iran as the prime source of chaos in the region. In addition to recommending the pursuit of the negotiation strategy, the GCC states have also demanded participation in any Iranian negotiations with the West as they suspect that the West may grant Iran an enhanced regional status as a reward for halting its enrichment programme.

Nevertheless, Syria and most Arab civil society groups have different views, arguing that Iran is entitled to uranium enrichments under the NPT, and should be allowed to use such a privilege. They also argue that excessive Western pressure against Iran will persuade that country to produce the nuclear bomb. Further, they contend that the Iranian nuclear programme should be assessed in the context of other nuclear programmes in the Middle East, namely the Israeli programme, and that if Iran developed a nuclear capability, that would contribute to Middle East stability as it would establish a balance of terror with Israel (Shaker 2007; Al-Shobaky 2007; Mahmud 2007). Amr Moussa, the Secretary-General of the LAS, expressed a similar view when he emphasized that Iran did not represent a threat to the Arab world. During a meeting of the World Economic Forum in Shuneh, Jordan in May 2009, Moussa stressed that

> We do not regard Iran as the main issue. The Arab world does not have any problem with Iran. ... The main problem and major threat to the region and Arabs is Israel's nuclear activity. ... Nuclear disarmament is a global issue, and it is not possible to forget Israel, which possesses a nuclear arsenal and refuses to sign the NPT, and talk about the Iran 'threat' all the time. ... This is a mistake.[25]

Moussa also defended Iran's right to have a nuclear energy programme as long as the IAEA has not reported any deviation in Iran's nuclear programme. In an interview with the Mehr News Agency on the sidelines of the World Economic Forum meeting, Moussa stated that "according to the International Atomic Energy Agency, Iran has had no diversion from the NPT (nuclear Non- Proliferation Treaty)...Therefore, Iran has the right to develop its peaceful nuclear programme based on this international treaty".[26]

These perceptions were corroborated by the findings of a major survey project that was conducted by the Anwar Sadat Chair for Peace and Development at the University of Maryland under the leadership of Shibly Telhami, in collaboration with Zogby International. The Sadat Chair/Zogby International survey was an umbrella survey project under which five surveys were conducted at annual intervals between 2003 and 2008.[27] The survey, which covered respondents in Egypt, Jordan, Saudi Arabia, Morocco, United Arab Emirates, and Lebanon, found that the majority of Arabs believe that Iran has the right to develop a nuclear programme, and that international pressure on Iran to curtail its programme should stop. Indeed, the percentage of Arab approval for Iran's nuclear programme jumped from 60 per cent in 2004 to 67 per cent in 2008, although approximately half of all respondents in the surveys suspected that Iran's nuclear programme was, in fact, intended for weapons manufacture. When asked in 2008 about the potential outcome of Iran's acquisition of nuclear weapons for the Middle East region, the majority of correspondents said the outcome would be positive, viewing a nuclear-armed Iran as a desirable counterweight to US and Israeli military dominance in the region. In fact, the highest approval rate was recorded in Saudi Arabia – the hotbed of Sunni Islam in the Arab world – where 73 per cent of the population expressed positive views toward the Iranian nuclear programme.[28]

16.4.5 Hard Security Issues in the Arab Maghreb Region

The Arab Maghreb countries share with their Mashreq counterparts their perceptions of the previously articulated issues. However, these issues are not high on their agenda. They have their own hard security issues which are mainly related to the Western Sahara conflict, Spanish threats to Morocco, and the Western rapid intervention forces in the Mediterranean.

The Western Sahara question is a major source of conflict between Algeria, Morocco, and the Polisario (*Popular Front for the Liberation of Saguia and el Hamra and Rio de Oro*). Morocco has claimed that the Sahara is an integral part of its territory, and King Mohammad VI has charged Algeria with expansionist designs on the Sahara, and meddling in Morocco's internal affairs. For their part, the Polisario and Algeria perceive Morocco as a security threat to the right of national self-determination of the people of the Sahara (Al-Sherbeany 2007).

Further, Morocco views Spain as a source of security threat given its stance on the issue of the island of Lily, and the cities of Melilla and Ceuta. Morocco claims that the island and the two cities are part of its territory, while Spain has completely rejected these claims, and used military force to evict the Moroccans from the island when the Moroccans attempted to take it in July 2001. Spain has also asserted its claim to the cities of Melilla and Ceuta which are located on the northern coast of Morocco. Spain's readiness to use military forces in these conflicts has been viewed by the Moroccans as a major security threat.

Finally, since the 1990's the Maghreb countries have developed attitudes of suspicion and preoccupation towards the EU common defense policy in the Mediterranean. This was particularly the case with the EU decision in 1995 to develop two rapid reaction forces, known as EUROFOR and EUROMARFOR, within the framework of the European Security and Defense Policy, to act as peace-keeping and humanitarian intervention forces in troubled areas. The EU decision was made following the conclusion of the *Euro-Mediterranean Partnership* (EMP), and without prior notification to its Mediterranean partners. The decision has had a negative impact on relations with the Mediterranean Arab partners, who are concerned about the presence in the Mediterranean of European forces which have been mandated to intervene in their domestic affairs under the pretexts of humanitarian intervention and peacekeeping operations. The Force was, in fact, used in Sudan to supervise and monitor cease-fire arrangements in southern Sudan. It was also used in Bosnia, Macedonia (FY-ROM), and in the Congo in 2003 (Bourantonis/Tsakonas 2003; Shedeed 2004). However, it could be also employed if EU security was threatened as a result of the flow of refugees across the Mediterranean or the collapse of a Maghreb political regime (Al-Sherbeany 2007).

16.5 Conclusion

As the dawn of the twenty-first century appeared, Arab countries, especially those in the Mashreq, were thrown back into the Hobbesian state of nature, and the Middle East region has been militarized as never before. Wars and invasions dominated the region in Iraq and Palestine, including its neighbourhood in Afghanistan. Also, Arab countries had to cope with strong armed domestic opposition movements. In this context, and because of more fundamental cultural factors, hard and soft security issues were viewed as inter-related with priority being given to the hard security ones because they represented the most immediate threats. In addition to the Arab-Israeli conflict, which remained as a main hard security threat, other issues were added, the most important of which were the issues of the occupation of Iraq, Arabian Gulf security, and the Iranian nuclear programme. On the other hand, the hard security issues in the Maghreb remained marginal compared to the more acute hard security ones in the Mashreq.

This review of Arab perceptions of hard security threats has come up with two main observations. The first is that contrary to conventional theory, Arab civil society is more hawkish than the ruling elites as far as its perceptions of Israel and the USA are concerned. In light of this finding, one should question the accuracy of the contention that interaction among civil society groups across the region would facilitate peace under conditions where there is a dominance of hard security issues. Further, the dovishness of Arab ruling elites, compared with civil society groups, has not led to any significant breakthroughs in dealing with hard security threats. This failure has discredited these elites and reinforced the perceptions of civil society groups. This has been acutely reflected in the 'Arab Peace Initiative' of 2002 which was an official Arab collective proposal for regional peace with Israel. The Initiative was rebuffed by both Israel and the USA, which led many civil society groups to call for its withdrawal. The second observation is that Arab perceptions of the Arab-Israeli and Iraqi security issues have

undergone major changes as a result of the American pressure. The changes have been in the direction of placing less emphasis on the Arab-Israeli conflict, and a greater focus on the 'Iranian threat'. In this, Arab countries had to conform to American policies under threats of regime change.

Finally, the dominance of hard security issues in the Arab world is reciprocal in the Middle East, allowing one to argue that these issues are also dominant in the Israeli and Iranian sides of the equation, which make the prospects of regional peace a remote possibility in the short-run.

17 Arab Perceptions of Soft Security Issues

Mohammad El-Sayed Selim

17.1 Introduction

The objective of this chapter is to review, compare, and assess Arab perceptions of 'soft security' issues and threats. In achieving this objective, there are two main themes. The first is that the concept of 'soft security' is hardly acknowledged in the Arab discourse on security. Although Arab politicians and analysts refer to the issues subsumed under the 'soft security' label, the concept itself is hardly employed in Arab public discourse on security. This is because the concepts of 'softness' and 'security' do not match in Arab thinking as the Arab region is plagued by mostly military and territorial (hard) security issues (chap. 16 by Gamal Selim). The second is that the Arabs have borrowed the concept from the Western literature, and in that literature the concept was vaguely defined, which was reflected in the Arab endorsement of the concept. The concept was originally used during the East-West détente era to distinguish military issues from other relevant security issues, including military-related issues such as confidence-building measures. It was later expanded to include about almost everything except defence proper. Consequently, the concept was vaguely defined in the Western literature. In some cases, the concept was used without a definition (Tanner 1996; Bell 2006), and when defined it was used as a generic concept which includes all non-military issues, which made it possible to study any set of such issues under the label of soft security (Lomagin 2002; Aldis/Herd 2004). This has led some analysts to call for the dismissal of the concept and its integration into a single concept of security on grounds that the dividing lines between soft and hard security in the post Cold War era are rapidly dissolving (Langlais 1999; Lindley-French 2004). These conceptual confusions have been projected into the Arab literature, and reinforced Arab reluctance to employ the concept, especially that its connotation in the Arabic language is disturbing.

This problematique calls for assessing Arab conceptualizations of soft security at two levels. The first is the assessment of the place of the concept of soft security in the Arabic literature on security; that is how the concept has been viewed and employed in that literature. The second is the identification of how the Arabs have viewed the issues which are traditionally categorized under the concept of soft security. Our assessment of the main Arab perceptions of soft security does not mean that these perceptions were articulated in the context of that concept. Rather, we selected certain issues traditionally categorized as soft security ones, and assessed how they have been perceived in Arab countries, by which we mean the twenty-two member states in the *League of Arab States* (LAS). These perceptions will be reviewed at the official and non-official levels as well.

17.2 Arab Conceptualizations of Soft Security

Some Arab analysts reject the concept of soft security outright. They argue that the concepts of hard and soft powers are inter-linked as soft power cannot be achieved or employed without hard power. This means that we should be talking about 'comprehensive power' which includes both branches of power. Whereas comprehensive power should be employed in international conflicts, soft power may be used in some aspects of international cooperation. Further, hard power is more crucial in achieving national objectives, especially in cases of the liberation of occupied territories, as soft power by itself cannot solely contribute to the achievement of these goals. For these reasons, advocates of this line of thought recommend the abandonment of the concept of soft security, and argue that if used at all, it should be used as meaning the ability to create a national model of development (Marzouk 2009).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_17, © Springer-Verlag Berlin Heidelberg 2011

Further, Arab politicians do not use the concept of soft security, and Arab academicians hardly use it, although all of them frequently refer to issues related to that concept. It seems that the concept is the domain of Arab non-governmental groups, who use it in conjunction with their conceptualizations of the issues related to their own missions.

Few Arab analysts have employed the concept, arguing that soft security has become, or should become more crucial than hard security at least for the Arabs. In fact, most of those who use the concept subscribe to the view of the relative centrality of soft security in the process of maximizing Arab security, a view which is not widely shared by the Arab official and intellectual community on security.

Arab analysts, who employ the concept of soft security, do not agree on a definition of soft security. They define the concept in the context of one of four main schools. The first school adheres to the traditional definition of soft security as referring to issues of a non-military nature. Advocates of this school view soft security from the angle of the issues involved, which are all issues not directly related to military power. For example, Al-Mabrouk, the chairman the Academy of Higher Studies in Libya, argued that globalization has transformed the concept of security from the hard dimension to the soft one. He went on to argue that whereas the soft security refers to economic and social security issues, hard security deals with military security issues.[1]

The second school comprises those who define security in a more complex way to include two main elements, the issues and their controllability. They argue that soft security refers to issues which are of a non-military nature and can be influenced and managed by Arabs. This includes issues related to development, reform, education, population composition and expatriate labour, sectarian rifts, and diversification of income. This is in contrast with issues which are of a military nature and cannot be controlled by the Arabs.[2]

The third school uses the concept interchangeably with the concept of 'human security'. Prince Al-Hassan bin Talal of Jordan defined soft security as referring to maintaining human security, which could best be achieved by providing the people with their basic needs.[3] Likewise, Al-Hafez (2003) differentiated between two forms of security; those which attend to the dignity and spiritual needs of individuals, and those which focus on their material needs such as food, water, and military security. For him, soft security means preservation of the basic rights of individuals, human empowerment, and good governance, that is, human security. Whereas the first school considers food security as one of the elements of soft security, Al-Hafez classifies it under the category of hard security as it deals with material needs rather than spiritual ones.[4] Likewise, Al-Sayyid, (2008) a Lebanese political scientist, argued that whereas soft security is related to the people, hard security refers to defence issues.

The fourth school defines soft security from the perspective of the strategies used to promote it. It equates soft security with non-obtrusive and non-confrontational strategies of security. Jordanian analysts tend to use that version of the definition of the concept. They argue that soft security is best maintained when the state applies measures which create cordial relations with its citizens including police-people relations and tacit airport security measures. Al-Khawaja (2009) used the concept of soft security in that sense with a focus on how the police could create bonds with its larger community.[5] Ayasra (2006) also pleaded for a focus on soft security, which he defined as meaning issued related to the promotion of social dialogue and social peace.

The four main schools of Arab definitions of soft security have in common an emphasis on the non-military dimensions of the concept. However, they differ in their view of these dimensions. Whereas some analysts view soft security as also related to issues which

1 See at: <http://www.alacademia.edu.ly/letter10.asp>. This is the definition also used by some Arab analysts in a symposium of the Al-Arabiya, and Arab TV satellite station on 2 October 2005; at: <http://www.alarabiya.net/programs/2005/10/02/17332.html#>.

2 This was the definition used by Aisha Sultan (2007) and by Al-Shaiji (2008) and also in his presentation at the conference of the Gulf Center for Strategic Studies and Research in Abu Dhabi in March 2007; see at: <http://www.aljazeera.net/news/archive/archive?ArchiveId=1035107>.

3 Interviews with Prince Hassan; see at: <http://www.deutsche-welle.de/dw/article/0,,1953109,00.html>; and at: <http://www.alarabimag.net/arabi/Data/2009/5/1/Art_88739.XML>.

4 Yasser Kassem, an Iraqi Kurd, has also used the concept along the same lines in an article published in Al-Ittihad, the newspaper of the Kurdish Patriot Union; see at: <http://www.alitthad.com/paper.php? name=News&file=print&sid=22886>.

5 See also at: <http://ourhim.wordpress.com/2008/08/16>; and at: <http://ammannet.net/look/eom/eom_jo.tpl?IdLanguage=18&IdPublication=3&NrArticle=7642&NrIssue=5&NrSection=26>.

cannot be fully influenced by Arabs, others focus on the spiritual dimensions or the use of non-confrontational methods in dealing with societal issues. Further, these schools represent a small fraction of the Arab literature on security, which we argued earlier is mostly concerned hard security issues.

17.3 Arab Perceptions of Soft Security Issues

The choice of the issues of soft security perceived by the Arabs is based on two main criteria: the substance of the issue; and its relevance to the Arab world. The first criterion refers to whether the issue has been identified in the security literature as a soft security one. The second refers to whether the issue is relevant to the Arab regional system. For example, the issue of the safety of nuclear reactors is considered in the literature as a soft security issue. However, it is not relevant to Arab perceptions of soft security as there are virtually no significant nuclear reactors in the Arab world.

According to these criteria, the most important soft security issues perceived by most Arab countries are those related to terrorism, foreign interventions to promote democracy, foreign labour in the GCC states, sectarian rifts, environmental threats, and energy security. Arab perceptions of these issues will be viewed in the following sections.

17.3.1 Terrorism

Arab perceptions of terrorism differ from the mainstream Western definitions on several grounds. Arabs define terrorism more according to the motivations of the combatants rather than by the nature of the act. In this respect, they make a clear distinction between those individuals and groups involved in armed struggles against the illegal occupation of their land, and those using violence against civilian targets or legitimate governments to achieve their own self interests. This was clearly stated in *The Arab Convention for the Suppression of Terrorism*, adopted by the Council of Arab Ministers of the Interior and the Council of Arab Ministers of Justice held within the framework of the LAS in 1998. The Convention affirmed

> the right of peoples to combat foreign occupation and aggression by whatever means, including armed struggle, in order to liberate their territories and secure their right to self-determination, and independence and to do so in such a manner as to preserve the territorial integrity of each Arab country, of the foregoing being in accordance with the purposes and principles of the Charter of the United Nations and with the Organization's resolutions.[6]

Soon after the attacks of 11 September 2001, former Egyptian Foreign Minister Ahmad Maher expressed misgivings about American and Israeli attempts to confuse resistance with terrorism. Maher stressed that "the difference between terrorism and armed resistance is clear. ... People under occupation have the right, according to international conventions and the United Nations Charter, to struggle against the occupying power."[7] On that premise, before September 11, most Arab countries supported Palestinian and Lebanese armed resistance to Israeli occupation, but this support never included the Al-Qaeda organization headed by Osama bin Laden. The differentiation between terrorism and resistance to occupation was also found in survey projects conducted in 2005 by the *Centre for Strategic Studies* (CSS) of the University of Jordan on the perceptions of the Arab public toward a number of issues. The CSS project, entitled *Revisiting the Arab Street: Research from Within*, was conducted in collaboration with partner institutions in Jordan, Syria, Lebanon, Palestine, and Egypt across four samples in each country. On the question of terrorism, almost 90 per cent of those polled in the five Arab countries believed that the movements of Hamas, Islamic Jihad, al-Aqsa Martyrs Brigades and Hezbollah were 'legitimate' resistance organizations.[8] Whereas civil society perceptions of the difference between terrorism and resistance to occupation persisted after 11 September 2001, governmental stances changed in the direction of removing the dividing lines between terrorism and resistance to occupation and de-legitimizing both. This was evident in their stances towards Iraqi groups fighting American occupation, and Lebanese and Palestinian groups, namely, Hezbollah and Hamas, fighting against Israel.

In addition, Arab civil society does not subscribe to the exclusion of 'state terrorism' from Western definitions. In the West, 'terrorism' is mostly used to depict the violence of individuals or groups pursuing specific political agendas, not that inflicted by states. The U.S. State Department also restricts terrorism to

8 The survey project is available online at: <www.css-jordan.org>.

individuals or groups, and to states 'sponsoring terrorism'. Arabs add to this conceptualization the category of 'state terrorism,' according to which states themselves commit acts of terrorism. This includes depriving civilians of essential needs and damaging the institutional fabric of their societies. In this respect, the Arab civil society views the exclusion of states as agents of terror as intended to legitimize certain practices and policies that are carried out by Western states, and Israel against civilians in Afghanistan, Iraq, and Palestine. Al-Amir, an Egyptian analyst, noted that

> fundamental elements of the debate on terrorism, which included the legitimacy of armed resistance against foreign military occupation, the illegal acts of state terrorism committed against people under occupation and the persecution of individuals by dictatorships in the name of state security, were overlooked in favour of a broad, indiscriminate definition.

The result is that the whole issue of fighting terrorism has been "reduced to how to protect Western civilization against Muslim marauders who are incited by a murderous religious cult."[9] Bishara shared a similar view, arguing that for the United States and Europe, the notion of civilians has been used to refer only to the citizens of the US, NATO countries and Israel, while the abuse, punishment or elimination of other peoples for political reasons have been normalized under different pretexts.[10]

Further, most Arabs do not share the American view about the origins and causes of terrorism. In the aftermath of the attacks of 11 September 2001, the US administration linked terrorism with regime type in the Arab world, and viewed the attacks as an outcome of the presence of authoritarian regimes that do not provide legitimate channels for their citizens to express their political and social demands. In this respect, democratizing the Arab world was viewed as a fundamental element to uproot terrorism. In the Arab view, however, terrorism is a function of Western policies of un-balanced interventions in the Middle East. Matar advocated this view by tracing the recent upsurge of terrorist activities throughout the world to American arrogance and bullying in dealing with other nations, peoples, and cultures. In the Middle East, Matar referred to America's unlimited support of Israeli expansionism and its policies in the region as the major factors that have created unprecedented levels of hostility towards the US and Israel.[11] Sid-Ahmed also linked the present phenomenon of terrorism to the political, socio-economic injustices inherent in the US-led new world order. In his view, the new world order has brought the United States as the uncontested superpower which acts unilaterally outside the domain of the United Nations. It has tempted the United States to pursue its own agenda regardless of considerations of international law, state sovereignty or international public opinion. The result has been an unprecedented rise in the feelings of resentment and hatred toward the United States, and subsequently the creation of new breeding grounds for terrorism in many regions, particularly in the Arab and Muslim world.[12]

By and large, Arab analysts agree that terrorism cannot be uprooted using military means only. In fact, they contend that the USA has failed to combat terrorism by resort to military invasions, and that such invasions have led to the spread of attacks against American targets (Shady 2008).

Finally, there is the question of the link between terrorism and Islam in the Western, especially American media. Most Americans and Europeans tend to equate terrorism and extremism with Islam. This perception should not be viewed as an outcome of the events of 11 September 2001 as some observers might conclude. Rather, it is an outcome of accumulative historical memories that can be traced back, according to Edward Said, to the middle ages when the Muslim empire and armies were perceived as a direct threat to the West (Said 1997). Even with the decline of the Muslim empire, Western perceptions of the linkage between violence and terrorism on the one hand, and Islam on the other hand continued to persist for centuries.

Arabs reject the portrayed link in the West between terrorism and Islam (Abou-Soliman 2002). The Secretary-General of the LAS, Amr Moussa, expressed Arab resentment when he described Western media attempts to link terrorism with Arabs and Islam as 'catastrophic'. Moussa stressed that terrorism has no home or religion, and that there is a clear misunderstanding of the teachings of Islam in the West.[13] Al-

13 *Al-Ahram Weekly* (Cairo), Issue No. 558, 1–7 November 2001. The best reviews of most Arab perceptions of the question of terrorism are Eid (1999), and Ayoub (2003)

Sayyid (2002), an Egyptian scholar, shared a similar perception, arguing that attributing terrorism to a particular religion or faith is a misleading proposition that does not accommodate reality. He refuted the stereotyped linkage between terrorism and Islam, arguing that Islamist groups who view Islam as a guide to a different political order do not necessarily seek to establish that order through the use of violence. In this respect, he referred to many Islamic political movements that try to seek political power using peaceful methods, such as the Rafah Party in Turkey, the Muslim Brothers in Egypt, the Islamic Salvation Front in Algeria, and the Nahda Party in Tunisia. Al-Sayyid also warned against reductionism when it comes to the interpretation of Islam by particular individuals and groups. In his view, "just as no one in his or her right mind would charge all Protestants or Catholics of being terrorists because certain Protestant or Catholic groups in Northern Ireland resort to armed action, by the same logic, the presence of certain terrorist groups that call themselves Islamic does not make Islam and all its adherents potential terrorists and a threat to the rest of humanity." Fahmy (2008) also enumerated a number of terrorist organizations working in Israel exercising terrorism against the Palestinian people.

17.3.2 Foreign Intervention to Promote Democracy

The question of political reform in the Arab world has come to the forefront of the Arab agenda as a result of Western pressures following the attacks of 11 September 2001. The administration of George W. Bush Jr. claimed that the attacks emanated from the Arab world, and viewed them as an effect of Arab authoritarian regimes. In this respect, neo-conservative circles close to the US administration lobbied for the use of all means of American political and military power to support democracy in the Arab world, with arguments that the war against 'terrorism' would require social, political and economic changes in the Arab world. This new American policy was first expressed in the 2002 National Security Strategy and in a number of democracy-promotion initiatives, such as in the 2002 *Middle East Partnership Initiative* (MEPI) and the 2004 *Greater Middle East Initiative* (GMEI). The new policy also culminated in the US invasion of Iraq, and the toppling of the Saddam Hussein regime in April 2003. One of the rationales of the invasion was that it would lead to a democratic Iraq and subsequently to the spread of democracy to the rest of the Arab world, as Japan and Germany became democratic states friendly to the USA after their occupation, which was clearly articulated in the Bush statement on 5 April 2002.

The Anglo-American occupation of Iraq and the growing American pressures for political reforms in the Arab countries triggered an intensive debate in the Arab world on the question of reform from outside. Whereas some groups subscribed to the basic philosophy of the Euro-American projects of democratization in the region, others have rejected it, or at best have given it a lukewarm endorsement. The advocates of Western intervention argued that this was the only available avenue for Arab societies to democratize as local regimes are not likely to move in this direction. These groups, which consist mainly of intellectuals and civil society activists promoting Western liberal values, constitute a minority within Arab societies and are often viewed as 'Westernized' elites. Al-Hashem, a Kuwaiti analyst, welcomed the idea of external intervention to bring about political reform in the Arab world, arguing that waiting for political reform to take place from within is a waste of time.[14] Former Jordanian Information Minister Al-Qallab also supported Western reform projects in the Arab world. He expressed no objection to political reform being imposed from outside if it was impossible to achieve it from within by peaceful means and mutual persuasion. In his view, the Arabs must not panic when the West talks about reform and democracy in the framework of the GMEI, or any other framework. Rather, the Arabs should take advantage of these initiatives to push for democratization in their countries.[15] Sa'id, the director of Al-Ahram Center for Political and Strategic Studies in Egypt, went further in defending Western reform initiatives, arguing that the Arabs should not link their endorsement of Western reform initiatives in the region to the resolution of the Palestinian-Israeli conflict. In his view, making reform conditional upon resolving the Palestinian problem has triggered a "definite political and moral tragedy" in the Arab world, since it has made the realization of Arab human rights hostage and conditional upon the realization of Palestinian rights.[16]

On the other hand, there are the rejectionists, who are sceptical of the trans-regional democratization projects, and view them as attempts to serve only the political agenda of great powers, rather than real at-

16 *Al-Ahram Al-'Arabi* (Cairo), 27 March 2004.

tempts to democratize the Middle East. This group represents the mainstream trend within the Arab world, and is characterized by its diversity in terms of the type and number of actors involved. In this respect, one could distinguish between two types of actors within this group: i) Arab states, and ii) Arab civil society, which consist mainly of nationalist and Islamist groups as the most significant sector of civil society in the Arab world in terms of number. With respect to Arab states, one could refer to four main grounds upon which they have rejected the Western reform initiatives. First is the lack of consultation with Arab countries. Virtually all international projects for reform in the Arab world were unilaterally designed by the Western sponsors. Arab countries were viewed as a domain for implementation rather than partners in the agenda formulation and implementation. In the G-8 summit held in the USA in June 2004 some Arab leaders were invited, but as 'legitimizers' of the Western plans rather than as partners in the process. It was not thus surprising that some Arab leaders declined to participate. Second, there is the question of the marginalization of the Arab-Israeli conflict. Most Western reform projects overlooked the question of the Arab-Israeli conflict as a major cause of instability and insecurity in the region. Rather, the emphasis in these projects is on domestic change in the Arab world. Although the G-8 summit Declaration of June 2004 referred to the importance of resolving the Arab-Israeli conflict, it added that such resolution should not delay the reform process. More importantly, no single action was suggested in the Declaration to deal with the Arab Israeli conflict. Third, there is the question of the projection of Western values. Euro-American approaches to reform are postulated on the assumption that the reform process in the Arab world must emulate the Western experience. While this could represent a valid argument if one is dealing with economic and technological issues, such validity certainly declines if it impinges on cultural and religious values. In this respect, Arab governments viewed the external democracy-promotion projects as attempts to dominate Arab countries and dilute the Arab-Islamic identity of its people, as was clearly stated by Ahmad Maher, the former Foreign Minister of Egypt. Last but not least, there is the question of the very definition of the Greater Middle East. It was argued that that concept entails an arbitrary definition of a region that includes countries with little commonality with respect to their social, political and cultural backgrounds. This in turns makes it difficult to apply such a broad set of policies to a diverse geographical area.

In addition to mobilizing opposition against the Euro-American projects at both domestic and international fronts, Arab governments also reacted to such reform projects by offering their own reform programmes in an attempt to "avoid being perceived at home as unresponsive to demands for change at a time when the international community was set to take unprecedented (if largely rhetorical) action in support of political reform in the Arab world" (Gambill 2004). This led to the mushrooming of Arab reform initiatives in the period between February and June of 2004. In February 2004, for example, the Yemeni government hosted a regional conference on democracy, human rights and the role of the international criminal court, which produced the Sana'a Declaration. The Declaration reiterated delegates' support for the principles of democracy, called for an end to the occupation of Arab territories, and suggested the establishment of an Arab Democratic Dialogue Forum to foster communication on human rights and democracy between governments and civil society groups. In March 2004, the Egyptian government hosted a similar conference that was attended by non-governmental activists and intellectuals from several Arab countries. The conference produced the Alexandria Document, which called for individual Arab countries to push forward on their own reform programmes, while conforming to a general framework agreed to by all Arab countries. In May 2004, the LAS summit in Tunisia adopted a resolution on political reform in an attempt by Arab governments to take ownership of the reform process, rather than leaving it to independent Arab intellectuals and civil society groups.

While it was not surprising that Arab governments would not endorse the trans-regional reform projects for fear of losing their grip on political power, we find that, contrary to expectations, the largest segment of Arab intellectuals, opposition groups, and civil society activists have also rejected these projects. This rejectionist attitude toward the trans-regional reform projects should not come as a surprise, however, when viewed within the context of existing historical and cultural memories in the Arab world vis-à-vis the patterns of interactions with the West over the last two centuries. In the context of these historical memories, democratization in the Arab world has been shaped by its historical encounters with the European powers since the 19th century expansion of imperialism into the region. Even with the end of European colonialism by the mid-20th century, the Arab region has continued to be subjected to several forms of

Western domination that ranged between political and economic domination. The result is that the West has always constituted "a source of domination that must be resisted" in the Arab consciousness (Pratt 2007). In this context, attempts by Western governments to impose reform on the Arab world act to reaffirm the perception of Western dominance and interference in the internal affairs of Arab countries. Al-Beshri, a highly respected Egyptian scholar and ex-judge, exemplified this intellectual trend in the Arab world. He rejected the philosophy of the Euro-American projects to reform the Arab world, arguing that the West is indifferent to the existing types of governing structures in the Arab world, and when it (the West) talks about reform and democracy in the region, it does so to serve its interests rather than the interests of Arab societies. Further, the Arab world, he contended, cannot have imposed Western values and systems imprinted in the region as Arab societies have undergone different historical trajectories from those experienced by the West.[17] Howaidi, a prominent Egyptian intellectual, shared a similar view, arguing that the American democracy promotion projects in the Arab world are an attempt to restructure the political and ideological map of the region in a way that serves American interests, and thus he perceived these projects as a threat to Arab national security.[18] Darwish, a Syrian analyst, also noted that "the term 'Greater' as in the GMEI is aimed against Arabs and Muslims. ... Its objective is to erase the term 'Arabism' and destroy Muslim beliefs, then leave the gates wide open for the greater Zionist initiative, under the cover of American influence and its military machine that is (already) heavily concentrated in the area. ... Arabs will be the first to pay the price out of their land, sovereignty, dignity, and most importantly their identity."[19]

In addition to Arab intellectuals, the vast majority of Arab civil society and opposition groups have also rejected the trans-regional projects for reforming the Arab world. Perhaps the most outspoken in this respect were opposition parties and civil society groups in Egypt. On 14 March 2004, the general-secretariat of the Nasserite Arab Party issued an official statement in which it warned of replacing pan-Arabism with Middle Easternism if the suggested political and educational reforms of the GMEI were to be implemented. The statement viewed the GMEI as a revival of both the Baghdad Pact, proposed by US President Eisenhower in 1955 to expand American influence in the region, and the New Middle East Project, proposed by Shimon Peres in 1993, and aimed at replacing the Arab regional system with a Middle Eastern one that incorporates Israel into the region.[20] The liberal New Wafd Party adopted a similar view. In a speech before the Wafd Party's youth congress on 14 March 2004, the Party's leader Noman Goma'a viewed the Euro-American reform projects as an aggression on Arab sovereignty, stressing that their goal is to bring the protectorate back to the Arab world in another form.[21] Further, the Muslim Brotherhood movement – the biggest opposition bloc in the country – rejected the Western projects to democratize the Arab world. On 4 March 2004, the movement issued an official statement in which it denounced Western attempts to dominate the Arab world and impose values that would threaten its security and stability. The statement called upon the ruling regimes, political parties, and civil society groups in the Arab world to adopt a firm stance against such attempts, and emphasized that democracy should emanate from within Arab and Islamic societies and in tandem with their cultural traits and heritage.[22]

A panel study was conducted by the Washington Institute for Near East Policy (Carpenter 2008) on how 'Arab democrats' viewed the role of foreign powers in promoting democracy. Arab participants in that study are liberals and are more or less hostile to the Islamists. They argued that the USA should support Arab democrats by getting behind them, not in front of them, step back and allow local actors to engage Islamists as appropriate, consider linking foreign aid to progress against official corruption, focus on policy reform, which is much more important than funding for programmes, fix the democracy assistance infrastructure, broaden private-sector participation in support of reform efforts, and develop a specific strategy to engage the youth in the region. However, Arab nationalists and Islamists would take an issue with these views arguing that the USA, and any Western power, has no mandate to get involved in the democracy agenda in the Arab world.

17.3.3 Sectarian Rifts in the Arab World

There are a number of sectarian rifts in the Arab world, the most important of which is the one between the two main systems of beliefs in Islam: Sunni and Shiite. Both of them adhere to the five main principles of Islam; however, they differ in their conceptualization of the political-religious leader. Whereas the Sunnis believe that such leader should be freely chosen by the believers and be held accountable to the Muslim Umma, the Shiites believe that such leadership (Imam) is the prerogative of the Prophet's cousin Ali Ibn Abi-Talib and his sons, and in fact the caliphs who succeeded Prophet Mohammad had usurped power (Halm 2001). That conflict had been indelibly imprinted on the history of Muslims, especially after Persia turned to Shiism in 1500. The subsequent three centuries witnessed major conflicts and wars between the various Persian Shiite dynasties and the Ottoman Sunni one.

The Sunni-Shiite political rift was resurrected after the Iranian revolution of 1979, but became a major feature of Middle East politics after the Anglo-American invasion of Iraq. The Americans built a new order in Iraq based on a sectarian quota system, through which the Shiites controlled power by virtue of being the majority of the population, especially after the return of Iraqi Shiite political parties which were based and trained in Iran. This trend spilled over other Arab countries as the Shiites began to emerge as significant political forces especially in Arab countries in which they are a majority (Bahrain), or a significant minority, such as in most other GCC states. The Sunnis were alarmed by that trend, and that was especially felt in Saudi Arabia whose version of Sunni Islam does not consider Shiites as true Muslims. It was also felt in Egypt as the Mubarak regime felt that the rise of political Shiism means the rise of Iranian influence in the Middle East. In fact, Mubarak charged that the loyalty of all Shiites, Arabs and non-Arabs, is to Iran, a statement which outraged the Arab Shiites. Further, King Abdullah II of Jordan warned that a "Shiite Crescent" is emerging, extending from Iran to Lebanon where Hezbollah, a Shiite organization, has been on the rise. The Saudis also subscribed to these perceptions, although they have been more restrained in articulating them. They have intervened in Lebanese politics to support Sunni forces against Shiite ones. These perceptions were shared by many Sunni scholars, the most important of which has been Sheikh Al-Qaradawy, based in Qatar, who warned against the rise of Shiism and its negative consequences on Sunni Muslims.[23] They have also been reciprocated by Shiite religious leaders who deny any Shiite domination in the Arab world (Fadlallah 2008).

Perceptions of threat are mutual among Shiites and Sunnis alike. Whereas the Sunnis believe that their traditional grip on mainstream Islam is being challenged, the Shiites believe that they were being denied their legitimate share in power in most GCC states, and argue that the Sunni governments are out to marginalize their role using repressive tactics. This can be clearly seen in Bahrain where the ruling family is Sunni, and almost 75 per cent of the population are Shiites. Sheikh Ali Selman, the leader of Al-Wefaq Group (a Shiite political organization), has frequently charged the ruling elite of discriminating against the Shiites by establishing a parliamentary system that denied them their fair share in law-making. However, the Arab Sunni civil society views the rise of Shiism from the angle of the political struggle against Israel. As Hezbollah has been the only organization that has been able to stand up to Israel as was seen in the July 2006 War, Arab civil society was more than ready to recognize its role including its leader Hassan Nasrallah, who was viewed as the legitimate leader of Arab resistance to Israel, even though he was a Shiite.

Civil society perceptions were corroborated by the findings of a survey project that was conducted in the Arab world in late 2006 by Zogby International, and designed by Shibley Telhami, a senior fellow at the Saban Centre for Middle East Policy. The survey, which covered a total of 3,850 respondents in Egypt, Jordan, Saudi Arabia, UAE, Morocco and Lebanon, found that around 80 per cent of Arabs consider Israel and the United States as the biggest external threats to their security, whereas only 6 per cent view Iran as a threat. Further, respondents rated Hezbollah leader Hassan Nasrallah as the most admired leader outside of their own country, followed by former French President Jacques Chirac, and Iranian President Ahmadinejad, while they rated US President George W. Bush as the worst world leader, followed by former Israeli Prime Minister Ariel Sharon, former Israeli Prime Minister Olmert, and former British Prime Minister Tony Blair.[24] These findings suggest, according to Telhami, that "the public of the Arab world is not looking at the important issues through the Sunni-Shiite divide. ... They see them rather through the lens of Israeli-Palestinian issues and anger

23 *Al-Masry al-Youm*, (Cairo), 9 September 2008.

24 See at: <http://www.brookings.edu/views/speeches/telhami20070208.pdf>.

with U.S. policy [in the region]. Most Sunni Arabs take the side of the Shiites on the important issues" (cited in Lobe 2007).

17.3.4 Foreign Labour in the GCC States

The issue of foreign labour is strictly related to the GCC states. The oil boom in these countries has resulted in a social and economic expansion and with the shortage of local labour, millions of professionals and labourers were contracted to work in the GCC states. Increasingly, foreign expatriates became a majority of the population in some GCC states, and a majority of the labour force in all GCC states. There are around 10.6 million foreign labourers working in the GCC states representing 37.5 per cent of the population. In the UAE, Qatar, and Kuwait foreign labour represents almost 82 per cent, 58 per cent, and 57 per cent of the total population respectively. These percentages are 39 per cent, 30 per cent, and 24 per cent, in Bahrain, Saudi Arabia, and Oman respectively (Al-Hajry 2008). Indian labourers represent almost 28.3 per cent of the total foreign labourers in the GCC states, but this percentage is the highest in the UAE where it represents almost 36 per cent of the total population (including foreign labourers) and 41 per cent of the foreign labourers. In fact, in that country the percentage of the citizens and Arab expatriates is 26 per cent of the total population which is less than the Indian expatriates (cited in Al-Najjar 2008).

Foreign expatriates have contributed tremendously to the development of the GCC states in virtually all fields. However, foreign labourers are now viewed in these states as an actual and a potential security threat. As 63 per cent of the foreign labourers are Asians, they impacted upon the fabric of the GCC societies in terms of language, culture, and domestic security. Sometimes, regional conflicts among South Asian states were projected into the GCC states through the South Asian labourers. Perhaps the most serious security threat perceived by the GCC in this field is the growing pressures from the labour-exporting countries and international organizations to grant them citizenship after a certain number of years of residence (Al-Hajry 2008). During the Manama Dialogue held in December 2008, the Indians officially asked the GCC states to grant Indian labourers, who have lived in one of these countries for five years or more, citizenship. The GCC ministers, especially the Bahraini Labour Minister Majid Al-Alawi, vigorously rejected the Indian request arguing that it would turn their societies into Indian ones. Many GCC intellectuals also criticized the Indian request and persuaded their countries to pursue a more strict policy towards reliance on foreign labour especially South Asian labour (Hareb 2008). Other Arabs viewed this request in the context of the Indian naval expansion and increasing regional influence which has been reflected in numerous visits by the Indian navy to the GCC states, and in the context of India's quest to isolate Pakistan by cutting off its economic support in the GCC states, as naturalization of foreign labour in the GCC states would work to the advantage of Indian labour and would lead to the 'Indianization' of the GCC states (Selim 2008a). There have also been a number of suggestions to deal with the threat of the domination of foreign labour in the GCC states such as orienting citizens to accept manual work, and shifting to Arab labour which is more oriented towards local cultures of the GCC states.

17.3.5 Environmental Threats

The concept of environmental security emerged in the Arab public discourse in the early 1990's in policy statements and academic writings referring to linkages between environmental concerns and security strategies. Arab perceptions of the environment as a security concern is characterized by its managerial and apolitical paradigm, which views environmental issues as a primary result of processes of industrialization and modernization, and the lack of proper state control and governance. It deals with these issues at the organizational level focusing mainly on relations among various state organizations. The state is seen as the major reference point in dealing with the problem. The essential tools for addressing environmental concerns is improved state management and control, and better coordination between various state organizations. The Arab perceptions of the environment are of a technocratic nature focusing mainly on technical issues related to the environment and do not frame them within its conceptualization of national security. However, some Arab intellectuals articulate a discourse on the environment quite close to the main arguments of the class paradigm. They tend to view environmental issues in political terms and put the responsibility for environmental problems in developing countries on the shoulders of the rich classes and developed countries. They refer to the emergence of a 'new global environmental system' characterized by the dominance of a 'new environmental imperialism'. This system is the main source of most environmental problems of developing countries such as nuclear

waste disposal in developing countries, ozone depletion and global warming.

Three major environmental threats are perceived in the Arab world: water scarcity, desertification, and land degradation (Brauch/Oswald Spring 2009; chap. 47 by both). Water scarcity is the most serious environmental threat to Arab security, as virtually all Arab countries are well below the line of 'water stresses'. The problem is further aggravated by high population increase, the geographical location of Arab countries in the Great Desert belt, and the lack of national programmes to rationalize water consumption. Almost 60 per cent of water resources in the Arab world originate from outside the region which gives rise to tensions in using jointly-shared water. This is acutely clear in the cases of the Nile (Adly/Ahmed 2009: Kameri-Mbte/Kindiki 2009), the Euphrates and Tigris (Aydin/Ereker 2009; Scheumann 1998, 2003). These cases are a source of present and potential conflicts and will be reviewed later. Further, deserts cover most of the Arab world. Almost 11 per cent of Arab lands are suitable for agriculture (with rainfall up to 400 mm), and about 89 per cent of Arab land receives a rainfall below 100 mm. Most of these areas are deserts or desertified sand suitable only for grazing. Most Arab lands are threatened by desertification due to anthropogenic activities including overgrazing of Arab land which is responsible for almost a quarter of the desertification.

There is an increasing awareness in the Arab world at the governmental and non-governmental levels of the urgency of these environmental problems. This has been reflected in establishing national institutions (ministries, or public corporations) on issues related to the environment, issuing national strategies for environmental protection, developing NGOs to support the work of the governmental institutions, issuing various journals to deal with the environmental issues, and establishing academic institutions to major in the study of environmental issues. Arab countries have also signed and ratified most international and regional governmental conventions and agreements on the protection of the environment. At the Arab regional level, there has been a concerted effort within the framework of LAS to co-ordinate Arab environmental strategies. A *Council for Arab Ministers Responsible for the Environment* (CAMRE) was also established in 1989. CAMRE meets annually to review common environmental issues. There have also been various regional initiatives to combat desertification such as the *Sub-Regional Action Programme* (SRAP) for West Asia and the Arab Maghreb Union (Selim 2009).

17.3.6 Energy Security

Arab perceptions of energy security passed through two main stages (Selim/Sahar 2009). The first stage extended from the second half of the twentieth century. The question of energy was viewed from a dominantly technical perspective. The emphasis was on securing world markets for Arab oil exports, and comparing the economics of various sources of energy, oil, natural gas, coal, solar, hydro, and nuclear energy. Perceptions were dominated by references to oil as the main energy source. Other sources were viewed as residual. The main exception was Egypt's emphasis on hydro-electric power as a main source of energy, which led to the establishment of 'the High Dam' in Aswan in the 1960's. After the October 1973 War, Egypt moved in the direction of building an ambitious nuclear programme, with a view of generating electricity, and there was a genuine debate in Egypt over the merits and de-merits of such a programme. However, the Egyptian programme abruptly ended in 1986 and the debate subsided. Further, Arab states established a regional organization, the *Organization for Arab Petroleum Exporting Countries* (OAPEC) to coordinate their oil policies.

By the beginning of this century, the discourse on energy expanded towards the integration of other dimensions such as alternative energy sources, rationalizing the use of energy, diversifying global partners in marketing and producing oil and other energy sources, and injecting into that concept the pan Arab cooperation dimension. Further, as Arab countries joined the Kyoto Protocol, they became mindful of the environmental consequences of energy (especially oil) production and consumption which led to an assessment of the impact of the Protocol on the continued access to global markets in the light of the necessity to reduce carbon dioxide emissions. This trend in Arab discourse on security began in 2003 with the convening of a conference in Abu Dhabi on 'Energy and Environment'. The main themes discussed in the conference were the impact of energy on environment, the social and economic impacts of energy policies, and the development of sustainable energy sources. Under these themes, the main issues for discussion were, the implications of energy related policies on the environment, fossil fuels for economic development and security, energy policies and their implications for sustainable development, socio-eco-

nomic aspects of energy policies, promoting participation in developing sustainable energy policies in the Arab countries, environmental management systems as tools for energy management, and compliance with energy related environmental standards in the Arab countries. The Conference also issued "the Abu Dhabi Declaration", which recommended the development of a new strategy that deals with the environmental consequences of energy production and consumption. The *Council of Arab Ministers Responsible for the Environment* (CAMRE) issued a document entitled "Action Plan on Environment and Energy for Arab Countries" in 2004. For the first time, The Action Plan put the question of energy into the larger framework of the environment. The Abu Dhabi Declaration and the following Action Plan represent a noticeable shift in the Arab discourse on energy in the direction of linking the issues of energy and environment.

In 2006, Egypt and the *Gulf Cooperation Council States* (GCC) began to advocate a nuclear option to generate electricity. This came in the context of the global debate on the Iranian nuclear programme and the revelations that Iran has succeeded in building an elaborate programme for uranium enrichment. After twenty years of the abandonment of the nuclear energy option, Egypt re-introduced the question of nuclear energy claiming that its traditional energy sources are fast declining. Surprisingly, GCC states followed suite as the 27th summit of the GCC held in 2007 resolved to embark on a GCC nuclear programme and these states approached the *International Atomic Energy Agency* (IAEA) to help in developing such a programme. Until that time, the GCC states used to criticize Iran for embarking on a nuclear programme as it has plenty of oil resources. We have argued earlier that the actual objective of these programmes is to justify the signing and ratification of the Additional Protocol of the *Nuclear Non-Proliferation Treaty* (NPT) rather than to launch real nuclear programmes as these countries had no expertise in the area of nuclear energy.

A number of security threats have been articulated by Arab intellectuals and energy experts. It is interesting to note that these threats have not been reflected in the official Arab discourse on energy which implies the existence of a gap between actual threats and perceived ones. These threats are the emergence of new oil producers in global markets, over-dependence on oil which has become the rationale to develop nuclear energy, over-dependence on foreign markets in the utilization of oil, the decline of the global demand for oil, the inefficiency in the energy utilization in Arab countries, and the environmental consequences of energy production and consumption in the Arab world. It is interesting to notice that, with few exceptions, Arab policy-makers tend to downgrade these threats in their public discourse.

Recently, Arab policy-makers began to articulate some non-traditional security threats emanating from the energy sector. The first is the threat of terrorist attacks on Arab oil fields. This has happened in Iraq after the Anglo-American invasion in 2003. On average, there are eight attacks a month, mostly pipeline bombing which kept Iraqi oil production 27 per cent below its pre-invasion level. There was also a failed attack on Saudi oilfields in February 2006. The last attack led to an increase of about 4 per cent of the price of the barrel of light crude. Osama bin Laden, the leader of Al-Qaeda, has persuaded his followers in December 2004 to attack oil fields in order to "stop the greatest theft of (Arab) oil in history."

As for the perceived strategies to deal with these threats, one can detect an emphasis on improving the efficiency of the oil sector and promoting the natural gas option, diversifying partners, and resort to alternative sources of energy such as the nuclear one. At the regional level, the countries of the Arab Orient and the GCC states have devised strategies of integration in the energy sector. Egypt, Jordan, Lebanon, and Syria have already begun connecting their electricity grids, and buildings natural gas pipelines that connect these countries to supplying them and Turkey with the Egyptian surplus natural gas. The GCC states have also approved a plan to connect their electricity grids. In 2001 these states formed "The Electricity Grid Authority of the GCC states" based in El-Dammam, Saudi Arabia to supervise the linking of their electricity grids.[25] The gas networks, through which Algerian gas is exported to Europe, also connect with Tunisia and Morocco.

At the international level, the main emphasis is to reduce reliance on Western markets and to diversify oil-importing partners by going east. This is mainly the strategy pursued by some GCC states. It evolves around creating partnerships with Japan, China, South Korea and India through which Arab countries would secure oil importers. Sometimes this takes the form of joint ventures, as with China, South Korea, and India. China seems to be the main long-term reliable partner upon whom most Arab countries are counting to secure oil partners.

25 *Al-Siyassa*, (Kuwait), 8 May 2007.

Arab energy analysts have recommended certain strategies to boost energy security such as rationalizing energy consumption, developing new and renewable energy sources, improving the quality of local industries so as to reduce the 'domestic elasticity' of energy consumption, and building inter-Arab networks for the exchange of electricity in emergency cases. Arab governments are partially pursuing these strategies. The main trend is to reduce, if not eliminate, state subsidies for electricity consumption which mostly hurts the underprivileged classes in Arab countries and those who need access to electricity. Recently, the electricity grids of Egypt, Jordan, and Syria were connected so as to exchange energy in cases of emergency. Also Egypt has built a trans-Arab Mashreq pipeline to sell natural gas to Jordan, Lebanon, Syria, Israel, and possibly also Turkey. The natural gas pipeline became operational in 2003. The main objective was to secure continued access in this part of the world to energy supplies.

The dramatic increase and decline of oil prices between 2005 and 2009 has increased the sense of vulnerability among Arab oil-exporting countries. As the prices of oil sky-rocketed they draw ambitious plans for future development which were quickly dashed as the oil prices fell sharply. To make matters worse, the global financial crisis has inflicted heavy losses on Arab countries which were estimated by Sheikh Mohammad A-Sabah, the Foreign Minister of Kuwait, to be around US$ 2,500 billion. He added that almost 60 per cent of the construction projects in the GCC states came to a halt.[26] Although policy makers in most Arab countries, especially the GCC states, claim that these developments will not seriously influence their economies, there are signs that they are beginning to acknowledge that the decline of oil prices and the global financial crisis represent serious threats to Arab economies (Abdel-Hamid 2007).

17.4 Conclusion

The concept of soft security is not known to be a central component of the Arab conceptualizations of security, as the Arab region is still plagued by hard security issues. It is not used by politicians and remains as a limited and elitist concept mostly used by civil society groups. Those who use it argue that Arabs should focus on soft security issues rather than hard security ones as the former are essential to create a solid Arab security structure and at the same time more manipulable by the Arabs. They also agree that soft security is mostly related to non-territorial and non-military issues. However, they differ on the issues subsumed under that label of soft security. For example, whereas some Arabs would categorize food security under the label of soft security, others would not necessarily agree, and whereas some Arabs would use the concepts of soft and human security interchangeably, others would prefer to distinguish between them.

The label aside, the issues of soft security have been widely debated in Arab literature on security, although the debate is not as central or intensive as the one on hard security issues. In other words, the limited employment of the concept did not necessarily mean that its components have not been perceived, and conceptualized. Traditionally, the issues of the environment and energy were the main soft security issues perceived by most Arabs. During the first decade of the twenty-first century other issues were added such as those related to terrorism, Sunni-Shiite rifts, the threat of Asian labour dominating the GCC states, and the threat of foreign powers using a heavy hand to promote their values in the Arab world under the guise of democracy promotion. In fact, some of the new issues, such as terrorism, have become more central than some of the traditional ones. With the exception of the two traditional soft security issues, environment and energy, and the newly-introduced question of terrorism, the Arabs do not seem to have devised any strategies to deal with the new soft security issues, because of the newness of these issues and their control by external powers.

18 Military Challenges and Threats in West Africa

Kwesi Aning and Andrews Atta-Asamoah

18.1 Introduction

Much of the violent and protracted conflicts characteristic of sub-Saharan Africa in the post-Cold War years occurred in West Africa,[1] particularly in countries of the *Mano River Union* (MRU).[2] Apart from the fourteen years of intermittent conflict in Liberia, the West African sub-region also witnessed civil war in Sierra Leone; instabilities in Guinea-Bissau, Côte d'Ivoire, Niger and protracted rebellions in the Southern Cassamance Province of Senegal; resource-related conflicts in Nigeria, ethnic conflicts among the Nanumba and Konkomba in northern Ghana; and political instability in Togo.

Owing to these instabilities, innumerable human lives have been lost, massive property and natural resources destroyed, millions displaced, national economies shattered and untold human rights abuses have been meted out to non-combatants particularly women and children. In addition, the region has witnessed phenomenal spill-over of violence across boundaries. These happenings made West Africa globally famous in the 1990s for violent intra-state conflicts which provided the basis for some analysts to perceive the sub-region as representing the 'coming anarchy' and to describe it as a 'real strategic danger' requiring a re-colonization by former colonial masters in order to stabilize it (Cohen 1995: 95; Pfaff 1995: 4–6; Kaplan 1994: 44–76).

Insecurity in the individual states of the sub-region became closely linked together sufficiently so that the national security of individual states could hardly be considered independent of each other. The inter-relatedness of threats, which became known as the West African security complex, fundamentally highlighted the commonality of vulnerabilities and threats among states in the sub-region and the need for a sub-regional response to prevailing challenges.

Consequently, the *Economic Community of West African States* (ECOWAS), an organization of 15 West African states, metamorphosed from its initial focus on economic development, cooperation and integration to embrace security as an indispensable part of its remit. The Organization subsequently created structures and frameworks with which it has attempted to deal with the security challenges of the region. In addition to individual state efforts and the support of regional and global organizations particularly the *African Union* (AU) and the *United Nations* (UN), ECOWAS has been able to restore relative peace to the sub-region. In this regard notable hot-spots such as Liberia, Sierra Leone and Guinea have in recent times witnessed peace and stability.

Despite the achievement of relative peace and security, however, the sub-region has been far from eliminating threats to its peace and security. It is still bedevilled with myriads of security threats many of which are direct or indirect fallouts of previous security challenges or threats emerging from transnational challenges. These include intra-state armed conflicts; proliferation of small arms and light weapons; child soldierism; mercenarism; cross-border criminality; refugees and internally displaced persons; spread of deadly diseases especially HIV/AIDS; and exacerbating forms of poverty.

Within this panoply of threats in West Africa, this chapter examines existing military challenges and threats and their associated sub-regional responses. It thus provides responses to important questions such as: What are the military challenges, threats and vul-

1 West Africa (figure 18.1) is made up of Benin, Burkina Faso, Côte d'Ivoire, Cape Verde, The Gambia, Ghana, Guinea, Guinea-Bissau, Liberia, Mali, Mauritania, Niger, Nigeria, Senegal, Sierra Leone and Togo. Apart from Mauritania, all West African countries are members of the Economic Community of West African States (ECOWAS).

2 The Manor River Union (MRU) comprises Guinea, Liberia and Sierra Leone. The Union was formed to promote sub-regional economic integration and the implementation of development projects among the three member states.

nerabilities in West Africa? What are the military implications of the identified security threats in West Africa? And what is the sub-regional response to the military challenges? The chapter first reviews military threats and challenges in West Africa together with empirical cases of individual country responses. It then identifies prevailing vulnerabilities upon which the threats thrive and then analyses the sub-regional response before concluding on the way forward.

18.2 Conceptual Clarifications

Certain terms used in social theory are essentially contested concepts. Nevertheless, it does not imply that it is difficult to agree on a definition of a concept, but that there are some concepts whose meanings are inherently a matter of dispute because no neutral definition is possible. This is classically true of the key concepts involved in this chapter. As a result, this section clarifies the concepts of military challenge, threats and vulnerability in the context of usage in the West African sub-region and particularly below.

18.2.1 Security

Security is herein perceived as the preservation of a state from external aggression, protecting its territorial integrity and internal cohesion (Giacomo 1989: 151). In the context of the international system, security is perceived as the ability of states and societies to maintain their independent identity and their functional integrity whilst pursuing freedom from threats. International security is determined basically by the internal and external security of the component individual states (Bellany 981: 102).

18.2.2 Threat

According to a United Nations study, a *threat* is any event or process that leads to large-scale death or lessening of life chances and undermines states as the basic unit of the international system. These are listed to include economic and social threats such as poverty, infectious disease and environmental degradation; inter-state conflict; internal conflict; nuclear, radiological, chemical and biological weapons; terrorism, and transnational organized crime (UN 2004: 2).

Threats are generally relative and evolve in nature. For example, if the immediate threat to global peace and security was nuclear war and its accompanying

possible use of *Weapons of Mass Destruction* (WMD) earlier in history, today it combines with the threat of terrorism as the greatest. In its relative sense, however, what constitutes a threat to individual states, sub-regions and regions and their intensities differ: Whereas to the United States terrorism could be the major threat, to Africa, it may be HIV/AIDS.

A brain-storming session of West African scholars, however, defined a threat as any phenomenon that may cause human society to be vulnerable to deprivation, misery, and/or annihilation such as intra-state armed conflicts; proliferation of small arms and light weapons; child soldierism; mercenarism; cross-border criminality; refugees and internally displaced persons; spread of deadly diseases especially HIV/AIDS; and exacerbating forms of poverty.[3] This chapter discusses threats in West Africa against the backdrop of the latter definition.

18.2.3 Military Challenge

Responses to security threats at the national and sub-regional levels in West Africa are as diverse as the list of threats. Whilst poverty and HIV/AIDS, for instance, have required civil society and government engagement rather than military intervention, other threats particularly the proliferation of small arms and light weapons, child soldierism, mercenarism and cross-border criminality have required the direct involvement or active participation of the security apparatus of states to contain. On the basis of the nature of responses, threats in West Africa can be categorized broadly into two: (a) those that require military response such as intra-state armed conflicts, the proliferation of small arms and light weapons, child soldierism, mercenarism, and cross-border criminality especially drug trafficking, and (b) threats that do not require direct military involvement such as poverty and the spread of diseases. Against the background of this categorization, this chapter discusses those threats that have required or require the active involvement of any of the state security apparatus as the primary response at the national and sub-regional level as the military challenges of the sub-region.

3 This definition emerged from a brainstorming session of West African scholars on the United Nations High Panel on Threats, Challenges and Change organized by the *Legon Centre for International Affairs* (LECIA) and UNDP-Ghana at the Cresta Royal Hotel, Accra, Ghana-West Africa, 18 August 2004.

18.3 Military Challenges in West Africa

18.3.1 Intra-state Armed Conflicts

West Africa's history of violent armed conflicts in the post-Cold War era started in 1989 when the *National Patriotic Front of Liberia* (NPFL) led by Charles Taylor launched an uprising against the leadership of Samuel Doe. Since then Sierra Leone, Guinea and Cote d'Ivoire have all encountered different intensities of armed conflicts. Even countries such as Ghana, Mali, Niger, Nigeria, Senegal and Togo that have not encountered full-blown conflicts have variously grappled with internal unrests resulting from economic, political, cultural and structural factors such as corruption, age-old animosity among different ethnic groups, quest to control natural resources by different warring factions and the abuse of the concept of citi-zenship (Brown 1996: 12–13).

During the Cold War these factors were held under control by superpower rivalry and support for authoritarian regimes. Following the end of the Cold War, therefore the lid on simmering tensions, hatreds and economic hardships in the sub-region was lifted providing an avenue for the exploitation of the region by:

- Sub-regional economic networks that directly and indirectly fuel insecurity through the exploitation and sale of natural resources particularly diamonds;
- Regional political and economic networks that provide support mechanisms and facilitate economic predation;
- Networks that comprise illicit smuggling activities and cross-border family ties that facilitate trade in valuable goods; and,
- Regional military networks that supply weapons and training facilities to combatants who are willing to destabilize countries, conflicts subsequently became prevalent in the sub-region as these networks exploited the emerging political, economic, structural and ethnic fault-lines to satisfy parochial interests (Aning 2007: 2–5).

West Africa has since witnessed about a dozen major intra-state armed conflicts that have had untold effects on the population and development strides of the sub-region (table 18.1; chronology: box 18.1).

Table 18.1: List of major conflicts in West Africa (1990-2006). **Source:** Marshall (2006: 45-48).

Begin	End	Country[a)]	Type	Major actors[b)]	Estimated deaths[c)]
1990	1995	Mali	Ethnic Violence (Tuareg)	• Tuareg rebels, • Government forces	1,000
1990	1997	Liberia	Civil war	• RUF, • Government forces	40,000
1990	1997	Niger	Ethnic violence	• Azawad • Toubou	1,000
1991	2001	Sierra Leone	Civil-Ethnic warfare (RUF, Mende)	• RUF, • AFRC, • Kamajors • Government forces	25,000
1992	1999	Senegal	Cassamance separatism	Movement of Democratic Forces of Casamance (MFDC) rebel movement	3,000
1994		Ghana	Ethnic Violence	• Nanumba ethnic group • Konkomba ethnic group	1,000
1997	2004+	Nigeria	Communal Violence	Delta province; Ijaw, Itsekeri, and others	1,500
1998	1999	Guinea-Bissau	Civil war	• Government forces • Senegalese army • Ansumane Mané • Guinean army	6,000
2000	2003	Liberia	Civil violence	• LURD guerrillas • Government forces	1,000
2000	2004+	Cote d'Ivoire	Civil war	• Patriotic Movement of Ivory Coast (MPCI) • Ivory Coast Patriotic Movement (MJP) • Ivorian Popular Movement of the Great West (MPIGO) • Forces Nouvelles	3,000
2001	2004+	Nigeria	Ethnic Violence	• Christians • Muslims • Plato and Kano regions	55,000

Notes:
a) Only countries with major armed conflicts are listed. Minor clashes are not listed.
b) Only the main actors in the conflict are listed. In some cases splinter groups exist apart from what has been listed.
c) Casualty figures for most conflicts in West Africa vary widely. In this compilation only estimates available in the public domain are used.

Notwithstanding their typically intra-state nature and dynamics, conflicts in West Africa assumed perturbing international dimensions that posed unprecedented challenge to their management and resolution.

First, neighbouring countries sometimes meddled in conflict situations by covertly supporting belligerents waging war against government forces. In the Liberian conflict, for instance, Charles Taylor is alleged to have been introduced to Muammar Gadaffi of Libya by Blaise Campaore of Burkina Faso and was subsequently trained, conditioned and equipped in Libya for the uprising. In 1991, Taylor also lent support to Foday Sankoh's *Revolutionary United Front* (RUF) to launch a similar uprising in Sierra Leone.[4] He is again alleged to have supported rebel forces in Guinea and Ivory Coast. Similarly, Lansana Conte of Guinea is also alleged to have provided military support to *Liberians United for Reconciliation and De-*

Box 18.1: Brief chronology of the major armed conflicts in West Africa (1990-2006). **Source:** Based on authors analysis of the region.

	Begin	Brief description of actors and international dimensions
1990	Tuareg Rebellion	This conflict was between the Tuareg separatists and the Malian army after the former attacked government buildings in Gao over complaints of marginalization by the Malian government. After reparations by Alpha Konare's government the conflict subsided. It was however re-ignited in 1994 following the Tuareg attacks in Gao. The Tuaregs are alleged to have been trained and armed in Libya. The situation has since remained a protracted conflict in Mali to date.
1990	Liberia civil war	The Charles Taylor led invasion of Liberia escalated into a bloody civil war. The main actors were the *National Patriotic Front of Liberia* (NPFL), the Independent National Patriotic Front of Liberia led by Prince Johnson and government forces loyal to the Samuel Doe regime. The NPFL forces were broadly supported by Cote d'Ivoire and Burkina Faso, both of whose leaders harboured family grudges against Doe, and Libya where Taylor trained for the invasion.
1991	Sierra Leone civil war	The *Revolutionary United Front* (RUF) launched an attack to overthrow the government of Sierra Leone. The initial attacks were launched from bases in Liberia with the support of Taylor and the NPFL. The main contenders in the conflict were the RUF and government forces. Other groups such as AFRC and Kamajors were also involved. Apart from Charles Taylor, the uprising was also supported by Guinea which supplied arms to the RUF.
1992	Cassamance separatism in Senegal	The *Movement of Democratic Forces of Casamance* (MFDC) begins violence in demand of the autonomy and independence of the Casamance region in Senegal. The MFDC wages the war against government forces. The situation has remained protracted and persists to the present (July 2009).
1994	Konkomba-Nanumba Violence in Ghana	Longstanding enmity between the Konkomba and Nanumba ethnic groups in Ghana erupted into violence in the Northern Region of Ghana. Government forces were sent to contain the situation.
1998	Guinea-Bissau Civil war	Troops led by Ansumane Mané begin an uprising to topple the government of João Bernardo Vieira. With the support of Senegalese and Guinean soldiers, troops loyal to the government attempted unsuccessfully to regain control of rebel held areas of the Bissau and heavy fighting subsequently ensued.
2000	Cote d'Ivoire Civil war	Troops mainly from the northern parts of Cote d'Ivoire started a mutiny by launching attacks in many cities, including Abidjan over the ivorite question. The contenders in the conflict are the *Patriotic Movement of Ivory Coast* (MPCI), *Ivory Coast Patriotic Movement* (MJP), *Ivorian Popular Movement of the Great West* (MPIGO), and the Forces Nouvelles. There has been a general ceasefire but the situation still remains volatile till date.

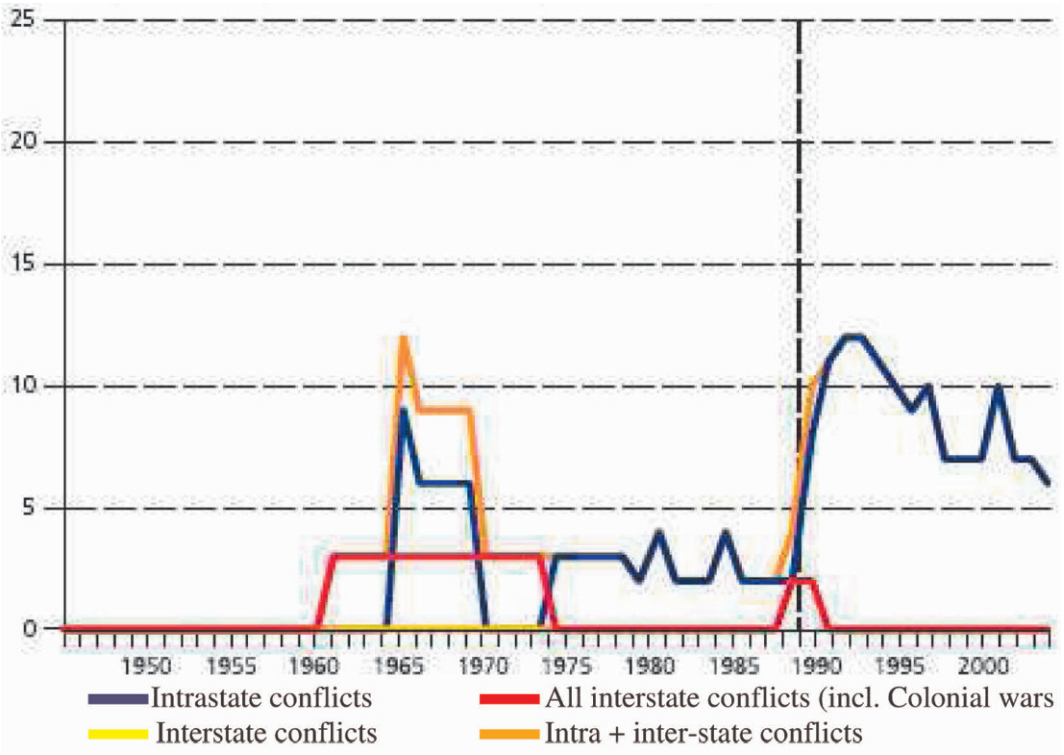
mocracy (LURD) to fight against the Taylor regime (Ero/Ndinga-Muvumba 2004: 228). Different reasons explain the readiness of external actors to support belligerents in such situations: Apart from ideological, political, or economic reasons as was the case in Taylor's support to the RUF, such support can also be understood within the rhetoric that "my friend's greatest enemy should rather become my friend." The covert support some rebel movements got from certain states granted rebels access to safe-havens, combat training and continued supply of weapons with which they sustained combat against regular armies.

The complexity of the Liberian uprising and the accompanying multiplicity of connected international actors enabled the uprising to thrive and eventually spill-over into neighbouring states; a feature which highlighted the *second* international dimension of conflicts in the sub-region.

The *third* dimension was the regionalization of the effects through refugee outflows and rippling economic effects. Conflicts in West Africa produced thousands of refugees into neighbouring countries. As

4 Taylor's support for Sankoh can be explained from two perspectives: For ideological purposes of supporting Sankoh who shared a similar revolutionary conviction and had also been trained in Libya. Secondly, it was to enable Taylor to have access to diamond as a critical resource with which he could fund the protracted war he was waging.

Figure 18.2: Trends in West African Armed Conflicts (1946-2004). **Source:** Marshall (2006: 45-48).



of 2006, for instance, the sub-region still had about 273,050 refugees after about 115,950 had been returned (UNHCR 2006: 12).

Apart from the international dimension of the conflicts, the mutilation of civilian non-combatants as part of counter-insurgency has since become characteristic of West African conflicts. Consequently, warfare in the sub-region since the 1990s have recorded untold violence against civilians. In Sierra Leone, for example, Foday Sankoh's RUF in the name of 'Operation No Hands' and 'Operation Pay-for-Yourself', committed untold atrocities against civilians. In 'Operation No Hands', victims were made to choose either 'long sleeve' or 'short-sleeve'. Based on the choice, a victim lost either a limb at the elbow for the former or a severed wrist for the latter (Aning 2005: 3). Child soldiers, particularly, under the influence of alcohol, drugs, Hollywood action movies and tyrannical interests of warlords committed grievous atrocities to children, women and aged people.

The deterioration of security in West Africa during the 1990's required a sub-regional response, besides efforts by individual states. Following the worsening of the Liberian civil war, the Heads of State and Governments of ECOWAS met in August 1990 in Banjul, Bamako and set up ECOMOG with the mandate to get the parties in the Liberian conflict to stop all military activities, surrender weapons, stop the importation of weapons, release prisoners, and respect the authority of the interim government of national unity.[5] This decision and its subsequent implementation by ECOWAS made the organization an emerging regional security actor and ECOMOG became the first African-led peacekeeping operation to deployed in sub-Saharan Africa after the Cold War (Nivet 2006: 15).

Although ECOMOG suffered setbacks in Liberia due to poor definition of its mandate, inadequate funding, organizational difficulties, uncertain legitimacy and over-reliance on Nigeria, the lessons learned from the deployment of ECOMOG in Liberia helped in the second deployment of the force in Sierra Leone (Olonisakin 2000: 100–144). The deployment of ECOMOG in Guinea-Bissau to help form a transitional government, organize elections and disarm combatants in 1998 was the third deployment of the force in the sub-region. ECOWAS reacted with an *ECOWAS Mission in Cote d'Ivoire* (ECOMICI/

5 Decision A/DEC. 1/8/90 on the Ceasefire and Establishment of an ECOWAS Ceasefire Monitoring Group for Liberia, ECOWAS.

MICECI or ECOFORCE). Despite been harshly criticized as ineffective and weak, the use of ECOMOG by ECOWAS has no doubt highlighted the commitment of its member states to the quest for peace in the sub-region. Through ECOWAS the sub-region has established an appropriate framework for realizing security through the adoption of protocols and declarations, notable among which are:

- The Revised Treaty of ECOWAS (1993);
- The Declaration of a Moratorium on Importation, Exportation, and Manufacture of Light Weapons in West Africa (1998);
- The Protocol Relating to the Mechanism for Conflict Prevention, Management, Resolution, Peacekeeping and Security (1999), and
- The Supplementary Protocol on Democracy and Good Governance (2001).

These documents provide a sub-regional framework that expresses the determination of West Africa's leaders to contain emerging security vulnerabilities, threats and challenges after the Cold War period.

18.3.2 Proliferation of Small Arms and Light Weapons

The West African sub-region is awash with *small arms and light weapons* (SALWs) primarily from years of legitimate purchases, local manufacture and illicit transactions by European arms merchants who traverse the sub-region. During the Cold War, many African countries benefited from arms transfers from the United States and the Soviet Union principally motivated by ideological or geopolitical considerations such as fuelling proxy wars. After the Cold War, remnants of these weapons found their way through the covert activities of economically motivated arms dealers, private military companies and local smugglers across the continent.

As a result, out of the 600 million SALWs currently estimated to be circulating globally and which account for the about 300,000 arms-related deaths yearly, an estimated 7–8 million are circulating within the boundaries of the sixteen countries of West Africa. Though this practically constitutes a minute fraction of the entire global challenge, the real threat it poses to West Africa can be understood against the background of the already existing instability and volatility in the sub-region. The proliferation of small arms and light weapons cannot be wholly blamed for the trendy violent conflicts in the region. Notwithstanding, the ease of weapon acquisition in the region poses dire security threats since weapon availability is a significant factor in the willingness of individuals and groups in conflict to consider peaceful alternatives. Where weapons are cheap and accessible, peaceful alternatives to dispute resolution are least considered. This contributes to the creation of abjectly insecure social settings typified by violence, destruction of life, property and an eventual strain of development efforts.

West African societies even in times of peace are still threatened by armed robbers, bandits and elements who employ violence to settle social and political scores. A notable example is the ongoing unrest in the Niger Delta region of Nigeria in which young people have employed the use of arms in registering their grievances against oil companies and government policies in the region. From this perspective, the proliferation of small arms and light weapons is practically related to societal insecurity.[6] The proliferation of SALW has therefore continously undercut efforts at combating crime, conflict resolution and management, disarmament, demobilization and re-integration efforts which are indispensable for the attainment of peace in West Africa.

Individual countries have made strides to contain this phenomenon by formulating policies and instituting projects towards curbing the challenge. Mali's efforts date back to 1993 when the country decided to tackle the small arms challenge as part of efforts to confront the instability posed by cross-border rebel activities in the country. In partnership with the United Nation various programmes were launched most remarkable of which was the March 1996 *La Flamme de la Paix* (The Flame of Peace) which saw the destruction of about 3,000 weapons handed over by the Tuareg rebels (Ero/Ndinga-Muvumba 2004: 228). In Ghana after a two-week arms retrieval amnesty granted by the government for individuals to hand over illegal SALWs without prosecution in February 2001, a joint police-military operation named 'etuo mu ye sum' forcibly retrieved unregistered weapons from owners.[7] In some West African countries, particularly Ghana, the response has been institutionalized into a Small Arms Commission to ensure effec-

6 Many West African countries particularly Nigeria, are noted for small arms-related high profile political assassinations and armed attacks. The Small Weapons Project (Prof. Keith Krause, Geneva) with support by the Swiss government has analysed this challenge critically and the Human Security Network has tabled these issues to the UN among others.

7 *Daily Graphic* [Accra], 6 February 2001: 1.

tive implementation, monitoring and evaluation of programmes. There are also commendable civil society involvements in confronting the situation. Particularly the *West African Action Network on Small Arms* (WANSA) which is a network of civil society organization in the individual countries is actively involved in confronting the challenge in the sub-region.[8]

At the sub-regional level, the realization of the devastating effects of the proliferation of SALWs led to the October 1998 Declaration of the *ECOWAS Moratorium on the Importation, Exportation and Manufacture* of SALWs. The Moratorium, among other things, basically seeks to confront the phenomenon through a *Plan of Action* under the *Programme for Coordination and Assistance for Security and Development* (PCASED) and the *ECOWAS Small Arms Project*. Despite the active involvement of various UN agencies especially the UNDP and many civil society organizations in the implementation of the programme which has resulted in many situations in the retrieval and destruction of SALW, the phenomenon has been far from curbed. Despite wide publicity, many of the initiatives aimed at retrieving SALWs merely succeeded. Many of the programmes despite the publicity merely succeed in retrieving old weapons many of which are out of use.

One of the critical challenges to the control of the phenomenon is that many states routinely flout the sub-regional restrictions on the importation, exportation and manufacture of small arms. Coupled with lax arms export controls in supplier countries, the activities of profit-motivated transnational arms traffickers and the presence of regional allies ready to provide cover and funds arms importation by belligerent groups, the sub-region still grapples with small arms and light weapons. In mid-2003, for example, the government of Guinea imported arms from Iran some of which finally ended up in the hands of members of LURD who were at the time waging an offensive in Monrovia. Our argument is that until the individual member states of West Africa unanimously pool their political will to implement and to respect the provisions of the sub-regional provision, the entire sub-region will continue to grapple with the phenomenon for a long time to come.

Besides the huge importation and subsequent trafficking across the lax borders of the sub-region, West African local manufacturers are increasingly improving in their arms manufacturing efficiency. Therefore even if the sub-region is finally able to institute stringent measures against small arms importation, the lack of a reduction in the demand will only put more pressure on local manufacturers to manufacture more. Given any correlation between increased manufacture and improvement in efficiency, the sub-region could then begin to churn out substitutes for imported arms and thus perpetuate the threats associated with SALW in the sub-region. Our argument is that West Africa's greatest threat related to SALW in the future will emerge around local manufacture. This is because unlike imported SALW that can be contained by improved border security and political will, local manufacturing is surrounded in secrecy in underground economies sustained by social structures and family allegiance thus making it difficult to contain.

18.3.3 Child Soldierism

The popularity of SALWs is due to the widespread availability, accessibility, durability, relative low-price, transportability and simplicity of use. Due to these characteristics, warlords in West Africa, particularly Charles Taylor and Foday Sankoh, found it an incentive to engage the services of children in their armies. Even though other factors such as the ease of recruitment and conditioning, and reduced proclivity to boredom are other factors, the ability of child soldiers to handle weapons and to subsequently use them in combat are important considerations in recruiting them.

About 300,000 child soldiers are currently estimated to be fighting in about 41 countries around the world with up to 120,000 of them in Africa. In post-Cold War West Africa, significant populations of the fighting forces that have waged the many intra-state wars have been children below age 18. In the Liberian civil war alone, an estimated 15,000 children engaged in combat and were largely culpable for offences such as rape, killings and other unimaginable human rights abuses (Doyle 2004: 1–2).

Children from West African cultures are noted for strict adherence to commands from adults. Conditioning them to transpose this disposition into combat therefore produces child soldiers with sharp obedience to combat command. In the hands of tyrannical warlords, such children are easily conditioned into professional killing machines that retaliate minor offences with excessive violence. Their involvement partly account for the trend of unparalleled vio-

8 WAANSA aims, among others, to work for the reduction of demand and supply of small arms and light weapons in West Africa. See for details <http://www.iansa.org/regions/wafrica/waansa.htm>.

lence and terror against non-combatants especially children, women and elderly people characteristic of West African warfare.

As reported by a journalist of the French *Le Figaro* a Liberian child soldier stated that

> at 2 pm, they gourge out two eyes, at 3 pm, they cut off one hand, at 4 pm, they cut off two hands, at 5 pm, they cut off one foot and ... at 7 pm it is the death which falls down.[9]

In a similar scenario, a young Liberian commander is quoted to have described a regular ritual of his armed group as:

> Before leading my troops into battle, we would get drunk and drugged up, sacrifice a local teenager, drink their blood, then strip down to our shoes and go into battle wearing colourful wigs and carrying dainty purses we'd looted from civilians. We'd slaughter anyone we saw, chop their heads off and use them as soccer balls. We were nude, fearless, drunk and homicidal (Weiss 2005: 2).

The involvement of children presents a military challenge in terms of strategy and confrontation. The lack of combat training and conventional warfare theories lead children to employ strategies that satisfy the interest of warlords but which draw warfare away from conventionality into practically murky and barbaric forms incompatible with conventional military strategy.

In post-conflict societies in West Africa, efforts are being made by UN agencies and civil society organizations to demobilize, disarm and reintegrate child soldiers into society. However, the lack of professional skills for lawful occupational opportunities seriously undermines efforts in many countries. In some cases, the combat experiences of child soldiers provide them with the skill to rob or involve in criminal activities. In the absence of substantial jobs, therefore, some children have found their way back into combat as veteran soldiers simply to enable them 'live by the gun' by pilfering, robbery and looting (Ball 1997: 85ff.; Malan 2000: 35ff.).

18.3.4 Mercenarism

Mercenarism in Africa is traceable to the early post-independence era when European soldiers of fortune such as 'Mad Mike' Hoare and Bod Denard had presence on the continent (McNeil 1997; Dumont 1997; McKinley 1997). In West Africa, the alliances between warlords, mercenaries, traffickers and marauders especially in the *Mano River Union* (MRU) countries, have been a notable factor in the dynamics of instability in the sub-region.

Executive Outcomes, a South African corporation that was established in 1989, for instance, has since its official closure in 1998 operated in the sub-region. During the Sierra Leone civil war, the corporation was hired by Valentine Strasser's government in 1995 to help defeat the *Revolutionary United Front* (RUF) rebellion, and to establish peace and order in the country through the provision of basic training, intelligence information, combat assistance and radar for night attacks (Winslow 1995: 36; Aning 2001). Their operation is argued to have assisted in the recapturing of the vital diamond-mining region of Kono and the retreat of the RUF from some of its bases (Rubin 1997: 44–45).

Executive Outcomes was officially disbanded following South Africa's promulgation of the Military and Foreign Assistance Act which banning its citizens from taking part in mercenary acts abroad. Yet, it is doubtful if the establishment has not simply relocated to Eastern Europe and metamorphosed into another corporation and still meddling in the security affairs of the sub-region. Such an argument is tenable in that even after reports of its official closure; the cooperation was still operating with the Angolan rebels in 1999 (Rubin 1997: B17).

Sandline International, like the Executive Outcomes, has also played very important roles in the security situation in West Africa.[10] In Sierra Leone, Sandline international is reported to have played a central role in the reinstatement of ousted Ahmed Tejan Kabbah as President by providing intelligence, logistic and air support. In the Ivorian crisis, reports of Sandline's involvement alongside European, South African and Angolan mercenaries fighting on the side of the government have been denied. Notwithstanding, the British Foreign Ministry warned United Kingdom companies against recruiting mercenaries to meddle in the situation.[11]

Despite arguments that the involvement of private corporations helped in stemming the tide of instabilities in the sub-region, it is notable that non-indigenous

9 See: Stuart Maslen, Coordinator of the Coalition to Stop the Use of Child Soldiers: "The Use of Children as Soldiers in Africa. A country analysis of child recruitment and participation in armed conflict", 15 May 2002; at: <http://www.reliefweb.int/library/documents/chilsold.htmt>.

hired military assistance sometimes distorted the smooth operations of legitimate government forces in countries such as Sierra Leone. In many cases their continued presence and operation have only led to further insecurity and instability.

The activities of foreign mercenaries can be predicted to reduce in the sub-region with increasing stability. Yet is important for the sub-region to pay attention to veteran combatants or roving fighters whose allegiance can be bought by state and non-state actors on the basis of financial gains. Examples of such roving fighters have been recorded in the Liberia, Sierra Leone, Guinea and Cote d'Ivoire conflicts.[12] The West African security environment is such that such combatants easily cross existing porous borders to fight in other countries where they are needed or to pilfer across borders. Such actors are more deadly because apart from the lack of professional regard for conventional warfare, they are familiar with the local terrain and conditions of the sub-region and therefore present dire challenges for any military action against their activities.

With the advent of roving fighters in West Africa, mercenarism is far from disappearing from the sub-region. This is because worsening economic hardships, failure of disarmament and reintegration efforts and the protracted cycle of unrests in other parts of the continent such as Chad, Democratic Republic of Congo, Sudan and Somalia implies that there would be plenty of places for veteran combatants to fight and new wars that produce continued supplies of hireable weapons and fighters in Africa some of whom could end up in West Africa.

18.3.5 Underlying Vulnerabilities

About 15 of the world's 50 less developed countries are in West Africa where large fractions of the population live below the poverty line and survive on less than a dollar per day. Apart from worsening human development indices (table 18.2), societies in the region are in their early stages of demographic transitions and thus are exhibiting rapid population growth, very large number of children and adolescent dependents, and a relatively few working age adults per dependent (Concitta/Engelman/Anastasion 2003: 32).

Given the prevailing economic non-performance, corruption, and inept leadership, West African countries have large populations of poverty-stricken young people who are literally coping with life and expect only a bleak and uncertain future. This has led to the creation of young desperadoes who have been ready-made cannon fodder for exploitation by individuals who recruit them for criminal activities or as child soldiers.

In an interview conducted by Human Rights Watch with some sixty former West African combatants, all respondents unanimously identified crippling poverty and hopelessness as the fundamental factors which motivated them to participate in armed conflicts across the boundaries of their countries. Many of them recounted the extent to which they battled daily against abject poverty and the hallucinations of hellish daily survival. Given the difficult present, unpredictable future and unlikely fulfilment of their dreams, many of them thought that going to war was their best option for survival. The surrounding psychological and physical complexities then aided their recruiters – mainly the warlords (HRW 2005).

Once these situations got them into combat, many of them willingly crossed borders as veteran combatants or roving fighters into other wars in neighbouring countries. To them, warfare always provided an avenue for survival by looting and pillage of property

10 See its website at: <http://www.sandline.com/site/>. It describes itself as: "Sandline International is a Private Military Company (PMC) which specializes in problem resolution and the provision of associated consulting services. The business was established in the early 1990's to fill a vacuum in the post cold war era. Our purpose is to offer governments and other legitimate organizations specialist military expertise at a time when western national desire to provide active support to friendly governments, and to support them in conflict resolution, has materially decreased, as has their capability to do so. Sandline is a privately owned and independent business. It is incorporated in the Bahamas and maintains representative offices in London, England and Washington, DC in the United States." On 16 April 2004 Sandline closed its operations and its website: "The general lack of governmental support for Private Military Companies willing to help end armed conflicts in places like Africa, in the absence of effective international intervention, is the principal reason behind Sandline's decision. Without such support the ability of Sandline (and other PMCs) to make a positive difference in countries where there is widespread brutality and even genocidal behaviour is irretrievably diminished." Sandline was a member of: International Peace Operations Association, 1900 L Street, NW | Suite 320 | Washington, D.C. 20036, at: <http://ipoaonline.org/php/index.php>.

(HRW 2005). One of the most important underlying vulnerability to West Africa's security is the prevalence of exacerbating poverty among young adults. This communicates that realistic development efforts should be made inevitably part of conflict prevention and management processes since economic hardship is a function of resort to arms by ex-combatants.

West African countries have long borders which are poorly controlled due to inadequate resources, corrupt border officials and the existing ECOWAS mechanism for free movements among West Africans which makes it relatively easy for West Africans to cross borders into neighbouring countries. The ease with which individuals and covert networks are able to traverse the sub-region makes the regionalization of security threats easy. The smuggling of SALW, human and drug trafficking, mercenaries and illicit trade of minerals are able to flourish. For example, the illicit trade of Sierra Leonean diamonds that funded the RUF uprising involved cross-border smuggling through Liberia and Guinea to the world market. Through these the weak borders of West Africa becomes a critical vulnerability to the stability of the sub-region and the containment of all forms of military challenges.

The military capacity of West African states, compared with other parts of Africa, is one of the most tested in Africa due to the sub-region's experiences in intervention initiatives. However, military composition predisposes many of them to internal weakness. Some West African armed forces are endemic with divisions resulting from politicization, religion, clientelism and, most of all, ethnicity which are fallouts from both colonialism and of the extent of military participation in politics. As a result, whereas some officers of the army are capable by all standards, others became members of the army through neo-patrimonialism without regard to capacity and competence. The result is that whereas some West African armies are efficient and professionally capable, others are

grossly incompetent with inherent weaknesses and combat unpreparedness that render the state vulnerable to armed rebel activities (Metz 2000).

The Ivorian army, for instance, was created in 1960 and was primarily involved in political and development activities including administration, health care, and diplomatic representtation rather than the preservation of the territorial integrity of the state. The combat readiness and response of the army was thus weak or at best limited. About 80 per cent of its budget was meant for salaries of military personnel rather than for materiel and training. Under President Bedie the army's role, was changed towards its utilization as a political tool to suppress anti-government protests. The army's inherent weaknesses and unpreparedness became instantly evident when it was put to test by the uprising which plunged Cote d'Ivoire into civil war.

18.4 Military Implications of the Challenges

The complex security environment created by these threats and challenges in the sub-region has diverse military implications, particularly in terms of combat strategy or tactics, deployment of troops and security spending. The phenomena of child soldierism, warlordism, the proliferation of SALW and the oscillatory motivation for conflict in West Africa have murkily influenced the dynamics of warfare in the sub-region. Consequently, warfare in West Africa is typically unconventional and thus employs fluid combat strategies including the gross mutilation of civilian noncombatants and displacements as strategies of insurgency. These present crucial challenges for conventional combat strategies as is evidenced by the ability of rebel armies to sustain combat against government forces for decades, as was the case in Liberia, without being immediately quashed.

Since the deployment of *ECOWAS Ceasefire Monitoring Group* (ECOMOG) in Liberia, peacekeeping deployment has become a norm in ECOWAS's response to armed conflicts in the sub-region. So far the organization has deployed four key peacekeeping missions – Liberia, Guinea-Bissau, Sierra Leone and Cote d'Ivoire. Such deployments have financial implications and also stretch the military capacity of participating countries. In deploying the ECOMOG in Liberia, Nigeria had to bear the larger fraction of the cost of funding because Nigeria was economically better than the other countries that had contributed troops for the operation. Concurrently, however, West African economies are recovering from years of economic non-performance and debts since the early 1970's and 1980's. Defence spending, therefore, competes with many other national development goals leading to a relatively low and austere funding for the military. Given the need for a constant deployment in a volatile region like West Africa, apart from over-stretching the army, also puts undue financial pressure on governments to fund armies from the already over-stretched budgets readiness in response to crisis or an eminent insecurity.

18.5 Sub-regional Responses and the Evolution of ECOWAS

ECOWAS has since the deployment of ECOMOG in Liberia continued with efforts towards the establishment of permanent institutional and legal structures for the realization of peace and security in the sub-region. Notable among these efforts is the December 1997 extraordinary summit of the Authority held in Togo. The summit, among other things, sought to shift emphases from the ad hoc conflict resolution procedures that guided ECOWAS's response to crises in the sub-region to more permanent structures by establishing a mechanism for conflict prevention, management and peacekeeping. A technical document that outlined the modalities for such a mechanism formed the basis for an expert meeting in July 1998. Its conclusions resulted in a *Mechanism for Conflict Prevention, Management, Resolution, Peacekeeping and Security,* which was adopted in 1999.

In the area of conflict prevention, management and resolution, some of the established institutions include the *Mediation and Security Council* (MSC) which harmonizes decision-making regarding deployment and operates at the level of the Heads of State, Ministers of Foreign Affairs, and Ambassadors. ECOWAS also established an early warning system and an Observatory with threat perception analysis. Since it is increasingly being realized that the nature of new conflicts have deep roots, the Observatories have the duty of examining the root causes of impending conflicts and forwarding reports to an *Observation and Monitoring Centre* (OMC) at the ECOWAS Secretariat where such reports are analysed. The reports are then synthesized and expedited immediately with suggestions concerning the appropriate strategy to be applied by the MSC and the countries concerned.

ECOWAS's response mechanism is based on such reports upon which the Executive Secretary devises response strategies. Based on the reports forwarded to the Executive Secretary and subsequently to the CMS, four options may be opened to diffuse any potential conflict. These are: (a) to set up a fact-finding commission; (b) employ the services of the Executive Secretary; and (c) call on a Committee of Elders; or (d) recommend military intervention.

Three major circumstances warrant community intervention and these are spelt out as situations or event that:

- threaten to trigger a humanitarian disaster;
- pose a serious threat to the peace and security in the sub-region; and
- erupt following the overthrow or the attempted overthrow of a democratically elected government.

The operationalization of the response mechanism to the diverse security challenges in West Africa has set the ECOWAS apart as a sub-regional body with a peacekeeping and peace enforcement apparatus. It has also resulted in the transformation of the organization from a purely economic entity to one with security as one of its primary priorities.

18.6 Conclusion

The West African sub-region has grappled with myriads of security challenges in the post-Cold War era that have required military response and involvement. Despite commendable strides by individual countries and ECOWAS to contain them, the sub-region is still pragmatically bedevilled with intra-state armed conflicts, the proliferation of small arms and light weapons, child soldierism, mercenarism, and cross-border criminality especially drug trafficking. Even though they pose individual challenges, the threats are practically interwoven and are mutually reinforcing of each other. The armed conflicts of the sub-region, for instance, are sustained by the proliferation of SALWs, yet SALW proliferation is also worsened by the existence of armed conflicts in which combatants get weapons to use for combat. Similarly child soldiers, whilst contributing to the insecurity, are also recruited because of their ability to handle weapons.

Practically, however, the combined effects of all the challenges determine the security situation in the sub-region. Commendable strides have been made towards the realization of peace and stability in the sub-region, yet the region is practically far from what citizens of the region's individual countries expect. Whilst many of the countries cannot be said to be at war presently; they can equally not be said to be at peace. This has led to the existence of what can best be described as a 'no peace and no war situation' in which the above discussed military challenges are key in the calculus of the sub-region's peace presently and in the future. Underlying the situation, however, is the prevailing exacerbating forms of poverty which is critical in maintenance of peace and the resolution of conflict.

It is thus important for the ECOWAS to step-up the various programmes and projects that target the above discussed challenges. This is because given the extent of easy regionalization of the effects and implications of the challenges a sub-regional response will be more comprehensive than individual state initiatives. The efforts of the ECOWAS therefore require support and commitment from ECOWAS member states and the international community as a whole.

19 Weak States and Security Threats in West Africa

John Emeka Akude

19.1 Introduction

Since the late 1980's, repeated cases of breakdown of states' institutions and the concomitant internal wars in West Africa have called the attention of observers to the abysmal level of insecurity in this sub-region. Images of wanton killings, of mutilations and displacement of thousands of people alerted the world to the orgy of violence in the wake of states' incapacity to protect its institutions. Endemic insecurity in West Africa is not restricted to state institutions but pervades almost all aspects of citizens' lives. Political instability with a high degree of violence has accompanied these states since the post-colonial period. A calculation showed in 1991 that 485 post-colonial African rulers were threatened with a 60 per cent chance of being killed, imprisoned or exiled as a consequence of holding office (Wiseman 1993: 657–660). Restricted to the West African region, this percentage may dramatically increase.[1] Prior to the series of state collapse and the attendant internal wars, most West African states have experienced military coups, civil wars or violent secession attempts involving thousands of civilian casualties. In most West African states, internal political struggles are sometimes akin to wars. Thus, internal sources of insecurity by far exceed external sources. In general, peoples and states in West Africa are confronted with a constant state of fear.

How do we define (in)security and state weakness and how are they linked? Why is insecurity common place in West Africa? What constitute threats, risks and challenges to security in West Africa and why are the states vulnerable to them?

This chapter seeks to provide answers to these questions by conceptualizing security and insecurity as well as state strength and weakness (19.2). It then theorizes state weakness in West Africa in a historical context (19.3). Finally, the challenges to security and vulnerabilities to insecurity in West Africa are reviewed with policy recommendations regarding the improvement of the situation.

The hypothesis of this chapter is that the historic trajectory of the emergence of the modern state in Africa precluded the imperatives for creating strong bureaucratic state structures with the consequence that the states remain weak, dependent on the international system (superpower politics) and incapable of securing themselves as well as their citizens. This specific historic trajectory equally obliterates the necessity of pursuing economic development among the political elite, who instead, concentrated their energies on using state power to accumulate private wealth. Decades of economic underdevelopment left the youths with fewer prospects for decent lives and drove a majority of them into violence, crime and prostitution. The considerable decline in economic and military support from international sources at the end of the Cold War resulted in the collapse of some states and thereby increased the level of insecurity for states and citizens in the sub-region. As states collapsed and civil wars arose, the youth became willing tools for warlords to spread insecurity, deaths and chaos on West African states and citizens.

19.2 Clarifying the Concepts of Security and State Weakness

The study of international relations has a (realist) tradition that considers security primarily from the perspective of the state. The state is the subject as well as the object of security. Only it has the right to securitize an issue.[2] The protection of the state thus has priority over all other issues. This is understandable due

1 Apart from Senegal and Cape Verde, all West African states have witnessed violent military coups. This does not imply that Senegal is more secure than other West African states, as there have been violent skirmishes between the Senegalese government and Casamance separatists for some decades.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_19, © Springer-Verlag Berlin Heidelberg 2011

to the fact that today's international relations started in Europe where, as Adam Smith (1776) points out, the defence of the realm is the state's *raison d'être*. This naturally includes the defence of citizens. It was superfluous to consider other dimensions of security – the human dimension for example - because the states protected their citizens as a survival imperative. The survival logic in the development of the modern state in Europe automatically disposed the state to have an interest in protecting the lives of citizens within its territories. The goal was to pre-empt external aggressors exploiting the disgruntlement of some sections of the citizenry to attack and possibly dismember the state (Jackson 1990; Tilly 1992). In view of the credible sources of insecurity being external, it was understandable for the realist version of international relations theory to be mainly concerned with the external dimensions of a state-centred security concept. For example, Stephen Walt (1991: 212) considers security as dealing with the threat, use and control of military force with states being the actors that prepare for, prevent or engage in war. This implies that states have to, first of all, perceive something (real or imagined) as a threat to their existence and then act on it. The significance of perception led Arnold Wolfers (1962a) to see security as consisting of two dimensions: objective and subjective. Objectively, security implies the absence of threats to acquired values and subjectively, it implies the absence of fear that such values will be attacked.

Conversely, the development of the modern state in West Africa took an opposite logic in which the state's protection of citizens is not obligatory – at least from the point of view of states' political elite (Akude 2008). It is a logic that, now and again, induces the endangering of the lives of citizens within the state's territory by the state itself. In West Africa for example, anti-democratic and dictatorial rulers have often hidden behind the cloak of state security to victimize, torture and even kill political opponents. Victimizations and discriminations could even be extended to the ethnic origins of those opponents in an atmosphere of politicized ethnicity and have sometimes led to civil wars.

The warning of Barry Buzan (1991: 102) regarding the unqualified application of the concept of state security to weak states is therefore appropriate. He maintains that "the weaker a state is, the more ambiguous the concept of national security becomes in relation to it" and warns that an unqualified application could be dangerous because the logic of state security could be exploited by factions in control of the state to legitimize the factional use of force.

International relations study was reluctant to acknowledge these facts due to the dominance of superpower politics in international relations during the Cold War. The termination of the Cold War removed the barriers to the acknowledgment of the dangers associated with the state-centric definition of security and coupled with analyses of states preying on their societies; attempts were made to alter that. Furthermore, globalization and the increasing salience of economic, environmental and identity issues in international relations contributed enormously to a demand to altering the state-centrism of the security concept. These developments culminated in a widening of the spectrum of security discourse. One could therefore identify two schools of thought: the post-modern 'wide' and the traditional 'narrow' (Buzan/Wæver/de Wilde 1998: 1ff; Brauch 2003, 2005, 2005a, 2008, 2008a, 2009). Current concepts of security therefore ramify all dimensions of human life, albeit with a danger of being analytically unclear.

Of all these new dimensions of security, the concept of human security is the most comprehensive and happens to be the most appropriate to West African states because it goes to the heart of the dangers associated with and neglected by the state-centred concept of security. It also calls attention to the amelioration of such social problems associated with less-developed states and which feature prominently on the development policy agenda as the general poor quality of life, abuse of citizens' rights and their denial of political liberties among others. Furthermore, if the protection of the realm is the main reason for states' existence as Adam Smith claims, then the concept of human security should be prioritized over state security because the best real protection of the state is the protection of its citizens. One of the lessons to be drawn from the collapsed states of West Africa is that unprotected citizenry could (in the search of self-help

2 For a detailed discussion of the concept of securitization, see Wæver (1995, 2008, 2008a) and Buzan/ Weaver/ de Wilde (1998: 23–33). The usage of the term in this chapter is limited to expressing the necessity of emergency in dealing with an issue which if not done, could sooner or later; threaten the existence of either the state or its citizens. This should not be misconstrued to indicate a plea for increasing the powers of the state against the society. Of course, a humane, democratic and socially cohesive state, based on the rule of law and interested in the economic well-being of its citizens is preferable than other types of states in the securitization of issues.

protection mechanisms) facilitate the collapse of states which invariably increases the level of insecurity of the citizenry. Taking cognizance of this fact means that neither 'state' nor 'human' security should be pursued at the expense of the other. How is human security to be understood? Although the concept still suffers from analytical clarity which makes it problematic for research purposes, a certain consensus could be gleaned out of the definitions offered by different experts.

The *United Nations Development Programme* (UNDP 1994: 23) defined human security as safety from such chronic threats as hunger, disease and repression as well as protection from sudden and hurtful disruptions in the patterns of daily life – whether in homes, in jobs or in communities. Its long list of aspects of human security includes economic, food, health, environmental, personal, community and political security (UNDP 1994: 24–25). This represents a fundamental change in the concept of security by placing human beings at the centre and making their protection the benchmark of security.

The Japan-sponsored *Commission on Human Security* (CHS), for example, sees it as 'freedom from want'. The Human Security Network (involving 12 states) regards human security as 'freedom from fear'. Kofi Annan's (2005) definition stressed the 'freedom to live in human dignity' (including the rule of law, respect for human rights and democratic principles) while the United Nations University's Institute for Environment and Human Security considers it as the 'freedom from hazard impacts' or the aftermaths of catastrophes, emphasizing the reduction of social vulnerabilities through early warning and institutional resilience (Bogardi/Brauch 2005; Brauch 2005, 2005a, 2008a). Thus, the concept of human security drives security beyond the state by stressing the primacy of the protection and empowerment of the individual. Human security is considered in this chapter as the capacity of eliminating, or constantly reducing the vulnerability of individuals and their communities to political, economic, environmental, and socio-cultural threats.

Security in general is considered here as having two main dimensions in West Africa - the state-institutional and the human – and threats to the lives, properties, health, well-being, environment and the community as well as threats to the smooth functioning of state's institutions, including the pursuit of economic and social development and respect for human rights, democratic principles and the rule of law as security threats: They directly or indirectly impinge on the ability of human beings to live in a social condition devoid of threats identified by the definitions above. This demarcation is merely analytic. I would later on demonstrate that there are constant spill-over effects of threats between the two dimensions. Practically, what threatens one, *ipso facto*, threatens the other. Evidently, the concept of human security is automatically linked to the institutional capacity of states because it implies the willingness, readiness and capacity of states to protect their institutions, territories, environments and citizens. Of course, weak states fare worse in these areas than strong states.

The terminology of weak statehood is from its very nature a comparative one as it distinguishes a class of states from others. It is also relative for the fact that there are several stages of weakness. The conceptualization of state weakness demands *ex ante* a conceptualization of the state for the mere fact that a weak state, to paraphrase Clapham (2000: 1), is characterized by what it is not. So what is a state proper? Jean Bodin (1986, 1576) is generally regarded as the founding theorist of the modern state and defines the state on the basis of sovereignty which he sees as "la puissance absolué d'une republique" – absolute and perpetual power vested in a commonwealth. He contends that sovereignty has an impact on the internal as well as the external affairs of a state and is the highest power of dominance immanent to a state. This implies that states with "quasi-sovereignty" (Jackson 1990) are seriously constrained in their exercise of authority internally as well as externally. To Alan James (1986: 39), sovereignty "is a legal, absolute and unitary condition". It is legal; because a sovereign is not subordinate to another sovereign and enjoys equality with other sovereigns in international law, absolute; because sovereignty is either present or absent, and unitary; because a sovereign state is the supreme authority within its jurisdiction (Jackson 1990: 32). Sovereignty is thus the quality on which the equality of all states in international relations rests. Below, this is discussed as being more apparent than real as it often negates international political fact. This aspect of the historical violation of the long-standing principle of sovereignty rather justifies its characterization as "organized hypocrisy" (Krasner 1999).

Max Weber (1968) defines a state, rather from the means at its disposal, as an entity that claims legitimate monopoly of instruments of violence and taxation for purposes of order in a populated territory, using violence if necessary, to achieve its aims. Critical attention should be paid to the word 'claim' due to the fact that the capacity of states to monopolize tax-

ation and violence, maintain law and order as well as the acceptance of this by societies vary. States claim to perform these functions based on the rule of law. A state therefore consists of a territory, a population and a sovereign government that regulates the affairs of the state guided by the law. This corresponds to the definition of state in international law (Montevideo Convention on Rights and Duties of States of 1933: Article 1).[3] However, the state as a human organization has developed further and taken up more assignments to itself since the times of Bodin and Weber.

Rotberg (2004) wants these expanded assignments reflected in the definition of the modern state which he maintains, exists to supply the citizens with political goods. Critical among these political goods are security, law and order, infrastructures, economic well-being, political rights and civil liberties etc. "But it is according to their performances – according to levels of their effective delivery of the most crucial political goods – that strong states may be distinguished from weak ones, and weak states from failed or collapsed ones" (Rotberg 2004: 2). He constructs a hierarchy of political goods with security, especially human security at the apex, proceeded by the provision of law and order, free and open political participation, medical care, educational facilities, physical and social infrastructures etc. in that order. Strong states generally perform well (albeit with variations) across this spectrum but weak states do not. Weak states therefore are those economically poor states that possess negative sovereignty, lack the legitimate means of effective monopoly over instruments of violence and taxation which then impinge on the will or capabilities of providing the society with political goods.

19.2.1 West African Discourses on Security and the State

The end of the Cold War and the collapse of states in West Africa have spawned discussions and academic researches on security issues in that region. Most of these studies have revolved around the the conception of security, the dynamics of security, the sources of insecurity, conflict management and how to improve the security situation in West Africa within the context of the post Cold War order.

The literature demonstrates a consensus on certain issues: They criticize the realist school (Musah/Fayemi 2000; Hutchful 2000; Obi 2006), emphasize the historical trajectory of the states and personality cults as fundamental in precipitating insecurity (Musah 2000; Adebajo 2002: Adedeji 2002), stress the international as well as local dimensions of violent conflicts (Musah/Fayemi 2000; Musah 2000; Hutchful 2000), criticize the conflict management method that conflates cessation of hostilities with peace and conduct of elections with democracy (Adedeji 1999; Musah/Fayemi 2000) and see bad governance as the major causes of insecurity in West Africa (Adedeji 1999; Abdullahi/Muana 1998). There is, however, disagreement on the causes of the conflicts. Some consider conflicts as being caused essentially by poverty and identity-driven (Musah/Fayemi 2000a: 39). Adedeji (1999a: 17) disagrees slightly. To him, identifying tribalism and ethnicity as causalities is a misunderstanding of African conflicts, seen through Western lens. He identified political failures as lying behind economic crises and political conflicts in Africa. He writes, "It is now generally accepted that Africa's persistent economic crisis, severe as it has been, is but a consequence of its political crisis. Civil wars and civil strifes are but violent reactions to the pervasive lack of democracy, the denial of human rights, the complete disregard of the sovereignty of the people, the lack of empowerment and accountability and, generally, bad governance" (Adedeji 1999a: 7). West Africa is home to a critical and radical academic tradition that considers ethnic conflicts as being engineered by politicians jockeying for posts that enables access to state's resources. Ethnic conflicts are therefore essentially class conflicts with the state acting as the arena for class formation (Ake 1996; Nnoli 1978, 1998).

Indigenous West African security pundits are generally critical of the realist, state-centric conception of security and appear to favour the postmodern "wide" variant. Musah and Fayemi (2000) criticize the emphasis on the coercive power of the "established" and "legimitate" State as the primary source of stability and order by international security experts in the search for "quick-fix solutions" to problems of internal conflicts. They state: "By reading violent sub-national challenges to the supreme authority of the nation state as 'irrational', and expressing disgust at the methods used by some belligerent parties and the need to 'do something' about these 'barbaric acts', the potent identity-based factors and wider perceptions of

3 Art. 1 of the Montevideo Convention (1933) reads: "The state as a person of international law should possess the following qualifications: a) a permanent population; b) a defined territory; c) government; and d) capacity to enter into relations with the other states."

economic and social injustice which combine to fuel these conflicts conveniently escape serious attentions" (Musah/Fayemi 2000a: 14).

Working within the "state as an organized crime" paradigm (Tilly 1975), Eboe Hutchful (2000) sees the state-centric concept of security as a racket. He considers security an ideological construct which force is broadened when linked to other normative states such as 'national', thus creating the impression of a common good to which all citizens have access. This illusion is laid bare, if one deconstructs the concept. Thus, "security has always been dispensed very selectively within both national and international community, reflecting socioeconomic status, residency and state of citizenship (...); in other words, differential perceptions of human worth" (Hutchful 2000: 214). National security instruments could even be employed against citizens by the state. Additional to the governance problems of African states, he states, there is a problem with the governance of security; i.e., the effective management of the institutions of violence: The attempt at strengthening the internal security of a state could threaten the position of the ruler by increasing the power of 'strongmen' within these security institutions. This, he calls, the "rulers security dilemma" (Hutchful 2000: 212). Rulers could react by deliberately weakening state security institutions and even creating private armies often known as national guards with long term fatal consequences for the states. This security dilemma goes down the line as it affects managers of security in terms of technical efficiency of the production of force as well as in terms of similar threats from strongmen from within the ranks of the institution. Officers therefore resort to relying on primordial relationships against formal structures of bureaucracy as a basis for trust. This explains the dominance of informal links and structures of power as well as primordial and family relationships over formal hierarchies and chains of command. Thus, the rulers security dilemma increases insecurity through incompentence: recruitment and promotion are based not on merit but on trust out of primordial relationships.

That security is an ideology that could be framed to suit differential purposes, for example, the framing of state collapse and terrorism, is also stressed by Obi (2006). This is his explanation of drawing West African states into the war against terror without a clear evidence of international terrorism in West Africa; an act which he considers a globalization of the region's security. The US has gone ahead to engage militarily in West Africa through establishing an Africa Command and an *African Contingency Operations Training Assistance* (ACOTA) to aid West African states prepare for counterinsurgency. She is already building facilities (air and sea military bases) in West Africa. By so doing, the US is positioning herself to dominate the extraction of West African oil which is supposed to supply 25 per cent of US oil imports by 2020, maintains Obi. Thus, the US disregards her avowed promotion of good governance and democratic principles in order to ease extraction agreements with West African rulers. In this sense, US projection of her interests could reinforce state's high-handedness and consequently insecurity in West Africa. Obi also raised the critical issue of West African states being held captive by external security interests and projects. He further criticizes the state-centrism that emphasizes institutional and military approaches to anti-terrorist arrangements while little attention is focused on providing the national and international resources badly needed for addressing the harsh political and desperate socio-economic conditions that may provide the nourishment for dissent, violence, repression, proliferation of small arms and mobile youth fighters, and possibly terror (Obi 2006: 89).

Thus, foreign interests affect conception and provision of security in West Africa. The security complex in West Africa is therefore driven by the link between security and trade, the historic context of the geostrategic rivalry between Nigeria and France (often appearing as Francophone versus Anglophone), the security and development nexus, international trade interests, US, Chinese and European resource interests and the personal interests of the region's rulers.

Analyses of sources of insecurity in West Africa often stress the international political and economic dimensions. The absence of superpower protection as a result of the end of the Cold war coupled with the emergence of sub-state elements as a result of globalization, budget and military downsizing in the course of neoliberal reforms which left a "security vacuum in Africa" as well as inappropriate conflict management methods based on rebuilding the coercive power of the state have contributed to insecurity in West Africa (Musah/Fayemi 2000). The marginalization of African states in international political economy which produces order at the global centre and disorder at the global periphery (Musah 2000), marginalization of the people by the governments (Adedeji 1999; Abdullahi/Muana 1998) and neoliberal international economic linkages (Nnoli 1998; Hutchful 2000; Nanga 2005) feature as proven sources of insecurity in West Africa.

Internally, they bemoan the state as an agent of insecurity (Obi 2006: 96). "Tyranny and political repression are a fundamental cause of domestic and regional instability (Huchful 2000: 218). Driving this point home, Hutchful (2000: 214) observes that "Africans have too often seen the 'force' than the 'security' in 'security forces'." They mention logistic problems such as poor security planning as being partly responsible for rampant insecurity in West Africa. Kwesi Aning (2006), for example, problematizes the police – population ratio, maintaining that it is too far below the international average of 1–5 policemen for 1,000 citizens.[4]

Generally, West African security experts criticize the involvement of 'mercenaries' – private military companies – in West African conflicts and highlight the availability of light weapons and security advisers (following the demise of Soviet Union and Apartheid regime in South Africa) as having adversely affected the security situation in the subregion.[5] They emphasize the necessity and relevance of a regional approach to the problem by strengthening the subregional body – *Economic Community of West African States* (ECOWAS) – and are proud of the pioneering role of this body as the first subregional organization with conflict management mandate globally (Ogwu 2008). Subregional bodies and the African Union should be encouraged to take care of peacekeeping. They criticize the post-conflict reconstruction that seeks to rebuild the collapsed states in exactly the same pre-collapse form and recommend an innovative and dynamic approach to conflict management which is holistic, bottom-up and transformative of the state.

19.3 State Weakness in West Africa

Not only do West African weak states perform badly in the provision of political goods, they are not really sovereign in the classical (Bodian) sense of the word. Their sovereignty is not empirical, rather derived from an international jurisprudential fiat that outlawed colonization following the Second World War (Jackson 1990). The fact that most of these states are not economically independent – they derive a large part of their national revenues from develop-ment assistance (table 19.1) – is a pointer to their perennial weakness and lack of sovereignty. Klingebiel (2006) calculates that *Official Development Assistance* (ODA) contributes 55 per cent of total financial flows to Africa. They have very low *Gross Domestic Products* (GDP), high levels of unemployment, high infant mortality rates, high levels of illiteracy etc. The weighted averages of the *Human Development Index* (HDI) of these states are the lowest in the world, with 13 out of the 15 member states of the *Economic Community of West African States* (ECOWAS) counting amongst the 27 countries with the lowest scores on the Human Development Index (UNDP 2008).[6] Even though most African states have been making tremendous progress in economic development and management with some recording growth levels of 5 per cent and more since the year 2000 (World Bank 2006) with an average of 5.7 per cent in 2008 (Ruffing 2008), it has to be stated that the general level of global economic development still remains lowest in Africa.[7] The level of industrialization is still very low compared with the global average and the economies remain monocultural. There are wide discrepancies in income inequality; and the neglect of the provision of infrastructure by successive regimes which leave a large percentage of the population hopeless. These, coupled with a fast-growing and unchecked population, rapid and uncontrolled urbanization delineate West Africa (World Bank 2006) and constitute the backgrounds to a thriving culture of crime and violence.

They could hardly claim broad legitimacy or capabbility in their monopoly of violence. Some West African states are under challenges from sub-state actors with particularistic tendencies; e.g. the Casamance in Senegal, MASSOB, Ogoni, MEND and OPC in Nigeria, Ewe in Togo, MPIGO and MPCI in Cote d'Ivoire to mention just a few.[8] They lack the institutional capability and robustness to protect lives and properties of citizens even if they wanted to.[9] The

4 While Singapore has about 1 police officer to 119 citizens, Nigeria has 1:371 and Ghana 1:1421.

5 They are very critical of the exploits of Executive Outcomes and Sandline International in Sierra Leone.

6 The report omitted Liberia due to lack of data.

7 It has to be remarked that this statistic shows the average growth rate and thus masks a reality: there are staggering differences in growth rate across individual African countries. And within the majority of African states, the impact of this growth has not been felt by majority of the citizens.

8 MASSOB stands for the *Movement for the Restoration of the Sovereign State of Biafra*; MEND abbreviates the *Movement for the Emancipation of the Niger Delta* while OPC stands for *Oduduwa People's Congress*. MPIGO refers to the *Mouvement Populaire Ivorie du Grand Ouest* while MPCI stands for *Mouvement Patriotique de Cote d'Ivoire*.

Table 19.1: Ratio of official government's income to income from development aid (ODA) in selected African countries in 1998 (in million US$). **Source:** Calculated by Bierschenk/Elwert/Kohnert (1993: 89).

Country	Income from ODA Absolute	per cent GDP	Current total of central government income per cent GDP	ODA as percentage of central government income
Burkina Faso	298	16.0	17.1	90
Benin	162	9.0	12.0	75
Guinea Bissau	100	13.8	'8.2'	168
Nigeria	120	0.4	18.5	2
Sierra Leone	102	7.3	7.3	100

degree of social cohesion in these states is low. This is extremely significant in the discussion of state weakness/strength for the fact that it directly affects the legitimate exercise of political authority. Barry Buzan (1991: 96–107) writes that the concept of weak and strong states rests on the degree of socio-political cohesion within the states, maintaining that cohesion is the very essence of what makes them states (Buzan 1991: 97). Kalevi Holsti (1996) made similar points by stressing that the lack of horizontal and vertical dimensions of legitimacy is the bane of African statehood.[10] The lack of community feeling is underscored by violent interethnic and inter-community conflicts, coup d'etats, civil wars and states collapse which have constantly accompanied the political history of West African states.[11] A leading Nigerian politician, Chief Obafemi Awolowo, once referred to Nigeria as a mere geographical expression and underscored with that, the blatant lack of community feeling in that country. His statement applies, sadly enough, to most West African states.

19.3.1 Background on State Weakness in West Africa

The basis of state weakness in West Africa is to be found in the historical trajectories of the development of the state in Africa. African states lacked the processes which led other states, mainly European, to develop robust bureaucratic structures. Basically, the international environment under which states develop is critical for state strength and weakness. This becomes clear if one compares the international environment under which the strong states of today developed with the international environment under which the West African states are developing.[12]

Those processes of development imbued those European states with the compulsion of erecting strong bureaucratic institutions. States' strengths are predicated on their institutions and institutions are as strong as state makers make them. Thus, strong institutions have a tendency to develop if state makers are compelled to strengthen institutions for whatever purposes; often of state survival, and vice-versa. The compulsions could be summarily treated as 1) the necessity of the state to sustain itself through taxation, 2) the exigency of the state to maintain internal stability in order to ward off external aggressors, 3) the ability of the state to derive revenue from elastic bases, 4) the separation of economic from political power bases and 5) nationalism or the desire to catch up with the West (with reference to late-late developers (Kohli 2004). These processes may not be sufficient but are definitely necessary for the emergence of strong statehood: robust security and administrative apparatuses and social cohesion.

19.3.2 The Imperatives of State Survival[13]

Charles Tilly (1992) advances the thesis that war and its preparation played a significant role in the emer-

9 The assassination of Nigeria's Justice Minister Bola Ige in 2001 has not been cleared and there has been no conviction up till this day. It is not even clear if the Nigerian justice system is still investigating the issue.

10 Horizontal legitimacy refers to a feeling of community among the constituent parts of the state and vertical legitimacy refers to the acceptance of the state amongst these constituent parts. See Holsti (1996: 84–97 and 102–103 for horizontal legitimacy and 84–97 and 102–104 for vertical legitimacy).

11 The states of Ghana and Chad collapsed in 1981 and 1982 respectively.

12 As argued above, the terminology of a 'weak state' is a comparative one because it implies that some other states are strong It is thus necessary to investigate the reasons for the strengths and weaknesses of states. The participation of these states in the same international system which also constitutes a parameter for judging their strengths or weakness further justifies this comparison.

13 See Akude (2008) for an elaborate development of this analysis.

gence of robust administrative and durable state structures because preparation for war and deployment of coercive means in war saddled warriors with two dilemmas which could best be resolved by regular administration of lands, goods and people in order to maintain the subjugation of conquered people, on one hand, and the erection of an infrastruc-ture of taxation, supply and administration in order to ensure continuity, on the other (Tilly 1990: 2). Robust state structures were thus necessary for the survival of the state.

The fact that other states could exploit the existence of internal recalcitrant elements to attack a state and that states that could not militarily withstand such attacks merely perish made this necessity even more urgent (Jackson 1990). Mearsheimer (2001: 46) postulates that "great economic prosperity invariably means greater wealth, which has significant implications for security, because wealth is the foundation of military power." States therefore involved themselves, for this reason, in the promotion of economic development (in order to optimize taxation) by means of state institutions which get strengthened in the process.

Securing state survival through optimization of taxation has further consequences for economic development and state strength. For example, Robert Bates (1999) states that the ability of states to derive revenue from elastic bases – bases that react favourably to the provision of infrastructure – catalyzed the introduction of democracy in England which invariably strengthened the state by fostering social cohesion. In this vein, Sidney Mitchell Knox (1951) illustrates that the desire to tax movable property (livestock) drove a medieval English monarch to devolve power to owners of large livestock by setting-up a parliament which enabled them have a say in government. This process is largely regarded as the inception of democratization efforts in Western Europe.

The separation of wielders of economic power from the wielders of political power also has a state strengthening implication for the fact that these groups need one another to function smoothly and this smooth-functioning is regulated through state institutions. That is, wielders of economic power (resource bearers) depend on peace and security provided by state makers which is necessary for planning and projecting into the future; and wielders of political power (warriors) depend on finances from this sector to finance security. Thus, a cooperation between the warriors (state makers) and resource-bearing group in the European society (bourgeoisie) created the modern European state as wielders of coercion "drew for their own purposes on manipulators of capital" (Tilly 1990: 16).

Nationalism has been described as the social fabric that held European states together in the match to economic development and strong statehood (Arendt 1951). Late late-developers outside of Europe (East Asia, some former Communist states, Botswana) that have seriously pursued and achieved a modicum of development have been propelled in this direction not only by the desire to survive in a hostile world but also by the desire to catch up with the West and subsequently be in a position to resist Western imperialism (nationalism). The crux of this argument thus far, is that certain processes that midwived the emergence of strong statehood in other parts of the world are lacking in Africa and this is the bedrock of state weakness in Africa as will be argued below.

19.3.3 Deviation in the African Situation

None of the mentioned imperatives of state survival was available in Africa at the inception of the states.[14] It was not imperative for African rulers to encourage economic development because the international state system into which they emerged bankrolled their administrations through development aid, international trade on articles controlled by the state and foreign investment in extractive industry, thereby obliterating the importance of internal sources of revenue. The excessive focus on the economic gains that accrued from relations to exogenous forces (with special reference to raw material extraction) has devastating conesquences for the emergence of the most important imperative of strong statehood in a modern economy: the derivation of revenue from elastic bases. Elastic bases could be positively motivated through the provision of infrastructure, security, investment in qualitative education, economic policies that favour the accumulation of capital by indigenous forces, transparency in government's management of state revenues which facilitates the confidence of society's resource bearing groups in government, forward and backward linkages of production sectors, etc. Furthermore, improving the quality of life through the provision of functional infrastructure in an atmos-

14 The Republic of South Africa presents an exception on two points – separation of political from economic power and the derivation of revenue through elastic bases. The whites still control economic power and the blacks political power.

phere of rule of law and order enables several groups in society to identify with the state project – social cohesion. The efforts at these were rather neglected and thus, nothing prevented them from personalizing power which invariably meant demeaning and abjuring state institutions in the process of personal enrichment via state power. Using state power to accumulate private wealth (corruption) destroyed the social fabric of the society by politicizing ethnic and religious affiliations and making the struggle for political power a violent zero-sum game that threatens national and human security. State weakness that was inherited from colonialism worsened.

The concentration on drawing revenues from natural resources which are inelastic does not promote the development of the imperatives of strong statehood. In fact, it could have the opposite effect whereby the state cordons off the areas rich in mineral deposits with state (or expatriate) security apparatus and uses the extracted resources to enrich top officials while simultaneously neglecting the whole society (Reno 2000). The point here is that the quality of governance does not have much impact on the amount of extractable revenue and disbursable funds at the disposal of governments. And because the rulers and their cronies control these natural resources which constitute the lion shares of overall state revenues, there is no separation between the wielders of economic and political power. As a corollary, there still is no impetus to formal rational-legal institutionalization of state administration in Africa. Rather, personalization of state power for purposes of accumulation spawned a state bureaucracy that is not worth the appellation: neither employment nor promotion were based solely on merit, rather than on cronyism, nepotism and personal loyalty, no respect for institutional hierarchy, payments were made (when at all) not only through fixed salaries but more so through access to national revenues, officials with contacts to the top were not subjected to systematic discipline, etc. It is therefore no wonder that the states remained weak and some even collapsed with the alteration in international politics at the end of the Cold War.

The African postcolonial state system plays a negative role in strengthening African states. African leaders accepted the colonial boundaries and enshrined the inviolability of those boundaries in the first Charter of the *Organization of African Unity* (OAU), a deed that earned the OAU the appellation of Trade Union for African Heads of State by the then Tanzanian President, Julius Nyerere. Thus, there was no need to spread effective administrative structures all over their territories in order to ward off external aggression. The appearance of states remains restricted to cities, often only in capital cities and disappears as one travels inland where societies are still largely regulated by pre-stately institutions.

Furthermore, the class character of the new African rulers – petit-bourgeois elements without a productive or solid financial base – coupled with the illegitimacy of the states they inherited from the colonialists led to a political situation in which the determination to pursue economic development is infinitesimal. They rather tried to compensate their weak resource bases by using state power at their disposal to amass private wealth. In this process, state bureaucratic institutions get emasculated, abjured and or subjected to the goals of private accumulation. Laws get disregarded with impunity leading to a culture of violence and lawlessness. Even state security apparatus becomes instrumentalized in the private accumulation process, a fact which became evident with the end of the Cold War, leading to a widespread threat to national and human security. The increasing intensification of this practice has spawned the concept of "criminalization of the state" (Bayart/Hibou/Ellis 1999). They argued that corruption, the marginalized position of Africa in the international political economy, the mismanagement of this economy coupled with the vagaries of the *Structural Adjustment Programme* (SAP) and the demand for democratization have led to "a noxious cocktail of commerce and violence" in Africa (Bayart/Hibou/Ellis 1999: xiv). Thus, the development trajectory of West African states precludes the emergence of strong state capacity for coping with threats of all sorts, making the states vulnerable to sundry sources of threats. All these constitute security threats for the mere fact that they threaten the very existence of those states and their citizens. The reality of this development in West Africa has led to state collapse in some cases and civil wars in others; all posing clear dangers to the security of the state and humans in this sub-region.

19.4 Security Risks and Vulnerabilities in West Africa

The issue of vulnerability of states and citizens to security threats relates directly to the protective capacity of states in the sense that with a strong state capacity, the number of issues that states could be vulnerable to diminishes. The conception of state strength used here is not limited to bureaucratic and security appa-

ratuses but includes (very significantly) the degree of social cohesion and the ability of the state to constantly legitimize itself through the provision of public political goods including the conduct of free and fair elections. In the context of the new security paradigm, West African states are threatened by issues that an administrative machinery of the state could easily take care of, given normally functioning state institutions. Thus, the prevalence of insecurity in West Africa underlines more the weakness of the states as it expresses less the destructive qualities of the issues in question. Even the implementation of well-intentioned, but flawed programmes could become sources of security threats.[15] In this section, I would examine issues and developments that have become security threats in West Africa while taking the vulnerability of the states to these developments as given due to endemic state weakness.[16]

The greatest threat to 'state' and 'human' security in West Africa is the synergism of endemic state weakness and the accumulative tendencies of the political class. This weakens the state through a reduction of state's financial capacity and enmeshing state institutions in social struggles. Manifest state weakness encourages a disgruntled section of the elite to militarily challenge the state. In the process, mayhem is visited on human beings. In an atmosphere of insecurity, crime thrives, legal businesses lose interest in the region, underdevelopment deepens and qualified professionals leave (brain drain). Thus, the greatest threat in West Africa as an entity in the last few decades has been the subregionalization of the Liberian conflict. The collapse of the states of Liberia, Sierra Leone and Ivory Coast involved civil wars with a total casualty of about 500,000 deaths, not to mention the maiming of civilians and the destruction of state institutions (chap. 18 by Aning/Atta-Asamoah).[17] State collapse thus demonstrates the interconnection between state and human security.

Regionalization of internal conflicts has variously been termed 'contagion effect' or 'spill-over effect'. But these terminologies hide more than they expose because they never delve into the mechanisms of contagion. Furthermore, they make the regional spread seem so natural. Contrarily, research evidence shows that regionalization is appropriate to the political economy of post-Cold War violence that results from a political culture of resource predation. Neoliberal globalization simplifies access to the international market by undermining boundaries and in the attempt to exploit this simplification, actors disregard national boundaries in search of access to raw materials needed in the international market. Warlord rulers and their allies spread insecurity in West Africa through the disruption of authorities across state borders in the process of accumulation.

Using state power for capital accumulation which weakens states also predispose politicians from neighbouring states to establish contacts with warlords: they help warlords with state sovereignty while warlords pay in cash or with resources. Thus, judging by the role played by some social and political forces in Ivory Coast, it is not surprising that the Liberian conflict which became the West African conflict by engulfing Sierra Leone and Guinea had later on to spread to Ivory Coast. One researcher notes that covert support was given to the Taylor rebellion by Ivorian officials. This involved providing the rebellion with a rear base and a route for weapon smuggle. The intention of Ivorien officials was to use the access to tropical woods and mineral resources in Liberia to compensate for the decline in proceeds from the plantation economy that Ivory Coast experienced at the time (Johnson 2001: 82). Another researcher estimates that diamond exports routed through Ivory Coast vary from US$ 300 to US$ 500 million (Atkinson 1997: 10). One Abidjan daily newspaper at the time commented that the "consequence of all this for Cote d'Ivoire is the rise of crime rates thanks to the weapons we are supplying to Liberian rebels, and which are in turn sold on the Ivorian black market by these very same Liberians" (quoted in Reno 1998: 98). Reports also indicate the involvement of unpaid Guinean soldiers in the lucrative but illegal cross-border trade in small arms and light weapons which is condoned by the Guinean authorities in order not to further destabilize an already weak state (International Crisis Group 2005: 14ff., 2007: 12). Thus, in the attempt to satisfy their accumulation tendencies, high-ranking military personnel and politicians endanger the lives of citizens and operational efficiency of state institutions. This tendency has become worse since the end of the Cold War and the collapse of states in West Africa.

15 This was the issue with the *Structural Adjustment Programme* (SAP).

16 Vulnerability refers to the inability or considerably low ability to react to unpleasant stimuli.

17 See Piero Scaruffi: "Wars and Genocides of the 20th Century"; at: <http://www.scaruffi.com/politics/massacre.html>.

19.4.1 End of the Cold War and Insecurity in West Africa

For a long period, (apparent) security in West Africa hung on a precarious balance of superpower conflict and elite accommodation. This arrangement was disrupted at the demise of that conflict with grievous consequences for security in the sub-region. It has been noted that the end of the Cold War and the demand for economic and political reforms from international capital led to a fragmentation of elite networks in West Africa, extension of clandestine commercial channels and new conditions of external patronage (Reno 1998). One of the effects of neoliberal globalization in West Africa was to shift accumulation operations from reliance on access to state power to establishing connections with global economic actors including criminals.[18]

Charles Taylor, whose rebellion in Liberia catalyzed the West African conflict and states collapse, therefore harnessed these conditions in combination with the availability of portable or lootable raw materials (alluvial diamonds, timber, iron ore etc.) to launch his rebellion. Because his rebellion (and rule) was tied to commerce, he could not restrict his politics to rigid boundaries.[19] "The invasion of Sierra Leone in part followed the NPFL's sharp business practices and efforts to add to Taylor's profits from regional trade in diamonds, timber, and cash crops beyond Liberia" (Reno 1998: 98).[20] Taylor was alleged to have earned about US$ 450 million during the Liberian and Sierra Leonean civil wars between 1989 and 1996 and this sum gave him an electoral war chest which his opponents could not rival and thus paved the way for his electoral 'victory' in 1997 (Adebajo 2002: 65).

The triumph of neoliberalism as the guiding principle of international political economy which coincided with the end of the Cold War equally has devastating consequences for security in West Africa: it eased and quasi-legalized the smuggle of small arms which flourished in the sub-regional black market via already porous borders. These weapons emanated from the demise of the Soviet Union and the concomitant plundering of her military arsenals. As a result, West Africa was awash with cheap light and small weapons which sustained the various violent political conflicts that have characterized the sub-region since 1989. The realization of this fact led the Heads of States of West African States under the auspices of the *Economic Community of West African States* (ECOWAS) to declare a moratorium on the importation, exportation and manufacture of small and light weapons in West Africa. This was adopted and signed in Abuja (capital of Nigeria) on the 31 October 1998 and was renewed for a further three years on the 9 July 2001. Despite this declaration, small arms and light weapons continued to flourish and fuel conflicts in West Africa, prompting the ECOWAS Heads of State to replace the moratorium with a Convention on 14 July 2006. All these efforts have been less than fruitful in curtailing the spread of small arms and light weapons in West Africa. This is hardly surprising because nothing has been done to alter the conditions that gave birth to their spread (neoliberal globalization and politics of private accumulation) in the first place.

The end of the Cold War equally reduced the strategic significance of West African states in international politics with the consequence that military support from the great powers was reduced. In practice, this meant a considerable reduction in the strike capability of those military forces. The consequence was that they lost the capability to defeat even rag-tag and underfed rebel forces. The civil wars thus became prolonged and with that, the insecurity of peoples and states.

Further consequences of the end of the Cold War in spreading insecurity in West Africa include the lack of political will on the part of the United States, a long time ally of Liberia, and the international community to intervene in the Liberian conflict. Nigeria therefore mobilized some members of ECOWAS to set up a peacekeeping operation, the *ECOWAS Monitoring Group* (ECOMOG) which tried to put an end to hostilities. But due to personal interests between the then Nigerian president, General Babangida, and Liberian president, Samuel Doe, Liberian rebel forces considered the Nigeria-led ECOMOG a partial arbiter and attacked them as they landed in Liberia. Prior to

18 This should not be misconstrued to indicate the superfluousness of the state in the process of accumulation. Only that it is no longer mandatory. Opportunities have been widened by neoliberal globalization.

19 The state of Liberia collapsed before Taylor's rebellion while the states of Sierra Leone and Ivory Coast collapsed in the course of the conflict. However, the terms of state collapse and violent conflict are used interchangeably, *nota bene* that although the two concepts must not accompany one another theoretically, in the empirical study of West Africa, they do.

20 NPFL is the acronym for *National Patriotic Front of Liberia*, Taylor's rebel group. It is necessary to state that decades of bad governance gave birth to the rebellion, not necessarily accumulation tendencies.

the landing of ECOMOG-forces in Monrovia, Taylor's NPFL have commenced the killing of innocent Nigerians in the streets of Monrovia. Thus, the intervention increased, rather than decreased the level and duration of insecurity in the region and partially contributed to extending the Liberian conflict to Sierra Leone and other West African states.

Additional to the political, logistic and organizational inadequacies, the misuse of official positions for private accumulation (corruption) bogged down ECOMOG's assignment (Adebajo 2002). ECOMOG commanders (mostly Nigerians) scented accumulation opportunities in their conflict management assignment and proceeded to partake in the war economy which extended the duration of the war and concomitantly, human insecurity in the region. For example, as the conflict engulfed Sierra Leone, the Indian and Jordanian contingents of the *United Nations Mission in Sierra Leone* (UNAMSIL) once gave notice of their intention to withdraw from the operations because a secret document in which the Indian general accused the Nigerian Chief of Staff of being involved in diamond businesses with the rebels was made public (McGreal 2000: 2).

19.4.2 Conflicts and Insecurity in West Africa

Other factors that have influenced insecurity in the context of the conflicts in West Africa include the interests of several West African rulers in the conflict, the method of conflict management, the failure of disarmament, demobilization and reintegration of combatants (DDR) and Taylor's insecurity.

The Liberian conflict displayed a complex web of family connections and private interests which underline the lack of the institutionalization of the state as well as the personalization of state power, often a prelude to its criminalization. The killing of Tolbert's son (Houphouét-Boigny's son-in-law) by Samuel Doe in the course of his military putsch despite pleas from Houphouét-Boigny to spare him drove the then Ivorian president to swear revenge against Doe.[21] He therefore supported Taylor's rebellion logistically and otherwise (Ellis 1999; Adebajo 2002). Taylor, on his part, was related to Quiwonkpa by marriage and the murder of Quiwonkpa by Doe contributed to his resolve to rebel against Doe (Ellis 1995: 57)[22]. Thus, politicians and military officers do not shy away from endangering the lives of innocent citizens in the course of protecting family and private commercial interests.

The method of conflict management whereby rebel groups are accepted as negotiating partners and apportioned political posts in the interim governments contributed to the dynamic especially as the expansion of the area under a rebel's control was a criterion for the invitation to participate in the interim government. This was the case in Liberia. The message to the protagonists was clear: spread as much mayhem and terror as possible in order to take control of an area and use the control to obtain participation in the conflict management and membership of the governments of national unity. Rebels were therefore not discouraged in any form, they were rather encouraged. Rebel groups were converted to political parties and their leaders appointed ministers in the interim government. The wars were therefore profitable. One of the major consequences of this method was the spawning of rebel groups as ambitious individuals sought to partake in the loot. Thus, the NPFL that was the sole rebel group in Liberia disintegrated continuously, and in the course of conflict management, the number of rebel groups rose astronomically.

The failure of *disarmament, demobilization and reintegration* of combatants in to normal life (DDR) programme contributed to the extension of insecurity in West Africa. The DDR was an essential pillar of the conflict management with the aims of cementing the end of hostilities and most importantly, pre-empting their repetition. Subsequently, combatants were requested to give up their arms and ammunitions to the ECOMOG or UN soldiers, receive remunerations and depending on age, be sent back to (non-existent) schools or be advised to learn a trade. This practice failed and gave birth to a form of lucrative 'arms race' in West Africa: This author received reports that the UN conflict management missions were paying about US$ 100 to 150 for an AK-47 which cost about US$ 22 in the West African black market at the time (2002–2004). A majority of the combatants gave up their old AK-47s and with the money collected from the conflict management missions bought new weapons for which they gave up for more money. Furthermore, most combatants were disappointed as the promises

21 William Tolbert was the president of Liberia from 1971 until he was killed in a military coup by Samuel Doe in 1980. Houphouét-Boigny was the president of Ivory Coast from independence in 1960 till his death in 1993.

22 General Quiwonkpa, a popular military general who led the military coup against Tolbert in the course of which Doe declared himself president was murdered by Doe in 1985.

made to them were not met. In a well-researched publication, Human Rights Watch (2005a: 2–4) reports that the majority of the combatants who participated in the 2000–2003 UN-sponsored Sierra Leonean DDR programme received only partial benefits, were kept out of the skills training component of the programme or failed to receive any benefits at all. Similar complaints were heard from participants of the UN-sponsored 2003–2005 DDR programme where a severe shortage of US$ 39 million left some 40,000 combatants at the risk of missing out training on the job and education. Corruption and inadequate grievance-treatment procedure within the DDR programme were mentioned as serious problems. As a result of their helplessness and hopelessness, the young men had to continue to risk their lives in order to earn a living by offering their services to other conflicts. The result was that the same group of desperate-young men-turned-combatants were patrolling the coast of West Africa as an itinerant labour force armed with weapons of war. The report continues:

> since April 2004, well over two-thirds of the Liberian ex-combatants interviewed, in addition to several of the Sierra Leoneans, had been asked to join fighting 'missions' in Guinea and Cote d'Ivoire. Among those approached to fight in Guinea about half had been approached by commanders claiming to represent a fledgling Guinean insurgency, and the other half by those claiming to be supporters of the Guinean President Lansana Conté. Aid Organizations and United Nations officials working in Liberia say that hundreds of recently demobilized combatants, including children, have since at least November 2004 been re-recruited to fight in Cote d'Ivoire. The majority have, according to the reports, gone to fight alongside militias associated with the Ivorian government (Human Rights Watch 2005a: 4).

This conclusion confirms the views expressed in an interview with an erstwhile Commander of the United Nations Forces in Sierra Leone in early 2003, General Daniel Opande, who estimated that only 25,000 to 30,000 out of the 75,000 militia men that were supposed to be disarmed, demobilized and reintegrated in the Sierra Leonean conflict actually underwent the process. He went on, "if these people could not be kept busy for a relatively long period of time, they will shift into the next troubled area to foment further conflict." And this they did.

Closely allied to the above point is the issue of insecurity for Charles Taylor who has built up a war machine (a collection of unemployed youths) that had to be kept busy with war and booty so that they don't constitute a security nuisance to him. According to Ibrahim Abdullah, a Sierra Leone born professor of history at the University of Cape Town, South Africa, while referring to the conflict in his motherland, "if you can't give Taylor what he wants from Sierra Leone, you can give him anything and he won't stop. What he is getting from Sierra Leone is jobs for his boys and diamonds."[23] There is another sense in which insecurity for Charles Taylor has led to geographical escalation of the Liberian conflict. After becoming President of Liberia in 1997, he created an unwieldy security apparatus that dangerously slipped out of his control.

> While continually feeding the ego of his Anti-terrorist Unit and Special Security Service forces with vehicles and money, his inability to pay his militia and army has led to severe competition for looting. With guns plentiful and competition for loot, Taylor's ability to control the chaos is in doubt (ICG 2002: 14).

These unemployed youths are products of several decades of irresponsible and negligent governance by successive regimes of West African states with fewer prospects of getting good education and meaningful employment. In the midst of poverty, crime, a mode of accumulation that has been facilitated by neoliberal policies and state failures, becomes an option. Decades of bad governance and undifferentiated application of neoliberalism have thus resulted in the criminalization of the West African youth. The problems associated with youth unemployment and insecurity in West Africa led the *United Nations Office in West Africa* (UNOWA) to publish a special report (UNOWA 2005). Its statement reads that "youth unemployment - and its corollary, underemployment – has become a central political security issue in West Africa", maintaining that unemployment fuels conflict and crime. The threat posed by crime to human and state security is not restricted to West Africa. The UN has in a report published in 2004, indicated the increasing threat that transnational organized crime poses to individuals and states (UN 2004). However, the effects become pressing in West Africa due the abysmal weakness of the states. In his address to the France-Afrique Summit in Bamako (Mali) in December 2005, the then Secretary-General of the United Nations, Kofi Annan said that "tens of millions of youths across the continent lack prospects of decent work. This is not only a precious waste of human resource. It can also have security implications for almost every country in the continent, since despera-

23 See: Douglas Farah: "Al-Qaida tied to African Diamonds", in: *Washington Post*, 30 December 2002: 1.

tion often leads young people to fall prey to warlords, criminal gangs or illegal migration syndicates." With specific reference to West Africa, Ahmed Ould Dada, the Special Representative of the UNO-Secretary General in West Africa, estimates the level of youth unemployment in most West African states at about 50 per cent. He emphasizes that this is the background to profound and rampant insecurity in West Africa, dangerous escape to Europe, drug trade and related crimes, prostitution and human trade (UNOWA 2005: iv). Similarly, Mazzitelli (2007) argues that corruption and criminalization of the state reduce risks to criminal operations while increasing profits and has therefore made West Africa a safe haven of operation for transnational organized criminal syndicates whose operations endanger the lives of West Africans.

These criminal activities include drug trafficking, trafficking in people (especially women and children), stolen vehicles, natural resources, smuggling of firearms and contraband, counterfeiting and intellectual piracy, and cybercrime (Mazzitelli 2007: 1074). Statistics show sharp rises in the quantity of narcotics seized in West Africa. In 2005, 1,200 kilograms of cocaine were seized; in 2006, the quantity rose to 2,000 kilograms and within the first seven months of 2007, it rose to 4,300 kilograms (Mazzitelli 2007: 1075). In 2001, the *International Labour Organization* (ILO) estimated the number of children trafficked each year for sexual exploitation and forced labour at between 200,000 and 300,000 (UNICEF 2001). West African women and girls are regularly smuggled to Europe for prostitution. Recruiters collude with corrupt government officials to facilitate such operations and could make profits of up to US$ 10,000 after having spent about US$ 2,000 on bribes and transportation for one woman (Mazzitelli 2007: 1079).

Economic hardships occasioned by underdevelopmental governance has driven frustrated West Africans in the search of a modicum of meaningful livelihood to risk their lives by crossing the Mediterranean with shanty boats en route to Europe via Spain and Italy, a journey for which they have to sell all valuables in order to foot the bills. About 36,000 (mostly) West Africans arrived in the Canary Islands in 2006 and about 7,000 people are estimated to have died in the dangerous odyssey (Mazzitelli 2007: 1080). A 2006 report of the United Nations Office on Drugs and Crime puts the volume of such transactions at above US$ 300 million annually (UNODC 2006). There have also been reports of West African transitionally organized criminal networks including rebels groups (the RUF of Sierra Leone) collaborating with Al Qaeda in the smuggling of diamonds and other precious stones. These reports state that the Al-Qaeda-RUF-Taylor connection began after the US freezing of US$ 240 million Taliban and Al-Qaeda assets given intelligence information that Al-Qaeda was involved in the bombing of US embassies in East Africa in 1998 (Farah 2002, Gberie 2002).

West African criminal syndicates smuggle everything from fake CDs to fake drugs. Smuggling fake drugs is a phenomenon that is very pronounced in Nigeria and has cost a host of lives. And they stop at nothing to protect their businesses. On 26 December, 2003, drug smuggling syndicates tried to assassinate the Director of the *Nigerian National Food, Drug Administration and Control* (NAFDAC) after several unsuccessful attempts at bribing her (WHO 2006).[24]

In Nigeria, decades of corrupt and negligent governance has driven the hopeless youth of the Niger Delta region to resort to crime and violence out of desperation.[25] Environmental pollution in the course of crude oil extraction and gas-flaring has damaged agricultural and aquatic life (the bases of livelihood) in the region. As decades of complaints and protests did not elicit appropriate response from the Nigerian government and the oil companies, the youth was left with no credible option than to take the issue in its own hands. Crime and violence (including blowing up of oil pipelines) in the region arose out of disappointment of the youth with the chiefs that have often colluded with the Nigerian federal government to enrich themselves at the expense of their communities.[26] 'Oil bunkering' (illegal tapping of oil pipelines for sale in West Africa and international market) was the initial response of the youth.[27] Ken Saro Wiwa (once a collaborator with the Nigerian government) made efforts to put a stop to the environmental pollution and pau-

24 Prof. Dr. Dora Akunyili was resolved and incorruptible in her fight against fake drugs in Nigeria because she lost her sister as a result of fake drugs administered to her.

25 The focus on Nigeria is necessary because Nigeria happens to be the giant of the region. Experts and observers have expressed the opinion that a major political crisis in Nigeria will definitely engulf the whole West African region (US National Intelligence Council' 2020 Report on Sub-Saharan Africa, May 2005).

26 See: "Niger-Delta wants direct Allocation to Host Communities", in: *Vanguard Newspapers Online Edition*, 31 March 2006: at: <www.vanguradngr.com/articles/2002/cover/march06/310306> (31 March 2006).

27 This is a dangerous activity that has cost thousands of lives in cases of pipeline explosions that often accompany bunkering.

perization of the region through a radicalization and internationalization of the protest and thus, increasing the pressure on the Nigerian federal government. The military dictator at the time (1997), General Abacha, charged him and 8 other members of MOSOP to court, found them guilty and killed them by hanging.[28] The consequence was a splintering and spawning of protest groups all over the region. The groups and freelancers became increasingly violent and developed their own economy of violence: oil bunkering and kidnapping. Incidences of oil bunkering have therefore increased and so have the financial losses to the Nigerian state and the oil companies. The size of bunkered oil has been estimated at about 10 per cent of annual production with a market cost of about US$4 billion (Shell 2003). Since 2004, there have been threats and cases of vandalizing oil pipelines as well as kidnap of oil companies' expatriate workers and ransom in millions of US dollars paid to regain their freedom.[29] Part of this money has been used to finance the purchase of weapons to foment further insecurity in the region.[30]

19.4.3 Human Rights Violations in Conflicts in West Africa

The Liberian Civil War and the proximate conflicts in West African featured several human rights violations. These include forced labour, robbery, killing and maiming of innocent civilians and raping women. As a result of scarcity of combatants, children, as young as 10 years old, were conscripted into wars without military training.[31] Several agency reports confirm the widespread use of child soldiers by almost all rebel groups. The children were said to be permanently on drugs which leads to erratic and incalculable actions and therefore makes them more dangerous. Young girls were kidnapped and converted to 'wives' by several commanders of various rebel groups. These children were often victims of abuse. Having lost their parents and guardians during the war, they were often left at the mercy of the rebel commanders who did all they wished with them, including using them as looters of the civilian population or as porters and labourers.[32] The number of casualties in the war (civilians inclusive) is estimated at about 150,000 people; and about 500,000 internally displaced persons between 1989 and 2004.[33] Another report claims that direct and indirect casualties vary between 60,000 and 200,000 (Ellis 1999: 316). In Sierra Leone, the rebel group (RUF) once launched an orgy of violence, mutilating innocent citizens apparently to deny them participation in the billed elections or the pursuit of normal farming business (Richards 1996).

Insecurity has been on the increase in West Africa as a result of governments' inability and unwillingness to provide security. This situation has worsened the area boys' phenomenon whereby a group of young men arm themselves and extort the society in the pretence of providing security.

19.5 Conclusion

The issues sketched above that are associated with security in West Africa could have been taken care of by functioning state bureaucracies. It is principally the absence of such that makes them intractable security issues. After all, some of these issues ramify the globe but do not constitute security issues in other states. The international community seems to have realized

28 MOSOP stands for *Movement for the Survival of Ogoni People*. Ogoni is an ethnic group in the Niger Delta region.

this fact by making the building and strengthening of state institutional capacity one of the bedrocks of development policy since the 1990's. However, rampant cases of abuse of state power against the societies have driven donor community to go beyond the state and try to strengthen the society against the state. Recently, this has been criticized as denying the state the means (qualified manpower and funds) of fulfilling its traditional role in society. Apparently, the donor community finds itself in a state of confusion as to how to handle the issue. This confusion results from the dominant mental frame of state vs. society. A better approach could be that of state and society: looking at the intersections between the two in order to elicit a complementarity of interests between them. Credible solutions lie in correcting the anomaly in development trajectory of the African state. My point of departure is that in a global system still regulated by an international sovereignty regime, there is a limit to the effects of the corrective actions of the international community if the rulers of West Africa do not see any existential sense in running good (developmental) governance. The guiding principle of development policy should be to reward states that run developmental governance. This could be the avenue to a secure West Africa for the fact that the pursuit of economic development necessitates the utilization of state bureaucratic institutions which get strengthened in the process and develop the capacity to secure itself as well as citizens.

This analysis result sin the following recommendations:

1. To the *international and donor communities*: Support good governance and respect for human rights and democratic principles. Don't let this be sacrificed for economic and strategic interests. Make the performance of states and the needs of the citizenry the criteria for development aid.
2. To the *African Union*: Continue the efforts towards the erection of a credible and independent peacekeeping force. Most critically, intensify the relaxation of the sovereignty concept as applied to African states through intervention in cases of abuse of power. Seize this opportunity to harmonize the emerging unilateral, bilateral, multilateral, formal and informal, regional and subregional peacekeeping arrangements.
3. To the *West African States*: Respect human rights and democratic principles. Increase the sources and mechanisms of internal revenue by promoting economic development and providing infrastructures. Create national economies and middle classes that could sustain democratization.

20 Environmental Challenges and Risks in North Africa

Béchir Chourou

20.1 Introduction

On 18–20 November 2007 the International Solidarity Conference on Climate Change Strategies for the African and Mediterranean Regions was held in Tunis (Tunisia). It was attended by some 40 Ministers of the Environment and other government members from the European Union, Africa and the Mediterranean region, the Chairman of the Intergovernmental Panel on Climate Change (IPCC, co-recipient of the 2007 Nobel Peace prize), representatives of United Nations agencies and regional organizations, representatives of funds, donor states and funding institutions, and scholars and experts on climate change. According to a Conference's Working Document, the purpose of the event was to examine, first, the challenges that Africa and the Mediterranean region will face in trying to ensure that the impact of climate change does not hamper the economic and social development of people living there and, secondly, the efforts made by the concerned countries to improve their peoples' living conditions, ensure their food security and wipe out the blight that still haunts the region both as regards human health and as regards the environment.[1]

The President of Tunisia, in a message addressed to the Conference and read by the Prime Minister at the opening ceremony, recalled that various international reports and scientific studies agree that Africa in general and North Africa in particular are among the most exposed regions to the nefarious effects of climate change, and called on participants to make practical proposals and recommendations to make all stakeholders better aware of the consequences of climate change and of the need to coordinate efforts aimed at reducing the impact of climate change and ensuring the sustainable development of threatened societies. At the conclusion of its work, the Conference adopted a declaration (the Tunis Declaration) underlining the need to put the fight against climate change and adaptation to that change among the top priorities of the international community, national governments and civil society at large, recognizing the existence of synergies between adaptation to climate change and efforts to combat other environmental problems such as desertification and degradation of biodiversity, and calling on the international community to extend assistance to vulnerable countries so that they can anticipate and adapt to risks arising from climate change.

Concurrently, an ad-hoc expert group meeting on "Sustainable Development in North Africa: Experiences and Lessons" was held at the initiative of the North Africa Office of the *United Nations Economic Commission for Africa* (UNECA) to examine in greater detail the impact of climate change on North Africa and to make practical recommendations for achieving sustainable development in the region.

These are only the latest of a long series of events dealing with environmental issues that have been held in North Africa in the last 15 years, indicating that policy makers and analysts are well aware of, and concerned about, the seriously and rapidly deteriorating state of the environment in the region. This chapter will review the present state and future evolution of environmental security in the North African region (with a focus on Algeria, Morocco and Tunisia, for which data are more readily available). It will concentrate on three major problems: land degradation/desertification, water scarcity and extreme weather events. This does not mean that other environmental problems are inexistent or irrelevant, but for the sake of policy relevancy the decision was made to focus on those areas where urgent action is most needed and is most likely to have rapid beneficial effects.

The chapter will be organized as follows: After this introductory section, section 20.2 will deal with conceptual and theoretical considerations related to

1 The author attended the conference and was able to obtain privately a copy of the document. The document indicates no author, publisher or date of publication.

	Referent object (Security of whom?)	Value at risk (Security of what?)	Source(s) of threat (Security from whom or what?)
National Security [political, military dimension]	The State	Sovereignty, territorial integrity	Other states, terrorism (sub-state actors)
Societal security	Nations, social groups	National unity, identity	(States), Nations, migrants, alien cultures
Human security	**Individuals, humankind**	**Survival, quality of life**	**State, globalization, GEC, nature, terrorism**
Environmental security	**Ecosystem**	**Sustainability**	**Humankind**
Gender security	Gender relations, indigenous people, minorities	Equality, identity, solidarity	Patriarchy, totalitarian institutions (governments, religions, elites, culture), intolerance

environmental security, environmental threats, risks, challenges and vulnerabilities (20.2.1), the views of Islam on environmental questions (20.2.2) and the current status of research on environmental security in the Maghreb (20.2.3); it will also give an overview of the region's main physical, social and economic features (20.2.4). Section 20.3 will discuss these three environmental challenges and risks. Finally, section 20.4 will give an overview of on-going and additional adaptation and mitigation measures to deal with those challenges and risks and evaluate the prospects of environmental rehabilitation in the region.

20.2 Concepts and Theories

20.2.1 What is Environmental Security?

In a seminal work Brauch reviewed the evolution of the concept of 'security' from Cicero's era to the present (Brauch 2005a). He points out that the concept has evolved from referring to protection of the state against threats to its physical and political integrity (war, occupation, absorption) to protection of human beings against threats to their physical, social and psychological integrity. That evolution is summarized in table 20.1.

Brauch further indicates that when the concept of human security was introduced in the 1990's it was broadly defined as 'freedom from fear and freedom from want' but he advocates that a third 'pillar' be added to this definition, that of 'freedom from hazard impact'. Such an extension of the concept of human security is justified by the fact that societies have become aware that their security is becoming increasingly affected not just by military power but also by such factors as watersheds, croplands, forests, genetic resources and climate, and that these may become sources of international conflicts (Brauch 2005a: sect. 8). Prior to that Kofi Annan, who was then UN Secretary General, suggested that 'freedom of future generations to enjoy a healthy environment'' should be an element of human security (Brauch 2005: 23).

Several definitions have been proposed for environmental security. One that has the advantage of being short and concise is that proposed by Glenn, Gordon and Perelet (1998): "Environmental security is the relative safety from environmental dangers caused by natural or human processes due to ignorance, accident, mismanagement or design and originating within or across national borders" (table 20.2 for examples of environmental security threats). Myers proposed another one which is more precise: "The environmental security issue can be defined as the relationship to established security of those environmental factors – water, soil, vegetation, climate, and whatever others are prime components of a nation's environmental foundations – that ultimately underpin all our socioeconomic activities and hence our political stability. Conversely, when these environmental resources are degraded or otherwise depleted, so our security declines too."[2]

The Millennium Project, conducted under the auspices of the *World Federation of UN Associations* (WFUNA) proposed to a panel of scientists a number of definitions and asked them to rank those definitions according to their pertinence and usefulness. The definition that received the highest score (3.2) on

Table 20.2: Some Examples of Environmental Security Threats. **Source:** Adapted from Millennium Project (Glenn/Gordon/Perelet 1998).

	By Ignorance and/or Mismanagement	By Intention	Mix of Natural and Human Actions
Within a Country	C.1 Oil spills in Ogoniland Nigeria Aral Sea depletion in Russia Indonesian fires Ground water contamination and fresh water scarcity Hazardous wastes Soil erosion Human settlement and development patterns	C.2 Sarin gas attack in Tokyo subway Chemical attacks and draining marshes in Iraq Poisoning or diversion or misuse of water resources	C.3 Floods Famines Salinization Earthquakes Introduction of exotic species
Trans-border	C.4 Rain forest depletion River usage in (Jordan, Nile, Tigris, Euphrates) Chernobyl nuclear accident Diminishing biodiversity Ozone depletion Fisheries depletion Global climate change Acid rain and air pollution Poverty Radioactive waste	C.5 Burning oil fields in Kuwait Poisoning water Dam construction and water diversion Biological weapons	C.6 Solar radiation changes Global warming New, emerging, and drug resistant diseases such as AIDS and others affecting plants and animals Desertification Population growth Rich-poor gap

a scale of 1 (excellent) to 5 (not useful) was the following: "Environmental security is the relative public safety from environmental dangers caused by natural or human processes due to ignorance, accident, mismanagement or design and originating within or across national borders" (Glenn/Gordon/Perelet 1998).

The international panel that participated in the project identified the following (without rank order) as the most important environmental security threats over the next ten years:

- Human population growth and loss of biodiversity;
- Climate change – not for its manifestations but for the momentum or lack of action;
- Water scarcity and pollution including ground water contamination;
- Food security;
- Environmental refugees (or environmentally-induced migration);
- Deforestation;
- Industrial contamination of air and oceans;
- Soil conservation/erosion;
- Nuclear safety issues;
- Ozone depletion;
- Global warming.

Brauch provides a "heuristic compilation of possible linkages between environmental causes, stressors, impacts or outcomes that may pose security threats, challenges, vulnerabilities and risks for human beings or humankind within their respective natural environment" (Brauch 2005a: 64). That compilation is partially reproduced in table 20.3 where only the environmental factors and their impacts that are most relevant to North Africa are included.

The *Intergovernmental Panel on Climate Change* (IPCC 2007, 2007a, 2007b, 2007c) in its fourth assessment report (AR4) on climate change identifies the same problems as likely consequences of climate change in Africa, and predicts that this will delay or even prevent the realization of the *Millennium Development Goals* (MDGs) on the continent (see box 20.1).

Table 20.3: Aspects of Environmental Security Relevant to North Africa. **Source:** Adapted from Brauch (2005a: 64).

Environmental problems: they cause: ➔	Threats for ⬇	Challenges affecting ⬇	Vulnerabilities for ⬇	Risks for ⬇
Climate change: Temperature increase	• human health • agriculture (yield decline) • biodiversity • desertification	• tourism • food security • fisheries • government action • economic action	• infectious disease • damage to crops • natural systems • water scarcity	• human populations • the poor, old people and children
Extreme weather events – floods	• habitat, technical infrastructure and people	• flood-prone areas	• peoples living in those areas	• human life and property
Soil erosion, drought desertification,	• water scarcity • agriculture • habitats	• food security • human livelihood (forced migration)	• Arid and semi-arid zones • Rural areas • agriculture	• peasants and livestock in affected areas
Water scarcity & degradation	• agriculture, food, security, people	• economic behaviour • human health	• poor in slums • [people in rural & arid zones]	• Elderly, children, poor
Forced migration	• Resident population, clash over water & food	• Overgrazing on marginal soils • Environment	• Fragile ecosystems • People on the move	• Migrants & their animals

Box 20.1: Potential impacts of climate change on the Millennium Development Goals. **Source**: Excerpts from Boko, Niang, Nyong, Vogel, Githeko, Medany, Osman-Elasha, Tabo and Yanda (2007: 458).

Climate Change (CC) may reduce poor people's livelihood assets, for example health, access to water, homes and infrastructure. It may also alter the path and rate of economic growth due to changes in natural systems and resources, infrastructure and labour productivity. A reduction in economic growth directly impacts poverty through reduced income opportunities. In addition to CC, expected impacts on regional food security are likely, particularly in Africa, where food security is expected to worsen.

Other expected impacts include:

- declining quantity and quality of drinking water, which worsens malnutrition, since it is a prerequisite for good health;
- reduced natural resource productivity and threatened food security, particularly in sub-Saharan Africa.

Direct impacts:

Climate change may alter the quality and productivity of natural resources and ecosystems, some of which may be irreversibly damaged, and these changes may also decrease biological diversity and compound existing environmental degradation.

Climate change would alter the ecosystem-human interfaces and interactions that may lead to loss of biodiversity and hence erode the basic support systems for the livelihood of many people in Africa.

Indirect impacts: links to climate change include:

- • Loss of livelihood assets (natural, health, financial and physical capital) may reduce opportunities for full time education in numerous ways.
- • Natural disasters and drought reduce children's available time (which may be diverted to household tasks), while displacement and migration can reduce access to education opportunities.

One of the expected impacts of climate change is that it could exacerbate current gender inequalities, through impacting on the natural resource base, leading to decreasing agricultural productivity. This may place additional burdens on women's health, and reduce time available to participate in decision-making and for practicing income-generation activities. Climate-related disasters have been found to impact female-headed households, particularly where they have fewer assets.

Global climate change is a global issue, and responses require global co-operation, especially to help developing countries adapt to the adverse impacts of climate change.

20.2.2 Environmental Issues in Islam

It may appear that attention to the environment and concern about its degradation under the effect of human actions have appeared only recently, but in fact the two fundamental sources of laws and rules that regulate the behaviour of Muslims, the Holy Koran and the *Sunna* (the words and deeds of the Prophet Mohamed which serve as references for questions that the Koran does not treat in detail) contain numerous references to such concepts as environmental preservation, interdependence of ecosystems, scarcity of resources, etc. It is not the purpose here to give a full description of the extensive treatment of environmental questions in Islam, but a few examples will show that more than 14 centuries ago Islam had already taken up many current concepts and issues related to the environment. Consequently, Muslim should – in principle – have an environment-friendly behaviour as a matter of faith and religious obligation and not merely as a matter of civic duty or legal obligation. However, as it will be argued below, if more and more citizens in the Maghreb and other Arab and Muslim countries appear to deliberately destroy their environment, it is not because they are unconcerned about the environment or because they reject some of Islam's teachings, but because they consider that behaviour as a form of protest against authoritarian rule.

It is commonly acknowledged that the environment is one and indivisible – what we call the ecosphere – and that its several components constitute a well-balanced but delicate system, and that the system will be adversely affected every time one or more components are disturbed. In this respect the Koran says:

> Verily! In the creation of the heavens and the earth, and in the alternation of night and day, and the ships which sail through the sea with that which is of use to mankind, and the water *(rain)* which Allah sends down from the sky and makes the earth alive therewith after its death, and the moving *(living)* creatures of all kinds that he has scattered therein, and in the veering of winds and clouds which are held between the sky and the earth, are indeed Ayat *(proofs, evidences, signs, etc.)* for people of understanding (Koran 2: 164).[3]

Elsewhere it is stated:

> Those who break Allah's Covenant after ratifying it, and sever what Allah has ordered to be joined, and do mischief on earth, it is they who are the losers (Koran 2: 27).

Thus, Muslims have been told that the universe is a complex system of interconnected components and have been admonished not to interfere with nature's workings (disturb what has been designed to function as a unit). The Koran further states that everything in nature (including the living creatures that Allah has scattered on earth, i.e. biodiversity) has been designed to make life possible. There are two notions in particular that deserve to be underlined because they are gaining wider and wider acceptance: the first is that all natural resources have been created in carefully designed and finite quantities, and the second is that no one can claim ownership over these resources since they all belong to Allah. These themes are found in different parts of the Koran, e.g.:

> And the earth We spread out, and placed therein firm mountains, and caused to grow therein all kinds of things in due proportion. And We have provided therein means of living, for you and for those whom you provide not *[moving (living) creatures, cattle, beasts, and other animals]*. And there is not a thing, but with Us are the stores thereof. And We send it not down except in a known measure. And We send the winds fertilizing *(to fill heavily the clouds with water)*, then caused the water *(rain)* to descend from the sky, and We gave it to you to drink, and it is not you who are the owners of its stores *[i.e. to give water to whom you like or to withhold it from whom you like]* (Koran 15: 19–22).

If natural resources (such as water) are the common property of humankind, it follows that humankind is collectively responsible for their management, including their preservation against waste and degradation. In this regard the Prophet Mohammed has repeatedly enjoined Muslims not to pollute water (so that Muslims can be ensured that water they use for ablutions is pure) or spaces that the public does use (such as roads, mosques, marketplaces...) or may use (such as shaded areas where travellers may rest). The Prophet also has urged Muslims not to use too much water for their ablutions even when the supply seems plentiful (such as rivers). Of course, it is quite natural that Islam – which appeared in the arid lands of Arabia – attaches a particular attention to water (water is mentioned 63 times in the Koran), but what it teaches about water applies equally to all other natural resources inasmuch as Muslims are expected to show moderation and wisdom in the use of all resources.

Nowadays many Muslims try *individually* to abide by the teachings of Islam (at least as far as the environ-

3 In references to the Koran the first number refers to the number of the *sourat* (chapter) in the order in which it appears in the Koran, and the second to the number of the *aya* (verse) within that *sourat*.

ment is concerned), as it can be seen e.g. in the way nomads live in the deserts of the Mashreq and the Maghreb. However, Muslim societies (especially urbanized ones) have been unable – or unwilling – to live in harmony with nature and to respect its laws. Such deviancy is not peculiar to our era and the Koran has forewarned about its consequences:

> Evil has appeared on land and sea because of what the hands of men have earned *(by evil deeds, etc.)*, that Allah may make them taste a part of that which they have done, in order that they may return *(by repenting to Allah, and begging His Pardon)* (Koran 30:41).

Because man has disobeyed divine law, Allah inflicted punishment upon him while he was still on earth, and that punishment, dire as it may be, is only a mild foretaste of what is awaiting him on the Day of Judgement.[4]

In sum, Muslims should be keenly aware, in principle, of the duty to respect nature so that they and future generations have a safe environment in which to live. In practice, however, Muslims – or, for that matter, other segments of humanity – have not consistently behaved in a friendly manner towards the environment. The consequences of this behaviour are becoming more evident and more numerous every day. They may vary in kind and intensity from one region to another, but they are present everywhere.

The concluding section will propose some explanations for this behaviour which is seemingly inconsistent with Islam's precepts and values. In the meantime, two points may be worth mentioning. First, governments in the Maghreb have attempted to appeal to people's attachment to Islam to convince them to show greater respect for nature and the environment. However, this approach does not necessarily stem from any deep concern for the environment or a desire to enlist popular support for measures designed to protect the environment. Rather, it is part of campaigns waged in the Maghreb to stem the rise of Islamist/Fundamentalist movements in the region and that include such measures as increasing the number of new mosques built, or giving greater visibility to the celebration of religious holidays, or making it easier for citizens to meet their religious obligations (Hajj, Ramadan...). The overall message that governments want to convey is that people do not need the Fundamentalists to promote and protect their Muslim identity. In fact, most messages that governments attempt to transmit are couched in religious language, including respecting the environment and ... being faithful and obedient to one's ruler.

The second point is that Fundamentalist movements in the Maghreb have – surprisingly – failed to include the environment in the list of issues about which they have expressed an opinion. There are many aspects of official environmental policy that can be easily criticized but few Fundamentalists have taken advantage of that. This does not mean, however, that they will continue to do so in the future.

Having confirmed that interest in and knowledge about environmental issues are present in Islam and Arab culture, we can now turn to their status in academic research.

20.2.3 Research on Environmental Security in the Maghreb

Scientific interest in the environment in general and environmental security in particular is of recent origin in the Arab world (Selim 2009). The first book dealing with the environment written in Arabic was published in 1976. It was followed by other books that discussed various environmental issues without any specific reference to the Arab world or to environmental security. This was followed by a series of studies published in the 1990's dealing with the relationship between the environment and development, and a few books dealing with two issues relevant to the Arab world: water scarcity and desertification. It should be noted that most of these studies tend to be technical, focusing on identifying environmental problems and approaches for resolving them. Only a small number of Arab scholars have attempted to identify actors responsible for the emergence of environmental problems or assign responsibilities for resolving such problems. Furthermore, the environment has not been a topic of public debate until recently, except for the highly sensitive issue of water resources which is a major element of the Middle East conflict. As one study points out,

> While there is an interest in and concern about the environment (*bi'a*) – perceived generally by those surveyed as their social as well as physical surroundings – only a few equate the environment directly with pollution (*tallawuth*). ... Air and water pollution were noted in their more visible aspects (dust and turbid water), while more concern was expressed for the health effects of air than of water or noise pollution. Issues such as global warming, nuclear radiation and the depletion of the ozone layer attracted very little attention. Respondents seemed

4 For more details on the treatment of the environment in the Koran and Sunna see, *inter alia*, Jamil (1999), Lahlou (2000), ISESCO (2002) and ISESCO (2005).

> largely unaware of lead pollution.... (Hopkins/Mehanna 1996: 1).

In the Maghreb scientific interest in environmental issues has existed for a number of years and is expanding. In Algeria, Morocco and Tunisia there is a number of research centres and institutes that have acquired an international reputation, especially in such fields as desertification, dryland agriculture and the mobilization and management of water resources. Furthermore, the environment has become a major topic of public policy: Most governments have a ministry of the environment and play an active role in various international fora dealing with environmental questions. However, the general public does not effectively participate in the debate of environmental issues in general and environmental security in particular, the reason being that public policy in any field is rarely submitted to a public debate and decisions are taken by decision makers with, in the best of cases, only a perfunctory consultation of the public. Of course, the absence of the participatory approach from the process of defining and implementing public policy is likely to lead to the failure of that policy, but that is an issue that falls outside the scope of this study.

After a brief overview of the main features of the region under consideration an examination of the main environmental risks and challenges that confront it will be offered.

20.2.4 A Profile of the Maghreb

The five states to be studied are Morocco, Algeria, Tunisia, Mauritania and Libya (inclusion of the last two in some sections being tributary of data availability). The region covers an area of about 5.7 million km² and is bordered by the Atlantic Ocean to the west and the Mediterranean Sea to the North. The mountain range of the Atlas stretches in a south-westerly to north-easterly direction across Morocco, Algeria and Tunisia and separates the coastlines from the Sahara Desert (figure 20.1). Only a small portion of the area is actually or potentially useful for agricultural use.

In Mauritania, aside from the northern bank of the Senegal river (which constitutes the natural border with Senegal) where agricultural activity is possible, the totality of the country is desert. Libya is in a similar position, with about 98 per cent of its area being totally barren, and so is Algeria where the Sahara covers nearly 97 per cent of the territory. In Morocco an area of about 95,000 km² (or about 20 per cent of the country's total area) is used or can be used for agricultural production. As for Tunisia nearly 85 per cent of its area is totally barren or classified as savannah / grassland / rangeland, the remaining 15 per cent being more or less fit for some agricultural production (see table 20.4). In addition, a growing proportion of the arable land in this region is suffering from various environmental problems (degradation, erosion, pollution...) or is being taken over by urban growth.

In the coastal zones the climate is Mediterranean, with hot dry summers and mild (and intermittingly) wet winters. Rainfall is irregular in occurrence and in quantity. It increases as one moves from the coast to the mountain ranges where it may reach 2000 mm per year in the Moroccan Atlas, then decreases as one moves towards the Sahara where no more than a few millimetres of rain may fall every few years. Most often rain falls in large quantities over short periods of time, causing flash floods and a great deal of erosion. The entire region is subject to recurrent and extended droughts and it suffers from water scarcity – a problem to be discussed in greater detail below.

The five countries have rather contrasting economic situations. In 2005 per capita GDP ranged from $ 603 for Mauritania to $ 6621 for Libya and stood at $ 3112 for Algeria, $ 2860 for Tunisia and $ 1711 for Morocco. To a large extent national income is related to each country's endowment in natural resources. Algeria and Libya have vast resources of oil and gas and both of them derive most or all of their income from the export of these products. Morocco and Tunisia, on the other hand, have little or no energy products – hence their lower income. However, they both have major phosphate deposits which are an important source of revenue, as well as small deposits of other minerals (coal, lead, silver, iron...). As for Mauritania, the poorest of the five countries, its main mineral resource is iron ore (it is the world's 13th producer of this commodity) from which it derives 95 per cent of its revenues. However, some oil has recently been discovered and the country started exporting it in 2006, which should improve its economic situation.

The region's total population, estimated at 82 million, is unevenly distributed; Algeria and Morocco have over 30 million inhabitants, Tunisia has 10 million, Libya 6 million and Mauritania 3 million. Average demographic growth for the period 1975–2005 was 2.4 per cent in Algeria, Libya and Mauritania and moderate 1.9 per cent in Morocco and Tunisia. Youngsters under the age of 15 represent about 40 per cent of total population in Mauritania, about 30 per cent in Algeria, Libya and Morocco and 26 per cent in

Tunisia. Adult illiteracy rates averaged during the 1995–2005 period 16 per cent in Libya, 26 per cent in Tunisia, 30 per cent in Algeria and 48 per cent in Mauritania and Morocco. Unemployment is high in all five countries, especially among young people and university graduates for whom unemployment rates exceed 25 per cent and may be as high as 40 per cent (reliable unemployment figures are not available). On the basis of the *Human Development Index* (HDI) all five countries are considered as having a medium human development. Out of 177 countries ranked in 2005 according to their HDI values Libya ranked 56th, Tunisia 91st, Algeria 104th, Morocco 126th and Mauritania 137th (table 20.1). As it will be seen, many of these features are simultaneously causes and consequences of the environmental problems that beset the region.

20.3 Environmental Risks in North Africa

It has been established that industrialization and the modes of production and consumption associated with it have caused severe environmental problems that are either irreversible or difficult to resolve. Pollution of the atmosphere, oceans, rivers and land, global warming, destruction of the ozone layer and degradation of ecosystems are but a few of the consequences of industrialization. North Africa has been affected, to one extent or another, by most of these problems but the discussion will, as already indicated, focus on those that most observers consider as critical and requiring immediate attention. Scientists from the region as well as international organizations such as the *United Nations Food and Agriculture Organization* (FAO) and the *United Nations Environ-*

Tunisia	Mediterranean coastline vulnerable to sea level rise. Increased water stress.	Floods, drought	38	459	150

ment Programme (UNEP) agree that the most critical risks that confront the region are the loss of arable land under the effect of erosion, degradation and desertification, the limited supplies of fresh water and exposure to extreme-weather events such as floods and droughts (table 20.5).

20.3.1 Desertification, Land Degradation and Drought (DLDD)

According to the 1994 *United Nations Convention to Combat Desertification* (UNCCD), the term desertification means "land degradation in arid, semi-arid and dry sub-humid areas resulting from various factors, including climatic variations and human activities" (Art. 1). This definition, which is the result of a political consensus, needs further clarification. Desertification has nothing to do with deserts or advancing deserts. On the one hand, it is now scientifically established that deserts do not move out of their limits to invade neighbouring areas.[5] On the other hand, deserts such as the Sahara and Kalahari are extreme environments that offer little productive potential and where no one lives permanently. Rather, desertification is the transformation of productive arid or semi-arid areas into unproductive, sterile desert-like lands. In the words of the authors of the Millennium Ecosystem Assessment:

> Desertification is a result of a long-term failure to balance demand for and supply of ecosystem services in drylands. The pressure is increasing on dryland ecosystems for providing services such as food, forage, fuel, building materials, and water for humans and livestock, for irrigation, and for sanitation. This increase is attributed to a combination of human factors and climatic factors. The former includes indirect factors like population pressure, socioeconomic and policy factors, and globalization phenomena like distortions to international food markets and direct factors like land use patterns and practices and climate-related processes. The climatic factors of concern include droughts and projected reduction in freshwater availability due to global warming (Millennium Ecosystem Assessment 2005: 1).

By definition dry zones receive little rain (between 5 and 65 mm a year) and extended droughts are common there, but human beings, animals and plants have been able over centuries to develop strategies to adapt to this situation. Under the impact of various factors those strategies have been disturbed. For example, as population grew new plants or new techniques (mechanical ploughing, use of fertilizers, irrigation...) or new forms of social organization (sedentary living) were introduced to meet new demands. The

5 Cornet, Antoine, 2001: "La Désertification à la croisée de l'environnement et du développement", paper published by the Comité Scientifique Français de la Désertification; at: <www.csf-desertification.org/catalogue/2001_csfd_cornet.pdf>: p. 4.

novelties may have met short-term expectations but in the long run they disturbed the delicate equilibrium of the ecosystems. The new systems proved to be unsustainable and the original ones lost their adaptive capabilities and their resilience. The process of degradation was thus initiated, leading ultimately to the transformation of the arid and semi-arid zones into quasi deserts. This process is schematically described in figure 20.1.

Recent figures indicate that nearly half a billion people throughout the world are already affected by desertification and that one billion are threatened by desertification. At the global level it is estimated that 54 per cent of productive land (61 per cent of Africa's) is drylands, 70 per cent of arid areas are affected by desertification, 130 million ha (1.3 million km²) suffer from severe degradation, 470 million ha (4.7 million km²) from moderate degradation, and some 10 million ha (0.1 million km²) of arable land are degraded annually (figure 20.2).[6]

This is a schematic graphic showing how drylands can be developed in response to changes in key human factors. The left side of the figure shows developments that lead to a downward spiral of desertification. The right side shows developments that can help avoid or reduce desertification. In the latter case, land users respond to stresses by improving their agricultural practices on currently used land. This leads to increased livestock and crop productivity, improved human well-being, and political and economic stability. Both development pathways occur today in various dryland areas.

In the Maghreb arid, semi-arid and dry subhumid areas cover about 700,000 km² (or 13 per cent of the total land area). Historically, these areas have been inhabited by nomads who practiced itinerant agricul-

ture and herding, moving from one zone to another according to seasons and climate conditions (and also to escape tax collectors!). As soon as a chosen zone became less productive (i.e. degraded) the tribe would move to another one. Of course, this could be considered as the origin of the degradation process but in reality, there was enough space to move around and people did not come back to a previously occupied spot until it had a chance to recover.

These practices survived for centuries until the modern era when new considerations came into play. During the first half of the 20th century when Algeria, Morocco and Tunisia were under French authority, the administration wanted to exploit local resources and to control the Bedouin population. Consequently, the best lands were given to French settlers, agricultural resources were exploited for maximum profit (e.g. alfalfa growing in arid areas was harvested extensively to produce paper, which led to the disappearance of ground cover and exposure to erosion) and restrictions were imposed on the movements of Bedouins in rangelands (which led to the over-exploitation of the assigned zones). After independence, other requirements came into play. Governments had to ensure that food was available to a growing population, that employment and social services (education, health) were provided and, generally, that poverty was reduced and eventually eradicated.

To increase food production various measures to 'modernize' agriculture were taken, such as the introduction of mechanization, the use of chemicals, irrigation and the exploitation of marginal lands that were used for grazing. Ironically, the decisions taken at the time, and which were to prove ill-advised, emerged in a context where nearly all experts and decision-makers at the national level and in international organizations believed firmly that only industry, and not agriculture, could lead to development, growth and modernization. The ambition of every African country that achieved independence in the 1960's was to produce steel, not wheat. In fact, a country like Algeria decided to just ignore the agricultural sector altogether. Those early decisions were to start a chain reaction that would ultimately lead to the current state of advanced deterioration of lands in the Maghreb (table 20.6 for figures supplied by the FAO; concordant estimates may be found in UNECA 2003: 9).[7]

In a nutshell this is how the degradation process evolved (UMA 1999: 22–25: Le Houérou 2002: 6ff):

- Traditional subsistence agriculture having been declared a backward activity incapable of contributing to development and progress, and modern agriculture being a capital-intensive rather than a labour-intensive activity, peasants who could no longer live off their land left their rural areas to flock to cities to seek factory jobs, housing and social services.
- Cities were not properly equipped to receive this influx of inhabitants. Consequently, shanty towns began to appear on the outskirts of cities but existing urban infrastructure and services, unable to cope with the rapid growth of the population, began to fall apart, creating new environmental problems (e.g. air pollution) or aggravating existing ones (water scarcity, loss of arable land...).
- Food had to be supplied at prices that the largely unskilled (and often unemployed or underemployed) labour force could afford, which meant that governments had to control the prices at which farmers sold their crops and subsidize the prices of basic staple goods (bread, oil, sugar...) so that the average consumer could afford them. In practice, government-set prices proved too low to provide farmers with a decent income and too high for the urban population whose income remained quite limited.
- In an effort to increase the productivity of the agricultural sector, various measures were taken to eliminate what were deemed to be inefficiencies. For example, farmers in Tunisia were encouraged (and sometimes forced) to integrate their small farms into kolkhoz-style cooperatives, or to switch

7 It may be noted that in the last few years desertification has been causing the annual loss of about 22,000 ha of arable land and of $ 1 billion in income in Morocco, and of 8,000 ha of land and $ 100 million in income in Tunisia. In Algeria about 130,000 km² of land have been degraded in the last decade, 4 per cent of which irreversibly.

Table 20.6: Land degradation: Severity of human-induced degradation. **Source:** FAO TERRASTAT[a)]

from subsistence agriculture to the production of cash crops for export or for transformation by the nascent food processing industry. Whatever benefits may have been expected from or achieved by such measures, the one consequence that they did have and that was to become a chronic feature of Maghreb countries is the incapacity of those countries to feed themselves (figure 20.3 illustrating the wheat deficit in Morocco and Tunisia).[8]

- The orientations given to the agricultural sector and the deliberate bias in favour of industry rarely took into consideration the impact they could have on the environment.
- This process of land degradation resulting in the emergence of "desert land forms and landscapes [in] areas where they did not occur in a recent past" is then due mostly to a "long-lasting mismanagement of natural resources under the pressure of excessive human and livestock populations" while natural factors such as increased aridity may at best aggravate or accelerate the process: "In an attempt to justify the lack of soil and water conservation policies and the absence of actual action on the watersheds to combat the scourge [of human-induced desert making], degradations are often blamed on climate change towards increasingly arid conditions. In most cases, blaming the climate is a fallacy aimed at providing politicians with good conscience and favourable polls" (Le Houérou 2002: 3).

The manifestations and causes of land degradation in range-land, rain-fed and irrigated areas are summarized in box 20.2. Degradation does not affect just land areas but also littorals and marine ecosystems. In this respect it has been established, *inter alia*, that large portions of the Mediterranean coastline of Tunisia and Egypt have been severely eroded causing, among other damages, the loss of large tracks of land and the infiltration of seawater into aquifers. It is also known that chemical pollution in the Mediterranean has caused the degradation or death of coral reefs, the disappearance of native algae such as *Posidonia oceanica* and the invasion by the 'killer algae' *Caulerpa taxifolia* and other unicellular algae which release toxins that absorb oxygen dissolved in water and thereby asphyxiate native marine fauna. However, space does not allow a discussion of these problems and their environmental consequences.[9] Therefore,

8 Food security is likely to become a critical problem if current trends in the international markets of cereals (tight supply, high prices) persist. Two figures illustrate amply the difficulties that are awaiting the region. During the first seven months of 2008 Morocco spent one billion dollars on wheat imports, which is more than double the amount it spent in 2007, and Algeria's wheat imports during the first semester of 2008 reached $2.26 billion against $1 billion spent during the first 7 months of 2007 (Source: Le Maghreb, 2008a: "Marché des céréales – Une forte demande des pays méditerranéens"; at: <http://www.lemaghrebdz.com/lire.php?id=13111> (15 September 2008). For oil producing countries such as Algeria and Libya the problem may not be acute as long as oil prices remain sufficiently high to finance food imports, but the situation will be very serious for countries that do not produce oil, for they will have to find resources not only to feed themselves but also to purchase the oil they need.

- Manifestations
  - Destruction of land cover
  - Decline of productivity
  - Soil erosion
  - Sanding up
  - Silting (of dams)
  - Salinization/alkalinization
- Immediate causes
  - Overgrazing
  - Growing inappropriate crops
  - Overexploitation of ecosystem resources/services
- Underlying causes
  - Increased human pressure
  - Inadequate management techniques and methods
  - Aridity, droughts
  - Fragile ecosystems
- Fundamental causes
  - Demographic growth
  - Inappropriate control of access to resources
  - Economic crises, poverty
  - Nonexistent/inadequate institutional framework and/or development strategies

the next environmental risk that confronts the Maghreb will be discussed: the availability of fresh water.

20.3.2 Fresh Water Resources

Water resources used by humans are divided into two categories: conventional and non-conventional. Conventional resources may be either renewable or non-renewable. Conventional renewable water may be either surface or underground water (Oswald/Brauch 2009). Surface water is found in rivers, lakes, freshwater wetlands or artificial reservoirs (e.g. water trapped behind dams). It is naturally replenished by rain and naturally lost through discharge into the oceans, evap-

9 Invasion of the Mediterranean by alien plants and animals is described in UNEP/MAP/MED POL (2005: 38ff). A thorough discussion of Mediterranean coastline degradation may be found in Benoit and Comeau (2005: 300–350).

P: Average precipitations **CP**: Contribution of precipitations **IRW**: Internal renewable water **IRUW**: Internal renewable underground water **IRSW**: Internal renewable surface water **TRW**: Total renewable water **POP**: Population size **POT**: Volume of renewable water resources/inhabitant/year **DEP**: Dependency ratio on outside water resources **VRW**: Volume of renewable water. The gap between the total amount and the sum of the volumes of surface and underground water results from the overlap between the two types of water.

oration or infiltration through the ground to feed water tables and aquifers. Non-renewable fresh water is usually found in deep underground reservoirs formed millions of years ago; because it is not renewable it is also called fossil water. Non-conventional water is water that is treated to make it fit for human use. It may be obtained by treating brackish water, seawater (desalinization) or wastewater.[10]

At present, existing and potential water resources are insufficient to meet present and future water demand and all Maghreb countries, with the exception of Mauritania, already suffer from more or less severe water scarcity; furthermore, this situation is expected to worsen in the coming years.[11] On the other hand, it is known that

> [T]he availability of adequate, safe water is critical to health, economy and environment. This is not only true for the arid and semi-arid regions of the world, but also for the humid regions. Insufficient water supply will seriously hamper the welfare of people, industrial and agricultural production and the quality of the environment. However, excess of water, resulting in floods and inundation, may cause many casualties and seriously damage property. Our human society depends very much on a timely and reliable supply of water and adequate handling of excess water. In the arid region [of the Middle East and North Africa] water shortage is already a problem. Water is an important limiting factor for ecosystems, agriculture, human settlements and human health. Huge disparities exist between water demand and water availability. [...] Limited water supplies restrict present agricultural productivity and threaten the food security of some countries. Overexploitation of these limited water supplies often results in land degradation problems (van Deursen 2000: 3, 6).

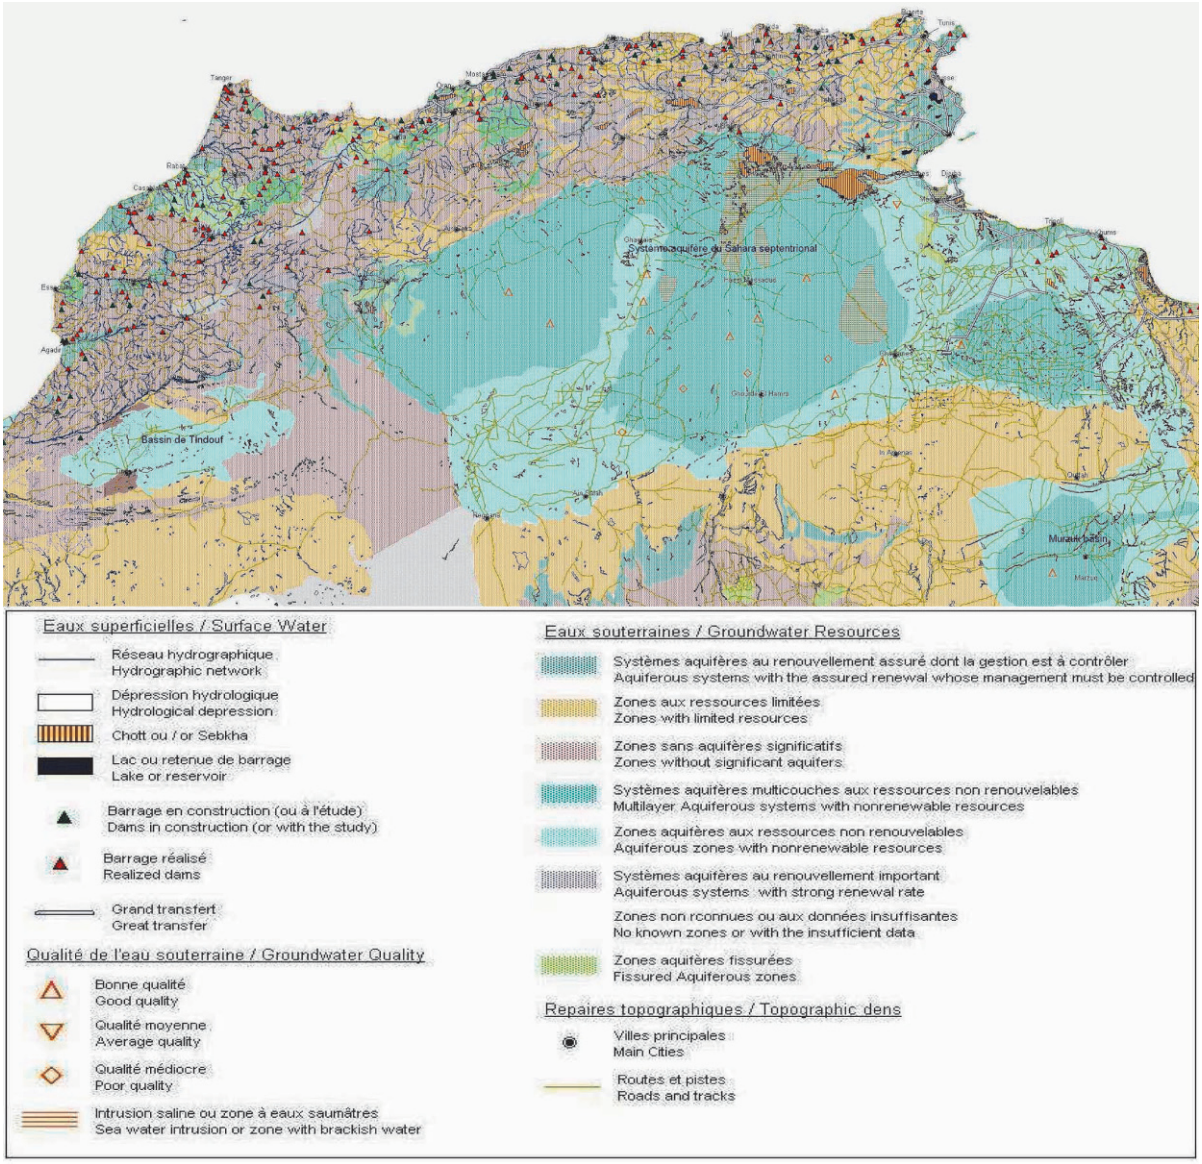
As already indicated, the Maghreb has an arid or desert climate with irregular rainfall (in frequency and amount). This lack of regularity makes it difficult to establish meaningful average precipitation figures. With that caveat in mind, figures provided by national institutions and the FAO indicate that annual precipitations vary from 346 mm in Morocco to 56 mm in Libya, but only a small fraction of that water is or can be mobilized (the inventory and location of surface and underground water resources are given in table 20.7 and figure 20.4). The *total renewable water* (TRW) potential of the region is estimated at 57 km^3 of which 50 km^3 are produced internally (37 km^3 of surface water and 16 km^3 of underground water).

Starting with surface water, Algeria, Morocco and, to a lesser extent, Tunisia have non negligible quantities of *internal renewable surface water* (IRSW) resources. Thanks to a vast programme of dam construction that it had initiated since the 1970's Tunisia

10 For more detailed definitions see e.g. UNESCO 2006: chap. 4 or Rosegrant, Cai and Cline 2002: 23.

11 Water-stressed countries are those with annual water resources of between 1,000 and 1,700 m^3 per person and countries suffering from water scarcity are those with annual supplies of less than 1,000 m^3 per person. Projections indicate that by 2025 per capita water availability will be 47 m^3 in Libya, 288 m^3 in Tunisia, 313 m^3 in Algeria and 751 m^3 in Morocco (Hinrichsen 1997: table 1). It may be noted that the minimum amount of water required to sustain human life is about 10 m^3 per year per capita; a reasonable supply to maintain health may be 40–80 m^3 per year per capita; and the minimum amount to sustain an acceptable livelihood (food production and other uses) is 1000 m^3/year/capita.

Figure 20.4: Water Resources in the Maghreb. **Source:** African Organization of Cartography and Remote Sensing (AOCRS); at: <http://www.oact.dz/oact/sirepan.htm>.



has so far been able to mobilize 90 per cent of its surface water potentials. Morocco's rate of mobilization is estimated at 75 per cent achieved through the utilization of 114 dams of various sizes with a total capacity of 16.3 km^3 (Oubalkace 2007). As for Algeria, it is lagging behind with only a small fraction of its potential surface water being mobilized in its existing 59 dams, but the country expects to have 10 additional dams going into service in 2009 and 50 new ones being completed by 2020 (Le Maghreb 2008b).[12]

However, the usefulness and even the viability of dams are threatened by silting. Because inappropriate agricultural methods and land clearing practices are used in catchments areas and watershed basins, water going into the reservoirs is loaded with sediments and solid material which are deposited in the bottom of reservoirs, thereby reducing the storage capacity of most dams in the region and exposing some of them to structural defects or even collapse. In this respect, a study has estimated the annual loss of capacity of dams in Algeria, Morocco and Tunisia due to silting

12 Le Maghreb, 2008b: "Dix nouveaux barrages à l'horizon 2009"; at: <http://www.lemaghrebdz.com/lire.php?id=5118> (1 November 2008).

for the year 2000 at 133 million m^3 or the equivalent retention capacity of a major dam; the figure is projected to reach 310 million m^3 in 2030 (Lahlou 2000: table 1.8).

In areas where rainfall is insufficient to justify building dams for collecting runoff water, other techniques of water harvesting may be used; some of them are quite ancient and most had been abandoned but they are now being revived as useful tools of sustainable agricultural production in arid areas (these techniques are described in FAO's website dedicated to water harvesting at: <http://www.fao.org/ag/agL/AGLW/wharv.htm>, chap. 52 by Laureano).

Turning now to underground water resources, these include water contained in water tables located at various depths and which comes mostly from rainwater that seeps through the ground or sometimes from artificial recharge. Libya and Mauritania have very small quantities of *renewable underground water* (RUW), whereas resources in the other three countries are more significant (especially in Morocco, with an annual volume of 10 km^3; see table 20.7). The other kind of underground water is fossil water found notably in the *North-Western Sahara Aquifer System* (NWSAS) (*Système Aquifère du Sahara Septentrional* or SASS in French) which covers a total area of over one million km^2: 700,000 km^2 in Algeria, 80,000 km^2 in Tunisia and 250,000 km^2 in Libya. It contains important quantities of water but most of that water is either non renewable or needs a lot of time to be renewed.[13]

Conventional water resources in the Maghreb are confronted with several problems. Practically all available surface water has been mobilized and groundwater is already extracted at rates that are beyond renewal rates. Yet the region is suffering from water stress and will be faced with water scarcity in the near future. The fundamental problem is the need to provide food for a growing population while there are limited areas of arable land and even more limited amounts of water. One of the solutions adopted was to use marginal lands for irrigated agriculture. Thus, agriculture became the main consumer of water (table 20.8).

But resources being scarce, especially in arid zones, it was inevitable that those resources would be overexploited and as a result, what was to be a solution became itself a problem or, more precisely, the starting point of a series of problems. Without going into lengthy technical details, it may be said that overextraction of groundwater leads to a lowering of the groundwater table and a deterioration of the groundwater quality due to sea water intrusion and/or the upward diffusion of deeper saline water. Furthermore, by extracting water from the soil, evaporation and evapotranspiration tend to increase salt concentrations. Also, direct evaporation from the soil surface causes a rapid accumulation of salt in the top layers, and when the volume of rainwater is insufficient to dissolve the salts generated by the soil and provisions for leaching of salt are inadequate, the soils rapidly become salty and sterile.

a) FAO Aquastat, 2005: web page entitled "General Summary on the Near East and North Africa"; at: <http://www.fao.org/nr/water/aquastat/regions/neast/index.stm>.

Similarly, water storage in reservoirs, where evaporation is intense, tends to increase the salt concentration of the stored water, and using saline water for irrigation may in turn increase soil salinity. In all the countries of the Maghreb as well as in the coastal zones of Libya and Tunisia the salt content of the groundwater used for irrigation has been steadily increasing.

As a result of overexploitation of renewable water resources and excessive withdrawals of fossil water, the index of unsustainable water production is estimated at 22 per cent for Tunisia, 35 per cent for Algeria and 84 per cent for Libya. According to the Bleu

13 The *Sahara and Sahel Observatory* (Observatoire du Sahel et du Sahara – OSS), an intergovernmental organization with headquarters in Tunis, Tunisia, <http://www.oss-online.org> has initiated a major project to study this major aquifer system; it has published a monograph summarizing the results of that project and giving the main characteristics of the system (OSS 2008).

Plan (<www.planbleu.org>) the percentage of unsustainable water supplies derived from fossil sources or from over-exploitation will grow. The rise in the demand for water will be steepest in the least water-rich countries, which will then be exposed to structural shortages. Under these circumstances, some fossil resources will rapidly be depleted and coastal aquifers further destroyed by salt water intrusion. Moreover the silting up of water retained in dams limits their original capacity. Growing quantities of industrial and urban waste and reduced run-off resulting from increased extractions will also affect the quality of water and aquatic systems. These elements further aggravate the factors leading to increasing water vulnerability (costs, health and conflicts).

Various measures are being used or contemplated to mobilize additional water resources, particularly those called unconventional resources derived from the treatment of wastewater and from desalinization of brackish water and seawater. However, the availability of unconventional water is likely to remain limited for most countries in the region. With respect to treated wastewater the main source of supply is urban centres which are generally located far away from the sites of utilization (irrigated perimeters). Furthermore, the quality of treated wastewater needs to be carefully monitored to avoid health hazards and soil contamination. In addition, and on the basis of experiments carried out in Tunisia, the public is not likely to accept that food products be irrigated with treated wastewater. Finally, wastewater treatment creates by-products (solid waste) that are not easily disposed of. Nevertheless, treated wastewater is used extensively in Tunisia (but not for food production) and, to a lesser extent, in Morocco.[14]

As for desalinization, it remains a costly process despite economies achieved in recent years and, more importantly, it requires large amounts of energy. For some countries (Algeria, Libya) the availability of energy resources poses no problems, but this is not the case for other countries in the region.

To summarize (UNEP/MAP/MED POL 2005), the Maghreb is one of the most water-stressed regions in the world. In 2005 the average volume of water available to each inhabitant was 363 m^3. Certain countries are facing a critical situation; e.g. water availability in Tunisia is projected to decline from the current 432 m^3 to 285 m^3 in 2020. The shortage of water is a major constraint for agriculture. Irrigation is the largest consumer of water. National strategies have favoured supply-side policies through the construction of dams and boreholes. However, many dams will lose most of their storage capacity because they are becoming silted up. Aquifers, many of which consist of non-renewable fossil water, are being over-exploited or irreversibly degraded by saline intrusion. Hydrological systems are deteriorating as a result of the degradation and over-exploitation of catchment areas.

Arid areas, by definition, suffer from lack of rain and long periods of dry weather are quite common. However, those periods may at times last for months or even years. On the other hand, when rain does come the quantity of water may reach catastrophic proportions. In other words, arid areas are just as likely to suffer from drought as from flooding – two forms of natural hazards which will be reviewed next.

20.3.3 Extreme Weather Events and Other Natural Hazards

As the UNDP indicates, "[c]limate variability, of which drought is a component, is a normal part of climate. It is a characteristic feature of the drier areas of the globe [...]. Nevertheless, drought is an 'extreme' climatic event or a climate shock: an extended period of unusually low rainfall" (UNDP 2004a). In the Maghreb it is estimated that about 10 per cent of the area receives on average between 100 and 400 mm of rain per year and 85 per cent receives less than 100 mm. In general it has been observed that in the last two decades amounts of precipitation have been decreasing and totally rainless periods have become more frequent and more extended. For example, a study covering the period 1988–1998 shows that in the zones that are considered as semi-arid (annual precipitation less than 600 mm) there have been 4 years of drought in Algeria, 5 years in Mauritania and Tunisia, 7 years in Libya and 8 years in Morocco (UNECA 2001: 54). Other studies indicate that drought frequency after the 1960's increased in Morocco, Tunisia and Algeria. In the specific case of Morocco drought occurred on average once every five years before 1990 but subsequently it occurred once every two years, and of the twenty-two drought years in the twentieth century ten occurred during the last two decades, including the three-year drought of 1999–2001 (Medany 2008: 134).

Another weather-related risk that confronts the Maghreb is flooding. As already indicated, semi-arid and sub-humid areas are characterized by rainfall which is unevenly distributed in time and space. There may be more or less extended periods during which there is little or no rain, but there may also be periods where large amounts of rainfall during a short period of time. As a study published in 2003 points out, "[h]undreds of millimetres of water can fall on arid regions in a few days with no other precipitation for the rest of the year. Arid soil, erosion, and excessive runoff are characteristic of the [Maghreb] region and promote natural disasters related to strong precipitation and flooding" (Agoumi 2003: 2)

Between 1970 and 2008 there have been 44 flood occurrences in North Africa (table 20.9). It may be noted that floods have become more frequent since the turn of this century, particularly in Algeria. This is probably part of a global pattern of a higher frequency of extreme-weather events attributable to climate change. According to a report published by the Worldwatch Institute, "weather-related disasters around the world have been on the rise for decades: on average, 300 events were recorded in the 1980's, 480 events in the 1990's, and 620 events in the last 10 years."[15]

In addition, the impact of flooding on humans and infrastructure in the Maghreb has worsened with time. This is due to the separate or combined effects of several factors:

- Demographic growth increases the number of people at risk.
- Increased urbanization has led to the use of lands unfit for construction (such as dried riverbeds) or devoid of appropriate installations (rain water sewer system), as well as to the breakdown of existing installations.
- The disappearance of land cover as a result of human action (deforestation, overgrazing), which leaves lands vulnerable to wind/water erosion and landslides, and creates other problems such as the silting of dams.

The *Arab Forum for Environment and Development* (AFED) reports that simulations assessed by the *Intergovernmental Panel on Climate Change* (IPCC) pre-

dict that surface temperature in the Arab region will increase between 2 °C and 5.5 °C by the end of the 21st century. This warming will have various consequences, including greater climate variability which, in turn, will increase the frequency and/or the intensity of extreme-weather events: "Drought-affected areas will probably increase, and extreme precipitation events, which are likely to increase in frequency and intensity, will augment flood risk" (Medany 2008: 134).

Other natural hazards to which parts of North Africa are exposed include earthquakes (6 occurrences in Morocco between 1999 and 2006, one occurrence in Algeria in 2004), heat waves (a three-month wave in Morocco in 2004), and cricket infestation (most recently in Mauritania in 2004).

20.4 Conclusion

'Freedom from want' and 'freedom from hazards impact' are two fundamental pillars of human security. Human survival depends on the availability of food and water. To produce food humans require productive land, water and good health. Good health, in turn, depends on food and water of acceptable quality being available in sufficient quantities. But physical survival depends also on the absence of various forms of violence – war, repression, poverty, discrimination, verbal aggression, etc. In other words, human security is indivisible.

With respect to environmental security the Maghreb's score card is mixed. On the one hand, the region's contribution to global problems such as climate

change, ozone depletion, loss of biodiversity and degradation of ecosystems is small proportionately to its population. Nevertheless, it could and it should participate more fully in the protection of the environment. On the other hand, the impact of environmental risks is harsher on developing countries than on richer more industrialized ones, mostly because the former often lack the know-how and/or the financial means to deal with that impact. Thus, more frequent and severe extreme weather events have been observed everywhere – in the US, Europe, the Maghreb – but the impact of a minor event (say, heavy rain for a day or two) in Tunisia, e.g. could have an effect that is equivalent to that of major hurricane that hits the United States. Therefore, developing countries need and deserve assistance to mitigate and recover from the adverse effects of environmental catastrophes. Nevertheless, they have the duty and the responsibility to take measures to reduce their vulnerability to such events.

There is little doubt that our environment is at an advanced state of degradation, and scientists have warned that this situation will get worse unless we radically change our behaviour. Most countries, including those in the Maghreb, have made commitments to protect our common planet by ratifying many conventions related to the environment such as the UN *Framework Convention on Climate Change* (UNFCCC), the UN *Convention to Combat Desertification* (UNCCD) and the *Convention on Biological Diversity* (CBD). Some of those commitments are included in the *Millennium Development Goals* (MDGs) as Goal 7: Ensure Environmental Sustainability. This goal includes 3 targets:

- **Target 9:** Integrate the principles of sustainable development into country policies and programmes and reverse the loss of environmental resources;
- **Target 10:** Halve, by 2015, the proportion of people without sustainable access to safe drinking water and basic sanitation;
- **Target 11:** Have achieved by 2020 a significant improvement in the lives of at least 100 million slum dwellers.

Reaching these targets and, more generally, setting the Maghreb on a course of sustainable development requires effective and efficient measures to deal with desertification, land degradation and drought (Brauch/Oswald Spring 2009), water scarcity (Oswald Spring/Brauch 2009) and vulnerability to natural hazards. However, such measures must be integrated in a global strategy that seeks to achieve *simultaneously* economic development, social equity and improved governance (UNEP/MAP 2005: 13). The principle that these three objectives cannot be disassociated must be taken as an axiom and constitute the foundation of any action designed to achieve human security.

Specialists in environmental protection and politicians are well aware of the environmental problems that beset the Maghreb and of the measures needed to resolve those problems. In fact, some countries have initiated actions aimed at achieving specific targets such as providing access to potable water and improved sanitation, rehabilitating degraded lands or protecting ecosystems. However, outstanding problems are numerous and the resources to resolve them remain insufficient. .

This chapter has highlighted some of the problems confronting the Maghreb:

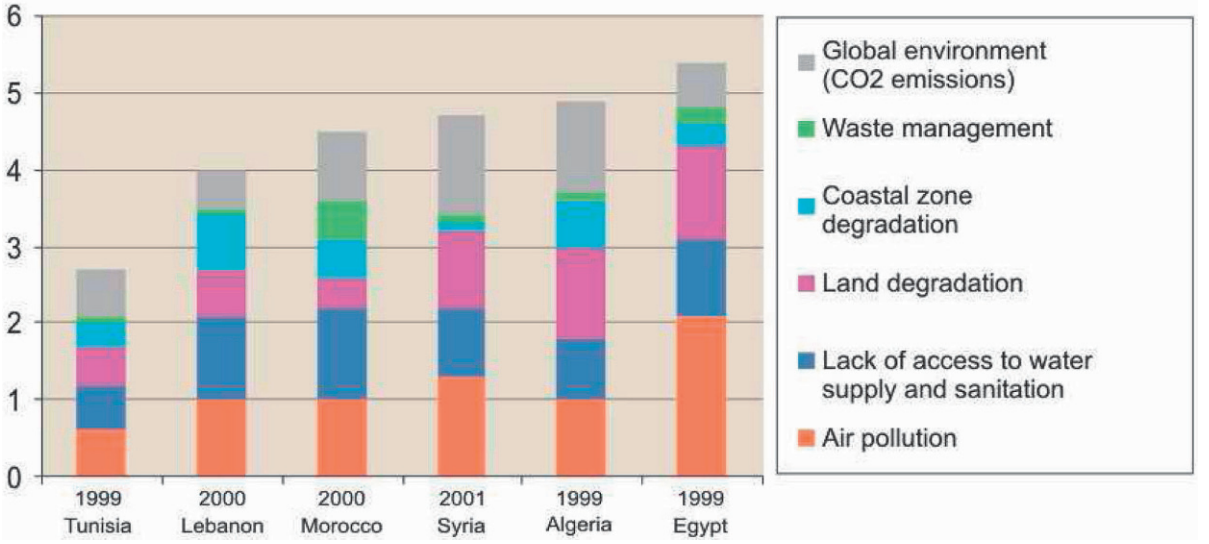
- scarcity, vulnerability and misuse of arable lands;
- scarcity, vulnerability and mismanagement of water resources;
- vulnerability to natural hazards that may or may not be linked to climate change and insufficient preparedness to deal with the effects of such hazards;
- conflict between the need to achieve economic growth to provide prosperity and the pressure to protect the environment.

This last problem is particularly difficult to resolve. On the one hand, social conditions in many Maghreb countries continue to be unsatisfactory, although extreme poverty is rare. Consequently, all countries need to intensify the production and provision of goods and services to meet a growing demand, which pushes them to adopt expedient methods that are not always sustainable or environmentally friendly. For example, marginal lands and scarce water resources are used to grow food; prime land is used for housing, roads, factories and hotels; projects are undertaken without appropriate studies of their environmental impact; etc.

On the other hand, governments are under pressure to incorporate environmental protection in most of their policies. This may be either the result of commitments they have undertaken under various international instruments to which they have adhered, a response to requirements imposed by trading partners, or simply an attempt to pursue enlightened self-interests.

Caught between the need to satisfy immediate and concrete social demands and the necessity of dealing

Figure 20.10: Average annual costs of environmental degradation (per cent of GDP). **Source:** Estimates from World Bank, 2004, cited in UNEP/MAP/Blue Plan (2008: 7).



with long-term environmental concerns, policy makers tended until the turn of this century to either ignore environmental questions or to adopt piecemeal actions that proved ultimately to be ineffective. At present, we see a different approach being used: long-term comprehensive plans are proclaimed to deal with all environmental issues simultaneously. However, and as the editors of the *2008 Report of the Arab Forum for Environment and Development* point out in their introductory chapter, "While looking forward to the future is needed for sound environmental planning, ignoring current problems will not solve them, however noble the long-term goals might be. Problems unaddressed in the present will multiply, creating even bigger challenges in the future" (Tolba/Saab 2008: xxi).

The cost of environmental degradation is too high to be ignored. According to the World Bank, some Arab countries may lose annually between 4 per cent and 9 per cent of their GDP as a result of environmental degradation (figure 20.10), whereas the loss in the OECD is 2–3 per cent. Land degradation and lack of access to water supply and sanitation are major contributors to those losses. It is not clear whether World Bank figures include the cost of infrastructure destroyed by natural hazards such as earthquakes and floods, but that cost is certainly high. Consequently, urgent action is needed to deal with these environmental risks. On the basis of recommendations made to Arab states in general by various institutions such as the *Arab Forum for Environment and Development* (AFED), the World Bank and the *United Nations Environment Programme* (UNEP), Maghreb countries need to focus on the following:

- Preserve and increase water resources through soil and water conservation measures, agricultural and forestry practices, small-scale irrigation, run off and spate irrigation and the mobilization of non-conventional sources of water, as well as the recycling of urban and industrial wastewaters and drainage water, taking into account quality standards.
- Reorient water policies to integrate water demand management in agriculture and other sectoral policies and encourage demand-side approaches with the aim of improving water use efficiency, reducing unnecessary losses, implementing water saving techniques in irrigation and involving industry, tourism and cities in controlling wastewater. It is also necessary to reduce the overexploitation of groundwater and fossil water and promote the artificial recharge of aquifers.
- Promote investment in wastewater treatment systems to prevent and reduce pollution from urban and industrial sources.
- Reduce the vulnerability of rural communities by providing adequate social services (education, health); offering training in sound and innovative practices such as the thrifty use of water, fertilizers and pesticides; promoting organic agriculture, the reintroduction of local varieties and species of plants and animals, the restoration of soil fertility, and the rehabilitation and reintroduction of traditional knowledge and practices. There is also a

need for greater governance through an effective participation of local communities in decision-making and also for encouraging the participation of women in community life.

- Prepare contingency plans to deal with the aftermath of earthquakes and floods. Of course, natural hazards can be neither predicted nor prevented, but it is possible to take measures to provide assistance to their victims and help them reorganize their lives after the catastrophe. It is also necessary to take preventive measures to minimize the impact of natural hazards when they occur. For example, urban land use regulations should be adjusted to prevent construction on lands at risk (such as banks and beds of dry rivers), and building codes applicable in areas at risk should include specifications that make buildings resistant to quakes and high currents.

Implementation of these measures requires technical and financial resources. In the Maghreb resources needed to carry out such complex and costly undertakings as research, training, mobilization of resources, and project design, implementation, monitoring and follow-up may be unavailable or insufficient in some cases, but they are readily available in others. Yet in all countries the current state of environmental security in particular and of human security in general is mostly unsatisfactory and citizens are confronted with threats, risks and vulnerabilities that could have been avoided and that are set to worsen as a result of global phenomena (climate change, ozone depletion, global warming) and prevailing local conditions (demographic growth, unchecked urbanization, overexploitation of resources...).

Clearly, there are certain conditions over which man has no control: climate, geography, geology and the like. But people in the region have lived and even prospered under those same conditions for centuries. Social mores, cultural practices and religious values all show that people are admonished to respect nature and protect the environment. Some of those practices and behaviours have persisted to these days in some isolated parts of the Maghreb that have not been too affected by 'modernization.'

If the environment has suffered in the last fifty or sixty years the greatest and fastest degradation in the region's history, it is partly because of evolutions and changes that were perhaps unavoidable and may have been even desirable, and partly because public authorities failed to take appropriate measures to avoid or reduce the negative impact of those changes. When colonial rule in the Maghreb ended in the middle of the 20th century social and economic conditions were quite bad: educational and health services were limited; income-generating activities were restricted mostly to traditional agriculture and handicrafts; infrastructure (roads, electricity, running water, sanitation...) were concentrated in a few urban centres; the little manufacturing or industrial production that may have existed was in the hands of foreigners...

Under those circumstances it was only natural that governments in the newly independent states set out to pull their societies out of backwardness and underdevelopment. It should be kept in mind that we were at that time in the midst of confrontation between capitalism and communism, two ideologies that made no distinction between politics and economics. For leaders of what was to become the 'Third World' the East (in fact, the Soviet Union) became the model to follow in all matters of public life, although the 'scientific' term used to identify that orientation was socialism. Politicians were not the only ones to espouse socialism. Many economists, including some in the West, advocated the virtues of industrialization as a fast track towards development and modernization, and the need to adopt an industrial approach to agricultural production.

When the Cold War ended with the disintegration of the Soviet Union and the dismembering of the Eastern Bloc, it was claimed that the victory of the West proved the fallacy of socialism and the superiority of capitalism and of the market economy. The former had therefore to be abandoned and the latter became, in the absence of a 'third way', the only theory or ideology to govern public policy.

The critical issue of concern here is that, as far as the Maghreb is concerned (along with other Arab and African countries), regimes continue to adopt policies and decisions without submitting them to public debate. Whenever a policy is adopted, regimes either do not bother to offer justifications for it or present it as the best or only means to achieve the national interest. Any criticism or challenge of official policy is proclaimed to be an act of treason and a clear indicator of irresponsible and unpatriotic behaviour. Thus, retaining certain cultural or religious practices may be deemed at one time as backward and reactionary, only to become at a later stage a sign of authenticity and an indispensable aspect of national identity – neither position being based on any rational explanation.

This type of behaviour is characteristic of authoritarian regimes. Dictators are convinced that they are infallible and come to view any questioning of their decisions as rebellion. The result is that oppression

and arbitrary rule become widespread. In reaction to that, the majority of the population choose to withdraw from the public space, fearing for their safety and security. However, a few opt for confrontation with the regimes; in most Arab countries it is extremist religious groups who choose this course of action. But this does not mean that the majority is as 'silent' as it may appear. Unable to openly challenge their rulers, more and more people try to find a variety of acts which they would undertake as forms of civil disobedience. In general such acts are illegal but they are carried out precisely because they are illegal and would then constitute challenges to the authority. They may range from smoking in buses to vandalizing public property to throwing garbage in the street.

Of course, such behaviour is irresponsible and ultimately self-defeating. At the end of the day, it is the citizens themselves who will be deprived of the public infrastructure or of a clean environment. But we have to consider that in such cases citizens who live in constant frustration and despair may do things that appear pointless and even childish. Just consider the young man trying to stop the advance of a column of tanks on Tiananmen Square, or Palestinian children throwing rocks at Israeli tanks.

The point here is that citizens in the Maghreb are well aware of environmental issues, their culture and their religion having taught them to live in harmony with nature and to respect the environment. But when they find themselves confronted with regimes that strip them of their most fundamental rights and that allow them no form of protest or contestation, they may feel that they have no choice but to act in a manner that an outside observer would consider as irrational.

Clearly, there is at present no scientific method to test the validity of this hypothesis: in the Arab world public opinion surveys are as likely as rain in August. But for anyone who has lived under an authoritarian regime, it would not be difficult to understand how despair may shape human behaviour.

There is no doubt that the Maghreb is confronted with major environmental challenges, risks and vulnerabilities and that these will worsen in the coming years and decades. In some cases, damage suffered by the environment is at present irreversible, but there is still time to protect the environment from further degradation and hence ensure the security of future generations. In terms of environmental security, the fate of the Maghreb is inexorably linked to that of the rest of humanity but there is still room for the Maghreb to inflect the course of events in this area. Governments have been showing concern about the state of the environment and have undertaken many actions to preserve it from future degradation. However, the success and effectiveness of any public policy, whether pertaining to the environment or any other area, will ultimately depend upon the public's commitment to that policy and its active participation in its implementation. At present, any government initiative is received with suspicion – if not hostility, regardless of its intrinsic value; this is becoming a quasi Pavlovian reflex. In some cases, financial and administrative means are used to force compliance or deter infractions, but such measures may sometimes become counterproductive.

The daunting but inescapable conclusion is that for *people* in the Maghreb achieving human security in general and environmental security in particular will depend mostly on two exogenous factors: the goodwill of industrialized countries which need to change theit behaviour that is damaging to the global environment, and the willingness of national governments to become accountable to their citizens.

Come senators, congressmen
Please heed the call
Don't stand in the doorway
Don't block up the hall
For he that gets hurt
Will be he who has stalled
There's a battle outside
And it is ragin'.
It'll soon shake your windows
And rattle your walls
For the times they are a-changin'.

From Bob Dylan's song
"TheTimes They Are A-changin'" (1963).

21 Water Degradation as a Human Security Challenge in Jordan

Bassam Ossama Hayek and Nisreen Daifallah Al Hmoud

21.1 Introduction

Water is vital to sustain lives. Thus, its availability in the appropriate quantity and quality is crucial for a healthy society. The water resources available for use are only three per cent of the total available water. Due to the uneven distribution of usable water, some nations are deprived of the minimum amount, while other nations suffer in handling too much water. People living in areas of scarce water resources became increasingly vulnerable due to the rise in water demand from a growing population and the associated needs for development. In water scarce areas like Jordan, water is a very valuable commodity and water demand management is an essential element in the national efforts for water management. Such concerns are even addressed at the highest level, where His Majesty King Abdullah II defines water in Jordan as forming a strategic challenge that cannot be ignored, and that a balance has to be reached between drinking water needs and the industrial and agricultural needs, while drinking water remains the most essential and the highest priority issue.[1]

Jordan – in the eastern Mediterranean – has an area of about 90,000 km^2 and a semi-arid to arid climate, where temperature ranges from -3°C to 45°C. More than 70 per cent is covered by desert (figure 21.1). Precipitation ranges from less than 50 mm in the Badia to about 650 mm in the Highlands, but only about four per cent of Jordan receives more than 300 mm of rain.

The annual per capita water availability has declined from 3600 m^3/year in 1946 to 145 m^3/year in 2007. Jordan's population has significantly increased during the past five decades, and reached 5.6 millions in 2004 (national census of 2004) compared with less than 0.5 million in the 1940's. The population is expected to grow to over 7.8 million by 2022, where the projected WATER demand is estimated to be 1,673 MCM (Jordan 2009). However, the population growth has greatly been affected by the in-flow of immigrants, refugees, and returnees due to the conflicts in the region (in 1948, 1967, 1991, and in 2003).

Although the Kingdom of Jordan takes its name from the biblical Jordan River, the name hardly reflects the reality of the water situation. Its scarce water resources are the major constraint for development. At present, the per capita water availability puts Jordanians in an absolute water scarcity level; in fact, Jordan is rated the fourth driest country in the world. Jordan's water resources available for use were estimated at 867 MCM in 2007, while the demand reached 1505 MCM; thus, posing a deficit of 638 MCM reflecting a severe challenge for the development and human security. Therefore, the water strategy included measures for resource exploitations and efficient management to counteract the increasing deficit. According to the water strategy the resources are to be developed to 1,632 MCM by 2022. Among the actions are implementing the major water resources exploitation projects like the Red Sea to Dead Sea Project, Dissi Water Conveyance Projects, and the development of reclaimed water (or treated wastewater) as an additional resource that is estimated at 91 MCM in 2007 and will develop to around 247 MCM by 2022 (Jordan 2009).

From the above introduction, it is evident that water availability will be a prevailing problem unless a super cooperative solution is adopted to meet the challenges. Water scarcity in Jordan poses not only a challenge to the development process, but it may also interfere with the quality of life and health status of the people.

21.2 Interpreting Water Degradation as a Human Security Challenge

According to The Universal Declaration of Human Rights,[2] human rights include "the right in a standard of living adequate for the health and well-being of the person and of his family." Although the right to safe water and environment is not mentioned explicitly, however, the authors would interpret that "the standard of living adequate for the health and well-being" implies having safe water in quality and quantity. At present many nations including Jordan are facing water degradation challenges; water demands are increasing, groundwater levels are dropping, surface-water supplies are increasingly contaminated, and delivery and treatment infrastructures are ageing. For Jordan, this is clearly reflected in the water poverty situation where every Jordanian has only 145 m^3 of water per year. For a water-poor country the matter is not only in quantity but also in quality, and the risks would propagate as the quality of available scarce wa-

2 See: <http://www.un.org/en/documents/udhr/index.shtml#a25>.

ter resources deteriorate due to overexploitation of the resource or to the pollution load caused by urban development.

This poses eventually a human security challenge of complex nature where the people have the right of good living including safe water and food, while these resources are not available on one hand and the chain propagates to cause health risks and compromised quality of life. It can also be argued that water security encompasses this inherent duality: without it there is no development, but with it the most vulnerable can leave poverty behind. Thus, water availability is a necessity to reduce poverty which is a prominent human security issue. The challenge would include that poor communities may not have only safe water to drink and safe water for their good hygiene but also sufficient water to operate their production activities, including food production. Thus, a poor society may become poorer and new poor societies may evolve. Here, poverty is interpreted as being poor in income, health, water, and quality of life. Improving water security of poor people will help to eradicate poverty and support sustainable development in direct and material ways.

In his advocacy towards better life for future generations and recognizing water security as part of human security, HRH Prince El Hassan bin Talal has repeatedly called for the need to work and think on the supra and intranational level and independently to be able to address our common problems of scarce resources and thus saving our regional identities. The issue of water and the availability of resources are not limited to a certain identity or country, as HRH said

> if you respect my identity, I respect your identity and we have mutual respect in the context of *Territoriality Identity and Migration* (Movement) (TIM), then we could work towards a carrying capacity for demography in relation to human, natural and economic resources.[3]

It is therefore clear that the security issue of water is not to be addressed solely on a national level; it must become an object of a dialogue at multinational levels as, for example, a drought will not differentiate between one nation and another. During the 21st century, the human drama caused by climate change will evolve globally. Threatening reversals in development gains and blocking further achievements, climate risks will continue to impede opportunities that vulnerable populations can benefit from economic growth. As a direct consequence, inequalities in water access will further intensify as water stocks deplete – in combination with other changes, citizens in the region will directly enter an era of scarcity (UNDP 2006).

Given the wide-ranging importance and influence of these changing contexts, water security requires cooperation among nations to address climate change impacts and associated water and health issues and thus human security. "Ironically, climate change offers humanity an opportunity for a quantum leap in sustainable development and peacemaking."[4]

In the following sections, the authors outline key issues related to water degradation and associated health impacts as a challenge for human security. This analysis is supported by case studies and examples from the field that capture on-the-ground realities, successes, and lessons learned. These actions are also shared to contribute to safeguarding the health of Jordanians and possibly as lessons learned for other nations facing scarce water resources.

21.3 Health Impacts Due to a Low Water Share per Capita

Water consumption varies greatly among regions due to differences in economic development. A total of 284 MCM/year are presently used in Jordan to satisfy domestic uses. Calculating the per capita domestic water use in Jordan shows that it averages around 85 l per capita per day (l/c/d). Compared to the domestic uses in Europe of 150–250 l/c/d., to those of Israel of 280–300 l/c/d., to the Gulf States of 280–450 l/c/d., and to Iraq, Syria and Egypt of 130 l/c/d, Jordanians are using the least of all, not only because they are rationing water use, but also because water is much less available. Concerning domestic water use, especially during summer, 85 per cent of Jordanians live at the hygienic brink. Less water would imply public health detriments.

Water quantity and quality are key elements for good health. Despite the *World Health Organization* (WHO) standards relating to water quantity, the WHO has not previously published specific guidance on the quantities of water as targets for health protection and promotion (Howard/Bartram 2003).[5] This conflicts with the concerted efforts on establishing in-

3 Opening keynote address by HRH Prince El Hassan bin Talal at the 2nd annual CAUX FORUM for Human Security, Geneva, July 2009).

ternational standards and later guidelines for drinking water quality (WHO 1985; WHO 1993). The WHO estimates that nearly two billion people consume contaminated water, experiencing a significant risk of developing water-related diseases. According to Bradley (1977), there are four major categories of water-related diseases; water-borne diseases (diarrhoeal diseases, infectious hepatitis, typhoid), water-washed diseases (diarrhoeal diseases, eye diseases, skin diseases), water-based diseases (schistosomiasis, dracunculiasis, other helminthes), and water-related diseases 'vector-borne diseases' (malaria, dengue, filariasis, onchocerciasis, trypanosomiasis, yellow fever, etc.). Some suggest that water-washed diseases should be restricted only to skin and eye infections that solely relate to the quantity of water used for hygiene (e.g. Cairncross/Feachem 1993). However, Howard and Bartram (2003) recognized the particular value of Bradley's original classification as its focus is on the potential impact of different interventions.

Studies concluded that an increase in water consumption (quantity) is as important as or more important than water quality for the prevention of diarrhoea (van der Hoek/Feenstar/Konradsen 2002; Kirchhoff/McLelland/Pinho 1985). There are several studies that indirectly discuss water quantity and diarrhoeal incidence using the type of service level and geographical and temporal access to water sources (e.g. Gorter/Sandiford/Smith/Pauw 1991; Prost/Negrel 1989). Yet, there are few published studies that directly address water quantity in relation to the prevention of diarrhoea.

Those published attributed lower diarrhoeal incidence realized through consumption of larger quantities of water to personal hygiene activities. Washing hands particularly after defecation and before eating and cooking are effective timings to prevent diarrhoea (Curtis/Cairncross/Yonli 2000; Birmingham/Lee/Ntakibirora/Bizimana/Deming 1997; Stanton/Clemens 1987). Yet, hygiene education is of limited value unless water supplies are improved and larger quantities of water are readily available (Gilman/Marquis/Ventura/Campos/Spira/Diaz 1993).

Hepatitis, a broad term for inflammation of the liver, has a number of infectious and non-infectious causes. Two of the viruses that cause hepatitis (hepatitis A and E) can be transmitted through water and food; hygiene is therefore important in their control. Both hepatitis A and E are found worldwide. Hepatitis A is particularly frequent in countries with poor sanitary and hygienic conditions (in Africa, Asia, and Central and South America). Countries with economies in transition and some regions of industrialized countries where sanitary conditions are sub-standard are also highly affected, e.g. in Southern and Eastern Europe and in some parts of the Middle East.

The vulnerability and adaptation team of the *Second National Communication* (SNC) on climate change conducted an epidemiological study to assess the health status in Jordan. Monthly data on water-borne diseases 'hepatitis A, typhoid fever and diarrhoea' and vector-borne diseases such as 'cutaneous leishmaniasis' were obtained from the Directorate of Communicable Diseases of the Jordanian *Ministry of Health* (MoH). The vulnerability assessment was designed as an ecological study, where the unit of observation is the population or a community. The disease rates and exposures are measured in populations to identify correlations between them (Jordan 2009a). The annual diseases incidental rate between 1996 and 2007 (table 21.1) shows that the *incidence rate* (IR) has significantly been reduced for hepatitis A and typhoid fever, while it is still very high for diarrhoea that results from gastroenteritis caused by viral infections, parasites or bacterial toxins (Wilson 2005).

Although the data are not explicit enough to relate the diseases to its cause, but water-borne diseases are being considered as a major root cause. Many cases of hepatitis A outbreaks in small towns were attributed to a lack of hygiene; however, such a disease should rather be classified as a water shortage disease in communities that lack sufficient quantities of water for their basic daily use.

21.4 Risk of Microbial Diseases due to Reclaimed Water Reuse

Reuse of reclaimed water is a necessary component of water resources management in Jordan where the supply of water is very limited and the demand is rapidly increasing (Carr/Blumenthal/Mara 2004). Yet, water recycling presents some risks for public health and the environment, and it is perceived negatively in the public eye.

Worldwide, it is estimated that (18 per cent) of cropland is irrigated, producing about (40 per cent)

5 In 2000, WHO and UNICEF proposed 20 l/c/d as a part definition of 'access to improved water supply' in their recent joint work *Global Water Supply and Sanitation Assessment 2000*. However, it does not refer to ensuring health protection and/or promotion such as less diarrhoeal incidence (WHO/UNICEF 2000).

* IR: Incidence Rate = (no. of cases per 100,000 persons),

of all food (Gleick 2000). A significant portion of irrigation water is wastewater. Hussain, Raschid, Hanjra, Marikar and van der Hoek (2001) report on estimates that at least (20) million hectares in (50) countries are irrigated with raw or partially treated wastewater. In many developing countries, wastewater used for irrigation is often inadequately treated. WHO and UNICEF (2000) estimates the median percentage of wastewater treated by effective treatment plants to be 35 per cent in Asia, 14 per cent in Latin America, 90 per cent in North America, and 66 per cent in Europe. The use of untreated wastewater in agriculture implies a high actual risk of transmitting intestinal nematodes and bacterial infections. Moreover, the quantitative microbial risk analysis has suggested that low levels of virus in irrigation water can result in a significant risk of infection to consumers (Petterson/Teunis/ Ashbolt 2001). Stine, Song, Choi and Gerba (2005) estimated that less than one hepatitis A virus per 10 l of irrigation water could result in a risk exceeding 1: 10,000 per year considering the efficiency of the transfer of the virus to crops and its survival until harvest time. The 1: 10,000 risk of infection per year is currently the acceptable level used by the United States Environmental Protection Agency (Regli/Rose/Haas/Gerba 1991).

In Jordan, wastewater has been used for irrigation for several decades. Some treated effluent has been used directly on restricted crops of relatively low value, but the main practice has been to discharge effluent to the environment where it mixes with freshwater flows before being used downstream. In 2001 more than (70 MCM) of reclaimed water was used either directly or indirectly in Jordan (McCornick 2001). In 2009 this amount exceeded 91 MCM/year and this amount is projected to grow to around 250 MCM by 2022. The categories of use have been: a) planned direct use within or adjacent to *wastewater treatment plants* (WWTPs). Several sites are pilot projects with some research and limited commercial viability, b) indirect use after mixing with natural surface water supplies and freshwater supplies downstream, primarily in the Jordan Valley (treated effluent from As-Samra WWTPs is discharged to Wadi Zarqa, the wadi flows into the King Tala Reservoir). Water in the reservoir, blended with water from the King Abdullah Canal, is used for irrigation in the southern portion of the Jordan Valley. However, health aspects and risks related to this reuse have not yet been investigated within a coherent framework of procedures and activities, including the integration of various components of technical, social, economical, environ-

mental, institutional, and public participation requirements.

Demand for public water supplies had recently increased since access to safe drinking water supplies has been impressively reaching over 96 per cent of the population. Accordingly, wastewater generation increased that led to the deterioration of reclaimed water quality coming out of sewage treatment plants due to the increasing hydraulic and organic loads that far exceed design criteria. The most recent strategy has counteracted again this problem by adopting a goal to planning for more efficient treatment systems, and even expanding the reuse of wastewater in an efficient and economical way.

Grey water[6] treatment and reuse has become increasingly popular in water scarce and even in water rich countries. In fact, grey water application is complicated not only due to technical feasibility but also due to human issues. A major argument has been the public perception of water reuse and the risk associated with it, which ultimately dictate the standards required for water quality, and so the appropriateness of candidate treatment technologies. A holistic approach to water recycling is thus crucial, and the efficacy of individual treatment technologies or overall treatment schemes must be precisely evaluated (Jefferson/Palmer/Jeffrey/Stuetz/Judd 2004).

The rationale for treating grey water is based on the biological characterization of grey water. It has been documented that grey water may contain at least 10^5 MPN/100 ml of potentially pathogenic micro-organisms (Dixon/Buttler/Fewkes 1997). Based on the repeatedly high counts found on faecal indicator bacteria, regulatory agencies enforced combined treatment, or strict separate treatment of the grey water when it was separated.

Interest in adopting innovative, non-conventional grey water management strategies is rapidly increasing worldwide for economical, structural, and ecological considerations (Asano/Levine 1996; Gunther 2000). Domestic and industrial water is given a higher allocation priority than irrigation water. However, the agricultural sector is faced with the challenge to produce more food with less water (Al-Jayyousi 1999). Therefore, attention has been paid to the possibility of reusing grey water, especially in arid areas (Trujillo/Hanson/Zachritz/Chacey 1998; Casanova/Gerba/Karpiscak 2001). This should be supported by a suitable health system to control such a practice.

As part of the health control of grey water reuse, an overview of the health aspects of grey water reuse was published in 2004 by the WHO in Arabic that reviewed all health issues and regulations in the world for grey water treatment and reuse. This overview included guidelines for grey water reuse in East Mediterranean countries. This overview was approved and certified in a workshop at the WHO Regional *Centre for Environmental Health Activities* (CEHA) in Amman, 20–22 October 2003.

Based on the new WHO guidelines (2006), a research project is carried out at the *Environmental Research Centre* (ERC) of the Jordanian *Royal Scientific Society* (RSS) that investigates the optimal modalities for application in practice of the new WHO guidelines on the safe use of grey water in agriculture in the context of poor urban communities. The project evaluates the current status of the use of grey water in agriculture, and describes associated health issues at the 'Jerash Refugee Camp' (box 21.1, case study on water safety). So far the study revealed as the cause of diarrhoea the exposure to polluted grey water, the risk assessment posed a lack of hygiene to be the transfer route; hence awareness campaigns were lunched to educate the community on the risks and to improve the level of hygiene. This would not be sustainable if the supply of adequate quantity and quality of water were not assured.

21.5 Risk of Groundwater Pollution Due to Human Activities

Despite its importance, groundwater is often misused, usually poorly understood and rarely well managed. The main threats to groundwater sustainability arise from the steady increase in demand for water (from rising population and per capita use, increasing need for irrigation, etc.) and from the increasing use and disposal of chemicals or biological material to the land surface where it can ultimately reach and pollute groundwater.[7] In most cases, contamination of groundwater by chemicals derived from urban and in-

6 Grey water is untreated domestic wastewater originating from bathtubs, showers, kitchen activities and laundry facilities. It does not include toilet waste.

7 It is noted that pollution of a body of water occurs when an impurity (micro-organism or chemical) is introduced by or as a result of human activities, creating an actual or potential danger to human health or the environment when present at high concentrations (Morris/Lawrence/Chilton/Adams/Calow/Klinck 2003).

Box 21.1: Safe use of grey water for agriculture in the Jerash Refugee Camp focusing on technical, institutional and managerial aspects of non-treatment options. **Source:** The authors.

The Jerash refugee was set up as an 'emergency' camp in 1968 for 11,500 Palestinian refugees and displaced persons who left the Gaza Strip as a result of the 1967 Arab-Israeli war. The selection of the site is based on specific criteria that focus on poor vulnerable urban areas that exhibit grey water separation and reuse for agriculture without any treatment and the relatively high presence of indicators of adverse water-related health issues.

The camp is provided with basic infrastructure of electricity, water supply and basic sanitation services (latrines) from which black water is disposed to cesspools. The camp contains (2050) housing units, which are all provided with water tabs and 1560 of them are provided with latrines from which the wastewater is disposed to cesspools or septic tanks. Grey water is separated at the houses and discharged through small open ditches and collected in ten collection points all over the camp. Water then flows in a natural channel that crosses several farms. Along the open channel, a series of more than four earth ponds were excavated just besides the channel to collect and store water for irrigation. Pumps are placed in the ponds and they are being used to distribute the stored grey water to farms on both sides of the channel. Farmers use grey water in these farms as a supplementary water to irrigate trees, and vegetable fields between tree strips with olive and almond trees as well as vine. Eggplant, okra and beans are also being planted in the areas between olive trees. It is observed that the trees are very close to the grey water channel and in many places the distance between the trees and the grey water is about one metre, which means that during harvest time the farmers will work very closely to the polluted water and the fruit themselves would be dropped and collected very near to the source of pollution.

Health records from the *United Nations Relief and Works Agency for Palestine Refugees in the Near East* (UNRWA) health centres reveal that the Bloody Diarrhoea (waterborne disease) weekly records at Jerash refugee camp are high compared with records of another refugee camp in the same Governorate. The limited area of the Jerash camp makes the construction of a treatment plant in the camp very difficult. At the same time, the environment and public situation in the camp urges the adoption of non-treatment approaches that aim at managing health risks associated with grey water and promoting health protection measures.

In this study, the target groups were the farmers (in the farms close to the refugee camp) and the households (in the refugee camp itself). The camp became an object of an environmental health risk assessment and management approach with a focus on grey water management. Current pollution sources including grey water and wastewater were mapped. Hazards which result from direct or indirect exposure to grey water were characterized through structured interviews and observations. Data on environmental exposure, epidemiological conditions, and hygiene behaviour were used to construct the Epi Info. to assess the risks in the camp and nearby farms. The survey proved the significant relation between the hygiene behaviour of the children in the camp and the incidence of diarrhoea (the main health problem in the camp, figure 21.2). The safety of the public water network was confirmed. As a result, the health-oriented behaviour and personal hygiene for the targeted groups were promoted by developing personal skills through awareness campaigns, training, and other means. The output of the study enhanced hygiene education and health-oriented behaviour among school students and housewives.

dustrial activities, modern agricultural practices, and from waste disposal takes place almost imperceptibly. The slow movement of water from the surface through the unsaturated zone to deep aquifers means that it may be many years after a persistent chemical has entered the ground before it affects the quality of groundwater supplies (Morris/Lawrence/Chilton/Adams/Calow/Klinck 2003).

Biological contamination may, however, indicate a faster track than chemical pollution. As many human activities generate a significant microbiological contaminant load at the land surface (for example, irrigation by wastewater, intensive livestock raising and

meat processing, on-site sanitation), when detected in the groundwater, they indicate relatively rapid movement to the water-table from ground surface. This is because most pathogenic micro-organisms have only limited persistence; however, some viruses are known to survive for up to 150 days and encysted protozoa even longer. In the case of indicator bacteria (microbes commonly associated with pathogens but more easily incubated and identified), a half-life in low-temperature groundwater can be as high as 22 days, with a survival of appreciable numbers up to 32 days (Morris/Lawrence/Chilton/Adams/Calow/Klinck 2003).

Serious incidents of groundwater pollution have occurred due to accidental spills, or unsatisfactory disposal of industrial chemicals. In addition, solid and liquid waste generated by modern society is often spread over the land surface without control. In such a case moisture from the waste and rainwater form leachate that may percolate down through the underlying soil. Depending on the type of waste, the leachate may be highly acid, have a large organic load or contain a high concentration of ammonia, toxic metals or various organic compounds, all of which may contaminate underlying groundwater.

Typical examples of the effect of a rather persistent microbial pollution of groundwater are the outbreaks of cryptosporidiosis. These have been documented in countries around the world; over 45 outbreaks have been reported with the greatest documentation in the USA and in the UK (Smith/Cacciò/Tait/McLauchlin/Thompson 2006); a significant number of these outbreaks was directly associated with contaminated groundwater (wells and springs not properly protected from sewage and runoff). Water-borne cryptosporidiosis presents a serious threat to human health due to the ubiquitous distribution of cryptosporidium spp. in humans, animals, and water and the resistance of the oocysts to harsh environmental conditions, various disinfectants, and some treatment practices.

In Jordan some 10,000 people experienced such an outbreak in July 2007 (noting that previous outbreaks may have been happening but could not then be identified), when precious groundwater wells (even at depths of 150–290 m) were subjected to microbial pollution due to compromised solid waste disposal practices, including household and livestock wastes (Hayek/Al-Hmoud/Al-Kilani 2007, Hayek/Al-Hmoud/Al-Kilani/As-Sayyah 2008). The transfer of pollutants was enhanced by the coinciding heavy rainfall causing flooding every ten years or so. The outbreak started with a large increase of gastroenteritis cases in a community in northern Jordan (Munshiyat Bani Hassan, Al Munshiyat) were reported and led to an investigation of the water supply. The outbreak was investigated, taking into consideration the prevailing symptoms of the patients (which matched the symptoms of cryptosporidiosis) and some key environmental conditions. The investigation then focused on testing for cryptosporidium in the water supply; this is in addition to the classical microbial surveillance. Moreover, the geophysical data (including the existence of faults, groundwater level, and the activities around the wells) of the area were studied. The results proved the presence of cryptosporidium spp. oocysts with other faecal pollutants in groundwater wells used for consumption. The cause was related to the existence of livestock farms (dairy cows and calf raising), permeable cesspools, a dump site, grazing and uncontrolled handling of cows manure within the wells' catchment area, where also many geological faults exist. As a consequence, efficient reclaiming procedures and further water supply treatment and groundwater monitoring activities were recommended (box 21.2) for more details on the case study. The study presented a clear example of how the geophysical and human data should adequately be taken into account in striving for sustainable resources management!

Box 21.2: Case study on the outbreak of cryptosporidium in Northern Jordan. **Source:** Prepared by the authors.

An outbreak of cryptosporidiosis among the residents of Munshiyat Bani Hassan (Al-Munshiyat community in the North of Jordan) occurred in the mid summer of 2007 that affected more than 1,000 confirmed cases. Initially, the cause of the outbreak was unclear. The management team launched several investigations of the affected people, the way the infection was spreading, the microbiology of the illness and all possible causes. The study investigated the site, surveyed residents with cases of water diarrhoea and gathered data from the Al Munshiyat Health Centre. Then, samples of the tanks and wells were examined during the outbreak for cryptosporidium oocysts, and a risk analysis was undertaken for a safer approach to identify the safe wells. Based on this study, measures to avoid and minimize future risks from such incidents were proposed.

The investigations concluded that the outbreak was water-borne and linked to the main water supply of the Al-Za'atari tank. The initial analysis of the water quality in the town showed that the water supplied to the network

when the investigation started had a sufficient chlorine level. But the number of cases rose to 600 when the investigation was launched. The clinical analysis of the cases included Watery diarrhoea, abdominal cramps, fever, and vomiting, which are the symptoms of cryptosporidiosis, which do not show until five to ten days after becoming infected. Cryptosporidiosis is a diarrhoeal illness caused by a parasite called cryptosporidium, which is a major public health threat because of its insensitivity to disinfection and the increased likelihood that infected oocysts are present in conventionally treated (coagulation, sedimentation, filtration, disinfection) drinking water. Therefore, The authors assumed that the presence of cryptosporidium was the cause of this water-borne disease after food was ruled out as a direct cause. Most cryptosporidium outbreaks are the result of faecal accidents (contamination) coupled with oocyst resistance to chlorine.

Samples from house tanks of old water contained shigella and E. coli already prior to the outbreak. Water-borne outbreaks of the cryptosporidium infection were documented for drinking water from a contaminated artesian well. The authors immediately surveyed the 37 wells that fed the Al-Za'atari tank for microbial contamination in order to segregate contaminated wells from clean ones. Several wells showed positive results for faecal coliform and E. coli. In parallel, the hydrogeology of the area and the activities surrounding the wells were studied for possible sources of contamination of the wells. Based on these findings, a risk analysis matrix was made to identify the most likely clean wells to be connected to the water supply.

Water samples from 19 wells were tested for cryptosporidium. Eight wells were tested positive for cryptosporidium (figure 21.3), and giardia (figure 21.4) was detected in one well. The remaining wells tested negative for cryptosporidium and were therefore reconnected for water supply.

Environmental investigations were confirmed by microbiological tests, and a risk analysis identified the cryptosporidium oocysts that resulted in the outbreak in Al Munshiyat. Possible sources include cattle farms, cow waste, cesspools, and a dump site that are all located close to the wells and the geological faults (figure 21.5). It is possible that heavy rains and floods in April and in early May 2007 increased the groundwater recharge and thus carried some pollutants (e.g. cryptosporidium oocysts) from the surface to the groundwater. In 2005 in North-west Wales heavy rain was linked to outbreaks of cryptosporidiosis.

Further tests by the study team of the water quality of the Za'atari tank that was supplied by 13 reconnected wells proved negative for cryptosporidium. Thus, after the outbreak a periodic monitoring was recommended.

Figure 21.3: Cryptosporidium oocysts found in a well. **Source:** Photo by the authors.

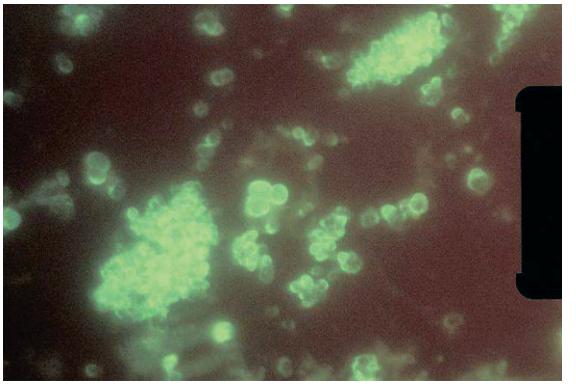

Figure 21.4: Giardia oocyst seen in a well. **Source:** Photo by the authors.

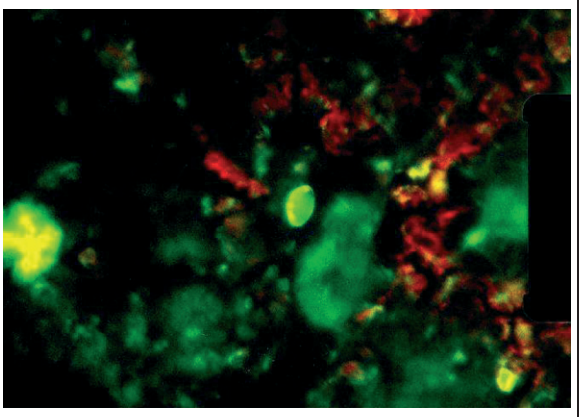
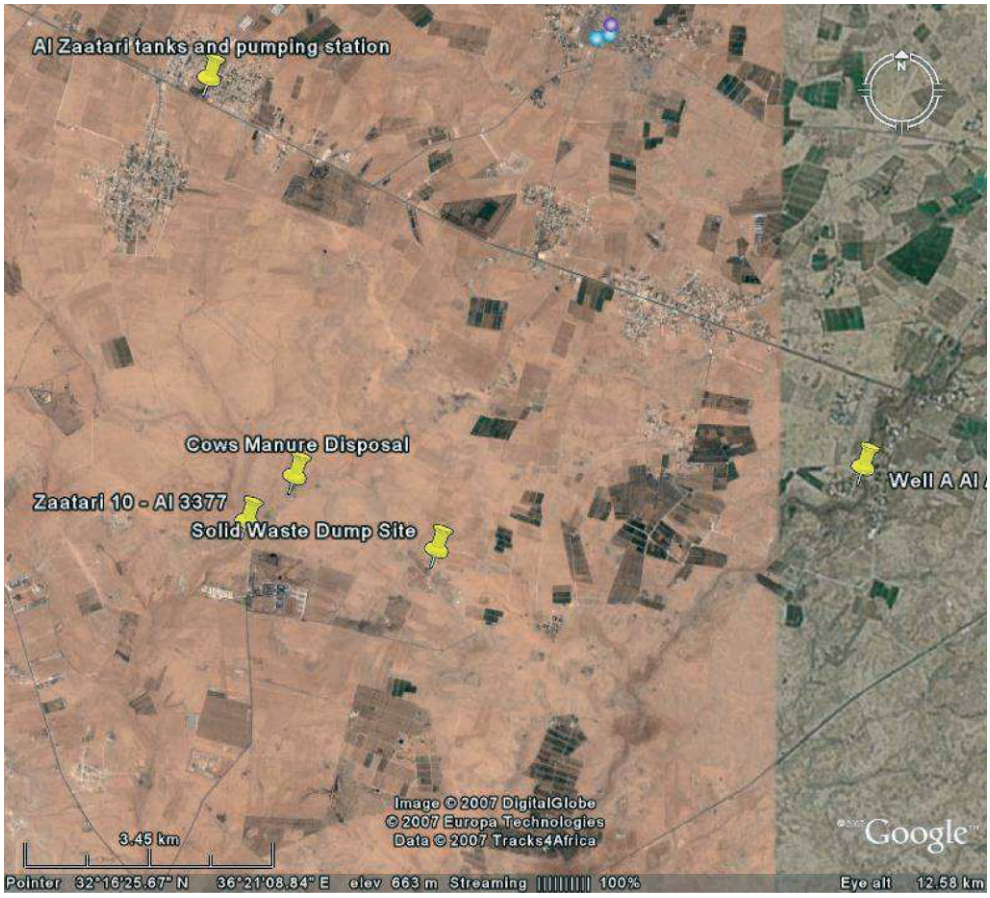


It is difficult to see how the outbreak could have been prevented, or its impact reduced, given what was known before it started and what became apparent when it spread. But if the drinking water and the wells had been adequately monitored, the problem could have been avoided much earlier. This requires an effective and frequent monitoring of the water resources including tests for microbes like shigella, cryptosporidium, and giardia. The best practice would be to test the combined water (of the Za'atari Tank) before it is supplied to consumers. This should be improved. It is essential to identify the quality of different wells and to detect any deterioration in the water quality before it spreads.

More than hundred people from different national institutions (Royal Scientific Society of Jordan, Ministry of Health, Ministry of Water and Irrigation and others) participated in this investigation for over a month. This was the largest and the first recorded water-borne outbreak of cryptosporidiosis in Jordan.

Figure 21.5: Illustration of existing activities around the wells of Za'atari. **Source:** Prepared by the authors.



This example illustrates how small communities experienced groundwater pollution. Despite water shortage there is a huge deficit in the protection of water resources. Although huge efforts are made to treat water and to monitor its quality; protecting the resource would be a better and more feasible option. In many areas water resources are subject to incidental pollution, for example by uncontrolled solid waste dump sites that may pose threats to surface and groundwater quality. Accidental disposal of chemicals may severely disrupt water resources (RSS 2009). Thus, a coherent solution of environmental issues is needed. A better approach is to think and act holistically as part of an integrated environmental resource approach.

21.6 Impacts of Climate Change

Human health and the environment are intimately interrelated. During past decades environmental quality has significantly declined in many geographical regions, increasing both the severity and complexity of numerous human health problems (Foster 1994). In the future environmental quality and human health will be greatly affected by climate change. A great deal of climate change research has focused on the potential and actual health impacts experienced by individuals, communities, regions, and nations (Martens/McMichael 2002; McMichael/Campbell-Lendrum/Corvalan/Ebi/Githeko/Scheraga/Woodward 2003). The health impacts of climate change will be influenced by interactions with other determinants of health, and by the coping and adaptation strategies adopted to reduce the health risks and threats (IPCC 2001c).

A myriad of physical impacts are associated with climate change. The physical impacts of environmental deterioration and climate change range from an increase of asthma due to air pollution, of diarrhoeal illness due to contaminated water, of vector- and rodent-borne diseases due to global warming and an

increased morbidity and death of the elderly due to heat stress. The physical and health impacts will be mediated by the social vulnerability and adaptive capacity of individuals (Erskine 2004).

The preliminary impacts of climate change have already been well documented in many parts of the world, and the remaining most threatening impacts are affecting the fragile economies and ecosystems of developing countries, including Jordan. The combined impact of climate change on the already exhausted water supply in Jordan has barely been studied. First steps were undertaken in Jordan's Second National Communication to the *United Nations Framework Convention on Climate Change* (UNFCC), which was coordinated by the *Ministry of Environment* (MoEnv) relying on the knowledge of about 40 Jordanian experts (Jordan 2009a). Although the document has not been officially endorsed yet, the main findings about the water sector's vulnerability to climate change provide a worrisome perspective.

In Jordan an increase of temperature is projected by no more than two degrees until 2050. In addition, a decline in rainfall has been projected by the models assessed by the *Intergovernmental Panel on Climate Change* (IPCC). The Jordanian study selected the Yarmouk and Zarqa basins for an analysis of the impact of climate change on water resources. The results indicate a significant change in spatial and temporal distribution of precipitation by about 20 per cent. However, the authors indicated that the inconsistency of historical data did not allow them to develop a comprehensive future scenario (Wardam 2009). It was estimated that an increase in temperature by 2 ºC would result in a higher demand for irrigation by 18 per cent, while a 10 per cent reduction in precipitation would increase the water demand for irrigation by about 5 per cent (Jordan 2009a). Considering these combined effects on the water supply, the competition for water is inevitable among the different sectors. Thus, agriculture will rely on low quality water what will eventually result in more challenges for soil and water management, i.e. in more biosafety risks and concerns.

Declining precipitation and resulting shortages will increase the probability of water-borne epidemics, such as cholera, dysentery, giardiasis, and bilharziasis. This may lead to a re-emergence of some diseases that were under control for a long time, such as malaria or the emergence of new diseases in Jordan, such as the West Nile virus fever, dengue fever or Rift Valley fever. Climatic variables have affected the seasonal pattern of respiratory and cardiovascular diseases and their mortality (Jordan 2009a).

In Jordan the actual disease burden that may be attributed to climate change is unknown. Environmental and health datasets are poorly matched and methods for analysing the relationships between them have not been applied locally. But it is very important to link available data to better understand the relationships between climate variables and actual health outcomes (Jordan 2009a). Not surprisingly, the recurrence of the peak of diarrhoea cases coincides with drought years (table 21.1). It is unknown how the projected climate change in the Middle East will impact on health.

21.7 Quest for Drought Tolerance: Risks of Genetically Modified Food

Water shortage is the most significant challenge that will confront the farmers in the Middle East in the coming decades. Drought tolerance is a feature of some crop plants, and for many years farmers and, more recently, plant breeders have taken advantage of these tolerant varieties in traditional breeding. Can biotechnology accelerate the development of urgently needed drought-tolerant crops? Biotechnology and gene technology are tools which may contribute to climate change solutions.

> Breakthroughs in molecular genetic mapping of the plant genome have led to the identification of bio-markers that are closely linked to known resistance genes, such that their isolation is clearly feasible in the future. Two forms of stress resistance especially relevant to climate change are linked to drought and temperature. A number of studies have demonstrated genetic modifications to major crop species (for example, corn and soybeans) that increased their water-deficit tolerance, although this may not extend to the wider range of crop plants. Similarly, there are possibilities for enhanced resistance to pests and diseases, salinity and waterlogging, or for opportunities such as change in flowering times or enhanced responses to elevated CO_2 (IPCC 2007a).

Although altering plants through genetic engineering has allowed for changes that traditional selective breeding could not achieve. However, the risks of introducing genetically engineered plants into the environment have not been fully characterized with regard to the ecosystem and human health. There is a growing concern that introducing foreign genes into food plants may have an unexpected and negative

impact on human health. Scientists warn that the consumption of GM foods in general might result in new allergies, resistance to antibiotics, inability for the body to absorb vitamins or minerals, and other health problems (Whitman 2000; WORC 2004).

In Jordan, the future use of *Genetically Modified Organisms* (GMOs) – their release into the environment, cultivation, importation and particularly, their utilization as food or foodstuff – should be regulated by setting up strict procedures. This is of great importance since the annual costs for imports of food and livestock have increased by 36 per cent from 2001 to 2005. With regard to food supply Jordan is a deficit country. It is expected that by the year 2010, and based on an annual growth rate of 3.3 per cent, the population of Jordan will exceed 7.1 million. Therefore, the number of GMOs ready for commercial release may expand considerably in the next few years. While the GMO applications are increasing in the near future, tools are needed to assess and implement international instruments and standards of governance which ensure health and environmental safety.

According to Jordan's Second National Communication to the UNFCCC (Jordan 2009), the agricultural sector will be most vulnerable to climate change based on studies on the impact on rainfed agriculture.[8] Both livestock and overall food production were identified as most affected due to its impact on rainfed cultivation and on the arid and semi-arid rangelands.

21.8 Discussion and Further Actions

Jordan's national water strategy (2008–2022) excluded the impact of climate change among the most pressing challenges facing its future water resources. However, the effect of climate change on water resources in Jordan is expected to be significant. Higher temperatures and lower precipitation are expected due to climate change. Significant changes in the spatial and temporal distribution of precipitation are projected due to climate change (Abdulla/Al-Omari 2008). Changes in rainfall patterns will further push rain-fed areas towards irrigated agriculture. This may cause many health effects, particularly in communities in or at the edge of deserts where water is scarce, highly polluted or salinated, and in communities where there are competing demands from households, agriculture, and other industrial sectors.

Given the natural water scarcity and the projected decline due to climate change, the dependence on reclaimed water (treated wastewater) for agriculture is growing in order to decrease the pressure on fresh water. Use of reclaimed water can increase crop yields because of supplemental irrigation and nutrients in the wastewater. However, farming communities using treated wastewater and the consumers of crops face an increase in water-borne diseases. Therefore, a proper system requiring health risk management programmes should be implemented. Such a system should cover all stages from the wastewater treatment facility to the reclaimed water transfer system, the use of this water by farmers to the consumer of their products. This system should be prepared not only for tests of major bacteria and chemicals but it should also include viral and protozoa tests. Thus the monitoring of water quality should be connected to disease surveillance and avoidance. Emergency response plans should be prepared and tested. The current system is still insufficient. The present monitoring focuses solely on major bacterial organisms and key chemical pollutants but it does not relate this knowledge to the public health, and the communication with users and farmers is still poor.

A quarter of Jordan's population, primarily living in lower income areas, use less than 50 l/c/d where repeated local outbreaks of water-borne diseases have occurred. Although in the past no proper records linked these cases to water, this does not mean that such cases did not occur. The first recorded outbreak occurred in 2007 that was reviewed above. The case study found that the waste management system is insufficient and should be upgraded to safeguard the water resources. The study showed how geophysical, environmental, and socio-economic data can help to address the problem and respond to it. As a result of this experience the preparedness of the national laboratories has been advanced. Some developed their capacity further to test for parasites, which is a rather delicate test. This gave the national laboratories, such as the ERC, confidence in meeting such challenges in the future. A case of water pollution in 1998 due to a deterioration of water quality from the presence of algae and nematodes in parts of Amman was a major incident that did not cause major health effects. Transparency and an early rapid response was a key factor for the successful management of that outbreak.

8 The investigation was done using a *Decision Support System for Agrotechnology Transfer* (DSSAT) model on two main crops, wheat and barley (Jordan 2009a).

Regarding water quality, the improvement of water supply must remain a top priority due to foreseen stresses on water resources. Jordan has witnessed some deterioration of its water quality during the last two decades due to industrial pollution, overuse of agrochemicals, drainage water, overloading of wastewater treatment plants, over-pumping of aquifers, seepage from landfills and septic tanks, and improper disposal of dangerous chemicals by certain industries. Thus, the water supply treatment system has to be upgraded to include *ultraviolet* (UV) treatment rather than chlorination, as it is commonly practised. The UV treatment will ensure an elimination of organisms resistant to chlorine such as cryptosporidium. The other concern is to ensure the non-existence of viruses. This is also an issue to be included in the water monitoring activities in addition to parasites. An adequate water quality early warning system for Jordan is needed. At present, a system covering 13 stations is operated by the RSS in cooperation with the Higher Council for Science & Technology.[9] The system covers water quality flowing from neighbouring countries (Syria and Israel) in addition to certain points downstream along the King Abdulah Canal as well as the King Talal Reservoir. These major water bodies are of concern as the water there is used for agriculture and some for drinking after treatment. The warning system should be expanded to include all water supply points from wells to surface water or desalinated brackish water.

The above preparations include adaptation measures to climate change referred to in Jordan's second National Communication to the UNFCCC that includes a wider list of measures, in addition to those above that addressed the impacts on agriculture and health. A new programme funded by the Spanish government links five ministries and four UN agencies in implementing a programme on: "Adaptation to Climate Change to Sustain Jordan's Millennium Development Goal Achievements." This programme will focus on the water sector to sustain access to improved water supply despite increased water scarcity due to climate change, and to enhance the adaptive capacity for health protection and food security to climate change under conditions of water scarcity. This programme will be the first integrated effort in Jordan to incorporate climate change adaptation in natural resource management and it is expected to set the standards and norms for future action.

The recent development in biotechnology may provide a significant potential for producing food from drought tolerant seeds and seedlings. However, in order to keep track of any negative effects of this technology, it is necessary to establish a system for monitoring probable side effects in the long-run. It is also vital to regulate the applications and use of *genetically modified products* (GMP). Developing countries like Jordan should establish their standards as to which GMP may enter the market, may be planted, and how they are to be administered. The present national regulations do not yet adequately account for GMP. At present it is unknown how many GMPs enter Jordan. This deserves full attention given the anticipated stresses from droughts and future water stresses (chap. 62 by Oswald Spring).

The challenges from water degradation and the associated human security issues should be addressed on a regional and international level. This case should be based on a fair distribution and allocation of resources reflecting considerations of equity.

22 Water Scarcity and Degradation in Palestine as Challenges, Vulnerabilities, and Risks for Environmental Security

Marwan Haddad

22.1 Introduction

Historic Palestine consists of Israel, the West Bank, and Gaza Strip. Palestine or the *Occupied Palestinian Territory* (OPT) as presented in this paper consists of the West Bank including East Jerusalem and the Gaza Strip. The OPT equals 23 per cent of the land of historic Palestine. The West Bank and the Gaza Strip are those parts of historic Palestine which were occupied by the Israeli army during the 1967 war between Israel and Egypt, Syria, and Jordan. The land area of the West Bank is estimated at 5,572 km^2 extending for about 155 km in length and about 60 km in width. The Gaza Strip, with an area of 367 km^2 extending for approximately 41 kilometres in length and approximately 7 to 9 kilometres in width (figure 22.1; Abdel Salam 1990; Haddad 1998).

Water resources in the OPT are relatively limited due to the country's hydrological, geographical and geological, and demographic conditions and factors. Average annual rainfall over historic Palestine was estimated at 409 mm. The estimated average annual groundwater recharge in Palestine is 698 to 708 mcm/yr (648 mcm/yr in the West Bank and 50–60 mcm/yr in the Gaza Strip). The only surface water source in the West Bank is the Jordan River and its tributaries. In the Johnston plan, the Palestinian share in the Jordan River of 257 mcm/yr was considered as part of the Jordanian share of 774 mcm/yr as the West Bank was then under Jordanian rule. Since 1967 and until the present, Palestinians were prohibited by the Israeli army from using the Jordan River water, and their lands and farms located along the western side of the river were confiscated and the area declared as a restricted security zone (Haddad 1993).

The *Millennium Project* (ACUNU 2007) defines environmental security as environmental viability for life support, with three sub-elements: preventing or repairing military damage to the environment, preventing or responding to environmentally caused conflicts, and protecting the environment due to its inherent moral value.

Environmental safety and/or security caused either by natural or man-made purposeful water-related risks, is an essential component of the quality of life (livelihoods and health). Man-made purposeful risks are generally subject to and influenced by government/authority regulation/control. In the case of the OPT this authority is the Israeli military (fully controlling 97 per cent of the land and its resources, and partially the rest) with a few exceptions here and there where the Palestinian authority takes responsibility.

Israeli Military Order No. 2 of 7 June 1967 stated that all water resources in the newly OPT were to be state-owned by Israel. Three subsequent Military Orders in 1967 and 1968 granted full control to the military authority designated: an officer to be appointed by the Israeli military commander for implementation of the orders, the establishment of a permit system for the drilling of new wells, fixed pumping quotas, and the declaration of all prior settlements of water disputes to be invalid. The Israeli water companies, Mekorot and Tahal, were given an important role in planning, implementing, and operating water projects in the territories under occupation. With few exceptions, Palestinian institutions were only responsible for the delivery of water and the disposal of sewage (UNEP 2003).

Current forced water shortage can be reflected in Palestine's total per capita water use of 82 m^3/person/yr, which is among the lowest in the world. In comparison, the Israeli water use is about 350 m^3/person/yr. If Palestinians would acquire their water rights in 2010, the available water would be about 275 m^3/person/yr, what is the lowest in the southern Mediterranean region (WWF 2003), and still very low compared to regional and world figures (Tropp/Jägerskog 2006).

On 26 April 1995, the *Palestinian Water Authority* (PWA) was established. The PWA is the official body

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_22, © Springer-Verlag Berlin Heidelberg 2011

Figure 22.1: General location Map. **Source**: Amnesty International 2009.

that regulates and is responsible for overall water resources in the West Bank and Gaza Strip. Unfortunately, the PWA and according to Oslo II agreement (Oslo II 1995) cannot implement any single developmental act related to Palestinian water resources before getting the permission of the Israeli military

authorities through the so-called *Joint Water Committee* (JWC).

The 1995 Oslo II interim agreement has physically fragmented the West Bank into three areas: A (3 per cent of the total area of the West Bank), B (24 per cent), and C (73 per cent), with different security and administrative arrangements and authorities. The physical fragmentation of the land under Palestinian control and the stringent closure policies on the movement of goods and people in the OPT by Israel have negatively impacted the lives and national development of the Palestinian population (UNEP 2003).

For example, it was estimated that 46 per cent of the Palestinian population are either vulnerable to food insecurity (12 per cent) or totally insecure (34 per cent; see WFP/FAO 2007). Another example, there is a noticeable urbanization of the Palestinian population: the percentage of rural population in the West Bank was 54 per cent in 1995 and 31 per cent in 2007 (PCBS 2008).

Isaac and Ghanyem (2001) attribute the depletion of water resources, continued desertification, deforestation and the uprooting of trees, and general pollution within the West Bank as a direct outcome of Israeli government policies aimed at ensuring physical security over the land.

Due to the specificity of the OPT, water scarcity and degradation as challenges for environmental security are not self-limiting factors but an integral part of the overall Palestinian societal development. Therefore, the discussion in this chapter cannot solely be based on natural, technical, and technological causes of environmental insecurity, but must also include political, legal, human, and socio-economic security aspects and threats.

The main objective of this chapter is twofold: (1) to identify the environmental threats associated with water scarcity and degradation in the OPT, and (2) to test the hypothesis of whether these threats cause loss, harm, and damage to the Palestinian people and their environment leading to environmental insecurity.

22.2 Background

22.2.1 Historic Backdrop

At the end of the 19th century, historic Palestine was almost 100 per cent inhibited by Palestinian Arabs and there were no Jewish immigrants in Palestine (Haddad 2007). In 1873, the Royal Scientific Society of Great Britain sent a delegation to Palestine to investigate two issues; the first was the available water resources and the second was the possibility of settling Jews in the southern part of Palestine- (known as Al-Naqab in Arabic or Negev in Hebrew). The delegation reported that water could be brought to Al-Naqab from the northern parts of Palestine and Jews could be settled there (Haddad 2007).

After WWI (1917), historic Palestine was put under British mandate. Between 1875 and 1948 successful attempts were made by both the Jewish organizations in Europe and later the British mandate forces to increase Jewish immigration to historic Palestine, and in parallel to increase the Jewish physical control of the Palestinian land and water resources (Schmida 1984; Dillman 1989; Ali 1964)· During their mandate over historic Palestine, the British authorities granted concessions to immigrated Jewish groups to exploit some of the Palestinian water resources (Schmida 1984; Dillman 1989).

From 1948 until the present, many water plans and projects evolved and were presented including the Oslo II agreement (Dillman 1989; Ali 1964; Oslo II 1995). However, none of these plans and/or agreements has managed to settle the water dispute between Palestinians and Israelis. Thus, Palestinian water resources have remained under the full control of the Israeli military authorities as the occupying power.

22.2.2 Palestinian Population and Urbanization

Palestinian population census in the OPT reveals that the population in 2007 totalled 3.771 million persons, 2.345 million in the West Bank and 1.417 millions in the Gaza Strip. It was reported that 40.1 per cent of the Palestinian population is less than 14 years of age, indicating a young society with high developmental needs.

There are 686 localities in the OPT (PCBS 2008). The localities are distributed by type as 54 urban, 603 rural, and 29 refugee camps. These localities are distributed by type of authority as 107 municipalities (89 in the West Bank), 11 local councils, 374 village councils or project committees, and 29 directors of refugee camps (additional 76 rural localities are either not inhabited or joined to a larger locality).

In 2005, the distribution of land use in the OPT was 25.5 per cent agricultural land, 1.6 per cent forests and wooded land, 10.0 per cent build-up areas, 3.2 per cent Jewish colonies, and 62.9 per cent bare land

and other uses (PCBS 2008). The built-up area was distributed by urban, rural and camps, 63.7 per cent, 5.1 per cent and 31.2 per cent respectively. The trend for 2000–2005 shows that the annual increase in the built-up area in the Gaza Strip was 19.1 per cent (ARIJ 2006).

22.2.3 The Palestinian Water System

According to PCBS (2008), the total water supply for domestic purposes in the OPT was 160 mcm/yr distributed by means of supply as follows: 86.7 per cent piped networks, 3.4 per cent tankers, 6.7 per cent rain water harvesting, and 3.2 per cent by other means. This domestic water was 68.5 per cent through municipal wells, 0.9 per cent agricultural wells, 3.2 per cent through springs, and 27.4 per cent through Israeli water companies. The average rate of *unaccounted for water* (UFW) in urban areas was estimated at 42 per cent of total water supply (it varies between 25 and 55 per cent), therefore, the average consumed per capita domestic water consumption in these areas was 36.5 l/d (or as surveyed, 55 l/d as average consumed since not all UFW is lost in the ground).

The PWA (2003) also estimated that 256 rural communities in the West Bank with a population of more than 200,000 are still without access to the public water supply. The people in these communities depend on local springs and harvesting cisterns to get water for all purposes, and the water used is usually not suitable for drinking.

Water infrastructure (the system of water wells, springs, reservoirs, networks, pumping stations, etc.) in the OPT is characterized by the existence of disjointed remote sites and locations. As such, in addition to the problems associated with the job and the related administrative and legal control problems, there is no integrated water system, neither physically or on paper. As a result, it will take considerable time and money to convert the complex set of sources into a reliable and integrated national water system.

Existing water institutions in the OPT do not have the technical, technological, managerial, or financial ability for either planning or developing of resources and services, or operating and maintaining them (Haddad 2005a). Accordingly, these water institutions have high overhead costs and an inability for cost recovery.

22.2.4 Palestinian Agriculture

Agriculture has historically been a very important sector of Palestine's economy. About 63 per cent of the water allowed to Palestinians or 52 m^3/person/yr is used in agriculture. Although more labour force was employed in agriculture (15.6 per cent of total labour force employed in 2007 compared to 13 per cent in 1996). The share of Palestinian agriculture of the GDP dropped from 9 to 8.4 per cent and consequently was no shelter for the suffering Palestinian economy (PCBS 2008).

Approximately 2,180,000 durums (35 per cent of the total area of the West Bank and Gaza Strip) are considered as natural grazing areas. The eastern slopes region of the West Bank makes up most of the OPT rangeland. It represents about 1,500,000 durums or 69 per cent of the range area. Of the total grazing area only 700,000 durums are accessible to Palestinian livestock owners, while the remaining 1,480,000 are currently not accessible as a result of land confiscation for Israeli colonies, nature reserves, or closed military areas. This led to overgrazing and progressive desertification in these areas (Isaac/Ghanayem 2001).

It was estimated that 23 per cent of the forest area has been destroyed from 1971 to 1999. The majority of this destruction has been caused by the construction of Israeli colonies and military camps. Rangeland and natural grassland are also negatively affected in the last three decades due to the political situation. The limitation of the access to Palestinian herds resulted in intensive grazing to the remaining small area that is estimated to be about 15 per cent of the former area (Dudeen 2008).

22.3 Water-related Environmental Threats in the OPT

22.3.1 Natural Threats

22.3.1.1 Climate Change

Although the causes of climate change are rooted in human activities, its impacts are global and pose multiple natural hazards or risks. Multiple scenarios are projected for the 2050's, declines in annual precipitation in North Africa and in West Asia by 20 to 25 per cent. This decrease in rainfall is projected to be accompanied by a temperature rise between 2 °C and 2.75 °C, while nearer the coast the rise may be lower (around 1.5 °C). In winter (October to March), rainfall is projected to drop by about 10 to 15 per cent but

would increase over the Sahara by about 25 per cent. In the coastal areas of the Mediterranean temperatures are projected to increase but by only 1.5 °C on average while it will rise in the hinterland by 1.75 °C to 2.5 °C (Ragab/Prudhomme 2002).

Thus, it is expected that the recharge of water resources in the OPT will gradually decline due to climate change leading to an aggravation of existing water scarcity and degradation and to higher vulnerability which may contribute to a further destabilization and conflict, especially when it is combined for the Palestinians with a lack of access to their national water resources.

22.3.1.2 Droughts

An analysis of the historical rain data of Jerusalem and Nablus for the past 162 years (since 1846) reveals that an average annual precipitation of 400 mm or below occurred for 25 times or on average once every seven years (Central Water Authority 1967; PCBS 2008). With the present increase in population in the OPT and in Israel, and the increase in demand for fresh water either for domestic or agricultural sectors, the long-term availability and sustainability of water supply and food security will drop. The synergistic effect of climate change and drought will aggravate the situation and negatively affect existing size and ecosystem of the drylands.

22.3.2 Man-Made Purposeful Causes

22.3.2.1 Access and Mobility to Water Resources

Since the start of the Israeli military occupation of the OPT in 1967, Palestinians were prohibited to freely access and develop their own water resources. Furthermore, since Israel has controlled the West Bank, its authorities have prohibited with Military Order No. 92 the publication of water testing or research. Thus, the full testing of water sources was difficult for Palestinian planners (Lonergan/Brooks 1994). Palestinian researchers were also limited where they were allowed to travel to conduct such tests (ARIJ 1996).

The other major standing body of water of concern in the region is the Dead Sea that is linked to the Sea of Galilee by the Jordan River. While this is not a source of drinking water, it is a major tourist and industrial spot, as well as an important environmental ecosystem. At 411 metres below sea level, the Dead Sea is already the lowest point on the surface of the Earth. The problem is that its water level is dropping by approximately 1 metre annually, leading to the loss of one third of the sea's original surface area (FOEME 1999). This decline is expected to continue, so that the surface level reaches 430 metres below sea level by 2020. The decline in precipitation results in a drop of water inflow by 10 per cent of the original volume. This trend is expected to worsen with annual inflows expected to decline from 375 mcm/yr to 135 mcm/yr in the near future (FOEME 1999).

Israel decided to establish a permanent barrier between the West Bank and Israel in April 2002. The construction of the wall subjected Palestinians to several water vulnerabilities, including irrigation infrastructure devastation, impeded access and mobility to water resources and irrigation land, increased land aridity, and detrimental effects on community socioeconomic and migration (Haddad 2005b; Twite 2008).

Agriculture will probably be most negatively affected by the construction of the separation wall. Palestinian villagers are especially sensitive to these impacts and consequences as they heavily rely on farming. More than 100,000 trees have been uprooted. More than 36,000 metres of irrigation networks have been destroyed. Delays associated with travel through the limited gates of the wall have undermined the daily routines, productivity, and efficiency of Palestinian farmers, delaying and altering their agricultural operations. During the first construction phase of the wall, about 42 per cent of the West Bank's agricultural sector was affected. The land that was blocked contains 80 per cent of the operating water wells in the West Bank and provides 53 per cent of its water-sector employment. Currently, a minimum of 50 productive water wells and 15 villages are being trapped in the buffer zone and west of the wall (Haddad 2005b).

22.3.2.2 Colonization of Land and Resources

In 2004, the *International Court of Justice* (ICJ 2004) ruled that "Israeli settlements in the Occupied Palestinian Territory, including East Jerusalem, are illegal and an obstacle to peace and to economic and social development [... and] have been established in breach of international law."

While the second largest refugee population in Asia consisted of more than 2 million Palestinian refugees under the protection of the *United Nations Relief and Works Agency* (UNRWA), the Israeli integration of large numbers of Soviet and other Jews conflicted with the interests of the Palestinian population in the OPT with regard to land and natural resources (UN 1993). In 1970, the Israeli settler popu-

lation living in the OPT amounted to 1,514 persons. It rose to 12,424 in 1980, and ten years later it was 76,000. It nearly doubled over the next five years to reach 146,207 people, and in 2000 it reached 203,067 persons (UNEP 2003). Palestinian sources estimate that there are between 145 and 198 colonies in the West Bank with about 390,000 Jews living in, occupying, and controlling about 42 per cent of the land area of the West Bank (The Palestine Monitor 2007).

To secure the Israeli-Jewish colonies in the West Bank, Israel built a large network of by-pass roads, as well as a water and energy infrastructure. It was reported that Jewish settlers in the West Bank use much higher per capita water than the Israeli population proper. This lead to an increase in the physical fragmentation of the West Bank and made Palestinian development more difficult, since not only the land taken for the colonies but also much of the land between the roads (each road enjoys a buffer zone of 50–100 m on either side) has become dangerous to reach and to develop for agricultural or any other purpose.

The Israeli practice in the OPT of giving the Israeli army and the defence establishment the major role in deciding on the zoning and development of the land use had major impacts on the local environment in the OPT. An example is the continuous approval and direct assistance of the Israeli military authorities for the Israeli-Jewish colonies in the West Bank to develop Palestinian water resources for their full supply, while Palestinian communities are forced by the same military to use a minimum water quota.

The Israeli-Jewish colonization of the West Bank has resulted in the Israeli army increasing in Palestinian land acquisition, water resources development and withdrawal for colonies water supply, and further limitations of movement and access to their natural resources for Palestinians.

22.3.2.3 Water Pollution from Israeli Military Activities

Because of the unique geographic and political situation of the OPT, significant Israeli military forces were concentrated here for more than four decades, occupying a significant land area. So far, the environmental hazards encountered with or from Israeli military activities and the prolonged use and control of the OPT are unidentified and/or not measured. Israeli military operations and/or production and/or testing of various weapons and ammunitions in the OPT are most often secret. Munitions, for example, contain harmful and environmentally dangerous chemicals such as explosives which when released into the environment may have serious negative effects and cause contamination of soil, water, and air. In addition, the Israeli military hazardous wastes in the OPT must be basically and essentially approached, surveyed, and made definable. This matter poses a special environmental threat in many areas of the OPT where the Israeli army and Israeli colonies have military camps, munitions storage and buried facilities, and possibly industrial plants (Twite 2009).

There has been concern that depleted uranium has been used by the Israeli military against Palestinian targets (EQA 2002; Dajani 2009).

22.3.2.4 Overexploitation of Water

Despite the Israeli military control there is presently an overexploitation of water resources in Israeli as well as in the OPT areas. The water exploitation index taken as a percentage of renewable annual water resources is: 83 per cent for Tunisia, 92 per cent for Egypt, 140 per cent for Israel, 169 per cent for Gaza, 644 per cent for Libya, 50 per cent for Syria, 25 per cent for Lebanon, 20 per cent for Algeria and 40 per cent for Morocco (Acreman 2000; Pearce 1996).

A field survey of this author found that annual discharges of most springs in the West Bank were declining and some springs, such as the Al-Faraa spring (14 km north-eastern of Nablus), were totally dry in early summer. This condition affects the livelihood of many Palestinian communities and farmers. This is mainly due to the Israeli water abstraction by using deep water wells.

While Palestinians in the West Bank have limited and controlled access to their national water resources and use only 10 per cent of the annual recharge capacity of the water system (Aleiwi/Assaf 2007), it is estimated that Gaza's aquifer pumping was estimated at one point to be withdrawing 110 mcm/yr (Davis/Abumojhli/Castaldi/Hamady/Hodgkin 1996). It was also reported that a water deficit of approximately 68–90 mcm/yr and of 70 per cent of the aquifer's water in the Gaza Strip is brackish to saline water due to the over-abstraction (Nettnin 2005). The excessive use of water resources in the OPT and their degradation will damage the natural system of the Gaza aquifers, and thus threatens the present and future livelihood and health of the Palestinians living there.

22.3.2.5 Intermittent Water Supply and Unequal Water Allocation

All Palestinian communities in the OPT receive an intermittent water supply amounting to a few hours, two or three times a week. Accordingly Palestinian people install water tanks on the roofs of their houses and/or buildings to collect the maximum water volume during the limited pumping hours and manage their water use from what they get until they receive the next water pumping. This practice neither exists in Israel nor in the Jewish colonies of the West Bank.

Current estimates of total water use show that Israel is using 344 m^3/yr per person, while Palestinians in the West Bank and the Gaza Strip use approximately 93 m^3/yr per person. Per capita quantities for domestic use are estimated at approximately 40 m^3/yr for Israelis and 35 m^3/yr for Palestinians (Postel 1997).

If the present Palestinian population living in the OPT use the WHO average domestic water consumption standard of 150 liter per person per day, they would need 206 mcm/yr of fresh water, comparing this average consumption with the existing forced demand for Palestinians of 132 mcm/yr. This implies a deficit of 74 mcm/yr. If equity and equality maintained only in domestic water consumption among humans living within the same hydrological cycle, i.e. between Israelis and Palestinians, this deficit would rise to 397 mcm/yr.

In summary, the Palestinians are using much less water than required for domestic purposes according to WHO standards, and this is affecting their socio-economic situation and livelihood. It is not possible for Palestinians to develop or plan any water project, neither in the past nor at present, due to military occupation and control of land and water resources, territorialism and ownership disputes; uncertainty about key facts; political evolution; an ongoing shift in ethos; and a certain apathy, or at least a tendency towards inaction, without a crisis which would otherwise motivate.

22.3.2.6 Economic Growth

Where water is scarce, competition for limited supplies can lead nations to interpret access to water as a matter of national security (Gleick 1998). National security concerns include not only socio-economic issues of water allocation, but central political, legal, and territorial claims as well. The negotiations over water between Palestinians and Israelis did not conclude with the signing of an interim agreement and were postponed to the final status agreement. As a result, Israeli military authorities continue their full control of Palestinian water resources in the West Bank, with minor exceptions, since June 1967 until the present time. This means that water policies in the West Bank regarding quantity and quality are in the hands of the Israeli military authorities and not of the Palestinians.

Since the onset of the Israeli occupation in 1967, the economy of the OPT has been an 'income economy' rather than a 'production economy' – making the OPT extremely vulnerable to the Israeli market of labour and goods. With the beginning of the current Intifada in late September 2000, economic conditions have deteriorated in the OPT (FAO/WFP 2004). Access to food remains the most significant food security concern with food price increases resulting in drastic reductions of livelihoods (WFP/FAO 2007).

Since 2000, a progressive fragmentation of established patterns of economic activity among districts and urban and rural communities has occurred in the West Bank, involving a breakdown of relations with Israel. The Israeli army imposed military curfews on Palestinian communities, thus paralyzing all aspects of life. For example, during the last half of 2002, the imposed military curfews in the West Bank applied to 70 per cent of the time, affecting approximately 75 per cent of domestic production, what seriously disrupted the movement of goods into and from the West Bank (UNSCO 2005; UNEP 2003).

According to the PCBS (2008) the per capita GDP in the OPT was US$1,129, what reflects a sharp decline in economic growth and high poverty levels in the OPT. In its report '*The Economic Effects of Restricted Access to Land in the West Bank*', the World Bank (2008) states that the Israeli administration caused a 40 per cent decline of the gross domestic product per capita in the West Bank from 1999 to 2008. The UN *Office for the Coordination of Humanitarian Affairs* (OCHA) shows that Palestinians do not have access to 38 per cent of the West Bank, resulting in drained resources and limited development in the illegally occupied territory.

The Israeli restrictions imposed on Palestinians including movement, import and export, entering of raw materials needed for production, the limitation of funding and fund movement, has lead to suppressed and negative economic growth in Palestine. Negative economic growth in Palestine has lead to a high level of migration especially among young people. The Israeli practice in the OPT of giving the Israeli army and the defence establishment the major role in

deciding on who should invest when and where have major impacts on the local environment in the OPT.

A decline in water supply and consumption always accompanies limited economic growth and development. Limited economic growth leads to declining taxes what freezes government plans for development. Insufficient water supply and inadequate wastewater treatment and reuse capacity along with negative economic growth in the OPT are three critical factors that have negatively affected and threatened the Palestinian environment. The high adaptive capacity of the Palestinians in their national resistance to Israeli occupation is the reason that the situation has not become catastrophic.

22.3.2.7 Palestinian Population Growth, Returnees, and Water Demands

The estimated population of Palestinians all over the world reached 9.7 millions, by mid-2004 of which 4.9 millions are in the Diaspora and the rest are in historic Palestine including Israel, and the OPT (UNRWA 2005).

Future Palestinian population growth in the OPT is uncertain, since the establishment of a Palestinian state could encourage an influx of Palestinian emigrants. Some sources estimated that as many as 1 million refugees may be returning (Lonergan/Brooks 1994). The Palestinian Water Authority is officially planning for 500,000 refugees, which would increase water demand enormously. Moreover, since the goal of many planners is for an equal domestic per capita consumption of water for both Israelis and Palestinians of around 100 m^3/yr, the demands by Palestinians for water will increase enormously, since current domestic per capita use is 35 m^3/yr (Assaf/Bargouti 1999).

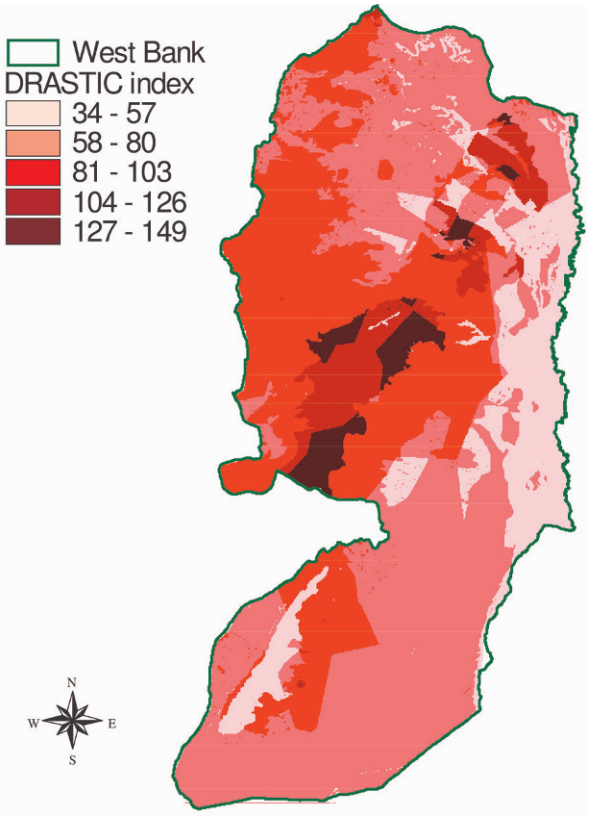
22.3.2.8 Water Quality Deterioration

At present, Israel treats its drinking water to standards which it believes are safe, yet which allow mineral concentrations higher than those considered safe in the United States or Europe (Tenne 1995). Palestinians meanwhile are struggling to maintain drinking water standards anywhere close to that of Israelis, being hampered by insufficient funds and infrastructure (Assaf/Barghothi 1999).

It was indicated that 14.9 per cent of the water supply problems in the OPT were directly associated with water contamination (PCBS 2008). About 15 per cent of the water samples taken from springs in the West Bank have nitrate concentration between 55 and 320 mg/l exceeding the WHO water quality standards (WHO 1993). Most of the springs surveyed have very high hardness levels – over 700 mg/l as $CaCO^3$ (Scarpa/Abed Rabbo/Zeitoun 2004)

A preliminary groundwater vulnerability map for the West Bank has been produced (Qamhieh 2006; Zayed/Abadi/Rajoub/Moe 2008; figure 22.2). Results indicated that most Palestinian drinking water sources can be considered as highly vulnerable to pollution. Documented and suspected sources of pollution relate to both Palestinian communities (mainly due to anthropogenic sources of pollution) and Israeli settlement activities (due to both anthropogenic and industrial sources of pollution).

Figure 22.2: The map of the groundwater vulnerability to contamination for the West Bank. **Source:** Qamhieh (2006).



Currently most pesticides on the West Bank come from Israel where there is no requirement for bilingual Hebrew or Arabic as well as English or Arabic labelling. Thus farmers often misuse pesticides with risks to their crops, groundwater, and personal health (Lonergan/Brooks 1994). In the OPT, the indiscriminate application of 1,471 tons of 123 different pesticides includes in the West Bank the use of seven of

the internationally banned 'dirty dozen' pesticides, such as DDT, that do most environmental damage (Isaac/Gasteyer 1995).

There are very few estimates of the amounts of hazardous waste generated in the OPT. In the West Bank, the amount has been estimated at 2,500 tons per year (EQA 2002). This amount refers to waste that has been explicitly identified as hazardous. The true amount is likely to be much higher, but is not apparent since there is no separation (and collection) or inventory.

Due to high rates of UFW, poor operation and maintenance of water system, and poor water infrastructures, illegal practices on the part of consumers, it is expected that public health will be negatively affected. A massive public health hazard did not happen yet, however, many individual water-related health infections were reported in the West Bank and the Gaza Strip (Haddad 1998).

The main quality problem in the Gaza Strip is the increase in salinity and nitrate concentrations. It was reported that the Gaza aquifer has nitrate levels over 100 mg/l and chloride levels averaging 1000 mg/l (Nettnin 2005). The PWA reported that total dissolved solids were greater than 1500 mg/l in the western area of Khan Yunis and in the south-eastern part of Rafah Governorates (PWA 2003). This deterioration could be attributed to water over-pumping, poor management of waste disposal, and the excessive use of fertilizers and pesticides, in addition to possible sea and salt water intrusion.

Water quality of the lower Jordan River is deteriorating as Israel diverts the saline water from springs around Lake Tiberias in addition to the dumping of polluted and industrial wastewater in the river (El-Musa 1996).

In summary, the livelihood and public health of the Palestinian population in the Gaza Strip are already experiencing a great damage due to a degradation of water supply quality, while there is also a potential for water quality deterioration in the West Bank.

22.3.2.9 Decline in the Social Value of Water

Water is needed for humans to convey all aspects of life. Water supply in the OPT is intermittent, meaning that there is no continuous pumping and most households receive water from municipal water services twice a week for a few hours only. Accordingly, each household maintains a roof water tank to collect the water when it is supplied and use it later within the limits of supply. Because supply is insufficient, Palestinian women while water pumping from the source try to finish as much household activities as possible. The water quota enforced on Palestinians caused a change in social behaviour.

22.3.2.10 Ecosystem Services

The intentional neglect of the preservation of the historical land terraces along the mountains of the West Bank is a clear example of negative ecosystem services in the OPT, leading to soil erosion and a decrease in water percolation to groundwater, in addition to its effect on the green land cover and its biodiversity. Another example is the wastewater management practices in the OPT which consist of mostly collecting wastewater from urban centres and then letting raw wastewater flow untreated into the wadis. A third example is the lack of access and mobility of the Palestinian population to their land and more specifically to government owned land, where still no political agreement is reached to allow the Palestinian Authority to plan and plant in drylands. This situation caused a decrease in green cover and soil moisture, and consequently an increased evaporation of rainwater and increased soil erosion. The reduced vegetation cover and the break of the soil crust lead to water and wind erosion of the topsoil, and with it an irreversible loss of productivity resulting in desertification. The loss of vegetation cover reduces aquifer recharge and increases the losses of floodwater (National Academy of Science 1999).

22.3.2.11 Food Supplies

The FAO and the WFP (2004) found that the OPT is not self-sufficient in food and relies on commercial imports to supply domestic demand. It was also found that with rising poverty and unemployment, the food security situation has considerably deteriorated between 2005 and 2008, with four out of ten Palestinians now being food insecure. Food insecurity is a reality for 1.4 million people (40 per cent of the population) and a near constant worry for an additional 1.1 million people (30 per cent) who are under threat of becoming food insecure should current conditions persist. People's physical access to food and farmers' physical access to the inputs and assets to produce food have been severely affected by restrictions on the movement of people and goods and the damage to personal property. Many areas in the OPT with an agricultural potential are affected by stringent closures (e.g., Qalqilya, Tulkarm, the Jordan Valley) and their isolation from urban markets (e.g. Nablus). Recently,

food aid in the OPT has become even more prominent as a major source of food supply (WFP/FAO 2007).

22.3.2.12 Wastewater Management

Sewage collection networks serve approximately 66.8 per cent of the population of the OPT, while the rest is being served either by septic tanks, cesspits or drypits (PCBS 2008). There are eight treatment plants in the OPT, five in the West Bank in the cities of Ramallah, Jenin, and Tulkarm, Al-Bireh, and Salfit, and in the Gaza Strip in Beit Lahia-Jabalia, Gaza, and Rafah. There is no real monitoring of wastewater disposal and/or reuse and therefore, it is possible that some water quality deterioration be attributed to wastewater disposal especially in the Gaza Strip.

Palestinians have recently begun to reuse wastewater as an additional water source. The total quantity of wastewater from domestic and industrial uses in the OPT is estimated to be roughly 40 mcm/year (WRAP, 1994). In the West Bank, most of this wastewater is used for irrigation without any kind of treatment. In the Gaza City area, sewage from non-functioning treatment plants is discharged onto neighbouring land.

22.4 Perceptions of Vulnerability and Risk

Water vulnerability is not a measurable property; it is a probability (i.e. 'the tendency or likelihood') of environmental damage or harm either at present or in the future. In this sense, a vulnerability assessment of scarce water resources is a predictive statement and accordingly a simple matrix of water-related threats against the impacts or responses expected from these threats was formed (see table 22.1). Based on the available data and author experience; impacts were given a scale from 1 (very low) to 5 (very high). Then the sum of scales for each threat and each impact was estimated.

As listed in table 22.1; the highest sums for the water-related environmental threats revealed that the following five environmental threats – listed in order – have the highest sum of impact weights:

- Controlled access and mobility to Palestinian water resources;
- Colonialization of Palestinian land and water resources by Israeli Jews;
- Decline in Palestinian economic growth;
- Water resources overexploitation, and
- Drought occurrence.

The highest sums for the impacts or responses connected with the water-related environmental threats revealed that the following five environmental impacts – listed in order – have the highest sum of impacts weights (see table 22.1):

- People's livelihood decline;
- Political conflict aggravation;
- Decline of available water resources;
- Declining economic development;
- Refusal of an equitable water allocation.

The least important impacts of water-related environmental threats with minimum weights of scale were exposure to radiation, people's immigration, employment decline, soil erosion, and unknown environmental hazards.

Human security or human well-being is an essential part of environmental security, as human beings are a precious element of the environment. With the decline in the livelihood of the people, the environmental insecurity in the OPT has reached a critical point.

22.5 Concluding Remarks

Palestine or the OPT need not be water self-sufficient; nor food self-sufficient. It is fully realized that there are limits to natural resources, and to our human activities. Regardless of the water deficit numbers, the water scarcity problem in the area is a long-term complex that needs continuous serious attention. For the Palestinians in the OPT, water scarcity and its impacts on environmental security cannot be disconnected from the overall abnormal status of the territories. Palestinians are subject to natural as well as man-made purposeful water scarcity, and the above water-related threats and their impacts are significant constraints on the ability of the Palestinian people to plan any aspect of their lives either for the present or for the future.

An assessment of impacts and of responses clearly indicates that the water-related threats in the OPT are causing loss, harm, and damage to Palestinian people and their environment, and consequently Palestinians and the OPT are experiencing environmental insecurity. If these threats continue and/or are aggravated, this environmental insecurity might lead to catastrophic consequences.

To overcome and/or minimize the environmental threats facing Palestinians and their scarce water re-

Table 22.1: Matrix of water-related threats and their impacts.

Water-related Environmental Threats	Impact/Response																		
	People relocation	People immigration	Public health problems	Urban congestion	Contaminated land/soil	Contaminated water	Exposure to radiation	Land use planning deficiency	Employment decline	Desertification increase	Land acquisition increase	Equitable water allocation Refusal	Water availability decrease	Political conflict increase	Agricultural production decrease	Ecosystem/biodiversity damage	Unknown environmental hazards	Peopleislivelihood decline	Soil erosion/green cover decrease	Economic development decline

Colonization of land and resources	4	1	2	4	4	4	1	3	1	3	4	4	4	4	4	3	4	4	3	4
Water quality deterioration	1	1	4	1	4	4	1	1	1	1	1	3	3	3	3	3	1	4	1	3
Ecosystem services decline	1	1	1	1	1	1	1	1	1	3	1	1	1	1	1	1	1	2	1	1
Poor wastewater management	1	1	3	1	4	4	1	3	1	1	1	1	1	2	1	2	3	3	1	1

Note: 5 = very high, 4 = high, 3 = medium; 2 = low, 1 = very low.

sources, and in addition to the main factor which is the ending of the military occupation of the Palestinian land and resources including water, there is a need for several immediate interventions including a) local increase of water availability, b) safeguarding the quality of the environment, c) awareness and guidance of public behaviour to limit over-pumping, and d) enhancement of economic growth.

Resolving water scarcity problems and minimizing their impacts on environmental security requires from riparian sides that they start reaching and strengthening the implementation of agreements including water allocation and basin water management. Cooperation among riparian and other regional parties on jointly working on regional water availability options could follow or become the second step.

23 Social, Environmental and Security Impacts of Climate Change on the Eastern Mediterranean

Hilmi S. Salem

23.1 Introduction[1]

This chapter discusses climate change impacts for the Eastern Mediterranean, with a particular emphasis on the *Occupied Palestinian Territories* (OPT) that comprise the West Bank, including East Jerusalem, and the Gaza Strip. According to the *Intergovernmental Panel on Climate Change* (IPCC 2007a: 13), the average global temperature is projected to rise until 2100 by a range of 1.1–6.4°C, and the sea level has been projected to rise between 18 and 58 cm.[2] Data on the projected climate change at the regional scale are lacking (IPCC 1990, 1996a, 1998, 2001a, 2007a, 2007b, 2007c, 2007d).

Climate change will have many negative impacts for the Eastern Mediterranean region and the OPT that include increases in temperature and sea-level rise (SLR), of hydro-meteorological hazards (heatwaves, droughts, storms, floods, spread of diseases, etc.), changes in precipitation and evaporation rates, water scarcity, and desertification. These complement other environmental challenges, such as increased salinity of soils and of surface-water and groundwater, depletion of stratospheric ozone, and loss of biodiversity. All these physical impacts may result in declining crop yields and failure (leading to food insecurity), and to societal effects, such as 'environmentally-induced migration'.

The projected SLR poses a threat to the Eastern Mediterranean cities with a high population density and concentration of economic activity along the coast. A typical example is the Gaza Strip, which is particularly vulnerable to these effects, as it lacks the resources to prepare for potential hazards. The climate change impacts will and should lead people to take new measures, actions, and strategies that aim to engage them in combating climate change, by changing their mindset and utilizing the situation to catalyse actions for long-term improvements.

This chapter discusses potential climate change impacts for the OPT by specifying environmental, technical, economic, social, political, geopolitical, and security consequences, besides adaptation policies, on the local and regional context, for a SLR between 23 cm and 200 cm (0.23–2 m) until the year 2100. These seven issues are:

1. Possible ecological effects of the *Israeli Segregation Wall* (ISW) on the local climate;
2. Impacts of sea-level rise (SLR) on the Gaza Strip;
3. Climate change impacts on water scarcity and transboundary aquifer systems;
4. Climate-change coping strategies for the *Jordan River Basin* (JRB), and water conflict;
5. *Red Sea-Dead Sea Conveyance* (RSDSC) project and its possible impacts on regional climate;
6. Deforestation, desertification, and land degradation as causes of and effects on climate change;
7. Mitigating climate change impacts with renewable energy.

Global climate change is to a large extent due to human activity, resulting from the burning of fossil fuels and land-use changes, such as deforestation that reduces the amount of CO_2 being absorbed (Brauch/Spring/Grin/Mesjasz/Kameri-Mbote/Behera/Chourou/Krummenacher 2009). On possible political and societal effects of global climate change, three main scenarios were developed by US experts. The *German*

1 The Author wishes to extend his sincere thanks to his colleagues at the *Geographic Information Systems* (GIS) and Remote Sensing Unit of the *Applied Research Institute – Jerusalem* (ARIJ), Palestine, for their help in providing the maps for this chapter.

2 Rahmstorf (2007) assumed even much higher increases in the SLR – up to 140 cm (1.4 m). The IPCC Chairman R.K. Pachauri (2008) referred to potential SLR, for assumed stabilization levels of greenhouse gases (GHG) in the atmosphere between 445 and 710 ppm, of between 40 cm and 240 cm (0.4–2.4 m) (table 23.5 below).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_23, © Springer-Verlag Berlin Heidelberg 2011

Advisory Council on Climate Change (WBGU 2008, 2008a, 2008b) distinguished four conflict constellations due to climate-change induced effects.

23.1.1 Three Policy Scenarios for US National Security

The three scenarios developed by a team of American experts (Campbell/Gulledge/McNeill/Podesta/Ogden/Fuerth/Woolsey/Lennon/Smith/Weitz/Mix 2007: 55–92; chap 42 by Scheffran) are:

1. The *Expected Scenario* projects the effects of an average global temperature increase of 1.3°C and an SLR of 23 cm by the year 2040. Global implications for this scenario would include: internal and cross-boundary tensions for US national security by environmentally-induced migration; conflicts sparked by resource scarcity; and increases in diseases and health-related problems in general, which will have economic consequences. The physical effects of climate change will have societal, political, economic, and security impacts.
2. The *Severe Scenario* foresees profound and potentially destabilizing global effects when the average temperature will increase by 2.6°C and the sea level will rise by 52 cm by the year 2040, what will trigger massive societal events, leading to a dramatic rise in migration and changes in agricultural patterns and water availability. Armed conflicts among nations due to natural resources scarcity could also take place in various parts of the world.
3. The *Catastrophic Scenario* assumes an increase in the average global temperature of 5.6°C and an SLR of 200 cm (2 m). It foresees strong and surprising interactions between the two great security threats of global climate change and international terrorism posing almost inconceivable challenges as human societies would struggle to adapt to it.

23.1.2 Four Conflict Constellations for International Security

From an international security perspective, the WBGU in its report on *Climate Change as a Security Risk* has mapped the most highly affected regions by identifying four major issues, for which climate change is expected to cause critical developments (WBGU 2008a: 79–130; they are summarized in chap. 41 by Bauer; Brauch 2002, 2007, 2009a, 2009c):

1. *Climate-Induced Degradation of Freshwater Resources*: About 1.1 billion people are currently without access to safe drinking water. The situation could worsen for hundreds of millions of people as climate change alters the variability of precipitation and the quantity of available water. Demand for water is increasing due to population growth and mounting aspirations. This triggers distributional conflicts and poses major challenges to water management in many countries. The countries which will suffer the greatest water stress are generally those which lack the political and institutional framework necessary for the adaptation of water and crisis management systems. This could overstretch existing conflict resolution mechanisms, ultimately leading to destabilization and violence, specifically in the Middle East.
2. *Climate-Induced Decline in Food Production*: More than 850 million people worldwide are currently undernourished. This situation is likely to worsen in future as a result of climate change, as food insecurity in the lower latitudes, especially in many developing countries, will increase with a temperature rise of just 2°C. With global warming of 2–4°C, a drop in agricultural productivity is anticipated worldwide. This trend will be substantially reinforced by desertification, soil salination and/or water scarcity. In North Africa and the Middle East this may trigger regional food crises and further undermine the economic performance of weak and unstable states, thereby exacerbating destabilization, the collapse of social systems, and violent conflicts.
3. *Climate-Induced Increase in Storms and Flood Disasters*: Climate change is likely to result in more intensive storms and heavy precipitation that will affect many cities and industrial regions in coastal zones. Conflicts are likely to occur more frequently in future, because: a) certain regions, especially at risk from storm and flood disasters (e.g. Central America, which have weak economic and political capacities), will make adaptation and crisis management more difficult; b) frequent storm and flood disasters along the densely populated east coasts of India and China could cause major damage and trigger or intensify migration processes.
4. *Environmentally-Induced Migration*:[3] Migration may increase conflicts in transit and target regions. In developing countries, in particular, the increases in drought, soil degradation, and water scarcity, in combination with high population growth, unstable institutions, poverty and high lev-

els of dependency on agriculture, imply a significant risk of environmental migration. Transboundary environmental migration will mainly occur as south-south migration, but Europe and North America must expect increased migratory pressure from regions which are most at risk from climate change. The question as to which states will have to bear the costs of environmentally-induced migration in the future also contains conflict potential.

Of these four conflict constellations, the first two are highly relevant to, and pertinent for, the national security of a future Palestinian state and for the human security of the Palestinian people.

23.1.3 Impacts of Climate Change on Human Security

From a human security perspective (Barnett/Adger; Brauch 2005, 2008), the *Human Security Network* (HSN), during the Greek Chairmanship in 2007–2008, addressed the climate change impact on vulnerable groups (Brauch 2009a, 2009c; Fuentes Julio/Brauch 2009). The *Friends of Human Security* (FHS) and the *United Nations Office for the Coordination of Humanitarian Affairs* (OCHA) also discussed issues of climate change and human security at a symposium on 31 July 2007.[4] Prior to the first debate on climate change at the UN Security Council, a group of scientists submitted a policy memorandum[5] that addresses challenges for the people, which are also highly relevant for the Palestinian people in the OPT, with a high degree of social vulnerability. Poor and underdeveloped nations, e.g. in the Middle East, may have fewer resources and less endurance to deal with climate change and its impacts and consequences.

23.2 Middle East

The Middle East is one of the most water-stressed regions. Climate change is expected to make water resources even scarcer in the *Middle East and North Africa* (MENA), particularly in Jordan and the OPT[6] that will experience an even greater regional water stress.[7]

During the 20th century, observations have shown that global climate change has already caused less rainfalls, higher temperatures and higher evaporation rates, SLR, extreme weather events, and biodiversity loss. As a result of climate change, many species are

3 The WBGU (2008, 2008a, 2008b) study identifies the four 'conflict constellations', which "are defined as typical causal linkages at the interface of the environment and society, whose dynamic can lead to social destabilization and, in the end, to violence." The WBGU study summarizes the climate change impacts for regional 'hotspots', including *the Middle East and North Africa* (MENA). For an expert study on Southern Europe and North Africa, see Brauch 2007b; chap. 26 by Brauch.

4 See: Workshop on: "Climate Change from the Perspective of Human Security" (UNTFHS 2007). See the presentation by Under-Secretary-General for Humanitarian Affairs and Emergency Relief Coordinator, John Holmes, on: "Human security and disaster reduction" (Holmes 2007).

6 To better understand the water scarcity and conflict and some other important issues related to the water situation in the MENA region, this literature survey may be helpful: Davis/Maks/Richardson 1980; Shuval 1980; Khouri 1981; Stauffer 1982; Stork 1983; Cooley 1984; Matson/Naff 1984; Dillman 1989; El-Hindi 1990; Issar 1990; Lee/Bulloch 1990; Nijim 1990; Salameh 1990; Wishart 1990; Casa 1991; Hurwitz 1991; Pearce 1991; Al-Weshah 1992; Baskin 1992; Salem 1992; Sexton 1992; Bulloch/Darwish 1993; Postel 1993; Vesilind 1993; Biswas 1994; Isaac/Shuval 1994; Kliot 1994; Moore 1994; Neff 1994; Allen/Mallat 1995; Elmusa 1995; Haddadin 1995; Hof 1995; Libiszewski 1995; Lowi 1995; Schulz 1995; The Economist 1995; Wolf 1995; Isaac/Selby 1996; Rouyer 1996; Shuval 1996; Wolf 1996; Hof 1997; Pastor 1997; Kubursi/Isaac 1998; Allan 1999; Soffer/Copaken 1999; Alatout 2000; Amery/Wolf 2000; Brooks/Mehmet 2000; B'tselem 2000; Isaac 2000; Rook 2000; Allan 2001; Castelein/Otte 2001; Hass 2001; Allan 2002; Daibes 2003; Issar 2003; Mair/Kamat/Liu 2003; Rouyer 2003; Seitz 2003; Selby 2003; Brauch 2004; Haddad 2004; Handcock 2004; Hayek 2004; Issar 2004; Issar/Zohar 2004; Klawitter/Qazzaz 2004; Schwarz 2004; Soffer 2004; World Bank 2004; Frederiksen 2005; Khatib/Assaf/Claeys/ Daoud 2005; Messerschmid 2005; Selby 2005; Abu Zeid 2006; Bashir 2006; Bohannon 2006; Brauch 2006; Feitelson 2006; Fisher/Huber-Lee 2006; Gray/Hilal 2006; IRIN 2006; Tal 2006; Tropp/Jaegerskog 2006; Aliewi/Assaf 2007; Allan 2007; Baker/Freeman/Steinber 2007; Brauch 2007a, 2007e; Frederiksen 2007; Isaac/Salem 2007; Pearce 2007a, 2007b; Phillips/Attili/McCaffrey/Murray 2007; RSS 2007a; Salem 2007; Salem/Isaac 2007; Shuval/Dweik 2007; UNESCO 2007; Bergstein 2008; Bigman 2008; Biswas/Rached/Tortajada 2008; Dinar 2008; Fischhendler 2008; Hoetzl/Moeller/Rosenthal 2008; Lendman 2008; Makdisi 2008; World Bank 2008c; Zeitoun 2008; Zeitoun/Allan 2008; Zereini/Hoetzl 2008; Abdel Hamid 2009; Pedersen 2009; Picow 2009).

expected to disappear. A recent IPCC (2008) report warns that temperatures in the Middle East have increased 2–3°C in the last century, which is faster than the global average of about 1°C (Pedersen 2008). As a result, the Middle East region is expected to have fewer but more intense rain events, increased droughts, and decreasing resources of fresh water. More than 80 per cent of climate models have shown that rainfall in the MENA region will decrease by up to 40 mm per year (ENN 2008). With rainfall decreasing, the growing seasons for farmers will be shorter.

The Middle East is already experiencing a severe water crisis that is partly due to a mismanagement of freshwater resources. Within the next few decades, climate change will have severe regional impacts, not only for the natural environment, but also for the political and socio-economic context, adding to the political instability and tensions in the region. The dispute over water has been and will remain part of the Israeli-Palestinian, and of the Israeli-Arab conflict.

If water becomes too scarce under the climate change scenarios and conflict constellations discussed above, given the political circumstances affecting the region, then the Palestinians in the OPT will become the first victims who will further suffer from climate change. Water prices will rise dramatically. The Palestinians in the OPT presently purchase water for 5 NIS (*New Israeli Shekel*) or about 1.5 US$/m^3 (Salem/Isaac 2007) from *Mekorot*, a semi-private Israeli water company whose major shareholders are the Jewish Agency and the Jewish National Fund. Further, the decrease of agricultural lands will result in higher food prices, particularly for fruits, vegetables, and cereals, and, thus, their food security will be badly affected.

The projected SLR could affect the nearby aquifers due to the sea water intrusion. The *Gaza Coastal Aquifer System* (GCAS), which provides water to approximately 1.5 million Palestinians, is a typical example for such a disaster. Higher temperatures, annual decreases in precipitation, and higher rates of evaporation have already reduced the available fresh water (surface-water and groundwater) in the OPT. Israel, for example, which consumes more than 85 per cent of the water that should be allocated to the Palestinians in the OPT, must urgently take decisive measures to reduce the large-scale planting of water-consuming crops, and reduce the huge amounts of water that irrigate large areas, in order to conserve the use of water.

23.3 Historical Palestine – Occupied Palestinian Territories

Historical (or Mandate) *Palestine* (HP, including the OPT and Israel), with its small territory of about 27,000 km^2, is characterized by drylands and a natural habitat, where significant topographic and climatic variations prevail, what is a unique phenomenon in the MENA region (figure 23.1). Being located in West Asia, at the edge of the 'Fertile Crescent', and east of the Mediterranean Basin, HP has been a centre where human civilizations originated and spread throughout human history (Issar/Zohar 2009). Its long history of indigenous and invading cultures, and human movements for trade and politics have made HP a migration route for the exchange and dispersion of crops, seeds, flowers, and animal species. Many species have, thus, entered the region throughout history, making HP highly biodiverse by hosting over 4,000 plants, 120 mammals, 500 birds, 100 reptile and amphibian species, about 1,000 fishes, and an unknown number (5,000 to 10,000) of insects (Zohary/Feinbrun-Dothan 1984). Several species experience threats of degradation and extinction, and many are classified as 'endangered species'.

Based on its geographic attributes and geomorphologic and topographical characteristics, HP is recognized as rich and diverse, composed of five climatic zones: the coastal zone, the semi-coastal zone, the central highlands zone, the eastern slopes zone, and the Jordan Valley zone (Salem 2008a) that have a common flora and fauna. HP was primarily an agricultural country, and the West Bank in particular, has been a major food producer. Agriculture makes up a large part of the Palestinian economy and land use, representing 30 per cent of the Palestinian *Gross National Product* (GNP), with more than 50 per cent of the population benefiting directly from food production. Only 31 per cent of the land in the OPT is cultivated, 32 per cent is classified as grazing land, and the rest is classified as urban and barren land. Of the cultivated area, 28 per cent is considered rain-fed, and 3 per cent is irrigated mainly for vegetables.

The West Bank is located on the central highlands of HP, just above the Jordan Valley, while the Gaza

7 The MENA region is one of the most water scarce regions of the world, where 5 per cent of the world's population has access to only 1 per cent of the planet's freshwater resources (World Bank 2004, 2007a, 2008c). By 2025, most countries in MENA will face an absolute water scarcity (Abu Zeid 2006).

Figure 23.1: Historical Palestine within the Current Regional Context. **Source**: ARIJ (2009).

Strip runs along the South-eastern Mediterranean. The OPT, located between 31° 13' and 32° 33' latitude, and between 34° 13' and 35° 34' longitude, comprises a total area of 6,023 km^2, whereby the West Bank covers 5,661 km^2 and the Gaza Strip covers only 362 km^2.

The US *Population Reference Bureau* (PRB 2004) estimated the population of the OPT at 3.8 million (with an *annual population increase* (API) of 3.5 per cent); of Israel at 6.8 million (API: 1.6 per cent); of Jordan at 5.6 million (API: 2.4 per cent); of Lebanon

Table 23.1: Projected Population Growth for the Narrow Middle East countries for the Period 2005-2050. **Source:** UN (2001, 2005, 2009).

	Population in 2005 (UN 2009)	Projected Population in 2050 (UN 2009)	Projected Population Difference 2005-2050
Egypt	77 154 000	129 533 000	52 379 000
Syria	19 121 000	36 911 000	17 790 000
Jordan	5 566 000	10 241 000	3 957 000
Israel	6 692 000	10 649 000	3 957 000
OPT (Palestine)	3 762 000	10 265 000	6 503 000
Lebanon	4 082 000	5 033 000	951 000

at 4.5 million (API: 1.7 per cent); of Syria at 18 million (API: 2.4 per cent); and of Egypt at about 74 million (API: 2.0 per cent).

Table 23.1 shows the highest *projected population difference* (PPD, in percentage) for the OPT (Palestine) followed by Jordan, where PPD reaches to 269 per cent and 139 per cent, respectively. The lowest PPD is for Lebanon followed by Israel, where it reaches to 43 per cent and 67 per cent, respectively. Egypt and Syria will have lower PPD (68 per cent and 125 per cent, respectively) than the OPT (Palestine) and Jordan, and higher PPD than Lebanon and Israel. A PPD in the range of 43–269 per cent over 45 years will put extra pressure on the region's water resources and on the environment, taking climate change impacts into account.

According to the *Palestinian Central Bureau of Statistics* (PCBS 2008, 2008a), the OPT's population was about 4 million in the year 2007, about 2.5 million in the West Bank and 1.5 million in the Gaza Strip. The present estimated natural population growth rate for the Palestinians in the OPT is 3.5 per cent (3.1 per cent in the West Bank; 3.7 per cent in the Gaza Strip), being one of the highest growth rates in the Middle East (Salem 2009a). The average population density in the West Bank is 432 persons/km^2 in the total area, and 6,842 persons/km^2 in urban areas (PCBS 2006), while in the Gaza Strip, the average population density is 3,981 capita/km^2 in the total area, and 7,485 capita/km^2 in urban areas (PCBS 2006), making it one of the most densely populated areas in the world.

The climate in HP is typically Mediterranean, with a long, hot and dry summer; a short, cool and rainy winter, and a dry autumn. The temperature and the evaporation rate increase in the south and east. The average annual rainfall ranges from less than 50 mm to 800 mm, almost 70 per cent occurs between November and February, and the rest between March and May. The climate change impacts on rainfall, evaporation, desertification and storm intensity have been observed in the OPT which has suffered from severe shortages of natural resources, particularly water.

23.4 Climate Change Impacts on the OPT

This section reviews major physical and socio-economic impacts of climate change on the OPT for water resources (23.4.1), agriculture (23.4.2), due to Sea-Level Rise (23.4.3), for biodiversity (23.4.4), and human health (23.4.5).

23.4.1 Water Resources

Interest in water resources in the Mediterranean has risen due to population growth and increase in density in urban areas (Brauch 2007). The water demand in the OPT is dominated by three major user groups: agricultural irrigation, domestic use, and industry. Even without climate change the water scarcity in the Middle East is a huge problem, politically, demographically and economically. A rapid growth in agricultural and industrial output is needed to sustain the growing population, which requires a good water management.

23.4.2 Agriculture

In the OPT fruit production is a primary source of income for agricultural areas, which is extremely vulnerable to temperature extremes which the OPT experienced since the 1980's (table 23.2).

The following impacts of climate change are projected for agriculture in the OPT:

- Increases of temperature and extreme-events frequency will reduce crop yields (some crops are

Table 23.2: Extreme Weather Events in the OPT (1997-2004). **Source:** Salem (2007).

Date	Event
18-19 March 1997	A heavy storm hit the central and southern parts of the West Bank, which was the second heaviest storm in March during the past 60 years.
July-August 1998	The hottest summer in 35 years where the temperature rose up to 46.8°C in Jericho.
September-November 1998	The driest and warmest autumn during the past 58 years.
24 January 1999	A hail storm hit Jerusalem with hail stones as big as marbles (1.3 cm in diameter).
28 November 1999	Unusually cold and dry weather. The temperature in Jerusalem dropped to 6°C below zero.
July 2000	The hottest month of July in the last 50 years, with a mean temperature of 4°C higher than average. The highest recorded temperature (41°C) in Jerusalem since 1888.
February 2003	The wettest month since December 1991, and the wettest February ever recorded.
29-30 May 2003	Lowest pressure (995 mb) ever recorded in May, accompanied by an incredible sand storm that covered the entire OPT and the region with thick red sand and dust.
9-10 May 2004	Very intense heat affected the OPT, especially during the night of 9 May, when 32°C was recorded in Jerusalem. In the following nights, the temperature in Jerusalem was 20°C lower than the temperature at noon.

more tolerant than others), and will negatively affect marginal land and its farmers.
- Mean-temperatures modification will induce changes of the agricultural distribution of crops.
- Water scarcity will force farmers to abandon marginal land and will increase desertication.
- Socio-economic impacts, associated with the loss of agricultural and other related jobs, will result in increasing unemployment and in the loss of income, as well as in political disorder.

23.4.3 Sea-Level Rise

The Gaza Strip covers 40 km of the South-eastern coast of the Mediterranean Sea and is only 11 km wide. The *sea-level rise* (SLR) due to global warming will enhance erosion of the Gaza Strip beaches, and will also cause sea water intrusion into the *Gaza Coastal Aquifer System* (GCAS). Some low-lying coastal structures will be affected or damaged, causing a huge loss in valuable lands and buildings and forcing inhabitants to migrate.

23.4.4 Biodiversity

During the 20th century global warming has already resulted in extensive biodiversity losses. The Mediterranean Basin is one of 25 'global biodiversity hotspots' (Myers/Mittermeier/Mittermeier/Fonseca/Kent 2000). The biodiversity in HP has been high, being at a crossroad of African, Asian, and Mediterranean bio-geographic regions. The speed and magnitude of climate change may elicit different responses at different levels of ecological organizations, namely the people, the species, and the communities, and at all levels of the ecosystems.

23.4.5 Human Health

Climate change is expected to have critical impacts on human health in the Mediterranean and in the OPT, due to the lack of advanced medical care. It will have both direct and indirect impacts on the Palestinian society (Salem 2008b). People who suffer from pollen and dust allergies will suffer more from changes in climate, as the allergy season will start earlier, last longer, and become more intense. In the past, the allergy season started in May but now it starts in March. An increase in respiratory diseases is expected among children, the elderly, and those with chronic diseases. In addition, the very young, the very old, and the very weak are likely to be affected by heatwaves and, thus, mortality rates may increase in these groups.[8]

Many prevalent human diseases are linked to climate fluctuations, including cardiovascular mortality and respiratory illnesses (due to heatwaves), infectious diseases, and malnutrition from crop failures. The *World Health Organization* (WHO) estimated that the warming and precipitation trends, due to anthropogenic climate change during the period of 1972–2002, had claimed annually over 150,000 premature lives (WHO 2002). The global warming trend has already increased mortality rates (Patz/Campbell-Lendrum/Holloway/Foley 2005).

Indirect impacts of climate change may appear from diseases being transmitted by insects. Many diseases may spread in the OPT, particularly in the Gaza Strip, where impacts are expected to be severe. A cause of greatest concern is the possible spread of malaria (Kovats/Menne/McMichail/Corvaln/Bertollini 2000). Approximately half of the world's population is at risk of malaria, with over 270 million cases per year and more than one million deaths (WHO 1998, 2009).

23.5 Climate Change Impacts due to Man-Made Activities

For a healthy and productive environment, the impact of climate change and its causes must be taken into account (Pararas-Carayannis 2003). These factors have contributed to anthropogenic climate change: a) burning of fossil fuels; b) rise in urbanization, industrialization and consumption; c) production of huge amounts of waste; d) increased air, water, and soil pollution; e) lack of appropriate land and water management; f) deforestation; and g) many wars.

23.5.1 Effects of the Israeli Segregation Wall on Climate Change

The construction of the *Israeli Segregation Wall* (ISW) was started in 2002. Until December 2008 its total length had reached 768 km on the northern, western, and southern borders of the West Bank and it encircled East Jerusalem. The ISW (table 23.3; figure 23.2) consists of a 4–5 m high double-layered electric metal fence, reinforced with barbed wire, trenches, surveillance cameras, sensors, footprint-detection tracks, security patrols, and military roads. Other parts of the ISW, dividing Palestinian population centres, consist of 8–12 m high concrete segments that form an immense solid concrete barrier with military watchtowers lined up to 250 metres apart. The ISW has devastated an area of 40–100 m along its route. Besides its huge cost, the ISW has major environmental, social, economical, and political impacts on the Palestinians in the West Bank (ARIJ 2007, 2008).

Table 23.3: Changes in the Route of the Israeli Segregation Wall (ISW) between June 2004 and December 2008. **Source:** ARIJ (2008).

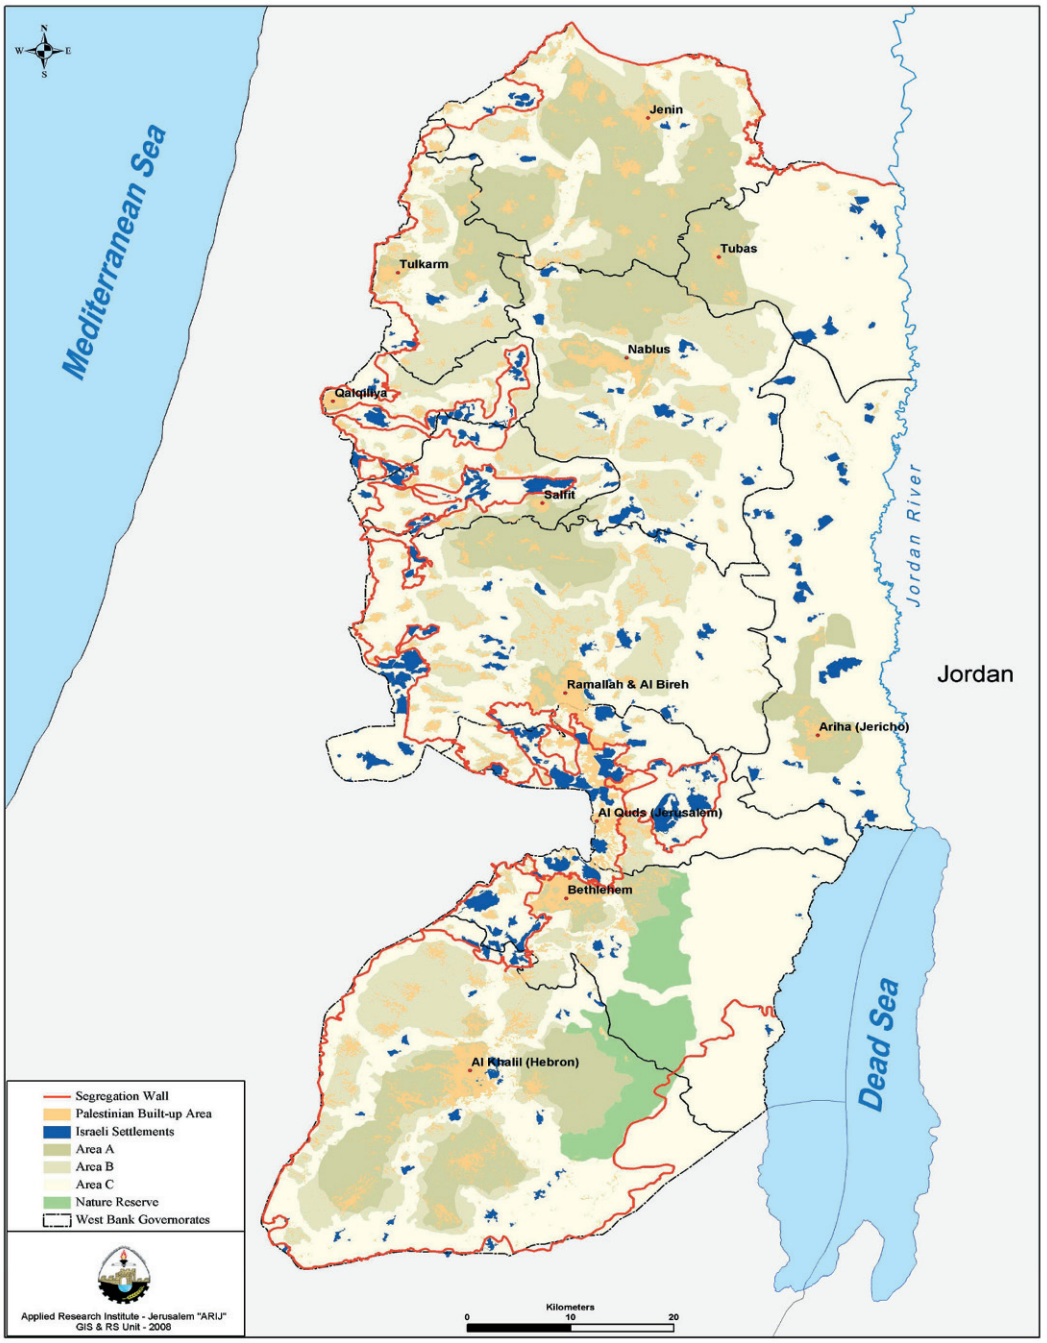
Date of Change	Wall Length (km)	Area Isolated (km²)	Of the West Bank's Area (per cent)
June 2004	645	633	11.2
February 2005	683	565	10
April 2006	703	555	9.8
April 2007	770	713	12.6
December 2008	768	734	13

In June 2002, the Israeli Government launched its policy of unilateral segregation of Israel and the OPT by establishing a segregation zone along the western terrains of the West Bank which covers large areas that are rich in natural resources (groundwater, springs, agricultural lands), grabbing fertile agricultural land, isolating Palestinian communities in enclaves, undermining the territorial contiguity between Palestinian villages and cities, controlling the natural resources, and encapsulating most of the Israeli settlements built illegally on Palestinian lands since 1967.

A decision of the *International Court of Justice* (ICJ) of 9 July 2004 saw the ISW as an attempt to connect illegal Jewish settlements in the West Bank to Israel by annexing Palestinian land. The ISW will have significant impacts on future negotiations on borders. By building the ISW (and of 200 Jewish settlements) on confiscated Palestinian territory, Israel violated the Hague Convention of 1907 and the Fourth Geneva Convention of 1949 (IHL 1907, 1949). The ISW violates the right to self determination and basic human rights, especially the right of free movement and access to holy places, work, health, education, and to an adequate standard of living. 'Self-defence' cannot be used to justify violating international legal principles and the rights of a people living under military occupation (McMahon 2005). The ICJ concluded

8 On May 18, 2007, Greece assumed the tenth Chairmanship of the *Human Security Network* (HSN) founded in 1999, which includes countries from Europe, North and South Americas, Africa and the Middle East. The HSN supports the United Nations' principles and aims at raising the awareness of the international community in the direction of effective support and protection of vulnerable population groups against modern threats to human security, which undermine development prospects in many parts of the world. Within the framework of its Chairmanship, Greece's priority is to point out the relationship between climate change and human security at international level. The aim is to raise the international community's awareness of the impact of climate change and global warming on human security, with regard to vulnerable groups, particularly children, women and persons fleeing their homes, due to climate change impacts (GMFA 2007).

Figure 23.2: The Israeli Segregation Wall (ISW) and Segregation Zones in the West Bank. **Source:** ARIJ (2008).



that the ISW was contrary to international law and, therefore, Israel must cease the wall's construction.

Since 2002 the route of the ISW has been changed several times (table 23.3) to benefit Israeli settlements in the West Bank, thus expanding the segregated zones. In September 2004, the Israeli army issued military orders that created a buffer zone of 150–200 m on the Palestinian side where new construction by Palestinian citizens is prohibited. As a result, an additional area of 252 km^2 (or 4.4 per cent) of the West Bank has become inaccessible to Palestinians.

Until December 2008 the ISW was 768 km long, of which only 80 km (10.4 per cent) follows the 1949 'Armistice Line' or 'Green Line' (figure 23.1, 23.2). The

ISW has isolated 734 km^2 (13 per cent) of the West Bank's area (table 23.3). By its completion, the ISW will enclose 107 Israeli settlements (with 425,000 Jewish settlers), and it will totally enclose East Jerusalem. The settlers that will be enclosed represent more than 80 per cent of all settlers in the West Bank (ARIJ 2008). Israel has made a few cosmetic changes of the ISW's route that do not ameliorate its devastating effects on the Palestinians and their lands and properties. The goal of these small changes has been to include more settlements between the ISW and the 1949 Armistice Line.

The Israeli army has consolidated its control over the West Bank in the Eastern segregation zone (1,555 km^2, or 27.5 per cent of the West Bank), through 28 military checkpoints. Until December 2008, Israel has illegally established 670 checkpoints in the West Bank (ARIJ 2008). After the 1967 War, Israel classified some 925 km^2 as a 'closed military area', and it illegally classified an additional 632 km^2 of the Eastern segregation zone as 'state land', which includes the settlements and the military bases, and parts of the closed military areas. The Israeli segregation plan appropriates more than 40 per cent of the West Bank (ARIJ 2007, 2008).

Until winter 2008, about half (377 km) of the ISW's total length (768 km) was completed; 12.4 per cent (or 95 km) of it was under construction (ARIJ 2008), and plans to complete an additional 38.5 per cent (or 296 km) were confirmed. The boundaries of 29 Palestinian villages (or 216.7 km^2) are trapped in enclaves behind the ISW, and another 138 Palestinian villages (or 555 km^2) are significantly affected and lost behind the path of the ISW. Furthermore, 45 Palestinian communities with more than 43,000 people will be isolated in the Eastern segregation zone.

The Western segregation zone includes 107 Israeli settlements in the West Bank that cover an area of 106.7 km^2 (or 15 per cent of the zone). In addition, 56 settlement outposts are located in this zone. Settlements in the Eastern segregation zone cover an area of 38 km^2 (or 2.4 per cent of the zone). In the Eastern segregation zone 12,550 Israeli settlers live in 39 settlements, besides 30 settlement outposts. Until December 2008, the total number of settlement outposts has reached 220, in addition to the 200 settlements spreading all over the occupied West Bank (ARIJ 2008).

The ISW has considerable impacts on the region's water supplies around it. "The climate of Palestine is semi-arid, and water sources are precious. In villages around Qalqilya and Tulkarm, more than 30 wells will be lost in the first phase of the wall [ISW]. These wells, located in the western groundwater basin, were drilled prior to the 1967 Israeli occupation of the West Bank. As a result, Palestinians will lose nearly 18 percent of their share of the basin's water" (Reese 2003). The Israeli journalist Meron Benvenisti claimed, "terrible environmental damage is being inflicted on large areas in the heart of the country. Seventeen million cubic meters of soil, with tens of thousands of olive trees, thousands of dunoms of orchards and groves, tens of thousands of dunoms of natural growth, hot houses, archaeological sites and [water] wells – as well as the fabric of life of hundreds of thousands of people [Palestinians] – are being crushed by giant bulldozers. Yet the environmental organizations have nothing to say about the damage caused by the fence [ISW]. On the contrary, they exploit the tragedies of others to promote their own interests. The destruction of the Palestinian environment presents the opportunity to demand 'environmental compensation' within Israel. Moreover, the environmentalists are fighting for safe passage for small wildlife, while ignoring the fact that freedom of movement is being denied to hundreds of thousands of people – including small children – in an arbitrary manner. What selective sensitivity!" (Benvenisti 2004).

Due to the ISW, the Palestinians in the West Bank have already lost huge amounts of their water in the *Western* (WAS), *North-Eastern* (N-EAS) and *Eastern Aquifer Systems* (EAS). Further, parts of their agricultural land and many water wells and springs were lost (Salem/Isaac 2007):

- Up to 192 km^2 of agricultural lands are isolated in the Western, in addition to 844 km^2 in the Eastern segregation zone, which both constitute 18.3 per cent of the West Bank's total area (5,661 km^2).
- Up to 247 km^2 of forest land and areas with shrubs are isolated in the Western and 708 km^2 in the Eastern segregation zone, which constitute 16.9 per cent of the West Bank's total area.
- The Eastern segregation zone has isolated 204 groundwater wells and 43 springs, and the Western segregation zone has isolated 29 groundwater wells and 29 springs.

The negative ecological footprint of the ISW is enormous, as huge areas of fertile Palestinian lands in the West Bank are lost, being isolated behind the ISW and thus beyond the reach of Palestinian communities. With the construction of the ISW a large number of trees have been uprooted, what has severe impacts on the hydrology of the watersheds in the affected areas.

As a result of the ISW, considerable changes in water quantity and quality have occurred in the stream channel morphology, in the groundwater levels, and in the region's water supplies. The surface water flow has been altered, and severe increases in the rates of erosion and sedimentation have already occurred. Given this complex geopolitical situation, politics has, directly and indirectly, contributed to local changes of the climate (Salem 2008c). The OPT is not only suffering from Israeli policies and practices but also from the SLR due to the impacts of global climate change.

23.5.2 Sea-Level Rise Impacts on the Gaza Strip

The Gaza Strip (figure 23.3), with a total area of 362 km^2 and a population of about 1.5 million, is one of the most densely populated areas worldwide. The Israeli buffer zones along Gaza's northern and eastern borders are based on a clause of the Oslo Agreement (1994), under which Israel maintains a 0.5 km wide zone along the 58 km long northern and eastern borders of the Gaza Strip. This buffer zone occupies 29 km^2 (8 per cent) of Gaza's territory and is controlled by the Israeli army with a Palestinian security monitoring. In September 2000, the Israeli army unilaterally expanded this zone from 800 up to 1,300 metres.

This buffer zone is off limits for Palestinians who are not allowed to build, cultivate, or to be in or close to that area. When the Israeli army completed its disengagement from the Gaza Strip in late 2005 the buffer zone then covered 61 km^2 (or 17 per cent of the territory of the Gaza Strip). On 28 June 2007, the Israeli army expanded the buffer zone along the Gaza Strip's northern and eastern borders to become 1.5 km wide. Accordingly, this newly defined buffer zone occupies an area of 87 km^2 (or 24 per cent of the Gaza Strip; Salem 2007). No recent information is yet available about the new size of the buffer zone after Israel's most recent war in the Gaza Strip from 27 December 2008 to 18 January 2009.

The Gaza Strip is a foreshore plain gradually sloping westwards to the Mediterranean Sea. It has four ridges with different elevations, ranging from 20 to 90 m above sea level. With its extremely large population and low altitude, the Gaza Strip is highly vulnerable to climate change impacts.
