Recently Turton, Hattingh, Roux, Claassen, Maree and Strydom (2007) have described strong governance as depending on a 'trialogue' between the state or governments, the civil society and the scientific or technocratic experts. Their hypothesis is that the trialogue model, consisting of six essential elements, effectively reveals the degree of successful governance. It denotes the balance between the three elements because governance requires the existence of effective science, government and society processes. Governance also requires effective interfaces between each of the three processes, namely society and science, government and society, and society and science. Thus, irrespective of the philosophical perspective of the experts, rethinking its *management* seems to be the direction towards future water security for not only the South Asian region, but also for Bangladesh. Thus, the crisis of water management may also be defined as the crisis of governance by several equations (figure 58.8).

These equations stress the significant relationship of non-climatic conditions for water security with regard to governance.

58.3 Prospect of Social Networks to Form Local Good Governance: Better Water Resources Management

Although it is difficult to draw a clear-cut boundary line between 'good' and bad' governance of water, following UNESCAP, eight major characteristics are outlined: 1) participation, 2) transparency, 3) consensus oriented, 4) responsiveness, 5) equity and inclusiveness, 6) effectiveness and efficiency, 7) the rule of law and 8) accountability of what is commonly seen as good governance (UNESCAP, 2007). Coming from another perspective, Bohle (2009) considered these factors as the key to sustainable livelihoods security.

With regard to social networks, our thesis is that they are invaluable in mobilizing good water resource management in Bangladesh under a scenario of change driven by both climate and non-climatic factors. Despite a large state bureaucracy on water, non-state actors continue to operate and manage water in the informal sphere based on traditional social institutions. The following section briefly outlines social institutions, social capital and social network theories to explore how they generate good governance from the local to the national level for the security of water resources in Bangladesh.

58.3.1 Social Institutions

The term 'institution' includes social activities, values, norms, social structures and cultural systems (White/Mohr 2008). It may also be used for 'social institutions', which represent several interlocking social networks. The theory of social institutions examines cultural networks (shared stories, shared narratives, systems of value) and relational structures (linking meanings, values, and stories together), which are significant to organize social life that is directly or indirectly related to the development of local governance and WRM in Bangladesh. Social institutions theory also analyses different linkages that occur across various orders of social phenomena (Varvasovszky/

8 Shiva, Vandana, 2006: "World without Water", in: *Channel 4* [*True Vision Productions* broadcast, UK], *29* April.

9 Asit K. Biswas is the founder of the Third World Centre for Water Management and of the *International Journal of Water Resources Development*. He received the 2006 Stockholm Water Prize.

10 "Governance" simply means, "the process of decision-making and the process by which decisions are implemented (or not implemented)" (UNESCAP 2007: 1).

Brugha 2000). Such analyses are highly applicable to rural areas in Bangladesh, where a duality of styles and institutions exists, often somewhat separating the formal and informal spheres. Both styles represent different sets of values that correlate with the principles of social institutions. In Bangladesh the actors in WRM operate through social institutions through their values based on their behaviour.

58.3.2 Social Capital

Social capital is about values and social relationships that facilitate human beings to act collectively. The concept of social capital is not about "what you know, it's who you know" (Woolcock/Narayan, 2000: 225). This statement recognizes the benefit of social relations. For instant, individuals who form interactions and networks with others, mostly increase their chance of benefit. Lin (2001) argues that 'information and influence' are some of core reasons to study social capital in social networks. Sharing information with others through social ties thus enhances the outcomes of organizations or the activities of individuals. By using the theory of social capital, it will be possible to explain the investment in social ties that increases the level of information and would then influence the actors, the key players in decision-making or holding strategic positions who can influence developing good governance to improve WRM in Bangladesh.

58.3.3 Social Network

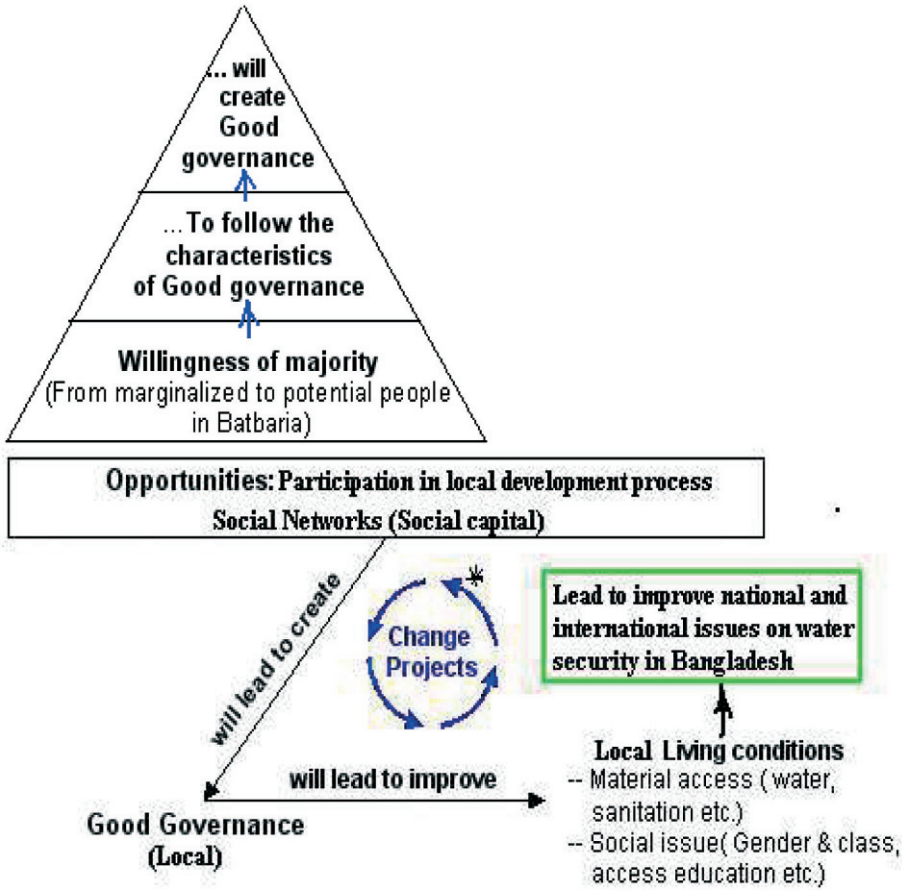
Social network analysts argue that the social environment is based on the relationships among interacting units. According to Wasserman and Faust (1994) social network analysis looks critically at the characteristics of social units and understands how these ties influence properties of the social structural environment. In Bangladesh, a significant part of the analysis is influenced by social relationships. By using social network analysis, key concepts (such as actor, rational tie, dyad, triad, subgroup, and group) of the theory are used to explain how WRM is influenced by social prestige, groups or clique, social cohesion, social position, social role and mutuality in the local areas in Bangladesh. Selection to use the social network to represent the relational tie, where actors are linked by social ties with each other and it establishes a linkage between two actors or a pair or three actors or groups of actors. At the local level in Bangladesh, a group is recognized as a collection of all actors where relationships are considered.

58.3.4 Coping with the 1998 Floods by Social Networking

As an example of how the social elements play a crucial role during a great crisis the case of the 1998 flood in Bangladesh is discussed below. Heavy monsoonal rain, lack of sufficient culverts and insufficient drainage contributed to an intensive flood where about 39 out of the 64 districts were flooded, breaking all hydrological records (Nasreen 1999). The flood waters devastated agricultural crops and disrupted farming activities for several months, and destroyed the sources of fisheries and farm livestock (Ahmed 1999). Millions of people lost their homes and took shelters on higher grounds, such as the river embankments. Not only were their houses destroyed, roads and other communication infrastructure were also damaged. Flood refugees took shelter in nearby schools and colleges around the villages, and it was extremely difficult to send food and other relief aid immediately to all remote locations. However, there was a low number of fatalities; villagers managed to survive based on mutual support in flood-affected communities. Many civil society organizations mobilized their strengths and brought assistance to those in need. Ordinary citizens helped each other, large amounts of clothes, *khicuri* (cooked rice and lentil) and drinking water were provided to them by local unaffected people. Students from colleges and schools collected food, money and medicines from *bazars*. Imams, priests and gurus of mosques, churches and temples collected food, clothes as gifts to flood affected people. Even those who were affected by the flood tried to extend their help to others to transport their goods and cattle to higher locations. Mobilization of the civil society helped to avert a major post-flood disaster. This case of a disaster response illustrates the use of social theories in the communities in Bangladesh.

Looking back at the social mobilization, a noted Bangladeshi thinker, Sobhan (1999: 41) prescribed: "Efforts by the government to keep track of such emerging problems would be greatly facilitated by drawing upon the efforts of civil society that is already in the field fully involved with the relief process." The collection of best practices, examples of difficulties, storing of this information in an easily accessible form, and easy communication of such information can play an important role in averting human tragedies in a post-flood situation. Bangladesh is a flood-prone land, where climatic and non-climatic drivers add to these flood risks. Unless social institutions are

Figure 58.9: Participatory approach facilitates creating good governance. **Source:** Zillur (2007).



strengthened at the local level and social capital is mobilized, it will remain impossible to grant security to ordinary citizens.

58.3.5 Theories of Social Capital and Social Networks as Inputs for Good Governance

Participation by all is the first step to create an environment of good governance. Social capital and balanced social networks facilitate the willingness of all people, including the poor and the marginalized, to participate (core of good governance), and it opens potentials for development, by using more local knowledge collectively and increasing the chance of *consensus-oriented* activities in the communities. Strong social networks and ties will develop transparency to participants since people will be more interested to keep progress in the society. Automatically, it creates local public accountability.

Therefore, social networks and approaches based on social capital enhance local participation and promote inclusiveness, transparency and accountability, which are the fundamental characteristics of good governance. Figure 58.9 shows the input of social networks (social capital) to generate a willingness to participate in community activities. This leads to the formation of good local governance. When there is good governance, there is a good management. This will then contribute to improve local people's living conditions thereby encouraging top authorities and politicians to adopt and implement good approaches and efficient policies for water security in the country.

58.3.6 Social Networks for Creating Good Governance

Based on the above discussion, increased motivations of local actors and water users holds the potential to trigger bottom-up changes in WRM in Bangladesh with regard to changes by climate-driven and non-climatic factors. Local practices of good governance may influence local elites, who have good connection with higher authorities responsible for decision-mak-

ing in the formal sphere. Since political leaders are well-connected in local areas, there are possibilities that they may be influenced to adopt local principles of good governance on a national and international scale. Such changes in governance may cross national boundaries to address complex transboundary water issues that are essen-tial for securing water resources for Bangladesh. In other words, good WRM practices arising from the local context can spread to governance of the global level.

Flood mitigation, after all is not a so-called simple matter of controlling a natural hazard. Floods are indeed a natural occurrence, but they are also "socially produced" through the interaction of the physical incident and social vulnerabilities (Lebel/Nikitina/Manuta 2006: 3). Consequently there is a need to go beyond the purely technical solutions to mitigating the risks of increased flood or other water insecurities that are envisaged for the future. The technical measures, as noted by Dixit (2003: 166) only intensify flood and related problems and largely ignore the mitigation potential during the period of normalcy between two extreme events. Shen has also consistently emphasized the importance of perception as the key factor for developing a mitigation plan to reduce flood risks, and has suggested that instead of risk externalization, the interests of vulnerable social groups needs be considered and an integrated flood mitigation approach needs to be adopted. As suggested by Yohe and Strzepek (2007), for reducing the risks of climate change impacts on the waters of South Asian countries, mitigation and adaptation strategies will need to go hand in hand, and for this purpose, a greater understanding of the social institutions will be absolutely vital to improve the governance of water.

58.4 Conclusions

This chapter has addressed a diverse range of issues related to the security and sustainability of WRM in Bangladesh in the context of the looming threat of climate change and the complex social and political factors including weak governance in the country. It has suggested that social networks could play an important role in ensuring security at the micro-levels, and the promotion of people-centred water management, particularly for the densely populated country, Bangladesh. Whilst the increasing gap between demand and supply of water has led to a deepening water crisis in the country, climate change has posed a serious challenge for future water resource management. On the one hand there will be further reductions to freshwater supplies, on the other the melting of the Himalayan glaciers will change the volume and frequency of monsoonal floods and change the river regimes in Bangladesh.

The chapter ends with a question for further research: what are the determinants of social networks for the sustainability of WRM in rural areas of Bangladesh? This question will address the existing research gap by incorporating social networks to explore what parts of social networks are important, why they are important, and how they influence the development of sustainable WRM strategies in Bangladesh.

59 Applying Bottom-up Participatory Strategies and Traditional Methods of Water Harvesting in the Thar Desert, Rajasthan

Kanupriya Harish and Mathews Mullackal

59.1 Introduction

With the increasing evidence on climate change policy-makers and researchers are searching for ways to cope up with its impacts and consequences. Adaptation is particularly important for developing countries as impacts of climate change will deeply affect the geographical locations of developing countries (Walker/King 2008: 60–63). They are most vulnerable due to their limited economic capacity as: "the people who will be exposed to the worst of the impacts are the ones least able to cope with the associated risks" (Smit quoted in Adger/Huq/Brown/Hulme 2003: 180). The management of water resources will be most troublesome due to the unpredictability of the climate (Walker/King 2008: 55), thereby seriously affecting not only the availability of drinking water but also other sectors such as agriculture, sanitation and health. The vulnerability of the water sector is much worse for most developing countries as their policy frameworks are "less mature, with weaker institutions, and less capable of providing for adaptation to climate change" (Levina 2006: 6).

Nevertheless, important lessons can be learnt from the experiences of water harvesting in the Thar Desert, where the climate has been already harsh and unpredictable. From this experience a bottom-up participatory approach could be a realistic way forward in developing adaptive strategies to climate change. The chapter traces the water crisis in the Thar Desert (59.2), the scope of the bottom-up participatory approach in natural resource management (59.3), traditional wisdom in the region (59.4) and a success story of coping with adverse and changing climate in the region (59.5).

59.2 Thar Desert and Water Crisis

The Thar Desert in Western Rajasthan, with a population density of around 100 persons per square kilometre compared with three to ten in other deserts, is the most densely populated arid zone in the world (Dhir 2003: 1). The Thar, the world's seventh largest desert, is a hot season rainfall region, situated in the north-west of India. The aridity in the region is considered as relatively new in geological scale and a cause for the end of the Riparian and Harappa-Kalibangan civilization (Jaiswal 1977). The Palaeobotanical evidence indicates an increasing trend in aridity due to geological and climatic changes in the region since the Miocene times. The desertification was exacerbated by the demise of a well-knit river system with the diversion and disappearance of three classical rivers: the Yamuna, the Saraswati and the Ghaggar (Jaiswal 1977).

About 10 per cent of the Thar Desert eco-region is composed of sand dunes, and the other 90 per cent of craggy rock forms, compacted salt-lake bottoms, and interdunal and fixed dune areas. The weather is extreme with temperatures varying from almost-freezing in the winter to more than 50 °C during the summer. All rainfall is associated with the short July-September southwest monsoon that brings a mere 100-500 mm of precipitation, while the average rainfall in the region is only 200 mm (Khan 1998: 167). Also the ground water in most of the region is saline and unsuitable for drinking. Although these factors make this region inhospitable, the population of human settlement in the region has only been increasing (figures 59.1 to 59.6).

The history of the current and uniquely high human settlement in this region dates back to over 2000 years. Historians believe that the influx to this rather inhospitable but physically secure tract started soon after Alexander's invasion in 327 BC. Thereafter the population continued only to increase. By the

beginning of the second millennium the entire region was not only well settled, but also politically organized (Dhir 2003). Since the census of 1921, the population growth was even higher than for the rest of India (figure 59.7). Development of infrastructure and transportation facilities, which facilitated easy access to the previously less explored region, could have contributed to this recent trend.

However, recent years saw increasing challenges for human settlements in the region, with an increasing number of drought years. The fragile desert ecosystem is currently subjected to increasing human and livestock pressure, non-sustainable use of natural resources and neglect of traditional wisdom. To make things worse, droughts have become a recurring phenomenon; on an average the region witnesses six drought years in a decade (Mohnot 2003: 3). Though it seems natural in this region, Indira Khurana argues: "it is truly a human made or rather a government made disaster" (Khurana 2003: 138).

These increasing incidents of droughts are the result of two major shifts of water management that happened in the last century. Firstly, responsibility of water management was taken by the State from individuals and communities. Secondly, modern technologies promoting large exploitation of natural resources such as dams and deep tube wells replaced traditional and simple rain water harvesting methods (Khurana 2003). This change has resulted in mismanagement of water resources and also in unsustainable water use

behaviour, as the "Statement of Shared Concern" (Agarwal/Narain/Khurana 2001: 448) concluded, that was adopted by the participants of a national conference (New Delhi, 3–5 October 1998) of the Centre for Science and Environment, a leading think tank on environmental issues in India, on potential of water harvesting.

The modern paradigm has resulted in a mismanagement of both groundwater sources and river water, and also in water use behaviour, which does not reflect concerns for the growing scarcity of water. Subsidized water services by the state has further encouraged this behaviour and put limited water sources under stress (Agarwal/Narain/Khurana 2001: 449).

Although the people in this area have developed a variety of coping mechanisms for centuries, it is increasingly observed that the resilience of the community, particularly of the poor, to adverse climatic conditions has considerably declined. The causes include population growth along with a change in land use and a decline in altruistic attitudes (Scott 2008: 9). The already stressed water sector in this region is predicted only to get worse with looming impacts of climate change. Although there were uncertainties about human-induced climate change

until this decade, now there is a wide consensus and it is predicted that the average surface temperature would increase at least by 2 °C in this century (IPCC 2007c).

The first national communication of India to the *United Nations Framework Convention on Climate Change* (UNFCCC) reveals that Rajasthan is one of the most vulnerable states in India, due to a weak social capital and various impacts of climate change. Particularly, the Luni river, the west flowing river of Kutch and Saurastra that benefits 60 per cent of the area of Rajasthan is likely to experience acute physical water scarcity (GOI 2004: 78). Also the rain-fed agriculture in this area, a major livelihood source, would be adversely affected by climate variability which has been impacting on the lives of millions of poor people.

These challenges necessitate an adaptive governance to manage water resources in the region. According to the IPCC, vulnerability is not only a function of sensitivity or exposure, but also of adaptive capacity. It is increasingly realized that adaptation must not start from scratch. A bottom-up participatory approach that acknowledges various coping mechanisms developed through traditional iterative learning process

would be a realistic way forward. It helps people to adapt to present climate variability based on past experiences and to develop strategies for responding to future climate variability.

59.3 Bottom-up Participatory Approach

Most development programmes in the past have adopted a top-down approach or an external expert approach, in which an external agency puts itself outside the local system and makes decisions about the system. The participatory or bottom-up approach that incorporates the participation and ownership of local people, has emerged against the top-down approach. This radical idea envisages an empowerment of the disadvantaged section of humankind to fight against oppression and to claim denied choices (Gujith/Cornwall 1995: 3).

Nowadays, participatory methods have become a dominant paradigm in development and are considered as the backbone of bottom-up development. The participatory approach is often considered as being superior to the conventional approach in development, and has gained an increasing thrust particularly in the natural resource management discourse. Since the government ownership and management of natural resources has resulted in their overexploitation, in the name of development, the participatory management has indeed increasingly become relevant (Mishra/Bajpai 2001: 9). Also it is ever more realized that natural resource management cannot be effective without involving the local communities, whose livelihood is directly dependent on it.

There are many outcomes of the participation in development or natural resource management. The foremost outcome of a real participatory approach is to create a self energized community that is sufficiently capable to analyse their own situation, both the gaps and their potential, and to strategize and plan a course of action for their integrated development. It means that participatory development not only brings positive changes in development indicators but also in the social structure in terms of an enhanced social capital, self-reliance, social equity and lower dependence on the government.

Therefore, a participatory development worker should have appropriate facilitation skills, while respecting the capabilities of the community and their traditional wisdom. Apart from the above key outcomes, there are at least three objectives or immediate outcomes for the participatory approach (Biswas 2000: 167).

- Firstly, what has been realized for a long time, it generates a wealth of quality information about a local region and community. Indeed, the whole idea of a participatory approach evolved from experiments of anthropologists when they rapidly collected information from rural communities. Later techniques, like a *participatory rural appraisal* (PRA), have become unavoidable in development initiatives. Despite a faster methodology of data collection, it is often emphasized that data collected through a participatory approach is more trustworthy than other methodologies (Biswas 2000). It has a unique advantage to get information about sensitive and surprising realities that are not accessible with traditional methods (Chambers 2003: 40).
- Secondly, the participation increases the involvement of communities, as people get psychologically attached to the decision taken through a participatory approach. When people are involved in a decision, they tend to take ownership of the decision and there is a motivating force for them to ensure that the activity undertaken succeeds.
- Thirdly, participation results in enhanced knowledge generation, as participation of many people result in a culmination of complimentary knowledge leading to a better understanding of an issue (Biswas 2000: 168). Moreover, participation of indigenous people would reflect time tested traditional wisdom in development interventions. Furthermore, such a process will improve the knowledge of local people as well as of the external facilitator, and it would be more widely accessible when properly documented.

Participation of communities in the development process, however, remains a much contested notion. The term participation itself is very dynamic, and lacks a universal definition. There are broadly two different notions of participation, those that relate to the means and ends of a development process (Singh/Murari 2001: 14).

- The first school of thought views participation as 'means' of a development process. In other words, participation of local communities is a strategic component to attain the objectives of a project, as participation ensures smooth and effective implementation of the project.
- Conversely, the second notion, which sees participation as an 'end' of a development process, envi-

Figure 59.13: Mobilization of communities through village meetings and interactions. Jal Sabha (village water user association) interacting with JBF Trust functionaries. **Source:** Photo by Kanupriya Harish.

> sions developing and strengthening capacities of communities whereby common people access and control resources which would improve their living conditions (Singh/Murari 2001: 14).

Clearly the second notion, as it is a process that unfolds over time, is more sustainable and long term in nature than the first one which lasts only during the implementation of a project. This is particularly relevant since underdevelopment is increasingly recognized as a result of non-participation and lack of 'voice' of local communities in managing and controlling the natural resources. Therefore, the authors believe that the participation of the community in the development process should be emancipatory, leading to community ownership and sustainable control of natural resources. Apart from the above notion there are broadly three different interpretations of participation (Oakley 1991: 8).

- Firstly, the dominant interpretation of participation views it as implying a 'community contribution' in development projects. The contribution, either cash or kind, would ensure ownership of communities in the development initiative. However, such a participation can be merely perfunctory and need not necessarily ensure control of local communities on natural resources.
- Secondly, 'participation as organization' is a widely adopted interpretation of participation. There are many village level or watershed level community organizations in India, formed by NGOs or government projects. These community-based institutions are widely seen as fundamental instruments of participation and essential for a bottom-up development. These institutions could enhance social networking and social capital and make positive interventions for development which would reflect traditional and collective wisdom. Nevertheless, these institutions could bring undesirable changes or reconstruct disparities, if the communities were not empowered and or all the sections in the community were not included.
- Thirdly, participation is interpreted as empowering local communities. In practice, empowerment of communities is a prerequisite for realizing the

Figure 59.16: Traditional water harvesting systems supported by Jal Bhagirathi Foundation in the Thar desert, in Rajasthan. **Source:** Photo by Kanupriya Harish.

Figure 59.19: A *talab* or village pond in the Thar desert in Rajasthan. **Source:** Photo by Kanupriya Harish.

above two interpretations of participation in letter and spirit. The term empowerment of communities has mainly two dimensions: enhancing the capacities and skills of communities and transferring the power of decision-making to communities.

A careful analysis of these different interpretations would reveal that all interpretations have their own merit, while none of them is comprehensive in encapsulating the objectives of participation mentioned earlier. Also, it is not possible to treat the above as either discrete or inseparable categories. However, an all-encompassing approach can definitely bring positive changes in the development of a region. Such an approach will include all the three above alternatives: community contribution, community organization and community empowerment. This approach would ensure community ownership, informed decisions, collective action, and best use of traditional wisdom.

59.4 Traditional Wisdom in the Thar Desert

The traditional water management in the Thar desert was embedded in a holistic and ecologically prudent matrix of *Agor* (catchment area), *Gauchar* (pastureland), and *Oran* (sacred groves-biodiversity repository) – the AGO (Mohnot 2003: 3; JBF 2009:

Figure 59.20: A village *talab* with a water channel in the Thar desert in Rajasthan. **Source:** Photo by Kanupriya Harish.

Figure 59.21: A woman filling water from a *talab* in the Thar desert, in Rajasthan. **Source:** Photo by Kanupriya Harish.

Figure 59.22: A camel drinking water from a *talab* in the Thar desert in Rajasthan. **Source:** Photo by Kanupriya Harish.

Figure 59.23: Water channel bring water from the catchment area to the *talab/nadi* in the Thar desert in Rajasthan . **Source:** Photo by Kanupriya Harish.

16). The *Agor* was well maintained and protected to feed and sustain village water bodies such as *talabs* (village ponds) and *nadis* (grassland ponds), situated in common pastureland (*gauchar*) were maintained as a support system for the livestock economy. On the other hand the *orans*, often associated with a water body, was and remains the most effective approach to protect biodiversity and improve retention and quality of water. *Orans* are the oldest natural resource depositories in the region. Some of the region's *orans* are 150–500 years old, while a few might even be 800 years old (Mohnot 2003: 9). These crucial community resources existed in most villages and were traditionally managed by the village community. Bringing spiritual values and worship, AGO remains the most effective way in conserving natural resources in villages.

The AGO matrix, however, has deteriorated due to the transfer of common property resources to centralized governance. The large population growth, of humans as well as livestock, also resulted in a mismanagement of AGO. These changes have resulted in severe ecological degradation and increasing desertification leading to a scarcity of water. Consequently the resilience of the community, particularly of the poor, to adverse climatic conditions has declined considerably (JBF 2009: 16). Although the government has attempted to promote centralized and huge water supply schemes, few of them have been sustainable in ensuring adequate water supply for the desert communities. Nowadays, there is an increased awareness about the importance of preserving traditional wis-

dom in addressing drinking water scarcity in the region.

Though the rainfall in this region is meagre (average 200 mm per year), harvesting rainfall is the effective way to address water scarcity. In fact, by collecting only rainwater, water security can be achieved in the region. Even with the lowest rainfall of 100 mm per year, one square kilometre in the region receives 100 million litres of water, which is equivalent to 1 million litres per capita per year. If one percentage of this rain was captured and stored for the use of humans, each person would get 10,000 litres per year or 27 litres per day, which is more than sufficient considering the demand in the region. However, the challenge remains in harvesting and storing one per cent of the rainfall. Even though one per cent efficiency in rain water harvesting appears an easily achievable task, it requires collective initiatives and appropriate technologies, since the rainfall in the region is erratic with varying intensity.

Recognizing the fact that rainfall in the region is meagre and unreliable, indigenous people, had learnt how to harvest rain effectively. The water harvesting systems such as *tankas, nadis* and *talabs* in the region deserve special mention. *Tankas or kunds* (figure 59.16 and 59.17) are underground cisterns, constructed for collecting and storing runoff water from natural or artificial catchments, or from a roof top (Singh/Sharma 2003: 143). This is the essential source of drinking water in many villages in the region. With capacities ranging from 10,000 litres to 600,000 litres, these are efficient ways of collecting and storing rain water (Khan 1998: 168). *Nadis* or *Talabs* are ponds, dug at natural depression in land to collect water from catchment areas which could be *agor, gauchar* and or *oran*. The runoff from the catchment area is tapped through water channels and directed to the ponds. With a storage capacity ranging from 15,000 m^3 to 250,000 m^3, the *nadis* and *talabs* are convenient but suboptimal water harvesting structures in the Thar Desert (Athavale 2003: 96). The traditional ponds are suboptimal because of seepage and evaporation loss. The water availability in *nadis* and *talabs* ranges from 2 months to 12 months depending on its size as well as the size of the catchment area.

Box 59.1: Jal Bhagirathi Foundation. **Source:** JBF.

The *Jal Bhagirathi Foundation* (JBF) was established as a Trust in India on 15 January 2002. The organization serves to regenerate community leadership and institutional support to strike a balance between environmental capacities and people's needs, especially in the access of drinking water. By positioning its work and learning at a wider level for further replication, it contributes towards the ongoing debate on pro poor policies.

Working in the Marwar region of the Thar desert the Foundation has been focusing on improving the water security of poor communities through renovating and creating traditional water harvesting and storage structures, and building community institutions for their management. This focus underscores a strategic approach for adaptation to climate change by providing an enabling environment for people to increase resilience to their hostile and varying climate. JBF is driven by its strategic vision of "Water security sustained by responsive governance and inclusive growth leading to sustainable development."

The Foundation is headed by HH Maharaja Gaj Singh of Marwar, and Shri Rajendra Singh (winner of Magsaysay Award and popularly known as the 'Water Gandhi'). With the leadership of great visionaries and the proactive involvement of highly qualified professional staff, JBF is probably the only NGO in India that works with internationally recognized management standards, and has been awarded an ISO 9001-2000 certification. JBF has a strong partnership with the UNDP and Italian Development Cooperation, and has also been supported by the Wells for India, the Prince's Charity and UNICEF.

59.5 Coping with a Harsh and Changing Environment

This section reviews the activities of the *Jal Bhagirathi Foundation* (JBF), a leading NGO in the region (box 59.1), to support communities in coping with the harsh and changing environment by adopting a bottom-up participatory approach. The JBF has been working in a project area spread over 2,500 km^2 in the districts of Jodhpur, Pali and Barmer in the Marwar region, situated in the western part of Rajasthan in the Thar desert (figure 59.27).

The term 'Marwar' is derived from the Sanskrit word of 'Maruwat', which means 'Land of Death', referring to the harsh environment. Since the Foundation's mission is to create an enabling environment in which desert communities can access adequate drinking water, it envisions participation of communities leading to community ownership and sustainable control of water resources by them. The JBF pursues bottom-up participatory strategies for strengthening the capacity of desert communities to manage their scarce water resources through adaptive strategies built on traditional best practices of water harvesting. The participatory approach followed by the JBF is encompassing all three interpretations introduced above: a) community organizations, b) community contribution and c) community empowerment.

The Foundation emphasizes strengthening *community organizations* to effectively manage natural resources, especially water. A four-tiered system of community institutions from the village level called the *Jal Sabha* (village water user association) to the regional level called the *Jal Sansad*, ensures active participation of the actual beneficiary community, including women and marginalized sections of the society, from the formulation of the project to the actual implementation.

- The *Jal Sabha* or the Water Users' Association is a village level forum where people from all habitations in a village congregate, discuss problems, seek solutions and assert priorities. This institution at the base level of the tier is considered critical for the participation and community ownership and develops micro-plans as well as specific proposals for water and natural resource development in the village. It is also responsible for the execution of micro projects and mobilization of community resources.
- The *Jal Samiti* or the Water Development Group is a block level forum and comprises of members of *Jal Sabha* and key community leaders from the area. They meet on a periodic basis to review the proposals received from *Jal Sabhas*. They interact with village representatives and help them to collectively assess the prevailing situation, voice their concerns, develop strategies to counter problems, and advocate and build equitable systems for managing and disbursing financial resources within the block.
- The *Jal Parishad* or the Water Forum has been set up at division level with members consisting of people's representatives as well as experts from reputed resource institutions and members nominated by the JBF. The *Parishad* meets every month to review projects and sanction new ones. It also plays a very active role in assisting the JBF for

Figure 59.27: Project Area of Jal Bhagirathi Foundation in Rajasthan State, India. **Source:** © JBF 2009.

developing future strategies and providing a road map for strengthening community action.

- Lastly, the *Jal Sansad* or the Stakeholders Forum has been constituted for the entire Marwar region and it is represented by all stakeholders, i.e. key community leaders, government representatives, staff of the JBF, renowned development practitioners from the NGO sector and volunteers. The Sansad reviews the annual progress made by JBF and finalizes the next year's work plan. It is a common platform where all stakeholders of the JBF projects meet and interact to finalize its annual strategic planning document.

The four tier institutional arrangement promotes 'participation as organization' and a strong sense of ownership of development projects from the planning phase among community members. It also entrusts the community with decision-making power.

In the process of developing micro projects by *Jal Sabhas*, the need for a *community contribution* has been well established as a norm and practice. In all cases at least 30 per cent of the contribution of the total cost of a micro project is raised by the Jal Sabhas. In the case of *Jal Sabhas* with the upper caste communities the contribution is 50 per cent, which highlights the policy of positive discrimination for the backward communities to ensure inclusive growth. In

Box 59.2: *Rodwa Khurd*: Achieving water security in the desert. **Source**: JBF.

The village Rodwa Khurd comprises of 275 households. It is situated at a distance of 50 kms from Jodhpur in the Barmer District of Rajasthan State. The main occupation of the villagers is agriculture and animal husbandry that is mainly dependent on the monsoon rains.

The village was facing acute scarcity of drinking water because the groundwater in the area is saline and unsuitable for drinking. The '*talab*' (pond) in this village is called the '*gawai talab*' (meaning the *talab* of the village) was the only source of drinking water. However, due to improper maintenance, it was silted and could hold water only for three to four months forcing residents to buy water from long distances for the remaining eight months. Although there is a government *Ground Level Reservoir* (GLR), a *Reinforced cement concrete* (RCC) storage tank connected to the government distribution system, it has erratic supply (once or twice a month) and the water supplied from a nearby well is unsuitable for drinking due to salinity. Women in the village had to go long distances walking under the scorching sun to fetch water, spending most of the day time.

Given the above situation of severe shortage of drinking water, the villagers decided to increase the capacity of the *talab* to harvest rainwater. They knew, the rain provided them with enough water for most of the year, if only they were able to retain it.

Facilitated by JBF, they organized themselves into a '*Jal Sabha*' (Water User's Association). With an NOC (no objection certificate) of gram *panchayat* (local government), they made a micro project to enhance the capacity of the *talab* by 8,500 m^3. The Jal Sabha members collected money from the villagers collecting 30 per cent of the total cost and deposited it in the *Jal Kosh* (Development Fund). The project was completed at a total cost of 153,043 Indian Rupees in 2007, with 70 per cent of the cost given by JBF as a grant.

Following the completion of the excavation and the increased capacity of the talab to retain water, the village now has water security for 12 months; the *talab* retains water for the whole year and they store water in *tankas* (underground concrete tank) closer to habitations, reducing the drudgery of women.

Most importantly, this community institution could establish norms for managing the scarce water resource efficiently. Now, people in the village have to pay a fixed contribution every month for cleaning and maintaining the *talab*. For this, Jal Sabha maintains a token system and deposits the collected money in a bank account for ensuring transparency and accountability. This fund (*Jal Kosh*) also ensures sustainability of the project. Moreover, the *Jal Sabha* meets regularly, monitors and controls the use of water from the *talab*, ensuring that it is distributed equitably. For drought years and in years of low rainfall, the Jal Sabha employs stricter norms of usage, to avoid wastage of water and conserve it for a long time, thus adapting to the adverse climate.

both cases the contribution is made as a collective effort with the participation of every individual in the village depending on their capacities. The people's contribution is called *Jal Kosh* (development fund) and deposited in a bank account ensuring better transparency and accountability. Furthermore, it raises resources through a nominal water tariff charged for water transported from the village pond to the tanks of the community or of individuals for ensuring the maintenance of the structures, thereby ensuring sustainability of the project. This strategy of the participatory approach has resulted in a high sense of ownership of the community over its harvesting structures. Also, costs have been brought down by at least 140 per cent for the average household because water catchment and storage capacities eliminate the need to purchase water during most of the year, and in periods of low rainfall.

The institutional arrangement and community contribution is complimented with *community empowerment* programmes to support village level institutions to adopt a pragmatic approach towards development of common property resources, and proper management of ecological resources. Regular field level trainings as well as organized training programmes are conducted to equip community representatives, village volunteers and facilitators in microplanning, community mobilization, technical aspects of water harvesting structures, and project planning and management. Additionally, exposure visits to successful community based projects are organized both within and outside the state. These programmes empower community institutions, particularly the *Jal Sabha* at the base level, to make informed decisions themselves on various development initiatives. To further advance capacity development programmes and networking the JBF has established a Water Resource Centre in Bijolai, in Jodhpur (box 59.2).

Thus, the JBF is involved in creating an enabling environment for communities to develop adaptive strategies and to initiate location specific interventions. With the participation from the community, the JBF acts as a catalyst and facilitator for the construction and restoration of traditional water harvesting systems such as

Box 59.3: Water Resource Centre. **Source**: JBF.

Jal Bhagirathi Foundation has established a 'Water Resource Centre', as an institution that is a conclave to exchange ideas and experiences by civil society groups as well as knowledge centres from all over India and abroad. Refurbishing the historic Bijolai Palace in Jodhpur and recreating the traditional ambience of this heritage property, the Centre has a world class facility for conferences, training and accommodation. It is the organizational entity concerned with capacity development, knowledge generation and information dissemination activities of the Foundation.

The 'Water Resource Centre' is also facilitating knowledge networking and policy advocacy. It has partnerships with national and international resource centres, technical agencies, and knowledge networks; it thus serves as a channel for the flow of knowledge and experience. It is envisioned as a centre for knowledge, best practices, useful data and information related to water quality and availability. Furthermore, it would facilitate dialogues on water-related debates and policies, based on knowledge generated from field experiences and action oriented research with partnerships of think tanks and other knowledge centres. Thus, it will also contribute to innovation in natural resource development and social engineering.

Additionally, it acts as a venue for national and regional conferences, conventions, workshops and symposiums to support the objectives of the Foundation. This is also the venue for networking to create public awareness and optimize social cohesion among communities by providing a platform for continued interaction. Thus, this institution disseminates 'best practices' in community management and control of natural resources and strengthens existing civil society networks to promote community participation in adaptive strategies to climate change and environmental regeneration. Effectively, the Centre promotes an active and enlightened rural community by training and capacitating rural volunteer groups by accomplished social workers to mobilize communities in water resource management.

Furthermore, it is becoming a favourable location for researchers and students who are studying various issues relating to water and rural development including community-based development, social capital, civil society, water resource management, adaptation to climate change, rain water harvesting, water quality and so on. With direct access to the rather isolated desert communities and experiences in working with them to address the water crises, the Foundation has an unmatched potential for undertaking collaborative and multi disciplinary research projects.

- *talab* – a village pond used for drinking water by human and livestock,
- *nadi* – a pond situated in grasslands,
- *nahar* – or water channels situated in catchment areas for directing runoff to ponds,
- *beri* – shallow wells for collecting rain water from subsurface soil. Usually located near to sand dunes or close to ponds, from which water seeps into the well.
- *tankas* - rainwater harvesting tanks.

The aim is to enable people to adapt to climate variability and to provide drought relief to a region extremely distressed with repeated droughts and also focus on community-driven solutions for long-term drought proofing of the project area**.** Thus emphasis is laid on a 'bottom-up approach' as against the 'top-down' approach aiming at a revival and improvement of traditional water harvesting practices.

Over the past six years the JBF has supported the construction of 300 village water harvesting structures in nearly 200 villages. Through these structures, nearly 180,000 people or 2.7 per cent of the population in the project area have benefited directly in terms of improved water availability and access. Additionally, an evaluation study commissioned by UNDP reveals that water availability in a year has now been extended to 6–8 months from an average of two months, despite the increasing climatic variability. This includes a number of villages with water availability around the year. Most importantly, the distance to the water sources has been considerably reduced, which reduces the drudgery of women who spent nearly half of the day in fetching water.

The process is found successful in strengthening decentralized governance particularly at the local level supporting the national policy of inclusive development. All the projects of *Jal Sabha* get approval from the panchayat (local governing body) before submitting it to *Jal Parishad* and there is active representation of panchayat members in *Jal Sabhas*. There are some cases where Jal Sabha influences decision making of the local government relating to development projects in their villages. Thus a convergence of the political and volunteer groups has taken place that are together involved in developing and managing traditional water harvesting micro projects.

Through its participatory methodology, JBF has ensured that the *Jal Sabhas* render equal opportunities for all the sections in the community, which enables inclusive governance at the village level. Representation of women and marginalized sections in Jal Sabhas, particularly in leading positions, ensures that

voice of the disadvantaged is heard in community decision making in addition to equitable access of natural resources. Particularly, JBF's inclusive policy of community contribution ensures that all the community members, irrespective of caste and class, contribute to a micro project. This provides ownership of the project to everyone in the village.

Most significantly, these simple structures of community governance are found as effective means to cope with the changing climate. In the year 2009, which is a drought year, there is only little production from agriculture, but a large number of project villages have drinking water security. This has become possible with effective use of traditional technologies as well as adaptive norms established by the *Jal Sabhas* for efficient use of the limited water resources. The adaptive norms developed with the social capital ensure the control of water usage, restrain waste of water and promote conserving water for distressed months, resulting in a successful coping mechanism.

Consequently, a 'Community Led Water Management System' has evolved in the project area. The village level water harvesting structures such as *talabs* and *nadis* tap runoff from the catchment (AGO) through feeder channels. Though these structures are normally located at the outskirts of the village, water is being transported to *tankas* in the vicinity of the households. It helps to reduce the drudgery of women in fetching water from far away located water harvesting structures and also to reduce the evaporation and seepage losses which are greater for surface water harvesting bodies. Some of the villages in the project area of JBF have become self-reliant in terms of drinking water by adopting this water management system and successfully established replicable and sustainable models of community-led traditional water management for the region. Furthermore, Jal Sabhas have started to give emphasis on the protection and sustainable management of agors, gauchars and orans (they act as catchments for ponds) that are repositories of biodiversity and the source of multiple products such as water, grass, fodder, fuel-wood, timber, and non-timber tree products. Management of these resources is also fundamental to ecosystem stability and contributes to adaptation in the context of climate change.*J*

59.6 Conclusion

From this case study of the Thar Desert, the most densely populated desert in the world, it could be seen that a bottom-up participatory approach is a realistic way forward to develop adaptation strategies in the context of climate change. The region is characterized by low and erratic rainfall, less nutritious sandy soil, deep and often saline ground water, sparse vegetation, and strong sun and winds. Rainfall in the area is very low, with an average of 200 mm per annum. Droughts of varying intensities are a recurring phenomenon in the region. The already stressed water sector is also a victim to climate change; the region has been identified as one of the most vulnerable states in India. A bottom-up participatory approach is being followed by a leading NGO in the region named Jal Bhagirathi Foundation, which has been supporting the desert communities in developing strategies to cope with adverse and changing climatic conditions. It helps people to adapt to present climate variability based on traditional wisdom and then to develop strategies to initiate responses to future climate variability. The process involves facilitating social capital through creating community organizations, promoting community contribution and empowering communities. This approach is based on the realization that adaptation need not be started from scratch. A bottom-up participatory approach that acknowledges various coping mechanisms developed through traditional iterative learning process and that envisions control of natural resources by local people would be effective in developing appropriate adaptation strategies, not only in the Thar Desert but also in a wider context. The examples set by JBF, can be enhanced further and replicated to other villages through local governments, leading to a convergence of voluntary and political spheres.

This participatory bottom-up approach, unlike the conventional external expert approach, enables communities to enhance their coping capacities resulting in adaptive local governance. Since it is rooted in the tradition and local knowledge, the approach is easily understandable and internalized by the communities. This approach, which surrogates the conventional external expert approach, would also have large potential in other sectors like energy, agriculture and health, leading to a more integrated and meaningful adaptation to climate change.

60 Coping with Water Scarcity in the Sahel: Assessing Groundwater Resources in the Western Sahel

Abdelkader Dodo, Mohamedou Ould Baba Sy and Jihed Ghannem

60.1 Introduction[1, 2]

The *Iullemeden Aquifer System* (IAS), shared by Mali, Niger and Nigeria, consists of a number of sedimentary deposits containing two large aquifers: the *Continental intercalaire* (Ci)[3] superseded by the *Continental Terminal* (CT).[4]

It covers a total area of approximately 500,000 km² and constitutes the main sustainable source of water for most communities in the region. The Iullemeden Aquifer System's water resources are considerable but slightly renewable. These water resources are subject to an exponential rise in abstractions – which went from 50 million m^3 in 1970 to 180 million m^3 in 2004 – spurred by a growing water demand linked to population growth (6 million inhabitants in 1970; 15 million in 2000; and a projected 30 million in 2025). This has resulted in an overexploitation since 1995. Studies have revealed that the Niger River receives an estimated 125 million m^3 annually from the Iullemeden Aquifer System. The rational and informed management of the water resources of the Iullemeden Aquifer System appears to be a must.

The analysis of annual rainfall reveals a clear trend starting from the year 1969–1970 (figure 60.1). Three trends can be observed in the basin: a 'wet' period before 1970, a 'dry' period from 1970 to 1993 and the beginning of a 'wet' period from 1994 to date (Anonymous 2003; Hubert/Carbonnel 1987; Hubert/Carbonnel/Chaouche 1989; Traoré/Abdou 2005).

Rainfall data collected in Guinea (Diallo/Diallo 2004), at the Koulikoro and Diré stations in Mali (Diarra/Cissé 2004) and the Niamey station in Niger (Soumana/Barhouni 2004) reveal a rainfall deficit starting from the year 1969–1970 and estimated at 20 to 30 per cent below the levels of the wet period.
This rainfall deficit has caused isohyets[5] to migrate southwards by approximately 100 km, thus reflecting rising aridity (figure 60.2). It has had a significant

1 This chapter draws on several studies in which the authors were involved at OSS (2007, 2007a, 2008). A summary in English is at: <http://www.oss-online.org/pdf/synth-sai_En.pdf>. The material is used here with the permission of the director of OSS. This paper has been produced under the supervision of Mr. Youba Sokona, the OSS Executive Secretary. This paper is the result of an important endeavour undertaken by the *Sahara and Sahel Observatory* (OSS) in partnership with Mali, Niger and Nigeria on the *Iullemeden Aquifer System* (IAS) since 2004 in the framework of the regional project "Managing Hydrogeological Risks in the Iullemeden Aquifer System (IAS)". The authors wish to thank the anonymous reviewers for their suggestions and critical comments.

2 Keywords: Shared aquifers, Continental intercalaire, Continental Terminal, database, Geographic Information System, Mathematical model, transboundary risks, joint management, arid and semi-arid regions, West Africa.

3 The Continental intercalaire indicates a thick series (> 1000 m) of detrital formations of secondary age (Jurassic – Cretaceous) with alternations of sands, sandstones, clays, coherent gravels and conglomerates which accumulated before the marine transgression of the Upper Cretaceous. The Continental intercalaire is the greatest multi-layer aquifer system in the Iullemeden basin. It is unconfined at the edge and confined in the centre of the basin. Detrital is a geological term used to describe particles of rock derived from pre-existing rock through processes of weathering and erosion.

4 The *Continental Terminal* (CT) is a multi-layer aquifers system contained in a heterogeneous continental series of tertiary age of the Iullemeden basin. Its sediments are presented by the alternations of sand and clays, and by sandstone with coherent gravel intercalation. The series is characterized by the many ones and fast lateral and vertical variations of the facies. (Facies refers to a body of rock or sediment with specified characteristics.) These two main principal aquifers of IAS (Ci and CT) are separated by an *aquitard* mainly made up of the Palaeocene and Eocene formations and which locally includes (in Mali) part of the Upper Cretaceous.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_60, © Springer-Verlag Berlin Heidelberg 2011

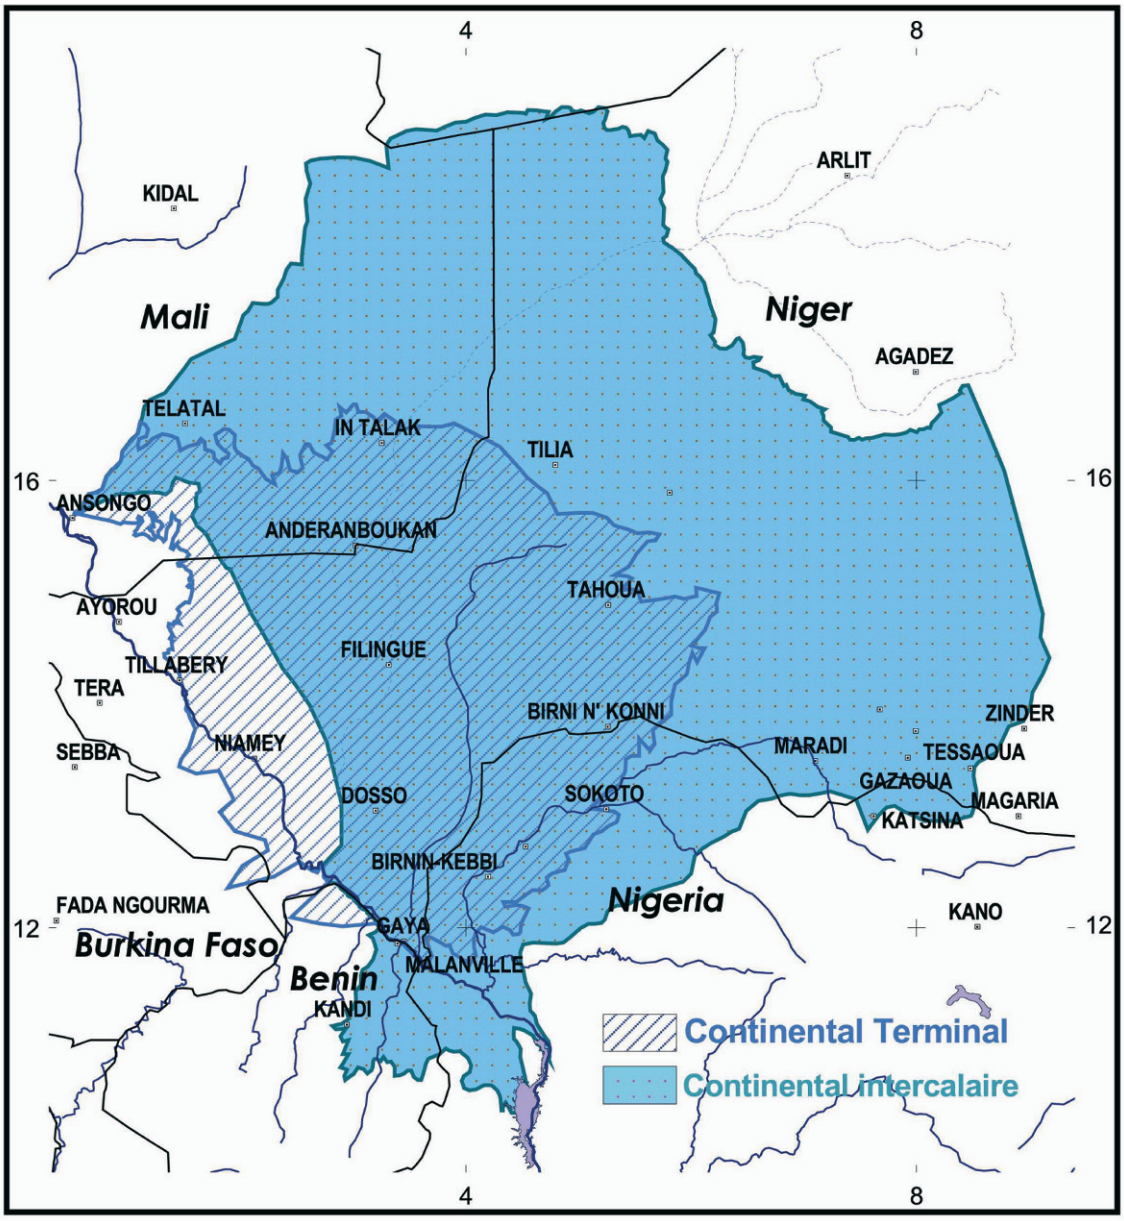
impact on the Niger River regimes. As a matter of fact, the runoff diminished by approximately 20 to 50 per cent with a sharp decline in the flow that has caused the runoff to stop at the Douna station in Mali in 1983, in 1984 and in 1987, and in Niamey in 1985 – an occurrence in which the Niger River's bed literally dried up.

5 Isohyets: A line drawn through geographical points recording equal amounts of precipitation during a specific period.

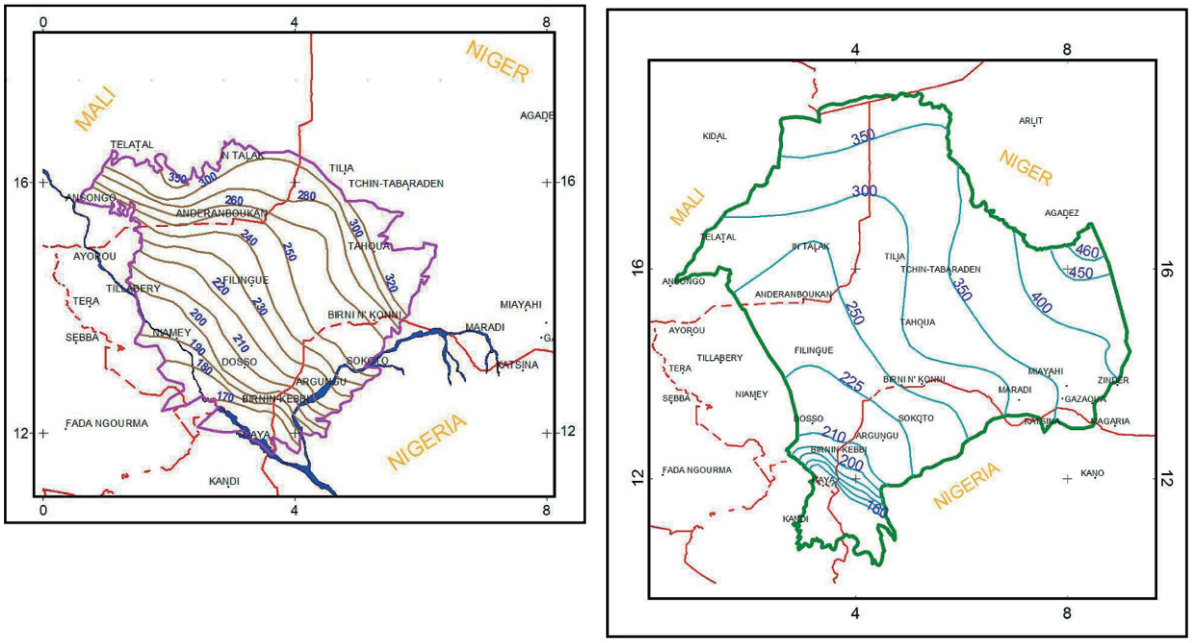
Figure 60.3: Limits of the main aquifers of the Iullemeden Aquifer System. **Source:** OSS.



The decline in rainfall has led to the intensification of abstractions from the water tables of both the *Continental intercalaire* (Ci) and the *Continental Terminal* (CT) (Greigert 1978; Margat 1982; Bonnier/Jackou/Karbo 1991; Dodo 1992) under the pressure of rising water demand. These resources constitute the main source of sustainable water supply for the communities in a region which has witnessed significant population growth during that period. The quality of the groundwater is degrading due to pollution of various origins (Diarra/Cissé 2004; Soumana/Barhouni 2004; Hanidu/Ude 2004). Resorting to increasingly deeper water with high levels of fluoride (between 9 to 12 mg/l in the border zone of Niger and Nigeria) causes various water-related diseases such as dental and skeletal fluorosis (more than 600 children were irreversibly disfigured) (OSS 2007).

In light of this situation, the comprehensive and joint assessment of the water resources of the Iullemeden Aquifer System has become crucial. This assessment has been undertaken with a database, a *Geographic Information System* (GIS) and a mathematical model.

Figure 60.4: Piezometric map of the CT and the CI in 1970. **Sources:** OSS.



60.2 Hydrogeological Setting

The *Iullemeden Aquifer System* (IAS) is located in West Africa. It is shared by Mali, Niger and Nigeria and consists of a number of sedimentary deposits containing two large aquifers, namely the *Continental intercalaire* (Ci) which is superseded by the *Continental Terminal* (CT). The IAS covers a total area of approximately 500,000 km², and is crossed by the Niger River – the third longest river in Africa with 4200 km (figure 60.3).

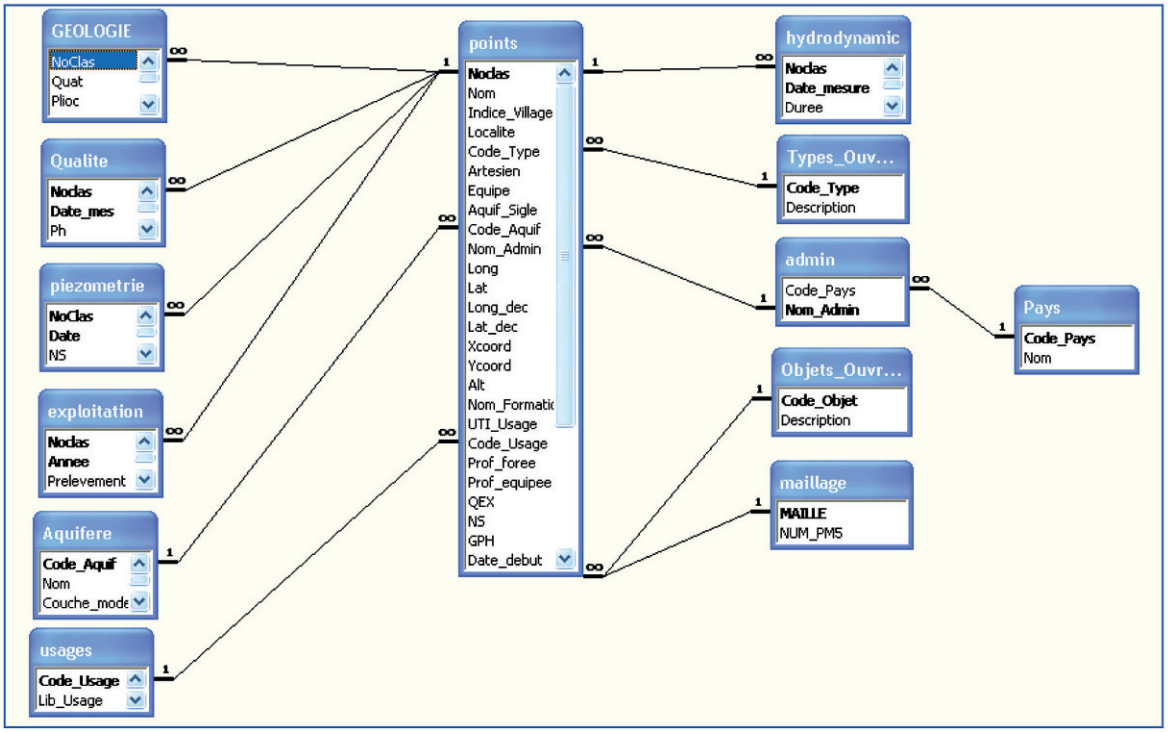
The *Continental Terminal* (CT) includes the tertiary aquifers (CT_1, CT_2 and CT_3) and the shallow aquifers located in quaternary alluvial deposits (Boeckh 1965; Greigert 1978; Margat 1982; Dodo 1992). The *Continental intercalaire* (Ci) is the largest cretaceous aquifer in the Iullemeden basin given its extent and the thickness of its layers (more than 1000 meters at certain locations). It also includes the top level of the lower cretaceous (The Continental Hamadien) (Greigert 1978; Margat 1982; Dodo 1992). The Continental Terminal and the Continental intercalaire have average transmissivity ranging from 10^{-4} to 10^{-2} m²/s.

These two components are separated by an aquitard consisting of Palaeocene and Eocene formations which include – in Mali, for example – thick, mainly marine, upper cretaceous sediments. It stimulates leakage between the Ci and the CT with a mean vertical permeability value of 2.5 x 10^{-10} m/s (ETH 1999).

The piezometric maps of these aquifers were drawn up for the year 1970 – considered as the baseline defining the state of equilibrium of the aquifer system untouched by abstractions (OSS 2007). The piezometric map of the Continental Terminal (figure 60.4a) shows the CT water table's main drainage axes as being oriented North-West South-East and North-East South-West. Recharge zones are located on the North-Eastern (in Niger) and North-Western periphery (in Mali, the Taoudeni basin). They also include the Southern part with the contributions of Goulbi de Maradi – or River Rima. Groundwater resources flow mainly from the North-West towards the South. The discharge zones are mainly the Niger River and the Goulbi de Maradi – which is one of the Niger River's tributaries (OSS 2007).

The piezometric map of the Continental intercalaire (figure 60.4b) shows that the main recharge zones are the Hoggar Mountains to the North, and Goulbi de Maradi to the South. Groundwater resources flow mainly from the North, the North-West and North-East to the South. The Niger River constitutes the main discharge of the Ci water table (OSS 2007).

Figure 60.5: Structure of the IAS relational database. **Source:** OSS.



60.3 The Database and Geographic Information System

The IAS database is administered by Microsoft ACCESS (2000). The software allows the use and management of the database in the three countries (Mali, Niger and Nigeria), and provides an interface with the *Geographic Information System* (GIS). The 2000 edition of this software allows a smooth migration to the SQL-Server as envisaged by the countries (OSS 2003, 2007, 2007a, 2008).[6] The common database of the Iullemeden Aquifer System (IAS) contains data collected in the three countries. The data cover the climatic, hydrological, geological and hydrogeological aspects. The hydrogeological data concern approximately 17,200 water points – 740 in Mali (4 per cent), 16,170 in Niger (94 per cent) and 300 in Nigeria (2 per cent). These data were collected, formatted, organized and stored in a relational database (figure 60.5) shared by the three countries. This, in turn, makes it easier to use these data effectively.

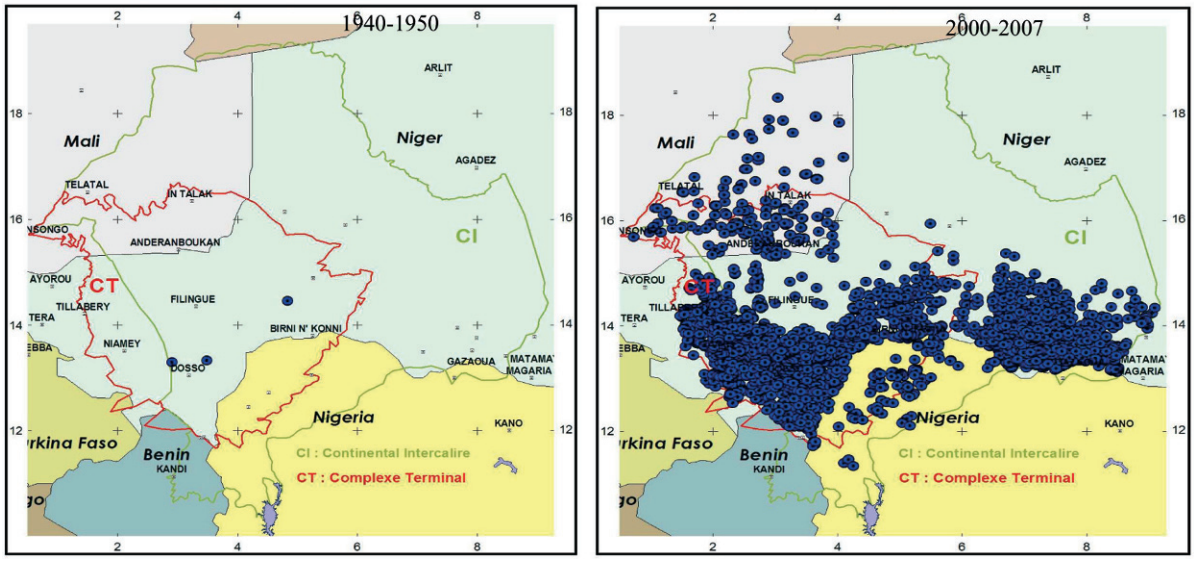
The database's structure shows the central role of the 'points' column which is related, on the one hand, to the identification tables (country, hydrodynamic parameters,, type-'ouvrage', admin, object 'ouvrage', 'maillage', ...)[7], and, on the other hand, to the variables tables (geology, quality, piezometry[8], exploitation, aquifers, uses,...). The relations between the central 'points' column and the other can be univoque (1 to 1) or multiple (one to ****). The processing and formatting of information is performed by tolls such as 'Rockworks' and 'Photoshop' for geological data, and 'Arcview' and 'Mapinfo' for hydrogeological data.

6 The Microsoft SQL Server is the high-performance relational database engine by Microsoft for its Windows Servers and development tools. It is an excellent back-end database for web server applications and software, and is highly recommended for active web sites.

7 Ouvrage = Water point (borehole, well dug well, spring). Admin= administrative unit. Maillage= Model grid: division of the region into equal square cells.

8 Piezometry is the use of a water point for quantitative monitoring (fluctuation of the water level) of an aquifer. It allows to obtain regularly continuous serial data.

Figure 60.6: Evolution of water points since 1940 to date. **Sources:** OSS.



60.4 The Geographic Information System (GIS)

The ARCVIEW software has been selected for its user-friendliness, performance, perfect compatibility with ACCESS and its common use for studies in the water sector. Its powerful scripting language allows the development of the customized modules required to link the GIS with the mathematical model. Thus, a database-GIS-Model interface has been developed in order to produce thematic maps which enable the processing and allow a better visualization of the information. This has in turn provided valuable decision-support tools (figure 60.6). These include maps describing decade-long trends in the number of water points, piezometric maps, transmissivity[9] maps, and geological and hydrogeological correlations. It is therefore possible to see a clear rise in the number of water points across the IAS Basin over the last 40 years, particularly during the transition from the decades from 1960 to 1970 to that from 1980 to 1990. The latter had been declared by the United Nations General Assembly as the "International Decade for Drinking Water and Sanitation." During that period, countries had committed themselves to improve the standards and the quality of drinking water supply and sanitation, notably through developing water points.

60.5 The Mathematical Model of the IAS

The hydrodynamic model of the IAS has been built by using version 5 of the processing modflow (PM5) software package (Chiang/Kinzelbach 1998) based on the modflow code improved by the US Geological Survey (McDonald/Harbaugh 1988) which allows the modelling of water transfers within a multilayered aquifer system through the finite difference method.

Through the database-GIS-model interface, the data required for the calibration and operation of the model were imported directly from the database. Similarly, the results yielded by the model are exported to the database with no risks of alteration or distortion. In addition, the links between the database and the GIS allow the utilization of both the data and the modelling results for various outputs and graphic or cartographic illustrations. The model has yielded initial results on the dynamics of groundwater runoff, the assessment of the state of utilization of the groundwater resources, and the drawdown trends in the two aquifers.

9 The transmissivity of an aquifer is a measure of how much water can be transmitted horizontally, such as to a pumping well.

60.5.1 The Water Balance of the Iullemeden Aquifer System

The water balance of the *Iullemeden Aquifer System* (IAS) has been established in 1970 – with that year serving as a baseline (table 60.1). The main source of aquifer recharge comes from the direct infiltration of rain water estimated at 3.8 m^3/s, which constitutes 78 per cent of the global recharge estimated at 5 m^3/s, and 150 million m^3/year.

Table 60.1: Water balance of the Iullemeden Aquifer System in steady state (1970). **Source:** OSS.

Continental Terminal			
In (m^3/s)		Out (m^3/s)	
Direct infiltration from rainfall	3.29	Niger River	2.50
Leakance Ci[a]	0.013	Dallols	0.45
		Rima River	0.35
Total In	3.30	Total Out	3.30
Continental intercalaire			
In (m^3/s)		Out (m^3/s	
Direct infiltration from rainfall	0.55	Niger River	1.60
Recharge from Northern Boundary	0.29	Leakance CT	0.013
Rima River	0.77		
Total In	1.61	Total Out	1.61

a) Leackance refers in groundwater to the flow of water from or into an aquifer through an underlying or overlying semi-pervious layer.

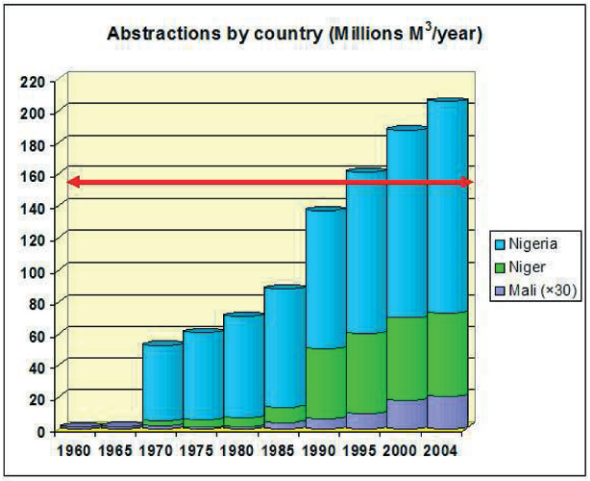
60.5.2 Groundwater Support for the Niger River

The model has revealed and quantified the support provided by groundwater to the flow of the Niger River and vice versa. The Niger River receives approximately 46 million m^3/year from the Continental intercalaire and 79 millions m^3/year from the Continental Terminal – with a total of 125 million m^3 per year. The Goulbi de Maradi, a tributary of the Niger River, contributes approximately 20 million m^3/year to the Continental intercalaire and receives about 12 million m^3/year from the Continental Terminal prior to its confluence with the Niger River.

60.5.3 Overexploitation of the Aquifers

The overexploitation threshold was exceeded in 1995. Starting from that year, abstractions estimated at 152 million m^3/year have outstripped recharge (the red line) estimated in 1970 at 150 million m^3/year (figure 60.7).

Figure 60.7: The overexploitation treshold was exceeded in 1995. **Source:** OSS.

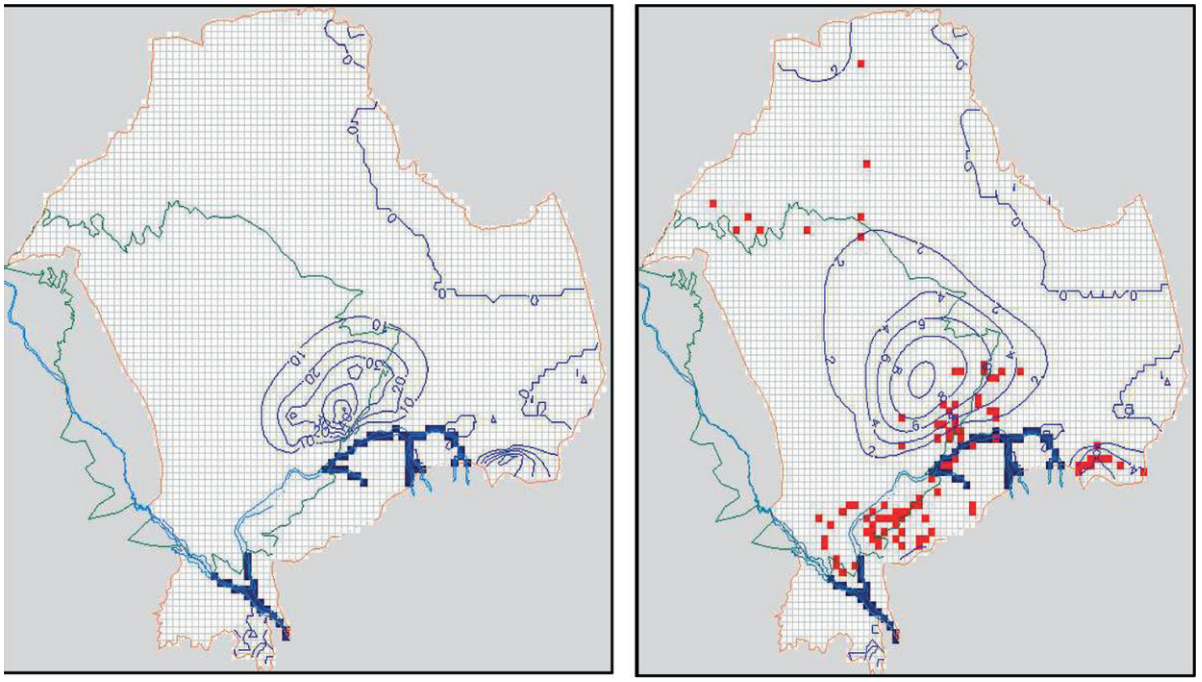


60.5.4 Exploratory Simulations

The hydrodynamic model of the IAS has allowed several simulations and forecasts to be performed. The system behaviour was simulated for the 1970–2004 period (figure 60.8a) and for the 2004–2025 period on the basis of the 'null hypothesis' (figure 60.8b). This hypothesis consists in maintaining abstractions at their 2004 levels and simulating their impact on the resources by 2025.

In the Continental intercalaire, for example, the most acute drawdowns in 2004 occurred in the eastern part of the basin around the Nigerien locality of Birni N'Konni with a maximum of 62 metres (figure 60.8a). The model's forecasts for 2025 show an additional ten-metre drawdown in the Ci (figure 60.8b). The risk zones are characterized by important drawdowns caused by an ever rising utilization. Being hardly renewable, the water resources of the Continental intercalaire (Dodo 1992) are subject to the threat of mining-style exploitation.

Figure 60.8: Drawdown in the Ci (a) in 2004 and additional drawdown in the Ci (b) by 2025. **Sources:** OSS.



60.6 Conclusion

The water resources of the Iullemeden Aquifer System are exposed to rising abstractions under unfavourable conditions caused, notably, by the impacts of climate change and natural variability. The main results and outputs obtained from the shared database, the Geographic Information System and the mathematical model provide Mali, Niger and Nigeria with an opportunity to acquire, for the first time, a kit of common decision-support tools. The support provided by groundwater to the runoff of the Niger River constitutes an alternative, particularly in periods of dramatic decline of the river's flow. While the Continental Terminal benefits from an annual recharge through direct infiltration of rainwater and contribution from the Niger River, the Continental intercalaire is almost totally confined. Its water resources are hardly renewable and exposed to a mining-style exploitation pattern.

61 Global Threats, Global Changes and Connected Communities in the Global Agrofood System

John Grin and Esther Marijnen

61.1 Introduction

61.1.1 Global Challenges

Maybe the most disturbing feature of the global influences discussed in this and previous volumes in this book series is that their impacts are not evenly distributed over the globe. For instance, as Úrsula Oswald Spring (chap. 62) points out below, while the benefits of using genetically modified organisms (GMOs) are likely to bestow especially on northern countries, their more problematic aspects are likely to be exacerbated by, and add to, the negative conditions prevailing in the South. As her analysis makes clear, only in an economically more equitable world economy and a more sustainable global agrofood system, GMOs may provide solutions to some of the more pressing challenges facing global food production. But how realistic is it to expect such global changes in food production?

Sreeja Nair's chapter 64 on adaptive management and co-management strategies as responses to climate change in India leaves us with similar questions. For instance, even for a large country like India, with a significant research and development capacity, it will not be easy to develop the type of scientific knowledge that is tailored to being integrated with local knowledge into appropriate technologies which match local conditions. Research and development are an essentially transnational undertaking, and around the globe they have hitherto been dominated by a modernist approach, which implies precisely the reverse. As Jim Scott has so eloquently put it, modernization processes, and the types of knowledge that have co-evolved with it (Grin 2010a) have brought about a "logic of homogenization and virtual elimination of local knowledge" and, with an Aristotelean notion, mtis – the craft to take contextual conditions into account (Scott 1998: 302; 309–341). Individual countries which, as Nair and Cecilia Conde (chap. 65) propose, wish to promote the converse kind of innovation, are facing the challenge that the required knowledge basis is globally underdeveloped, and that without further change this type of innovation will be economically disadvantaged. How to bring about, globally, a new type of development – one that like the currently dominant type of development benefits from the (implicit) alignment of innovation systems, governance arrangements and markets around the globe, but with a very different normative orientation?

61.1.2 Global Challenges Seen from Modernization Theory

This chapter seeks to help develop a conceptual basis for developing strategies to promote the process of global change required to deal with contemporary global problems. It does so, by drawing upon insights from Ulrich Beck, whose work on (global) risk society and reflexive modernization suggests fruitful ways of appreciating the complex relations between previous development patterns, current problems, and the conditions for future global changes implied in the brief discussion above. In the next section, we will briefly introduce some of his insights. To be sure, we are aware of the criticisms his work has evoked, and we share the complaint of frequently definitional and conceptual ambiguities. However, in the scope of this chapter we limit ourselves to discussing and elaborating some of his notions in a way which we ourselves feel helps us here, leaving aside the debates on his work. More specifically, we will mobilize his insights so as to appreciate, with some depth, the relations between earlier, global development processes, contemporary problems, and the conditions needed to resolve these by promoting a different sort of development.

At the core of our use of Beck's work are three insights. The first is his understanding of what he calls 'risk society'. This notion refers to the fact that many

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_61, © Springer-Verlag Berlin Heidelberg 2011

contemporary problems are rooted in the negative externalities that have come with past development processes (Beck 1992). Thus 'risk' in 'risk society' should be seen here as a broad, somewhat metaphorical designation comprising societal and physical risks (i.e. potential negative effects) as well as negative side effects that have already become manifest. They may, as Beck puts it, be seen as the dark side of the 'simple modernization' processes of 'first modernity', tailored to realizing progress on basis of knowledge to promote mankind's capacity to control nature and society. It is in the context of simple modernization that many of the uses of GMOs, discussed by Oswald Spring, have been conceived are producing their negative impacts on southern countries. The institutions of modern nation states that have co-evolved with simple modernization processes, have developed blind spots for risks and side effects (constituting 'unawareness', Beck 1999: 109–132) and lack capacities for designing and pursuing strategies which are able to deal with them effectively.

The second insight we wish to emphasize is that, now that concerns about risks have become increasingly widespread ("the politicization of side effects", Beck 1997), they start to feed back into the very processes and associate institutions that have generated them. A re-orientation of modernization is therefore necessary towards the vision of a "radicalized modernity" or "second modernity" (Beck 1997): the vision that we may and must eventually realize the "demand of the Enlightenment" through a process of reflexive modernization – modernization driven by the desire to pre-empt side effects. The modes of food production argued for by Oswald Spring, and the strategies for meeting climate changes proposed by Conde and Nair, may serve as examples of the type of development hinted at here.

More specifically, reflexive modernization implies growing awareness in industrial enterprises, governmental organizations, and knowledge institutes – awareness of the risks associated with simple modernization processes, and awareness of the incapacity of these actors and their institutionalized relations to maintain societal trust in the face of these risks, and to come up with novel solutions (Beck 1992, 1999: 72–90). The consensus underlying the institutional realms of state, society, market, and science and their mutual alignment becomes disputed (Beck 1999: 100). Firms no longer can hide behind the backs of governmental regulations or 'objective reports' when responding to criticism on the environmental effects of their production processes, or their being engaged in child labour. Other than ideal typical, Weberian bureaucracies, current governmental bodies can no longer presume legitimacy of their decisions solely on the basis of the input legitimacy (Scharpf 1997a) of democratic procedures or of expert judgement. And experts have lost self-evident public trust (Giddens 1991). *Vis-à-vis* an increasingly aware civil society, they can no longer rely on the earlier consensus on simple modernization.[1] Our remarks above on the difficulties implied in Nair's recommendations may be understood as acknowledgements of this unawareness and incapacity.

Novel modes of social, economic, and technological development need to be developed, and trust and legitimacy need to be actively produced in the process. As a consequence, "[r]eflexive modernization becomes discursive modernization" and requires novel institutional loci in order to reach novel understandings and create novel connections between the institutional realms in-between which they are located (Beck 1999: 101). These processes Beck calls sub-politics: politics which is being informed by an increasingly knowledgeable civil society. *Subpolitics* does not rely on 'standard' expertise, but mobilizes a plurality of experts as well as sources of more informal or local knowledge in order to design modes of development driven by the desire to pre-empt risk. *Subpolitics* thus may be seen as a communicative rationality according to Habermas, but incorporating a reflexivity that also feeds back into the Latourian dominance of institutionalized discourses as well as incumbent institutions.

Finally, we will draw on a set of interconnected insights that fare under the designation of *global* risk society. Risks produced at one place may be felt at a variety of locations around the globe – though often unequally distributed (Beck 2007; Oswald Spring, chap. 62). Also, mass media and the internet have helped to produce a transnational civil society which may nurture solidarity and share concerns around the globe (Kaldor 2003). Against that background, Beck (1999: 37–40, 2005: 103 ff.) argues, in a Deweyan way, that risks may produce new, global publics that engage in subpolitics that may affect national and transnational policy-making organizations as well as (transnational) firms.

The publics that thus come together may be very different in nature. Some, especially on the African continent, have experienced the dark side of Euro-

1 For a more precise discussion of these transformations, see Grin (2010a: 237–248).

pean first modernity, colonization. Amongst such publics, there may be differing views on what sort of modernization can avoid a new round of European (western) imperialism. In other countries, especially in Asia, critique may be driven by the desire for a modernity with room for national identities and cultural heritage, for modernization without the problematic outcomes of western modernization. Others, especially in Europe, may be primarily driven by concerns on the ecological side effects of early modernization (Beck 2005: 106–110). Thus, Beck argues, the meaning of 'risks' and 'side effects', as well as the strategies to deal with them, are contingent. Thus, as he (Beck 2005: 1010) quotes David Held, global subpolitics arises from "overlapping communities of fate."

61.2 Research Questions and Case Study

Clearly, the idea of reflexive modernization with different communities of fate as key players connects well to the increasing recognition of the need to design strategies from local contexts and in cooperation with the stakeholders involved (chap. by Conde, Nair and Oswald Spring). Yet, one crucial question remains underexplored in Beck's work: how may such different communities actually join forces, across space and in spite of differences in context and prehistory, in order to generate the transformative power needed to re-orient development patterns? This is the central question we set out to answer in this chapter.

To that end, empirically, we will draw on an example from the global agrofood system: the 1992 reforms of the European Union's *Common Agricultural Policy* (EU-CAP) and its implementation in three different EU member states in the late 1990's. The reforms must be contextualized in the then ongoing Uruguay Round of the world trade negotiations as well as internal debates within the EU and its member states on the CAP's financial, social, and ecological aspects. The policy process was influenced both by the politicization of side effects and the global trend towards liberalization, which is often seen (also by Beck 2005) as a competing tendency.

This case therefore brings together a variety of communities of fate: ecologists in Europe, concerned about the ecological effects of modern agriculture; southern countries, who attempted, through the Uruguay Round of the world trade negotiations to combat the EU-CAP for the inequity it implied in global agrofood trade; and European farmers, who faced the disappearance of institutional provisions that were of great importance to modernization of agriculture. On the road towards the reforms, southern countries' strategies and concerns from small farmers and ecologists came together, creating a window of opportunity for, and shaping, the reforms. In the years following the reforms, earlier processes of subpolitics appeared to shape how, and to what extent, the reforms led to real changes in agricultural policies.

Taking a historical example has the advantage that ex-post analysis allows a rich analysis, fitting our primarily conceptual objective in this chapter. Yet, in order to explore the utility of the understanding developed, we will eventually relate our findings to the contemporary examples cited above. Methodologically, we will rely on secondary analysis, employing sources that are based on solid empirical work: literature on the 1992 reforms and their prehistory, as well as a thorough study, by a team of French, German and Portuguese researchers, of their implementation in France, Germany, and Portugal (Bruckmeier/Ehlert 2002) This comparative study is based on document analysis, interviews, and surveys, as well as on the authors' intimate knowledge of the countries they study. For our purposes, the three cases are well chosen. As we will see, there are important differences between France and Germany regarding the preceding subpolitics. And Portugal differs from both in the sense that it had much less been part of earlier agricultural modernization. Thus the reforms hit the ground in Portugal, with many small, relatively traditional farming practices in a very different way than in France and Germany. These three cases enable a comparative argument to discern the way in which earlier, 'simple' modernization as well as subpolitics have shaped the reforms and the degree to which they promoted a 'second modernity'. In particular, we intend to elucidate the global encounter of 'communities of fate' across the continents; the politics and subpolitics to which this gave rise at the global level, the European Commission and its member states; and diverse practices in the primary sector in European countries.

Our central question thus translates into two subquestions:

1. to what extent and how may the CAP reforms of 1992 be understood as resulting during a prolonged encounter in global risk society between overlapping communities of fate; more specifically, which practices of politics and subpolitics contributed in what way to this process?
2. how did these reforms on their turn affect policies as well as agricultural practices in France, Ger-

many and Portugal, and how can we explain the differences between these member states?

61.3 Understanding the 1992 CAP Reforms

The *Common Agricultural Policy* of the European Economic Community extrapolated to the European level the national policies its founding member had created to secure the food self-sufficiency and safety of Europe after two world wars and an economic crisis, and to free labour from the primary sector so as to stimulate industrialization, from which economic growth was expected (Wells 1994).[2] These countries sought to improve productivity and competitive power on the world market through rationalization, relying on the development and rapid diffusion of advanced knowledge and technology. This was accompanied by measures to promote the associate scale enlargement and intensification, especially in terms of physical planning and water management. In order to ensure both a good income for farmers and affordable prices for consumers during post-war reconstruction, there were also price and market policies, in particular product subsidies (Tracy 1989).

Especially the latter policies were, virtually from the EEC's inception, also established at the European level. The CAP comprised two kinds of price subsidies. On the one hand, farmers received product subsidies to ensure low food prices for consumers and a decent income for farmers. This led to a process of increasing food production, which contributed to rapidly increasing surpluses. Simultaneously, as product subsidies kept prices artificially high, European farmers could not compete in the world markets. In order to remedy this, export subsidies were put in place as well (Hennis 2005: 39 ff.).

Together, these structural policies at the national and European level implied strong incentives for productivity increase, intensification, and scale enlargement. Around 1970, this led to outright overproduction, perceived as a moral problem by many citizens, who due to the then recent penetration of television were confronted in an unprecedentedly direct way with the world food problem: graphic images of the effects of famine in the southern hemisphere.

In the 1980's, this system came under increasing pressure from various exogenous trends. Not only did public concerns on overproduction increase; the steady production increase also implied that the volume of the two, mutually reinforcing, subsidy systems grew enormously, leading to a very high share of the CAP in the European budget. The so-called 'stabilizers reform', adopted in 1988, plagued by major disagreements between member states, had not been able to resolve these problems (Ackrill 2000). Without new measures, this share was bound to increase further, also because of the ongoing process of EU expansion with Central and Eastern European countries – a consequence of another exogenous trend, the end of the Cold War. This occurred during the era of the adoption by most member states as well as the EU itself (in the 1992 Maastricht Treaty) of the monetarist paradigm. Finance ministers and 'their' commissioner were pushing on their agrarian colleagues, often with strong political support. In the same trail, liberalization and deregulation were becoming increasingly influential principles (Hennis 2001).

Parallel to these financial-economic trends, concerns on the environmental side effects of modern agriculture were increasing in the wake of the 1987 report *Our Common Future*, drafted by the World Commission on Environment and Development. Concerns especially about water quality and pesticides started to develop, and soon the realization became widespread that these – and others, like over-fertilization – were directly connected to the intensity of production (Hennis 2005: 54). As the 1985 Single European Act had put environmental policy on the EU agenda, this led to EU policies that also started to affect agriculture which thus no longer was the monopoly area of agrarian policy-makers: also consumer and environmental organizations became involved. Maybe most tellingly, already the 1988 reforms had been discussed not in the agricultural council, but in the general council (Hennis 2005: 59).

A second expression of the politicization of side effects concerned the impact of the CAP on world trade negotiations. More than forty southern countries with relatively strong primary sectors, together with Canada and Australia made concerted efforts in the so-called Cairns group, to press for liberalization of the world trade (Higgot/Cooper 1990: 590–593). The shift towards liberalization in the US, helped by lobbies of the country's transnational corporations, led to governmental pledges on far-reaching liberalization of world food trade (Hennis 2005: 47–48). In order to prevent one-sided liberalization, which would damage the American primary sector, the US government started to put pressure on Europe to join the liberalization game (Wells 1994: 2; Higgot/Cooper 1990).

2 This section strongly draws on Grin (2010a: 297–300).

Thus, next to financial concerns, both ecological and world trade effects of intensive agriculture got place on the agenda. It was in this situation that in 1989 Raymond MacSharry became European Commissioner for Agriculture, with the explicit intention to reform the CAP in spite of EU policy-making routines, whereby "the Commission proposes and the Council of Minister disposes" (Petit/De Benedictis/Britton/de Groot/Henrichsmeyer/Lechi 1987: 14). He had an inclination towards sustainable development, and, given his Irish background, was relatively susceptible to the needs of small farmers, whereas the CAP hitherto had privileged larger farming practices. He was not alone in these respects; there was increasing recognition in EU policy-making circles that both overproduction and environmental problems pointed towards less intensive production, and that this would favour the small scale farmers who hitherto had been less privileged by the CAP. Environmental measures came to be seen as a way to protect European farmers now that world trade talks were pressing for less protectionism (Hennis 2005: 59; Latacz-Hohmann/Hodge 2003: 134–137).

MacSharry set up his own team, a small group operating behind closed doors that started to draft a plan, about which even most of his fellow Commissioners were not informed. Thus he managed to produce a plan without being bothered by conventional EU policy arrangements, which included the game of 'commitology', or providing room to powerful lobbies, of which earlier attempts at reform had suffered (Patterson 1997: 151 ff).

Already in February 1991, when a formal green paper was not yet published, a so-called reflection paper was leaked to the press. This plan emphasized the need to retain rural populations, radical price cuts, and direct compensatory aid payments to farmers in certain sectors. Thus benefits "would be switched from the intensive grain and animal product growers in the North to the smaller less-intensive landholders of the Mediterranean and other peripheral areas (including Ireland)" (Patterson 1997: 154). In addition, through subsidizing acres rather than produce, farms were stimulated to have part of their land out of production. All in all, the policy shifted from price support to income support and increasing emphasis on environmental measures (European Commission 1993: 10).

When the reform proposal itself was published in July 1991, the shift from product subsidies to income support was maintained, but compensatory payments had become technically less complex and price cuts less drastic. Thus, many perceived the eventual measures as less drastic than they had feared. Nevertheless, reaching consensus on this proposal would appear far from trivial. Especially France and Germany had always strongly opposed such proposals (Patterson 1997: 136; Ackrill 2000). How, then, did MacSharry manage to succeed?

One important element was that for negotiations on the plan, he created another exceptional policy-making venue, a 'niche' venue within the normal EU structure. He defined a highly closed arena for negotiating it with individual member states. Decision-making within the agricultural council had traditionally taken place in a rather suspenseful dynamic, marked by sharp conflicts on the one hand and a huge measure of solidarity on the other. Different national interests of member states coexisted with a shared conviction that reforms were necessary (Patterson 1997: 149–152). Throughout the process, MacSharry played the card that it would be best to decide on reforms internally rather than having reforms forced onto agriculture from other domains, such as finance or environmental affairs (Patterson 1997: 153–154).

During the final stages of the negotiations of the 1992 reforms, the commission used this tension in combination with its power to define the venue for negotiations to come to an agreement, by having each of the member states articulate their priorities separately, to the Commission. In so doing it monopolized information and turned itself into an "obligatory passage point" for all talks, as well as into the actor who would define the issues of conflict. Eventually, it could thus produce an "accept it or not" attitude because one could claim it was the only workable compromise. Also, ministers were able to speak out freely during these bilateral talks outside the reach of public opinion or special interest organizations. This made it possible for MacSharry to meet the French on, for instance, cereal export subsidies and quota, but not on price cuts (Patterson 1997: 160–161). In combination, this led to a point of departure in which ministers said what they really opposed; they could agree on the issues that would not give them too much trouble at home.

Second, while EU member states' positions in the GATT negotiations had initially been largely influenced by the primary sector's lobbies, both these countries and the rest of the world became increasingly aware of the pressures that the CAP exerted on both world trade relations and the EU budget. Agrofood was the most important file in the Uruguay Round, and without agreement on agrofood trade; no

agreement would be possible on other matters that also pertained to other economic sectors than agriculture. Thus, the GATT introduced also actors from other sectors onto the stage, increasing the pressure on the CAP and reducing the monopoly of farmers' interests on that area. Simultaneously, also main players within the agricultural sector now increasingly recognized that the 1988 stabilizers would not solve the problem (Patterson 1997: 153). They understood that in a globalizing world, also in their domain international cooperation and the influence of global capital had become crucial (Hennis 2001: 833–836).

Against this background, and keeping a firm eye on his tactic of resolving these issues 'internally', MacSharry publicly denied any connection between the CAP reforms and the GATT negotiations until the ministers had formally adopted his plans (Patterson 1997: 153). Yet, it is plausible that he played this card (as well as that of pressure from national and EU financial and environmental policy-makers) behind the closed doors that he himself had put in place (Atkin 1993). Moreover, he used his discretion to include his reforms first of all in the so-called Blair House agreement with the US – an international agreement that had to be submitted to the Council only after the fact (Coleman/Tangermann 1999: 400-401). As implied above, GATT matters will always have been on the minds of national policy-makers.

Third, 'taming' the CAP was also a *sine qua non* for the establishment of the highly desired European Monetary Union (Hennis 2001: 831). Fourth, and more specifically, the German and French governments started to tone down their traditional resistance against changes in the CAP. As regards Germany, unification brought with it a financial crisis, which made the German government reconsider its position on the EU's increasing agricultural expenditures. Unification also changed the nature of the German farming sector, and it mobilized several additional special interest groups. Thus, the political power of actors from the primary sector had significantly declined, and the German government came to consider the interests of a more heterogeneous coalition of interest groups (Patterson 1997: 145). Also, the reunifying Germany was sensitive to good international trade and political relations.

Meanwhile, in France concerns on both budget deficits and environmental damage had steadily increased. In addition, pressure from other policy domains, with a stake in GATT (like intellectual property) more generally, had built up. Finally, it had helped that quotas on cereal – a backbone of the French agricultural sector – were eliminated from the package (Patterson 1997: 157).

The measures adopted reduced the dynamics towards ever increasing CAP budgets as well as the surpluses. To be sure, the wider immediate impacts were limited. As income protection remained in place, and agricultural research and development remained oriented towards productivity increase, the measures did not lead to radical reform of agricultural practice (Hennis 2005: 50). The export subsidies remained in place as well. Yet, the CAP had become more transparent, also to taxpayers (Patterson 1997: 17). In addition, parallel to these reforms (and partly as part thereof) the European Commission launched an agro-environmental policy. This too increased the influence of actors from that domain (Hennis 2005: 65–66). While the measures on changing the subsidy system had been most controversial and drawn most political energy, they were accompanied in EC Regulation 2078/92 by environmental measures aiming at less pollution, less intensive production, more organic farming, and creation of leisure activities in the rural areas. These measures included novel forms of financial support, aimed at activities for:

- promotion of farming practice which reduce the polluting effects of agriculture;
- environmentally favourable extensification of crop;
- sheep and cattle farming;
- environmentally friendly ways of agricultural land use;
- upkeep of abandoned farmland;
- long-term set aside of agricultural land;
- land management for public access and leisure activities; and
- education and training of farmers for environmentally-friendly types of farming (Bruckmeier/Ehlert 2002: 21).
- Overall, the package comprised in Regulation 2078/92[3]– eventually published in June 1992 – was tailored as a response to the negative side-effects of intensive agriculture: overproduction and environmental measures. It encouraged extensification practices. Realizing that this was more of concern in the northern states, the European Commission also included some measures to address some of the concerns of the southern states.

3 Council Regulation (EEC) 2078/92 of 30 June 1992 on agricultural production methods compatible with the requirements of the protection of the environment and the maintenance of the countryside.

61.4 Impact of CAP Reforms on Member States' Agricultural Policies and Practices

61.4.1 The French Case: Linking Environmental Concerns with Agricultural Practice

61.4.1.1 Agricultural Policy and Practice in France Before 1992

France has a large, versatile agricultural sector covering a wide range of products. From the onset of the CAP, it has been one of Europe's largest food exporters (Bowker 1985: 178). The country has exceptionally widespread grasslands. In France, environmental concerns had penetrated national agriculture policy in the late 1980's (Bignal/Baldock/Tubbs 1996: 7). While the growing sense of urgency amongst the public and politicians about ecological problems had initially focused on industry and urban sources, around 1980 also agriculture became a focus. Until then, this had been unthinkable, given the strong position of the farming community in the nation, the important position of agriculture in the French economy, and the influential farmers' lobby in national politics (Hennis 2005: 99–103). Thus, in the early 1970's the point of departure was that the process of modernization and intensification should not be bothered by environmental concerns; if farmers structurally damaged the environment, they should just pay compensation. The first real environmental measure was the protection of water quality. There was little support for these measures, which had been designed without any serious involvement of farmers. The main exception was the successful, but small-scale attempt of one nature organization to have farmers participate (Billaud/Pinton 2002: 45).

This started to change when the problem of abandoned land became more apparent. As the government wanted farmers to take the role of protectors and owners of the rural landscape, it decided to involve individual farmers in the policy-making process. The relevance of doing so was shared, and practised, by environmental groups as well. Through their active involvement farmers came to share the need for environmental improvement, and to appreciate their role and as well as the opportunity to influence policy-making. This also generated debate within the two main farmers' organizations in France (Hennis 2005: 121).

This successful 'subpolitics' approach to dealing with the issue was partly inspired by the decentralization launched in 1983 by the French government (OECD 1999). Especially in the agricultural domain, regions attained more influence. The consequent local political struggles possible between local authorities, farmers, and occasionally environmental and nature organizations, helped to tune agri-environmental measures to regional circumstances and geographic realities (Billaud/Pinton 2002: 46). This gradually created some support amongst farmers for taking into account the environment in their practices, a mechanism well known from experiences elsewhere (Van de Graaf/Grin 1999).

The first official challenge for the sector emerged from 'Article 19', the first set of environmental measures from the EU. It offered subsidies for efforts for the protection and preservation of natural areas and natural resources in ecologically sensitive zones. The French government responded by sponsoring several experiments. These were launched in 1989, at four different sites which were particularly sensitive ecologically. They were managed by the National Centre for the Development of Farm Structures. These had been jointly designed with regional governments, farmers, and other actors in a particular area. The development programmes in these sites grew rapidly, partly because they quickly attained the additional meaning of providing support for disadvantaged agricultural regions. Shortly they had outsourced the budget (Billaud/Pinton 2002: 48).

These experiments, a novel round of subpolitics, offered interesting perspectives, not only in the eyes of the farmers that had been involved, but also amongst many other French farmers to whom these examples were much more credible and helpful than proposals based on mere scientific evidence (Billaud/Pinton 2002: 49–54). Also, the limits encountered encouraged both environmental and farmers associations to demand better policies from the national government. In 1991, the Ministry of Agriculture introduced the Sustainable Development Plans (*Plans de Développement Durable*, PDD) where they connected modes of production with environmental issues (Billaud/Pinton 2002: 48–49).

As a consequence of these developments, such linking was no longer a taboo in France. Moreover, it had become clear that environmental concerns could be sensibly incorporated in agricultural practice. The project approach adopted in the implementation of Article 19 and the PDDs, with policy design focusing on a particular local context and involving local farmers and environmental groups, appeared to have many of the effects Beck ascribes to such forms of subpoli-

tics. It had proven successful in producing plans that respected local circumstances, and could be accommodated by farmers. Also, it had led offered spaces where farmers could discuss their practices and learn from each other, as well as from environmentalists, on changes therein. In other words, this approach helped farmers to appropriate policy. In the process, trust increased amongst farmers (Billaud/Pinton 2002: 54).

All this cleared the road for the 1992 agri-environmental measures. An additional helpful factor was the fact that French farmers had positively appreciated the CAP for over 30 years. Over the decade, it had had significant influence on national agriculture policy (Billaud/Pinton 2002: 46).

61.4.1.2 Implementing EU Agri-environmental Measures in France

The task to implement EU Regulation 2078/92 was adopted by the Ministry of Agriculture and the Ministry of Environment. This partnership symbolized that the government wanted actors in both domains to cooperate. By 1993, the following measures were announced (Dupraz/Rainelli 2004: 169; Billaud/Pinton 2002: 50):

1. a national programme for the maintenance of extensive livestock systems, mainly through premiums;
2. national plans for sustainable development; and
3. local and regional agri-environmental programmes in line with EU Regulation 2078.

It was clear from the outset that farmers' organizations supported the new link between the environment and agriculture. This significantly contributed to the measures' legitimacy in the French primary sector. However, they criticized the agri-environmental measures for not having been elaborated in a scientific way, as they did not incorporate knowledge about local circumstances. Also, they considered the time span proposed in the measures as unrealistic, given natural and investment cycles (Billaud/Pinton 2002: 74–76).

Against this background, the government decided to adopt the participatory project approach that had proven so successful in implementing Article 19 and designing the PDD programme. It initiated so-called pilot projects with a farmer in the role of an independent manager. Substantively, most farmers focused on stopping the decline of grass land, a widely shared objective amongst them. In addition, water quality problems got attention as did, though less, organic farming.

As had happened earlier, this induced learning processes between farmers and environmental groups. Farmers could thus design changes in their practices that they deemed sensible, and appropriate the policy so as to tailor it to local circumstances and needs. They proposed that, rather than fixing practices in detailed, formal contracts, a more loose contract approach would be adopted that would allow farmers to further experiment with novel approaches. This would also imply the flexibility to adopt measures that worked best, both agronomically and ecologically (Billaud/Pinton 2002: 54).

According to Billaud/Pinton, these measures eased the implementation of the 1992 CAP reforms. Like the earlier experiments, they have generated a significant 'social echo', creating support for different practices amongst French farmers. The effect of that achievement was, however, limited by the short time horizon (5 years) of the measures; that some impact could arise was because of the fact that the experiments launched in 1989 had provided a basis (Billaud/Pinton 2002: 94). Also, financial support was limited by the size and uneven spread of available budgets over the regions, as well as by discouraging bureaucratic procedures.

From the viewpoint of our analysis two other findings are of interest. First, Billaud and Pinton (2002: 94) observe that farmers appear more willing to implement measures that do not change their practices too radically – the bottom line is that they should feel able to take these changes, in an economically sound way. Even stronger, some economic benefit in many cases appears to provide the incentive needed for change (Van de Graaf/Grin 1999). Precisely in these respects, experiments had proven such an effective approach. One potential explanation why the changes explored in these experiments remain relatively limited is that they need to fit a structural context (including existing market structures, available knowledge, governmental policies) that over time has co-evolved with modernization and intensification and tend to provide less support and economic viability to drastically different types of practices (Roep/van der Ploeg/Wiskerke 2003; Bos/Grin 2008 for evidence from Dutch experiences). This underlines the importance of institutional change, a condition for innovating societal practices (Billaud/Pinton 2002: 49).

The second finding concerns the fact that there are interesting differences between regions that support the implicit presumption above that the policy's success could be attributed to earlier developments and to the project approach adopted. Billaud and Pin-

ton (2002: 63–80) compare two regions, Burgundy and Poitou-Charentes. Both regions are facing problems with drinking water quality, and both have a mix of intensive and extensive farming practices. They differ from each other, first, since the executive department of Poitou-Charentes was already familiar with agri-environmental measures, while the issue was largely new to the department in Burgundy. Second, in Poitou-Charentes the relationships and collaboration between agricultural and environmental groups was much better developed than in Burgundy, although there were occasional attempts to renew the dialogue between for example the managers of a regional park and the farmers (Billaud/Pinton 2002: 75). In line with our presumption, Poitou-Charentes saw indeed many more participants (818) than Burgundy (400) in grass-premium initiatives (Billaud/Pinton 2002: 69). Water protection attracted most applicants in both regions. Interest in organic farming was larger in Burgundy than in Poitou-Charentes and it rapidly grew from the second year onwards with the budget as the limit (Billaud/Pinton 2002: 70).

61.4.2 Germany: Challenge of Turning a Critical Debate into Changed Agricultural Practices

61.4.2.1 German Agricultural Policies and Practices Before 1992

Post-war German agricultural policy was really focused on overcoming the shortage in food production and to ensure some income security for the farmers through a combination of modernization and market and price policies. This focus was laid down in the 1955 Agricultural Act (*Landwirtschaftsgesetz)* it shared with the five other countries, including France, with whom it co-founded the European Communities. Not coincidentally, thus, the CAP, when it was established a few years later, was well compatible with German policies (Ackrill 2000). This massive policy support helped agricultural modernization gain momentum and helped Germany to greatly expand its food export already in the course of the 1970's (Bowker 1985: 173 ff.).

Still, many German farmers had been critical against the CAP in general since its inception, and especially against the pressure towards modernization implied in it. Historically, rural society sees itself as an important pillar of German identity (Craig 1982). They felt marginalized and unable to manoeuvre themselves out of their bad economic and social position, and abandoned by politicians, who should have come to their rescue, but 'instead' went for a modernization of farms (Bruckmeier/Riegert 2002: 232).

Already in the 1970's in Germany – like for instance in the Netherlands, but unlike in Portugal and France – other societal parties became also critical of agriculture. A critical public debate emerged on the environmental effects of agriculture (Feindt/Gottschick/Mölders/Müller/Sodtke/Weiland 2009: 11–14). This debate was a clear example of the politicization of side effects. It triggered a variety of actors from civil society and especially from science to develop clear visions and a wide range of proposals to realize them. Yet, while these processes of subpolitics generated proposals beyond normal institutional constraints, their Achilles' heel was that there were hardly any links between these critical scientists and the primary sector. Proposals did not incorporate local and informal knowledge, farmers hardly understood the economics of extensive agriculture, and the distance between them and the new paradigm developed by scientists remained large. Farmers neglected or rejected these proposals. Also, their impact on policies remained very limited.

The debate continued but only after German unification in 1990 the government adopted and started to implement visions for a more ecologically sound agriculture. As we already noted above, unification implied several reasons for Germany to leave the one-sided focus on productivity increase; in addition, EU Regulation 2078/92 offered a new impulse for realizing the ideas generated earlier (Patterson 1997; Bruckmeier/Riegert 2002: 119–122).

61.4.2.2 Implementing EU Agri-environmental Measures in Germany

It took a while until agri-environmental measures were implemented in Germany. Re-unification took a lot of energy. In addition, the process was complicated by the federal political system (Bruckmeier/Riegert 2002: 124). According to the constitution, in agricultural policy the Länder are responsible for structural policy, education and nature protection, while the federal government deals with social aspects and taxes. Furthermore, the *Länder* are responsible for environmental issues, thus also for the implementation of the agri-environmental measures. The federal government is only responsible for funding the policy.

Yet, following EU Regulation 2078/92 federal and state authorities decided to formulate together a joint framework for supporting the market and local production first and then the Länder would adopt agri-environmental programmes of their own emphasizing

nature protection and conservation. Also, a 'Basic Programme' was agreed upon comprising a few objectives each Land would include: a) extensive arable land and permanent crops, b) extensive grassland use, with specified maximum cattle density, and c) organic farming. The *Länder* could then quantify these objectives in a way that reflected their specific situation, and add specific measures for their regions (Bruckmeier/Riegert 2002: 125–126).

Indeed important differences between regions existed in terms of types of agricultural production traditions and associate structures. Some Länder reserved more money for these measures than others and promoted their implementation more than others. This partly was due to the fact that some were familiar with environmental measures regarding agriculture and had already promoted an extensification before 1992 (Bruckmeier/Riegert 2002: 133–135).

Underlying federal and state policies was the belief, fed by earlier scientific endeavours, that agriculture and environment go hand in hand with each other. Yet, a huge gap appeared to exist between governmental actors and the primary sector that hardly shared this belief and the underlying assumption. Implementation, especially of the measures most alien to established agricultural practices, remained limited (Bruckmeier/Riegert 2002: 128).

While the 1992 EU Regulation was a new impulse to realize earlier generated ideas, the agricultural sector – that had scarcely participated in the earlier debate – did not really work along to turn it into a success. As noted above, they never had very warm feelings towards CAP and national policies, and Bruckmeier/Riegert's survey data show that they did not feel personally responsible for improving their position as well as the environment. Against this background, farmers adopted primarily those measures that could be easily integrated in their farming practices, and fit instrumental and economical motives (Bruckmeier/Riegert 2002: 163–6). Through political campaigns, governmental and other actors tried to influence policy formation. While a variety of governmental and non-governmental (environmental and agricultural) organizations expressed their views, eventually the Länder governments decided, using hearings to build the policy in a "symbolic consensus" (Bruckmeier/Riegert 2002: 129–130). However, there were no deliberations or even negotiations between authorities and the farmers. Also, implementation was done through rather traditional bureaucratic routines; any interaction was lacking between implementing agencies and the primary sector regarding the application of the resulting measures at the farm level. This did not help to improve the already tense relationship between the government and individual farmers, and it was hardly satisfactory for the latter that they shared this fate with many others. This has certainly contributed to the lack of success (Siebert/Laschewski 2009: 170).

61.4.3 Portugal: CAP Reforms in a Country Relatively Untouched by the Earlier CAP Modernization Policies

61.4.3.1 Portuguese Agricultural Policies and Practices before 1992

The case of Portugal, a southern European state that entered the European community in 1986, differs from that of France and Germany. Portugal lacked the powerful modernization programmes due to limited budgets the EU founding members had adopted in the post-war years (Rodrigo/Ferragolo da Veiga 2009: 214). It had become exposed to the CAP many years later, when the CAP had become tuned to the needs and realities of early member states that had gone through a process of significant intensification and modernization (Ackrill 2000). In Portugal, the structure of the agricultural domain reflected primarily subsistence farming, and farms were often family owned following traditional practices. Thus, well into the 1980's, agricultural production remained relatively extensive, and the country produced only half of its domestic food supply.

In Portugal this way of farming came under increasing pressure. The primary sector lacked competitiveness on the world market. Farmers felt that they received too little money for their products, especially in view of their high production costs. They saw their bad economic situation as the main problem in agriculture. Urban life became also increasingly attractive for new generations, leading to massive rural to urban migration. The countryside was increasingly abandoned and important demographic changes occurred: the farming population was getting older, and especially men were taking jobs in the cities what resulted in a "feminization of farming" (Patrício/Valadas de Lima 2002: 170; Covas 1990; Bock 2004).

By 1990, the Portuguese government was primarily interested in an intensification of agricultural production, deemed necessary to preserve the primary sector. The government hardly considered the changing nature of rural areas as a problem in and of itself, but mainly as a consequence of the stagnant modernization of the primary sector. Environmental concerns

play a role in its agricultural policies only to the extent that they are deemed necessary to maintain the production function of rural areas. The primary sector focused on economic survival and many farmers wanted to maintain traditional practices (Patrício/Valadas de Lima 2002: 167–168).

61.4.3.2 Implementing EU Agri-environmental Measures in Portugal

Against this background, Portugal faced the CAP reforms quite differently than the German and French governments had done. It considered the environmental problems described in EU Regulation 2078/92 primarily as the consequences of the intensive production modes in more northern states. Thus, it saw a clear northern bias in the reforms, and felt that the interests of countries like Portugal had been neglected. More specifically, it badly lacked agri-environmental measures in the reform package that were tailored to the specific problems facing Portugal (Patrício/Valadas de Lima 2002: 167–168).

When it implemented EU Regulation 2078/92 into national policy, the Portuguese government focused on those measures that would help resolve the social problems of its rural society, help maintain traditional farming practices, and help preserve the environment for future production. Policy measures were based on the assumption that the character of most Portuguese farming practices protected the environment. It used the agri-environmental policy in support of these practices and adopted these measures (Patrício/Valadas de Lima 2002: 183 ff.):

1. offer of training and demonstration projects for farmers, rural specialists and technicians;
2. reduction of the pollution caused by agriculture through water quality protection by reducing and rationalizing the use of pesticides and promoting organic farming:
3. extensification and the preservation of traditional agriculture;
4. conservation of the landscape and natural resources through the maintenance of forest areas, and undertaking agriculture in ecologically sensitive areas.

Measures that might help mitigate the flight from the rural areas and desertification attained more priority than others. Most of the budget was spent on extensification and preservation of traditional agriculture. This was in line with the general idea and discourse in Portugal, that agriculture and the environment are in harmony with each other. Agri-enviromental measures were thus first and foremost interpreted and elaborated as ways to protect the farmers (Patrício/Valadas de Lima 2002: 186–7). Only a small percentage of the budget was spent on the training programme. Meeting the problems of the (small) sector of intensive agriculture in Portugal through that measure got little priority. Also tackling pollution was of relatively little concern.

Portuguese farmers, just like their government, viewed the agri-environmental measures as a support more for agriculture than for the environment. In general, they resisted a role as environmental protectors, and those measures which they deemed economically most attractive had most impact (Rodrigo/Ferragolo da Veiga 2009: 210).

A crucial problem was that the number of available rural and technical experts was rather limited, and varied amongst regions. Therefore, most information and knowledge had to be transferred orally (Patrício/Valadas de Lima 2002: 187). This lack of training capacity also contributed to the limited reach of the little knowledge of the programme. Only a small number of farmers joined the programme, and those who did were primarily economically motivated. Part of the problem was that the (ageing) farming community had for a long time not improved their production methods and neither had they introduced new production techniques at any significant scale (Patrício/Valadas de Lima 2002: 199).

Patricio and Valadas de Lima conclude that the CAP reforms confronted Portugal with several fundamental choices. First, "if policy-makers recognize the potential role of farmers as preserving and maintaining rural society than a social policy is necessary. The maintenance of rural society requires not only a policy preserving traditional agricultural systems of production but one which supports the social and cultural dimensions of rural society" (Patrício/Valadas de Lima 2002: 202). And such survival of the family farm also requires better economic preconditions.

But, second, will this type of production, subsistence farming, eventually survive? Is more intensification not necessary to prevent the rural exodus and abandoning of the land? If this is what Portugal needs, the extensification policy of the EU is not really helping Portugal.

Finally, as Patrício and Valadas de Lima (2002: 204–207) argue, the agri-environmental measures offer considerably more opportunities and reduce environmental problems. In that sense, this policy is also suitable for Portugal. While in Portugal Regulation 2078/92 could not build on earlier debates, policies

and practices, implementing these measures may prove to be the first step towards fuller recognition of the problems that are also caused by traditional agriculture.

61.5 Conclusions

Returning to our research questions, we may understand CAP reforms indeed as an expression of the way in which global risk society makes the side effects of modernization feed back into the modernization processes that generated them in the first place. *In casu*, the modernization process concerned rationalization and scale enlargement of agrarian production, tied together in national policies and the EU's CAP that promoted intensification. Side effects indeed brought together different communities of fate. These effects included, first, overproduction which, together with European and American protectionism, affected the economic chances of farmers in the southern hemisphere. Over time, this had led to increasing pressure form the South on the world trade organizations. Second, the environmental effects were sensed by European environmental groups and policy-makers. Both concerns were addressed by CAP reforms that focused on an extensification of agrarian production in Europe.

Thus put, and leaving the question aside of the long term impacts, it seems a perfect example of the global risk society theory's idea that reflexive modernization in the sense of institutional reforms may result from an encounter of communities of fate. Yet, at least two qualifications are in place. The first is that the reflexive modernization that occurred may certainly not be ascribed solely to the two communities of fate just mentioned. At least as important were two forces rarely considered in risk society theory as a positive force: the emergence of the neo-liberal paradigm, and the fact that globalization turned also northern countries into a 'community of fate': given global competition, the USA and Europe (as well as Japan) could hardly decide on their own how to respond to southern pressures. From the viewpoint of those interested in the politicization of side effects, this is a case of how the 'wrong' means may realize the 'right' objective. In that sense, the case illustrates that it is too simplistic to argue, as is often done, that regions in Africa and Asia are bound to remain marginalized in the global economy, lacking access to the global market. The Cairns Group demonstrated that it may be possible strategically to connect their concerns to other, northern concerns and interests. Yet, we must stress that this did require significant strategic agency, not only on the side of the Cairns Group, but also from, amongst others, Ray MacSharry. Also, and more fundamentally, it could not have occurred had it not been that one and the same structural factor, the price support system, was behind monetarist concerns, intensification, and associate ecological problems and inequitable trade relations. This system thus could become the common ground where communities of fate could join forces.

The second qualification is that such reflexive modernization may generate its own communities of fate. The CAP reforms produced not only winners, but also losers, such as the farmers in Germany who felt betrayed and marginalized, and the rural poor in Portugal who felt that the reforms, like the CAP, were tailored to solve very different problems than the ones they had. This reminds us of Manuell Castells (2000: 168), who has argued that a 'fourth world' is developing, comprising people from all regions, including the European Union.

This takes us to the question *how* CAP reforms were realized. On the basis of section 61.3, we must immediately note that, at the EU level, it was certainly not only, and even not in the first place, subpolitics which shaped this outcome. On the contrary, it was – admittedly, extra-ordinarily skilful and non-standard – hard boiled politics that was quintessential to MacSharry's successful exploitation of the opportunities offered by such trends as the changing world trade situation, the emergence of the monetarist paradigm, and the end of the Cold War. The case should be taken as a profound warning against a too romantic picture of subpolitics as 'the prime mover' of reflexive modernization. This is not to say that subpolitics had been unimportant. First, MacSharry partly drew upon the fact that since around 1970 all kinds of subpolitics had sensitized both national and EU policy-makers for the need to take into account environmental concerns. The comparison between France and Germany on the one hand, and Portugal on the other, indicates that the reception of, and resistance against, the agri-environmental measures co-depended on the degree to which, in Beck's terms, earlier politicization of side effects had helped to break open institutional unawareness. Second, as the comparison between the French and the German case in section 61.4 shows, the financial support for the extensification and ecological improvement may simply have been neglected, had it not been for farmers who had been participating in subpolitical initiatives.

How then, more precisely, did CAP reforms as examples of Beck's meta-governance, lead to changes in agrarian practice? Let us make some comparisons between our case studies in order to demonstrate that it was precisely at this level that subpolitics appeared important. First, comparing Portugal with France and Germany, we see that in the perception of the 1992 CAP reforms were much better where the ground had been prepared by previous subpolitical activities. The other way around, CAP reforms may eventually appear to contribute to the emergence of subpolitics as well as changed practices. While some might argue that there simply was no reason for such subpolitics in the Portuguese situation, we have shown that this is at best a position in the debate, rather than a given: also in Portugal, the point was made that agricultural production led to environmental problems; and that dealing with these problems might contribute to improving the rural areas' social and economic viability.

Second, comparing Germany and France, we also see that subpolitics may prepare the ground for translating meta-governance, such as the CAP reforms, into changes in agrarian practice, especially if it mobilizes tacit, informal knowledge in addition to formal knowledge. In France, it was precisely the fact that farmers and local environmental groups had brought in such knowledge in the 1989 and 1991 experimental projects that generated legitimacy for the CAP reforms. While farmers initially criticized the CAP's underlying scientific assumptions, it was these projects, and the room they attained through administrative decentralization, that helped them to relate the measures to their own practices. Conversely, in Germany, concern on side effects had led to proposals, developed by scientists, and based on formal knowledge. Thus farmers did not see how to relate these concepts to their own practices. As a result, these proposals could inform national and regional policies, but could hardly legitimize them, certainly not to the extent needed for effective implementation. These findings confirm and specify Beck's point on the need for subpolitics to involve local actors and to benefit from their knowledge to produce contextually relevant concepts.

The previous points together suggest another theoretical conclusion. They indicate that neither structural change nor innovative, 'subpolitical' practices should be conceived of as *the* motor for reflexive modernization; rather, they may presuppose and drive each other. And they raise a next, much more complex question: how structural change (as an act of meta-governance, Beck/Bonss/Lau 2003), and changes in a diversity of practices, may come to reinforce each other so as to develop into a prolonged transition towards sustainable development (Grin 2010: 265–314). That is a question for further study, which would have to focus on a much more prolonged period of development.

Let us now return to the question we asked in our introduction: how may different communities of fate actually join forces, across space and in spite of differences in context and prehistory, in order to generate the transformative power needed to re-orient development patterns? In sum, we have seen that the needs and wants of different communities of fate may come together *if* they are all related to the same structural factor(s). Even then, significant 'political' work needs to be done in order to actually realize structural changes. These changes on their turn may help promote (innovative) practices of the various communities, when these have been prepared through earlier subpolitical practices. Strategic agency is needed to bring about such connections.

Changes in the financial incentive structure, as in the CAP case, are but one possible kind of structural change. Translating the above lessons, for instance, to agricultural reform in India and Mexico (chap. by Nair and Conde), another crucial factor may be structural changes that lead to the development of a different kind of agricultural knowledge and technology. Transnational intermediaries could bring together the knowledge needs of practices and strategically connect them to each other and to national and international research programming practices, such as EU Framework programmes, the IPCC or national science foundations (Grin 2010b). Examples are the recently emerging European intermediaries for urban responses to climate change. In an evaluation of these intermediaries, Hodson and Marvin (2009) conclude that in order to succeed, such "intermediaries must constantly work at developing and re-developing the knowledge base which they have access to" in order to help cities to integrate a wide variety of formal and local forms of knowledge and societal perspectives. They also must be able to connect to local practices as well as to transnational venues in the worlds of policy, science, and the market. This clearly demands a peculiar set of non-standard competences, implying that there is indeed reason to trust this task to new intermediaries that may build up the required competences.

As a second conclusion, simultaneously, without further measures those 'communities of fate' whose needs and wants are not well served by that particular

structural change may be the losers of the process. While this may, under circumstances, be the price that must be paid for resolving some pertinent problems, the example of the Portuguese farmers suggests that in other cases parallel policies may be conceivable to serve these groups. Here again, competent intermediaries, as spiders in complex webs, may be the best way to mitigate the risks of unduly creating losers. In all likelihood, for our example, this requires that a diversity of intermediaries may be needed: in addition to the expert group for technical advice on organic production which the EU started to form in the autumn of 2009, also non-governmental organizations such as the International Union for Conservation of Nature.

62 Genetically Modified Organisms: A Threat for Food Security and Risk for Food Sovereignty and Survival

Úrsula Oswald Spring

62.1 Introduction

After the first agricultural revolution ten thousand years ago, people have gradually increased the yield by crossing different varieties of crops. As a result of multiple adaptations five basic food crops have emerged: rice in Asia, wheat in the Fertile Crescent (originally from Ethiopia), maize and beans from Mesoamerica, and potatoes from South America that offers the nutritional base for 6.6 billion people. During the 21st century, agriculture will be confronted with great challenges. Due to population growth until 2050 more than nine billion people must be fed. Most of them will live in poor countries, still threatened with hunger (FAO 1999; 2000, 2008b). Most of these countries are also affected by *global environmental changes* (GEC), and they will face more floods and droughts, a decline in biodiversity, and in the fertility of soils. Due to a rapidly growing food demand due to biofuel and a gradually declining supply, additional land, water, and seeds for food purposes are needed (FAO/WHO 2003; FAO 2005; Ghosh/Jepson 2006).

A public dispute has developed on the benefits and dangers of *genetically modified organisms* (GMO) or transgenic crops (Stone 2002). The promoters of GMO offer miraculous seeds that are able to overcome the negative effects of climate change, salinity, plagues, loss of fertility, and drought. Potrykus (2003) accused the critics of a "crime against humanity", when they demand further analysis of possible effects on the environment and health and regulatory processes to reduce risks related to GMO. *Transnational enterprises* (TNE), some multilateral organizations (e.g. FAO), and governments have been promoting GMO as a kind of panacea. The critics – often allied with international governmental (IGOs)[1] and nongovernmental organizations (INGOs)[2] – spoke of 'Frankenstein food'. In several countries consumers have demanded labelling GMO products, and pressured their governments to guarantee innocuous, healthy, and nutritional food (Royal Commission 2005; TWN 2006; Ackerman 2002; Bongiorno 2005).

This chapter addresses the complexity of the threats and risks associated with GMO (Ayra 2003; Boell Foundation 2002) for food sovereignty (Oswald Spring 2009). Transgenics represent a cornucopian answer to the existing and probably increasing food crises that is further aggravated by the use of grains for biofuel. Today one billion people suffer from hunger, above all children under five years, where 947 million are living mainly in poor countries. Some 65 per cent of all hungry people come from India, China, the Democratic Republic of Congo (at war), Bangladesh, Indonesia, Pakistan, and Ethiopia. Only China, India, and some other Asian countries could reduce the number of hungry people. 36 millions belong to Sub Saharan African countries and 51 millions to Latin America (FAO 2008c). Due to neoliberal agrarian policies, speculation with food prices in the stock market and an unprecedented increase in food prices, the use of food crops in biofuel have increased the number of hungry people in several countries in Central Asia, in Sub-Saharan Africa, Asia, and Latin America.

Can GMO feed 8 or 9 billions people without damaging human health or creating greater ecological footprints? What could happen when a small number of transnational monopolies control seed production worldwide? How are the income, livelihood, and survival of peasants affected and their self-sufficiency in food? What will occur with the food market for poor people when the world food is produced by a tiny number of TNEs? How will a reduced number of

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_62, © Springer-Verlag Berlin Heidelberg 2011

seeds affect biodiversity and how can further pollution be avoided? Are GMOs also posing health threats, and what are the long-term risks of this technology for humankind and nature?

To respond to these questions, first the concept of transgenic or GMO is introduced in relation to a wider context of biotechnology (Harvard University 1999). GMOs are compared with the evolutionary process of traditional seeds. Since 1995 in few countries GMO crops have boomed, what has posed risks to crops in open fields and for biodiversity. Due to many mergers of transnational chemical and pharmaceutical enterprises a few TNEs in this sector can impose prices and models of production and consumption. Smaller producers are either pushed out of business or must produce under contract for these TNEs (62.2). Then the risks of potential impacts of GMOs on health and possible long-term threats for human beings, animals, and biodiversity are examined. This is followed by an ethical evaluation of the cornucopian model of TNEs (62.4) that addresses potential threats and proposes a precautionary principle to reduce the related risks. It suggests limits for economic expansion when common goods and the biodiversity are threatened.

62.2 Cornucopian Response to Food Security

Within the framework of the *Convention on Biological Diversity* (CBD), the Cartagena Protocol on Biosafety (2000) defines "modern biotechnology" as the application of:

> (a) In vitro nucleic acid techniques, including recombinant deoxyribonucleic acid (DNA) and direct injection of nucleic acid into cells or organelles, or
>
> (b) Fusion of cells beyond the taxonomic family, that overcome natural physiological reproductive or recombination barriers and that are not techniques used in traditional breeding and selection (Secretariat of the Convention on Biological Diversity 2000)

FAO's *Glossary of Biotechnology* defines biotechnology broadly as in the CBD and narrowly as "a range of different molecular technologies such as gene manipulation and gene transfer, DNA typing and cloning of plants and animals" (FAO 2001).

62.2.1 Genetically Modified Organisms or Transgenic

According to the FAO (2005: 13):

> Three distinctive types of genetically modified crops exist: (a) 'distant transfer' in which genes are transferred between organisms of different kingdoms (e.g. bacteria into plants); (b) 'close transfer', in which genes are transferred from one species to another of the same kingdom (e.g. from one plant to another); and (c) 'tweaking', in which genes already present in the organism's genome are manipulated to change the level or pattern of expression. Once the gene has been transferred, the crop must be tested to ensure that the gene is expressed properly and is stable over several generations of breeding. This screening can usually be performed more efficiently than for conventional crosses because the nature of the gene is known, molecular methods are available to determine its localization in the genome and fewer genetic changes are involved (FAO 2005: 13).

62.2.1.1 History of Evolution

Long before human beings existed the first one cell organisms experienced modifications, probably through the interaction with viruses and bacteria, adapted to the natural environment, and transmitted the DNA to the next generation of cells. Based on extensive empirical observations Charles Darwin (1859) developed his theory of evolution on the mechanisms of natural selection and the evolution of more complex organisms, where the fittest survived. In 1865 Johann Gregor Mendel developed the first laws of heritage based on genetic selection. In 1953 James Watson and Francis Crack discovered the double helix structure of the *Deoxyribonucleic Acid* (DNA), and in 1973 Herbert Boyer and Stanley Cohen succeeded to genetically modify or recombine the transmission of genetic characteristics of *E. Coli* in a salmonella gene (Cohen/Chang/Boyer/Helling 1973).

Herbert Boyer founded the first company that used recombinant DNA technology and in 1978 Genentech announced the creation of an *E. coli* strain that produces the human protein insulin 'Humulin'. When the US Supreme Court resolved in 1981 that GMO could be patented, many private biotechnological laboratories were founded. In 1982 the US Food and Drug Administration (FDA) approved this first genetically modified medicine. In 1983, experiments with GMO started for tobacco and tomato that were slowly displacing the hybrid seeds produced during the green revolution.

Table 62.1: Evolution of agricultural development. **Source:** Adapted from van der Walt (2000) and FAO (2002; 2005: 6-7).

Technology	Era	Genetic interventions
Traditional	Ca. 10,000 years BC	Civilizations harvested from natural biological diversity, domesticated crops and animals began to select plant materials for propagation and animals for breeding.
	Ca. 3,000 years BC	Beer brewing, cheese making and wine fermentation.
Conventional	Late 19th century	Identification of principles of inheritance by Gregor Mendel in 1865, laying the foundation for classical breeding methods.
	1930's	Development of commercial hybrid crops.
	1940's to 1960's	Use of mutagenesis, tissue culture, plant regeneration. Discovery of transformation and transduction. Discovery by Watson and Crick of the structure of DNA in 1953. Identification of genes that detach and move (transposons).
Modern	1970's	Gene transfer through recombinant DNA techniques. Use of embryo rescue and protoplast fusion in plant breeding and artificial insemination in animal reproduction.
	1980's	Insulin as first commercial product from gene transfer. Tissue culture for mass propagation in plants and embryo transfer in animal production.
	1990's	Extensive genetic fingerprinting of a wide range of organisms. First field trials with genetically engineered plant varieties in 1990 followed by the first commercial release in 1992. Genetically engineered vaccines and hormones and cloning of animals.
	2000's	Bioinformatics, genomics, proteomics, metabolomics.

62.2.1.2 Mutagenesis and Natural Breeding Techniques

For thousands of years, indigenous people, and above all women, observed the natural evolution of plants and started a cross breeding process to enhance the quality of seeds or of domestic animals. These natural modifications improved the quality and productivity of crops. During the 20th century with the molecular technique small segments of DNA were inserted to remove unwanted genetic linkages which required backcrossing and the process was relatively slow while researchers had to wait for the production in the next cycle (table 62.1).

The results of these scientific efforts were hybrid seeds, promoted during the green revolution, that were able to improve multiple times the yield productivity, but induced also pollution of agro-chemicals into soils, the air, and water. FAO data indicate that for all developing countries, from 1960 to 2000, yields rose for wheat by 208 per cent; for rice by 109 per cent; for maize by 157 per cent; for potato by 78 per cent and for cassava by 36 percent (FAO 2008; ISNAR 2001).

62.2.1.3 Genetically Modified Organisms or Transgenics

Different molecules are combined *in vitro* into one molecule to create a new gene, which is transferring the modified novel traits into an organism or seed. *Genetically Modified Organisms* (GMOs) contain altered genetic materials through genetic engineering techniques, also called recombinant DNA technology. Thus, GMO implies the modification of the genetic characteristics of a micro-organism, plant or animal by inserting a modified gene or a gene from another variety or species. GMOs may be micro-organisms designed for use as bio-pesticides or seeds that have been altered genetically to give a plant better disease resistance or growth. The main difference of GMO in relation to breeding is allowing the addition of a single or multiple characters of novel genes from *unrelated* plants, microbes, and animals into the genome of a plant.

For transgenics, different techniques are employed:

a.) recombinant nucleic acid techniques with the insertion of nucleic acid molecules, involving the formation of new combinations of genetic material through insertion. They are produced by different means (any virus, bacterial plasmid or other

vector system) and incorporated into a host organism in which they do not naturally occur but where they are capable of transmitting the genetic information;

b.) techniques involving the direct insertion of a hereditary material into a molecule or organism, prepared outside by micro-injection;

c.) cell fusion (including protoplast fusion) or hybridization methods, where live cells with new combinations of heritable genetic material are formed through the fusion of two or more cells by biotechnological methods.

The main difference of a GMO is the transfer of its hereditary mechanisms, not through the normal process existing in nature, but forced by the above techniques.

In agriculture most GMO seeds produce resistance to herbicide roundup or combat insects through a gene called Bt (*Bacillus turengiensis*; Oswald Spring 2002: 55–56). Recently, breeding aims in plants are generating crop improvements. While conventional breeding techniques rely on the random rearrangement of existing genes between two closely related parent plants, genetic engineering offers possibilities to known genes to be inserted (even from completely unrelated organisms such as fungi or bacteria), giving specific crop traits to plants.

Genetic engineering is used to combat plant diseases such as virus infections where no treatment was previously possible. GMOs may enhance food quality not only in industry, but from crops on oilseeds, stark crops, and vitamin A. Confronted with climate change, water scarcity, salty soils, heat waves, floods and droughts, GMO seeds are being developed to resist these known stresses. For example, silk proteins, biodegradable plastics, or industrial enzymes and vaccines are opening new processes for the pharmaceutical industry. Vaccines in banana reduce the risk of using needles and the obligation of refrigerators. Finally, several fruits and vegetables are genetically modified (tomatoes, melon, apples) to retard the maturation process. This often happens also during the process of transformation.

Diverse GMO products were developed and three generations can be distinguished globally:

- *First generation:* referring to characteristics induced as agricultural inputs (Roundup, Bt), able to combat plagues, insects and weeds;
- *Second generation* where characteristics of post-harvest are modified such as tomatoes, melons, and others through the introduction of a gene that can extend the maturation process or the elimination of the maturation gene;
- *Third generation* where the nutritional value of a product is modified, such as 'golden rice' in Asia, or seeds resistant to drought, to acid soils, and those able to produce vaccines and medicaments.

62.2.2 Evolution of Transgenics

In 1992, when the *US Food and Drug Administration* (US FDA) declared genetically engineered organisms as innocuous without requiring any regulation; this triggered a global boom for commercial production (figure 62.1). In 2007, the area expanded from 12 *million hectares* (Mha) to 114 Mha, where maize alone increased from 10 Mha to 35 Mha.

Figure 62.1: Genetically modified plants (in Mha), **Source:** GMO Compass of Genius GmbH, Darmstadt (Germany); at: <http://www.gmo-compass.org/eng/news/> (15 February 2008).

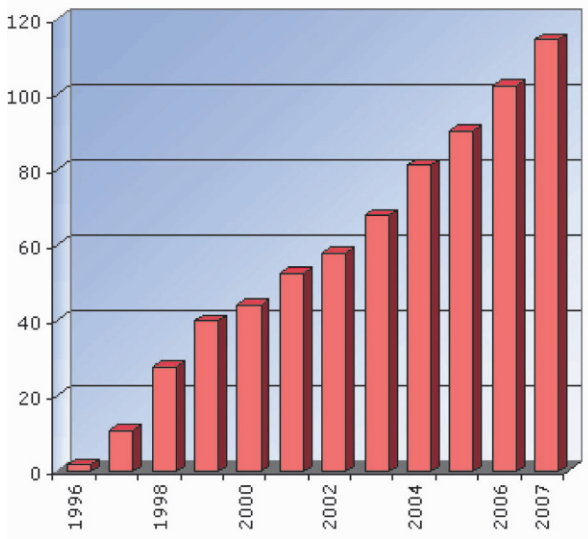

Figure 62.1 refers to a rapid global expansion of GM crops since 1999. From 1996 to 1999 GMO crops increased from 1.7 Mha to 39.9 Mha, and between 2003 and 2004 they expanded from 13.3 Mha to 67.7 Mha. In 2005, after ten years of GM field production, about 8.5 millions farmers in 21 countries were cultivating 90.5 Mha, thereof 55 per cent in the USA. James (2004, 2005) estimated for the year 2010 an extension to 150 Mha in 30 countries. ISAAA (2006) estimated GM crops in 21 countries, were 8.5 millions farmers bought 71 per cent of seeds that were resist-

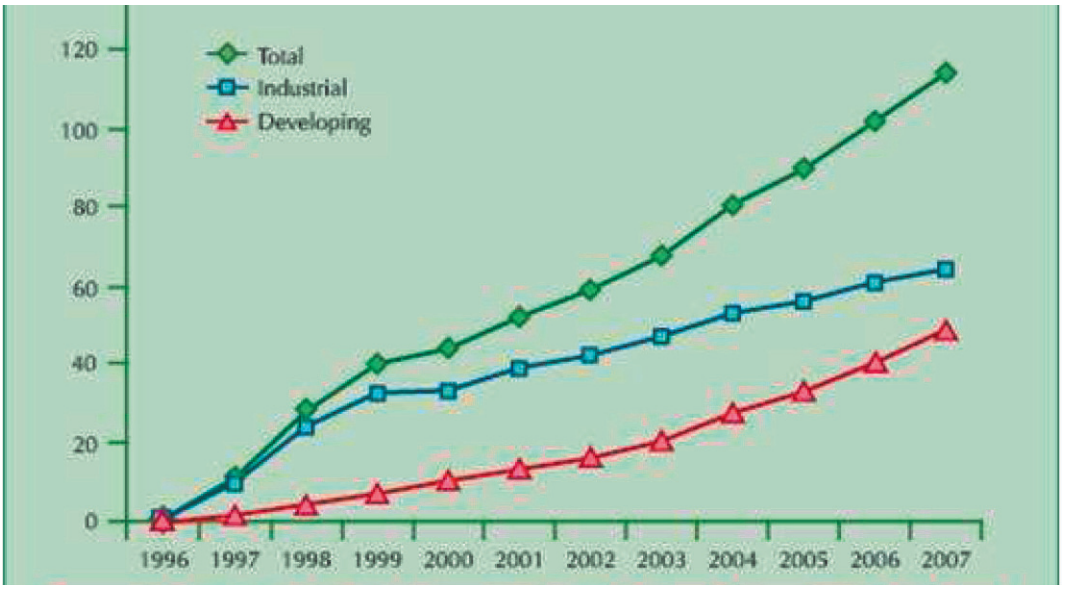
Figure 62.2: Global areas of GM crops in million hectares (1996-2004). **Source:** ISAAA (2007); at: <http://www.isaaa.org/resources/publications/briefs/37/executivesummary/default.html>.



ant to herbicides, 18 per cent to insects, and 11 per cent to both.

In 2007, 22 countries used transgenic technologies (figure 62.2). GM crops were concentrated in the USA with 57.7 Mha of soya, maize, cotton, canola or rapeseeds, squash, papaya and alfalfa; followed by *Argentina* (19.1 Mha of soya, maize, cotton); *Canada* (5.4 Mha of canola, maize, soya); *Brazil* (5 Mha of soya, canola); *India* (6.2 Mha of cotton); *China* (3.8 Mha of cotton, poplar, papaya, tomato, sweet pepper); *Paraguay* (2.6 Mha of soya); *South Africa* (1.8 Mha of maize, soya, cotton); *Uruguay* (0.5 Mha of soya, maize); *The Philippines* (0,3 Mha of maize); *Australia* (0.1 Mha of cotton) and *Mexico* (0.1 Mha of cotton). *Colombia* (carnation, cotton), *Chile* (maize, soya, canola), *Honduras, Spain, France, Portugal*, the *Czech Republic, Germany, Slovakia, Rumania* and *Poland* with less than 0.1 Mha of GMO produced maize (ISAAA Briefs No 37–2007; FAO/WHO 2008). There are also smaller productions of potatoes and other food crops. The GMO production is basically concentrated in four crops: soya, cotton, maize and canola (table 62.2).

The expansion of GM crops is limited to few crops and regions (table 62.2; figure 62.3), where countries with huge populations have produced GMO to overcome food scarcity. While China and India improved their food production, India still has most hungry people, what shows that production alone will not resolve world hunger.

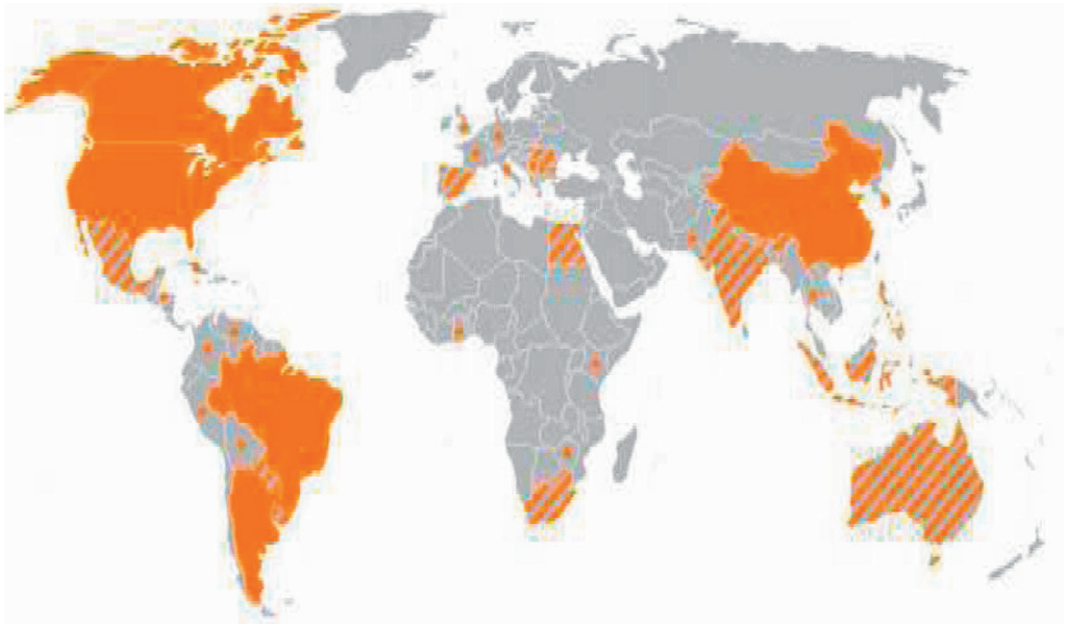
Table 62.2: Areas and types of GM seeds worldwide. **Source:** ISAAA (2007), Brief No. 37; at: <http://www.isaaa.org/resources/publications/briefs/37/executivesummary/default. html>.

Product	Area	Area GM	Proportion GM/total area (in per cent)
Soya	91	58.6	64
Maize	148	35.2	24
Cotton	35	15	43
Canola	27	5.5	20

The greatest controversy over GMO exists in Europe, where in 2008 some 108,000 ha were dedicated to Bt maize. France banned the CM cultivation of corn and 21,000 ha were abandoned, what was compensated by Romania (7,000 ha), Poland (3,000 ha), Czech Republic (8,380 ha), and Slovakia (1,900 ha). With 79,269 ha Spain had the greatest area of GM crops and the largest area of GM maize within the EU. In 2008, Portugal produced on 4,851 ha and Germany on 3,173 ha of corn.

The *International Service for the Acquisition of Agri-Biotech Applications* (ISAAA 2007) estimated that in 2007 global biotech crops amounted to US$ 6.6 billion (maize: US$ 3.2 billion; soybean: US$ 2.6 billion; cotton: US$ 0.9 billion; GM canola: US$ 0.2 billion), or 16 per cent of the global crop and 20 per cent of the commercial seed market (US$ 34 billion). A total of 76 per cent of the GM crop market was in

Figure 62.3: Countries with GM-crops in 2006. **Source:** ISAAA (2006). Legend: Light grey: no GMO; dark grey: GMO without constraints, light/dark grey: GMOs are experimentally accepted with legal constraints.



industrial countries and 24 per cent in developing countries (US$ 1.6 billion). This includes the sale of seed plus technological fees. For 2008 the market for GM crops was projected at US$ 7.5 billion. Between 1997 and 2007 the value is estimated at US$ 42.4 billion.

European Union (EU) countries adopted special regulations for GM crops and require a strict labelling. Some countries have declared unilateral moratoriums on GM-food products, such as France in 2008. Other crops followed including sugar beets, oilseed rape with a herbicide tolerance, and potatoes with modified starch (Altieri 1996, 2001). Several European countries are not commercially growing GM crops, but they have accepted slow ripening tomatoes, soya resistant to herbicides (glyphosate), insect-resistant maize, and herbicide-resistant rape seeds for oil. In response, the USA launched a trial at the *World Trade Organization* (WTO), accusing the EU of creating trade obstacles.

62.2.3 Biotechnology and Food Security: Threat to Biodiversity?

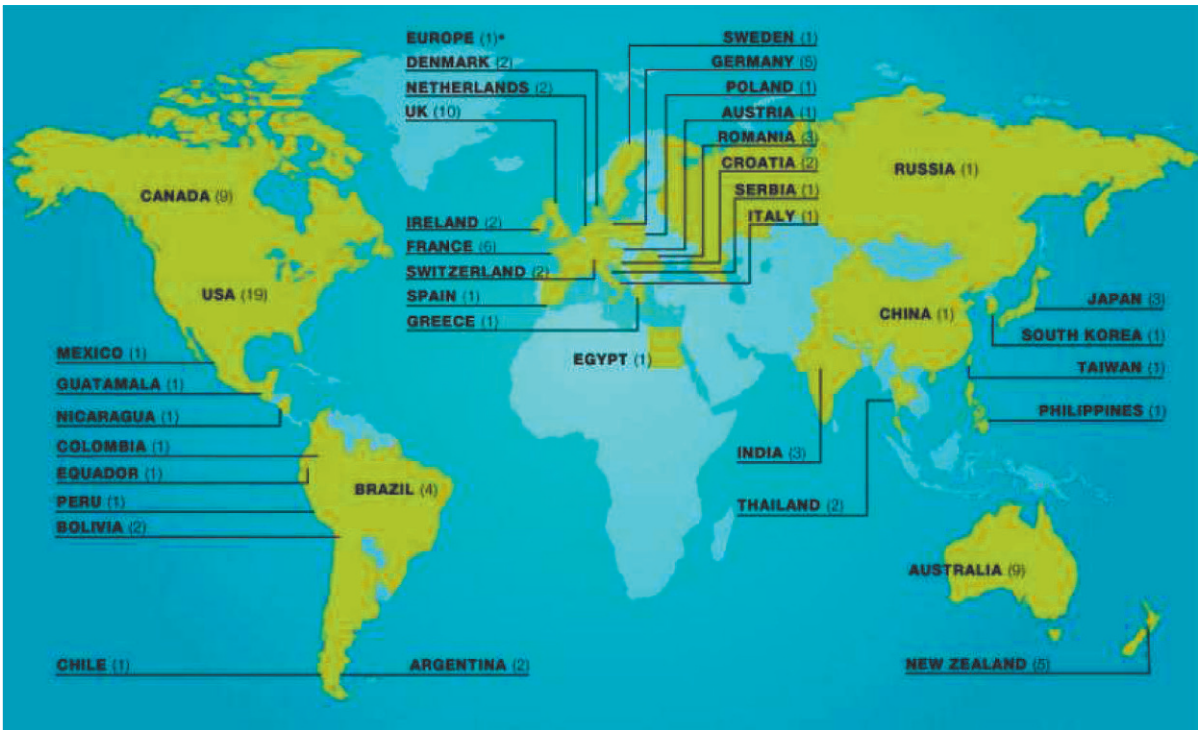
Biotechnology is a much wider field than GMOs, encompassing genomics, bioinformatics, marker-assisted selection, micro-propagation, tissue culture, cloning, artificial insemination, embryo transfer, and other related technologies. However, GM crops are the most public pressing concerns and for some governments it has become a policy issue. There are also opportunities, risks, and threats related to the process which will be analysed below. During the rapid expansion of GMOs, some accidents occurred (figure 62.3) with non-authorized genes that provoked major critiques. Several countries noted a loss of biodiversity[3] both nationally and globally. Among the 217 countries (2007) only 13 are mega diverse[4], and they combine 70 per cent of the biodiversity on earth.

Gene Watch UK and Greenpeace (2006) documented cases of pollution, illegal crops, and collateral negative effects on the environment. In June 2005, GM maize with Bt10 (StarLink), an unauthorized product, was found in Japan. Syngenta acknowledged that it exported these seeds between 2001 and 2004 to the USA without permission under the *Codex alimentarius*. This GM seed produces resistance against

3 Biodiversity includes the variety of all forms of life, from gene to any species, living within the ecosystems of this planet. It encompasses all agricultural species developed during human history and adapted for food. Peasants, women and indigenous people depend on this biodiversity for their survival.

4 Brazil, Mexico, Costa Rica, Colombia, Ecuador, Venezuela, Peru in Latin America; China, India and Indonesia in Asia; Kenya and South Africa in Africa are all developing countries, and only Australia is an industrialized nation.

Figure 62.4: GM Pollution, accidents, and collateral effects of GM in the world. **Sources:** GeneWatch, UK; Greenpeace International (2006: 35).



the antibiotic ampiciline (Nature 2005). Genetically modified soya tolerant to Roundup (a potent herbicide from the same multinational enterprise) generated resistance in the *Conyza canadensis*, due to a genetic transfer which produced a thirteen fold increase of this weed. New plagues may require farmers to use more potent herbicides (Owen/Zelaya 2005).

In Canada, similar processes occurred with GM strains in canola from different laboratories, what required the use of nine different herbicides due to plant resistance (Schmeiser 2002). Therefore, each crop has a different pollination radius and gene flow from out-crossing, what poses for natural relatives dissimilar threats that must be taken into account when field trials are undertaken (table 62.3).

The USA is not only the first producer of GM crops, but has also experienced the highest number of accidents. This means that the legal enforcement has been weak and during the Bush Administration the interests of TNEs prevailed, e.g. within the Environment Protection Agency (EPA). Thus, the controlling body pursued a policy that represented the interests of GM monopolies. No global control system exists that can prevent accidents and punish violators. With a faster growth in GM crops, new abusive practices will rise which may threaten the environmental security of some countries and possibly of the whole world.

Table 62.3: Frequency of gene flow from out-crossing. **Source:** Eastham and Sweet (2002: 9).

Crop	Crop to crop	To wild relatives
Oilseed rape	High	High
Sugar beet	Medium to high	Medium to high
Maize	Medium to high	No wild relatives are known
Potatoes	Low	Low
Wheat	Low	Low
Barley	Low	Low
Fruits: strawberries, apples, grapes, plums	Medium to high	Medium to high
Raspberries, blackberries, blackcurrants	Medium to high	Medium to high

The benefits and risks of GMO in biodiverse countries refer to the ecological stability of GMOs. Their collateral impacts could be harmful or fatal to ecosystems. A report on mustard seed that was engineered for herbicide resistance concluded "that

twenty times as many resistant progeny received their resistance from the transgenic plants as from the mutant plants. It is unclear why these transgenic plants had such an abnormally high incidence of out-crossing, but the results demonstrate that genetic engineering can substantially increase the incidence of out-crossing in a selfish species," probably by an unintentional disruption in the recipient organism of the sequence controlling pollination and fertility (Bergelson 1998).

Cross-pollination raised concerns that pollen of modified plants can be dispersed over large areas by wind, animals, and insects (table 62.3). Recent research with creeping bent grass supported this concern when modified genes were found in normal grass up to 21 km away from the experimental site. This hybridization of GMO with free living relatives is reported and the extension of changes depends on the plants.

> Danish field trials have shown that oilseed rape modified for herbicide tolerance can easily cross wild Brassica species such as wild mustard. Consequently, cross-pollination between GM and non-GM oilseed rape has been detected at distances up to 2 km (IUCN 2004: 30).

Potatoes do not exceed 10 m and US EPA recommended for Bt maize a distance of 200 m with non-GM crops. Herbicide glyphosate is creating less resistance than Bt insecticides. In Australia herbicide resistance was documented in 1995 to ryegrass, quackgrass, birdsfoot trefoil, and *Cirsium arvense* (Gil 1995). The resistance to glufosite passed from *Brassica natpus* to populations of weedy *Brassica napa* and persists under natural conditions (Snow/Moran 1997). In Europe, the herbicide tolerant gene transfer from *Brassica* oilseed to *Brassica nigra* and *Sinapis arvensis* is being researched (Goldberg 1992).

Bt proteins are becoming highly bioactive substances used everywhere in agro-ecosystems. Most herbivore ingests plant tissue containing Bt-genes, which they can pass on to their natural enemies in more or less transformed forms. Theses genes can affect unintended victims such as monarch butterfly or lacewing (*Chrysoperla* carnea), adversely affected by gene Cry1Ab. In laboratory conditions the mortality of monarch butterflies was documented, but in the field differences with traditional field management could not be found. These facts received a high-profile press announcement that Bt-genes poisoned butterflies and moths, but the critique did not distinguish between a Bt-gene expressively inserted in maize to avoid the damage from caterpillars and unintended effects of wild species.

The benefits are sometimes a reduction of agrochemicals and an increase in agricultural production with a maximization of yield productivity or lower losses of harvests and during storage. This can support food security, whenever the problem of hunger is not the lack of food, but the lack of money to buy it. A third positive effect is related to wider development processes, to research and job opportunities, whenever, in field research the contrary is documented, due to a lack of integrated rural development policies, where agribusiness with monoculture and high technology is expelling manpower from rural areas. Most scientists agree that the reduction of pesticide is a positive answer, especially the use of organophosphate and pyrethoid insecticides. Recently, the carbon-storage in GM wood was discussed that can reduce the greenhouse gases and mitigate climate change. Edible vaccines permit not only to vaccine massively people without needles, due to the fact that transgenic bananas and tomatoes could produce a vaccine against cholera, saving millions of persons from diarrhoea. As an additional positive effect, cold storage of vaccines is avoided and a vector of transmission of HIV/AIDS through needles is eliminated.

Achieving a balance between positive and negative effects on biosafety issues (box 62.1) justifies a continuous need for monitoring and research that must be independent from commercial or industrial development, and from governmental interests. In Europe there is much concern on the option and technologies that permit coexistence between GM and traditional farming. This includes research on biological containment strategies that prevent cross-pollination and enable coexistence without threats of pollution.

62.2.4 Transnational Transgenic Enterprises: Threats to the Economy and to Food Sovereignty

The key argument for transgenic food is the eradication of famine in the world and the nutritional improvement for people by creating food safety[5] according to the life sciences (Oswald Spring 2009).

5 "*Food security* exists when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food which meets their dietary needs and food preferences for an active and healthy life. Household food security is the application of this concept to the family level, with individuals within households as the focus of concern." (FAO/SDWW 2001; Oswald Spring 2009a)

Box 62.1: Most common biological threats posed by GM crops. **Source:** IUCN Programme (2000:17-19).

1. Genetic contamination by interbreeding of GMO with wild relatives and other sexually compatible species in the area. Reduction of the fitness of non-target organisms through acquisition of transgenic traits by hybridization.
2. Competition with natural species, when one trait increases productivity faster and therefore an organism can become invasive. When interbreeding with wild species, it may force them and generate a possible extinction.
3. Rapid evolution of resistance of insect pests (Lepidoptera to Bt).
4. Risk of super-pests or super-insects can grow in monoculture with GM-crops, while they homogenize biodiversity and debilitate immune systems of plants and may turn them more vulnerable to disease and pest attacks.
5. Increased selection pressure on target and non-target organisms, when a pest-resistant GM-crop could induce agricultural pests to evolve distinct population that are resistant to certain toxins.
6. Disruption of biocontrol mechanisms and natural control of insects and other pests through intertrophic-level effects of Bt-toxins on predators.
7. Unexpected effects on non-target herbivorous insects (i.e. Monarch butterflies) through transgenic pollen of surrounding wild vegetation.
8. Transgenic crops can produce environmental toxins that move through the food chain into water and soil and may affect invertebrates and nutrient cycling.
9. Ecosystem impacts, while combined processes can go beyond one single species, affecting the trophic chain or inducing the collapse of a particular ecosystem.
10. Vector-mediated horizontal gene transfer and recombination can create new pathogenic organisms.
11. Broad-spectrum herbicides and insecticides will expand, increasing resistance problems.
12. Impossibility of follow-up: once GMO is released to the field there is no ability to call them back or to eliminate them. This process is not only related to GMO, but is widely documented by the introduction of alien species that destroyed or displaced the native ones.

Peasant movements, above all Via Campesina, have criticized this productivity approach and struggled for *food sovereignty* as a cultural holistic process, where food production and consumption are linked to social justice, land reform, livelihood and cultural diversity. Hunger is not only related to lack of food, but also to scarce money and income. For the poor it is a problem of access due to lacking financial resources.

Regarding the economic impacts of GMOs three main concerns must be observed. The *first* is related to the high costs of GM seeds as a result of the monopoly position of a limited number of TNEs. The *second* approach requiring risk-benefit analyses has been often lacking and in most cases the evaluation of costs of non-acting or opportunity costs (or the loss of valuable opportunities) are underestimated or not taken into account. *Third*, in most countries in the south the natural resources (water, soil, air) are considered as free, belonging to the communities who care about their conservation. The modernization process rarely takes into account social costs of displaced communities, abolished cultures, and destroyed potential environmental services. For an integral economic approach direct information on land productivity, livelihood of peasants, and regional food production is required, together with studies on oligopolies of seed controls and GM technologies, the costs of scientific development and surveys of transgenics already used in the field. All these factors should be listed and later the impact of GM seeds and the agriculture without gene modification should be compared.

Comparative studies show the complexity to quantify agricultural activities, as multiple factors intervene (seeds, land, water, fertilization, pesticides, energy, biodiversity, environmental services, labour, technology, machines, and repercussion in health, environment, and disasters) and new risks must be included. The *European Union* (EU) evaluated the impacts of GM soya, cotton, maize and canola, and their resistance to insects and herbicides (Gómez-Barbero/Rodríguez-Cerezo 2006: 34–38). Most studies in different parts of the world found that GM crops require less agro-chemical products. Besides some direct positive effects in income, farmers have more free time due to simplified production processes. In some cases, GM are taken as a kind of insurance against the effects of climate change and droughts. On the field size the studies did not find differences between large and small farmers (FAO 2005).

For crops, the best results were obtained in China, Kenya, Argentina, and Mexico for Bt-cotton. But in India the seeds that were developed for northern conditions did not always produce the same results. By loosing their output and accumulating large debts for purchasing GM seeds, in many cases Indian and Korean farmers committed suicide.[6] Poor countries lack research centres to produce their proper seeds and depend on technology import from industrialized countries which often requires fees for patents and

royalties. FAO/WHO (2003) noted that countries with well developed agricultural research establishments and explicit procedures for biosecurity and clear property rights can assimilate GM technologies much faster.

A field study with 638 cotton farmers in La Laguna in Mexico (Traxler/Godoy-Ávila/Falck-Zepeda/Espinoza-Arellano 2003) found that the yield increase/ha was 11 per cent, and the use of chemicals dropped by 77 per cent, but the costs for seeds increased by 165 per cent and net benefits were only 12 per cent, of which the farmers obtained 86 per cent and the TNEs 14 per cent. In the USA in 2003, Bt-cotton increased the income of farmers by US$ 105 million, the TNEs gained US$ 80 million in profits and consumers saved US$ 45 million. In China, due to the role of the public sector in seed production, small producers avoided high prices for seeds. Globally, of the profits for Bt-cotton, about 75 per cent went to producers and 25 per cent to multinational seed suppliers (FAO 2005).

Beber and Potrykus (2001: 10) compared 'golden rice' with GM-Vitamin A and iron genes with a traditional Vitamin A drug supplement. They found in 100 million people treated with drugs (including costs of administration and distribution) the costs per year were US$ 50 million, or US$ 500 million in ten years. The costs for iron supplements as drugs were the same. If GM seeds are developed through a government programme with bio-fortification including Vitamin A and iron, the costs would be US$ 25 million/decade for both. These are economic savings for the Indian health system. But people eat rice with other traditional food products (NAVDANYA 2001: Annex 1).

Monsanto justified the high prices of GM seeds with research and development costs of US$ 200 and 400 million in a decade. This explains why the price for GM-seeds is ten times higher than for traditional seeds. Farmers may not stock seeds for the next year. When they use GM seeds they must pay for the patents. Many enterprises have established their own monitoring system to penalize anybody who illegally uses their seeds. Even for natural GM pollution by wind, water or insects, farmers must pay the TNEs for their *intellectual property rights* (IPR).[7] To better protect its patents, Monsanto used the 'terminator' technology that destroys the germplasm of seeds, thus stopping reproduction. Due to the pressure of governments and scientists, who documented that this required tetracycline (a wide spectrum antibiotic), Monsanto stopped this technology.

The high price for GM seeds is also due to the oligopolic structure of few seed producers, most of them are huge TNEs. In 1998, Monsanto bought Delta/Pine Land and since then Monsanto controls 57 per cent of the US market for cotton seeds, and can thus impose the price. This leaves farmers few alternatives for cheap seeds (table 62.4). Furthermore, Monsanto is eliminating a toxin within the cotton seed for feeding animals and humans (Monsanto 2006).

Table 62.4: GM seed market of cotton in the USA in 2005. **Source:** USDA (2005).

Company	per cent of the seed market
Delta & Pine Land (bought by Monsanto)	43.37
Stoneville (Monsanto)	13.93
Bayer CropScience	25.32
Phytogen (Dow AgroSciences)	2.64
Others	14.74

The world market for GM seeds reflects this monopoly. Four agro-chemical and pharmaceutical TNEs control this market, two US companies *Monsanto* (including Pharmacia and Upjohn) and *Du Pont/Pioneer*, *Syngenta* in Switzerland (a merger of the Swiss Novartis, former Ciba Geigy and Sandoz with the British-Swedish Astra-Zeneca) and *Sanofi-Aventis* (merger of Hoechst in Germany with Rhône-Poulenc in France). Globally, these four TNEs sell half of traditional seeds and almost all transgenics. These four oligopolies control 75 per cent of the world seed market of vegetables. This vertical integration allows market controls and forces farmers to work only with this technology. Thus, they lose control of their produc-

6 The Ministry of Agriculture in India noted that between 1993 and 2003 about 100,000 peasants committed suicide, and between 2003 and October 2006 about 16,000 suicides by farmers occurred each year, in total almost 150,000 suicides for the period from 1993 to 2006, with an average of 30 dead/day in 14 years. These fatalities reflect a missing adaptation of technology to southern conditions and they refer to economic pressures on poor peasants (Shiva 2009, 2009a).

7 In Canada, Percy Schmeiser's (2002) canola seeds were polluted with Bt-genes from Monsanto. He was sued by Monsanto and lost his case in the Supreme Court. He was condemned to pay for the patent of the Bt-seeds and thus lost his livelihood as a natural producer of canola seeds.

Table 62.5: Summary of the status and trends in major bioprospecting industries. **Source:** Millennium Ecosystem Assessment (2005: 109).

Industry	Current Involvement in Bioprospecting	Expected Trend in Bioprospecting	Social Benefits	Commercial Benefits	Biodiversity Resources
Pharmaceutical	tends to be cyclical	cyclical, possible increase	human health, employment	+++	P,A,M
Botanical	high	increase	human health, employment	+++	mostly P,A,M
Cosmetics and natural personal care	high	increase	human health and well-being	+++	P,A,M
Bioremediation	variable	increase	environmental health	++	mostly M
Crop protection and biological control	high	increase	food supply, environmental health	+++	P,A,M
Biomimetics	variable	variable, increasing?	various	++	P,A,M
Biomonitoring	variable	increase	environmental health	+	P,A,M

P= plants, A = animals, M= microorganisms

tion process. Often their land gets polluted or they lose it due to high debts from the purchase of seeds.

These oligopolies also control the trade with agricultural products. Enterprises, such as Cargill, Monsanto and also Maseca (a Mexican), rejected in 2007 to buy maize and wheat produced with seeds developed in Mexico by the *National Institute of Agricultural Research* (INIFAP). They qualified these grains as unusable for flour and pasta. In some cases these oligopolies have become monopsonies that control both the sale of seeds and the purchase of cereals. Freedom of consumers for traditional seeds is further limited due to higher prices for natural products and small markets.

Globally about 1.4 billion poor peasants, increasingly women, produce 15 to 20 per cent of food with traditional seeds that are carefully selected each year and conserved for the next cycle. This subsistence production does not reach the market and they are in environmental terms sustainable (Barraclough 1995). In social terms, they represent a kind of family insurance, guaranteeing the daily intake of basic food. Accidents with GM pollution may destroy this agricultural diversity and leave these peasants without opportunities for survival, and force them to abandon their land due to hunger. For millennia these peasants have also developed traditional medicine and practised a rational use of biodiversity with environmental services for other communities.

TNEs are interested in their knowledge and *bioprospection* emerged as a new multi billion US dollar business branch of the pharmaceutical, botanical, cosmetic, crop protection, horticulture, and seed production industry (table 62.5).[8] According to WTO rules, the IPR of TNEs are protected by patents. The original owners of this knowledge can rarely prove their IPRs. In the US and elsewhere, many natural products are transformed by TNEs, mostly without compensation to the community that has developed, maintained, and supplied this knowledge for millennia (table 62.6). When living organisms are taken from their original owners without compensation, people often refer to *biopiracy*.

8 Traditional medicine, natural colours, and multiple sub products are useful in industrial and pharma-ceutical processes. As they are transformed, it is difficult to prove that the origin of the product was a plant or a root (e.g. the barbasco for anti contraceptive pills and steroids).

Miltefosine		Acta Medica
Porfimer sodium		Quadra Logic
Sorbuzoxane		Zeuyaku Kogyo
Zinostatin		Yamamouchi

62.3 Risk Analysis as a Scientific Response

62.3.1 Potential Threats to Health Security

Several studies have documented that agro-chemicals could be substantially reduced with GM seeds (FAO 2005). This could increase the income of farmers, and protect the environment and human health from undesirable toxic effects of organophosphates and organoclorates. Besides these undeniable advantages other multiple doubts exist. Only very few independent researchers who study the full food chain and its repercussions for human health have the capacities to prove that hazards for the health system may develop when GM seeds are massively produced and eaten either directly or indirectly from meat of animals that were fed with transgenics.

In the literature, one case has been widely documented that refers to the pollution of L-Tryptophane, an essential amino-acid in brain functions. The laboratory Showa Denko KK (USA) utilized not only transgenic soya beans, but changed at the same time also the system of filtration for the production of Trypotophane by using less carbon in the purification process. From 60 pollutants found in the lab, six produced the *eosinophilia-myalgia syndrome* (EMS), causing 37 fatalities, 1,500 people handicapped, and another 500 affected through consumption of this drug. After reviewing this case, the US Federal Drug Administration (FDA) concluded that the purification process was responsible for the pollution and not the GM seeds:

> The incident cannot be taken as clear evidence of the inherent risks of genetic modification or the need to prohibit the use of genetic modification outside laboratory containment. There are, however, some useful lessons. For example, the short time it took the United States authorities to withdraw the production in question illustrates the need for such authorities to maintain the ability to respond rapidly to indications of harmful effects. The length of time it took to identify accurately all the toxins responsible for the harm, however, highlights the need for ongoing research into the hazards of the technology (Royal Commission on Genetic Modification 2005: 44).

This procedure is relevant as other complex problems are related to potential health hazards. Any GMOs contain a 'genetic construction' of sequences of DNA and each could imply proper risks in relation to vectors developed between the promoters. The first arise when viruses are used as transgenic vectors (the so-

called genetic pistol). Like the virus, these genes can infect the body and the GMO could get converted into a new reservoir of unknown illnesses or a means to sustain the evolution of new pathogens when the physiology and biochemistry is altered (Oswald Spring 2000).

In the case of the sequence of a strong promoter, e.g. the virus of the cauliflower mosaic (CaMV35S) could activate genes that were before inactive, thus creating potential new illnesses. There are fears that GM genes are resistant to antibiotics (e.g. Monsanto's 'terminator technology'). There are other concerns on the horizontal transfer between genes from one species to another, when the vegetable material rests in the soil and starts a process of decomposition. During this process the GM DNA is drained into the soil, where it can get stabilized through the absorption of polymers such as acid and humid particles in the soil that may pollute other crops and micro-organisms.

Another health problem is related to maize that was modified by StarLink (Cry9C) that has been produced by Aventis since the year 2000. It was banned by the *US Department of Agriculture* (USDA) and only permitted in animal food, when it was linked to allergies. Aventis had to stop its sale, USDA issued a formal recall and the US government purchased its seeds. The polluted maize was found in eight countries (Canada, Bolivia, Egypt, Japan, Nicaragua, South Korea, USA, and China). In 2003 genetic strains could still be spotted in the fields. Greenpeace (2005) found it in rice in China. Similar problems occurred in Brazil with a nuts gene protein in soya beans that could create allergies, and with a 'marker' gene that could render cells resistant to antibiotics.

Negative or hazardous research results are often not published by TNEs and scientists had to sign confidential letters forbidding them future publications on such cases. Monsanto did not publish any information on MON863, a GM maize with Bt-toxin (Cry3Bb1). In April 2004, *Le Monde* referred to doubts by French scientists on the security of this GMO. A comparative study on rats had shown that after 90 days MON863 had produced significant alterations in the white blood cells that are further indicators for kidney affection and inflammatory processes. These independent data proved that the health of rats was affected. This GMO interfered also in the metabolism of humans and animals, once this transgenic was liberated. Therefore, the permission was denied (Greenpeace 2004). But the lack of transparency on the publication of results refers to a lack of ethical considerations of TNEs and in some countries to severe deficits of rigorous independent evaluations. TNEs can not simultaneously be judges and producers of new GMOs before they can be widely marketed. Independent bodies must evaluate the risks of a new product and continue to monitor it.

Worries also relate to remaining parts of transgenics in the human body. During cooking and digestion with enzymes and micro-organisms most of the DNA is broken up into so small parts that are no more functional. With more sophisticated analytic methods traces of Bt maize were found in the lymphocytes of cows and in muscles, liver, spleen and kidney of chickens. Furthermore, pregnant rats have transmitted fragments of DNA through the placenta to their foetus (ESF 2001). Only when the GM DNA reaches the large intestine is it fully degraded. The survival of the DNA of GM soya in the small bowel in rats was supported with data found also in sheep and humans. The gene transfer in the small intestine must be considered for future safety assessment of GM food (Scientific American, April 2001: 6). Heritage (2004: 170–171) emphasized

> on the balance, the data presented ... support the conclusion that gene flow from transgenic plants to the gut micro flora does occur. Furthermore, because transfer events seem to have occurred in three of seven subjects examined, it may be that transgenic gene transfers are not as rare as suggested by the UK GM Science Review Panel.

Michael Antoniou (2002) concluded:

> to my knowledge [data] have demonstrated clearly that you can get GM plant material in the gut bacteria...it suggests that you can get antibiotic resistance marker genes spreading around the stomach which would compromise antibiotic resistance.

Watson and Crick discovered the structure of DNA as the blueprint of life, where the characteristics can be predicted and replicate themselves in a stable way. Recent research on the human genome questioned this. By looking at proteins such as RNA, but concerned with illnesses such as BSE, scrapie and other degenerative brain diseases, the biochemical analysis could not find any nucleic acids, nor DNA or RNA. Based on these new findings their theories on DNA as the basis of all life were challenged. This is probably the most complex issue related to GMOs as bacteria and viruses are often used to introduce a particular characteristic into a seed. "The horizontal gene transfer is a relatively new concept that has been described as the capacity of genetic information to be passed between species in ways that are unrelated to the usual parent-offspring inheritance of gene" (IUCN 2004a: 17).

This horizontal gene transfer occurs frequently among viruses (Jain/Rivera/Lake 1999).

There is also new evidence that not all genes rely on mutations, but can copy themselves. The salivary amylase, an enzyme encoded by the *AMY1* gene, helps humans to digest starchy food. In a comparative study between high-starch eaters and low ones researchers from the University of California and from Arizona State University found "that rather than having mutations that boosted *AMY1*'s activity, the high-starch eaters had extra copies of the gene. On average, the high-starch eaters had seven copies of the gene, whereas the low-starch populations had only five" (Cohen 2007: 1483). This could mean if a gene is working well it can copy itself several times, what poses a new threat for transgenics. Therefore in most countries precautionary means were developed. Their results suggest that other factors exist beside the DNA transmission and they act as constituent processes of life, but there is no solid knowledge yet to fully explain them.

These comments refer to risks and as the DNA is part of all plants and animals, it belongs to all parts of the human diet. Thus, GMOs should be monitored more carefully on their effects on human beings. Epidemiological studies in the USA have shown that clinically food allergies in small children have increased after 1995, when GM seeds were introduced. The TNEs that produce baby food have stated that all their products are free of GM genes. Paediatricians have recommended avoiding transgenics in the diet of babies (above all GM soya) to reduce the risk of food allergy in small children. But most food products contain ingredients of soya and soya is mostly transgenic. There exist also doubts about the impact on the food chain of GM-food (Oswald Spring 2006a).

The analysis has revealed that transgenic food offers benefits by reducing agro-chemicals and thus of pollution of soils, water, food, and the air. But doubts on animal feed with GM food have not been overcome, when they later enter the human food chain. The clinical increase of allergies among children in the USA calls for utmost precaution.[9] Moreover, accidents and global GM pollution indicates that any technology could represent failures, and errors that could be fatal for the health of millions of people and for the biodiversity of the whole planet. If risks exist, only careful surveys and the precautionary measures can reduce these threats (Puttagunta 2000).

62.3.2 Risks of GMO Maize for Mexico

For gene flow maize there is a medium to high risk crop due to open pollination. Empirical evidence has shown that a recommended isolation distance of 200 metres would avoid hybridization, but no known wild relatives of maize exist in Europe (ESF 2001) or in South Africa (Haasbroek 2004).

Maize originates from Mesoamerica, and developed over 9,000 years when wild varieties of *Tripsacum* were crossed with teocinte (*Zea mexicana*). For thousands of years the indigenous people in Mexico have selected plants and have developed maize from a small corncob of one centimetre to up to 20–40 cm (*Zea mays*). Maize is reproduced by cross-pollination and pollen is able to mix with different genetic varieties of maize. In Mexico maize has been produced dynamically and therefore it is continuously changing as a result of human and natural selection. Thus, across the country different regional strains of maize exist, as the basic food crop for Mexicans, maize was adapted from the tropical rain forest up to the height of 3,000 metres on the hills of the Popocatepetl. Mexico has a total of 44 principle races and 300 varieties that can combat weeds (Greenpeace 2003; Wisniewski/Fragne/Massonneau/Dumas 2002). This biodiversity is unique in the world.

According to the *Convention on Biological Diversity* (CBD), biodiversity has "ecological, genetic, social, economic, scientific, educational, cultural, recreational, and aesthetic values" that are needed for human life. This cultural diversity has led to more than 600 different food varieties, and for '*nixtamal*' (cooked maize with chalk) at least 112 recipes exist. This culinary, cultural, and environmental diversity gives maize an important status not only in Mexico but also as a patrimony of humankind.

9 The USFDA established four levels of precaution: BL1-P with basic limits such as controlled access to greenhouses and mechanisms avoiding the propagation of GM by insects, cross-pollination and rodents. BL2-P for agents with potential moderate threats demand additionally cement soil. Mosquito nets to avoid the entrance of small insects and sterilization processes for transgenic material before confining. BL3-P for agents with serious threats, where liquids and solids must be sterilized, windows fully sealed and ventilation equipped with filters. The entrance must be controlled and protection clothes are obligatory for workers inside the facilities. BL4-P is required for extreme dangerous organisms related to exotic pathogen organisms, where all mentioned security issues are reinforced (IUCN 2000, 2004a).

Native species of teocinte exist all over Mexico in maize fields. They are associated with cultural, symbolic, and spiritual values as representations of Mother Earth. They grow together with maize. Thus, many peasants are threatened by the introduction of GM maize and they are concerned about their cultural, personal and community safety, but also about their biodiversity, traditions, and beliefs. Regarding this cultural context,

> Mexican government officials reported contamination of local varieties of maize with transgenic sequences in communities in the states of Oaxaca and Puebla. In January 2002 the Mexican government further reported that in 11 of the communities' contamination levels were between three and 13 percent; in four localities levels of contamination found were much higher – between 20–60 per cent. In Diconsa (Mexican government food distribution agency stores), 37 per cent of the grains were found to be transgenic (CEC 2004).

The RR maize (tolerant to some herbicides) and Bt maize (resistant to insects) represent risks introducing new elements to the environment that threaten the existing biodiversity. As the country of origin and adaptation of maize, Mexico has a special mandate to conserve its biodiversity.

Mexico is a member of the *North American Free Trade Agreement* (NAFTA), of the *North American Agreement for Environmental Cooperation* (NAAEC), of the Convention on Biological Diversity (CBD) and its Cartagena Protocol on Biosafety, of the WTO (including its Trade-Related Aspects of Intellectual Property Rights: TRIPS), and of the Ad Hoc Intergovernmental Task Force on Foods derived from Biotechnology of the Codex Alimentarius. Based on these legal obligations Mexico must establish *Sanitary and Phyto-sanitary* (SPS) Agreements, taking also *Technical Barriers to Trade* (TBT) in the framework of WTO into account. The CBD applies to the transboundary movement, transit, handling, and use of all *living modified organisms* (LMO; Art. 4). The Protocol regulates the transboundary movement of LMOs,

> consistent with their international obligations, socioeconomic considerations arising from the impact of living modified organisms on the conservation and sustainable use of biological diversity, especially with regard to the value of biological diversity to indigenous and local communities (CBD, Art. 26).

The high level of poverty and the dependence on subsistence agriculture for most maize producing peasants that represent a significant number of indigenous populations are the results of a rural crisis that evolved during the past four decades. This crisis has severely affected the most marginal in the remote rural areas in the south-east of Mexico. Even if the gene flow between land races of maize and modern GM varieties is infertile or produces fertile progeny, the gene flow also occurs between maize and teosinte, where nobody knows how long these genes persist after the hybridization. The gene flow in Mexico is a dynamic process with in situ management of genetic resources of maize and peasants' trade or interchange of seeds from different sources occurs permanently and therefore with risks of GM pollution.

The NAAEC recommended more field research on positive and negative effects from particular varieties of GM strains, taking socio-cultural matters of poor peasants and of indigenous people into account. Besides better education and training, small farmers should be involved and GMOs should be labelled with specific indications of the strains, and of the transgenic maize entering into Mexico. There is a logistic problem how to mill 6 million tons of maize on the border to avoid a potential contamination of natural seeds. But there is also a phyto-sanitarian issue related to milled maize, because it can get quickly affected by aflatoxines (*Aspergillus flavus*), a dangerous fungus for both humans and animals.

From January 1994 to 2008, Mexico was importing yellow and white maize from the USA with a tax reduction of 206.4 per cent (table 62.7).[10] Over 40 per cent of maize sold in Mexico is transgenic and without labelling, and peasants often reproduce it in their fields. Production costs and yields differ: In Mexico the average is US$ 79.68/ton with a yield of 2.4 tons/ha, while in the USA it is only US$ 19.89 and 8.4 tons/ha. This is a result of differences in the mechanization process, geological and social conditions, and in the extension of fields. Until 2008 the production of white maize was protected by negotiated import taxes, but since then any maize may be imported without customs clearance (Mexico, Chamber of Deputies 2008)..

In this complex situation, TNEs have exercised pressure on the *Intersecretarial Commission of Biosecurity and GMO* (CIBIOGEM), the national regulatory board, to allow the production of transgenic maize in open fields (Gobierno Mexicano 2003). But there is no knowledge about the effects of GM maize in open fields and the flux of pollen is not sufficiently

10 Beside this reduction, Mexico has not applied the obligatory taxes for the surplus of maize importation, to protect the livestock grower.

Table 62.7: Minimal obligations to import, customs on imported maize and imports. **Source:** Banco de Comercio Exterior (Foreign Trade) for the years 2000 to 2008.

Year	Minimal imports	Customs on maize (per cent)	Yellow maize	White maize	Broken maize	Total maize
2000	2,986,325	145.2	–	–	260,108	5,558,791
2001	3,075,915	127.1	5,648,904	489,173	862,878	7,000,955
2002	3,168,192	108.9	4,023,798	645,176	2,029,902	6,698,876
2003	3,263,238	90.8	5,401,119	323,666	2,684,989	8,409,774
2004	3,361,135	72.6	5,095,596	346,101	2,300,380	7,742,077
2005	3,461,969	54.5	5,110,590	66,225	2,705,080	7,881,895
2006	3,565,828	36.6	7,278,315	253,533	3,203,173	10,735,051
2007	3,672,803	18.2	9,500,000			
2008	3,782,987	00.0	913,069.8 (only January)			

known. No real experiments were undertaken under field conditions that include studies on the genetic flux, its impact on natural maize, its footprints on near relatives, on biodiversity, the throphic chain, and on future generations of maize. In such a study, environmental and socio-cultural restrictions should be taken into account, along with the impacts of potential extreme hydro-meteorological events (hurricanes, drought, and landslides). Indigenous people, peasants, and women have only a low level of education and they lack a culture of prevention. Given these difficulties, Mexico should not permit the cultivation of transgenic maize in open fields to conserve for future generations its biodiversity as a key potential for development.

Box 62.2: Complex situation of maize production in Mexico related to globalization and Free Trade Agreements. **Sources:** Data compiled by the author.

The inventory of maize in the world and in Mexico has diminished for various reasons (table 62.8). Due to population growth the demand for cereals will grow globally. Also the change of the diet in China and India with more animal proteins further increases the demand for cereals. Then there is the use of maize for biofuels (Bourne 2007). And finally, there has been a yield decline due to overexploitation of soils, desertification, salinization processes and disasters (droughts, floods). In Mexico this resulted in very low reserves of maize that can neither guarantee food security for the people nor for animal feed. This decline is a direct consequence of a lacking rural policy and of false investments priorities that have affected the maize-producing small peasants who increasingly face the impacts of climate change in rain-fed fields. Therefore, a different governmental policy must be adopted that offers the people both safe and high quality maize.

Maize production in Mexico has developed a highly complex and structured system of production and industry. Due to NAFTA and speculative interests, Mexico imported an increasing amount of cereals, substantially above the amount agreed with the US and Canada (table 62.8). While the white maize for human consumption is still mostly produced in Mexico, the yellow and broken maize for tortilla industry and livestock is imported from the USA, most of them is transgenic, but without labelling.

Table 62.8: World inventory of maize stock (million tons) **Source:** USDA (2007).

Countries	2004/2005	2005/2006	2006/2007
USA	53.7	50.0	19.1
China	36.6	35.2	33.4
Mexico	4.5	2.7	2.7
Others	36.0	37.1	31.2
Total	**130.8**	**125.0**	**86.4**

The lacking food security policy had repercussions on the price. From October 2006 to January 2007 the price of white maize increased from US$ 135/ton to more than US$ 273/ton, as a result of the rise in international prices and the speculation by big monopolies (Cargill, Maseca) and local intermediaries. The higher price was also a result of an increased demand of maize for biofuels due

to new subsidies by the US government. Thus, the price of the tortilla – the basic food staple for Mexicans – suddenly doubled in some weeks from 6.5 up to 15 pesos/kg (table 62.9). Massive protests within Mexico forced President Calderón to reach an agreement with the tortilla industry. As a result the official price was fixed at 8.5 pesos for six months, but the tortilla was mostly sold around 10 pesos. This crisis implied a serious warning to adopt a rural policy that supports the national production of maize, but also avoids dangerous experiments with transgenic maize. In the future, even without speculation, the price of maize will further rise due to declining international reserves and the greater demand of maize for humans, animals and biofuels, but also due to growing losses caused by GEC. Therefore, food security for peasants and poor people should be the goal of the Mexican government. Data of the last Household Review indicate (INEGI 2008) that around 2 million Mexicans became food poor in 2008, due to this price rise, and thus countered a decade of poverty alleviation.

Table 62.9: International maize prices in Mexico (in 1.000 Pesos per ton; 12.9 Pesos = 1 US$; 18.4 Pesos = €, in August 2009). **Source**: INEGI (January 2007).

City	White Maize (humans)	Yellow Maize (animals)
Mexico City	3,125	2,400
Guadalajara	3,154	2,437
National Average	2,575	2,147

62.4 An Ethical Approach Responding to Growing Food Demand

The studies reviewed above have shown both the potential, but also new risks and threats posed by GMOs, and they referred to much ignorance on the processes related to transgenic food. Undoubtedly there is a need for more sustainable food production. With the present production model the soil and water – also understood as 'virtual water' (Allan 2009) – are getting depleted and polluted. The complexity of these socio-economic, health, environmental, and cultural factors posed by transgenic food is aggravating risks for society and the environment.

Beck (2007) refers to a world risk society related to the modern technologies (genomic, transgenics, nanotechnology), where the society as a whole is exposed to irreversible threats. Habermas (1984a, 2002) defines ethical limits of these scientific developments when future generations will lack an opportunity to ratify this process or to revert it, or when GM-genes are breeding with wild relatives. Thus, risk was defined in different ways: as a function of hazards multiplied by the frequency and impact, and aggravated by social vulnerability (CENAPRED 2004; Birkman 2006), or as "the probability of harmful consequences, or expected loss of lives, people injured, property, livelihoods, economic activity disrupted (or environment damaged) resulting from interaction between natural or human induced hazards and vulnerable conditions" (IARF/DR 2006). For GMOs risk means harmful consequences for humans, their activities, and the ecosystems.

Thus, transgenic seeds in a megabiodiverse country such as Mexico with high levels of cross-pollination in maize, and peasants with low level of education and elevated marginalization could introduce irreversible processes both for specific communities and for the country as a whole. This would result in the definitive loss of biodiverse wild crops for humankind. Therefore a generational and intergenerational responsibility is needed that takes up the principle of sustainability (Brundtland Commission 1987) and risk reduction through prevention. Challenging the life of future generations may be considered as unethical (General Council of the United Church in Canada 2003).

As Beck insists, risks are unequally distributed in the world and affect more the highly vulnerable societies. GMOs and transgenic food seeds were developed in the north by a small number of TNEs. But they will primarily affect the south, due to marginalization and poverty, high biodiversity, population growth and severe effects of GEC, creating new potentials for complex disasters. Experts at the University of Michigan (2006) studied in Sub Saharan Africa the risks and benefits of transgenic crop seeds and their interrelation with the USA. Their conclusions are also valid for Europe, Asia, and Latin America. The pollution with GM crops may reduce biodiversity. The homogenization of the productive process with a small number of GM seeds could erode genetic reserves, create monocultures of food, and vulnerability to plagues in basic crops. The 1846 Irish famine resulted from a disease in the monoculture of potatoes. But there are also unknown health threats for human beings and nature. Confronted with these risks, the European Union declared a partial and some countries a total moratorium on GM seeds, while research continues.

Is it ethically permissible to create global risks due to an oligopolistic control of the highly profitable GM

seed market? Can this cornucopian model (Gleditsch 2003) control risks within the limited understanding of science, technology, and progress? Many accidents have occurred worldwide and proven the inherent risks. Therefore, a bioethical approach is needed to analyse possible implications of both biological research and biotechnology on health, the environment, and society.

Whereas traditional biotechnology brought an increase of food production and reduced mobility and morality in humans and animals, nevertheless the recent discovery of the human genome and of gene manipulation in live organisms offers researchers and enterprises a powerful instrument to alter the natural cycle of evolution and of life. These technologies require regulations of the economic interests of companies and scientists. They must protect the common good and the human race, its civilization process and the conservation of nature (Oswald Spring 2002: 57).

62.4.1 Bioethics: Precautionary Principle and Prevention

When confronted with this cornucopian model where GMOs promote tomatoes and broccoli to combat cancer; rice, sweet potatoes, and cassava as vitamins (Golden rice: Beber/Potrykus, 2001; IFPRI 2006); soya and peanuts for controlling allergies; bananas for vaccines and oil as medicines that is recommended by physicians against cancer and cardiovascular problems, the question remains what are the costs for the most vulnerable? Since the mid 1990's, the US government supervised transgenic food and the USFDA is responsible that no known or new toxics enter into the food chain or products generate resistance to antibiotics or alter the nutritional levels of food processes. The complexity of the outcomes with multiple socio-economic, environmental, and health concerns in the long run cannot be assessed by a single governmental agency. There exist benefits, but there are also new and increasing risks posed by transgenic food crops (table 62.10; figure 62.4). The effects differ for the USA, the EU, and for the poor countries of Asia, Africa, and Latin America that are often the most biodiverse regions but also experience the highest level of undernourishment.

For poor countries GM crops imply multiple risk factors (table 62.10):

1. Political risks are high in countries with ineffective governance and legal deficits, but high levels of corruption. There are few concerns on the mega-biodiversity as a patrimony of humankind. Thus,

Table 62.10: Global and regional risks and benefits from transgenic food crops for Africa, Latin America, and Asia. **Source:** Adapted from a study by the University of Michigan (2006).

Political
• Inadequate supervision
• Corruption
• Technological dependency
• Dependence on GM seeds from foreign countries
• Limitation of food sovereignty
• Destruction of local seed markets and native crops
• Food insecurity
Economic
• Destroying markets for exportation
• High costs of GM seeds and patents
• Dependency on foreign technology
• Privatization of world genetic patrimony
• Monopoly and oligopoly of world seed market
• Submission to the international trade model
• Horizontal integration of GM business (seeds, pesticides)
Societal and socio-economic
• Affecting children with weak immune system (allergies)
• Reduction of jobs (Bt-cotton reduced number of rural workers)
• Conservation of seeds is forbidden and also reuse during the next cycle
• Monoculture of food crops with health risks
• Legal persecution due to 'natural' pollution with GMOs
• Poverty and hunger increase among the socially vulnerable
Environmental
• Damage and loss of biodiversity by cross-breeding
• Contamination of soils and water
Scientific and Cultural
• Destruction of autochthonous sciences
• Destruction of peasant economy
• Changes of traditional food culture
• Cultural dependency
• Gap in science and technology
Benefits:
• GM crops resistant to plagues
• GM crops resistant to different pesticides
• If GM seed would be cheap and yield production improved, hunger could be reduced with cheap food
• GM crops requires less jobs
• GM crops uses less pesticides and insecticides
• GM crops could mitigate negative effects of desertification

the control on GM seed companies must be globally, but nationally and locally implemented. These countries require from independent institutions and experts scientific advice to conserve their natural capital.
2. Benefits from this technology must be shared and public research should not subsidize TNEs. Academic research should support countries threatened by food scarcity, desertification, and where yields can be improved with organic agriculture or GM seeds resistant to plagues and adverse soil or water conditions.
3. Local socio-economic conditions must be improved. Inequality and inequity within vulnerable groups must be reduced. GM technologies aggravate existing gaps among social groups. Poor peasants depend on self-sufficiency crops from small plots of land. GM pollution may destroy their precarious livelihoods.
4. Environment is a global patrimony for humankind. Plants, wildlife, and ecosystems must be protected. All parts of Mother Earth require nutrients and should be protected from unnecessary risks or threats to biodiversity. Humankind depends on environmental services and no economic interests or short-term profit should destroy the complex natural equilibrium.
5. The present level of development evolved from traditional knowledge. Modern science and technology should enhance this indigenous knowledge helping to restore the destroyed ecosystems and maintain the complex ecosystems by feeding and nurturing humans and nature.

These five approaches create obligations for cooperation at the global, national, and local level between industrialized and developing countries:

1. There should be a *global agreement* for dealing responsibly with the risks of GM seeds to control these enterprises, to prevent potential hazards, and to resolve accidents. Research on GMOs must be monitored and controlled in a non-bureaucratic way to grant the most vulnerable countries a right for access to modern technologies on reasonable terms and without threats for their biodiversity.
2. At the *national level*, industrialized countries must control their GM firms and support independent scientific research, accessible to poorer countries. In countries of origin of basic food crops, GM seeds and imports of GM food should be prohibited by national law.
3. At the *local level*, campaigns must be launched on risks and preventive measures and adapted to the educational standard of poor peasants and indigenous people to improve biodiversity and biosecurity and prevent future hazards.

Practical conclusions may be summarized with these principles of bioethics:

1. GMOs should be researched by independent scientists and their effects on health, environment, and society should be assessed. Technology for the evaluation must be improved and related security issues must be better understood, especially the processes of the horizontal transfer of genes.
2. So far, the massive use of transgenic food crops has not improved food security (IUCN 2004; FAO/WHO 2008). On the contrary, it poses new risks for the health and environment by creating potential resistance, new pests and viruses, resistant crops and plants to herbicides, and possible toxins that may enter the food chain, affecting complex biodiverse ecosystems and interrupt existing trophic chains (figure 62.4; table 62.3).
3. Oligopolies controlled by few TNEs that produce GM seeds have increased local seed costs and increased food insecurity (tables 62.3, 62.8, 62.9), whenever they have reduced productive costs for commercial farmers. Their interests in short-term profits without bioethical considerations increase risks and there is no possibility to predict long-time effects for a massive and indiscriminate use of transgenic seeds.
4. Peasants without basic education do not understand the risks of GM seeds and could pollute native species. Biodiverse production and selling of organic crops are feasible alternatives for achieving food sovereignty.
5. GMOs should be planted in open fields in countries without wild relatives and only when they are closely monitored, to avoid irreversible damages and a loss of biodiversity (table 62.3).
6. Microbes and transgenic microbiologic transgenic crops may reduce pollution processes. They may represent a feasible cost-benefit alternative for bioremediation,[11] when they are not threatening

11 Bioremediation is the use of biological organisms such as plants, microbes of GMO to aid in removing hazardous substances from the soil, the air or the water.

existing biodiversity (table 62.2; figures 62.1, 62.2, 62.3).
7. Countries with limited financial and legal capacities should rely on independent researchers, and adopt national laws, and implement them with regard to dangerous experiments with transgenic crops. This includes financial compensations and from GMO producers for damages caused by accidents (table 62.10).
8. A clear labelling should be required for any GM food that allows the people to make their own choice and to decide whether they want to consume transgenics or not.
9. Only a responsible prevention may avoid new and unnecessary risks. Therefore global treaties and independent research should contribute to avoid accidents.
10. Global legal agreements and national laws should protect biodiversity. Countries should decree regions without GM crops in open fields (table 62.3), GM crops that could pollute this biodiversity and should be prohibited. These GM free areas should obtain international financial and technical support.

In synthesis, modern agriculture with monocultures, synthetic agrochemicals, GM seeds, irrigation and heavy machinery, i.e. both the 'green revolution paradigm' with modern life styles, and the 'life-science paradigm', are not sustainable (Oswald Spring 2009). Both paradigms erode biodiversity in plants and animals, lose natural fertility of soils, exhaust and contaminate water resources and aquifers, pollute air, and affect negatively human health. All these factors may challenge and in some cases even destroy the basic elements of survival of humanity and nature.

Nevertheless, further population growth requires more food, while water and land are increasingly limited, above all in southern countries. GM seeds are expensive and the present hunger crisis has shown that scarcity is related to poverty and lack of money to buy food. Therefore self-sufficiency and food sovereignty promote a sustainable model of production. Yield increases are obtained through crop rotation, association of different crops (maize, beans and squash), biological control of pests and illnesses, nitrogen fixation from the air to the soil, integral management of soils, water, flora and fauna, mixed agriculture and the integration with environmental services. This combination opens up opportunities for a 'green paradigm' that can offer poor peasants in the South and small farmers in the North possibilities to create environmental conditions for an increasing diverse food production also for poor people (Oswald Spring 2009). This model of biological and cultural diversity today feeds three billion poor people and offers a livelihood with dignity to future generations (Oswald Spring 2001).

62.4.2 Ethics of Sharing vs. Intellectual Property Rights

Since the WTO was established, *Intellectual Property Rights* (IPR) have been main concerns of TNEs. They are directly linked to the controversy on GMOs. Many sources of genetic materials come from developing countries and are considered as being their common goods. Indigenous people have used the species and their traditional knowledge has evolved over thousands of years through trial and error. Therefore the 'benefit-sharing' principle should be applied to traditional and poor societies that support environmentally sustainable activities such as reforestation, integral river basin and water management, and conservation of biological diversity to mitigate GEC. However, no negotiation process exists to compensate the autochthonous people for bioprospection. Shareholders of TNEs benefit from this knowledge. They justify the lack of compensation for biopiracy with the high costs for developing new technologies.

TNEs sue peasants when their traditional crops get polluted with GMOs through 'natural contamination' (air, water, animals). Within the WTO rules the *Agreement on Trade-Related Aspects of Intellectual Property Rights* (TRIPS) grants these enterprises a right to request penal actions in national courts and oblige small peasants to pay for these unwanted genes (Schmeiser 2002). This process not only threatened the food sovereignty of poor peasants and indigenous people, but has also increased injustice.

62.4.3 Risks Mitigation

62.4.3.1 Gene Banks and Labelling

Gene banks in biodiverse countries can guard ownership rights against the greed-driven TNEs that want to patent genetic plant material that was the result of thousands of years of ingenuity of indigenous societies. They protect the definitive loss of wild species. But crops are dynamic organisms and the best conservation of biodiverse crops is the permanent use of regionally adapted seeds without GMOs.

At the Earth Summit in Rio de Janeiro in 1992, the *Convention of Biodiversity* (CBD 2002) was signed

that entered into force on 29 December 1993 to which 190 countries and the European Union have become members. In January 2000, the *Cartagena Protocol on Biosafety* was adopted in Montreal that entered into force on 11 September 2003.[12] Until December 2008, 153 countries and the European Community had ratified the protocol, but the USA, the host nation of most GM TNEs, has opposed doing so (also Russia, Australia, and Israel). Several other countries have signed the protocol but so far did not ratify it, among them are Argentina, Canada, Chile, Haiti, Jamaica, Pakistan, and Uruguay,[13] several of these countries are intensive users of GMOs (figure 62.3).

Art. 7 of CBD identifies the activities that could or are probable to have negative effects on the conservation of biological diversity. *Art. 8* establishes the conservation *in situ*, where each part has to establish the means to regulate, administer, and control the risks deriving from the utilization and liberation of living modified organisms that are able to affect the biological diversity and human health.

The *Cartagena Protocol on Biosafety* (2000) requires from its members an *Advanced Informed Agreement* (AIA) procedure to ensure that countries can make informed decisions on whether to import GMOs into their environment. Shipments of GMO commodities must also fulfil strict documentation requirements. Exporters must notify the identity of GMOs, its level of security, the taxonomic situation of the receptor organism, its centre or origin, and the genetic diversity in its normal habitat. In Annex III, the resulting characteristics, its probable use, and the volumes of GMOs must be notified. As sufficient and validated data on the effects of GMOs on biodiversity are lacking, a precautionary approach is required in megabiodiverse countries to avoid future losses, based on Principle 15 of the Declaration of Rio on Environment and Development, in the framework of the Protocol of Cartagena and national laws implementing biosafety.

62.4.3.2 Biosafety

The EU has already an extensive legislative framework on GMOs that was complemented in 2003 by a regulation on transboundary movements of GMOs in line with the provisions of the Biosafety Protocol. Rules and procedures for liability and redress for damage caused to the environment from transboundary movements of GMOs are expected to enter into force by 2010. The European Food Security Authority is to resolve disputes among EU countries on the sale of GMOs and decides with a qualified majority or in case of opposition without a vote. This was applied in the case of the approval of corn MON863 against the will of citizens who opposed GMOs.

Researchers, enterprises, and efforts by SIGMEA[14] look for appropriate tools and mechanisms such as biological containment methods, distances of isolation, and pollen barriers. New research is needed to document the impacts on the food chain and explore unexpected side effects. As GMOs offer standardized and rapid methods to transfer inheritable qualities faster than in the traditional way, these modifications are not found in nature. Therefore biosafety protocols are required (ISBR 2002). Furthermore, GMOs have triggered an intensive debate about the benefits and threats or risks to life, the ecosystem, and especially unmodified organisms (Linacre/Falck-Zepeda/Komen/Mac Larn 2006). The popular viewpoints range from generally safe and beneficial processes, to unknown risks and threats, to processes of discovering illegal activities by TNEs. They rely on a critical understanding and distrust governments, TNEs, and the scientists employed by these TNEs.

Through the involvement of independent scientists biosafety could be improved by finding potential side effects and the real interests behind a specific process. Recently a scientific approach emerged where the demand is for optimum yields with a minimum of agro-chemicals that can feed the growing global population. There are many examples for diverse and sustainable ways of production with traditional agriculture.

62.5 Conclusions with Precautionary Means

GMOs have resulted in higher prices for GM seeds. GMOs have not solved the global problem of hunger. Today there are more hungry people on Earth than ever before, and the risks inherent in this model of

12 For a history of the CBD see at: <http://www.cbd.int/doc/publications/CBD-the-first-years.pdf>.

13 "See the members of the Cartagena protocol; at: <http://www.cbd.int/biosafety/signinglist.shtml>.

14 The overall objective of SIGMEA is to set up a science-based framework, strategies, methods and tools for assessing the ecological and economical impacts of GM crops and for an effective management of their development within European cropping systems, i.e. to create a practical toolbox." <http://sigmea.dyndns.org/>.

production may create new threats and require utmost precaution. The high number of suicides by peasants with harvest failures after using GM seeds refers to economic failures and fatal societal consequences in some countries.

With regard to public health, increasingly more doubts emerged on the horizontal gene transmissions due to the fact that DNA is unable to explain many combinations in the transmission of genotype of the simplest forms of life. Biodiversity and food culture have slowly developed during the past ten millennia and long-term risks inherent in this technology and biosafety concerns are not resolved. The use of pesticides and the labour force could be substantially reduced, but multiple 'accidents', often a result of an unethical and profit-driven behaviour of TNEs, require greater precaution (figure 62.4).

Food security should not be left in the hands of economic interests; rather, governments, international organizations and societal organizations must protect the genuine long-term interests of society. Complex emergencies (environmental destruction, desertification, economic and food crises, hunger riots and international conflicts) could destabilize wide regions, inducing massive migrations and refugees (IOM 2007, 2008).

The key question remains how the world and its productive sectors can solve the growing demand for food for about nine billion human beings by 2050, and for the animals to feed them. The persistence of hunger has shown that production is not the key issue, as enough food exists in the world to overcome famine and chronic undernourishment. The problem is linked to the access to food at low prices, where the most vulnerable lack enough money to purchase it, many of them living in rapidly growing urban slums in developing countries.

As poverty also exists in marginal rural areas, and the livelihood of poor peasants is increasing getting destroyed by regressive globalization, the political focus should shift from food security to food sovereignty and from modern techniques of food production to holistic development policies. New models of self-sufficiency in remote rain-fed areas with traditional methods of production and local seeds should be integrated into environmental services and microbusinesses within an economy of solidarity. Furthermore, biological equilibrium is not only threatened by GMOs, but also by GEC, thus precaution and prevention will even become more important in the decades ahead.

The basic principles of this precautionary approach include at least three defences:

1. Lost species and damage or destroyed ecosystems will never be regained with GMOs. Therefore, fatal outcomes and further loss of biodiversity must be avoided at any cost. *Genetic use restriction technologies* (GURT) include the abolition of terminator seeds, which destroy the reproduction mechanisms of a plant, but could create wider effects such as antibiotic resistance in soils, plants, and humans. Also the release of GMOs in the country of origin and adaptation of a basic food crop, such as maize in Mexico, should be forbidden, in order to conserve for humankind the biodiversity of genes of this vital plant and its native races.
2. A multi-faceted approach to GMOs includes a holistic environmental management, environmental and food education, with precise and extensive information of sustainability, including recycling, reuse and reduction practices, clean production, waste management, adaptive processes to GEC and alternative energy sources, water conservation, and cleaning and soil fertility, and biodiversity conservation. Not only uncertainty about GMOs, but active conservation and alternatives to risky technologies are central objectives for sustainable resource care.
3. In the South, risk reduction management includes precaution as part of an integral livelihood, understood as long-term socio-economic, cultural, environmental, and political stability of complex and dynamic interrelations. Thus, hazardous effects on the people and environment should be avoided and biodiverse practices should be promoted by multilateral organizations, organized society, academics, and private business. In the northern context, GM research and surveys offer a kind of filter to avoid processes that could pose undue risks due to a lack of information and precaution. In the South, missing education opportunities and manipulation through mass media often impede the understanding of rising risks and threats. Therefore, governments have an obligation to explain comprehensively the potential dangers related to new technologies and to create mechanisms of protection such as labelling.
4. Diversity of food was an important part of the civilization process, and it was always linked to rituals and fiestas. Only these modern technologies were able to convert a genuine human pleasure into a risky process, where long-term effects on health

can still not be understood and where new scientific analysis bring up increasing new preoccupations.

5. Therefore, the traditional way to produce within a paradigm of green agriculture, with natural waste recycling and locally adapted seeds, mixed agriculture and integration of environmental services, represents today the most feasible manner for harmless food crops. It includes cultural alternatives, community integration, and governmental support with active involvement of society and business. This different paradigm of cultural and biological diversity is able to create a livelihood with dignity for poor peasants, marginal slum dwellers, and other vulnerable groups, without risks and threats for people and the environment.

63 Natural Disasters and Major Challenges towards Achieving Food Security in the Sahel: The Experience of CILSS

Issa Martin Bikienga

63.1 Introduction

Natural hazards and environmental disasters are major challenges that require a policy response from all African policy-makers that are responsible for the survival and future of their populations. This is particularly due to the extreme poverty which often forces their populations to overuse natural resources and causes an ecological imbalance. Hydro-meteorological hazards increasingly produce significant adverse effects as a result of human activities that increase the vulnerability of the ecosystem. In addition to these worrying developments, water-related natural hazards are projected to increase in intensity and frequency due to climate change and environmental pollution. Thus, activities to advance food security and sustainable development through international strategies and other poverty reduction instruments must take natural disasters and their impact into account in the medium and long run. Food security and sustainable development are closely linked to vulnerability due to climate change and natural disasters.

This chapter will discuss solutions for these challenges by addressing natural disasters worldwide and in Africa (63.2), and analysing specifically the linkages among natural disasters, food security, and sustainable development in the Sahel (63.3). It reviews the activities of the *Permanent Inter-State Committee for Drought Control in the Sahel* (CILSS) on food security, the prevention of natural hazards and societal disasters, and on sustainable development (63.4). It concludes with practical proposals for international community (63.5).

63.2 Natural Disasters on Earth and in Africa

An African regional workshop on environmental disasters on 28–30 July 2003 in Nairobi assembled experts from international, intergovernmental, and non-governmental specialized organizations with the goal to exchange their experience on policies, programmes, and tools for the preparedness for and prevention of natural and technological disasters that have serious environmental consequences, and to develop ways and means for promoting cooperation within Africa.

In his opening speech Mr. Svein Tveitdal, director of UNEP's Division of Environmental Policy Implementation (DEPI), argued that natural disasters have grown in number and frequency, and affect most African countries. Especially droughts (figure 63.1) and floods (figure 63.2) pose a threat for food and water security in Africa. While natural hazards are global phenomena, in Africa the rate of reported catastrophes has risen during the past decade, while it has declined in Asia and America. Compared with all globally reported natural disasters (1992–2001) the share of Africa rose from 15 per cent (1992) to 26 per cent (2001), while the share of Asia fell from 44 to 41 per cent and that of America from 24 to 18 per cent.

Between 1992 and 2001, the major disaster type was flooding (figure 63.2), with 207 reported events and 19 million affected people, followed by droughts and famine (figure 63.1), with 113 cases recorded and 113 million people affected, followed by windstorms, with 49 events that affected 5 million people. These events accounted for 89 per cent of all hazards that hit Africa with serious impacts on human health, infrastructures, and the environment.

In the Sahel, a major threat is posed by locust invasions. The agro-pastoral losses caused by the desert locusts in 2004 in most of the Sahel persuaded the governments of these countries of the need for a continuous surveillance system to monitor this disaster. The 2004 locust invasion was the major concern for many CILSS member states, especially for the most affected countries: Mauritania, Senegal, Mali, Niger, and Burkina Faso. The damage caused to rangelands

ranged between 50 and 95 per cent in the most affected areas. In Mauritania the shrubs fed on by animals were most affected and this resulted in an early transhumance, hence the risk of concentration, epizootic diseases, and conflicts between farmers and pastoralists in reception zones. The most significant crop

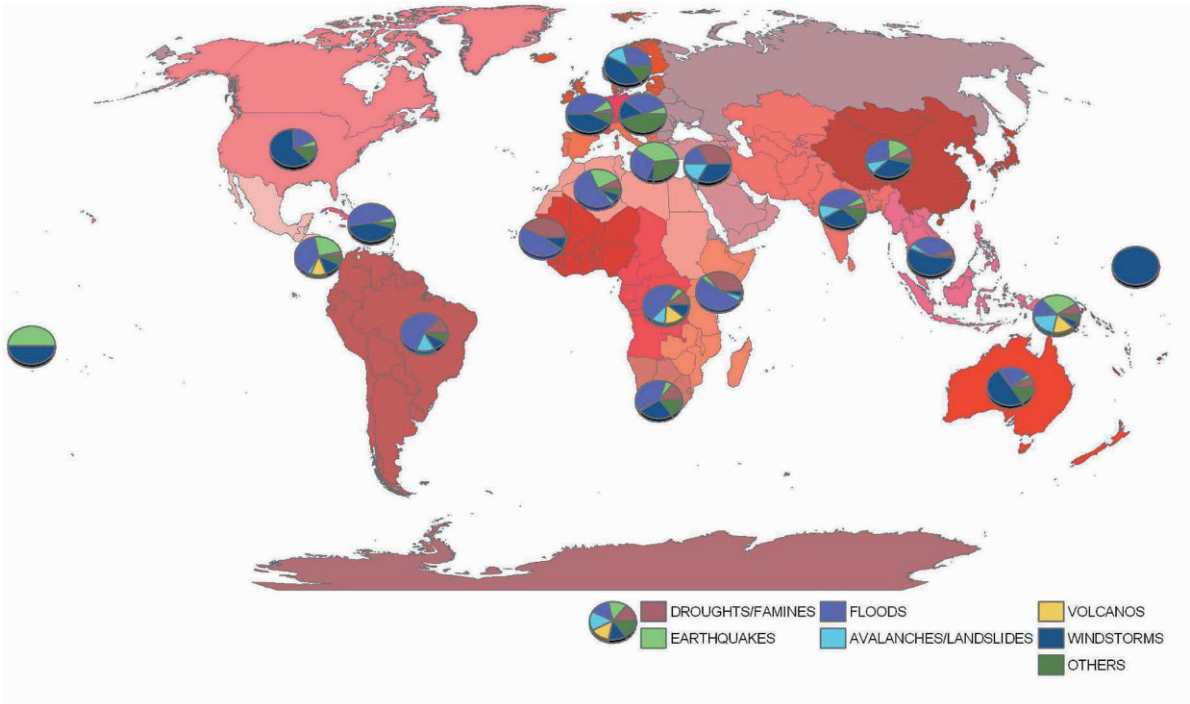
damages were recorded in Mauritania where a 95 to 97 per cent decline in yields were observed for millet and early sorghum, of a 35 per cent for late sorghum and bottomland crops, and a 30 per cent drop for irrigated rice. The rainy season market-gardening crops were totally destroyed. In Senegal, Mali, Niger, Cape Verde, and Burkina Faso, certain communities in the northern limit of the agricultural zones experienced food problems as a result of the damage caused by endemic crop pests (grasshoppers, grain-eating birds,

Figure 63.5: Disaster Type Proportions by UN Sub-Regions (1974-2003). **Source:** EM-DAT, The OFDA/CRED International Disaster Database; at: <www.em-dat.net>, Université Catholique de Louvain, Brussels, Belgium. .



etc), the locust invasion, and drought. In these farming communities the majority of its population is structurally vulnerable to food insecurity, but they contribute less than 20 per cent to national production.

Other factors have also contributed to a worsening of the conditions for these harsh natural disasters in Africa, including: a) climate change and its impacts; b) demographic growth and an increase in the people's vulnerability; and c) a lack of or weak early environmental warning systems. All these factors clearly show that in the 21st century food security and sustainable development will be seriously jeopardized by natural disasters.

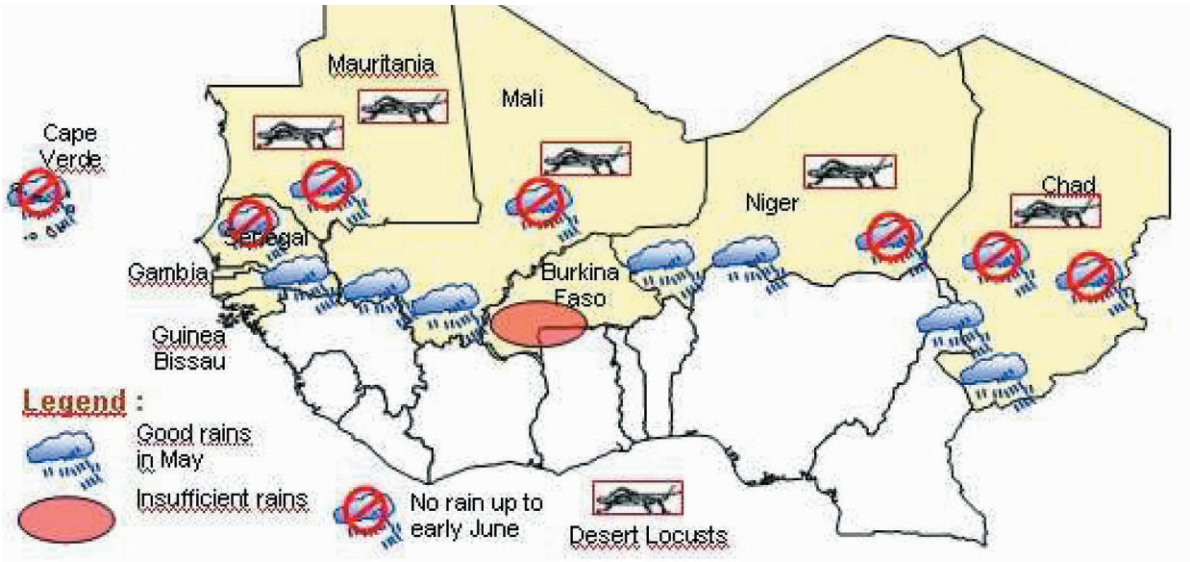
63.3 Natural Disasters and the Threats Posed to Food Security and Sustainable Development in the Sahel

63.3.1 The Environment in the Sahel

Covering an area of 5.4 million km^2 of sub-Saharan West Africa, the Sahel region includes nine countries, namely, Burkina Faso, Cape Verde, The Gambia, Guinea Bissau, Mali, Mauritania, Niger, Senegal and Chad. These countries make up the CILSS member states. The region is characterized by a variety of agro-ecological zones:

- The *Saharan zone*, in the north, which is a dry zone, with annual rainfall below 200 mm. This arid region covers parts of Chad, Niger, Mali, and the major part of Mauritania;
- The *Sahelian zone* with an annual rainfall between 200 and 600 mm with an agricultural production primarily of cereals grown only during a short and irregular rainy season. The zone is characterized by its austere climate marked by the harmattan winds blowing for many months throughout the year;
- The *Sudano-Sahelian zone*, with an annual rainfall oscillating between 800 and 1,000 mm. In this zone with an annual rainfall below 800 mm, the farmers produce 90-day-cycle cereals such as sorghum and millet. This zone extends to the northern part of The Gambia, and the southern parts of Mali, Niger, and Senegal;
- The *northern Guinean zone*, with annual rainfall between 1,400 and 1,800 mm, is a wetland allowing for the production of most cereals, roots and tubers, as well as export crops. This zone includes the best arable lands and is also most populated.

Figure 63.6: The Locust Invasion (as of 9 June 2004) affecting the Sahel Countries. **Source:** FAO; at: <http://www.fao.org/DOCREP/006/J2517E/J2517E00.HTM#bkf>.



This agro-ecology covers the major part of Guinea Bissau;

- The *coastal zone*, with annual rainfall above 800 mm, where primarily roots are grown. This includes the coastal part of Guinea Bissau.

In year 2000, the CILSS member states represented approximately 56 million inhabitants, of which about 70 per cent live in rural areas. A majority of these rural people live in extremely arid and semi-arid environments, and 95 per cent of them rely on arable land that is extremely vulnerable to desertification. Recent studies show that 27 million Sahelians, that is to say approximately 62 per cent of the population, live below national poverty lines, ranging between 46 per cent in Cape Verde and 86 per cent in Senegal.

The annual population growth rate is 2.7 per cent and the population tends to double every 25 years. According to minimal projections, the Sahelian population will rise up to above 100 million people by the year 2025, of which 50 per cent would be living in urban areas.

In the 21st century a major challenge for the Sahel is how to feed its fast growing population. By the year 2015, the Sahel must provide food for a population of about 85 million people. In year 2000, the urban population accounted for about 30 per cent of its population but the urban growth rate is above 6 per cent. This transformation constitutes both a constraint and an opportunity for food security. It is a constraint insofar as urban development is very expensive in terms of satisfaction of the requirements for basic social services and infrastructure development. It is an opportunity insofar as it constitutes a whole set of outlets for the agricultural and food produce. But it is also an opportunity as it creates a growing demand for agricultural and food products.

The climate in the Sahel is very fragile and is characterized by strong rainfall variations, with very long dry seasons and short rainy seasons lasting between one and four months. The isohyets shifted from 200 to 300 km southwards during the past 30 years. Severe droughts occurred between 1968 and 1973 that caused major losses in human and animal lives, a significant degradation of the environment that resulted in famine and malnutrition. Although the region has not experienced any serious drought of comparable extent since 1985, the threat of a severe drought remains a source of constant concern.

Agriculture is an important sector in all CILSS member states and it contributes with approximately 31 per cent to their GDP. During the past decade, the GDP increased by about 5 per cent/year, to US$16 billion in 1999. It is estimated that only 18 million hectares are cultivable, i.e. approximately 12 per cent of 156.3 million hectares that are available for agriculture in the Sahel. Subsistence farming and livestock production play a predominant role in the economies of CILSS countries. The overuse of natural resources and deforestation, desertification, poverty, and the sensitive soil condition have worsened due to accelerated degradation and overgrazing, coupled with limited production resources upstream from the agricultural sector, which lead to low agricultural production

Table 63.1: Population Change and Projection for the Sahel Countries (1950-2050). **Source:** UN, Populations Division, 2006 Revision; at: <http://esa.un.org/unpp/>.

Sahel countries	Population change		Population projection		Projected increase
	1950	2005	2025	2050	2005-2050
Burkina Faso	4.0	13.9	23.8	37.5	23.6
Cape Verde	0.15	0.5	0.75	1.0	0.5
Chad	2.4	10.1	17.5	29.4	19.3
The Gambia	0.3	1.6	2.5	3.6	2.0
Guinea	2.6	9.0	14.5	22.7	13.7
Guinea Bissau	0.5	1.6	2.9	5.3	3.7
Mali	3.3	11.6	20.6	34.2	22.6
Mauritania	0.7	3.0	4.5	6.3	3.3
Niger	2.2	13.3	26.3	53.2	39.9
Senegal	2.5	11.8	18.1	25.3	13.5
Total	**18.65**	**76.4**	**131.45**	**218.5**	**142.1**
In comparison: Nigeria	34.0	141.4	210.1	288.7	147.3

levels far below their potentials. The CILSS countries have important water resources that permit agricultural production, fishing, and stockbreeding. Their irrigable land ranges between 4 and 33 per cent of cultivable soils.

The combined effects of accelerated demographic growth, fast urbanization, migrations, climatic variations, and irregular and unpredictable rainfall, added to the permanent threat of drought, have generated ecological and socio-economic crises in the CILSS member states. This crisis is manifested through ecological degradation, demographic pressure and unsound use of natural resources, and through food insecurity which negatively affects most vulnerable groups, in particular women, either pregnant or breast-feeding women, children, and young as well as old people. These problems constitute the main cause of poverty and hamper human and socio-economic sustainable development of the Sahel countries. For these reasons the CILSS programmes have been designed to address these problems first.

63.3.2 CILSS Mandate and Objectives of Sustainable Development

The *Permanent Inter-State Committee for Drought Control in the Sahel* (CILSS) was formed on 12 September 1973 in Ouagadougou (Burkina Faso) in the wake of the disastrous droughts of 1968 and 1973, with the mandate to achieve food security and to combat desertification and the effects of drought aiming at a new ecological balance in the Sahel. Ever since, CILSS has implemented many programmes that have promoted sustainable development in the Sahel within the framework of regional integration. The first efforts focused on emergency aid, but CILSS realized very early the need to direct its actions more towards structural development issues in order to achieve its long-term goals and to live up to the expectations of its member states.

In 1994, the 11th summit of the Heads of State and Government tasked CILSS, in the framework of its *Plan de Restructuration et de Relance Durable* (a restructuring and sustainable revival plan), to concentrate its efforts on achieving food security and combating the effects of drought and desertification to preserve the region's ecological balance.

At a Summit conference on 25 January 2004 in Nouakchott (Mauritania), the Heads of State and Government of CILSS countries after reviewing its reports highlighted its overall positive results. They stressed that CILSS should invest more in concrete actions and adopted these priorities for the 2004-2008 period, namely that it should do the following:

- refocus on its initial objectives of food security, desertification control, solving the problems of water, and policy coordination to identify synergies;

- promote its achievements (best practice) and share its expertise with other sub-regional intergovernmental organizations;
- prepare a specific food security programme that would reorient trade towards production of surpluses among member states;
- intensify the dialogue between IGOs and the states in order to eliminate duplications of activities among CILSS, national and other IGO programmes.

These reorientations reflect the mission of CILSS for the period from 2004 to 2008.

63.4 CILSS Contributions to Combat Natural Disasters

63.4.1 Activities of the AGRHYMET Regional Centre

The AGRHYMET Regional Centre was established as a specialized CILSS body in Niamey (Niger) for undertaking research, development, and training activities on agronomy, hydrology, and meteorology. Its major objectives are to contribute to sustainable food security, rational management of natural resources, and the environment in the Sahel through capacity building (training, equipment, and assistance) of the national institutions concerned, production and dissemination of information for the decision-makers (national authorities, partners, etc.) and users (institutions, NGOs, and producers). As a regional centre of excellence AGRHYMET focuses on:

- Training of management staff from CILSS countries and the rest of Africa;
- Agro-meteorological and hydrological monitoring at the regional level;
- Collection of agricultural statistical data and crop monitoring;
- Maintenance of regional databanks;
- Management and dissemination of information on natural resources monitoring in the Sahel;
- Documentation on agroecology;
- Maintenance of meteorological instruments and electronic system packages.

The information basis of the AGRHYMET Regional Centre is satellite data supplemented with local data collected by the national correspondents in CILSS member states. This information is to improve food security, desertification control, and natural resources management within all CILSS countries and in West Africa. It is processed, analysed, and disseminated through the internet, special bulletins, and sent to CILSS member states, and to technical and financial partners. AGRHYMET has strengthened its information system with the implementation of big regional projects such as:

- *Permanent Diagnosis* (DIAPER);
- *Early Warning and Agricultural Productions Forecasting* (AP3A);
- Adaptation to climate change in the Sahel.

63.4.2 Vulnerability of Sahel Countries to Climate Change Project

The CILSS member countries are all highly vulnerable to climate change due to widespread poverty, cyclic droughts, high dependence on climate fluctuations for its sensitive farming and breeding systems, soaring demography, low level of basic social infrastructures, and high deforestation associated with the energy requirements of its people which limits their adaptive capacities. Weather disturbances further reinforce the threats the environment and its people already face. They would undermine ongoing sustainable development efforts. Therefore, national and regional policies of sustainable development in the Sahel must mainstream henceforth the 'climate change' dimension, based on adequate scientific knowledge. To reduce the vulnerability of its people to climate change, the AGRYHYMET Regional Centre of CILSS obtained funding of CAN$ 5,000,000 from the Canadian Government for project in support of capacity development for adapting to climate change that pursues these goals to:

- develop the capacities of the AGRYHYMET Regional Centre to address climate change-related issues;
- promote and strengthen the capacities of Sahel countries and communities to cope with climate change;
- set up pilot projects of adaptation jointly with the populations on water resources, water erosion, pastoralism, agricultural production, and soil fertility.

Through the AGRYHYMET Regional Centre this project should help the people in the Sahel to:

- create knowledge on impacts of climate change on the natural resources management and environmental protection;

- increase the capacity of Sahel countries and their population to minimize the adverse effects of climate change;
- strengthen food security information systems at the sub-regional and country level;
- define indicators to monitor the evolution of vulnerability to climate change and adaptations to such change;
- transfer appropriate technology for controlling climate change;
- integrate new knowledge about climate change into the training programmes of students in the AGRYHYMET Regional Centre, with a view to future applied researches in this field;
- develop adaptation strategies to climate change to be incorporated into national sustainable development strategies;
- develop pilot strategies for adaptation to climate change with the grassroots communities, which could be integrated into future strategies, policies, and programmes for sustainable development of the states involved;
- establish a scientific partnership with at least one Canadian institution in the field of climate change.

63.4.3 Support to Locust Control

In response to the damage caused by desert locusts in 2004, supported by various donors CILSS launched very strong and immediate actions. In 2005, through its AGRHYMET Regional Centre, CILSS developed operational capacities of its member states on desert locust control by providing equipment and organising training courses for agents from crop protection departments, their supporting staff, and producers. Of the total funding of US$ 1,350,000, a major contribution was made by the *United States Agency for International Development* (USAID) and the *Arab Bank for Economic Development in Africa* (BADEA). CILSS also obtained funding for a project on locust control from USAID for a three-year term (US$ 1,236,000) to develop the capacities of the AGRHYMET Regional Centre to support CILSS member states in locust monitoring and control efforts.

Based on the AGRHYMET Regional Centre's mandate on food security and on its great capacity for analysing satellite images, meteorological and agricultural production data and its large communication network across the nine Sahel countries that are all facing the risk of locust invasion, this project will supplement the activities of FAO and of the World Bank through their African desert locust emergency control project. This project is to reduce the economic damage from desert locust while limiting the harmful effects of chemical control operations on the environment. Several regional and national activities are planned, including:

- capacity building of the Sahel Institute, a specialized institution of CILSS based in Bamako (Mali), on the certification and use of new environment-friendly pesticides for controlling locusts;
- improvement of the monitoring of locust populations for early control purposes;
- capacity development for crop protection services and of their support staff in CILSS countries to monitor and control locusts, grasshoppers, and other transboundary pests;
- applied research on environment-friendly control strategies (use of the 'green muscle' bio-pesticide and the locust Pheromone, Phenylacetonitrile or PAN) and their promotion;
- promotion of cooperation with Maghreb countries and the international community.

63.4.4 Land Use and Land Cover Project

The Land Use/Land Cover Project is to promote awareness and use of graphic and spatially explicit information on trends of natural resources among national and regional decision-makers and to get them involved in designing future scenarios which will help to formulate rational and sustainable intervention policies, leading to a better management of natural resources. The project comprises two phases:

- The first phase (1997–2000) devised the methodology for data collection, socio-economic studies, air photography by the Corona and Argon satellites in CILSS countries;
- The second phase (since 2001) focuses primarily on the long-term monitoring of the land use and cover in the Sahel and West Africa. It promotes an opportunity for documenting, describing, and quantifying the impact of trends on environmental and terrestrial resources in Western Africa.

Through this project, the AGRHYMET Regional Centre has been able to obtain a full-time series of data images from the 1960's to date, which represents an immense and significant resource. The interpretation of these images, and the study of anthropogenic actions and the climate on the earth resources, will make it possible to anticipate the most probable trends during the next fifty years, and the possibilities

of mitigating their negative effects. This project contributes to natural disaster forecasting.

63.4.5 African Monsoon Multidisciplinary Analysis Project (AMMA)

The Sahel countries, with their high dependence on agriculture, are particularly vulnerable to the late or irregular occurrence of the monsoon. This irregularity has seriously affected its population between 1970 and 1990, resulting in massive crop failures and mortality of cattle. The global climate models show that due to climate change the Sahel will face more irregular weather conditions. To help farmers adapt to the fluctuations in rainfall, it is necessary to develop tools that can forecast this change, and the potential yield and crop failure risks. Policy-makers also need early warning systems whose accurate forecasts enable them to better manage cereal stocks and to cope with national and regional deficits. These pertinent questions are addressed by the *African Monsoon Multidisciplinary Analysis Project* (AMMA) that is implemented by American, European, and African scientists and experts. It is financed by various donors, among them the European Union. Its specific objectives are:

- Characterization and assessment of the impacts of regional climate change on biophysical processes on the farm plot and farming system scales;
- Identification and evaluation of probable adjustments of agricultural systems and their components to climate change, including the selection of crops and their management strategies;
- Assessment of the impact of climatic variability on food security on a national scale;
- Characterization of key productivity trends of natural vegetation and its relationship to local climate;
- Identification of anomalies in vegetation trends across West Africa.

Through this project, the AGRHYMET Regional Centre implements several activities: analysis of rainfall data, assessment of the impact of climate change on water resources and agricultural output, assessment of the level of vulnerability of the farming systems, early warning for food security, capacity building of CILSS member states.

63.4.6 Regional Project for the Prevention and Management of Food Crises in the Sahel (PREGEC)

The strategic objective of this project is to enhance the capability in the Sahel to prevent and manage food crises resulting specifically from climatic hazards. Despite technical progress that can be achieved, the weather conditions in the Sahel are so fickle that crop failure can always occur. Only through the capacities of its people to control the political and technical dimension of food crisis prevention and management can the regional vulnerability be reduced. The project pursues two goals: a) to develop appropriate tools for the prevention and management of food crises; and b) to reduce the degree of vulnerability to food crises for the most underprivileged people within a harmonized sub-regional framework. The specific objectives are part of the general strategy of consolidating the political and technical control of the situation by the people in the Sahel that focuses primarily on the most underprivileged and vulnerable population to food crises. Four results are expected: 1) An operational and efficient sub-regional mechanism for the prevention and management of food crises is developed and set up within a consultative framework bringing together the states and CILSS. 2) The existing food crisis prevention and management mechanisms in the member states are strengthened and improved. 3) The Food Aid Charter in the Sahel is implemented. 4) The effectiveness of the Food Crisis Prevention Network is improved.

63.4.7 Vulnerability monitoring in the Sahel Project

This project is carried out along three thematic lines: a) prevention of food crises through consideration of national and regional early warning systems; b) poverty reduction through methodologies of vulnerability analysis and programme impact monitoring, and by developing adequate information for producers; c) environmental monitoring to assess the climate change zoning and the supportive measures provided for by the Kyoto Protocol.

63.4.7.1 Prevention of Food Crises

These activities want to improve the capacities for the prevention and management of crises at the regional and national level to achieve a higher food security level in CILSS countries. More specifically, it will contribute to a closer monitoring of the cropping season

A	Sustainable management of shared and/or transboundary natural resources.	Sustainable management of shared water resources.
		Sustainable management of shared and/or transboundary plant and animal resources.
		Sustainable management of energy resources.
B	Sustainable control of NRM constraints and risks.	Management and control of crop and plant pests.
		Early warning and mitigation of effects of drought.
C	Measures in support of sound natural resource management.	Scientific and technical cooperation.
		Information, training, communication.
		Development of intra-regional trade in local products.

to prevent cyclical food crises. Its components include: a) production of information for early warning purposes; b) preliminary estimates of harvests; and c) finally, drawing up of the provisional food situation for policy-makers and the international community.

63.4.7.2 Poverty Reduction through Desertification Control

Population growth, climate change, land degradation, and falling prices of raw materials have strongly changed the reference framework by making the current model quite inappropriate to describe the existing regional dynamics. A review of the development model, which addresses poverty reduction issues in a much broader manner in relation to food security and desertification control, should take account of a reality in the changing process and be able to identify the causes behind the progressive marginalization of the region.

Poverty reduction has increasingly become the primary objective to be achieved in the region during the last few years because all countries have developed appropriate strategies and policies to implement specific plans for the various population groups. But the results achieved so far have not lived up to expectations because the indicators available for each programme are either very limited or almost nonexistent. This project will provide national decision-makers with technical support for the planning and management of poverty reduction programmes.

63.4.7.3 Climate Change and the Environment

The *United Nations Conference for Environment and Development* (UNCED) in Rio de Janeiro in 1992 adopted two environmental framework conventions, including: a) the *United Nations Framework Convention on Climate Change* (UNFCCC), and b) the *Convention on Biological Diversity* (UNCBD) and launched negotiations for c) the *Convention to Combat Desertification* (UNCCD). These three conventions have produced tools for a sustainable management of natural resources based on the findings of the assessments by the scientific community. The potential synergies among them must be included in their implementation. Achieving these objectives rests to a large extent on the interaction of these conventions.

63.4.8 Sub-Regional Action Programme to Combat Desertification in West Africa and Chad

The UNCCD in article 11 calls for the situation in which "affected country Parties shall consult and cooperate to prepare, as appropriate, in accordance with relevant regional implementation annexes, sub-regional and/or regional action programmes to harmonize, complement and increase the efficiency of the *National Action Programmes* (PAN)." In accordance with this provision, under the aegis of CILSS, ECOWAS and CILSS, countries decided in July 1995 in Dakar (Senegal) to cooperate in the preparation and implementation of a *Sub-Regional Action Programme to Combat Desertification in West Africa and Chad* (SRAP/WA).

Its goals are in line with the spirit and overall objective of the UNCCD which is: "to combat desertification and mitigate the effects of drought in countries experiencing serious drought and/or desertification, particularly in Africa, through effective action at all levels, supported by international cooperation and partnership arrangements, in the framework of an integrated approach which is consistent with Agenda 21, with a view to contributing to the achievement of sustainable development in affected areas." The goal of the SRAP/WA is to develop sub-regional cooperation on rational management of shared natural resources (NRM), and to contribute to the sustainable development of West African countries and Chad.

Three lines of action and eight areas of intervention were defined for the SRAP/WA:

The SRAP/WA is an orientation, reference, arbitration and coherence framework for actions to combat desertification and mitigate the effects of drought. Its ambition is to increase compatibility and synergies of activities of all desertification control stakeholders in order to consolidate the bases for sustainable development in the region. This sub-regional action programme includes a Sub-regional Coordinating Committee chaired by ECOWAS and a technical secretariat handled by CILSS. The issues at stake under the SRAP/WA include:

- to put an end to increasing poverty by protecting the production potential;
- to prevent and solve conflicts related to natural resource use;
- to remove the current risks of food dependency; and
- to harmonize, complement, and increase the efficiency of the national action programmes.

As can be noted, the SRAP/WA is a regional instrument for the prevention of natural disasters and the promotion of sustainable development on the West African scale.

63.5 Proposals for the International Community

In conclusion a few practical proposals are offered to address natural disasters and to attain sustainable development. These proposals are articulated around the following points:

Information Services

- To collect and disseminate information on the resources and capacities on the environmental dimension of disaster management;
- To facilitate communication and information exchange among international partners and among the sub-regions;
- To facilitate access to the sources of information for the development of prevention and management systems of the environmental consequences of disasters.

Education and Training

- To promote and provide training in the field of prevention and management of environmental disasters;
- To promote the holding of regional and sub-regional symposia on strategies for tackling environmental disaster-related risks;
- To develop tools and guidelines for capacity building, including disaster management policies and strategies.

Technical Services

- To facilitate cooperation on research and development on early warning;
- To promote considerations for indigenous knowledge on early warning;
- To provide the regions and sub-regions with technical assistance, expertise, and resources needed when environmental disasters occur;
- To support regional disaster management initiatives.

63.6 Conclusion

All African policymakers face natural and environmental disasters due to the extreme poverty of their populations, a fact which often forced them to overuse their natural resource base which has resulted in an ecological imbalance. Therefore food security and sustainable development, as well as the international strategies and other instruments for coping with food insecurity and poverty, must take natural disasters and their medium- and long-term impacts into account.

Through its specialized bodies, its projects and programmes, CILSS can contribute to an effective response to prevent and manage such environmental disasters. This action can still be strengthened by the scientific and technical assistance from various international, intergovernmental, and non-governmental organizations concerned with these problems.

64 Responding to Climate Variability and Change: Opportunities and Challenges for Governance

Sreeja Nair

64.1 A Changing World in a Changing Climate[1]

"*There is nothing permanent, except change*"

Heraclitus of Ephesus

The developmental pathways of the society have been associated with changes in the utilization patterns of natural resources and environmental goods and services. Given the need for societies to develop, the key challenge has been to manage the available natural resources and preserve the environmental structure and function so that they continue to support societal development in a sustainable manner. Among a multitude of stressors that have emerged as offshoots of unsustainable development, one of the gravest repercussions has been the change in the climate of the earth (beyond natural variability). The change in the climate attributable to human activities has already begun to register impacts on the earth's life-supporting ecosystems with serious implications for the society. Short-term and long-term changes in climatic variables can compound the impacts of existing stressors (such as rise in population and consequent increases in demand for space and other resources) on the environment and living systems.

Despite considerable progress in terms of understanding the changing climatic conditions, human existence and development are constantly plagued with the issue of uncertainty about the future climate. In the face of uncertainty, the biggest challenge and opportunity both, is the ability for forward-looking decision-making. Neither a top-down nor a bottom-up approach alone can determine successes or failures of policy frameworks in a dynamic world. Imposition of top-down rigid governance mechanisms might often fail to incorporate feedback and learning from the grassroots in response to changing environmental conditions (Urwin/Jordan 2007: 187). An equitable policy mechanism to address such complexities would be to craft specific policy solutions for the regions and communities at risk (Bohensky/Lynam 2005: 15 of 20). This paper is an attempt to discuss the multiple facets of how governance can influence the capacity of individuals and the society to best adjust to the risks associated with climate change. Since every individual is affected differently and responds differently, the paper tries to highlight why governance needs to be nested at different levels to reflect these ground conditions appropriately.

A case study of India's multi-level governance structure is used to support the discussion. India has 28 states, 7 union territories, 604 districts and over 600,000 villages with twenty-two scheduled languages and over 1500 minor languages.[2] Successful adaptation across a diverse country such as India, with a vast geographical area spanning mountains, flat terrains, deserts, forests, deltas and coastal areas, will require concerted action at different scales of governance.

1 The author is thankful to the *Federal Ministry of Education and Research, Germany* (BMBF) and the *International Human Dimensions Programme on Global Environmental Change Programme* (IHDP) for providing grants that supported the presentation of this paper at the 2008 Berlin Conference on the Human Dimensions of Global Environmental Change. The author also expresses deep gratitude to Hans Guenter Brauch for giving an opportunity to develop this presentation into a full research paper. The author also acknowledges the initial discussions with Dr. Prodipto Ghosh and Dr. Ligia Noronha, TERI as the motivation for development of this paper.

64.2 The Response to Change: Vulnerability, Resilience and Adaptation

Considered as a composite unit, human society and nature, i.e. *Social-Ecological Systems* (SES), are *complex adaptive systems* (CAS) experiencing multiple cross-scale[3] interactions ('complex') and with time, adjusting to conditions of stress such as climate change ('adaptive')[4]. Essentially, the functioning of CAS fall between anarchy where interactions between group members determine the final characteristics of the entire group and hierarchy with a top-down decision-making approach (figure 64.1).[5]

A major barrier for policy implementation in response to uncertain future conditions has been the lack of a complete understanding of the mechanisms that influence the SES (Allison/Hobbs 2004: 1 of 25). Vulnerability of SES to climatic stress, is a factor of the level of exposure to the stressor, the degree to which the system is affected by the stressor ('sensitivity') and the ability of the system to adapt to the stressor ('adaptive capacity') (Smit/Pilifosova 2001: 894). Studies at the community level have revealed that the conditions that define vulnerability in terms of exposure, sensitivity and the capacities to adapt are community-specific (Smit/Wandel 2006: 286, 287). In response to long-term climate change, SES can undertake an "*adjustment in response to actual or expected climatic stimuli and their effects or impacts*" (Smit/Pilifosova 2001: 881). These actions constitute adaptation and can be initiated at the individual and/or organizational level by public entities, such as the governments (Adger/Arnell/Tompkins 2005: 77). Some factors that may define the capacities of societies to adapt may include access to technology, availability and distribution of resources, institutional setup, presence of infrastructure, access to education, access to opportunities for risk – spreading and the ability of decision-makers to manage information inter alia (Yohe/Tol 2001: 26).

In the face of stress, SES do not rapidly change their form owing to several self-reinforcing mechanisms that try to maintain the original structure and function as far as possible (Walker/Carpenter/Anderies/Abel/Cumming/Janssen/Lebel/Norberg/Peterson/Pritchard 2002: 1). Under stress, SES slowly assimilate the new conditions while trying to maintain their earlier critical processes, attempt to self-organize and build the capacity to learn and adjust to these conditions. These processes define resilience of the system (Carpenter/Brock 2008: 1). Both vulnerability and resilience are dynamic and change from person to person and time to time. While vulnerability is the suite of factors that create the potential for damage, resilience is the ability of the system to respond after the exposure to stress (acute or chronic). CAS are dynamic and have several stable states based on the interactions between their individual units and the external environment (Allison/Hobbs 2004: 3 of 25).

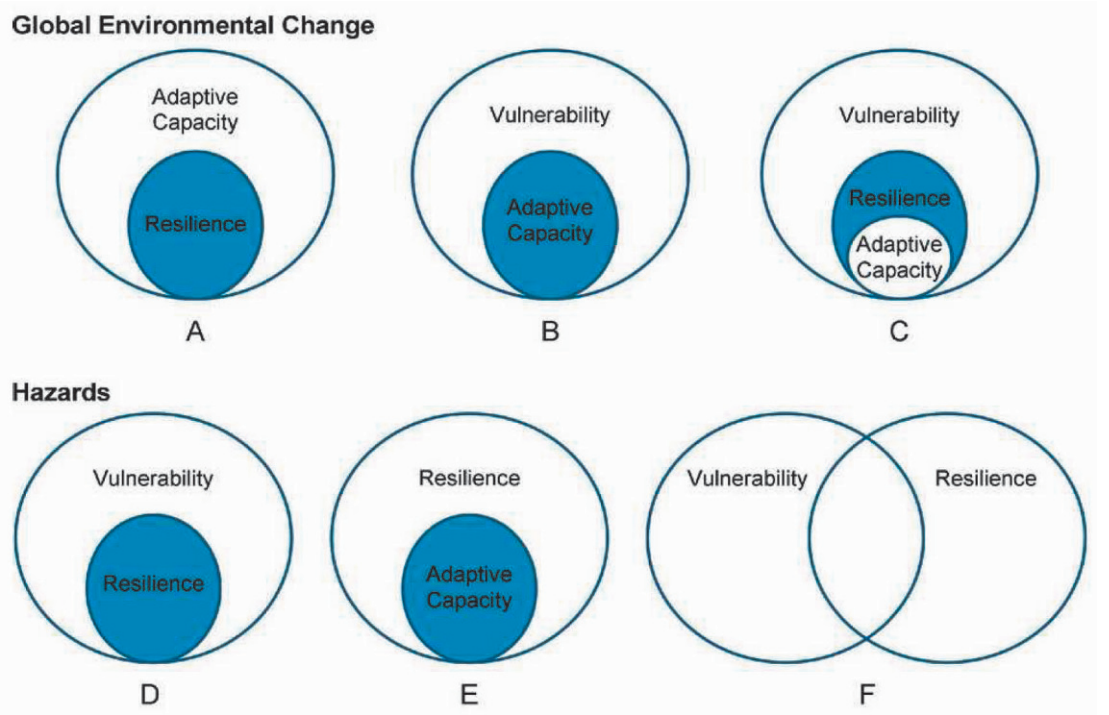
The identical treatment of the discourse on the resilience of ecological systems and social systems has

3 Scale allows for the measurement of any event or phenomenon. Scale, for example, can measure the variations across space, time, jurisdiction and/or institutions. There can also be 'levels' within a particular scale at which the phenomenon can be observed and measured (Cash/Adger/Berkes/Garden/Lebel/Olsson/Pritchard/Young 2006: 3 of 12).

4 Black-Hughes, C.; Eoyang, G.; Smilonich, D., 1997: "The Robin Hood Syndrome: Street Gangs as Complex Adaptive Systems"; at: <www.hsdinstitute.org/e-clarity/asp_documents_0001/Documents_Publish/83.pdf> (2 February 2008): 6 of 30.

5 Eoyang, G.; Berkas, T., 1999: "Evaluating Performance in a Complex Adaptive System. Complexity in Organisations"; at: <www.chaos-limited.com/EvalinCAS.pdf> (20 January 2008): 5 of 21>.

Figure 64.2: Conceptual linkages between vulnerability, resilience and adaptive capacity. **Source:** (Cutter/Barnes/Berry/Burton/Evans/Tate/ Webb 2008: 600).



often been contested. However, ecologists argue that just as resilience allows ecological systems to cope with change similarly resilience allows social systems to innovate, learn and cope with change gradually (Adger 2000: 350). Three properties define the future response of ecosystems, agencies and people to change; the potential for change and the range of options available, degree of flexibility of their internal system processes to respond effectively to external conditions and their resilience (Holling/Gunderson 2002: 32). When institutions become highly rigid and self-reinforcing they are less open to any change and hence less resilient (Carpenter/Brock 2008: 2). Being a dynamic process that evolves with time, vulnerability, resilience and adaptation crucially depend on timescales. While vulnerability in the short-term will depend on the ability of the system to cope with the climatic risk, vulnerability in the medium to long-term will depend on the ability of the system to adapt to that risk (Brooks/Adger/Kelly 2005: 153).

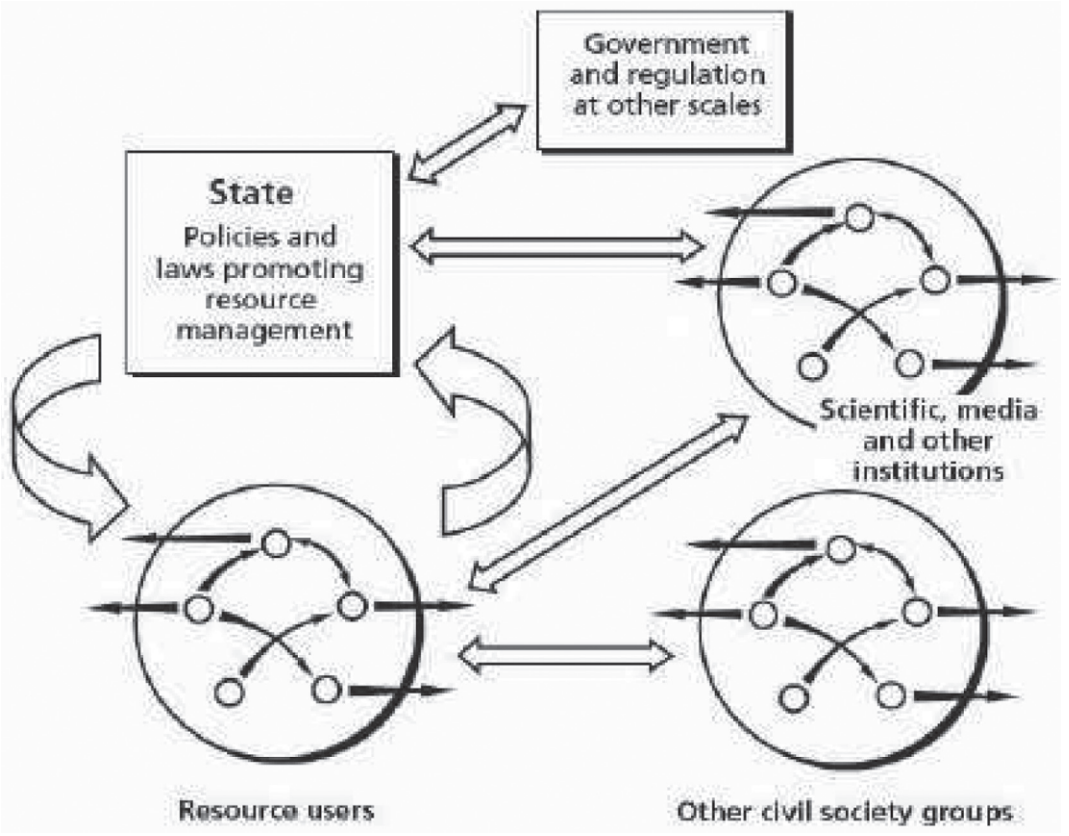
The concept of vulnerability, adaptation and resilience has been subject to interpretation through different perspectives including that of environmental change, political-ecology, sustainability, social justice and disaster risk-reduction (Vogel/Moser/Kasperson/Dabelko 2007: 350). According to some researchers, while resilience is the main component of adaptive capacity, others view adaptive capacity as a key determinant of vulnerability or both resilience and adaptive capacity under the aegis of vulnerability (figure 64.2). Policymakers and developmental planners have increasingly become interested in understanding these concepts to better inform humanitarian response to disasters and undertake proactive response measures (Dayton-Johnson 2004: 10 of 45). When the stressor is a climatic extreme event or a natural disaster, resilience is measured in terms of the ability to survive, cope and recover with minimum impact (Cutter/Barnes/ Berry/Burton/Evans/Tate/Webb 2008: 599).

64.3 Why Governance Matters?

Many of the impacts of climate change are new and challenging, hence the traditional coping strategies might fail and will not be applicable for most of these risks. Therefore there is a need for vulnerable communities to be innovative and devise new strategies. The 'Innovative Communities[6] Initiative' – a joint venture

6 The word 'communities' here refers to a group of people having some common criteria defining them. For example, geographic location, economic status, social background, political boundaries inter alia.

Figure 64.3: Co-management: fostering linkages between stakeholders at all levels. **Source:** Adger/Arnell/Tompkins (2005: 6); at: <http://www.ecologyandsociety. org/vol10/iss2/art9/>.



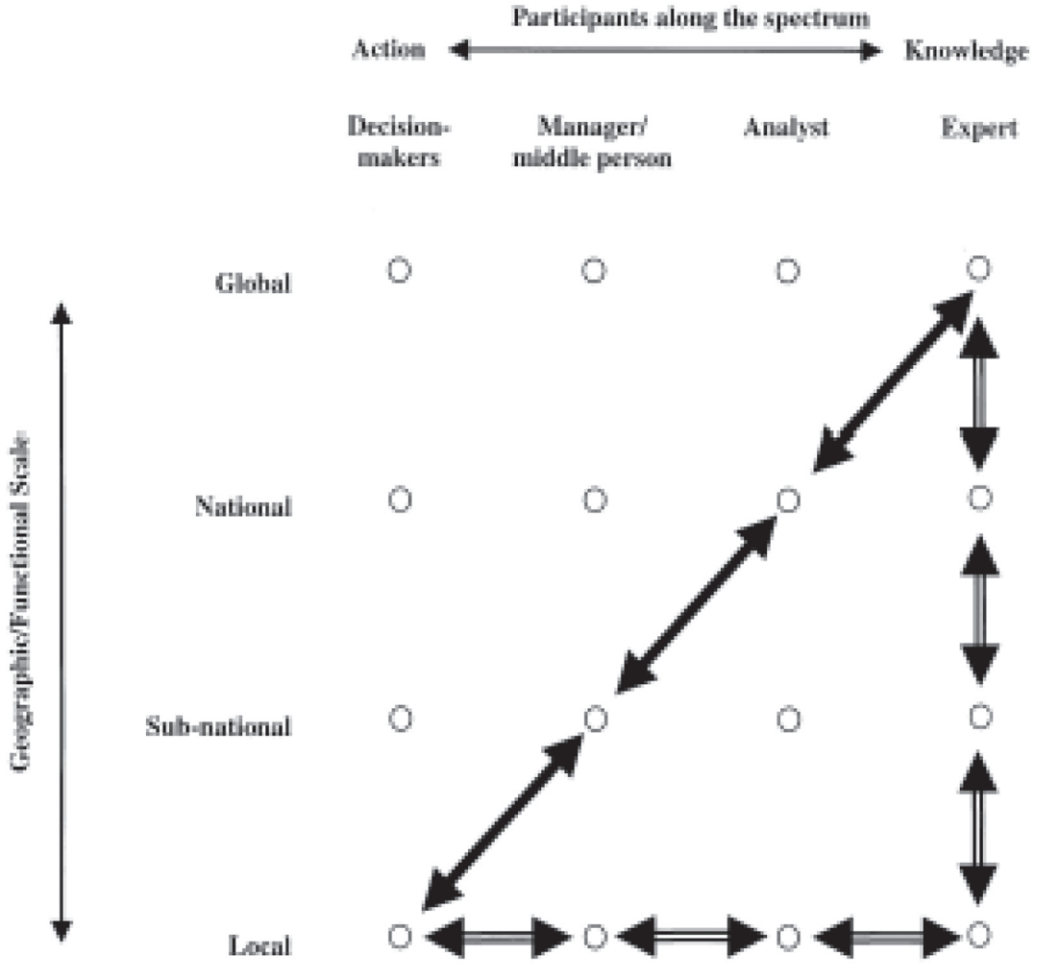
of *United Nations University* (UNU) and the *United Nations Environment Programme* (UNEP) defines innovative communities as those that can bring in novel solutions to respond to changing environmental conditions. Good governance facilitates the formation of innovative communities (UNEP-IETC 2003: 6 of 21). However, the challenge is to develop institutional structures that understand the underlying ecological and social processes at different scales and take them into consideration for decision-making (Folke/Carpenter/Elmqvist/Gunderson/Holling/Walker 2002: 440).

Adaptive governance is a concept that involves the evolution of institutions in response to changing conditions. This is especially critical to issues whose understanding evolves over time and engages a host of stakeholders, often with diverse views and interests. A governance structure that is adaptive would essentially need to co-ordinate between multiple stakeholders and interests across different scales and levels (Guerin 2007: 13). Another related concept is that of co-management i.e. sharing of rights and responsibilities between multiple stakeholders (figure 64.3; Cash/Adger/Berkes/Garden/Lebel/Olsson/Pritchard/Young 2006: 8 of 12). These linkages between stakeholders at different scales can be regulated through the creation of social networks as a platform for sharing of knowledge (Adger/Brown/Tompkins 2005: 6 of 14). This background leads to the next section on the need for governance mechanisms to be nested at different levels in order to address the differential vulnerabilities.

64.3.1 Why Does Governance Need to be at Multiple Levels?

The 'Rio Declaration on Environment and Development' (1972) emphasized the importance of establishing decision-making entities at different levels in order to appropriately reflect the interests and concerns of the vulnerable and disadvantaged communities. Institutions can facilitate the flow of information and sharing of resources between stakeholders at various levels (Cash/Moser 2000: 115; figure 64.4). An approach to enable the participation of vulnerable communities in decision-making and planning for their own well-being, would essentially need to be multi-level; which

Figure 64.4: Cross-scale interaction between institutions. Circles indicate potential points of entry for cooperating individuals or institutions. Black arrows and open arrows indicate hypothetical pathways. **Source**: Cash/Moser (2000: 115).



may involve the national and sub-national levels and interactions between them (Paavola/Adger 2006: 605).

Multi-level governance (MLG) is "a system of continuous negotiation among nested governments at several territorial tiers – supranational, national, regional and local" (Lemos/Agrawal 2006: 313). Institutions having a multi-level structure have the potential to improve the fit between theory and action at the ground level, especially in a heterogeneous[7] environment (Lebel/Anderies/Campbell/Folke/Hatfield-Dodds/Hughes/Wilson 2006: 4 of 21). While it is crucial for public policies to reflect ground aspirations, engaging all the stakeholders can be a cumbersome process in terms of the time and resources involved. This happens due to the existence of diverse interest groups, that can influence the dynamics of policymaking. For example, the strong engagement of civil society organizations does contribute to mobilizing social forces, creating consensus, ensuring transparency and decentralization (Reuben 2004: 202). Cooperation among various stakeholders such as the government, civil society and the private sector forms a critical pillar to lay the foundation for good governance (Punyaratabandhu 2004: 2 of 22).

Another drawback of a multi-level functional arrangement can arise due to the inefficiency of coordination among the diverse units within the same level and between levels. Furthermore the accountability is often directed towards the higher authorities but not towards the lower levels (Lebel/Anderies/

7 Heterogeneity may arise due to difference is social status, economic power, demographic profile etc. The constitution of heterogeneity may differ from region to region.

Campbell/Folke/Hatfield-Dodds/Hughes/Wilson 2006: 4 of 21).

64.4 Federalism and Multi-Level Governance in India

With the end of the British rule in India and the partition, it seemed that only a unitary rule controlled at the Centre[8] could maintain law and order in the country. Though a strong central rule was important in the newly-independent India, given the heterogeneity of the population in India, having another level of authority was inevitable. A federal structure of governance has two levels – the centre and the state, each being an autonomous legal and administrative entity. Under a federal framework each level has independent tax bases, a written constitution and independent courts to resolve potential disputes between the centre and constituent states. The Indian constitution has a clear division of power between the centre and the state governments, both elected directly through elections.

The Centre controls the issues that involve interstate matters, national security and foreign affairs; while subjects such as agriculture, land and water are under state governments. The centre possesses a higher fiscal power because it has under its control sources of revenue such as import/export duties and income and corporate taxes. On the other hand, the sources of income for the states are declining due to the pressing need to reduce taxes associated with land, education, health and development, owing to a rise in population. A part of the Central Government income goes to the state but the allocation of finances and investment priorities are defined by the Planning Commission which is under the purview of the Central Government. Furthermore, there are wide disparities between the socio-economic and demographic profile of different states in India that often makes it difficult to have adequate state-level representation in the decision-making process at the centre (Mitra 2000: 51).

Both federalism and MLG were designed to avoid the concentration of power at one centre. The MLG is in many ways an extension of a federal form of governance that only has two levels – the centre and the state. The points of difference are that while federal governance is still restricted to the political domain of government, MLG goes beyond that to engage multiple stakeholders, vertically and horizontally. Being concentrated in the political arena, the federal form of governance allocates the decision-making authority to the top level of government, however in MLG, decision-making assumes a shared nature with every unit having a say in the decision. With several functional units, there may be huge transaction costs in MLG thus making the decision process time-consuming and resource-intensive (Stein/Turkewitsch 2008: 11 of 35). The next section discusses how India evolved from a purely federal form of governance to a multi-level governance system that exists today.

64.4.1 From Federal to Multi-level Governance

Till 1992, the Indian federal structure of governance was two-tiered, with powers divided between the central and the state level only. Local government units existed in urban and rural areas as informal structures. In rural areas, Panchayat Raj Institutions facilitated the basic community services and justice. The 73rd and 74th Amendments to the Constitution in 1992 gave the rural and urban local governments a proper constitutional status. In many states, a three-tier structure of local government was formed with Panchayats being established at the village, block and district level (Rao 2000; figure 64.5).

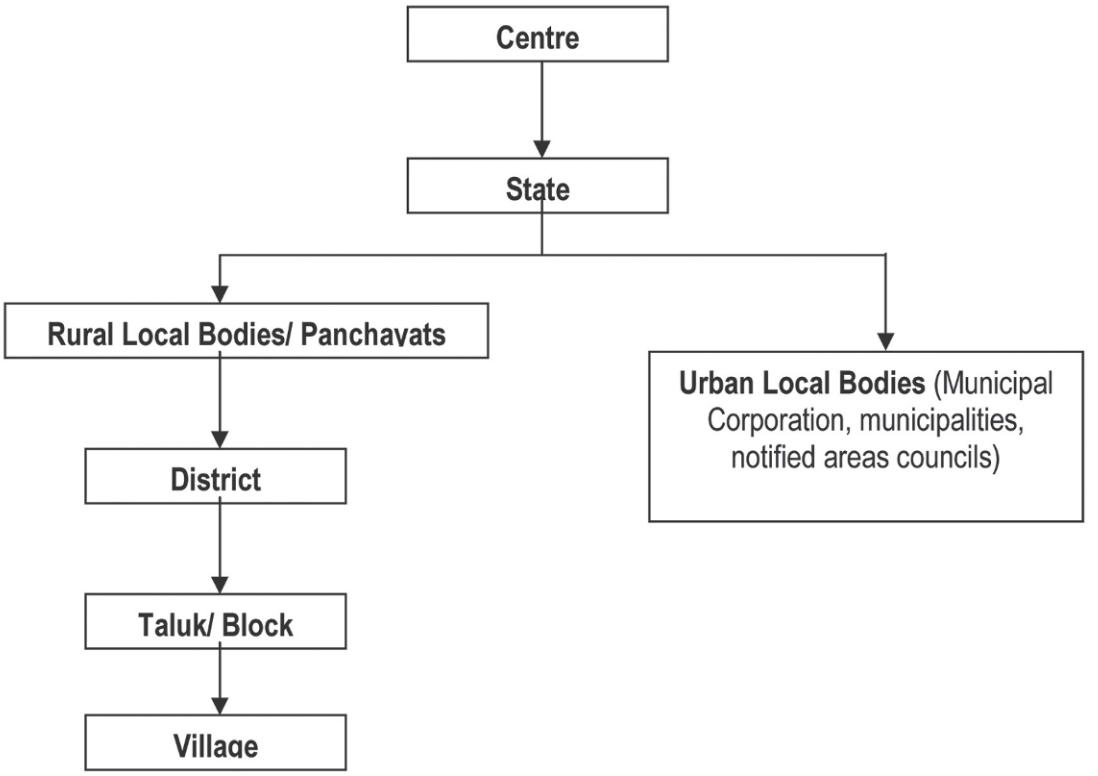
64.4.2 Decentralization and Local Governance

With the development of local level governance, the concept of decentralization became widely popular in India. Decentralization can be defined as the "transfer of powers from central authorities to lower levels in a political-administrative and territorial hierarchy" (Larson/Soto 2008: 216). Globally the concept of decentralization gained momentum from the mid-1980's also marking the dethroning of two global trends – colonialism and authoritarianism. This was the period that increasingly recognized the potential of the society as a solution to the problems related to the environment and natural resources rather than just being a source of the problem.

Decentralization can influence how decisionmakers at the lowest level of jurisdiction relate to those at the highest level; how local decision-makers connect to the grassroots community and how community members interact with each other and their environment (Lemos/Agrawal 2006: 303). One of the benefits of decentralization is that it often induces compe-

8 The Centre here refers to a unitary rule with powers concentrated at the national level or the highest level of authority in the country.

Figure 64.5: Structure of multi-level government in India. **Source:** Rao, G. (2000: 11); at <http://www.imf.org/external/pubs/ft/seminar/2000/fiscal/rao.pdf>.



tition among local governments for better efficiency in terms of responding to local needs. On the other hand, corruption can lead to unscrupulous bias towards certain elite or special interest groups (Hooghes/Marks 2009, 227: 225–241).

The efficiency of decentralization depends to a large extent on its design. Certain factors that govern efficiency of decentralization include the authority to react to local needs, accountability and mechanisms that enable a free flow of information to obtain feedback from the grassroots level. Factors that impede effective decentralization include the creation of parallel structures that overlap with those of the local governments, inadequate public participation and representation of diverse groups (especially women and minority groups) and lack of adequate functional and fiscal authority. Despite the third tier being created under the federal structure of India in 1992, the states continue to maintain their control over the Panchayats, in a way that often undermines the decision-making authority of the third tier – the local government (Jayal 2007: 42). One of the biggest challenges is associated with fiscal decentralization. The sources of revenue for the Panchayat are mainly derived from taxes on local resources such as land, animals, user fees and charges for local activities such as grazing, fishing. There are also many other routes of transfer of fiscal resources from the centre to the states. These are mainly in the form of grants provided by the Central Government as approved by the *Central Finance Commission* (CFC) and the Planning Commission and partial and full grants provided by various central ministries to their respective state ministries (Rao/Singh 2001: 8). The issue is that the local governments have not been empowered to raise their own funds and the funding received from the state is often premarked for specific activities, thereby restricting the fiscal autonomy of the *Panchayats* to spend these funds. This is critical because, adaptation activities are very region-specific and often require targeted investments. The inability of local governments to divert funds towards local level adaptation from these 'tied' funds can impede capacity building activities at the local level (Jayal 2007: 43).

Decentralization by itself will not necessarily produce systems that are more effective or more accountable to local needs and interests. This would require fiscal and political support from the higher levels of governance and decision-making. Another important factor is the presence of leaders and visionaries to

build sustainable partnerships and create institutional mechanisms and an enabling environ-ment for appropriate actions (Johnson 2003: 8 of 60). India abounds with examples of local leadership. For example, the case of village Hiwre Bazar in the Ahmadnagar district *of* Maharashtra and the *Adarsh Gaon Yojana* (AGY) or the 'Ideal Village Programme' that was launched across 300 villages in the state of Maharashtra in 1995 with the idea of developing one village from each taluka as an ideal village by providing safe drinking water, employment, fodder, education and health services. The steps under the full implementation of the programme included donation of labour, family planning, ban on grazing, ban on tree cutting and ban on liquor. Hiwre Bazar was a drought prone village with an average annual rainfall between 625–700 mm, rampant soil erosion due to heavy runoff, declining water tables and reduced water availability, making agriculture an unfeasible option for this village. In 1989, Popat Pawar was elected as the sarpanch (village headman/leader) and the village adopted a holistic development plan giving high priority to drinking water, irrigation and education. In the course of years under his leadership and the aid of AGY, the community also shifted to less water-intensive cropping patterns and is a prosperous village today.[9]

In terms of the proportion of the total government expenditure that occurs below the state level, India is one of the most fiscally decentralized countries in the world. However, a major concern that is encountered is in terms of revenue sharing with states. Some states are able to better manage funds owing to better endowments, less climatic stress and better socio-economic conditions as compared to their less-endowed counterparts (Kletzer/Singh 1996: 9 of 27). More than 2.7 million people have been elected to official posts for the three levels of Panchayats. However the formal transfer of functions has not been matched by a parallel transfer of funds for effectively performing specific adaptation functions. To address all these issues, during the Eleventh Five Year Plan (FYP) for the country (2007–2012) reforms would focus on building mechanisms for increased participation of communities in decision making and streamlining fiscal systems to match these activities (GoI 2006, 18 of 80). The Eleventh Five Year Plan of India has laid the details for district-level planning to prepare an integrated plan for the local level governments by taking stock of allocated tasks in terms of the institutional, financial and human resources available. This information would provide inputs into a vision document for each district and local-level government encompassing agriculture and allied sectors, water resources, infrastructure including power, water and sanitation, education, poverty alleviation, gender equality and social justice. Such a need-based assessment at the Panchayat level can aid in strategizing the activity-wise funding to be allocated to the local governments and accordingly assigning specific purpose grants and partial and/or fully untied funds (GoI 2008a: 16 of 25).

The planning process in India has been driven by the agenda of poverty alleviation. However, despite considerable poverty reduction efforts, about 280 million persons in rural India still fall below the poverty line[10] with many being agricultural labourers and artisans. Furthermore, there are wide inter-state variations in these rural poverty figures that can be strongly attributed to the regional variations in agricultural productivity among other factors. To plan targeted programmes for strengthening adaptive capacities given these regional variations, there is a need for the activities at the national and state level to link with those at the community level.

64.5 Adaptation to Climate Change in India: Opportunities and Challenges for Governance

64.5.1 Sectoral Impacts of Climate Change in India

The *Initial National Communication* (NATCOM) submitted by the Government of India to the *United Nations Framework Convention on Climate Change* (UNFCCC) highlights the potential threats to India due to changes in climatic variables and occurrence of climatic extreme events such as droughts and floods. These threats include:

- Changes in agricultural yields, pestilence and crop diseases and food insecurity;
- Reduction in the availability of freshwater;

9 Retrieved from <http://www.rainwaterharvesting.org/catchwater/aug2001/initiative.htm> (22 April 2009).

10 Government of India, Planning Commission, 2008: *Report of the XI Plan Working Group on Poverty Elimination Programmes* (New Delhi: Planning Commission); at: <http://planningcommission.nic.in/aboutus/committee/wrkgrp11/wg11_rdpov.doc> (6 January 2008): 5 of 91.

- Shifts in the forest boundaries and changes in species diversity;
- Impacts on sensitive ecosystems such as mountainous regions and coastal ecosystems including wetlands, mangroves and coral reefs;
- Sea-level rise and inundation of low-lying regions and coastal zones;
- Adverse impacts on human health due to changes in virulence patterns of disease-causing agents; and
- Impacts on infrastructure and energy demands (GoI 2004).

In 2008, the Council on Climate Change headed by the Prime Minister of India released the country's first *National Action Plan on Climate Change* (NAPCC). The objective of the NAPCC was to strategize national priorities in response to climate change and associated risks. The NAPCC identified eight national priorities including solar energy, enhanced energy efficiency, sustainable habitats, sustaining the Himalayan ecosystem, increasing forest cover, sustainable agriculture, information sharing and dissemination for climate change and water resource management (GoI 2008c: 9 of 56). Governance mechanisms will have to be bolstered in each of these sectors in order to adequately boost capacities of individuals, communities and institutions to effectively respond to the impacts of climate variability and change. Adaptation in the forestry and agriculture sector in India is discussed ahead, under the vulnerability and governance lens.

64.5.2 Adaptation in the Forestry Sector

Under a changing climatic scenario, vegetation model runs for India indicate a likelihood of shifts in forest boundaries and associated changes in forest types, changes in net primary productivity and changes in species diversity. These impacts will have large-scale repercussions on a population of nearly 200 million that is dependent on forests and forest produce for their livelihoods (GoI 2004: 94 of 266). The NATCOM also identified several strategies to enable adaptation in the forestry sector. These steps include:

- Forest fire protection and management;
- Promotion of sustainable harvest and reduction in over-extraction of forest-based products and non-timber forest products;
- Fuel wood conservation programmes;
- Forest conservation, afforestation and reforestation measures;
- Promotion of natural regeneration in degraded forest lands and agroforestry on degraded non-forest lands;
- In-situ and ex-situ conservation of endangered flora and fauna (GoI 2004: 103 of 266).

During the mid-1970's and 1980's several dialogues emerged around efficient institutional mechanisms for sustainable natural resource management. The idea of community–state partnership was put forward as a practical method to bridge gaps between the government and the grassroots communities (Kumar/Vashisht 2005, 28: 28–38). In 1988, the *Joint Forest Management* (JFM) programme in India, emerged as an attempt to establish synergies between the state forest department and the indigenous forest communities for forest conservation and restoration. JFM sought to build the capacities of forest-dependent communities using incentives for forest conservation. However, a critical analysis of JFM throughout India reveals that the state forest department still maintains stringent authority over the entire decentralization process, with the local governance structures being dependent on the state to a great extent, rather than being autonomous. JFM has received criticism because of the apparent deployment of the local community by the state government as a cost-effective way to maintain forests rather than a mode to create local capacities and self-reliance of the forest-based communities (Kumar/Vashisht 2005, 31: 28–38).

The Eleventh Five Year Plan for India envisages a district-level plan for the forestry sector that includes the conversion of forest villages into revenue villages, settlement of disputes over forests, livelihood rehabilitation of the displaced forest-based communities and mapping of all occupied lands with due validation from the local government, the state Forest Department and Revenue Department (GoI, 2008a, 19 of 25). Under the NAPCC, the Prime Minister of India announced a Green India Campaign for the afforestation of 6 million hectares. This mission will be taken on degraded lands with the help of local communities facilitated through JFM Committees and the state Forest Departments (GoI 2008c: 9 of 56).

64.5.3 Adaptation in the Agriculture Sector

The agriculture sector in India contributes to 21 per cent of the GDP, 11 per cent of the total exports and provides a source of income for 56.4 per cent of the total workforce (GoI 2007: 1 of 11). With over 600 million dependent on the sector directly or indirectly, the agricultural sector is vital to India's economy.

Nearly 66 per cent of cultivated land is rain-fed and nearly two-thirds of the total cultivation is done on arid and semi-arid lands. All these factors heighten the vulnerability of this sector to the impacts of climate change. Other issues that cause concern in the agriculture sector include rapid degradation of the natural resource base, slow development of relevant technology, lack of proper institutional mechanisms for financing, widening economic gap between irrigated and rain-fed areas, presence of perverse subsidies and rapid decline in groundwater levels, with small and marginal farmers being at maximal risk (GoI 2008d: 12 of 85).

Strong institutional mechanisms in the form of community-based organizations often play a major role for coping with the impacts of climatic stresses on the agricultural sector, especially considering the paucity of formal sources of financial assistance such as credit and insurance services in the rural areas. Key areas where governance can play a role in enabling communities to cope with impacts of climate variability and change on agriculture include the following:

- *Information availability and access*. Timely and quality information on climatic variables can enable farming communities to conduct advance decision-making to reduce risks and agricultural losses associated with changes in the climatic variables. There is a need to address the issues such as generation of region-specific data on a continual basis to represent different time periods, conversion of data into a form that is easily comprehendible at the grassroots level, dissemination of the generated information, ability of the vulnerable communities to access and use this information to alter their short-term and long-term decision-making related to agriculture (changes in cropping pattern, timing of irrigation, harvesting and application of fertilizers etc.) to minimize their agricultural losses and maximize the market benefits.
- *Development of appropriate technologies combining scientific know-how and traditional knowledge*. Traditional knowledge is representative of the local biophysical and social capabilities hence these indigenous strategies should form the basis for technological innovations in order to ensure local acceptability and function effectively under changed climatic conditions. Investments in research and development based on a thorough knowledge of the local conditions such as soil type, ground elevation, water availability – includes surface water and groundwater, farming practices etc. could be used to develop cultivable varieties that are tolerant to harsh enviro-climatic conditions (such as droughts, excess salinity, pestilence etc.). Furthermore, based on past and current climatic trends, new and improved scientific models and assessment techniques can be used to predict changes in climatic variables and associated impacts on water availability, soil nutrient availability, crop yields etc.
- *Climate-risk proofing of rural development activities*. Government-assisted programmes are often not directly aimed to reduce vulnerability to climate change; but indirectly they enhance adaptive capacities by reducing poverty and enhancing overall development and access to services. There are numerous options that can enable integration of direct and indirect vulnerability reduction strategies into regular developmental activities in the agricultural sector. These include crop-breeding techniques for introduction of drought-tolerant and salt-tolerant varieties, efficient irrigation techniques, early warning systems and strengthening of *information and communication technologies* (ICTs) in rural areas. To cope with the damage potential of climatic extremes, the deployment of a mix of structural and non-structural measures is critical. However, the key concern is to facilitate these mechanisms while ensuring equitable access for the communities and ensure a participatory mode of community-level management of resources and developmental investments. It is also essential to enable and strengthen access to financial products (such as credit/loans, insurance etc.) that enhances the resilience of the communities to climatic shocks and to identify the role of community-based organizations to promote such products.
- *Water Resources Management*. Since the agricultural sector is inextricably dependent on water resources, hence to ensure the sustainability of agricultural production and addressing food security concerns, there is a need to target water resources management. Apart from water conservation, the issue of supply and demand side management needs to be addressed. While agriculture suffers in certain areas because of continuous water shortages, others suffer because of excess water inundating or washing away the fields or spoiling the crops. This underscores the need for effective management of available water resources by addressing policy issues related to river basin management, groundwater and surface water management.

During the Eleventh FYP, the main assistance planned for the agriculture sector at the district level will be related to access to credit and other financial and risk-sharing and pooling mechanisms such as insurance. Specific steps would involve revival and restructuring of the agricultural credit and cooperative societies and groups, provision of credit and loans for purchase of land by the landless, enhancement of the public distribution system inter alia (GoI 2008b).

64.6 Conclusions

The impacts of climate change are already being felt on different ecological and biological systems. Though there are several mechanisms to temporarily cope with the impacts of short-term changes in the climatic variables, however, in the long-term adaptation is inevitable. Adaptation not only encompasses risk reduction strategies but also strategies to make use of the opportunities under the changing climatic conditions. These strategies may be taken up at the individual level or at the level of a community. Just as vulnerability is not the same across the society, similarly adaptation strategies will not be the same for all. Government bodies and other non-government stakeholders can enable vulnerable individuals and communities to adapt to climate change. The success or failure of these efforts depends on the governance framework under which all these stakeholders operate. A multi-level governance framework allows for adaptation strategies to be devised at the level at which the vulnerability is most felt. In structure, a multi-level governance framework can be considered to be an extension of a simple federal structure that operates on two levels – the centre and its constituent states. India since the time of its independence has had a federal structure of governance. In 1992, a third tier of local level government was added to this federal structure making it multi-level. The impacts of climate change are most felt at the local level owing to high vulnerability due to heavy dependence on climate-sensitive sectors, lack of adequate adaptive capacities and low levels of socio-economic development. Creation of this third tier paved the way for decentralization and an entry point to build capacities at the local level. However, effective decentralization faces several obstacles that limit the decision-making power and fiscal authority at the lowest level.

The Eleventh Five Year Plan of India seeks to address the bottlenecks in the path of effective decentralization and empowerment of grassroots communities. This will further allow for the development of appropriate adaptation strategies at every level of governance with particular importance to the local level. The vision of the great leader of India, Mahatma Gandhi was,

> in this structure of innumerable villages, there will be ever widening, never ascending circles. The outermost circumference will not wield power to crush the inner circle but will give strength to all within and derive its own strength from it.

To propel this vision into reality, it is essential to realize the opportunities and overcome the bottlenecks within the existing multi-tiered governance framework to enable effective adaptation to climate change.

65 Coping with Climate Change Impacts on Coffee and Maize for Peasants in Mexico

Cecilia Conde

65.1 Introduction

In the Mexican states of Tlaxcala (figure 65.1; no. 29) and Veracruz (no. 30), two case studies cases were developed to assess the impacts and possible responses to climate change and climate variability on maize and coffee producers. These two types of producers have differences but also similarities.

Maize production has been developed for more that 500 years in Mexico. Maize is the main source of food for the Mexican population, and it is cultivated mainly for subsistence purposes. Impacts on maize production have and will have severe consequences on food security in Mexico (Ziervogel/Nyong/Osman/Conde/Cortés/Downing 2006: 16). Currently, governmental policies oriented to support these subsistence peasants are scarce, and have been weakened since 1994 because almost all agricultural subsidies were withdrawn, in the context and due to the implementation of the *North American Free Trade Agreement* (NAFTA; Nadal 2000: 19). In this situation, it is difficult for maize farmers to develop or apply coping measures.

On the other hand, coffee production is mainly oriented to exportation, and became economically important during the last fifty years, when the demand of foreign markets and the agricultural policies in Mexico impelled peasants to switch from other cultivars to coffee production. Given the international fall or volatility of coffee prices, the organic production of coffee for some producers has been seen as an alternative, which might be consistent with environmental preservation and with adaptation to climate change (Muller 2009: 4).

Regardless of their differences, the coping capacities of these two types of producers have been diminished. In both study sites the increase of climatic extreme events have affected the agricultural production, but also the drop of prices and the lack of adequate agricultural policies have expelled rural population to urban areas or, mainly, to the United States of America (USA). Although the study was conducted only in one county (Tlaxco, Tlaxcala; figure 65.2) with maize producers (Conde/Ferrer/Orozco 2006: 182) and in one county (Coatepec, Veracruz; figure 65.2) with coffee producers (Gay/Conde/Eakin/Seiler/Vinocur/Wehbe 2006: 170), both cases shared main characteristics that might support some general conclusions for both types of peasants in Mexico.

For more than a decade, climate change studies have followed the path of generating climate change scenarios, introducing those scenarios to models that are used to assess potential impacts, and from there, draw some general conclusions regarding vulnerability and adaptation (Gay 2000: 95). New studies are now centred on understanding the sources of vulnerability, and the practices, barriers and opportunities of adaptation (Adger/Agrawala/Mirza/Conde/O'Brien/Pulhin/Pulwarty/Smit/Takahashi 2007; Carter/Jones/Lu/Bahdwal/Conde/Mearns/O'Neill/Rounsevell/Zurek 2007: 727; Lim/Burton/Huq 2005: 1). For that purpose, interdisciplinary research teams are assembled, stakeholders' involvement takes place since the beginning of the projects (Conde/Lonsdale 2005: 52), and new tools are being tested to elucidate and communicate current and future climatic threats. These new approaches have not diminished the quality of regional climate change scenarios, nor have they abandoned potential impact models, but they have shifted the emphasis to those issues that are regarded as urgent in Mexico, and that are highly demanded by policy makers.

The focus of these studies was on the observed climate changes, including more frequent or intense extreme climate events, which are of high concern for peasants in both regions. Considering the climatic trends, farmers perceived that their coping capacity is being reduced, not only because of climate variability and change, but mainly because their socio-economic conditions have reduced their ability to cope with those climatic events.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_65, © Springer-Verlag Berlin Heidelberg 2011

Figure 65.1: Federal states of Mexico and the study area in Tlaxcala (No. 29 in the list of states) and Veracruz (No. 30 in the list of states). **Source:** OECD (1998: 3).

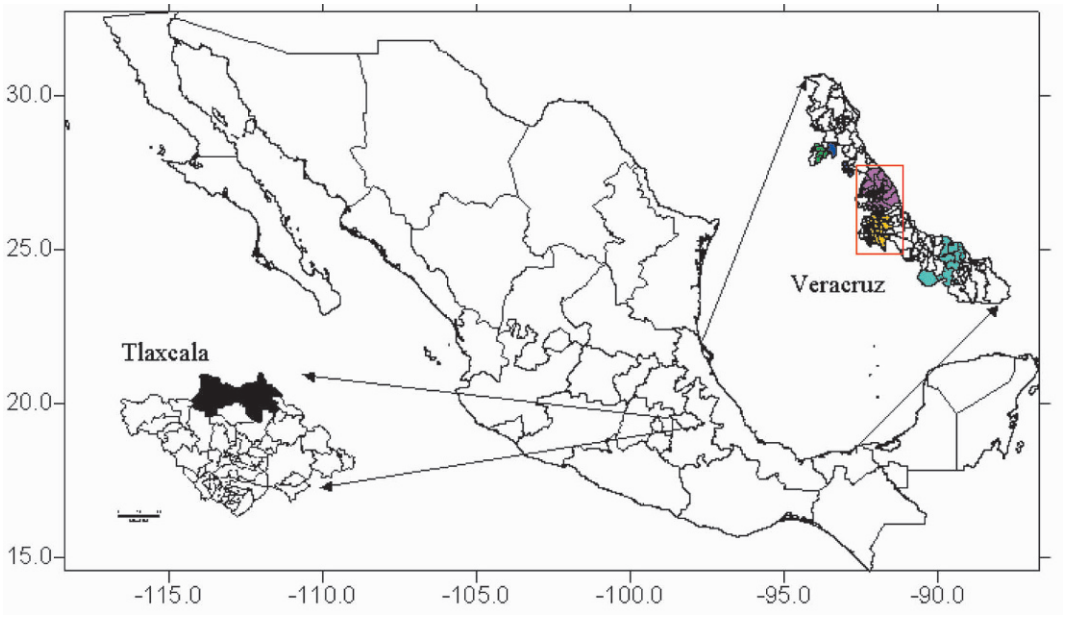
Given the current climate and future climate projections, in one study area (Tlaxco, Tlaxcala, figure 65.2), adaptive measures were implemented (Conde/Ferrer/Orozco 2006: 186) but only partial success was gained, indicating that adaptive measures were constrained to the achievement of the know-how or 'ownership' of those measures by the peasants involved in the project. That is, adaptation was determined not by those measures, but by the adaptive capacities acquired (or not) by the key stakeholders.

Based on that previous experience, the concern of the ongoing study in Coatepec, Veracruz (figure 65.2) will be the detailed analysis of the viability of possible adaptation measures. The coffee producers decided that the project should be focused on environmental services (Castro/Conde 2006: 1; Conde/Calderón/Castro 2008: 9); since they expect that they will have other sources of income with such services. No practical adaptation measures have been implemented so far. Instead, studies are currently being developed that sustain the payment of environmental services, such as carbon dioxide sequestration by coffee plantations, regional biodiversity conservation, and regional climate benefits rendered by the forests where coffee has been planted. Stakeholders' involvement in both studies can be considered nevertheless as an adaptation measure, because it might ensure the viability of future practical measures. Factors that determined the adaptive capacity of coffee producers is currently being assessed.

In this chapter, the background of climate change studies is first presented to explain why the current efforts are centred now on the enhancement of the adaptive options of the agricultural sector. In the description of the applied methods (participatory and regional climate change scenarios) the participatory techniques are emphasized as means to bridge knowledge between researchers and farmers on observed climate changes and the current responses to it, but also to communicate possible climate changes in the future and to discuss the viability of the chosen adaptation measures.

The methods to generate regional climate change scenarios that were presented to farmers in both study sites are also described in this section. Even though communicating climate change scenarios is a difficult task, in our research we did not 'average' those scenarios or have tried to minimize the impor-

Figure 65.2: Map of the two study areas in Tlaxcala (Tlaxco county in black) and Veracruz (coffee regions are shaded; inside the box is the central region, that includes Coatepec, and that is the most productive region), Mexico. **Sources:** elaborated by the geographer Raquel Araujo, postgraduate student (unpublished).



tance of uncertainty associated with future climate change.

Finally, the results achieved in these two studies are discussed, showing that the perception of current climate change is shared by both types of peasants, that their adaptive actions are being reduced by the lack of agricultural policies that can support their adaptive choices. In both study sites, migration of young farmers is a source of current and future vulnerability that can jeopardize any adaptation strategy.

Migration of the rural population has occurred in both study sites for decades. Migration of young men and – more recently – also of young women to cities in Mexico or to the United States of America, is one of the non-climatic factors that have determined the current vulnerability in the agricultural practices in Mexico. In 2004, 10.23 million Mexican migrants – especially from rural areas – lived in the USA, a population that has grown at an annual rate of 4.2 per cent since 1994.[1] In the same year, 16,613 million US$ in remittances were sent by migrants to Mexico.[2] The remittances to Mexico represented the second largest source of foreign income, after oil exportations.

These factors have determined that the rural population is one of the oldest in Mexican history. In 2003, according to a study for the Minister of Agriculture (Gay/Conde/Gómez/Cortés/Monterroso/Rosales/Eakin/Paz/Echanove 2004: 2–3), the majority of those who received governmental support were more than 50 years old, and one third of the beneficiaries were women. Households are supported by older men and women who would require specific adaptation strategies to cope with climate variability and change.

65.2 Research on Climate Variability and Change in Mexico

Mexico occupies around 195 million hectares, 85 per cent of them have arid and sub-arid climates. Only 7 per cent of the territory (in the southeast) receives almost 40 per cent of the total annual rain of the country (Reyes-Castañeda 1981: 58). The Tropic of Cancer can be seen as the division between the arid and semiarid with the humid and sub-humid climates (Rzedowski 1978: 33).

The climate in Mexico is mainly established by the interaction of tropical systems in summer and the middle latitude systems during winter (Magaña 1999: 23). Other meteorological phenomenon that also influence the rainy season in Mexico are: the position

1 CONAPO, 2004: "Población nacida en México que reside en Estados Unidos. 1990 a 2004"; at: <www.conapo.org.mx> (20 July 2005).

2 Banco de Mexico, 2004: *Informe Anual 2004*; at: <www.banxico.org.mx> (20 July 2005).

of the *Intertropical Convergence Zone* (ITCZ), the North American Monsoon, and the hurricane activity. Regardless of those generalizations, there are differences in regional climate determined by latitudinal and orographic conditions.

These climatic circumstances are fundamental for the agricultural activities, which are developed mainly in rain fed conditions during the spring – summer season. Climate variability – particularly extreme events – can then severely impact production and the well-being of the rural population.

Climate variability in Mexico has been highly associated with El Niño/Southern Oscillation (ENSO). In Mexico during strong El Niño events (Magaña 1999: 29), generally summer droughts, followed by spring droughts, are expected. These droughts are coupled with high temperatures in both seasons, conditions that have affected agricultural production all over the country (Conde/Ferrer/Gay/Magaña/Pérez/Morales/Orozco/ 1999: 109). In contrast, floods and landslides have occurred during strong La Niña events, because over than normal precipitations usually occurs during those events.

Other climatic extreme events, such as unexpected frosts, or strong winds, are also part of the most worrisome climatic events for farmers. Therefore, the possible enhancement in frequency or intensity with climate change of ENSO or other climatic extreme events are of more concern to peasants in Mexico than the changes in the climatological values usually shown in the climate change scenarios.

Working Group I of the *Intergovernmental Panel on Climate Change* (IPCC, WGI 2007: 5) states that the warming of the climatic system is unequivocal, and that at continental, regional and ocean basin scales, numerous long-term changes in climate have been observed. Studies for Mexico have shown that the country's averaged summer temperature and precipitation have increased (i.e. Conde 2003: 2–38), but regional differences were found. For both study sites of this chapter, and considering a 90 year period, summer temperatures have indeed increased, but precipitation has decreased.

WG1 of the IPCC (IPCC, WGI 2007: 7) also stated that there have been "changes in the precipitation amounts, ocean salinity, wind patterns and aspects of extreme weather including droughts, heavy precipitation, heat waves and the intensity of tropical cyclones". Regional studies related to the change in the intensity, frequency or duration of extreme climatic conditions are being developed (López 2009: 3; Lozano 2009: 1), but some indication of those changes were pointed out by Conde (2003: 2–42). Climate change studies have been developed in Mexico for more than a decade (box 65.1). High resolution scenarios have been developed, new methods for impact assessments are applied, and projects focused on capacity building and the enhancement of adaptive capacity are now being performed.

The Mexican government has supported many of the studies that are listed in box 65.1. The *National Strategy for Climate Change* (2007) and the *Special Programmes for Climate Change* (2009) – although they are centred mainly on mitigation options - have included important analyses of the possible impacts and adaptation options for productive sectors and regions: biodiversity, agriculture, hydrological resources, fisheries, livestock, coastal zones, human health, and human settlements. Goals and activities that will be supported are also included in those documents.

However, more in depth studies are needed to assess the viability of listed adaptation measures, and current vulnerability and adaptation assessments should sustain the analysis of future adaptation options, since current policies, practices or processes may be barriers for adaptation or even the source of increasing vulnerability.[3] Without these analyses, adaptation measures suggested by researchers or even by key stakeholders involved in the study might be frustrated.

65.2.1 Tlaxcala Case Study

Rain fed agriculture is predominant in Mexico, and the main crop is maize. Subsistence of poor peasants is based on the year to year production, an activity that is constantly threatened by drought, and that usually renders low yields of maize. In the Mexican history (Florescano/Swan 1995: 55–56; chap. 51 by Arredondo/Huber Sannwald), drought events have produced severe social and economical stresses, particularly in the years previous to the independence of Mexico (1810) and previous to the Mexican Revolution (1910–1917). Some of those severe droughts were associated with strong El Niño events (Jáuregui 1995: 41). At the national level (Gay/Conde/Gómez/Cortés/Monterroso/Rosales/Eakin/Paz/Echanove 2004: 5–7) drought is still the source of most agricultural losses. The intensity and duration of recent drought

Box 65.1: Overview of Research on Climate Change in Mexico. **Source**: The author.

Initial studies related to climate change were developed in the Center of Atmospheric Sciences (i.e. Adem/Garduño 1984: 55; Conde 1996: 2), mostly based on simulated atmospheric responses to the increases of CO_2 and other greenhouse gases. Other studies focused on historical trends of climatic variables and extreme events (i.e. Jauregui 1995: 96, 1997: 39–40; Gay/Estrada/Sánchez 2009: 148). Recently, regional climate change scenarios were generated for Mexico and for Central America with a resolution of 5' x 5' (≈ 10 km x 10 km). Also a guide to generate those scenarios for different regions and at different scales.[a)]

Studies that generated climate change scenarios and the possible potential impacts on relevant sectors or regions in Mexico were initially developed in the U.S. co-sponsored Country Study Project.[b)] The organization of that project followed a similar structure of the IPCC, creating the critical nucleus for future investigations.

The Mexican Government has strongly supported the research on climate change issues, involving most of the researchers that participated in the Country Study Project. Since then, Mexico has delivered its Third National Communication (SEMARNAT/INE 2006)[c)], to the *United Nations Framework Convention on Climate Change* (UNFCCC), and in 2009 it is finishing its fourth. The Mexican government has also launched a *National Strategy for Climate Change* (ENAC)[d)] that was presented by the President of Mexico in 2007 and *Special Programmes of Climate Change* (PECC) has been announced to support that Strategy.[e)]

Initial studies of the impacts of climate change on rain fed agriculture in Mexico[f)], showed that Mexican agriculture is highly vulnerable to climate variability and change. Current studies related to potential impacts of climate change were developed recently for the *Fourth National Communication*. Results concerning human settlements, fisheries, livestock, hydrological resources, forestry, and guides for generating scenarios and developing regional Action Plans can be found at the web page of the Center of Atmospheric Sciences.[g)] Regardless of these advances, few projects have involved key stakeholders in the design of adaptive measures. Some examples can be found in the results reported in the project: *Integrated Assessment of Social Vulnerability and Adaptation to Climate Variability and Change Among Farmers in Mexico and Argentina* that integrated interdisciplinary research groups and focus more on vulnerability and adaptation. This project was developed in the context of the project *Assessments of Impacts and Adaptations to Climate Change (AIACC) in Multiple Regions and Sectors that* supported 24 regional studies in 46 countries.[h)] In the project *Capacity Building for Stage II Adaptation to Climate Change in Central America, Mexico and Cuba,* whose results were presented to the *United Nations Development Programme* (UNDP) by 2006–2007, the methods to involve stakeholders described in the Adaptation Policy Frameworks (Lim/Burton/Huq 2005: 1; Conde/Lonsdale 2005: 52) were applied, and the goal in the Mexican study case for the agricultural sector (Conde/Ferrer/Orozco 2006: 186) was the application of several adaptation measures.

events is highly correlated with El Niño events (Conde/Ferrer/Gay/Magaña/Pérez/Morales/Orozco 1999), particularly during the strong events of 1982–1983 and 1997–1998, when the summer droughts during the first year of El Niño (1982 and 1997), and the spring droughts during the second year (1983 and 1998), severely impacted rain fed maize production in the country.

Economic policies have lead to a dramatic drop of maize prices, being in 2005 about 45 per cent below those in 1988. In contrast, the *tortilla* price (basic nutritional staple in Mexico) increased in the same period by almost 279 per cent (Nadal 1999: 145; Zier-

vogel/Nyong/Osman/Conde/Cortés/Downing 2006: 17), accelerating the mal-nutrition conditions and poverty of the rural and urban population. Even though yields have then decreased, the Mexican production of maize has been more or less stable since 1988, except for 1998, when corn production was affected by a severe drought (Nadal 2000: 32; Conde/Vinocur/Gay/Seiler/Estrada 2008: 13).

Tlaxcala is the smallest state in the country, with the highest soil erosion in Mexico[4]: 82 per cent of the surface dedicated to agriculture in the state has severe erosion for wind processes, and 57 per cent has been eroded by hydrological processes. More than 80 per cent of the surface dedicated to rain fed agriculture[5], and at least half of it is dedicated to maize production, with averaged yields of 2.4 ton/hectare. Maize peasants are mainly smallholder producers (with less than 10 hectares), and most do not have insurances nor do they receive any credits. Another environment problem in the region are various pests, which are treated with agrochemical pesticides that also affect the quality of soils and water.

Its agriculture is mainly oriented at maize, with averaged yields of around 2.4 ton per hectare. Even though governmental programmes are oriented to convince farmers to switch from maize to wheat, barley or oats, peasants still preferred to plant maize. Primarily, because it is the main source of their food and that of their families. Also, because they know and control all agricultural conditions that surround this cultivar (Conde/Eakin 2003: 11).

From 2004 to 2006, a project supported by UNDP was developed: *Capacity Building for Stage II Adaptation to Climate Change in Central America, Mexico and Cuba*. For the case study in Mexico, the state of Tlaxcala was chosen, mainly because organized producers have asked for specific climatic studies during the 1997–1998 strong El Niño event. That first contact gave us the advantage of having previous studies and relationship with farmers and decision-makers. Because of that previous research, adaptive measures could be more readily discussed and applied.

In-depth studies of climate variability and climate change were presented to key stakeholders (producers' organizations, policy makers, peasants involved in the project) that were involved since the beginning of the project. Several studies showed that drought conditions in Tlaxcala during strong El Niño events (Conde/Ferrer/1998: 31; Conde/Eakin 2003: 11; Conde/Ferrer/Orozco 2006: 188) render very low yields or even total losses for maize producers. A maize simulation model (Ceres Maize model; Jones/Kiriny 1986) was used to assess the possible impacts under strong El Niño events, and also to project the impacts of climate change under several scenarios.

65.2.2 Veracruz Case Study

Veracruz borders the coast of the Gulf of Mexico. The climate in the state is mainly warm, humid or subhumid. However, the altitudinal variations (from sea level to almost 3,000 m) produce high climatic variations. Its central region is considered a region with high biodiversity (Gordon/Manson/Sundberg/Cruz-Angón 2007: 261–262; Manson,/Sosa/Contreras 2008: 283), which is threatened by land use change. Coffee plantations are imbedded in the rainforests, so they can be seen as a source for biodiversity conservation.

Coffee production occupies more than 152,000 hectares in Veracruz, and in the central regions concentrates 90.2 per cent of all the coffee producers in the state. This production was developed in Veracruz as an option to achieve greater incomes for small farmers (mostly, less than 5 hectares). Veracruz ranks as Mexico's second largest coffee producer although coffee plantations in that state are relatively recent, becoming an important agricultural activity since the 1950's, particularly due to the good prices after the Second World War.[6] This activity was the source of a major income until the 1990's, when agricultural policies changed and subsidies and technical support was extremely reduced and market prices dropped drastically. Organic coffee production was a response to lower prices, and new markets emerged for a small group of coffee producers. Coffee producers are currently struggling with pests (Castillo/Contreras/Zamarripa/Méndez/Vázquez/Holguín/Fernández 1997: 53) such as 'broca' (*Hypothenemus hampei, Ferr*) which apparently is reaching higher altitudes with increasing temperatures.

Change Among Farmers in Mexico and Argentina (Gay/Conde/Eakin/Seiler/Vinocur/Wehbe 2006: 8), one of the chosen study sites for the case of Mexico was the central region of Veracruz, where coffee has been produced for the last decades.

An important outcome of that project was the generation of an econometric model (Gay/Estrada/Conde/Eakin/Villers 2006: 264), that showed that in the central region of Veracruz (where Coatepec is situated), the temperature and precipitation conditions are ideal to produce coffee (mainly *Coffea arabica* L). Other biophysical studies (Villers/Arizpe/Orellana/Conde/Hernández 2009: 323) agreed with those results. Nevertheless, drought, frosts, heavy rains and strong winds can affect the quantity and quality of coffee. As in the Tlaxala study, old peasants and women are the major population in most of coffee properties (known as *fincas*), since a huge number of young men have migrated to the USA.

65.3 Methods

65.3.1 Participatory Techniques

Given the climate variability and change studies, and the assessments of potential impacts on maize and coffee, one should expect that adaptation options could be chosen and readily applied by policy makers or peasants. Nevertheless, the results must be communicated to the stakeholders in the region in such a way that they can use them for decision making. Awareness of current and future threats can be generated during workshops, in focus groups, in-depth interviews, and with the support of local experts and policy makers.

Participatory methods are relatively new in climate change studies. They are being adopted and adapted from other disciplines, such as sociological, psychological and anthropological research, and from studies related to development, poverty, and political issues (i.e. Ruggieri-Laderichi 2001: 5; Geurts/Joldersma 2001: 302). These methods have rendered important results and have motivated high expectations for developing integrated assessments (Kloprogge/Van der Sluijs 2006: 364). In agricultural studies (Pretty 1995: 1253), *participatory rural appraisal* (PRA; i.e. Chambers 1994) methods have been applied and developed for at the least two decades.

Participatory techniques (Conde/Lonsdale 2005: 954) were developed with farmers in two study sites (in Tlaxcala and in Veracruz), and the results obtained allowed the development of an assessment that considered the climatic and the non-climatic factors that determined adaptive capacity (O'Brien/Leichenko 2000: 221; Brooks/Adger 2005: 168; Gay/Conde/Eakin/ Seiler/Vinocur/Wehbe 2006: 173). Current climate threats, current practices and past and current environmental, economic and household problems were analysed with the farmers involved in the study (Conde/Ferrer/Orozco 2006: 186).

Several meetings with farmers were arranged before developing the focus groups, which were the basis of the two studies. A minimum of five and a maximum of ten farmers participated in each focus group (figure 65.3). In some occasions, five of those groups worked simultaneously, and the results were later compared by the research team.

In the case of Tlaxcala, since the first workshop it was recognized that the most worrisome environmental problem was the loss of soil fertility. Also, those maize producers were highly concerned with frosts, drought, changes in the precipitation patterns, and strong winds. Farmers also found interesting that during El Niño events most of those climatic events could be magnified. In those focus groups a shared knowledge was assembled on the regional climate, on critical climatic years were identified, on those regions that are more at risk, and on the observed impacts of extreme climatic events.

The activities developed during those meetings with focus groups were mainly: 1) presentation of the theme; 2) explanation of the map of natural resources and land use; 3) transect of an altitudinal diagram and of soil classification; 4) development of a calendar on the cultivation of maize and coffee; and 5) analysis and prioritization of problems.

Except for the first one, each of these activities consumed at least one hour, so the research team provided soft drinks, coffee and food to all participants. One member of the research group acted as a facilitator, while the other members took notes, sometimes photographs, and only asked questions (such as 'what is your opinion?'), when they perceived that some farmers were set aside of the activity (for example women).

The initial presentation was one of the main activities. Several techniques could be applied, but in these studies the 'spider web' (figure 65.3) was the most frequent activity performed to 'break the ice'. Mainly, the facilitator of the focus group used a skein or piece of rope to start the presentation of all participants. The facilitator gave his or her name, briefly explained what he or she wants to learn by this focus group

Figure 65.3: Focus Group in Coatepec, Veracruz. Presentation on climate impacts. **Source:** photo by Beatriz Palma (2008).

Figure 65.4: Focus Group in Coatepec, Veracruz. Review of the map of natural resources and land use. **Source:** Photo by Beatriz Palma (2008).

(such as 'I study climate, but I do not know well the climate of your region or locality, nor how extreme events have affected your activity, or what has or could be done in those circumstances'). Then one end of the rope is tossed to any member of the group, which will also give his or her name and his or her purposes or expectations. Finally, all participants are part of a web, seeing the importance of the bond that could be formed if all members of the group are willing to participate, with respect and attention for the others' opinions. The facilitator could also pull or drop the cord, to demonstrate how easily the web could be broken if only one participant's opinions prevails, or if one member of the group does not participate.

The research group shows then a map (satellite or aerial images) that helps the participants to locate their community (figure 65.4). The facilitator can give those images as a gift to the participants. After the localization of the main features of the study site, a cardboard is placed, and with the use of colour markers, the members of the group constructed their own map, describing their natural resources and land use (such as forests, sources of water, working fields, houses, roads, etc.).

The activity of 'transecting the altitudinal diagram and of soils classification', helped to deepen the previous one, since farmers described the differences of natural resources or agricultural activities depending on soil types and the natural resources at different altitudes. In this activity a brief description of the spatial distribution of the climatic conditions can be achieved, situating in the map those regions were climatic hazards have occurred more frequently or have been more intense.

With the 'calendar of cultivars' (maize and coffee); temporal – usually monthly – crop requirements of temperature and precipitation were described, correlating those with the crop management developed by farmers. The purpose was to relate climate with the fenological stages of the crop, and to establish in which stage specific climatic events are more dangerous for agricultural activities. With this activity, the costs of the inputs (seeds, fertilizers, labour, etc) and the expected production and economical benefits can also be assessed.

Finally, with the 'analysis and prioritization of problems', the most worrisome climatic events were described and prioritized. This activity helped to establish which climatic aspects must be investigated with more detail, projecting – if possible – their changes in the context of climate change.

65.3.2 Climate Change Scenarios

Climate change scenarios were generated (Conde/Estrada/Martínez/Sánchez/Gay 2009: 16) using the outputs of several *general circulation models* (GCMs). Even though there is no consensus on how to manage the uncertainty associated with those multiple outputs (Estrada/Gay/Conde 2008: 514; Schneider 2001: 18; Jones 2000: 403), these scenarios were developed using the criteria suggested by the *Task Group on Data and Scenario Support for Impact and Climate Assessment* (TGICA) of the *Intergovernmental Panel of Climate Change* (IPCC-TGICA 2007: 26). These criteria are: *vintage* (the more recent GCMs outputs); *resolution* (the must higher resolution available, with more spatial details), *validity* (simulation of present-day climate faithfully); and *representativeness*

Figure 65.5: Example of the base scenario for mean temperature (in July). **Source**: See at: <http://www.atmos-fera.unam.mx/gcclimatico/index.php?option=com_content&view=article&id=77&Itemid=74> (1 September 2009).

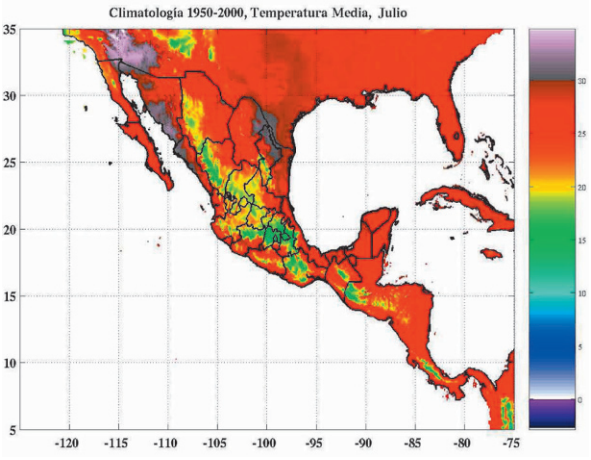

Figure 65.6: Example of climate change scenario, EHCAM5 model, A2 emission scenario, and horizon 205. Mean temperature (in July). **Source**: <http://www. atmosfera.unam.mx/gcclimatico/index.php?option=com_content&view=article&id=77&Itemid=74> (1 September 2009).

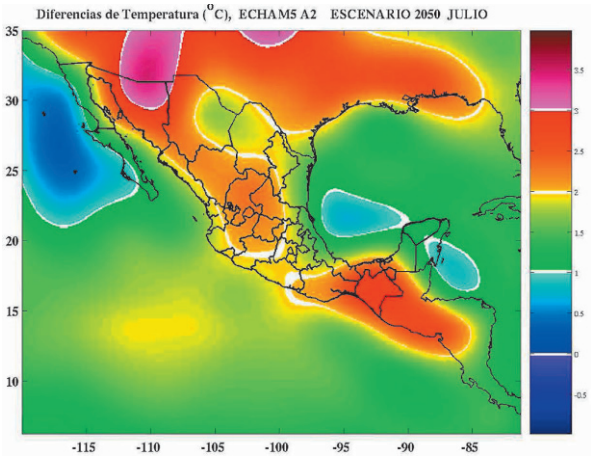

of the results (range or outputs that represent the uncertainty related to climate change). Another important criterion applied, was that those regional scenarios must satisfy the needs of impact modellers. They must be tailor-made instead of thinking that any scenario can be useful *per se*.

Using those criteria, scenarios were recently generated using the outputs of three General Circulation Models (GCMs: *GFDL CM2.0* (Geophysical Fluid Dynamics Laboratory), *ECHAM5* (Max Planck Institut für Meteorologie) and *HADGEM1* (Hadley Centre for Climate Prediction and Research)). These GCMs were evaluated, using some statistical conditions that their performance should accomplish (globally and for Mexico): the pattern correlation, the mean squared root error, the bias, and, the mean squared root error corrected by the bias (Wigley 2008). Also, following the criteria of *representativeness*, the output of the chosen GCMs should have no similar range of changes in temperature, and even different signs (positive and negative) for the changes in precipitation. The basis of this procedure is to establish that decision making in the context of uncertainty must be considered in climate change studies.

For the two study cases, previous versions of the GCMs were used, but for the project in Veracruz the new GCMs' outputs (since the Fourth Assessment Report [AR4] of the IPCC) and the criteria described above, are being used. Two emission scenarios were chosen (A2 and B2),[7] and two time slices were selected to project future climate: for the 2020's (for the period 2010–2039 centred in 2020) and the 2050's (2040–2069, centred in 2050). The outputs of those GCMs were obtained using the Model for the Assessment of Greenhouse Gas-Induced Climate Change and a Scenario Generator (Magicc/Scengen Model; version 4.1; Wigley 2003), and the more recent outputs obtained from the Canadian Climate Impact Scenarios that can be also useful when specific localities are under study.[8]

For Veracruz, regional climate change scenarios were generated using the methods described above.[9] Those scenarios were used in the Climatic Action Plan for Veracruz. These regional climate change scenarios were generated with a resolution of 5' x 5' (≈ 10 km x 10 km). The base scenario (1950–2000) includes extreme temperatures and precipitation, with the stated resolution (Hijmans/Cameron/Parra/Jones/Jarvis 2005: 1967). In the guide that was delivered for potential impacts assessments,[10] the multiple methods that could be applied are described. The intention of

the guide was to be user friendly, but also, to adjust to different users.[11]

65.4 Results

The participatory techniques described above showed that peasants have a great knowledge of the natural resources in their region. Spatial description of the rivers and underground water resources, forests, flora and fauna, were described in detail by farmers. Comparing the current with past conditions, a great concern was detected with regard to the loss or decline of those resources associated with land use changes, combined with intensive agricultural activities, such as low yields and extreme climatic events.

65.4.1 Tlaxcala Case Study

Using the results obtained from the Ceres – Maize model (Conde/Ferrer/Orozco 2006: 190), and the focus groups, it was found that the most vulnerable group of the agricultural sector in the state are the rain fed maize producers. The most worrisome climatic events are frosts, droughts, heavy rains and strong winds. During strong El Niño years, those events can be strengthened. Given the observed trends (Conde/Ferrer 1998: 29; López 2009: 138), minimum temperature is increasing, so it is possible to expect a larger planting season, free from frosts, which will benefit the maize production in the state.

There is no adaptation measure among maize peasants for unexpected frosts. Planting dates usually are established with the beginning of the rainy season (preferable in April: "April rains, thousand grains", peasants use to say) and harvesting labours must be developed by the end of August or September, before the frost events began. Farmers have a great knowledge of maize varieties, using seeds with shorter growing season (called *violentas*: violent) when the rainy season is delayed. Strong El Niño events usually last from the summer of the first year (i.e. 1982, 1997) to the spring of the second year (i.e. 1983, 1998), and drought conditions are expected during both seasons.

No adaptive measure can be applied during the summer of the first year. Since peasants planted usually in April, maize plants have developed to a stage were a drought will cause that all production will be lost. Only those who have water reservoirs (called *jagüeyes*) can rescue part of their production, the one that they planted in the most protected areas of their property (depressions or dips). During the spring drought, farmers can wait until May for the beginning of the rainy season, when they can plant 'violentas' varieties. If the rain delays more, then changing to another crop is one possible solution for farmers (oats for forage purposes was planted during 1998, for example). In this case, they will select seeds with shorter development cycle: barley, wheat or oats.

Strong winds and heavy rains affect the maize plants and also soil fertility. The measures that farmers have adopted in the past to cope with those events are constructing ditches or tree barriers. Nevertheless, these activities cannot be easily performed by old peasants and women, which also do not have the economic capacity to hire workers for these tasks.

The main coping measure that peasants have applied to assure their subsistence is to extend the planting area. This has been documented previously (Nadal 2000: 68), and is a measure that threatens the other elements of regional biodiversity (particularly forests, soils, and water reservoirs). In the short term, it can be seen as a zero cost measure for peasants, but this is an environmental aggressive strategy, that can be called a mal-adaptive measure. In contrast, usually peasants practice policultivars, since they include other crops in their maize planting area (such as some varieties of bean). This practice has demonstrated to preserve soil fertility (Altieri/Trujillo 1987: 198), and assures the maize peasants a broader food supply.

In synthesis, maize peasants have coping strategies that depend on the season, and on their human and economical resources. There are measures that can be applied with zero or minimum costs (Parry/Rosenzweig/Livermore/Fischer 2005: 2128), such as shifting planting dates, changing maize varieties (both tested with the Ceres – Maize model); extended the planting surface, or using part of their water reservoirs. Other adaptation measures, with higher costs, could be changed to other cultivars, increased fertilizer application, or pay for irrigation or labour force.

Besides these crop management measures, most of the rural families have developed outside-farm strategies (Saldaña 2008: 587). These can include incomes from a second job, governmental support after an extreme climatic event, remittances of relatives living in the cities or in the USA (Gay/Conde/Gómez/Cortés/Monterroso/Rosales/Eakin/Paz/Echanove 2004: 2–20), or, finally, the abandonment of the activity,

11 See at: <www.atmosfera.unam.mx/gcclimatico/index.php?option=com_content&view=article&id=144&Itemid=81>.

caused by migration to urban areas or to another country.

The described extreme climatic events, but also the reduced household capacities, and environmental and economic factors, show that the coping capacities of maize peasants have diminished (Ziervogel/Nyong/Osman/Conde/Cortés/Downing 2006: 32).

65.4.2 Veracruz Case Study

A brochure that synthesizes the results of the first year of the project (Rosales/Conde/Palma/Ferrer, Rosa/Monterroso 2009: 12) was delivered to the *Consejo Regional del Café de Coatepec, A.C.* (Regional Coffee Council), the organization that coordinates the actions taken by coffee producers in the region. Forty three peasants participated in the focus groups, and all their names were included in the brochure.

Peasants in the region classify climate depending on the altitude. In Coatepec County, three climatic zones were identified and described during the focus groups. In the higher zone, low temperatures are usual, and the rainy season is expected to start by 15 May (called San Isidro day), and last until September, with a regular distribution during those months. In the last years, there is uncertainty when the rainy season will begin, and heavy rains have occurred more frequently. At middle altitudes, the climate was temperate, but higher temperatures are now more frequent, which have increased evaporation. In a similar way, the temperatures have risen on the plain zone, were hail events have decreased.

The climatic events that could affect more the coffee production are heavy rains, particularly during the beginning of the spring season (April), frosts and high temperatures. Also, cold northern winds (called *Nortes*), and hot southern winds (called *Surada*) could impact on the coffee production if they intensify in the future.

Peasants use to say 'the flower might turn into leaves', since with heavy rains during spring, even if the coffee plant might survive, flowers could drop, diminishing that year's production. It has been documented that this relative drought in the spring is needed for the flowering stage of coffee.[12] Nevertheless, regular rains are needed during spring, because coffee plants do not flourish in drought conditions, such as those that occurred in 1983 and 1998 (El Niño years).

During the focus groups, peasants also highlighted that frost events are critical during the spring season. This was also found in previous studies and newspaper sources.[13] High temperatures and heavy rain events during summer could affect the quality of coffee, and also increase pests and plant diseases. This information matched also with other sources, which showed that the high temperatures and floods during 1970, 1973, 1996, 1997 and 1981 reduced the coffee production in those years.[14] Producers also recalled that during the El Niño event of 1982, farmers also struggled with the increase of broca (*Hypothenemus hampei, Ferr*) and nematode pests. The econometric model (Gay/Estrada/Conde/Eakin/Villers 2006: 262) showed that the winter and summer temperatures, and the spring precipitation, were indeed the climatic variables that had high correlation with coffee production in the region.

Coffee producers identify also other constrains to their agricultural activities. The lack of labour force (young producers) limits management and harvest activities. Low prices, and the lack of financial support (subsidies, insurance, or no access to loans) limits also their coping capacities. On the other hand, the coffee plants are immersed in forests, which provide coffee producers with alternative income sources, and can be seen as the basis for their coping capacities.

With coffee, peasants cultivate fruits such as oranges, lemons, bananas, passion fruits, chiles, and, in some cases, maize. Forests also provide farmers with medicinal plants, such as Piocha (used as an insect repellent), Chicha (used for diabetes), and other plants used for hypertension and to heel insects bites or stings. Forests micro-climates sustain also the birds and mammals diversity, which are also a nutritional source for farmers and their families (Rosales/Conde/Palma/Ferrer/Rosa/Monterroso 2009: 10). Coffee producers then envision the possible current and future adaptation strategies with forests' care and preservation.

65.4.3 Climate Change and Coping Strategies

With the previous information, the potential impacts of climate change and the possible strategies could be assessed. The climate change scenarios are synthe-

Figure 65.7: Projected changes in temperature (A) and precipitation (B), for Tlaxcala (2020 and 2050), using 3 GCM (G: GFDL; H: Hadley; E: ECHAM) outputs and two SRES scenarios (A2 and B2). **Source:** Conde, Ferrer and Orozco (2006).

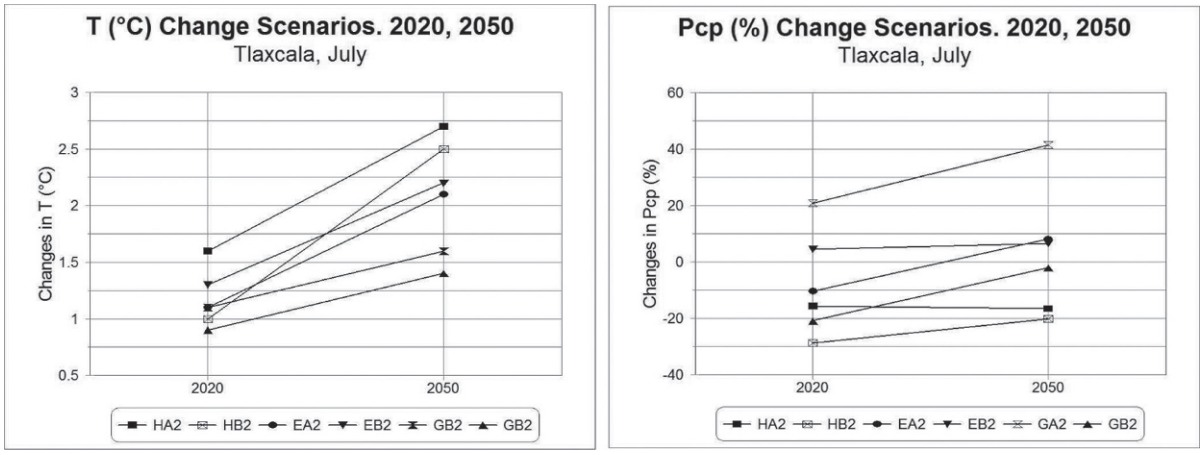

Figure 65.8: Projected changes in temperature (A) and precipitation (B), for Veracruz (2020 and 2050), using 3 GCM (G: GFDL; H: Hadley; E: ECHAM) outputs and two SRES scenarios (A2 and B2). **Source:** Conde, Vinocur, Gay, Seiler and Estrada (2008).

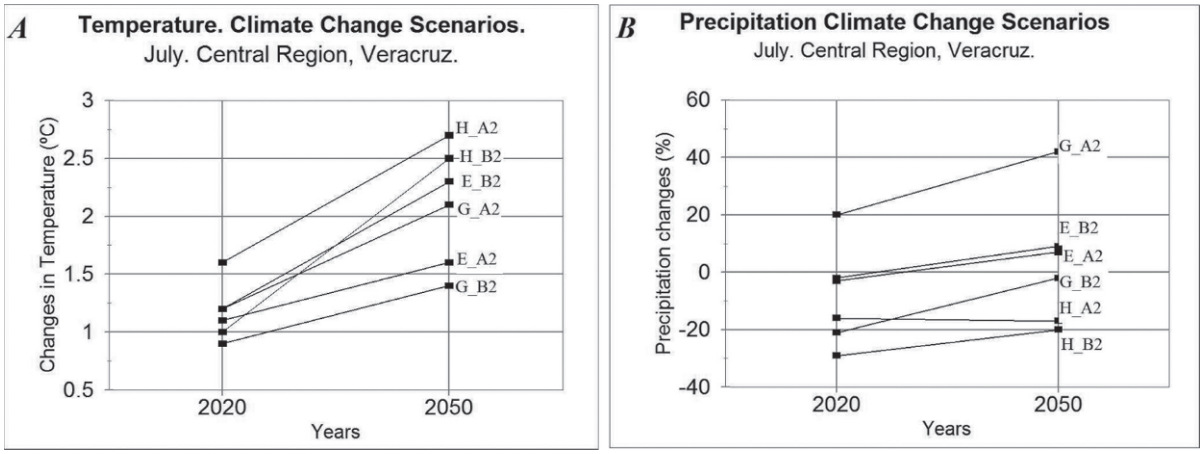

sized in figures 65.7 (for Tlaxco, Tlaxcala, see Conde/Ferrer/Orozco 2006: 190) and figure 65.8 (for Coatepec, Veracruz, see Conde/Vinocur/Gay/Seiler/Estrada 2008: 295), where summer (July) scenarios are shown as an example for both study cases.

In the first case, ranges of changes in temperature could vary from 1.3 °C to 2.8 °C (for the 2050 scenarios), and summer precipitation could vary from -20 per cent to +40 per cent; while for the second case study these ranges varied from 1.5 °C to 2.7 °C, and for precipitation, changes around -20 per cent to +40 per cent are also projected.

For Tlaxcala, frost risks could diminish, given the projected increase in minimum temperatures, but if climate change could also represent an increase of El Niño events, or of more intense or frequent heavy rains, then the possible opportunity for maize producers might be diminished.

In the case study on Tlaxcala it was possible to implement three actions (use of compost, small greenhouses, and drip irrigation) that were considered adaptation to a changing current climate and could have viability in the future. Given the high losses of fertile soils, compost was applied to cultivars (tomato and chile). To start the project: *Capacity Building for Stage II Adaptation to Climate Change in Central America, Mexico and Cuba*, the Autonomous University of Mexico (UNAM) donated 5 tons of compost. Greenhouses were considered ideal to deal with a variable climate, since temperature could be stabilized

inside them, and their dimensions (96 m^2) allowed them to be inside their house gardens. Tomatoes and chiles were chosen because of their prices in local markets and their great demand in Mexican food.

Four greenhouses were planned to be constructed, in 4 different localities in the state. Nevertheless, only two were finally constructed. One producer did not allow his wife to participate in the greenhouse activities (because his religion, he stated), and the other one found it too small, and had strong opinions on how it should be constructed. The failure of 50 per cent of our goals was quite frustrating for the research team, but finally it was clear that the basic adaptation measure was the interaction, decision-making, and activities developed between the researchers and farmers.

In the case study for Veracruz, reforestation, the increase of protected areas and more strict forests management regulations, are the key measures that coffee producers considered that could preserve the regional climate. In that context, the main objective of the ongoing project (Conde/Calderón/Castro 2008: 7) is to demonstrate that the payment of the environmental services can reduce the future vulnerability of coffee producers and that is a win-win measure for them and their communities. Measures have been made of the rates and amount of carbon dioxide sequestration by forests in the region, but the results are still not conclusive.

Thermometers have been placed inside and outside of a coffee plantation; these data will be introduced into the econometric model, showing that with climate change that difference of temperature can give coffee producers a lag of time before the worst projected impacts occurred. The list of local fauna and flora can support further studies of regional biodiversity, and activities such as ecotourism.

65.5 Conclusions

Current coping capacities are being diminished by the frequent and intense extreme climatic events and they could be more reduced under climate change conditions. These capacities are also currently being reduced by the agricultural policies (reflected in the lack of financial and technical support), the low prices and market changes. Given those circumstances, farmers expect an increase in their current vulnerability.

Stakeholders' involvement is fundamental in projects oriented to support adaptation measures, and force climate researchers to develop studies that are tailor-made for the peasants involved, and to seek for participative techniques that can facilitate the communication of their results to farmers.

The case studies showed that peasants are willing to apply adaptation measures to current the climate such as increasing soil fertility by compost techniques (Tlaxcala) or to promote the payment of environmental services (Veracruz). Farmers' participation is critical for the success of those measures, which are viable under climate change scenarios. On the other hand, the success of any adaptation measure depends on the farmers controlling the know-how of any of those measures.

Participatory techniques are an invaluable tool to assess current and future climate vulnerability and adaptive capacities, since climatic studies can focus on the most worrisome climatic events and their possible projection into the future.

Coping measures applied by farmers depend on the cultivar (maize or coffee). The coping capacities of maize producers highly depend on their traditional knowledge, acquired during centuries that allows them to change in planting date or to chose different varieties. They also can perform changes in crop management, such as changes in the amount of fertilizers or pesticides, but the increasing costs of those products might not be compensated with the incomes.

In the case study on Tlaxcala, the spring - summer droughts and early frost events have always been the worst climatic events, for which peasants have very low coping capacity. The construction of small greenhouses to produce tomatoes and chile, and the expectation to apply in those greenhouses drip irrigation and compost, highlights the urgency for those maize producers to change or combine cultivars and practices as a coping strategy. The abandonment of governmental support has critically reduced the coping capacity of maize producers.

In contrast, coffee producers have a permanent cultivar, embedded in highly diverse forests, that contribute in the preservation of microclimates, and from which they can acquire other products (i.e. fruits). In that study case, heavy rains and high temperatures are the most worrisome climatic events, for which also limited or no coping measures can be applied. The environmental services that the forest provides, opens a possibility for those farmers to adapt, since their incomes can also be diversified. As in the previous case, the lack of governmental support and the very low prices for coffee have also reduced these peasants' coping capacities.

In both cases, migration of young individuals can be seen as the extreme adaptive action for individuals, but not for the agricultural sector.

66 The Impact of AIDS on Women's Social Life in a Mexican Rural Community

Fátima Flores and Wolfgang Wagner

66.1 Introduction

66.1.1 The Setting

According to the United Nations official statistics for 2002, there were one billion poor people in the world, 70 per cent of whom were women, a figure that reflects a serious problem of gender inequity and a harsh social inequality. Some 40 million of the world's poor live in Mexico, 26 per cent of them in conditions of extreme poverty. Given this panorama, there is a clear and urgent need not only for actions designed to achieve an understanding of the multiplicity of the causes of poverty but, more importantly, to generate interventions by different sectors that will bring about a gradual transformation of this reality. This entails adopting a posture that orients discussion and exposes basic aspects of poverty. In particular, there is a need to analyse elements that affect women in particular.[1]

We intend to show how economic, social, and psychological vulnerability impacts on women's capability to cope with adverse health conditions, such as having acquired HIV. The lack of resources critically heightens the subjective feeling of insecurity and perceived lack of coping strategies in situations of threat. Vulnerability, in this sense, is subjectively perceived defenselessness and negatively affects social integration and personal well-being.

This research on women's health and their associated social life was conducted in a rural community, Coatlán del Río, a municipality in the state of Morelos that is characterized by high indices of migration[2] that have specific repercussions on the dynamics of everyday life and the social relations that develop among people (figure 66.1).

According to data from the population census (INEGI 2005), this town has 4,523 male and 4,833 female inhabitants. The average age is relatively low, as the largest cohort is the 1 to 15 years age group. In Morelos, 15 per cent of migrant women and 14 per cent of non-migrant women are heads of households (Chávez Galindo 2008: 52). The most common illnesses in this jurisdiction are infectious diseases and parasitic infections of the digestive tract, mainly intestinal amebiasis, caused by the lack of clean drinking water and sewer systems. These ailments affect mostly children and young people from 5 to 14 years of age. Communicable diseases such as hemorrhagic dengue and sexually-transmitted diseases, especially the *Human Papillomavirus* (HPV) and HIV, are also present. The most common non-transmissible, chronic-degenerative diseases are arterial hypertension, diabetes mellitus, rheumatoid arthritis and, especially, cervical-uterine cancer. The latter is detected in 30 per cent of cases analysed and is the most common cause of death there; indicating clearly that women's health suffers from a lack of preventive measures and medical attention.

The community's economic activity is based on agriculture because of its favourable climate. Though located in a region rich in natural resources with broad extensions of arable land, residents live in somewhat precarious conditions mostly due to a lack of orientation, support systems, and official resources for developing programmes. Given the lack of employment opportunities, slow emigration has become a 'naturalized' phenomenon, as men – mostly – have assimilated

1 A perspective much in vogue in public policies during the 1990's that emerged from denunciations of male/female inequities in different contexts fostered by the women's liberation movement in the 1970's.

2 Among the states with high levels of migration registered by CONAPO in the 2000 Census, we find: Aguascalientes, Colima, Guerrero, Hidalgo, Jalisco, Morelos and San Luís Potosí. Morelos showed a migratory flow of 10,495 people in that year.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_66, © Springer-Verlag Berlin Heidelberg 2011

Figure 66.1: Location of the research: Coatlán del Río, Morelos, Mexico.

migratory processes and flows, leading to a consolidation of shared imaginaries and collective identities. Most of the women with whom the researchers had close contact have experienced the migration of their partners at some point in their relationship and assume that at any moment their family dynamics may have to be reoriented. This uncertainty propitiates a state of emotional alert related to their ambivalent feelings and this, in turn, generates tension as well as states of anxiety and contradiction.

Against this backdrop, our research represented an attempt to identify: 1) the psychosocial and gender indicators that are constructed through the subjective experiences of a group of women exposed to the migratory process in that setting; and, 2) how those women have come to signify HIV/AIDS in their condition.

66.1.2 Social Representations in the Community

The present research takes social representation theory as the starting point. The concept of social representation refers to socio-cognitive processes by which social actors render their reality comprehensible and endow it with sense and meaning. By providing an everyday epistemology, social representations are the prerequisites for constructing and maintaining systems of communication among the members of communities. This approach allows conceptualizations of everyday thinking and experience within the frame of community discourse and personal communication.

A community is the place where personal communication intersects with the wider social setting and mass-mediated communication. A village or a city block has a size that allows villagers and residents to meet on a regular basis and to engage in personal contact that involves exchange of private matters as well as of societal and political ones (Jovchelovitch 1995, 2001; Moscovici 1976). The wider public sphere enters via the representations entertained and transported by the mass media, which provide topics for conversation and dispute among the members of the community. In this sense the community settings are pivotal in the generation, elaboration, and change of social representations that always emerge when discourse unfolds about some new phenomenon and some preconditions are met (Wagner/Hayes 2005).

Illness appears to be first and foremost a matter of private interest. Maintaining and re-establishing one's personal physical well-being depends on lifestyle and personal preferences. However, what counts as well-being and what counts as an adequate and preferred lifestyle is defined in the deeply social fabric of cultural and societal discourse. There is no private desire or behaviour that is not directly and indirectly informed by, and directed towards, other actors as well as towards the collectivity. Each person's subjectivity is the historical product of collective processes that converge in an individual as a member in families, social groups, communities, nations, and cultures.

The illness of AIDS or HIV-positivity is a case in point. People are affected by HIV infections as patients, as family members of patients, and as members of societies that are struggling to contain the societal consequences of this virus. The appearance of AIDS/HIV a few decades ago was shocking and serious enough to give rise to a full-fledged representational system. The emergence and development of how the public collectively coped with this issue showed all attributes that social representation theory postulates. First, it was an issue that immediately gained high significance in the media, thus setting AIDS on the agenda of the wider public discourse. Second, in the course of this developing discourse a multitude of images, metaphors, and stories emerged that anchored thinking about the novel illness in existing systems of everyday knowledge. Third, once objectified, the images and metaphors condensed into an amalgam of practical and symbolic public knowledge that, to a certain degree, contains the symbolic frames as well as the practical means of avoiding the infection, for example by the use of condoms. This representation, hence, is the prerequisite of people's participation in public, media, and personal discourse (Joffe 1995; Marková/Wilkie 1987; Marková 2003; Wagner/Kronberger/Seifert 2002).

Besides providing an example of the symbolic realm representing AIDS and HIV, this chapter also contributes to a more theoretical understanding of how the social sphere and the individual experience interact in community discourse about other issues such as public health and the implementation of health programmes (Joffe 2002, 2003). The social and psychological processes in all these realms do not differ significantly from each other since they all require forms of public and symbolic coping as well as individual responses to novel developments. Normal societal innovations as well as personal hazards are a threat to the security that one feels while following an established way of life as recognized in several UN documents (cf. Brauch 2008a).

66.2 Method

Our starting point is the fact that certain personality characteristics and features of the individuation process universally differentiate between the sexes, and that these, in their representation of themselves, articulate multiple representations that become current as a function of the situation. At some point, one of those variants is established circumstantially as constitutive of the subject in the 'centre' of her/his consciousness (Flores 2001).

Our first approach to this town was through informational talks and workshops focused on HIV/AIDS and *sexually transmitted infections* (STIs). These activities allowed us to detect certain needs that called for an urgent intervention due to the conditions of vulnerability to which the population is exposed. The intervention was designed using the perspective of communitarian psychology[3] in a series of stages that were carried out from April to November 2006. Ethnographic methodology included survey visits, contacting key informants, and organizing focus groups.

66.3 Results and Discussion

66.3.1 First Stage: Approaching the Community

In this stage, survey visits were conducted and the search for key informants begun. We contacted individuals who exercise some degree of leadership in the community in order to facilitate access to the main features of local dynamics, though it also allowed us to publicize our planned activities. A talk called "Women, Health and Daily Life" was organized, dealing with some of the hardships associated with gender

3 In this approach, the community is not seen as bereft of power because it is excluded from many social benefits. Rather, it naturalizes a situation in which the dispossessed, poor, excluded and, in general, all social groups that do not enjoy statutory power or adequate socioeconomic conditions are seen as weak, incapable and deprived of any possibility of transforming their lives. In this view, community members participate actively in the search for solutions and transformations by potentializing their resources.

conditions and some aspects of STIs and HIV/AIDS in the context of migration.

The event was attended by 20 women and one man who were between 30 and 45 years old and had finished junior high school (*secundaria*). Seventeen had a life partner (married or common-law) and on average 3 minor children. Most were housewives. Family income, consisting mainly of remittances, was less than three minimum wages.[4] These data showed a somewhat higher economic income than those of a preliminary study, though perceptions were quite similar. This activity allowed us to enter the community in a favourable manner that paved the way for the next stage: a focus group designed to identifying people's needs.

66.3.2 Second Stage: Focus Group

The focus group employed 10 of the women from the first stage, all from the same municipality. We decided to use this technique because it is a productive tool in social psychology, especially in efforts to use group interaction to understand the meaning and attributions that people associate with their own existence. Also, it is an exploration method that focuses on culture (Marková 2003).

The focus group lasted three hours. Participants demonstrated their interest in being involved by signing an informed consent form. The following topics were explored: 1) the impact of migration on daily life; 2) health, HIV/AIDS and vulnerability; and 3) marital relations; themes chosen on the basis of women's contributions in the first stage.

The information obtained in this second phase was transcribed literally so it could be systematized using a 'content-type' analytical technique that makes it possible to draw valid, reliable inferences with respect to context (Bardin 1982; Krippendorf 1988). Given the nature of the study, this technique turned out to be pertinent as it combines the rigour of objectivity with the richness of subjectivity by generating revelations that precede the initial meanings.

66.3.3 Third Stage: Reinforcement

Eight women participated in this stage, all of whom had attended the other two sessions and stood out because of their great interest in the community and the leadership they exercised. This final stage of the intervention focused on the goals of reinforcing and consolidating the other two phases through a specific activity based on thematic guides taken from the women's own discourse. Once again, these women deliberated over the issue for three hours, speaking freely about their personal processes and meanings, and their life experiences in the town. Then, we presented all the information that had been systematized up to that point. The group's psychological contention was observed, several dynamics[5] were conducted, and the need to set up support networks among them was reinforced.

It must be noted that in this activity special attention was paid to reinforcement[6] as a strategy for developing and transforming communities through the members' own active participation. This potentializes their capacities and abilities so that they can achieve positive change that will improve their quality of life. Community-based support networks propitiate reinforcement in certain ways, as they constitute alternatives for political action and, at the same time, demonstrate their capacity to transform, to provide social support, and to exercise solidarity and power, as well as their reinforcing character. Finally, they are a source of leaders for the community (Montero 2003).

The results of this intervention revealed various aspects of women's life experience and that constitutes the specific meanings developed in the face of the particular adversity they confront.

4 The daily minimum wage in the state of Morelos, which came into effect 1 January 2007, is $47.60 pesos (about 2.8 €), established by the *Comisión Nacional de los Salarios Mínimos* [National Minimum Wage Commission] in a resolution published in: *Diario Oficial de la Federación*, 29 December 2006.

5 In the first dynamic, participants were asked to complete a series of incomplete phrases alluding to their feelings and what they needed to fulfill their different roles (as women, partners, housewives, mothers, friends). The second was an exercise on imaginaries, the main objective of which was to have them reflect on how they cared for themselves (enjoyment, appropriation of their bodies, self-esteem). The third dynamic consisted in symbolizing a support network among participants as a means of creating an atmosphere of trust and mutual support.

6 This is the Spanish term for "empowerment", a neologism that appeared in the USA as a homologous word. However, as Montero (2003: 61–63) notes, the Spanish words for "strengthening" (*fortalecimiento*) and "potentialization" (*potenciación*) have been used in Latin America since the late 1970's.

One of the first elements that caught our attention in the town were references to HIV/AIDS, mainly due to an increase in contagion in the November-January period, the time of year when male migrants to the USA return home to take part in Christmas festivities. During the first stages, it became clear that the system of social beliefs and representations regarding the origins of HIV were strongly based on the stigmas that attribute the causes of this pandemic to groups such as homosexuals, sex-trade workers, and people who have casual, unprotected sex.

Women also judged that adolescent boys and girls were especially vulnerable and, therefore, required information to avoid transmitting the virus. This shows how women shift their concern towards their adolescent children who could become infected; but this is a representational shift that impedes them to some degree from recognizing their own susceptibility to infection or from seeing themselves as potential victims of AIDS. This situation has been established as part of a social imaginary that holds that "the disease is present but doesn't affect us", a discourse similar to those found by other groups of researchers (Flores/ Leyva 2004).

Another observation was that though some women were aware of the importance of condoms as a form of protection and prevention, this did not necessarily translate into their use during sexual relations. This was attributed mainly to factors that might affect or impugn their spouses, as they specifically mentioned elements such as faithfulness and trust; however, in these negotiations, gender status puts women at a disadvantage.

In the focus group, we found that the impact of migration on women's everyday life was strongly marked by emotional states that reflected how gender conditioning operates through their daily activities.

The first significant element to emerge was that women often expressed a fear of dying, though they related this fear to how their absence would affect others, seeing it as a 'failure' on their part. This attitude indicates their feelings of total responsibility and devotion to the family that places them in a permanent state of anxiety, as the following extract shows: "... what really worries me is that I might leave this world and my children would be left alone with relatives..."

Here, the perspective of the social construction of feminine subjectivity suggests it would be extremely difficult to find a suitable substitute for a mother's care, much less someone who could take her place, a situation that has constituted a contradiction throughout history:

> "...I also worry about my children because I have a boy who's 16, one who's 10 and a baby of 11 months; so yes I worry that something might happen to me, like getting sick, because I'm their right arm, what worries me is getting sick ... or dying ..."

In the third stage, this anguished thinking about death led to discussions about the emotional links women have established with their children and how those links lead them to stop thinking about themselves and to live their lives through those children. Together with them, costs and benefits of this kind of relationship were analysed:

> ...and what if I die? What if I'm not around? That's the question day after day, every night... oh God, dear God, I don't want to die because my children need me. ... I think that's what worries us as mothers because whether you have a husband or not, death is the biggest worry, if we were to leave our children on their own. ...

The women in this group also said that they experienced feelings of loneliness and of not being understood, that they were left alone and unprotected by their partners and by their close family members. One participant said that her father told her: "... you chose your life, now you deal with it. ..." Another said:

> ...men don't worry about anything, they never say 'hey son, how'd things go at school today' or 'how're you doing', they do their part just by working; ... they get home and say 'come on, rub my feet and get me something to eat'... It's us, the women and mothers who worry, the father's job is just to work, bring home the money and, well, that's it...

The loneliness and lack of comprehension that mark these women's lives lead to poor self-esteem and to the idea that their feelings are of little importance in the conditions of poverty and migration in which they live. In the face of adversity, their feelings are relegated to 'second-place' and this contributes to the development of gender-related maladies that have repercussions for their mental health. Vulnerability that women in this group expressed with respect to HIV is intimately associated with their gender status, especially in view of their partners' activities and their own fear of contracting the virus due to men's behaviour, whether as migrants or living in the town:

> ... for example, in my case [my partner] lives with another woman in the United States. I'm careful not to have any other partner here, but it would be impossible anyway because [you know] he might come back tomorrow or maybe next year, and I'm his wife. I don't know

> how many other relationships or partners he may have had, but if he'd use condoms...

As this extract shows, it is considered natural and is widely tolerated for men to have relations with other partners. Thus any negotiations on the use of condoms that involved these women – who see themselves as distinct due to their identity as wives – centre on the danger of contracting the HIV virus and not on the condom as a naturalized practice in the exercise of their sexuality. It is assumed that *he* can be with other women but that *she* cannot be with other men, and it stamps the husband-wife relationship with an assumed inequality that clearly contributes to feelings of malaise.

Some of the participants in this group agreed that because of the sexual behaviour and absences – short or prolonged – of their men, it is the women who are in greater danger of exposure to HIV, as the following testimony from an interviewee reflects:

> ...we run a greater risk, because if a husband goes to bars, drinks and has relations with *individuals* who don't always get checked or who pay the doctors not to check them ... it's really dangerous, I knew of a case of one *individual* who worked there and never had any supervision or didn't go where she was supposed to; she just kept hanging around the bars... then he comes home to me and he's not going to use a condom, I mean if he doesn't use one with that *individual*, there's no way he's going to use one with me, so that's why we need to be more careful than other people. ...

As mentioned above, in this community the stigma against sex-workers is deeply-rooted and it is an element that differentiates among social groups. Also, it is a central aspect of the social representation that people have of AIDS as a disease. Paradoxically, this centrality actually promotes preventative actions in the non-stigmatized population, as in the case of these women, though what they really need is more information, more means of prevention, and a change of attitude on the part of both men and women in relation to AIDS.

Another finding was that although these women spend long periods alone and assume complete responsibility for their households, which they resolve through a diverse repertoire of survival strategies that includes selling food and consumer products, this is not sufficient to counteract a certain imaginary subjection or to give them a greater sense of self-worth. One woman, for example, said:

> ...the place of my children's father is respected, though he's not around, we know he'll be back... but meanwhile I have to work and make sure my children can get ahead.

During our observation period another feeling of contradiction in the exercise of this dual role as mother *and* father became clear. On the one hand, this was due to satisfaction women feel when they are recognized by their families and society for their strength, and on the other, due to the emotional malaise they are never quite able to explain but is reflected in the physical weariness caused by daily tensions. This often leads them to turn to self-medication as a way of reducing their suffering and keeping up with their daily activities. Also, it helps them to avoid feeling that they may be losing control, a sentiment they expressed constantly.

On another topic, participants also referred to problems of violence and expressed feelings of vulnerability and loneliness in a world full of hostility towards them because of their condition as women. They said they had been victims of sexual harassment by men in their hometowns, as this extract shows:

> ... often when I have to go out alone on some errand, men's looks and comments really bother me [but] because I'm a woman I never say anything ... but they just have the right to annoy [us]. ...

In addition, they mentioned feelings of insecurity and a lack of protection, especially when they spoke of the situation of their daughters in the town, another important source of latent fears that women and daughters discuss and share with each other because of their common condition as women.

This aspect is central to the analysis of the construction of subjectivities characterized by situations that are reflected among mothers and daughters because of their gender status. They may be a constitutive element of a certain social and psychological defencelessness that will be very difficult to change in their lifetime. As Chodorow writes (2003), while subjectivities are being constructed they are anchored in lived processes of gender.

As mentioned above, self-medicating is a common practice among women in taking care of their own physical and mental health. Almost all of them, at some point in their lives, have taken non-prescribed anti-depressants or anxiety-reducing drugs; a finding that supports data from the National Psychiatric Epidemiology Survey (*Encuesta Nacional de Epidemiología Psiquiátrica*).[7] When we asked them about the reasons for self-medication in our study, women said that while they knew it was not advisable to take such

7 See: Medina-Mora/Borges/Lara/Benjet/Blanco/Fleiz/Villatoro/Rojas/Zambrano/Casanova/Aguilar (2003).

drugs, it was one of the few alternatives they have to make themselves feel better and keep up with their heavy daily workload. They also reflected unease with respect to the future, as one said: "...there's no good medical service here, so you just have to take whatever you can. ..."

Once again, here it remains clear that women do not consider their own health as a matter of high priority. In fact, their prime concern is their responsibility to care for others; hence, they tend to trivialize their feelings of malaise and symptoms or illnesses that may manifest themselves.

For most women in the group the meaning of their bodies has basically been annulled: i.e., the body does not exist to feel pleasure or to be cared for. A defence mechanism operates here that leads them to somaticize their tensions and therefore turn their bodies into recipients for their emotional states.

The symptomatology of depression in the group was also connected to their role as caregivers and the person responsible for their households. This immerses them in a condition of personal and social vulnerability arising mostly from their obligation to confront life's travails practically bereft of support, a burden that tends to leave them physically and emotionally spent, as one interviewee described: "... I often get depressed, I feel a sadness invading me, the only thing that keeps me going is ... my children."

This situation of abandonment, perceived loneliness, the absence of their partners, and the minimal personal compensating resources they have at hand, all combine to keep these women in a tension-filled state that often leads them to commit acts of violence against their children. Of course, such incidents almost immediately engulf women in feelings of guilt, a recurrent situation that turns into a form of family coexistence that is recursive and accepted as a result of abandonment. In this situation, their sexuality is obviously forgotten and enjoyment or pleasure does not exist in their immediate subjective register, a fact that also contributes to the gender-related maladies they suffer, which with time can become illnesses.

In addition, we observed that though these women share the common experience of being migrants' wives, they have been unable to build support networks, a fact they explain by referring to the difficulty of trusting people, their isolation, and their almost non-existent mutual recognition. Here, the intervention group emphasized the importance of several elements: 1) consolidating support networks; 2) recognizing and accepting themselves *and* their peers as women, in spite of their individual differences; and, 3), the importance for their subjectivity of having their actions and desires validated as strategies of change oriented to a process of reconstruction that would valorize them as people and offer new representations that support their capacity to exercise power and thus raise their self-esteem.

In the final stage of the intervention –'reinforcement'– we sought to conduct a process in which the women would deconstruct-reconstruct the gender-based systems of representation that have psychosocial referents in the subjective constitution of the group. Our hope was that this analysis of their practices would allow us to extract highly significant nonverbalized symbolic elements related to the signification of a representation (Flores 2001).

In that phase of our work, we conducted an analysis of their discourse and narratives using certain group dynamics and techniques designed to isolate significant elements that reflected some of the tensions identified in the previous stages. This analysis centred on the relation between the meanings women attribute to their surroundings and their personal experiences. It revealed emotional ambivalences related to their double role as female heads of households and as women. What stood out was their need to feel loved, protected, and cared for by a masculine figure, a finding that agrees with González (1993: 78), who reported that "throughout their lifetime women do not obtain the amorous nourishment that they provide [to others]." As one participant said: "...when he calls me from the US, he never asks me how I'm doing ... instead he's surprised to hear I'm working and says I'll probably get fired before long."

When asked about their life projects, these women reached the conclusion that no such thing existed or, if it did, that it was centred exclusively on the family, a situation causing feelings of frustration. They feel insecure about undertaking any other project outside the family context, and this attitude limits their search for new possibilities and contributes to their low self-esteem. It proved very difficult for them to identify with the ability to carry out a life project of their own; one that would benefit them and proffer them some degree of comfort. The following comments illustrate this: "... I always wanted to study, but didn't have the chance, I've always had to work ...", and "... I'd really like to be someone, to study, but I don't know how."

Upon becoming conscious of their role as caregivers, they began to critically question the survival strategies they had constructed, which also centred on others. Eventually, they came to realize that this process *is* reversible and constrains their personal growth

Table 66.1: Summary of the results by objective factors and subjective expression. **Source**: The authors.

Objective factors	Subjective expression	Discourse
Migration	Fear due to the spouse's absence and the lack of his social support	"When he went ... I was left completely alone."
HIV, AIDS	Fear of dying and leaving the children	"What disturbs me most is that my kids remain alone."
	Loneliness and depression	"When I can't continue anymore I take a pill."
Community	Low self-esteem	"I am nobody."
	Continuing dependency on spouse	"Even though he is not here, his space is being respected."
	Helplessness, lack of recognition and power	"Nobody understands me. I am alone with my kids."

to a considerable degree. Malaise, pain, and sadness were expressed time and time again as the feelings they associate with the context of migration and, clearly, with their poverty, low self-esteem, feelings of guilt, self-censorship and feelings of dependence.

Recognizing and revalidating these feelings, necessities, and thoughts supported the process of becoming more sensible that led to an analysis of the dynamics of visual imagery related to their death. The pain they manifested in this context – one that all of us must face sooner or later – oriented them more towards the 'here and now' when they spoke of the things they needed for their physical and emotional well-being: taking control of their bodies, recovering lost pleasures and their sexuality, generating a life project that will strengthen and give them a new dimension as women.

Table 66.1 summarizes the overall results in a grid contrasting the objective situational factors, the subjective expression of the stressors and examples of the women's discourse as illustration.

66.4 Conclusion

The results obtained in this research allowed us to see subjective processes, social representations, and the sense and meaning that these women give to their existence in a context of migration and conditions of poverty and vulnerability. The women's statements and contributions to the focus group and intervention reveal a deep emotional undercurrent in subjectivity and sense making that colour all discursive production. We think that most realms of life, including general health-related behaviour as well as behaviour implied by the lack of critical resources show a similar structure. Also in these areas of everyday life and coping with the novel, affective underpinnings have a crucial effect upon cognition, action, and language use.

Besides, the present study on women and HIV reveals how public knowledge is displayed in the conversations of people affected and their family members. It illustrates the finding that the stable core of social representations comprises primarily affective and emotional elements (Wagner/Valencia/Elejabarrieta 1996). In this study, we find concern for the well-being of one's beloved children, fear of the unknown future of living with HIV, distress about the husbands' absence for work in a foreign country and their extramarital relationships there, and the desire for community support. All these are 'hot' ideas linking the general societal discourse about AIDS to one's private subjectivity. The subjective weight of women's own experience of HIV in the light of their dialogues is also reflected by the fact that they do not hesitate to openly talk about deeply sexual issues in their private lives, while sexuality usually falls prey to rules of decency and prudishness in most other conversations.

On a more general level, the research highlights that "to be secure is to feel free from threats, anxiety or danger. Security is (...) a state of the mind in which an individual (...) feels safe from harm by others" as stated in the Report of the UN Secretary-General's High Level Panel on Threats Challenges and Change, 2 December 2004. Such a subjective state of security, however, does not only depend on identifiable others, but also on structural characteristics of a social system. These characteristics have to do with the social status of their gender and the associated lack of power which are central constituents of the women's subjectivity. Consequently, the risks entailed by migration and HIV become overwhelming for a single person.

The study also illustrates that the pillars of human security, particularly the 'freedom of want' and the

'freedom of hazard impact' as defined in United Nations documents (Brauch 2008a), are crucially interconnected. The ability to cope with the impact of potentially lethal health hazards depends on a nation's public health infrastructure as well as on the economic and, even more so, on the social resources available to the individual. The stories of the women recounted in the focus groups vividly illustrate the plight of HIV positives to realign their life in the community under their changed condition. Even though purely existential fears in the face of a serious disease can never be completely alleviated, a general feeling of security can very well be achieved through community resources backed by a nation's social and gender policy.

67 Integrated Assessment of Vulnerability to Heat Stress in Urban Areas

Tanja Wolf, Glenn McGregor and Anna Paldy

67.1 Introduction: Global Environmental Change

Throughout human history societies have changed their environment by developing agriculture, settlements, practicing commerce and conquest and becoming increasingly industrialized and urbanized (McMichael 2002: 1145). Today we are in a historically unprecedented situation: the aggregate environmental impact of humankind has begun to alter aspects of the Earth system. The human-induced changes in the large-scale biosphere and atmosphere are called *Global Environmental Change* (GEC). They include stratospheric ozone depletion, biodiversity loss, land degradation, coral reef degradation, depletion of freshwater supplies, spread of invasive species, the disruption of nutrient cycles (e.g. nitrogen, sulphur, and phosphorus) and the dispersal of persistent organic pollutants. Furthermore, the increased concentration of human related atmospheric trace gases has lead to one of the most widely discussed of these environmental changes, namely climate change (Martens/Mc Michael 2002).

Four assessment reports of the *Intergovernmental Panel on Climate Change* (IPCC) have summarized the knowledge on climate change and increasingly attribute this to human activities. Greenhouse gas emissions have now reached unprecedented concentrations and in parallel to continuous efforts to mitigate present and future greenhouse gas emissions, massive adaptation to unavoidable climate change and its impact is required. Climate change will particularly affect vulnerable countries and populations. Their vulnerability is a function of the hazard they are exposed to and their sensitivity. To understand and assess vulnerability to hazards has practical benefits for identifying 'hot spots' as targets for adaptation strategies. Accordingly an approach to assess vulnerability to heat stress using indicators for risk is presented here.

67.2 Assessment of Climate Change by the IPCC (1990-2007)

Over the past decade, the fact that the world's climate is changing has become clear. Initially the responsibility has been attributed to both, natural processes and numerous human activities that transfer gases into the atmosphere which enhance the natural greenhouse effect. The Third and Fourth Assessment Report of the IPCC stated that there is "new and stronger evidence" that most of the warming observed during the past 50 years is attributable to human activities (IPCC 2007; IPCC 2001). The IPCC describes that the global average surface temperature has increased since 1861 and that the increase in temperature throughout the last hundred years is the largest of any other century during the last 1000 years. The recent warming has taken place in a much shorter time span than similar changes in paleo-times. Over the past 100 years, the global mean temperature has increased by 0.6 °C and in Europe, the increase amounts to about 1.3 °C over the past 100 years. Ten of the 12 hottest years in the 20th century occurred after 1988. Climate models indicate a temperature increase by 2100 of 2.4–6.4 °C (IPCC 2007).

67.2.1 Projections Until 2100

Regional climate models for Europe forecast that in 2071 to 2100 compared to 1961 to 1990 there will be an increase in temperature and an increase in the variability of temperature (Schaer/Vidale/ Luthi/Frei/ Haberli/Liniger/Appenzeller 2004: 332). Cold winters are expected to nearly disappear during the next century and hot summers are expected to become much more frequent (Parry 2004: 1). Recent regional scenarios predict warming in central and south-western Europe to peak in summer, with very large temperature increases reaching 6–7 °C locally and perhaps even 10 °C (Räisänen/Hannson/Ullerstig/

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_67, © Springer-Verlag Berlin Heidelberg 2011

Doescher/Graham/Jones/Meier/Samuelsson/Willen 2004: 13).

Climate change has and will have effects on regional weather conditions[1], physical environment, ecosystems, economic environment and society (EEA 2003; IPCC 2007). One of the major consequences of climate change will be the increasing occurrence of extreme weather events and changes in temperature, precipitation, wind and especially an increased climate variability that will make heat-waves, drought, flooding and storms more probable. In combination with other recent processes of global environmental change (urbanization, stratospheric ozone depletion, biodiversity loss, land degradation, depletion of freshwater supplies) and demographic and epidemiologic transitions, the potential health effects are grave.

Climate change will affect human health in many ways but mostly adversely. Epidemiological evidence of how climate variations and trends affect various health outcomes has been assessed and estimates of future health effects of climate change over coming decades have been published (Campbell-Lendrum/Pruess-Uestun/Corvalan 2003). Kovats, Campbell-Lendrum and Matthies (2005: 1409) have estimated avoidable deaths and disease from climate change due to heat stress, air pollution, weather disasters, mosquito, tick and other vector borne diseases, water- and food-borne diseases and under nutrition. Evidence and anticipation of adverse health effects will strengthen the case for pre-emptive policies, and will also guide priorities for planned adaptive strategies (McMichael/ Woodruff/Hales 2006: 859).

67.3 Heat Stress as a Health Risk

For the direct health impact of heat, the summer of 2003 provides strong evidence. First estimates suggested approximately 22,000–35,000 heat-related deaths across Europe during the first two weeks of August 2003 (IFRC 2004; Kovats/Wolf/Menne 2004). Later the Centre for Research on the Epidemiology of Disasters updated the estimated deaths from the heatwave in fourteen European countries to 72,210 deaths (CRED 2007: 1). Other studies looked at the mortality in small administrative units during the exceptionally hot summer compared to other summers without taking temperature into account, resulting in estimates of 74,483 deaths (Robine/Cheung/LeRoy/VanOyen/Griffith/Michel/Herrmann 2008: 177). Although the 2003 heatwave was unique in many ways, heat-related health outcomes have been and continue to be a problem in Europe (Kovats/Koppe 2004) and the rest of the world (CRED 2007). The fact that many heat-related deaths could be avoided if single and ill people were better looked after should be an imperative for health systems and society.

The adverse health effects of heat are most evident in urban areas. Often cities are built in a way that temperatures are several degrees higher compared to the surroundings and considering the trend in increasing urban sprawl, this certainly does not help future situations under climate change (Patz 2005: A84). The urban heat island effect (the ambient air temperature within cities is higher than in rural surroundings) poses a risk to urban inhabitants' health (McMichael 2001). The heat island in summer is due to the heat-retaining characteristics of the built environment, the treeless expanses of inner cities and the physical obstruction of cooling breezes (Kim 1992: 2319; Oke/Johnson/Steyn/Watson 1991: 339). In summer, the symptoms of diurnal heating begin to appear by mid-morning when temperatures can be about 10 °C warmer than nearby woodlands. Furthermore, the health of urban inhabitants may in addition be impaired due to urban air pollution from industry and traffic (Sartor/Snacken/Demuth/Walckiers 1995: 105; Smoyer/Kalkstein/Greene/Ye 2000: 881).

The identification of high-risk patients and taking appropriate measures to avoid hypothermia is essential for decreasing mortality during heatwaves. Outreach to populations at risk can be improved when it is known where they are and where the heat stress is greatest (Wilhelmi 2004: 147). Part of the risk management of heat stress in urban areas is therefore the identification of high risk areas. The challenge to manage the health risks related to heat stress in urban areas is becoming even more relevant under conditions of a changing climate and an increase in climate variability and the frequency of heatwaves (Confalonieri/Menne/Ebi/Haugengue/Kovats/Revich/Woodward 2007). To provide decision support on how and where vulnerability to heat stress occurs and where it can be reduced requires risk assessment and prioritization, understanding of vulnerability of the population and identifying geographic 'hot spots'.

1 By definition, climate is the average state of the atmosphere, while weather is the day-to-day manifestation of climate.

67.4 Sustainable Prevention of Adverse Health Outcomes from Heat Stress: The Challenge

67.4.1 Response and Lessons learnt from the 2003 European Heatwave

In response to the 2003 heatwave several countries in Europe implemented heat health plans. Besides national plans in Italy, France, Spain, Portugal and the United Kingdom, some regions and cities have also developed mechanisms to be able to better respond to future heatwaves. These plans include mainly four strategies to reduce adverse effects of hot weather: changes in long-term urban planning towards creating a benign urban climate, adaptation in buildings and housing, education, information and preparation of people as well as heat health warning systems which trigger an alarm when a specific threshold condition (temperature) is forecast to be exceeded (Kirch/Menne/Bertollini 2005: 277).

67.4.2 Long-term Changes in Urban Planning

Long-term urban planning can achieve climate rehabilitation of the environment. Adjusting the layout of cities to the climate in which they are located, changing the traditional skyline of the city (straight lines of high rise buildings with open spaces in between instead of bell type skylines) and using urban underground space for underground building (doubling of the urban area without changing the urban climate) are examples of some of the long-term measures that can be implemented on the city scale. At the building and neighbourhood scale, reduction in the use of artificial air-conditioning, heating and lighting, urban shading projects, greening of the urban environment through parks and public gardens or green roofs and the use of alternative sustainable energy like solar, wind, water, biomass and waste are examples of adaptation strategies (Koppe/Jendritzky/Kovats/Menne 2004; Keatinge 2003: 512).

67.4.3 Adaptation in Building Requirements

Buildings designed following guidelines for high energy-performance may in the medium term reduce the exposure to heat load indoors (Bitan 2003). While in many areas building codes require the possibility to warm a rented dwelling in winter, similar requirements for cooling in summer are rare (Eliasson 2000: 31; Kilbourne 2002: 328). Air-conditioning is a common approach to cooling indoor environments in developed countries with high summer temperatures. However, besides the high energy consumption, which if not produced from renewable energy contributes to further greenhouse gas emission and climate change, air-conditioning systems produce heat which may enhance the urban heat island effect.

67.4.4 Education, Information and Preparation

The general population, health professionals and staff in institutions need to be informed and made aware of what to and what not to do when confronted with heat. Raising awareness of a range of simple measures to combat the effects of heat can be achieved through public education programmes. Measures include wearing light and loose fitting rather than excessive clothing, to avoid prolonged sun exposure, avoid acute alcohol intoxication, continue to eat regular meals and drink enough water, open windows, to use fans wisely, avoid unnecessary exertion, sprinkle water on clothing and check that windows can be opened and that a fan is available in advance (Basu/Samet 2002: 190; Ebi/Teisberg/Kalkstein/Robinson/Weihe 2004: 1067; Keatinge 2003: 512).

67.4.5 Implementation of Heat Health Warning Systems

In the short term *Heat Health Warning Systems* (HHWS), run by or in cooperation with national weather services, can be used to trigger warnings to the population and health care providers. The success of HHWS depends on availabitiy of effective intervention strategies. These may include a 'buddy system', a 'hotline' telephone service, heat advisories via mass media, organization of transport to air-conditioned areas and extra health and social services staffing during heat events (Kalkstein 2000: 650). Ebi, Teisberg, Kalkstein, Robinson and Weihe (2004: 1067) calculated, based on a number of assumptions, that for the HHWS in Philadelphia an individual warning lowered the daily mortality by about 2.6 lives on average and that the benefits in terms of lives saved far outweighs the operational costs of such systems.

67.5 Risk Management and Vulnerability Mapping

To analyse risk means to understand and measure the probability of the occurrence of a damaging event. For each risk, its likelihood or probability to occur and the extent of the impact or consequences are required to assess the risk. Risk management is a systematic approach to setting a course of action under uncertainty by identifying, assessing, understanding, acting on and communicating risk issues. The final aim of understanding risks is, to help to anticipate dangers and mitigate them. To understand and assess vulnerability to hazards has shown to be directly relevant and applicable to a number of risks as it can be useful for identifying 'hot spots' as targets for adaptation strategies.

Mapping of vulnerability to heat stress is just starting to make its way onto risk assessment agendas. For example mapping of the impact of heat has been done by the *Institut de Veille Sanitaire* (INVS 2004) after the 2003 heatwave, the health risks due to high temperatures have been assessed in Canada (Dolney/ Sheridan 2006: 94; Vescovi/ Rebetez/Rong 2005: 71) and in the US vulnerability to heat stress in relation to microclimate has been studied (Harlan/Brazel/ Prashed/Stefanov/Larsen 2006: 2862).

One way of assessing vulnerability is to build an index, composed of the factors influencing vulnerability to heat stress. Criteria of a vulnerability index for identification of hot spots of vulnerability with the aim of supporting decision makers where to target vulnerability reduction measures are:

- *Significance*: the index needs to be able to identify hotspots of vulnerability where evidence indicates an elevated vulnerability compared to the surrounding area
- *Stability*: the index needs to be able to identify hot spots of vulnerability that are stable for some time (or show repeating patterns in dynamics) in order to allow vulnerability reducing measures.
- *Relevance*: the hotspots of vulnerability need to match with hotspots of hazard-related mortality and morbidity
- *Feasibility*: the data fed into the index need to be cheap, reliable, recent, routine and at a sufficient spatial resolution
- *Transferability*: the index should – in its fundamentals – be applicable to several European cities

A vulnerability index is presented here to describe and assess the dimension of vulnerability within cities. Vulnerability is defined as a function of hazard, exposure and sensitivity (IPCC 2001). The composition of the index is based on experiences with risk and vulnerability assessment through the application of indices in other disciplines (INVS 2004). Vulnerability depends on various factors which have been identified in epidemiologic studies and which have often been reviewed, for example in Kovats (2007). To assess the vulnerability and the factors determining the vulnerability to heat, the following aspects have to be evaluated:

- the hazard in form of heat load
- the exposure to the hazard[2]
- the sensitivity of the population[3]
- the degree of adaptation to and prevention of the hazard

In this study, because of the need for generalization and a lack of specific data, sensitivity and adaptation capacity are regarded together, since both are influenced by similar factors. To assess population vulnerability, reliable, recent and readily available routine data is necessary.

The spatial overlay of several vulnerability indicators can help to identify hotspots of vulnerability. Based on the findings of epidemiologic studies, vulnerable areas in cities are characterized firstly by a high 'outside' heat load due to the heat island effect, the city morphology and the lack of vegetation or ventilation. Secondly, residences with high 'inside' heat load due to building height, quality of thermo-isolation and ventilation and exposure certainly carry a higher risk of adverse health effects from hot weather. Thirdly is a concentration of people lacking resilience due to age or impaired health and fourthly, a lack of adaptation capacity. Together these make an area and its population sensitive. Where more than one of the determinants of vulnerability appears, the vulnerability is even higher. To assist with identification of 'hot spots' heat risk factors can be mapped as a vulnerability index. The mapped vulnerability index, composed of individual or combined risk factors, can then be validated with spatial health data, such as mortality, for hot weather events.

2 Adaptation may be defined as adjustment to a new or changing environment, see next chapter

3 Vulnerability to health effects of heat may be high due to age, impaired health, medication and other risk factors

67.6 Example Budapest

Budapest has a continental climate with cool winters and hot summers. Hungary has defined heatwaves as periods when the daily mean temperature exceeds 26.6 °Celsius for three consecutive days, which corresponds to the 98th percentile for the period 1992–2000. From 1992 to 2003 11 heatwaves occurred, with 5 between 2001 to 2003 (table 67.1). The average mortality in summer has been reported as about 61 deaths per day, while the maximum number of excess deaths during heatwaves was about 100 per day. This trend shows that there is a need to assess vulnerability to heat stress in Budapest. In order to identify hotspots of vulnerability, the vulnerability index – as described above – was applied to Budapest.

Table 67.1: Number and period of the heatwaves in Budapest (1996-2003). **Source**: Páldy/Bobvos/Vámos/Kishonti (2006); Páldy/Bobvos/Kovats (2005).

Year	from	to	No of days	total
1994	28.06.1994	01.07.1994	4	14
	30.07.1994	08.08.1994	10	
1998	22.07.1998	25.07.1998	4	7
	03.08.1998	05.08.1998	3	
2000	13.06.2000	15.06.2000	3	6
	20.08.2000	22.08.2000	3	
2001	14.07.2001	16.07.2001	3	3
2002	21.06.2002	24.06.2002	4	9
	09.07.2002	13.07.2002	5	
2003	07.06.2003	14.06.2003	8	18
	04.08.2003	06.08.2003	3	
	13.08.2003	20.08.2009	7	

To assess the outdoor heat load in a city, satellite images of thermal emission (Terra ASTER) for a warm summer day can be used. The potential of satellite imagery for heat detection is described in detail by Voogt and Oke (2003: 370). Important urban climate-related variables can be obtained from the *Moderate Resolution Imaging Spectroradiometer* (MODIS). The value of using satellite imagery lies in the instantaneous observation, the global coverage and the promising quality of MODIS products such as Landsat and ASTER (Lo/Faber 1997: 143; Menglin/Shepherd 2005: 681). Spatial temperature patterns in Budapest have been analysed via remote sensing by Pongracz, Bartholy and Dezso (2006). They also analysed the urban heat island intensity. They found that the warmest part of the city is the downtown area (administrative and commercial centre) on the left bank of the Danube River whereas the western part of the city is hilly, covered by forests and relatively cool. However, satellite images only give information on surface temperatures. With regard to housing, the roof top temperature is revealed by satellite images. How far this can be an indicator for temperatures within buildings is not yet known sufficiently. Besides this, no cheap data on heat load at a sufficient spatial resolution and temporal stability is available. Therefore, heat load is not included in the index presented here.

The best source for indicators of vulnerability is census data. This data is available for 2001 for Budapest from the Central Statistical Office and contains demographic, socio-economic and housing data for 23 city districts of relevance as vulnerability indicators. According to expert opinion, information on the level of education is an important vulnerability indicator in Budapest. Therefore the variables indicating high population vulnerability and used to construct the vulnerability index are:

- High age: Percentage of population over 65–75
- Very high age: Percentage of population over 75 (separate variable to account for very high age)
- Living alone: Percentage of single households
- High population density: Percentage of more than 11 flats per block
- High indoor temperature due to poor insulation: Percentage of buildings with a low housing quality
- Percentage of people with low level of education (maximum of 8 years of school visited)

For each indicator the range of the percentage values is divided into 5 equal intervals and a value of 1 to 5 is attributed to each class with respect to the extent to which it indicates higher or lower vulnerability. In this way, the expression of an indicator is normalized by the values occurring to each indicator (see table 67.2 for some basic statistics of the variables).

Figure 67.1 shows the share for each variable by district. It is clear that some districts accumulate high shares in more than one of the risk variables. In those districts (1, 5, 6, 7, 8, 9, 13) where the threshold of 150 per cent is exceeded, it is obvious, that many people are characterized by a double burden of vulnerability.

The index, which is the sum of the values from the classification (1–5) for the various indicators for every spatial unit (district) gives an estimate of the overall vulnerability in the district. The results have been

Table 67.2: Descriptive statistics of the variables. **Source:** Central Statistical Office Budapest.

	Descriptive Statistics (N = districts)								
	N	Range	Maximum	Minimum	Mean	Std. (?)	Variance	Skewness	Std. Error
Population density/ km²	23	30180.10	507.50	30687.60	6407.09	6738.77	45411026.47	2.52	0.48
km²	23	5274.00	209.00	5483.00	2283.30	1503.16	2259504.31	0.17	0.48
Per cent over 65	23	16.03	12.04	28.07	18.12	4.51	20.32	0.75	0.48
Per cent over 75	23	9.24	5.08	14.33	8.20	2.71	7.36	0.95	0.48
Per cent of single households	23	26.52	20.59	47.11	34.32	8.52	72.65	0.17	0.48

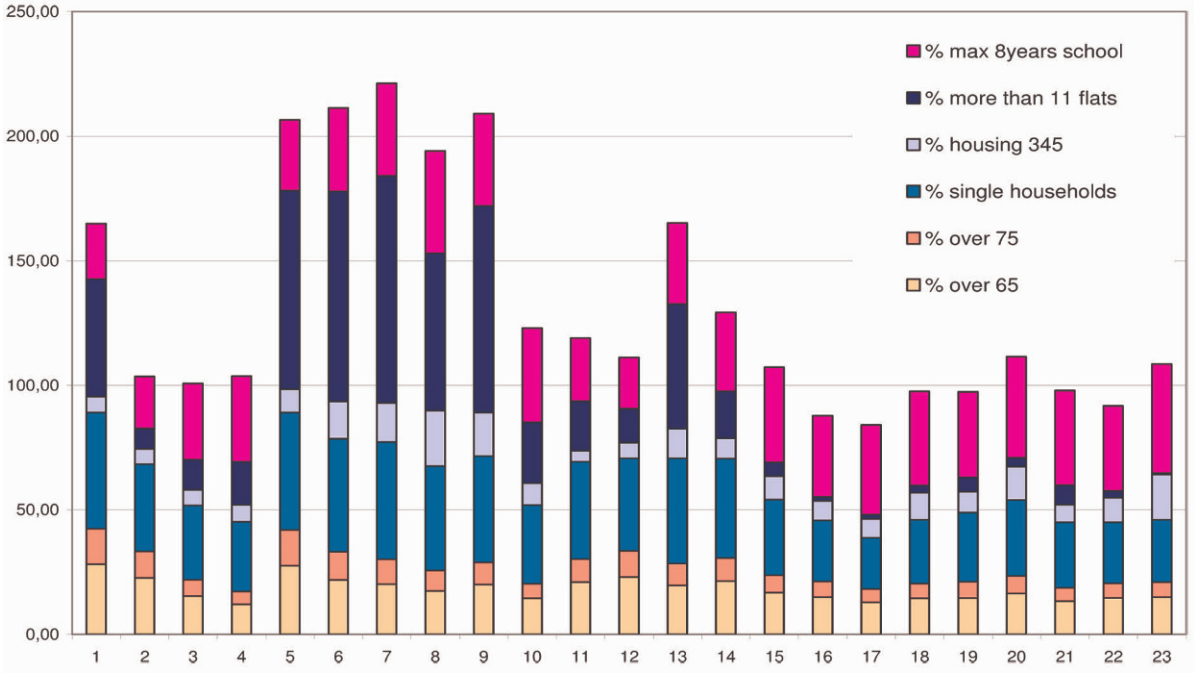
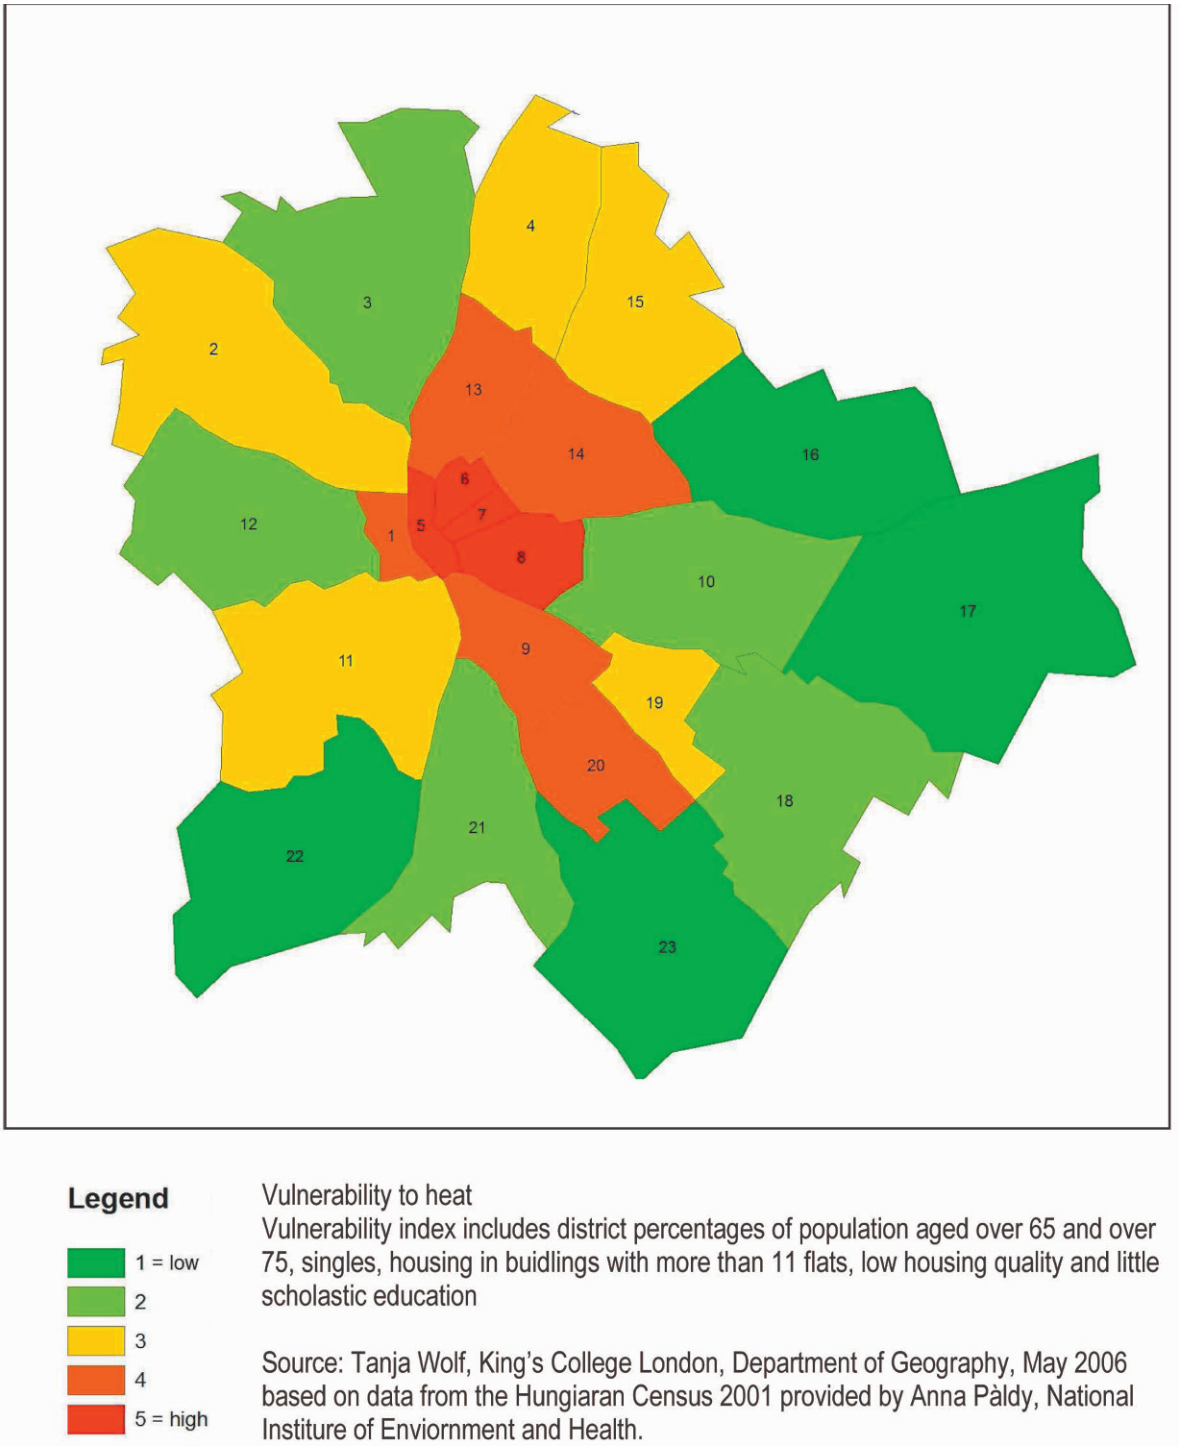
Figure 67.1: Shares of populations with characteristics attributable to vulnerability indicators by district. **Source**: Central Statistical Office Budapest.



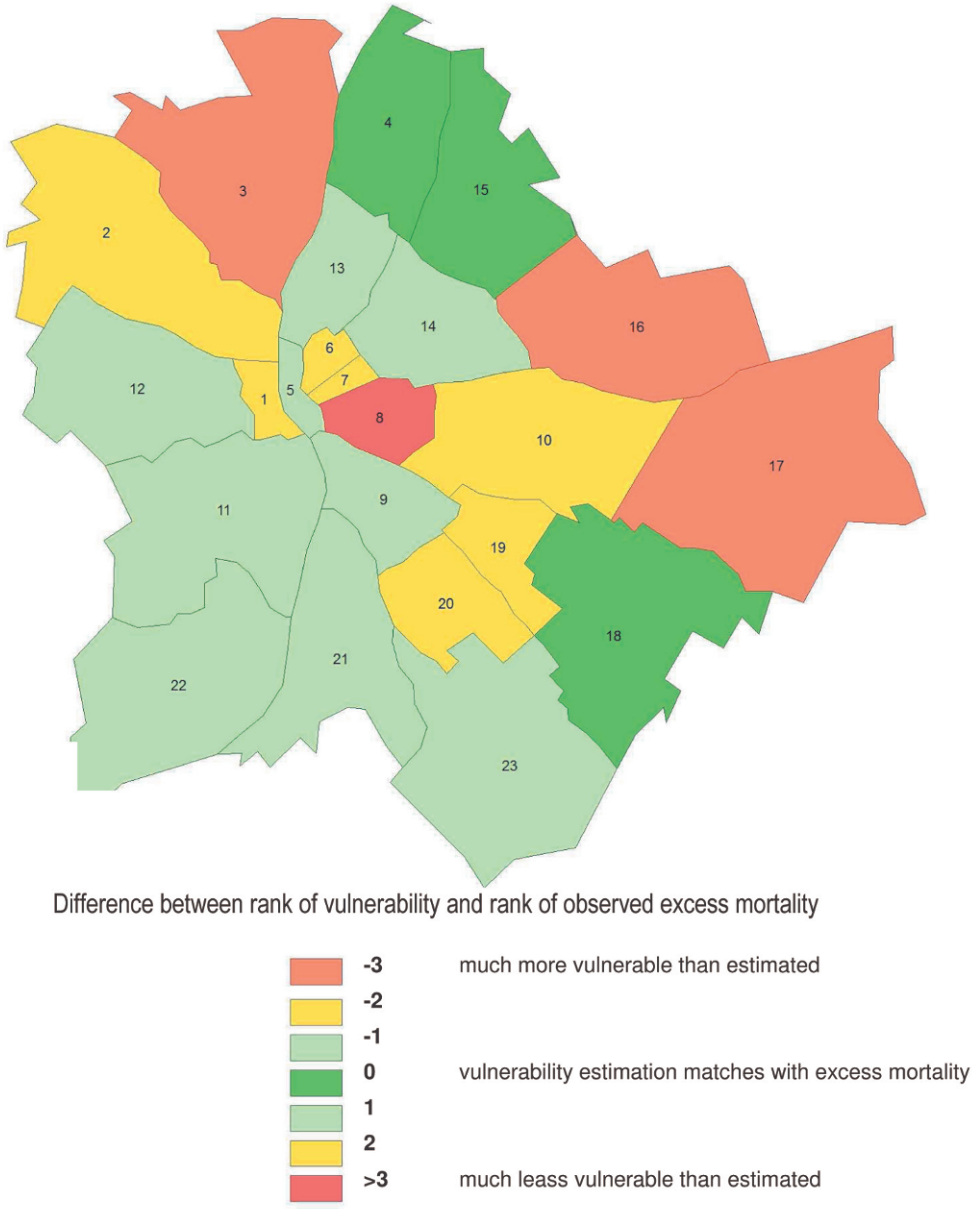
mapped in figure 67.2. Taking into account the nature of a hotspot as being of high interest because of the severity of the threat and the number of the people affected in relation to the size of the district, the index calculation based on percentages of the population are adjusted by the population density in the district. Finally, class 1 has the lowest value of being a hotspot of vulnerability, class 5 the highest. Following this approach, the districts with the highest vulnerability are number 5, 6, 7 and 8, in the centre of the city, then district 1, 13, 14, 9, and 20 as the second highest class (figure 67.2).

Figure 67.2: Vulnerability Map. **Source:** Wolf (2006).



As a last step the results of the vulnerability assessment have to be compared with the observed spatial distribution of summer heat-related mortality. For such a bottom up approach data on the location (address, district) of individual deaths during a hot period is necessary. A comparison of hotspots of vulnerability with the observed distribution of heat-related mortality will show whether a spatially inhomogeneous distribution of mortality correlates with the patterns of the physical and socio-economic landscape.

Figure 67.3: Test result: Difference between vulnerability index and observed excess mortality. **Source**: Wolf (2006).



In order to compare the vulnerability map based on the information on population vulnerability and population density with the spatial distribution of the heatwave mortality, daily mortality data is used. The cases from 1996 to 2003 have been made available by NIEHS. This data identifies total mortality for male and female as well as by age group (15 to 46, 47 to 65, 66 to 74, 75 to 84 and over 84). Mortality of under 15 year olds is negligible in Budapest during a heatwave so this age group is not considered.

From 1.1.1996 to 31.12.2003 a total number of 206,130 deaths were registered. During those seven years, in total and in all districts there is a trend of decreasing numbers of deaths, except for a marked winter influenza peak in 1999. Throughout the year, more deaths occur in winter. The share of deaths by district is fairly equally distributed, the differences

occur constantly through the years and the months. The weekly and daily distribution of mortality has not been assessed; few deaths occur in each district daily and the fluctuation on this level may be just by chance.

In order to assess if the hotspots of vulnerability match with observed locations of excess mortality during heat events, the excess mortality was mapped. To reach a level of significance, some aggregation of the cases is necessary. Since the spatial resolution (23 districts) is quite low, further spatial aggregation has to be avoided. Instead, the number of deaths that occurred during those days which have been defined as heatwave days (43 days) has been calculated. During the 43 heatwave days, 3251 people died in Budapest. A comparison with the average number of deaths during summer shows that the mortality during heatwave days is always and in every district, except in district 8, higher than the average of the seven year study period.

As a next step, the range of excess mortality in each district has been classified into quintiles and has been compared with the vulnerability classes for every district. Figure 67.3 shows, that there is some matching, but in some districts high mortality does not coincide with high estimated vulnerability.

The only district which did not show excess mortality during heatwave days compared to average summer mortality (district 8) is also the one which shows much less sensitivity to heat than expected from the assessment. This district had an outstanding low housing quality. Perhaps in this district the low housing quality is not linked with high vulnerability. In contrast, for districts 3, 16 and 17 the excess mortality was instead high, while the vulnerability was estimated to be low. Here, some factors influencing vulnerability seem to be not captured by the variables comprising the vulnerability index.

67.7 Conclusion

In this chapter a new method for identifying hotspots of vulnerability to heat stress in urban areas has been presented. Many caveats, such as the lack of freely available spatial data concerning exposure, but also the rather low spatial resolution of data on the vulnerability side have been shown. In the near future, technical progress might make thermal remote sensing and the analysis of urban heat islands more sophisticated and cheaper. But the information on roof-top temperatures does still not give evidence on the exposure of populations to heat inside buildings. Furthermore, to increase the spatial resolution of census data is probably an even bigger challenge.

The vulnerability mapping tool presented here should provide evidence on hotspots and where action is most urgently needed. However it would appear that the tool needs to be more precise. Of the 23 districts vulnerability matched the observed excess mortality for 12. For the remaining 11 it was either under- or overestimated.

Notwithstanding methodological constraints, the potential of this tool as part of an adaptation policy framework, even if able to predict the health impact of heat events to a high degree, is still an open question. This is because moving from scientific knowledge to policy and action is a difficult process. Also, to incorporate insights from vulnerability analysis into policy and practice is a challenge and a lack of correspondence between vulnerability theory and action indicates weak links between analyses and decision-making. Pertinent questions in this context include how successful and precise does risk assessment need to be in order to really lead to policy and action? How much uncertainty on the one side and how much precaution on the other side allows for inaction? And importantly, when hotspots of vulnerability reflect patterns of social inequality or environmental injustice, will action be taken?

68 Regulation and Coupling of Society and Nature in the Context of Natural Hazards

Jörn Birkmann

68.1 Introduction

Disasters are often viewed as sudden onset events triggered by external shocks impacting on societies and causing major harm and losses. However, most disasters linked to hazards of natural origin – such as the Cyclone Nargis (May 2008) which devastated the Irrawady-Delta in Burma with more than 100,000 fatalities, the Hurricane Katrina (August 2005) that caused major losses and harm particularly in New Orleans, and the Indian Ocean Tsunami (December 2004) that left more than 230,000 dead behind – are characterized by a major crisis and partial collapse of communities and socio-ecological systems as well as by important changes and feedback processes during and after the disaster. To achieve a better understanding of disasters and to derive lessons learned for future risk reduction endeavours, a more comprehensive perspective on these regulation and coupling processes is needed.

Adger, Hughes, Folke, Carpenter and Rockström (2005: 1036) argue that social and ecological vulnerability to coastal hazards – as in the Indian Ocean Tsunami – is influenced by building-up or erosion processes of resilience both prior to and after the disaster. Furthermore, Bohle (2006a: 4) underlines that research on social vulnerability and risk must emphasize social science theories to understand and explain disasters. Disaster studies and management strategies have often paid little attention to theories and conceptual frameworks.

This chapter introduces concepts of socio-ecological crises and examines different theoretical notions currently applied for describing interactions, coupling and regulation processes between society and nature, as well as socio-ecological crises and catastrophes. Particular emphasis will be given to concepts and theories regarding regulation based on economic regulation theory and the newer concept of the regulation of societal relationships with nature by Görg (2003) on the one hand (68.2), and the theories and concepts of general systems theory and cybernetics (68.3), including newer applications of these concepts in the Syndrome approach of the WBGU and the Archetype approach of UNEP's Global Environmental Outlook. Additionally, the concepts of Ecosystem Services and Human Well-Being developed within *the Millennium Ecosystem Assessment* (MA 2005) will be analysed in terms of their explanatory value for explaining coupling processes between society and nature. It will be explored whether and to what extent different concepts and frameworks focusing on socio-ecological interactions (systems) as well as on socio-ecological crises phenomena can offer a first theoretical and conceptual background for explaining key terms such as coupling and regulation as well as different response processes like coping, adaptation, stabilization, and change. Based on this theoretical and conceptual review, a critical analysis of pre-analytic visions of disasters is conducted in order to explore different problem views and perceptions on how disasters and crises are generated and what kind of phases are linked to these conceptualizations of disasters (68.4). Furthermore, regulation theory and the newer concept of Görg (2003) underline the importance of change and transformation due to larger crises. In this context, the author also examines how change and transformation can be linked to key terms in the disaster risk research such as coping and adaptation. This differentiation provides also an important basis to better understand – from a conceptual perspective – how to account for change within the context of crises and disasters linked to natural hazards (68.5).

These theoretical and conceptual sections will be juxtaposed against the practical research and experience of regulation and coupling processes of socio-ecological systems in Sri Lanka after the Tsunami 2004 (68.6). Major emphasis is given to different views and problem definitions, key coupling processes between coastal communities and their natural

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_68, © Springer-Verlag Berlin Heidelberg 2011

resource base, post-disaster stabilization and destabilization processes, and different feedback and response processes that also reveal new arenas of conflict and different agendas of the various actors involved in the recovery and reconstruction process. The conclusions summarize key findings of the empirical case study work and also formulates a kind of synthesis in terms of key-questions for capturing coupling and regulation of socio-ecological systems within crises and disasters linked to natural hazards (68.7). These questions are based on both the conceptual framework discussion in the first part of the chapter (68.2 to 68.5) and the empirical case study work in the second part of the chapter (68.6).

68.2 Regulation

Coupling and regulation are key terms when dealing with the interactions of human-environmental systems or so-called coupled socio-ecological systems (see e.g. Turner/Kasperson/Matson/McCarthy/Corell/Christensen/Eckley/Kasperson/Luers/Martello/Polsky/Pulsipher/Schiller 2003). Although there is a general consensus that coupling processes between society and nature are key for understanding coupled socio-ecological systems, there is yet a large gap regarding a sound conceptual and theoretical approach that can explain coupling and regulation processes within these coupled systems linked to crises and disasters due to hazards of natural origin. Therefore, the following chapter will examine different theoretical and conceptual approaches that have attempted to explain the nature of coupling and regulation.

68.2.1 Introduction to Regulation Theory

Increasingly, regulation theory has been applied within the concept of societal relationships with nature and in the framework of global change research. In the context of the discourse on crises and disasters linked to hazards of natural origin – regulation theory, based on newer concepts of societal relations with nature – may offer a theoretical framework to explain why certain crises and disasters lead to change while others do not. It might also help in examining the different interests and strategies prior to and after disasters. On the other hand, its limitations to the analysis of socio-ecological crises phenomena must also be better understood (Görg 2003, Görg/Brand 2008; Becker/Jahn 2006).

The term 'regulation' plays an important role in different disciplines and scientific fields, such as political economy and cybernetics. During the 1970's, regulation theory was developed by Michael Aglietta (1979) to improve our understanding of socio-economic change. Regulation theory aims to explain the economic and extra-economic mechanisms that can stabilize capitalist societies despite their fundamental contradictions generating crisis and disintegration (Danielzyk/Ossenbrügge 2001). Regulation theory discusses fundamental historical changes and respective stabilization and destabilization mechanisms in societies as well as the interplay between continuity and discontinuity using two central concepts, namely the 'regimes of accumulation' and the 'modes of regulation' (Aglietta 1979). In this context, regulation is based on the assumption that capitalist societies are inherently linked to and influenced by contradictions, which permanently endanger their own societal reproduction. Therefore, action and production patterns, economic development models, and other principles that structure and shape society (modes of accumulation and modes of regulation) are seen as core factors questioning the reproduction and further existence of society. 'Regulation'[1] within this context is not understood as an authoritative steering or governing process of the economy, but rather as a self-regulating process that conceptualizes the evolution and temporary stability of a crisis-driven capitalist society in which major conflicts and contradictions remain (Lipietz 1985; Görg 2003: 121; Danielzyk/Ossenbrügge 2001). However, this self-regulating process is based on the interests of different stakeholders that do act intentionally whereby the consequences of their actions are contingent and not always match the original intent.

From the perspective of social ecology and newer work done by the Institute for Social-Ecological Re-

1 An example of a regime of accumulation was 'fordism' which was characterized, among other features, by large automatization processes, mass production and mass consumption in industrialized countries. The historic change to post-fordism – often linked with terms such as flexibility, decentralized production units and new technologies etc. as the dominant economic model – was a fundamental change which is explained and discussed by regulation theory. In this perspective, the term regulation refers to the stabilization of structures and processes within societies and between society and the economy while major contradictions among different social groups and the economic development model remain.

search in Frankfurt (Germany), Wissen (2004: 45) points out that regulation realizes itself through different institutions, forms, and norms that structure and frame individual and societal behaviour, which together constitute a mode of regulation. These institutional practices, forms, and norms often stabilize conflicts and contradictions within societies and between society and economic development models for a certain period of time (Wissen 2004; BMBF 2004).

Aglietta (1979) examined the specific relations and interplay between continuity and discontinuity within different phases of socio-economic development in capitalist societies. This school of thought defines regulation as a contingent result of an open process of social contest that can be based on stakeholders acting intentionally. Regulation does not mean steering or controlling as clearly intentional and planned behaviour. In its core meaning, regulation describes the processes and structures – as a result of intended and unintended consequences – which lead to a stabilization of societal structures and relations linked to a specific economic development model while major conflicts and contradictions remain. The term regulation and some of the theoretical aspects developed by the 'French School' (Aglietta 1979; Lipietz 1988) are further developed and transformed in order to explain societal relationships with nature.

68.2.2 Regulation of Societal Relationships with Nature

Görg and Brand modified and transferred regulation theory which had originally been used to explain stability and crises within capitalist societies to the field of societal relationships with nature (Görg 2003; Brand/Görg 2008; Becker/Jahn 2006). The original meanings of both modes of regulation and modes of accumulation seem to disappear. The concept of 'modes of regulation' is used as a core element to explain the stabilization of specific ways on how societies view and use nature and natural resources (Görg 2003, Becker/Jahn 2006). Regulation in the new concept of societal relationships with nature tries to explain why contradictions and destabilization processes in societal relationships with nature do not lead to a collapse of societies or the corresponding societal relationships with nature.

The concept of the regulation of *societal relationships with nature* (Görg 2003) defines the institutional practices that determine the modes of regulation as key factors within the stabilization of societal development and societal relationships with nature. Furthermore, the concept of Görg (2003) distinguishes between small and large crises[2]. While a small crisis is seen as a process which can be managed and dealt with by existing institutions and organizations and does not exceed the problem-solving capacity of important stakeholders, large crises imply a major disruption, transformation, and change within existing institutions, modes of regulation and organizations. Görg (2003) underlines that his new approach of societal relationships with nature can help understand the social context in which crises occur. Thus, the general conditions of economic production and reproduction as well as the structures and approaches that configure societal development and the fundamental norms and values are embedded in and linked to this societal development (Görg 2003). That means that the term regulation is used for societal relationships with nature to describe the stabilization of societal structures and reproduction patterns, – while major contradictions in society (for example class, income, gender, etc.) as well as between the specific economic development patterns (logic of production, distribution, and consumption) and the natural resource base (ecosystem requirements) often remain.

According to Görg (2003), the concept of societal relations with nature has at least four major implications: *firstly*, the metabolism between production and reproduction is embedded in nature and has to be examined in the context of social values and norms. *Secondly*, he argues that knowledge and interpretation patterns must be taken into consideration as discursive representations of societal relationships with nature. *Thirdly*, he shows that norms and interpretations are the result of societal contest. *Fourthly*, the different phases of development in societies are also characterized by structural constraints (Görg 2003: 121–122).

Furthermore, strategies regarding societal relationships with nature and environmental problems do not start with the discussion about alternative solutions, but with the identification and definition of the problem itself. Thus, to acknowledge that a certain process, development, or structure can lead to crises or has already become a problem is often a disputed subject between major stakeholders. This issue is particularly important since the problem identification and definition themselves already determine the corridors in which solutions will be developed.

2 This distinction of small and large crises and their consequence is similar to the regulation theory of the French School see Aglietta (1979) and (Lipietz 1985).

68.2.3 Critique and Limitations

Regulation theory, as used in the context of the regulation of societal relationships with nature (Görg 2003), has undergone an enormous differentiation during the last decades, i.e. various concepts and variations of regulation theories were generated. In this context, Danielzyk and Ossenbrügge (2001) concluded that the thematic diffusion of regulation theory has dissolved into a broad stream of critical social science.

Thus, when trying to examine the value of the theory for analysing socio-ecological crises with a clear geographical perspective and a local and sub-national research focus, several limitations become visible. The original work by the 'French school' (Aglietta 1979; Lipietz (1985) focuses on the explanation of fundamental changes within societies, for example the change from 'fordism' to 'post-fordism'. The examples used within regulation theory clearly encompass changes which are taking place at the international level, such as transformation and change related to the industrial paradigm, accumulation regime, and mode of regulation as well as the overall model of development. For an analysis of socio-ecological crises linked to natural hazards at the local and sub-national level, regulation theory overemphasizes macro-structures, macro-economic forces, and large-scale institutional mediations and changes, while issues of local feedback and response processes, scale interactions, governance and social learning – which become more important in order to understand change and transformations at local scales – are underrepresented. The concept of the regulation of societal relationships with nature by Görg (2003) also focuses on international crises phenomena, especially the contested terrain of the use of biological resources, instead of investigating change on local scales.

The second limiting factor of the approach is the vagueness of some of its terms. Within the description of the change from fordism to post-fordism, the term 'post-fordism' remains fuzzy not only in original regulation theory but also in its application to societal relationships with nature. Critical reviewers argue that within regulation theory it remains unclear whether the term 'post-fordism' can be a guiding concept for a new development model at the end of the 20th century or whether it is rather an overloaded catchword showing the inability of regulation theory to deliver a coherent explanation of change (Danielzyk/Ossenbrügge 2001). They point out that also other key terms within regulation theory also remain vague, such as the key concept of 'regulation', which is defined either as a process or a result of intended and unintended consequences of social practices or as a contingent combination that might operate to support accumulation. According to Danielzyk and Ossenbrügge (2001), these terms are too broad for a coherent theoretical framework.

The third limitation is that most approaches in regulation theory have paid little attention to ecological and environmental questions. Although Lipietz (1985) argued that the Western mode of production has neglected the environmental resources and carrying capacity of the earth system, most approaches ignored the environmental aspects or society-nature relations as key factors that might determine future economic and social changes. Thus, by addressing the societal relationships with nature Görg (2003) made an important extension of the concept of regulation to society-nature interactions. Nevertheless, his understanding of what exactly nature means and includes also remains quite open. The analysis of stabilization and destabilization processes is too much centred on a societal perspective, while a better understanding of socio-ecological systems and crises phenomena would require a better theoretical understanding of coupling and feedback processes as well as destabilization and stabilization processes from the social and environmental perspective.

In summary, it seems promising to use at least parts of Görg's theoretical approach in order to explain changes in socio-ecological crises linked to natural hazards, especially regarding stabilization versus destabilization processes. However, regulation theory in general and his concept of regulation theory are too broad and in some parts too deterministic to explain the various characteristics that shape socio-ecological crises. The reason might be his focus on major societal transformations on the macro-level that neglects a detailed analysis of local level changes. Thus, additional theories and concepts must be reviewed for an improved theoretical understanding of socio-ecological crises phenomena linked to natural hazards. From the perspective of geographical and spatial science, theories from the social and natural sciences should be linked and combined to enhance our understanding of 'disasters of natural origin' (Rauch 2008: 204). The development of more integrative theoretical concepts and theories to capture socio-ecological interdependencies remains a challenge and faces many difficulties and obstacles, particularly when considering the different epistemologies applied (see e.g. Egner 2008; Wardenga/Weichhart 2006). But for

geography and planning – as interdisciplinary sciences – this challenge may result in new theoretical concepts that are needed to better explain socio-ecological crises linked to natural hazards.

This chapter reviews approaches linked to general systems theory and cybernetics that try to explain socio-ecological systems and socio-ecological interactions. Within this context, applied concepts such as the syndrome approach of the WBGU and the concept of the ecosystem services and human well-being within the Millennium Ecosystem Assessment will be discussed.

68.3 Approaches Related to Systems Theories

The discourses on resilience and coupled socio-ecological systems, on syndromes of global change and archetypes of vulnerability (Folke 2006; Berkes/Colding/Folke 2003a; WBGU 1996; UNEP 2007), as well as on societal relationships with nature (Görg 2003, Becker/Jahn 2006; Brand/Görg 2008) have existed mainly in parallel. However, during the past decades, several authors have at least tried to combine natural science and social science perspectives (Berkes/Colding/Folke 2003b: 9–13). But most of the approaches described by Berkes, Colding and Folke (2003) often prioritize either the social or the ecological/environmental perspective as the limiting condition. Although important links have emerged out of both schools, particularly within the Resilience Alliance, core elements in this research field – such as the coupling processes between social and ecological components of socio-ecological systems – still need a better understanding. Several case studies and examples use processes in ecosystems to explain coupling processes in coupled socio-ecological systems rather than societal or institutional changes. Changes, however, often reveal important insights into the functioning and hence the coupling of socio-ecological systems. The central conceptual frameworks for the analysis of coupled socio-ecological systems (Berkes/Colding/Folke 2003b: 22) as well as for the building of resilience (Folke/Colding/Berkes 2003: 359), such as the adaptive cycle, offer an important basis for progress in socio-ecological research. Nevertheless, it must be better explained how coupling and regulation processes work during normal times and in crises and how (generic) responses to a crisis develop prior to, during, and after a disaster. The dominant view that societal responses occur only after environmental shocks and crises may become questionable in the context of climate change. In this context, predictions about future changes in climate conditions already trigger societal responses (e.g. regarding insurance regimes or land management) – although bio-physical changes in environmental conditions have not yet occurred.

Against the background of resilience research (e.g. Holling 2003; Berkes/Colding/Folke 2003a) and the analysis of the concept of the societal relationships with nature (Görg 2003), the following analysis focuses on the description of coupling and regulation within the discourse on socio-ecological interactions in general systems theory and cybernetics (von Bertalanffy 1972, and newer applications by Vester 1990), within network theory and within the newer discussion of Society-Human-Environment-Interactions (Egner 2008) that are linked to the theoretical discourse in geography. These schools of thought should contribute to a better understanding of socio-ecological interactions and socio-ecological crises phenomena. The chapter cannot give an in-depth overview of the various schools of thought and sub-research fields. Rather, it will outline the use and meaning of coupling and regulation within the selected approaches described above. Furthermore, conceptual frameworks of coupled socio-ecological systems described within the syndrome concept of the German Advisory Council on Global Change (WBGU) (1996) and the archetype approach (UNEP 2007) as well as the concept of ecosystem services and human well-being introduced by the *Millennium Ecosystem Assessment* (MA 2005; Leemans 2009) are briefly reviewed, since they represent the school of thought on applied systems theory approaches with a strong emphasis on the environmental component.

68.3.1 Society Nature Interactions under the Perspective of General Systems Theory and Cybernetics

General systems theory (von Bertalanffy 1972), Cybernetics (Wiener 1948; Ashby 1985; Vester 1990, 2002, 2007), as well as complex systems theory (Lewin 1996) are used in different research fields including sustainability science, resilience research (Berkes/Colding/ Folke 2003b: 5), urban development and traffic system analysis (Vester 2007). All these research fields focus on the structure of complex systems, interdependencies, communication and interaction processes and, particularly, positive and negative feedback processes as well as control and regulation mechanisms within and between the different ele-

ments of a system. Moreover, it is important to note that the different contributions mentioned above also encompass specific historic context components.[3]

In geography and spatial planning, general systems theory and cybernetics play(ed) an important role for example in human-environmental systems research, in environmental assessment and in traffic and mobility research (see e.g. Vester 1990; 2007; e.g. the research on environmental *Life Cycle Assessment* (LCA) linked to cybernetics). Additionally, the work on social systems theory by Luhmann (e.g. 1990) received an increasing recognition within the social science oriented risk and systems theory research (see e.g. Egner 2008).

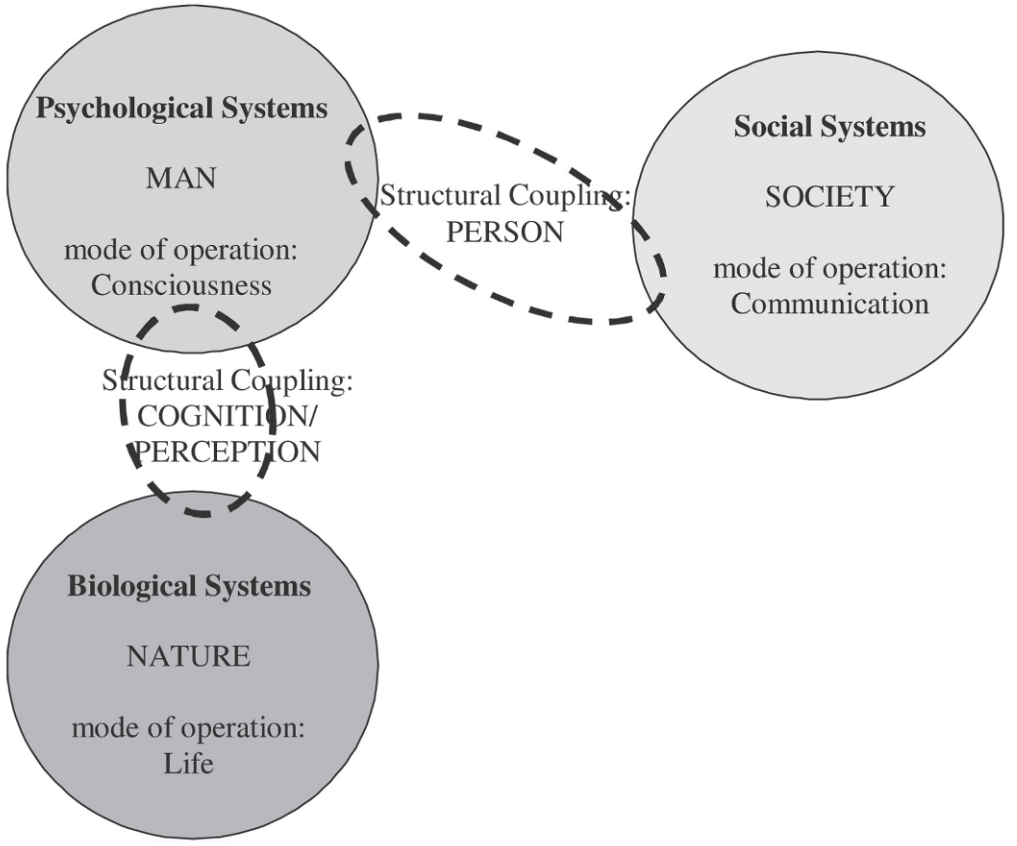
Important influences of network thinking and cybernetics in the field of planning and applied geography stem for example from Frederic Vester (1990, 2002), who applied these concepts to urban development as well as traffic problems. This school of thought within cybernetics views coupling and regulation as linked mainly to the process of interaction between different variables of a system; key in this understanding of coupling and regulation are feedback processes within feedback loop systems. Vester distinguished between more technically understood cybernetics – often practised in economics - on the one hand and bio-cybernetics of living systems on the other hand. Particularly the concept of feedback loop systems in bio-cybernetics has close links to and overlaps with newer concepts of coupled socio-ecological systems and resilience (Davidson-Hunt/Berkes 2003: 75). The resilience community extended these basic concepts by putting more emphasis on areas such as: adaptation, uncertainty, and surprise, as well as issues of centralization, flexibility, and resilience within the systems analysis (Davidson-Hunt/Berkes 2003: 75; Berkes/Colding/Folke 2003a). Today, cybernetics as a research area is seen as a key component of systems theory thinking, although both research fields had developed separately in the beginning (Egner 2008: 56).

The terms coupling and regulation within cybernetic models are often mixed and used simultaneously to explain key processes between interdependent subcomponents of the system as well as to describe the ability of a system to absorb, compensate for and deal with external shocks within the system's own capacity (self-regulation). Thus, key aspects of this understanding of coupling and regulation within cybernetics are negative feedback processes that limit the impact and buffer the consequences of external shocks to the overall system as well as processes that move the systems from the actual status to the targeted status (Vester 2007: 43). Furthermore, Egner (2008) underlines that this field of science is also based on the assumption that the transfer of information (communication) between individual components of the complex system constitutes the system as a system (Egner 2008: 57). Further extensions of cybernetics and general systems theory were made by adding and linking these theories with concepts and theoretical elements of chaos-research and complexity theory, including concepts such as self-organization and non-linearity – for example within the context of resilience research (Egner 2008: 37ff., 56ff.; Davidson-Hunt/Berkes 2003: 76.). Egner (2008) points out that the principles of self-organization extended the idea of the regulation of systems regarding the fact that systems are not solely technically viewed as steered from outside, but rather encompass a component of autonomy – that manifests itself in principles of self-organization (Egner 2008: 59). Additionally, the extension of cybernetics – within the framework of social systems theory – towards self-referenced systems was another milestone within the further development of newer systems theory. The theory of self-referenced systems refers mainly to work done by von Foerster (1987) and further developed by Luhmann (1988), who underlined that the separation and distinction of a system is generated by the system itself. This implies that research not only needs to examine the observed system, but should also analyse the observer as a part of the description and explanation of the system (concept of first and second order observations; see Luhmann 1992: 98; Egner 2008: 60–64).

While concepts that stem from general systems theory and cybernetics often just distinguish systems according to a "more natural" and a "more anthropogenic or human/social sphere" (WBGU 1996), Egner (2008) differentiates – based on social systems theory concepts of Luhmann – three systems, namely a) *Soci-*

3 While Wiener (1948: 133) focused his work on key elements of cybernetics using examples from medicine and technical instruments linked for example to issues of the precision of anti-aircraft fire control (using mathematical equations for their description) (context second world war), von Bertalanffy (1972: 17–21) stressed that general systems theory and cybernetics do not necessarily have to be linked to mathematical equations and technical systems; rather, systems theory aims to identify similarities within the operational mode of very different systems and can also be linked to philosophy. For the role of system thinking in security research and in economics see Mesjasz (2008, 2008a, 2009b).

Figure 68.1: The basic concept of human ecology and the relationship between Society, Man and Environment (nature) through the lens of a differential theory perspective. **Source:** Egner (2008: 135) based on Luhmann (1988).



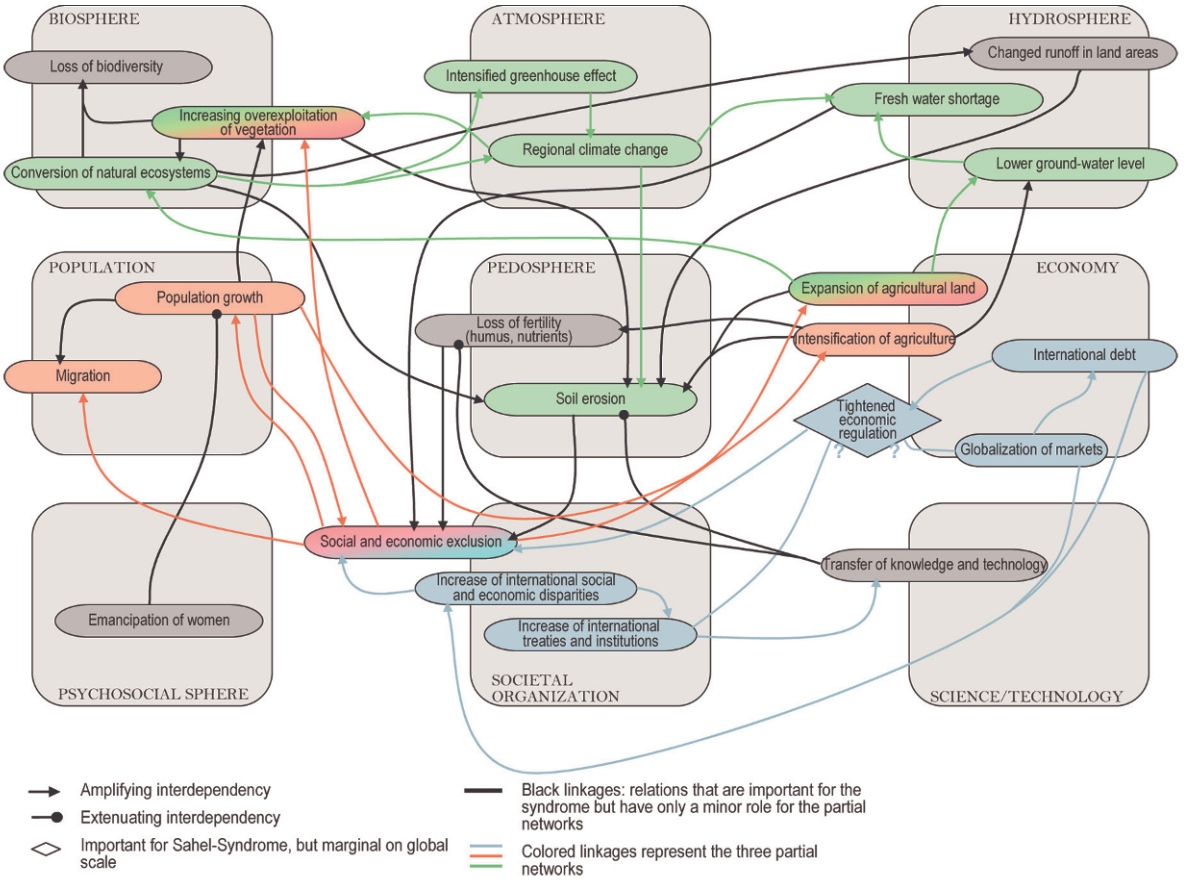
ety, b) *Humans* and c) *Nature* (figure 68.1). According to this differentiation, society has no direct access and link to biological systems (nature), but rather needs the consciousness or a state of awareness that allows for the observation and interpretation of biological processes within the 'nature' system. The 'human' system itself can be separated into two components: one dealing with consciousness (a), and another dealing with the body (b). The system logic of consciousness implies that the human system is a kind of transmitter that selects stimuli and information of the system 'nature' through system internal capacities and processes. Through its consciousness the human system is closely linked and structurally connected to the social system (society) (figure 68.1). The framework underlines that 'structural coupling' might need to be differentiated from other forms of coupling when dealing with the analysis and framing of socio-ecological crises phenomena.

Based on the discussion of different schools of thought within the heterogeneous group of systems theories and the analysis of key terms, the following chapter will review applied frameworks of coupled socio-ecological systems within global environmental change research with a particular emphasis on the syndrome approach of the WBGU (1996), the approaches used within the GEO-4 report (Jäger/Kok 2007), and the *Millennium Ecosystem Assessment* (MA 2005).

68.3.2 Syndrome Concept and Archetype Approach

The syndrome approach of the *German Advisory Council on Global Change* (WBGU) – based on the notion of cybernetics and complex systems theory – examines various global phenomena that indicate unsustainable developments within the natural and anthropogenic components of the syndrome. Thus syndromes as functional patterns illustrate undesirable effects and constellations of natural and anthropogenic trends and interactions (WBGU 1996: 4–7). A key thesis of the WBGU is that the variety of characteristics of the complex nexus of environmental and develop-

Figure 68.2: The Sahel-Syndrome. **Source:** WBGU (1996: 141). Permission was granted by WBGU.

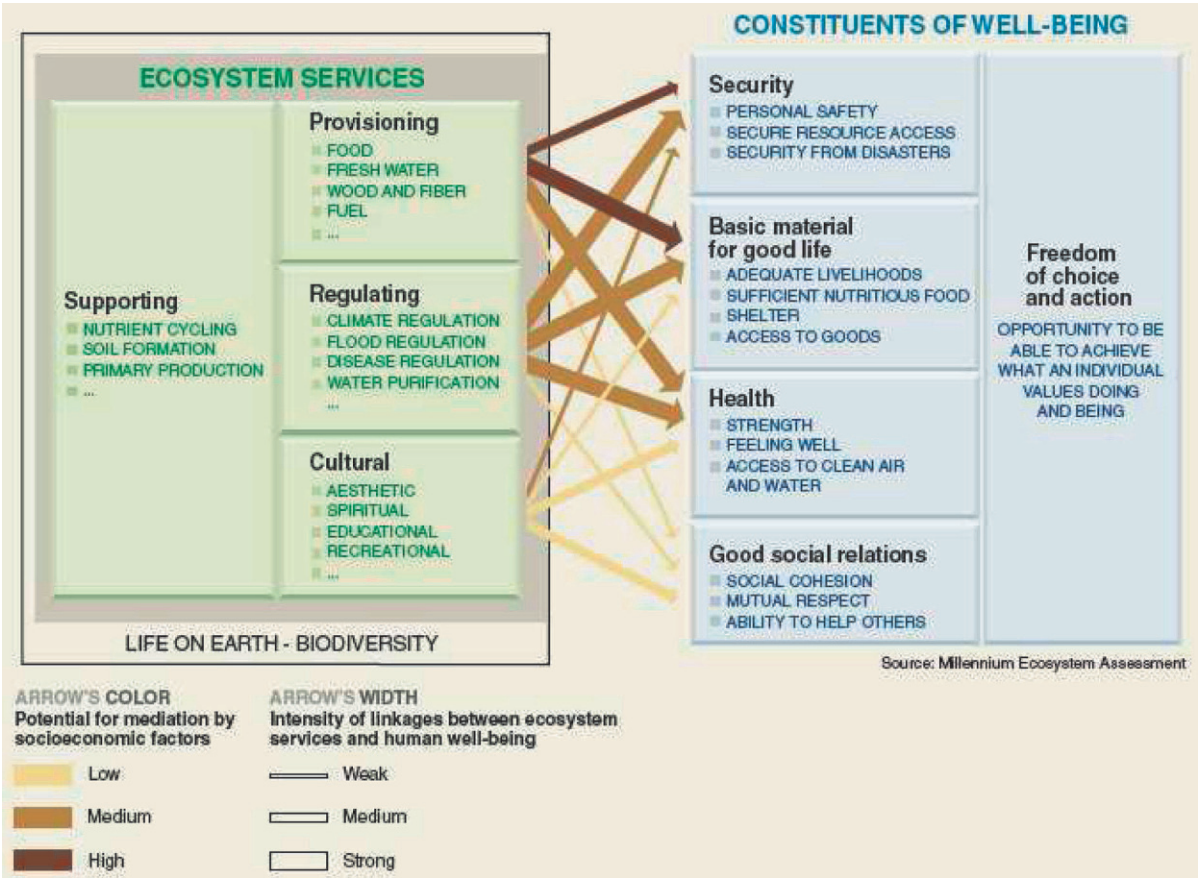


ment problems can be reduced to a manageable amount of syndromes representing key patterns of environmental degradation (WBGU 1996: 4). In contrast to disciplinary and sectoral approaches, the syndrome concept aims to explain and capture the interrelations between civilization and environment based on the identification of typical interaction and key degradation patterns in a transdisciplinary way. 16 syndromes have been identified by the WBGU to describe global change and respective degradation patterns, classified into three syndrome groups: a) utilization, b) development, and c) sinks (WBGU 1996: 5). Syndrome approaches range from the Dust Bowl-Syndrome regarding land degradation to the Katanga-Syndrome which focuses on environmental degradation due to the use of non-renewable energies (WBGU 1996). Figure 68.2 offers an illustration of such a syndrome that focuses on the core components and the key interacting variables or trends which are also linked to the concept of the 'vicious circle'.

Compared to earlier applications of the vicious circle, the syndrome approach also accounts for the broader interactions between the vicious circle and other trends that determine global change. Although the concept shown in figure 68.2 is rather descriptive, the WBGU underlines that also action-oriented research questions such as the analysis of the options for action of affected societies, regional climate change, and surrounding economic conditions are taken into consideration in the system analysis of the Sahel-Syndrome (WBGU 1996: 150).[4] Coupling and

4 This approach – particularly the Sahel-Syndrome – has also been applied to regions outside the Sahel, such as the *Middle East and North African* (MENA) region, in terms of projected regional climate change (Brauch 2003a: 935). Additionally, the Syndrome-Approach of the WBGU has also informed other research areas and frameworks, particularly aiming at developing mitigation strategies for the identified syndromes of global change. This is for example the case within larger North-South Research Partnerships between Swiss universities, the Swiss Development Cooperation, and countries in the South (see overview in Brauch 2003b: 108).

Figure 68.3: Linkages between Ecosystem Services and Human Well-Being. **Source:** MA (2005: VI) and Leemans (2009: 56).



regulation in this framework is understood as the operation mode, particularly the causal linkages between different components of the syndrome and their interdependencies. Furthermore, the framework aims to identify general rules determining how syndromes operate independent of space and time specific differentiations.

The syndrome approach was an important basis for newer applications such as the 'archetype' concept in UNEP's (2007) *Global Environmental Outlook* (GEO 4). This approach is used to address patterns of vulnerability to environmental and socio-economic changes (Jäger/Kok 2007: 301). Archetypes of vulnerability are – according to their conceptual bases - linked to the syndrome approach. The seven archetypes of vulnerability show specific, representative patterns of the interactions between environmental change and human well-being. The 'archetype' approaches are broader than the syndrome concept of the WBGU (Jäger/Kok 2007: 317). Overall, the notion of the feedback loop system and the intensive discussion about the interplay of socio-economic and natural conditions as well as regarding responses at various scales and from various actors underlines the strong linkages with concepts of general systems theory and cybernetics (e.g. feedback processes, principles of self-organization).

68.3.3 Millennium Ecosystem Assessment

A third approach of global research on socio-ecological systems and linkages between nature and societies was offered by the *Millennium Ecosystem Assessment* (MA 2005). Contrary to the syndrome and archetypes of vulnerability, this approach outlines the importance of ecosystem services for human well-being (figure 68.3).

While the syndrome and archetype approaches have used a negative definition to describe socio-ecological phenomena and sustainability, the MA examines the different phenomena using a positive definition for the connections between ecosystem services

and human-well-being. This differs widely from an overall conceptual strategy. Furthermore, interaction processes are rather one-dimensional[5], which means that the different ecosystem services are linked to human well-being rather than connecting to them through larger feedback and response processes. The term regulation is explicitly mentioned and used to describe interventions or management options relating to, for example, climate or ecosystem services (MA 2005: 20).

68.3.4 Critique and Limitations

The selected approaches presented above underline that from the natural and environmental science perspective, coupling and regulation of society and nature are much broader defined and dominated by a perspective originating from general systems theory and environmental impact assessment. For example in the *Millennium Ecosystem Assessment*, major emphasis is given to the characterization on how human well-being depends on environmental resources and services. Less and very limited attention is given to the conceptualization on how these environmental services are redistributed and accessed within society. Additionally, the framework does not give any information on how societies and communities respond to potential or actual degradation processes and changes of ecosystem services. These questions regarding the societal responses are neglected, while they are key in Görg's concept of societal relationships with nature – in order to capture and understand regulation processes. Likewise, the coupling effects – understood as the positive and negative feedback processes within systems (cybernetics) – are not sufficiently acknowledged.[6]

Compared to the MA approach, the 'syndrome' (WBGU 1996) and 'archetype' approaches (UNEP 2007) offer a broader view and emphasize the interrelations, i.e. positive and negative feedback processes, within a larger system or problem phenomena. The understanding of the syndromes and archetypes is therefore linked to the examination of how the different components and parts operate together. Regulation – if the term is used at all – is often linked to feedback loop processes and the description of drivers within socio-ecological systems. In this regard, regulation is primarily understood as a kind of self-regulation. Self-regulation is used to describe the processes and capacities of a system to deal with external shocks through negative feedback loops. Thus, self-regulation mechanisms within the syndrome approach of the WBGU are processes that ensure that external impacts may be absorbed so that they do not lead to a direct collapse or restructuring of the system. Both concepts seem to imply that most processes and feedback loops are known. But complex systems theory applied in resilience research (Berkes/Colding/Folke 2003a) underlines that complexity originates from the problem that dynamic interactions are often characterized by non-linearity, uncertainty and emergence, scale interactions and self-organization (Berkes/Colding/Folke 2003b: 5). In this respect, the self-organized interaction of the components of a system might lead to the emergence of new, unpredictable structures and processes (non-linearity). Therefore, a new challenge for these approaches will be the modification and integration of aspects such as uncertainty, surprise, and self-organized criticality (Bak 1997; Berkes/Colding/Folke 2003a).

Additionally, the syndrome approach is criticized due to the fact that it encompasses mainly a macro-perspective that might exclude important features and differences at the micro-level. This is particularly true for example for the dualistic nature of some of the processes and system components, such as it is the case for the issue of migration in the above mentioned Sahel-Syndrome. Krings (2002) and Müller-Mahn (2008: 400–402) outline that migration for drought-affected communities can have either negative or positive implications – thus it can be both a negative coping process or a type of adaptation which allows to sustain certain income generating activities even in times of droughts.

Furthermore, it becomes evident that these three approaches give too little attention to social concepts and theories. Although the livelihood framework as a social science concept is noted in the work of the MA and the GEO 4 report, the integration of natural science and social science concepts and theories is still underdeveloped.

Questions of different types and intensities of coupling - between society/humans on the one hand and natural/biological components/resources and processes on the other – as well as regulation processes – here understood as unintended and intended forma-

5 Ashby (1957: 48–51) explains coupling with a one directional technical process between machines.

6 Overall, the 'MA approach' is closely linked to the discussion and conceptualization of environmental impact assessment which also encompasses protection assets such as the environmental media (air, water, and soil), health, humans, and their interrelations.

tion and organization processes of societal interactions with 'nature' (encompassing material and energy flows as well as non-material flows and components) have to be better understood. Moreover, issues of similar or different thresholds and tipping points - for social and ecological components of socio-ecological systems or within socio-ecological crises phenomena are just being discussed (Renaud/Birkmann/Damm/Gallopín 2009) and should also be incorporated into the further development of these approaches.

While the theoretical concept of social relationships with nature (Görg 2003) examines the environmental problems and the use of environmental resources and nature in the broader context of societal development, institutions, market processes, and political frameworks to explain and understand socio-ecological crises, the syndrome and archetype approaches tend to outline mainly the different natural and human components that characterize the different interactions within a specific phenomenon (syndrome). The interplay of different actors, the role of institutions and power structures are often neglected or underrepresented. The term regulation within cybernetics and the syndrome or archetype approaches are used primarily to describe self-regulation and feedback processes that buffer the impacts of external shocks, which is different to the understanding of the term in regulation theory.

Although the interpretation and the use of the term regulation differs among the various schools and approaches outlined above, a certain added value could be seen in a combination of the more social science oriented perspective on the one hand, and the environmental science perspective on the other. While the school of thought represented by Görg (2003) emphasizes the stabilization of conflicting and contradicting processes and strategies in societies and different societal occupation strategies of nature – including power relations - the concept of regulation in the context of the socio-ecological system debate also refers to a kind of stabilization linked to self-organization within and between the direct interactions of society and nature. Thus the potential application of both the concept of societal relationships with nature (Görg 2003) and the understanding of socio-ecological crises from a more environmental perspective could be beneficial if both the coupling process in the social and in the environmental sphere could be better understood and further explained by different elements and forms of regulation, including, e.g., direct forms of regulation that occur in biophysical exchange processes (e.g. material and energy flows, emissions) and symbolic and cultural processes (e.g. risk perceptions, interpretation of nature). An improved understanding of these processes is a prerequisite for developing effective strategies to stabilize or change socio-ecological systems towards a more sustainable development.

Although a full integration is not desirable and presumably not possible (different epistemologies), the added value for both streams can clearly be seen in a better understanding of the so-called coupling effect between society and nature – from a social science and natural science perspective. Furthermore, the analysis of newer developments in general systems theory and cybernetics also showed (Egner 2008) that additional theoretical concepts, such as complexity theory, might be necessary to account for non-linearity, surprise, and sudden changes, which are observable phenomena within coupling processes of socio-ecological systems in crisis and disaster situations.

Against the background of the different theories and conceptual approaches discussed, developed within the social and natural science field to capture coupling and regulation within socio-ecological systems and within the context of socio-ecological crises, the following sections will deal with the different views and conceptualizations of disasters and crises processes linked to natural hazards. Additionally, a differentiation of coping and adaptation is presented that helps to better understand change and transformation (link to regulation theory) within the context of disasters. Thereafter, the conceptual sections are juxtaposed against the empirical analysis of actual coupling and regulation processes of socio-ecological systems in Sri Lanka after the Tsunami 2004. In this context, different feedback and response processes by various actors are outlined as well as different arenas of conflict which indicate the contradictions between different response strategies and respective stabilization and destabilization processes.

68.4 Contested Views of Disasters and Crises

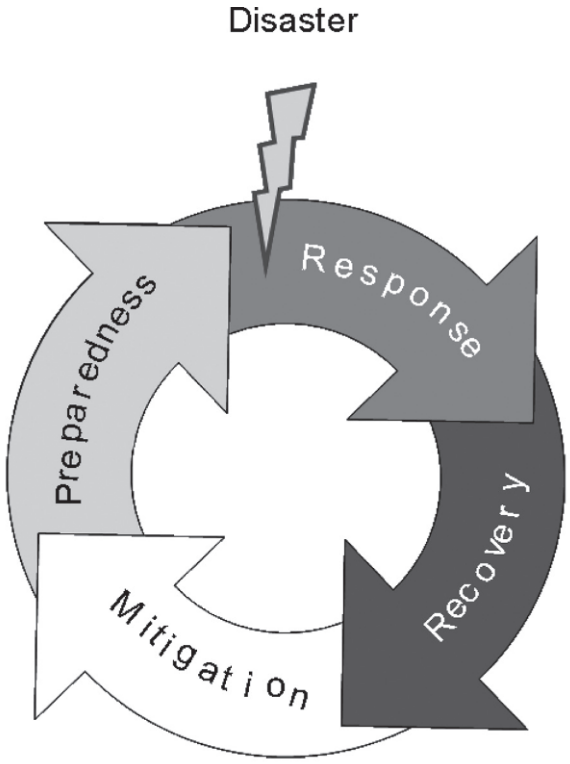
For socio-ecological crises linked to natural hazards it is a challenging task to review prevailing views and problem definitions. 'Socio-ecological crises' refer to the fact that the crises and disaster can not be sufficiently explained by social or natural factors only, thus emphasis has to be given to the critical interactions between society and nature that shape the crises. Furthermore, these crises encompass different stages,

where parts or components of the socio-ecological system might be disrupted or destroyed. This term may also encompass temporal tipping points like disaster which do not imply an irreversible breakdown of a society, but rather a peak of un-sustainable developments that is often followed by coping, recovery, and reconstruction processes.

From a process perspective, most politicians, a large majority of society and also most disaster management agencies worldwide view disasters linked to natural hazards mainly as a catastrophe triggered by an external shock impacting on societies. The external shock causes major or minor harm and disruptions within a society. Within the 'disaster cycle' it is assumed that societies respond, recover and mitigate before a potential new hazard occurs. These actions are followed by phases of risk reduction, prevention, and preparedness (figure 68.4). This cycle is a widely accepted pre-analytic vision in disaster and emergency management. According to the US *Federal Emergency Management Agency* (FEMA)[7], this cycle describes processes through which managers prepare for emergencies and disasters, respond to them when they occur, help people and institutions to recover and mitigate their effects, and reduce the risk of loss and prevent new disasters. Although preparedness and prevention are taken into consideration, the dominant view defines disasters as events caused by external forces such as floods or earthquakes. FEMA points out that "a major disaster could result from a hurricane, flood, tornado or major fire which implies that the President determines warrants supplementing federal aid" (FEMA 2007). Thus disasters are characterized as events which go beyond state capacity to deal with them effectively, and they are viewed as a result of a hazard event which is external to the society (figure 68.4).

Its underlying pre-analytic vision emphasizes the external stressor. But in reality disasters are observed as a result of parallel developments – of problematic land use, urbanization processes, lack of preparedness, a hazard event, of limited knowledge, a lack of appropriate warning procedures and surprises – which sometimes reach a tipping point where a hazard event triggers a disaster. Thus, a disaster is often caused by vulnerable conditions manifesting themselves in urbanization trends, social segregation, lack of hazard awareness, or degradation of local knowledge on socio-ecological dependencies (Wisner/Blaikie/Cannon/Davis 2004).

Figure 68.4: The Disaster Risk Cycle. **Source:** Cutter/Gall (2008: 356) based on FEMA (2007, see footnote no. 7).



Rather than viewing disasters as a single event caused by an external shock, socio-ecological crises, including disasters – understood as a broader spectrum of sudden-onset and creeping processes which might lead to a disruption or degradation of coupled socio-ecological systems – are more appropriately viewed as processes which emerge within coupled socio-ecological systems. Recent disasters, such as Cyclone Nargis (May 2008), Hurricane Katrina (August 2005), and the Indian Ocean Tsunami (December 2004) show that various past and present human-induced development trends have created a context where a hazard event could trigger a disaster. Furthermore, under the perspective of the regulation of societal relationships with nature (Görg 2003), it is important to examine intended forms of regulation to prevent or mitigate the effects of a disaster, in other words, interventions of society in socio-ecological processes prior to the occurrence of adverse events.

In the context of Hurricane Katrina for example, Kates, Colten, Laska and Leatherman (2006: 14653)

7 FEMA, 2007: "Disaster Life Cycle", at: <http://www.fema.gov/about/what.shtm>; former version at: <http://www.4uth.gov.ua/usa/english/politics/agencies/fema.html> (17 May 2008).

argue that the 'levee-effect' – i.e. levees that induced additional developments leading to much larger losses when they collapsed – was a major (negative) development chain that caused the disaster. They conclude that the US political culture often rewarded patronage at the expense of safety and efficiency. Thus, the completion of an effective hurricane protection system suffered from misplaced priorities particularly since the early 1920's (Kates/Colten/Laska/Leatherman 2006). Furthermore, misperceptions of the magnitude of the hurricane by people staying in New Orleans as well as the institutional vulnerabilities revealed after the flooding, e.g. in terms of insufficient disaster management strategies and operations, must be viewed as inherent components of the crises.

Alternative views on disasters were published since the 1980's (Hewitt 1983; Watts/Bohle 1993; Cardona 1993). The *pressure and release* (PAR) framework of Wisner, Blaikie, Cannon, and Davis (2004) also documents an alternative pre-analytic vision of disasters. The pressure and release framework underlines the development of vulnerability from general or macro-economic root causes that cause dynamic pressures and lead to unsafe conditions (Wisner/Blaikie/Cannon/Davis 2004: 50ff.). In contrast to the 'disaster cycle' or 'disaster life cycle', these frameworks view disasters as a result of different development patterns. Watts and Bohle (1993) underline the step-wise intensification of a crises process which starts with a trigger, leading for instance to a food crisis which in turn may cause a hunger crisis, along with the related consequences and potential stabilization and coping processes (Watts/Bohle 1993). Although this framework focuses primarily on a social science perspective, it can generate an added value for the discussion on socio-ecological crises by discussing those processes that stabilize or further intensify crises (figure 68.5).

While the standard disaster cycle views a catastrophe or disaster as a single major event, the framework for hunger-famine vulnerability of Watts and Bohle (1993) underlines that between the triggering event or various stressors on the one hand and the famine crisis as the most severe phase in hunger crises, additional steps and phases can be observed such as food crises. This view points out that crises and disasters are often characterized by different development steps and that the capacity to cope and deal with the different forms of destabilization as well as the baseline vulnerability are key factors that determine whether the external stressors or triggers will ultimately lead to a crisis that ends up in a disaster (figure 68.5).

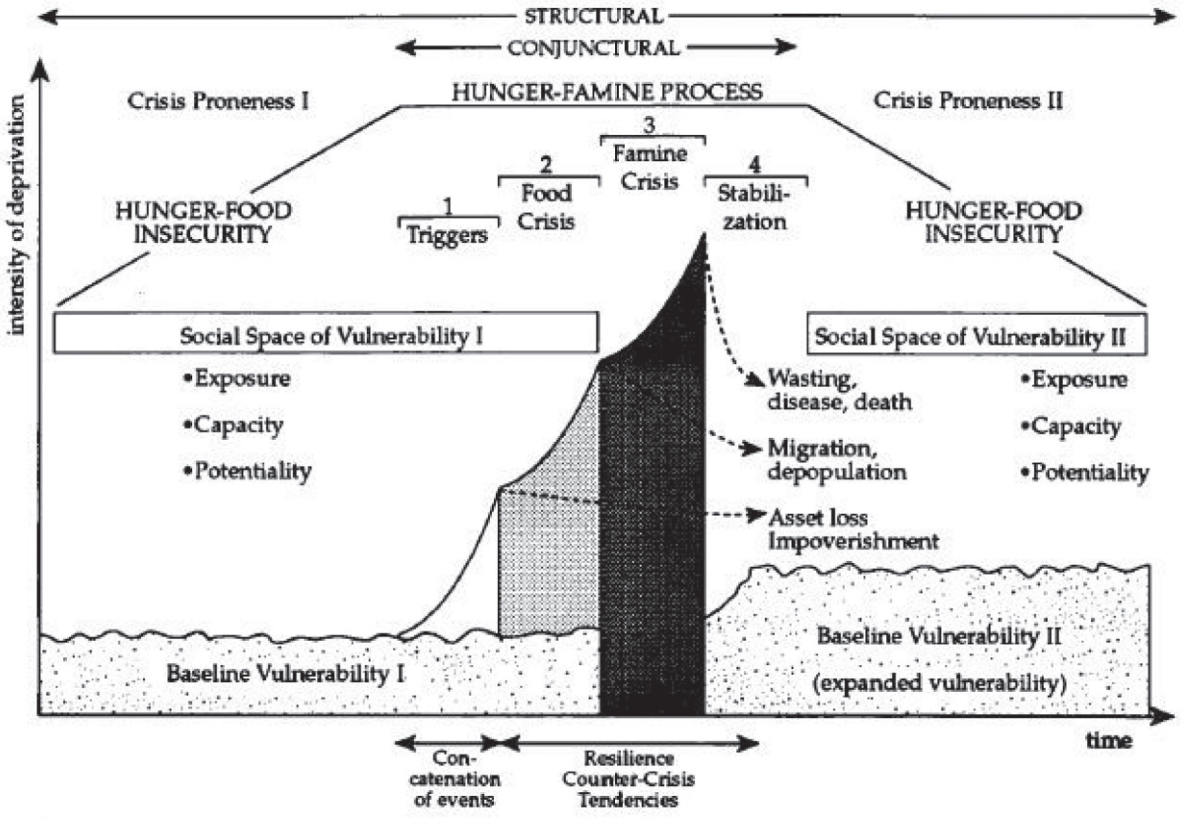
Overall, it is important to acknowledge the existence of different phases of crises and disasters due to hazards of natural origin and to examine how feedback processes, such as 'coping' or 'adaptation' as major terms in risk and disaster research, can be linked to 'stabilization', 'change', and 'transformation' that are used within the field of the regulation of societal relationships with nature (Görg 2003). These terms are discussed in the following section taking into account the theoretical and conceptual discussion of regulation and coupling reviewed above (68.2).

68.5 Coping and Adaptation – Change and Transformation

For an analysis of socio-ecological crises in the context of different concepts and theoretical approaches of regulation and self-organization, Görg's (2003) approach of societal relationships with nature distinguishes large and small crises for their influence on change and transformation. Large crises and disasters reveal the inadequacy as well as lack of capacities of institutions and organizations. Thus large disasters challenge existing structures and can trigger transformation and subsequent change. In the disaster and natural hazard literature, transformation and change due to disasters are rather new topics, since disasters used to be viewed predominantly as solely negative events which need to be prevented. However, recent studies underline that disasters might function as an important catalyst of change and social learning (Birkmann/Buckle/Jäger/Pelling/Setiadi/Garschagen/Fernando/Kropp 2009). The importance of the ability to learn individually and institutionally from past disasters is also a key insight of the newer resilience discourse (Folke 2006; Berkes/Colding/Folke 2003a).

Issues of destabilization versus stabilization as well as the notion of transformation can indirectly be linked to 'coping' and 'adaptation' (figure 68.6) in the natural hazard and vulnerability literature. If coping and adaptation are used as key feedback processes prior to, during, or after disasters to prevent harm, to bounce back or to reorganize the system at risk, more rigour is needed in the use and differentiation of terms. Do these concepts or terms differ according to their time dimension – short versus long-term actions? Or do the qualities for coping and adaptation differ? Further, in the light of cybernetics and the concept of self-regulation it is essential to understand whether and how coping and adaptation lead to stabilization or destabilization.

Figure 68.5: The hunger-famine process or chain. **Source:** Watts and Bohle (1993: 43ff.).



Different notions of coping and adaptation are used, e.g. by the *United Nations International Strategy for Disaster Reduction* (UN/ISDR) that defines coping' as:

> The means by which people or organizations use available resources and abilities to face adverse consequences that could lead to a disaster. In general, this involves managing resources, both in normal times as well as during crises or adverse conditions (UN/ISDR 2004: 16).

The *United Nations Environmental Programme* (UNEP) defines 'coping and coping capacity' in its *Global Environmental Outlook* (GEO) 3 and 4 as:

> 'The ability to cope with threats includes the ability to absorb impacts by guarding against or adapting to them' (UNEP 2002: 426), and as 'The degree to which adjustments in practice, processes or structures can moderate the potential impact for damage, or take advantage of opportunities' (UNEP 2007: 517).

The first definition clearly underlines the time specific coping characteristic, thus the processes or resources that help to face the adverse consequences of a disaster in normal times and during crises, and is thus linked to the immediate consequences of a hazard event that might lead to a disaster. The GEO reports link 'coping' to the potential to limit the impact for damage and for the GEO 3 report, coping encompasses the ability to absorb impacts by adapting to them. While UN/ISDR defines coping primarily as the immediate response capacity to a hazard event, UNEP's GEO reports view coping as a broader concept which includes adaptation.

'Adaptation' has gained a high recognition mainly within the climate change discourse. Interestingly, UN/ISDR's (2004) *Living with Risk* did not refer to adaptation among its definition of key terms. In the GEO 4 report 'adaptation' is defined as:

> Adjustment in natural or human systems to a new or changing environment, including anticipatory and reactive adaptation, private and public adaptation, and autonomous and planned adaptation (UNEP 2007: 515).

The *Intergovernmental Panel on Climate Change* (IPCC 2001: 365) defines adaptation' as:

> Adjustment in natural or human systems to a new or changing environment. Adaptation to climate change refers to adjustment in natural or human systems in response to actual or expected climatic stimuli or their

effects, which moderates harm or exploits beneficial opportunities.[8]

These definitions document that 'adaptation' implies adjustment to changing conditions or a changing environment. The time dimension is kept relatively open, thus adaptation could encompass various actions and measures. However, when examining additional literature such as Vogel/O'Brien (2004) it is evident that coping and adaptation are different concepts. While coping encompasses immediate measures that might help to deal with an actual hazard event (impact), adaptation measures should allow for a longer-term adjustment (change). Thus 'adaptation' should allow for the maintenance of the 'standard of living' also during the time of shocks and stresses linked to natural hazards, while 'coping' is short term and might imply the selling of important assets for survival. Pelling (2008) points out that adaptation requires having the information necessary to identify a potential future hazard or cause of vulnerability and to identify an alternative mode of working or living. Birkmann and Fernando (2008: 82–104) argue that coping capacities in the tsunami of 2004 in Sri Lanka were those resources and measures that helped to overcome its primary and secondary impacts. Coastal communities had to cope with the tsunami itself but also with the secondary effects, including the lack of drinking water due to the salinization of wells.

'Adaptation' rather refers to a long-term process that allows communities exposed to natural hazards or climate change to live with the hazard impacts and changes in their environmental or social conditions. 'Coping' might imply the selling of important assets or eating less during a drought, while in contrast 'adaptation' means that people change or adjust their livelihoods to the altered conditions in order to maintain major activities during droughts without losing assets and capital. Major differences between 'coping' and 'adaptation' can also be shown by linking them to 'impact' and 'change' (figure 68.6) due to disasters. In this framework coping refers to a feedback process that is directly linked to hazard impacts, while adaptation is determined by medium- and long-term adjustments and reorganization processes that correspond with the notion of change. Furthermore, the link between adaptation and change constitute transformation, which is often a pre-condition for a phase and place specific stabilization of coupled socio-ecological systems.

68.6 Regulation and Coupling of Socio-ecological Systems in Sri Lanka after the Tsunami Disaster

On the background of the theoretical concept of the societal relationships with nature (Görg 2003) and of selected approaches linked to general systems theory and cybernetics (von Bertalanffy 1972; Wiener 1948; Ashby 1985; Vester 1990, 2002, 2007), as well as resilience research (Davidson-Hunt/Berkes 2003; Berkes/Colding/Folke 2003a), the Indian Ocean Tsunami disaster and particularly the post-tsunami process including formal and informal feedback processes will be analysed below with a focus on empirical research regarding regulation and coupling of society and nature in post-disaster and recovery processes in Sri Lanka – particularly based on research in the tsunami affected cities of Galle and Batticaloa. Several coastal disasters – such as the Indian Ocean Tsunami 2004 – underline the interrelatedness of social and ecological systems, of different capitals and their crucial contribution to human well-being (Constanza/Farley 2007: 252).

68.6.1 Views and Problem Definitions

The Indian Ocean Tsunami of December 2004 with its 230,000 fatalities was a mega disaster (Birkmann 2007a). Thus, the problem identification was not controversial. But in the post-tsunami process the problem definition and respective solutions were contested, especially those factors that had contributed to the magnitude of the disaster. Many national and international organizations viewed the magnitude of the hazard event and the lack of effective hazard detection and early warning measures as the root causes which led to the disaster. Also the lack of awareness of tsunamis and the uncontrolled occupation and urbanization of the coastal belt were seen as key factors that allowed the tsunami wave to trigger this mega disaster.

Based on this assessment, various countries, including Sri Lanka, developed regional and national early warning systems in cooperation with the international community.[9] Also new organizations, such as

8 See: "Annex B. Glossary of Terms", in: IPCC (2001: 365)"; at: <http://www.ipcc.ch/pdf/glossary/tar-ipcc-terms-en.pdf> (16 June 2007).

9 IOC [Intergovernmental Oceanic Commission]/UNESCO at: <http://ioc.unesco.org/iocweb/index. php>. (14 May 2008).

disaster management centres were established. Thus, the prevailing view within national governments and organizations saw the lack of technical early warning capacities, insufficient disaster management, and uncontrolled urbanization as root causes which had led to the devastating consequences of the tsunami. Issues of inadequate land distribution, marginalization, and migration were not addressed in the first analyses made by these officials. Consequently, solutions for preventing future tsunami risks were dominated by a view that privileged technological and disaster management solutions in terms of the establishment of early warning systems as well as the strengthening of disaster management organizations (with primarily former and active military personnel) should be the underlying principles.

68.6.2 Coupling Processes

The analysis of coupling processes and of interdependencies between the coastal communities impacted by the tsunami and the tsunami itself has shown that this hazard was not generated by human actions. But its devastating impact has been directly linked to the strong dependence of affected communities on coastal livelihoods, land use changes, and the urbanization of the coastal belt. Therefore, coupling processes between social and ecological systems (see above e.g. MA or WBGU perspective) and the societal relationship with nature (Görg 2003) play a dominant role when disaster impacts and feedback processes are addressed. Thus, disaster impacts and feedback processes in the short- and medium-term, caused by different actors, must be analysed in light of the various interlinkages between coastal environmen-

tal resources and the respective social and economic structures.

In Sri Lanka, about 95 per cent of the affected communities depend on fishing or tourism as major sources of income (IPS 2005). Historic development trends and past patterns also had an important influence on the specific socio-ecological crises phenomena observed during and after the tsunami. Urbanization trends and a rapidly growing hotel sector characterize and influence the present societal relationship with nature in the south of Sri Lanka, as well as in Indonesia and the Maldives. Another important societal feature of the socio-ecological crises has been the migration of poor households to the public coastal belt during the past decades, which encompasses the immediate land by the sea which had not been occupied or sold so far. In general, in the area of the first 300 meters from the seashore, the construction of buildings is limited and requires approval of the Coastal Conservation Department (Coast Conservation Regulations, No. I of 1982).[10] While the development of the hotel industry in the coastal belt had been clearly planned, the occupation and migration of the rural poor into the coastal belt was largely influenced by the lack of alternative locations and in some cases the patron-client relationship with the politicians in that specific area (governmental land). Thus, many of these people did not choose to live close to the sea due to its attractiveness, but rather as the only place they could migrate to (Birkmann/Fernando 2008). Along the coastal strip in Galle in Sri Lanka, encroachers also settled next to the railway tracks as this is 'no-man's-land' and belongs to the state-owned railway department.

68.6.3 Key Coupling Processes of Coastal Communities in Sri Lanka

Important reciprocal interactions and coupling processes within socio-ecological systems (see e.g. general system theory and cybernetics discussed above) are determined by the strong reliance of people in coastal communities on livelihoods that are linked to coastal resources and the coastal landscape. The coupling of socio-ecological systems is especially strong for those people who are directly and indirectly working in the fishing and tourism sector. Both sectors depend directly on the access and quality of natural resources of the coastal landscape. Households working in the agricultural sector in coastal communities in Sri Lanka and Indonesia were also highly affected by the tsunami. The salinization of wells showed that for people engaged in agriculture, the tsunami and other coastal hazards can have severe consequences for the functioning of socio-ecological systems. The salinization of wells was a direct threat for humans as it disrupted the major sources of drinking water. Irrigated crops which survived the tsunami had to cope with higher degrees of salinity (Renaud 2006: 117–127).

The tsunami wave had several consequences particularly for the communities and households that were highly dependent on coastal resources, on the access to the sea, and on the environmental quality in coastal regions. Their lack of other income sources or the dependence on only one freshwater resource made households very vulnerable to direct and indirect tsunami impacts. As a consequence, unemployment was particularly high among fishermen and people who worked in the hotel sector during the first phase (first 6 months) after the tsunami (Birkmann/Fernando/Hettige 2006).

68.6.4 Post-Disaster Stabilization and Destabilization Processes

Changes of coupled socio-ecological systems after the disaster were diverse. Besides the total collapse of some coupling processes – for example for households of fishermen and their fishing activity (which was nearly absent in the direct aftermath of the disaster) - also fundamental changes in terms of the traumatization of people and the disruption of social and demographic structures could be examined.[11] The massive destabilization of a whole region due to the direct tsunami impact was rapidly followed by internal and external feedback processes that aimed to stabilize the situation. Based on research in Sri Lanka, at least six phases of stabilization and destabilization can be distinguished.

- The *first phase* is characterized by the destabilization due to the direct tsunami impact, causing death, disruption and loss of livelihoods, infrastructures and communities.

10 "Coast Conservation Regulations, No I of 1982", in: *Gazette of the Democratic Socialist Republic of Sri Lanka*, 2 September 1983.

11 See Birkmann, Fernando, Hettige, Amarasinghe, Jayasingam, Paranagama, Nandana, Naßl, Voigt, Grote, Engel, Schraven and Wolfertz (2007); Birkmann and Fernando (2008); Birkmann, Buckle, Jäger, Pelling, Setiadi, Garschagen, Fernando and Kropp (2009).

- The *second phase* was characterized by an enormous inflow of external aid and support. The analysis of the national and agency reports presented in the Relief Web[12] and by the RADA report (2005) show that Sri Lanka received (2005) financial donations and support of up to a total sum of 3.3–5 billion US$ during the first year after the tsunami (RADA 2005). Besides this enormous amount of external financial support, also various actors and aid agencies were entering the country after the disaster. Among other things, the direct disaster aid and relief included the provision of food, tents, mobile hospitals, water tanks and measures to clean drinking water within days. This rapid and massive external aid and international disaster response regimes (UN/OCHA; Flash Appeal etc.) prevented the outbreak of epidemics and – at least during the direct relief and recovery phase – functioned as an important stabilization factor. The unexpected magnitude of the tsunami donations (positive factor of surprise) and the international support received allowed the affected countries to be relatively generous on financial support for households in the most affected regions. But this stabilization also contributed to indirect destabilization processes, when local communities and affected people were receiving support without a stimulus for self-initiated action.
- The *third phase* of the stabilization and destabilization process can be separated from the direct disaster assistance in terms of the establishment of major interventions and feedback processes particularly through formal organizations at the national level. These interventions and rules comprised among other measures for example the establishment of a buffer zone and the strategy of relocation – intentionally introduced to support disaster resilient communities through a reduction of exposure to tsunamis. But these measures and interventions also induced major destabilization processes for some households – that are explained in detail below in chapter 68.6.5.
- The *fourth phase* can be linked to the reconstruction of houses and the replacement of destroyed fishing boats in the first and second year after the tsunami. The rapid reconstruction was relatively successful particularly in Aceh and South Sri Lanka, while in contrast the intensification of the civil war destroyed the progress achieved in north and east Sri Lanka.
- A *fifth phase* can be observed in some communities, such as in Galle in southern Sri Lanka, after the reconstruction of the houses and the rebuilding of the fishing fleet. Particularly in relocation sites far from the city centre and in parts of the buffer zone, social and physical infrastructure is (still) missing or insufficient. In our surveys, particularly the access to schools, the lack of appropriate transportation, and the limited access to hospitals were mentioned as problems especially in relocation sites located far from the city, such as in Walahanduwa and Kuruduwaththa in the region of Galle. This implies for some households that they have serious difficulties in sending their children to school or to commute to work on a daily basis. Thus, some of these people and relocated households – particularly those who are engaged in the fishing or tourism sector - were therefore exposed to additional problems in terms of finding a job and getting to work. Also, our household surveys revealed that the number of people shifted into another employment sectors was relatively low particularly among people engaged in fishing and tourism.
- In a *sixth phase*, re-migration from the relocation site to the buffer zone can be observed in some cases, particularly in those cases where the household owns a land plot in the buffer zone. This re-migration is a clear indicator of households aiming at a more stabilized situation, which has not been sufficiently secured in the respective relocation site.

68.6.5 Response Actions: Different Agendas, Demands and Interests

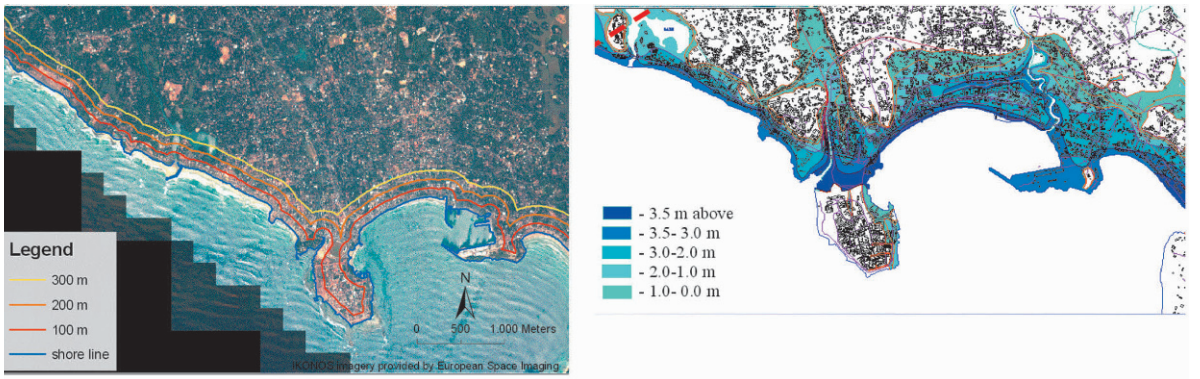
This section focuses on societal response processes where formal and informal response and feedback processes can be distinguished. Formal response actions and feedback processes included the establishment of an early warning system and the buffer zone. The latter not only posed various uncertainties for the population living in the area, but it was also a potentially positive trigger particularly for some encroachers (landless households) to overcome their chronic poverty by getting an official land title (Birkmann/Fernando 2008).

12 See at: <http://www.reliefweb.int/rw/db.nsf/doc100?OpenForm> (11 May 2008) and "Appeals & funding: Sri Lanka funding received 2005"; at: <http://www.reliefweb.int/rw/fts.nsf/doc105?OpenForm&rc=3&cc=lka&yr=2005> (11 May 2008).

Figure 68.7: The actual inundation in Galle and the 100 metre buffer-zone.

The proposed 100 Meter Buffer Zone (red line) based on own calculations. **Source**: Naßl/Voigt (2007).

Actual inundation due to the tsunami in Galle, Sri Lanka. **Source**: Hettiarachchi/Wijeratne (2008).



In Sri Lanka, according to the Coast Conservation Regulations (No. I of 1982)[13], the first 300 metres from the sea fall under the authority of the Coastal Conservation Department. Only with a special permission of the coastal conservation director is it permitted to construct or build houses for residential purposes, tourist hotels, commercial buildings, or any other structures in this area.[14] Generally, the construction of buildings without permission is illegal and the Coastal Conservation Department can order their demolition. After the tsunami, the government introduced a 'non-construction zone' which comprises a 100 meter zone from the sea in south Sri Lanka and a 200 meter zone from the sea in north and east Sri Lanka. This amendment of the Coast Conservation Act (No. 57 of 1981)[15] implies that no permission is given to build a house or other constructions for residential purposes in this buffer zone. Exceptions can be made for development activities that encompass special projects of national interest as well as for buildings and infrastructures regarding fishery or tourism (Coastal Conservation Department, no year)[16]. The leaflet of the Coastal Conservation Department states that the rules are enforced until new regulations are adopted.

The introduction of the buffer zone rule was justified with the high fatalities from the tsunami 2004 in the first 100 and 200 meters (Birkmann//Fernando/Hettige/Amarasinghe/Jayasingam/ Paranagama/Nandana/Naßl/Voigt/Grote/Engel/Schraven/Wolfertz 2007). But the buffer zone also created many problems. In particular, it generated destabilization processes with regard to recovery and the planning security of households who were affected and living in the buffer zone before the tsunami (Ingram/Franco/Rumbaitis-del Rio/Khazai 2006: 608–609). The exceptions that could and can be made for the hotel and fishery sector clearly outline the contradictory nature of the formal response (feedback processes) to the tsunami disaster. While normal residences were not allowed to return to the buffer zone, constructions and buildings for the hotel and fishing industry were allowed with special permissions. While some hotel buildings are more robust than houses of encroachers or poor households, the overall conflict between different occupation rights in the coastal belt intensified. Normal residents had to migrate out of the zone, while the hotel industry saw a chance of extending their influence and their access to land which was 'cleaned' from normal residents and encroachers after the tsunami (Klein 2007: 543). In light of the concept of societal relationships with nature (Görg 2003), the buffer zone was meant to be an instrument to promote disaster resilience against tsunamis, while it was

13 "Coast Conservation Regulations, No I of 1982", in: *Gazette of the Democratic Socialist Republic of Sri Lanka* (2 September 1983).

14 This Department can issue two kinds of permissions: a) a so-called *major permission* issued by the Coastal Conservation Department (CCD), and b) *minor (or primary) permissions* which are issued by the Divisional Secretary (DS), the equivalent of a local city district manager.

15 "Coast Conservation Act, No 57 of 1981", in: *Gazette of the Democratic Socialist Republic of Sri Lanka, Supplement to Part II* (11 September 1981): 1–21.

16 Coast Conservation Department (CCD) (n.y.): "Relevant Regulations and Permit Process for any development activity in the Coastal Conservation Zone", in: *Bulletin-CCD*, Colombo.

in reality a terrain and arena for different interest groups and stakeholders to compete against each other regarding the access to the beach and coastal belt. The actual formulation of the buffer zone rule – particularly of the exceptions made for the hotel and fishing sectors – clearly privileges the economically oriented use of the land. Thus, specific economic interests lay behind the introduction of restrictions for normal residents. The implementation of protective measures against future tsunamis and coastal hazards can therefore not be separated from the discussion about the access rights of different stakeholders to coastal resources. Formal interventions conducted after the tsunami were therefore selective and the consequence of different power structures. Additionally, the example shows that a coherent and integrative strategy was not developed; rather the example shows the temporal stabilization of the conflict structure through a formal intervention.

The large involvement of international donors and internationally operating NGOs as well as the interest of home owners generated a lot of critique with the consequence that the buffer zone was frequently amended and shortened. Paradoxically, however, the fuzziness of the actual regulation made the situation even worse, since people did not know whether they were allowed to rebuild in the same place or whether they should relocate. Hyndman (2007: 366) concludes that the buffer zones have created spaces of fear and mistrust and generated a climate of uncertainty and hopelessness regarding the reconstruction of permanent houses.

68.6.6 Arenas of Conflict

The dispute about the buffer zone regulation, but also about the general aid distribution mechanism, occurred at various levels, from the local municipality and community to the arena of international donor meetings. Although the government of Sri Lanka tried to centralize the disaster aid and recovery process at the national level within the newly created *Task Force for Rebuilding the Nation* (TAFREN), the international donors and INGOs were able to bypass these institutions by providing direct support to affected households (figure 68.8).

In some cases, this allowed for a faster and direct support for affected households, but some INGOs and donors also introduced their own procedures, agendas, and funding rules. For example in the case of the relocation site 'Salzburg', the respective manager checked and reviewed the list of selected households developed by the Divisional Secretary. In some cases the managers found that households seemed not to face major difficulties and severe losses, and therefore deleted those households from the official list for the specific relocation site 'Salzburg village'. This procedure generated confusion and difficulties, since the official list and the actual list of the specific relocation sites sometimes differed. Although the general idea of specific donors to evaluate the list of households provided by the official local government might be reasonable, the actual procedure increased the uncertainty and insecurities for people waiting for new houses in relocation sites.

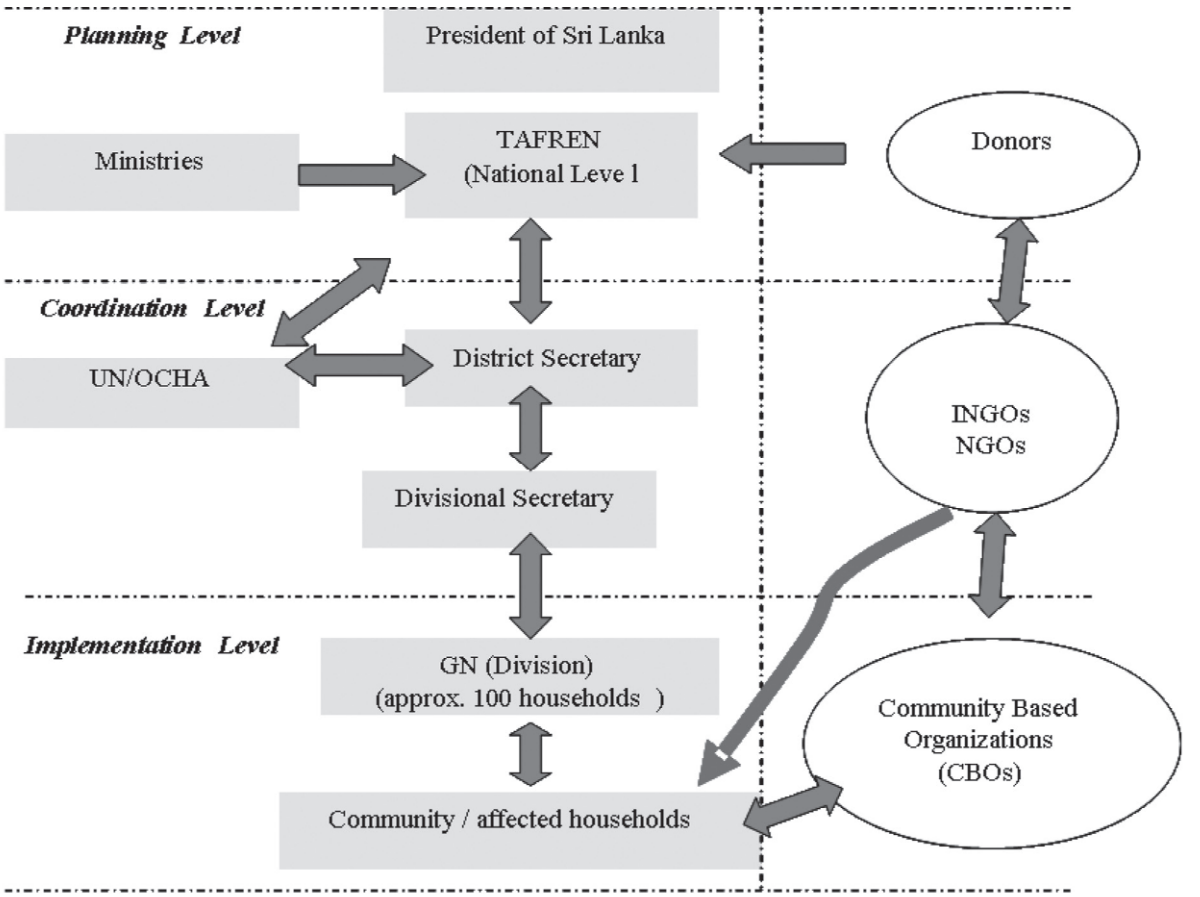
Some donors, aid agencies, and INGOs were very selective regarding the beneficiaries of their support, for example, in some cases Muslim households were primarily supported by NGOs from Muslim countries. These client-oriented policies generated additional conflicts over access and distribution of aid. In the case of Sri Lanka, particularly the civil conflict between the army and the *Liberation Tigers of Tamil Eelam* (LTTE) intensified partly due to the recovery process. Whilst international support was needed, it was not free from specific interests and agendas which in some cases generated additional conflicts within the affected regions.

In this context, Hettige (2007) concluded that the sudden influx of large numbers of aid providers overwhelmed the capacity of state institutions to effectively coordinate relief and reconstruction efforts (Hettige 2007: 5). Furthermore, the enormous inflow of external aid and financial support also generated a climate in which fast and short-term solutions were favoured while in most cases – for relocation projects and new settlements – time was needed to plan and communicate appropriately. Ingram, Franco, Rumbaitis-del Rio and Khazai (2006: 612) concluded that hurried policies with long-term implications should be avoided in disaster recovery and reconstruction to ensure that long-term vulnerability reduction can also be achieved.

68.6.7 Actors and Changes in Competence

The role of organizations also changed during the tsunami disaster response. Due to the strong financial support and funding received by INGOs, NGOs, and aid agencies, some organizations – like the Red Cross – suddenly started to rebuild whole villages, although their competence had consisted until then in relief work and disaster assistance. This may have contributed to the additional problems identified within the

Figure 68.8: Key stakeholders and their structure in the post-tsunami process, **Source:** Own figure based on Amarasinghe (2005) and Hettige (2007).



context of the (unequal) development of relocation sites and the insufficient integration of these sites into an overall planning and development strategy. Interestingly, in the study area of Galle, most relocation sites were constructed by INGOs and NGOs only, while the government had promised to build and/or secure the physical and social infrastructure in these new settlements. But in relocation sites and in the buffer zone this was not successfully accomplished. The government has not provided sufficient access to schools, transport, and hospitals in some relocation sites. Therefore, the work share between the INGOs and the government was questionable. Furthermore, Muggah (2008) also argues that the hundreds of international NGOs that moved into the country after the Tsunami 2004 undermined community structures and contributed to a misdirected distribution of assistance including the allocation of new houses (Muggah 2008: 186–215)

Further, the changes in the agendas of major external stakeholders shifting from disaster aid to the development of new villages also created new problems and difficulties, since their experience in integrated urban planning, land use, and the region was often very limited or at least not secured and audited. This distribution of work might have also allowed the state and municipalities to sneak out of their responsibility to provide adequate transport as well as physical and social infrastructure for these new settlements.

The divergent power structures with a powerful central government and rather weak local institutions also hampered the development of specific local concepts and solutions. Destabilization processes were caused by the problematic location of some relocation sites and the type of aid which entered the country. Regarding the relocation sites, the analysis of risk perceptions based on own household surveys conducted in 2005, 2006, and 2008 in the region of Galle clearly showed that some locations had been built close to flood prone areas with the consequence that people had difficulties during the flood season to get

to their place of work or to the city. The analysis of individual risk perceptions showed that particularly among those who are still living in relocation sites and who are not fishermen, the tsunami risk is viewed as significantly lower than by the average population, whereas flood risk is significantly higher prioritized by this group than by the average population interviewed.

68.6.8 Type of Assistance

Moreover, the type of assistance given may also have severe long-term consequences for the coupling processes between society and nature in the affected communities. Many donors and agencies involved in the rehabilitation focused first and foremost on the construction of buildings or the donation of fishing boats. Although all these items were heavily needed after the tsunami, some reports clearly outline that for example the fishing boats were just brought in from outside, with little opportunities for the local economy to benefit from this development (Risvoll 2006). In some regions, more fishing boats were donated than fishermen had previously owned. This tendency might lead to new destabilization processes, since the fishing grounds near the shore were already overfished in many parts. Overall, a tendency could be observed towards replacing physical structures and 'media marketable' items such as fishing boats and houses, compared with livelihood programmes or intangible support. Additionally, it was a positive surprise for the international community (UN/ISDR, UN/ISDR-PPEW, UN/OCHA) and many INGO's (e.g. German Red Cross; Misereor, etc.) that governments and the public in the 'North' donated large amounts of money for disaster aid and recovery programmes.[17] The magnitude and the speed of the money inflow for example through donations over the internet or donations by governments might also have contributed to a certain type of assistance and the spending attitude.

17 The extraordinary magnitude of financial donations made for the Indian Ocean Tsunami Disaster 2004 may also have been influenced by the huge coverage of the disaster in the mass media, the specific period of the year (duuring Christmas), and also the fact that these regions were major tourist destinations.

68.7 Conclusions

The conclusions encompass two parts. The first summarizes major findings of the empirical case study regarding the analysis of coupling and regulation within post-disaster processes. The second part combines the review of theoretical and conceptual approaches (68.2–68.5) with the empirical case study based results from Sri Lanka (68.6), and formulates key-questions that can guide future research for capturing coupling and regulation within socio-ecological crises.

68.7.1 Conclusions Based on the Empirical Case Study

Overall, the tsunami could have been an opportunity to reorganize, reconsider, and reshape management practices and organizational structures and livelihood dependencies on the sea – and could have been used as an opportunity to promote more sustainable and resilient socio-ecological systems. However, in most of the cases examined, there have been very few stimuli for these reorganization processes. While important organizational changes were introduced after the tsunami – for example the establishment of the Disaster Management Centre in Sri Lanka (Birkmann/Buckle/Jäger/Pelling/Setiadi/Garschagen/Fernando/Kropp 2009) - the most affected communities remain within their livelihood patterns and dependencies. That means that transformation of or adaptation to the tsunami risk, for example through the development of multiple livelihood strategies for coastal communities, was very limited.

Although the tsunami was a major disaster and caused a severe disruption of the life of the coastal communities, it did not bring about a fundamental change at the national or international level. Only rather technical interventions and rules were introduced amongst which the buffer zone and the relocation strategy figure most prominently.

At the individual level, most dependencies and practices in the societal relationships with nature and the reciprocal interactions within coupled socio-ecological systems were just re-established after the disaster - also due to massive external support, e.g. donation of fishing boats, etc. But the awareness of the tsunami risk is still high – as analysed in studies in the city of Galle in Sri Lanka and in the cities of Padang, Cilacap, and Kuta in Indonesia conducted by UNU-EHS. Thus there is clear evidence that the tsunami did change the perception of risk and therefore also changed some elements of the regulation of relation-

ships of society-nature interactions. The reasons why these changes in individual risk perception did not lead to further changes in communities are manifold and comprise among other issues the lack of alternative options in the post-disaster process. Thus, it is still difficult to come to a final judgement about the success or failure of different strategies to make these communities, which are deeply embedded in coupled socio-ecological systems, more disaster resilient. Particularly the diversification of livelihood patterns is still a problem. We know from our own and other disaster studies that diversified livelihood patterns in a household can make these households more resilient to the impact of the tsunami. That means insufficient attention has been given to the strengthening and reorganization of diversified livelihoods. Most donors and agencies involved in reconstruction often solely emphasized the rebuilding of physical structures and the replacement of the destroyed fishing fleet.

It has become evident that the concept of societal relationships with nature can provide an additional lens to examine different problem perspectives and respective solutions or interventions before a crisis or disaster and thereafter. Further, the concept can provide a basis for examining different phases of stabilization and destabilization that might also imply contradictory measures and actions. In contrast, the general concept of regulation theory (Aglietta 1979) does not provide a sufficient framework, since, according to this theory, changes would bring about major transformations in economic development models that are rather unlikely after disasters of natural origin. Nevertheless, the Indian Ocean Tsunami triggered many societal changes, for example the peace process in northern Sumatra, so that other pre-existing structures were indeed contested.

The discussion of these more social science based approaches and the more environmental and natural science driven approaches (e.g. MA 2005) show that the integration and combination of both perspectives is still underdeveloped. The field of system theory and cybernetics might offer an opportunity to improve the linkages between these concepts, particularly if feedback processes are examined from both perspectives, namely the social and the natural sciences. However, in this context, also epistemological differences have to be acknowledged that represent important barriers for integration.

One of the conclusions is that it seems to be more and more important to conduct longitudinal studies on the progress and failure of recovery and reorganization of communities affected by disasters linked to hazards of natural origin. This requires on the one hand a better understanding of the stabilization and destabilization processes in the medium and long run and on the other hand a more in-depth review and evaluation of changes regarding regulation elements and coupling processes of coupled socio-ecological systems influenced by the disaster from the social and environmental science perspective. Capturing these aspects is particularly difficult in north and east Sri Lanka, since these regions are still difficult to visit due to the intensification of the military conflict. In the context of interventions in coupled socio-ecological systems after disasters, international disaster aid regimes also need to be critically evaluated, for example, regarding the period of funding (often short-term) and the respective funding items.

Overall, the analysis of coupling and feedback processes in the post-disaster process in Sri Lanka underlines that besides theoretical and conceptual frameworks, the specific spatial context and the place-specific destabilization and stabilization processes in socio-ecological crises have to be examined. To better understand these coupling and feedback processes, different theories need to be applied to and modified for the specific context. As shown before, coupling and interlinkages between social and ecological systems might change fundamentally also due to the influences from higher levels, such as in this case the international aid and support received.[18]

In the context of crises, catastrophes, and collapse, Bohle (2008: 81) underlines that, given the uncertainty and the limited knowledge, one of the most important challenges is to provide affected communities and decision makers with adequate knowledge on how socially induced destabilization processes within socio-ecological systems function and how coupling processes as well as the regulation of societal relationships with nature work in case of crises.

Finally, the chapter (68.7.2) offers some guidance for further research and a synthesis of the theoretical-conceptual discussion and the empirical case study by deriving key questions for capturing coupling and regulation between society and nature within socio-ecological crises linked to natural hazards. These key

18 The actual breakdown of coupling processes (fishing, water supply etc.) could be compensated mostly through disaster aid and relief organizations for a certain period of time. The general feedback processes expected and known in normal times also change due to new rules and response actions introduced by formal organizations and governments during and after disasters.

questions are a first entry point to combine different perspectives and apply them to disasters and crises linked to natural hazards.

68.8 Key Questions for Capturing Coupling and Regulation of Socio-ecological Crises in the Context of Natural Hazards

The analysis of different theories and conceptual approaches to identify and explain coupling and regulation processes showed the variety of existing concepts. Overall, the critical review of the theories regarding their value to explain regulation and coupling processes within socio-ecological crises in the context of natural hazards showed that no theory alone can capture and/or explain the diversity of the different coupling and regulation processes between society and nature, particularly when taking into account the observed coupling and regulation processes based on the empirical case study work in Sri Lanka. However, it became evident that empirical research can benefit from parts of the theories and concepts used, since these theories are able to sharpen the research focus and to explain different aspects and processes observed and examined in the empirical case study on the post-disaster process in Sri Lanka after the devastating tsunami in 2004. While traditionally, most disaster research focuses on the sudden-onset event itself and its consequences, the theoretical approach of Görg regarding the 'regulation of societal relationships with nature' can help to draw attention to the role of crises to trigger changes within societies and their relationship to nature. Particularly the conceptual differentiation between large and small crises can also be transferred to natural hazard phenomena which might not be taken into consideration when they are small. In contrast, larger disasters can not be managed by existing institutions and organizations and therefore imply major disruptions and might lead to change. Relocation policies and the buffer-zone established after the Indian Ocean Tsunami 2004 in Sri Lanka are, among other issues, signs of these changes. However, one also has to acknowledge that the disaster response and recovery process missed the opportunity to promote change towards the development of more resilient and sustainable coastal communities as shown in the case study example.

The following key questions will serve as a guide when analysing regulation and coupling processes of society and nature within socio-ecological crises linked to natural hazards:

- What are the different views and definitions of the problem?
- Who defines the situation and relations as a problem?
- What are the major characteristics of the socio-ecological crises phenomena which manifest themselves in dynamic interactions of different components of socio-ecological systems or societal nature relations?
- What are the key interactions between the different components of these systems and relations?
- What are the elements and processes that stabilize or destabilize the relationship or coupling processes between society and nature?
- What are the changes observed after crises within the relationship of society and nature?
- Are the changes linked to the intensity of the crises (large versus small crises)?
- Is it possible to distinguish between different phases of stabilization and destabilization?
- What are the key factors underlying the transformation of relationships between society and nature or of socio-ecological systems before a collapse takes place?
- Which demands and agendas do different stakeholders have when utilizing nature or environmental resources and services?
- In which way are such contested terrains structured (actors, agendas)?
- What are potential tipping points of social, ecological, and socio-ecological systems?
- How do shocks and disruptions generate feedback processes at different scales?
- In which way do these feedback processes at different scales influence coupled socio-ecological systems within disaster affected communities?
- How do feedback processes manifest themselves in the ecological, social, and cultural dimension of relationships between society-nature and/or coupled socio-ecological systems?
- How do different temporal scales influence regulation, stabilization, and transformation?
- What types of intended regulation exist or are being implemented after disasters and which feedbacks do they provoke?
- How do issues of non-linearity and surprise manifest themselves within disasters and disaster response processes?
- What are potential interventions to promote sustainable transformation?

Overall, the questions above are a lens to examine coupling and regulation processes within socio-ecological crises linked to natural hazards. This set of questions might need to be adjusted and modified for the place and hazard specific characteristics of the respective crises. Nevertheless, these questions can guide further research particularly when aiming to explore dynamic coupling and regulation processes between society and nature in the context of natural hazards and disaster responses. Lastly, these questions should also be considered by actors dealing with recovery and reconstruction in order to ensure that strategies and actions taken after a disaster are based on a more comprehensive understanding of the complexity and dynamics of coupled socio-ecological systems. At the moment, most disaster response agencies conduct damage and needs assessments solely without taking into account the various dependencies, coupling, and regulation processes within socio-ecological systems.

69 Differentials in Impacts and Recovery in the Aftermath of the 2004 Indian Ocean Tsunami: Local Examples at Different Scales in Sri Lanka

Katharina Marre and Fabrice Renaud

69.1 Introduction and Conceptual Framework[1]

During the 26 December 2004 Indian Ocean Tsunami, Sri Lanka was one of the hardest hit countries in the affected region. The tsunami impact was most severe in the island's East and South. It was the first tsunami that occurred in Sri Lanka in living memory. Therefore, Sri Lanka was entirely unprepared for such an event.[2]

This disaster in particular re-enforces the call for a shift from a hazard focused disaster reduction strategy to a vulnerability focused approach, because the human influence on the occurrence of a tsunami (the hazard) is zero. Engineered protection measures such as breakwaters and seawalls in the near shore area of Sri Lanka do not yield a favourable cost-benefit ratio given its high costs and the very long return periods of such a tsunami (at least 400 years according to Stein/Okal 2005b). In that context Kawata (2006) recommended structural measures only for high frequency-low impact events while rare, catastrophic events should be addressed through 'soft preparedness measures' such as information and education.

The ongoing paradigm shift in the understanding of disasters from a hazard-centred perspective to a vulnerability-centred perspective leads to more multi-dimensional concepts, and more complex strategies and policies in disaster reduction (Birkmann 2006a). Extreme phenomena only become disasters if people are affected. As noted above, more often than not, there is no control over the imminent extreme phenomenon itself. However, there are usually a number of measures to directly and sustainably influence the underlying vulnerability of people with its complex, multi-disciplinary and multi-dimensional characteristics. Understanding vulnerability is the starting point for sustainable and effective policies for its reduction.

The number of definitions and concepts for vulnerability is large with no universal definition at hand and many disciplines have developed their own work-

1 The research reported here was implemented in partnership with scientists based in Sri Lankan Universities, notably Prof. K. Thedchanamoorthy, Eastern University; Prof. A. Ranasinghe, University of Colombo; and Prof. Raveendranath of Eastern University. Prof. Raveendranath has sadly been a direct victim of the civil conflict in the country shortly after the surveys were completed.

2 Seismo-tectonic Setting: From a seismo-tectonic perspective the Indian Ocean is and was known to be prone to tsunamis. Particularly along the subduction zone of the Sunda Trench the geological and seismological conditions are conducive to tsunamis and have triggered tsunamis in the past: in 1797 a M8.4 earthquake tsunami flooded Padang; in 1833 a M8.7 earthquake tsunami flooded the southern part of western Sumatra; in 1861 a M8.5 earthquake tsunami affected the western coast of Sumatra; in 1881 a M7.9 earthquake tsunami of 1 m height hit the eastern Indian coast; in 1883 after the Krakatau explosion a large tsunami affecting Java and Sumatra; in 1941 a M7.7 earthquake probably caused a tsunami. However, a tsunami like the one of 26 December 2004 with that magnitude and with that direction of propagation had not been recorded before (NOAA/NGDC 2008).
The Sumatra-Andaman Island earthquake was caused by a thrust faulting on the interface of the Indian Plate and the Burma plate (subduction rate 45–60 mm/yr). The rupture length was about 1,200 km with a width of ~200 km. The maximum displacement on the fault zone is assumed to have been ~20 m – the sea floor would have been uplifted by several meters (Stein/Okal 2005a; Liu/Lynett/Fernando/Jaffe/Fritz/Higman/Morton/Goff/Synolakis 2005). Sri Lanka is all but aseismic. The earthquake occurred some 1,600 km away and it took almost 2 hours after the rupture on the Sumatra Trench at 7:58 am local time for the first tsunami wave to reach Sri Lanka.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_69, © Springer-Verlag Berlin Heidelberg 2011

ing definition. An overview of many of those definitions can be found for example in Cardona, Hurtado, Duque, Moreno, Chardon, Velasquez and Prieto (2003a), Schneiderbauer and Ehrlich (2004), Green (2004), Brauch (2005), Birkmann (2006), and Thywissen (2006).

The research presented in this chapter focused on the differential impacts of the tsunami and is embedded in the conceptual framework of Turner, Kasperson, Matson, McCarthy, Corell, Christensen, Eckley, Kasperson, Luers, Martello, Polsky, Pulsipher and Schiller (2003) for vulnerability assessment. This framework postulates that vulnerability rests largely within the conditions and dynamics of the coupled human-environment systems exposed to hazards. According to Turner and his colleagues (2003: 8074) "Vulnerability is the degree to which a system, subsystem, or system component is likely to experience harm due to exposure to a hazard, either a perturbation or stress/stressors". Further, vulnerability is formally composed of exposure, sensitivity and resilience; these elements are dynamic, interactive and scale dependent.

Here the authors define the exposure component of vulnerability as the number of elements at risk (individuals, houses, households etc.) and the physical/environmental conditions of the location which can enhance or dampen the impact of a specific hazardous phenomenon. Those physical/environmental conditions can be the distance to the coast (for coastal hazards), the topography of the area, protective vegetation along the coast etc. The sensitivity component, as described by Turner, Kasperson, Matson, McCarthy, Corell, Christensen, Eckley, Kasperson, Luers, Martello, Polsky, Pulsipher and Schiller (2003), is the social and biophysical capital that influences the existing coping mechanisms, which take effect when the exposure is experienced. The social and biophysical responses and coping mechanisms may have a mutual effect on each other, so that a response in the human subsystem could make the biophysical subsystem more or less able to cope and vice versa. The responses of the coupled system and their outcomes determine its resilience. In general, the resilience of the coupled system can be characterized by complex feedback loops altering the vulnerability of the system altogether.

In order to prevent and mitigate for future disasters the understanding of vulnerability is crucial. Since vulnerability is a forward looking and predictive parameter there is no way of verifying it except after a disaster. In that sense the damage pattern of a disaster and the observed dynamics of disaster recovery provide unique information because they reveal all underlying vulnerability factors – known or unknown (e.g. Birkmann/Fernando 2008).

The research presented here is based on two *rapid appraisals* (RA) which were carried out with the objective to shed light on two different components of vulnerability: impact sensitivity and resilience. The authors identify some critical interactions in the coupled human-environment system that at the same time represent response opportunities for decision and policy makers leading to a reduction of vulnerability.

69.2 The Empirical Approach and its Limitation

The research in this chapter is based on two *rapid appraisals* (RA) of different characteristics and objectives (Kachandham 1992).

The first study, a comparative analysis on the district and divisional level, was carried out with the objective to gather existing data from many different sources in a relatively large area of the two districts Galle and Batticaloa. The RA offers the best results for the given financial scope, time frame, and the size of the study area. Defining a fast and low cost methodology was particularly important for the authors in order to develop a procedure that is easily repeatable with Sri Lankan capacities at a different point in time and/or in a different area. The data used was intentionally data that is generated on a routine basis in Sri Lanka, but often not easily accessible (stored in remote data repositories, in hardcopy format and written in the local languages). Thereby, this analysis provides a tool ready to use in Sri Lanka that does not involve the high costs of data acquisition.

The data gathering for this study was carried out in close collaboration with the Eastern University in Batticaloa and the University of Colombo. The meta data collection in each of the two districts of Galle and Batticaloa focused on the affected coastal *District Secretary* divisions (D.S. division which is the next smaller administrative unit in a district). Teams of researchers from Eastern University and from the University of Colombo identified data repositories, collected the data, translated them into English and converted them into electronic format. Data availability was limited and inhomogeneous and the data quality was often poor. Certain data were available in some divisions but not in others. A difficulty also arose from the fact that the political boundaries in Batti-

caloa are ambiguous. The size and number of the D.S. divisions in Batticaloa change depending on the data source. Information on many socio-economic parameters was only available on the district level (if at all). But particularly for an impact assessment it is important to consider damage and impact parameters (number of fatalities, people affected etc.) on a D.S. division level (see 69.3).

The second study, a questionnaire-based household study, had to generate new data since the information needed did not exist at this high level of detail. The RA was conducted in the Batticaloa District and targeted rural communities. It was designed to collect information on the human, natural, financial, physical and social capitals available at the household level after the tsunami, thus broadly following the sustainable livelihoods concept of DFID (1999). However, in this RA, only targeted questions pertaining to the various above assets were considered. These were incorporated in a structured questionnaire addressing personal information; household information; land ownership; crop cultivation before and after the event and irrigation methods; losses to property; affected agricultural land; distance of the agricultural activities to the coastline; displacement following the event; post-impact biophysical problems; availability of inputs (including labour) and their costs; yields of the following cropping cycle; and assistance received. The surveys were conducted in communities engaged either in paddy or vegetable cultivation systems.

The choice of the two study areas of Galle and Batticaloa was driven by one or several of the following conditions and is summarized in table 69.1 below:

- locations should be strongly affected by the tsunami;
- the locations should allow for a comparison between a Singhalese and a Tamil context;
- the towns should be large enough to encompass a number of sectors (administration, agriculture, industry) and to represent a variety of livelihood approaches;
- the locations should be accessible with respect to the security level (this condition applies to the location in the Tamil area which was and still is subject to acute conflict and restricted access).

The structure of this chapter is as follows: first the results of the two empirical case studies are presented starting with the lower resolution study analysing the impact sensitivity on the basis of selected parameters (69.3) followed by the high resolution household study analysing the resilience and coping capacity (69.4). The chapter concludes by summarizing the most important results of both case studies and discussing their implications for policy making (69.5).

Table 69.1: Selection criteria for the choice of the study areas. **Source:** For the number of victims, see DCS (2005b).

Selection Criteria	Galle	Batticaloa
Location	South West	East
Size (population)	90,000 (City of Galle)	80,000 (City of Batticaloa)
Ethnic majority	Singhalese	Tamil
Tsunami impact based on no. of victims per district	3,315	4,852
Accessibility/Security	easily accessible, safe	access limited, but possible, elevated UN security level

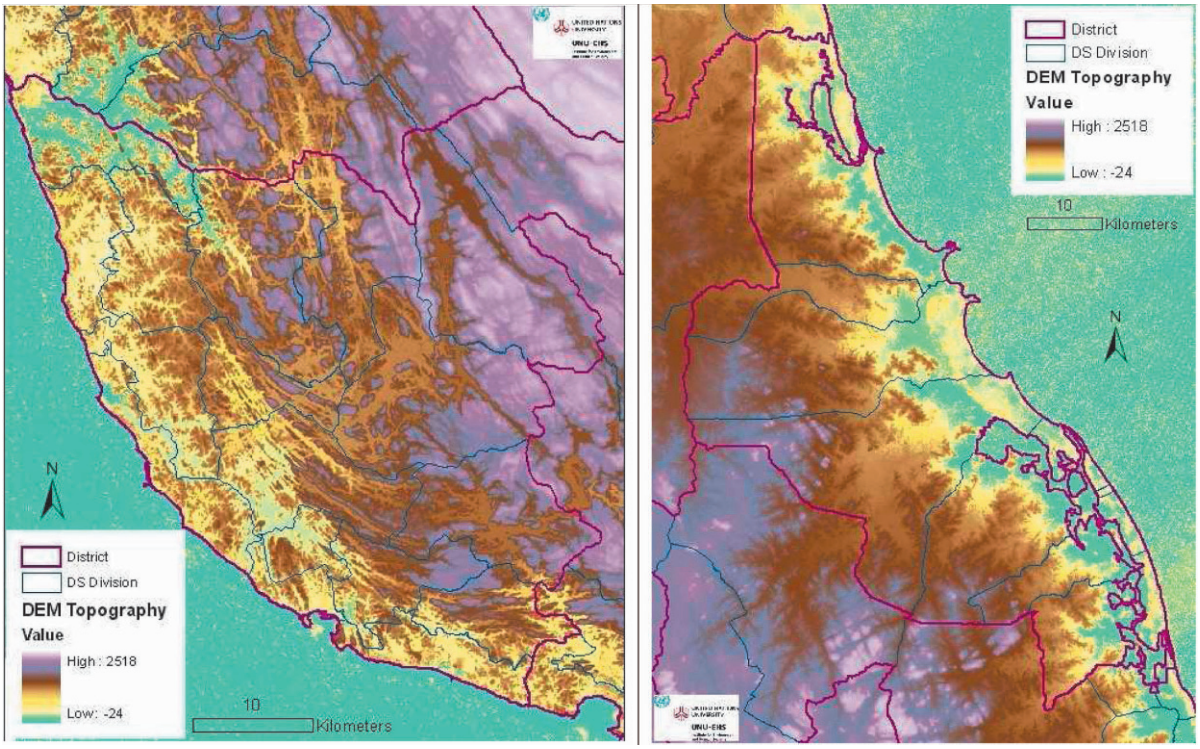
69.3 Empirical Case Study: Impact Sensitivity on the District and Divisional Level

This case study was carried out with the objective to shed light on the sensitivity towards the tsunami impact in the districts of Galle and Batticaloa by analysing and comparing the tsunami impact on the basis of a number of selected physical, environmental, socio-political and economic parameters. Thereby this study identifies those parameters that were driving the impact pattern. The authors do not claim to provide a complete picture of all possible impact parameters, but the selected parameters and their relative influence on the damage pattern provide important information for the design and implementation of disaster reduction policies that target vulnerability.

69.3.1 Physical and Environmental Characteristics of the Study Areas and Their Influence on the Tsunami Impact

The general geographic layout of the two districts is quite different: Batticaloa, located on the Eastern coast of Sri Lanka, is characterized by its 251 km long coastline and a large lagoon which parallels the coast for about 110 km. The total district area comprises 2,854 km^2 with a total population of ca. 520,000. The district capital is the city of Batticaloa with a population of ca. 80,000 in 2001 (Dept. of Census and Sta-

Figure 69.1: Landsat DEM (resolution 90 m) showing the topography in both districts. **Source:** The data for this digital elevation model (DEM) was provided by the International Water Management Institute; at: <http://www.iwmidsp.org> and processed by the authors with ArcGIS. The DEM data stem from the United States Geological Survey (USGS) that are in the public domain.



tistics 2005). The majority of the population is concentrated on the land strip between the lagoon and the seashore. The region to the west of the lagoon is sparsely populated and accommodates about 90 per cent of Batticaloa's paddy lands.

Galle, with a total population of about 991,000, is located in the Southwest of the island with a coastline of about 80 km length and a total area of 1,652 km² (table 69.2). The district capital is the city of Galle with about 90,000 inhabitants (2001). The city of Galle is the site of the second largest port in the country.

Table 69.2: Distribution of land and inland water areas for the inland water ways. **Source:** DCS (2005).

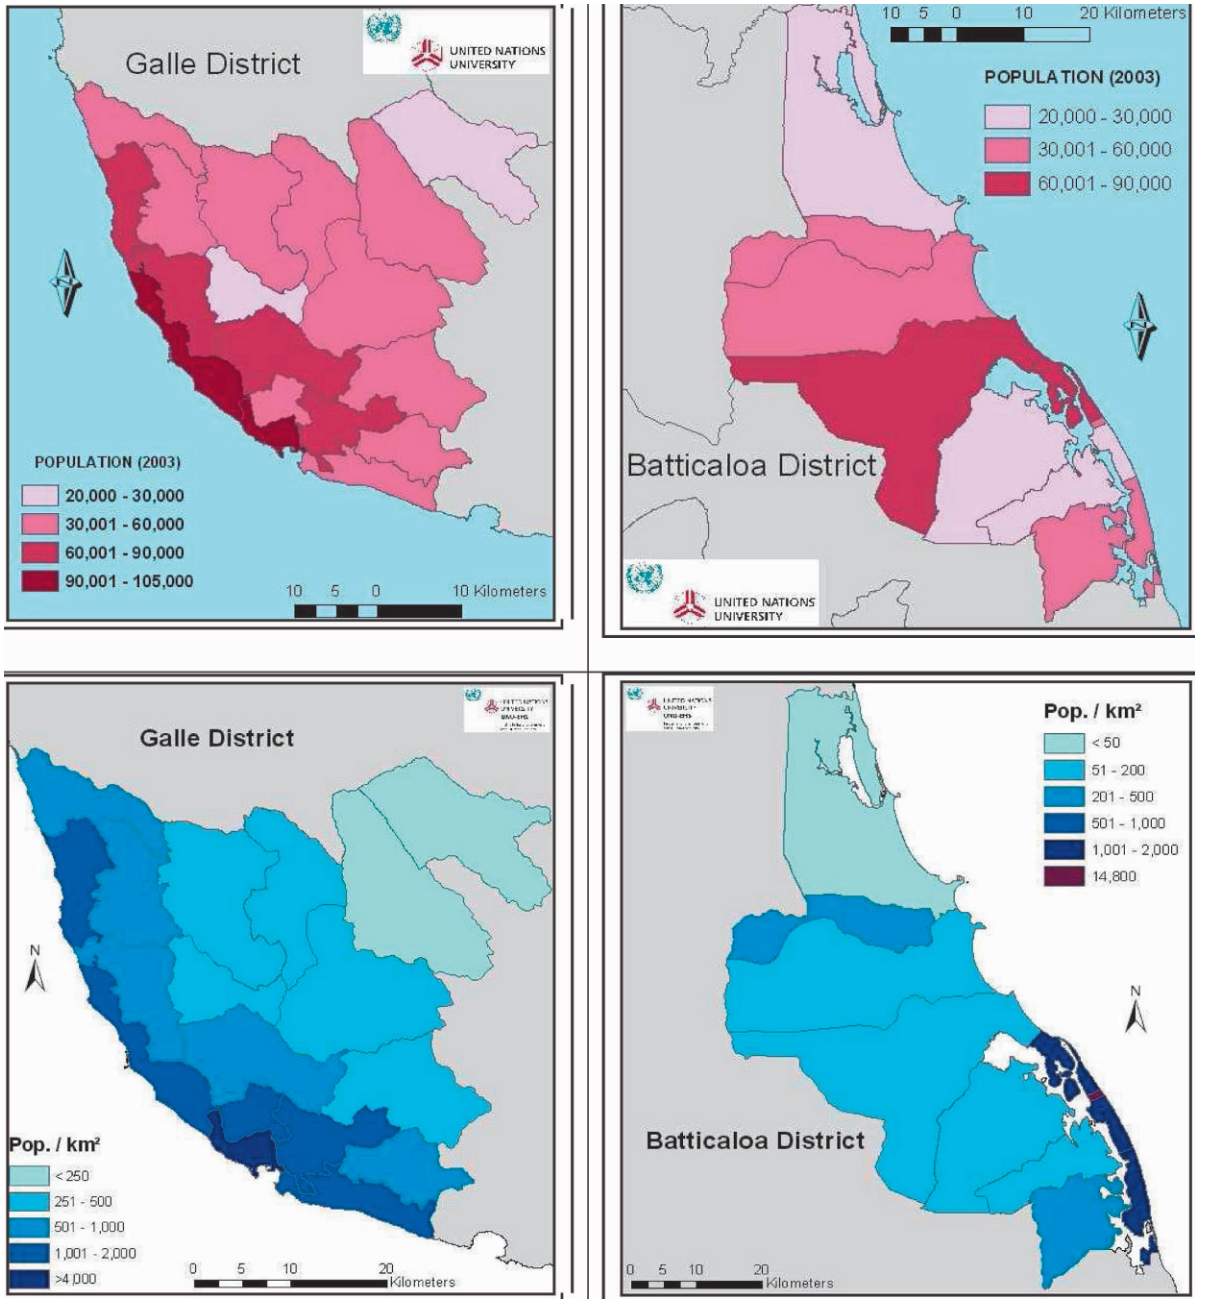
	Total area (km²)	Land (km²)	Inland water (km²)
Galle	1,652	1,617	35
Batticaloa	2,854	2,610	244

The shape of the affected districts as well as coastal topography are driving factors for the number of fatalities and affected people as well as for economic damage. A long coastline results in a higher tsunami exposure than a short coastline and hence, will prove more damage prone. Similarly, a division paralleling the coast versus one stretching far inland will suffer more losses. Of the two districts under consideration Batticaloa has the longer coastline and as the Landsat (digital elevation model with a resolution of 30 m) shows the topography along the coast is markedly flat while Galle is more elevated (figure 69.1). In both districts most of the population is concentrated along the coastline leading to a high exposure towards coastal hazards such as storm surges and tsunamis.

The tsunami reached Batticaloa between 8:00 and 8:50 in the morning (IUCN 2005). In Galle the first wave arrived at about 9:22. The wave heights documented by Liu (2005) reached a maximum of about 5 m in Galle and about 4 m in Batticaloa. The maximum inundation distance from the coast in Batticaloa was about 1,700 m according to IUCN (2005) while the median depth of encroachment was 130 m. The median depth of inundation in Galle was 70 m (UNEP 2005).

The number of people at risk is one of the basic preconditions for a large damage. The total popula-

Figure 69.2: Population distribution and density by D.S. Division in the Districts of Galle and Batticaloa. **Source:** Based on data by the Sri Lanka Department of Census and Statistics (2005b: 1-21) the figures were produced by the authors.



tion of the Galle district is almost double the population of the Batticaloa district and in both districts the majority of the population is concentrated along the coast as the population density map points out (figure 69.2).

The number of people at risk along the coast of the two districts is higher than the average population density of the districts implies, resulting in the high numbers of fatalities and affected people because a large portion of the population is exposed to the tsunami impact. Considering only the population of the coastal D.S. Divisions it turns out that in Batticaloa a higher percentage of the population is concentrated along the coast (52 per cent) as opposed to Galle (45 per cent). In addition, in Batticaloa the exposed population lives on a narrow, water-locked strip of land

(figure 69.2) of which large parts were inundated by the tsunami. This represents one important element for vulnerability assessment in the framework used here.

A scaling effect is observed when the impact on a district level is compared to the impact on the division level as the percent of the dead and missing doubles (table 69.3).

Table 69.3: Tsunami impact in terms of fatalities and people affected for Galle and Batticaloa on a district level and a D.S. divisional level. **Source:** DCS (2006: 18, 22).

Impact on the whole districts (in percent)		
	dead and missing	people affected
Galle	0.5	14
Batticaloa	0.6	49
Impact on the affected divisions only		
	dead and missing	people affected
Galle	1	31
Batticaloa	1	75

Table 69.3 shows the percentage of victims and people affected and illustrates that the tsunami impact in both districts seems to be comparable in terms of fatalities, but Batticaloa has a significantly higher percentage of affected people. The main reason for that presumably lies in the different topography. Batticaloa has a flat landscape so the tsunami waves could progress farther inland than in Galle. That is also confirmed by the inundation depths described earlier. The fact that one does not see the same difference in impact when it comes to the percentage of fatalities and missing can be explained through the wave dynamics: tsunami waves are most fatal where they have their highest momentum (determined by water level and velocity). The wave momentum attenuates rapidly when it advances inland. Therefore, the area of high-momentum impact is probably comparable in Galle and Batticaloa leading to a comparable number of fatalities.

To create the link with the vulnerability concept of Turner, Kasperson, Matson, McCarthy, Corell, Christensen, Eckley, Kasperson, Luers, Martello, Polsky, Pulsipher and Schiller (2003), this damage pattern is the result of the coupled human-environment system where certain factors in both subsystems, the human subsystem and the environmental subsystem, play unfavourably together leading to a strongly elevated vulnerability: the population distribution and density together with its atypical building stock (usually single-floor, simple brick or wood structures) of the human subsystem that intersects with the topographic and vegetation features of the environment subsystem.

69.3.2 Socio-political Factors of Vulnerability

The data on the tsunami victims show that age and gender have a strong influence on the vulnerability of the population at risk as was also shown by the survey of Birkmann and Fernando (2008). The data in table 69.4 and table 69.5 only include the number of dead and missing according to the population that lived in the damaged housing units. In comparison to the number of dead and missing recorded by the district secretariats the post-tsunami census captured only a portion of the victims: in Batticaloa 53 per cent of the victims (1,751 vs. 3,315) and in Galle 37 per cent of the victims (1,783 vs. 4,852) were captured. Therefore, there remains some uncertainty in the following statistics on age and gender.

Table 69.4: Age distribution of the tsunami victims in Galle and Batticaloa based on the post-tsunami census. **Source:** DCS (2006: 17, 21).

	Age Structure				
	0 - 4	5 - 9	10 - 18	19 - 29	> 29
Galle Population 2001	9%	9%	19%	15%	48%
Galle Tsunami Victims	13%	8%	7%	10%	63%
Batticaloa Tsunami victims	15%	14%	15%	11%	45%

The data in table 69.4 and 69.5 show that the young and very young children suffered the highest mortality. The Galle data and other reports from the literature also indicate that the elderly were highly vulnerable. This latter tendency is not clearly visible in Batticaloa, but there was no reference point for the age structure of the district before the tsunami. Overall the data showed that the 0–10 and >61 years age groups (irrespective of gender) had higher relative mortality in Batticaloa when compared to other age groups.

A systematic pattern regarding the victims' gender is even more distinct. In both districts about two thirds of the victims were women. The data from the Batticaloa District Secretariat reflect this tendency less clearly where 56 per cent of the victims are

Table 69.5: Age and gender distribution among the tsunami victims according to the post-tsunami census. **Source:** DCS (2006: 19, 23).

Dead & Missing Galle					
	Row Percentage		Column Percentage

5 to 9	46	54	18	12	14
10 to 18	33	67	13	15	15
19 to 29	18	82	6	15	11
Over 29	32	68	41	47	45
Total	36	64	100	100	100

women. Despite the different data structures, the gender and age biases revealed above are similar to observations summarized by Birkmann and Fernando (2008) in the cities of Galle and Batticaloa where they observed that female casualties and missing were significantly higher in both areas.

The causes for the high mortality among women have not been clearly identified yet, but there are numerous, rather anecdotal and speculative reasons described in the literature (MacDonald 2005):

- women stayed behind to look after their children and relatives;
- women in these areas often cannot swim or climb trees;
- the tsunami hit on Sunday morning when they were at home and the men were out on errands away from the seafront;
- women play a major role in processing the fishing catch and were waiting on the shore for the fishermen to bring in the catch.
- In Batticaloa the tsunami hit at a time when women who lived on the east coast usually took their baths in the sea.

Beyond age and gender it was of interest to this case study to find out if ethnicity and/or religion led to quantifiable differences in the damage pattern. The ethnic and religious representations in Galle and Batticaloa are expectedly very different as it was a selection criterion for the case study areas (tables 69.6, 69.7).

With 94 per cent Singhalese, Galle has less ethnic diversity than Batticaloa where 62 per cent are Sri Lanka Tamils and 36 per cent are Sri Lanka Moors. The relative homogeneity of the districts does not allow for an analysis of systematic differences within one district regarding ethnic or religious differences.

The Tamil dominated areas are located in the North and the East of the country which are also the areas that had to bear the brunt of the tsunami impact. Therefore, there is a disproportionately high percentage of Muslims among the tsunami victims. Nine per cent of Sri Lanka's population are Muslims (this percentage does not include the Northern and Eastern districts) but they account for 41 per cent of the dead. Out of the total of about 30,718 people killed in Sri Lanka 12,562 were Muslims; the Amparai district alone accounted for 7,258 (58 per cent) of the total Muslim fatalities.[3]

With respect to the coupled human-environment system, the above paragraph provides insights on the demographic subsystem. It also points out a crucial issue for any vulnerability assessments on the basis of the coupled human-environment system: It is important to determine which of the subsystems contain the drivers and which contain the circumstantial factors. According to the fatality statistics the Muslim population group seems to have a much higher vulnerability. However, the historically, politically and culturally determined distribution of the Muslims places the majority of them in the North, East and South East. Those areas coincide with the highest physical tsunami impact and the flattest topographic profile. Therefore, the vicinity to the hazard together with the environmental factors (environment subsystem) are the driving parameters of the impact pattern, while the ethnicity in this case represents the circumstantial factor.

3 The number of Muslim fatalities were mentioned in Yahoo India News, 2005: "Lanka's tsunami dead."; at http://in.news.yahoo.com/050515/32/5yjxx.html> (30 June 2006): 1.

69.3.3 Economy and Poverty as Vulnerability Factors

Sri Lanka is economically, ethnically, linguistically, and religiously very diverse. In addition civil unrest and conflict between the *Liberation of Tamil Tigers Eelam* (LTTE) and the Singhalese government of Sri Lanka has been going on since the 1950's. This conflict has strong repercussions not only on the welfare and security of the population but also on the national economy and development as well as severe impacts in conflict areas such as in Batticaloa (Bohle 2007). Sri Lanka's main source of gross national product is agriculture, forestry and fishing is 17.9 per cent in 2004 (Economist Intelligence Unit 2006). The main export goods are textiles, tea, precious stones and petroleum.

The tsunami of December 2004 caused tragic human loss and trauma to Sri Lanka's population but the immediate impact was restricted to the coastal areas. Even though the GDP at constant 1996 prices dropped from 2004 to 2005, this drop was more likely to be related to political unrest and high oil prices rather than to the tsunami (table 69.8).

For the Sri Lankan economy the course of the peace process was then a major uncertainty and immediate threat. In the aftermath of the tsunami, the Economist Intelligence Unit (2006: 2) noted:

> Even if the country does not revert to war, increased militant activity could dampen growth through its negative impact on the services sectors (primarily tourism) and investment. [...] Nevertheless, GDP is likely to expand by an annual average of 5.7 per cent in 2006/7, owing to a strong recovery in agriculture in 2006 and ongoing robust growth, both in industry and also in services sectors [...]. Growth in services will return to trend in 2006/7 as tourism recovers from the effects of the tsunami. Tsunami-related reconstruction, combined with the start of infrastructure projects in power, roads and ports, will boost investment.

For 2006/2007 the Economist Intelligence Unit indicated that the tsunami could even have an economically stimulating effect. On a national scale the impact of the tsunami had reached a turning point where the losses were turned into opportunities. The relatively positive outlook made in 2006 was overshadowed by the deterioration of the conflict situation in Sri Lanka that was prevailing then. After numerous violent incidents inflicted on both sides in 2007, the government formally annulled the ceasefire agreement in January 2008 that had been signed with the LTTE in 2002. Those developments were then expected to dampen the eco-nomic development: foreign investments were likely to decrease, the real economic growth could slow to 4.6 per cent from an estimated 6.5 per cent in 2007 (Economist Intelligence Unit 2008). The conflict-related situation in Sri Lanka has dramatically changed in 2009 and the projections made before that date have now to be reassessed.

According to the summary of the national economic situation in 2005/6 the tsunami had only a

minor impact on Sri Lanka. Since large and economically strong parts of the country were not affected by the tsunami this national overview can only provide a smoothed picture of the economic impact of the tsunami. As it will be shown in this section, the higher the resolution of the analysis the more drastic an effect of the tsunami will be revealed, the highest impact being seen on the household level.

In UNDP's (2006) ranking of 177 countries according to their *Human Development Index* (HDI) Sri Lanka occupies rank 93. The mean household income differs quite strongly from province to province and is lowest in the conflict stricken Northern and Eastern Provinces (table 69.9).

Table 69.9: Mean monthly household income per province. Source for all Provinces except Northern and Eastern. **Sources:** DCS (2004: 2). *Source for the Northern and Eastern Province: DCS (2003: 3).

PROVINCE	Mean monthly household income (Rs) 2002
Western	17,732 (170 USD)
Central	11,175 (107 USD)
Southern	11,229 (108 USD)
North Western	10,918 (105 USD)
North Central	9,926 (95 USD)
Uva	10,388 (100 USD)
Sabaragamuwa	8,439 (81 USD)
Northern*	**8,155 (78 USD)***
Eastern*	**7,640 (73 USD)***

The level of poverty, social and human security in the country changes with the region, profession and other parameters. Poverty has been defined by the Department of Census and Statistics (DCS 2002) as the barrier to prosperity and lack of resources and opportunities, feelings of being disenfranchised from various support systems (i.e. educational, economic, cultural, and social), and diminished feelings of empowerment to obtain these resources and opportunities. As such it is a very complex and personalized parameter and rather difficult to quantify in its entirety. Thus, poverty is usually measured by means of proxies, such as income and expenditure. The Sri Lanka *Department for Census and Statistic* (DCS) carries out a '*household income and expenditure survey*' (HIES) in a 5 years interval.

The poverty information in this study stems from the HIES in 2002 and 2003. The DCS defines the poverty line as the amount necessary to purchase a defined consumption basket that is needed to meet nutritional and basic living needs and the per-capita expenditure needed to meet a nutritional intake of 2030 kcal, which was set at 1,423,- Rs in 2002. Due to cost, that survey has only been possible on a district level excluding the Eastern and Northern districts. Based on the district data the Department for Census and Statistics estimated poverty levels for the D.S. Divisions based on the 'small area estimation technique', by combining census and household data. It becomes evident that this study compares a district in the poorest province (Batticaloa in the Eastern Province) with a district in one of the most affluent provinces (Galle in the Southern Province). On a district level this already indicates very different financial coping capacities (table 69.10).

Table 69.10: Comparison of the monthly household income [in Rs] in Galle and the Eastern Province. Data on the district of Batticaloa alone were not available. **Sources:** *Data source (DCS 2002: 4) and **data source (DCS 2003: 5).

	Mean household income 2002	Median household income 2002	Monthly average household expenditure (2002) (food and non-food)	Poverty line (2002)
Galle District*	12,724	8,800	11,901	1,466
Eastern Province**	7,640	5,500	10,769	No data

According to the DCS (2002) 27 per cent of the population in Galle lived below the poverty line. In Batticaloa no information on the poverty line was available but the district profile from 1999 specifies that 76 per cent of the families lived on less than 1,000 Rs per month (equivalent to 10 USD). Bearing in mind the incomparability of the numbers at hand, the general differences in poverty between these two districts is still evident with Batticaloa being the much poorer district.

The Census Department has carried out a survey on the damaged housing units in all tsunami affected districts. This survey revealed that the household income of the completely damaged housing units (completely damaged + partially damaged un-usable) and the partially damaged housing units (partially dam-

Table 69.11: Grouping the affected housing units by damage degree and household income. **Sources:** DCS (2006: 18, 22).

		<5,000 Rs	5,000-9,999 Rs	>10,000 Rs
Batticaloa	Completely damaged	73	17	7
	Partially damaged	63	23	11
Galle	Completely damaged	49	25	25
	Partially damaged	36	27	35

aged usable) varies systematically between the two damage classes.

Table 69.11 shows that the damage degree is selective, with poorer households suffering more severe damage to their houses. This trend occurs in Galle as well as in Batticaloa but in the latter district this trend is more pronounced. The reason for this trend can most likely be found in the distribution of the breadwinner's occupation and their general level of income. Families living close to the coast, i.e. the more exposed families, were more likely making their living from fishing, which provided lower incomes than e.g. the service sector. That means the pattern of occupation of the coastal population often puts poorer households and lower quality houses close to the more exposed shoreline.

Table 69.11 also illustrates that the households in Batticaloa with their smaller income have significantly smaller financial coping capacities. That was confirmed in a household survey by Birkmann and Fernando (2008) who estimated the time span households needed in both districts to fully recover from their economic losses. Batticaloa households needed significantly longer to recover than households in Galle.

69.3.4 Livelihood Factors of Vulnerability

The employment distribution has been surveyed by the DCS in 2004 before the tsunami (table 69.12).

The type of occupation proved to be an important factor for the Tsunami impact and recovery where two factors interact. The first factor lies in the different exposure of the various occupations. Nearly 90 per cent of the fishermen have been seriously affected, with nearly 80 per cent of the country's fishing vessels being destroyed (ITDG 2005). According to the DCS (table 69.13 below) only 22 per cent of the persons engaged in fishing (that does not include subsistence fishing families) were still engaged in fishing after the tsunami in Batticaloa. In Galle that percentage amounted to 35 per cent. In contrast, 95 per cent of the persons under government employment in Galle and 92 per cent in Batticaloa were still engaged in that sector after the tsunami.

Table 69.12: Comparison of the employment distribution of 11 different employment groups in Galle and Batticaloa (in per cent). **Sources:** DCS (2004a: 11).

	Galle	Batticaloa
Senior Officials and Managers	0.6	0.7
Professional s	5.9	6.5
Technical and associate professionals	6.2	7.7
Clerks	4.3	2.1
Proprietors and managers of enterprises	14.5	2.0
Sale and service workers	6.6	12.3
Skilled agricultural and fishery workers	15.4	22.2
Craft and related workers	14.1	17.0
Plant and machine operators and assemblers	3.8	5.9
Elementary occupation	27.5	23.4
Unidentified	1.0	0.2

Table 69.13: Number of people employed in fishing and government before and after the tsunami. In both districts the government sector is much less affected by the tsunami . **Sources:** DCS (2005: 1).

	Engaged in fishing		Government employment	
	before	after	before	after
Galle	2,213	769	2,445	2,313
Batticaloa	4,413	949	2,615	2,397

In Batticaloa the proportion of the population engaging in fisheries is significantly larger than in the Galle District (table 69.14). Thus, the economic impact of

the tsunami on households was more severe in Batticaloa.

Table 69.14: Number of fishing households in Galle and Batticaloa. **Sources:** Ministry of Fisheries and Aquatic Resources (2004), quoted in: DCS (2005).

	Fishing Villages	Fishing households	Active fishermen	Population of fishing households
Batticaloa	172	16,700	21,600	86,020 (~17)
Galle	155	6,700	6,300	21,960 (~2)

The second factor lies in the wages paid in different industries (table 69.15). Agriculture and fisheries are paying the lowest wages, whilst the service sector pays the highest. Hence, in Batticaloa, with more people working in the fisheries and in the agricultural sector, the economic coping capacity has been lower than in Galle. Table 69.13 above shows that the ratio between government employees to fisheries employees (before the tsunami) was 59 per cent in Batticaloa and 110 per cent in Galle.

Table 69.15: Comparison of the monthly wages in Sri Lanka between the sectors agriculture (incl. fisheries), industries, services. **Source:** DCS (2006a: 9); * Includes fisheries.

Monthly wages [Rs]			Daily wages [Rs]		
Agriculture*	Industries	Services	Agriculture	Industries	Services
5,866	9,016	12,791	4,048	6,630	6,089

In terms of impact sensitivity, the type of occupation is one of the driving factors of economic vulnerability and coping capacity of the affected population. However, that relationship between the type of occupation and vulnerability is strictly hazard specific. That particular pattern of relationships is only valid for tsunamis and storm surges (coastal hazards). The pattern would look very different for other hazards such as droughts, storms, river floods or fires. In the case of droughts for instance, the most exposed occupational group is the farmers not the fishermen.

In Batticaloa many livelihoods are based on agriculture (29,000 families) and fishing (16,000 families) (Eastern University 2001). Coastal agriculture was also severely affected by the tsunami. The force of the tsunami waves, salt water and debris intrusion affected the crops in the fields and salt water intrusions polluted many freshwater wells in the coastal area. However, overall paddy production of the district was not severely impacted (table 69.16).

Table 69.16: Comparison of the paddy yield (kg per Ha) in the Maha seasons from 2002 to 2006 **Source:** DCS (2007: 4).

	Maha 2002/3	Maha 2003/4	Maha 2004/5	Maha 2005/6
Galle	3,438	3,383	3,711	3,498
Batticaloa	2,581	2,815	2,360	3,207

Here again, the aspect of scale is crucial as productivity lost in the narrow tsunami-affected coastal fringe could have been compensated by increased productivity outside of that fringe. When looking at the tsunami impact on agricultural households in Batticaloa the strong impact as well as different coping capacities and recovery strategies between different farming communities and households becomes evident. The next part discusses this issue based on a field study that was carried out in the district of Batticaloa in 2005.

69.4 Empirical Case Study: Differentials in Recovery on the Household Level in the Agricultural Sector

So far the different characterization of the two districts in combination with a scale-dependant extent of damage highlighted the inherent difficulty to measure and compare vulnerabilities. It also showed which parameters were the driving underlying vulnerability factors of the damage pattern that was observed after the tsunami (environmental conditions, age, gender, poverty, occupation/income). The public interest in disasters usually tapers off rapidly after the immediate humanitarian relief phase. But the length and course of the recovery phase is a crucial aspect of the disaster impact. Are affected families able to return to a pre-disaster impact stage and how long does it take them, what aid mechanisms are being used? These questions in an agricultural context were the basis for the household study that was carried out in Batticaloa one year after the tsunami. The aim was to find out if and how farmers in seven tsunami affected villages in Batticaloa were able to re-engage in agriculture, what were their main obstacles and what aid they had received if any – within the specific conflict constraints of the country at the time. The area under consideration was

highly exposed to the tsunami, sensitivity before the tsunami was already high with respect to both human (poor communities living in a conflict area) and environmental (e.g. pollution of coastal aquifers) conditions. Coping responses were reduced because of the conflict situation, the impact of the event was high and adaptation opportunities reduced, again because of the conflict. All these elements underline the high vulnerability of communities when referring to the vulnerability model of Turner, Kasperson, Matson, McCarthy, Corell, Christensen, Eckley, Kasperson, Luers, Martello, Polsky, Pulsipher and Schiller (2003). Nevertheless, there were disparities in impact and recovery between the surveyed areas which are analysed further below.

The impact of the tsunami in terms of agricultural production at the national scale was not significant. This is illustrated by the fact that the performance of the agricultural sector nationwide improved in the first quarter of 2005 thanks to favourable weather conditions as paddy rice value-added grew by 19.1 per cent (DCS 2005a). This is also due to the fact that the tsunami affected only relatively small amounts of arable land when considering the entire country, whereas an activity that takes place almost exclusively on the coastline such as fishery, saw its value added decrease by 68 per cent in the same quarter of 2005 (DCS 2005a).

Although the impact on the agricultural sector nationwide was not detected in official statistics, the tsunami destroyed the livelihoods of many farming families locally, notably in the East of the country. The tsunami destroyed or severely affected most of the resources required for agricultural production such as human and financial assets, land, water, and equipment. However, the time-scale of the effect varied depending on the asset considered.

The study area belongs to the low country dry zones with a mean rainfall in the district of 1,500 mm with close to 80 per cent falling during the Maha season from October to January (Raveendranath/Arulnandhy 2005). Approximately 80 per cent of the population of the District depended on agriculture for their main source of income (Raveendranath/Arulnandhy 2005). Two agricultural systems were investigated.

Farmer households were interviewed in a total of seven villages in September and October 2005: Mavadiodai (n = 29 farmers), Kokkuvil (n = 4), Farm Colony 211F (n = 6), and Mankerny (n = 21) all engaged in paddy cultivation (hereafter called PS for Paddy System), constituting a total sample of 60 farmers out of a total of 107 farming families living close to the seashore in these areas; and Kaluthawala (n = 60), Mankadu (n = 10), and Cheddipalayam (n = 10) all engaged in the cultivation of vegetables (hereafter called VS for Vegetable system), a total sample of 80 farmers out of a total of 305 farming families living between the sea and the lagoon. Farmers were selected randomly from the survey areas and interviewed individually. The paddy cultivation system is only rainfed in this region with one crop per year during the maha season. The vegetable cultivation system consists in the cultivation of various crops such as brinjal, onions, okra, tomatoes, chilli, various legumes such as bushitao or cowpea, and gourds such as snake gourd. Crops such as brinjal, okra, tomatoes are cultivated twice a year, cowpea three times a year and all the rest once a year. The crops are irrigated from either wells tapping shallow groundwater (agrowells) or from surface retention ponds.

69.4.1 Results of the Agricultural Household Survey in Batticaloa

Despite the fact that farmers interviewed had the same ethnic background (100 per cent Tamil) and similar religious beliefs, there were large differences in household parameters between the two locations as is depicted in table 69.17.

Table 69.17: General information concerning the household heads. n = 60 for paddy area and n = 80 for vegetable area. **Source:** Based on the field study by the authors and their collaborators.

Parameter	Distribution (per cent)			
Age	< 30	30-60	> 60	
Paddy	41.7	55.0	3.3	
Vegetable	16.3	73.7	10.0	
Religion	Hindu	Muslim	Christian	Burger
Paddy	80.0	0.0	20.0	0.0
Vegetable	98.7	0.0	1.3	0.0
Education	No schooling	Primary	Secondary	Tertiary
Paddy	60.0	30.0	10.0	0.0
Vegetable	2.5	41.2	36.3	20.0

Farmers involved in vegetable farming generated a higher monthly income than those involved in paddy farming, an indication of the higher value of the commodity they produced. However, it needs to be kept

in mind that investments in vegetable farming are higher than those in paddy farming (e.g. Kielen 2005).

Table 69.18: Income distribution for the two agricultural systems under consideration. Income distribution (per cent) in the two agricultural systems. Income is in Sri Lankan Rupees (USD 1 = 100 Rs). **Source**: Based on the field study by the authors and their collaborators.

Monthly income (Rs)	**Paddy System**	**Vegetable System**
< 2000	28.3	16.3
2000 ñ 5000	70.0	21.3

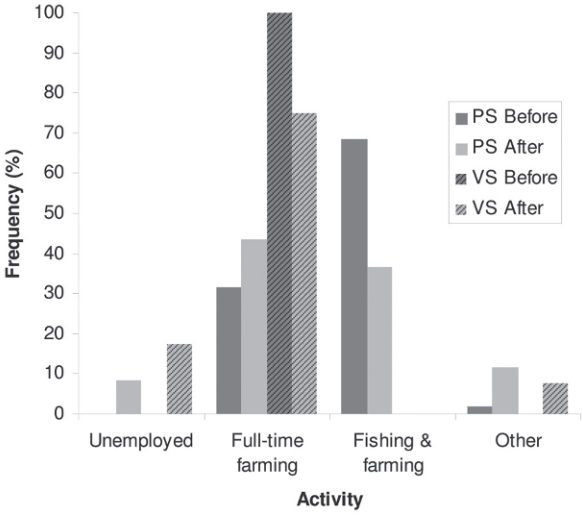
Only 32 per cent of the household heads in paddy farming considered themselves full-time farmers with 68 per cent of the reminder having other activities aside from farming (predominantly fishing but also waged labour and small businesses). Since the dependency on one type of income is not as strong as for less diversified households which fully depend on one type of income, this relatively high percentage of alternative incomes make, in principle, the paddy farming households less vulnerable than the vegetable farming households, particularly in terms of coping. Unfortunately this principle does not apply in this case as the fishing sector was also severely affected by the tsunami.

In contrast, 93.6 per cent of the vegetable farmers considered themselves full-time farmers and had more farm experience than paddy farmers (80 per cent had been involved in farming for more than 10 years as opposed to 21.6 per cent in paddy farming). This is due to the fact that their main activity is farming so the farming tradition and generational transmission is stronger than in paddy farming. In addition, 43 per cent of the adults other than the household head in paddy farming were involved in farming before the tsunami, decreasing to 32 per cent after the event, whereas the proportions for vegetable farming were 47 per cent and 43 per cent, respectively.

69.4.2 Consequences of the Tsunami on the Agricultural Activity

The impact of the tsunami on the resources of the farmers combined with opportunities brought about by reclamation activities affected employment patterns in the villages surveyed. After the tsunami, the proportion of full-time farmers engaged in paddy cultivation increased to 43.3 per cent as sea-fishing activities were severely disrupted and more government land was made available to farmers. 20 per cent of the farmers either became unemployed (8.3 per cent) or engaged in other activities than full- or part-time farming (11.7 per cent). Changes also took place in vegetable farming where all farmers were involved in farming before the event (97.5 per cent full-time and 2.5 per cent part-time) while 17.5 per cent of them became unemployed and 7.5 per cent were engaged in other activities after the event.

Figure 69.3: Farming activity before and after the tsunami. **Source:** Based on the field study by the authors and their collaborators.



Paddy farmers mainly farmed government land (67 per cent of surface area), while owned land represented approximately 29 per cent of their cropped area and the amount of leased land was very small (table 69.19). To farm government land, farmers have to apply to the Divisional Secretary and are then allowed to clear land and farm rent-free. Land ownership did not change after the tsunami but there was a slight increase in the amount of government land availability. It is important to note that having access to government land does not mean that the land was farmed at the time of the interview as some farmers could not re-engage in agriculture for various other reasons. In contrast, most vegetable farmers owned land (78 per cent of farmed land), the remainder being leased. This ownership is an important component of vulnerability as it represents an important criterion in terms of sensitivity and coping representing an available capital that can be accessed in case of

Table 69.19: Land ownership before and after the tsunami (ha). **Source:** Based on the field study by the authors and their collaborators.

Crop System / Land	Before tsunami			After tsunami

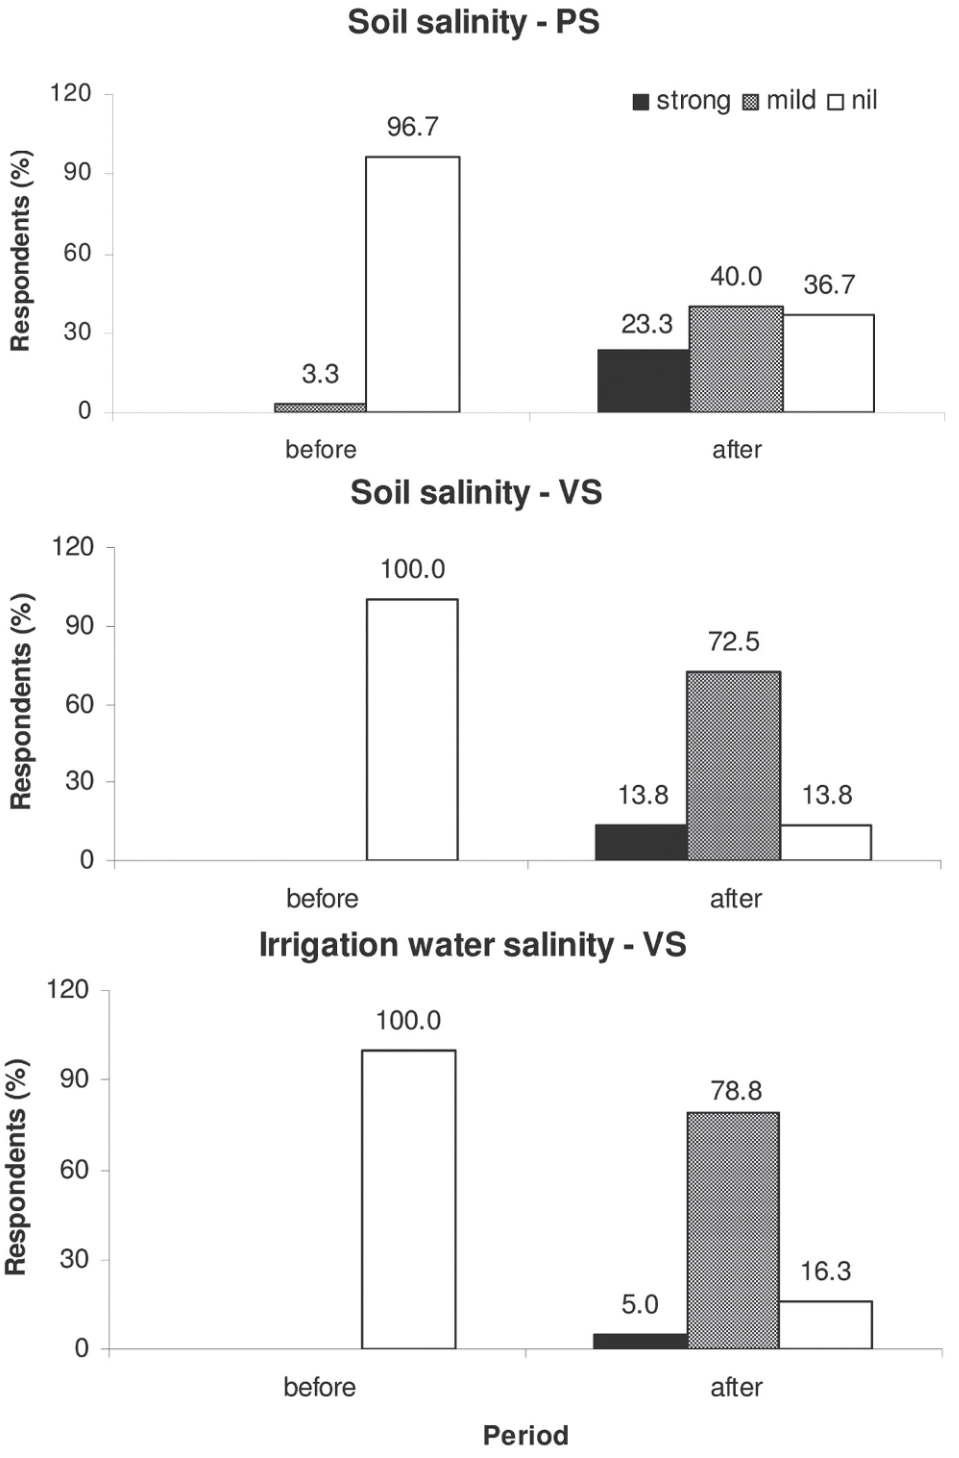
need (see Ingram/Franco/Rumbaitis-del Rio/Khazai 2006). Here too, land ownership did not change, but there was a decrease in the number of farmers leasing land and in the surface area of leased land after the event (table 69.19), reflecting the fact that some farmers were not able to re-engage in farming after the event. Some leases were still running though and although not farming, some farmers still had to pay rent.

69.4.3 Impact on Crops, Land, Irrigation Water and Equipment

More than three-quarters of all the land (79 per cent) farmed by the respondents in paddy farming after the tsunami was affected by the seawater while 86 per cent of the land farmed by farmers after the event in vegetable farming was affected. The term affected implies here a loss of income whereby some crops were destroyed during the event or subsequent problems were observed such as salinization of land or freshwater. For vegetable farming, the surface area cultivated decreased by more than 50 per cent the season following the tsunami when compared to the pre-impact situation, although it needs to be noted that in a few occasions, the exact quantified extent of cultivated area was not exactly known to the farmers and the collected data were estimations. With the exception of gourd, all other crops were cultivated on less land. A similar comparison could not be made for paddy farming as no data were available concerning the extent of rice put in production at the time of the interviews. The monetary loss was much higher in

Figure 69.4: Farmersí opinion of post-tsunami soil and irrigation water salinity problems one year after the event (PS = paddy system, VS = vegetable system). **Source:** Based on the field study by the authors and their collaborators.



vegetable farming than paddy farming as vegetables require more investments than paddy rice but then are sold at much higher prices (table 69.20). This partly explains why the amount of land cultivated after the event in vegetable farming decreased by more than

half as farmers could not afford to cultivate (and thus re-invest) the entirety of their land.

The perception and/or experience of the farmers was that a year after the tsunami, some of their land still suffered from salinity problems despite the fact that a full cycle of rainy seasons had taken place (figure 69.4). For paddy farming, only 3.3 per cent of the respondents considered that some of their land was having mild salinity problems before the impact.

One year after the tsunami, 23 per cent of farmers estimated that some of their land still had severe salinity problems and 40 per cent believed their land had mild salinity problems (the degree of impact was based on their perception of the disruption of their activities). In vegetable farming, no salinity problems for soil or irrigation water were observed before the tsunami. However, mild salinity was reported by a majority of the farmers for both soils (72 per cent) and irrigation water (79 per cent) and strong salinity by 14 per cent and 5 per cent of farmers, respectively. Paddy farming is rainfed but in vegetable farming irrigation is required and 32.5 per cent of the respondents had agro-wells.

In addition, the tsunami affected the agricultural equipment of farmers as well as other means of production. Paddy farmers participating in the survey estimated that a total of USD 970 worth of equipment (particularly hand tools) was lost. In vegetable farming, the total amount was roughly USD 3,200 but in addition the farmers lost machinery (e.g. water pumps) worth USD 27,000 and farm houses worth USD 900. The much larger extent of loss in vegetable farming when compared to paddy farming is, again, due to the fact that vegetable farming requires much more inputs and equipment than in the paddy system. The per cent breakdown of losses in vegetable farming is given in table 69.21 which shows that when damages occurred, the piece of equipment or machinery was totally lost for the farmer.

Table 69.21: Estimated damage to agricultural equipment in the vegetable cropping system. **Source:** Based on the field study by the authors and their collaborators.

Degree of damage	Percentage of respondents			
	Machinery	Equipment	Tools	Farmhouse
No or little damage	5	49	34	91
Some damage	0	0	1	0
Severe damage or destruction	95	51	65	9

69.4.4 Resource Availability After the Tsunami and Assistance

Following the tsunami, many of the resources required for re-initiating farming activities were missing to variable degrees (table 69.22). In paddy farming roughly 50 per cent of the respondents claimed that there was an insufficient supply of water, fertilizers, pesticides and equipment a year after the tsunami. These are usually available in normal circumstances. The lack of seeds was emphasized by 72 per cent of respondents. Regarding water, although farmers do not use irrigation and only grow rice during the Maha season, water is insufficient during the Yala season (March to August), regardless of the impact of the tsunami. This is reflected in table 69.22. Similar observations could be made for vegetable farming except that only 53 per cent of respondents claimed that seeds were in short supply and 99 per cent had no problem with the supply of water for irrigation, taking a quantitative perspective only (more farmers complained about water quality issues). This weakness in institutional support is another factor of vulnerability particularly influencing the resilience of the coupled human-environment system.

Table 69.22: Availability of resources to re-start agricultural activities in the paddy and vegetable cropping systems (per cent of respondents). For all categories, n = 60 for paddy system and n = 80 for vegetable system. **Source:** Based on the field study by the authors and their collaborators.

Availability	Water	Seeds	Fertilizers	Pesticides	Equipment
Paddy					
Sufficient	48	28	48	48	43
Not sufficient	52	72	52	52	57
Vegetable					
Sufficient	99	47	54	59	50
Not sufficient	1	53	46	41	50

In addition, labour availability for agricultural operations decreased following the tsunami. This was high-

lighted by farmers of both paddy farming and vegetable farming and probably contributed to the fact that not all the land that could potentially be cultivated was farmed in vegetable farming.

69.5 Conclusions

The vulnerability was found to be driven by a number of factors, most of them not new. They include physical parameters such as the distance to the coast, topography of the area, density of the population exposed; socio-economic parameters such as household income, the type and diversity of livelihood; and socio-cultural parameters such as age and gender.

The case study on the district and D.S. division level confirmed that the physical/environmental factors together with the number of people exposed to the hazardous phenomenon create the precondition for disaster. More interestingly, the topographic situation of the affected divisions could explain the differences between the two study areas that were observed in numbers of fatalities versus number of affected people (69.3.1).

The comparison between the different scales (district and division) revealed that severity of a disaster is a relative – and to a certain extent also a subjective measure. Conclusions regarding disaster impact have to be drawn with care. The informative value of damage or impact statistics depends to a large extent on the scale and the context to which they are applied. Common disaster measures such as the number of fatalities or economic losses have to be considered in their local context which is defined e.g. by the size of the area, population density as well as living costs and poverty level of the region under consideration. If death tolls for example are expressed in relation to the population of larger administrative units, such as districts in Sri Lanka, the resulting ratios can severely underestimate the impact since large parts of the district are not exposed to a tsunami. In terms of poverty, the same monetary loss can mean two quite different disasters in two affected divisions, if in one division the majority of the population lives below the poverty level and in the other division the majority of the population lives well above the poverty level.

Comparisons on the district and divisional scale not only showed that scaling effects (e.g. from a divisional to the district level) encumber vulnerability analyses, they also underline that the conclusions to be drawn from correlating data need to be differentiated – correlation often cannot be taken at face value. For example the level of poverty measured in household income correlated quite well with the level of tsunami damage in a way that decreasing monthly family income correlated with an increasing incurred damage level (housing damage). However, that correlation is driven by the fact that the low-income households are often fishing households and hence, they are situated closer to the coast and more exposed to the tsunami hazard.

Age and gender were important factors to explain observed fatalities with the very young children, the elderly as well as women representing the most affected groups. Besides the obvious physical reasons that explain the higher risk of those three groups with their lower physical strength, there are also socio-cultural implications that are not yet fully understood, such as behavioural patterns of women, who, in their role of the care taker, might perish in their attempt to help and protect the children and the elderly. Other assumptions place women at the shore at the time of the tsunami because they were awaiting the fishermen to process the catch. Those explanations still remain more anecdotal than scientific and call for further investigation.

The case study on the household level showed on the basis of the damage and recovery situation that in one and the same district communities with an agricultural livelihood approach engaged in the path of recovery in different ways and had to face different challenges to resume their activities. Notwithstanding the differential of physical impacts of the tsunami (such as wave height, run-up distance which was not evaluated), differences in the agricultural systems (paddy vs. vegetable) also implied differences in socio-economic systems (education, production means, wealth) which determined in part the different recovery paths of the communities. This is similar to the conclusions reached from the analysis of data at the district level and presented above but highlights the fact that even within one social grouping or profession ('farmer') great differences in recovery potential existed and thus targeted and adapted help is required.

The household study also illustrates the vulnerability concept of Turner, Kasperson, Matson, McCarthy, Corell, Christensen, Eckley, Kasperson, Luers, Martello, Polsky, Pulsipher and Schiller (2003) who postulate that there are usually multiple interacting stressors. The tsunami waves were only the primary stressor, but other stressors linked to the tsunami include the pollution and salinity of the drinking water and the irrigation water. Feedback loops created through response measures often lead to further

stresses. Those feedback loops were observed in the farming community: since most surface water reservoirs were contaminated more irrigation water was pumped from the freshwater aquifers which could lead to an increasing salinization of the aquifers (through, for example, salinity intrusion) jeopardizing the long-term farming perspective in that area. Another feedback loop resulting in a new stressor was identified in the household study in relation to relief operations that employed the local affected population in the clean-up process. Without doubting the good intentions and the immediate benefits of these measures, they negatively influenced the agricultural sector. Since the wages offered by relief organizations were significantly higher than the wages offered in the agricultural sector, the farmers were faced with a lack of labour to work the fields. Another example can be found in the relocation measures taken in Sri Lanka during the early recovery phase. The social problems arising from that relocation are described in other places (Ingram/Franco/Rumbaitis-del Rio/Khazai 2006; Birkmann/Fernando 2008; Grote/Engel/Schraven 2006).

What are the implications for policy-makers? The two empirical case studies revealed a number of complex causal relationships between different components and factors of vulnerability that offer a large field of response opportunities. Just to name a few, it became evident that policies for the reduction of vulnerability have to be very diverse and specific at the same time to make them effective and sustainable. Long-term land use planning needs to take the physical characteristics and exposure towards all relevant hazards into account. Not only poverty but also the lack of livelihood diversity makes people vulnerable. This is where vulnerability reduction and development agendas need to be linked – from the local to the subnational level. More protection and response measures need to target women, children and the elderly more explicitly. The recovery process can be sped up if the different and very specific needs of relatively small groups can be met, such as the different needs of vegetable and paddy farmers. A more detailed oriented relief plan will reduce the loss of relief money and help more people to recover faster. A win-win situation.

70 Risks in Central America: Bringing Them Under Control

Juan Carlos Villagrán de León

70.1 Introduction

For centuries Central American communities have been experiencing disasters which provoke fatalities, injuries, and losses of various kinds. During the conquest in the early 1500's the Spanish conquerors experienced their first disaster when a hurricane on 11 September 1541 triggered a massive landslide that buried the town of Santiago de los Caballeros which was the seat of the Spanish government at the time in Central America. As a consequence, the town was relocated from the skirts of the Agua volcano (Guatemala) to the central part of the Panchoy valley, almost 10 kilometres away. Unfortunately, two centuries later, the new city of Santiago de los Caballeros was destroyed by a series of massive earthquakes in 1773 which provoked many fatalities, injuries, as well as losses of many kinds. As in the previous case, the Government decided to relocate the city to another valley farther away from the active Fuego volcano, and supposedly, farther away from earthquakes. Unfortunately, the destruction of villages, towns, and cities in Central America has been a rather frequent occurrence due to the location of Central America in a highly seismic zone which gives rise to active volcanoes. The situation is worsened when considering the fact that the region lies on the path of hurricanes which provoke floods and massive landslides.

But while in colonial times such disasters were associated with punishments by God, and images of the Virgin and of Christ were brought out to the plazas and local governments prompted people to pray for forgiveness; in the last century such events began to be recognized as rising as a consequence of the dynamical nature of the planet in terms of its geology and its atmospheric activity.[1] The newest view which has risen in the 1990's points to the notion that disasters are not just such natural phenomena, but the combination of socially constructed vulnerabilities in geographical areas exposed to such phenomena.[2] This new risk paradigm is being introduced at the national and local levels within Central America by authorities and by NGOs to promote an awareness with respect to the fact that disasters are a consequence of the traditional frameworks of development, which have not been adapted adequately to the different types of phenomena which manifest themselves in this region of the world.

This chapter outlines factors which have been contributing to the generation of risks and subsequent disasters in the region during the past centuries, and the efforts carried out within this region to promote a more sustainable development, where the term 'sustainable' is linked to a framework of development which is capable of resisting the impacts of such natural events, and therefore the cycle of destruction-reconstruction-destruction is eluded. The analysis is conducted within the framework of disaster-risk reduction proposed by the *International Strategy for Disaster Reduction* (UN/ISDR 2001), where the assessment of risks and impacts related to disasters leads to the identification and implementation of measures along the lines of awareness raising, political commitment, the application of risk reduction measures, and efforts along the lines of early warning and

1 Accounts of such religious responses to catastrophes during colonial times can be found in: Domingo Juarros (1936). An indicator of the change in this paradigm regarding the origin of such disasters could be the establishment of national institutes or observatories by governments of Central America to conduct research and to monitor natural phenomena such as earthquakes, volcanic activity, and meteorology. Another indicator could be the explicit reference to the disasters as provoked by such natural phenomena by national authorities during interviews with the press when documenting such events. The explicit introduction of the term 'reduction of vulnerability' by the governments of Central America can be found in the 'Declaration of Antigua' (Guatemala) on the occasion of the XX Summit of Presidents of Central America, held in October 1999, in which the *Strategic Framework for the Reduction of Vulnerability and Disasters in Central America* was presented as the outcome of this summit.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_70, © Springer-Verlag Berlin Heidelberg 2011

preparedness. Figure 70.1 offers a schematic diagram for this framework.

Figure 70.1: Framework for disaster-risk reduction adapted from ISDR's framework. **Source:** author.

The selection of this framework is based on the fact that it highlights explicitly two relevant facts:

- The crucial role in terms of political commitment required for risk management measures to be implemented.
- The fact that risks can be conceived as composed of hazards, vulnerabilities, and deficiencies in preparedness (chapter yx by Villagrán de León).

This chapter describes a variety of factors which have led to the generation of risks and subsequent disasters within Central America (70.2); it assesses in more detail those which contribute to the generation or enhancement of vulnerability (70.3) and documents recent measures which have been introduced in the region to reduce the impacts related to such events (70.4).

70.2 Risks and Disasters in Central America

Due to its geographical location, Central America is exposed to multiple natural hazards. Much of the landscape of the region is shaped by the interaction of three tectonic plates: the Caribbean plate on which most Central American countries are located; the North American plate in which the northern segment of Guatemala resides, and the Cocos plate, which interacts with the Caribbean plate through a subduction process, giving rise to the chain of active and inactive volcanoes that spans the entire region. In addition, chains of mountains such as the ones in Guatemala and Honduras are also shaped by the interaction of the North American and the Caribbean plate. As a result of this tectonic interaction, the region is characterized by steep slopes on mountains and volcanoes, some valleys in central areas, and coastal plains leading to the Pacific Ocean in the south and to the Caribbean Sea in the north and the east.

The geographical location of the region in terms of latitude and the fact that it is bounded by the Caribbean Sea and the Pacific Ocean predisposes this region to be affected by hurricanes. Hurricanes and tropical storms have continually provoked floods in some valleys and flood plains. In addition, the high seismic activity within the region has altered the geological formations, leading to unstable conditions in terms of landslides. As such, earthquakes, storms, and hurricanes can sometimes trigger massive landslides. In contrast to floods, droughts can also manifest themselves in various regions of Central America. In fact, in some regions of Central America, the El Niño impact manifests itself as drought, particularly in the northern areas.

2 Since the early 1990's, members from the *Network of Social Studies on Disaster Prevention in Latin America* (La Red) have published books and articles in the journal '*Desastres y Sociedad*' on the subject of disasters and their prevention in Latin America, among them: *Los Desastres no son Naturales*, compiled by Andrew Maskrey (1993). The Inter-American Development Bank commissioned the design of an index to measure risks at the national level in Latin American countries which has been coordinated by O.D. Cardona, National University of Colombia in Manizales. A collection of theoretical documents and the methodology to assess risks can be found at the University of Manizales; at: <http://www.manizales.unal.edu.co/idea/modules.php?op=modload&name=Web_Links&file=index&req=viewlink&cid=1>; at the Inter-American Development Bank; at: <http://www.iadb.org/SDS/ENV/news_2533_s.htm>; The World Bank also published a variety of books and reports on the subject of disasters and their reduction in Latin America; at: <http://web.worldbank.org/WBSITE/EXTERNAL/TOPICS/EXTURBANDEVELOPMENT/EXTDISMGMT/0,,contentMDK:21415621~menuPK:341035~pagePK:210058~piPK:210062~theSitePK:341015,00.html>. Material on risk management and disaster reduction has been also published and distributed by UN-ISDR, UNDP-BCPR, ECLAC, the German Technical Cooperation Agency (GTZ), the Swiss Cooperation Agency for Development; CARE, and OXFAM.

	Total		**63,563**	**12,335,492**	**12,260.3**

Data corresponding to the two earthquakes which took place on Jan. 13 and Feb. 13, 2001.

From a disaster perspective, the establishment of many cities during the conquest and colonial periods may be considered as a process leading to such disasters. With no prior knowledge regarding the region in terms of earthquakes, hurricanes, and volcanic eruptions; many towns were established in hazard-prone areas, only to be relocated after experiencing grave consequences. Until present, many cities in Central America have experienced centuries of calamities provoked by such events, and continue to be exposed to future events.

Hurricane Mitch which impacted the region in late October of 1998 can be considered as the worst regional disaster in Central America during the last decades; it caused nearly 19,000 deaths in four of the five countries of the region. Honduras and Nicaragua experienced major economic losses in agriculture for export and local consumption, as well as destruction of vital road infrastructure, lifelines, and public and private infrastructure. Box 70.1 contains a brief description of the impacts provoked by this hurricane in the five countries of the region.

Other factors leading to disasters in Central America can be associated with the adoption of building techniques imported from Spain during colonial times, which again were not adapted to the types of natural events taking place in Central America. Private, public, and religious buildings all succumbed to earthquakes in the centuries following the conquest due to the combination of building techniques and construction materials not adapted to this hazard. In fact, the use of adobe as a material for the construction of walls in combination with extremely heavy clay-tile roofs in Latin America is a tradition within urban and rural settings which continues to cause fatalities during earthquakes when these houses collapse, burying their dwellers instantly.

Since the 1950's, Central America has seen an emergence in risks and disasters which stem from the combination of high population growth in the region (compared with developed countries), the lack of land-use policies that minimize exposure to these hazards, and migration processes to cities due to both pull effects of cities due to their economic boom, as well as push factors from rural areas which are no longer able to provide the quality of life and other conditions which are demanded from the local population. In addition, the region has experienced extensive migrations due to the political conflicts stemming from the Cold War, a process that started in the 1950's in the region. In this context, migration to cities was a solution to the human insecurity problems faced by people living in rural areas, where the battle between armies and guerrillas took place (Rojas 2008, 2009. Table 70.1 offers data on the most catastrophic disasters in Central America from 1972 to 2008 triggered by natural phenomena.

Earthquakes and hurricanes have occurred once or twice every decade, provoking more than 60,000 fatalities and affecting nearly twelve million people. The impacts of volcanic eruptions, landslides, and drought were less severe. Financial losses during the last four decades top nearly twelve billion US dollars for these events alone. In addition to affecting people in urban and rural areas, these events have a direct impact on the foundations of development in these

countries, as impacts also include the destruction of public infrastructure, in particular highways necessary to fuel local, national, and regional economies; hospitals and health facilities; schools, markets, and productive facilities (industries). Another impact on the development planning process once a disaster has taken place is the necessary deviation in terms of national and municipal budgets which would have been allocated for development programmes to target reconstruction efforts, which can last up to a decade.

As stated above, one factor which has been enhancing risks is population growth in combination with migrations to urban areas, a process which may lead to the exposure of people to a variety of hazards. The rates of population growth for Central American countries between 1950 and the 1990's range between 3.2 per cent and 4.1 per cent in urban areas, and between 1.8 per cent and 2.7 per cent in rural areas (table 70.2; ECLAC 2001).

Table 70.2: Average population growth rate for Central American countries for urban and rural areas (1950-1990). **Source:** CEPAL: Boletín Demográfico (2001: 75-109).

Country	Urban growth rate (per cent)	Rural growth rate (per cent)

Box 70.1: Hurricane Mitch and its Impacts in Central America. **Source:** The author.

Rising as tropical depression number 13 in the year 1998, Mitch was declared a hurricane on 24 October 1998, and subsequently a category 5 hurricane in the Saffir-Simpson scale on 26 October. As a late event in relation to the typical hurricane season, it hit Central America between 17 October and 2 November 1998. The hurricane followed a path initially impacting the Caribbean coasts of Honduras and Nicaragua, and later impacting the central areas and Pacific coasts of Nicaragua, El Salvador, Honduras, and Guatemala. The human and economic losses were heaviest in Nicaragua and Honduras where both the floods and rainfall-triggered landslides contributed to heavy death tolls and destruction of infrastructure.

Table 70.3: Impacts provoked by Hurricane Mitch in 1998. **Source**: EM-DAT: The OFDA/CRED International Disaster Database (Brussels: Université Catholique de Louvain, Data version v03.07); at: <www.em-dat.net> (26 January 2008).

The *Economic Committee for Latin American and the Caribbean* (ECLAC, CEPAL), carried out an assessment of the economic impacts of the hurricane in all countries of the region and estimated direct damages totalling 2,918 million US dollars, and indirect damages totalling 3,100.3 million US dollars. The hurricane provoked extensive destruction and damage in most sectors such as housing, health, education, energy, agriculture, transportation, telecommunications, and lifelines. Additional assessments of the impacts of this event were carried out by the *Inter-American Development Bank* (IADB), by the *Pan-American Organization of Health* (PAHO), and by the *Office of United States Foreign Disaster Assistance* (OFDA). However, data contained in the various institutional reports display some differences which can be related to the original sources consulted for such a purpose.

As a result of the catastrophic impacts, international agencies for development from developed nations and international agencies such as the United Nations and the European Union launched humanitarian assistance programmes, and later established additional programmes to strengthen disaster preparedness and to promote efforts along the lines of disaster reduction in all countries of the region.

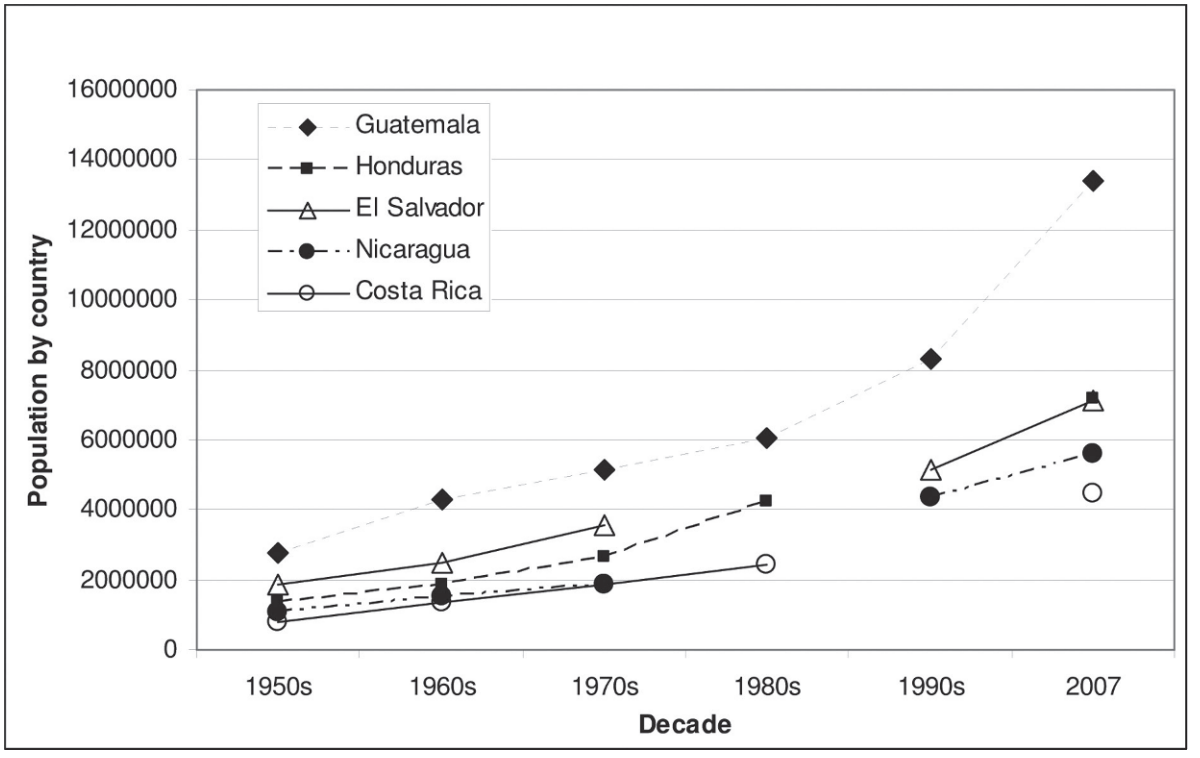
Figure 70.2: Growth of population for the five Central American countries between 1950 and 2007. **Sources:** ECLAC (2001); Central American Population Center (2007).



Guatemala and El Salvador have the lowest growth rates in urban areas, whereas El Salvador has the lowest in rural areas. Nevertheless, the growth rates in urban areas exceed those in rural areas in all countries. In absolute figures by the UN Population Division, the population of the five above Central American countries plus Belize and of the whole Central American region (including Mexico and Panama) has grown significantly between 1950 and 2005, and it has been projected to continue to grow in Belize, and Guatemala even more (according to the medium variant) intensively, while the projected population growth for the next 45 years will be below the real

population growth for the past 55 years in Costa Rica, El Salvador, Honduras, and Nicaragua (Table 70.3).

Figure 70.2 documents the population growth for each country since the 1950's. In 2007 Guatemala had the largest population, followed by Honduras and El Salvador, then Nicaragua and finally Costa Rica. Population growth has been highest during the last decade.

Within the context of risks, the previous paragraphs not only depict the existence of hazards, vulnerabilities, and deficiencies in preparedness in Central America, but also processes which are leading to the establishment or enhancement of such risks, in particular vulnerabilities.

70.3 Vulnerability: The Social Cause of Disasters

Vulnerability has been defined by the International Strategy for Disaster Reduction of the United Nations (UN/ISDR 2004: Annex 1: 7) as "the conditions determined by physical, social, economic, and environmental factors or processes, which increase the susceptibility of a community to the impact of hazards." Unfortunately, as pointed out by several researchers (Alwang/Siegel/Jorgensen 2001; Brooks 2003; Brauch 2005; Thywissen 2005; Villagrán de León 2006a), there are many connotations given to this term by researchers from different disciplines, and as Cardona states (Cardona 2001) there is no single definition which may unify or collect in a consistent and coherent fashion all those found in the literature. Comprehensive reviews of the term in the context of risk management have been carried out by Villagrán de León (2006a) and in the wider framework of security threats by Brauch (2005).

In the context of drought, Chambers (1989: 2) introduced the notion of vulnerability as "the exposure to contingencies and stresses and the difficulty which some communities experience while coping with such contingencies and stresses." Thus, Chambers defines the internal side of vulnerability to focus on conditions of defencelessness and *incapacity to cope* with damaging losses; and the external side of vulnerability as related to *exposure* to external shocks and stresses.

In 2004, Birkmann and Bogardi introduced the BBC conceptual framework (Birkmann 2006) which integrates these notions of exposure, coping capacity, and vulnerability with the social, economic, and environmental spheres of sustainable development. The risk framework is complemented with an intervention system which proposes measures in the context of risk reduction along these three spheres, as well as in relation to hazards. The incorporation of the spheres of development links the vulnerability framework with social, economic, and environmental aspects, blending itself to handle such aspects as climate change, as well as social and economic factors related to exposure and coping capacity. But the link to the sustainable development framework in terms of these three spheres neglects explicitly to the physical dimension of vulnerability. Disasters around the world have demonstrated that this dimension of vulnerability can lead to fatalities, injuries, and massive economic losses for earthquakes, landslides, and tsunamis, where the collapse of infrastructure has led to massive fatalities and injuries.

Within the academic community devoted to research regarding natural disasters in Latin America, Cardona and other members of LA RED (Cardona/Hurtado/Duque/Moreno/Chardon/Velásquez/Prieto 2003: 13; Cardona 2004: 43) have proposed a definition of vulnerability as "the predisposition of an element, a system, or a community to be affected or susceptible to damage." In the context of risk, vulnerability is defined as the internal risk factor in contrast to hazard which is defined and the external risk factor. Cardona has proposed that vulnerability originates as a consequence of three factors:

- *Physical fragility or exposure*, linked to the susceptibility of human settlements to be affected by natural or social phenomena due to its location in a hazard-prone area.
- *Socio-economic fragility*, linked with the predisposition to suffer harm due to marginalization, social segregation in human settlements, and due to poverty and similar factors.
- *Lack of resilience,* related to the limitations of access and mobilization of resources, and incapacity to respond when it comes to absorbing the impact of a disaster. It can be linked with underdevelopment and the lack of risk management strategies.

One important aspect with regard to vulnerability is its dynamic nature. There are several factors which can augment, maintain, and reduce them at any time (Villagrán de León 2004: 25). Figure 70.3 outlines several of these factors which can modify vulnerability, including poverty, weak governance, as well as factors which can be attributed to the people themselves. Among them, population growth, migration to urban

Figure 70.3: Factors which generate or enhance vulnerability. **Source:** The author.

areas, unwillingness to change, and the lack of a culture regarding vulnerability management.

Two issues that characterize most Central American countries, except Costa Rica, are the large percentage of their population which can be classified as poor and the disproportionate differences between the wealthy and the poor (table 70.4 based on UNDP 2006). In the framework proposed by Cardona, poverty leads to economic fragility, while in the BBC framework poverty would be linked to the incapacity to cope in case of an event. In the proposed framework, the economic limitations which are connected with poverty inhibit poor people from securing low vulnerable housing for example.

Linked to poverty is the limited access to assets which may inhibit poor people to emerge from poverty and to reduce their vulnerabilities, and may restrain their capacity to cope with extreme events. Within Latin America, Attanasio and Székely (2001) have pointed out that policies and poverty alleviation programmes in Latin America have not targeted the elimination of the restrictions that prevent the poor from accessing and accumulating assets.

Migration from rural to urban areas generates additional vulnerabilities as the new settlers in most cases migrate with little or no economic resources to build proper houses, and they live in weak structures, based on their initial perception that they will remain only temporarily in high hazard areas. As mentioned in the previous section, several countries underwent massive migration processes related to armed conflicts fuelled by the Cold War between the United States and the former Soviet Union. Nevertheless, while the conflicts ended since a decade ago or more, the migration process continues to take place, fuelled by the lack of opportunities and high degree of poverty which exist in rural areas, and the attraction which the capital city may offer for such people from rural areas to satisfy their needs and opportunities to improve their way of life.

With respect to weak governance, one of the main problems which some countries experience, with the exception of Costa Rica, is the continuous change of staff in government institutions and the tradition of launching new government programmes by newly elected government officials. In addition, short-term goals are preferred to complete tasks within one electoral period, rather than long-term goals such as disaster prevention which would require decades to be completed.

In the context of building codes it is important to stress that most codes do not necessarily include relevant aspects for all hazards, and their enforcement by authorities remains a problem. The problem is enhanced when people with limited economic resources build their own houses or hire unqualified workers to construct houses which are vulnerable because guidelines contained within such building codes are sidestepped.

Regarding the lack of awareness and experience managing vulnerabilities to natural hazards and the practically inexistent disaster prevention culture, the variety of day-to-day social and economic problems which people have to face, and the vast needs which governments have to satisfy in terms of human security, health, education, and social welfare inhibit both the people and governments to shift from a reactive approach to a more proactive or preventive one. Since the 1960's governments opted for a disaster response approach by setting up national emergency committees to manage such disasters once they have occurred.

As a final remark, the issue of unwillingness to change must be addressed. This refers in some cases to the use of adobe as a material for walls, which has been a tradition imported by the Spanish conquerors centuries ago and which is difficult to change in many parts of Central America, particularly in areas where earthquakes are not frequent.

70.4 Recent Advances in Central America in Disaster-Risk Management

Three emergent processes which may allow Central American communities and governments to deal with risks and disasters are:

1. The adoption of a framework of risk management which emerged from the International Decade for Natural Disaster Reduction which took place between 1990 and 1999.
2. The support of the international donor community to conduct various projects and programmes to strengthen capacities at the regional, national, and local levels promoting the disaster-risk management framework.
3. New sources of income for rural areas from remittances of legal and illegal migrants in the United States.

In response to Hurricane Mitch (1998), most Central American countries modified their legislation incorporating risk management, except in Guatemala that had adopted its new legislation already in 1996. Prior to Hurricane Mitch all Central American national emergency committees had the mandate to respond in case of disasters, but not to prevent such disasters or to prepare for them. After Hurricane Mitch the governments modified their legislation permitting these committees to coordinate and execute a variety of tasks before, during, and after such events at all levels (national, regional, municipal, and local), and they have been strengthened with additional budgets and resources.

The Presidents of Central America incorporated the goal to reduce the vulnerability in their 20th Presidential Summit in Antigua City (Guatemala) in October 1999. According to the Presidential Summit Declaration, the reduction of vulnerability should embrace all sectors of development. Based on this mandate, the *Central American Coordination Center for Natural Disaster Prevention* (CEPREDENAC) established the Quinquennium for the Reduction of Vulnerability 2000–2004, which concluded with a symposium in December 2003 to review progress and to discuss future needs and approaches for the management of vulnerabilities. In the context of the Disaster-Risk Management framework presented in figure 70.1, such actions manifest the commitment of governments at the highest level in relation to disaster reduction through risk management.

The request for humanitarian assistance by Central American governments during Hurricane Mitch and the subsequent adoption of this risk management framework in new laws prompted the international donor community not only to provide typical humanitarian assistance, but also to establish long-term programmes of support through special lines of funding to facilitate risk management efforts during the reconstruction period. Since 1999, the *European Community Humanitarian Office* (ECHO) supported such efforts with its *disaster preparedness programme* DIPECHO facilitating European NGOs and international organizations to reach local communities throughout Central America with a variety of projects focusing on local- or community-based risk management and disaster preparedness. USAID established similar programmes, as well as other NGOs such as CARE, OXFAM, Action Against Hunger, and the German Agro-Action to name a few. In addition, several governments have also provided technical assistance to national agencies in Central America to facilitate

the incorporation of risk management into government practices. The *German Technical Agency* (GTZ) has been executing projects along these lines in all countries of the region since 1997 as part of their efforts to strengthen municipal governments. Several United Nations agencies have also contributed to these efforts, in particular the *International Strategy for Disaster Reduction* (UN/ISDR), and the *Bureau of Crisis Prevention and Recovery of the United Nations Development Programme* (BCPR-UNDP), as well as the *International Federation of the Red Cross* (IFRC). In the context of factors which enhance vulnerability, these efforts by the international community are helping to establish a culture regarding disaster prevention and are aiding communities to become aware of experiences and ways regarding vulnerability management and preparedness.

Among the measures which have received much attention both by national and local government agencies, as well as by international NGOs and development agencies, are the topics of disaster preparedness and early warning. Since 1998, all countries in the region have improved their capacities to:

- *Operate early warning systems for hazards* such as floods, drought, volcanic eruptions, tsunamis, and famine. Efforts target both systems operated by national scientific and technical agencies, as well as by communities under the coordination of disaster-management agencies.
- *Manage information and coordinate inter-institutional response* efforts through the set-up of Emergency Operation Centres at the national level, as well as locally.
- *Coordinate humanitarian assistance and international relief* efforts through the establishment of protocols for this purpose.

The third element related to disaster-risk-management refers to additional sources of income from remittances sent by millions of people who have migrated to the United States which target vulnerable rural areas throughout Central America. In recent years the remittances have become substantial compared with other sources of funding which drive local economies. The World Bank (2007) estimated that remittances for Central American countries are reaching a level somewhere between 12 and 20 per cent of the gross domestic product (GDP). These funds are transferred directly to the people in rural and urban areas, and are used to reduce poverty, and to some degree also vulnerability (IADB/FOMIN/Pew Hispanic Center 2003), as part of the remittances are used for health, education, and housing needs. In many rural areas of Central American countries such additional funding alleviates poverty, allows local citizens to reduce the structural or physical vulnerability of their houses, and enhances their capacities to cope with disasters.

Other factors contributing to the reduction of vulnerability in the housing sector were triggered by the impact of earthquakes. As a result of the post-earthquake assessment of seismic hazards in 1973, Managua City, the capital of Nicaragua, shifted from a tradition of high buildings to one or two storey houses. It also adopted land-use norms that prohibited the reconstruction of entire sectors in the city centre.

The 1976 earthquake in Guatemala destroyed many towns where the use of adobe as material for walls and clay-tile roofs was common. The correlation between these construction materials and the pattern of destruction provoked by the earthquake changed the mentality of surviving Guatemalans who now use cement blocks and reinforced concrete structures with a very light roof made of metallic sheeting. This modern, seismic-resistant technique was adopted in most areas that were severely affected by the earthquake, where considerable reconstruction was necessary. However, in areas far away from the epicentre, traditional adobe-built houses still exist.

A review of the progress achieved in vulnerability and risk reduction are contained in the report based on the evaluation of the Quinquennium for the Reduction of Vulnerability 2000–2004 that is documented in table 70.5 (Novelo/Smith 2005). While such efforts contribute to a reduction of vulnerabilities, it remains a challenge to ensure that these processes are carried out in an integrated fashion, and that disaster prevention is recognized and accepted as a long-term goal which should be respected by electoral processes. The aim of governments, the private sector, and the people should be to achieve the goal of risk management by combining efforts instead of advancing in isolation sector by sector.

70.5 Conclusions

Central America, due to its geographical location in the central segment of the American continent, as well as its setting on top of three interacting tectonic plates, is a multi-hazard region that is constantly impacted by hurricanes, earthquakes, volcanic eruptions, floods, landslides, and other natural phenomena. While native ethnic tribes might have adapted to such phenomena, the Spanish Conquest led to the estab-

Table 70.5: Main results of the evaluation of the Quinquennium for the Reduction of Vulnerability (2000-2004). **Source:** Novelo/Smith (2004: 3-6).

Topic	Main achievements and progress	Comments, suggestions, identified needs
Institutional strengthening	Strengthening of capacities of institutions in charge of risk management and disaster response within the region.	It is important to insert such institutional strengthening in the national development plans of every country.
Information and research	More systematic monitoring of hazards. New academic programmes at the level of universities on risk management have emerged. In some countries, advances can be seen in improvement of building codes. Research has been geared towards the assessment of potential impacts related to hazards.	Advances on the use of Geographical Information Systems (GIS) to manage information regarding risks (hazards, vulnerabilities, risks). There is a need to socialize the newly generated scientific information regarding risks as a support for the planning process, budgeting, and decision-making process at national, regional, and local levels.
Early Warning	Strengthening of early warning systems, particularly in the case of hydro-meteorological hazards. Enhanced technical capacities at the regional level to design and implement early warning systems.	A need has been identified for promoting people-centred early warning. It is important to consider issues related to the sustainability of such early warning systems.
Strengthening of local capacities on risk management.	Advances in some countries through projects and actions carried out at the local level. Enhanced awareness concerning risks and risk management at the level of communities and decision-makers. Strengthening of capacities of grass-root organizations.	The need has been identified to incorporate risk management measures in local development plans, as well as in the national agendas of development.

lishment or risks, which continue to be the root causes of disasters faced by most of these five countries. Settlements with vulnerable conditions in high hazard areas impacted by floods, mudslides, and volcanic eruptions, have been destroyed and rebuilt over centuries, and in some cases, relocated due to extreme patterns of destruction.

Within the proposed framework some addressed factors generate or enhance vulnerability. The region is also faced with processes which have led to vulnerabilities, and processes which have reduced it, such as poverty, migration from rural to urban areas, and armed conflicts.

However, by the 1960's, governments in Central America established national emergency committees to respond to disasters of multiple kinds. Such committees played crucial roles during such disasters as the Nicaraguan, Guatemalan, and El Salvador earthquakes in 1972, 1976, and 1986 respectively. In a similar fashion, the committees were engaged in response efforts during hurricanes such as Fifi in 1972 and Mitch in 1998. During the 1990's, the United Nations launched the International Decade for Natural Disaster Reduction which promoted the framework of risk management as a means for countries to minimize the impacts of disasters. Having been severely impacted by Hurricane Mitch, Central American governments modified their approach to disaster management by changing the operational framework of the emergency committees into risk management agencies. By 2006, all Central American countries introduced legislations to complete this transition from disaster-response to risk management. Such a transition is fuelling efforts to change the paradigm related to disasters, introducing the notion of vulnerability as one of the two causes which explain why such countries continually experience disasters.

In recent years, two additional complementary processes have contributed to the management of such vulnerabilities. On the one hand, the efforts by donor agencies and developed nations which have established tailor-made programmes to promote the adoption of this new paradigm of risk management at the national, regional, and local levels in all countries of the region, and the emergence of new sources of funding at the local level for families to cope with such vulnerabilities and disasters through monetary remittances from the United States.

While the region continues to face serious problems associated with poverty, unequal access to

resources, weak governance, and social problems such as uncontrolled migration from rural to urban areas, delinquency and organized crime; initial results can be seen on a variety of fronts regarding the adoption of this new paradigm of risk management within the region. Such results include the strengthening of institutional capacities, the establishment of academic programmes focusing on the subject, enhanced awareness at national and local levels, and the establishment of legislation to target vulnerability by recognizing it as the leading cause of disasters at the highest political levels.

Efforts in all Central American countries regarding risk management are now carried out by governments at national and local levels, by civil society, and by the private sector. However, it will take years before such efforts reach all corners of the region, as the needs in other areas of development continue to press governments and the people of this region. Nevertheless, the new paradigm regarding vulnerability as a root cause of disasters is allowing people and decision-makers to understand the root causes of disasters differently. Factors which are linked to its generation or enhancement have been identified, and now the need remains in ways to assess it, as well as on the allocation of national and local resources to reduce it. It is interesting to note the fact that complementary resources are being allocated by the international community, national governments, as well as by the people themselves to reduce such vulnerability.

Whether such efforts will have the desired impact in reducing typical disasters, the true test will come in future decades due to climate change, which is projected to lead to more frequent and more intensive hydro-meteorological events (IPCC 2007a: 583–607; chap. 32 by Lacambra/Zahedi; chap. 85 by Zapata-Marti).

Considering both the positive changes within the region in terms of policies, institutional strengthening, awareness efforts, and disaster preparedness; as well as trends related to environmental degradation, population growth, and migration to urban areas which may increase vulnerabilities and hence risks, it is important to conduct inter-disciplinary studies which may focus on the multi-faceted nature of disasters and disaster-risk management.

While this chapter has presented a review of factors which may increase and constrain risks, it is important to conduct assessments of risk at the national, provincial, municipal, and local levels, and to identify trends with respect to changes which can be linked to different hazards. While there are some efforts to assess vulnerability and risk, there is yet no consensus on which methodology to use for such purposes. There is a lacking consensus on methodologies, as well as on definitions of key terms like risk, vulnerability, and risk management. This issue must be addressed in each country, but the challenge remains also at the global level.

Box 70.2: Projected Climate Change Impacts for Central America and of the probability of hydro-meteorological hazards until 2100. **Source**: IPCC 1998, 2007: 892-896, 2007a: 583-607.

According to the assessment presented in section 11.6 of chapter 11 of the IPCC Fourth Assessment Report: Working Group I Report "The Physical Science Basis" (2007: 892–896), Central America is expected to experience a warming trend in the next century which could be in the order of one to three degrees Celsius by the year 2050 and between 1 and 5 degrees by the year 2080, depending on the review of models used to forecast the temperature change.

With regard to precipitation, the models forecast decreases in mean precipitation during all seasons, which could lead to water stress and hence food insecurity, given that the majority of the population relies on subsistence farming for their livelihoods. By the year 2050, precipitation may change between -12% and +5% during the dry season and between -15% and +5% during the wet season. Forecasts for the year 2080 imply changes ranging from -20% to +8% in the dry season and between -30% and +5% during the wet season.

However, as stated in the report, such models do not take into consideration the effects of hurricanes. In such cases precipitation may increase during such events, as has been seen in recent years. In addition, it is expected that the frequency and magnitude of such events may increase in decades to come.

71 Economics and Social Vulnerability: Dynamics of Entitlement and Access

Koko Warner

71.1 Introduction

This chapter examines the dynamics of entitlement and access, and the degree to which economic and social capital are substitutes during and after natural disasters. It explores how individuals manage a shock from a natural disaster by accessing a spectrum of social and economic assets, and it illustrates the importance of accounting for social capital and its affect on access to entitlements during and after shocks like natural disasters. This chapter discusses substitution of economic and social capital to explain in part why and how shocks affect certain groups disproportionately.

The approach points towards two insights for social vulnerability and natural hazards: *First*, it examines the relevance of imperfect substitution between a relational good (social capital) and a private good (economic capital) in shock situations such as natural hazards. *Second*, it explores how this substitution effects may mask the impacts of hazards on society's most vulnerable following natural hazards (negative externalities).

Research on evacuation efforts in New Orleans before and after Hurricane Katrina (August 2005), compared with other hurricanes in the Caribbean region, indicates the role of social capital for those affected by natural hazards. Entitlements failures and lack of access can lead to a social capital gap (social vulnerability) which arises when shocks prevent people from substituting social and economic capital. With this perspective, a more differentiated view of the effects of Hurricane Katrina and other hurricane events in the region on vulnerable groups emerges. Preliminary results suggest the importance of pursuing a research agenda to better understand the disruption of social networks and social vulnerability during and after shocks.

Research suggests that vulnerable groups, particularly impoverished groups, bear a disproportional burden of direct and indirect damage from natural hazards. One author notes

> For both developed and developing countries, the lower the economic, political, and social status of the people ... affected by hazards, the larger the loss burden. ... Consequently, the people and activities most affected by natural hazards are bound to be those belonging to the poorest and most powerless social sectors of less developed countries, especially in those countries undergoing rapid transition with little or no regard for social consequences at the margin (Albala-Bertrand 1993).

Every major study of the impacts of natural catastrophes in developing countries reaches this conclusion (Otero/Marti 1995; Sen 1999; World Bank 2000; UN-ISDR 2002a; Benson/Clay 2004), which will be further exacerbated by climate change (IPCC 2007a). The poor generally are more vulnerable, suffer greater costs, and have less capacity to take compensating action than richer societies or households. By 'vulnerable', the definition provided by Blaikie, Cannon, Davis and Wisner (1994) is applied here, namely "the characteristics of a person or group in terms of their capacity to anticipate, cope with, resist, and recover from the impact of a natural hazard. It involves a combination of factors that determine the degree to which someone's life and livelihood is put at risk by a discrete and identifiable event in nature or in society" (Blaikie/Cannon/Davis/Wisner 1994: 12). While there is consensus that vulnerable groups suffer the larger loss burdens from hazard events, the mechanisms of how shocks affect the coping capacity of households require greater understanding.

The chapter first briefly looks at the discussion of entitlement failures that can result from shocks which prevent substitution between different types of capital (71.2), and reviews economic valuation methods of the impacts of natural hazards and some of the shortfalls of these approaches (71.3). It examines evidence of the effects of social capital on disaster management, and compares the experience of Hurricane Kat-

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_71, © Springer-Verlag Berlin Heidelberg 2011

rina with that in managing hurricane risk in the region. It assesses evidence of how entitlement failures and lack of access affects the management of disaster situations such as Hurricane Katrina and other hurricanes (71.4) and it analyses why approaches are needed that capture the effects of social capital on access to entitlements during and after shock situations (71.5). Finally, it draws conclusions and makes recommendations for further investigation (71.6).

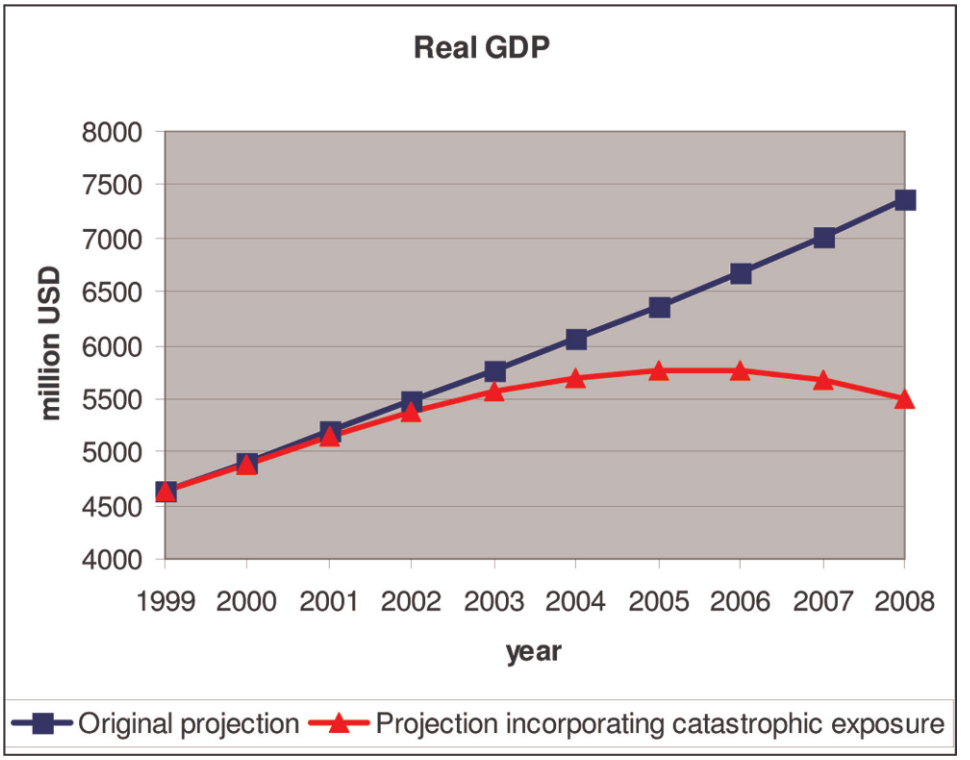
71.2 Entitlements, Access, and Substitution

Amartya Sen argued that to understand vulnerability, it was also necessary to understand all the various substitutions or channels through which a community accessed the resources it needed to survive (Sen 1981). Entitlement failure, resulting from an inability to obtain the necessary resources for survival, occurs when the entitlement of a person or community is disrupted and they cannot substitute to another method of obtaining the necessary resources (Sen 1981). This failure in entitlements and inability to substitute different types of capital results in vulnerability (Sen 1986). The entitlement framework is useful because it disaggregates the reasons why a person or group may become vulnerable to shocks such as natural disasters. It is not only the physical shock which poses problems – communities worldwide face large and small physical hazards on a regular basis but not all communities are devastated. The entitlement perspective allows more insight into how the ability to substitute between capital endowments (here social and economic capital are discussed) affects vulnerability to such shocks. This chapter characterizes coping capacity as a spectrum of economic and social capital that people substitute imperfectly to achieve their objectives in the face of a shock.

Here social capital is defined with two major components reflecting the primary understanding in the literature: Social capital is the collection of those productive assets which are incorporated in the social structure of a group, and which allows cooperation among its members to reach common goals. Social capital is used as a collective asset held by the group and depending on interpersonal relationships for capital accumulation or depreciation (Bordieu 1983; Coleman 1990; Putnam 1995; Becker 1996; DiPasquale/Glaeser 1999; Dasgupta/Serageldin 2000; Sacco/Vanin/Zamagni 2004). Examples of social capital include trust, effective civic codes of conduct/norms, and networks of voluntary associations. A particular feature of social capital is that it is not accumulated through a standard mechanism of individual investment, since most of its benefits are not privately appropriable. Rather, social capital is accumulated to a large extent through social participation in group activities (Uhlaner 1989; Comeo/Jeanne 1999; Gui 2000). This participation may only partially be regarded as an investment since it is perhaps mainly an activity that entails the simultaneous production and consumption of relational goods.

There is a long discussion about the effects of the growth in economic capital on social development (see e.g. Alexander 1993; Knack/Keefer 1997; Edwards/Foley 1998; Woolcock 1998; Putnam 2000). For example, Hirsch (1976) as well as Foley and Edwards (1999) argued that negative social externalities may accompany private growth as individual time constraints become increasingly binding, thereby inducing a shift from time-intensive activities including social participation to time-saving ones including many forms of private consumption. People may substitute between both types of capital – such as relying to a greater extent on social networks if economic capital fails (such as the breakdown of financial infrastructure following a natural hazard), or substituting economic capital for social capital when interpersonal networks may become disrupted, such as during evacuation in the face of a hazard. A challenge can arise for certain segments of the population during shock situations when substitution is imperfect. Situations may arise in which it may become difficult for people to substitute social for economic capital. For example, if people become isolated from their normal social relations, they may not be able to organize activities that require high degrees of social capital and trust, such as child care when parents need to organize reconstruction or other shock-related responses. Further, shocks can reveal underlying social isolation or lack of entitlements that prevent people from substitution like increasing labour supply. In such situations people are prone to experience a social capital gap – or social vulnerability – when their social networks fail to sustain them (either through lack of participation, exclusion/isolation, etc.) and when they cannot substitute towards economic capital (such as increasing their labour supply). The literature has still to examine the implications of shocks like natural disasters on the ability to substitute between social and economic capital, in particular when certain groups have a predisposition to vulnerability because of their stock (or lack thereof) of social capital.

Figure 71.1: Shocks disrupt economic performance over time. **Source:** Freeman/Warner (2001: 27), reprinted with permission.



71.3 Do Valuation Methods Capture the Dynamic of Access Failure after Shocks?

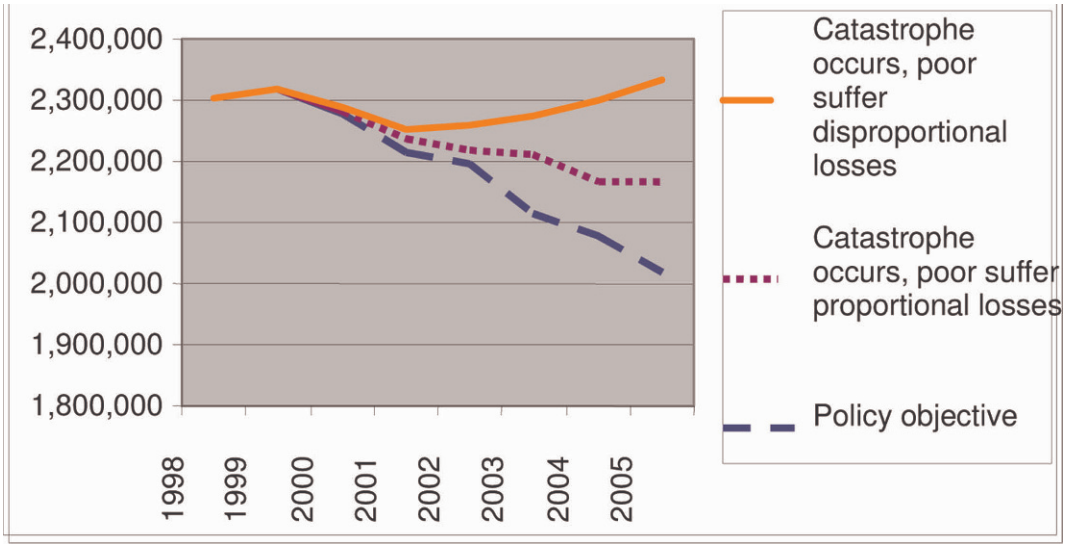
Current economic valuation methods examine the disruption of capital assets (capital stock), and a part of this literature focuses on macroeconomic effects (Freeman and Warner 2001, Freeman et al. 2002 and 2003). Economic impact information available in most cases is aggregated, often stated in terms of GDP per capita losses or estimates of direct damage in currency terms. One study estimated the impacts of a natural hazard destroying a percentage of capital stock in Honduras. The authors found that economic growth at first did not deviate significantly from the planned growth trajectory (figure 71.1). With time, however, economic growth lagged and even started to decline. It was estimated that Honduras would need an additional $170 million annually of currently unbudgeted financing to stay on its projected macroeconomic growth path (Freeman/Warner 2001).

Figure 71.1 shows that in the immediate years following the shock, economic performance closely mirrors the projected macroeconomic growth path. This is in line with literature which finds that negative externalities can actually stimulate economic growth, and may in part explain why inflationary spikes are observed in the aftermath of natural hazards as economic capital including aid money may become more available.

While such macroeconomic approaches (see e.g. Atkins/Mazzi 2000; Freeman/Warner 2001; Freeman/Martin/Warner 2004) provide insights about economic impacts of natural hazards, they are less suited to generating information about patterns of losses, such as what groups are more affected when hazards occur. Even if the macroeconomic costs are small, the costs for the most vulnerable within society may be large yet underrepresented using current evaluation techniques. Natural hazards can pose a more serious threat to particular groups than would appear from the macroeconomic data (Albala-Bertrand 1993; Bartolina/Bonatti 1997, 2004; Vatsa/Krimgold 2000; Antoci/Sacco 2001; Benson 2003).

Some work has been done on measuring the impact of natural disasters on the poor, by supplementing macroeconomic modelling with household models. For example, figure 71.2 illustrates the results of

Figure 71.2: The number of people in poverty increases if the poor suffer disproportionately from catastrophic events. **Source:** Freeman/Warner (2001: 32). Reprinted with permission.



an assessment done on the impacts of Hurricane Mitch on the poor. This figure suggests that hazards slow or stall the reduction of poverty, and can even worsen poverty over time if the most vulnerable are affected disproportionately (Freeman/Warner 2001).

Beyond widely accepted conclusions that the poor bear the heavier load from direct damages to capital stock from extreme events (Ferroni/Mody 2002; Martines/Guzman 2002; Carter/Little/Mogues/Tewodaj 2007) quantifying this burden has proved difficult. Because the poor are not well reflected in macroeconomic data, analysis of that data alone disguises the consequences of natural hazards on the most vulnerable segments of society, and the role that social capital plays in failures to access entitlements that are available during and after a disaster.

Different research approaches have sought ways to address this need (Putnam 1995, 2000; Antoci/Sacco 2001; Vanin 2005) but not from the perspective of shocks and social vulnerability. Some economists have begun experimenting with approaches that extend the understanding of the mechanisms by which people who are vulnerable to shocks might manage the risk, and the consequences of an inability to substitute economic and social capital to manage the shock.

Box 71.1 outlines an approach by Bartolini and Bonatti (2004) as an example of how social capital might be incorporated into production and utility functions. The interesting point is that social capital is modelled as a homogenous asset, rather than as an asset with different substitution characteristics in different situations (such as shock situations).

71.4 Relevance for Social Vulnerability

Bartolini and Bonatti (2004) attempted a modelling approach that included social capital in the production and utility function to examine the effects of social capital on economic outcomes. This approach is discussed briefly in the annex. The relevance for such approaches to social vulnerability requires further research, and simulation under shock situations and under the assumption of imperfect substitution are needed.

Entitlement failure results from an inability to obtain the necessary resources for survival occur when the entitlement of a person or community is disrupted and they cannot substitute another method of obtaining the necessary resources. This failure in entitlements and inability to substitute different types of capital results in vulnerability (Sen 1981, 1999). The entitlement framework is useful because it disaggregates the reasons why a person or group may become vulnerable to shocks such as natural disasters. It is not only the physical shock which poses problems – communities worldwide face large and small physical hazards on a regular basis but not all communities are devastated. The entitlement perspective allows more insight into how the ability to substitute between capital endowments (here social and economic capital are discussed) affects vulnerability to such shocks. This chapter characterizes coping capacity as a spectrum of economic and social capital that people substitute imperfectly to achieve their objectives in the face of a shock.

Table 71.1: Social capital types and access to entitlements during times of shock or disaster. **Source:** Compiled by the author.

	Bonding social capital • geographically specific • useful for survival, group identity	**Bridging social capital** • geographically flexible • useful for (individual) access to entitlements
Degree of substitution with economic capital	Low to medium Most useful in securing group goods. If entitlements are linked to the group, bonding capital may be fungible with economic capital.	Medium to high Most useful in securing personal goods such as employment or entitlements (if defined individually). Less useful for securing social safety in times of physical danger (group identity is not a market good).
Relevance to disaster situations	May ensure physical survival (particularly relevant within first 72 hours to few weeks following event), less helpful in accessing entitlements (depends on characteristics of the group).	Useful for recovery process, reestablishment of normalcy, accessing entitlements like aid, help in reconstructing, getting jobs back, getting insurance payouts, etc.

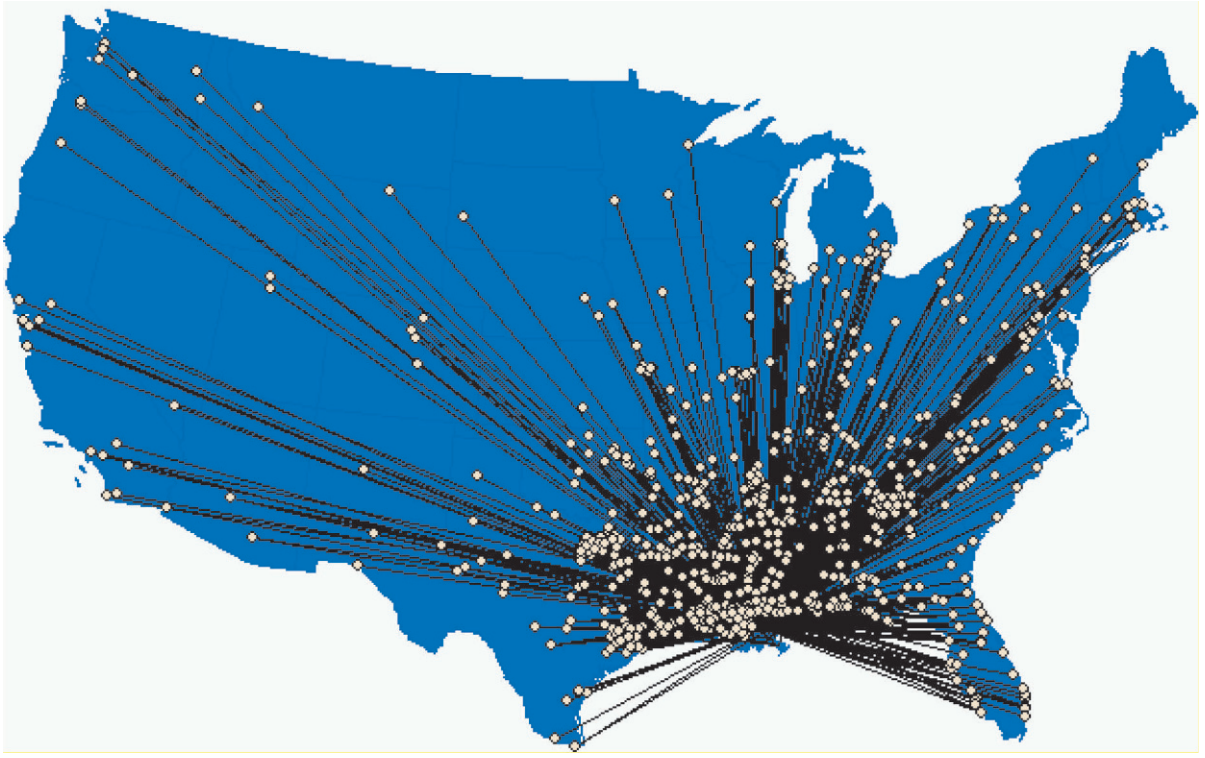
Using this approach, Bartolini and Bonatti (2004) suggest (in non-shock situations) that social capital deterioration is represented as a negative externality. Modelling approaches to capture the effects of shocks often do not account for the negative externality of social capital deterioration, i.e. when social capital of different types (bonding and bridging) is lost or seriously disrupted. Social capital forms are often overlooked until a shock situation. In such times of stress, people may not be able to substitute their particular endowments of social capital with their endowments of economic capital. These losses can be systematic, so that groups of people experience a loss of resources they may need to access entitlements that help them deal with the effects of a shock. As social capital deteriorates, agents compensate for this deterioration by increasing their labour supply and accumulation in order to increase the output used to substitute diminishing social capital. Table 71.1 presents a simple matrix of social capital and its affects on access to entitlements during times of shock or disaster.

The degree of substitution between social and economic capital depends on spatial or temporal factors. In times of disaster, for example, people can experience disruption of their normal routines and in some cases must even be evacuated. Groups possessing a relatively large endowment of bonding social capital may be particularly vulnerable to developments that disrupt the spatial arrangement of their social ties. Evacuations which have a disorganizing effect on neighbourhoods, such as the Superdome experience following Hurricane Katrina, can cause bonding social capital to deteriorate and reduce the ability of people to cooperate in order to gain access to services and goods they need to manage the situation. In contrast, those individuals with bridging social capital – useful for securing employment or individually defined entitlements – were able to find shelter and resources they needed through a combination of economic capital such as money (i.e. to rent hotel rooms, travel away from the hurricane- and flood-affected areas, or find new jobs in new locations).

The relevance of bonding and bridging social capital types in disaster situations also has bearing on access to entitlements. Bridging social capital may have helped affected people substitute economic capital to gain safety from the effects of Hurricane Katrina. Further studies must be performed to test the hypothesis that those with greater endowments of bridging social capital were those that were able to either successfully move away from the New Orleans area and re-establish themselves in other locations, or facilitated better recovery in the New Orleans area following the hurricane. Group identity may be sacrificed (bonding social capital) but access to entitlements needed to recover from the disaster at least in economic terms may have been enhanced due to larger endowments of certain groups of bridging social capital.

Applying these arguments to shock situations sheds some insight into the economic and social impacts of natural hazards. It is hypothesized that, if the shock disrupts social capital (such as social networks), people will substitute labour and other economic capital to compensate for the diminished social capital. Further, it is hypothesized that the most vulnerable segments of a population may be less able to substitute social capital and economic capital and that these segments may experience social vulnerability, or a so-

Figure 71.3: Places of displacement following Hurricane Katrina. **Source:** Epodunk website, 2007: "Places of Displacement Following Hurricane Katrina"; at: <http://www. epodunk.com/top10/diaspora/destination-map.html> (21 March 2007). Reprinted with permission.



cial capital gap. To explore these hypotheses, the chapter turns to qualitative evidence from agent behaviour during and after Hurricane Katrina and other devastating hurricanes in the Gulf of Mexico.

71.5 Evacuation, Entitlement Failure, Social Vulnerability

Research on evacuation efforts in New Orleans before and after Hurricane Katrina indicates the role of social capital for those affected by natural hazards. Entitlement failures and lack of access can lead to a social capital gap (social vulnerability) which arises when shocks prevent people from substituting social and economic capital. Emerging understanding of the social dynamics surrounding Hurricane Katrina sheds some light on the mechanisms through which people cope with natural hazards. Hazards can disrupt social networks that facilitate cooperation, especially in the reconstruction and recovery phase.

Hurricane Katrina was initially a category 5 hurricane which was 'weakened' to a category 3 when it made landfall just outside of New Orleans, Louisiana in August of 2005. The hurricane devastated much of the north-central Gulf Coast of the United States, threatening millions of people and their assets. The hazard was the costliest and one of the deadliest hurricanes recorded in the USA (estimated at $150 billion, Munich Re 2006).

Hurricane Katrina resulted in the largest displacement of Americans in the country's history, dwarfing the impacts of the Dust Bowl – another case of environmental degradation and migration, in a period of about 14 days. Hurricane Katrina ultimately caused about 1.5 million people to be displaced temporarily (Wood 2001).[1] Figure 71.3 shows the places of displacement for these hazard-induced migrants. Of the 1.5 million displaced people, an estimated 107,000 illegal immigrants and temporary guest workers experienced secondary displacement due to Katrina.[2]

1 Peter Grier: "The great Katrina migration", in: *The Christian Science Monitor* (12 September 2005); at: <http://www.csmonitor.com/2005/0912/p01s01-ussc.html>.

71.5.1 Social Capital and Hurricane Katrina

Yet, given these widespread negative impacts, economists projected a 0.5 per cent impact on GDP and the formal economy including oil and gas production appeared to recover quickly, not incorporating the negative social and environmental externalities of this hurricane.

The evacuation strategies of most upper and middle-income people living in the New Orleans area reflected a relative ease in substitution between social capital and economic capital. Among the first to leave New Orleans before Katrina arrived were those who had family and friends to assist them and give them shelter in safe places. Affluent people withdrew cash from their bank accounts, left the city in their cars, rented hotel rooms in a safer area.[3] This relatively affluent group had sufficient economic capital to evacuate in an orderly way that did not leave them exposed physically to the storm or the ensuing flooding. Access to economic capital or the ability to substitute social capital for economic capital made this group less vulnerable to Hurricane Katrina. Additionally, the temporal opportunity costs of early evacuation – in the one to two days before landfall – were relatively low, since the storm was predicted to arrive on a Monday. Few if any work or school days were missed for the affluent group which evacuated early.[4]

In comparison, lower income New Orleans residents had fewer entitlements to help them prepare for Hurricane Katrina. Those without social networks outside the neighbourhoods of New Orleans were among the last to evacuate and were most dependent upon the different levels of government offices to provide transportation, shelter, food and water, and medical assistance. The nature of this later evacuation was forced, with the strategies of evacuation depending on the degree of social capital available. Evacuation strategies depended upon whom people could count on for help. Shelters were set up for these storm victims, but systems were not in place to allow a reestablishment of social networks and substitution effects. Research notes that these shelters did not take advantage of the shelter residents' own social capital, especially social networks. The result was a longer-than-necessary recovery period.

Economic capital flows were at a low point when Hurricane Katrina came. The storm came at the end of the month, when people receive their pay checks. At the time, economic resources for evacuation (hotel rental, cash, purchasing emergency supplies and fuel) were scarce. Low-income residents were less likely to own cars, making voluntary evacuation more costly and difficult to arrange. Although 35 per cent of the city's black households did not own their own automobile (only 15 per cent of white households did not own a car), city planners based emergency evacuation plans on individual car ownership.[5] Federally subsidized housing where the poorest residents of New Orleans lived was located in the lowest-lying areas that were most dramatically affected by the levee breeches following the storm. This group was hardest hit by the storm and at the same time had the fewest entitlements that would allow evacuation.

71.5.2 Social Capital and Declining Trust

There appears to be an increase in transaction costs connected with a decline in trust, the main source of cooperative behaviour (Fukuyama 1995; Levi 1996). Reputational mechanisms may be less effective or spatially bounded. That is, the hazard shock may force people to leave the bounds of their spatial networks such as the forced migration caused by the hurricane, causing them to become anonymous which in turn reduced the efficacy of such mechanisms in forming bonding social capital (Oliver-Smith 2007). There appears to be a negative externality for groups with deteriorated social capital such as undocumented migrants. The degree of opportunism and the degree to which reputational mechanisms that contribute to bonding social capital break down is related to how the hazard affects the group's social capital (Rodríguez/Dynes 2006). Further study is needed to explore whether groups with intact social capital will experience less opportunism and interruptions to these mechanisms than groups with less social capital.

This loss of trust was manifest in New Orleans immediately following Hurricane Katrina in the form of increased opportunism of individuals relative to the degree of disruption in social capital experienced by that individual's group. Katrina heavily affected specific social groups in New Orleans. One-fifth of those

displaced by the event were likely to have been poor, and 30 per cent had incomes more than one and a half times below the poverty line. Many of those displaced had strong community ties, and some of those displaced such as the elderly, disabled, and children relied almost exclusively on social capital for their survival (Gabe/Falk 2005). Studies suggest that the social networks of many Katrina refugees were disrupted, in part due to the physical disruption of the hurricane and levee breaches, as well as the evacuation attempts and longer-term reconstruction issues (Kates/Colten/Laska/Leatherman 2006). Media reports indicated declining trust and cooperative behaviour in the aftermath. Looting and deterioration of civic order in New Orleans erupted as social and physical networks, and behavioural norms were unsettled by the hurricane (Rodríguez/Dynes 2006).[6] It has been observed that in post-hurricane reconstruction, sharp reductions in supply chains allowed 'unscrupulous' businesses to charge prices far above market equilibrium for services like roofing or other repairs to damaged housing, as well as energy (Browne-Dianis/Lai 2006; Fletcher/Pham/Stover/Vinck 2006; Fussel 2006).

71.5.3 Social Capital in Caribbean Countries facing Hurricanes

In comparison, social capital has played a central role both in the preparatory phase to reduce the effects of the disaster and in response to the reconstruction and return to development following a disaster in the Gulf region. In Grenada those communities which could organize quickly and without outside facilitation fare well even in the face of dangerous hurricanes. Bonding social capital gives group members a deep sense of connectedness and has historically helped them fare better during and after hurricanes than newcomers to these communities. Villages that display strong bonding social capital include Apres Tout and Rose Hill (Kambon 2007). Members of these groups organized immediately following hurricanes to clear roads, repair roofing and buildings, and take care of those members who are not as strong (elderly, sick, children). Although these villages are aware of entitlements, they also have strong social capital and a tradition of self-reliance and independence (substituting bonding social capital for entitlements or economic capital) (Abramowitz 2001). The Economic Commission for Latin America and the Caribbean (ECLAC) reports that those households where members did not feel a strong sense of bonding social capital, were also noticeably slower in repairing homes following hurricanes. These communities include immigrant destinations like the Grande Anse Valley. The immigrants possessed little bridging social capital, were not informed about their entitlements, and required more assistance in order to better their circumstances (ECLAC 2007).

71.6 Summary and Discussion

Results from recent major natural disasters point towards the importance of pursuing a research agenda to better understand the disruption of social networks and social vulnerability during and after shocks. The impacts of shocks such as natural disasters often rely on economic valuation methods to indicate the extent of damage and the rate of recovery. Often the negative externalities of these shock events – those aspects which are not measured as results of a shock and which can work to the detriment of goals such as recovery – also prevent people from accessing entitlements which further dampen recovery. The loss of social capital – both bonding and bridging – can be one explanatory variable in why certain groups do not recover well following a disaster. Certain types of entitlements cannot be accessed, or can be accessed only with great difficulty, because available social capital has either deteriorated beyond a certain point or because it is not readily substitutable with other forms of capital such as money or other resources. The observation is important for disaster management and planning, particularly for socially vulnerable groups.

First, current measurement methods for the effects of natural hazards often do not account for losses to social capital, and disaster management plans sometimes assume that people or groups of people can substitute economic and social capital almost perfectly. Economic methodologies aid planning for measures to reduce the impact of natural hazards. Some gaps exist, however, which hinder the ability to understand the degree of economic impact and the vulnerability of different demographic groups to natural hazards. The deterioration of social capital does not necessarily manifest itself in lower GDP. While the nationwide economic effects of the hurricane were subtle and even growth-creating in specific sectors, it appears that the deterioration of social capital worsened the welfare prospects of individuals in the

6 See: "Governor: Evac Superdome, Rescue Centers", in: *FoxNews*; at: <http://www.foxnews.com/story/ 0,2933, 67653,00.html> (30 August 2005)

regional economy. Disasters appear to pose a largely unmeasured deterioration of social capital which imposes a loss of welfare for group members. This welfare loss is not reflected in current techniques to estimate the costs of natural hazards on society.

Long-run economic growth is not necessarily slowed by shocks to groups with the least social capital; hence the effects on these groups appear underrepresented in the current literature. Economic performance following the shock may mask the substitution between social and economic capital, so that a deterioration of social capital may lead the economy towards inefficiently high levels of per capital output. This further masks the loss of social capital (negative externality), and may drive individuals to continue substituting social capital for economic capital.

This situation can lead to rising social vulnerability as the social capital stock is further depleted. Diminishing trust appears to have imposed a loss of welfare for group members affected by Hurricane Katrina which is not reflected in current techniques to estimate the costs of natural hazards on society. With the growth of new types of approaches which explore the effects of substitution between social and economic capital, the effects of social vulnerability are becoming more prominent in the discussion.

Second, social capital has a spatial/network element that can break down and relax the constraints on behaviour that facilitate cooperation in shock situations. Hazards can negatively affect groups who have social vulnerability, i.e. multiple stressors lead to a breakdown of the ability of social networks to secure actual or potential resources. An erosion of trust and social capital led individuals – such as the undocumented Hispanic migrants discussed above – to increase labour, spending, or other economic activities.

A household can smooth consumption and manage the effects of a natural hazard by substituting social assets such as trust, solidarity, and cooperation if hazards destroy material and financial assets. A household may likewise substitute economic capital to manage the effects of a natural hazard if social assets cannot be sufficiently accessed. Economic and social assets are imperfect substitutes in part because many types of social assets are bounded, spatially or institutionally. Social assets such as trust can deteriorate in the face of shocks that affect the way people relate to one another in specific settings such as communities, church groups, or neighbourhoods (Oliver-Smith 2002). One of the immediate social impacts of natural hazards is the disruption of social networks, and efforts to re-establish contact with family members and friends is one of the first post-hazard activities undertaken by people (Blaikie/Cannon/Davis/Wisner 1994; Pelling 2003; Cole 2004; Schelling 2007). Media attention of post-hazard recovery efforts sometimes highlight – as it did after Hurricane Katrina – the abject conditions of poor people affected by the storm. Social vulnerability is a pre-existing state, but often made manifest when a large disruption such as a natural hazard occurs.

Future research will move this modest beginning forward, including theoretical articulation of shock situations, substitution, and social vulnerability. Applied research may examine the implications of disaster management policy, such as evacuation, resettlement, and reconstruction in ways that encourage the accumulation of social capital and the avoidance of disrupting social networks so important for social resilience. Such research will expand the understanding of underlying social vulnerability, and make the negative externalities associated with deteriorating social capital more explicit (box 71.1).

Box 71.1: Substitution between Social and Economic Capital in Hazards. **Source**: The author.

Recognizing the need to better understand how and why shocks affect certain groups disproportionately, the chapter examines one example of a strain in the economics literature showing how negative externalities can foster growth. This approach augments a Solow-Ramsey growth model by including a labour-leisure choice, social capital in the production function, negative externalities affecting social capital and which deteriorate social capital while increasing economic activity, and substitution of social for economic capital. It is useful to try to understand the consequences of social capital substitution for specific groups of people. The utility and production functions following Bartolini and Bonatti (2004) will now be examined.

The *utility function* is constructed in each period t, where the utility of the representative household is an increasing function of consumption and leisure:

(1a) $U_t = \ln(C_t) + \varphi\ln(1-L_t)$, $\varphi < 0$, $L_t \leq 1$,

where C_t is consumption and L_t is the time spent working in period t by the representative household (total amount of time available to each household in time t is normalized to be one).

The *production function* shows how each household produces a single good Yt according to the technology used such that:

(1b) $Y_t = L_t\alpha K_t\ 1-\ \alpha A_t\beta$, $0 < \alpha < 1$, $0 < \beta \leq 1$

where K_t is physical capital and A_t is a variable affecting factor productivity.

The physical capital evolves according to the following function:

(1d) $K_t+1 = I_t(1 - \delta)K_t$, K0 given , $0< \delta <1$ where I_t is investment.

The variable affecting factor productivity A_t depends on a state variable that evolves with time, and on the amount of output that each household devotes in period t to boosting factor productivity such that:

(1c) $A_t = R_t + \Phi X_t$, $\Phi > 0$

where R_t is the state variable and X_t is the amount of output devoted by the representative household to boosting productivity. For simplicity, R_t and X_t are assumed perfect substitutes.

The state variable R_t evolves according to

(1d) $R_t+1 = \gamma R_t + S - \eta Y_t$, R0 given $0< \gamma <1$, $S > 0$, $\eta \geq < 0$, $R_t \geq 0$ t

where S is constantly influencing the growth rate of R_t. The evolution of R_t may be influenced (if $\neq 0$) by the productive activities undertaken by households.

The representative household must satisfy its period resource constraint such that:

(1e) $Y_t\ I_t+X_t+C_t$

Therefore the intertemporal optimization problem amounts to choosing $\{L_t\}0\infty$, $\{I_t\}0\infty$, $\{X_t\}0\infty$ and $\{C_t\}0\infty$ in order to fulfil the following:

$$\infty$$

(2) $\max \Sigma\ \theta\ Ut$, $0 < \theta <1$, subject to (1)

$$t=0$$

Using this approach, Bartolini and Bonatti (2004) suggest (in non-shock situations) that social capital deterioration is represented as a negative externality. As social capital deteriorates, agents compensate for this deterioration by increasing their labour supply and accumulation in order to increase the output used to substitute diminishing social capital. A modelling approach by Antoci and Sacco (2005) is related to the one presented above and assumed perfect substitutability to simplify the mathematics. Relaxing this assumption – a step that in part suggests that social capital has different characteristics (i.e. relational social capital, bridging social capital) – could reveal some more subtle economic consequences for social vulnerability, but makes closed-form solutions hard to obtain. Antoci, Saco, Vanin (2005) simulated a version of the model with the hypothesis of imperfect substitution, but did not gain any interesting insights.

The point of the Bartolini/Bonatti (2004) approach is to examine economic growth and negative externalities. However, the approach is examined above to consider the implications of substitution in shock situations, especially for socially vulnerable groups. The substitution of economic and social capital is of particular interest during times of shock. The innovative features of an approach like Bartolini/Bonatti (2004) which are relevant to risk management of natural hazards include the following:

- Deterioration of social capital imposes a loss of welfare for group members. This welfare loss is not reflected in current techniques to estimate the costs of natural hazards on society.
- Social capital has a spatial/network element that can break down and relax the constraints on behaviour that facilitate cooperation in shock situations.

The approach suggested by Bartolini/Bonatti (2004) indicates that long-run growth is not necessarily slowed by shocks to groups with the least social capital; hence the effects on these groups appear underrepresented in the current literature. Economic performance following the shock may mask the substitution between social and economic capital, so that a deterioration of social capital may lead the economy towards inefficiently high levels of per capital output. This further masks the loss of social capital (the negative externality referred to by Bartolini/Bonatti (2004)), and may drive individuals to continue substituting social capital for economic capital.

72 Social Vulnerability, Discrimination, and Resilience-building in Disaster Risk Reduction

Úrsula Oswald Spring

72.1 Introduction[1]

Discrimination represents a harmful as well as an unfair treatment of a person or a group, based on prejudice. Therefore it is related to a 'rejection process' of the other, emphasizing critical attributes such as race, sex, age, gender, social and marital status, class and caste, migrant or refugee status, religion, incapacity or handicap. These attributes are socially constructed and are results of the complexity of daily life and of existing power structures. Discrimination induces people to simplify their behaviour by identifying themselves with the ideology of the group and to reject the other. This often creates stereotypes of how to think, to believe, and to act. Thus, a system of values, ideas, beliefs, and practices influences discrimination, and often oversimplifies complex life situations.

This chapter deals with discriminative behaviour, attitudes and actions during dangers, hazards impacts, and disasters. Discrimination can lead to emotional and material benefits for the discriminator and increases social vulnerability of the discriminated. The hypothesis postulates that social, psychological factors, and race and ethnic concerns justify discrimination and therefore reduces effective *disaster risk reduction* (DRR). They often make existing complex disaster situations worse by impeding preventive behaviour, early warning (Villagrán 2006), and solidarity during and after a disaster. Discrimination and risks are not equally distributed. To overcome inequality and favouritism, the root causes of discrimination must be searched and a legal framework with sanctions must be adopted. Simultaneously, in each society the root causes of discrimination and social vulnerability must be analysed and politically overcome. An efficient combat against discrimination empowers the socially vulnerable and discriminated from the bottom up through special training, workshops, and daily life practices. The combination of top-down and bottom-up activities can reduce the existing social vulnerability and therefore enhance resilience of the discriminated, shorten their human suffering, and contribute to a fast recovery. Thus, an effective DRR response must be arranged prior and during disasters, but also during the reconstruction phase. A society with less discrimination and greater social equity can improve health and livelihood conditions for everybody, but also its human, gender, and social security.

The increase in number and magnitude of disasters induced scientists, international organizations, governments, and insurance companies to better understand the different impacts of disasters among regions, gender, social groups, and age groups. Social vulnerability tries to explain why the same type of an event could have different outcomes depending on the position of the people in the social structure, their personal preparedness, their social vulnerability, and the readiness of governments to help. Social vulnerability can be further aggravated by an inherent process of discrimination that may trigger already existing difficult situations. Thus, discrimination is a crucial political, psychological, social, and political phenomenon that can affect life, dignity, and wealth. As a socially constructed reality it can be changed. Often people who are frequently exposed to disasters are creating resilience (Ariyabandu/Fonseca 2009; Wisner 2004) through bottom-up learning and social organization (Oswald Spring 1991; MST 2005, Freire 1998), which can be reinforced with legal and institutional support.

This chapter offers a brief conceptualization of discrimination (72.2), what is followed by a typology

1 I want to thank Ben Wisner and Hans Günter Brauch for their helpful observations and suggestions, and Ronald Lappin for his kind efforts in improving the English. This chapter builds on previous studies by Oswald Spring (2007a, 2008, 2009) that evolved from her work as the first holder of the MunichRe sponsored chair on social vulnerability at UNU-EHS in Bonn, Germany (2005–2009).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_72, © Springer-Verlag Berlin Heidelberg 2011

of discrimination where gender, race, class, age, physical handicap, migrants, and institutional neglect are reviewed regarding their conscious or unconscious discriminative behaviour. Both may increase social vulnerability in difficult situations (72.3). Then theoretical questions related to identity processes and social representations are discussed and how social vulnerability often increases due to adopted values, beliefs, and behavioural patterns (72.4). The fifth part reviews the triggering effects of these processes that may destroy human lives and wealth (72.5). The sixth part explores the potential of resilience-building with a combination of bottom-up participation that can be reinforced by institutional interventions, laws, norms, and social behaviour controlling discriminative behaviour (72.6). The conclusions (72.7) combine the conceptual discussion with practical outcomes, explaining *social vulnerability* (SV) and discrimination during *disaster risk reduction* (DRR) and *disaster mitigation* (DM).

72.2 Discrimination, Social Identity, Social Representations, and Social Vulnerability

The concept of 'discrimination' comes from the Latin word *discriminare* and implies an unequal behaviour that can enhance (positive) or limit social situations (negative discrimination). Normally, it is understood as a harmful and unfair treatment of a person or a group based on prejudice. It is measured as the discrepancy between norms and socially accepted mindsets and social realities or understandings. Discrimination is therefore based on a 'rejection process' of the other, emphasizing critical attributes such as gender, race, sex, age, social and marital status, class and caste affiliation, migrant or refugee status, religion, incapacity or handicap. Indirect discrimination occurs when through apparently neutral governmental, societal, and economic behaviour a specific group experiences disadvantages and is obliged to justify its legitimate aim and the means for achieving it. In a discriminative behaviour, mind and action can be distinguished. People who discriminate often derive both emotional and material benefits, also understood as malice.

The complexity of daily life induces people to simplify their existence by identifying themselves with the ideology of the group and rejecting the other. Tajfel (1981; Tajfel/Turner 1978) showed that the intra-group discrimination is due to social identity. Social identity permits a social categorization, including large (nations) and small groups (clubs). They provide their members with a sense of who they are. Social identities not only describe but also prescribe appropriate behaviour. According to this theory, the mere act of individuals *categorizing themselves* as group members was sufficient to lead them to display in-group favouritism. A person has not only a 'personal self', but several selves that correspond to widening circles of group membership and to social representations. Moscovici (1973) described social representation as:

> systems of values, ideas and practices with a two-fold function; first, to establish an order which will enable individuals to orientate themselves in their material and social world and to master it; secondly, to enable communication to take place amongst members of a community by providing them with a code for social exchange and a code for naming and classifying unambiguously the various aspects of their world and their individual and group history.[2]

A system of social negotiation has created its meaning, thus it is not a fixed and defined thing, belief, behaviour and thinking (Oswald Spring 2009).

Social representations and identity processes maintain the *status quo* of any organization and are often not conscious. Thus, discrimination is acute and discerning, but normally stereotypes are oversimplifying complex life situations, where the group decides how to think, to believe, and to act. Discrimination underlies also a system of values, ideas, attitudes, and practices. It establishes and uses culturally diverse circumstances to justify unequal behaviour with other races, colour, professions, and social status. Society confronts an individual with obstacles who criticizes or tries new ways.

Discrimination exists in all human, political, and social behaviour. Nevertheless, the existing habitus (Bourdieu 1972, 1980, 1990) is difficult to eradicate and only civil rights movements in the USA and a longstanding struggle against Apartheid in South Africa was able to force the white minority to grant equal rights in daily life to black people and create a rainbow democracy in South Africa. Corruption, authoritarian regimes, and lack of democratic participation increase discriminative attitudes within governments, elites, and by politicians. During the WTO ministerial meetings discriminative trade behaviour prevented an agreement in the Doha Round, because industrialized countries were unwilling to reduce their

2 See "Social Representation Theory"; at: <http://changingminds.org/explanations/theories/social_representation.htm>.

subsidies in agriculture and wanted to continue to flood poor countries with artificially cheap and subsidized products, thus destroying their agriculture, food security, and community life. In any discipline discriminative behaviour exists and must be analysed and countered with a transdisciplinary approach.

During disaster situations historically existing and socially and politically accumulated discriminations, due to poverty, race and class differences, undemocratic power structures, and neglect of the handicapped often manifest themselves.[3] This results in social vulnerability, defined as "the characteristics of a person or group and their situation that influence their capacity to anticipate, cope with, resist and recover from the impact of a natural hazard" (Blaikie/Cannon/Davis/Wisner 2004: 11). Discrimination increases the social vulnerability of these groups. Often, it is triggered by long-term emergency situations such as famine, physical or sexual violence, water scarcity and pollution, economic crises, gender, caste and class, governmental and business corruption, performance and exploitation. It reduces preventive actions, limits early warning and aid during an emergency, and impedes a holistic development during the recovery phase. Before these theoretical concepts are developed further a typology of the most current discrimination processes is offered.

72.3 Typology of Discrimination

Discrimination can be both cause and effect of triggering processes during disaster situations. The most common types of discrimination lead to this typology, each with different degrees: 1) political and institutional discrimination (neglect of governments, aid agencies, sponsors); 2) gender; 3) race, colour, ethnicity, religion, sexual orientation, and other minorities; 4) class, cast, and different socio-economic conditions; 5) migrants and refugees; 6) age factors (children, adolescents, elderly): and 7) the physically handicapped (disability, illness, HIV/AIDS-status).

72.3.1 Political and Institutional Discrimination

Institutionalized or *institutional discrimination* (ID) is a behaviour that is often accepted as normal in governmental objectives, plans, practices, procedures, and laws. The best known examples were Apartheid in South Africa and the institutionalized racial segregation in the USA after the Civil War until 1960, when bottom-up civil rights movements changed these discriminative processes. Other examples of ID are anti-Semitism in Germany (Schmidt/Hesse 2006) and the re-education camps in several communist countries (USSR, China, etc.).

Nevertheless, ID by governments is almost universal. Governments offer a better treatment for nationals than for immigrants or foreigners when they enter a country (Bannerji 2000). There are also structural IDs when poor or unemployed citizens may receive subsidies or welfare benefits from public funds, while others may be denied these payments due to neglect or bureaucratic obstacles. A problem of ID exists, e.g. with the focal approach to poverty alleviation promoted by the *World Bank* (WB), instead of granting general subsidies for marginal areas.[4]

The complexity of ID induced the *European Union* (EU) to analyse this type of discrimination more deeply to better understand that underlying mechanisms and social representations created racial discrimination and xenophobia with different ethnic groups. The EU was also focused on 'speech acts' of public discourses, on party programmes, and on the mass media that reinforced these discriminative forms of behaviour.

The institutionalization of ghettos becomes a legitimating process for undermining an equal treatment beyond ethnic or religious beliefs (Bourdieu 1980, 1990). "Once established the category gives birth to the understanding of 'the other' in terms of quota, i.e. number of children belonging to ethnic minorities to be allowed access to a given school" (Parekh 2000: 5).

The ID is more common in countries with a weak implementation of laws and high corruption, where a minority gets privileged access to public resources, thus widening the social gap. In these states often the

3 Nearly 9,700 people were victimized in the U.S. in 2008 because of their race, religion, sexual behaviour, disability or of other forms of discrimination. This represents an increase of 2 per cent over 2007; at: <www.fbi.gov/publications.htm>.

4 Poverty among particular groups can be reduced, but it always creates excluded people and generally increases bureaucracy. During disaster and emergency situations financial support is often canalized through existing channels based on discrimination. But sometimes they are deviated for political support during the next elections (Mouffe 2000).

victims of a crime are blamed of having provoked it or when they denounce a crime they are considered as the key suspect. When things go wrong, individuals often blame others for a crime nobody committed, in order to be free, inducing a new variety into the concept of the 'prisoner's dilemma'. This type of ID if it is combined with inefficiency and corruption often transforms jails into centres of detention of innocent people, of ethnic minorities and poor people who are unable to struggle for their rights and a just enforcement of the law. A similar situation occurs when people see the poor standing in line for welfare support. The poor often see themselves or are considered by others as a problem, instead of examining the root causes of poverty and their lack of basic human security (Brauch 2009b). These are two different sides of a process of blaming the victims for social discrimination.

In disaster situations ID is also common and it is often combined with neglect. This applies to all stages from early warning evacuations to the reconstruction process. For example, on 2 May 2008 killed at least 100,000 people in Myanmar (Burma) and the outbreak of dysentery and cholera later was threatening the lives of a further 1.4 million people (Oxfam 2006a). In September 2005, during Hurricane Katrina the Latino population in New Orleans also faced an ID. The *National Council of La Raza* (NCLR) analysed the failed US governmental response "... on at least two occasions, law enforcement officers raided Red Cross shelters, racially-profiled Latinos staying at the shelters, and then asked them to leave under the assumption that they were undocumented workers and not hurricane survivors" (Muñiz 2006: 13).

In early October 2005, Hurricane Stan together with torrential rainfalls caused economic damage of 2 billion US$ in Mexico alone. The worst impact was in the Mexican state of Chiapas. Officially the Mexican federal government reported only 98 fatalities, but after a month still 30 persons were reported missing. Stan severely impacted on indigenous people, due to a lack of preventive evacuation, which started only after the hurricane had destroyed the livelihood of 4 million inhabitants, whereof 83,825 persons had to live in 492 refugee camps (García/Marín/Méndez/Bitrán 2006). Two weeks later on 21 October 2005 Hurricane Wilma hit Cancun, an international high-value sea resort. In this case, early warning and preventive evacuation avoided human fatalities, and only 8 persons died. More than one million inhabitants were affected; all of them depending on tourism, but already three months later the infrastructure was rebuilt and the resorts were ready again for international tourism. In both hurricanes, during the same month and in the same country the governmental assistance fundamentally differed: ID prevailed in the marginalized indigenous region while the government offered credits, subsidies, renegotiation of debts, and a prompt payment from insurance companies for the resort.

In synthesis, ID can be found in laws, judicial decisions, public attention, employment opportunity, tax exemptions, civil rights and use of public facilities, based on race, nationality, colour, age, sex, and creed. Democratic states have enacted laws[5] against discriminative forms of behaviour and permitted lawsuits to enforce equal rights and protect minorities. Nevertheless, only improvement of citizens' participation and "associational rights-claims" (Rocco 2000), transparency, improvement of socio-economic conditions, education and trained public functionaries in civil rights, combined with an efficient system of law enforcement against ID, can overcome discriminate behaviour in government (Connolly 1995). In relation to poverty alleviation, general programmes in marginal areas will help to combat ID and political (ab)-use. With regard to structural ID, immigration laws, civil rights trained migration functionaries, and free transit between neighbour countries (e.g. Schengen in Europe) will reduce further human rights violations.

Several countries experiencing foreign immigration have created the ideology of multiculturalism with multiple meanings.

> What is common in the sociological content of the term in the West – but never spoken of – is that it was formulated as a framework, a set of policies, for the national accommodation of non-white immigration. It was a liberal response that skirted the reality of the already racialized constitution of these societies and masked the existence of institutionalized racism (Sandercock 2004: 1).

Most countries have signed and ratified UN Conventions on human rights and non-discrimination. In their constitutions most industrialized countries have prohibited discriminatory practices and promoted individual merits instead of inherited social conditions. But unfair treatment of persons or groups, based on prejudice and established social representations, still

5 The Civil Rights Act of 1964, the Voting Rights Act of 1965, the amendment to the Constitution of the USA mandating equal rights for women in the "Equal Rights Amendment" are some of the legal procedures to grant greater equality and equity.

exists and is greater in poor countries which are also more affected by all kind of hazards.

Confronted with multiple discrimination processes and after the Apartheid period was over, South Africa decided to put in its Constitution the right to equity for all citizens, independent of race, colour, economic status, and sexual preference. But in many countries constitutionally granted basic rights are not properly implemented. Thus, disasters often exacerbate the contradictions that have existed before the hazard occurred.

72.3.2 Gender

Gender discrimination refers to a different treatment based on biological differences between women and men (sexual dimorphism).[6] It includes connotations of values that change within different cultural contexts. It refers to the most common and longstanding discrimination (Butler 1990; Tickner 1997, 2001, 2002). It includes structural discrimination which is reflected in different kinds of vulnerabilities, reinforcing each other, including social, political, economic and personal discriminations. Most of them are based on identity patterns and include the rejection of the other (Moscovici 1976, 1984, 2000). The outcomes in form of social representations (Flores 2001; Serrano 2004, 2009; Oswald Spring 2008, 2009) have constructed discrimination among genders that are taken for granted around the world. "The very subject of women is no longer understood in stable or abiding terms" (Butler 1990: 1) ... "consequently, there is a need for a radical re-thinking of the categories of identity within the context of relations of radical gender asymmetry" (Butler 1990: 11).

Gender discrimination affects multiple aspects: social and family position, labour (Calas/Smircich 1993; Fox/Hesse-Biber 1984), politics, abuse, sex trade (Jeffreys 2008, 2009), and the body of women as a battlefield during the war (Rehn/Johnson 2002). It is reflected in feminicides, female feticides (Das Grupta 1987, 1997), rape, higher girls mortality and undernourishment, low education, etc.[7] This male organized system brings multiple discriminative habits into government, agencies, enterprises and law-making processes, limiting the empowerment of women. In most societies a married woman's civil identity is now covered by that of her husband. Property she brought into the marriage, segregation within the family, and lower wages make women dependent on men. They become the servant of the extended family caring about people, the house and animals, often also the orchards and food production. Many times they are also victim of rape by family members and their human rights violations go far beyond sexual and physical violence, including also psychological stress and deprivation of the right to leave the house alone, to speak with neighbours, in synthesis a condition of a slave.

For professional and trained women, barriers for upward mobility and better payment (table 72.1) are limited by the 'glass ceiling'[8] (Neville/Pennicott/Williams/Worrall 1990; Insch/McIntyre/Napier 2008; Thomas-Hunt/Phillips 2004; Judge/Livingston 2008), related to identity patterns and an epistemological understanding of science, progress, and gender in a rigid and hierarchical way (Harding 1986, 1993, 2001). These structural obstacles become nearly impossible to overcome the limits and achieve equality (Ridgeway

6 Butler (1990: 6) argued: "When the constructed status of gender is theorized as radically independent of sex, gender itself becomes a free-floating artifice, with the consequence that man and masculine might just as easily signify a female body as a male one, and woman and feminine a male body as easily as a female one."

7 The mortality at birth gives girls in Punjab, India a rate of 1.18 as they better survive. However, from 1 to 11 months the ratio of male/female drops to 0.53; from 12-23 months to 0.51 and from 24–59 months to 0.65. The explanation is that child mortality in early childhood is higher for girls because they are neglected by their parents and they have to work from childhood on as servants, getting less and bad quality food. They are abused by other family members and the threat of dowry when they get married induces infanticide. Another discrimination exists through the abortion by sex, when Amartya Sen (1990) refers to "100 million missing girls" (China 44; India 37; Pakistan 5.2; Bangladesh 3.7; and South East Asia: 2 millions), due to female feticides. Reproductive health is sensitive: each year 35,000 women and babies die in Nepal alone due to insecure conditions of birth and neonatal management (WDR 2006). In Afghanistan every 20 minutes a women dies while giving birth due to insufficient health services; the second highest rate of maternal deaths in the world, it is only worse in Sudan. Each woman has an average of more than seven children and sometimes husbands or grandfathers decide that it is more important to buy a buffalo than to spend the money for a woman in a hospital (WDR 2006).

8 While the term *glass ceiling* is metaphorical, many women find it very real, indeed, when they try to climb the labour ladder. Along with the image of barrier is the idea of glass: it is real, but transparent and not obvious to the observer.

2001). A United Nations document (2006a) noted that: "Women constitute half the world's population, perform nearly two thirds of its work hours, receive one tenth of the world's income and own less than one hundredth of the world's property."

Of women between 15 and 64 years, 61 per cent enter the paid labour force, but 86 per cent of men. Nevertheless, there are different payments for comparable work (table 72.1; Giele/Stebbins 2003), sexual harassment in the workplace, lack of family-friendly workplace policies, and often open discrimination. According to Forbes, in 2009 only five of the 500 biggest enterprises were directed by a woman. In 2007 the *Equal Employment Opportunity Commission* (EEOC) in the USA received 24,826 charges of sex-based discrimination.[9] Workplace fairness, legal protection, and equal salaries for similar jobs are some of the processes that could reduce discrimination at the workplace. Then there is the discrimination in household work, where the non-paid labour of women represents 37 per cent of the GDP of the USA (Vaughan 2004) and in poor countries this percentage increases up to 80 per cent when subsistence orchards are giving also the food for the extended family (FAO 2008f). In political terms, of more than 202 sovereign states in December 2008 only 12 were ruled by women (UNIFEM 2008).[10] Tickner (1999) asks "why here are so *few* women in position of power even in countries where legal equality has been in place for a long time. The power that gender role expectations exert, can tell us about this". There is not only a quantitative problem with women in politics but also with their visibility. Female ministers are concentrated in social areas (14 per cent) compared with legal (9.4 per cent), economic (4.1 per cent), political affairs (3.4 per cent), and the executive (3.9 per cent). Only 7 per cent of the world's total cabinet ministers are women (UN 2006). There is also a low correlation between a high rank on the HDI and women's participation in politics, but countries such as Iceland, Canada, Switzerland, Japan, France, and the USA still have gender discrimination patterns in government (table 72.2). Norway, Sweden, Finland and Germany have a higher female political participation, while Latin American countries are still struggling for more equality.

Table 72.1: Different pay in the manufacturing sector by sex for comparable work; **Source**: UN (2006: table 5g).

Country	Payment for women compared with men (%)
Sri Lanka	85
France	79
Mexico	71
Brazil	54
Bangladesh	50

Gender discrimination has been high in disaster agencies and in UN organizations working on disaster management. Most of them are still run by men irrespective that gender discrimination increases social vulnerability. In the Aceh Besar district the surviving men outnumbered females in a 3: 1 ratio (Oxfam 2005a). In a case study on Sri Lanka women represented 65.3 per cent of the fatalities (Birkman/Fernando/Hettige 2006). Ariyabandu/Fonseka (2009) found that the distribution of aid during the tsunami relief in Asia and the earthquake in Pakistan discriminated against women. They found that most support was given exclusively to men, as heads of household; women did not get direct access to relief aid, even when they were head of a family. External support often reproduces gender biases: while fishermen in Indonesia and India got boats and fishing implements, fishing women did not get any tools, what impeded recovery with dignity through productive self help.[11]

These historically developed gender gaps are mostly invisible. Thus, social identity is complex (Moscovici 1990, 1998, 2000) and stereotypes are among the root causes of any discriminative behaviour (Halsam 1995; Haslam/Oakes/Turner/McGarty

9 The EEOC resolved 21,982 sex discrimination charges during 2007 and recovered $135.4 million in monetary benefits for the charging parties and other aggrieved individuals (this data does not include monetary benefits obtained through litigation <http://www.eeoc.gov/types/sex.html>).

10 The Philippines and India (before also Indonesia, New Zealand, Bangladesh, Sri Lanka) in Asia; Argentina and Chile in Latin America and Caribbean (before also Panama, Jamaica); Finland, Germany, Ukraine, Bosnia/Herzegovina, Island and Moldavia in Europe (before Latvia, Ireland), and since 2006 Ellen Johnson-Sirleaf, President of Liberia in Africa and Luisa Diogo, Prime Minister of Mozambique. In 2005, globally 14 per cent of the parliamentarians were women and 11 per cent held a ministerial or sub-ministerial post. In Niger only 1 per cent of the members of parliament are women and Sudan has no female ministerial official. Several Gulf States with parliaments did not yet give women the right to vote or to stand for election (UN 2006).

Table 72.2: Rank of countries according to the HDI and percentage of women at the ministerial level in June 2007; **Source:** IPU [Inter-Parliamentary Union] (2007).

Rank HDI	Country	2005
1	Iceland	27.3
2	Norway	44.4
3	Australia	20.0
4	Canada	23.1
5	Ireland	21.4
6	Sweden	52.4
7	Switzerland	14.3
8	Japan	12.5
9	Netherland	36.0
10	France	17.6
11	Finland	47.1
12	USA	14.3
22	Germany	46.2
38	Argentina	8.3
40	Chile	16.7
46	Uruguay	0
48	Costa Rica	25.0
59	Bahamas	27.7
50	Seychelles	12.5
51	Cuba	16.2
52	Mexico	9.4

1995). The traditional role assignment of a woman is to be a housewife who cares for children, the family, old people, domestic animals, and orchards.[12] But it is above all the social identity process that reduced their survival opportunities (Anderson/Billing 1992). Men and women acquire different functions and attributes in any society (military vs. childrearing; public vs. private), that are based on social roles, norms, and traditions. Women's self-identity, social pressure, and life-learning processes have internalized their role for mothering (Chodorow 1978). They feel morally self-obliged to care for family members and their livelihood. In a moment of risk, their first reaction is to save children, elders, the handicapped, and often domestic animals. While a man can reach the highest level of honour offering his life as hero for the 'fatherland'; a woman gets her sublime self-realization by giving her life for others in a silent way.

To address gender discrimination, a policy in myriad form must be developed, where procedural issues, structural phenomena, training, and empowerment will change the thousands of years fixed rules that have created theses discriminative forms of social behaviour.

> If identities were no longer fixed as the premises of a political syllogism, and politics no longer understood as a set of practices derived from the alleged interests that belong to a set of ready-made subjects, a new configuration of politics would surely emerge from the ruins of the old. Cultural configurations of sex and gender might then proliferate or, rather, their present proliferation might then become articulated within the discourses that establish intelligible cultural life, confounding the very binarism of sex, and exposing its fundamental unnaturalness. What other local strategies for engaging the "unnatural" might lead to the denaturalization of gender as such? (Butler 1990: 15).

Sexual discrimination was outlawed in the United States through the Civil Rights Act of 1964 in the hopes of allowing women to rise in the working world once proper experience has been achieved (Hesse-Biber/Carter 2005). There remains the question why feminism has been vilified and why famous women (e.g. Hillary Clinton) were very cautious to use it, due to so many negative connotations. Without doubt, this is a political issue that is related to the preservation of power in the existing system of vertical, authoritarian and violent relations, also called patriarchy. Only a deconstruction or decolonization will be able to open the door for gender equity and solidarity to achieve the proposed Millennium Development Goals (Mohanty 2004; Oswald Spring 2009).

11 Another example of gender gaps is the discrimination of relief aid for single mothers in Pakistan after the earthquake; or the rape of women in the refugee camps of Darfur when they have to search for fuel early in the morning. In the recovery phase in Sri Lanka, a good intended project ended with gender discrimination. Government promised new houses once the widowers married again. Adolescent girls were obliged by their families to marry elder men often with children, only to get out of the refugee camp.

12 During the tsunami disaster, this was one of the reasons why women were inside their houses, busy with domestic work. They did not perceive the imminent danger. Due to cultural and misogynist taboos they were not trained in swimming and were dressed with saris and had long hair. All these factors imperilled their hazard response.

72.3.3 Race, Colour, Ethnicity, Religion and Sexuality

Racisms is a system of beliefs, sometimes organized as a doctrine, where biological differences among human groups determine individual and social opportunities, declaring one's own race as superior and exercising domination over others by a specific belief system. The Macpherson Report (1999) describes it as

> the collective failure of an organization to provide an appropriate and professional service to people because of their colour, culture or ethnic origin. It can be seen or detected in processes, attitudes and behaviours which amount to discrimination through unwitting prejudice, ignorance, thoughtlessness and racist stereotyping[13] which disadvantage ethnic minority people.

Combined with institutional neglect, discrimination happens all over the world. Two hundred tribal Iruars in the Cuddalore district in India had not received any governmental help a month after tsunami. As an ethnic group, they represent the bottom of the social hierarchy. Even if the situation of caste and ethnicity is complex, the government has a legal obligation to guarantee the human rights of the discriminated. Small groups react to this discrimination with isolation and when they organize in a bigger group they defend their human right to equity (Levine/ Moreland/Ryan 1997).

> Racism can be both personal and institutional so efforts to combat it must address both aspects. Individual racism is an isolated act by a single individual. Changing laws and culture have helped to reduce, but not eliminate it. A recent CNN Poll indicated that 84 per cent of Blacks and 66 per cent of Whites considered racism to be a 'very serious' or 'somewhat serious' problem; and 51 per cent of Blacks and 26 per cent of Whites claimed to have experienced some form of discrimination. But a singular focus on individual racism and discrimination can divert attention from a more insidious and subtle contemporary form – institutional racism and discrimination (Barbour 2008: 1).

When discrimination is related to ethnic groups, it is often a reaction of *ethnocentrism* and when it refers to outsiders it is called *xenophobia* (Hogg/Moreland 1993). Colonial history and economic dominance often induced white people to think of themselves as being superior (Hage 1998). Ethnic discrimination is reported from all continents, but less known in Africa.[14]

Indifference, neglect, and insensitivity help foster aversive racism which may not be unrecognized by the majority because it is so embedded in the social culture and structure. As this is the 'normal behaviour' it perceived the system as fair and equitable. It assumes that everyone is treated equally thus situations where prejudice and discrimination occur are denied. Discrimination is often an act of omission and governments use their small budgets to justify their non-intervention and neglect of discrimination. Minorities who are affected and have experienced discrimination hold a different perception. They see discrimination as both acts of omission and commission. They start and organize to denounce it.

Worldwide, this type of discrimination is related to the appropriation of collective land rights and natural resources by minorities. They use the lacking legal definitions or existing conflicts with the modern system of private property and resource exploitation for personal interests. But they can not deny the institutional discrimination. They frequently experience complex disaster situations as e.g. in Nigeria with its oil reserves (Women's Commission for Refugee, Women and Children 2006) or in Myanmar in May 2008 during Cyclone Nargis, where the military rulers did not launch an early warning and evacuation policy as a region where the guerrilla movement is active

13 Maughan-Brown (1985) looks critically at the "use that is made of fiction as an instrument of propaganda, the way race myths and stereotypes are embodied in fiction."

14 Muzangi Mbella Liliane, an indigenous from Congo insists: "There is a mistake to think that there were no indigenous people in Africa. The ancient migration of peoples and tribes had sparked clashes and formed segmented societies long before Western colonization. Therefore, for African indigenous and tribal communities access to traditional lands and resources should not be denied, particularly... the vast amounts of which are in high demand worldwide." Johnson Ole Kaung, the Director of the African Indigenous Movement for Peace Advancement and Conflict Transformation, said "African's indigenous populations and communities were identified outright as second-class citizens and were systematically marginalized on the basis of their cultural identities and the traditions they practiced, which were considered 'primitive' by some bureaucrats. The key issue for Africa's indigenous dealing with conflicts and natural disasters ... is the protection of their rights and resources, and ensuring the legal recognition of those rights" (UN 2006). And the Ogiek, a tribe from Kenya, argued that "all Africans are indigenous and our complicated, ancient history of human migration in Africa had produced tribal groups and communities as nomads, pastoralists, hunter-gatherers, whose way of life attachment to particular land and ecosystems, and social and political standing ... had resulted in their discrimination within modern African States" (UNDP 2004c).

would be hit. The case of Hurricane Katrina was similar, where Afro-Americans and elderly people in New Orleans who lived below the level of the river and lake neither received adequate early warning, transportation, financial support for evacuation, nor protection and attention during their stay in the Superdome.[15] Throughout the recovery phase, the low lying parts, mostly occupied before by Afro-Americans and Latinos, were not cleaned up and not prepared for reconstruction due to toxic substances that were diluted in both water and soil (Salinas 2006). This slowness was also triggered by institutional discrimination.[16]

To combat racism, neglect, and institutional mismanagement, policies and executive decisions must be taken to combat actively the underlying factors (Rocco 2000). The rational actor, the organizational behaviour, the governmental politics, or the cognitive model can be used (Allison 1971; Allison/Zelikow 1999). These models are based on the assumption that human behaviour is influenced by values, emotions, personal experiences and biases. Political and organizational decisions are not always rational or linear (Gribbin 2004) and create often a cognitive dissonance due to both conscious and subconscious factors influencing perceptions of reality that limit the perception (Gray 1992). Thus, any institutional behaviour must take into account (Nye/Brower 1996) and reflect on these individual perceptions of reality and combat systematically the bias avoiding greater equity and equality of race, ethnic groups, and social classes.

A survey about the institutional and ethnic discrimination in San Angelo, Texas, demonstrates:

> that different groups in San Angelo hold different and conflicting perceptions about personal and institutional discrimination. An effective democracy, however, depends upon the faith citizens have in their government and the expectation that their public officials will respond to their problems and concerns. The role of the public administrator is to assist in the creation and maintenance of authentic discourse though which the concerns of divergent populations can be heard and attended to. Trust, however, varies among the various groups. Those possessing high levels of trust spend less time calculating what might go wrong in a given situation and have faith that public policies are working well. Individuals and groups with lower levels of trust are less willing to accept public policies as fair and equitable. These groups tend to become disengaged from community participation developing an 'outsiders' view relying more on rumour and half-truths which allow misperceptions and misunderstandings to persist within the community (Barbour 2008: 14).

Bottom-up indigenous and feminist movements forced the *World Intellectual Property Organization* (WIPO) – a UN body that is specialized to reward creativity, innovation, and safeguard public interests – to defend the traditional knowledge from indigenous and women developed during thousands of years from transnational patenting. In 2000, the General Assembly of WIPO established an *Intergovernmental Committee on Intellectual Property and Genetic Resources, Traditional Knowledge and Folklore* (IGC) to defend intellectual property of traditional knowledge and cultural expressions of folklore (UNESCO 2007a). While more than 150 indigenous groups affiliated themselves, the UN with its bureaucratic approach for dealing with complex discrimination patterns is not the best bottom-up approach to protect traditional knowledge.

72.3.4 Class, Caste, and Other Socio-economic Conditions.

Ethnicity and race combined are still often the single most overarching issue of class status in some societies. However, a distinction should be made between causation and correlation when it comes to distin-

15 The death toll and displacement of these groups has shown that their financial capacity was too low to evacuate by themselves, and their capability for resilience-building was also limited. This case illustrates a complex discrimination process, where institutional racism, ethnocentrism, discrimination, and neglect challenged the bases of democratic society in the USA with severe negative outcomes. Detailed statistics on the victims and economic losses of discriminated groups – to the extent that they have been compiled for Hurricane Katrina in 2005 – show a much higher degree of vulnerability of Afro-Americans. According to a report in the *Times Picayune* (New Orleans) of 6 March 2006: "Of the 1,840 people still catalogued ... as missing from Louisiana, 30 were 5 or younger; 74 were 80 or older. Women comprised 910 of the total. The majority – 1,422 people – were from New Orleans. Of 1,590 people whose race was known, 1,352 were Afro-American [representing 85 per cent]".

16 The Governor of Louisiana, Kathleen Babineaux Blanco, said on 23 January 2007: "For eighteen months, the Washington Republicans have consistently punished and discriminated against our people, all for partisan political purposes. A state with 80 per cent of the storm damage from two hurricanes received barely 50 per cent of federal relief funds. Mississippi, with far less damage, received far more money proportionately and six months earlier.... Just one recent example is the Katrina cottages programme. We have over 64,000 people still living in trailers, yet we received money to help only 600 of those families. The Mississippi received $280 million dollars, nearly four times as much.".

guish between race and class. Some societies have a high correlation between particular classes and race, but this is not necessarily an indication that race is a factor in the determination of class

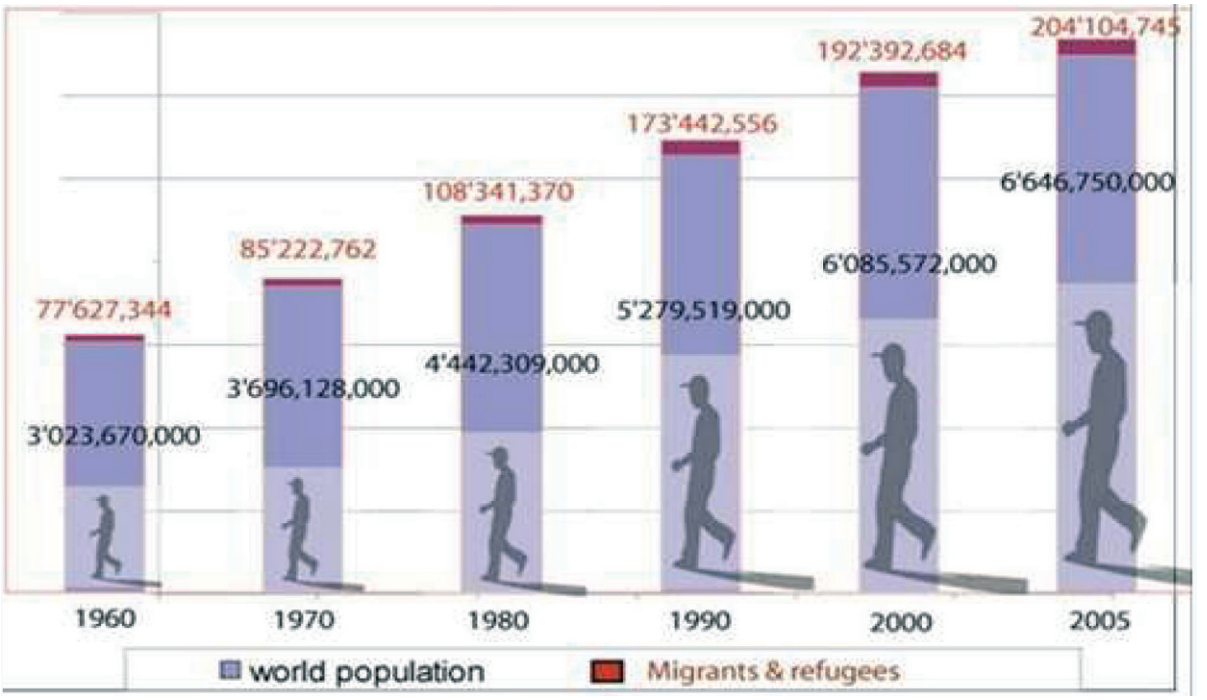
Social classes refer to a hierarchical distinction between social groups or individuals in a society depending on economic income and social status. Dennis Wrong (1998) defines class in a realist and nominalist way, where the realist definition relies on clear class boundaries and people adhering to social groupings. They identify themselves with a particular class and interact principally with people belonging to this class. The nominalist definition focuses on characteristics such as education and occupation. In the cast distinction individuals are grouped into a determinant cast based on their birth, and they belong to it during their whole life because in Hinduism it is their karma.

The Indian caste system is the oldest system of social rigidity lacking any upward and downward mobility. It divides society based on skill and qualification. Often it is understood as a social system but it must also be taken as a belief system consolidated with religious ceremonies. After independence, the Indian constitution tried to abolish the caste system with very little success. Therefore the *National Campaign for Dalit Human Rights* (NCDHR) claimed that they and tribal groups were discriminated by higher caste people from the same community. Thus, discrimination is often invisible and transformed into daily habits.[17]

In Latin America access to wealth and power is also related to ethnicity and race, and the *criollos* consider themselves as descendents of Spaniards born in America and therefore with access to the highest decision-making processes. Max Weber referred to the meritocratic society or the 'American Dream' where hard work, universalism, individualism, wealth, activ-

17 After the tsunami in 2004 in India conflicts raised between the behaviour of fishermen against *Dalits,* historically considered as 'without caste or untouchable'. The *Dalits* self-defence reaction was leaving the refugee camp when they were threatened by the higher caste. Often it is culturally so deeply ingrained that it appears as an unintentional or natural act. The *Indian Express* reported on 7 January 2005 that the fishing communities refused to share water and claimed 'that the *Dalits* would pollute the water'. But in the April 2009 elections an untouchable woman was elected as President of the Indian National Assembly.

Figure 72.3: World population, international migrants, and refugees (1960-2005). **Source:** Designed by Guillermo Peimberg of UNAM/CRIM based on data of UN Population Division (2007); at: <http://esa.un.org/unmigration/>.



ism, and rationality allow individuals to gain a higher social status and belonging to a certain class. In developing countries the system of family links dominates, based on birth and not on capacity. While social classes offer some social movement between lower and upper classes, in the caste system people belong to it for ever. Both distinctions establish a social hierarchy, where the structure of power privileges the upper class or caste, generate some social peace, and permits the exploitation of the lower classes and castes for their own benefit.

72.3.5 Forced Migration, Migrants, and Refugees

Climate change, economic crises (Bakker/Gill 2003), food scarcity, and high prices for basic goods, desertification, land degradation and drought (DLDD; Brauch/Oswald Spring 2009) and other climate related disasters have forced people to leave their communities and migrate to rural areas with better production potential. This process is creating greater tension on the land and the social structure, often aggravating DLDD processes, depletion of aquifers, and pollution.

A second process of migration is to urban areas, above all in poor countries to megacities. The case of Mexico City illustrates the earliest rural-urban migration process and created the biggest megalopolis in the South. Different phases can be distinguished, first from 1950 to 1970 the neglect of rural policies, a process of industrialization of import substitution and investments in industry induced a massive rural-urban migration. Between 1970 and 1990 import substitution, green revolution, economic crises, and subsidies concentrated in urban areas reinforced these migration processes, which is reflected in the growth rate in Mexico City (figure 72.1, 72.2) until 1980, when lack of land, high land prices, and saturated shanty towns forced the immigrants to settle in suburban areas. This spread the megalopolis to the municipalities in the states of Mexico and later to Hidalgo.

A third process is international migration in search of a better livelihood. The UNFPA (2007a) estimated more than 203 million migrants worldwide in 2005. India, China, and Mexico are among the nations with most emigrants due to the globalization process. After *the North American Free Trade Agreement* (NAFTA) between the USA, Canada, and Mexico entered into force in 1994, massive imports of cereals destroyed the peasant economy that was unable to compete with the subsidized cheap food prices. The lack of support by the government for basic crops and a drier and hotter climate forced many small farmers to

Figure 72.4: Native Mexican residents in the USA; **Source:** Estimations by CONAPO based on *Current Population Survey* 1994-2007, elaborated by F. Lozano, CRIM, 2009.

emigrate to the USA and look for better paid jobs (figure 72.3). Since 2005 more intense natural hazards but also a decline in public security and the consolidation of international organized crime on drugs, arms, and human trafficking increased international migration that dropped in 2009 due to the global financial crisis.

Today Latinos and especially Mexicans (figure 72.4) represent the first minority in the USA with an estimated 45 million people of which approximately 12 to 14 million do not hold legal documents. With the changes in the US immigration laws after 1987 about 85 per cent of new immigrants were illegal. Muñiz (2006) insists:

> This dramatic growth in the Latino population, accompanied by that of other groups stresses the importance of recognizing the ethnic, cultural, and economic make-up of a given region in order to asses the prospective needs and challenges of those in a potential disaster area.

Poverty and neglected governmental support at home obliged them to emigrate. They had learned self-protection[18] and imaginative threat-reduction throughout their whole life. Later, the illegal crossing of a dangerous and militarized border created experiences of how to deal with hazardous situations, and how to optimize marginal opportunities for achieving their goal. Furthermore, living in a permanent illegal status and facing continuous deportation risks created a habit for self-protection.

Besides economic migrants and those leaving after disasters, there are forced migrants and refugees[19] that left due to complex emergencies where natural disasters, famine, internal conflicts and destruction of their livelihood compelled people to abandon their homes (Newman/van Selm 2003). In 2008 the UN High Commissioner for Refugees estimated 11.4 million refugees and 26 million other internally displaced

18 In the three southern Gulf states that were affected by Hurricane Katrina, the growth rate of Latinos between 1990 and 2000 was between 148.4 and 207.9 per cent. Before Hurricane Katrina some 230,000 Latinos lived in the affected area, most of them were extremely vulnerable illegal immigrants. Being confronted with threats of deportation and with their low confidence in American institutions due to former experiences of discrimination, they evacuated themselves though their own social networks. An important number came from hurricane prone backgrounds. The Honduran Consulate in New Orleans spoke of 140,000 Hondurans who moved after Hurricane Mitch to New Orleans that had survived different types of disasters. This social learning has increased their resilience and helped most Latinos to save their lives. The post-disaster situation was mitigated with church support and solidarity among Latinos living in safer regions. After the disaster, the Latino community worked together and repaired what was repairable. For masons, carpenters, plumbers and cleaners, restoring damaged houses and buildings, above those which were badly insured, offered new job opportunities

persons due to conflict or persecution at the end of 2007 based a global annual survey (UNCCD 2007). This migration is expanding in Sub-Sahara Africa. More than half of the 13 million *internally displaced persons* (IDP's) live in 19 countries; alone 6 million in Sudan and 2.3 millions in DRC. Africa also accounted for the world's highest number of returning refugees. In the DRC, more than 1 million IDPs returned home in 2004 and after the end of civil war in Angola in 2002, some 900,000 started to return.[20]

In Africa, the Sahel zone, and recently Darfur, became an environmental hotspot for forced migration. A climate-induced decline in food production, violent conflicts between herders and farmers, due to lack of water for extensive livestock, arms trade, lacking negotiations for water for the herds, privately owned former communal land and the expansion of agriculture and livestock due to new demand, and a substantial decline in precipitation by 16–30 per cent, resulted in depleted aquifers. During the past 40 years the desert in northern Sudan advanced southward by 60 miles. All these developments produced a decline in local staple of up to 70 per cent. The armed conflict escalated into a civil war with 2.5 million internally and externally displaced people from Darfur and an estimated 225,000 killed people. UNCCD (2009) estimated that in 2050 drought and desertification will threaten the livelihood of over 1.3 billion people in more than 110 countries around the world. If other natural disasters and their socio-economic and political impacts are included, their number can increase substantially.

Globally urbanization and migration are overwhelming phenomena of the 21st century that may result in local conflicts. Migration creates social vulnerability and has complex roots. People flee from disasters, socio-economic crises, poverty, marginalization, public insecurity, personal problems, famines, internal conflicts, and wars. During the migration process people are highly vulnerable to be killed or women to be raped, and when they have to cross illegally borders, the situation is getting worse. In the new host community or country, they are often confronted with xenophobia that is sometimes aggravated by scarce resources that could generate new conflicts over land, water, jobs, food, and houses. Immigrants suffer simultaneously from discrimination in many ways and are often offered the least desirable, lowest-paid and most hazardous jobs. An extreme case occurred in May 2008 in South Africa, where mobs attacked and killed immigrants, arguing that they take away jobs.

As modern immigration from South to North is mostly illegal, several additional threats exist not only for these 'non-existent' persons, but also during an epidemic for the guest country and its people. The UN explores a legal status to protect this highly vulnerable group. At present, they must develop their own resilience and survival strategies.

72.3.6 The Elderly, Children, and Adolescents

Discrimination due to age is directed not only against the young in poor countries, but also against older people, and the situation is getting worse due to the economic crisis and high unemployment. In Asia, the number of people over 60 will grow from 9.4 per cent in the year 2000 to an estimated of 23.5 per cent in 2050, what equals 1.2 billion old people. Asia will then be home to 63 per cent of the world's elderly (UN 2006a).

During disasters and crises they are often neglected and threats are triggered by sex.[21] After the tsunami of 2004, in India, Indonesia, the Maldives and Sri Lanka, there was a similar discrimination. Old people in the camps suffered from their limited mobility due to a lack of wheelchairs, walking aids, and glasses. They had difficulty to sleep on the floor without mattresses. They suffered from lack of privacy and a noisy environment, as the shelters were taken over by the young. The dust from the open

19 UNHCHR defines a migrant as "a person who is living and/or working in a State of which s/he is not a national"; at: <http://www.coistine.ie/resources/resources-for-schools/6-migrants-and-refugees>. According to the United Nations Convention Relating to the Status of Refugees (1951), a refugee is a person who "owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group, or political opinion, is outside the country of their nationality, and is unable to or, owing to such fear, is unwilling to avail him/herself of the protection of that country."

20 See for details at: <http://www.forcedmigration.org> and UN [Economic and Social Council, HR/4892], 2006.

21 During the tsunami deaths in Matara, Sri Lanka of people aged over 60, 38 men vs. 91 women died; while below 10 the gender was less irrelevant: 31 boys vs. 41 girls. Old age also induced in the same place (Matara) multiple discriminations during disaster support and recovery: two weeks after the tsunami 1,507 elderly people had received very little or no relief assistance.

space increased their asthma or they lacked their special diets and medications.[22] Cases of institutional neglect worsened their situation of personal inability (WDR 2006). The question arose: is this neglect discriminatory and how does it limit the survival of the vulnerable? As this behaviour is based on deep-rooted social representations and learned behaviour, how can it be overcome by policy and resilience-building of the affected people?

Most old people in poor countries work due to missing pensions to maintain themselves and often a part of the family.[23] The 2004 tsunami, hurricanes Katrina and Stan, and other disasters severely affected people over 60 who made their living as fishermen, farmers, artisans, as waged or household support staff. After the disaster, but also during crisis situations when jobs are rare, older people worldwide are unable to get a job. This is a global phenomenon and in the USA a legal framework was established protecting them against discrimination.[24]

There is a structural discrimination related to the inequality among countries that is reflected by the life expectancy that is worldwide at 68 years but in Japan 83 years, while in Swaziland only 40; in Sierra Leone 42 years, where 58 per cent of children after 23 months are still only breastfed by undernourished mothers. Child mortality in Sierra Leone is 262; in Afghanistan 257, but in Sweden 3 for 1,000 children (UNICEF 2009: 118–121).

Population growth, megacities, and slum development represent permanent structural disaster problems that increase vulnerability among people in poor countries. World population is estimated to increase between 2007 and 2050 from 6.6 to 9.1 billion people. The industrialized countries will almost maintain their population with a total fertility rate of 0.2, while less developed countries will enlarge their population from 5.4 to 7.9 billion with a rate of 1.3. The poorest countries will have a population rise from 0.8 to 1.7 billion and a growth rate of 2.3, with the lowest urban development (UNFPA 2007a: 90). By 2025 India will have a population of 1.4 billion, overtaking China as the most populated country (Bos/Massiah/Bulato 1994; UNFPA 2007a; Visaria/Bath 1999; Natarajan/Jayachandran 2001; Dyson/Hanchate 2000).

Children are the future for the world, but 1.9 billion live in developing countries and one billion live in poverty and marginality: in East Asia and the Pacific there are 594 million, in South Asia 585 million, in Sub-Saharan Africa 340 million, in Latin America 197 million, in the Middle East and North Africa 153 million, and in Central and Eastern Europe 108 million children. About 640 million children do not have adequate shelter and 400 millions are without safe water, both phenomena are increasing child mortality and morbidity rates. Most of these children are born in Asia, in the region with the main population growth. During the tsunami disaster relief, the psychosocial services focused mostly on children and on the adolescent, especially orphans, to overcome losses, find family members, playgrounds and school facilities, while the old people were mostly forgotten. Nevertheless, older people often take care of both their own grandchildren and orphans.

Without doubt, to invest in reducing the stress of children is crucial. Quality and sufficient food in their critical growing process avoids a 'perverse poverty' syndrome (Oswald Spring 1990) that often causes brain damages before a child is born due to chronic malnutrition of the mother and child. These children with chronic undernourishment suffer for the rest of their life from lower intelligence and psycho-motoric limits (Álvarez/Oswald Spring 1993). In 2007, Stanford University published a *Post-Traumatic Stress Disorder* (PTSD) that affects the hypothalamic-pituitary-adrenal (HPA) axis due to an excess of cortisone in the blood of a child. This is a direct result of extreme and chronic stress. During disasters PTSD occurs in many children when a hazard is linked to loss of family members and sexual or emotional abuse. This brain damage is irreversible and negatively affects the future of these children, but also their capacity for adaptation and resilience-building.

22 The person in charge of the Memana Camp in India said "There should be special facilities for the health care of the older persons and there should be provision of special monetary assistance for them" (www.helpage.org).

23 Nagalingum, a 77 years old woman from Nagatttinam in India lost her daughter in law. "My son is unable to support his family and now, I have to take care of him as well as his two sons. I cannot manage it on the Rs 200 that I get as my pension. I need additional support." In Thailand an 85 year old man confirmed that he was doing unskilled work "packing fish, crabs and squid fishing wharfs". In India older peasants loss their plot of land for growing rice, groundnut, coconut, cashew, mango, banana, millet and vegetable, which were destroyed or land was salty.

24 In the USA since 1967, the Federal Age Discrimination in Employment Act has prohibited age discrimination in employment (hiring, termination, benefits, training and promotions), protecting employees from 40 to 65. In 1978, the US Congress raised the upper age limit to 70, and in 1986 the Act eliminated an upper age limit.

Contrary to the Malthusian prophesy, until today enough food is produced worldwide to feed all persons, including the projected increase. Hunger is not a problem of production, but of distribution. It is a result of missing access to food and of money to buy it. The present food crisis has not been a result of scarce basic food, but a problem of price speculation, the use of food items for biofuels and animal feeding, also due to an increase in the demand for food and animal proteins in China and India, and a structural poverty and mismanagement of agricultural policy in undemocratic countries. Climate change will impact more seriously on food production in poor countries with the highest population growth and lack of transparent governments, what may lead to famine and to forced migration and complex emergencies.

Finally, climate change and sea-level rise will impact above all on coastal areas, where today 10 per cent of the world population and 13 per cent of urban dwellers live on 2 per cent of the land. Asia may loose 18 per cent of its land with 13 per cent of its population, while small islands are estimated to loose 16 per cent of their land affecting 13 per cent of their population (UNPFA 2007: 62) if the sea-level rises by 50 cm. Thus, high demographic growth rates, marginality, discrimination by class, caste, age and sex, and global environmental change are presently triggering the multifaceted situation of poverty, slum dwellers, food scarcity, risky land and low life expectancy, and could induce in the future situations of complex emergencies.

72.3.7 Physically Handicapped (Disability, Illness, HIV/AIDS)

About 10 per cent of the world population is disabled; in developing countries often twice as many, or nearly 1.3 billion persons. Eighty per cent of them live in hazard-prone poor countries, often affected by conflicts, weak governance, and disasters. Limited capacity for early warning, weak laws, insufficient support for refugees, and mostly negligence for the handicapped prevails. An approach to give special attention and a policy of separation of the handicapped is criticized by disability mainstreaming.[25] They focus on a multisectoral approach to integrate these people. But often during a disaster their former social vulnerability and discrimination deteriorates, not only due to their highly vulnerable situation, but in refugee camps the disabled often lack support to cope with their fate.

During disasters the non-disabled are often confused, but people with handicaps are even more confused.[26] Helen Sullivan (2006) proposed that their education should start in normal daily life, preparing them for different eventualities and threats. Through this rising awareness, they increase their preparedness and with specialized training, concrete actions and effective communications, adapted to different disabilities, they could reduce their vulnerability and increase their survival prospects. This resilience-building is not limited to the disabled.

More than 39.5 million persons, or 37.2 million adults and 2.3 million children are living with HIV/AIDS. In sub-Saharan Africa, 5.9 per cent of the population is infected and in the Caribbean 1.2 per cent. This illness ranks as fourth among the leading causes of death worldwide (2.9 million) and as the first in sub-Saharan Africa (2.1 million). People living with HIV/AIDS are prone to develop other illnesses and infections due to their weak immune system (UNAIDS/WHO 2005). Frequently they get tuberculosis or pneumonia, and children under 5 years have a high mortality rate when they are infected. During normal times, HIV/AIDS is a highly stigmatized illness and during disasters the existing discrimination is worse. In an ambience of open space everybody recognizes

25 In 1990 the US Congress enacted the Americans with Disabilities Act, where 43 million disabled citizens have been "subjected to a history of purposeful unequal treatment", due to "stereotypic assumption not truly indicative" of their personal abilities "to participate in, and contribute to, society."

26 During the tsunami emergency, the handicapped male and female children were also victims of sexual harassment and abuse, not only during the rescue or when they stayed in camps or shelters, but even more during the reconstruction phase. In Sri Lanka activists warned tsunami survivors of rape and stated that trafficking of women and children existed in several Asian countries before the disaster and increased substantially after it. Macan-Markar (2006) noted that these networks continued to operate during the post-tsunami tragedy. In Asia Amnesty International denounced that "sexual abuse and exploitation, often extortion for food or roof must end and the handicapped must be specially protected in their dignity. Almost never rape and sexual abuse is reported, if there is no special report system or network, trained to attend theses cases." Thus, there are also complaints that in relief kits no anti-conceptive pills, condoms or medical attention is available, and precisely in a highly dangerous situation "the worst a woman wants is to get pregnant, when she has no roof, no income and no future. And pregnancy from a rape without knowing who is the father is the worst perspective", remarked a handicapped women in a refugee camp in Sri Lanka.

the HIV/AIDS illness and immediately discriminates the sufferer. Due to fears of potential contagion ill people are often forced to leave the shelter. They require also special medical care and retroviral medicines, which are difficult to get after disasters.

Homosexuality is erroneously identified with AIDS, but is often also perceived as a perversion or a psychological sickness. Thus, a different sexual preference is in many countries stigmatized as socially defective and often persecuted by intolerant social representation groups, and the stigmatized individuals are often victims of crimes. Dangerous 'homophobia' groups take upon themselves the right to monitor sexual preferences and assassinate those who hold sexual preferences different from their own. In machismo cultures, lesbians experience still greater persecution as their sexual behaviour challenges the established social representation of motherhood that cares for others. South Africa was the first country to give any person the freedom to decide on their sexual preference. Sexual discrimination is common enough during normal time, but increases during a disaster, as the emotional stability is lost and people try to reorganize their world with stereotypes, often affecting highly vulnerable groups. As these examples have shown, complex discrimination patterns exist that often reinforce each other.

72.4 Social Vulnerability Due to Identity Factors and Social Representation in Disaster Situations

Discrimination is the background of neglect and of violent behaviour before, during, and after any disaster that is reinforcing existing social vulnerability. Tajfel (1981: 31) argued that social identity means how "we live in a world in which processes of unification and diversification happen with gigantic steps and with a rapidity never ever before seen in history." Hogg and Abrams (1988: 78) added: "Persons have a basic need to simplify and to impose an order to their reality." This process induces them to categorize their social environment through social comparisons, where self-esteem is affirmed and maintained in a positive way. It explains also why this individual self-esteem depends on belonging to a group not necessarily within its own social system of reference.

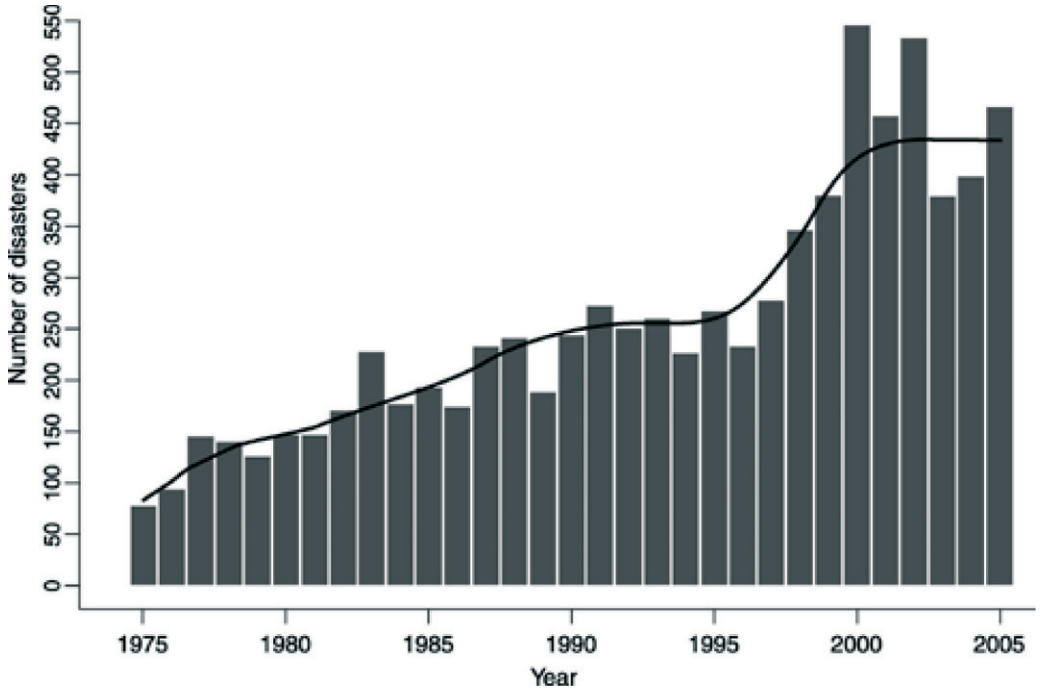
The "systems of value, ideas and practices ... establish an order that permits an individual to get familiarized and to arrange its material and social world" (Moscovici 1976: xiii). For this reason, social representations originate in daily life[27], where the society is the thinking system. Consequently, a continuum exists between personal and social identity; between inter-personal and inter-group behaviour. It includes social beliefs and social mobility, understood both as a result of personal efforts able to induce social changes (Tajfel, 1981; Haslam/Oakes/Turner/McGarty 1995, 1999; Béjar 2007). In this sense, the subjective dimension of identity is interrelated with the objective processes where identity is manifested and transformed (Serrano 2004).

The two basic processes of historical production of social knowledge are linked to anchoring and objectification. *Anchoring* is a process that permits to integrate the unknown situation within the existing representation (internalization); and *objectification* permits that these new representations are projected into the world as concrete objects (Duveen 1997: 87). These functions are *symbolic,* orienting and facilitating communication from the elaboration of attitudes, opinions, stereotypes, identity presentation of group relations, attributes of responsibility or control, narrative of original myths, ideological domination and illusions. But they are also *pragmatic*: motivation orients the activities, planning, social description, and norm-building. The acquisition of these control mechanisms (Maslow/Frager/Fadiman 1998) permits in independent situations to internalize in women several basic psychological processes: a) women *should be*: assigned identity (social facts); and b) women *should be for other*: self-identity (socialized) with interdependence to patriarchy. The results of these complex processes of identity and social representations are structural disadvantages and the discrimination of women worldwide.

Further, social vulnerability is also related to poverty, marginalization, illiteracy, sickness, unsatisfied human needs, and limited access to resources (Melillo/Suárez/ Rodríguez 2004), and therefore the loss of human security is understood as 'freedom from fear' (in the Canadian) and 'freedom from want' (in the sense of Ogata/Sen (2003). Bogardi and Brauch (2005; Brauch 2005a, 2005b, 2009b), who were concerned with issues of *global environmental change* (GEC), developed an additional pillar of human security as 'freedom from hazard impact'. The data indi-

27 These social representations could be reinterpreted as an equivalent for contemporary myths, rites (Eliade 1963, 1965; Graves 1985), and belief systems in primitive societies (Moscovici 1976, 1984: 181, 1990, 1998, 2000).

Figure 72.5: Long-term trend in the global number of natural disasters (1975-2005). **Source:** EM-DAT: The OFDA/CRED International Disaster Database, Université de Louvain, Brussels, Belgium; at: <http://www.em-dat.net>.



cate that climate change increased the number and the intensity of disasters (figure 72.5). Thus, policy and institution-building should strengthen the links among these three pillars of 'freedom from fear', 'freedom from want', and 'freedom from hazard impact' to guarantee to its citizens a minimal access to basic resources, early warning, preventive evacuation in case of a serious threat, and effective reconstruction without discrimination and gender insecurity for the most vulnerable in a community[28].

72.5 Discrimination Affecting Human Lives and Wealth

The examples discussed above allow an understanding of how a combination of different types of discrimination exists in daily life. The outcome is social vulnerability, and human and gender insecurity as a result of historical inequity, inequality and exploitation, aggravated by all types of discrimination. The accumulation of these triggering factors threatens not only an already precarious lifestyle, but affects the future of children living in absolute poverty, badly nourished, without access to schooling, being officially and personally neglected. For the elderly it takes away their possible survival with dignity, causing dependence on public and family support.

Statistics on disasters and official reports from the World Bank, the International Federation of the Red Cross/Red Crescent Society, ISDR, CRED, the ProVention Consortium, as well as from CARE, UNDP, UNOCHA, UNEP, SwissRe and Munich Re offer in their compilations of disaster data only figures on human fatalities, on affected people, economic and insured losses, both globally and by country or region. So far, all available sources do not disaggregate demographic data (Bankoff/Frerks/Hilhorst 2004). There are no international statistics distinguishing between gender, social classes, race, ethnic groups, religion, handicapped and age, and there is a lack of data and policies on the so-called 'historical disasters' of extreme poverty, often exacerbated by physical and cultural violence, creating additional risks which could lead to complex emergencies.

28 Such a combined human security approach may reduce the unjust distribution system of food where over-consumption coexists with under-consumption among the socially vulnerable. A different system of distribution worldwide would satisfy the basic needs of the vulnerable in case of scarcity irrespective of geographical, social, age or gender status. A stable livelihood and policies for equity in all levels and sectors could also reduce discrimination, and accelerate the recovery process, and above all work preventively to avoid complex emergencies and massive migration.

In addition, hazards in and of their own do not discriminate between the various cleavages existing in society, e.g. between men and women, rich and poor, white and coloured, disabled, high and low social classes or castes, but the impacts of a disasters differs for each social group. Thus, hazards make existing historical and social vulnerabilities explicit. Social gaps reinforce existing inequity and increase threats and fatal outcomes. This can be further aggravated by political and institutional neglect and discrimination or racisms.

In most hazards the death toll for women is higher. Their social representations lead to social constructions, norms, and behaviour to save the life of others. To be identified and socially constituted as 'a man' or 'a woman' entails gender discrimination, violence, and power loss. Women are often confined in private spaces to reproduction and made dependent, what increases their social vulnerability. But also their self-identity to care as *homo donans* (Vaughan 1997, 2004) 'force' them in case of threats to save children, the elderly, and even animals, often risking their own lives (Yonder/Akcar/Gopalan 2005).

The fact that risks are not equally distributed, neither geographically nor socially requires addressing the root causes. More frequent and more serious hazards occur in the tropics and affect to a larger extent poor people due to their precarious life conditions and shelters. GEC is mainly caused in industrialized countries, thus these countries must assume their moral and historical responsibility to mitigate technically and financially the impacts of hazards in poor countries through transfer of technology for energy saving techniques and sustainable energy sources, but also integrating environmental forced migrants in their societies.

In socio-psychological terms, under normal conditions humans live in networks, trying to compensate and survive difficult socio-economic circumstances. However, during emergency situations these networks often break down, leaving individuals or small groups to fend for themselves alone. This loneliness is reinforced by a lack of coordination or even competition among government agencies, different aid organizations, and NGOs. Thus, assistance required to re-establish as soon as possible these lost networks, independent of the initial costs. They will be able to support the reconstruction and to return as soon as possible to normality, reduce corruption, discrimination and long-term effects. Apparently they seem to be expensive and funds are basically limited for emergencies and reconstruction, but they reduce substantially future costs and above all improve life quality for affected persons. It is a core reason while hazards turn into disasters and often increase social vulnerability and discrimination, where poor people have to find their own way to overcome their precarious situation.[29]

72.6 Conclusions

During disasters the trigger effects from different types of discrimination often generate a long list of failed actions that are aggravated by a lack of governmental sensibility and aid agencies for vulnerable situations. Efforts to overcome discrimination often result in long lists of recommendations, norms, and codes of behaviour, including global UN human rights pacts (IASC 2006). Discriminative practices are changing between cultural and social contexts. If these measures are applied mechanically, discrimination can even increase as the allocation of houses for widows in Sri Lanka has shown. Thus, a fragile balance exists between a general, comprehensive non-discriminative human behaviour and a culturally specific conduct. This requires sensitivity and special knowledge from institutions and aid workers involved and practice of equity in all governmental activities.

Thus a *first* conclusion is related to a mental shift and a new culture of care to better perceive and understand the underlying and invisible factors which create or reinforce disasters in social and physical terms. National and international priority should be given to consolidate institutional bases for DRR, but also citizen consciousness to be prepared and train for preventive disaster practices, mitigation, and resilience-building.

The *second* factor deals with a needed demographically and culturally differentiated data collection, and missed opportunities to prepare for non-discriminative strategies of disaster risk reduction (DRR). Risk analyses and assessments should be able

29 UNESCO estimated that at least 18 per cent of disaster costs could be saved with efficient preventive measures and learning, which represent less than 5 per cent of the initial costs. Normally budgets are tight, not accounting funds for preventive disaster management and resilience-building. Even UN organizations can dispose of only limited resources for preventive management and restoration of social networks. Often, privately raised money is given with clear indications for direct disaster relief; segregating support for war refugees, famine, and disasters prevention. These limits in aid avoid effective preparedness and awareness-building, able to reduce future damages, and to prevent further disasters and possible conflicts.

to identify regional differences and to train people to monitor and care about their own vulnerability. Together with modern systems of monitoring and regional and national coordination, the preparedness and an effective early warning is more efficient. Therefore permanent training, identification of vulnerable regions and their environmental restoration by reforestation and sustainable planning can reduce the risks for all citizens and negative economic impacts for the whole country.

Finally, there is an increasing uncertainty due to climate change and a growing number of hydro-meteorological hazards with more severe impacts for the most vulnerable communities (figure 72.3). This requires a new culture for sustainable safety and risk reduction, but also bottom-up adaptation and mitigation. The number of disasters and their local and regional impact has grown, affecting mostly the marginal, thus reinforcing discrimination. A holistic approach is needed for resilience-building aiming at human, gender (understood here in a wide sense, including all minority groups), and environmental security or HUGE (Oswald Spring 2007a, 2009) that can avoid more serious vulnerabilities worldwide and regionally. Knowledge of the socio-psychological mechanisms, preventive innovation, and permanent education are some of the core elements to increase the safety and HUGE for all. Efforts for bottom-up resilience-building combined with institutional reinforcement are stabilizing within a short time highly vulnerable groups and help them to develop proper tools to better deal with coming threats and dangers.

Vulnerability and discrimination are often the result of human, gender, and environmental threats and insecurities. Capacity-building and special training for governmental officers, humanitarian institutions, journalists, and other decision makers facilitate a change in the perception and action for eradication of discrimination (72.1, 72.2). Combined with preventive training of discriminated groups it can increase the resilience-building in hazard-prone communities. A healthier environment, an integral management of natural and social resources, and prevention and remediation practices are the keys for a sustainable environmental culture.

A central challenge for policy is to empower gender, the disabled and other vulnerable persons at home through economic improvement and active political participation. This reduces social vulnerability, improves resilience to crises, increases survival opportunities for communities and individuals, and reduces gender violence and insecurity. By strengthening their livelihood, the whole community is enhancing its survival prospects.

The lessons learnt are clear. There exists a traditional way to deal with the coming threats and dangers, but a different vision will deal systemically with unknown and complex emergencies (table 72.3). In the first vision, a missing participation and lack of transparency can destroy entire communities; in the second approach still the future of children can be limited due to the loss of livelihood, the emergence of a survival dilemma (Brauch 2008b) with migration, and later as refugees often experiencing 'perverse poverty'. The third option promotes an integral alternative with citizen control of relief institutions and DRR to overcome discrimination and corruption. Transparent and democratically elected governments respond to the needs of the people. They improve pre-disaster preparedness (evacuation training, safe shelters, food, water and drug provisions, conflict management, self-protection measures, etc.). They establish differentiated data banks with efficient early warning procedures, and special care and involvement of the socially vulnerable (Villagrán 2006). Regional risk mapping and disaster organizations headed by locally trained aid personnel should prepare the population for new hazards and for a fast return to normality. Thus, democratic governments that combine preventive training and disaster relief management with participative resilience-building will be able to reduce fatalities, mitigate economic crises, and speed up the recovery process.

Hazard-prone countries can only surmount their situation of risk when they concentrate their technical, economic, and human capacity in a preventive restoration of destroyed ecosystems and efficient institutional disaster organization together with exposed society. The reduction of social vulnerability requires a bottom-up resilience-building and a top-down institutional support, disaster funds, and specialized and trained entities. It implies also rapid and non-discriminative support for those regions and social groups affected by different kinds of disasters. These measures facilitate also the integration of external aid. They reduce existing social discrimination and the probabilities that natural hazards turn into societal disasters.

> As nonviolent conflict resolution is a central part of personal and social identity in a world with rapid changes and increasing risks, the upcoming system of values and practices enhances simultaneously participatory democracy and governance with peace-building efforts. In summary, all these efforts may result in a 'HUGE' solidarity process for sustainable and equal development, and peaceful conflict resolution without discrimination.

Table 72.3: Three alternative visions to understand and combat discrimination. **Source**: The author.

Perception/ social actors	Common vision	Different vision	Alternative vision
Perception of discrimination and its manifestations	Discrimination is a common problem in any society; it is a natural selection process where able persons lead the rest, getting personal and social recognition and benefits.	Discrimination is a common problem affecting more vulnerable groups, especially women, children, non-whites, poor and the elderly. It recognizes some types of discrimination and its social effects, but psychological, gender and sex is not understood nor included.	Discrimination is a common problem affecting more vulnerable groups, especially women, children, different races, the poor and elderly. It is a mechanism of control and power exercise to maintain the status quo. Multiple ways exist to discriminate: socio-economic, gender, age, race, ethnicity, colour, class, caste, language, religion, physical, disability, health, psychological, sexually, politically and culturally.
Perception of causes of discrimination during disasters	External factors: gender, poverty, unemployment, marital status, age, social classes, castes, religion, economic differences, political power, nature *Personal factors:* insecurity, fear, low self-esteem, intelligence, age, divine law, character.	Lack of communication and social compromise; all are in a traumatized situation and require support; negative attitudes of relief institutions & governments; historical and social contexts (it was always so); family pressure, traditions and culture; guilt, self-punishment, victimization of the discriminated.	Abuse and manipulation of power and control; inequality among social groups, age, race and gender as a result of social stigmatization; subordination of women, children and the elderly in a patriarchal culture. The free market does not need the old and handicapped, but exploits workers, women, and self-employed people in the informal economy, often children. Illegal activities (sex, prostitution child soldiers, drugs, human traffikkers, pornography, money laundering) prevail.
Social actors involved in maintaining discriminative behaviour	Different institutions, undemocratic governments, military and police forces; local and national privileged leaders (elite).	Some relief institutions, self-interested NGOs and undemocratic local authorities; global & local economic and political elites; organized illegal crime; some youth organizations (gangs).	Institutions and organizations interested in maintaining physical, structural and cultural discrimination; globalization; free-market and neo-liberal ideology; transnational mass media, fashion and mass diversion; criminals.
Perception of solutions against discrimination during disasters	*External:* laws, punishment, separation of discriminated persons and groups, reinforcement of tolerance and positive practices; abolition of undemocratic institutions. *Internal:* individual change of behaviour; economic activities and income; personal growth.	*External:* treaties and legal reinforcements; human rights strengthening; institutional support; training of personnel; change of behaviour by group dynamics; dialogue and common work experience; social pressure; education to overcome discrimination; promotion of democratic leadership; transparency. *Internal:* love of others and myself; caritas; family support; learning through errors and success; personal empowerment and self-confidence; training and psycho-physical stabilization.	*External:* rapid assessment tools; reduction of accumulative dissatisfactions, tensions, conflicts, violence and disaster-related problems; intervention of transparent and participative governments, agencies and society; reinforced laws, norms; risk reduction; resilience-building; improvement of formal democracy and real social justice with consolidation measures; promotion of cultural and social change; empowerment through social, ethnic, cultural and political diversity; democratic NGOs, political parties, churches, teachers; critical relief institutions; organized women and youth groups; social training against discrimination and for tolerance and diversity, HUGE; peaceful conflict resolution. *Internal:* growth in self-esteem; self-protection; modification of personal behaviour; overcome prejudices; empowerment; decision-making reinforcement; self-love; entrepreneur mentality, resilience.

73 Coping with Global Environmental Change: Need for an Interdisciplinary and Integrated Approach

G.A. McBean

73.1 Introduction[1]

This chapter deals with three major issues confronting humankind, political leaders and the scientific community: climate change, disaster management and international development, as examples of the need for an interdisciplinary and integrated approach. These are major intersecting issues: natural disasters destroy or impede development and climate change will enhance their impacts. These relationships seem to be increasingly recognized, particularly in the international domain. However, better integration of these intersecting issues is needed in science and policy and global response. Sustainable development and an expanded climate change adaptation strategy to include disaster risk reduction may be the key to bringing them together.

Environmental change is now occurring due to the impact of human activities on the environment on local to global scales. Humans began impacting their local environments through pollution many centuries ago and as their activities expanded in scope and complexity the impacts spread beyond the local towards the global scale. The global environmental impacts have most clearly been seen for the past few decades, with increasing clarity, in their impacts on the global climate. These impacts on the environment have come back to influence human activities: it is very much a two-way interaction.

For environmental managers, the focus has been on managing the influence of people on the environment by, for example, controlling the emissions of pollutants into the environment, the hunting of species and the changes in the land use from forests to farming to urban sprawl, each of which contributes to changing the natural environment. Environmental management attempts to improve on this relationship by assessing and using regulations to reduce the impacts. Since regulation usually does not fully solve the problem, governments then have the role of informing and warning, when appropriate, people about the risks of a contaminated environment to their health and well-being. Environmental management, focusing on the negative impacts of humans on the environment, relies on scientific guidance from the global environmental change community.

Another side of the environment-people interactions is the impacts of weather-related (e.g., storms, floods, droughts) and geophysical hazards (e.g., earthquakes, volcanoes) on humans. There is need for services to advise and warn humans on how to reduce their vulnerability to hazards and how they can modify their influences on the environment, such as land-use change that reduce their vulnerability. This has been called disaster management and the more prevalent term today is disaster risk reduction.[2]

As our environment changes, locally to globally, humans need to be able to respond both to reduce their impacts on the environment and to reduce the impacts of the environment on them. Although clearly issues of human and natural resources with which to respond will limit or possibly preclude any effective response, one aspect that is essential to making our responses most effective is knowledge or information looking ahead to the future. This information can both shape and determine our response but also greatly influence the degree to which individuals and governments choose to act and the resources that they commit to those actions. It is the role of global

1 The author appreciates discussions with and assistance from his colleagues in the *Institute for Catastrophic Loss Reduction* (ICLR), The University of Western Ontario, London, Ontario, Canada. Preparation of the chapter was also greatly influenced by discussions with the members of the ICSU Planning Group for IRDR and colleagues on the UN ISDR S&TC.

environmental change research to provide an informed basis for the responses by individuals, governments and, where appropriate, international organizations. "We have options, but the past is not one of them" (Sauchyn/Kulshreshtha 2008). The capacity to see the future depends on that research basis and there are very different capacities to predict natural and social phenomena (McBean 2008; Mesjasz 2005, 2008b).

Other chapters of this volume have laid out major environmental change issues as: climate change; soil and desertification; water management; and food and health. Natural and human-induced environmental disasters have also been identified and will be further expanded below. Addressing global environmental change, disasters and security threats and their challenges, vulnerabilities and risks demonstrates the very broad scope of the issue. This includes understanding of economic drivers and responses and the social dimensions of issues will often be paramount in determining the response. Vulnerabilities and risks are determined not only by the threat of the environmental change or the hazard happening, but also by the social capacity for response or recovery if and when it happens. Resilience of communities is very much a social, economic and political issue. These issues are also very much at the centre of development and particularly of sustainable development.

The agenda of most governments usually starts from the fundamental premise that: "providing security for the nation and for its citizens remains the most important responsibility of government."[3] This statement sums up one of the most basic roles for all governments, which has long been the basis for protective services like national defence, law enforcement and fire protection. However, as always, governments must balance a broad range of policy issues and make difficult decisions regarding how to allocate scarce public funds. Key priority areas for any government will need to include the economy, the environment and international development. Beginning in the 1990's many governments adopted sustainable development as a framework for reconciling economic development and environmental conservation, i.e., "to ensure that it meets the needs of the present without compromising the ability of future generations to meet their own needs" (Brundtland Commission 1987: 8).

Another focus of many governments is addressing climate change. What are the linkages between management of natural hazards (disaster risk reduction), management of the environment, with a focus on climate change and long-term sustainable development? And how do these fit in the context of international development?

Although an interdisciplinary and integrated approach is clearly necessary across many environmental and related issues, this chapter will focus on three issues, as demonstrating the case. These are: climate change (73.3), natural hazards (73.4) and development (73.5). This chapter analyses these public policy issues related to disaster management, climate change and international development (73.2, 73.6) and argues that the science in support of providing good input into public policy decision-making needs to be interdisciplinary and integrated across these areas (73.7).

73.2 Linking Natural Hazards, Climate Change and International Development

Almost every day, some community around the globe is affected by a weather- or climate-related hazard, such as a flood, storm or drought, resulting in that community needing outside assistance – this is called a disaster. With the geophysical (earthquakes and possibly resulting tsunamis, volcanoes and landslides) and biological events, there are now about 470 disasters[4] per year with widespread impacts across the planet (chap. 40 by Guha-Sapir/Vos). These events result in great loss of human lives, livelihoods and economic assets in both developed and developing countries. The frequency of recorded disasters has been rising rapidly up to the present rate. From about 65 per year in the 1960's, 200 per year in the 1980's, almost 280 per year in the 1990's and about 470 per year for the

first part of this decade.[5] The economic costs of these disasters are also increasing.[6]

Most disaster losses, whether measured in terms of the number of events, the lives lost or material destruction, stem from extreme weather and climate related events such as hurricanes, cyclones, other major storms, floods, landslides, wildfires and drought (Berz/Kron/Loster/Rauch/Schimetschek/Schmieder/Siebert/Smolka/Wirtz 2001). Weather and weather-related events together make up more than three quarters of all natural disaster events, with floods (33 per cent), storms (23 per cent, including hurricanes, typhoons, tornadoes, mid-latitude winter storms) and droughts (15 per cent) coming in that order. Most avalanches and many landslides are also weather related. Hence, the obvious climate and climate change connection with disasters and disaster risk reduction. These events cannot, of course, be attributed solely to climate change, but they are in line with the pattern that we can expect in the long term: severe storms, more heavy rainfall and a greater tendency towards flooding[7].

The 2007 Report of the IPCC placed important, authoritative scientific assessments before the global community. Its *Fourth Assessment Report* (AR4) of Working Group I (IPCC 2007f) on the physical science basis reported that the planet has been warming with the linear rate of warming being 0.07 °C per decade over the past 100 years and that has now increased to 0.18 °C per decade over the past 25 years. Their analysis of global observations of the climate system led to the conclusion that the warming of the climate system was unequivocal and that this warming was *very likely* due to the observed increase in anthropogenic greenhouse gas concentrations. They further concluded that the observed changes in heavy precipitation events (increased frequency) and increased incidence of drought and intense tropical cyclone was *more likely than not* to have a human contribution.

The 2007 IPCC Working Group II on impacts, adaptation and vulnerability (IPCC 2007d: 7–22) added to the concern with their report that observational evidence from all continents and most oceans showed many natural systems being affected by regional climate change. From their assessment of data since 1970: "it is likely that anthropogenic warming has had a discernible influence on many physical and biological systems." These reports made clear that climate changes are happening, human activities are the main cause and that climate change was affecting both humans and natural ecosystems. There is a clear signal between the increased frequency of weather-related disasters and the increased frequency of the trigger events. The linkages across global environmental change issues are very evident.

Societies across the globe have generally become more vulnerable. While these disaster events have had clear impacts on all countries, their impacts on developing countries are larger (Mirza 2003). The Global Assessment Report on *Disaster Risk Reduction-2009*[8] included in its key findings and recommendations:

- Global disaster risk is highly concentrated in poorer countries with weaker governance.
- Weather-related disaster risk is expanding rapidly both in terms of the territories affected, the losses reported and the frequency of events.
- Climate change is already changing the geographic distribution, frequency and intensity of weather-related hazards and threatens to undermine the resilience of poorer countries and their citizens to absorb and recover from disaster impacts.
- The governance arrangements for disaster risk reduction in many countries do not facilitate the integration of risk considerations in development.

Changing weather conditions play a significant role:

> The vulnerability of human societies and natural systems to climate extremes is demonstrated by the damage, hardship, and death caused by events such as droughts, floods, heat waves, avalanches, and windstorms. While there are uncertainties attached to estimates of such changes, some extreme events are projected to increase in frequency and/or severity during the 21st century due

5 Part of the increase in numbers of disasters reported in disaster statistics may be explained by the increasing numbers of smaller and medium-level events that are registered as being related to natural and human-induced or socio-natural phenomena (ISDR 2007) and by better reporting mechanisms.

> to changes in the mean and/or variability of climate, so it can be expected that the severity of their impacts will also increase in concert with global warming (IPCC 2001c: 225).

Besides a changing climate, there are several factors contributing to the increase in natural disaster losses referred to above. Global population has been increasing and there has generally been more exposure of people to hazards meaning more people and communities are at risk. People, living by choice or circumstances in more hazardous zones, along coasts, riverbanks and mountain slopes, have put more people and communities at risk, particularly in low-lying as well as northern areas. There has also been a growing inequality between societies' wealthier and poorer sectors with the latter being more vulnerable. Human interventions in the environment can also increase vulnerability to natural hazards. Examples include changes in land cover that increase risks of landslides or flooding and destruction of mangroves that increases the susceptibility of coastal areas to storm and tsunami damage. There is more expensive infrastructure being damaged. In urban regions (and particularly in very large cities), the complex infrastructure systems that make life and economic activity possible, increase the vulnerability of populations to disruptions caused by natural hazards. The density of buildings has been growing and most infrastructure is aging. Commercial activities have become more interdependent and vulnerable, including relying more on the transportation of people and goods.

In awarding the 2007 Nobel Peace Prize to the *Intergovernmental Panel on Climate Change* (IPCC) and Albert Gore, the Nobel Committee of the Norwegian Parliament stated that it

> is seeking to contribute to a sharper focus on the processes and decisions that appear to be necessary to protect the world's future climate, and thereby to reduce the threat to the security of mankind. Action is necessary now, before climate change moves beyond man's control.

In so doing, it emphasized the possible impacts of climate change on humankind and placed it in the context of global peace and security.

Although earthquakes and related tsunamis comprise only 7 per cent of all events but their impacts are horrific as was seen with the December 2004 Indian Ocean tsunami and the more recent earthquakes in China and Kashmir. In 2005, there was the largest number of hurricanes ever recorded and Hurricane Katrina has now entered the record books as being the costliest in U.S. history (chap. 71 by Warner). Hurricane Wilma, with sustained winds of more than 260 km/h, was the most intense Atlantic storm ever recorded.

73.3 Climate Change – The Increasing Threat in the Future

The objective (Art. 2) of the *United Nations Framework Convention on Climate Change* (UNFCCC)[9], which has been signed and ratified by almost every country, is

> ...stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic [human-induced] interference with the climate system. Such a level should be achieved within a time frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened, and to enable *economic development* to proceed in a *sustainable* manner.

The italics has been added to emphasize the connection of climate change with sustainable development. Given the UNFCC's objective, how will the climate warm for the next decades? For realistic emissions scenarios (IPCC 2007f), the projected warming over the next few decades will be about 0.2°C per decade or a little larger than 0.18°C per decade observed over the past 25 years. By about 2040, the projected temperatures start to diverge with a lower emissions scenario leading to 1.8°C warming by 2100, with respect to the period 1980–99. A higher emissions scenario results in 3.4°C by 2100. There are uncertainties in the climate models of about +/- 1°C. For a range of scenarios and including the uncertainties, the warming by 2100 could be between 1°C and 6°C or about 1.5–7°C relative to the pre-industrial global temperature. For any of the scenarios, warming continues for centuries to follow. This range is what might be called the 'human choice' or 'our' impact.

Together with these temperature changes will come other changes in the climate system. Sea level rise is a critical parameter for the billions of people who live on or near the coasts. The IPCC projected a range of 0.2 m to 0.6 m rise by 2100. Due to larger uncertainties in projecting the melting rates of Greenland and Antarctic ice sheets, these were excluded from the projecttions. Post-IPCC 2007 results (Rahmstorf/Cazenave/Church/Hansen/Keeling/Parker/Somerville 2007) in-

9 See UNFCCC; at:<www.unfccc.int> for the Climate Change Convention (1992), the Kyoto Protocol (1997), the Bali Declaration (2007), and other information.

dicate that the sea level is rising along the upper limit of the 2001 IPCC projections, leading to estimates of closer to a metre rise by 2100. If the Greenland ice sheet were to melt, sea level would rise globally about 7 m, inundating many coastal zones. There are major uncertainties as to if, when and how this may happen.

The Global Carbon Project[10] reported on a comparison of projected global fossil fuel emissions and actual emissions up to 2007. Global carbon emissions have increased from 6.2 GtC per year (billions of tonnes carbon or carbon equivalents), in 1990 to 8.5 GtC in 2007, a 38 per cent increase from the Kyoto reference year of 1990. The growth rate of emissions was 3.5 per cent per year for the period of 2000–2007, an almost four-fold increase from 0.9 per cent per year in 1990–1999. Since 2004, global emissions have been about equal to or greater than the more pessimistic of the IPCC emission scenarios. Reflecting on the disaster loss statistics in the previous section, Munich Re (2007) reported that "in view of continued global warming, we anticipate a long-term increase in severe, weather-related natural catastrophes."

Approximately 20–30 per cent of plant and animal species assessed so far are likely to be at increased risk of extinction if increases in global average temperature exceed 1.5–2.5°C. They also noted that poor communities can be especially vulnerable since they tend to have more limited adaptive capacities, and are more dependent on climate-sensitive resources such as local water and food supplies. Are these changes "dangerous"? These examples of scientific analysis and discovery also demonstrate the need for effective interdisciplinary approaches across the physical, biological, chemical, as well as socio-economic sciences.

Article 3 laid out some principles, including that sustainable development was a principle of the Convention and resulting actions. The linkages between climate change and sustainable development have been explored in several papers (e.g. by Beg/Corfee Morlot/Davidson/Afrane-Okesse/Tyani/Denton/Sokona/Thomas/Lèbre La Rovere/Parikh/Parikh/Atiq Rahman 2002). The IPCC recognizes the clear connections between climate change, adaptation and sustainable development with a full chapter (IPCC 2007d) devoted to these linkages. The connections with extreme events are also clear in the IPCC reports.

In light of these future projections and already observed increases in costs related to weather-climate hazards, policies and programmes are necessary to both mitigate climate change (e.g., through emissions reductions) and to adapt to the inevitable effects of a changing climate. Adaptation refers to adjustments in ecological, social, or economic systems in response to actual or expected climatic stimuli and their effects or impacts and involves efforts to both reduce the negative impacts of climate change and to capitalize on its benefits (IPCC 2007e). The key features of climate change for vulnerability and adaptation are those related to variability and extremes, not simply changed average conditions. Enhancing adaptive capacity and providing better means to cope can simultaneously address issues of climate change and natural hazards while contributing to development. This is the natural means of connecting these intersecting issues. Adapting to climate change and mitigation strategies for natural hazards are essentially the same in concept and approach and they both link to sustaining development. Again an interdisciplinary and integrated approach is needed in addressing these challenges.

73.4 Disaster Management and Hazard Mitigation

In January 2005, the Government of Japan hosted the *World Conference on Disaster Reduction* (WCDR) as a review of the Yokohama Strategy and Plan of Action for a Safer World (1994) and to commemorate the 10th anniversary of the Kobe earthquake.[11] As the international community noted recently, "...we are deeply concerned that communities continue to experience excessive losses of precious human lives and valuable property as well as serious injuries and major displacements due to various disasters worldwide."[12] In light of this, it is increasingly important that governments at all levels acknowledge the impact of natural disasters and implement better policies and programmes for their management.

The *United Nations International Strategy for Disaster Reduction* (ISDR) was created to follow and

12 Hyogo Declaration, World Conference on Disaster Reduction, Kobe, Hyogo, Japan. 18–22 January 2005.

build upon the *United Nations International Decade for Disaster Reduction* (IDNDR). The UN ISDR has identified climate change as one of the issues related to disaster management. The ISDR has also provided formal definitions that are important in communications and working across countries and disciplines.

A hazard is a "potentially damaging physical event, phenomenon or human activity that may cause the loss of life or injury, property damage, social and economic disruption or environmental degradation"[13]. The vulnerability is determined by physical, social, economic, and environmental factors or processes, which increase the susceptibility of a community to the impact of hazards. Disasters result when there is the intersection of a hazard and vulnerabilities. Hence to understand the factors involved in disasters it is important to understand both the hazards with their occurrence and characteristics and the factors that make communities vulnerable.

Disaster management refers to policies and practices developed and implemented to manage the impacts of disasters. Effective disaster management requires extensive planning before a disaster, targeted at four elements: *preparedness* (policies and procedures designed to facilitate effective response); *response* (actions taken immediately before, during and after a disaster to protect people and property and to enhance recovery); *recovery* (actions taken after a disaster to restore critical systems and return a community to pre-disaster conditions); and *mitigation* (actions taken before or after a disaster to reduce the impacts on people and property of future hazards; see Godschalk 1991). Mitigation with its focus on preventing natural hazards from becoming natural disasters, includes policies and actions such as building public awareness and support; development of local and regional plans for land use to prevent inappropriate development in hazardous areas; changing building codes and standards to protect people, property and infrastructure from 'reasonable' extremes; structural engineering to increase resistance; and forecasting and warning systems which provide information to citizens and advise them regarding an appropriate response strategy (Godschalk/Beatley/Berke/Brower/Kaiser 1999).

Although hazard researchers generally agree that investment in mitigation is cost effective in that the savings in disaster recovery costs are larger than the mitigation investments (Mileti 1999), most government expenditures in Canada (Henstra/McBean 2005) and other countries (Mileti 1999) remain targeted at the recovery side of disaster management, for various reasons.

First, public demand for mitigation is generally weak. Many people continue to view natural disasters as 'acts of God' and thus conclude that there is little that an individual can do to prevent losses. In other cases, people may be disinterested in loss prevention because they believe they are covered by insurance. From a political perspective, hazard mitigation is less appealing than other public investments because, while the costs of mitigation are immediate and often substantial, the benefits are only realized in the case of another disaster, which may never occur. In a political system predicated on a four-year election cycle, investment costs borne by one government (and set of taxpayers) may only be realized by benefits to a future government and a different set of taxpayers. The costs are readily apparent while the benefits are not immediately obvious. Local governments are equipped to play an instrumental role in hazard mitigation, due to their close proximity to hazards and because they control many of the most effective tools to achieve this objective (e.g., land use regulation, building code enforcement; see: Prater/Lindell 2000). However, disasters in any particular community are statistically rare, local citizen demand for disaster mitigation is minimal and most of the burden for disaster recovery assistance is shouldered by central governments, so local governments have little economic or political incentive to invest in mitigation (Berke/Kartez/Wenger 1993). To shift this paradigm to one dealing most effectively with disasters requires an interdisciplinary and integrated approach.

73.5 International Development

Around the world natural hazards are another issue facing development. Poverty, hunger, disease, illiteracy, environmental degradation and discrimination against women continue to be major concerns. Within the broad range of commitments in human rights, good governance and democracy, world leaders, at the 2000 Millennium Summit, passed a Declaration which formally established a series of *Millennium Development Goals* (MDG) that provided a comprehensive and multi-dimensional development framework and set clear quantifiable targets to be achieved in all countries by 2015[14]. The important

13 UN International Strategy for Disaster Reduction, 2009: "UNISDR Terminology on Disaster Risk Reduction"; available in the five UN languages at: <http://www.unisdr.org/eng/terminology/terminology-2009-eng.html>.

goals include: halve extreme poverty and hunger; achieve universal primary education; reduce under-five mortality by two thirds and maternal mortality by three quarters; and ensure environmental sustainability. The latter MDG has four elements:

> Integrate the principles of sustainable development into country policies and programmes; reverse loss of environmental resources; reduce by half the proportion of people without sustainable access to safe drinking water; and achieve significant improvement in lives of at least 100 million slum dwellers, by 2020.

The linkage between sustainable development and development is clear in this objective. Although the MDGs do not explicitly address climate change, the action plan of the WSSD (see next paragraph) does call for action on assessing impacts of climate change.

In 2002, participants of the *World Summit on Sustainable Development* (WSSD) in Johannesburg, South Africa adopted a Summit Plan of Implementation as part of the strategy to meet the Millennium Development Goals.[15] The signatories agreed on a series of actions, one of which included protecting and managing the natural resource base of economic and social development. In the report which followed the Summit, strong connections were drawn between international development and natural hazards, which called for action, including:

> 37. An integrated, multi-hazard, inclusive approach to address vulnerability, risk assessment and disaster management, ..., is an essential element of a safer world in the twenty-first century. Actions are required at all levels to:
>
> (e) Improve techniques and methodologies for assessing the effects of climate change,
>
> (h) Develop and strengthen early warning systems and information networks in disaster management,
>
> (j) Promote cooperation for ... in order to enhance the capabilities of affected countries to cope with such situations.

Furthermore, the report drew connections between international development and climate change:

> 38. Change in the Earth's climate and its adverse affects are a common concern of humankind. We remain deeply concerned that all countries, particularly developing countries, including the least developed countries and small island developing States, face increased risks of negative impacts of climate change and recognize that, in this context, the problems of poverty, land degradation, access to water and food and human health remain at the centre of global attention.

Both the Millennium Summit Declaration and the World Summit report demonstrate explicit connections between natural hazards, climate change and the Millennium Development Goals. The call for integrated, interdisciplinary and multi-hazard approaches is clear.

Although all countries have been impacted by natural disasters, the relative impacts usually are larger in direct impacts on human lives in developing countries and larger in economic costs in developed countries (Mileti 1999). In highly developed countries, the average number of deaths per disaster is 23, while the number increases dramatically to about 150 deaths per disaster in medium and to over 1000 deaths per disaster in less developed countries (Mutter 2005: 164–165). While the absolute dollar costs of disasters in highly-developed countries are large they are usually less or much less than the *Gross Domestic Production* (GDP) of the country. Although the consequences of Hurricane Katrina were huge in economic terms, the costs were a small fraction of the US GDP. In comparison, the 1999 earthquake in Turkey had an economic impact of 8 per cent of its GDP and the hurricane in 1998 in Honduras amounted to over 75 per cent of its GDP. Losses from natural disasters are substantial and in some countries represent a major fraction of national GDP (Handmer 2003). In some places, natural disasters have turned back the clock on development by years or even decades. Development is then not sustainable. Part of sustainable development needs to be the consideration of decisions being made now, including decisions to invest or not, and how they will alter societies' exposure to the risk and occurrence of natural hazards.

In response, participants of the 2005 World Conference on Disaster Reduction agreed to the following declaration:

> 1. ... Disasters have a tremendous detrimental impact on efforts at all levels to eradicate global poverty; the impact of disasters remains a significant challenge to sustainable development.
>
> 2. We recognize the intrinsic relationship between disaster reduction, sustainable development and poverty eradication, ...

Again, an explicit link is drawn between disaster reduction and the achievement of international development goals.

73.6 Responding to the Need for Integrated and Interdisciplinary Research on Hazards

In 2004, the *International Council for Science* (ICSU) Panel on the Priority Area Assessment on Environment and its relation to Sustainable Development[16] recommended that an ICSU-led "Natural and Human-induced Hazards Research Programme" be created. Subsequently, after a planning process, the 29th ICSU General Assembly[17] in 2008 endorsed the scientific plan for the new research initiative, now called *Integrated Research on Disaster Risk* (IRDR) addressing the challenge of natural and human-induced environmental hazards. The title was chosen on the basis of the rationale of integration, risk and disasters. ICSU, the *International Social Sciences Council* (ISSC)[18] and the *United Nations International Strategy for Disaster Reduction* (ISDR)[19] are the IRDR co-sponsors, reflecting the needs for integrated approaches of the global natural and social sciences communities and governments and UN agencies as represented by the UN ISDR. The IRDR Science Programme is an integrated approach to natural and human-induced environmental hazards through a combination of natural, socio-economic, health and engineering sciences, including socio-economic analysis, understanding the role of communications, and public and political response to reduce the risk. It will build upon and collaborate with the Earth System Sciences Partnership and its research agenda (chap. 74 by Leemans, Rice, Henderson-Sellers and Noone).

The focus of the research programme is on disaster risk reduction. In order to reduce risk, there needs to be integrated risk analysis, including consideration of relevant human behaviour, its motivations, constraints and consequences, and decision-making processes in face of risks. The physical events themselves can sometimes be directly attributable to human agency (i.e. are 'human-induced'), as with many cases of small- and medium-scale flooding, landslides, land subsidence and drought in rural and urban settings related to environmental degradation and human intervention in ecosystems, as well as global climate change. These human-induced or socio-natural hazards are created at the interface of natural and human processes. In addition, human actions determine whether or not an event beyond human control (e.g. heavy rain or an earthquake) will lead to disastrous flooding (e.g. through construction on a flood plain) or building collapse (through inadequate building specifications and techniques). The seriousness of the consequences of any disaster will depend also on how many people choose (or feel they have no choice but) to live and work in areas at higher risk, as well as on organizational factors relating to protection and emergency planning, and on fundamental aspects of social equity.

The IRDR is guided by three broad research objectives that will lead to understanding of hazards, risk and vulnerability and enhanced capacity to model and project risk into the future; to the understanding of the decision-making choices that lead to risk and how they may be influenced; and how this knowledge can better lead to disaster risk reduction. The first objective is: 1. Characterization of hazards, vulnerability and risk; with three sub-objectives: 1.1: identifying hazards and vulnerabilities leading to risks; 1.2: forecasting hazards and assessing risks; and 1.3: dynamic modelling of risk. A challenge is the broad range of time- and space-scales for hazards and disasters. The response to these varying types of hazards leads to many challenges, and an objective of this research programme is to provide integrated, interdis-ciplinary understanding of these connections in ways that will lead to reductions in losses.

Over the past several decades, human knowledge and understanding of natural hazards has grown dramatically. Yet despite this growth in knowledge, losses associated with environmental hazards have risen during past decades. There is a great shortfall in current research activities on how science is used to shape social and political decision-making in the context of hazards and disasters, leading to the second objective: 2. Understanding decision-making in complex and changing risk contexts; with three sub-objectives: 2.1: identifying relevant decision-making systems and their interactions; 2.2: understanding decision-making in the context of environmental hazards; and 2.3: im-

proving the quality of decision-making practice. In focusing on understanding effective decision-making in the context of risk management, analysis will lead to improvements. In linking with the other objectives, the emphasis is on how human decisions and the pragmatic factors that constrain or facilitate such decisions can contribute to hazards becoming disasters and/or may mitigate their effects.

The third objective is: 3. Reducing risk and curbing losses through knowledge-based actions, where the 'reduction of risk' refers to all the factors that are contributing to the growing hazard and disaster losses and is an overall objective of the research programme. Objective 3 integrates outputs from objectives 1 and 2. The task of characterizing risk involves identification of hazards and exposure and vulnerabilities of places and people, and hence, assessing the level of risk and understanding how the risk can, may or will change with time. Risk identification requires a multi-hazards approach, since communities are commonly threatened by several different hazards that may be linked to one another.

The central thrust of research towards objective 3 will be to use the combined understanding from many different fields of expertise into an integrated approach to the understanding of the causes of disaster in order to provide practical guidance on the reduction of risk and the curbing of losses. The approaches suggested may be described as diagnostic or forensic. At a superficial or anecdotal level many of the reasons for past failures to reduce risks and curb losses are known. What is not well understood is how these factors work together in different ways and in different places to produce the adverse consequences with which we are more and more familiar. Over the first three years of IRDR the Scientific Committee will commission and encourage case studies to identify major research needs and gaps at the interface of the natural and social sciences.

There will be three cross-cutting themes and approaches: capacity building; case studies and demonstration projects; and assessment, data management and monitoring. Capacity or capability can be defined as a combination of all the strengths and resources available within a community, nation or region that can reduce the level of risk, or the effects of a disaster. It includes physical, institutional, social or economic means such as financial, political and technological resources, as well as skilled personal or collective attributes such as leadership and management at different levels and sectors of the society. Capacity building aims to develop human skills and societal infrastructures within a community, nation or region in order to reduce the level of risk.

The IRDR will draw upon the expertise and scientific outputs of many partners in research as it adopts an interdisciplinary, integrated approach to research on and risk reduction to hazards. The *Global Change System for Analysis Research and Training* (START)[20] will be the capacity-building partner and many of the other partners are described in other chapters of this book.[21]

The Hyogo Framework for Action calls for all-hazards approaches, people-centred systems and overall risk assessment. The IRDR Programme responds to that imperative for a research programme, sustained for a decade or more, that is integrated across the hazards, the disciplines and the geographical regions, wherein would lie its value-added nature. The coupling of the natural sciences' examination of hazards with the socio-economic analysis of vulnerability and mechanisms for engaging policy decision-making processes will be a major value added.

The legacy of IRDR will be an enhanced capacity around the world to address hazards and make informed decisions on actions to reduce their impacts. The legacy will also be the development of science and development of broadly-based capacity and the repository of information and data that have been acquired and that will be of continuing availability and value to the global community.

73.7 The Intersection of Issues and Barriers to Change

Because of conflicting agendas and pressures, it has been difficult for governments to develop programmes across a wide range of themes in a consistent way. This chapter dealt with three scientific and policy issues, disaster management, climate change and international development. Each is linked to the other and also to sustainable development. In each case there is also an element of uncertainty and risk – when will the next disaster happen; how will the climate actually change; and will other events, such as

20 See on *Global Change System for Analysis Research and Training* (START); at: <www.start.org>.

21 See chap. by Church, Asrar, Busalacchi and Arndt on the *World Climate Research Programme* (WCRP); See chap. 75 von Falkenhayn, Rechkemmer and Young on the *International Human Dimensions Programme on Global Environmental Change* (IHDP); at: <see at: <www.ihdp.unu.edu/>

war or revolution overwhelm international development.

In consideration of the linkages of disaster risk reduction and adaptation to climate change, Birkman, Tetzlaff and Zentel (2009) looked at the challenges and barriers that have to be addressed when developing integrative strategies for linking disaster risk reduction and climate change adaptation. One issue is the mismatch of scales – temporal, spatial and functional. Disaster risk reduction, particularly the response and recovery aspects are usually related to events of short-term duration while the climate change community is mostly focused on longer-term perspectives which go far beyond any political cycle of elections. While the disaster risk community is usually dealing with local issues, the climate community has mostly worked on the global scale and the prediction of events down to the local scale is still problematic. A functional scale challenge refers to the mismatch of organizations for the management of disaster crises and climate change adaptation. The different institutions will have different encompassing rules, norms and rights as well as the organizations that enforce their regulations. The lack of coordination between different agencies and ministries involved is factor that often leads to mismatches in addressing the problem and appropriate solutions.

Climate change is no longer and should not be seen as a pure environmental problem but as a risk that affects environmental systems and society alike, thus necessitating the involvement of natural and social processes and hence a communication and cooperation between natural and social scientists as well as the development community, with an increasing and appropriate emphasis on the economic dimensions (Stern 2007). Hulme (2009) in his provocatively titled book "Why We Disagree About Climate Change" discusses the various constraints and viewpoints that have led to controversy and inaction on climate change. Hulme reflects on issues and concerns such as: values; beliefs and fears of people; the challenges of development; and approaches to governance. The diversity of views, beliefs, cultures and approaches to an issue as complex as climate change make it very difficult to make progress and can lead to disagreements that may be interpreted as disagreeing with the scientific assessments but in reality more reflect some other fundamental belief that make it difficult to accept or undertake the necessary actions.

The normative dimension, such as legislative, cultural or behavioural norms, influences the functioning of human society in that individuals, organizations and societies are guided by certain rules and follow certain standards as they work to find solutions. For climate change this has evolved and become more complex as new actors get involved in finding solutions. But, as of yet, these actors are still different from those in disaster management. An issue is then the lack of clear norms when applying vulnerability and capacity assessment and when designing and implementing adaptation measures. There are opportunities after disasters, to build back in an adaptive way considering future climate change but these are in most cases not taken. Another challenge is the still different use of terms and definitions by both communities and the weak links between the different types of knowledge and work of both communities. This results in barriers for communication, joint programming and collaboration.

Some other barriers in the design and implementation of policies across integrated fields of disaster management, climate change and international development (e.g, Henstra/McBean, 2005) include how priorities should be set, what role each level of government should play, how strategies should be coordinated and how outcomes should be evaluated. Clearly it is important to have good governance recalling the assessment of the Global Assessment Report on Disaster Risk Reduction-2009[22] that disaster risk is "highly concentrated in poorer countries with weaker governance." Even with good governance a barrier is uncertainty regarding hazards and vulnerabilities; which are the most important and which are the most pressing, not necessarily the same thing. For hazards, Burton, Kates and White (1993) identify at least seven distinct characteristics of a hazard, each of which add to the complexity of the disaster problem and complicates policy-making. Common difficulties in dealing with climate change, disaster management and international development are issues of time scale and risk. In each case, investments are needed now and in the near term for benefits that will accrue later. Predictions of the future must play a major role in planning these strategies and investments (McBean 2000; Sarewitz/Pielke/Byerly 2000; McBean 2008). There is always uncertainty in predictions of forthcoming events. Risk analysis can lead to the optimum decisions but the setting of priorities is still difficult. The political, institutional cultural and economic aspects of decision-making and behaviour are also important and need to be explored. Many of the problems in de-

22 2009 Global Assessment Report on Disaster Risk Reduction. Available at www.preventionweb.net/gar09

cision-making are also political and social problems in that they involve divergent interpretations of what the problems and response options really are. There are often conflicting values and interests at work, and strikingly different opportunities to influence developments. The salience of strategic societal choices, and of competing rationalities, which cannot be subsumed within the language of risk and risk management, is recognized, so this broader context needs to be addressed as the research moves to the complexity of the political and social challenges encountered. These uncertainties are the raison d'être for an integrated disaster research program necessitating the building across disciplines and institutional boundaries.

The impacts of a changing climate or disaster events are largely determined by a society's or community's vulnerability, which is a function of its exposure to climate and other hazards, its sensitivity to the stresses they impose, and its capacity to adapt to these stresses (Henstra/McBean, 2009). That vulnerability can be reduced through actions to minimize exposure, reduce the sensitivity of people and systems, and strengthen the community's adaptive capacity. Each of these requires approaches that transcend issues and their implementation will necessitate surmounting barriers and constraints. For example, there are four factors important towards adaptive capacity; these are: access to information, expertise with information, analyses and translation information into policy, fiscal capacity, and political will to act, which cover a range of issues and organizations. Designing policies for adaptation to climate change and disaster risk reduction and sustainable development all require: assessments of the effectiveness, costs and feasibility of measures to reduce vulnerability; stakeholder analyses to identify targets and beneficiaries of interventions; analyses of the consequences of inaction; and other factors. One difficulty with regard to the fiscal capacity is that at least some level of public expenditure will be needed and that will be limited by competing demands on scarce economic resources. In the end, a critical issue will be generation of the political will to act which will most likely come with more general recognition that adaptation and disaster risk reduction are necessary and possible and that they are not only desirable but necessary towards sustaining development.

Implementation of a research program usually requires support from national scientific funding agencies. Putting aside for the moment the complexities of support across usually-disciplinary funding agencies, there is the question of costs and benefits – what will be the quantifiable benefits of the costs of investment in a research programme and a resulting policy initiative. Many policies are increasingly decided at sub-national levels of government and there is difficulty especially at those levels to ascertain the local benefits (Wolensky/Wolensky 1990). For example the decision to invest in preventative measures, to reduce the impacts of a hazard or to adapt to future climate change and gain financial benefits at some future time, must be weighed against immediate and potentially significant costs (Godschalk/Brower 1985). Related to this issue of costs and benefits is the political perception that there is a lack of public demand and hence political motivation to take action (Tierney/Lindell/Perry 2001). As people fail to engage or disengage from the issue, the interest of political actors wanes and integrated approaches at prevention are relegated down the policy agenda. Intergovernmental collaboration is considered essential for the development and implementation of policies for integrated approaches but this is difficult to do due to the lack of common interests. This requires the consideration of these issues in the context of risk management. Governments need to bring these issues together in a coherent and integrated policy development and implementation.

A continuing difficulty in taking integrated interdisciplinary approaches are the traditional structures of academic institutions, with faculties of natural, social, engineering and health sciences all separated. The "reward" systems of selection for honours to, for example, national academies and the competitions for research funds are still largely based on disciplinary criteria which put less merit for work across or within another discipline. These barriers are being lowered but still are a significant obstacle.

These issues represent a challenge and also an opportunity. Scientists need to make the case to governments of the importance of interdisciplinary and integrated science as a basis for action. This is in the best interests of citizens for their safety, social benefits and economic competitiveness.

73.8 Summary

This chapter has identified and discussed the issues of the need for interdisciplinary and integrated approaches to coping with environmental change, by looking at the intersection of three issues: hazard management, climate change and international development. Sustainable development provides possible frameworks for this integration. There is evidence

that this convergence or intersection is starting to happen

The Intergovernmental Panel on Climate Change[23], at its 30th session in spring 2009, decided to prepare an IPCC Special Report on *Managing the Risks of Extreme Events and Disasters to Advance Climate Change Adaptation* which will bring a scientific focus on the linkages between the two issues. There has also been a recent focus on integrating disaster risk reduction and climate change adaptation in terms of international policy – both under the auspices of the UN ISDR and of the UNFCCC.[24] At the 2009 Global Platform of the UN ISDR, J. Holmes, the UN Under-Secretary-General for Humanitarian Affairs and Chair of the Second Session of the Global Platform, underlined overarching themes of the meeting: the linkages between disasters, poverty and vulnerability, as well as the connection between disaster risk reduction and climate change. His summary highlighted the following areas to be considered critical for future progress:

- *Climate change*: DRR must be a concrete part of the climate change negotiations at the UN climate meeting in Copenhagen in December 2009;
- *Reduced risk*: Success in reducing disaster risk and adapting to climate change will depend on the development of innovative partnerships that recognize the mutual dependence of actions undertaken by central and local governments and civil society;
- *Financing DRR:* Proposals included a variety of innovations, such as incentives for retrofitting, risk transfer tools, risk-sensitive development, private sector involvement, debt swap to finance disaster reduction measures and linkages with adaptation financing; and
- *Setting DRR targets*: UN Secretary-General Ban Ki-moon called for a target to halve the losses of lives from disasters by 2015.

The Organization for Economic Cooperation and Development (2009) has provided policy guidance on integrating climate change adaptation into development cooperation. These links of disaster risk reduction, climate change adaptation and development are thus moving ahead but the 'silos' of governmental agencies, including science funding agencies, will continue to be a challenge. There is a clear need for leadership to make it happen for the benefit of all, in this generation and the next ones.

74 Research Agenda and Policy Input of the Earth System Science Partnership for Coping with Global Environmental Change

Rik Leemans, Martin Rice, Ann Henderson-Sellers and Kevin Noone

74.1 The Science of Global Environmental Change[1]

Human activities now match (and often exceed) the natural forces of the Earth System (Steffen/Sanderson/Tyson/Jäger/Matson/Moore/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004). Recent ice core data show that current levels of *carbon dioxide* (CO_2) and methane are well outside the range of natural variability over the last 800,000 years (Luthi/Le Floch/Bereiter/Blunier/Barnola/Siegenthaler/Raynaud/Jouzel/Fischer/Kawamura/Stocker 2008). Roughly half of the world's ice-free land surface has been altered by human actions. Humans now fix more nitrogen than does nature. Particles emitted by human activities alter the energy balance of the planet, as well as having adverse effects on human health. Human choices about how we use resources are at the heart of many of these changes. These may seem to be unrelated issues; however, over the last decades, we have gained a deeper understanding of the degree to which all of these separate issues are linked. The Earth System is a very complex coupled system with myriad feedbacks, and it has and inevitably can still exhibit rapid, global-scale responses to changes in environmental conditions (Costanza/Graumlich/Steffen/Crumley/Dearing/Hibbard/Leemans/Redman/Schimel 2007).

The kinds of questions now being asked of the research community have changed over the last decades reflecting the increasing appreciation of the interconnectedness of the Earth System (Noone 2006). As humans tackled scientific questions of societal importance initial investigations were by individuals; later some of the harder questions could be successfully addressed by concentrating on either individual or a small number of the components of the Earth System, although answering such questions required international, interdisciplinary collaboration. For example, establishing the cause-effect relationships of the Antarctic ozone hole required international collaboration among atmospheric chemists and meteorologists. Understanding the causes and consequences of acid rain required collaboration between atmospheric scientists and terrestrial ecologists. This innovative interdisciplinary research increased the understanding and helped to develop adequate solutions to these problems.

Now, however, the kinds of questions being asked of the scientific community increasingly underline the need for a more holistic or integrated approach. These emergent questions include, for example:

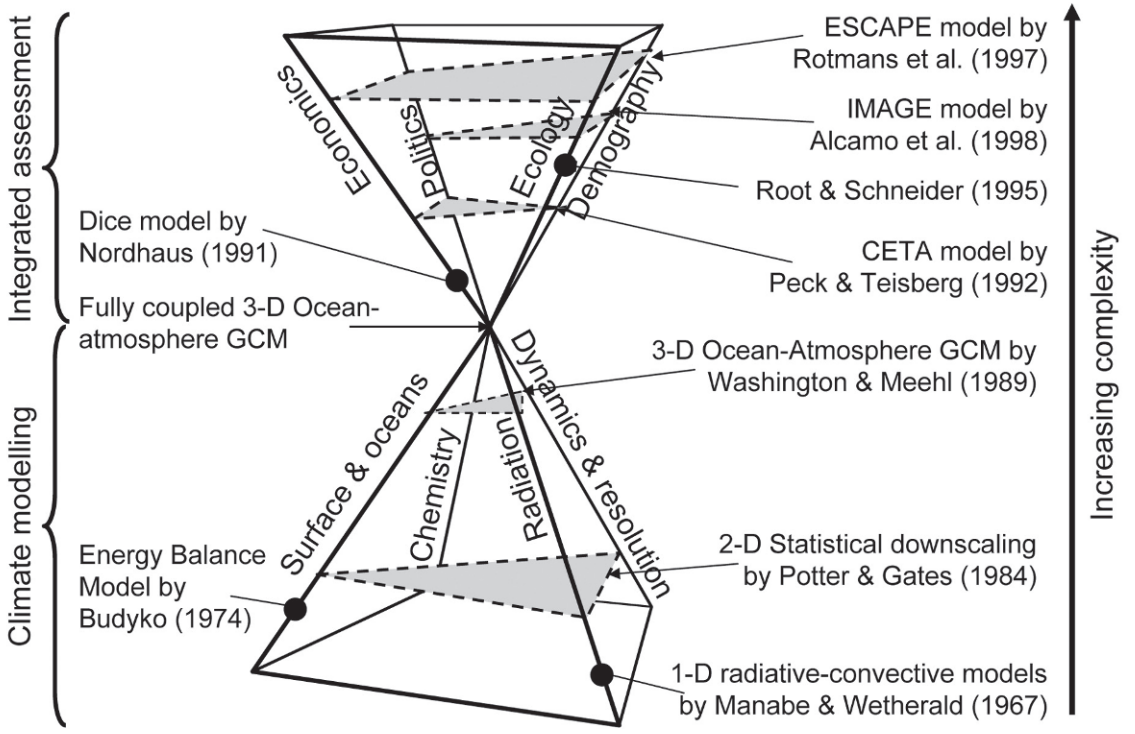
- How do urban-industrial emissions, land cover changes and global warming influence the Asian Monsoon circulation?
- How will changes in precipitation patterns caused by global warming, influence water management policies on regional and local scales?
- What will be the consequences of large-scale land use and ecosystem changes caused by moving towards large-scale biofuel use?
- What are the impacts of the predicted climate changes on food production and human security?
- What role does urbanization play in the health effects of air pollution?
- Do mega cities play a role in affecting the energy balance of the planet and in the hydrological cycle?
- What form of carbon sequestration scheme will have the smallest negative impact on the Earth System?

These questions cannot be answered without a close coupling of approaches from both the natural sciences, social sciences and humanities. Answering them will also require new observational and model-

1 The authors would like to thank Anne Larigauderie (Executive Director, DIVERSITAS), Kathy Hibbard (Executive Officer, AIMES) and John Ingram (Executive Officer, GECAFS) for providing invaluable input to this chapter.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_74, © Springer-Verlag Berlin Heidelberg 2011

Figure 74.1: The top-down integrated assessment pyramid balances on the apex of the bottom-up climate modelling pyramid. **Sources:** After McGuffie/Henderson Sellers (2005) based on models developed by: Budyko (1974); Nordhaus (1991); Manabe/Wetherald (1967); Washington/Meehl (1989); Peck/Teisberg (1992); Root/Schneider (1995); Rotmans/de Vries (1997); Alcamo/Leemans/Kreileman (1998); Potter/Gates (1984).



ling tools that to a much larger extent have to integrate the many different dimensions of the biosphere, the pedosphere, the atmosphere and the anthroposphere (Leemans 2009a). In addition, the *global environmental change* (GEC) research community faces an increasing challenge to present research results in more accessible and informative ways to stakeholders – particularly those concerned with mitigation of greenhouse gas emissions and other pollutants, adaptation to climate change and sustainable development of people, societies and their natural resources.

In response to all these challenges and questions the .*Earth System Science Partnership* (ESSP) was established, in which the four international global change research programmes (DIVERSITAS, IGBP, IHDP, WCRP)[2] collaborate to address such highly integrative and interdisciplinary questions, and communicate the answers in a timely manner to society. ESSP thus aims to address complex Earth system questions that are important to society and that require problem-solving skills from a range of natural and social sciences. In this chapter we aim to provide the philosophy behind the ESSP, present its major activities and discuss some of its preliminary successes.

The presentation and discussion of ESSP in this chapter is structured as follows. First, we present a concise history of global change research, resulting in the Amsterdam Declaration that led to the establishment of ESSP (74.2). Then we present the different elements of the ESSP that have been developed so that ESSP can achieve its goals (74.3). We show that this is research in progress but that major contributions to prominent assessments have been made, that capacity building efforts are mounting and that a different kind of outreach is being developed (74.4).

74.2 Supporting Structures for Global Environmental Change Research

Stakeholders seek local strategies to cope with ongoing and future environmental change. The research

community is therefore expected to address detailed questions on the effects of *global environmental change* (GEC) on regional and even local scales, while the tools to accomplish this are not robust enough. This dilemma has been illustrated using a double pyramid (figure 74.1). Here the convergence of a single scientific effort (in this case climate modelling) is overlaid by a rapidly diverging set of societal questions. Clearly the single disciplinary endeavour cannot ever provide answers to the myriad of questions arising from all aspects of societies' need for information and analysis.

Human interaction with and adaptation to a changing environment (including mitigation) can take many forms, and can have both positive and negative environmental impacts. Small-scale measures could include increased use of air conditioning as temperature increases, architectural changes for more efficient heating and cooling, better forecasting and warning systems for extreme events, and increased water usage. Larger-scale issues could vary from switching to renewable energy sources to attempts at geo-engineering (Leemans/Agrawala/Edmonds/MacCracken/Moss/Ramakrishnan 1996). The large-scale movement of people away from areas adversely affected by climate change and by other environmental and socio-economic stresses is also a form of adaptation. Each of these options has environmental consequences that must be carefully evaluated before they are implemented. The larger the adaptation scheme, the greater care needs to be taken in considering its impact before implementation. A fundamental outcome of adaptation schemes is that they will modify equity across the globe. The projections recently released by the *Intergovernmental Panel on Climate Change* (IPCC) (Parry/Canziani/ Palutikof/Hanson/Van der Linden 2007; chap. 79 by Parry/Canziani/Palutikof/Hanson) show that in many cases the areas facing the largest changes in climate are not only located in countries that have contributed the least to the atmospheric build-up of greenhouse gases, but also those that have the least ability to adapt to them. Clearly, the basic science research needed to support decisions about adaptation needs a tightly coupled natural-social science support structure. The flow of research into societal applications is not one-way nor is it linear. However, it may be helpful to schematize the exchanges at least to underline where research and assessments differ and how they tend to be separated by a societal needs segment (figure 74.2).

The need to understand how individual aspects of and processes in the natural and social domains work has not diminished but, in fact, underpins the answers to questions of sustainable development and adaptation. We still must concentrate on first class science involving the interactions and feedbacks between biological, chemical and physical processes and human systems. However, scientists, resource managers and policy makers require a common understanding in order for their interactions to be mutually beneficial.

The need for an international, multidisciplinary approach to aspects of global environmental change research is not entirely new. The *World Climate Research Programme* (WCRP) was established in 1980 in response to the need for a framework within which to organize and facilitate international climate research (chap. 78 by Church/Asrar/Busalacchi/Arndt). The *International Geosphere-Biosphere Programme* (IGBP) was initiated in 1987 with the intention to better link the biological and physical sciences and research communities (chap. 77 by Noone/Nobre/Seitzinger). The *International Human Dimensions Programme on Global Environmental Change* (IHDP) was started in 1996 to build a support structure for international multidisciplinary research in the social sciences (chap. 75 by von Falkenhayn/Rechkemmer/Young). DIVER-

SITAS was launched in its current structure in 2001 to build a global programme in biodiversity science (chap. 76 by Walther/Larigauderie/Loreau). Each of these international programmes is itself highly international and multidisciplinary in scope and are sponsored by the *International Council for Science* (ICSU), which congregates most national academies and international scientific unions.[3] However, it became apparent in the late 1990s that even these programmes could not individually address the new kinds of Earth System-level questions that were being asked. There was recognition at the time that the Earth System did not behave in a way that was easily understood by 'conventional' scientific approaches. Another kind of structure was needed. Such a need was further addressed by the Amsterdam Declaration on Global Change, which resulted from a thorough discussion among all programmes on future research issues at IIGBP's 2001 *Challenges of a Changing Earth: Global Change* open science meeting in Amsterdam. The scientific analysis and arguments on which the declaration is based are also carefully documented (Steffen/Sanderson/Tyson/Jäger/Matson/Moore/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004).

74.2.1 The Amsterdam Declaration on Global Change

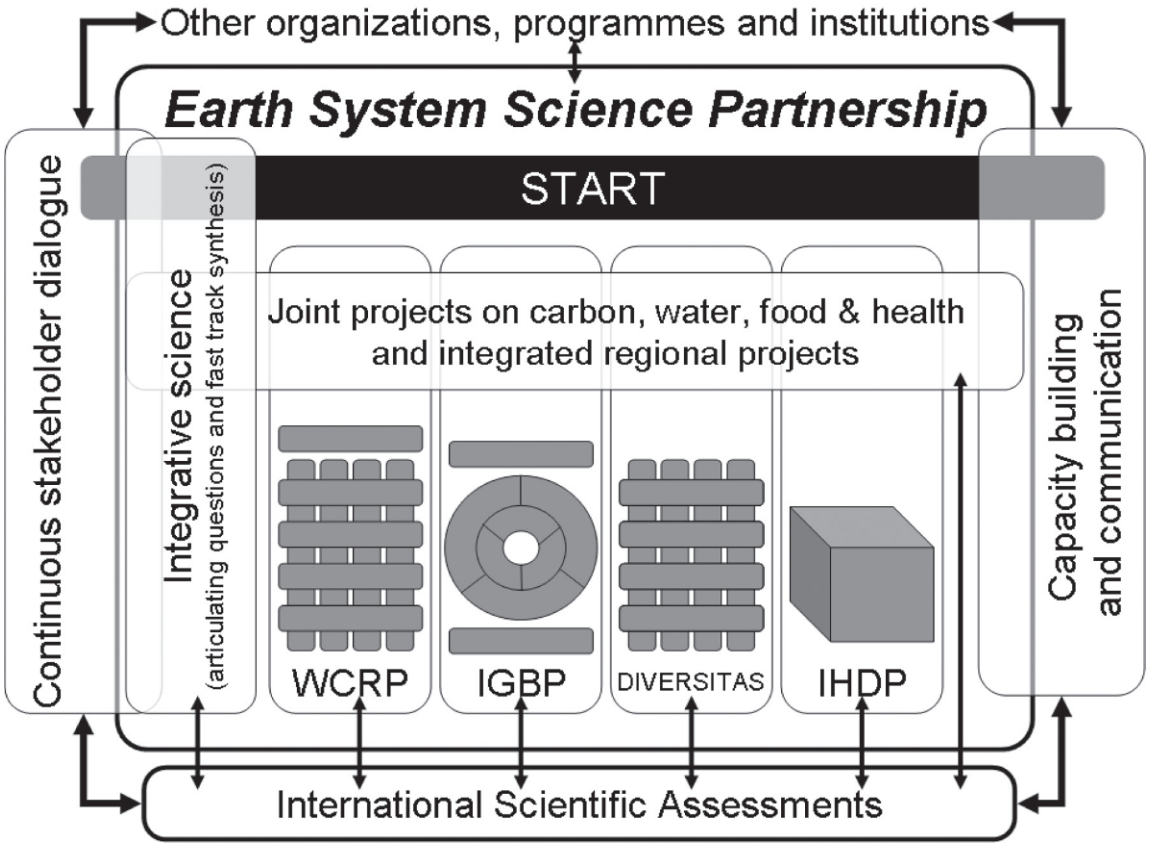
The scientific communities of four international global change research programmes - the *International Geosphere-Biosphere Programme* (IGBP), the *International Human Dimensions Programme on Global Environmental Change* (IHDP), the *World Climate Research Programme* (WCRP) and the international biodiversity programme DIVERSITAS - recognize that, in addition to the threat of significant climate change, there is growing concern over the ever-increasing human modification of other aspects of the global environment and the consequent implications for human well-being. Basic goods and services supplied by the planetary life support system, such as food, water, clean air and an environment conducive to human health, are being affected increasingly by global change.

Research carried out over the past decade under the auspices of the four programmes to address these concerns has shown that:

- The Earth System behaves as a single, self-regulating system comprised of physical, chemical, biological and human components. The interactions and feedbacks between the component parts are complex and exhibit multi-scale temporal and spatial variability. The understanding of the natural dynamics of the Earth System has advanced greatly in recent years and provides a sound basis for evaluating the effects and consequences of human-driven change.
- Human activities are significantly influencing Earth's environment in many ways in addition to greenhouse gas emissions and climate change. Anthropogenic changes to Earth's land surface, oceans, coasts and atmosphere and to biological diversity, the water cycle and biogeochemical cycles are clearly identifiable beyond natural variability. They are equal to some of the great forces of nature in their extent and impact. Many are accelerating. Global change is real and is happening *now*.
- Global change cannot be understood in terms of a simple cause-effect paradigm. Human-driven changes cause multiple effects that cascade through the Earth System in complex ways. These effects interact with each other and with local- and regional-scale changes in multidimensional patterns that are difficult to understand and even more difficult to predict. Surprises abound.
- Earth System dynamics are characterized by critical thresholds and abrupt changes. Human activities could inadvertently trigger such changes with severe consequences for the Earth's environment and inhabitants. The Earth System has operated in different states over the last half million years, with abrupt transitions (a decade or less) sometimes occurring between them. Human activities have the potential to switch the Earth System to alternative modes of operation that may prove irreversible and less hospitable to humans and other life. The probability of a human-driven abrupt change in the Earth's environment has yet to be quantified but is not negligible.
- In terms of some key environmental parameters, the Earth System has moved well outside the range of the natural variability exhibited over at least the last half million years. The nature of changes now occurring simultaneously in the Earth System, their magnitudes and rates of

3 ICSU (www.icsu.org) has officially endorsed the programmes together with other international sponsors, such as the World Meteorological Organization, UNESCO, the International Social Science Council and the United Nations University.

Figure 74.3: The activities of the ESSP as a partnership of the four global environmental change research programmes.



change are unprecedented. The Earth is currently operating in a no-analogue state.

On this basis the international global change programmes urge governments, public and private institutions and people of the world to agree that:

- An ethical framework for global stewardship and strategies for Earth System management are urgently needed. The accelerating human transformation of the Earth's environment is not sustainable. Therefore, the business-as-usual way of dealing with the Earth System is not an option. It has to be replaced – as soon as possible – by deliberate strategies of good management that sustain the Earth's environment while meeting social and economic development objectives.
- A new system of global environmental science is required. This is beginning to evolve from complementary approaches of the international global change research programmes and needs strengthening and further development. It will draw strongly on the existing and expanding disciplinary base of global change science; integrate across disciplines, environment and development issues and the natural and social sciences; collaborate across national boundaries on the basis of shared and secure infrastructure; intensify efforts to enable the full involvement of developing country scientists; and employ the complementary strengths of nations and regions to build an efficient international system of global environmental science.

The global change programmes are committed to working closely with other sectors of society and across all nations and cultures to meet the challenge of a changing Earth. New partnerships are forming among university, industrial and governmental research institutions. Dialogues are increasing between the scientific community and policymakers at a number of levels. Action is required to formalize, consolidate and strengthen the initiatives being developed. The common goal must be to develop the essential knowledge base needed to respond effectively and quickly to the great challenge of global change.

Table 74.1: The activities and achievements of the ESSP as a partnership of the four global environmental change research programmes. **Source:** Compiled by the authors.

Activity (acronym)	Website	Major objectives and achievements
Programmes		
An international programme of biodiversity science (DIVERSITAS)	<www.diversitas-international.org>	DIVERSITAS was launched in its current structure in 2001 to address the complex scientific questions posed by the loss of and change in global biodiversity.
International Geosphere-Biosphere Programme (IGBP)	<www.igbp.net>	IGBP was established in 1987 and addresses the overarching scientific questions that reflect the three major Earth System components (land, ocean and atmosphere) and the interfaces between them.
International Human Dimensions Programme on Global Environmental Change (IHDP)	<www.ihdp.org>	IHDP was founded in 1996 and generates scientific knowledge on coupled human-environment systems, achieves comprehensive understanding of global environmental change processes and their consequences for sustainable development.
World Climate Research Programme (WCRP)	<wcrp.wmo.int>	The WCRP was established in 1980 and integrates observations, experiments and modelling that provide the scientific breakthroughs essential to advance understanding of the processes that determine climate.
Joint Projects		
Global Carbon Project (GCP)	<www.globalcarbonproject.org>	GCP was established in 2001 in recognition of the enormous scientific challenge and fundamentally critical nature of the carbon cycle for Earth sustainability. The scientific goal of the project is to develop a complete picture of the global carbon cycle, including both its biophysical and human dimensions together with the interactions and feedbacks between them.
Global Environmental Change and Food Systems (GECAFS)	<www.gecafs.org>	GECAFS was launched in 2001 as a comprehensive interdisciplinary programme to study the links between food security and global environmental change. GECAFS improved the understanding of changes in food systems, its environmental consequences and possible adaptation strategies.
Global Water System Project (GWSP)	<www.gwsp.org>	GWSP was established in 2004 and addresses how humans are changing the global water cycle and the associated biogeochemical cycles and biological components. This also to understand the social feedbacks arising from these changes. Main achievements are the digital water atlas, the global water system lexicon and global reservoir and dam database.
Global Environmental Change and Human Health (GECHH)	<www.essp.org>	GECHH was launched in 2006 at the ESSP OSC in Beijing, in partnership with the World Health Organization (WHO). GECHH aims to identify and quantify current and future health risks posed by GEC, describe spatial and temporal differences in health risks to understand vulnerabilities and priorities for interventions, and develop cost-effective adaptation strategies for reducing health risks.

Activity (acronym)	Website	Major objectives and achievements
Capacity Building		
Global Change System for Analysis, Research, and Training (START)	<www.start.org>	START provides an international framework for capacity building. Its mission is to develop regional networks of collaboration between scientists and institutions to enhance scientific capacity in developing countries. START has trained many global change scientists and provided them with improved enhanced access to data, communication technology, and research skills.
Integrated Regional Studies		
Monsoon Asia Integrated Regional Study (MAIRS)	<www.mairs-essp.org>	MAIRS was established in 2006 and studies human interactions with the monsoon system. MAIRS assesses to what extent the human activities alter the monsoon climate and how this impacts the social and economic development of Asia. MAIRS also studies to what extent adaptation and mitigation are possible through policies, law and institutions.
African Network for Earth System Science (AfricanNESS)	<www.igbp.net/page.php?pid=412>	The AfricanNESS science plan and implementation strategy (published in 2008) focuses on four top-level issues: food and nutritional security, water resources, health and ecosystem integrity. The plan also outlines options to implement and organize a network of Earth system scientists in Africa, connecting them to scientists around the world.
Open Science Conferences		
The Open Science Conference 'Challenges of a Changing Earth' in Amsterdam, July 2001		All GEC programmes participated in this meeting and provided a smorgasbord of GEC science. Ongoing research was synthesized and this resulted in the Amsterdam Declaration and ESSP's establishment.
ESSP Open Science Conference in Beijing, November 2006.	<www.essp.org/index.php?id=42>	The conference showed that ESSP is actually improving the understanding of the modifications of the Earth system. Participants were concerned for the continuing adverse affects on the global environment and the resulting serious threats to sustainable development of human society.
IARU 'Climate Change: global risks challenges and decisions' Conference in Copenhagen, March 2009	<climatecongress.ku.dk>	The congress was organized by the *International Alliance of Research Universities* (IARU). The congress provided a synthesis of existing and emerging scientific knowledge necessary to make intelligent societal decisions concerning application of mitigation and adaptation strategies in response to climate change.
Collaborative Programmes		
CGIAR Challenge Program '*Climate Change, Agriculture and Food Security*' (CCAFS)	<www.essp.org/index.php?id=76>	CCAFS is a major collaborative endeavour between the *Consultative Group on International Agriculture Research* (CGIAR) and ESSP. It is aimed at overcoming the additional threats posed by a changing climate to achieving food security, enhancing livelihoods and improving environmental management in the developing world.

74.3 Earth System Science Partnership (ESSP)

The *Earth System Science Partnership* (ESSP) formed as a result of the Amsterdam Declaration in 2001 and is a partnership for the integrated study of the Earth System, the ways that it is changing, and the implications for global and regional sustainability (Canadell/Carson/Craswell/Göbel/Ingram/Larigauderie/Steffen/Virji 2004). The ESSP contributes to this endeavour through a number of activities, including joint projects, capacity building, integrated regional studies and open science conferences. The ESSP also conducts community-wide research, such as the recently established Earth system analysis of biofuels and the contributions and advice to the environmental assessments and international conventions (figure 74.3). ESSP's activities are summarized in table 1 and will be shortly discussed below.

74.3.1 Joint Projects

The aim of the *Joint Projects* is to build a GEC-oriented research agenda of direct relevance for societies, with particular emphasis on four fundamentally important issues. In brief, these projects aim to elucidate the additional challenges caused by GEC for carbon dynamics, food systems, water and health, and to understand the implications of human-driven changes in these issues for the functioning of the Earth System. The joint projects should capitalize on the comparative strengths of the parent programmes and link these to other, national and international efforts relating to science, development and policy. The joint projects are, therefore, designed to directly address the two-way interaction between GEC and global sustainability issues.

The need for *International Project Offices* (IPOs) for each joint project was foreseen to coordinate planning, implementation and reporting, and ideally funded by multi-donor support. Indeed the scientific administrative support that the IPOs provide (backstopped by the secretariats of the four global change research programmes) is in essence the backbone of international ESSP efforts. Without them ESSP would not be in a position to ensure quality standards and global consistency, and to identify key links and gaps, and collaborate with national programmes, which are often disconnected from each other. The development of coordinated, international science agendas, which the IPOs and Secretariats of the joint projects help facilitate, are perhaps one of the single most important added values of the global programmes, and is of great benefit to regional and national initiatives. These agendas often become a reference point for developing national agendas and are a reminder of the scale at which some of the questions need to be answered. Typically these are larger than national or regional and so cannot be effected without international core funding, the so called 'glue money'.

A recent example is where the *Global Environmental Change and Food Systems* (GECAFS) IPO has been instrumental in bringing together the ESSP and the *Consultative Group on International Agricultural Research* (CGIAR), each with their respective research partners. These two large international organizations have now jointly developed a "Challenge Program" designed to enable agricultural and global change researchers to benefit from the best agricultural, climate change and related environmental science (figure 74.4; CGIAR Alliance/ESSP 2008). The objective of this challenge program is to overcome the additional threats posed by a changing climate to attaining food security, enhancing livelihoods and improving environmental management.

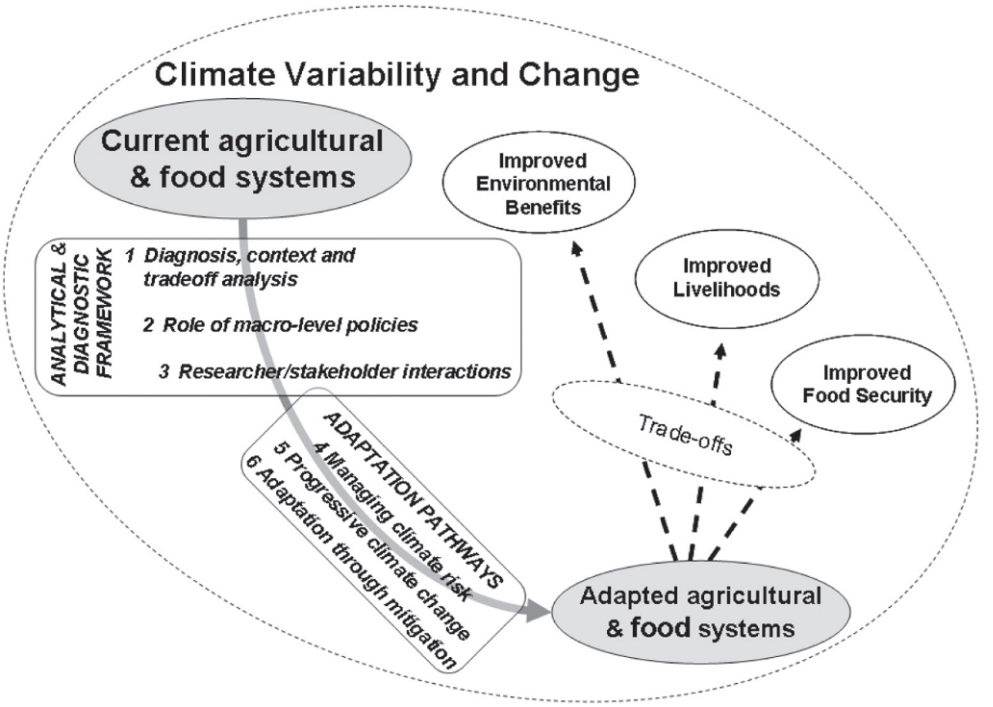
74.3.2 Capacity Building

> "Insufficient human capacity is a – if not the – major factor limiting Earth System Science research to achieve its full multidisciplinary breadth. A major accomplishment of the programmes of the ESSP has been the education of a new generation of scientists capable of making significant contributions to the integrated multidisciplinary science effort. An increased and sustained effort is needed however" (ESF 2002).

Capacity building and development is an essential function of the ESSP. Clearly, all the individual programmes and their core and joint projects do this already. At the ESSP chairs and directors meeting in 2006 a major capacity building and research activity called *SysTem for Analysis Research and Training* (START) was also incorporated into the ESSP (START has been co-sponsored by IGBP, IHDP and WCRP since its inception in the 1990's).

Building capacity of people and institutions capable of creative, integrative work is not a simple matter, and will not happen in business-as-usual. The ESSP should look at capacity development in a much larger, strategic manner. Capacity development will, therefore, be a comprehensive strategy towards the objective of having the people and institutions in place that can enable the promotion and catalyze of high quality and highly integrated Earth System science and facili-

Figure 74.4: Schematic representation of the structure and activities of the Challenge Program on Climate Change, Agriculture and Food Security (CCAFS). **Source**: CGIAR Alliance/ESSP (2008).



tate the application of its findings for the benefit of society and sustainability.

The ESSP is, therefore, developing integrative strategies for capacity development leading to:

- Active stakeholder engagement from the beginning and throughout the development and implementation to derive the benefits from the ESSP and expand support for ESSP;
- Enhanced capacity to conceive, plan and conduct future Earth System science activities;
- Effective internal and external communications; and
- A lasting legacy for Earth System science.

74.3.3 Integrated Regional Studies

The ESSP is developing a small set of *Integrated Regional Studies*, designed to contribute sound scientific understanding in support of sustainable development at the local level. These studies will also improve overall knowledge of regional-global linkages in the context of Earth System dynamics. The first such study is in *Monsoon Asia* (MAIRS). One of the most important issues that need to be addressed by these integrated regional studies, is the need to deliver regionalized climate and impact predictions that serve the questions being raised by policy developers and impact scientists.

74.3.4 Open Science Conferences

ESSP recognizes the importance of broad interaction amongst the many scientists that contribute to its activities. As such, the Partnership is committed to hosting major international science meetings. The *Open Science Conference – Challenges of a Changing Earth* - held in Amsterdam in July 2001 resulted in the Amsterdam Declaration (see 74.2.1) and led to the creation of the ESSP. In November 2006, the first ESSP Open Science Conference on *Global Environmental Change: Regional Challenges* was held in Beijing. The conference was preceded by a two-day meeting dedicated to the research of young scientists. START provided scholarships for many international students to participate. The quality of presentations and discussions was outstanding and awards for best young scientist presentations were given at the ESSP Open Science Conference closing plenary. At the ESSP OSC, the timely update of the global carbon budget by the GCP attracted major press attention. Their analysis showed that global growth in carbon dioxide emissions from fossil fuels was four times greater in the pe-

riod between 2000 to 2005 than in the preceding 10 years. Despite efforts to reduce carbon emissions, the global growth rate in CO_2 was 3.2 per cent in the five years to 2005 compared to 0.8 per cent in the period 1990 to 1999. This analysis was later published in the renowned Proceedings of the National Academy of Science (Canadell/Le Quere/Raupach/Field/Buitenhuis/Ciais/Conway/Gillett/Houghton/Marland 2007). In 2009, *International Alliance of Research Universities* (IARU) and ESSP organized the *Climate Change: global risks challenges and decisions* Congress in Copenhagen in March 2009. The congress synthesized existing and emerging scientific knowledge necessary to make intelligent societal decisions concerning application of mitigation and adaptation strategies in response to climate change. It attracted over 1500 scientists, who discussed and presented their latest results. As the congress synthesized three years of new research since IPCC's fourth assessment report (IPCC 2007c), the synthesis report of the congress (Richardson/Steffen/Schellnhuber/Alcamo/Barker/Kammen/Leemans/Liverman/Monasinghe/Osman-Elasha/Stern/Wæver 2009) will provide essential information to the UNFCCC negotiators that assemble in December 2009 to discuss and agree upon future steps in the *UN Framework Convention on Climate Change* (UNFCCC). This report stressed the increasing level of irreversible impacts at higher levels of changes in ocean acidification, atmospheric composition and climate, the likely limits to adaptation, the most vulnerable regions, people and systems, and the technical and biological possibilities for adequate mitigation efforts.

74.3.5 ESSP Interactions with the International Conventions and Assessments .

One role of the ESSP and its parent programmes is to inform and provide input to international conventions and assessments. Scientific assessments apply the judgment of experts to existing knowledge to provide scientifically credible answers to policy relevant questions (Leemans 2008). The assessments, such as the IPCC and the *Millennium Ecosystem Assessment* (MA), were instrumental in gathering and synthesizing scientific information for the use of policy processes. Both the IPCC and the MA were critically dependent on the science in the GEC programmes and ESSP.

74.3.5.1 The Intergovernmental Panel on Climate Change

WCRP's activities contributed significantly to the scientific basis for the landmark findings in IPCC's *Fourth Assessment Report* (AR4, IPCC 2007c), each one of which represents a major advancement in knowledge, including: "observed warming of the climate system is unequivocal"; "there is a very high confidence that the globally-averaged net effect of human activities since 1750 has been one of warming"; "most of the observed increase in globally-averaged temperatures since the mid-20th century is very likely due to the observed increases in greenhouse gas concentrations"; improved quantification of and confidence in the Earth's climate sensitivity provides "increased confidence in the understanding of the climate system response to radiative forcing"; model projections of future climate change indicate that "continued greenhouse gas emissions at or above current rates would cause further warming and induce many changes in the global climate system during the 21st century that would very likely be larger than those observed during the 20th century"; and there is now "higher confidence in projected patterns of warming and other regional-scale features".

A second very important feature of the IPCC's AR4 was the sheer number of WCRP scientists involved as coordinating, lead and contributing authors and reviewers of the various chapters in the Working Group I report (Solomon/Qin/Manning/Chen/Marquis/Averyt/Tignor/Miller 2007). Over 90 per cent of the coordinating authors, half of the contributors and some 70 per cent of the reviewers are scientists associated with WCRP, IGBP and the ESSP Global Carbon Project. The majority of these contributors were climate modellers, carbon cycle experts, diagnosticians and cryospheric scientists.[4] These contributions facilitated the discussion that led to a much more uniform and consistent application of the phrasings of uncertainties across all chapters on Working Group I.

IGBP, IHDP and DIVERSITAS science contributed to Working Group II on impacts and adaptation. IHDP scientists were engaged with Working Group

4 For the purpose of the statistics, we considered those climate researchers as 'GEC programme-associated' that are or were (at some stage of their career) active in any of the working groups, panels, core projects or crosscuts of the GEC programmes or that are/were sponsored by the GEC programmes to participate in workshops, seminars and conferences.

III on mitigation, amongst which where about five lead authors including two past IHDP chairs. START also stimulated contributions to IPCC's AR4. Its *Assessments of Impacts and Adaptations to Climate Change* (AIACC) in Multiple Regions and Sectors project supplied thirty contributing authors and more than a hundred citations of AIACC publications were cited in the last IPCC reports.

One of the fixtures of all the four IPCC assessment reports has been the consistent method through which climate model experiments have been carried out. The central approach here is the use of a series of scenarios of plausible future emission and climate change levels. As illustrated in the upper panel of figure 74.5 (taken from Hibbard/Meehl/Cox/Friedlingstein 2007), the traditional process starts with a number of storylines for socio-economic development, from which various emissions patterns are estimated. These emissions are then fed into climate models, and future concentrations of greenhouse gases, and climate parameters like surface temperature, precipitation are calculated. Two drawbacks with this approach are 1) uncertainties increase in each step of the process, and 2) it does not lend itself to comprehensive connections between research communities looking at *integrated assessment modelling* (IAM), *climate modelling* (CM), and *impacts, adaptation, and vulnerability* (IAV). This method has served its purpose very well through the first four reports, but along the way the climate research community realized that perhaps a different approach may help address some of the drawbacks. [5]

Through a series of meetings, the climate research community came up with a suggestion for an entirely new approach to scenarios. This approach, illustrated in the lower panel of figure 74.5, effectively starts in the middle. The process initially assumes a number of 'reference concentration pathways' for greenhouse gases. The process would then go in two directions simultaneously. One direction would be to calculate the changes in climate parameters and their impacts, which would arise given these concentration pathways. The other direction would be to calculate the emissions necessary to produce the given concentration pathway, and the socio-economic development and choices that are consistent with these emissions profiles. By starting in the middle, uncertainties are propagated through fewer sequential steps, An additional advantage is that this process also better connects the various research communities earlier on in the process and at a deeper level than the traditional method.

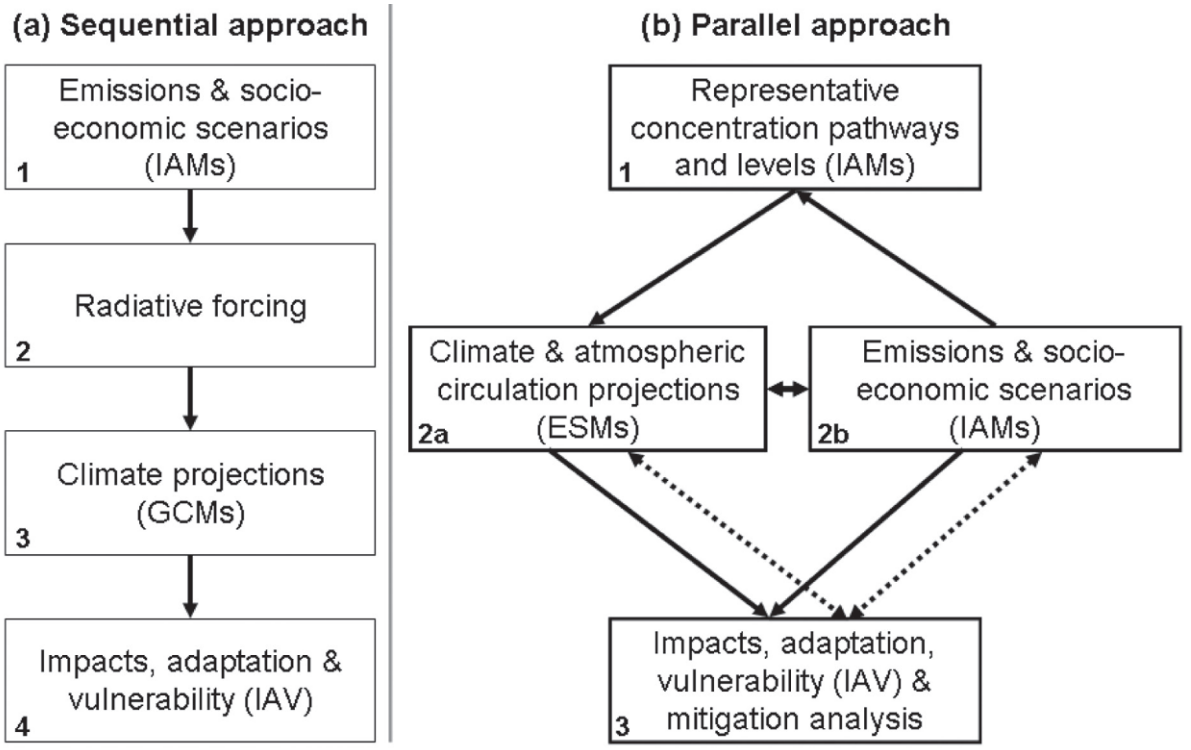
This new scenarios approach was proposed to the 28th IPCC's plenary meeting in Budapest, Hungary in April 2008 (IPCC-XXVIII/Doc.8, 19.III.2008). The suggestion was subsequently adopted by the IPCC. This is an excellent example of how the research community (particularly IGBP-AIMES and WCRP Working Group on Coupled Modelling (WGCM)) have a direct and collaborative influence on the IPCC process. This was also clearly expressed by Solomon and Manning (2008):

> The IPCC does not plan or carry out research, and this separation between research and assessment is essential if the IPCC is to be an objective assessor. The mandate of the IPCC is to evaluate information that must be independently documented, primarily as peer-reviewed literature. The planning and coordination of international research are best carried out by organizations such as the World Climate Research Programme, the International Geosphere-Biosphere Programme, and the International Human Dimensions Programme on global environmental change. These bodies often consider IPCC assessments and help provide the means for the scientific community to produce related research.

Overall, there is an excellent relationship and good communication between IPCC and the GEC programmes and ESSP. WCRP and IGBP, for example, held a workshop in Sydney in October 2007 to define the future research and observation agenda by learning from IPCC's AR4 (GCOS/WCRP/IGBP 2008). The workshop was jointly organized by WCRP, IGBP, the *Global Climate Observing System* (GCOS) and IPCC. The ESSP was also represented. The workshop aimed especially to bridge the climate research community and the climate modelling, and the impacts, adaptation, and vulnerability communities. A new framework was developed to accomplish this (figure 74.6). The observation and research requirements that lead to better climate change risk analyses and adaptation measures, and that result in lower vulnerability and impacts to a changing climate must be identified and the research to address them must be developed. This will lead to clear priorities for new observations and research expected to be needed in support of future IPCC assessments. Furthermore, the ESSP and IPCC are planning a joint workshop on critical gaps and knowledge needed from the social and economic

5 See Hibbard/Meehl/Cox/Friedlingstein 2007; Moss/Babiker/Brinkman/Calvo/Carter/Edmonds/Elgizouli/Emori/Erda/Hibbard/Jones/Kainuma/Kelleher/Lamarque/Manning/Matthews/Meehl/Meyer/Mitchell/Nakicenovic/O'Neill/Pichs/Riahi/Rose/Runci/Stouffer/van Vuuren/Weyant/Wilbanks/van Ypersele/Zurek 2007).

Figure 74.5: Approaches to the development of global scenarios: (a) traditional sequential approach; and (b) proposed parallel approach. Numbers indicate analytical steps (2a and 2b proceed concurrently). Solid arrows indicate transfers of information. Dotted arrows indicate integration of information (IAM: *integrated assessment model*; GCM *general circulation model*; ESM *Earth system model*; IAV *Impact, adaptation and vulnerability assessment*). **Source:** Moss/Babiker/Brinkman/Calvo/ Carter/Edmonds/Elgizouli/Emori/Erda/ Hibbard/Jones/Kainuma/Kelleher/Lamarque/Manning/Matthews/Meehl/Meyer/Mitchell/Nakicenovic/ O'Neill/Pichs/Riahi/Rose/Runci/Stouffer/van Vuuren/Weyant/Wilbanks/van Ypersele/Zurek 2007).



sciences to take place in January 2009, with support from The Netherlands. This workshop further integrated adaptation and vulnerability research into the broader climate change research agenda.

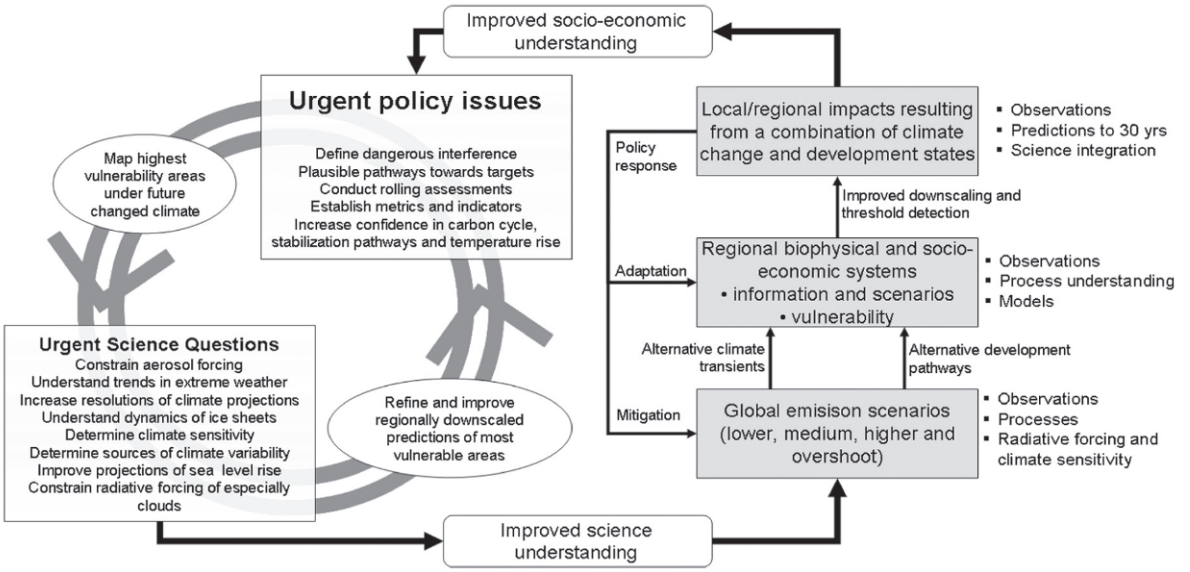
While there is an excellent relationship with IPCC, ESSP's organization is such that its contribution is not always recognized. The WCRP Working WGCM, for example, organized the provision of essentially all of the modelling results that are central to IPCC's Working Group I and Working Group II reports but these results are persistently referred to as IPCC results despite their official name of WCRP-CMIP3. ESSP thus needs to continue taking responsibility for tracking and heralding contributions from its programmes and projects to these policy relevant assessments.

Another example of ESSP interaction is the 2007 conference on *Integrating Analysis of Regional Climate Change Response Options*, in Nadi, Fiji, which was co-sponsored by IPCC, START and the Pacific Center for Environment and Sustainable Development. This conference explored innovative research approaches for addressing multi-scale and multidisciplinary challenges associated with climate change impacts, adaptation, vulnerability and mitigation. Participants included scientists active in ESSP, including a keynote presentation from the ESSP joint project on GEC and Food Systems.

74.3.5.2 Millennium Ecosystem Assessment

Many of the scientists involved in DIVERSITAS have been also contributing to the work of the *Millennium Ecosystem Assessment* (MA 2005; Leemans 2009b). For example, DIVERSITAS' Global Mountain Biodiversity Assessment was charged with drafting the mountain chapter of the MA. The structure adopted for the new DIVERSITAS in 2002 matches the framework of the MA. One of the most brilliant conceptual innovations brought about by the MA was the idea of ecosystem services. Again, this concept allowed for broader engagement of scientists from various disciplines in the natural and social sciences, economists

Figure 74.6: New framework for interactive and transdisciplinary research designed to deliver on societal demands for climate change. **Source:** GCOS/WCRP/IGBP (2008).



and the humanities. Talks have been launched recently to look into the possibility of a new incarnation of the MA, which would then hopefully have the potential to make the array of scientific input even broader, and hence pose a huge opportunity for ESSP to engage strategically.

74.3.5.3 The UN Framework Convention on Climate Change (UNFCCC)

The ESSP and its parent programmes have participated in recent informal discussion sessions of UNFCCC's *Subsidiary Body for Scientific and Technological Advice* (SBSTA) on how to improve communication between the Parties and the Research Programmes. These meetings have proved to be a great success and invaluable with presentations on emerging science and enhanced dialogue between the research community and the Parties. The ESSP regional inter-governmental research partners, the *Asia-Pacific Network for Global Change Research* (APN) and the *Inter-American Institute for Global Change Research* (IAI) have been involved in these SBSTA sessions, as has the IPCC. The ESSP and its parent programmes have also convened in-session workshops at UNFCCC-SBSTA on, for example, climate modelling, scenarios, downscaling, and on vulnerability, adaptation and resilience. The workshops provide the cutting-edge science for informed decisions.

WCRP and START have also responded to various calls for submissions arising from the *Nairobi Work Programme* on *Impacts, Vulnerability and Adaptation to Climate Change*. IHDP as well has embarked on talks with the UNFCCC Secretariat regarding the *Nairobi Work Programme* and the IHDP was well represented at the Conference of Parties in Bali (December 2007).

74.3.5.4 UN Convention on Biological Diversity (CBD)

DIVERSITAS signed a Memorandum of Understanding with the CBD in 1997. The Secretary General of the CBD Secretariat is represented on DIVERSITAS' Scientific Committee. Over the years, DIVERSITAS has been called upon by the CBD and its *Subsidiary Body on Scientific, Technical and Technological Advice* (SBSTTA) on a number of occasions to provide scientific advice. This included expertise on the *Global Taxonomy Initiative*, Assessment of knowledge on key species groups, Invasive Alien Species, Mountain biodiversity, and the valuation of ecosystem services (on-going). DIVERSITAS has regularly held side events at SBSTTAs or CoPs on various topics including invasive species, mountain biodiversity and the *International Mechanism of Scientific Expertise on Biodiversity* (IMoSEB).

At CoP9 (Bonn, May 2008), DIVERSITAS with the *International Union of Biological Sciences* (IUBS) sponsored a pre-CoP scientific biodiversity summit. This is a formal part of the CBD-CoP process and a scientific statement was communicated to delegates. The first of such events successfully took place at

CoP8 in Curitiba, Brazil in 2006. IHDP also held side events during CoP9 focusing on human and societal dimensions of biodiversity.

74.3.5.5 UN Convention to Combat Desertification (UNCCD)

A new scientific assessment on climate change and desertification is urgently needed. The results of a recent WCRP-sponsored workshop on "*Climate Change and Desertification: monitoring, modelling and forecasting*"[6] in 2007 and an earlier IGBP/IHDP sponsored Dahlem Workshop on *Integrated assessment of desertification* (Stafford Smith/Reynolds 2002), demonstrated that scientific knowledge about desertification and climate change is scattered in the literature of many disciplines and that there is an urgent need to establish a policy-relevant scientific assessment (Vlek 2005). The results of these meetings also highlighted that the processes and implications of desertification are of great and widespread concern, as well as affecting particularly the poorer segments of the global population.

The most recent IPCC and MA projections indicate that dryland areas may be expanding. Although research related to desertification is on-going, recent results have underscored a number of challenges to policy and a lack of a consolidated intellectual understanding of the underlying causes and effects (Hein/De Ridder 2006, Reynolds/Stafford-Smith/Lambin/Turner/Mortimore/Batterbury/Downing/Dowlatabadi/Fernandez/Herrick/Huber-Sannwald/Jiang/Leemans/Lynam/Maestre/Ayarza/Walker 2007). The development of a special assessment report and a better integration between climate change and desertification research results would establish synergy and provide a unique opportunity to examine future impacts of climate change and assess the consequences for the livelihoods of people in arid regions. The rate of climate change projected by IPCC echoes the rate of environmental change in the Sahel experienced in the past three or four decades, providing a test case of how humans have had to respond and adapt. Adaptation has already occurred to some extent in the Sahel, while massive dislocations and adjustments have taken place in central Asia after the collapse of the Soviet Union and associated institutions. Areas facing the future risk of reduced precipitation, and drylands in particular, host numerous inhabitants, who may not have been severely affected yet, and thus may not have built the necessary expertise or conducted sufficient preparatory actions. These examples provide opportunities to examine, inter alia, the relationship between science and policy under projected climate change. Exactly how this relationship can be strengthened is less clear but the ESSP clearly links research and scientific progress with both the assessment and policy communities and other users (figure 74.3).

The WCRP workshop in September 2007 also highlighted the relationships between climate change and desertification processes, which include many feedbacks at different scales. To understand these complex relationships, both global, regional and local assessments and accessible data sets are needed. It is particularly urgent to consider vulnerability as well as food and environmental security. Tackling desertification by means of ecosystem restoration and sustainable land management can positively influence micro and meso-climates, as well as the land surface energy and moisture budgets at landscape levels. Last but not least, sustainable land management and ecosystem restoration can and is being used to sequestrate additional carbon.

The 2007 workshop participants strongly supported a recommendation for IPCC to issue a *Special Report on Climate Change and Desertification*. Additionally, IHDP has also engaged in an ongoing dialogue with the UNCCD Secretariat and will come up with a joint work programme, which results from strong UNCCD interests for interdisciplinary input from the social and economic sciences.

74.3.5.6 Meeting the UN's Millennium Development Goals

The UN *Millennium Development Goals* (MDGs) are an inspiring and formidable challenge for society (UNDP 2003b). Within a decade we must aim to eradicate extreme poverty and hunger; achieve universal primary education; promote gender equality and empower women; reduce child mortality; improve maternal health; combat deadly diseases; ensure environmental sustainability; and construct a global partnership for development. At the same time, society is faced with other challenges such as global climate change, air pollution, declines in global biodiversity, changes in food resources and the ways in which all of these issues tie into global security.

Some have argued that it is not feasible to address all of these issues at once, and that we should simply use some sort of cost-benefit analysis to choose one or two on which to concentrate. This view may be

6 See at: <www.unige.ch/climate/Workshops/wengen07.html>.

appealing, but it is fundamentally misguided. It would be a tragedy if, for instance, we were able to completely eradicate HIV/AIDS only to discover that by ignoring *global environmental change* (GEC) issues, malaria had become even more widespread or fresh water resources even scarcer. We do not have the luxury of solving these problems one at a time; they need to be tackled together (Wall/Rabbinge/Galopin/Khoday/Lewis/Lubchenco/Melillo/Schmidt-Traub/Sombilla/Cimarrusti 2005). Understanding the coupled human-environmental system – how the natural Earth System works, and how we humans influence (and are influenced by) it – is at the very heart of addressing these issues, and achieving the MDGs.

74.4 Concluding Remarks

Achieving the MDGs strongly resonates with the recent international review of the ESSP, which stated that the Amsterdam Declaration, which launched the ESSP "is even more valid today than seven years ago. There is a clear need for an internationally coordinated and holistic approach to Earth System science that integrates natural and social sciences from regional to the global scale. In principle, the ESSP should be able to assume this role" (Fresco/Brito/Bremauntz/Gruber/Hydén/Reid/Rockström/Williams/Schellnhuber/Conway 2008: 7). The ESSP is now rapidly evolving into an alliance to initialize and catalyze highly integrative studies of the Earth System including its human dimensions, to enhance capacity building and to facilitate dialogue between science and society. ESSP, therefore, aims to integrate and communicate high quality Earth System Science for the benefit of society, including providing the necessary guidance towards sustainable futures.

The ESSP plans to address emerging science challenges (e.g. international trade in the Earth System; globalized land use competition; global environmental change and development; and the dynamics of sustainability transitions, transformations and thresholds) in concert with ESSP fora to further articulate the societal environmental challenges by involving top-level stakeholders, by advising on research and policy agendas, and by evaluating and communicating the consequences of recent findings. This interactive process must make the GEC research timelier and more relevant to society. It will involve stakeholder engagement early on and during the entire process. This should enable an open and continuous dialogue, mutual learning and the delivery of information in a timely manner. All this in an internationally coupled network in which renowned and young scientists can contribute independent of location, culture or institutional background.

The evolving dynamic agenda and high quality, integrative science of the ESSP and its parent programmes places us on the front line working with the research and policy communities and society at large. We still need, however, to enhance this effort and instil a greater sense of urgency. Coping with global environmental change is an enormous challenge, and one that the world must face up to now.

Since its establishment in 2001, ESSP has made substantial progress. The ESSP has put into place a structure that enabled joint research projects on global environmental change and the carbon cycle, food systems, water systems and (more recently) human health. All these joint projects aim to bridge the global, regional and local levels. These activities actually are the first elements of a system of global environmental science and construct the essential knowledge base needed to respond effectively and quickly to the great challenge of global change. More importantly perhaps even than these successes is the fact that ESSP and its Joint Projects offer a genuine home base for the new type of interdisciplinary (and transdisciplinary) researcher, who is so urgently needed to tackle today's global change and sustainability challenges (e.g. Schmidt/Moyer 2008).

In the short time that they have been in operation, the *Global Carbon Project* (GCP), *Global Water System Project* (GWSP) and *Global Environmental Change and Food Systems* (GECAFS) have each in their own way and with their own different methodologies and approaches gone about building the scientific infrastructure that allows us to take a more integrated approach to global environmental change science. The annual updates on the global carbon budget (Canadell/Le Quere/Raupach/Field/Buitenhuis/Ciais/Conway/Gillett/Houghton/Marland 2007), for example, have received a large media attention. We now also have established the new *Global Environmental Change and Human Health* (GECHH) project that will tackle global environmental change from again a different perspective. Capacity building is integrated throughout the ESSP, most notably through START, but also to differing degrees in all Joint Projects and MAIRS.

The ESSP and its parent GEC programmes (DIVERSITAS, IGBP, IHDP and WCRP) have also contributed greatly to the international scientific assessments and have provided policy relevant information to numerous UN conventions, governments,

NGOs and the private sector. These interactions have further emphasized the need for a well coordinated international GEC research effort, which helps to shape adequate policy strategies on climate change, biodiversity, desertification and sustainability. In essence, this sums up one of most important added values of ESSP.

75 The International Human Dimensions Programme on Global Environmental Change – Taking Stock and Moving Forward

Louise von Falkenhayn, Andreas Rechkemmer and Oran R. Young

75.1 Introduction[1]

Human actions dominate the Earth's great biophysical and geochemical cycles and consequently lie at the very heart of every effort to come to terms with the phenomenology of global environmental change. Research on the so-called human dimensions of global change concerns human activities that alter the Earth's natural environment, the sources or causes of those activities, the consequences of *global environmental change* (GEC) for societies and economies, and the responses of humans to the experience or expectation of global change. Human interferences with the Earth's system are so significant that the recent era has been suitably named the 'Anthropocene'. Human activity continues to intensify sharply and increases pressures on the Earth's resources and, for instance, on the planet's capability to assimilate/absorb wastes (e.g. Crutzen 2002). Thus, climate change is the most prominent, but only one of the various changes that humanity presently faces and which threaten social welfare. Global environmental change also encompasses changes in terrestrial and aquatic ecosystems, and its full extent and complexity is only now being realized. Global environmental change research in recent years has increasingly recognized the importance of humans as the central elements of the Earth System and its cycles. This has given rise to the concept of socio-ecological systems, a frame of reference that serves as a model for all human dimensions research.

Global Environmental Change, a phenomenon that is occurring at an ever increasing rate, encompasses the set of biophysical transformations of land, oceans and atmosphere, driven both by human activities and natural processes. These transformations take place at the local, regional and global scale, and affect the quality of human well-being, social and economic welfare, and sustainable development worldwide. Advanced research on the human dimensions of global environmental change puts people, their actions and responses – both at the individual as well as the societal or aggregate level – into the very centre of the analysis of environmental changes. It also takes into account that global environmental change is driven by and influences processes of socio-economic, political, and cultural globalization. Whether we are interested in reducing *greenhouse gas emissions* (GHG), sequestering carbon dioxide already in the Earth's atmosphere, or adapting to the impacts of climate change, it is important if not critical to find ways and means to influence the actions of humans from the lifestyle and behaviour of individual energy consumers to collective choices about GHG emissions control policies. The same goes for issues of land degradation and the destruction of habitat and ecosystems vital to endangered species as well as the depletion of marine life arising from overfishing and the spread of dead zones in the oceans. More often than not, we know what human actions or combinations of actions are implicated in these large-scale environmental problems. Research on the human causes of global environmental change has shown that human activities, such as deforestation, urbanization or energy consumption, are determined by factors such as population growth, economic and technological development, cultural forces, values and beliefs, institutions and policies, and interactions among them. When examining the human dimensions of environmental change, the study of ecosystem services illustrates the strong interlinkages existing between both socio-ecological sys-

tems and global change. Ecosystem services are inextricably linked to human well-being and play a central role in sustainable adaptation strategies. Environmental impact of global change can both add to social vulnerability and change resilience by altering the supply of ecosystem services and the trade-offs that can occur. It is when examining such phenomena that the importance and abilities of governance systems to shape change and responses are seen.

Growing knowledge and rising awareness of the critical importance of humans and their societies both in causing and in addressing environmental changes have led scientists, governments, and international organizations to become increasingly interested in understanding the role of human interaction with the natural environment, and in implementing policies designed to promote sustainable interaction between human societies and their environmental resources. One of the most pressing challenges is the need to establish the scientific foundations for sustainable livelihoods. Scientists worldwide are studying the causes and consequences of such changes, as well as the possible responses. Natural, life, and environmental sciences constantly add to our understanding of the dynamics of environmental change processes. However, traditionally, research on these processes has focused mainly on the biophysical elements, which are just one part of these complex and dynamic systems. Research was previously widely based on the assumption that anthropogenic actions are basically of little influence on the workings of these systems or represent only sporadic disturbances that can be discounted for purposes of analysis. To better understand and to respond more effectively to the manifold challenges of global environmental change major inputs from the social and behavioural sciences are required to provide crucial insights into the human and social dynamics of global environmental change. It is only when the social element is linked with the environmental elements that ecosystem change and successful implementation of coping strategies can be achieved. Hence, understanding these global environmental changes requires coordinated contributions from natural scientists (e.g. ecologists, climatologists and oceanographers) and social scientists (e.g. economists, anthropologists, political scientists and sociologists). This stream of research requires an interdisciplinary approach together with combined inputs from scholars in developed and developing countries, focusing on local, regional, and global scales.

Towards this end human dimensions research plays an important role in both co-producing with the natural sciences in order to achieve a deeper understanding of the very nature of the global change challenge and in informing responsible and sustainable policy and practice making at all levels. In this connection, the scientific community has organized itself to study these complex issues and provide science-based solutions using interdisciplinary and global research networks. This is the rationale for the establishment of the *International Human Dimensions Programme on Global Environmental Change* (IHDP). The programme's overall goal is to provide leadership in framing, developing, coordinating, and integrating social science research on global change and promoting the application of key findings to help address environmental challenges.

75.2 IHDP's First Decade: Establishing the Programme

IHDP, in its current form, was established in 1996. But its origins date back to 1990 when the *International Social Science Council* (ISSC) created the *Human Dimension of Global Environmental Change Programme* (HDP) as the social science counterpart to other Global Change Programmes that were at the time focused on the natural sciences. At the time, the sciences were changing rapidly, the effects of global change were becoming more and more visible, and there was a growing realization that human actions both contributed to the generation of and were impacted by these changes. In 1996, the *International Council for Science* (ICSU) joined ISSC as a co-sponsor, and the name of the programme was changed to the *International Human Dimensions Programme on Global Environmental Change* (IHDP). The Secretariat was relocated from Geneva to Bonn with a major infusion of funding from the German government.

During this first phase, which ended in 2006, IHDP contributed significantly to the mobilization of both researchers and resources at a time when few scholars and even fewer national and international policy-makers were making an explicit link between societal relations and major changes in the global environment. The decade 1996 to 2006 was dedicated to the establishment and the branding of human dimensions research as a distinctive entity through the development of a number of core scientific projects addressing global environmental changes from a

social science perspective. The first of four initial core projects was the *Land-Use and Land-Cover Change* (LUCC) Project, co-sponsored with the *International Geosphere Biosphere Programme* (IGBP). In addition to LUCC, IHDP established projects on the *Institutional Dimensions of Global Environmental Change* (IDGEC), *Global Environmental Change and Human Security* (GECHS), and *Industrial Transformation* (IT). With project life cycles of approximately 10 years, each project made important contributions to our understanding of global environmental change, to the formulation of economically, socially, and culturally feasible adaptation and mitigation strategies, and to the pursuit of global sustainability.

75.2.1 Land-Use and Land-Cover Change (LUCC)

The *Land-Use and Land-Cover Change* (LUCC) Project completed its research activities in October 2005. It produced a synthesis volume (Lambin/Geist 2006) and a large number of other publications dealing with global change themes ranging from desertification and drought to land-use changes in the tropics. LUCC developed statistical methods for analysis of patterns of land use, inventoried mapping activities of major crops, developed a form of meta-analysis to compare the results of many existing case studies, and organized the development of a number of new case studies on critical zones in the world. LUCC established a worldwide community and network of leading scholars interested in issues of land use and cover change.[2]

75.2.2 Institutional Dimensions of Global Environmental Change (IDGEC)

Focusing on the roles that institutions play both in causing and addressing large-scale environmental problems, IDGEC was launched in 1998 and completed its work with a major synthesis conference in December 2006. This was followed by the publication of a synthesis volume on the scientific legacy of the project (Young/King/Schroeder 2008). IDGEC brought the intellectual capital of the 'new institutionalism' to bear on environmental issues and contributed to our general understanding of the causal role of institutions and the prospects for institutional design. A particular focus of the project was an emphasis on the analytical themes of fit, interplay, and scale involving the match between institutions and ecosystems, interactions among institutions, and the generalizability of findings about institutions across levels of social organization.[3]

75.2.3 Global Environmental Change and Human Security (GECHS)

GECHS has sought to place environmental changes within larger socio-economic and political contexts by examining how these shifts shape the capacity of communities to cope with and respond to change. The GECHS research agenda focuses on the way diverse social processes such as globalization, poverty, disease, and conflict combine with global environmental change to affect human security (GECHS 1999). Broadly defined by the United Nations as 'freedom from fear' and 'freedom from want' (UNDP 1994), human security encompasses many elements of human well-being. GECHS addresses the literature on environmental security but seeks to broaden its focus to understand the interactive character of the range of elements encompassed in the concept of human security. GECHS organized a synthesis conference in June 2009.[4]

75.2.4 Industrial Transformation (IT)

Launched in 1999, the IT core project tackles the challenging task of improving the understanding of the

2 See for a documentation of its major activities at: < http://www.ihdp.uni-bonn.de/html/projects/i-lucc.html> and at: <http://www.igbp.net/page.php?pid=250> and for its publication at: < http://www.ihdp.uni-bonn.de/html/publications/reports/report10/luccisindex.htm>. The LUCC International Project office was first hosted by the Clark University, USA from 1994 to 1996, by the Institute Cartografic de Catalunya (ICC) in Barcelona, Spain (1997–1999), and finally by the Université Catholique de Louvain, Belgium (2000–2005) with generous support from the Belgian Federal Science Policy Office.

3 See for a documentation of its major activities at: < http://www2.bren.ucsb.edu/~idgec/>; ifs publications at: <http://www2.bren.ucsb.edu/~idgec/publications/newpub.html> and for the presentations at its synthesis conference are at: <http://www2.bren.ucsb.edu/~idgec/abstracts.php>. An IDGEC International Project Office (IPO) was established in 1999 at Dartmouth College with funding provided by the US National Science Foundation. The IPO was later located at UCSB and played a critical role with the identification of issues ripe for systematic analysis and continuing through to the presentation and publication of findings.

ways in which societies can combine economic and social development to reduce pressures on the environment and facilitate transformation of the industrial system towards sustainability. Its particular emphasis is on processes of macro-economic change that determine the impacts of human activities of large-scale biophysical systems. Having gone through a phase of community building, IT has begun in recent years to focus its work on the way transformations to sustainability unfold and how ongoing changes can be influenced so that they lead to sustainable development. IT is expected to go through a synthesis process in 2010.[5]

Towards the end of the first decade, IHDP added a number of new projects to the original four core projects. These included the project on *Urbanization and Global Environmental Change* (UGEC) and, in collaboration with IGBP, two joint projects, the *new Land Ocean Interactions in the Coastal Zone Project* (LOICZ) and the *Global Land Project* (GLP).

75.2.5 Urbanization and Global Environmental Change (UGEC)

UGEC seeks to provide a better understanding of the bidirectional interactions and feedbacks between global environmental change and urbanization at the local, regional, and global scales through an innovative conceptual and methodological framework. To capture the benefits of urbanization and mitigate and adapt to negative environmental and socio-economic impacts, a stronger collaboration between academics, policy-makers and practitioners is encouraged by the project. As urbanization represents a topic of special policy relevance today, the UGEC core project provides an unrivalled opportunity to address critical issues of worldwide importance that have so far not received adequate attention.[6]

75.2.6 Land Ocean Interactions in the Coastal Zone Project (LOICZ)

Based on the outcomes of its first ten years of activity, the 'new' LOICZ project (which became a joint core IHDP project in 2004), features an expansion of its predecessor to analyse the world's coastal zones as heterogeneous, relatively small but highly productive, dynamic and sensitive systems that provide a significant proportion of the life support systems for most human societies. The project aims to provide an integrated framework to address the primary issues of sustainable human use of coastal systems. Issues relating to the vulnerability of coasts and risks for human uses play a key role. An important underlying principle of LOICZ is the need to engage continuously in a science-policy-public dialogue addressing needs for scientific information in achieving sustainable development in the coastal zones.[7]

75.2.7 Global Land Project (GLP)

The *Global Land Project* (GLP) is a successor both to the jointly sponsored IGBP/IHDP core project LUCC and the IGBP core project on *Global Change and Terrestrial Ecosystems* (GCTE). GLP focuses on the interactions of people, biota, and natural resources of terrestrial and aquatic systems. The GLP Science Plan (2005) emphasizes the study of changes

4 See for a documentation of its major activities at: <http://www.gechs.org/> and for its publication at: <http://www. gechs.org/publications/> and a summary on the synthesis conference in June 2009 in Oslo is at: <http://www.gechs.org/downloads/GECHS_kompendie.pdf>. GECHS is overseen by a scientific steering committee <http://www.gechs.org/science-committee/>, enriched by the contributions of associates <http://www.gechs.org/associates/>, and coordinated from an international project office (IPO) located in the Department of Sociology and Human Geography at the University of Oslo that was supported financially by the Norwegian Research Council.

The LOICZ International Project Office is based at the Institute for Coastal Research at the GKSS-Research Center, Max-Planck- Str. 1, 21502 Geesthacht, Germany.

in the coupled human-environmental system at local to regional scales. Changes in coupled systems affect the rates of cycling of energy, water and biota at the global level, while global-level political and economic changes, such as international treaties and market liberalization, in turn affect decisions about resources at local and regional levels. The goal of GLP is to measure, model, and understand the coupled human-environmental system ('land system') as part of broader efforts to address changes in Earth processes and subsequent social, economic, and political consequences.[8]

75.2.8 Results of the Four Initial IHDP Core Projects

The four initial IHDP core projects made important contributions to understanding global environmental changes, to the formulation of economically, socially, and culturally feasible adaptation and mitigation strategies, and to the pursuit of global sustainability. During the first decade, IHDP made substantial progress in widening research networks and building capacity. The publication of the Science Plans for IDGEC, GECHS and IT, and the LUCC Implementation Strategy was one visible step, as were the various international conferences and meetings held during these years, including the 1999, 2001, 2003, 2005 and 2009 Open Meetings of the Human Dimensions of Global Change Research Community. The development of networks and capacity development activities, especially in the developing countries, led to the establishment of the *International Human Dimensions Workshops* (IHDW) as a biennial event, and the organization of the first Science-Policy Dialogue held in Berne, Switzerland in 2006.

Another important step occurred when IHDP joined the newly established *Earth System Science Partnership* (ESSP, chap. 74 by Leemans/Rice/Henderson-Sellers/Noone) in 2001, recognizing the close links between human dimensions and other areas of Earth System changes. This partnership includes the International Programme on Biodiversity (DIVERSITAS, chap. 76 by Walther/Larigauderie/Loreau), the *International Geosphere-Biosphere Programme* (IGBP, chap xy by Noone/Nobre/Seitzinger), and the *World Climate Research Programme* (WCRP, chap. 78 by Church/Asrar/Busalacchi/Arndt) as well as IHDP. ESSP works towards an integrated study of the Earth System, with particular attention to large-scale changes and the implications of these changes for global and regional sustainability. The ESSP addresses this concern through a number of distinct activities, such as the joint research projects on food, carbon, water, and health:

- *Global Environmental Change and Food Systems* (GECAFS);
- *Global Carbon Project* (GCP);
- *Global Water System Project* (GWSP);
- *Global Environmental Change and Human Health* (GECHH).

IHDP contributes to the joint projects on carbon, water, food and health, and actively facilitates the establishment of the *Monsoon Asia Integrated Regional Study* (MAIRS). IHDP also cooperates closely with START (*Global Change System for Analysis, Research and Training*), which is the capacity building and regional research component of ESSP.

75.3 The Second Decade: Innovative Science

In 2005–2006, IHDP underwent an external review organized by ICSU and IGFA (*International Group of Funding Agencies*). This review noted the programme's accomplishments but also offered a number of recommendations for strengthening the programme in the next phase. In response, the IHDP Scientific Committee (SC) embarked upon the development of a new IHDP Strategic Plan (2007) to guide the programme for the period from 2007 through to 2015. In addition to responding to the external review, the Strategic Plan identifies areas of innovative and cutting-edge science in the realm of human dimensions research. With the recognition of the importance of coupled systems or socio-ecological systems, IHDP moved into a new and important scientific phase. The experience of the initial core projects demonstrated the need to broaden views further and to ask even more holistic questions. At the beginning of 2007, the *United Nations University* (UNU) joined ICSU and ISSC as a third institutional sponsor for IHDP.

As we move deeper into the era of the Anthropocene (Crutzen 2002), there is a need to raise the profile of the social sciences concerning matters such

8 See for a documentation of its major activities at: <http://www.globallandproject.org/> and for its documents are at: <http://www.globallandproject.org/documents.shtml>, The GLP International Project Office is funded and hosted by the University of Copenhagen.

as climate adaptation and mitigation. A new brand of social science is needed, one that addresses the roots of human actions affecting the Earth System and explores possible applications of its findings to efforts to avoid the most serious impacts of developments like climate change and to facilitate adaptation to these impacts once they become unavoidable. There has been an increasing realization that human-environment interactions give rise to complex and dynamic socio-ecological systems in which anthropogenic and biophysical drivers play central roles and interact with one another. The current challenge is to understand the dynamics of these coupled socio-ecological systems well enough to anticipate large-scale changes and to take steps either to reduce their likelihood or to minimize their impact once they occur. IHDP plays a significant role in this effort, providing intellectual leadership and offering a means to facilitate research and interaction between scientists and policy-makers.

The IHDP Strategic Plan 2007–2015 (2007) developed four major propositions intended to provide general guidance for the work of researchers and policy-makers concerned with the human and societal dimensions of global environmental change:

1. Social science must take centre stage during the next round of efforts to understand and come to grips with global environmental changes;
2. Understanding the dynamics of socio-ecological systems must receive top priority;
3. A portfolio approach to the development of methods suitable for understanding global environmental changes is needed;
4. A rich dialogue between scientists and policy-makers or practitioners more generally at all stages in the process of framing and conducting research on large-scale environmental changes is beneficial.

Human societies define the boundaries and character of their environments, frame their environmental problems, and devise solutions to them, based on their perceptions of what constitutes the environment, what drives and constrains its dynamics, what creates environmental challenges, and what may be done to deal with them. The 'Human Dimensions Science's' approach is to place the society at the centre of the global environmental change debate, a perspective that frames current global problems as social and societal challenges. Research on the human dimensions of global environmental change poses a number of methodological challenges. Many associated concepts like ecosystem services, sustainable development or human security are difficult to measure, especially in a manner that permits comparisons across space and time. Another barrier is the interaction of numerous variables with one another to form causal clusters whose constituent elements are hard to separate. These new challenges have also contributed to the pronounced tendency in this recently established study field to engage in methodological innovation and trans-disciplinary cross-fertilization.

75.4 Scientific Agenda of IHDP

75.4.1 Mission and Structure

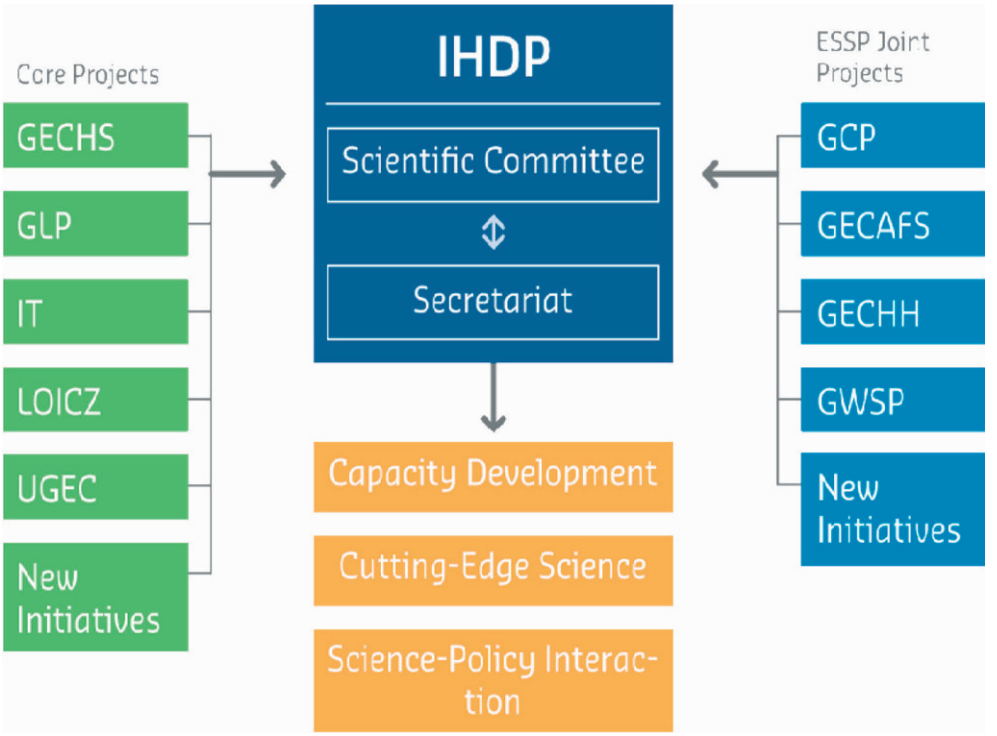
Following publication of its Strategic Plan 2007–2015 (2007), IHDP has implemented its mission through core projects, joint projects, and cross-cutting themes together with its three pillars of cutting-edge science, capacity development, and science-policy interaction. The programme's aim is to generate state-of-the-art scientific knowledge on coupled socio-ecological systems, achieve comprehensive understanding of global environmental change (GEC) processes and their consequences for sustainable development, and make scientific contributions to explore the impact of global environmental change on human welfare, the anthropogenic drivers of global environmental change and societal responses to mitigate and adapt to global environmental change. This output of knowledge should be relevant and produced in a way so that it can feed into scientific assessments and ultimately into the policy process at local, national, regional, and global levels.

The IHDP's mission is:

- To foster, coordinate, and conduct social science research that helps to understand and address the challenges of global environmental change and improve societal responses.
- To contribute to the interdisciplinary attempts to understand the interactions of humans with the natural environment that cause global environmental change.
- To strengthen the capacities of research and policy communities toward a shared understanding of the social issues and implications of global changes.
- To facilitate dialogue between science and policy.

To achieve these goals, IHDP has a number of strategies. New knowledge is created by framing the social science of global environmental change in conjunction with a variety of stakeholders; creating new con-

Figure 75.1: IHDP's programmatic structure. **Source:** IHDP.



ceptual frameworks and methods; bringing together people to create new research networks and collaborations. New generations of researchers are encouraged by: training scientists; networking; providing research and career opportunities. Knowledge and practice is linked by: providing for science-practitioner interactions and developing science digests for academia and policy-making. Communication is promoted by stimulating scientific outputs and publishing outputs targeted at broad and diverse audiences. Funding is mobilized by identifying and liaising with funding sources, and building partnerships with funders. With both a comprehensive vision and strategies in place, IHDP's vision is to provide international leadership in framing, developing, and integrating social science research on global change, and to promote the application of the key findings of this research to help address environmental challenges.

IHDP has developed an effective programmatic structure (figure 75.1) over the course of the last decade. This structure features a set of core projects operating as relatively autonomous activities, a number of joint projects managed on a collaborative basis with the other global change research programmes and the *Earth System Science Partnership*, and several cross-cutting themes of particular interest to the members of the IHDP scientific community. To support these efforts, the programme has added a growing engagement in capacity development. The pattern of project development is now well established. Individual core projects have a life cycle of approximately 10 years, ending with a synthesis process.

75.4.2 Current Synthesis Projects and New Core Research Themes

Two of IHDP's core projects, *Global Environmental Change and Human Security* (GECHS) and *Industrial Transformation* (IT) have reached their synthesis phase, a phase where the projects collate their results. GECHS has inspired a new area of research that, back in the late 1990's, was not well understood or structured. In bringing people into the centre of the security agenda, GECHS played a central role in identifying the social challenges of global change. Discussions about people's vulnerability, systems' resilience or adaptive capacity emerged from this process (Barnett/Matthew/O'Brien 2008). IT has strengthened our understanding of transition pathways, particularly towards industrial sustainability. With its recent focus on the developing countries of Asia, IT contributes to a debate that is regional in scope but of global importance (Wieczorek 2006). The development pathways

of Asia will shape the face of the world in the 21st century.

Responding to emerging human dimension themes a number of new projects were initiated in the last two years, for instance *Earth System Governance* (ESG) and *Integrated Risk Governance* (IRG).

Earth System Governance is a project that builds on the accomplishments of IDGEC but brings a number of new scientific elements to the analysis of efforts to guide or steer human-environment interactions. Central to the project is an emphasis on the role of non-state actors and the development of governance systems in which multinational corporations and elements of civil society play prominent roles. Priority themes for ESG include: architecture, agency, allocation, accountability, and adaptation (Biermann/Betsill/Gupta/Kanie/Lebel/Liverman/Schroeder/Siebenhüner 2009). ESG has made a prompt start to build cooperative efforts with other projects, including the ESSP joint projects, that will illuminate issues of governance in a number of substantive areas while, at the same time, producing insights about the nature of governance that are generic in character.

The IRG pilot project was initiated in response to the growing intensity and frequency of natural disasters in recent years. Societies face risks not only from extreme weather conditions, but also from negative effects on the normal operation of social infrastructure and the service capacity of the Earth's ecological system. International frameworks, governance bodies at all levels, and national governments have expressed strong interest in improved risk governance, such as reflected in the *United Nations International Strategy on Disaster Reduction* (UN/ISDR). The stress on governance in this initiative is meant to direct attention to a number of concerns, including policies designed to reduce the vulnerability of individuals and communities to the impacts of extreme events, decision-making processes relating to the establishment and deployment of response capabilities, and institutional arrangements (e.g. insurance schemes) capable of protecting individuals from the worst impacts of extreme events, while avoiding the problem of moral hazard.

75.4.3 Cross-cutting Themes

An important feature of IHDP's second decade is the development of four cross-cutting themes (figure 75.2) that address issues that arise in one form or another in all of IHDP's core and joint projects. The emergence of these themes reflects the desire of the IHDP Scientific Committee to engage in challenging scientific efforts crucial for the whole programme. Each cross-cutting theme is multi-dimensional and multi-scalar. Together, they offer an opportunity to link scientific knowledge to concrete practices designed to mitigate and adapt to the negative consequences of global environmental change. Four cross-cutting themes have emerged:

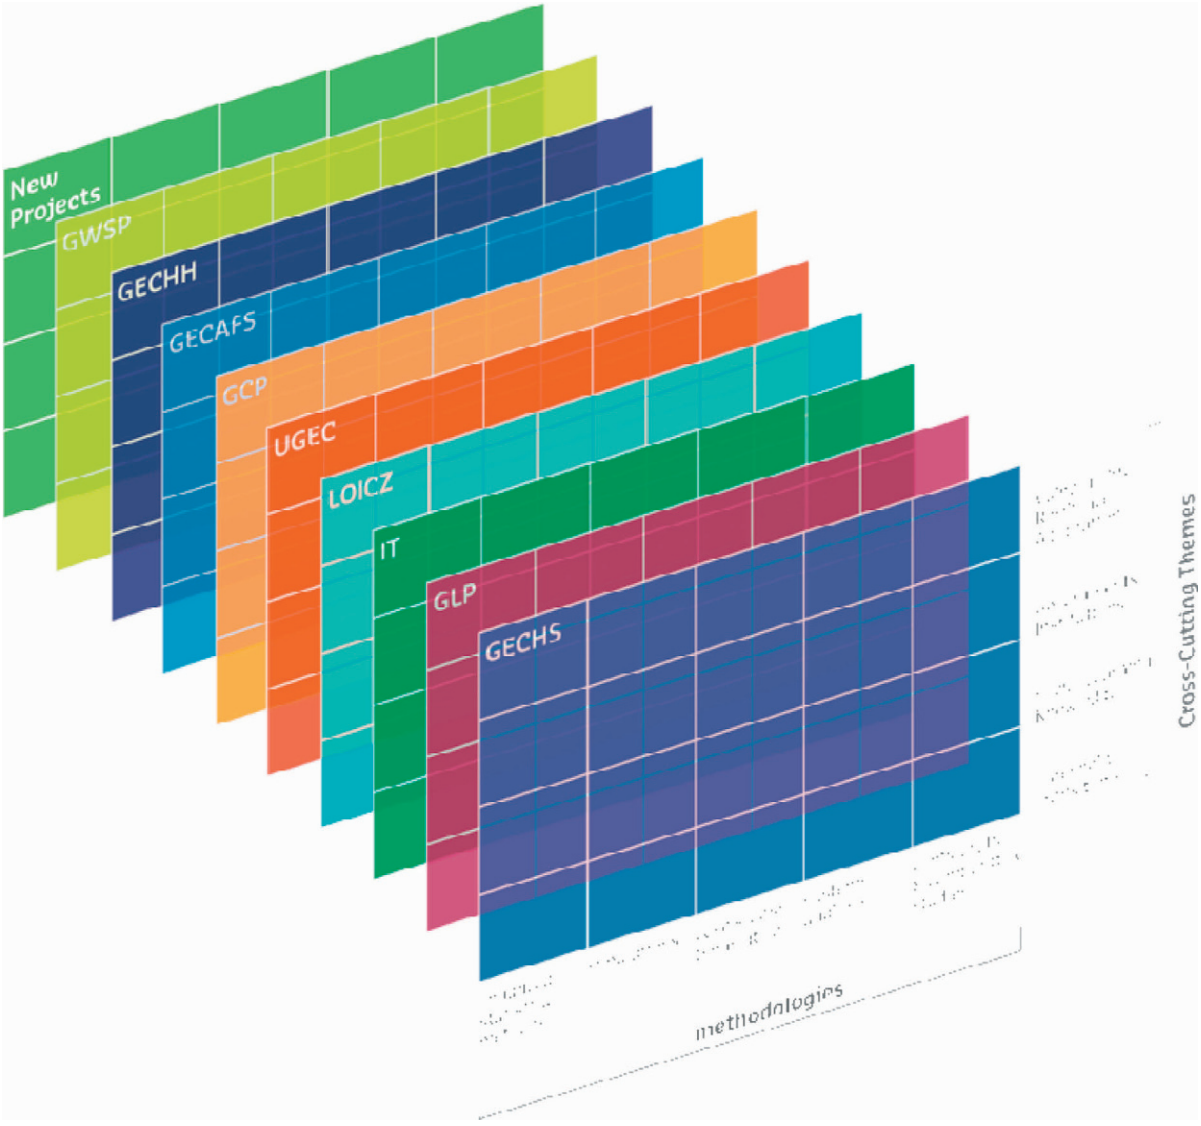
- *Vulnerability, Resilience and Adaptation* (VRA) (Janssen/Ostrom 2006). How can we build the capacity of socio-ecological systems to maintain resilience in the face of growing and often interacting stresses?
- *Thresholds and Transitions*: How can we recognize long-term trends in forcing functions and ensure orderly transitions when thresholds are passed?
- *Governments and Institutions*: How can we steer tightly coupled systems towards desired goals or away from undesired outcomes?
- *Knowledge, Learning and Societal change*: How can we stimulate social learning in the interest of managing the dynamics of tightly coupled systems?

75.4.4 The IHDP Cube

Integrating these elements of IHDP's work programme produces what has become known as the IHDP cube (figure 75.2). The Programme has a portfolio of core and joint project that are subject to analysis using a variety of methodologies as well as to comparative study on the part of those concerned with cross-cutting themes (e.g. resilience or thresholds). The goal is to strengthen the bonds linking members of the broader community of producers and consumers of knowledge who make up the IHDP family. Some members of this community will focus on particular core projects using a variety of methods; others will seek to use a particularly promising method to study issues relating to more than one core project; still others will use a number of methods in an effort to compare work carried out under the various core projects in the interests of gaining insights relating to one of the cross-cutting themes. The goal here is to transform the collection of people associated with IHDP into a close-knit community pursuing common concerns in contrast to a loosely related set of researchers who, for the most part, go their separate ways.

In figure 75.2 the three-dimensional framework of research on the human dimensions of global environ-

Figure 75.2: The IHDP Cube. **Source:** IHDP.



mental change is displayed, consisting of the predominant research areas, cross-cutting themes, and the main methodologies employed. The main research areas include human security, land-use and land-cover change, industrial transformation, governance and food systems. A key feature of the framework is the cross-cutting themes that are of essential importance and relevance for each of the research areas. Finally, the mentioned methodologies are often innovative as they must address trans-disciplinary challenges. For example, enhanced statistical methods or the ever growing field of simulation and modelling is one of the crucial factors that have helped lift global change science into a new realm of importance.

75.4.5 IHDP Cross-cutting Research Areas and Approaches

75.4.5.1 Ecosystem Change, Vulnerability, and Resilience

Climate change has been occurring naturally for millions of years and the Earth's biosphere has been exposed to large variability and extremes of CO_2 and climate. However, anthropogenic climate change has occurred over a much smaller time scale and has had a greater magnitude of change. Ecosystems are sensitive to climate change. For instance, significant biological changes, such as species extinctions, have accompanied large climatic perturbations of the past (Overpeck/Cole/Bartlein 2005). More recently, dis-

ruptions in precipitation regimes in the Pacific region, such as those in Australia during *El Niño/Southern Oscillation* (ENSO) events, can disrupt vegetation cover and composition through drought, heat stress, spread of parasites and disease (Diaz/Markgraf 1992). However, ecosystems are not only sensitive to climate change but also to anthropogenic changes such as land use, pollution and invasive species. While climate change has been estimated to be a major driver of biodiversity loss in tropical and cool conifer forests, and coral reefs[9], in other ecosystems land-use changes may be a stronger driver of biodiversity loss, especially in the short term (Fischlin/Midgley/Price/Leemans/Gopal/Turley/Rounsevell/Dube/Tarazona/Velichko 2007). Land-use change and related habitat loss and fragmentation have long been recognized as important drivers of past and present ecosystem change, particularly biodiversity loss (Heywood/Watson 1995). Additional, prevalent examples of drivers of ecosystem change are changes in fire regimes and exotic species. Fire influences community structure by favouring species which are fire tolerant and consequently change the biodiversity of a region. Introduction by humans of invasive exotic species represents a major threat to endemic or native biodiversity in both terrestrial and aquatic systems (Scavia/Field/Boesch/Buddemeier/Burkett/Cayan/Fogarty/Harwell/Howarth/Mason/Reed/Royer/Sallenger/Titus 2002). Overall, ongoing shifts in anthropogenic disturbances such as fire regimes are important in altering ecosystem structure, diversity, and function (Timoney 2003).

These environmental changes will of course then also affect the provision of an ecosystem service. Consequently, it is important to be aware of the synergistic effects of these multiple drivers, both natural and anthropogenic, climatic and non-climatic. This is difficult, however, due to non-linear, rapid, threshold type responses in ecological systems (Burkett/Wilcox/Stottlemyer/Barrow/Fagre/Baron/Price/Nielsen/Allen/Peterson/Ruggerone/Doyle 2005) and, despite the importance of multiple drivers of ecosystem change, they are rarely included in climate and ecosystem models used for assessing climate change impacts on ecosystems and their services (Hansen/Neilson/Dale/Flather/Iverson/Currie/Shafer/Cook/Bartlein 2001; Zebisch/Wechsung/Kenneweg 2004; Feddema/Oleson/Bonan/Mearns/Buja/Meehl/Washington 2005).

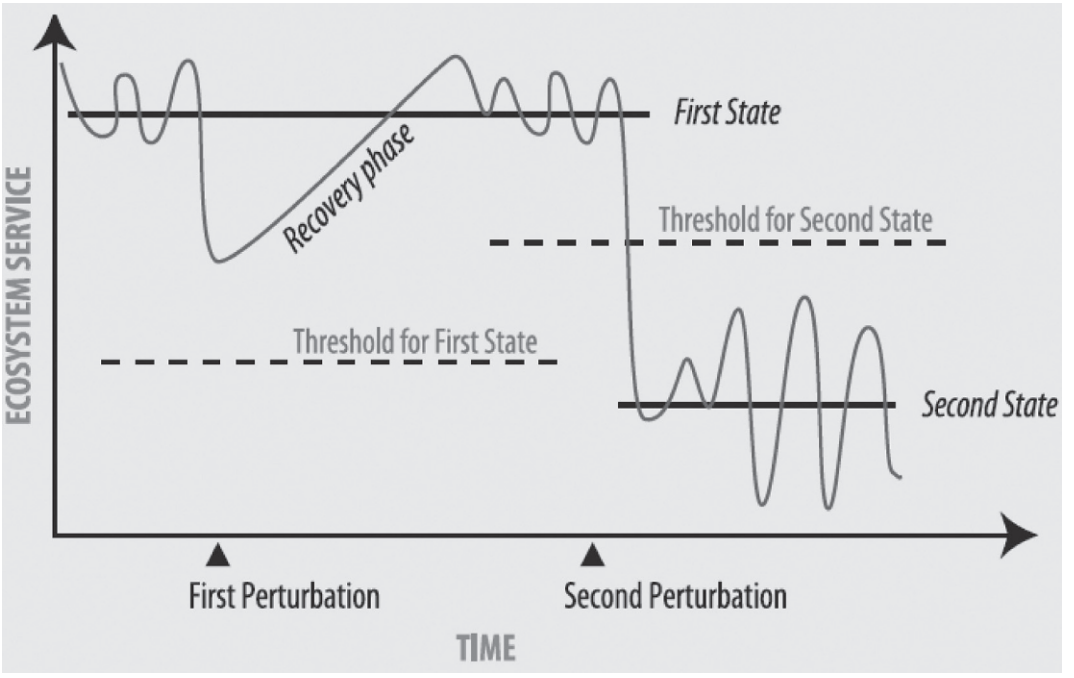
There are multiple drivers of ecosystem change which impact on the production, quantity, and quality of services. An ecosystem response to impacts depends not only on the increasing magnitude of the driver of change but also on the threshold of a system. Many ecosystems do not respond to changes in a linear fashion but rather thresholds are reached and surpassed, and rapid, non-linear changes follow. Ecosystems may have more than one state with a self-stabilizing mechanism, so that a shift between states does not occur frequently and is not readily reversible (Genkai-Kato 2007).

If thresholds in magnitude or rate of change are surpassed then transitions between ecosystem states may be triggered to a less desired state (Folke/Carpenter/Elmqvist/Gunderson/Holling/Walker 2002), or the ecosystem may even collapse to a much less productive and/or species poor assemblage with lower biomass and other impairments. Passing a threshold marks a sudden change in feedbacks in the ecosystem, which can bring about sudden, sharp and dramatic change in the responding state variables, for example, the shift from clear to turbid water in lake systems (Carpenter 2003). These large changes are termed regime shifts (illustrated in figure 75.3). Regime shifts are increasingly reported in natural environments (Scheffer/Carpenter/Foley/Folke/Walker 2001) and are large system changes that are beyond the normal range seen at the microscopic scale (e.g. stable points and limit cycles) (Genkai-Kato 2007).

Regime shifts are difficult to predict in part because there is a dearth of knowledge about capacities and vulnerabilities. The theoretical basis for regime shifts has been described by such researchers as Beisner, Haydon and Cuddington (2003), Carpenter (2003) and Scheffer, Carpenter, Foley, Folke and Walker (2001). Figure 75.3 illustrates the level of provisioning of an ecosystem service that has been perturbed twice. The dashed lines represent the two thresholds. The natural variation of an ecosystem service is represented during its initial state, before and after the first perturbation. It is evident that the ecosystem service is resilient to the first perturbation and recovers to a stable state. However, the service has become vulnerable to change and this is indicated by the lower threshold for the second state. The second perturbation causes the service to cross the second threshold, which leads to a regime shift and to an alternative stable state.

9 See Thomas, Cameron, Green, Bakkenes, Beaumont, Collingham, Erasmus, de Siqueira, Grainger, Hannah, Hughes, Huntley, van Jaarsveld, Midgley, Miles, Ortega, Peterson, Phillips and Williams (2004); Malcolm, Liu, Neilson, Hansen and Hannah (2006).

Figure 75.3: Dynamics and Stability in Ecosystem Services. **Source:** Millennium Ecosystem Assessment (2005).



Undesired shifts between ecosystem states are caused by a combination of the magnitudes of external forces and the internal resilience of the system. As resilience declines the ecosystem becomes more vulnerable, and progressively smaller external events can cause shifts. Resilience is the capacity of a system to absorb disturbance and reorganize while undergoing change so as to retain essentially the same function, structure, identity, and feedback (Walker/Holling/Carpenter/ Kinzig 2004). Alterations to ecosystems in many cases change the natural self-stabilizing mechanisms inherent in ecosystems such as those that resist daily and seasonal changes in temperature and light conditions (Genhai-Kato 2007), increasing ecosystems vulnerability. Consequently, regime shifts in ecosystems are increasingly common as a result of external forces such as human activities that erode resilience for example through the exploitation, pollution and land-use change, climate change impact, and altered disturbance regimes.

These impacts, which have increased in intensity since the industrial revolution, have reduced the capacity of ecosystems to cope with change. Triggers for regime shifts are often slow variables such as global warming and nutrient loading (Carpenter 2003) which originate from anthropogenic impacts as emissions of CO_2 and polluted water from industrial and agricultural activities. When these impacts exceed the internal resilience and threshold of a system, a regime shift may manifest itself in ecological surprises such as rapid and abrupt changes in temperature and precipitation, leading to an increase in extreme events such as floods and fires and the irreversible loss of ecosystem services which were dependant on the previous state (MA 2005). Although studies on regime shifts have just begun and there are many unknown issues to be addressed, such as the prediction of threshold points, there are many examples of regime shifts in ecosystems and their consequences for humans.

A continental scale example of an irreversible shift occurred in Australia where the over-hunting and use of fire by Aborigines approximately 30,000 to 40,000 year ago removed large marsupial herbivores. Without these animals to prevent fire and fragment vegetation, an ecosystem of fire and fire-dominant plants expanded and irreversibly changed the ecosystem from a state dependent on rapid nutrient cycling to a less productive state with slower cycling (Flannery 1994). This has consequently impacted the agricultural productivity of the land and the magnitude and quality of ecosystem services available to the present society. Society then becomes less resilient to change as it has less resources and variety of resources from which to draw from. At a local scale, for example, the initial pockets of deforestation in a large tropical forest may have little or no impact on the number of species of animals or birds. However, as the forest becomes more fragmented, the rate of species loss can increase

sharply (Noss 1996). As humans continue to impact the global environmental, regime shifts in ecosystems are not just ecological problems causing changes in ecosystems services, but they also become economic problems leading to changes in human well-being.

75.4.5.2 The Missing Links

How do ecosystem services interact and work together? What are the thresholds and resilience of an ecosystem and its services? How can governance facilitate sustainable management of ecosystem services, manage the effects of trade-offs between services, and consequently decrease their vulnerability? Each of these questions illustrates just a few of the current knowledge gaps when tackling the global problem of addressing and adapting to changes in ecosystems services. Effective response depends on knowledge of regional climate and ecological changes and their interactions with society.

Current ecosystem models can translate climate and land changes into changes in ecosystem service supply (Schröter 2005). However, ecosystem models need a transdisciplinary collaborative approach, for instance prediction models are needed which take into account climate change, ecosystems at all levels, and human impact such as poverty. However, this is not possible while we have an incomplete understanding of the socio-ecological system. Coupled with this, monitoring environmental change including climate and associated ecosystem responses is vital to allow for adjustments in management strategies.

Consequently, one of the first aims should be to raise social, political, and scientific awareness of the importance of ecosystems and the services they provide and the complexity which exists between them. The Millennium Assessment has done this to a good extent. But many more studies are needed to identify services, to understand how services interact and to quantify such things as the supply of services and thresholds. Additionally, the awareness of the importance of ecosystems and services should be promoted at all societal levels as human well-being is inextricably linked to ecosystem services. Scientific and political awareness alone is not enough, local awareness is just as important especially in developing countries where the local communities often alone manage the impact on ecosystems and especially their provisional services. For societies to adapt and respond to change, 'the public' needs to become more informed and engaged, and scientists and policy-makers must also take on the responsibility to learn from, understand, and respond to their community's knowledge, concerns, and needs, if research and policy are to lead towards sustainability. Consequently, it is important that both an increase in knowledge and awareness is coupled with a multidimensional and transdisciplinary approach to address issues of global environmental change.

Global environmental change is a global issue and affects all scales, local, regional, national and global. Thus, efforts to maintain and enhance resilience and adaptation to the long-term effects of change need to be addressed by all levels of governance. In situations in which uncertainties and change are key features of the ecological systems and social organization, critical factors for sustainability are resilience, the capacity to cope and adapt, and the conservation of sources of innovation and renewal (Lebel/Anderies/Cambell/Folke/Hatfield-Dodds/Hughes/Wilson 2006). Interventions in socio-ecological systems with the aim of altering resilience, whether it is an ecosystem service or a community, immediately confront issues of governance. Who decides what should be made resilient to what? For whom is resilience to be managed, and for what purpose? How do certain attributes of governance function in society to enhance the capacity to manage resilience?

The increased unpredictability and scale of current environmental changes are becoming more difficult to deal with, and new adaptations are required. Adaptation to environmental change, including climate change, involves a diverse range of environmental services, which enable people to sustain their livelihoods, to diversify their production strategies, and to incorporate adaptive management schemes into their domestic infrastructures. Ecosystem managers, whether political, local or indigenous, can proactively alter the context in which ecosystems develop (Fischlin/Midgley/Price/Leemans/Gopal/Turley/Rounsevell/Dube/Tarazona/Velichko 2007), thus improving resilience. This involves not only anticipatory adaptation options and responses but also resilience which is largely involved in the process of adaptation. Societies need to strengthen their capability for responding and adjusting to disturbance and uncertainty, while keeping their livelihoods flexible and open to change. Enhancing resilience involves many elements including innovation, knowledge and learning, diversity, adequate human-environment interactions and the capacity of self-organization, all of which can be governed.

75.5 Science-Policy Interaction

To improve both the conduct of research and the selection and implementation of policies to address global environmental change and to bridge the gap between scientists and practitioners, IHDP has made extensive use of the scientific community built through its projects and networks to enable and encourage interaction between science and policy. An open dialogue between the scientific and policy communities is necessary not only for the development of well-guided policies but also for the formation of pertinent research agendas. By extending IHDP's original mandate to disseminate knowledge, science-policy interaction has become a new strategic pillar of the IHDP. The programme acts as a matchmaker and dialogue facilitator, organizing a number of capacity development, communication, and outreach activities. IHDP is a network of networks capable of building bridges among scientists in different disciplines, different issue areas, and different national and regional settings. Bringing members of the scientific and policy communities together, Science-Policy Dialogue Workshops have been held annually starting in 2006. A second series, e.g. the Bonn Dialogues on Global Environmental Change, was started in 2007. These activities exemplify IHDP's effort to mainstream science-policy with a dialogue process targeting the public.

75.6 Capacity Development

Capacity development forms an important part of IHDP's work to strengthen and broaden the network of global environmental change researchers. IHDP's capacity development activities provide an avenue for encouraging new researchers and incorporating their research into the network. Key mechanisms include the *International Human Dimensions Workshops* (IHDW) started in 1998 and the Open Meetings of the Human Dimensions of Global Environmental Change Research Community initiated in 1995 to promote interdisciplinary collaboration on a global basis.

In its second decade, IHDP has redefined its capacity development approach and expanded its efforts in three ways:

- The traditional concept of capacity building has been supplanted by capacity development, indicating that IHDP will not only build new capacity but also strengthen and further develop existing capacity;
- IHDP's capacity development strategy not only targets individuals from developing countries and countries in transition but also includes scientists from developed countries who contribute to IHDP's goals;
- Although IHDP's investments in capacity development mainly target individual researchers, institutions backing individual scientists will also benefit as enhanced international visibility and career development of single researchers will ultimately support their home institutions.

75.7 Conclusions

This chapter illustrates both the importance of human dimensions research when addressing global environmental change and how this focus of research has changed over the past decade, with the incorporation of and emphasis on socio-ecological systems. Human decisions and actions have become a decisive influence on terrestrial, marine, and atmospheric systems at a global scale. Based on this, human responses to current global environmental change define future social and environmental conditions. Human-environment interactions and the socio-ecological systems to which they give rise are complex, marked by changes that are often non-linear, sometimes abrupt, and quite frequently irreversible. It is because human dimensions science is central to addressing global change issues, and their many associated complexities, that it is thriving and increasingly in demand.

Despite these efforts and advances in knowledge, global environmental change continues at an unprecedented rate, causing loss in ecosystem health for instance and threatening human security. While it is clear that the problems we face are largely social rather than purely biophysical, there remain a number of challenges for the human dimensions community in the decade ahead. Human dimensions research needs to become more translatable and thoroughly integrated into policy and human dimensions perspectives, and approaches need to be more relevant and effective in fostering social transformations necessary to address change challenges. Greater attention must be paid to the relationships and interactions between and across disciplinary boundaries in order to understand complex coupled socio-ecological systems. This would enable recognition and integration of different types of knowledge, perspectives, and approaches to science that are crucial to human dimensions research, especially as we live in a world that is experiencing rapid changes that have far-reaching implications.

76 DIVERSITAS: Biodiversity Science Integrating Research and Policy for Human Well-Being

Bruno A. Walther, Anne Larigauderie and Michel Loreau

76.1 Introduction

Biodiversity, or the variety of life on earth, makes up and sustains all life processes of the biosphere. Therefore, biodiversity contributes utilitarian values, such as ecosystem goods and services, option values for future use, as well as cultural values, such as educational, intellectual and recreational opportunities, aesthetic and spiritual enjoyment, and a sense of identity, to human well-being.

Biodiversity is almost invariably impacted negatively by unsustainable human resource consumption. The main drivers of biodiversity change are direct overexploitation of natural resources as well as the more important indirect drivers of change such as habitat conversion and fragmentation caused by land use changes, pollution, and invasive species.[1] Consequently, current scientific evidence overwhelmingly demonstrates a continued decline in the status of biodiversity since humans became the dominant species on earth.[2] About 1.5–1.8 million species have been scientifically described, but the number of undescribed species is rather uncertain, with the currently accepted estimate being about 10–15 million species; however, estimates range as high as 50–100 million.[3] While the total global number of species will remain uncertain for the foreseeable future, we already know that extinction rates of known species now exceed normal rates by 100–1000 times due to human impacts on the biosphere (Lawton/May 1995; Regan/Lupia/Drinnan/Burgman 2001). Rates of global biodiversity change have reached a magnitude and speed that greatly surpass change due to natural processes except those of cataclysmic events such as meteor strikes. Therefore, many biodiversity scientists insist that we are already experiencing the beginning of a 'sixth extinction event' on the scale of other massive die-offs during the earth's history, such as the disappearance of dinosaurs at the end of the Cretaceous (Wilson 1988; Savage 1995; Myers 2003).

Moreover, even if many species are not yet extinct, their populations have severely declined, both in numbers and distributions. These population declines not only make these species more vulnerable to local and global extinction (Gilpin/Soulé 1986; Hanski 1999; Oborny/Meszena/Szabo 2005) but also reduce their genetic diversity and therefore their future potential to adapt to environmental changes[4], at exactly the time when environmental changes are accelerating dramatically due to human actions.[5] Changes in population have led to reduced and restructured habitats and to altered ecosystem functions, biogeochemical cycles and chemical composition of soils, water and

atmosphere (Gitay/Suárez/Dokken/Watson 2002; Millennium Ecosystem Assessment 2005a).

Such massive declines and changes in species distributions invariably affect the functioning of ecosystems. For example, the widespread application of herbicides and insecticides has led to dramatic decreases in insect pollinators and their food plants, so that there is now a 'pollinator crisis' in some agricultural areas such that agricultural crops are no longer sufficiently pollinated.[6] More importantly, the widespread human transformation of once highly diverse natural ecosystems into relatively species-poor managed ecosystems (e.g., food monocultures) has led to irreversible biodiversity loss, with consequent loss of various ecosystem services (see 76.3.3 below). It is becoming increasingly clear that biodiversity of both pristine and well-managed ecosystems delivers important services such as the production of foods and other goods, the capacity to store carbon and recycle nitrogen, or the natural spaces for ecotourism to thrive in, to name just a few (Daily 1997; Farber/Costanza/Wilson 2002; Millennium Ecosystem Assessment 2005a). These examples demonstrate that ecosystem services directly affect human well-being, and biodiversity decline leads directly and indirectly to reduced benefits for people and increasingly limiting opportunities for development and livelihoods options in the short and long term, as well as increasing occurrences of sudden negative changes in the world's ecosystems and life processes (Millennium Ecosystem Assessment 2005a). Further understanding of the status, trends and functions of biodiversity is therefore critical if decision-makers at all scales, as well as the public, are to be informed about the global scale of biodiversity degradation, and the consequences of such degradation on ecosystem services and human well-being.

Based on this rising awareness of the importance of biodiversity to human well-being, society and governments are increasingly prepared to define and implement rules which allow for the long-term sustainable use of biodiversity. Therefore, the most pressing challenge is the need to establish the scientific foundations for the appropriate future social, political and economic actions aimed at maintaining an acceptable level of biological diversity and functional ecosystems on Earth. Towards this ultimate goal, biodiversity science will play a crucial role in understanding the Earth system and thus informing responsible and sustainable policy making. Faced with these challenges, the scientific community decided to organize itself in order to study these complex issues and provide science-based solutions using interdisciplinary and global research networks. This was the ultimate rationale for the establishment of the DIVERSITAS programme.

The DIVERSITAS Science Plan (2002) states that the overall goals of DIVERSITAS are to (1) promote an integrative biodiversity science, linking biological, ecological and social disciplines in an effort to produce socially relevant new knowledge, and (2) provide the scientific bases for the conservation and sustainable use of biodiversity. DIVERSITAS achieves these goals by implementing a portfolio of international scientific projects and networks which are detailed below. Each programme is built around a few central research challenges (or foci) which advance our scientific knowledge of biodiversity status, trends and functions. With its special focus on the science of the conservation and sustainable use of biodiversity, this increased knowledge in turn supports decision makers to make more rational policies regarding environmental threats, challenges, vulnerabilities and risks.

Below, we will specify the specific scientific contribution of each DIVERSITAS programme to help humankind to cope with global environmental change, disasters and security. Whenever possible, we use work contributed by scientists associated with the DIVERSITAS programme to support our arguments; therefore, citations are made selectively, reviewing the work of DIVERSITAS and not necessarily the entire biodiversity research and conservation community.

After a brief history of DIVERSITAS (76.2), we present the scientific agenda of DIVERSITAS (76.3), beginning with its overall mission and structure (76.3.1). The central message of this chapter is contained in the sections (76.3.2–76.3.4) in which we portray some of the main scientific achievements of DIVERSITAS which have relevance to the theme of this book, i.e. how biodiversity research can identify threats, challenges, and risks to human well-being and thus help humanity to better cope with global environmental change. We round this off with a brief description of the various DIVERSITAS Cross-cutting Networks (76.3.5), of the science policy bridge supported by DIVERSITAS (76.3.6), and our conclusions (76.4).

76.2 DIVERSITAS History: Building Biodiversity Science

76.2.1 Phase I: 1991-1998

DIVERSITAS, in its current structure, was launched in 2002. However, its birth dates back to 1991. In the wake of the negotiations on the *Convention on Biological Diversity* (CBD), the *United Nations Educational, Scientific and Cultural Organisation* (UNESCO), the *Scientific Committee on Problems of the Environment* (SCOPE) and the *International Union for Biological Sciences* (IUBS) – later joined by the *International Council for Science* (ICSU) and the *International Union of Microbiological Societies* (IUMS) – established an international, non-governmental umbrella programme that would address the complex scientific questions posed by the loss of and change in global biodiversity, and provide scientific advice to the CBD. Two main axes were developed during this period:

The first axis consisted in contributing to the implementation of Articles 6–8 and 10 of the CBD, and particularly article 7a: "Identify components of biological diversity important for its conservation and sustainable use." A number of workshops were held and papers were published, e.g., to implement the *Global Taxonomy Initiative* (GTI) of the CBD (DIVERSITAS 1999). Furthermore, DIVERSITAS initiated the Species 2000 Programme which focused on a global linking of taxonomic databases.

The second axis was the development of a new field for biodiversity science looking at the links between biodiversity and ecosystem functioning. The books below, which were the results of a series of workshops organized under the auspices of SCOPE, established this new field and laid the groundwork for further experimental and theoretical research carried out under DIVERSITAS and the *International Geosphere-Biosphere Programme* (IGBP). These books also contributed to the *Global Biodiversity Assessment* (Heywood 1995), an initiative of the *World Resources Institute* (WRI).

- *Biodiversity and ecosystem function* (Schulze/Mooney 1994).
- *Mediterranean-type ecosystems: The function of biodiversity* (Davis/Richardson 1995).
- *Arctic and alpine biodiversity: Patterns, causes and ecosystem consequences* (Chapin/Körner 1995).
- *Islands: Biological diversity and ecosystem function* (Vitousek/Loope/Adsersen 1995).
- *Biodiversity and savannah ecosystem processes* (Solbrig/Medina/Silva 1996).
- *Functional roles of biodiversity: A global perspective* (Mooney/Cushman/Medina/Sala/Schulze 1996).

Toward the end of its first phase, DIVERSITAS also contributed to the establishment of the *Gobal Invasive Species Programme* (GISP) in 1997 to investigate how invasive species affect biodiversity. During this first phase, which ended in 1998, the DIVERSITAS Secretariat was hosted by UNESCO's *Man and the Biosphere* (MAB) Programme.

76.2.2 Phase II: Biodiversity Science Evolves

After a lapse of three years, the sponsors of DIVERSITAS decided in 2001 to launch a second phase. They opened a new Secretariat, hosted by ICSU in Paris, and called upon a task force of scientists to develop an international framework for biodiversity research. DIVERSITAS undertook a series of workshops and consultations engaging scientists around the world. The DIVERSITAS Scientific Committee met for the first time in April 2002, marking the beginning of the second phase of DIVERSITAS.

The DIVERSITAS Science Plan (2002) reflects the will to build a dynamic and integrative approach to biodiversity science which took account of the changing concept of biodiversity, which by this time was no longer just the 'property of biologists' but had become a concept at the heart of many human activities (Barbault/Cornet/Jouzel/Mégie/Sachs/Weber 2002). Scientists acknowledged that biodiversity changed as a result of its own evolutionary and ecological dynamics, but increasingly also as a result of deliberate human actions as well as their unintentional consequences. In turn, these changes affect the well-being of human societies.[7] To understand this reciprocal interaction of coupled ecological and human systems, a more integrative biodiversity science had to be developed. Therefore, DIVERSITAS recognized the need to continue efforts to integrate its community, which was still fragmented among types of ecosystems (terrestrial, freshwater, and marine), types of organisms and disciplines, especially biology and ecology on one side and the socio-economic sciences on the other (Dirzo/Loreau 2005).

7 See: Liu/Dietz/Carpenter/Folke/Alberti/Redman/Schneider/Ostrom/Pell/Lubchenco/Taylor/Ouyang/Deadman/Kratz/Provencher (2007).

Another important integrative step occurred when DIVERSITAS became a founding partner in 2002 of the *Earth System Science Partnership* (ESSP; chap xy by Leemans/Rice/Henderson-Sellers/Noone), recognizing the links between biodiversity and other areas of global concern, such as climate change and land use change. The ESSP includes three other partners which are: the *International Geosphere-Biosphere Programme* (IGBP; chap. xy 77 Noone/Nobre/Seitzinger), the *International Human Dimensions Programme on Global Environmental Change* (IHDP; chap. 75 by Falkenhayn/Rechkemmer/Young), and the *World Climate Research Programme* (WCRP; chap. 78 by Church/Asrar//Busalacchi/Arndt).

76.3 Scientific Agenda of DIVERSITAS

76.3.1 Overall Mission and Structure

After publication of its Science Plan (2002), DIVERSITAS implemented its mission through the initiation of four Core Projects and five Cross-cutting Networks (see DIVERSITAS website, Box 76.1). DIVERSITAS can be considered as a think tank for promoting cutting-edge, innovative and internationally relevant biodiversity research, and its main achievement is the establishment of several interlinked scientific communities, built around these Core Projects and Cross-cutting Networks. Over the years, various types of activities have been performed, which include:

- provide common international frameworks for collaborative research on biodiversity;
- build scientific networks across countries and disciplines;
- perform scientific syntheses;
- engage scientists in scientific workshops and conferences;
- promote standardized methods;
- guide and facilitate global databases;
- build an important link with policy makers.

Box 76.1: The DIVERSITAS programme and related initiatives. **Source**: Compiled by the authors.

DIVERSITAS <http://www.diversitas-international.org/> is one of the four international global environmental change research programmes, the others being the International *Geosphere-Biosphere Programme* (IGBP) <http://www.igbp.net/>, the *International Human Dimensions Programme on Global Environmental Change* (IHDP) <http://www.ihdp.unu.edu/>, and the *World Climate Research Programme* (WCRP) <http://wcrp.wmo.int/wcrp-index.html/>.

Together they founded the *Earth System Science Partnership* (ESSP) <http://www.essp.org/>) which is a partnership for the integrated study of the Earth System, the ways that it is changing, and the implications for global and regional sustainability. Other programmes and initiatives mentioned in this chapter are here listed alphabetically with complete names and websites given:

It is not the subject of this chapter, however, to summarize the many activities of these various projects, but to portray some of the main scientific achievements of DIVERSITAS which have relevance to the theme of this book, i.e. how biodiversity research can identify threats, challenges, and risks to human well-being and thus help humanity to better cope with global environmental change. Three main themes have crystallized over the years:

1. To improve our capacity to observe and model biodiversity change, which in turn improves our ability to identify challenges and threats much earlier (early warning function).
2. To develop a better understanding of how biodiversity change affects ecosystem functioning and services, and how ecosystem services link to human well-being.
3. To investigate the social, legal, economic and political motivators that have an impact on the drivers of biodiversity change to guide the sustainable use of biodiversity and its associated ecosystem services.

Below, we present the contribution of DIVERSITAS towards each theme.

76.3.2 Improving Capacity to Observe and Model Biodiversity Change

While it is widely accepted that we are in the midst of a biodiversity crisis, with both populations and species experiencing often dramatic losses, we still experience major gaps in our global observation of biodiversity status and trends. There are several reasons for this: (a) the myriad forms of biodiversity, from genes to populations, species and ecosystems, are often extremely localized in their distribution, relatively expensive to sample and tantalizingly difficult to identify, and thus do not render themselves easily to global observation, unlike, for example, atmospheric gases; (b) biodiversity observation needs to include not just composition, but also structural complexity, functional relationships and evolutionary dynamics, as these factors greatly determine the responses of biodiversity to environmental change; (c) while some biodiversity observation systems exist, there are still large geographical gaps (often in the most biodiversity-rich regions, e.g., tropical rainforests), taxonomic gaps (most monitoring is focused on vertebrates and higher plants), or methodological gaps (most monitoring is not long-term and inconsistent in space and time and between observers); and (d) biodiversity data is held by a very large number of heterogeneous data providers (e.g., government agencies, NGOs, scientists, lay people, etc.), and many of these data are then only used by the data collector but do not become globally available because the delivery pipeline is blocked, either because data sets are not made available or because they are not made interoperable for use through global search engines and internet providers (Scholes/Mace/Turner/Geller/Jürgens/Larigauderie/Muchoney/Walther/Mooney 2008).

DIVERSITAS addresses these challenges mainly through three initiatives, its two Core Projects called bioGENESIS and bioDISCOVERY and the newly formed network called *Group on Earth Observations Biodiversity Observation Network* (GEO BON).

One of the aims of bioGENESIS is to facilitate the development of new strategies and tools for discovering and documenting biodiversity (Donoghue/Yahara/Conti/Cracraft/Crandall/Faith/Häuser/Hendry/Joly/Kogure/Lohmann/Magallón/Moritz/Tillier/Zardoya/Prieur-Richard/Larigauderie/Walther 2009). For example, it would revolutionize our ability to document and monitor biodiversity to develop rapid-capture technologies for identifying known species and discovering new ones. Of special interest is the development of a cost-effective, hand-held, automated species-identifier. The idea is to analyse a tiny sample of an organism; quickly extract, amplify, and sequence a set of target DNA markers; and then compare these to known sequences to situate the unknown within the tree of life. In this context, a key bioGENESIS initiative is to coordinate workshops aimed specifically at connecting the current efforts to develop DNA barcoding as a global standard for species identification (represented by the *Barcode of Life Initiative* (BOLI) and the *Consortium for the Barcode of Life* (CBOL) and the 'Tree of Life' activities, represented by the *Assembling the Tree of Life* project (ATOL)). Furthermore, new technologies are being promoted, e.g., real-time analysis of field images, use of remote-controlled microscopes, development of image recognition identification tools and automated digital capture of museum specimens and associated information (for a good example, see the HERBIS project). Information gained through such methods then needs to be connected to knowledge bases used by decision-makers, including the emerging *Encyclopedia of Life* (EOL).

While bioGENESIS thus addresses challenges of identification, bioDISCOVERY aims to promote the science that will improve our ability to objectively assess, monitor and predict biodiversity status and

trends on a global scale. Such knowledge is essential given that biodiversity underpins all life processes on earth, and with it all the ecosystem services so vital to human well-being (76.3.3). Given the inherent complexity of biodiversity outlined above, bioDISCOVERY tackles this challenge from both a scientific as well as an institutional angle.

The scientific goals to address this challenge are outlined in the bioDISCOVERY Science Plan (Ash/Jürgens/Leadley/Alkemade/Araujo/Asner/Bachelet/Costello/Finlayson/Lavorel/Mace/Mooney/Parr/Scholes/Soberon/Turner/Prieur-Richard/Larigauderie/Walther 2009) whose aim is to develop a scientific framework to assess the current extent of biological diversity, to monitor its change, to understand the underlying processes responsible for those changes, and to predict future changes. Assessment of global biodiversity must be improved across spatial and temporal scales, at different levels of biological organization (i.e. genes, populations, species, functional groups and ecosystems), and in terms of the various attributes and functions of biodiversity. This will lead to advances in the spatial and temporal assessment of genetic, population, species and ecosystem biodiversity, and of the interactions between them. For example, almost nothing is known about the global status of genetic, microbial or marine biodiversity, while global data on land-cover change also remain elusive. In addition to encouraging the collection of more primary biodiversity data, existing but often dispersed and heterogeneous data need to be better linked through the use of global data clearinghouses.[8] Improved data availability would enable the inclusion of a wider range of taxa[9] as well as an assessment of their functions; e.g., assess functional groups which deliver essential ecosystem processes, such as nitrogen-fixing soil organisms (Barrios 2007) or which deliver disservices such as invasive species.[10] Broader, functional approaches to classification will thus provide a considerably improved foundation for assessment, particularly in light of increasing attention of decision-makers to ecosystem functioning and services (76.3.3).

While assessments evaluate the status of biodiversity, continuous monitoring is essential to establish time lines that can detect biodiversity change, e.g., the disappearance of global fish stocks.[11] Detecting trends must go hand-in-hand with the identification of the main drivers of biodiversity change, e.g., land degradation or harvesting levels, so that not only the species or ecosystems at greatest risk can be pinpointed (early warning function) but that also the underlying causes of declines can be determined (cause-effect relationship). This will give decision-makers much better scope to identify risks and avert disasters before they happen.[12]

To operationalize global biodiversity monitoring, bioDISCOVERY has played a key role in developing the scientific framework during the early planning stages for the GEO BON which is a global partnership to collect, manage, analyze and report on the status and trends of the world's biodiversity.[13] The network will provide a scientifically robust framework for global biodiversity monitoring and define a strategy to reach strategic network goals and objectives.[14]

However, monitoring systems cannot monitor everything. Because of the complex nature of ecosystems, any effective early warning system will have to

9 A taxon (plural: taxa) is the term used for a taxonomic unit, with each taxon receiving a name which designates an organism or a group of organisms. In biological nomenclature according to Carl Linnaeus, a taxon is assigned a taxonomic rank and can be placed at a particular level in a systematic hierarchy reflecting phylogenetic relationships. Taxonomy is the science of classification, and taxonomies are composed of taxa arranged in a hierarchical structure which should, but not always do reflect phylogenetic relationships between the taxa.

14 See: Andrefouet/Costello/Ferrier/Geller/Höft/Jürgens/Lane/Larigauderie/Mace/Miazza/Muchoney/Parr/Pereira/Sayre/Scholes/Stiassny/Turner/Walther (2008).

include a fair amount of modelling (Anderson/Bugmann/Dearing/Gaillard 2006). Therefore, another scientific challenge is to fill monitoring gaps with ecological modelling which uses the inevitably limited data base to extrapolate biodiversity status and trends across space and time.[15] For example, one of the key weaknesses of remote sensing is its uncertain link to lower levels of biodiversity. While a West African forest may still be structurally intact to the eyes of a remote sensor, with an undisturbed canopy of healthy trees, hunting may have completely decimated the mammalian fauna.[16] Furthermore, forests with the most intense hunting pressures may often be in civil war zones, making on-the-ground monitoring a practical impossibility. Therefore, to get a true picture of biodiversity change in such intractable situations, we need ecological models that may use parameters such as human population, food consumption or gun availability as proxies to estimate biodiversity loss. Likewise, modelling may be needed to estimate biodiversity trends for mega-diverse taxa such as invertebrates, fungi and microbes, where monitoring simply cannot do the job.

It is of further strategic importance for biodiversity science to turn monitoring data, which by themselves are rather useless to data users such as conservation or government agencies, into products which relay critical information to data users. Some of the most important such products are biodiversity indicators.[17] It is widely acknowledged that current global indicators of biodiversity are insufficient to provide representative measures of biodiversity change – due to lack of data and methodological constraints. Building on ongoing initiatives such as the CBD (CBD 2003; Mace/Baillie 2007) and its associated *2010 Biodiversity Indicators Partnership* (2010 BIP), the review and refinement of existing[18] and the development of new, global biodiversity indicators is a high priority. For example, indicators need to be developed that monitor not just the conservation status of various taxa, but also relate to ecosystem functions and services such as carbon sequestration, water regulation (76.3.3) or to ecosystem productivity, stability and resilience *per se*, and can easily be incorporated into biodiversity models and scenarios. The aim is to develop indicators that are sufficiently robust, representative, and sensitive to monitor global biodiversity change, but also fulfil the requirement to communicate complex biodiversity data in an easily understandable manner to decision-makers and the public, e.g., by indicating when dangerous thresholds are being reached.[19]

The final goal of bioDISCOVERY is to enhance our understanding of biodiversity change in response to multiple natural and anthropogenic drivers based on integrated analyses of observations, experiments and models which will be used to develop improved, quantitative scenarios of future biodiversity change. Such computer-based model scenarios will have to integrate ecological concepts such as food webs, species interactions and community assemblage as well as conservation concepts such as meta-population theory, minimum viable population, area selection algorithms, fragmentation and connectivity, into a spatially explicit *Geographic Information System* (GIS) modelling framework that draws on data gathered from various monitoring approaches.[20] Furthermore, variables such as drivers of change and ecosystem services need to be linked into the modelling framework to finally create an operational biodiversity model that can render regional and global biodiversity scenarios given various socio-economic inputs, thus delivering a key tool for conservation managers and policy makers which will allow them to weigh the consequences of various policy options for biodiversity,

ecosystem services, and, ultimately, human well-being.[21] How ecosystem services and socio-economic drivers of change are related to biodiversity change is the subject of the next two themes.

76.3.3 Exploring the Links between Biodiversity Change, Ecosystem Functioning and Services, and Human Well-being

Given that the world is in the midst of a biodiversity crisis, what are actually the arguments for conserving biodiversity? Three main arguments on how biodiversity enhances human well-being have been advanced:

1. Biodiversity has an intrinsic value because it enriches life by providing educational, intellectual and recreational opportunities, aesthetic and spiritual enjoyment, and a sense of identity. While some argue that all such services can be enumerated in economic terms (e.g., earnings from ecotourism), others argue that they are essentially fundamental rights to a good life, equivalent to human rights and thus cannot be given a monetary value. Conservation and sustainable use of biodiversity thus become ethical issues of good moral conduct towards other life forms as well as towards fellow human beings and cultures.
2. Biodiversity has an economic value by providing ecosystem goods and services, which can be extracted goods (e.g., foods, fibres, medicines) or indirect services (e.g., pollination, carbon sequestration, nutrient cycling, pest control, ecotourism).
3. Biodiversity has an option value by providing future services, especially as a legacy to future generations and as an insurance against future challenges and risks, e.g., by storing genetic diversity which might be needed to design new foods or medicines or to adapt to rapid environmental change.

Because of a growing realization among biodiversity scientists that the second argument may have the strongest impact on current decision-makers, a conscious effort was made by DIVERSITAS to advance the science of ecosystem functioning and how it relates to biodiversity on the one side and ecosystem services on the other. DIVERSITAS addresses this challenge through its Core Project called ecoSERVICES which examines the impact of biodiversity changes on ecosystem functioning and services (Bulte/Hector/Larigauderie 2005). While the very concept of ecosystem services goes back to at least Plato (Daily 1997), the recent scientific interest in ecosystem services has been staggering. There has been an exponential increase in the number of publications on this topic over the last two decades (figure 76.1), perhaps only comparable to the explosion of interest in global climate change. DIVERSITAS has been at the forefront of this scientific endeavour with a series of workshops, publications and policy initiatives beginning in 1991.

Together with SCOPE and the *United Nations Environment Programme* (UNEP) which early on published global summaries on the subject (Heywood 1995; Mooney/Cushman/Medina/Sala/Schulze 1996), DIVERSITAS developed the field of ecosystem functioning and services through several landmark publications on the topic which were also the basis for some of the conclusions made in the *Millennium Ecosystem Assessment* (2005a).[22]

From all this research, several important conclusions for the relationship between biodiversity and ecosystem functioning were drawn:

1. The loss of genetic variability within a population of a species can reduce its flexibility to adjust to environmental change, e.g., climate change.
2. The loss of biodiversity within ecosystems generally reduces resource utilization, productivity and the capacity to resist changing environmental conditions and rebound from extreme conditions, while increasing spatial and temporal variation in ecosystem processes as well as susceptibility to invasion (however, several other factors, such as propagule pressure, disturbance regime, and

resource availability also strongly influence invasion success).

3. The addition or deletion of dominant or keystone species (even if they are rare, such as top predators) can have profound effects on the capacity of an ecosystem to provide services. Keystone species are those with unique traits, e.g., for fixing nitrogen, capturing water, avoiding erosion, causing disturbance, and so forth; consequently, the effects of their removal or addition can be predicted *a priori*. Although the success of an invasive species in a new habitat is difficult to predict, its impact on ecosystem functioning upon establishment can be predicted based on whether the new species utilizes or produces a unique resource.
4. The simplification of ecosystems to produce greater yield of individual products (e.g., food monocultures) comes at the cost of the loss of ecosystem stability and ecosystem services, which then need to be subsidized by the use of often costly inputs, e.g., water, fertilizers and pesticides.
5. Certain ecosystems, e.g., those found in arid regions and on islands, appear particularly vulnerable to disturbance and hence alteration of their functioning. These sensitive systems all have low representation of key functional types (organisms that share a common role).
6. Anthropogenic alteration and fragmentation of ecosystems and landscapes reduces the overall amount of ecosystem services. Many of these ecosystem changes are difficult, expensive, or impossible to reverse or fix with technological solutions. Therefore, human societies will have to learn to maintain and increase the buffering capacity provided by biodiversity to ensure the long-term sustainable use of ecosystems.

While these conclusions hold in general, they can to some extent differ among different ecosystems, and should be treated with more caution for freshwater and marine ecosystems, as these have been severely understudied compared to terrestrial ecosystems.

These important conclusions on the link between biodiversity and ecosystem functioning and services then led to the next phase of scientific inquiry which is to link ecosystem services to human well-being, e.g., through quantification of economic benefits. Consequently, the scientific goals of the ecoSERVICES Science Plan (Bulte/Hector/Larigauderie 2005) are not only to further expand the research on the above conclusions by expanding the scale and complexity of future studies[23], but also to include economic and social researchers to investigate (1) how preferences for certain ecosystem services influence decision-making both at the individual and the societal level and (2) how to translate scientific knowledge about ecosystem services into economics to inform decision-makers about current versus future costs and benefits in comparable units of impact on human well-being.[24] Towards this goal, experimental and field studies need to be supplemented by the development of integrated ecological-economic models.[25] Such models

23 See: Loreau/Mouquet/Gonzalez (2003); Naeem/Wright (2003); Cardinale/Ives/Inchausti (2004); Gessner/Inchausti/Persson/Raffaelli/Giller (2004); Giller/Hillebrand/Berninger/Gessner/Hawkins/Inchausti/Inglis/Leslie/Malmqvist/Monaghan/Morin/O'Mullan (2004); Petchey/Downing/Mittelbach/Persson/Steiner/Warren/Woodward (2004); Raffaelli (2004); Vinebrooke/Cottingham/Norberg/Scheffer/Dodson/Maberly/Sommer (2004); Hooper/Chapin/Ewel/Hector/Inchausti/Lavorel/Lawton/Lodge/Loreau/Naeem/Schmid/Setala/Symstad/Vandermeer/Wardlem (2005); Balvanera/Pfisterer/Buchmann/He/Nakashizuka/Raffaell/Schmid (2006); Bulling/White/Raffaelli/Pierce (2006); Raffaelli (2006); Duffy/Cardinale/France/McIntyre/Thebault/Loreau (2007); Hector/Bagchi (2007).

24 See: Costanza/D'Arge/de Groot/Farber/Grasso/Hannon/Limburg/Naeem/O'Neil/Paruelo/Raskin/Sutton/van den Belt (1997); Daily/Söderqvist/Aniyar/Arrow/Dasgupta/Ehrlich/Folke/Jansson/Jansson/Kautsky/Lubchenco/Mäler/Simpson/Starrett/Tilman/Walker (2000); Balmford (2002); Farber/Costanza/Wilson (2002); Wätzold/Drechsler/Armstrong/Baumgartner/Grimm/Huth/Perrings/Possingham/Shogren/Skonhoft/Verboom-Vasiljev/Wissel (2006); Baumgärtner (2007); Tschirhart (2007).

will contribute towards a scientific basis for sustainable ecosystem-based management which is essential to achieve conclusion 6 (Tschirhart 2007); in other words, without reliable ecological-economic models, decision-makers and managers will find it difficult to choose policy and management options that maintain the buffering capacity of functional ecosystems and, at the same time, satisfy other societal needs, e.g. the provision of foods and fibres.

Yet quantifying the value of ecosystem services in specific localities and measuring their worth against that of competing land uses is no simple task. For example, a typical tradeoff is to quantify the economic benefits of a particular development project versus the benefits supplied by the ecosystem that would be destroyed. While in many cases the value of ecosystem services remains highly uncertain, the pace of destruction of natural ecosystems and the irreversibility of most such destruction warrants that we begin valuing ecosystem services, even if such an enterprise is fraught with difficulties. Just as societies have recognized fundamental human rights, it may be prudent to establish fundamental ecosystem protections even though uncertainty over economic values remains.

Two short examples shall illustrate that the research led by DIVERSITAS and many others on the value of ecosystem services is already making an impact on actual decision-making and global policy setting.

In the rush to produce sugar cane for biofuels, Uganda's President Yoweri Museveni wanted to give away a third of the 30,000 hectare Mabira Forest Reserve which is globally recognized as an *Important Bird Area* (IBA).[26] However, in October 2007, after months of intensive campaigning by several environmental organizations, the Uganda Ministry of Finance and Economic Planning announced that these plans had been dropped. What made this decision significant was that it was heavily influenced by a report published by *Nature-Uganda* which clearly showed that the economic value of the forest if conserved would surpass the anticipated economic value from future sugarcane harvests. The list of 'ecosystem services' (livelihoods, food, clean water, protection from soil erosion, ecotourism, etc.) provided by the reserve to over 120,000 adjacent community members was another important finding in the report which eventually won over the government.[27] This may very well be the first instance in which the explicit enumeration of ecosystem services changed a major policy decision within one of Africa's poorest nations.

Going from the local to the global scale, the German Federal Ministry for the Environment and the European Commission, with the support of several other partners, jointly presented an interim report of *The Economics of Ecosystems & Biodiversity* (TEEB) (European Communities 2008) during the Ninth Conference of the Parties to the *Convention on Biological Diversity* (CBD COP-9) in Bonn, Germany, in May 2008. The study evaluates the costs of the loss of biodiversity and the associated decline in ecosystem services worldwide, and compares them with the costs of effective conservation and sustainable use. It is intended to sharpen awareness of the value of biodiversity and ecosystem services and facilitate the development of cost-effective policy responses, notably by preparing a 'valuation toolkit'. Mimicking the Stern report on the economics of climate change (Stern 2006) and hoping for a similar impact on global awareness and policy-making, the TEEB will continue its investigation and present its final report at the Tenth Conference of the Parties to the *Convention on Biological Diversity* (CBD COP-10) in Nagoya, Japan, in 2010.

76.3.4 Investigating the Socio-economic Drivers of Biodiversity Change to Guide the Sustainable Use of Biodiversity

Given the realization of the irreplaceable value of ecosystem services (be it intrinsic, economic or optional value), there is an urgent need to investigate what motivates people and societies to keep using biodiversity in unsustainable ways, and how human behaviour may

25 See: Williams/Moore/Toham/Brooks/Strand/D'Amico/Wisz/Burgess/Balmford/Rahbek (2003); Moore/Balmford/Allnutt/Burgess (2004); Santelmann/White/Freemark/Nassauer/Eilers/Vache/Danielson/Corry/Clark/Polasky/Cruse/Sifneos/Rustigian/Coiner/Wu/Debinski (2004); Polasky/Nelson/Lonsdorf/Fackler/Starfield (2005); Bulling/White/Raffaelli/Pierce (2006); Naidoo/Balmford/Ferraro/Polasky/Ricketts/Rouget (2006); Naidoo/Ricketts (2006); Pitcher/Ainsworth (2008); and especially recent issues of the journal Ecological Economics.

26 An Important Bird Area (IBA) is a definition adopted by BirdLife International to recognize those terrestrial areas which are key sites for bird conservation, especially of threatened and endemic species; at: <http://www. birdlife.org/action/science/sites/index.html/>.

27 Anonymous, 2007: "BirdLife Partners applaud Uganda's decision to drop Mabira Forest give-away"; at: <http://www.birdlife.org/news/pr/2007/10/mabira.html/> (6 June 2008).

be changed to guide us towards the path of the sustainable use of biodiversity and its associated ecosystem services. DIVERSITAS addresses this challenge through its Core Project called bioSUSTAINABILITY which investigates the social, legal, economic and political motivators that have an impact on the drivers of biodiversity change to guide the sustainable use of biodiversity and its associated ecosystem services (DIVERSITAS 2004). Within these broader goals, a major focus of bioSUSTAINABILITY is to understand the reasons for the successes and failures of current conservation policies. Failures can often be attributed to one of the following factors:

1. policies do not recognize and effectively address the underlying motivations and incentives of individuals, organizations, and governments whose actions impact biodiversity,[28]
2. society often fails to appreciate the full value of the ecosystem services that biodiversity provides[29] (76.3.3 above) and/or
3. society at large has become dysfunctional to such a degree that conservation is not feasible.[30]

To measure success or failure, bioSUSTAINABILITY is developing indicators of the effectiveness of programmes and policies that impact on biodiversity, e.g., by identifying the positive or negative net effects on biodiversity of various social, political and economic drivers.[31] Understanding the effects of drivers of change is a prerequisite to develop successful conservation policies and to understand the mechanisms and conditions associated with various outcomes. Finally, bioSUSTAINABILITY investigates how to (1) incorporate this information into decision-making processes, (2) improve understanding of cause and effect mechanisms, and (3) develop adequate incentives to minimize impacts.[32]

What makes evaluating different policy options so difficult is that different groups within society often have diverse views about which outcomes are desirable and which trade-offs are acceptable. For example, one group may be interested in the value of the production of commodities, while another one may be more interested in conserving biodiversity (Deacon/Parker 2008). Reaching decisions which are acceptable to all stakeholders is a complex process. While top-down decisions may be easy to formulate, they usually ignore important stakeholder groups and are therefore likely to fail in the long term. Efforts to reach a consensus from the bottom-up, which require participatory processes and the involvement of all stakeholder groups, are more difficult, but their inclusive nature means that solutions are more likely to persist. Using case studies ranging from the local to the international scale, scientists involved in bioSUSTAINABILITY have examined the dynamics of multiple stakeholder groups, the criteria used to decide who participates and who makes decisions and best practice for building consensus, including cost-benefit analyses of conservation investments.[33]

Even with an improved understanding of these decision-making processes, much uncertainty remains because both ecological and socio-economic systems exhibit complex dynamic behaviours that interact in often unpredictable ways.[34] A challenge for long-term

biodiversity conservation and sustainability is to understand the dynamics of these coupled systems to predict how these dynamics might be affected by different social and economic decisions.[35] However, the very complexity of these systems means that it will be difficult to forecast the future. Surprises and uncertainty inherent in such dynamics make traditional approaches, which assume nearly complete information, of little use. Long-term sustainable management of biodiversity resources requires novel approaches (see e.g. GEO BON in 76.3.2 above).

Therefore, the analysis of the potential usefulness of a range of methodological approaches to assess the sustainability of coupled socio-ecological systems is a key goal of bioSUSTAINABILITY. In particular, bioSUSTAINABILITY intends to analyse the following promising methods: stochastic dynamic programming;[36] management of resilience;[37] multi-agent systems;[38] integrated environmental assessment modelling;[39] safe minimum standards (Berrens 2001; Drucker 2006); and the precautionary principle.[40] Such methods promise to deliver better early warning functions which will be able to detect when dangerous thresholds are reached at which system functions may change in dramatic and irreversible ways (e.g., collapse of fisheries, coral bleaching, landslides due to deforestation). Wherever possible, reversible damage needs to be redressed through implementation of restorative efforts and sustainable policies.[41] Such investigations are therefore invaluable as human societies attempt to cope with the challenges associated with global environmental change.

76.3.5 DIVERSITAS Cross-cutting Networks

The work of the four Core Projects of DIVERSITAS is mirrored and amended by the work of five Cross-cutting Networks which have gradually evolved and focused on specific themes or ecosystems, embracing issues also partially addressed in the Core Projects:

- *agroBIODIVERSITY* investigates relationships between biodiversity and agriculture (Jackson/Bawa/Pascual/Perrings 2005).
- *ecoHEALTH* explores relationships between biodiversity and health.
- *freshwaterBIODIVERSITY* researches issues related to freshwater biodiversity.[42]
- *Global Invasive Species Programme* (GISP) addresses issues related to invasive species (McNeely/Mooney/Neville/Schei/Waage 2001).
- *Global Mountain Biodiversity Assessment* (GMBA) focuses on mountain biodiversity issues (Spehn/Körner 2005; Spehn/Liberman/Körner 2006).

In the context of this chapter, it would go too far to detail their substantial contributions (for details, see DIVERSITAS website, box 76.1), but they all contribute to building global scientific capacity to focus on how to address biodiversity change and its implications on human societies.

76.3.6 Strengthening the Science Policy Bridge

To cope with *global environmental change* (GEC), an efficient flow of information is crucial. To bridge the

gap between the monitoring, science and assessment communities dealing with biodiversity change, DIVERSITAS has made extensive use of the scientific community built through its Core Projects and Cross-cutting Networks to take the lead in the on-going consultations on a global monitoring network and a global assessment mechanism, namely the GEO BON (see 76.3.2 above) and the consultation on an *International Mechanism of Scientific Expertise on Biodiversity* (IMoSEB). IMoSEB was initiated by the French Government in January 2005 at a summit entitled "Biodiversity: Science and Governance"[43] and gained momentum in 2006 through a vibrant process involving hundreds of scientists, representatives of governments, international and non-governmental organizations, as well as UN agencies. The central focus of this consultation is the need for a new mechanism, called IMoSEB, which, like the *Intergovernmental Panel on Climate Change* (IPCC), would provide independent and regular scientific expertise on and assessment of biodiversity to the biodiversity-related conventions, such as the CBD, the *Ramsar Convention on Wetlands*, or the *United Nations Framework Convention on Climate Change* (UNFCCC).

During this consultation process, a broad consensus has been emerging on the fact that the current situation in terms of availability and use of scientific expertise for decision-making on biodiversity is not satisfactory. The *Subsidiary Body for Technical and Technological Advice* (SBSTTA) of the CBD is not fulfilling this role, and would benefit from such a mechanism. Issues that have been debated in the consultation include the governance of IMoSEB, the framework of IMoSEB (what should its relation with the CBD be?), the time frame (should IMoSEB produce regular assessments or fast expertise on emerging topics, or both?), and the geographical scale (could a global mechanism deliver relevant information at the local level?). A final meeting of the International Steering Committee, at the end of 2007, discussed all these major issues, and came up with final recommendations on the mandate and governance of IMoSEB.

IIn broad strokes, they recommend that IMoSEB should be:

- scientifically independent, credible and inclusive;
- policy-legitimate through inter-governmental and multi-stakeholder involvement;
- policy-relevant without being policy-descriptive;
- based on a robust and relevant conceptual framework;
- communicated in an appropriate form for consideration and possible action;
- supported by networking efforts of scientific and knowledge holders.

IMoSEB should address decision-makers from governments and other sectors of society at global, regional and national scales and promote dialogue between international agencies and decision-makers. IMoSEB would thus provide scientific support to multilateral environmental agreements, national governments and other decision-makers which are concerned with consequences of biodiversity change. The main activities of IMoSEB would include

- influencing the research agenda by highlighting scientific gaps,
- generating interdisciplinary knowledge through regular independent assessment,
- providing policy support by responding to requests for information on specific issues,
- identifying emerging issues and threats and
- building capacity at the regional and national level.

Since May 2008, IMoSEB and the follow-up process to the Millennium Ecosystem Assessment (2005a) have engaged in discussions and come to the agreement that a single mechanism for both initiatives would be more appropriate than two separate ones, given the high level of congruence between the two initiatives. All modalities of this new mechanism, referred to as the *Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services* (IPBES, <http://ipbes.net/en/index.aspx/>) were considered by governments and other stakeholders at an "ad hoc intergovernmental and multi-stakeholder meeting on an intergovernmental science-policy platform on biodiversity and ecosystem services" held in Putrajaya, Malaysia, from 10–12 November 2008 under the auspices of the UNEP Executive Director. Delegates from 78 countries and 25 organizations discussed needs and modalities to strengthen the science-policy interface on biodiversity and ecosystem services. There was broad recognition of the need to improve the science-policy interface which should use existing relevant assessments and the best available multidisciplinary knowledge (i.e., natural, social and economic sciences, including traditional and indigenous knowledge). Many delegates agreed that the role

43 See: Loreau/Oteng-Yeboah/Arroyo/Babin/Barbault/Donoghue/Gadgil/Häuser/Heip/Larigauderie/Ma/Mace/Mooney/Perrings/Raven/Sarukhan/Schei/Scholes/Watson (2006).

of an independent science policy platform should be to compile, assess and synthesize existing scientific knowledge, thereby indentifying areas of science requiring further development, and to provide policy-relevant, evidence-based and peer-reviewed information to multiple stakeholders including multilateral environmental agreements without being policy-prescriptive. A second meeting, most likely to be held in 2009, will continue this process. DIVERSITAS will continue to ensure a strong representation of the biodiversity community in this process.

76.4 Conclusions

This chapter illustrates how biodiversity science has changed over this past decade, moving from a purely 'naturalist' view of the world excluding humans to a vision that takes into account human activities and their interaction with earth system processes. Consequently, the scientific community has changed the way it works and built numerous bridges across disciplines. Biodiversity scientists have learned to interact with politicians and other decision-makers, and have increasingly been called upon to shape policies to protect biodiversity at the national and international level. Strong concepts have emerged, such as the consequences of biodiversity change and loss for ecosystem functioning and services and human well-being, thanks to DIVERSITAS and the *Millennium Ecosystem Assessment* (2005a).

Yet, in spite of all these efforts, losses of populations and species and destruction of ecosystems continue unabated. A strong case still needs to be made for biodiversity. Public opinion does not feel threatened by the loss of biodiversity, as is the case for climate change. Biodiversity losses remain seen by most as the disappearance of a charismatic species far away from home, a sad event, but not of a threatening nature to daily life. Therefore, the biodiversity crisis, even more than the climate change crisis, will require a multi-disciplinary approach both on the science side as well as on the policy, education and management side, combining and integrating different approaches, subjects and disciplines. The main challenge for the biodiversity community in the few years ahead is to make a strong enough case for biodiversity, to influence public opinion, and to make an impact on political agendas. Humankind does not have much time to avert the further irreversible loss of biodiversity in all its multifaceted splendour.

77 The International Geosphere-Biosphere Programme's (IGBP) Scientific Research Agenda for Coping with Global Environmental Change

Kevin J. Noone, Carlos Nobre and Sybil Seitzinger

77.1 Introduction[1]

The UN *Millennium Development Goals* (MDGs) are simultaneously an inspiring and formidable challenge for society: within the next few years we must aim to eradicate extreme poverty and hunger; achieve universal primary education; promote gender equality and empower women; reduce child mortality; improve maternal health; combat deadly diseases; ensure environmental sustainability; and construct a global partnership for development. At the same time, society is faced with other challenges such as global climate change, air pollution, decreases in global biodiversity, food and water resources, and how all of these issues tie into global security. Humankind does not have the luxury of solving these problems one at a time; they need to be resolved together. Solving these problems requires knowledge of how the coupled human-environmental Earth system works that is sufficiently broad and deep to allow us to accurately assess the causes of past and current changes and predict future ones.

In this regard, the need for process-level understanding of how the human-environmental system works has not diminished, but in fact underpins our ability to achieve sustainable development. The science community still must concentrate on understanding the interactions and feedbacks between biological, chemical and physical processes and human systems. However, scientists, resource managers, private enterprise and policy makers require a common understanding in order for their interactions to be mutually beneficial, and for us to be able to imagine, assess and implement solutions for the MDGs and address other issues of global environmental change.

The global environmental changes brought on by human activities have already and will continue to have significant, planetary-scale consequences. Rockström, Steffen, Noone, Persson, Chapin III and coauthors (2009a, 2009b) have recently identified nine "planetary boundaries" which if exceeded would increase the risk of the Earth System moving into a state less suited for the needs of our current society. They provide specific estimates for seven of the nine boundaries, and show that humanity has already exceeded three. This recent analysis itself builds upon work from a number of roots, among them the concept of limits to growth (Meadows/Meadows/Randers/Behrens III 1972; Turner 2008), studies of the coupled human-environmental system (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schnellnhuber/Turner/Wasson 2004; Schellnhuber/Crutzen/ Clark/Claussen/Held 2004; Liu/Dietz/Carpenter/Folke/Alberti et al. 2007) and resilience (Folke 2006; Walker/Barrett/Polasky/Galaz/Folke et al. 2009). A common characteristic of all of this work is the necessity of an interdisciplinary approach to framing and carrying out research in these areas. Attainment of global sustainability in a fundamentally interconnected world is only possible through coordinated, collective and cooperative efforts by all peoples. The scientific community has a special and significant role to play in this effort.

The goals of this chapter are to discuss the challenges of pursuing research in the area of *global environmental change* (GEC), give examples of the kinds of questions that require an international, interdisciplinary research approach, and outline how the *International Geosphere-Biosphere Programme* (IGBP) contributes to this effort.

1 The authors are grateful to three anonymous reviewers for helpful comments and to Hans Günter Brauch for his patience during the process of completing this chapter.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_77, © Springer-Verlag Berlin Heidelberg 2011

Figure 77.1: The 'big picture' puzzle. The left pane shows the unassembled puzzle, in which focused, disciplinary research serves to draw out detail in each of the puzzle pieces. The right pane shows the assembled puzzle, in which scientific effort has been expended to assemble the pieces together in order to view the big picture. A limitation of this depiction is the fact that the picture is changing all of the time, and is not static as shown here.

77.2 The Research Challenge of Global Environmental Change

Three hundred years ago, in the time of Sir Isaac Newton, science was called natural philosophy. In the centuries since, we have divided science up into a multitude of focused disciplines. In any University catalogue one finds departments of chemistry, physics, economics, meteorology, law, and many more. Agencies that fund scientific research are structured in similar ways. With this structure, we have sliced the 'big picture' up into a large number of smaller, more manageable pieces. There are some good reasons for taking this focused, reductionist approach. It is a necessary step in developing an understanding of the processes that determine how complex systems behave. If we view the complex earth system as a large puzzle, the reductionist approach helps us to bring out the details of each one of the pieces of the puzzle. However, regardless of how much detail we achieve for each of the individual pieces, seeing the 'big picture' is not possible unless all the puzzle bits are assembled. A major research challenge of GEC is developing the science of (and the institutional support structure for) putting together the big picture (figure 77.1).

In its two decades of existence, IGBP has attempted to develop and provide the structure within which international, multidisciplinary science can be organized and applied to both doing the fundamental, process-oriented research needed to bring out the detail in each of the puzzle pieces in the Earth System – as well as how the details are changing, but also (and perhaps more importantly) to put a structure in place that enables the puzzle to be put together. Even though IGBP has a very broad scientific base (se section 77.3.2 below), the challenges of doing research on global environmental change require an even more comprehensive base.

77.2.1 Investigating the Coupled Human-Environmental Earth System

The kinds of questions now being asked of the research community have changed over the last decades, and reflect the increasing appreciation of the interconnectedness of the earth system. In the past, many scientific questions of societal importance could be successfully addressed by concentrating on either individual or a small number of the components of the earth system, even though answering the questions still required international, interdisciplinary collaboration. For example, finding out what caused the development of the Antarctic ozone hole required international collaboration among atmospheric chemists and meteorologists. Understanding the causes and conse-

quences of acid rain required collaboration between atmospheric scientists and terrestrial ecologists. In contrast, the kinds of questions now being asked of the scientific community increasingly show the need for a more holistic approach; one that couples natural and social sciences methodologies and expertise from the outset. For example (chap. 74 on the ESSP):

- Can agricultural practices and water management policies on regional and local scales be adapted to changes in precipitation patterns caused by global warming?
- What are the trade-offs between food and biofuels production and what will be the consequences of large-scale land use and ecosystem changes caused by these activities?
- What are the impacts of the predicted climate changes on food production and human security?
- What new forms of governance and management systems do we need in order to implement equitable responses to the challenges of global environmental change?
- What role does urbanization play in the health effects of air pollution? Do megacities play a role in affecting the energy balance of the planet and in the hydrological cycle?

In addition, the GEC research community is challenged to present research results in more accessible and informative ways to stakeholders – particularly those concerned with adaptation and sustainable development. IGBP is frequently expected to answer questions on the effects of GEC on regional – and even local scales: stakeholders seek local strategies to adapt to future environmental change. Here in a nutshell we have some of the greatest challenges of doing research on GEC issues: a) mobilizing, coordinating and enabling researchers from around the globe and from a multitude of disciplines across the natural and social science spectrum to pursue collaborative research; b) develop the ability to pursue research that is relevant for scales going from local to global; c) involving end users in the design, production and use of the results of this research.

IGBP is one component in a larger effort aimed at pursuing GEC research – the *Earth System Science Partnership* (ESSP). Our own strategy is described in the following sections. However, it should be kept in mind that IGBP's current and future activities are intended to contribute to helping achieve the goals of ESSP as well as our own (chap. 74). Descriptions of some of the other partners and projects in ESSP can be found in chap 75 (on the International Human Dimensions Programme on Global Environmental Change), chap. 76 (on DIVERSITAS) and in chap. 79 (on the World Climate Research Programme).

77.3 IGBP's Scientific Strategy

IGBP's scientific strategy is aimed at achieving its overall vision: "to provide scientific knowledge to improve the sustainability of the living Earth". IGBP's scientific strategy has evolved since the start of the Programme in 1987. IGBP was created at a time when little understanding existed of how the Earth worked as a system, how the parts were connected, or even about the importance of the various component parts of the Earth system. Feedback mechanisms were not always clearly understood, nor were the dynamics controlling the Earth system as a whole. Herbert Friedman, in the introduction to the report *Toward an International Geosphere-Biosphere Program: A Study of Global Change* (NRC 1986) called for a "bold, 'holistic' venture in organized research – the study of whole systems of interdisciplinary science in an effort to understand global changes in the terrestrial environment and its living systems". IGBP's scientific implementation began in earnest in the early 1990's with the launch of five projects.[2] Five additional projects began over the course of the 1990's,[3] culminating in a transition between IGBP's first and second phases. Originally, the first of the IGBP core projects were essentially independent of each other, and were aimed at progressing fundamental understanding of the governing processes in each of their respective domains. They did so quite successfully, but as time went on the scientific community in IGBP realized that a much greater level of connectedness across the various domains was necessary in order to address system-level questions about the nature and function of the Earth system. A synthesis of key findings from IGBP's first phase (IGBP-I) was conducted during 2000–2003, and laid the groundwork for the

2 *Biospheric Aspects of the Hydrologic Cycle* (BAHC), *Global Change and Terrestrial Ecosystems* (GCTE), *International Global Atmospheric Chemistry* (IGAC), *Joint Global Ocean Flux Study* (JGOFS), and *Past Global Changes* (PAGES).

3 *Land-Ocean Interactions in the Coastal Zone* (LOICZ), *Land-Use and Land-Cover Change* (LUCC), *Global Analysis, Integration, and Modelling* (GAIM), and *Data and Information Service (DIS), Global Change System for Analysis, Research, and Training* (START).

transition into our second phase (IGPB-II: 2004–2013).

In this second phase, IGBP's mandate is "to describe and understand the interactive physical, chemical and biological processes that regulate the total Earth System, the unique environment that it provides for life, the changes that are occurring in this system, and the manner in which they are influenced by human actions" (Brasseur/Steffen/Noone 2005). The initial strategy for the second phase is described in detail in IGBP's science plan and implementation strategy (IGBP 2006).

As IGBP continues to evolve, the scientists involved in the network are realizing that in addition to the process-level discovery science that IGBP has facilitated, there is an increasing need to develop a kind of *applied* Earth system science – science that takes fundamental understanding about how the Earth system functions, and applies this knowledge to support decisions about issues of societal relevance. Engaging stakeholders is a necessary component of this new enterprise for IGBP. These issues were highlighted in an international review of IGBP (ICSU-IGFA 2009) that will guide IGBP's development in the coming years.

77.3.1 Linking Process Understanding with Decision Support

Human adaptation to a changing environment can take many forms, and can have both positive and negative environmental impacts. Small-scale measures could include increased use of air conditioning as temperature increases, architectural changes for more efficient heating and cooling, better forecasting and warning systems for extreme events, and increased water usage. Larger-scale issues could vary from switching to renewable energy sources to attempts at 'geo-engineering'. The large-scale movement of people away from areas adversely affected by climate change and by other environmental and socioeconomic stresses is also a form of adaptation. Each of these options, and the decisions behind them, has environmental consequences that must be carefully evaluated before they are implemented. The greater the consequences of a decision or an adaptation scheme, the greater care needs to be taken in considering its application. Another fundamental issue about adaptation schemes is whether they will contribute to an increase or decrease in equity across the globe. The predictions recently released by the IPCC Working Group 2 show that in many cases the areas facing the largest changes in climate are not only located in countries that have contributed the least to the atmospheric build-up of greenhouse gases, but also those that have the least ability to adapt to them (IPCC 2007). Clearly, the basic science research needed to support decisions about adaptation needs a tightly coupled natural-social science support structure. The need to understand how individual aspects of and processes in the natural and social worlds work has not diminished, but in fact underpins the answers to questions of sustainable development and adaptation (figure 77.2).

At the base of the pyramid are all of the myriad investigations into the nature of the individual processes that govern Earth system behaviour. This process-level research was mentioned earlier with the analogy of achieving a high level of detail in each of the puzzle pieces of the Earth system. The next level higher is one in which system-level integration can be pursued. This corresponds to the previous analogy of putting together the 'big picture' puzzle. The apex of the pyramid represents activities that aim to convert this system-level understanding into information relevant for decision support for global environmental change issues. This pyramid analogy highlights a few important points regarding discovery research and decision support:

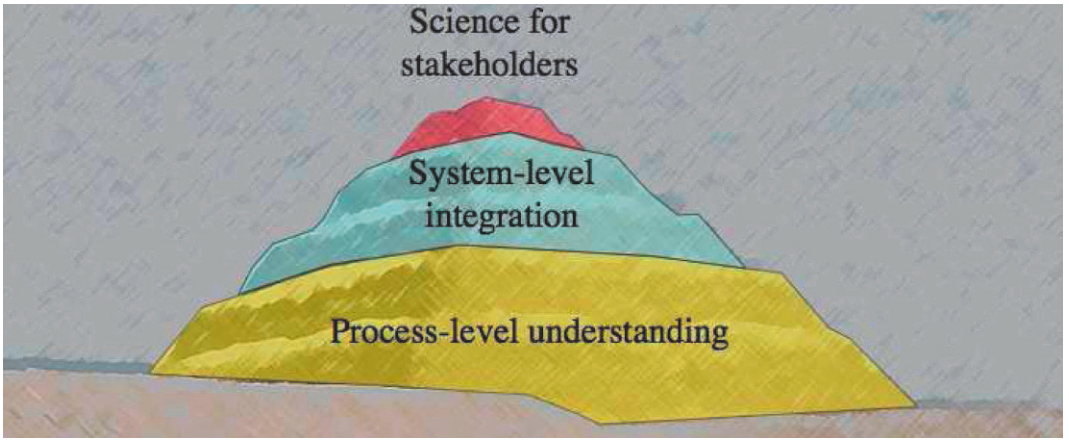
1. Robust decision support *requires* having a foundation of basic process-level research. Without this support, the risk of making incorrect (and ill-informed) decisions is much greater;
2. System-level integration and analysis is necessary for decision support, since the Earth system behaves as a tightly coupled human-environmental system;
3. The volumes of each of the layers are roughly proportional to the number of people and the amount of resources that need to be expended in each of the different endeavours.

We still must concentrate on first class science involving the interactions and feedbacks between biological, chemical and physical processes and human systems. However, scientists, resource managers and policy makers require a common understanding in order for their interactions to be mutually beneficial.

77.3.2 The IGBP Structure

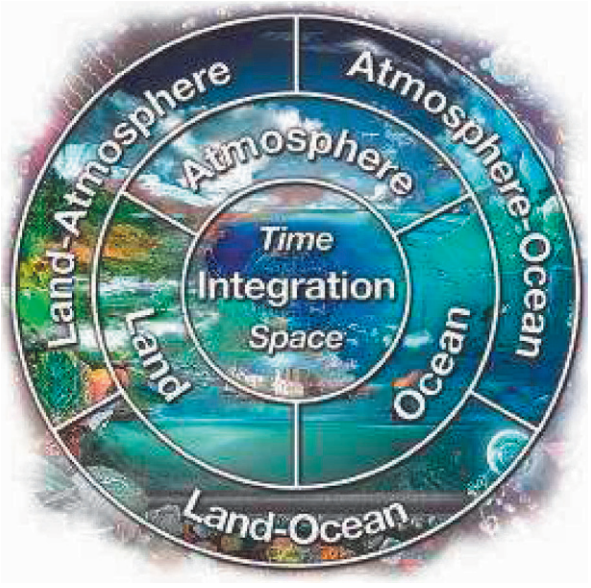
Given the need for investigating interactions and feedbacks between biological, chemical and physical processes and human systems, what sort of support struc-

Figure 77.2: Linking process understanding with decision support.



ture is needed? The support and organizational structure to fill these needs should facilitate international, multidisciplinary research. It should engender and enable connections between domain-oriented research efforts. It should combine observational and modelling approaches. IGBP has attempted to respond to these needs by taking on a structure depicted in figure 77.3.

Figure 77.3: The current structure of IGBP. The projects of IGBP focus on the main reservoirs (atmosphere, land, ocean), the interfaces between the reservoirs, and projects that integrate across time, space, and domain.



IGBP is organized around nine projects. Three look at processes affecting the main physical and biogeochemical reservoirs in the earth system: the *International Global Atmospheric Chemistry* (IGAC) project concentrates on the atmosphere; the *Global Land Project* (GLP) at terrestrial systems; and the *Global Ocean Ecosystem Dynamics* (GLOBEC) and *Integrated Marine Biogeochemistry and Ecosystem Research* (IMBER) projects look at the marine domain (the GLOBEC project formally ended in 2009). Three projects examine the interfaces between these reservoirs: the *Integrated Land Ecosystem-Atmosphere Processes Study* (iLEAPS) looks at the land-atmosphere interface; the *Land-Ocean Interactions in the Coastal Zone* (LOICZ) project examines the land-ocean interface; and the *Surface Ocean Lower Atmosphere Study* (SOLAS) project concentrates on the atmosphere-ocean interface. The two remaining projects are even more broadly integrative in nature. The *Past Global Changes* (PAGES) project tries to understand the Earth's environment in the past in order to enable predictions into the future, and the *Analysis, Integration and Modelling of the Earth System* (AIMES) project looks at the processes driving global biogeochemical cycling (including human activities) at many scales, both in the past and into the future.

This suite of tightly coupled projects mirrors the tightly coupled earth system. The coupling allows for a good deal of cross-fertilization between areas, and enables a holistic approach to understanding how the earth system works. In addition to the projects, IGBP sponsors *fast track initiatives* – activities intended to cross over several of the project subject areas and to allow us to identify and analyze horizon issues in earth system science. These initiatives are aimed at producing timely synthesis articles for leading journals; e.g., (Diaz/Lavorel/Bello/Quétier/Grigulis et al. 2007; Duce/LaRoche/Altieri/Arrigo/Baker et al. 2008).

PAGES		<http://www.pages.unibe.ch/>
AIMES		<http://www.aimes.ucar.edu/>

In many cases, IGBP projects and activities are co-sponsored and supported by partner organizations. These partnerships are both necessary and extremely valuable in terms of being able to approach complex issues relating the coupled human-environment system (table 77.1). Each project has developed a science plan and implementation strategy describing the projects goals and approaches.

While the list of acronyms may appear daunting, it does illustrate a few salient points:

- A wide range of both natural and social science disciplines and collaborations are necessary in order to build a holistic, 'big picture' view;
- No single organization is able to effectively support and sponsor this wide range of activities;
- The scientific community has become ever more connected in its attempts to learn about and predict the behaviour of the coupled human-environment system.

Form should follow function; the organizational structure should facilitate and not obstruct integrative, international, multidisciplinary research. The following section shows examples of this kind of science, and of how it is facilitated.

77.3.3 IGBP Products

In addition to the many scientific papers published as a result of centrally-coordinated activities or the work of scientists involved in IGBP projects, IGBP produces a suite of products aimed at different target audiences: the scientific community, the education sector, managers and funders, and the media. These are available via the 'Resource Room' at the IGBP website. One example of products aimed at the scientific community is the IGBP synthesis book series. A major synthesis activity was carried out at the end of the first phase of IGBP that led to a series of books published by Springer (table 77.2).

Presentation material about GEC issues (and about IGBP's approach) is available for the education community from the IGBP website, as are reports and popular science articles. Press releases are developed for the media, and are available for download.

IGBP has recently developed a 'climate change index' that brings together the key parameters from the atmosphere, ocean and cryosphere: atmospheric carbon dioxide levels – the main driver of change – global surface temperature, sea-level rise and summer arctic sea-ice extent. In doing so the index provides a compelling snapshot of which direction the Earth system is heading, and how fast.[4] Finally, IGBP produces annual reports about its yearly activities for managers and funders. These reports include science highlights, activity reports, and a budget summary.

77.3.4 Applied Earth System Science

In the pyramid metaphor, *applied* earth system science would be the apex. It would be the framework with which increases in our knowledge are converted of how the earth system works into information that can be of practical benefit to humankind. Actors in the policy, private, regulatory and other sectors are increasingly in need of assessments of the risks and op-

4 IGBP will publish the index annually and promote it to policymakers, government departments, the public, the media, and other organizations. It will be available on the IGBP website and as a PowerPoint slide, with easy access to the underlying data.

portunities presented by GEC. They need information in digestible form in order to be able to evaluate and manage risks, compare options, and evaluate the potential consequences of decisions. This kind of information requires the involvement of these sectors, and necessarily needs to involve the natural and social sciences throughout the process of knowledge generation. Within IGBP, the AIMES project is leading the development of a programme-wide effort to develop applications of earth system science. As a comprehensive set of examples of applied earth system science is beyond the scope of this chapter, two examples are presented as illustrations of the concept.

77.3.4.1 Marine Ecosystem Dynamics and Fisheries Management

Roughly 1 billion people worldwide are dependent on fish as their primary source of protein, yet about 75 per cent of global fisheries are over-fished or at their biological limit. Clearly, a sustainable global fishing industry requires understanding the end-to-end processes controlling the entire marine food chain (the entire chain from nutrient inputs to top predators), as well as how different management approaches influence the marine environment – ranging widely from e.g., regulations on agricultural fertilizer use, land use regulation in semi-arid regions and desertification, all the way to regulations on the catches of specific marine species. The combination of work carried out in the IGBP marine projects is a good illustration of attempts to achieve this truly end-to-end research. Work within the GLOBEC project has shown that changes in Arctic climate have contributed to shifts in the abundance and seasonality of many species of organisms in the northwest Atlantic Ocean (Greene/Pershing 2007). Further work has used a coupled physical, biophysical and ecosystem model to predict past and future cod production in the North Atlantic (Svendsen/Skogen/Budgell/Huse/Stiansen/Adlandsvik/Vikebø/Asplin/Sundby 2007), predicting increased cod recruitment for this region in 2007–2008. This kind of understanding and predictive tools will be of great use for understanding and assessing how climate change and human activities will impact marine ecosystems and food production.

77.3.4.2 Nitrogen and Sustainability

Humans have had a huge impact on the amount of nitrogen flowing through the earth system. In the century between 1890 and 1990, the total amount of reactive nitrogen created by human activities increased nine fold (Galloway/Cowling 2002)). However, the production of reactive nitrogen is far from uniform. In many developing countries, a persistent lack of nitrogen fertilizer has exacerbated food insecurity and continuing land degradation, while many developed countries have been challenged with pollution due to excessive nitrogen, including aquatic euthrophication and the loss of terrestrial biodiversity.

A major global management issue is how to optimize the use of nitrogen to promote human well-being, and at the same time minimize the negative impacts of nitrogen on the environment. The *International Nitrogen Initiative* (INI) was established in 2003 (<http://initrogen.org>) to address these challenges, and was helped on its way through an IGBP fast track initiative. The INI focuses on a) the production and assessment of basic knowledge on the production and distribution of reactive nitrogen, b) developing management solutions for regions with an un-

Box 77.1: Excerpts from the Cape Town Declaration. **Source**: <http://www.igbp.net/page.php?pid=415>. .

Attainment of global sustainability in an interconnected world is only possible through coordinated, collective and cooperative efforts by all peoples. The path to sustainability will be different for different parts of the earth, as a result of their history and environmental circumstances. The developing world has the opportunity to attain wellbeing of individual citizens without compromising the integrity of their natural environments. Likewise others, such as the developed world, must find effective ways to contribute to global sustainability. Science has a fundamental role in helping to realize these opportunities. ...

The participants of this Congress commit to work together to pursue science that will aid us in achieving sustainable development of our common, global resources. We commit

- To build upon the successes we have had of constructing a scientific infrastructure that brings together scientists from many nations, disciplines and backgrounds, from across the natural and social sciences;
- That we use this human and intellectual capital to build the next level of scientific infrastructure that is necessary to understand and predict the behavior of coupled human-environmental systems;
- That the framework for this scientific infrastructure be built around the ideas of sustainability and ethical global stewardship of the Earth System;
- That we challenge ourselves with using the understanding that we develop about these coupled systems as the scientific basis for assessments and communication of the options risks, vulnerabilities and possibilities for future sustainable development of our planet.

der- or over-abundance of nitrogen and c) developing engineering and policy tools to implement such solutions. For example, Galloway and Cowling (2008) suggest four interventions that could lead to a reduction in about 28 per cent of the amount of reactive nitrogen created in 2005. These include 1) controlling NO_x emissions from fossil fuel combustion; 2) increasing the nitrogen uptake efficiency of crops; 3) improving animal management strategies; and 4) building and improving urban sewage treatment facilities.

Besides direct anthropogenic production of reactive nitrogen, other human activities have had significant influence on the global nitrogen cycle. Duce, LaRoche, Altieri, Arrigo, Baker and co-authors (2008) showed that anthropogenically-produced atmospheric nitrogen could account for around one third of the ocean's external (non-recycled) nitrogen supply and up to three per cent of the annual new marine biological production. An important consequence of this anthropogenic fertilization of the oceans is the conclusion that from 1860 to the present, this deposition has led to a ten-fold increase in *nitrous oxide* (N_2O) emissions from the oceans. While anthropogenically-stimulated biological production in the oceans temporarily reduces atmospheric CO_2 concentrations, the emission of N_2O partially offsets the cooling due to reduced CO_2. Knowing the nature and magnitude of these competing effects will allow better judgments to be made regarding the efficacy and utility of biological carbon sequestration in the oceans.

77.4 Future Directions

These two examples illustrate how IGBP is moving from facilitating basic research into the functioning of the earth system into framing this new discovery research in ways that will be of more direct use to stakeholder communities. These efforts are entirely consistent with two of the recommendations of a recent international review of IGBP: a) developing priorities for the IGBP that are question- and problem-based; and b) maximize the scientific, policy and practice impacts of IGBP research. IGBP's future development will also be influenced by the 'visioning' process currently underway in our parent organization, the *International Council for Science* (ICSU).

In this regard, the strategic development of IGBP will include:

- Continuing the basic, international, multidisciplinary discovery research into the processes driving earth system dynamics;
- Organizing and conducting this research with increasing attention given to the end uses and end users of this new knowledge – building an *applied* earth system science;

These characteristics were nicely expressed in the 'Cape Town Declaration' (box 77.1), developed at the Fourth IGBP Congress on "Sustainable Livelihoods in a Changing System" in Cape Town, South Africa in May 2008. Achieving the commitments of the Cape Town Declaration is the centre piece of IGBP's plans for the future.

78 Climate Information for Coping with Environmental Change: Contributions of the World Climate Research Programme

John A. Church, Ghassem R. Asrar, Antonio J. Busalacchi and Carolin E. Arndt

78.1 Introduction[1]

Every day climate variability and change shapes the world, including the natural environment and its biodiversity on which society depends for water, food and other ecosystem services. Since the evolution of *homo sapiens* about 200,000 years ago, it is only in the last 10,000 years that we have moved from a hunter-gatherer existence to our modern society with its critical dependence on agriculture and exploitation of natural resources at an ever increasing rate. The relatively stable climate during the Holocene was an important component in making this transition possible (Burroughs 2005).

To provide the scientific basis for the provision of climate information that society has become increasingly dependent on, the *World Meteorological Organisation* (WMO), the *International Council for Science* (ICSU) and the *Intergovernmental Oceanographic Commission* (IOC) agreed to sponsor the *World Climate Research Programme* (WCRP). Since its inception, the two major objectives of the WCRP have been to determine a) the predictability of climate, and b) the effect of human activities on climate.

WCRP completes research projects designed to improve our knowledge of the climate system. It also develops observational programmes and models for knowing how climate has and is changing and how it is likely to change in the future. This information forms an essential scientific basis for the Intergovernmental Panel on Climate Change assessments (IPCC, 2007) which in turn help society respond to the threats and challenges and overcome the vulnerability and risks associated with global climate and environmental change.

This chapter outlines the links between climate and society (78.2), requirement for useful climate information (78.3) and establishment of the WCRP (78.4). Then progress in addressing these issues over recent decades is reviewed (78.5) and challenges and opportunities for the future (78.6) and the strategy for the next decade (78.7) are discussed, drawing on the *World Climate Research Programme Strategic Framework 2005–2015* (2005) and the *WCRP Accomplishment Report 2007–2008* (at: <http://wcrp.wmo.in>). Part 78.8 draws some general conclusions and highlights the policy relevance of the WCRP's achievements.

78.2 Climate and Society

Today, climate not only impacts on food and water supplies but it also has major impacts on human health, business, the economy and our society (figure 78.1). While our increasing mastery of technology and exploitation of energy reserves has given us some limited ability to adapt to climate variations and the associated environmental change, the burgeoning population of the world, increasing urbanization and the increasing demand we are making on our environment means that we are also becoming increasingly vulnerable to changes in climate, particularly as felt through extreme events such as floods, droughts, and other climate phenomena. These impacts are felt by the poorest of the poor struggling against drought or floods to the most well off in rich western nations devastated by the impact of events such as temperature extremes, hurricanes and storm surges. Failure to

1 This chapter is a contribution to the CSIRO Climate Change Research Programme and Wealth from Oceans Flagship and was supported by the Australian Government's Cooperative Research Centres Programme through the Antarctic Climate and Ecosystems Cooperative Research Centre. JAC was partly funded by the Australian Climate Change Science Programme. The authors are grateful for the sustained support and sponsorship of WCRP for the past 30 years by the WMO, ICSU and UNESCO/IOC, and for the long-standing voluntary efforts of the scientific community.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_78, © Springer-Verlag Berlin Heidelberg 2011

Figure 78.1: Human well-being and local economies are severely affected by droughts and floods. Tropical storms and in particular, the torrential rains and high wind speeds associated with them, cause damage to lives and properties in the order of tens of billions US$ worldwide. **Sources:** Photos clockwise from top left: J. Isaac: <FAO/13702/J.Isaac>; NASA: <www.travelblog.org/Rich>; SanSan Samuel: <www.freedigitalphotos.net/>, J. Barker Free Digital Photo; Texas Forest Service by Jan Amen.

adequately plan for and respond to these climatic changes leaves society vulnerable to the impacts of disasters and conflict, and the associated security risks.

Examples of the sectors critically impacted by climate include:

- *Agriculture* is vital in all parts of the globe and in many developing nations' accounts for over 50 per cent of GDP (World Bank 2008). In 2007, the number of undernourished people was approaching 1 billion. Large changes in productivity occur in response to interannual climate variations. Famine is all too often the result of the deadly combination of drought and war. Exploiting the good years and preparing for the bad years are both important.
- *Potable water* is a critical resource and today about one in six people worldwide, that is 0.9 billion people, lack access to clean water (UNICEF/WHO 2008). Water is also an important as an energy source, the extremes of which in the form of drought and floods also impact on agricultural productivity and the natural environment.
- *Health risk* from vector borne disease such as diarrhoe and malaria from which about 2 million peo-

ple died in 2008 (WHO 2008) is directly related to climate variations and indirectly to climate through availability of food and water. Human health is also impacted by extreme temperatures such as heat waves and cold snaps.

- *Temperature variations* affect the demand for energy for heating and cooling and also affect the efficiency of power plants. Renewable energy from hydro, wind and solar power are all sensitive to climate variations and change.
- *Tourism*, an important industry for developed and developing nations, will only flourish with good weather and climate conditions (UNWTO 2008).
- *The marine environment*, as a major source of protein, a haven for tourists and its role in transport is also directly impacted by climate variability and change (see for example http://www.millenniumassessment.org/en/index.aspx).
- *Civil infrastructure*, in the form of dams, roads, bridges and ports, built to last several decades, is vulnerable to changes in climate on these same time scales.
- *Banking and reinsurance* are impacted by damage from severe weather/climate events such as prolonged droughts or severe floods, temperature extremes and through economic conditions related to climate.
- *The natural environment* is under many sources of stress, with climate variability and change adding significantly to these, leading to desertification and rapid losses in biodiversity (see for example http://www.millenniumassessment.org/en/index.aspx).

Climate phenomena are many and varied. Hundreds of millions of people are affected by the monsoons of South and East Asia, Africa and the Americas. Sudden and severe onset of the monsoon can bring devastating floods and major loss of life. Failure of the monsoons bring drought and famine to millions. El Niño events and the associated droughts and floods affect nations surrounding the Pacific Ocean and more distant parts of the globe.

Perhaps the most important issue of our times is climate change resulting from the burning of fossil fuels. It will have far reaching and long lasting impacts on the natural environment and virtually every aspect of our existence on the Earth. Some aspects of climate change are clear – rising temperatures, changing rainfall patterns and rising sea level. But at what stage should climate change be considered 'dangerous'; for example will we cross a threshold leading to a disintegration of the Greenland and West Antarctic Ice Sheets and a sea-level rise of metres making many people stateless. These impacts are potentially severe, affecting the whole globe, the lives of many millions and even the viability of some nations. Clearly these changes will directly affect human welfare, peace and security, as recognized by the award of the 2007 Nobel Peace Prize to the *Intergovernmental Panel on Climate Change* (IPCC) and Mr Al Gore.

It is becoming increasingly clear that many of these climate variations are felt most acutely through extreme weather events such as heat waves, cold snaps, sustained drought, hurricanes and typhoons. The frequency and intensity of these events are directly related to interannual and decadal variations in climate as well as longer-term changes in climate. Perhaps the clearest example is the intense hurricane activity in the Caribbean region and the southern United States of America in recent years. To understand what is happening to climate and why, and to effectively predict future conditions and their impact, we have to recognize the connection across the time scales from extreme events through seasonal and decadal climate variations to centennial climate change. Similarly, we have to consider the range of space scales; all impacts of climate are local but they occur in a global climate system, with individual events sometimes related to conditions on the far side of the world; climate is a global issue with regional and local consequences.

Today, knowledge of how weather varies and predictions of tomorrow's weather are important to our everyday life and a wide range of businesses. Accurate predictions are critical to avoiding disasters that can occur in response to extreme events. Similarly, knowledge of seasonal to interannual variations in climate, including improved predictions in many regions and sectors, are proving increasingly valuable for agriculture, fisheries, water supply management and in some regions for minimizing the impacts of diseases such as epidemic malaria.[2] Projections of climate change have already had and are continuing to have a huge impact on society. Agreeing to appropriate mitigation and adaptation strategies in response to human induced climate change is a huge challenge for society. Robust climate science is required to respond to this challenge. However, there remains uncertainty in both the

2 See: Palmer/Alessandri/Andersen/Canteloube/Davey/Délécluse/Dequé/Diez/Doblas-Reyes/Fedder-sen/Graham/Gualdi/Guérémy/Hagedorn/Hoshen/Keenlyside/Latif/Lazar/Maisonnave/Marletto/Morse/Orfila/Rogel/Terres/Thomson (2004).

short-term predictions of seasonal climate variations and the long-term projections of climate change, particularly at the regional and local scale where decisions about adaptation are made. Much of our current planning is for developments and infrastructure for the next few decades. On these time scales, both the signal of natural variability of climate and the change of climate in response to changes in greenhouse gas concentrations are important. Demonstrated skill in predicting the natural decadal variability in climate is urgently needed.

If the challenges facing society are to be adequately confronted and overcome, sustainable development is to be accomplished and the United Nation's *Millennium Development Goals* (MDGs) achieved, society urgently needs robust climate science. This requires understanding of what is happening now to our climate, and what will happen over coming seasons, years and decades to centuries. Such information is critical to underpinning peace and security in the world.

There are three major challenges in the climate arena:

- *Improving our prediction of short term climate variability*. This includes improved observations and understanding of climate variability, extending the geographical range and the lead time of useful predictions. Specific issues to address include for example the timing and onset of monsoons, break periods in the monsoons, the next season's and year's rainfall and temperatures.
- *Reducing the uncertainty of projections of climate change, particularly at the regional and local scale*. Society needs robust prediction of how and why present climate is evolving, how phenomena such as the monsoons and *El Niño/Southern Oscillation* (ENSO) will change, how quickly sea level will rise, what long-term changes we are committing future generations to, what climate variations might be termed 'dangerous' and thus what are the appropriate long-term greenhouse gas stabilization levels.
- *Developing the capability to make decadal predictions of climate variations*. On decadal time scales, both natural climate variability and anthropogenic climate change are important. This is a new and developing area.[3]

All of these three challenges are closely related and felt most acutely through extreme events. It is essential to take a holistic view of the climate system if societies' demand for sound climate information is to be satisfied.

An additional and equally important challenge is building two-way communication between the climate science community and the many and varied stakeholders. This communication is required to ensure that progress in the science is exploited for the benefit of society and the environment and to ensure the development of sound international and national climate policy. This policy and societal relevance also provides a greater focus for climate science itself.

78.3 Requirements for Useful Monitoring and Prediction of the Climate System

Climate varies on all time scales, from seasons to years, decades, and a century and longer. Adequately understanding and predicting it requires consideration of the sun, the atmosphere (including its chemical state and both the troposphere and the stratosphere), the hydrosphere, the oceans, the terrestrial regions, the cryosphere, the biosphere and the interactions between all of these spheres and with society.

Monitoring climate and thus knowing how the current state differs from previous climate condition, and why it differs, is in itself valuable for decision making by society. Beyond the time-scale of weather forecasts, the ability to predict climate depends on the behaviour of the parts of the climate system with a longer 'memory' of past conditions (including the oceans, the biosphere, and the cryosphere) and variation in the 'forcing' of climate by both natural and human-induced factors. These 'forcings' include variations in the radiation received from the sun, changes in aerosols in the stratosphere as a result of violent volcanic eruptions, changes in the properties of the land surface as a result of natural variations (for example changes in snow cover) and also human activities (for example deforestation). Perhaps most importantly in recent decades and for the coming century are increases in the concentration of greenhouse gases in the atmosphere that trap some of the outgoing long-wave radiation and thus heat the earth.

Significant advances have been made in quantitative predictions of the climate system over coming

3 Meehl/Goddard/Murphy/Stouffer/Boer/Danabasoglu/Dixon/Giorgetta/Greene/Hawkins/Hegerl/Karoly/Keenlyside/Kimoto/Kirtman/Navarra/Pulwarty/Smith/Stammer/Stockdale (2009).

seasons. These predictions are dependent on the current state of the climate system and thus it is critical to have comprehensive observations if we are to accurately predict climate. Projections of climate on time scales of decades to centuries and longer are less dependent on the initial state of the climate system but they are critically dependent on the evolution of all components of the climate system, including those slowly evolving components. Observations and the understanding of the climate system are critical to the development and testing of models needed to accurately simulate climate on all time scales.

To be valuable, climate predictions need to include uncertainty estimates that can be obtained by performing an ensemble of predictions with slightly different estimates of the climate system at the start of the prediction and/or slightly different model parameters, and by rigorous comparisons with observations. The quantities predicted include the means, trends and statistical characteristics of a large number of quantities that may be of practical use, such as surface temperature, wind, precipitation, atmospheric chemical state, ocean state, soil moisture, snow cover, sea ice, and the state of the El Niño-Southern Oscillation and other climate phenomena. The time-scales for the predictions range from weeks to decades and to the projections of climate change over decades to centuries.

78.4 Recognizing the Need – Establishment of the World Climate Research Programme

The first World Climate Conference in 1979 focussed on the relationship between climate and humankind.[4] The Conference recognized the importance of climate variability, the impact of extreme events and the potential for climate change to impact on all aspects of society. As a result, the Conference called for the establishment of the *World Climate Research Programme* (WCRP) as a principal component of the *World Climate Programme* (WCP). The WCRP was initially (since 1980) sponsored jointly by the *World Meteorological Organization* and the *International Council for Science*. The *Intergovernmental Oceanographic Commission* of UNESCO also established a climate programme in the 1980's. In 1993, these two activities were merged with WCRP, now jointly sponsored by WMO, ICSU and IOC.

A WMO/ICSU/IOC *Joint Scientific Committee* (JSC) is responsible for formulating the overall scientific concepts and goals of the WCRP and for organizing the required international co-ordination of research efforts. The activities of WCRP are organized through a series of projects and working groups and increasingly through integration across the full spectrum of WCRP activities. WCRP is supported by its Joint Planning Staff and the individual projects are supported by International Project Offices.

Since its inception, the two major objectives of the WCRP have been to determine a) the predictability of climate, and b) the effect of human activities on climate. To achieve these objectives, the WCRP promotes and coordinates essential research into understanding the behaviour of the various components of the climate system and their interactions, and their relations to the broader Earth system and the needs of society. Particular foci of WCRP include:

- improving the knowledge and understanding of global and regional climate variability and change, and of the mechanisms responsible;
- assessing the evidence of significant trends in global and regional climates;
- developing and improving numerical models capable of simulating and assessing the predictability of the climate system over a wide range of space and time scales and suitable for operational predictions;
- investigating the sensitivity of the climate system to natural and human-induced change.

These objectives were reaffirmed at the *Conference on the WCRP: Achievements, Benefits and Challenges* in Geneva in August 1997 (WMO 1998), with the immediate research priorities:

- to assess the nature and predictability of seasonal to interdecadal variations of the climate system at global and regional scales, in order to provide the scientific basis for operational predictions of these variations for use in climate services in support of sustainable development;
- to detect climate change and attribute causes, and project the magnitude and rate of human-induced climate change, its regional variations and related sea-level rise, as needed for input to the WMO/UNEP *Intergovernmental Panel on Climate*

4 This conference was organized by the *World Meteorological Organization* (WMO), the *United Nations Educational, Scientific and Cultural Organisation* (UNESCO), the *Food and Agriculture Organisation* (FAO), the *International Council for Science* (ICSU) and the *World Health Organisation* (WHO).

Change (IPCC), the *United Nations Framework Convention on Climate Change* (UNFCCC), and other such Conventions.

WCRP now includes comprehensive investigations of all elements of the physical climate system (atmosphere, hydrosphere, oceans and cryosphere) and in partnership with the *International Geosphere-Biosphere Programme* (IGBP; chap. 77 Noone/ Nobre/ Seitzinger) and other international programmes chemical and biological components of the earth's climate system. WCRP's focus also includes the development of appropriate models for understanding the climate system, the rigorous testing of these models and their experimental use for prediction and projection on longer time scales of the climate system.

A critically important partnership is with the *Global Climate Observing System* (GCOS) and the *Global Earth Observations System of Systems* (GEOSS), to ensure the collection of sustained observations necessary for monitoring climate variability and change, understanding trends, and initializing models for the prediction of climate.

78.5 Addressing the Challenge: Achievements of the World Climate Research Programme

This section offers a brief overview of the achievements of WCRP since its formation.

78.5.1 Seasonal Climate Predictions

A number of centres around the world now produce regular predictions of climate conditions for the coming few seasons as a result of progress by the *WCRP Tropical Ocean-Global Atmosphere* (TOGA) Project (1985-1994) in understanding of tropical Pacific climate anomalies associated with the *El Niño-Southern Oscillation Phenomenon* (ENSO). This was a major breakthrough in climate forecasting and the TOGA project is widely recognized as being the first major success of the WCRP. The two most critical elements of the legacy of TOGA (Anderson/Sarachik/Webster 1998) are:

- An enhanced in situ and satellite observing system in the Pacific Ocean to monitor the evolution of El Niño events and to initialize models, and
- Coupled models capable of assimilating the observed data and providing useful predictions of conditions for the next few seasons in a number of regions of the world.

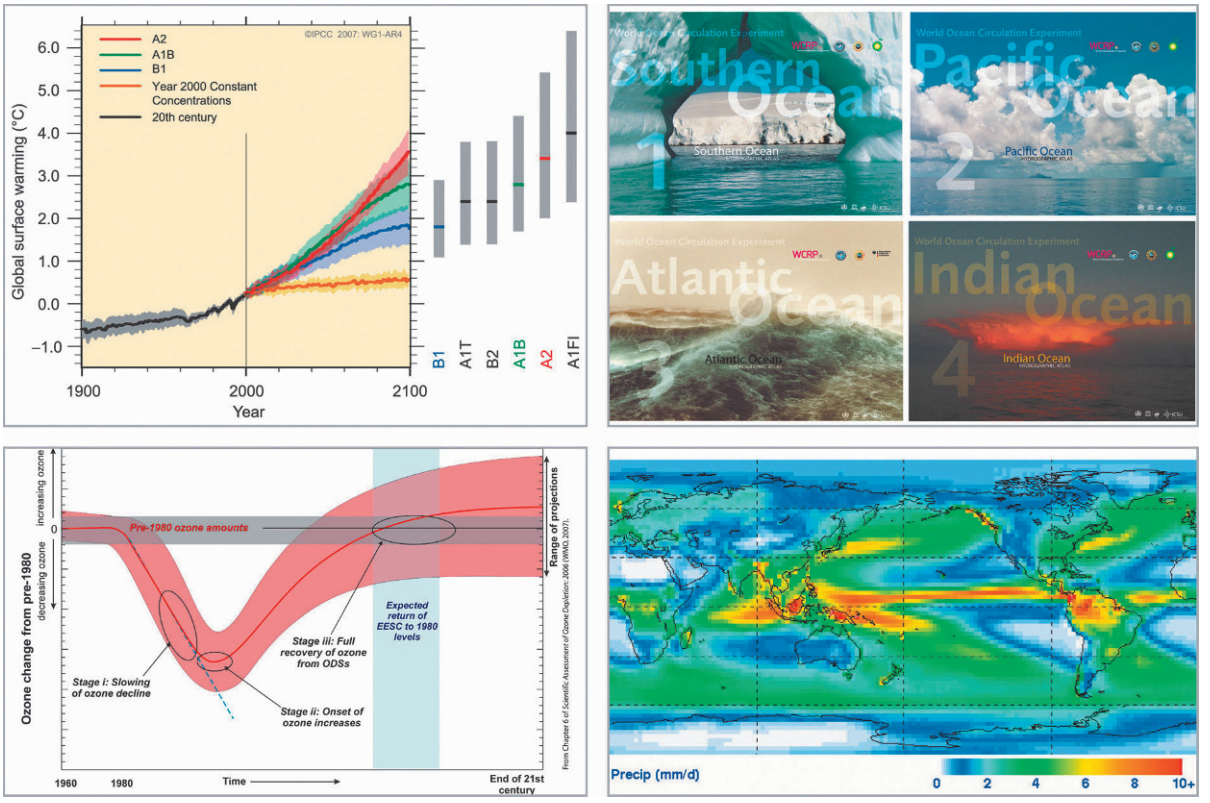
Through ongoing and increasingly integrated efforts of WCRP projects (CLIVAR, GEWEX, ACSYS/CliC, and SPARC), the skill of these models is increasing as the in situ observing systems are extended to other regions, improved satellite observing systems are implemented, greater understanding of associated processes such as the monsoons is achieved and the models are improved. The capability developed by the WCRP and now operational in a number of centres around the world are finding increasing application in a wide range of phenomena (for example minimizing the impact of epidemic malaria[5], and a greater appreciation of their potential is recognized (WCRP 2008d).

78.5.2 Understanding, Observations and Models of the Ocean and Climate

The *World Ocean Circulation Experiment* (WOCE 1990–2002) completed the first set of global observations of the ocean (as documented in a four-volume WOCE Hydrographic Atlas, top right panel of figure 78.2) and thus the first quantitative assessment of the ocean circulation's role in climate. WOCE also developed ocean observing systems (both *in situ* and satellite-borne) and led to improved ocean models that are now proving critical to improved projection of climate variability and change. The WOCE survey established a baseline to assess changes in time and to evaluate anthropogenic effects on the global ocean circulation. In partnership with the *Joint Global Ocean Flux Study* (JGOFS), a CO_2 and tracer chemistry survey was completed allowing robust documentation of the oceanic uptake of CO_2. Developments in float technology during WOCE led to the Argo programme; the global deployment of an array of profiling floats to measure temperature and salinity profiles in the upper 2 km of the ocean. Experimental devices such as gliders have the potential for performing repeat sections in historically difficult to observe regions of the ocean, such as western boundary currents. These developments (particularly Argo) are now central observational components that underpin the development of climate prediction on decadal time scales and

5 See: Palmer/Alessandri/Andersen/Canteloube/Davey/Délécluse/Dequé/Diez/Doblas-Reyes/Fedder-sen/Graham/Gualdi/Guérémy/Hagedorn/Hoshen/Keenlyside/Latif/Lazar/Maisonnave/Marletto/Mor-se/Orfila/Rogel/Terres/Thomson (2004).

Figure 78.2: Illustrative examples of WCRP accomplishments. Clockwise from top left: Projection of global averaged temperature for the 21st century as prepared for the IPCC AR4 using the WCRP *Coupled Model Intercomparison Project* results (IPCC 2007); The four ocean atlases produced by the WCRP *World Ocean Circulation Experiment*; Average global precipitation for 1979-2005 in mm per day (figure prepared by the WCRP-GEWEX Global Precipitation Climatology Project); Schematic observed and predicted evolution of global ozone (UNEP/WMO Scientific Assessment of Ozone Depletion: WMO 2006).



are critical in reducing uncertainties in the projection of climate change. The results are documented in almost 1800 refereed publications and summarized in Siedler, Church and Gould (2001). Much remains to be done in the exploitation of WOCE observations and in the further development of schemes to assimilate data into ocean models. These aspects of ocean research and model development are now being incorporated, as planned, into the WCRP *Climate Variability and Predictability* (CLIVAR) project, a successor to the TOGA and WOCE projects.

78.5.3 Snow, Ice, Frozen Ground and Climate

As demonstrated by the dramatic reduction in sea ice over the past few years, the Arctic region is both important for its role in climate and as a sensitive indicator of the impacts of climate change – how delicately balanced is the Arctic climate system? What is its role in global climate change? The achievements of the WCRP *Arctic Climate System Study* (ACSYS) Project provided: a basis for improved numerical simulations and reanalysis studies of the complex system involving polar atmosphere, oceans, sea-ice, and land; active development of an Arctic observing system, declassification of submarine sea-ice observations, generation of new satellite products, and collection and upgrading of circumpolar data sets; intercomparison projects which have led to advances in modelling of the polar environment and created a better basis for projections of amplified impact of the climate change in the polar region (an important aspect of the IPCC assessments). These studies have now been extended world wide to include considerations of all aspects of the cryosphere (ice, snow, frozen land) through the ongoing WCRP *Climate and Cryosphere* (CliC) Project. An important example of which is the need for improved understanding of ice-sheet dynamics and the stability of the Greenland and Antarctic ice sheets in order to understand better the potential for extreme sea-level rise.

78.5.4 The Global Water Cycle

Water is a critical resource globally, especially in certain regions. Its representation in models is critical to reliable predictions of fresh water quantity, quality and distribution. Understanding its movement and recycling around the globe is a central focus of the ongoing WCRP *Global Energy and Water Cycle Experiment* (GEWEX) project. Accomplishments of GEWEX include global datasets of clouds, precipitation (bottom right panel of figure 78.2), water vapour, surface radiation, and aerosols which have provided new insights about seasonal, interannual and regional variability of fresh water. These data sets have underpinned implementation of improved representation of the land-surface and clouds in climate models and improved prediction of precipitation in many regional and global weather forecasting and climate models. On a regional scale, GEWEX scientists are making significant progress towards the full understanding of the regional water and energy budgets and are helping determine the importance of these processes for regional predictions of climate, thus enabling the comprehensive modelling and evaluation of the components of the water/energy cycle over large river basins.

78.5.5 The Stratosphere and Climate and Ozone

Trends in stratospheric temperature, vertical distribution of ozone, and upper tropospheric and stratospheric water vapour and their representation in models are an important focus of the ongoing WCRP *Stratospheric Processes and their Role in Climate* (SPARC) project and an important element of climate change.[6] WCRP SPARC has made major contributions to the WMO/UNEP assessments of ozone depletion and IPCC climate assessments (lower left panel of figure 78.2), and is now working with the *International Geosphere-Biosphere Programme* (IGBP; chap 77 by Noone/Nobre/Seitzinger) to significantly improve our knowledge of the representation of atmospheric chemistry and aerosols in the models that will be used for weather forecasting and climate prediction. These efforts thus continue to support the Ozone and IPCC Climate Change Assessments.

6 See: Ramaswamy/Chanin/Angell/Barnett/Gaffen/Gelman/Keckhut/Koshelkov/Labitzke/Lin/O'Neill/Nash/Randel/Rood/Shine/Shiotani/Swinbank (2001).

78.5.6 Climate Change Detection, Attribution and Projection

The vast majority of the results assessed by the IPCC Working Group I in its successive reports are based on observations, research and model projections organized and coordinated by the WCRP and the vast majority of authors are closely associated with WCRP. Indeed without the model simulations coordinated by the WCRP there would be no climate change projections (top left panel of figure 78.2). Such WCRP coordinated results are the basis of key conclusions of successive IPCC scientific assessments such as the 4th Assessment Report (AR4) conclusions in 2007: "Warming of the climate system is unequivocal" and "Most of the observed increase in global average temperatures since the mid-20th century is *very* likely due to the observed increase in anthropogenic greenhouse gas concentrations."

Improved understanding of key climate processes by WCRP has led to significantly improved climate and operational weather and ocean forecasting models. WCRP's working groups have co-ordinated data analyses and climate model simulations that are the basis for our understanding of natural climate variability. In particular, improved modelling of the coupled physical climate system through systematic model diagnoses and intercomparisons has provided increasingly accurate simulations and predictions of natural climate variations, reducing uncertainty in their projections of human-induced climate change. In turn, the IPCC assessments provide the most authoritative, up-to-date scientific advice needed to inform the *United Nations Framework Convention on Climate Change* (UNFCCC). In this way, WCRP has helped provide the direct policy-neutral scientific underpinning of the political process. WCRP will continue to play an important role in helping to provide increasingly reliable climate change scenarios and making them (and their likely consequences) immediately available to decision makers, the media and the general public. These are critical contributions to deliberations on sustainable development, formulating mitigation and adaptation strategies, and managing the risks associated with climate variability and change on all sectors of the global environment and economy.

78.5.7 Global Climate Data Sets

Comprehensive climate observations are essential to climate prediction. Knowing how climate is changing underpins many societal needs. Provision of essential

global and regional climate observations are major components of all WCRP projects. Some of these have evolved into new operational climate observations and data-collection systems. In particular: the buoy array in the tropical Pacific is crucial for monitoring and for initializing model predictions of ENSO events; systematic observations of the ocean's three-dimensional structure, combined with satellite altimetry have provided the basis for establishing key elements of a *Global Ocean Observing System* (GOOS) and, in turn, also the *Global Climate Observing System* (GCOS). Indeed, the worldwide network of operational ocean profiling floats (The Argo Project) is a direct outgrowth from the global array of subsurface floats that was established in WOCE. The TOGA and WOCE projects established a solid foundation for the operational oceanography of today, and tomorrow.

78.5.8 Historical Atmospheric and Oceanic Conditions

Modern atmospheric and oceanic models can be used to assemble comprehensive estimates of past conditions from the relatively sparse historical data sets. These estimates (called *reanalyses*) are important in understanding climate variations and change. WCRP has provided strong support for the initiation and execution of atmospheric reanalysis projects and such activities are now well established. Oceanic reanalyses have started in the last decade as a result of the WOCE and CLIVAR projects and will become increasingly important. These activities are a major outgrowth of the Third WCRP-sponsored *International Conference on Reanalysis* held in Tokyo, Japan, in January 2008 (WCRP 2008c).

78.5.9 Capacity Building

WCRP has enabled scientists from countries with less developed scientific programmes to contribute to the global programme and to build up their research capability. The global change *System for Analysis, Research and Training* (START) has been established by the *International Geosphere-Biosphere Programme* (IGBP), the *International Human Dimensions Programme on Global Environmental Change* (IHDP, chap. 75 by von Falkenhayn/Rechkemmer/Young), and WCRP, to foster capacity building activities in developing countries, and thereby help them to become partners in international global change research. WCRP also benefits greatly from its partnership with regional networks such as the *Asia-Pacific Network* (APN) and the *Inter-American Research Institute* (IAI) to strengthen further its capacity building activities.

78.6 Challenges and Opportunities

The progress that WCRP has made in understanding the earth's climate system during the past 30 years and technological developments (in observations, computers and information systems, and telecommunication delivery mechanisms such as the internet) are enhancing our capability to serve increasingly greater segments of world society. This, coupled with the ever-increasing demand for reliable climate predictions and related products and services to establish policies to safeguard life and property and to better manage climate-sensitive natural resources and human developed systems and sectors, provides exciting new challenges and opportunities for WCRP. The challenges include:

- *Moving from daily/weekly weather forecasts to monthly, seasonal and longer-time climate prediction.* There is now a blurring of the distinction between shorter-term predictions and longer-term climate change projections and an increasing interest in demand for climate predictions for the next decade. These predictions will require knowledge of the current observed state of the climate system, particularly of the oceans, cryosphere, and land surface (including soil moisture, vegetation, etc.). Centennial climate projections also depend on scenarios for anthropogenic influence on the climate system and other factors, such as changes in the sun and volcanic eruptions which are not predictable but can be immediately taken into account as observed. The shorter time-scales and weather are important in influencing the longer-time-scale behaviour and the regional impacts of longer-term changes will be felt by society most acutely through changes in the shorter time-scale variability, including extreme events. As a result, and to obtain the information necessary for adaptation at the regional and local scale, climate models are being run with the highest possible spatial resolutions, resolutions that were employed in the best weather forecast models only a few years ago.
- *Environmental prediction and services.* The detailed physical prediction models of the coupled atmosphere, ocean and land system developed and used within WCRP are increasingly being extended to include atmospheric chemistry, the car-

bon cycle including evolving vegetation, and interactive marine ecosystems. It can be expected that full coupling with additional components of the Earth system will sometimes lead to quite different behaviour, as has been found for coupled ocean-atmosphere models.

- *Predictability of the climate/Earth system.* An important underpinning of the progress in weather forecasting has been the development of chaos theory and the notions of predictability. An essential aspect of the move to making predictions of the broader climate/Earth system is to further develop these ideas to provide a firm foundation, giving ideas on what predictions to attempt and what techniques to use. The possibility that the increasing breadth of models may lead to compounding the uncertainties in them, and therefore increasing the uncertainty in model predictions, provides a challenge that will require new theoretical and observational approaches.
- *Analysis of climate system behaviour.* There is a continuing and urgent need to analyse the behaviour of the climate system, assess what has occurred, define anomalies and trends in the climate system, and determine the extent to which these can be attributed to human activity or to natural variation.
- *Application of WCRP science to socio-economic problems and demonstration of the usefulness of WCRP-enabled analysis and predictions.* There is increasing use of weather and climate information and prediction services and products on the time-scale of weeks to seasons, but much more work is needed to improve these products. For longer time-scales, the IPCC requires the best possible climate science and climate projections to provide the scientific basis for its periodic assessments and hence its advice to the Parties to the UNFCCC. Most impacts of climate change depend on its regional manifestation and there is great political and social demand for more confidence in assessments and predictions at regional and local scales.

The following developments mean that there is now a real opportunity to meet the above challenges and deliver vastly improved products to the wide range of stake-holders.

- *New and increasing data streams*. Enormous quantities of data are available from the environmental satellites (upper left panel of figure 78.3) already launched or planned. Also, the Argo system of ocean profiling floats (lower left panel of figure 78.3), developed under WCRP projects is becoming an increasingly important source of oceanographic data and an integral part of a developing ocean observing system for climate. These and other *in situ* data are being integrated under the framework of the *Global Earth Observation System of Systems* (GEOSS), in order to optimize information products and services. They must be turned into quality-controlled climate data sets, requiring continuing pressure for observational data of climate quality and the continuous knowledge of data calibrations. Adhering to uniform international standards must be maintained as the observing system evolves.
- *The growth and availability of computing power.* The computing power becoming available (lower right panel of figure 78.3) means that in the future there will be an ability to run global models with resolution of a few kilometres (as required for many practical applications), very large model ensembles to assess uncertainty, simulations of paleoclimates with fully coupled global climate models, and, increasingly, highly-resolved regional models in response to the demand to develop adaptation policies and measures at the regional level.
- *An increase in the number of groups using global models*. As a result of greater and heightened attention to climate issues, there are now more groups capable of running climate models thus allowing the use of multi-model ensembles to overcome systematic deficiencies in single-model ensembles. This also increases the necessity to document the variety of model performance and understand the reasons for it.
- *The increasing complexity and realism of climate models.* High-resolution models including detailed physical parametrizations, cloud-resolving capabilities, and other detailed representations of relevant climate processes are being developed.
- *Modern data assimilation techniques applied to the Earth system models*. Numerical weather prediction has shown that maximum value can be obtained from the various streams of data by analysing them together in prediction models that are sufficiently accurate. This framework allows optimal state assessment based on past as well as present data. In the process, valuable information on model deficiencies can be obtained. Such data assimilation will increasingly be possible for the components of the coupled climate system and for the wider Earth system.

Figure 78.3: Satellite observations and in situ measurements taken in the ocean, the atmosphere and on land provide the basis for weather forecasts and climate predictions. The vast amount of observations collected on a daily basis is processed and then assimilated into models using the new generation of powerful computers. Training seminars in different parts of the world make sure that the users and decision makers properly understand and interpret the climate information products, and that the scientists receive feedback on the usefulness of their products and the users' needs. 78.7 Delivering on the Promise: The Future Strategy of the World Climate Research Programme

The WCRP has recognized the need to refocus its activities towards its original two aims and respond to the increasing demands of policy-makers and society for accurate and reliable climate predictions. As a result, WCRP developed its *Strategic Framework 2005–2015, Coordinated Observation and Prediction of the Earth System*. The aim of this WCRP Strategic Framework is: "To facilitate analysis and prediction of Earth system variability and change for use in an increasing range of practical applications of direct relevance, benefit and value to society" (at: <http://wcrp.wmo.in>).

This aim builds on the two overall objectives of WCRP that have guided its scientific activities for the past 30 years to deliver the best available state of knowledge on climate variability and change to decisions makers, in a manner consistent with the challenges/opportunities associated with the prediction of weather and climate across all time and space scales.

To meet this objective and to fulfil the existing and emerging societal needs for the best available knowledge of climate variability and change WCRP must focus its activities and partnership on five critical elements: 1) enhance understanding of the earth's climate system including the complex interactions among the major components (i.e. atmosphere, oceans, continents including the polar regions), and human activities, across the full spectrum of space and time scales; 2) support the continuity and innovation in observing systems to capture, document and analyse the state of the climate system; 3) exploit the resulting observations/information in conjunction

with climate models to predict and project earth's future climate; 4) enable the development of a climate information system to serve both the providers and users of observations and information in a timely and effective manner; and 5) establish a global network of experts (upper right panel of figure 78.3) to take full advantage of these capabilities to develop the best knowledge of the climate system for use by global, regional and local decision makers.

The focus is on developing mitigation and adaptation policies, strategies and solutions for managing the risks and opportunities associated with climate variability and change on major economic sectors (e.g. agriculture and food, water resources, energy and transportation, health and leisure, etc.). Some of these elements and/or their major components may exist today, but equally important is their integration and management as a continuum of activities to ensure efficient and timely delivery of the intended climate services to society in an effective and efficient manner. Such an approach will help shorten significantly the transition time from research and development to operations and services, thus meeting the emerging societal needs more efficiently. In short, developing a set of governance and operational principles is as important as the scientific and technical challenges associated with building and operating the climate information system.

The WCRP Strategic Framework facilitates addressing of these five elements by:

- integrating across the breadth of WCRP's projects and their activities;
- addressing the new challenges;
- regularly reviewing and assessing progress towards achieving the WCRP aims;
- identifying the emerging scientific objectives/priorities and addressing them in a timely manner;
- guiding existing and stimulating new scientific activities within WCRP; and
- increasing recognition and visibility for the scientific and societal relevance and importance of WCRP results and their impact.

Partnerships are essential to the successful development and implementation of the climate information system. The broadening of WCRP interest in climate/Earth system studies is necessary for climate prediction and projection and implies the need for continued and strengthened collaboration with the *International Geosphere-Biosphere Programme* (IGBP), The *International Human Dimensions Programme* (IHDP), *DIVSERSITAS* (a biodiversity programme) and with the *Earth System Science Partnership* (ESSP) as a whole. The seamless nature of the prediction problem and of many of its applications implies that close collaboration and coordination are also needed with the WMO *World Weather Research Programme* and its projects such as THORPEX. Ensuring that WCRP-developed scientific knowledge is used in an appropriate and timely fashion for an increasing number of practical applications also requires close collaboration with the other principal components of the WMO World Climate and Water Programmes, and their network of providers and users of climate information, e.g *Regional Climate Outlook Forum* (RCOFs) and *Regional Climate Centres* (RCCs).

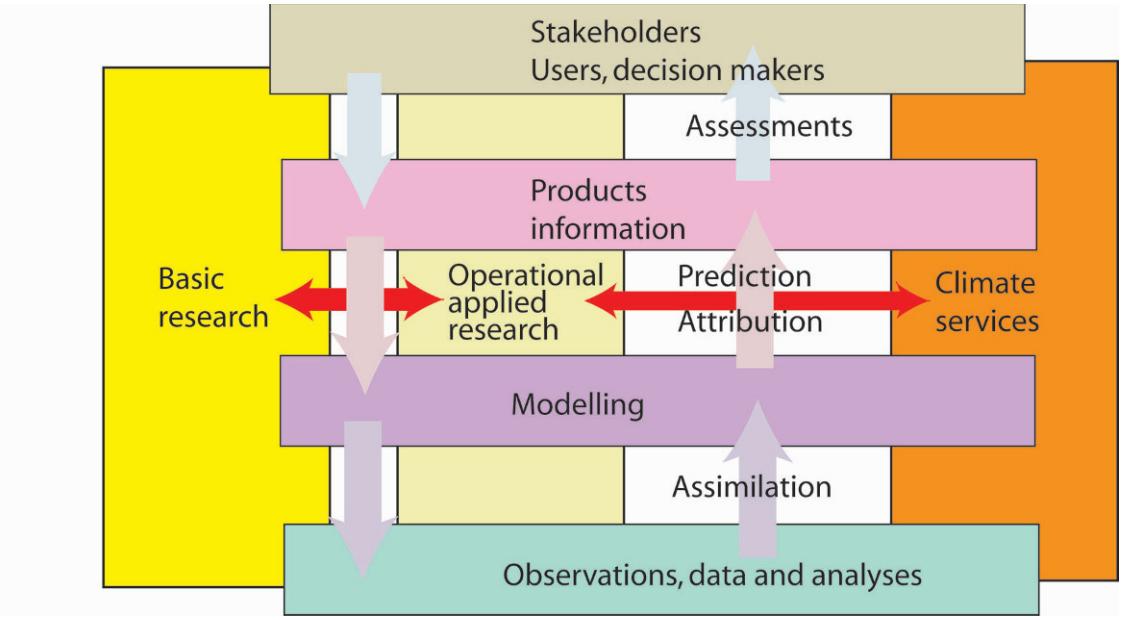
WCRP has taken a number of steps towards building the climate information system and network of experts with the aim to provide the best knowledge and information on climate variability and change to existing and emerging users of such information for decision making. These include:

- Before the *Fourth Assessment Report* (IPCC AR4) was completed, the WCRP in conjunction with IGBP had begun design of the set of model simulations that will underpin the climate change projections of the next IPCC report (Hibbard/ Meehl/ Cox/Friedlingstein 2007).
- Initiated a new field of climate science to provide the first ever coordinated set of decadal climate predictions.[7]
- With the *Global Climate Observing System* (GCOS) and the *International Geosphere-Biosphere Programme* (IGBP), the WCRP identified the key areas of scientific uncertainties in the AR4 (IPCC 2007) that need to be addressed by the climate observation and research communities during preparations for the Fifth IPCC Assessment Report.[8]
- With the *World Weather Research Programme* (WWRP) and the IGBP, the WCRP convened the *World Modelling Summit for Climate Prediction*. This summit made a clear statement calling for a revolution in climate prediction, requiring vastly

7 Meehl/Goddard/Murphy/Stouffer/Boer/Danabasoglu/Dixon/Giorgetta/Greene/Hawkins/Hegerl/Karoly/Keenlyside/Kimoto/Kirtman/Navarra/Pulwarty/Smith/Stammer/Stockdale (2009)

8 See: WCRP (2008a); Doherty/Bojinski/Henderson-Sellers/Noone/Goodrich/Bindoff/Church/Hibbard/Karl/Kajfez-Bogataj/Lynch/Parker/Prentice/Ramaswamy/Saunders/Simmons/Stafford/Smith/Stef-fen/Stocker/Thorne/Trenberth/Verstraete/Zwiers (2009).

Figure 78.4: A schematic of the flow of the climate information system, as basic research feeds into, and responds to the needs of, applied and operational research and the development of climate services. The system is built on the climate observing system that includes the analysis and assimilation of data using models to produce analyses and fields for initializing models; the use of models for attribution and prediction, and with all the information assessed and assembled into products and information that is disseminated to users. The users in turn provide feedback on their needs and how to improve information. **Source:** This figure was developed by K. Trenberth (2008: 18) and slightly modified by G. Asrar.



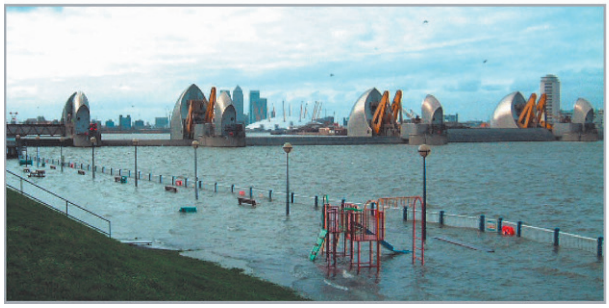
increased computing resources and appropriate personnel to develop further climate system models and verify their accuracy and adequacy, (Shukla/Hagedorn/Hoskins/Kinter/Marotzke/Miller/Palmer/Slingo 2009; Heffernan 2008). The resources required for such a Climate Prediction Project are small compared with the very large sums that will be required to develop solutions based on adapting to and mitigating the impacts of climate variability and change on aspects of our daily life, globally.

- Developed a series of cross cutting initiatives within WCRP to address critical and complex issues with tremendous societal impacts, including improved seasonal predictions (WCRP 2008b), the initiation of decadal predictions as referred to above, narrowing uncertainty regarding sea-level rise[9]; greater coordination of monsoon research activities in Asia, America, Africa and elsewhere; consideration of how to more effectively address the frequency and intensity of extreme events.
- Provided scientific expertise to, and coordinated research projects of the *International Polar Year*, leading to the agreement to establish a *Global Cryospheric Watch*.
- Established (for the first time and based on the need identified by the UNFCC, IPCC and WCRP constituencies) a *Regional Climate Modelling and Downscaling Task Group* to help with identifying scientific and technical foci for WCRP activities during the next decades.
- With the *International Geosphere-Biosphere Programme* undertaking a joint activity to significantly improve the representation of atmospheric chemistry and aerosols and cycling of carbon in the climate system models that will be used in future IPCC assessments.

The *Third World Climate Conference* (WCC-3) occurred in September 2009, 30 years after the first one. It is now the right time to propose and promote establishing a *Global Climate Information System* (figure 78.4). Such a system undoubtedly depends on the major components of observing systems that have been developed through international coordination and cooperation (e.g. *Global Climate Observing System*, etc.) and those under development. It must also

9 See WCRP (2006); Church/White/Aarup/Wilson/Woodworth/Domingues/Hunter/Lambeck (2008); Church/Woodworth/Aarup/Wilson (2009).

Figure 78.5: Climate adaptation solutions (clockwise from top left): A water reservoir in Africa; flood bunker in Bangladesh for protection during storm surges; water management and irrigation in China; flood prevention at the Thames barrier. **Sources:** <Treehuggerwww. PlayPumps.org>; International Federation of Red Cross and Red Crescent Societies (IFRC); UK Environment Agency; <www.WIKIMEDIA.org by J. Gao>.



take full advantage of the information management systems developed during the past 20 years, and the network of national and international global change research programmes, such as WCRP. However, to meet the challenges and opportunities identified earlier, operation and governance associated with this system must consider all components of the information system to be of equal importance and manage the two-way flow of information and decisions as a continuum. This implies that a weak link in this continuum will impact on the effectiveness of the system as a whole in capturing the required observations upstream and the timely delivery of required information to decision makers downstream. Another critical component of the system is an effective two-way communication between the climate science community and the rapidly growing user community and other stakeholders who are dependent on climate information. A number of examples of such operational Climate Information Systems are now being considered and implemented in several nations.

One very good example for the use of this system is the existing *UN Framework Convention on Climate Change* (UNFCCC) that has been in place for more than 20 years and is attempting to enable nations from around the world to develop environmental policies based on the best available scientific assessments. While there are many options for adaptation to the impacts of climate variability and change (figure 78.5), if these options are to be effective they all need to be supported by sound climate information (understanding, monitoring and robust predictions) and effective communication of that information to users and stakeholders.

78.8 Conclusions and the Science Policy Interface

WCRP has played a key role in encouraging and coordinating the very best of climate science that society needs to meet the challenges of *global environmental change* (GEC) and bringing this information to the attention of policy-makers and the public.

It was the international community of physical climate scientists that alerted the world to the reality of global warming, the prospect of anthropogenic climate change and its consequences. It is this same community that has determined the most likely causes of the recent global climate change and which has the capability to provide increasingly reliable climate change scenarios, which are crucial for many aspects related to planning for sustainable development.

Through the IPCC Assessments, WCRP has helped bring such climate-related issues to centre-stage by carrying out policy-relevant science and raising the level of scientific, governmental and public appreciation of the importance of climate issues, through fostering much greater cooperation between hitherto distinct scientific disciplines in understanding the whole climate system. As reviewed above, the vast majority of the results assessed by the IPCC Working Group I in its successive reports are based on research and model projections organized and coordinated by the WCRP and the vast majority of authors are closely associated with WCRP. Indeed without the model simulations coordinated by the WCRP there would be no climate change projections. Such WCRP coordinated results are the basis of key conclusions of successive IPCC scientific assessments such as the *4th Assessment Report* (AR4) conclusions (IPCC 2007). In turn, the IPCC assessments provide the most authoritative, up-to-date scientific advice needed to inform the UNFCCC. In this way, the WCRP has helped provide the direct policy-neutral scientific underpinning of the political process. In recent years, the WCRP, together with the *Earth System Science Partnership* (ESSP; chap. 74 by Leemans/Rice/Henderson-Sellers/Noone), has developed a dialogue directly with the Parties to the *United Nations Framework Convention on Climate Change* (UNFCCC). Similarly the work of the WCRP is directly relevant to the WMO/UNEP Ozone assessments, the UN *Convention on Biological Diversity* (CBD), the *Millennium Ecosystem Assessment* (MA), and the *UN Convention to Combat Desertification* (UNCCD) and of course directly underpins the achievement of a number of the UN's Millennium Development Goals (MDGs).

The WCRP will continue to play an important role in helping to provide increasingly reliable climate information and making them (and their likely consequences) available to decision-makers, the media and the general public. These are critical contributions to deliberations on sustainable development, formulating mitigation and adaptation strategies, and managing the risks associated with climate variability and change on all sectors of the global economy.

A critical further step is the development of a global climate information system that can capture the best available observations, climate system projections, and the expertise of the best minds from around the world to translate the available knowledge into a form and format that is useful to decision-makers. Providing easy and timely access to such information is the best gift that we can offer our generation, our children and those who will follow them. Such a system would be significant contribution to achieving the UN's *Millenium Development Goals* (MDGs) and responding to the threats, challenges, vulnerabilities and risks of global environmental change. This is indeed what the world expects from WCRP and its scientists and partners.

79 Key IPCC Conclusions on Climate Change Impacts and Adaptations

Martin Parry, Osvaldo Canziani, Jean Palutikof and Clair Hanson

79.1 Introduction

The IPCC Fourth Assessment on *Climate Change 2007: Impacts, Adaptation and Vulnerability* (IPCC 2007A) addressed three main issues: a) impacts of climate change which are observable now; b) future effects of climate change on different sectors and regions; and c) responses to such effects. The assessment included 12 key messages, which are summarized here.

79.1.1 Impacts of Climate Change are Occurring Now

A new development in the *IPCC's Fourth Assessment* (AR4) was the introduction of a chapter dedicated to observed and measurable impacts. The author team of this chapter examined more than 29,000 environmental data series and found that 89 per cent of these exhibited trends are consistent with warming. Most of the available data are terrestrial, rather than oceanic, and are concentrated in Europe and North America, leading to difficulties in drawing a global picture. Nevertheless, the conclusion is that natural systems around the world are being affected by regional climate changes, particularly temperature increases, and that these temperature increases are very likely to be the result of anthropogenic emissions *of greenhouse gases* (GHG).[1]

Most evident are reductions in snow, ice and frozen ground, which, in turn, are leading to enlargement and increased numbers of glacial lakes, and increased ground instability in permafrost and mountain regions. Although the greatest reduction in ice extent has occurred in the Arctic, some of the most obvious has been in tropical mountain environments, such as on Mt. Kilimanjaro, Kenya (figure 79.1).[2]

There is extensive evidence that recent warming is strongly affecting terrestrial biological systems, including such changes as earlier timing of spring events (e.g., leaf unfolding, bird migration and egg laying; and shifts in ranges of plant and animal species). In the oceans, and mainly at high latitudes, we can currently observe shifts in ranges and abundance of algae, plankton and fish.[3]

Probably the most important effect of GHG emissions is in the oceans, which have become increasingly acidic as *carbon dioxide* (CO_2) is absorbed by water to become carbonic acid. So far, we have recorded an average pH reduction of 0.1. Increasing acidity is expected to have major effects on shell-forming organisms, but research on this is in its infancy.[4]

Other effects of regional climate changes on natural and human environments are emerging, although many are difficult to discern due to adaptation and non-climatic trends such as land-use change. These include earlier spring planting of crops, increase in forest fires in northern high latitudes and warmer and drier conditions in the Sahel, leading to a reduced length of growing season.[5]

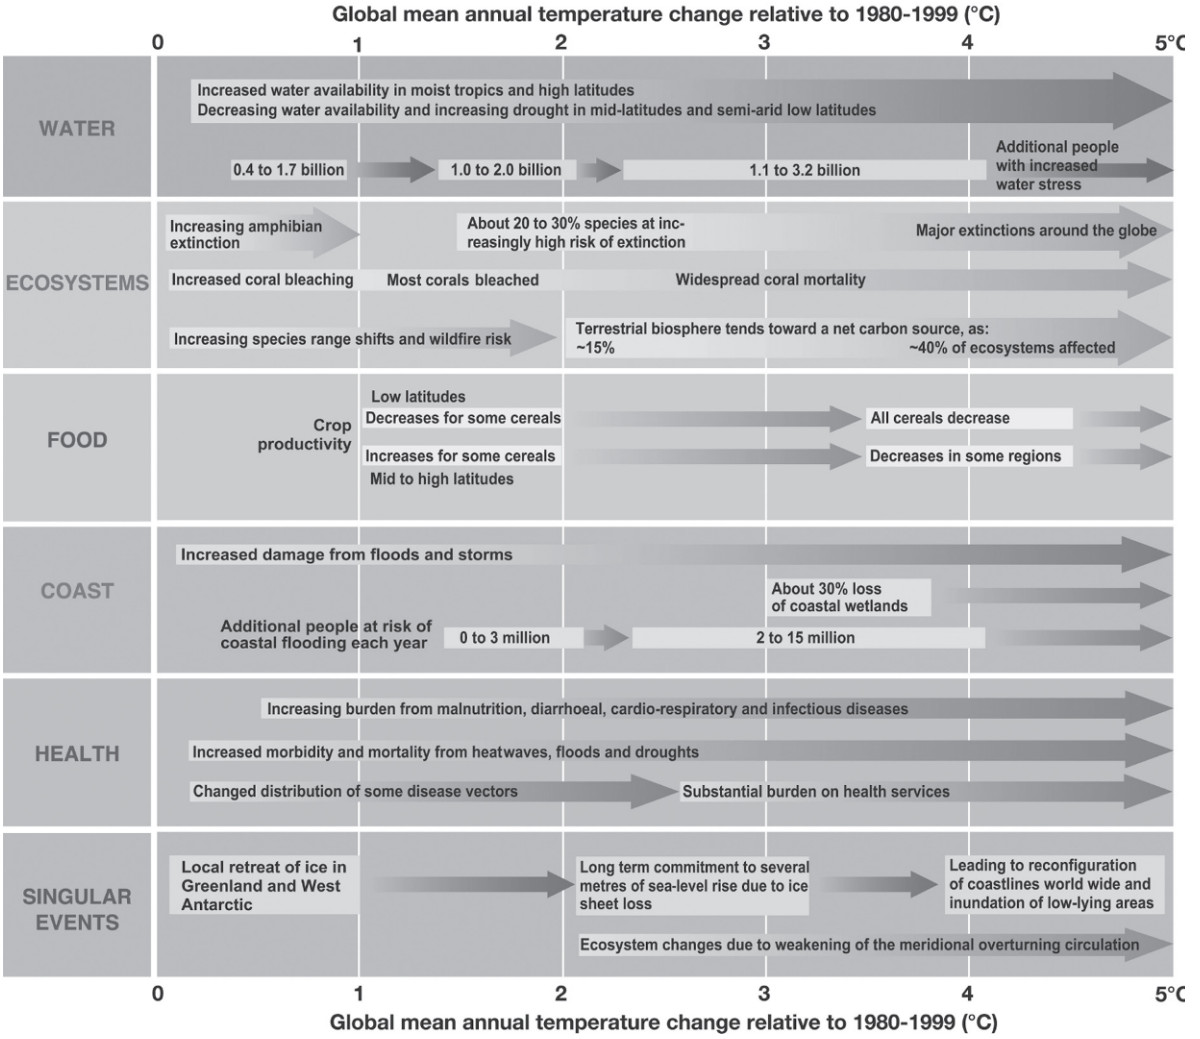
79.2 Key Impacts on the Most Vulnerable Places

Since the IPCC's Third Assessment (2001), many additional studies, particularly in regions that previously had been little researched, have enabled a more systematic understanding of how the timing and magnitude of impacts are likely to be affected by changes in climate and sea level associated with differing amounts and rates of change in global average tem-

Figure 79.2: Global impacts projected for changes in climate (and sea level and atmospheric carbon dioxide where relevant) associated with different amounts of global average surface temperature change in the 21st century. **Source:** IPCC (2007a: 66, Technical Summary).



perature.[6] The main conclusions regarding these impacts are summarized in figures 79.2 and 79.3.

From this assessment, the IPCC author team identified those systems (freshwater resources, management; ecosystems, properties, goods, services; food, fibre, forest products), sectors (industry, settlement, society; human health) and regions (Africa, Asia, Australia, Europe, Latin America, North America, Polar Regions, Small Islands) most likely to be especially affected by climate change.

The most vulnerable systems and sectors are:

- Some ecosystems, especially tundra, boreal forest, mountain, Mediterranean-type ecosystems, mangroves and salt marshes, coral reefs and sea ice biomes;
- Low-lying coasts, due to the threat of sea-level rise;
- Water resources in low-latitude regions, due to decreases in rainfall and higher rates of evapotranspiration;
- Agriculture in low-latitude regions, due to reduced water availability; and
- Human health, especially in areas with low adaptive capacity.

79.2.1 Case Study on Europe

Taking the European region as an example, to illustrate the points above, Europe's natural systems and biodiversity will be substantially affected by climate change. Sea-level rise is likely to cause inland migration of beaches and loss of up to 20 per cent of

coastal wetlands, reducing habitat availability for species that forage or breed in these areas (Nicholls 2004). Many ephemeral aquatic ecosystems in the Mediterranean are expected to disappear, and permanent ones become ephemeral (Alvarez Cobelas/Catalán/García de Jalón 2005). The northward expansion of forests is projected to reduce current tundra areas under some scenarios (White/Cannel/Friend 2000) and mountain communities face up to a 60 per cent loss of species under the SRES A1 scenario by 2080 (Thuiller/Lavorel/Araújo/Sykes/Prentice 2005). A large percentage of the European flora is likely to become vulnerable, endangered or committed to extinction by the end of the century (Thuiller/Lavorel/Araújo/Sykes/Prentice 2005). By the 2020's, increases are likely in winter floods in maritime regions and flash floods throughout Europe (Alcamo/Flörke/Märker 2007). Coastal flooding related to increased storminess and sea-level rise is likely to threaten an additional 1.6 million people annually by the 2080's (Nicholls 2004). Warmer, drier conditions will lead to more frequent and prolonged droughts as well as a longer fire season and increased fire risk, particularly in the Mediterranean region.[7] Water stress is likely to increase over central and southern Europe (river flow is expected to decrease by up to 50 per cent and 80 per cent, respectively in some rivers) (Santos/Forbes/Moita 2002; Alcamo/Flörke/Märker 2007). This has subsequent negative effects for the hydropower potential of Europe which is expected to decline on average by 6 per cent (around 20–50 per cent for the Mediterranean region by the 2070's) (Alcamo/Moreno/Nováky/Bindi/Corobov/Devoy/Giannakopoulos/Martin/Olesen/Shvidenko 2007). Crop pro-ductivity is likely to change with increases in the north and decreases in the Mediterranean region due to changes in temperature and precipitation (Alcamo Moreno/Nováky/Bindi/Corobov/Devoy/Giannakopoulos/Martin/Olesen/Shvidenko 2007). For human health, although there may be some health benefits from climate change for the European region, such as reduced cold-related mortality due to increased winter temperatures, on balance the overall impact will be negative (Alcamo/Moreno/Nováky/Bindi/Corobov/Devoy/Giannakopoulos/Martin/Olesen/Shvidenko 2007).

The most vulnerable regions are:

- The Arctic, because of high rates of projected warming on sensitive natural systems;
- Africa, especially the sub-Saharan region, because of low adaptive capacity and projected changes in rainfall;
- Small islands, due to high exposure of population and infrastructure to risk of sea-level rise and increased storm surge; and
- Asian megadeltas, such as the Ganges-Brahmaputra and the Zhujiang, due to large populations and high exposure to sea-level rise, storm surge and river flooding.

Within other areas, even those with high incomes, some people can be particularly at risk (such as the poor, young children and the elderly) and also some areas and some activities (for a summary see Wilbanks/Romero Lankao/Bao/Berkhout/Cairncross/Ceron/Kapshe/Muir-Wood/Zapata-Marti 2007, sections 1, 2 and 4).

79.2.2 Case Study: Africa

Africa is one of the most vulnerable continents to climate change and climate variability, a situation aggravated by the interaction of multiple stresses occurring at various levels, and low adaptive capacity. Africa's major economic sectors are vulnerable to current climate sensitivity, with huge economic impacts, and this vulnerability is exacerbated by existing developmental challenges such as endemic poverty, complex governance and institutional dimensions; limited access to capital, including markets, infrastructure and technology; ecosystem degradation; and complex disasters and conflicts. These in turn have contributed to Af-

6 Alcamo/Moreno/Nováky/Bindi/Corobov/Devoy/Giannakopoulos/Martin/Olesen/Shvidenko (2007); Anisimov/Vaughan/Callaghan/Furgal/Marchant/Prowse/Vilhjálmsson/Walsh (2007); Boko/Niang/Nyong/Vogel/Githeko/Medany/Osman-Elasha/Tabo/Yanda (2007); Confalonieri/Menne/Akhtar/Ebi/Hauengue/Kovats/Revich/Woodward (2007); Cruz/Harasawa/Lal/Wu/Anokhin/Punsalmaa/Honda/Jafari/Li/Huu Ninh (2007); Easterling/Aggarwal/Batima/Brander/Erda/Howden/Kirilenko/Morton/Soussana/Schmidhuber/Tubiello (2007); Field/Mortsch/Brklacich/Forbes/Kovacs/Patz/Running/Scott (2007); Fischlin/Midgley/Price/Leemans/Gopal/Turley/Rounsevell/Dube/Tarazona/Velichko (2007); Hennessey/Fitzharris/Bates/Harvey/Howden/Hughes/Salinger/Warrick (2007); Kundzewicz/Mata/Arnell/Döll/Kabat/Jiménez/Miller/Oki/Sen/Shiklomanov (2007); Magrin/Gay García/Cruz Choque/Giménez/Moreno/Nagy/Nobre/Villamizar (2007); Mimura/Nurse/McLean/Agard/Briguglio/Lefale/Payet/Sem (2007); Nicholls/Wong/Burkett/Codignotto/Hay/McLean/Ragoonaden/Woodroffe (2007).

rica's weak adaptive capacity, increasing the continent's vulnerability to projected climate change (Boko/Niang/Nyong/Vogel/Githeko/Medany/Osman-Elasha/Tabo/Yanda 2007).

79.2.3 Case Study: Asian Megadeltas

The IPCC Fourth Assessment reported that the eleven megadeltas contained within a 10,000 km^2 area of Asia's coastal zone support a population of millions (Nicholls 1995; Woodroffe/Nicholls/Saito/Chen/Goodbred 2006). The Zhujiang, Changjiang

and Huanghe deltas are also ecomonically important accounting for a substantial proportion of China's GDP (Niou 2002; She 2004). Ecologically, the Asian mega deltas are critical diverse ecosystems of unique assemblages of plants and animals located in different climatic regions (IUCN 2003b; ACIA 2005; Macintosh 2005; Sanlaville/Prieur 2005). The Asian megadeltas are vulnerable to climate change and sea-level rise which could increase the frequency and level of inundation of megadeltas through storm surge and flooding from river drainage putting communities, biodiversity and infrastructure at risk of damage. This impact would be most pronounced in the seven megacities located in the deltas, particularly where natural ground subsidence is enhanced by human activities, such as in Bangkok in the Chao Phraya delta, Shanghai in the Changjiang delta, Tianjin in the old Huanghe delta (Nguyen/Ta/Tateishib 2000; Li/Fan/Deng/Korotaev 2004; Jiang 2005; Li/Zang/Saito/Xu/Wang/Matsumato/Zh 2005; Woodroffe/Nicholls/Saito/Chen/Goodbred 2006).

Many of the regional differences in impact will stem from changes in water availability (which is essential for human health and food production). Over the past five years, we have developed a clearer picture of how water availability may change regionally, with indications of important decreases in southern Europe and in northern and southern Africa (as described above). If these projected changes should occur, then impacts in these regions could be severe.

79.3 Likely Impacts due to Altered Frequencies and Intensities of Extreme Weather, Climate and Sea-level Events

The IPCC's *Fourth Assessment Report* (AR4) concluded, with increased confidence over the *Third Assessment* (TAR), that some weather events, such as heat waves, storms and droughts, which can have large impacts, are likely to become more frequent and widespread in the future and, in some cases, more intense. In general, the related impacts are expected to be broadly negative, including reduced water availability, damage to crops and increased potential for diseases, especially those transmitted by insect vectors. For example, it is a conclusion of the Fourth Assessment that intense tropical cyclone activity is likely to increase through the 21st century. Thus, it is reasonable to expect events such as Hurricane Katrina, which hit New Orleans in August 2005 and caused an estimated 4,000 fatalities, to occur more often in the future.

79.4 Large-scale Climate Events with Potential to Cause Very Large Impacts after the 21st Century

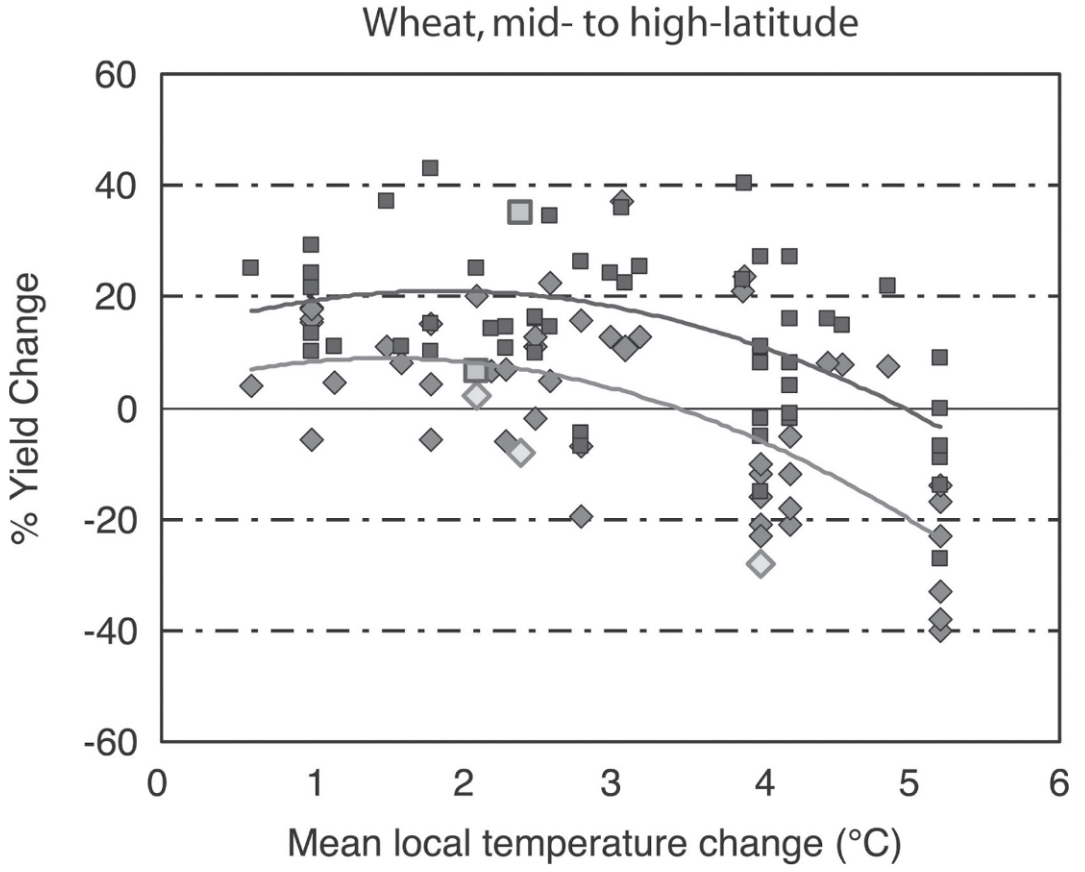
The IPCC Working Group I Fourth Assessment Report concluded that complete melting of the Greenland ice sheet, associated with a 1.9 °C to 4.6 °C global average temperature increase relative to pre-industrial levels, could lead to sea-level rises, over millennia, of 7 m. For the West Antarctic ice sheet, complete melting would contribute 5 m to sea-level rise. If this occurred, there would be widespread inundation of low-lying areas. Working Group II concluded that an abrupt change in the Meridional Overturning Circulation in the North Atlantic (i.e., weakening of the Gulf Stream), which could lead to cooling in northwestern Europe would be very unlikely to occur during this century.

79.5 Overall Negative Effect of Climate Change

The IPCC's *Fourth Assessment Report* (AR4) states that the impacts of future climate change will be mixed across regions, but negative overall. Some low-latitude and polar regions will experience net costs, even for small increases in temperature up to 2 °C or 3 °C before negative effects become more general. An example of this is possible increases in wheat yield for a temperature increase of 1 °C–3 °C at middle and high-latitudes but decreases in yield above 3 °C (figure 79.4).

These regions are the current 'breadbaskets' of the world, so the effects here would be keenly felt on food prices elsewhere; and, since agricultural production is a major part of global production, this explains why there is a wide band of uncertainty about the aggregate effects of climate change (with global losses between 1 and 5 per cent of *gross domestic product* (GDP) expected for a 4 °C warming – a conclusion which reinforces that of the IPCC's TAR (2001a). It is virtually certain, however, that such aggregate estimates of costs mask significant differences in impacts across sectors, regions, countries and populations. In some locations and among some groups of people with high exposure, high sensitivity and/or low adap-

Figure 79.4: Sensitivity of wheat yield in mid- to high latitudes. Responses indicate cases without adaptation (light grey dots) and with adaptation (dark grey dots). The studies analysed here include a range of precipitation changes and CO_2 concentrations (from IPCC 2007a: 286)



tive capacity, net costs will be significantly larger than the global aggregate.

79.6 Necessary Adaptation to Address Impacts from Warming From Past GHG Emissions

Working Group I (IPCC 2007d: 13) concluded that, even if emissions were stabilized now, global temperatures would increase on average by a further 0.6 °C by 2100. Furthermore, some current targets to reduce emissions assume a global average temperature increase of about 1.5 °C above present (i.e., 2 °C above pre-industrial temperatures). A significant amount of potential impact will therefore need to be adapted to, regardless of how effective are our efforts at mitigation.

79.7 Limited Current Adaptation and Needed Action to Reduce Vulnerability to Climate Change

There is growing evidence of human ability to adapt to observed and anticipated climate change. For example, climate change has been included in the design of infrastructure projects such as coastal defences in the Maldives (MOHA 2001; Mimura/Nurse/McLean/Agard/Briguglio/Lefale/Payet/Sem 2007) and the Netherlands.[8] Other examples include prevention of glacial lake outburst flooding in Nepal (Adger/Agrawala/Mirza/Conde/O'Brien/Pulhin/Pulwarty/Smit/Takahashi 2007), policies of water management in Australia[9], and government responses to heat waves in some European countries.[10]

8 See Government of the Netherlands (1997, 2005); Adger/Agrawala/Mirza/Conde/O'Brien/Pulhin/Pulwarty/Smit/Takahashi (2007).

Much more adaptation is needed, however. The array of potential adaptive responses available is very large, ranging from purely technological (e.g., sea defences), through behavioural (e.g., altered food and recreational choices), to managerial (e.g., altered farm practices) and to policy (e.g., planning regulations). We do not know, however, how effective various options are at fully reducing risks, nor their cost. This is especially true for larger amounts of warming over the long term and the IPCC authors concluded that adaptive capacity cannot be expected to cope with large amounts of long-term warming (IPCC 2007a: Section TS.5). This is why (as argued below) the combination of mitigation and adaptation will be essential.

79.8 Increased Vulnerability to Climate Change due to Other Stresses

Non-climate stresses can increase vulnerability[11] to climate change by reducing resilience and can also reduce adaptive capacity because of resource deployment to competing needs. For example, lower-than-normal receipts of rainfall in the Sahel have contributed to the reductions in the area of Lake Chad over the past 30 years. Equally important, however, may have been increased human abstraction of water from the rivers and streams that feed the lake. It is probably the combination of climate change and other trends that explain the lake's shrinkage.

79.9 Future Vulnerability Depending on Climate Change and on Development Pathways

Projected impacts of climate change can vary greatly due to the choice of future economic and social development pathway. New research on potential impacts allows for differences in regional population, income and technological development can be a strong determinant of vulnerability to climate change (Mimura 2001; Nicholls 2004, 2006).

To illustrate, figure 79.5 shows estimates of the global number of people at risk of flooding under different assumptions of socio-economic development (Nicholls 2004; Nicholls/Wong/Burkett/Codignotto/Hay/McLean/Ragoonaden/Woodroffe 2007). This indicates that the projected number of people affected is considerably greater under the A2-type scenario of development (a future world characterized by low per capita income and large population growth) than under other futures such as A1 (a high income/high population world); B1 (sustainable development/global governance); and B2 (sustainable development/local governance). Thus, difference in impact between these future conditions is largely explained, not by climate change, but by differences in vulnerability due to wealth and technology. This is important because it suggests that the choice of the development pathway can be a key to reducing impacts from climate change (e.g., Brooks/Adger/Kelly 2005; Haddad 2005; Jung/Srinivasan/Tamura/Sudo/Watanabe/Shimada/Kimura 2005; Tompkins/Adger 2005; Shaw 2006; Yohe/Lasco/Ahmad/Arnell/Cohen/Hope/Janetos/Perez 2007).

79.10 Sustainable Development and Climate Change Linkages

Sustainable development can reduce vulnerability to climate change by enhancing adaptive capacity and increasing resilience.[12] At present, however, few plans for promoting sustainability have explicitly included either adapting to climate change impacts or promoting adaptive capacity (Hamlet 2003; Payne/Wood/

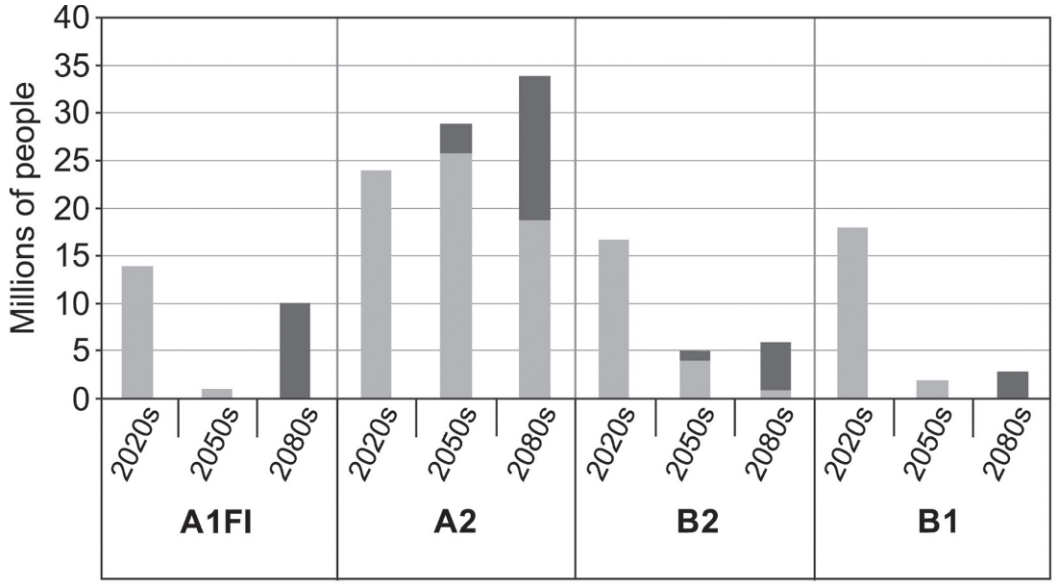
9 See Beare/Heaney (2002); Allen Consulting Group (2005); Hennessey/Fitzharris/Bates/Harvey/Howden/Hughes/Salinger/Warrick (2007).

10 See Garssen/Harmsen/de Beer 2005; Nogueira/Falcão/ Contreiras/Paixão/Brandão/Batista (2005); Pirard/Vandentorren/Pascal/Laaidi/Le Tertre/Cassadou/Ledrans (2005); Alcamo/Moreno/Nováky/Bindi/Corobov/Devoy/Giannakopoulos/Martin/Olesen/Shvidenko (2007).

11 Vulnerability, as used in the WGII Assessment is defined as: the degree to which a system is susceptible to, and unable to cope with, adverse effects of climate change, including climate variability and extremes. Vulnerability is a function of the character, magnitude, and rate of climate change and variation to which a system is exposed, its sensitivity, and its adaptive capacity.

12 See Kates (2000); Brooks/Adger/Kelly (2005); Haddad (2005); Jung/Srinivasan/Tamura/Sudo/Wa-tanabe/Shimada/Kimura (2005); Tompkins/Adger, (2005); Belliveau/ Smit/Bradshaw (2006); Ford/ Smit/Wandel (2006); Shaw (2006); Yohe/Lasco/Ahmad/Arnell/Cohen/Hope/Janetos/Perez (2007).

Figure 79.5: Estimated millions of people per annum at risk globally from coastal flooding. Light grey bars: numbers at risk without sea-level rise; dark grey bars: numbers at risk with sea-level rise. **Source**: IPCC (2007a: 75; Technical Summary).



Hamlet/Palmer/Lettenmaier 2004). On the other hand, it is very likely that climate change can slow the pace of progress towards sustainable development (e.g., impede achievement of Millennium Development Goals), either directly through increased exposure to adverse impacts or indirectly through erosion of the capacity to adapt (Arrow/Dasgupta/Goulder/Daily/Ehrlich/Heal/Levin/Maler/Schneider/Starrett/Walker 2004; MA 2005; Yohe/Lasco/Ahmad/Arnell/Cohen/Hope/Janetos/Perez 2007).

79.11 Avoided, Reduced or Delayed Climate Change Impacts due to Mitigation

A small number of impact assessments have now been completed for scenarios in which future greenhouse gases are stabilized. Although these studies do not take full account of uncertainties in projected climate under stabilization, they nevertheless provide indications of damage avoided or vulnerabilities and risks reduced for different amounts of emissions reduction (see for example Yohe/Malone/Brenkert/Schlesinger/Meij/Xing/Lee 2006).

79.12 Conclusion: Mix of Adaptation and Mitigation Measures to Cope with Climate Change Impacts

Even the most stringent mitigation efforts cannot avoid some impacts of climate change over the next few decades. Indeed, we are beginning to see these impacts now (Rosenzweig/Casassa/Karoly/Imeson/Liu/Menzel/Rawlins/Root/Seguin/Tryjanowski 2007). This makes adaptation essential, particularly in addressing near-term impacts. However, unmitigated climate change would, in the long term, be likely to exceed our capacity to adapt.

It is essential, then, to develop a portfolio or mix of strategies that includes mitigation, adaptation, technological development (to enhance both adaptation and mitigation) and research (on climate science, impacts, adaptation and mitigation). But analysis of the benefits of various mixes of strategy is severely restricted at present by lack of information on potential costs of impacts, by lack of comparable information on the damage that could be avoided by adaptation and, especially, by lack of understanding of how these impacts will vary under different socio-economic development pathways (Klein/Eriksen/Nass/Hammill/Tanner/Robledo/O'Brien 2007). It is important that these gaps in our knowledge are filled quickly.

80 Options for Mitigating Climate Change Results of Working Group III of the Fourth Assessment Report of the IPCC

Peter Bosch and Bert Metz

80.1 Introduction

In 2007 the United Nations Intergovernmental Panel on Climate Change (IPCC) completed its *fourth assessment report* (AR4). This report consists of three separate volumes on climate science, vulnerability to climate change and adaptation (chap. 79 by Parry/Canziani/Palutikof/Hanson) and mitigation of climate change, respectively. The IPCC reports are thorough and comprehensive assessments of published literature, put together by multidisciplinary teams of the best experts from around the world. These reports are subject to extensive review by independent experts and governments. The Summary for Policymakers of the reports is approved by the member countries of the IPCC.

This chapter focuses on the outcomes of the third volume, which is the product of working group III of the IPCC. This working group has evaluated the available literature to come up with an overview of all possible measures to reduce the worldwide emission of greenhouse gases, and an estimate of the global reduction potential and the costs involved. The chapter also includes references to a few major publications that appeared after the AR4 was completed, but it does not refer back to individual publications that have been assessed in the AR4.

The IPCC findings have already been very influential in shaping the international climate negotiations; especially during the *Conference of the Parties* (COP) of the *United Nations Framework Convention on Climate Change* (UNFCCC) in Bali in December 2007 that laid out the roadmap for the discussions on a new international climate agreement as a follow-up to the Kyoto protocol (chap. 83 by Egenhofer/Behrens/Georgiev).

In short, the conclusions of the AR4 on mitigation claim that it is possible to reduce *greenhouse gas* (GHG) emissions to levels that prevent dangerous warming of the atmosphere at reasonable costs. The economic potential for the mitigation of GHG emissions over the coming decades is enough to offset the projected growth of global emissions or to reduce emissions below current level. Beyond 2030 there are further opportunities for deep reductions of emissions, required for minimizing the risks of climate change. The economic impacts of such a low risk strategy would not amount to more than 3 per cent lower global GDP by 2030 than without controlling GHG emissions, or, in other words, a reduction of the yearly growth of world income by less than 0.12 per cent points. The measures to reduce GHG emissions will, however, not be taken without strong government policy action.

This chapter explores the required reductions of greenhouse gas emissions to prevent dangerous climate change impacts, taking a risk-based approach. It discusses the risks of climate change as a function of a change in climate, particularly mean global temperature increase (80.2); deals with the relation between GHG concentrations in the atmosphere and global temperature and the implications for reduction of GHG emissions (80.3); addresses the main question whether the technology is available to reduce greenhouse gas emissions to the desired levels of protection and provides a concise overview of options and costs involved (80.4). Further, it discusses policy action required to realize the emission reduction potentials (80.5), and in the conclusions it refers to questions for further research (80.6).

80.2 Coping with Climate Change

Continued GHG emissions at or above the current rates will cause further global warming and consequent changes in the global climate system that will be larger than those observed in the 20th century. For the next two decades most scenarios agree on a warming of 0.2 °C per decade. After this period the

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_80, © Springer-Verlag Berlin Heidelberg 2011

temperature projections depend on the emission scenario, that is, the assumptions with regard to population growth, economic growth and the choice of energy carriers. Best estimate temperature changes in 2090–2099 relative to the 1980–1999 period for the scenarios included in the IPCC Special Report on Emission Scenarios range from 1.8 to 4.0°C (with a likely range from 1.1 to 6.4°C; IPCC 2007: 747ff.).[1]

Associated changes in the climate are an increase in the frequency of hot extremes, heat waves and heavy precipitation, an increase in tropical cyclone intensity, a pole ward shift of extra-tropical storm tracks with consequent changes in wind, precipitation and temperature patterns, an increase in precipitation in high latitudes and a decrease in most subtropical land regions. It will lead to a decrease in sea ice extent (in some scenarios even a complete disappearance of Arctic sea ice in summer) and a decrease of the snow and permafrost areas.

Especially affected by climate change will be:

- The Arctic, because of the impacts of high rates of projected warming;
- Africa, because of low adaptive capacity and impacts on water resources;
- Small islands, due to the threat of sea level rise and extreme weather events;
- Mega deltas in Asia and Africa, with large populations exposed to sea level rise and river flooding (IPCC 2007a: 11–18).

Coping with climate change entails two types of action that are both needed:

1. *adaptation* to the impacts of changes in climate that are unavoidable as a result of large-scale GHG emissions since the industrial revolution, and
2. *mitigation* of climate change through reducing GHG emissions and maximizing carbon sinks (forests), so that additional climate change above the unavoidable is minimized.

Neither adaptation nor mitigation alone can avoid all climate change impacts, but together they can significantly reduce the risks of climate change and "prevent dangerous anthropogenic interference with the climate system" (the ultimate objective of the universally agreed UNFCCC).

Adaptation will be necessary in the short term to deal with the impacts that have been observed already and are expected for the near future (IPCC 2007a; chap. 79 by Parry/Canziani/Palutikof/Hanson). However, adaptation alone is not expected to cope with all projected effects of climate change, as in the long term unmitigated climate change would likely exceed the capacity of natural, managed and human systems to adapt. In other words, there are serious limits to adaptation, which we unfortunately do not yet understand well.

Mitigation of climate change, or reduction of GHG emissions and retaining or strengthening reservoirs of carbon in vegetation, is necessary to minimize the further build-up of the concentrations of GHG in the atmosphere that drive climate change. Given the very long lifetimes of GHGs in the atmosphere (25 per cent of *carbon dioxide* (CO_2) emitted today will still be in the atmosphere 5,000 years from now), emissions have to be reduced to almost zero in order to stabilize concentrations in the atmosphere. Because of slowness of the climate system, the effects of mitigation can only de detected after many years. After GHG concentrations in the atmosphere have stabilized, the rate at which the global average temperature increases is expected to slow down within a few decades.

80.3 The Mitigation Challenge

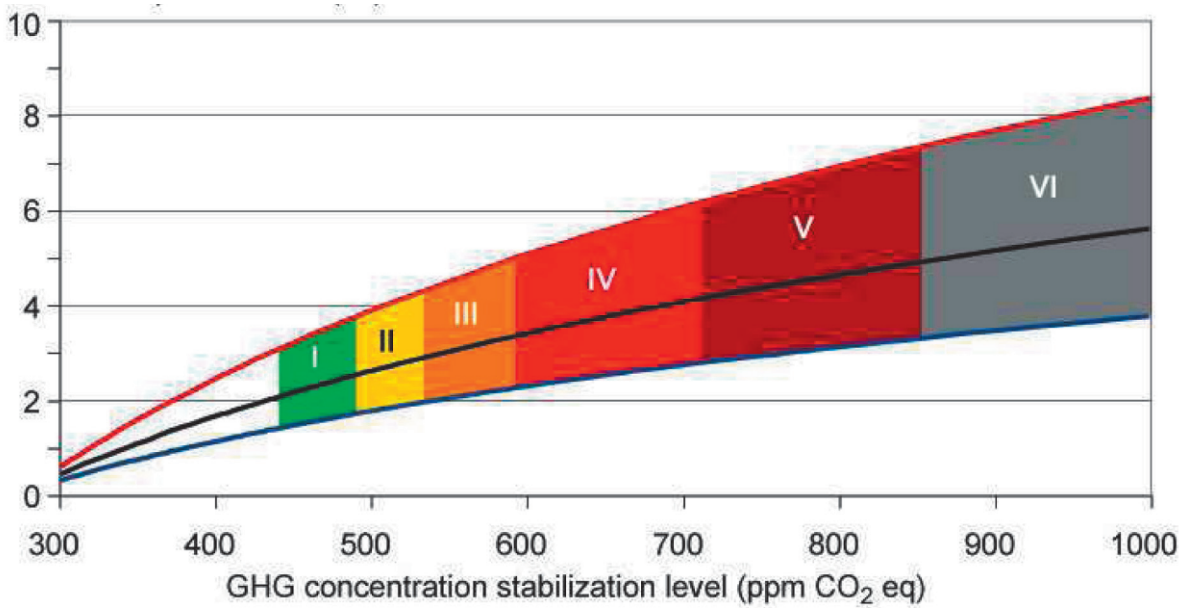
The challenge for the world is to stop the growth in GHG emissions and achieve an absolute reduction of emissions within the coming decades. In the past 30 years (between 1970 and 2004) global GHG emissions have increased by 70 per cent.[2] CO_2 emissions, the largest constituent, have even increased by about 80 per cent (data from Edgar database: Olivier/Van Aardenne/Dentener/Pagliari/Ganzeveld/Peters 2005; Olivier/Pulles/van Aardenne 2006).

Depending on the scenario assumed for future population growth, growth of GDP, choice of energy sources and land-use, GHG emissions in the coming thirty years will rise with another 25 to 90 per cent if no additional policies would be implemented. These numbers are based on the IPCC's *Special Report on Emission Scenarios* (SRES), which describes a collection of baseline scenarios without additional mitiga-

1 See Nakicenovic/Alcamo/Davis/de Vries/Fenham,/Gaffin/Gregory/Grübler/Jung/Kram/La Rovere/Michaelis/Mori/Morita/Pepper/Pitcher/Price/Riahi/Reohrl/Rogner/Sankovski/Schlesinger/Shukla/Smith/Swart/van Rooijen/Victor/Zhou (2000).

2 The six GHG emissions covered by the UNFCCC are: CO_2, CH_4, N_2O, HFCs, PFCs and SF_6, weighted by their *global warming potential* (GWP).

Figure 80.1: Stabilization scenario categories and their relationship to equilibrium global mean temperature change above pre-industrial temperatures in °C. **Source:** IPCC (2007b: 228).



Note: The central line uses the 'best estimate' climate sensitivity of 3°C (black line in middle of shaded area), the red line at the top of the shaded area is the upper bound of the likely range of climate sensitivity of 4.5°C, the blue line at the bottom of the shaded area represents the lower bound of the likely range of climate sensitivity of 2°C. Coloured shading shows the concentration bands for GHG stabilization in the atmosphere corresponding to the stabilization scenario categories I to VI as indicated in table 80.1. The data are drawn from IPCC (2007, chap. 10.8). The best estimate of climate sensitivity (3 °C) is higher than in the previous IPCC report (2.5°C), meaning that allowable concentration levels for the same temperature increase are now lower than indicated earlier.

tion measures (Nakicenovic 2000; IPCC 2007b: 31). In these scenarios, fossil fuels are projected to maintain their dominant position in the global energy mix to 2030 and beyond. Hence CO_2 emissions from energy use are projected to grow by 40 to 110 per cent between 2000 and 2030.

The precise size of the challenge of reducing GHG emissions depends on the impacts of climate change that societies are willing to accept, in light of the costs of taking mitigation measures. Since there is a direct link between climate change impacts and global mean temperatures, it is a matter of deciding at which temperature level climate should be stabilized. From there the allowable GHG concentration level can be derived. Figure 80.1 depicts the relationship between global mean equilibrium temperature and the GHG concentration in the atmosphere. The corresponding figure 80.2 shows for the same bands of temperatures/concentrations, the emission profiles as generated by a multitude of models simulating a stabilization of GHG concentrations in the atmosphere. Here, the coloured bands represent the spread over model outcomes. The lower the desired level of equilibrium GHG concentrations in the atmosphere:

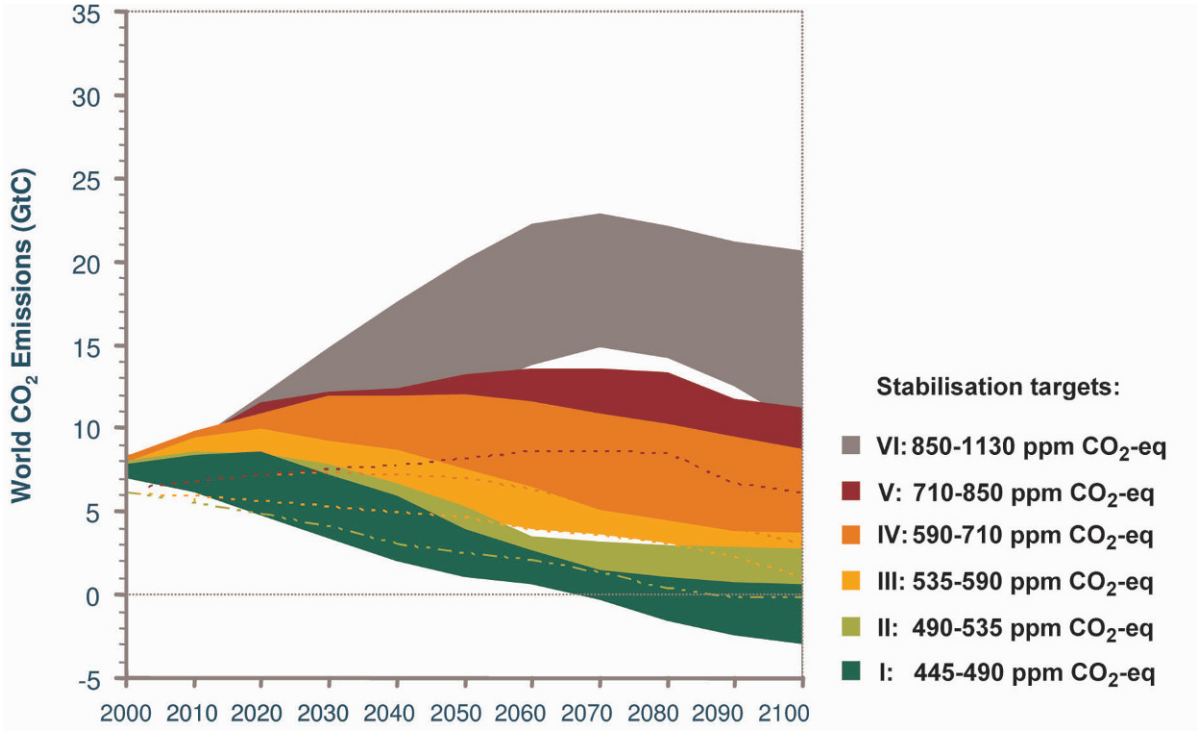
- the more emissions will have to be reduced at a given point in time; the political jargon for emission reductions linked with the lower concentration levels is 'deep cuts'.
- the earlier emissions have to peak; that means the moment global emissions start decline in absolute terms.

Table 80.1 summarizes the required emissions levels for different groups of stabilization concentrations and the associated equilibrium global mean temperature increase, using the 'best estimate' of climate sensitivity[3] (whereby the likely range of uncertainty is depicted in figure 80.1).

Especially for the lowest stabilization categories the time for implementing GHG emission reduction

3 Climate sensitivity is a measure of the climate system response to sustained radiative forcing. It is defined as the global average surface warming following a doubling of CO_2 concentrations.

Figure 80.2: Emission pathways of mitigation scenarios for alternative categories of stabilization levels (category I to VI defined in table 80.1). **Source:** IPCC (2007b: 199).



measures is very short. As shown in table 80.1 global GHG emissions will have to peak before 2015 in order to keep global temperature increase to 2.0–2.4 °C above the pre-industrial situation. This means that mitigation efforts over the next two to three decades will have a large impact on opportunities to achieve any of the lower stabilization levels.

Of course it can be debated what is the appropriate level of stabilization of GHG concentrations to strive for. This is a normative decision that cannot be made on scientific grounds alone. Science can, however, inform these decisions. In a risk management framework that means scientific information about the risks belonging to certain stabilization levels (and the temperatures and precipitation belonging to them) should be considered together with information about the costs and policy efforts needed to reach these stabilization levels. And then there are two fundamentally different ways to use that information: (1) determine the acceptable risk level and then realize that level at the lowest possible costs (least cost risk management approach), or (2) compare the cost of no action (climate change damages) with the costs of achieving stabilization and go no further than what the damage costs are (cost-benefit approach). The latter approach is fraught with problems, because it requires monetization of a wide range of climate change damages (economic losses, health effects, ecosystem disappearance and many other). Nevertheless it is an approach widely used by economists. The AR4, assessing the literature that shows a wide range of estimates for climate change damages, could only conclude that costs of damages and costs of aggressive mitigation action are of the same order of magnitude. The Stern report that was published almost at the same time, taking into account the risk of catastrophic climate change events, the irreversible nature of some of the effects and a much longer time horizon, concluded that the damage costs far outweigh the costs of aggressive mitigation action (Stern 2006).

80.4 Potential for Mitigating Climate Change and Its Costs

A politically interesting part of mitigation analysis is the question of the potentials and costs of reaching climate policy targets. The distribution of potentials and costs across economic sectors and regions of the world shapes the negotiations on a future international climate agreement and the instruments to be used, such as the *Clean Development Mechanism*

Table 80.1: Characteristics of stabilization scenarios published after 2000. **Source:** IPCC (2007b: 198).

Category	Radiative Forcing (W/m^2)	CO_2 Concentration (ppm)	CO_2-eq Concentration (ppm)	Global mean temperature increase above pre-industrial at equilibrium, using 'best estimate' climate sensitivity (°C)	Peaking year for CO_2 emissions (year)	Change in global CO_2 emissions in 2050 (per cent of 2000 emissions) (per cent)	No. of assessed scenarios
I	2.5 – 3.0	350 – 400	445 – 490	2.0 – 2.4	2000 - 2015	-85 to -50	6
II	3.0 – 3.5	400 – 440	490 – 535	2.4 – 2.8	2000 - 2020	-60 to -30	18
III	3.5 – 4.0	440 – 485	535 – 590	2.8 – 3.2	2010 - 2030	-30 to +5	21
IV	4.0 – 5.0	485 – 570	590 – 710	3.2 – 4.0	2020 - 2060	+10 to +60	118
V	5.0 – 6.0	570 – 660	710 – 855	4.0 – 4.9	2050 - 2080	+25 to +85	9
VI	6.0 – 7.5	660 – 790	855 – 1130	4.9 – 6.1	2060 - 2090	+90 to +140	5
						Total	**177**

(CDM). The AR4 has used two strands of analysis to estimate the potential of available mitigation measures. As a first approach the various technological measures that can be taken by economic sectors have been analysed from en engineering perspective and their costs and mitigation potential in the year 2030 versus a baseline economic development have been estimated. This 'bottom-up' estimate has been compared with a 'top-down' approach, in which the mitigation potential in 2030 was derived from macro-economic/environmental models running long term stabilization scenarios. Both approaches give comparable results (figure 80.3). This observation is confirmed by Hoogwijk/van Vuuren/Boeters/Blok, Blomen/Barker/Chateau/Grübler/Masui/Nabuurs/Novikova/Riahi/de la Rue du Can/Sathaye/Scrieciu/Urge-Vorsatz/van Vliet (2008), who elaborated the IPCC approach with a more consistent baseline and another selection of models and model runs. The economic mitigation potential for carbon prices of less than 100 US$/ton CO_2-equivalent is between 16 and 31 Gt CO_2-equivalent. This amount is sufficient to reduce the projected 2030 emissions to or below the global emissions in the year 2000. Such reductions in 2030 would be consistent with stabilization below 500 ppm CO_2-equivalent in the long run.

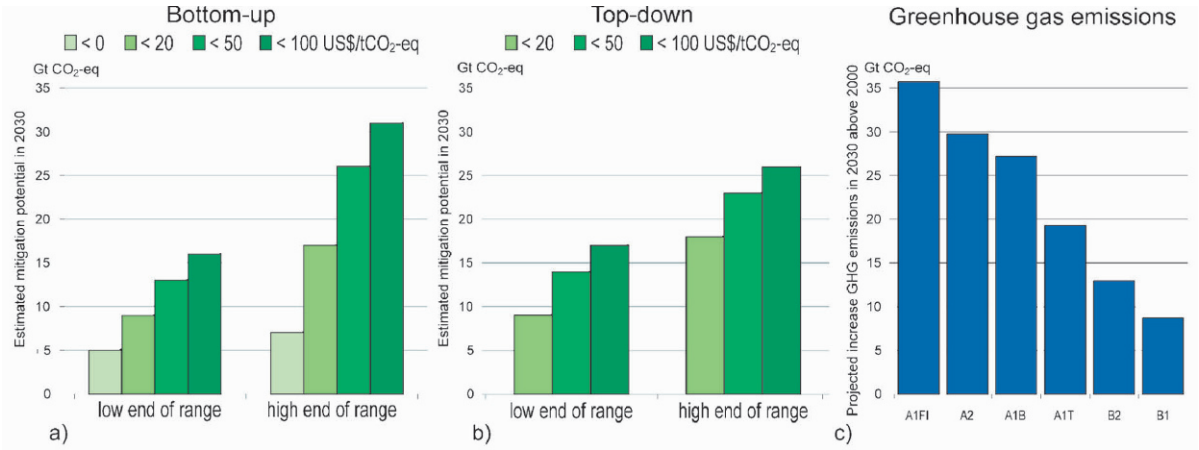
The uncertainties in the estimates reflect the ranges in assumptions on baselines, rates of technological change and factors that are specific to the 'bottom-up' or 'top-down' approach. Furthermore, uncertainties arise from the limited information for the global coverage of countries, sectors and gases (IPCC 2007b: 631).

This mitigation potential cannot be provided by one single technology or one single economic sector. If full use is going to be made of the economic mitigation potential, then all sectors will need to contribute. Figure 80.4 gives a summary of mitigation potentials and costs in economic sectors. It has been derived from the (bottom-up) technological information on a large number of technical mitigation measures. The potentials are compared to a baseline economic development and given for the year 2030.

The main mitigation technologies and practices currently available or projected to be commercialized before 2030 include:

- For the *energy supply* sector: Improved supply and distribution efficiency; fuel switching from coal to gas; nuclear power; renewable heat and power (hydropower, solar, wind, geothermal and bioenergy); combined heat and power; *Carbon Capture and Storage* (CCS) for gas, biomass and coal-fired electricity generating facilities.
- For the *transport sector*: More fuel efficient vehicles; hybrid vehicles; cleaner diesel vehicles; (second generation) biofuels; modal shifts from road transport to rail and public transport systems; non-motorized transport (cycling, walking); land-use and transport planning; higher efficiency aircrafts; advanced electric and hybrid vehicles with more powerful and reliable batteries.
- For *buildings*: Efficient lighting and day lighting; more efficient electrical appliances and heating and cooling devices; improved cook stoves, improved insulation; passive and active solar design for heating and cooling; alternative refrigeration fluids, recovery and recycle of fluorinated gases, integrated design of commercial buildings includ-

Figure 80.3: Comparison between global economic mitigation potential and projected emissions increase in 2030. **Source:** IPCC (2007b: 625-635).



Note: Global economic mitigation potential in 2030 estimated from bottom-up (panel a) and top-down (panel b) studies, compared with the projected emission increases from SRES scenarios relative to 2000 GHG emissions of 40.8 GtCO2-eq (panel c). GHG emissions in 2000 are exclusive of emissions of decay of above ground biomass that remains after logging and deforestation and from peat fires and drained peat soils, to ensure consistency with the SRES emission results. A price of 50 US$/ton CO_2-equivalent roughly equals a price increase of 25 US$/barrel crude oil, or 12 ct/litre gasoline (50 ct/gallon), or an electricity price increase of 5 ct/kWh for electricity generated in coal fired plants, or 1.5 ct/kWh for electricity from gas fired plants.

ing technologies, such as intelligent meters that provide feedback and control; solar PV integrated in buildings.

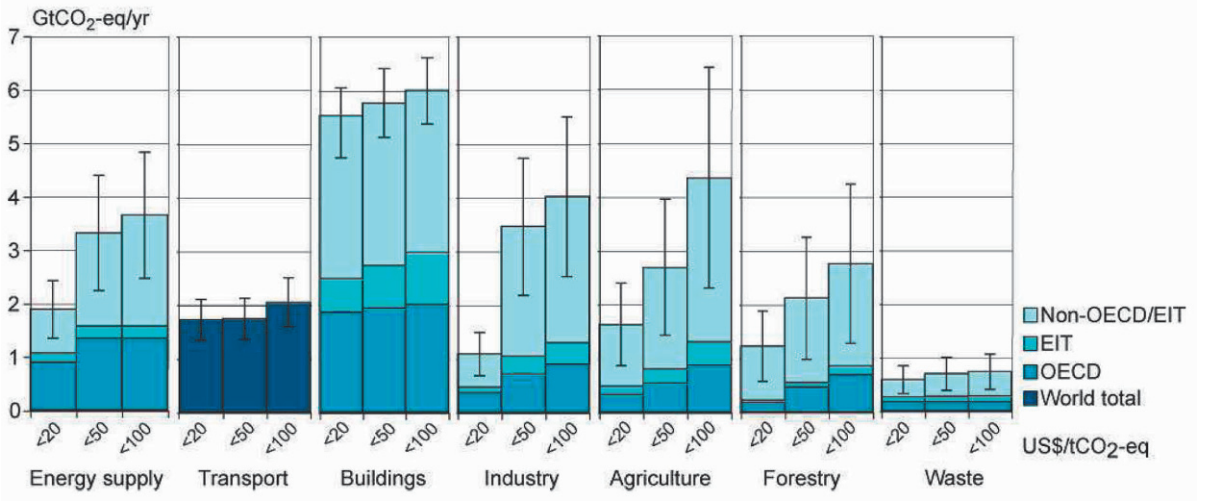
- For the *manufacturing industry*: More efficient end-use electrical equipment; heat and power recovery; material recycling and substitution; control of non-CO_2 gas emissions; and a wide array of process-specific technologies, CCS for cement, ammonia, and iron manufacture; inert electrodes for aluminium manufacture.
- For *agriculture*: Improved crop and grazing land management to increase soil carbon storage; restoration of cultivated peaty soils and degraded lands; improved rice cultivation techniques and livestock and manure management to reduce CH_4 emissions; improved nitrogen fertilizer application techniques to reduce N_2O emissions; dedicated energy crops to replace fossil fuel use; improved energy efficiency.
- For *foresty*: Afforestation; reforestation; forest management; reduced deforestation; harvested wood product management; use of forestry products for bioenergy to replace fossil fuel use, tree species improvement to increase biomass productivity and carbon sequestration.
- For *waste management*: Landfill methane recovery; waste incineration with energy recovery; composting of organic waste; controlled waste water treatment; recycling and waste minimization, biocovers and biofilters to optimize CH_4 oxidation.

Apart from these technical mitigation measures, there are many lifestyle and behavioural changes possible that can reduce GHG emissions. The impacts of these can, however, not yet be quantified. Examples are:

- For consumers: choosing the appropriate inside temperature at home can save a lot of heating or air-conditioning energy use; switching off lights and electrical appliances when not in use does the same.
- For employees: staff training, reward systems, regular feedback can help reduce losses in energy, steam, and hot water.
- For drivers: choosing an efficient driving style, but also choosing for appropriate alternative modes of transport such as walking, cycling or public transport.

In figure 80.4 the large economic potential at low costs for the building sector is striking. By 2030, about 30 per cent of the projected GHG emissions in this sector can be avoided with net economic benefit due to the savings made on energy use. There are, however, multiple barriers that make it difficult to realize this potential, which include the low priority for investing money that will lead to savings in the longer term, lack of reliable information, limited availability

Figure 80.4: Estimated sectoral economic potential for global mitigation for different regions as a function of carbon price in 2030 from bottom-up studies, compared to the respective baselines assumed in the sector assessments. **Source:** IPCC (2007b: 632).



Notes:

1. The ranges for global economic potentials as assessed in each sector are shown by vertical lines.
2. The estimated potentials have been constrained by the availability of studies particularly at high carbon price levels.
3. Sectors used different baselines. For industry the SRES B2 baseline was taken, for energy supply and transport the World Energy Outlook 2004 baseline was used; the building sector is based on a baseline in between SRES B2 and A1B; for waste, SRES A1B driving forces were used to construct a waste specific baseline, agriculture and forestry used baselines that mostly used B2 driving forces. The estimates are based on end-use allocations of emissions, meaning that emissions of electricity use are counted towards the end-use sectors and not to the energy supply sector.
4. Only global totals for transport are shown because international aviation is included.
5. Categories excluded are: non-CO_2 emissions in buildings and transport, part of material efficiency options, heat production and cogeneration in energy supply, heavy duty vehicles, shipping and high-occupancy passenger transport, most high-cost options for buildings, wastewater treatment, emission reduction from coal mines and gas pipelines, fluorinated gases from energy supply and transport. The underestimation of the total economic potential from these emissions is of the order of 10-15 per cent.

of technology, financing requirements, and limitations inherent in buildings designs. A well known obstacle is also that building owners have little incentive to invest in highly energy efficient buildings, while those that rent a house or an office have no incentive to invest either. Especially in developing countries these barriers are more important.

In general, the share of developing countries in the global economic mitigation potential is considerable. This highlights the importance of including appropriate mechanisms for technology transfer and financing of measures in developing countries in future international climate agreements.

The total direct costs of implementing the full package of technical measures at costs lower than 100 US$/ton CO_2-equivalent as described above, amount to between 1 and 2 per cent of global GDP in 2030.[4] The macro-economic costs, i.e. the effect on the size of the economy as a whole, have been calculated for multi-gas mitigation consistent with emission trajectories towards different stabilization levels of GHG emissions in the atmosphere. These macro-economic costs are estimated for 2030 at a range between a 3 per cent decrease of global GDP, compared to a reference scenario, for the most stringent scenarios (stabilizing at 445–535 ppm CO_2-equivalent) to a small increase (i.e. benefit) compared to the baseline for a stabilization at 590–710 ppm CO_2-equivalent.

4 This is the expenditure for mitigation measures, not the macro-economic effect. It can be calculated from the data in figure 80.4, assuming all measures are taken at the highest costs per cost class. Compared to the world GDP of the SRES B2 marker scenario of 66 trillion US$ in 2030 (Nakicenovic/Alcamo/Davis/de Vries/Fenham,/Gaffin/Gregory/Grübler/Jung/Kram/La Rovere/Michaelis/Mori/Morita/Pepper/Pitcher/Price/Riahi/Reohrl/Rogner/Sankovski/Schlesinger/Shukla/Smith/Swart/van Rooijen/Victor/Zhou 2000: 561).

Even the 3 per cent reduction in 2030 compared to a baseline is relatively small: it would mean a reduction of the average yearly growth of the world economy by less than 0.12 percentage points. With GDP growth rates assumed in most models it would mean that one year later the world would be equally well off compared to a situation without measures. Of course, these results are global averages based on least cost models. In reality costs may be higher and also regionally the impacts may differ from the percentages given above. On the other hand, these calculations do not take into account the benefits of climate policies in terms of avoided impacts of climate change and the co-benefits of taking mitigation measures. Especially the co-benefits from reduced air pollution in terms of improved health as a result of actions to reduce GHG emissions can be substantial (IPCC 2007b: 670).

80.5 Policies and Instruments

Without policy action the mitigation potential will remain a potential solution for addressing climate change. There is a wide variety of national policies and instruments available to governments to create the incentives for mitigation action (IPCC 2007b: 753). The literature provides a great deal of information on the effectiveness and appropriateness of these policy instruments. However, all instruments can be designed well or poorly, and stringent or lax. In addition, all instruments must be monitored and enforced to be attractive. The administrative capacity is thus of key importance for implementing the necessary policies and measures.

To motivate producers and consumers worldwide to take action, it will be necessary to create a price for GHG emissions, often shorthanded as 'carbon-price'. This allows the costs of emissions to be factored in when taking business or investment decisions. An explicit carbon-price can be created through taxes or *emission trading systems* (ETS). The latter is rapidly becoming popular. The EU ETS (EC 2008), operational in the 27 Member States of the EU, sets emission limits for about 10,000 companies and allows the trade of emission allowances between them. Other industrialized countries like the US, Australia and New Zealand are moving in the same direction. An implicit carbon price can be established through regulations and standards that force their subjects to take measures and/or invest in technology with lower emissions.

Regulations are generally more effective than financial incentives for sectors where economic aspects play only a limited role in decision-making, such as for purchasing decisions on a car, a house and household/office appliances. This points to fuel efficiency standards, building codes and appliance efficiency standards as the preferred policy instruments to increase energy efficiency in the household and small industry sector. Regulations have also proven to be more effective in the area of promoting the use of renewable energy. Minimum renewable supply requirements (so called Renewable Portfolio Standards, popular in the US) and feed-in tariffs (a guaranteed high price for renewable electricity supply, popular in Europe and elsewhere) have a good track record (IPCC 2007b: 20 and 753ff.).

Another important finding of the AR4 is that policies that are embedded in broader socio-economic policy are more effective that free-standing climate policies. The reason is that in most countries development objectives, such as creating employment, providing adequate transport, improving health, limiting dependence on imported energy, etc are seen as more important than dealing with climate change. Integrating climate change policy in these broader socio-economic policy areas is very well possible and generally is more easily accepted and more easily implemented. This however requires a truly integrated policy view that is fully supported at the highest level of government (IPCC 2007b: 700).

Most top-down, as well as some 2050 bottom-up assessments, suggest that real or implicit carbon prices of 20 to 50 US$/t$CO_2$-eq, sustained or increased over the coming decades, could lead to a power generation sector with low-GHG emissions by 2050 and make many mitigation options in the end-use sectors economically attractive. Modelling studies show that carbon prices rising to 20 to 80 US$/t$CO_2$-eq by 2030 are consistent with stabilization at around 550 ppm CO_2-eq by 2100 (IPCC 2007b: 206, 660). For stabilization at 450 ppm CO_2-eq carbon prices by 2030 would have to be around $100/t$CO_2$ avoided. Important in this respect is the timing of the price signal or the measures: energy infrastructure has a lifetime of many decades, and choices regarding the investments in the energy sector will determine the amount of carbon dioxide emissions, and hence future climate change, for many years to come.

80.6 Conclusions

In order to cope with the threat of climate change, the UNFCCC was adopted in 1992, and entered into force in 1994. The Kyoto Protocol, limiting the emissions of the developed countries by at least 5 per cent below 1990 levels in the commitment period 2008 to 2012, was adopted in 1997 and became operational in 2004. With the end of the first commitment period approaching, the negotiations have started, notably on Bali in December 2007, to work towards a new international climate agreement as a follow-up to the Kyoto protocol to be agreed in Copenhagen at the end of 2009.

The IPCC's Fourth Assessment Report was planned to feed relevant information into this process. The AR4 synthesis report, summarizing the three assessments, was launched just before the Bali climate conference.

The findings of the AR4 have more than any IPCC report before, played a role in these political discussions. The 'road map' as agreed in Bali, for instance, reflects, in a footnote on the first page, the contribution of IPCC working group III explicitly (UNFCCC 2008). The footnote originates in a text emphasizing the urgency to address climate change, and the text of the footnote refers to information about the need for global emissions to peak rather soon if low level stabilization is to be attained (see table 80.1 above) and information on emission reductions needed by developed and developing countries. As negotiations are very much focussed on the period till 2020, reference was also made to another finding of the AR4: the equitable distribution of efforts between developed and developing countries. Assessing a whole range of equity studies, the AR4 (IPCC 2007b: 776) concluded that for stabilization at levels of about 450 ppm CO_2 equivalent developed countries emissions would need to be reduced 25–40 per cent below 1990 values by 2020 and that developing country emissions should deviate substantially from the baseline. In a later publication by den Elzen and Hoehne (den Elzen/Hoehne 2008), this deviation was shown to be 15–30 per cent below baseline in 2020. This underlines the change in the debate that happened around 2007 whereby global warming is now considered unequivocal, and the policy discussion has moved on to the mitigation measures and the best way to implement them. The fact that at the time of the Bali conference, information on possible long-term targets was hidden in a footnote and not mentioned in the main text reflects the very controversial nature of setting these targets in light of the fear of developing countries that their development aspirations will be blocked by lack of available space to emit CO_2. At the UNFCCC meeting in Poznan, Poland, in December 2008, much attention was given to the findings regarding the 15–30 per cent below baseline for developing countries (paid by themselves, so not the result of off-sets bought by developed countries). There was no progress towards agreement on these numbers, however.

Whatever the form and extent of a post-Kyoto agreement will be, there will be a continuing need for information at all geographical levels (from municipalities to the globe) on the cost and potentials of climate mitigation measures. Remarkably, the weak points in information seem to be the same at the global and the local level: there is a need for harmonizing the methodology and the data for the residential and the service sector; more attention needs to be given to non-CO_2 greenhouse gases; the effect of behavioural changes need to be explored and its effects quantified; more data are needed on the mitigation options and mitigation potential in developing countries. Also emissions and sinks from agriculture and forestry need to be quantified more reliably. The information will be increasingly used to support governments and enterprises to reduce their 'carbon footprint', or even to become 'carbon neutral' in the long run. For supporting the national and global arena, economy-environment models can be improved by including more technological detail, by a better representation of the dynamics of taxes and expenditures, and of 'technology learning'. There is still a lack of empirical evidence on the interaction between climate policies and (sustainable) development policies, including adaptation to climate change (IPCC 2007b: 92).

The IPCC has started the preparations for a fifth assessment report due for 2013–2014, for which the scoping will start in 2009. There is still ample time for executing and publishing original research that can contribute to decreasing the risk of global climate disruptions.

81 Global Climate Change, Natural Hazards, and the Environment: an Overview of UNESCO's Activities

Walter Erdelen and Badaoui Rouhban

81.1 Introduction[1]

Under *United Nations* (UN) leadership, global climate change has been placed at the top of the international community's agenda and, to every possible extent, mainstreamed in the departments, funds, and programmes of the UN and its specialized agencies. At the 13th *Conference of Parties* (COP) of the *UN Framework Convention on Climate Change* (UNFCCC) in Bali, Indonesia, 12 December 2007, UN Secretary-General Ban Ki-Moon stated: "The latest report of the Intergovernmental Panel for Climate Change (IPCC)[2] tells us that, unless we act, there will be serious consequences: rising sea levels, more frequent and less predictable floods and severe droughts, famine around the world, particularly in Africa and Central Asia, and the loss of up to a third of our plant and animal species."[3]

Given its mission, areas of competence, and long-standing experience, the promotion of environmental protection and sustainable development is among the few overriding objectives of the *United Nations Educational, Scientific and Cultural Organization* (UNESCO). The Organization is one of the principal partners of international and intergovernmental environmental programmes and, as such, forms part of the group of "environment organizations" within the UN system. Sustainable development, including environmental issues, is a transversal theme cutting across all areas of competence of the Organization. While the major bulk of the activities are being carried out in the natural sciences and, to a somewhat lesser extent in other sectors of UNESCO, global climate change, natural hazards and environment-related activities have over the last 20 years increased and permeated various sectors of the Organization.

This chapter offers an overview on UNESCO's activities in the natural sciences that contribute to coping with global environmental and climate change, and to assessing natural hazards. This chapter does not intend to be a scientific study on UNESCO's work or to evaluate its effectiveness. It does not provide an exhaustive inventory of all relevant UNESCO activities, and it does not evaluate the impact of its action nor does it offer a comprehensive description of its results. The selected activities referred to below illustrate aspects of UNESCO' actions that are carried out by diverse units which address global climate change from different natural science angles such as the ocean sciences and climate, water sciences, ecological and earth sciences, education, social sciences and information, as well as local and indigenous knowledge.

Further work is being undertaken within UNESCO to refine a strategy for action on global climate change. In May 2008, at its 179th Session, the Executive Board of UNESCO approved in principle the overall terms of this strategy, which draws on two main pillars (UNESCO 2008a): the sound and unbiased generation and use of data, information and research concerning climate change (the knowledge base); and the application of educational tools, specific sectoral measures, and public awareness activities. This strategy aims at assisting Member States to build and maintain a requisite knowledge base; to adopt measures to adapt to the impacts of climate change; to contribute to mitigation of its causes, and to strengthen sustainable development.

81.2 UNESCO's Mandate in Relation to Global Climate Change, Natural Hazards, and the Environment

In conducting research on climate, hazard issues, and the environment in a development context, different disciplines from the natural sciences need to join forces through interdisciplinary work to bring solutions to complex problems (Petitjean/Zharov/Glaser/Richardson/de Padirac/Archibald 2006). Within the UN framework, UNESCO has unique sectoral competences encompassing the natural, social, and human sciences, and also the fields of education, natural and cultural heritage, public awareness, and the media. Regarding the environment and climate issues, UNESCO has been active in advancing basic scientific knowledge and in promoting interdisciplinary scientific work through and among its intergovernmental and international scientific programmes. UNESCO is interestingly placed to respond to the broader challenges of such issues because of its transdisciplinary approach to international scientific cooperation. While relevant to the climate problem, many of UNESCO's programmes are concerned with objectives such as sustainable development, biodiversity conservation, adapting to the impacts of global changes on hydrological systems, natural resources management, strengthening water governance for sustainability, oceans, the conservation of natural and cultural World Heritage, indigenous knowledge systems, solid Earth science, and natural hazard assessment.

Developing an effective response to global climate change and the threat of natural disasters calls for action in virtually all of UNESCO's areas of competence. Hence, UNESCO's mandate also covers many of the scientific disciplines involved in disaster preparedness and mitigation, with many programmes in place that deal in one way or another with the study and mitigation of natural hazards, such as earthquakes, volcanic eruptions, landslides, floods, droughts, and tsunamis.

81.3 Climate Research and Oceans

In the area of climate research, UNESCO's task is to provide scientifically rigorous and unbiased reviews of the state of knowledge about climate processes and their impact on vulnerable systems, whether environmental, economic or social. The *Intergovernmental Oceanographic Commission* (IOC) of UNESCO, which began its work in 1960, is the recognized UN mechanism for global cooperation in the study of the oceans. It leads the field in ocean research. Through its IOC, UNESCO as well as the *World Meteorological Organization* (WMO) have played a central role in providing authoritative scientific and technical information that has enabled evidence-based policy and decision-making, and has informed the work of the IPCC.

Global weather and climate observation and prediction systems are a unique resource coordinated by these UN entities. IOC hosts the secretariat of, or co-sponsors the main ocean entities, such as the *Global Ocean Observing System* (GOOS), the *Global Sea Level Observing System*[4], and the *Ocean Observations Panel for Climate*, all of which seek to provide accurate descriptions of the present state of the oceans, their living resources, and the actual or likely impact of global climate change. UNESCO co-sponsors two key research and monitoring programmes that were specifically developed following world climate conferences held in 1979 and 1992. These are the *World Climate Research Programme*[5] (WCRP), and the *Global Climate Observing System*[6] (GCOS). These programmes provide rigorous and unbiased reviews of the state of knowledge on climate processes and impacts. They contribute directly to the scientific assessments of the IPCC, and to the research and monitoring needs of the UNFCCC[7].

The WCRP aims to determine the extent to which climate can be predicted, as well as the way in which human activities influence climate. The programme encompasses studies of the global atmosphere, oceans, sea and land ice, the land surface, including water and the biosphere that together constitute the Earth's physical climate system. WCRP (chap 78 by Church/Asrar/Busalacchi/Arndt) develops much of the scientific evidence on global climate change, and organizes the model simulations that form the basis of projections by the IPCC.

GCOS is a system which provides observations and promotes research for monitoring, understanding, modelling, and predicting the climate system. GCOS was established to ensure that the observations

4 See at: <http://www.gloss-sealevel.org/> (30 June 2008): p.1 of 2.

5 See at: <http://www.wmo.ch/pages/prog/wcrp/> (30 June 2008): p. 1 of 1.

6 See at: http://www.wmo.ch/pages/prog/gcos/ (30 June 2008): p. 1 of 1.

7 See at: <http://unfccc.int/2860.php> (30 June 2008): p.1 of 3.

and information needed to address climate-related issues are obtained and made available to all potential users. GCOS addresses the total climate system including its physical, chemical and biological properties, and atmospheric, oceanic, hydrologic, cryospheric and terrestrial processes. Through the Joint IOC-WMO Technical Commission for Oceanography and Marine Meteorology, IOC coordinates and manages the implementation of an operational ocean observing system in support of GOOS and GCOS, and reports to the UNFCCC.

UNESCO co-chairs the capacity building committee of the *Global Earth Observation System of Systems*[8], which coordinates the development of an integrated observing system for the global environment. As co-chair, UNESCO assists in fund raising, coordination and training, and in the dissemination of information and teaching materials. The Organization is equally part of the *Integrated Global Observing Strategy* which seeks to provide a comprehensive framework to harmonize the common interests of the major space-based and *in situ* systems for global observation of the Earth. Furthermore, UNESCO co-sponsors the *Global Terrestrial Observing System*[9] (GTOS) which assists in the task of detecting and managing global and regional climate variations on land. GTOS carries out observations, modelling, and analysis in support of sustainable development, and facilitates access to information for researchers and policymakers.

In work co-sponsored by UNESCO and the *International Atomic Energy Agency* (IAEA), the Abdus Salam *International Centre for Theoretical Physics* (ICTP) in Trieste, Italy, carries out research in natural climate variability and predictability as well as climate change and related impacts. These efforts aim at improving our understanding of climate predictability at seasonal to decadal scales and anthropogenic climate change, while at the same time studying the impacts of climate variability and climate change on human societies and natural ecosystems. This is done through a combined strategy of data analysis and modelling from the global to the regional scale, and mostly focuses on the regions of Africa, Asia, Europe, and South America. In this respect, the ICTP develops regional climate models, which are currently used by a wide range of scientists for many applications, such as regional scale climate change simulation and the study of the effects of aerosols and land-use change on regional climates. The ICTP also investigates the dynamics and predictability of natural phenomena such as the *El Niño Southern Oscillation*, the *North Atlantic Oscillation* and the *African and Asian Monsoon Systems*. Among the impact activities, the ICTP currently focuses on the hydrological and agricultural impacts of short-term climate anomalies and long-term climate change. Finally, the ICTP coordinates a wide network of climate scientists, mostly from developing countries, provides models and datasets and a forum to exchange information, and organizes regular training workshops both at ICTP and in developing countries.

Since the beginning of the Industrial Revolution, the oceans have absorbed approximately fifty per cent of the man-made CO_2 released into the atmosphere, greatly reducing CO_2 concentrations in the atmosphere, and attenuating its impact on climate. The *International Ocean Carbon Coordination Project*, for which UNESCO provides the secretariat, monitors these vital ocean CO_2 processes through a global network of observatories. Furthermore, the IOC and the Scientific Committee on Oceanic Research periodically assess impacts on ecosystems, coral reefs, and fisheries due to the current rapid acidification.

This is done through a symposium series on '*The Ocean in a High CO_2 World*' aimed at providing sound, unbiased scientific information to decision-makers and the general public. The first symposium results were compiled in a special issue of *The Journal of Geophysical Research*. The Global Coral Reef Monitoring Network[10], which is co-sponsored by the IOC, coordinates global monitoring and seeks to improve the management and conservation of coral reefs, which are declining rapidly in many areas because of changes in acidity, in sea-level and in maximum sea surface temperatures. The *Global Ocean Ecosystem Dynamics Programme*[11] seeks to understand how climate change affects the abundance, diversity, and productivity of marine life. It has specific projects on small pelagic fish species, oceanic top predators, and cod.

81.4 Water Resources

With the projected global temperature increase the global hydrological cycle is expected to intensify. As a consequence fresh water will be significantly impacted by global climate change. Availability of fresh water and frequency and severity of extreme events like floods and droughts will be deeply affected. Changes in the magnitude and frequency of extremes will have extensive impacts on water management and agriculture, and will affect human security and livelihoods, aquatic ecosystems, industry, and trigger population movement and migration. The consequences are far-reaching and are likely to be felt most strongly by the most vulnerable.

UNESCO provides the secretariat for the *World Water Assessment Programme* and leads the production team of UN agencies that comprise UN-Water and contribute in an inter-agency collaboration to the *World Water Development Report*, the UN system's triennial reference document that tracks the water-related targets of the Millennium Development Goals (UNESCO 2006). The third edition of the Report, scheduled for publication in 2009, will focus on "Climate Change and Water". The World Water Development Report supports countries in addressing the challenges and achieving the water-related goals of Agenda 21, the UN Millennium Declaration, and the Johannesburg Plan of Implementation. The Report laid the foundation for a continuous, global monitoring system for water issues.

The *International Hydrological Programme* (IHP) of UNESCO is the only intergovernmental programme of the UN system devoted to water research, water resources management, education and capacity-building. Its activities directly address adaptation to the impacts of global changes including climate change on river basins and aquifer systems, on the hydrological cycle and consequent impact on water resources and hydrological extremes, aquatic ecosystems and biodiversity, specific regions such as arid lands and urban conglomerations, and societies most vulnerable to drastic changes in water availability or quality.

Box 81.1: Other projects and programmes. UNESCO carries out other activities addressing water issues, including the following.

- *The Water Programme for Environmental Sustainability*, funded by Italy. Operating in Serbia, North Africa, Vietnam and China, the programme identifies and establishes best practices in response to climate change impacts on water resources.
- *Integrated Urban Water Modelling and Management under Specific Climates* seeks to strengthen the analytical framework for integrated urban water management, with a special focus on developing countries.
- *Groundwater Resources Assessment under the Pressures of Humanity and Climate Change*, focused on Africa, attempts to understand the role of groundwater in the global water cycle, and the impact of climate changes on aquifers. A related programme called Quo Vadis Aquifers seeks to understand the parameters that determine vulnerability of populations dependent upon groundwater resources.
- *Worldwide Hydrological Mapping and Assessments Programme* seeks to summarize information about groundwater on a global scale, to produce a groundwater map of the world, and to evaluate recharge rates under present climatic conditions and under future climate change scenarios.
- *Hydrology for Environment, Life and Policy* (HELP) promulgates the use of modern hydrological monitoring and data transfer techniques, and disseminates understanding of the relationship between global processes and regional hydrology. The information is thus transferred to the public domain and made available to water managers and policymakers.
- *Flow Regimes from International Experimental and Network Data Sets* (FRIEND) was created to develop a better understanding of hydrological variability and similarity across time and space in a changing world through a mutual exchange of data, knowledge and techniques. The programme also provides support to researchers and operational staff of hydrological services in developing countries, thereby contributing to their capacity to assess and manage their own national water resources and furthering the goal of providing a reliable supply of fresh, clean water to the world's poor. Technical output of the programme inform and impact the water policies of national governments and sharing of data between countries and the establishment of regional hydrological databases have made a lasting contribution to international cooperation.
- *Groundwater for Emergency Situations (GWES)* is a UNESCO-promoted project that considers potential water-related catastrophes, and identifies groundwater resources that could temporarily replace damaged supply systems. Devastating natural hazards or weather catastrophes may make communities entirely dependent on groundwater resources, which need to be identified, replenished artificially and safeguarded before disasters strike.

81.5 Ecological Systems

The challenge of sustainable development is to reconcile economic development with the maintenance of a healthy environment. Sustainable development, climate change, natural resource management, and biodiversity are inextricably linked. UNESCO promotes the study of environmental protection, biodiversity conservation, climate change impacts, and sustainable development through its World Network of Biosphere Reserves representing 531 sites in 105 countries (UNESCO 2007). This Network uses the buffer and transition zones of the reserves for research into innovative combinations of afforestation, reforestation, rural energy, infrastructure development, and urban planning. In support of this Network and other biodiversity research and monitoring activities, UNESCO's *Man and the Biosphere Programme* (MAB) provides the scientific basis for integrated ecological approaches for the conservation and sustainable management of ecosystems and their resource bases.

UNESCO is giving consideration to mechanisms that would promote the sustainable management of biosphere reserves by local populations, thus linking interconnected objectives in reforestation for sequestration of greenhouse gases with those for the conservation of biodiversity.

The *Millennium Ecosystem Assessment* (MA 2005) has been instrumental in qualifying and quantifying for the first time ever the status of ecosystem services and how they relate to human well-being (Leemans 2009). The MA was implemented by the main multilateral environmental conventions and a number of UN specialized agencies and programmes, and also benefited from the endorsement by and participation of the World Bank, the Global Environment Facility, and the private sector. The MA succeeded in mobilizing the interest of all these stakeholders in changes in the capacity of ecosystems to deliver key services. As a co-sponsor of the assessment, UNESCO is engaged in a follow-up process, as part of a consortium of agencies led by the United Nations Environment Programme, which aims at translating the findings of the MA into adaptation and mitigation and other management measures in support of appropriate policy responses. UNESCO, the United Nations University, and the International Council for Science are currently developing a research programme aimed at filling the gaps in scientific knowledge identified by the MA.

81.6 Natural Hazards

Global climate change and natural hazards are closely interlinked: natural hazards are becoming more intense and frequent in some regions. UNESCO has been engaged in the study of natural hazards since 1960. It plays an active role in the UN *International Strategy for Disaster Reduction*. The Organization advocates the need to shift emphasis away from a purely relief and disaster response towards a culture of preparedness and prevention. Activities contribute to the studies of hazards of geological origin, such as earthquakes, tsunamis, volcanic eruptions and landslides, and of those of hydro-meteorological origin including tropical cyclones, floods, droughts and desertification (James 2007). Efforts are supported to study the mechanisms of these hazards, to identify their distribution in time and space, and to disseminate information on their occurrence. UNESCO also deals with activities aimed at reducing risks from such hazards through design and dissemination of mitigation measures and information, education, and public awareness (UNESCO-IOC 2006). Hence, support is given to the setting up of reliable early-warning systems, to rational land-use planning, to the development of suitable building design, to the protection of educational buildings and cultural monuments, and to the improvement of environmental defences such as mangrove forests. UNESCO also contributes to the UN *Platform on Space-based Information for Disaster Management and Emergency Response*, implemented as a UN programme under the UN Office for Outer Space Affairs, which provides access to and develops the capacity of all countries to use space-based information to support disaster management.

The ICTP carries out research in solid-Earth geophysics and space geodesy aimed at improving our assessment of earthquakes, tsunamis, and volcanic hazards. The ICTP is currently focusing on the mutual relationships between climate and tectonics, and on the effects of global change in terms of a wide spectrum of natural hazards. The institution is active in pre- and post-disaster investigations, and has mapped earthquake hazards in different countries and zoned the most hazardous megacities. The ICTP transfers cutting edge methodology to developing countries through joint projects and training workshops.

Box 81.2: Priority - Gender Equality
Gender equality is one of UNESCO's two priorities and is mainstreamed into several programmes and activities. There is evidence that women are affected differently and more severely by climate change, and its impact on agriculture, natural disasters, and climate change-induced migrations. There is also a wealth of evidence indicating that women play important roles in adapting to climate change. UNESCO will address this critical consideration in information sharing and outreach in the formulation of climate change adaptation strategies and climate-related disaster preparedness efforts to ensure that women and girls are informed to participate in planning and decision-making.

UNESCO and WMO, building on past cooperative success, launched the *International Flood Initiative* (IFI) during the 2005 World Conference on Disaster Reduction in Kobe, Japan to address existing management gaps and to provide a platform for further collaborative efforts. The overall objective of the initiative is to build the capacity necessary to understand and better respond to flood hazards, vulnerabilities, and benefits. The initiative will enable countries to stimulate research, improve training in both informal and academic settings, and to promote networks among professionals[12]. It also seeks to introduce adaptation strategies appropriate for each area.

UNESCO's MAB Programme has been particularly concerned with drought and combating desertification and has made a significant contribution to the *UN Convention to Combat Desertification* (UNCCD)[13]. MAB addresses the interface between development and environment studying the impact of human activities on fragile environments such as arid, semi-arid, and drought-prone lands. Dealing with global climate change in drylands requires innovative solutions, which seek to foster science education, preserve biological diversity, and raise environmental awareness. In the same vein, UNESCO has been involved in drylands research through IHP in facilitating the development of a Regional Integrated Drought Management Centre in Sub-Saharan Africa. A project called *Global Network on Water and Development Information for Arid Lands*, seeks to strengthen the global capacity to manage water resources of arid lands through international and regional cooperation networks. Another project, *Sustainable Management of Marginal Drylands* (SUMAMAD), is aimed at tapping the traditional knowledge of indigenous populations and using this as part of a management approach that promotes economic sustainability and resource conservation. Moreover, the SUMAMAD project explores soil and water conservation in drylands and proposes site-specific alternative income generating opportunities for local communities to promote sustainable development without disrupting fragile dryland ecosystems.

81.7 UNESCO's Additional Activities

81.7.1 Earth Sciences

One of the topics of UNESCO's *International Geosciences Programme* (IGCP) on 'Global Change and Evolution of Life: Evidence from the Geological Record seeks to understand how climate change has impacted on water supplies, the environment, and human society through time. Understanding climate trends relies heavily upon the preserved geological record. By studying this record, Earth scientists are coming to an understanding of how the climate system works, how it has changed in the past, and what its future state may be like.

Changes in climate and life on Earth are preserved in the geologic record. Ice and dust records, terrestrial and ocean sediments, and past chronological changes plant and animal communities, are all part of this record. Five major and ten smaller mass extinctions have punctuated the history of life. One of the 18 IGCP projects which deals with paleo-climate change is "*The rise and fall of the Vendian Biota*". Besides its scientific research on past global change, the project is also active in organizing public outreach and education projects.

UNESCO and the *International Union of Geological Sciences* (IUGS) are joint organizers of the *International Year of Planet Earth* (IYPE)[14], declared by the United Nations General Assembly. IYPE focuses on the fundamental role of the Earth sciences, and it aims to demonstrate new and exciting ways in which

12 International Flood Initiative, 2007. (UNESCO-IHP, Paris).
13 See at: <http://www.unccd.int/> (30 June 2008): p.1 of 2.
14 See at: <http://www.yearofplanetearth.org/> (30 June 2008), p.1 of 1.

they can help future generations to meet the challenges of ensuring a safer and more prosperous world by maintaining a healthy Earth system. Anticipating IYPE during the 34th session of its General Conference in autumn 2007, UNESCO organized a major exhibition on Planet Earth with five themes: the Earth system, dynamic Earth, diverse Earth, changing Earth, and sustaining the Earth. IYPE was launched in February 2008 at UNESCO Headquarters. One of the ten themes of the Year is dedicated to past and recent climate change and geohazards. The initiative will seek to raise the awareness of the contribution to, and role of the Earth sciences in society in the minds of politicians, decision-makers, the media, and the general public.

81.7.2 Education, Communication, and the Social Sciences

UNESCO as the UN specialized agency for education has also been designated as the lead agency for the United Nations *Decade of Education for Sustainable Development* (DESD) 2005–2014, which includes climate change as a thematic priority. DESD aims at mobilizing all strata of society and available expertise in both formal and non-formal education to further the principles, values, and behaviour linked to sustainable development, and at inducing the necessary behavioural and attitudinal changes required to minimize negative climate impacts, including through education for disaster risk reduction, and climate change education. DESD has four priority areas: promoting basic education, reorienting and revising education programmes, developing public understanding and awareness, and providing practical training. Education for sustainable development is an important means of mitigating natural hazards and slowing the effects of harmful climate change. It is also a way of building global partnerships for effective action, showing people that their activities can contribute either to harmful consequences or to lasting solutions. UNESCO's Associated Schools Project Network of some 7,900 educational institutions in 176 countries is used for pilot testing of prototype materials and awareness-raising tools, providing information to educators, teachers, and students worldwide. UNESCO's programmes provide support for institutions of higher education through the UNESCO Chairs programme and the *University Twinning and Networking Scheme* (UNITWIN) Network.

UNESCO's programmes in communication and education provide a scope for much greater involvement, since education and public awareness cut across all sectors and existing activities. The role of the mass media for an engaged discussion on mitigating the impact of and adaptation to climate change is a vital element. The Organization has produced a model for journalism education at diploma, undergraduate, and post-graduate level that includes a module on "Reporting climate change: assessing coverage past and present; issues of balance and expertise in climate change debate".

UNESCO's specialization in social and human sciences provides a specific contribution within the UN system. It helps to improve understanding of the vulnerability of human beings and their natural environment, as well as the political implications of this. Contributions from natural and human and social sciences are adding to the growing scientific knowledge base on climate change, variability, and their impacts. The UNESCO social and human sciences programme, including the *Management of Social Transformation* (MOST) Programme has recently begun working to develop knowledge, research and capacity on urban policy, giving consideration to the environmental impact of uncontrolled urbanization of rural and coastal territories due to climate change-related migration and consumption. This programme, in also addressing the issue of environmentally-induced and climate-induced migration (IOM 1996, 2007), is developing tools to assess the impact of climate change on migration flows and addressing the relevance of migration policies. UNESCO's environmental ethics programme will work to improve education and awareness on the ethics of climate change, addressing questions crucial for decision-making such as how to assess the needs and rights of future generations, and how to determine what is worth protecting, and at what cost or consequence.

81.7.3 Local and Indigenous Knowledge

UNESCO seeks to reinforce international recognition of local environmental knowledge as a component of sustainable development and as a critical factor in community-level natural disaster preparedness and response. The UNESCO *Small Island Developing States* (SIDS) Programme and its *Local and Indigenous Knowledge Systems* (LINKS) Programme promote local-level observations and understanding of climate change which provide the basis for community-based adaptation measures for vulnerable popula-

tions in remote areas (Boelens/Chiba/Nakashima 2006).

In collaboration with the Office of the UN High Commissioner for Human Rights (UNHCR), and the Secretariats of the UN Permanent Forum on Indigenous Issues of the *Convention on Biological Diversity*[15], UNESCO has recently launched an internet-based discussion forum that will explore local and indigenous peoples' observations of climate change impacts and opportunities for adaptation. These insights into climate change processes at the local level will provide an important complement to large-scale scientific observations, while also strengthening the voice of vulnerable communities in international processes.

81.7.4 World Heritage Preservation

UNESCO is the leading global guardian of the world's cultural and natural heritage, and as such, is closely involved in risk assessment and rescue operations to protect natural protected areas, monuments, historic urban quarters, archaeological sites, cultural landscapes, etc. In one of its most famous actions, for example, UNESCO assisted in the safeguarding of works threatened with destruction by floods in Florence and elsewhere in Italy in 1966.

UNESCO provides support to States Parties to the Convention concerning the Protection of the World Cultural and Natural Heritage of 1972 in implementing preventive and corrective measures including to combat climate change impacts on natural and cultural world heritage, by raising awareness and sharing of knowledge and experience, developing pilot projects, and developing policy on climate change impacts on world heritage (Colette 2007a). To address the concern about climate impacts on sites of natural or cultural importance, UNESCO's World Heritage Centre has established a working group to review the nature and scale of the climate risks threatening heritage properties, and to help countries devise appropriate responses (Colette 2007b).

Within its partnerships with space agencies, space research institutions, and universities, UNESCO has recently signed an agreement with Spot Image, a subsidiary of the French space agency. This partnership aims to use Earth observations from space in order to assist the World Heritage Convention[16] with its current programme on climate change. For the purpose of using earth observation from space for World Heritage sites, UNESCO and its partners are focusing on themes like: monitoring the state of glaciers, e.g. Argentinean World Heritage glaciers in close collaboration with the Argentinean Space Agency; monitoring the state of conservation of UNESCO World Heritage tropical forests (in partnership with various space agencies and universities); assessing the status of coral reefs and eventual bleaching effects in Meso-America (UNESCO and the European Space Agency); assessing the permafrost in the Altai Mountains and associated impacts to the archaeological frozen tombs (UNESCO and University of Ghent), and monitoring the effects of increasing rainstorms (e.g. Machu Picchu and Chan Chan, Peru).

81.7.5 Mountains, Coasts, and Small Islands

Many of the world's mountain ecosystems are undergoing important environmental changes, which could affect the ability of their populations to make a living. A UNESCO-supported programme called *Global Change in Mountain Regions* (GLOCHAMORE) is working with 25 mountain biosphere reserves in all world regions and the scientific community to detect signals of global (including climate) change in representative mountain ranges of the world (Gurung 2006). More specifically, GLOCHAMORE addressed the impacts of global climate change on the biophysical environment and the socio-economic conditions of mountain communities. As a result, the GLOCHAMORE Research Strategy is a blueprint providing guidelines on how to study biophysical, social, and economic aspects (e.g. glacial melt, biodiversity, hazards, and mountain economies) in site-specific contexts using mountain biosphere reserves as study and monitoring sites. The Research Strategy aims at establishing a global study approach with a view to harmonize and compare data and research results.

UNESCO gives particular attention to environment and development issues in SIDS through a broad range of activities supporting the implementation of the *Mauritius Strategy*, adopted at the UN SIDS meeting held in Mauritius in January 2005. UNESCO brings together experts in its area of expertise to mitigate the impacts of coastal erosion and other disaster risks through interdisciplinary and intersectoral action (Hadley/Ghina 2007). The impacts of climate change on SIDS and on indigenous communities is a central area of focus in this effort. As an example, UNESCO's Sandwatch[17] initiative provides a framework whereby students, teachers, and communi-

15 See at: <http://www.cbd.int/> (30 June 2008), p. 1 of 1.

16 See at: <http://whc.unesco.org/en/conventiontext/> (30 June 2008), p.1 of 9.

ties in 37 countries are learning first hand about the direct and indirect impacts of climate change on their beaches and coasts – impacts such as rising sea levels, increasing air temperatures, and more intense hurricanes/cyclones/typhoons – and how they can work together to devise and implement approaches and projects to cope with these changes (Cambers/Ghina 2005).

Making the public more aware of the threats created by coastal erosion and sea-level rise is essential in developing an effective coping strategy, which is also the object of the UNESCO project *Mainstreaming Awareness and Mitigation of Marine-Related Hazards and Risks in Integrated Coastal Area Management.* The project is being carried out to develop guidelines on the development and integration of hazard awareness, emergency preparedness and mitigation, and adaptation practices into coastal development planning.

With technical and financial support from UNESCO and its UNITWIN, institutions of higher learning in Malta, Mauritius, the Pacific SIDS, and the Virgin Islands have set up a University Consortium of Small Island States to promote practical, high quality training and research in the fields of climate change, natural and environmental disasters, waste management, resources management, culture, and sustainable living and development.

81.8 Conclusions and Outlook

The UN system is widely acknowledged as the central multilateral framework through which the international community can address global challenges, including by providing a coherent approach to global climate change and natural disaster reduction. UNESCO is committed to play its part in fulfilling this global mission. Action in these fields increasingly depends on the active involvement and support by all major stakeholders: governments, the private sector, and the different components of civil society including scientists, educators, parliamentarians, media, local authorities, youth, women's organizations, and other non-governmental organizations. UNESCO is expected to enhance cooperation with all these major groups. Moreover, cooperation between governmental and non-governmental stakeholders will have to be fostered; UNESCO will actively contribute to this process, in particular in the context of existing mechanisms and other global and regional environment-related events and processes.

The response to global environmental and climate change and natural hazards must be science-based, benefit from comprehensive analysis, and be continuously updated by monitoring of data, trends, and new insights. Greater understanding of the scientific foundations of emerging issues and threats will require increased investment of effort. The provision of unbiased and technically sound data and information is fundamental to global environmental and climate change action: it is critical for enabling adaptation and mitigation policies. Without such information, the causes, impacts, and appropriate levels of response are open to dispute. UNESCO will further support sound and unbiased scientific research and will help translate research results into advice for policy makers and information for the general public. In this respect, the governing bodies of IOC and the advisory bodies of the international and inter-governmental scientific programmes (IGCP, IHP, MAB, and MOST) will continue to play their important roles in defining priorities for their respective contributions to global environmental and climate change issues. Furthermore, the Organization will promote interdisciplinary scientific work among its scientific programmes and interdisciplinary and multidisciplinary activities between its programmes in the sciences, education, culture, and communication.

82 Climate Change and Development: UNDP's Approach to Helping Countries Build a New Paradigm

Veerle Vandeweerd, Yannick Glemarec and Vivienne Caballero

82.1 Introduction[1]

UNDP recognizes climate change as a key human development issue. Without immediate action, climate change will reverse decades of development achievements and undermine efforts to reach human security and achieve the *Millennium Development Goals* (MDGs). As the global development network of the United Nations, UNDP's goal is to align human development and climate change responses through a coordinated mix of policy and financial instruments. To achieve this, UNDP is engaging in strategic partnerships to support the efforts of developing countries and vulnerable groups to significantly scale up mitigation and adaptation action. Effective action is possible and affordable (Stern 2006). The benefits of moving towards less carbon intensive yet sustainable economies are likely to be immense, but so would be the costs of inaction (UNDP HDR 2007/2008: 8).

Calling for a new development paradigm that integrates climate change into strategies and plans at all levels, and that links the policy setting with the financing of solutions, UNDP is committed to enhance development taking into account the rapid global environmental changes in key ecosystems as well as in the economic and financial sphere (box 82.1).

The future of global human security is directly dependent on the success of the development measures put in place today by the international community. There is unprecedented scientific consensus that urgent decisive action is required now. The daily life of the poorest 40 per cent of the world's population – about 2.6 billion people – is already affected by climate change (UNDP HDR 2007/2008: 2). This segment of the population has contributed the least to global warming and is likely to be the least resilient to the impacts of climate change, such as worsening floods, droughts, crop failures, and more intense and frequent extreme weather events (IPCC 2007b: 373).

Cognizant of this critical global environmental change issue and aware of the need for a new development paradigm, UNDP is committed to empowering countries to alleviate poverty while meeting the challenges arising from a changing climate. In its role as the United Nations' global development network, UNDP aims at aligning human development and climate change management efforts by promoting mitigation and adaptation activities that do not slow socio-economic progress down but rather accelerate it.

Although the majority of efforts to tackle climate change have focused until now on reducing emissions (Schipper/Cigarán/Mckenzie Hedger 2008: 134), it is now clear, and fully accepted by the negotiators of the climate change regime, that the window of opportunity for action on adaptation is as narrow as the one for mitigation, if the MDGs (box 82.2) are to be achieved. Successful climate change management will require a remarkable scaling up of both mitigation and adaptation actions at the global, regional, national, and local levels.

This chapter discusses UNDP's strategy to help countries build a new development paradigm that effectively addresses climate change. Decades of experience in the international development arena allow UNDP to recognize climate change as a fundamental challenge with substantial implications for the entire spectrum of human development, including conflict-prone issues such as water scarcity, soil degradation, food security, poverty, and environmental migration.

1 The authors gratefully acknowledge the substantive contribution made to this paper by Luis Gómez-Echeverri, independent climate change expert, and the input provided by other UNDP experts. This paper is based on, and relies heavily on, the corporately endorsed *UNDP Climate Change Strategy* (2008), which is the result of a consultative and collaborative effort within UNDP and outside experts. The views expressed in this publication are those of the authors and do not necessarily represent those of the United Nations, including UNDP, or their Member States.

Box 82.1: UNDP. **Source**: <www.undp.org>.

UNDP is the UN's global development network, an organization advocating change and connecting countries to knowledge, experience and resources to help their people build a better life. UNDP works in 166 countries, assisting them to identify and develop their own solutions to global and national development challenges. As they develop local capacity, they draw on the people of UNDP and our wide range of partners.

World leaders have pledged to achieve the *Millennium Development Goals*, including the overarching goal of cutting poverty in half by 2015. UNDP's network coordinates global and national efforts to reach these goals. UNDP's focus is helping countries build and share solutions to the challenges of: democratic governance, poverty reduction, crisis prevention and recovery, environment and energy, and HIV/AIDS.

UNDP helps developing countries attract and use aid effectively. UNDP encourages the protection of human rights and the empowerment of women. Its annual *Human Development Report* (HDR) focuses the global debate on key development issues, providing new measurement tools, innovative analysis and often controversial policy proposals. The global HDR's analytical framework and inclusive approach carry over into regional, national and local HDRs.

Box 82.2: Climate change threatens achieving the MDGs. **Source**: <www.undp.org/mdg>

- *MDG 1 (Poverty and hunger):* People relying on subsistence agriculture and natural resource harvesting – such as fishing, hunting, forestry – will be among those most impacted by climate change. In addition to threatening livelihoods, a change in cropping patterns will affect food security, international production and trade, and international human security (WBGU 2008: 94). These expected changes fundamentally hinder the efforts to reduce extreme poverty and hunger.
- *MDG 2 (Education):* Weather events and climate related stresses can interfere with the time and opportunity for children to attend school. Climate change also threatens to destroy or force a change of use of infrastructure such as schoolhouses, and it may increase the displacement and migration of families, thus disrupting and limiting educational opportunities.
- *MDG 3 (Gender)*: Since a disproportionate percentage of the poor are women, climate change puts them most at risk in their traditional roles as the primary users and managers of natural resources, primary caregivers and unpaid labourers (Stern 2006:114). Efforts to include women in planning processes will help ensure that their particular needs and constraints are recognized and addressed.
- *MDGs 4,5,6 (Health related):* The effects of climate change on health are particularly important in water management since floods and droughts can lead to increased vulnerability to water-borne diseases, and lack of safe drinking water and sanitation (Biemans/ Bresser/ Kabat/van Schaik 2006:30). The spread into new areas of vector-borne and air-borne diseases and heat related stresses are also expected to increase. By 2020, between 75 and 250 million people, mainly in Africa, are projected to live under increased water stress. For 2080, the figure is estimated to be as high as three billion people (IPCC 2007:194). Water scarcity can lead to conflict over resources jeopardizing human security.
- *MDG 7 (Environment):* Climate change is a lead cause of global environmental change. It will impose fundamental alterations to ecosystem structure, function and productivity. This includes a serious threat to biodiversity and the need to rethink land use and natural resource management (WBGU 2008: 5).
- *MDG 8 (Partnership):* Addressing climate change and global human security will demand unprecedented cooperation among a wide variety of actors and institutions, including scientific, business, political and advocacy communities.

This chapter proposes that these issues need to be tackled at the very core of development: strengthening institutional capacities for more cohesive and efficient governance, integrating climate change into strategic planning as well as conflict prevention efforts, and equitable economic development. In the climate change context, this implies scaling up mitigation and adaptation actions.

Discussing UNDP's vision, this chapter presents a brief review of the current climate change context for action (82.2); an overview of UNDP's ongoing activities highlighting experience with mitigation, adaptation, and existing partnerships (82.3); and a discussion on the dimensions and strategic priorities for scaled up action (82.4).

82.2 Analytical Framework

The impacts of climate change will fall disproportionately on the poor and lead to greater inequality and insecurity in developing countries (Stern 2006: 29).

Climate change intensifies existing environmental crises thereby triggering land-use and water-use conflicts as well as environmental migration (GTZ 2008: 19). The effects of climate-induced shocks on critical governance function and structure will intensify the relationship between global environment and human security. As such, these effects may disrupt institutional and political stability and magnify the propensity to conflict. For instance, human migration from arid and land-locked Burkina Faso to coastal Cote d'Ivoire – due to environmental degradation – can be linked, along with other influencing factors, to the political collapse and civil war experienced in the region (UNDP 2009: 11).

Water shortages will be exacerbated, leading to water scarcity problems, reducing access to safe drinking water and having an impact on precipitation frequency and intensity, which affects local growing seasons as well as international production and trade (UNESCO-WWAP 2003). In particular, this will be the case for the poorest and most vulnerable countries, which are already facing serious development challenges and human security threats (Brown/Hammill/McLeman 2007: 1142). Climate change will also have a harmful effect on health and it will increase the level of risk for the most vulnerable particularly to the impacts of extreme weather events and severe droughts (Epstein/Mills 2005: 9). And there is evidence that these and many other effects are already being felt in many regions of the world, for instance the resurgence of malaria in East African highlands (Cox/Hay et al 2001: 1).

The *Intergovernmental Panel on Climate Change* (IPCC 2007) stated that the world is warming and that human activity – rather than just natural variations – has contributed to current levels of warming. The IPCC concluded that regional climate patterns are changing, for instance: crop yields could increase by 20 per cent in East and South-east Asia, but decrease by up to 30 per cent in Central and South Asia; and rain fed agriculture could drop by half in some African countries by 2020. The loss of biodiversity will have additional negative effects on people's livelihoods and ecosystem stability (IPCC 2007: 280).

The 2007/2008 *Human Development Report* (HDR) estimated that stabilizing greenhouse gas concentrations in the atmosphere at a level that prevents catastrophic climate change will require a global 50 per cent reduction of greenhouse gas emissions by 2050 from 1990 levels. The report recommended that both developed and developing countries reduce their emissions. Developed countries are to cut greenhouse gas emissions by at least 80 per cent by 2050, with 20–30 per cent cuts by 2020. For major emitters in developing countries, the recommendation is to have an emissions trajectory that peaks in 2020, with 20 per cent cuts by 2050. (UNDP HDR 2007/2008)

Addressing climate change will demand unprecedented efforts and currently available financial resources are likely to be insufficient. However, as suggested by the Stern Review (2006), failure to invest in activities addressing climate change could cost the global economy up to 20 per cent of its GDP (UNFCCC 2007d; IEA 2006).

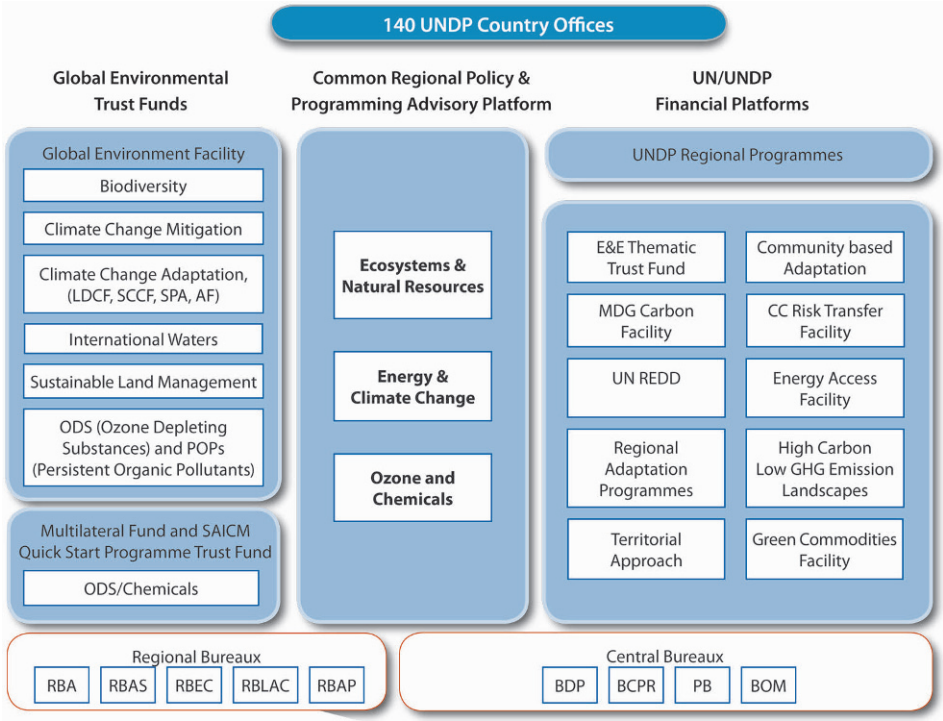
A number of major international events and agreements confirm the unequivocal consensus by the political, business, scientific, and advocacy communities to agree on a future climate change agreement as was stressed by the decisions of the UN Secretary-General's High Level Event (2007) and Summit on Climate Change (2009), by the discussion by the Security Council on the security implications of climate change impacts (2007) and the Communiqués of the G-8 Summits at Heiligendamm (2007), Hokkaido Toyako (2008) and Aquila (2009). The 'Bali Road Map' (2007), adopted by governments at the 13th *Conference of Parties* (COP-13) of the UNFCCC, established ambitious goals to be achieved by COP-15 in Copenhagen. With the Copenhagen Accord (2009), the world made essential progress towards a future international framework. While negotiations will need to continue through COP-16 in Mexico (2010), the Copenhagen Accord is the reflection of an unprecedented high-level political statement of purpose on the issue of climate change (Averchenkova UNDP 2010: 5).

The UN Secretary-General launched in February 2010 a High-Level Advisory Group on Climate Change Financing, aiming to mobilize new and innovative financial resources to reach US$100 billion annually by 2020, as agreed in the Copenhagen Accord. In the same spirit, UNDP continues to advocate for the recognition of sustainable development and poverty eradication as global priorities that need to be at the foundation of international negotiations if the world is to move forward in a path of greater climate security.

82.3 UNDP's Experience with Global Environmental Change

In accordance with its overarching mission to fight poverty, the focus of UNDP's work has been to align

Figure 82.1: Delivery of UNDP Environmental Finance Services **Source:** UNDP (2009a: 8).



sustainable human development and climate change policy responses paying special attention to the needs of the poorest and most vulnerable developing countries. Delivering environmental finance services, UNDP uses its resources to leverage new sources of environmental finance and to re-direct financial flows from public and private sectors towards environmentally sustainable practices (figure 82.1). Highlights of UNDP's results in environment for the period 2005–2009 include an estimated 413 million tonnes of CO_2 emissions avoided as a result of effective projects and 127 new protected areas covering more than 10 million hectares created in 50 countries.

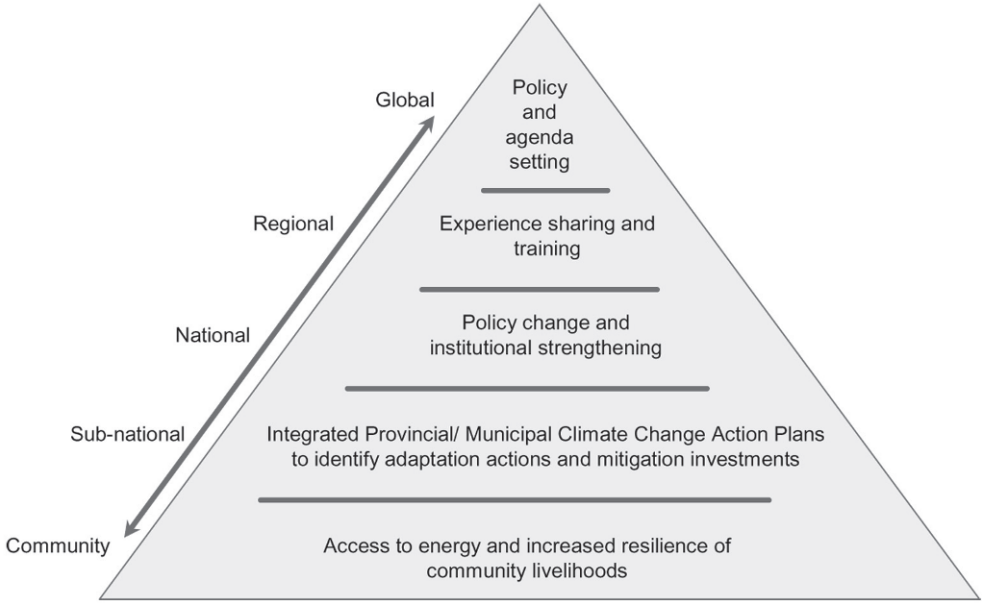
With widespread country office presence, UNDP has mobilized approximately $1.58 billion (and $3 billion in co-financing for the period 2004–2007) in over 140 countries through a diverse project portfolio that supports climate change responses at the global, regional, national, sub-national, and community/local levels (figure 82.2).

UNDP's partners comprise a variety of national, bilateral, and multilateral development agencies, financial institutions and civil society, including the World Bank, Regional Development Banks, other UN agencies, private sector, regional associations, NGOs, CBOs, faith communities and academic institutions, among others.

In partnership with the World Bank and UNEP, UNDP is an implementing agency of the *Global Environment Facility* (GEF), and also the recipient of large amounts of other funds dedicated directly and indirectly to global environmental change. With a growing climate change portfolio, integrated country level solutions are promoted in recognition of the fact that mitigation and adaptation are closely interlinked and essential to one another. For instance, reducing emissions through sustainable land management practices increases the resilience of ecosystems and in turn improves the resilience and adaptive capacities of vulnerable communities (UNDP 2009: 57). Moreover, a shift from fossil fuels to renewable energy alternatives can reduce the energy costs of oil-importing countries, reduce gender inequalities, improve health, increase energy security, provide increased access to energy for the rural poor, and reduce local environmental health impacts (UNDP 2008a: 12).

UNDP has made strides towards 'Delivering as One UN' by partnering with UNEP and committing to jointly lead the UN System in the task of incorporating climate change in development strategies and programmes at the country level. Both agencies are working in joint programmes such as the *Territorial Approach to Climate Change* (TACC), which promotes climate resilient and lower carbon territories

Figure 82.2: Support Levels for Global Environmental Change Responses. **Source:** UNDP (2008a: 27).



(box 82.7), and the *Poverty and Environment Initiative* (PEI), which mainstreams environment into national development planning.

Another step forward is the Nairobi Framework, agreed in 2006 by UNDP, UNEP, the World Bank, the African Development Bank, and the UNFCCC, with the purpose of supporting the capacity development efforts of low income countries vis-à-vis the CDM.

Launched in 2007, the UNDP-Spanish MDG Achievement Fund pursues a coordinated response of the UN system towards the achievement of the MDGs. The Fund has been supporting adaptation through an initial allocation of US$94 million, which finances inter-agency initiatives that strengthen the adaptive capacity of developing countries.

More recently, UNDP, FAO, and UNEP have inaugurated the United Nations Collaborative Programme on *Reducing Emissions from Deforestation and Forest Degradation in Developing Countries* (FAO/UNDP/UNEP: 2008). This multi-donor trust fund was established in 2008 to allow donors to pool resources and provide funding to assist developing countries in formulating and implementing national REDD strategies and mechanisms. At the national level, UN-REDD is implemented in coordination with the World Bank's *Forest Carbon Partnership Facility* (FCPF).

82.3.1 Climate Change Mitigation: UNDP's Experience

With over 15 years of experience in approximately 100 countries supporting energy efficiency and clean energy development, UNDP in partnership with GEF have been deemed particularly successful at developing countries' capacities to remove barriers to clean energy and create greater energy access for the poor. Five strategic priorities are addressed: (i) transforming market policies to promote energy efficient products and processes, (ii) increasing access to local sources of financing for renewable energy and energy efficiency, (iii) promoting power-sector policy frameworks to support renewable energy, (iv) renewable energy for poverty alleviation, (v) catalysing shifts in modes of urban transport.

The approach to mitigation has evolved from supporting technology demonstration projects, to establishing an enabling environment for direct investment towards environmentally-friendly and climate-friendly technologies (box 82.4). In the case of wind power, for example, where UNDP may have supported pilot wind farms in the past, it now focuses on the policy change and institutional development needed to promote greater private sector investment in wind energy, such as smart wind tariffs, power purchase agreements, and capitalization of pilot financial instruments (UNDP 2008a: 13).

UNDP has directly reduced CO_2 emissions from land use change, specifically from land degradation

Box 82.3: MDG Carbon Facility. **Source**: <www.mdgcarbonfacility.org>.

The MDG Carbon Facility assists developing countries to leverage carbon finance for clean energy development and sustainable land use practices. Building on UNDP-GEF market development activities and UNDP capacity development efforts for CDM and JI, the Facility provides dedicated project management services to individual project investors in emerging carbon markets. The core objectives of the Facility are: (i) up-scaling carbon finance in countries that are presently under-represented; and (ii) promoting carbon projects that contribute both to climate change risk management and to the MDGs. Once a carbon market is established and inclusive of private-sector investment and technologies conducive to long-term development, the MDG Carbon Facility is designed to exit that market as its goal of market transformation is considered accomplished (UNDP 2009: 119). UNDP proposes a three-step approach to capacity development and leveraging carbon finance:

Box 82.4: Montreal Protocol Programme. **Source**: <www.undp.org/montrealprotocol>.

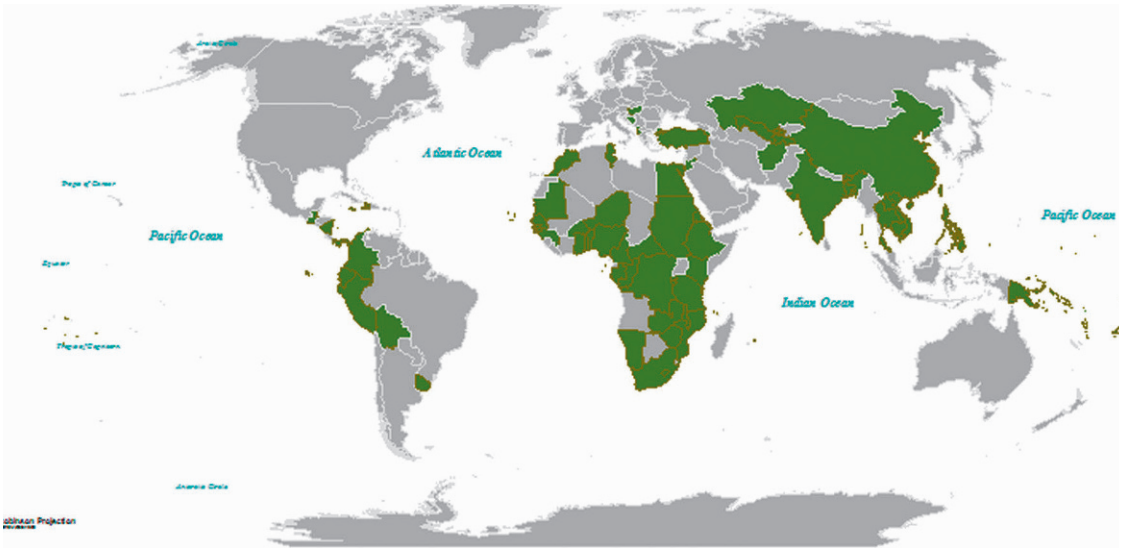
By 2010, the Multilateral Fund for Implementation of the Montreal Protocol on Substances that Deplete the Ozone Layer (MLF), as a whole, has prevented the equivalent of between 9.7 and 12.5 gigatonnes of CO_2 from entering the atmosphere. The acceleration of the phase-out of the last group of substances – HCFCs – that are both ozone depleting chemicals as well as global warming gases was approved in 2007, and will enable the MLF to continue to play an important role in climate change mitigation. As implementing agencies, over the last 20 years UNDP has eliminated over 60,000 tonnes of ozone depleting substances that are also potent greenhouse gases, mobilizing $500 million in 100 countries to adopt strategies that preserve the ozone layer and provide climate benefits.

Box 82.5: Capacity Development for the Clean Development Mechanism. **Source**: <www.undp.org/climatechange/carbon-finance/CDM/>.

Since 2000, UNDP has implemented CDM and JI capacity development activities in over 20 countries spanning several regions (UNDP 2006: 20). The ultimate goal is to enable developing countries to take maximum advantage of the new financing opportunities provided by the CDM. In countries where adequate technical assistance and private sector involvement has been sustained over an extended period of time, significant lessons have been learnt. These countries include Brazil, China, India, Morocco, the Philippines and South Africa. In Brazil, for example, UNDP, in association with a private energy company, led a multi-agency CDM project cycle for bagasse co-generation accounting for 120,000 tonnes of CO_2 per year mitigated over a 14 year period. The project used a learning-by-doing methodology and was coordinated with public-private capacity, creating an enabling environment to policy-making. Support to knowledge sharing include the completion of a worldwide review of experience with CDM "Clean Development Mechanism: An assessment of Progress" (UNDP 2006a) and "The Clean Development Mechanism: A User's Guide" (UNDP 2003).

and deforestation, over an area of more than 1 million km^2. This was achieved through strategic support to programmes on sustainable land management and biodiversity conservation. In doing this, UNDP has been able to prove methodologies and adopt best practices to help countries develop the systemic and institutional frameworks and capacities to manage *land use and land use change* (LULUC). For example, providing support to efforts towards decentralized and participatory governance, enhanced property rights, land use planning, and transforming market systems to deliver financial payments to small farmers and other landowners maintaining on-farm ecosystem goods and services, including carbon storage (UNDP 2008a: 13).

Figure 82.3: UNDP-GEF Adaptation portfolio. UNDP has leveraged over $800 million (including grants and co-financing) for climate change resilient development in 75 countries. **Source:** Data generated from UNDP 2010 <http://ccmap.undp.org>.



82.3.2 UNDP's Role in Enhancing Countries' Adaptive Capacities

The key focus in this area has been on building adaptive capacities and increasing long-term resilience of vulnerable ecosystems and economies in developing countries at the national, sub-national, and local levels. The aim is to integrate climate change responses into national development planning processes, policy-setting, and key sustainable development practices, while identifying and leveraging financing for adaptation activities (UNDP 2005). The overall objective is to promote 'no regrets' short- and long-term coping strategies to reduce adverse impacts on vulnerable communities and countries (figure 82.3).

Support to adaptation activities spans over a wide range of cross-cutting areas, including water governance and sanitation, public health, and disaster risk management. On the latter, the focus has been on working with vulnerable communities to increase their preparedness and resilience to weather-related shocks, in particular drought risk reduction in collaboration with the *Drylands Development Centre* (DDC) and the *Bureau for Crisis Prevention and Recovery* (BCPR).

Projected climate variability induced by climate change will have an acute influence over the hydrologic cycle, which in turn will put pressure on already scarce water resources, leading to increased competition, tension and conflict, particularly over shared water basins (World Bank 2009a: 3) In this context, responsive strategies to prevent climate-induced conflicts in transboundary basins become utterly important (IPCC 2007: 442; Stern 2006: 137). Through a combined portfolio in the areas of water governance and international waters, UNDP is assisting in developing the capacity of water-stressed countries as well as countries sharing large water bodies to identify, design, and implement remedial measures and to enable stakeholders to plan around increasing water scarcity in an equitable, transparent, and peaceful manner. In this process, support has been provided for adopting a framework for cooperation in the Nile Basin, initiating legal reform in the Kura-Aras Basin, and implementing of a conflict resolution mechanism in the Mekong Basin.

At the community level, UNDP implements on-the-ground activities through dedicated facilities such as the UNDP-GEF *Small Grants Programme* (GEF/SGP/UNDP 2007) and innovative partnerships such as the *Community Based Adaptation Programme* with UNESCO and the *United Nations Volunteers* (UNV).

Since 1992, UNDP-GEF has assisted over 100 countries to meet their reporting requirements to the UNFCCC in preparing National Climate Change Vulnerability Assessments and *National Adaptation Plans of Action* (NAPAs). Based on analyses of their NAPAs, assistance will be provided to more than 30 least developed countries to facilitate access to resources from the UNFCCC *Least Developed Countries Fund* (LDCF) for priority adaptation initiatives.

Box 82.6: Methodologies and resources on adaptation. **Source**: <www.adaptationlearning.net> and <www.undp.org/climatechange/pillar_adaptation.shtml>.

Focusing its efforts on climate risk 'hot spots' where both vulnerability and hazard are high, UNDP has developed a set of resources to assist developing countries in planning adaptation through development:

Methods for adaptation

- *Adaptation Policy Framework* (UNDP 2005): comprehensive guidance for policy-makers through a structured approach to formulating and implementing adaptation strategies, policies, and measures <www.undp.org/climatechange/adapt/apf.html>.
- *Strategic Environmental Assessment Approach to Adaptation* guidance to integrate climate change into national/sectoral development planning and processes www.seataskteam.net
- *Toolkit for Designing Climate Change Adaptation Initiatives* guidance on key steps to formulate adaptation projects <www.undp.org/climatechange/adapt/program.html>.

Programming strategy

- *Thematic Areas Guidance Paper* on baseline and impact projections by region and development challenge as well as opportunities in six thematic areas. <www.undp.org/climatechange/adapt>.
- *Monitoring and Evaluation Framework*: set of indicators linked to the MDGs, to support mainstreaming of vulnerability reduction and adaptive capacity into national development <www.undp.org/climatechange/adapt/program.html>.

Knowledge management

- The *Adaptation Learning Mechanism*: a UN Inter-Agency Global Knowledge Platform that captures and disseminates experiences and good practices <www.adaptationlearning.net>.
- *Country Adaptation Profiles* for 140+ developing countries with multi-model projections, historic trends and projected future changes <http://sdnhq.undp.org/gef-adaptation/profiles/>.

82.4 Scaling Up Climate Change Action: Adopting a New Development Paradigm

A large part of UNDP's portfolio focuses on helping developing countries to create a 'carbon-enabled' environment to attract and drive direct investment toward lower carbon technologies and sustainable land management at the national and sub-national level. This entails providing support and capacity building in the areas of policy formulation, regulatory frameworks, and production of strategies that embed climate change action.

Aiming to help countries achieve market transformation at the national level, UNDP taps into the resources of the wider UN system to complement and synergize its support. UNDP will enhance synergies within the UN family of agencies harmonizing the efforts of the UN at the country level and addressing the interface between the MDGs and climate change. An agreement between the UN and the Bretton Woods institutions on climate change is urgently needed. A collaborative compact on climate change among the UN, IFIs, regional institutions, donor community, and private sector is also a necessity.

UNDP's climate change strategy identifies six key dimensions to be reached through four strategic priorities, as described in sections (82.4.1) and (82.4.2) below.

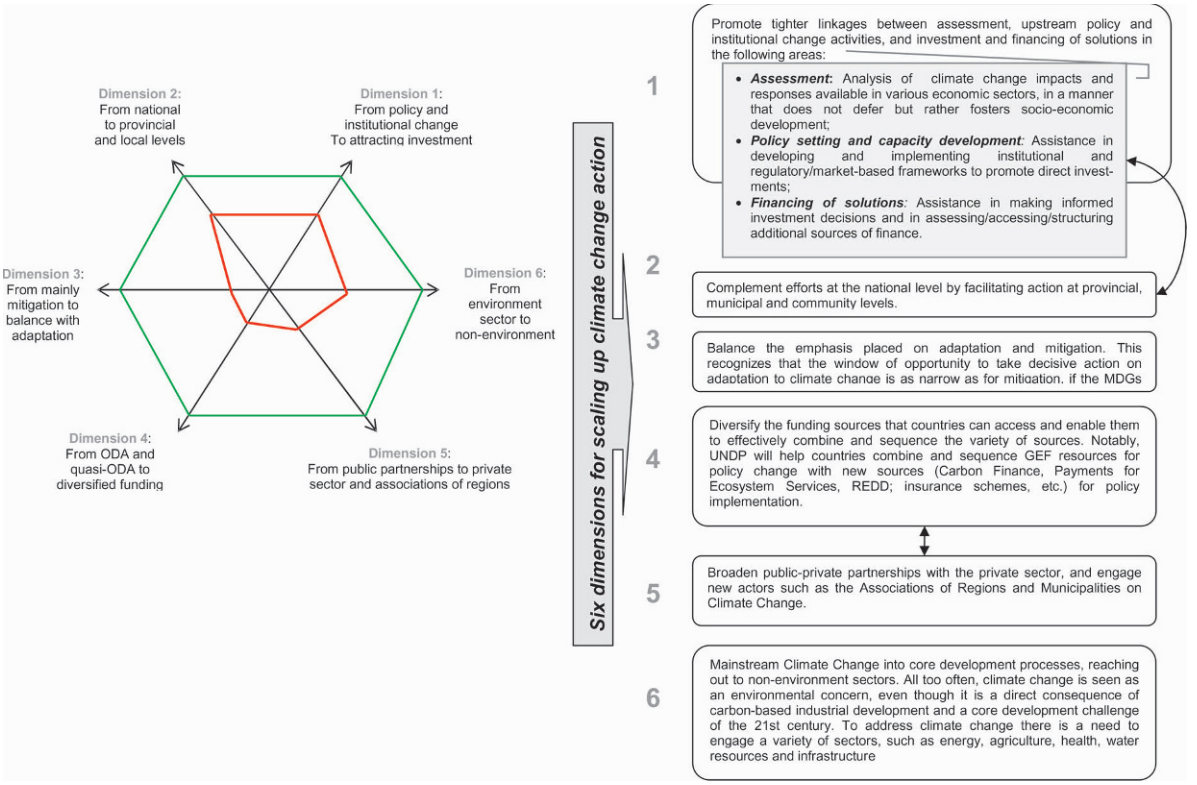
82.4.1 Six Key Dimensions for Scaling Up Climate Change Action

Figure 82.4 illustrates the scaling up of climate change actions along the six dimensions. The red lines are a qualitative description of current climate change action in a number of countries in terms of the six dimensions described above, whereas the green lines represent the scaling up required for a new development paradigm that mainstreams climate change into strategies and plans, and that links policy-setting with the financing of solutions.

82.4.2 UNDP's Strategic Priorities for Climate Change Action: Helping Countries Build the New Paradigm

Effectively integrating climate change with development work, UNDP is scaling up its on-going climate change services along these six dimensions through four strategic priorities. The first priority focuses on planning and policy, the second and third on implementation of adaptation and mitigation, and the fourth deals with mainstreaming climate change into UN programming at all levels from local to global.

Figure 82.4: Six dimensions for scaling up climate change. **Source:** Adapted from UNDP (2008: 17).



82.4.2.1 Strategic Priority 1: Strengthening the Capacity of Developing Countries to Design Integrated Climate Change Action and Investment Plans

Coordinated national policy positions will be necessary for solutions to climate change to be effective. These positions need to be developed by engaging a variety of stakeholders, including governments as well as private sector, NGOs, and civil society. For medium and small-size economies it will be imperative to receive assistance to integrate climate change in their sectoral planning, budgeting and decision-making processes, while leveraging innovative financing, and also capitalizing on any opportunities provided by emerging financing frameworks – e.g. the Copenhagen Green Climate Fund (CGCF).

Enhancing the capacity of decision-makers to assess the policy implications of international negotiations will be critical. In response, support will be provided for launching national capacity building workshops for government officials, members of civil society, NGOs, parliamentarians, and the business community.

To build the knowledge base and integrate the economics of climate change into national planning processes, in-depth sectoral and cross-sectoral economic analyses, including cost benefit analysis of alternative policy and mitigation and adaptation options need to be produced and subsequently shared globally, nationally, and sub-nationally through dedicated interactive knowledge platforms.

At the national level, activities under this strategic priority will build on climate change assessments such as National Communications to the UNFCCC, Technology Needs Assessments, and reports like the UNDP-led National Human Development Reports. These activities will complement such existing assessments with in-depth economic analyses and the engagement of a wider range of stakeholders at the subnational level (box 82.7; figure 82.5).

82.4.2.2 Strategic Priority 2: Enhancing the Long-term Adaptive Capacity of Developing Countries and Promoting Adaptation Actions

Early adaptation action generates economic benefits as it prepares communities for expected harmful impacts and can therefore reduce threats to human health, sources of livelihood, ecosystems, and infrastructure. Governments must play a pivotal role, by

Box 82.7: The Territorial Approach to Climate Change (TACC). **Source**: <www.undp.org/climatechange>.

The engagement of sub-national governments is crucial as it is estimated that decisions at this level can influence 50-80 per cent of GHG emissions and most site-dependent adaptation actions (UNDP 2009: 11). To respond to the growing demand from sub-national authorities, UNDP and UNEP will be joining efforts to enhance capacities for long-term planning at the territorial level (regions, provinces, states or municipalities). The TACC initiative encourages the creation of Integrated *Territorial Climate Plans* (ITCP) to identify and prioritize adaptation and mitigation policies, regulations and investment decisions, based on an assessment of physical and socio-economic climate change impacts through a comprehensive methodological approach (UNDP 2009: 69), as described in the diagram below.

TACC will be accompanying 50 regions in the formulation of ITCPs that respond to a dynamic, participatory and reiterative three-pronged process: (i) long-term vision that benefits the entire community, (ii) prioritization of integrated mitigation and adaptation activities around the most urgent problems, and (iii) inclusion of all relevant stakeholders within the community (UNDP 2009: 59). This work will be carried out with a new set of development partners engaging associations of regions such as: *Forum of Global Associations of Regions* (FOGAR), *Network of Regional Governments for Sustainable Development* (NRG4SD), the Northern Forum, the International Association of Francophone Regions, the Latin American Organization of Sub-National Governments, the European Assembly of Regions and a large number of national and multinational companies.

Figure 82.5: Methodologies and processes for developing an ITCP. **Source:** Glemarec (UNDP 2009: 60).

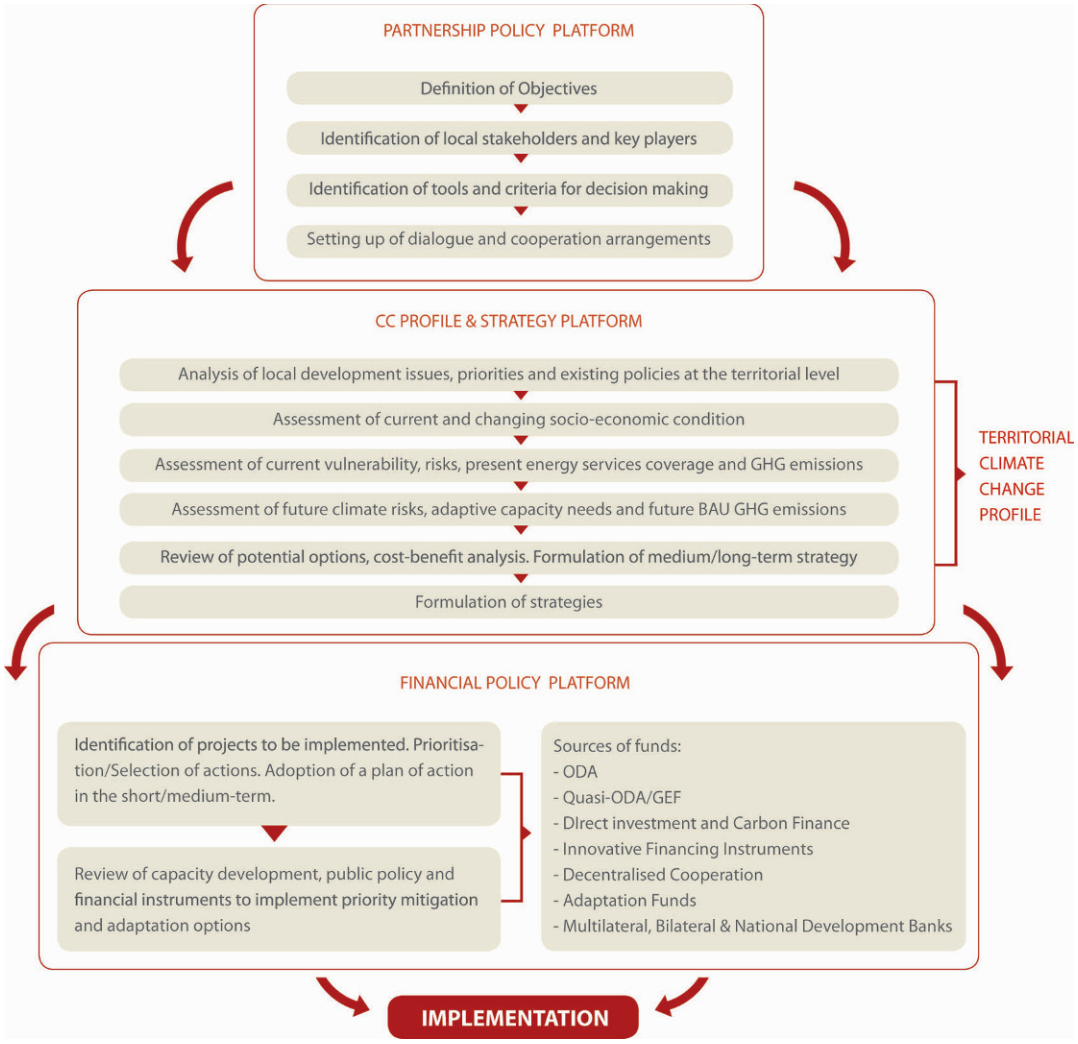


Figure 82.6: Key Steps in Assessing Adaptation Options **Source:** Kurukulasuriya/Mendelsohn (2008). Kurukulasuriya/Glemarec/Retiere (UNDP 2009: 103).

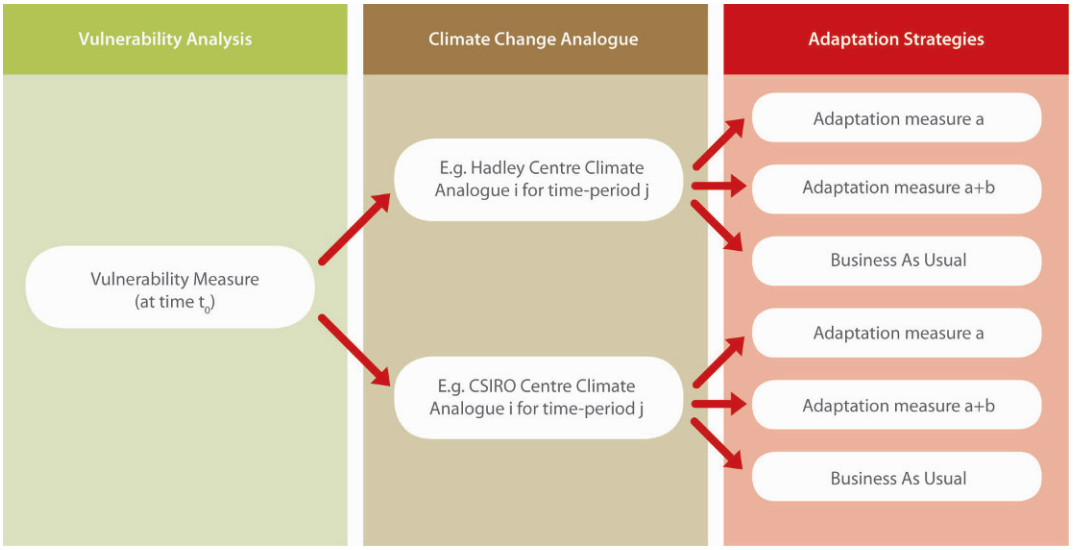


making a fact-based case for adaptation, encouraging direct investments and designing long-term policies that integrate adaptation. Developing countries can create an enabling environment to adaptation by overcoming three challenges: difficulty in getting political traction, difficulty in determining what the appropriate policy mix is and how to mainstream adaptation into national development processes, and difficulty leveraging finance to develop capacities and policies (UNDP 2008: 20).

Assistance needs to be provided to governments in addressing these challenges by carrying out economic assessments of adaptation versus inaction and determining early action incentives. In addition, it will be necessary to assess adaptation options by conducting prospective exercises to characterize future climate conditions. While dependent on available data, technical capacity and/or partnerships with Centres of Excellence, a possible alternative is to use global climate models to develop climate projections and identify climate analogues in others (UNDP 2009: 103). Figure 82.6 shows suggested key steps in characterizing future climate change conditions.

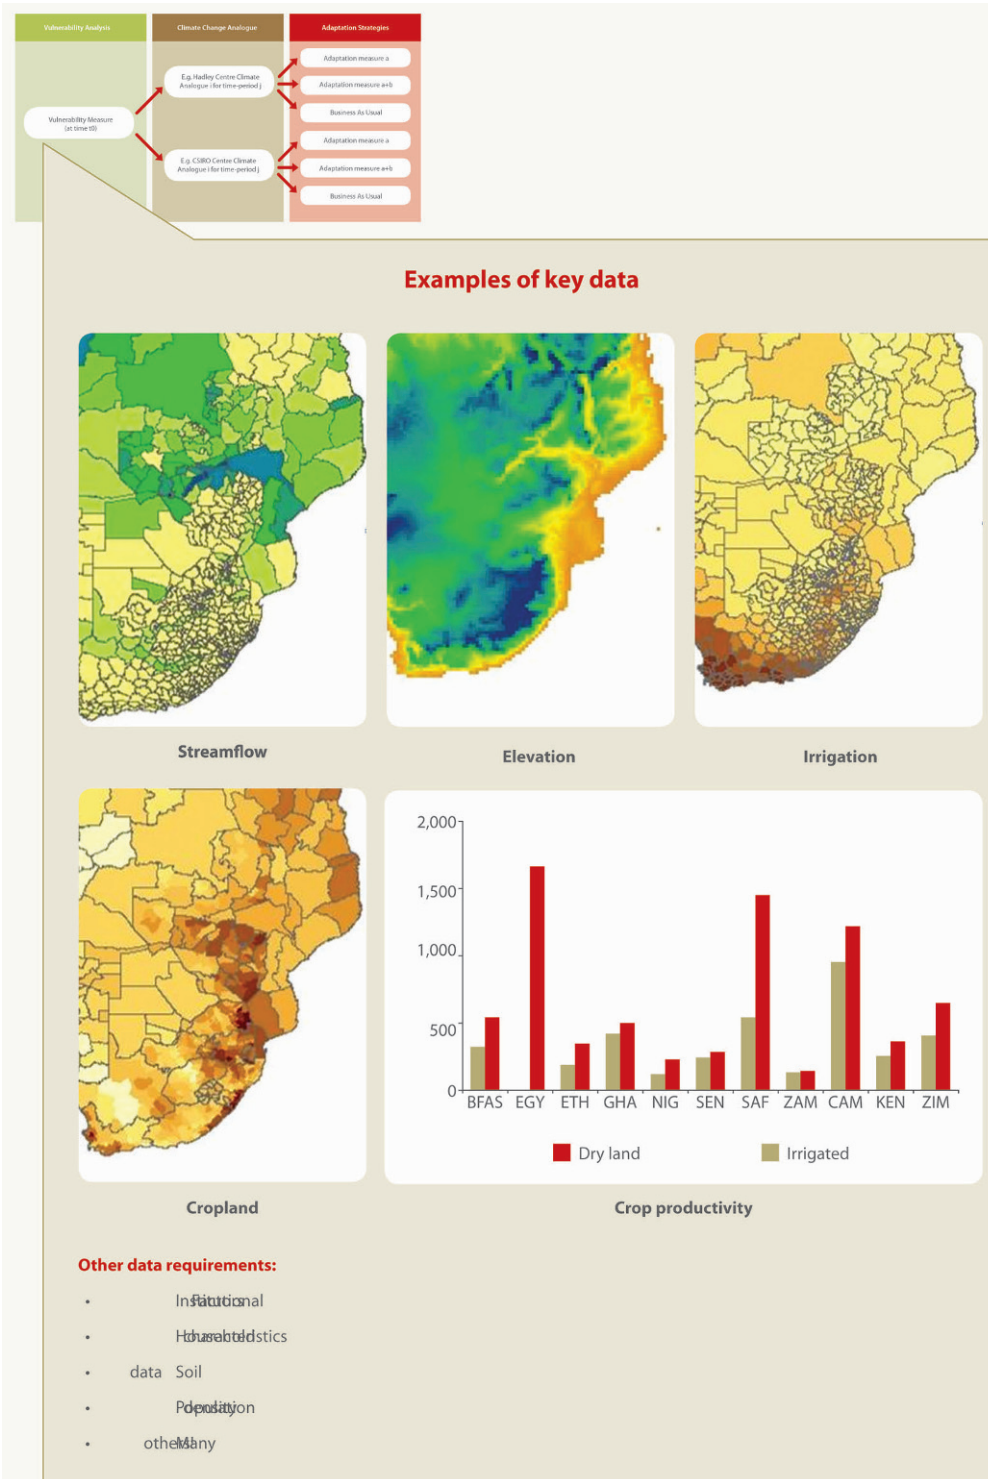
This set of actions will help countries and territories identify and prioritize short-term 'no regrets' adaptation measures, such as use of drought tolerant crops, revised land-use plans, and enhanced emergency preparedness.

To implement these adaptation responses, guidance needs to be provided for accessing dedicated funds, i.e. *Special Climate Change Fund* (SCCF), *Least Developed Countries Fund* (LDCF), and *Adaptation Fund*, and assistance for mobilizing innovative sources of funding (e.g., a tax on domestic air travel). Sustainability will be ensured by strengthening the capacity of developing countries to integrate adaptation into domestic plans, budgetary and fiscal policies, investments, and practices.

UNDP will provide most support to adaptation 'hot spots', such as LDCs and *Small Island Developing States* (SIDS). Support will move beyond isolated adaptation initiatives or projects, towards cross-sectoral programmatic approaches, with a focus on mainstreaming adaptation into development processes (box 82.6).

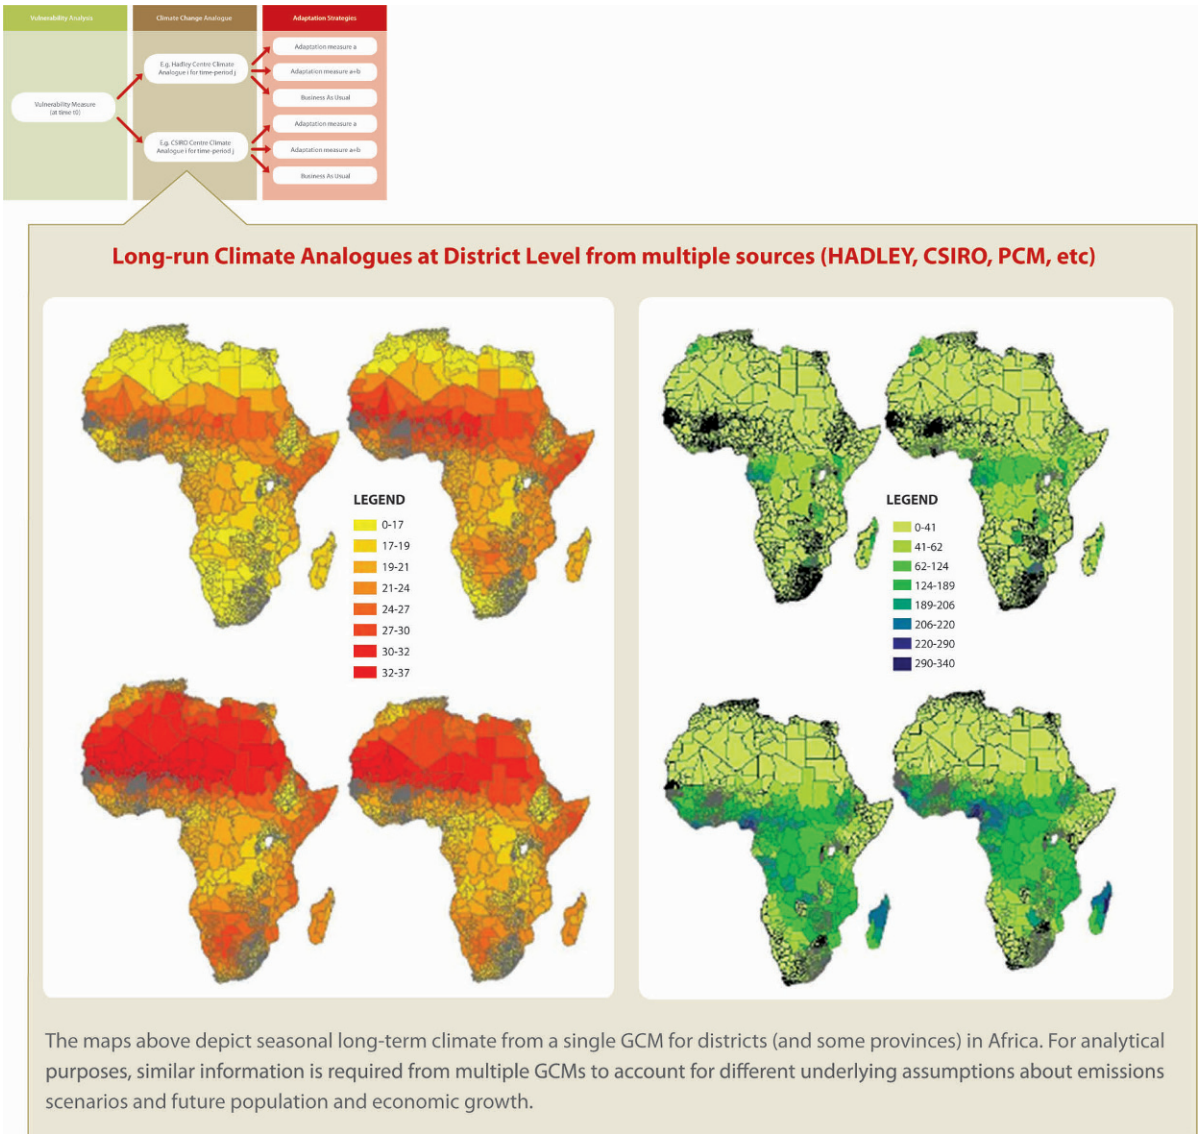
Figure 82.6 illustrates key steps in characterizing future climatic conditions using global climate models to develop climate projections and identifying climate analogues in others, following the approach suggested by Hallegatte et al (2007: 47). Assessing adaptation options requires: (i) a vulnerability analysis, (ii) a systematic analysis of the implications of alternative climate change analogues, and (iii) an analysis of key factors for adaptation strategies (e.g. income from crop production). By comparing analogue projections – in this case Hadley Centre and CSIRO Centre – it is possible to assess the vulnerability of each adaptation measure to incorrect climate projections and evaluate the likely net-benefit of a range of adaptation options (UNDP 2009: 103). The map series below (figure 82.7–82.9) provides an example on the assessment of adaptation options to cope with the impacts of climate change on African agriculture, based on research work conducted by Kurukulasuriya et al

Figure 82.7: Key Data for Vulnerability Analysis. **Source**: Kurukulasuriya/Mendelsohn (2006). Kurukulasuriya/Glemarec/Retiere (UNDP 2009: 106).



(2006). These types of maps are an example of powerful tools to convey complex information to decision-makers to raise awareness and develop planning and budgetary allocations for adaptation actions (UNDP 2009: 105).

Figure 82.8: Climate Analogues. **Source**: Kurukulasuriya/Mendelsohn (2006). Kurukulasuriya/Glemarec/Retiere (UNDP 2009: 107).

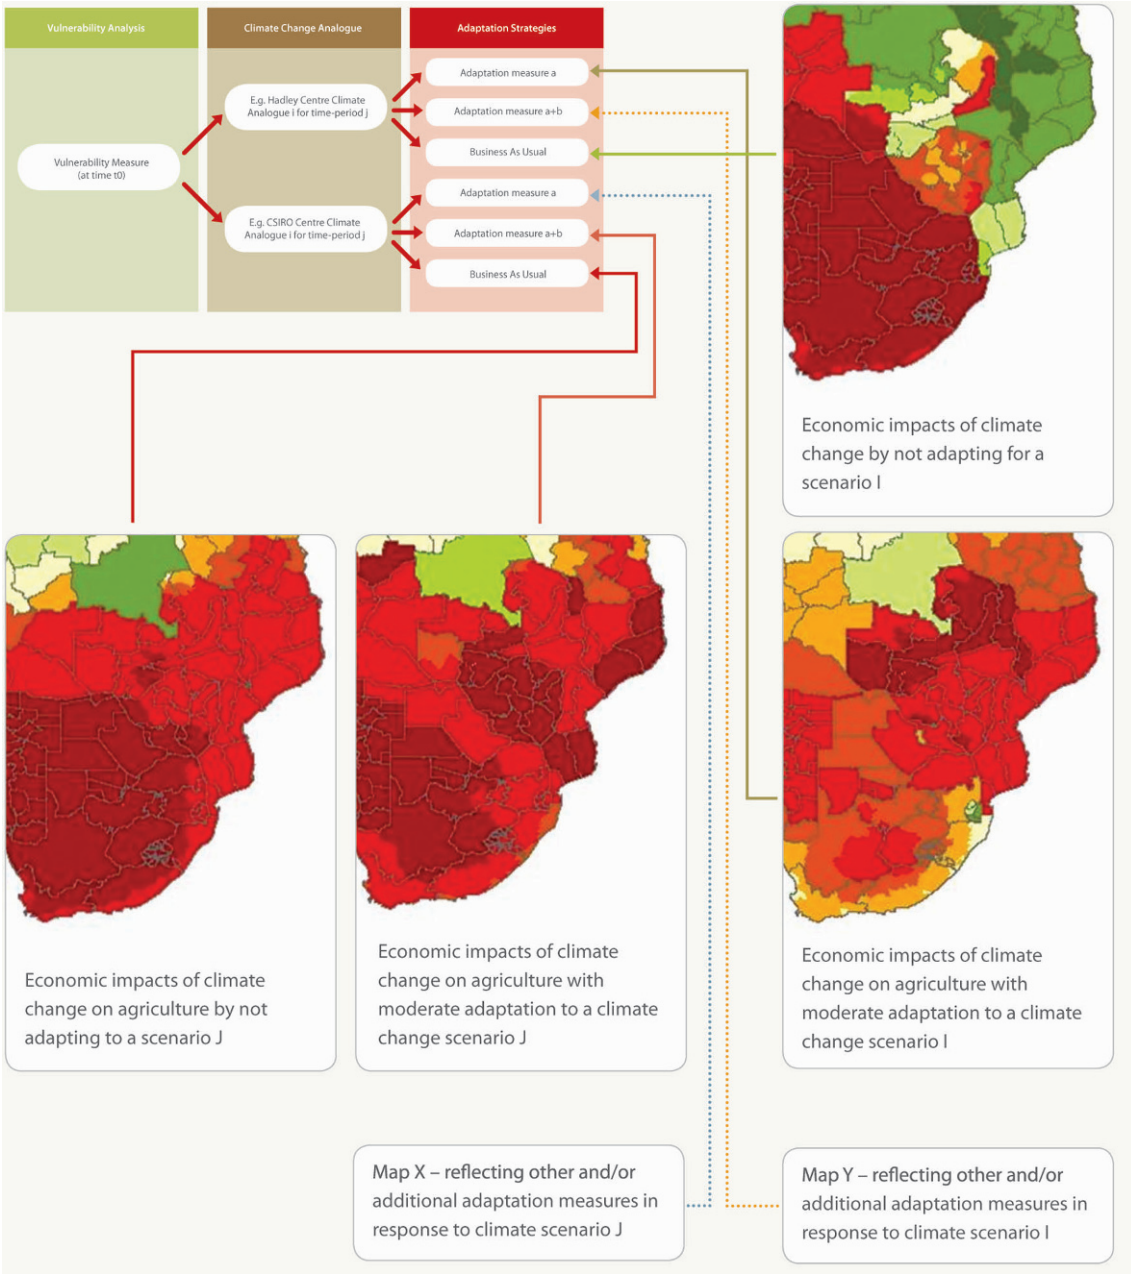


82.4.2.3 Strategic Priority 3: Enhancing the Capacity of Developing Countries to Attract and Drive Direct Private and Public Investment towards Lower Carbon Technologies and Sustainable Land Use Practices

This strategic priority aims at creating a 'carbon-enabled' environment (public policies, institutions, human resource capacities) for countries to be better positioned to access emerging sources of environmental finance (carbon finance, REDD, payment for ecosystem services, public-private partnerships, ODA, corporate social responsibility, green bonds, index insurance and weather derivatives, among others).

A substantial increase in total investment flows to developing countries will be needed for them to adopt technologies that reduce greenhouse gas emissions and do not slow-down economic growth. The rapidly expanding carbon market offers considerable potential to augment the flow of the needed finances and technologies. However, while the carbon market and other market instruments hold the promise of boosting resources in the coming years, it is evident that developing countries will need assistance to truly benefit from such opportunities. Capacity development services will play an important role in address-

Figure 82.9: Adaptation Profiles. **Source**: Kurukulasuriya/Mendelsohn (2006). Kurukulasuriya/Glemarec/Retiere (UNDP 2009: 108).



ing the disparities among countries in terms of accessing the CDM and other market instruments (UNDP 2003c: 11).

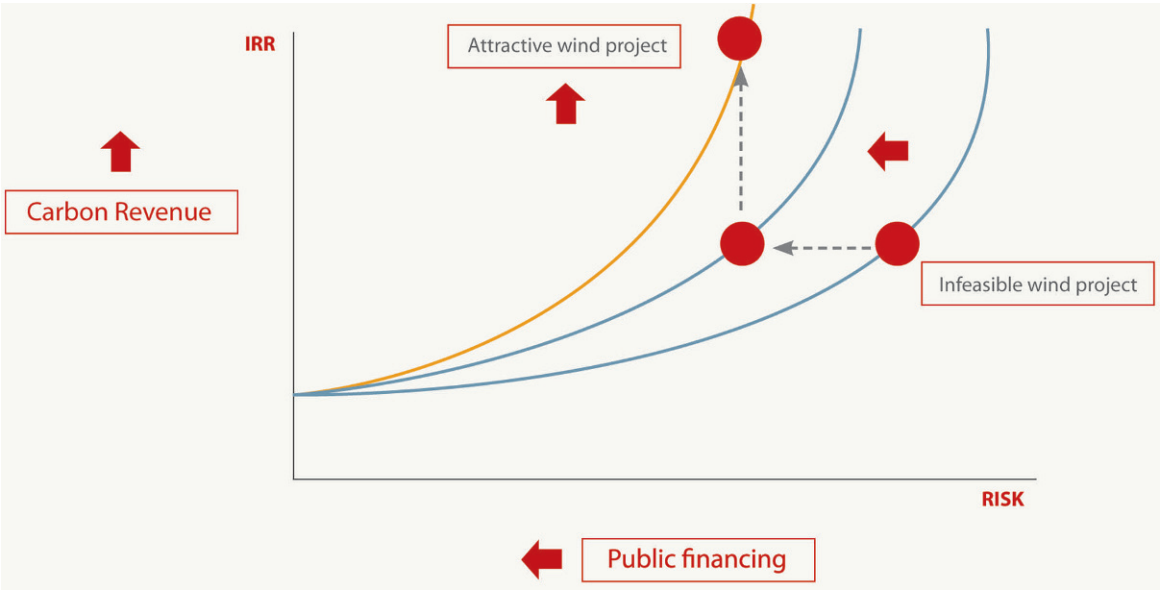
Furthermore, developing countries will need capacity development support to meet the challenge of driving massive shifts in investment patterns in a wide range of sectors, including power generation (box 82.8), industry, waste management, transport, buildings, agriculture and forestry.

In response, UNDP will help put in place effective public policies and markets to attract and drive direct investment towards lower carbon technologies. This addresses regulatory gaps, setting performance standards and codes for energy efficient infrastructure and appliances, and providing economic incentives for GHG reduction activities (smart tariffs, quotas). Assistance will also be provided to countries in implementing frameworks and investment pipelines to pro-

Box 82.8: An approach to mixing policies and financing for wind energy. **Source:** <www.undp.org/energy/>.

While wind energy is a rapidly growing technology, lessons learnt in this sector demonstrate that good wind resources alone are not sufficient to ensure sound and cost-effective development of this climate-friendly technology. The only countries that have been successful are those in which preconditions have been met through the set up of an enabling environment, comprehensive public policies and adequate financing strategies (UNDP 2009: 111). Figure 82.10 below illustrates an approach to sequencing financial instruments. In this example public finance is mobilized to remove barriers for direct investment, which reduces associated risks and makes it easier to (i) secure traditional finance for underlying projects, and (ii) access traditional finance from emerging carbon markets to increase the profitability of wind energy.

Figure 82.10: Sequencing public finance and carbon finance. **Source:** Glemarec (UNDP 2009: 112).



mote technology development, transfer, and dissemination. To help governments establish an institutional and regulatory infrastructure to access carbon finance, dedicated capacity building services should aim at operationalising *Designated National Authorities* (DNAs) and promoting solid legal frameworks such as clear ownership rights.

Encouraging innovative technological and non-technological solutions will be pivotal. UNDP will promote greater off-grid access to energy for rural communities (foundations, micro-grants, etc.), and will pilot REDD emissions reduction schemes, testing a number of alternative payment structures and benefit transfer mechanisms that reach end users in a transparent and equitable manner.

82.4.2.4 Strategic Priority 4: Integrate Climate Change into UN and UNDP Development Assistance Service Countries in Addressing Climate Change

With sustainable human development at the heart of its mandate, UNDP's core practices are all essential to addressing climate change not as a stand-alone but rather as a cross-cutting issue. Efficiently mainstreaming climate change into core activities and in its fiduciary policies will maximize opportunities to address potential risks. It will also ensure a double dividend in terms of climate change solutions and the improvement of human well-being. Moreover, it will lessen the possibility of reversing decades of technical assistance hard-won development achievements, and decrease the likelihood of threats to international human security (EC 2008: 2).

The interface of development and climate change support at UNDP is exemplified by the work of thematic areas such as *governance* (e.g. strengthening institutional capacity increases aid effectiveness); *pov-*

erty reduction (e.g. mainstreaming climate responses into PRSPs); *crisis prevention and recovery* (e.g. integration of climate change into risk reduction); and *environment and energy* (e.g. mainstreaming climate into the management of water resources, land, and biodiversity and energy access for the poor).

82.5 Concluding Remarks

Climate change has been described as a threat multiplier that may exacerbate current vulnerabilities, tensions, and conflicts in countries and regions (EC 2008: 2). Developing countries deserve particular attention, not only because they are most at risk from expected adverse impacts, but also because they offer a variety of cost-effective opportunities to reduce emissions while advancing sustainable development goals and addressing the security dimension of climate change.

However, current levels of finance channelled through the financial mechanisms of the UNFCCC, ODA, or other means, while significant, are not likely to be sufficient. The two-fold challenge is therefore to (i) find ways to attract enough direct investment to meet the needs of lower income countries so they can sustain their economic development, (ii) while driving these direct investments towards lower carbon technologies, preventing countries from being locked into unsustainable pathways for subsequent 30 to 50 years.

Stabilizing greenhouse gas concentrations at a level that prevents catastrophic climate change will require further work towards a sustainable development-centric international agreement that is universal, equitable, and cost-effective. It will be critical for developing countries to be actively engaged in the international negotiations that will define the specifics of such agreement in the reference framework of the Copenhagen Accord. Countries also need strengthened capacities to ponder the implications of the different negotiations within the context of their national sustainable development objectives.

To effectively participate in, and fully benefit from, a new climate resilient development paradigm, developing countries must engage governments, the private sector and civil society stakeholders to secure broad-based support at the local, national, regional and global level. They also need cross-sectoral coordination given that actions to promote increased resilience to the impacts of climate change and lower-GHG emissions is dependent on a wide range of sectors, such as energy, agriculture, health, water resources, and infrastructure.

Developing countries will tremendously benefit from assistance in taking immediate action to implement innovative approaches, as well as from support in assessing the most suitable opportunities under the provisions of the Copenhagen Accord and future frameworks reached by COP-16 in Mexico 2010 and beyond.

Given the opportunity to rethink the structure, logic, and potential of human development and security, the international community needs to address the challenges of climate change within the framework of a new development paradigm that sets the world on a path towards greater climate security.

83 EU Strategies for Climate Change Policy Beyond 2012

Christian Egenhofer, Arno Behrens and Anton Georgiev

83.1 Introduction

As early as 1996, the *European Union* (EU) adopted a long-term target of limiting global temperature increase to a maximum of two degrees Celsius (Egenhofer/van Schaik 2005: 2–3) above pre-industrial levels. This was reiterated over the years, most recently in the European Council of 18–19 June 2009 (European Council 2009: 11). According to the European Commission (2009a: 3) – making reference to the 4th Assessment Report by the *Intergovernmental Panel on Climate Change* (IPCC 2007, 2007a, 2007b, 2007c, 2007d) – this would require developed countries to reduce their greenhouse gas (GHG) emissions by 25–40 per cent by 2020 and 80–95 per cent by 2050 compared to 1990 levels. At the same time, developing countries would need to limit emissions growth to 15–30 per cent below baseline by 2020 (European Commission 2009a: 5). The tool to achieve this are the so-called *Nationally Appropriate Mitigation Actions* (NAMAs) mentioned in the Bali Action Plan of December 2007 (UNFCCC 2007a: 3).

The EU's stance must be understood in the context of the multilateral negotiations where the EU has traditionally played an important role. This is also the case regarding environmental issues. The EU as well as its member states have been actively promoting *Multilateral Environmental Agreements* (MEAs). In the case of climate change the EU has found itself being catapulted into leadership after US President George W. Bush pulled out of the Kyoto Protocol. While few would have bet at that time for the Kyoto Protocol to survive, active EU diplomacy ensured that Japan, Canada and Russia ratified the Protocol which entered into force in 2005. To prepare for this, the EU has adopted numerous legal texts (directives, regulations, decisions, recommendations and opinions; see Egenhofer/Kurpas/van Schaik 2009: 36–38) to fulfil its commitments. Among them have been policies to support renewable energy and to improve energy efficiency in buildings and transport. However, the centrepiece of EU climate change policy has been the EU *Emissions Trading Scheme* (EU ETS), which became operational in 2005. While these and other policies have focused on the implementation of the Kyoto Protocol commitments, in parallel the EU has been developing a new strategy to meet mid- and longer-term climate change objectives. The EU had realized that – in the absence of an US engagement – EU leadership was indispensible for reaching a global agreement on climate change. At the same time, this leadership position is regarded as an opportunity for shaping the new regime in line with the EU's climate agenda. Other benefits include the reduction of energy import dependency and the possibility to gain leadership in low-carbon technologies.

This chapter describes recent EU initiatives to achieve necessary GHG emissions reductions within the EU as well as the strategy to engage other developed and developing countries to reach a global agreement that can ensure global climate change mitigation in line with the EU objective of limiting global warming to a maximum of two degrees Celsius (83.2). Most of the analysis is concentrated on the EU ETS (83.3, 83.4) and potential implications on the competitiveness of European industry (83.5). However, the chapter also describes the intersections between climate change policy and international trade policy (83.6) and the role of low-carbon technologies (83.7). It finishes with external aspects, namely the role of and relationship with developing countries (83.8) and the EU's international negotiation position (83.9).

83.2 The Strategic Approach: Target Setting and Addressing Energy Security

EU climate change policy is based on the EU's long-term target to limit global temperature increase to a maximum of two degrees Celsius above pre-industrial levels (box 83.1). In order to achieve the medium-term

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_83, © Springer-Verlag Berlin Heidelberg 2011

Box 83.1: The meaning of the 2°C target. **Source**: Based on Neufeldt, van Vuuren, Isaac, Knopf, Edenhofer, Schade, Jochem and Berkhout (2009).

The EU target to limit the rise of global average temperature to 2 °Celsius above pre-industrial levels is based on the conviction that above this level the "risk of dangerous and unpredictable climate change increases significantly and costs of adaptation escalate" (European Commission 2007b: 3). In reality, however, significant impacts on the most vulnerable and exposed ecosystems and societies are to be expected even below a 2 °C temperature increase. The target is thus primarily a political statement whose credibility depends on its technical feasibility, economic viability and political manageability. In order to achieve it, GHG concentrations in the atmosphere (measured in CO_2 equivalents, CO_2e) will need to be stabilized at 450 *parts per million* (ppm). Such a stabilization level reduces the chance of overshooting the 2 °C to 50 per cent and requires global emissions to peak around 2020.

Research within the EU-funded ADAM project (*Adaptation and Mitigation Strategies: Supporting European Climate Policy*) shows that low stabilization is technically feasible. While the importance of negative emissions (i.e. bioenergy with CCS) increases with lower GHG stabilization targets, nuclear power appears to be of minor significance. The cumulative GDP losses until 2100 are estimated to be below 0.8 per cent and 2.5 per cent for the 550 and 400 ppm CO_2e scenario, respectively.

Low stabilization targets will require the EU to reduce GHG emissions in 2050 by some 60–80 per cent or more compared to 1990 levels. This will have implications for new and existing capital stock in all sectors. In buildings, energy demand for heating and cooling will need to be reduced by almost 60 per cent by 2050. The transport sector could reduce emissions by some 50–70 per cent and the industrial sector by 30–40 per cent until 2050. The energy conversion sector will need to switch to low-carbon technologies, to achieve a share of renewables of up to 70 per cent. In addition, energy efficiency measures are expected to reduce energy demand by 25 per cent by 2050.

GHG emissions reductions required of developed countries, the Council of the European Union formally adopted an integrated climate and energy package on 6 April 2009.[1] The package intends to operationalize the overall binding targets to reduce GHG emissions and to increase the share of renewable energy sources in the EU's energy mix, which were adopted by the European heads of state and government at their 8–9 March 2007 spring summit (European Council 2007: 12–21). Principle elements of the 2007 spring summit's conclusions include a set of EU targets – generally referred to as '20 20 by 2020' – and accompanying policies.

1. A binding absolute emissions reduction commitment of 30 per cent by 2020 compared to 1990 conditional on a global agreement, and a 'firm independent commitment' to achieve at least a 20 per cent reduction;
2. A binding target to reach a 20 per cent share of renewable energy sources in primary energy consumption by 2020;
3. A binding minimum target of increasing the share of renewables in each member state's transport energy consumption to 10 per cent by 2020 (this target initially focussed solely on biofuels but was later widened to include other forms of renewable energy sources);
4. A 20 per cent reduction of primary energy consumption by 2020 compared to projections (non-binding);
5. A commitment to enable the construction of up to 12 large-scale power plants using carbon capture and storage (CCS) technology.

With the aim to implement these general targets, the climate and energy package as adopted in April 2009 contains six elements, including a directive for the promotion of renewable energy sources, a revised EU ETS starting 2013, an 'effort sharing' decision setting binding emissions targets for EU member states in sectors not subject to the ETS, a regulation to reduce by 2015 average CO_2 emissions of new passenger cars to 120 g/km, new environmental quality standards for fuels and biofuels (aimed at reducing by 2020 GHG emissions from fuels by 6 per cent over their whole life-cycle), and a regulatory framework for CCS. Prior to that, the EU had already published the so-called *Strategic Energy Technology* (SET)-Plan (European Commission 2007a) to strengthen research, development and demonstration of new technologies including those relevant for addressing climate change. Finally, a review of the level and nature of allowed subsidies (or 'state aid') is ongoing.

Such an integrated approach to energy and climate change issues necessitated by various changing conditions faced by the EU. Domestic resources are dwin-

1 For a press statement on the Council's adoption of the 'climate-energy legislative package' as well as links to all of its elements, see >http://www.consilium.europa.eu/uedocs/cms_data/docs/pressdata/en/misc/107136.pdf>.

dling at the same time that government intervention in the energy industry is on the rise in precisely those countries that could potentially fill the gap.

While many supplier countries seem unable to increase production due to a lack of investments, the fact that supplies are tightly controlled by governments in exporting countries raises the fear of 'excessive' leverage of supplier countries such as Russia. Some supplier countries are hostile towards the West. Others are politically unstable. Many reserves will take years to develop due to problems of access, investments and physical conditions. A prolonged tight market might increase political tensions and possibly some sort of 'resource nationalism'. At last, the EU realized that success in integrating Russia into a strategic energy partnership is very unlikely. Despite an institutionalized energy dialogue (since 2000) and some recent foreign investments in the Russian energy sector, the strategy aimed at opening the Russian market to European and other western enterprises and thus to gain large scale access to Russian gas and oil reserves has largely failed and this is not expected to change in the foreseeable future.

In such a scenario, the EU and its member states have been examining domestic and external policy options to move to a more sustainable and secure energy supply. This includes, amongst others, investment in renewable energy sources, pushing CCS technology for fossil and other fuels and investment in nuclear energy in member states that wish to do so. To drive down costs for these technologies, there is a need for large-scale deployment. The *International Energy Agency* (IEA 2008a: 373; 554) makes the case, for example, that renewables (except wind) experience significant capital cost reductions for each doubling of capacity, such as 15–20 per cent for *photovoltaics* (PV) and 20 per cent for solar water heaters. This justifies pro-active support policies for low-carbon technologies.

Additional advantages of the EU climate and energy package include (Jansen/Gialoglou/Egenhofer 2005: 3–6):

- The renewable energy policy can provide for technological leadership in sun-rise technologies;
- Renewable electricity can reduce long-term electricity prices and their volatility;
- Substitution of fossils combined with renewables may reduce pricing power by Russia (notably on gas); and
- The introduction of the EU ETS (*emission trading system*) led to the retention of some of the economic rent of producer countries, including Russia.

To off-set the higher prices both for industry and domestic consumers, energy efficiency is a central piece, certainly for the transition period until new technologies and new fuels become available on a large scale. With increasing prices, reducing consumption gives a reasonable prospect for keeping the energy bill constant.

There has been an additional aspect of the '20 20 by 2020' targets which is often overlooked. The first phase of the EU ETS has shown that setting a hard cap in GHG emissions in the EU is next to impossible without some sort of legally binding constraint. In a scenario of a post-2012 agreement *without* absolute caps – which is possible – it is indeed difficult to see how the EU ETS could continue to exist in a meaningful way. Member states and the European Commission would most likely not be able to impose an ambitious emissions ceiling on industry without a legally binding constraint. The '20 20' targets address this risk.

83.3 Implementation of the '20 20 by 2020' targets

The *climate and energy package* should be seen in its entirety, including its six elements as mentioned above, the SET-Plan and new state aid guidelines. However, at the heart of the agreement are the '20 20 by 2020' targets. In addition to the revised EU ETS which will allow for a 21 per cent emissions reduction compared to 2005 in sectors covered by the EU ETS (European Parliament/Council of the European Union 2009a: 63–64), the implementation of these targets has been operationalized by the introduction of legally binding national GHG emissions reduction targets (referred to as 'effort sharing', ranging from -20 per cent to +20 per cent) for all sectors not covered by the EU ET (European Parliament/Council of the European Union 2009b) – such as buildings, transport, agriculture and waste – amounting to an overall reduction of 10 per cent below 2005 levels by 2020. In terms of the renewables target, differentiated national targets for the share of renewable energy sources in final energy consumption have been introduced (European Parliament/Council of the European Union 2009c). The different national targets are shown in table 83.1.

This approach raises the level of centralization, absent in other policy areas of shared competence like

Table 83.1: National overall targets for the share of energy from renewable sources in gross final consumption of energy in 2020 and member state greenhouse gas emissions limits in non-ETS sectors for the period 2013 to 2020. **Source:** European Parliament, Council of the European Union 2009b: 147; European Parliament, Council of the European Union 2009c: 46.

Member state	Share of energy from renewable sources in gross final consumption of energy, 2005	Target for share of energy from renewable sources in gross final consumption of energy, 2020	Member state GHG emissions limits in 2020 compared to 2005 GHG emissions levels (from sources not covered by ETS)
Austria	23.3%	34%	-16%
Belgium	2.2%	13%	-15%
Bulgaria	9.4%	16%	20%
Czech Republic	6.1%	13%	9%
Cyprus	2.9%	13%	-5%
Denmark	17%	30%	-20%
Estonia	18.0%	25%	11%
Finland	28.5%	38%	-16%
France	10.3%	23%	-14%
Germany	5.8%	18%	-14%
Greece	6.9%	18%	-4%
Hungary	4.3%	13%	10%
Ireland	3.1%	16%	-20%
Italy	5.2%	17%	-13%
Latvia	32.6%	40%	17%
Lithuania	15.0%	23%	15%
Luxembourg	0.9%	11%	-20%
Malta	0%	10%	5%
The Netherlands	2.4%	14%	-16%
Poland	7.2%	15%	14%
Portugal	20.5%	31%	1%
Romania	17.8%	24%	19%
Slovak Republic	6.7%	14%	13%
Slovenia	16.0%	25%	4%
Spain	8.7%	20%	-10%
Sweden	39.8%	49%	-17%
UK	1.3%	15%	-16%

the environment. Such centralization, i.e. hard caps and binding renewable obligations has only been possible as a result of a complex burden sharing, which essentially has been based on a mixture of efficiency and equity considerations. Hard targets for the EU ETS and the non-ETS sectors as well as for renewables have been set on the basis of an 'efficiency approach', i.e. reflecting a least-cost approach for the EU as a whole, however, with some adjustment to ensure that costs for member states remain roughly similar in per-capita terms.

- *GHG reduction ('effort sharing') targets:* Countries with a low GDP per capita are allowed to emit more than they did in 2005 in non-EU ETS sectors, reflecting projected higher emissions due

to higher economic growth. According to European Commission modelling, this increases overall EU compliance costs for the 20 per cent GHG reduction target by 0.03 per cent of total EU GDP.

- *Renewables targets:* half calculated on a flat-rate increase in the share of renewable energy and the other half weighted by GDP, modulated to take account of national starting points and efforts already made.
- *In the EU ETS sector:* uniform cap across member states and allocation based on EU-wide allocation methodologies. 12 per cent of the overall auctioning rights will be re-distributed to economically weaker member states in Central and Eastern Europe. Another two per cent of the total auctioning rights will be distributed to eight countries which have already achieved significant reductions before 2005.

According to assessments by the European Commission (2008a: 22–25, 2008b: 159–163), the total direct costs of implementing the two binding 20 per cent targets could be as high as 0.6 per cent of the GDP in the year 2020, or some €90 billion. However, through the access to the *Clean Development Mechanism* (CDM) and *Joint Implementation* (JI) costs are expected to be as low as 0.45 per cent of GDP in 2020 or roughly €70 billion (European Commission 2008c: 161). Rising oil prices would also contribute to lower costs. Annual GDP growth is estimated to decrease by approximately 0.04–0.06 per cent between 2013 and 2020, which would lead in 2020 to a GDP reduction of 0.5 per cent compared to the 'business-as-usual'. These calculations do not take into account possible macro-economic benefits (in the estimated magnitude of +0.15 per cent of GDP) from the reinjection of auctioning revenues back into the economy.

With expected costs of some €70-90 billion by 2020, the complete package has been one of the most important, if not the most important piece of legislation in the EU ever. Nevertheless, there have only been limited changes to the initial Commission proposal. The reason is that governments had already given their full political support to the key elements of the package at the 8–9 March 2007 European Council. Equally important, opening one of these key elements by one member states would almost certainly have lead to an unravelling of the full package, a price too high for any member state to pay, not least because of peer pressure in EU institutions but also due to the high public support that climate change policies enjoy.

Nevertheless, there have been intense debates within the Council of Ministers and the European Parliament on a number of issues. The most important has been about costs and their distribution across member states and between industrial sectors. Funding of the 12 demonstration projects for CCS has remained contentious until the very end. Although generally the renewables directive has seen little controversy, trading rules for renewable electricity quotas were a contentious matter. Some member states with very aggressive targets and electricity utilities argued for more flexibility in trade while other member states feared a rush to the cheapest source, thereby crowding out certain technologies. EU sustainability criteria for biofuels were another hot topic as they raise important trade issues.

The most contested issue of the package became the issue of whether industries would receive their emission allowances for free or whether they would have to buy them. The existing rules where allowances are given out for free, has led to power companies charging their consumers as if they were paying a carbon price, resulting in billions of windfall profits. Auctioning emission allowances would solve this problem, but is politically controversial as it would lead to high costs for greenhouse gas emitting industries (83.4). Another dominant issue has been about the distribution of costs between industries and member states. This was to be expected given that by creating the EU ETS, the EU has created allowances that can achieve a value of anything between €30–90 billion annually in case of a CO_2 price of €15 per ton or €50, respectively. It is interesting to note that neither industry nor EU governments had at any time of the discussion contested the overall ETS emissions cap of 21 per cent by 2020 compared to 2005, as proposed by the European Commission.

Regarding GHG emissions reductions in non-ETS sectors (covering about 55–60 per cent of EU GHG emissions), the Commission proposal permitted member states to use offset credits in order to meet up to two-thirds of their emissions reductions, and the remaining part by domestic abatement measures. The December 2008 agreement additionally allows for 11 (mainly western European) countries – including Spain and Italy – to use additional offset credits to meet their non-ETS targets.

83.4 EU ETS and Development of International Carbon Markets

The EU ETS remains at the centre of EU climate change policy. Since the adoption of the original EU ETS Directive in 2003, a broad consensus has emerged in the EU to use carbon pricing in the form of emissions trading, i.e. a cap-and-trade scheme, as the foundation of its climate policy. If properly designed, the EU ETS cap-and-trade scheme will create incentives for companies to reduce emissions in the most cost-effective way, will reward carbon-efficiency and create incentives for new and innovative approaches to reduce emissions. The incentive for efficient abatement will arise from the 'opportunity costs' of using allowances. Passing through the costs of GHG emissions allowances to consumers will create incentives to reduce the demand for GHG-intensive goods. At the same time, this will increase producers' cash flows to invest in abatement technologies. In a situation whereby all competitors are subject to similar carbon constraints in well functioning markets, the EU ETS would be the most suitable tool to achieve EU and UN-based targets at the lowest possible costs. However, the original design of the system had several flaws.

Ellerman and Joskow (2008: iii), for example, argue that although "there have been plenty of rough edges", the EU ETS managed to deliver "a transparent and widely accepted price for tradable CO_2 emissions allowances" as well as the necessary "infrastructure of market institutions, registries, monitoring, reporting and verification". The scheme covers somewhat less than 50 per cent of EU CO_2 emissions from power and industry, including process emissions. The pilot phase from 2005–2007 suffered from a number of teething problems such as significant delays of registries and *National Allocation Plans* (NAPs)[2], inconsistencies in the definitions of installations, as well as issues related to monitoring, reporting, verification, and data collection. However, the most severe deficiencies of the first phase of the EU ETS included over-allocation, distorting allocation between member states and windfall profits for the power sector.[3]

- Over-allocation has largely been the result of two factors: an excessive degree of de-centralization in the implementation of the EU ETS, and the absence of a hard constraint. In their NAPs, member states pitched their caps somewhere between "lesser than the business-as-usual" and moving towards a "path consistent with the Kyoto Protocol". Most NAPs foresaw modest caps and a high dependence on projections. However, it turned out that most if not all projections were largely inflated (AEA Technology Environment/Ecofys UK 2006). This combination of modest cuts and inflated projections has lead to over-allocation of as much as 97 Mt of CO_2 out of a total of about 2.2 billion annual EU allowances, i.e. almost 5 per cent of total annual allowances (Kettner/Köppl/Schleicher/Thenius 2007).
- Allocation in the first phase of the EU ETS has lead to each member state developing its own rules, notably for allocation to new entrants and closures. These rules varied considerably between member states. This high degree of discretion for member states has increased complexity, administrative burdens and transaction costs while decreasing transparency. Moreover, industry has been able to put pressure on governments not to hand out fewer allowances than other governments.[4]
- In Europe's liberalized (regional) wholesale power market, prices are set by the marginal production costs, including the value of emissions in the allowance market. If the marginal producer is a (high-carbon) coal power generator, the power price can increase significantly as a result of the EU ETS. Low carbon electricity sources such as renewables and nuclear benefit substantially from higher power prices without incurring extra costs. This effect was intended. However, fossil-fuel generators were also able to receive considerable windfall profits. Power generators operating essentially in a domestic EU market can easily pass on additional CO_2 costs. The windfall effect occurred as a result of power generators passing on the full costs of CO_2, while having received the allowances for free. Windfall profits have been estimated to amount to as much as €13 billion annually (Martinez/Neuhoff 2005: 67).

Over-allocation has been addressed for the second phase (2008–2012) where the European Commission could impose a formula[5] to assess member states' allocation plans. As a result, the European Commission

2 Some NAPs were late as much 1.5 years.

3 See Matthes, Graichen, Repenning (2005); Swedish Energy Agency (2006); Ellerman, Buchner, Carraro (2007); Egenhofer (2007); Ellerman, Joskow (2008).

4 See Zetterberg, Nilsson, Åhman, Kumlin, Birgersdotter (2004); Matthes, Graichen, Repenning (2005).

could shave off 10 per cent of member states' proposed allocations, leaving the ETS sector short of around 5 per cent for the second period. While the expected price for allowances had been around €20–25, the economic downturn has made prices tumble.

Experiences from the initial phases and design flaws have greatly helped the European Commission to propose radical, one could even argue revolutionary changes to the EU ETS. The principal element of the new ETS is a single EU-wide cap which will decrease annually in a linear way, starting in 2013, to reach 1.720 million tonnes of CO_2 in 2020. This corresponds to an overall cap being 21 per cent lower than the verified emissions for 2005. This linear reduction continues beyond 2020 as there is no sun-set clause. In addition, there are EU-wide harmonized allocation rules, full auctioning to sectors that can pass through their costs (e.g. the power sector), partially free allocation to industry based on EU-wide harmonized benchmarks. Overall, this translates into 50 per cent auctioning, which could equal about €30 billion per annum at a price of €30 per tonne of CO_2 (Behrens/Nùñez Ferrer/Egenhofer 2008).

Starting from 2013, power companies will have to buy all their emission allowances at an auction. Contrary to the original European Commission proposal, however, the EU government leaders agreed that for existing power generators in some (mainly Eastern European) countries the auctioning rate in 2013 will be at least 30 per cent and will be progressively raised to 100 per cent no later than 2020. This means that for instance existing coal-fired power plants in Poland still get their allowances for free, but that new power plants need to buy them.

These member states successfully made the case that their situation could not be compared to the one in 'old' member states. Full auctioning in 2013 would make many of the coal-based and often inefficient power plants uneconomic, resulting in a shut-down. This would lead in the short-term to significantly higher power prices and possibly to supply shortages as existing interconnections between these countries and their neighbours would not allow for compensation. In addition, full auctioning would withdraw necessary financial resources from sometimes under-capitalized power companies that would be required to build new, more efficient and low-carbon capacity.

For the industrial sectors under the ETS, the EU agreed that the auctioning rate will be set at 20 per cent in 2013, increasing to 70 per cent in 2020, with a view to reaching 100 per cent in 2027. The original European Commission proposal included 100 per cent auctioning already by 2020 rather than 2027. Industries exposed to significant non-EU competition, however, will receive 100 per cent of allowances free of charge up to 2020. Latest indications are that the majority of industry will fall into this category.

The original EU ETS directive allowed for linking the EU ETS with other emissions trading schemes by international agreement. The new directive goes a step further by providing for different types of linking arrangements, e.g. via a treaty, an international agreement as foreseen under EU law and through a reciprocal commitment applied through domestic systems. The latter provision is innovative both internally and internationally as schemes could be linked through administrative decisions. In essence, this could mean that over time non-EU emissions trading schemes could be linked to the EU ETS, the notion being the EU ETS as a docking station for the global carbon market. This could mean that the EU model becomes the blueprint for the yet to come global emissions trading scheme. The EU is also actively in dialogue with representatives from non-EU federal or sub-federal emissions trading schemes to ensure convergence and ultimately linkability.

83.5 Competitiveness of Industry and Carbon Leakage

The EU ETS has triggered a debate on the 'competitiveness' of European industry and carbon leakage as EU climate change regulation may lead to a relocation of industry to regions where no carbon policies exist. This could actually lead to an increase in global GHG emissions and is well documented in a sizable body of literature.[6] There is an emerging EU consensus that a number of sectors could claim a risk of carbon leakage (as a combination of CO_2 being a significant factor in variable costs and being subject to international competition). The new EU ETS directive has further

5 Verified 2005 ETS emissions x GDP growth rates for 2005–2010 based on the PRIMES model x carbon intensity improvements rate for 2005–2010 + adjustment for new entrants and other changes, for example in ETS coverage.

6 See, for example, Carbon Trust (2004); Reinaud (2005, 2008); McKinsey, Ecofys (2006); Hourcade, Demailly, Neuhoff, Sato, Misato; with contributions by Grubb, Matthes, Graichen (2007); Matthes, Neuhoff (2007).

Box 83.2: Criteria to define sectors 'exposed to carbon leakage' (based on Article 10a of the revised EU ETS Directive). **Source**: European Parliament/Council of the European Union 2009a: 72-75.

Sectors or subsectors are deemed to be exposed to a 'significant' risk of 'carbon leakage' if

a.) the sum of direct and indirect additional costs induced by the ETS would lead to a substantial *increase of production costs*, calculated as a proportion of the *Gross Value Added* (GVA), of at least 5 per cent; and

b.) the *intensity of trade with non-EU countries*, defined as the ratio between total value of exports to non-EU countries plus the value of imports from non-EU and the total market size for the Community (annual turnover plus total imports), is above 10 per cent.

In addition, sectors are exposed to carbon leakage if

a.) the sum of the *increase of production cost* caused by the ETS, calculated as a proportion of the GVA, is at least 30 per cent; and

b.) the *intensity of trade with non-EU countries*, defined as the total value of exports to non-EU countries plus the value of imports from non-EU countries and the total market size for the Community (annual turnover plus total imports from non-EU countries), is above 30 per cent.

Assessments will be based on an *average carbon price according to the Commission's impact assessment* and trade, production and value added data from the *three most recent years* for each sector or sub-sector, if available.

The European Commission will assess this risk based on periodic reports (5 years) to start by 31 December 2009.

defined 'carbon leakage' to avoid ambiguity. It mandates the European Commission to draw up a list of sectors "significantly exposed to carbon leakage" (box 83.2) by the end of 2009. In addition, the Directive has identified a hierarchy of three possible measures:

1. Free allocation
2. A global sectoral agreement, i.e. a global sectoral policy for one or all of the vulnerable sectors;
3. Border-measures, e.g. imposing carbon costs on importers.

Free allocation of allowances in effect amounts to a subsidy, thereby undermining the ETS' objective to pass through full carbon costs. It could, however, be justified by the fact that carbon prices are distorted already because costs for GHG emissions cannot be passed through globally. In this case, the market structure, especially price elasticity of demand, inhibits globally-trading industries' ability to pass-through their additional costs in full or even partially. As a result (European and global) product prices will not reflect the 'opportunity costs' of allowances and therefore the EU cost of carbon. For example, if firms in a European industry cannot pass through the allowance price partly or fully, it is these firms that eventually end up 'paying' for the allowance price. Failure to pass through would erode benefits from CO_2 abatement as well as producers' competitiveness. Furthermore, it would transfer allowance value abroad and would ultimately lead to carbon leakage.

While the choice of option one (free allocation) is a pragmatic approach of 'taking the heat' out of a potentially poisonous debate, it allows only for compensation of direct effects, i.e. costs arising due to the fact that emissions need to be covered by an allowance. It does not address the vulnerabilities of those sectors that results from indirect effects, i.e. through higher input costs, notably higher power prices as a result of the ETS. Therefore, member states have been given the possibility to provide financial compensation to sectors on the Commission's lists. Currently the European Commission is adapting EC state aid guidelines to allow for this.

The European Commission under the leadership of DG Enterprise and Industry has launched a process involving industry, member states, research and stakeholders to assess as exactly as possible the vulnerability of sectors and sub-sectors. Industry has submitted very detailed data for the European Commission to assess the degree of vulnerability. There is a willingness not to hand out allowances for free to those sectors that in fact can pass through all or parts of the carbon costs. Thereby the European Commission wants to avoid another round of windfall profits, although this time *not* for the power sector but for industry.

Nevertheless, there are voices from some member states and some companies calling for the introduction of border measures. So far, these voices are few and there is an overwhelming consensus among EU industry that border measures for an export-dependent economy like the EU would be self-defeating. However, it is clear that border measures are seen by the EU as a possible legitimate means to put pressure on free-riders in the global effort to reduce GHG emissions. This has been confirmed by the Environment Council of December 2008. In addition, they could be used as a 'stick' when entering the post-2012

negotiations. There appears to be a consensus that a multi-lateral approach towards border measures in a post-2012 agreement is sensible or necessary to address free-riding.

83.6 Integrating Climate Change Policy with International Trade Policy

The analytic and policy agendas arising from climate-trade intersections are becoming more extensive, specific and tangible than is generally reflected in the literature and the policy discourse and certainly go beyond border-measures, also in the EU. Intersections include on the one hand threats to the international climate and/or trade regimes. On the other hand they offer opportunities for win-win outcomes – or even win-win-win opportunities if sustainable development criteria are included along with climate and trade. Four types of intersections have been identified (Brewer 2008).

The *first* consists of issues that have emerged or are likely to emerge soon on the WTO agenda; they typically concern familiar issues of tariffs, non-tariff barriers and subsidies concerning goods, including in renewable energy industries. Elimination of such tariffs on a list of manufactured goods was proposed jointly by the EU and US in late November 2007, a few days before the beginning of COP13 in Bali.

The *second* set of issues is focused on sector specific issues, particularly international aviation and maritime shipping, which are currently outside the WTO as well as the Kyoto Protocol but which are of intense interest in the negotiations for a post-2012 international climate regime.

Third, there are international trade and investment issues associated with technology transfers of climate-related technologies for mitigation and/or adaptation, e.g. international climate change technology cooperation agreements. Such policies to promote exports, foreign direct investments and technology transfers, especially to emerging economies have been imbedded, for instance, in US energy legislation. The Asia Pacific Partnership, for instance, includes on its agenda the reduction of barriers to trade and investment in renewable energy goods and services.

Fourth, there are offsetting border measure proposals being discussed in the EU and the US. Such measures have been discussed in the EU in the European High-Level Group on Competitiveness, Energy and Environment and the EU ETS Review and are proposed in pending climate change legislation in the US Congress. The cap-and-trade bill sponsored by Waxman and Markey that has been approved by the US House of Representatives on 26 June 2009 equally foresees such border measures. This has triggered sharp responses from India and China, which both interpret this as 'protectionism in disguise'.[7]

83.7 Towards a Technology Vision

The 'EU vision' on technology is only gradually emerging but it is generally recognized that technology plays a fundamental role in advancing efforts to address climate change on three fronts:

- accelerating the deployment of existing low-carbon technologies, both to bring down the costs of technologies and to reduce emissions, which requires more ambitious government policies;
- developing and deploying new breakthrough technologies for the longer-term (beyond 2030), which requires stepping up the speed and scale of innovation; and,
- avoiding, at the same time, the lock-in of high-carbon technologies in developing countries, i.e. estimating the incremental costs of making future (energy) investments in developing countries and emerging economies low carbon and paying for them, which requires dealing with equity issues, and amongst others, financial transfers.

Domestic responses are regarded as the backbone of technology policy for addressing climate change. Innovation is seen as offering a prospect of a competitive edge, technological leadership, export markets and employment opportunities. International collaboration is considered as being crucial in order to achieve the necessary scale, to pool resources, provide financing, encourage investment and speed up knowledge-sharing. Increasingly, the EU debate on climate technology is framed in an 'innovation and competitiveness' context. EU industrial policy such as the 2007 mid-term review (European Commission 2007c) explicitly acknowledges the need to create incentives to unlock the full potential of low carbon and resource efficient goods, technologies and services in the EU.

The EU integrated climate and energy package aims at accelerating innovation strategies and finance

7 See "China joins carbon tax protest", in: *Financial Times*, 4 July 2009: 3.

mechanisms that support the *rapid* development and deployment of promising technologies such as CCS, biomass and biotechnology, other renewables and end-use energy technologies or hydrogen systems. Yet pricing strategies through cap and trade *alone* will not be sufficient to provide long-term incentives for all the breakthrough technology development and deployment needed for the stabilization of emissions. Most recently the EU has started its own long-term technology mapping exercise through the EU's Strategic Energy Technology Plan.

Internationally, the EU – quite predictably – is ready to explore existing international initiatives both within the UNFCCC and outside to identify some key elements of a complementary global technology track in the post-2012 framework. Areas are:

1. UNFCCC-based or related initiatives such as the *Expert Group on Technology Transfers* (EGTT), the *Global Environmental Facility* (GEF) or the *Clean Development Mechanism* (CDM);
2. non-UNFCCC-based initiatives such as the G8+5 process, the Asia-Pacific Partnership on Clean Development and Climate[8], the Major Economies Forum on Energy and Climate[9] and global sectoral (industry) approaches,
3. the specific instrument of technology-based agreements, and
4. Collaborative projects at the international or bilateral level.

83.8 Climate Change and Developing Countries

According to the IEA's *World Energy Outlook 2007* (IEA 2007: 42) under a business-as-usual scenario – i.e. if governments stick with current policies – the world's primary energy needs would grow by 55 per cent between 2005 and 2030, at an average annual rate of 1.8 per cent. As fossil fuels are expected to remain the dominant source of primary energy, accounting for 84 per cent of the overall demand increase, global energy-related CO_2 emissions between 2005 and 2030 are also projected to increase. Developing countries, whose economies and populations are the world's fastest growing, contribute 74 per cent to the increase in global primary energy use in this scenario, while China and India alone account for 45 per cent. Hence, any agreement that would not commit fast growing developing countries or at least China to reductions would be ineffectual. According to the *World Energy Outlook 2008* (IEA 2008b: 48), OECD countries alone cannot put the world onto a 450-ppm trajectory, even if they were to reduce their emissions to zero. By 2020 China's energy-related CO_2 emissions are projected to be by far the largest in the world, almost double the ones from the US. India is expected to become the fourth biggest emitter after China, the US and the EU27 (IEA 2008b: 46).

However, relations between the EU and emerging economies such as Brazil, India, China, South Africa or Mexico remain largely bilateral. Co-operation in climate change and energy play an increasing role in bilateral summits. Co-operation agreements are often detailed, focussing on specific issues. In addition EU 'messages' are reinforced by cooperation of member states with emerging economies. On the contrary, the relationship with other developing countries, notably least developed ones, forms part of EU development policy. Based on the rationale that climate change will significantly affect poverty reduction efforts and that climate change thus needs to be consistently integrated into development policies, the EU has implemented an *Action Plan on Climate Change and Development* (from 2004-2008). This Action Plan was essentially aimed at supporting partner countries in four strategic priorities: i) raising the profile of climate change, ii) support for adaptation to climate change, iii) support for mitigation of climate change, and iv) capacity development. This EU Action Plan came to an end in 2008. However, as the recommendations of the EU Action Plan remain valid it will remain relevant to the Commission beyond that year. In terms of implementation, the *Global Climate Change Alliance* (GCCA), which became fully operational in 2008, has become the main element of the EU's external development action in the area of climate change. As a platform for dialogue and exchange, the GCCA supports developing countries to realize the integration of development strategies and climate change by providing regular opportunities for meetings between the EU and participating countries. Beyond dialogue and exchange, the GCCA provides technical and financial support for adaptation and mitigation measures, and for the integration of climate change into development strategies. Assistance provided under the GCCA focuses on five areas: i) developing and implementing concrete adaptation strategies, ii) reducing emissions from deforestation, iii) helping poor

8 See website at: <http://www.asiapacificpartnership.org/english/default.aspx>.

9 See website at: <http://www.state.gov/r/pa/prs/ps/2009/04/122097.htm>.

countries to take advantage of the *Clean Development Mechanism* (CDM), iv) helping developing countries to be better prepared for natural disasters, and (v) integrating climate change into development cooperation and poverty strategies. Priority will be given to adaptation, *disaster risk reduction* (DRR) and climate change integration (Behrens 2008a).

83.9 The EU Position in International Negotiations

There have been few surprises regarding the EU position in international negotiations. Within international fora, the EU position has been well documented, essentially and consistently retaining a number of key elements. They include i) a shared vision to reach the ultimate objective of the UN Framework Convention on Climate Change of stabilizing the concentration of GHG in the atmosphere (i.e. through binding medium and long-term targets), ii) deeper absolute emissions reduction commitments by developed countries, iii) fair and effective contributions or actions by developing countries, iv) an extension of the carbon market with a view of linking national markets, v) cooperation on technology research, development, diffusion, deployment and transfer, vi) efforts to address adaptation including finance and technologies for adaptation, vii) addressing emissions from international aviation and maritime transport, and finally, viii) reducing emissions from deforestation and enhancing sinks by sustainable forest management and land use practices, including the possibility to integrate them into the carbon market.

In January 2009, the European Commission 'translated' these EU aspirations into a strategy in its so-called 'Copenhagen Communication' (European Commission 2009a, 2009b, 2009c, 2009d), which sets out the lines of its negotiation strategy for Copenhagen.

Starting point is the 2 °C target, which according to the EU would require by developed countries the well-known 25-40 per cent reductions of GHG emissions by 2020 and some 80–95 per cent by 2050, as compared to 1990 levels. The EU's long-term 2050-target is by and large in line with US and other developed nations objectives. On aggregate, the EU wants 30 per cent reductions by developed countries by 2020 including domestic reductions and emissions credits. While there is little disagreement about the need for absolute reductions by developed countries, there is wide disagreement on how tough this target should be. Closely linked to this debate is the choice of the base-year for reduction targets. The Waxman-Markey bill offers by 2020 to cut US GHG emissions by 17 per cent, however, compared to 2005. This would translate into a reduction of four per cent as compared to 1990. The Japanese Prime Minister on 10 June 2009 announced a mid-term target of 15 per cent compared to 2005, which amounts to a reduction of eight per cent compared to 1990. For comparison, Germany has a reduction target close to 40 per cent compared to 1990. Even if one acknowledges that the German target has been facilitated by the collapse of East German industry, the gap is still significant.

Beyond the burden-sharing aspects between developed countries, developed countries' targets have a direct effect on developing countries' actions. The UNFCCC has laid down the principle of differentiation when it refers to 'common but differentiated responsibilities and capabilities', notably between developed and developing countries.

- 'Responsibility' typically refers to both actual and historic GHG emissions (e.g. per capita emissions or total emissions since the beginning of the industrial age). Historic emissions matter because limate change is a stock problem. Climate impacts are caused by concentrations of GHG in the atmosphere and not by current levels of emissions.[10]
- 'Capability' is related to standard economic indicators such as per capita GDP or poverty indicators. This concept recogizes the fact that dissimilar capacities exist to mitigate (and adapt to) climate change due to different welfare levels (table 83.3).

The ambition of developed countries' targets will directly influence the level of ambition by developing countries. This has consequences for the burden-sharing between different countries (be they developed and developing) but also for the achievability of stabilization pathways. As table 83.2 shows, to be able to reach a 2 °C target, global emissions need to peak between 2000 and 2015, i.e. around now. Proposed targets ahead of Copenhagen will not allow for this and rather point to a 3–4 °C target scenario.

Although developed countries are not expected to take on absolute targets, the Bali Action Plan has specified that developing countries undertake so-called *Nationally Appropriate Mitigation Measures* (NAMAs). Such NAMAs need to be "reportable, monitorable and verifiable actions" while at the same

10 CO_2 typically stays in the atmosphere for 100 years.

time being conditional to developed countries providing assistance in the form of finance and technology. In addition to the overall level of developing countries' contribution, one of the most crucial international negotiations issue is how to ensure "reportability, monitoribility and verification".

The 'Copenhagen Communication' has called for the formulation of domestic low-carbon strategies by developing countries by the end of 2011 ('credible pathway') through NAMAs in *all* key emitting sectors (power, transport, energy-intensive industries, forestry and agriculture), supported by developed countries in the form of finance and technology, if NAMAs are verified. The EU has proposed to operate this through a Facilitative Mechanism for Mitigation Support entering into registry ('independent technical analysis'). While some sort of review will be needed, developing countries such as India and China are loath of excessive interference and insist on their sovereignty.

Box 83.3: The scope of finance. **Source:** Behrens (2008b, 2009).

Financial cost estimates for mitigating and adapting to climate change vary widely, depending – inter alia on the emissions reduction target and the time horizon for action. Behrens (2009) concluded that with a high level of generalization, average global costs of limiting climate change to 2 °Celsius above pre-industrial levels (i.e. mitigation costs) could be around €299 billion annually. According to UNFCCC (2007b), funds would mainly flow into the transport sector, buildings, industry and agriculture. Based on Behrens (2008b), adaptation measures may roughly add another €50-150 billion to the global climate change bill. However, due to severe limitations in estimating adaptation costs, these figures should be taken with extreme care. According to UNFCCC (2007b), the main driving forces for adaptation costs are infrastructure, agriculture, forestry and fishery, water supply and coastal zones (UNFCCC 2007b).

Roughly 50 per cent (or about €200 billion) of the additional annual costs will be required in developing countries, raising the question of absorption capacities. However, industrialized countries will need to shoulder considerably higher shares of the global costs than developing countries due to their historic responsibilities for global warming and their economic capabilities to make available sufficient private and public funding. With the private sector expected to cover the largest share of total costs, public sector contributions could be anywhere between four per cent and a third.

Ultimately, a deal in Copenhagen will have to agree on targets and financial transfers. Industrialized countries will promise to cut their GHG emissions by 2020 and make even more cuts by 2050 (always compared to 1990). For 2050, views are converging: 80–90 per cent or more will be offered by industrialized countries as it is believed that new technologies will be available to achieve this. The problem is with 2020; the EU offers 30 per cent, China wants a minimum of 40 per cent, the small island states 45 per cent, while India wants almost 80 per cent. And the US offers 4 per cent. At their summit in L'Aquila (Italy) in July 2009, the G8 countries recognized the broad scientific view that calls for a limit on global warming of 2 °C. Globally, however, such a target has not yet been accepted. This is partly so because a global target would irrevocably fix the available global carbon budget. Developing countries, notably India, argue that there is very little headroom left for increasing global GHG emissions (Egenhofer/Kjellén/Kartha/Kumar 2008: 2). Therefore, developing countries link an agreement on a global target to a binding commitment of developed countries for 'steep reductions' expressed in absolute figures.

The UNFCC estimates that developing countries will require some €74–78 billion ($92–97 billion) for mitigation and at least another €23–54 billion ($28–67 billion) for adaptation in the year 2030. Not all of these financial requirements will need to be financed by public budgets, but a good deal will. China wants 0.5–1 per cent of developed countries GDP to be used to help poor countries. The EU, normally a frontrunner on climate change has postponed a decision on finance until October 2009, or even more likely to the early December European Council meeting. One can assume that both the targets and the finance package will be agreed only in the final hours of Copenhagen.

It would, however, be misleading to say that only targets and finance matter. The agenda for Copenhagen and beyond is far broader than this. It also includes a framework and finance for adaptation, the tools to avoid further deforestation and enhance afforestation, technology transfer and the development of carbon markets – especially the shape and volume of future post-2012 flexible mechanisms such as the new CDM or Joint Implementation. In the run-up to the Copenhagen summit, some progress has been made in these fields, albeit mainly of a procedural nature.

83.10 Conclusions

With the integrated climate and energy package, the EU prepared the ground for the crucial climate negotiations in Copenhagen in December 2009. The EU and its member states have realized that EU leadership is one of the crucial elements to create momentum for these negotiations. Nothing could document EU determination to provide this leadership more than an ambitious and credible domestic climate change policy. The negotiations about the package, however, have also seen that ambitious targets create trade-offs between member states and between industrial sectors. These trade-offs were settled because there was leadership by the heads of state and government. Trade-offs were also eased because of the potential benefits of the package for energy security and the prospect to shaping the coming global climate change regime. In doing so, the EU also sees a potential to make Europe a global leader for new low-car-

bon technologies while at the same time gradually reducing its energy import dependency. Overall, EU leaders have judged that the benefits outweigh the costs. Whether they will reach the same conclusion in the case of the steep cuts that will be required in the future remains to be seen.

84 Coping with Climate Change in East Asia: Vulnerabilities and Responsibilities

Paul G. Harris

84.1 Introduction

With its extremely large population and huge landmass, East Asia is among the world's regions most vulnerable to – and increasingly responsible for – future climate change. This chapter briefly examines two issues that permeate debates about climate change policy and politics in the region: (1) the ecological and socio-economic impacts of climate change for the countries of East Asia, and (2) critical questions of international justice – what some prefer to call international equity or fairness – associated with climate change.[1]

These two overarching issues are unavoidable considerations for efforts to address climate change, and they are central to helping us understand why and how countries respond to it. Vulnerabilities to the impacts of climate change can drive concerns within countries, to be sure. But they are not the only considerations. Demands for justice affect the willingness of governments to join and implement climate change agreements, and the extent to which those demands are fulfilled can determine the ability of many countries to undertake the measures that are necessary to mitigate climate change and to deal with its adverse consequences.

This chapter reviews major scientific reports on the potential impacts of climate change in East Asia. While these reports vary somewhat in their findings and their degree of certainty, the preponderance of evidence is clear: climate change presents the region with extraordinary challenges, most of them unwelcome (84.2). The chapter then introduces some underlying ethical considerations with regard to the responsibility for climate change before summarizing how justice is part of the broader climate change regime, including the 1992 UN Framework Convention on Climate Change (UNFCCC), its 1997 Kyoto Protocol, and ongoing negotiations concerning how to build on it. The main concern here is on practical debates, their codification in international instruments, and the ways in which they are perceived by East Asian countries – and hence their impact on policy and behaviour (84.3). The conclusions are rather unpleasant. Increasing knowledge of the adverse effects of climate change has raised awareness and concern among East Asian countries, but questions of justice and responsibility mean that their worries about it do not automatically or easily translate into national action (84.4).

84.2 Threats, Vulnerabilities, and Risks in East Asia

Climate change will lead to many adverse consequences, difficult choices, and expensive adaptation measures for much of the world's population (IPCC Working Group II 2007). The countries of East Asia will not be immune to these changes, and in most cases will be among the worst affected due to their vulnerable geographies and economies. Several research reports over the last decade have sought to predict the effects of climate change for the region.

The IPCC's only full-length assessment of the *regional* impacts of climate change (IPCC 1997), reported that *temperate Asia* (including Japan, the Koreas, and most of China) experienced an average annual temperature increase of more than 1 degree Celsius in the 20th century, mostly after the 1970's, and substantial warming was expected in this century. Rainfall was predicted to change significantly in the area, with substantial declines expected in most of China (notably in the Northern provinces). Permafrost in Northeast China was expected to disappear (with release of methane, thus adding greenhouse

1 Many of these arguments were exercised in Harris (2001a, 2002b). This chapter updates regional impact scenarios described in Harris (2003a).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_84, © Springer-Verlag Berlin Heidelberg 2011

gases to the atmosphere) and glaciers were expected to melt. Northern China is particularly vulnerable to expected changes in rainfall, exacerbating existing water shortages (see Nielson/McElroy 1998; Ying 2000). The area is likely to experience changing agricultural yields, with many crops likely to see reductions and a northward movement of crop zones and anticipated shortages of round wood (partly due to increased demand). Delta coastlines in China are severely threatened by sea-level rise, which will include saltwater intrusion into aquifers. Japan will not be immune; already many parts of major coastal urban areas, with millions of residents, are below the mean high-water mark. Providing protection for only some of these cities will cost tens of billions of dollars. Japan's beaches, which comprise about a quarter of its coastline, will be subject to erosion - and over half of existing beaches may disappear. Additionally, heat-related deaths throughout temperate Asia may increase sevenfold by the middle of this century.

The potential effects of climate change for *tropical Asia* (encompassing Southeast Asia) were also described in the IPCC's (1997) regional assessment. It reported that, by the 1990's, the region was already suffering from increasing pollution, land degradation, and a host of major environmental problems resulting from rapid urbanization, industrialization, and economic development. Climate change was seen to be exacerbating these problems. In this sub-region, mean surface temperatures were already up by 0.3° to 0.8° Celsius over the preceding 100 years. Among the predictions of impacts were the following: Forest cover will change, possibly increasing, and forest types may vary from those of the present. Changes in evaporation and rainfall are likely to have detrimental effects on freshwater wetlands. Coastal areas will be most greatly affected by sea-level rise and increased ocean temperatures, the latter possibly preventing coral reefs from keeping up with sea-level rise. Mangrove and tidal wetlands will have difficulty adapting due to bordering infrastructure and human activities. Greater erosion, coastal flooding, and salinization of fresh water sources are probable. Delta regions of Southeast Asian countries are particularly vulnerable, and throughout this area several million people could be displaced by sea-level rise. The costs of responding to the impacts of rising seas, in the words of the IPCC, "could be immense" (IPCC 1997: para. 6.10). Glaciers feeding the area's rivers will likely melt, and there may be yearly reductions – albeit between seasonal flooding – in the flow of snow-fed rivers, adversely affecting agriculture, hydropower generation, and urban water supplies. Agriculture will probably suffer (despite CO_2 fertilization) from temperature and moisture changes and possibly from increased pests, affecting wheat, rice, and sorghum crops (although much uncertainty, confounding planning, will obtain). According to the IPCC report, poor rural populations depending on traditional forms of agriculture or living on marginal lands are especially vulnerable. Increased vector-borne diseases such as dengue, malaria, and schistosomiasis will adversely affect human health.

The IPCC's 2001 third assessment report (IPCC Working Group II 2001) showed that Asia is potentially more vulnerable to the impacts of climate change than are some other regions of the world.[2] It concludes that the developing countries of Asia are highly vulnerable to climate change, and their adaptability is low. (Developed countries of the region [e.g. Japan] are of course less vulnerable because they are more able to adapt to climate change.) Floods, forest fires, cyclones, droughts, and other extreme events were reported to have increased in temperate and tropical Asia. The third assessment report anticipated that while agricultural productivity could increase in northern parts of Asia, food security would suffer in arid, tropical, and temperate Asia due to reduced agricultural and aquaculture productivity from warmer water, sea-level rise, floods, droughts and cyclones. Water availability may decrease in arid and semi-arid Asia and possibly increase in northern Asia, and increased incidence of vector-borne diseases and heat-stress will threaten human health. Temperate and tropical Asia should anticipate increased rainfall and floods, and sea-level rise and more intense storms could "displace tens of millions of people in low-lying coastal areas of temperate and tropical Asia" (IPCC Working Group II 2001: 16). Some parts of Asia will see climate change effects on transport, increased demand for energy, and adverse impacts on tourism. Land-use and land-cover changes will threaten biodiversity, and sea-level rise will adversely impact coral reefs and mangrove areas that are important for fisheries.

Regional scenarios on the impacts of climate change in the IPCC's 2007 fourth assessment report (IPCC 2007) "confirm most of the key findings on impacts, vulnerabilities and adaptations for Asia" in the third assessment report (IPCC 2007: 472). *Observed* trends include increasing surface temperatures, especially during winter; decreasing annual mean rain-

2 The report does not distinguish East Asia. These findings are for Asia generally except where specified.

fall in Northeast and North China, Indonesia, the Philippines and parts of Japan; and increasing rainfall in Western China, the Changjiang Valley and along the Southeastern coast, as well as in the Philippines' western coasts (IPCC 2007: 472). Changes in extreme weather events in Asia that have been observed include "increasing tendency in the intensity and frequency of extreme weather events" (IPCC 2007: 473), including heatwaves in China, Japan, the Korean Peninsula, and Southeast Asia; intense rains and floods in China, Japan, and Southeast Asia; droughts in China and parts of Southeast Asia; and cyclones/typhoons in China, Southeast Asia, and Japan (IPCC 2007: 476). Damage in China, the Philippines, Japan, Vietnam, and Cambodia from more intense cyclones has "risen significantly" (IPCC 2007: 473). The impacts of alterations in climate trends, variability, and extreme weather events have already included adverse changes to agriculture and declines in food production, increased water shortages (including the drying up of lakes in parts of China), coastal erosion, and coastal flooding "resulting in substantial economic losses and fatalities" (IPCC 2007: 477), seawater intrusion in China's coastal plains, loss of coral reefs in Southeast and East Asian waters, fires in Southeast Asian peat lands, forest and brush fires in Indonesia, drying up of wetlands and "severe degradation of ecosystems" (IPCC 2007: 478) in China, loss of biodiversity, movement of animal and plant species to higher latitudes and altitudes, and diarrhoea-related diseases and outbreaks of cholera, hepatitis, malaria, dengue fever, and other infectious diseases "influenced by climate-related factors," such as floods and droughts, in association with other factors like lack of safe drinking water and poor sewerage (IPCC 2007: 478).[3]

The IPCC's latest assumptions about *future* impacts and vulnerabilities can bring little comfort to East Asia, not least the prediction that there will be "a significant acceleration of warming over that observed in the 20th century," particularly at higher latitudes and during winter (IPCC 2007: 478). Predictions foresee increased annual precipitation in East Asia, notably in summertime in Southeast Asia, but with a simultaneous increase in extreme weather events (e.g., intense rain and heatwaves). Japan, for example, can expect "enhanced" heatwave conditions and extreme daily precipitation, including typhoons (IPCC 2007: 479). East and Southeast Asia are likely to experience tropical cyclones that are 10–20 per cent more intense (based on 2–4 °C increase in sea surface temperatures), higher storm surges along coasts, and sea-level rise of 1-3 mm per year, above the predicted global average (IPCC 2007: 479). Key future impacts and vulnerabilities anticipated by the IPCC during this century include some good and much bad news (IPCC 2007: 479–489). The good news is that crop yields could increase up to 20 per cent in East and Southeast Asia according to some models (IPCC 2007: 479), but others point to decreased yields in some places, such as up to 40 per cent lower rice yields in parts of Japan and a fall in rain-fed rice yields by up to 12 per cent in China (IPCC 2007: 480). Indeed, rain-fed croplands in North and Northeast China will likely require more irrigation due to a water deficit, as will agriculture in much of East Asia (IPCC 2007: 482). The coastal waters of East and Southeast Asia are expected to experience a decline in fisheries production, but the predictions of how fisheries will be affected are foremost characterized by extreme uncertainty. Overall, combined with increasing demand, effects of climate change (such as increases in crop pathogens on food production in the region) are very likely to be adverse.

Water resources in the region will likely change for the worse. For example, the *maximum* monthly flow of the Mekong River will increase, leading to greater flooding in rainy seasons, but *minimum* flows will decrease, contributing to water shortages in dry seasons (IPCC 2007: 483). In other parts of the region, water cycles will change, with snowmelt run-off ending sooner and intense rains occurring over shorter periods, contributing to water shortages during much of the year (IPCC 2007: 484). Climate change will adversely affect rivers fed by glaciers. Already, glaciers in Asia are receding more quickly than in other regions, with some Chinese glaciers expected to decline by over 60 per cent and smaller glaciers expected to disappear altogether this century, with this "attributed primarily to [anthropogenic] global warming" (IPCC 2007: 493). About 250 million people in China alone could be seriously affected by melting glaciers (IPCC 2007: 483). Water quality will suffer in some areas due to salt-water intrusion from sea-level rise, and more frequent and more intense droughts (IPCC 2007: 483). Sea-level rise means that coastal areas will suffer increased erosion and seawater inundation, affecting agriculture and wetlands, while also flooding the homes of millions of people, especially in Southeast Asia (IPCC 2007: 484–485). Deltas, estuaries, and nat-

3 Many of the report's findings on climate-related trends in the region are summarized here (IPCC 2007: 475–478). Many of these environmental changes have been exacerbated by human activities.

ural ecosystems, including forests and grasslands, will suffer degradation and the effects of extreme weather events (IPCC 2007: 485–487). Other impacts directly felt by the people of East Asia are expected to be adverse (IPCC 2007: 487–489). Human health will likely be affected in a number of ways by, for example, more cases of dengue fever and increased heat mortality in China, more patients suffering from pollen disease in Japan, and increasing incidents of infectious bacterial diseases such as cholera and other waterborne diseases like dermatitis and gastrointestinal illnesses in Southeast Asia.

What comes from the IPCC and other reports on the impacts of climate change in East Asia is that many of the effects will be felt most by – and be most painful for – the poorest countries and the poorest people of the region who are generally more vulnerable and least able to cope due to poverty and existing environmental problems and resource scarcities (see Working Group on Climate Change and Development 2007). Problems of population, intensive development, overuse of resources, and degradation of the natural environment that characterize life in much of East and Southeast Asia today will be exacerbated, perhaps greatly so, by climate change. A very large number of people throughout East Asia live in low-lying coastal regions, and they are threatened by sea-level rise, land subsidence, inundation of fresh water aquifers by salt water, and more frequent and violent storms from climate change. Island countries such as Indonesia and the Philippines are especially vulnerable to climate change effects (Galvez 2003). They can expect freshwater shortages and damage to coastal areas and adjacent infrastructure, with concomitant adverse effects on tourism. Indeed, in extreme cases it may one day be necessary for some small-island Asian Pacific states to abandon their territory altogether. Representatives from these countries have for some time argued that they are *already* feeling the effects of rising oceans (UNFCCC 2007c). These effects are more than problems for people; they present developing countries with potentially existential challenges. Even those state governments overseeing strong economies and that have major resources of command at their disposal may be challenged. For example, in the case of China, "[t]he government's steering capacities could be overwhelmed by the rapid pace of modernization, environmental and social crises and the impacts of climate change" (German Advisory Council on Climate Change 2007). Weaker governments in more vulnerable countries could face these challenges and more.

Even the developed countries and regions of East Asia are unlikely to avoid harm from climate change. By way of example, reduced fish catches by Japanese fisherman have been attributed to changes in underwater currents triggered by climate change (Reuters 2001).[4] While Japan's coastlines are not as vulnerable as those of China, the Philippines, and other countries, it is reasonable to expect that it will suffer costly damage from sea-level rise, associated storm surges, and adverse weather, and it has direct interests in the health of surrounding seas and indirect interest in what happens throughout the region. And there will be adverse impacts for Japan's biodiversity, forests, agriculture, wetlands, and water systems, as well as for infrastructure and human health (Nishioka/Harasawa 1998; Working Group on Climate Change and Development 2007: 37).

Impacts are being felt in other developed countries: Australia, with the highest per capita greenhouse gases in the world, will likely see the Great Barrier Reef devastated by coral bleaching and national parks suffering major losses in biodiversity, and that already very dry continent will experience more severe drought conditions with adverse consequences for agricultural productivity and bush habitats (Working Group on Climate Change and Development 2007: 35–36). In South Korea, seasons are already being blurred, with negative impacts on flowering plants, forests and fisheries, and sea-level rise poses risks to coastal ecosystems (Working Group on Climate Change and Development 2007: 37). Even in Hong Kong, predictions see winters as vanishing within 50 years, with more hot nights trapped by concrete skyscrapers in an increasingly tropical city (Working Group on Climate Change and Development 2007: 34).

84.3 The Challenge of International Justice

It might be assumed that the key to increasing the participation of East Asian countries in the climate change regime is a function of knowledge about the problem and their capability to act. This would be a simplistic assumption. Much as people can be stubborn if they are not treated fairly, states can be as well,

4 See: Reuters: "Scientists, fishermen fear Sea of Japan slowly dying", 28 March 2001; at: <http://www.heatisonline.org/contentserver/objecthandlers/index.cfm?id=3672&method=full>.

including states in East Asia. To be sure, an increasing understanding of the regional and local effects of climate change logically influence governments' attitudes toward this problem, with the likelihood that improved understanding of adverse impacts will increase their willingness to do something about the problem. However, questions of justice and responsibility for climate change often obscure predictions about impacts or heighten resistance to action, especially when uncertainty about those impacts obtains. Developing countries of East Asia will be less willing (and less able) to address climate change if they believe that they are not being treated fairly in the context of the global regime – despite the increasingly clear dangers they face from the problem.

As suggested by the scientific findings summarized above, all countries of East Asia could suffer from climate change, although it is likely that the poor countries of the region will suffer most due to their vulnerable geographies and economies. However, it is the economically developed countries of the global North that have generated most greenhouse gases since the Industrial Revolution, and they have thereby benefited from using the global atmosphere as a sink for the harmful by-products of their economic development (Ponting 1991: 387–392, 405–406). During the negotiations for the UNFCCC, developing countries were unified in emphasizing the historical responsibility of developed countries for climate change. They agreed to participate in the climate negotiations only on the condition that they are not required to accept any substantial commitments of their own (Borione/Ripert 1994: 83–84). For developing countries in East Asia, this remains sacrosanct.

It is probably impossible to state definitively what is a 'just' or 'equitable' distribution of the burdens associated with climate change.[5] Nevertheless, the IPCC has grappled with the question (Bruce/Lee/Haites 1996). It seems unassailable that there ought to be a just and equitable distribution among countries of the benefits and burdens associated with climate change. One can say this because it is difficult to envision any reasonable person or government arguing that there ought to be an *unjust* or *inequitable* (as opposed to possibly unequal) sharing of climate change burdens. However, people and governments will disagree about the precise manner in which justice is to be operationalized. Indeed, that is much of what the continuing climate change negotiations are about.

In simple terms, justice (or equity) refers to the quality of being fair, impartial or even-handed in dealings with others. At the very least, as Henry Shue (1995) argues, justice and equity mean doing no additional harm to other countries and other people, as well as ensuring an adequate minimum for vulnerable people. International negotiators are involved in arbitrating these and other various definitions of international justice in the context of climate change. While philosophical conceptions of justice are important, and indeed they have informed the thinking of policymakers, they are often used to support demands of countries that derive from practical considerations and genuine feelings of injustice on their part. In fact, what passes for justice in the climate change regime is what governments can agree that it means.

International justice has been codified in a host of international environmental agreements, such as the 1987 Montreal Protocol on Substances that Deplete the Ozone Layer (and its amendments), the Convention on Biological Diversity, and the FCCC (Banuri 1996: 87–91; Harris 2001b: 1–88). Among the key principles in the UNFCCC is that of "common but differentiated responsibility," meaning that industrialized developed countries would take the lead in addressing the climate change problem, specifically excluding developing countries from binding greenhouse gas emissions reductions (Harris 1999). The developed countries are disproportionately responsible for historical emissions, and they have the greatest capacity to act. As the UNFCCC points out, "the largest share of historical and current global emissions of greenhouse gases has originated in developed countries" (Preamble). Thus the Convention makes few demands on the (until recently) much less responsible and usually much less capable developing countries. This exclusion of developing countries became one of the most contentious issues before and during the negotiations leading to the Kyoto Protocol – and remains so in negotiations for a post-2012 successor to the protocol.

In the spirit of common but differentiated responsibility, the first basic principle of the UNFCCC states that:

> The Parties should protect the climate system for the benefit of present and future generations of humankind, on the basis of equity and in accordance with their common but differentiated responsibilities and respective capabilities. Accordingly, the developed country Parties

5 This is analysed in detail in Harris (2001c), and the conceptions of equity in global environmental politics are discussed in Harris (2001b).

> should take the lead in combating climate change and the adverse effects thereof (Article 3[1]).

Thus the convention recognizes that all countries are responsible for climate change, and all should endeavour to limit the pollution that causes it. But, following the common but differentiated responsibility principle, it does not require developing countries to reduce their greenhouse gases. It instead requires the developed countries to take the "lead in modifying longer-term trends in anthropogenic emissions [of greenhouse gases] consistent with the objective of the Convention" (Article 4,2,a). The convention codifies the idea that it would be unfair to expect developing countries to limit their economic development when the wealthy countries of the world are most responsible for present concentrations of atmospheric greenhouse gases and most of the expected consequences of this pollution for the global climate in the next century.

Negotiations for the Kyoto Protocol were premised on the common but differentiated responsibility principle. The developed countries accepted this standard because they knew developing countries would not – and in many cases could not – join the climate regime and eventually limit their emissions otherwise. Throughout the international negotiations on a protocol to the UNFCCC, developing countries, often lead by China, consistently declared that they would not agree to any mandatory limitations (least of all *reductions*) in their greenhouse gas emissions until the developed countries substantially reduce theirs (see G-7 in 1997; Hatch 2003; Zhang 2003). The developing countries acted on these sentiments in the Kyoto negotiations, vetoing any language in the protocol that would call on them to make even voluntary commitments to limit their emissions of greenhouse gases (ENB 1997). Accordingly, the Kyoto Protocol requires *developed* countries to reduce their overall emissions of greenhouse gases by about 5 per cent below 1990 levels by 2012. Indeed, the Protocol is devoid of references to emissions limitations for developing countries. Rather, all its provisions apply to the developed 'Annex I' countries. In Article 10, the Protocol explicitly reaffirms common but differentiated responsibility when it states that all parties must take into account

> their common but differentiated responsibilities and their specific national and regional development priorities, objectives and circumstances, without introducing any new commitments for Parties not included in Annex I [i.e. the developing countries].

Subsequent international negotiations attempted to hammer out the details of implementing greenhouse gas emissions cuts mandated by the Kyoto Protocol. For example, at the eighth conference of parties to the UNFCCC in 2002, the developing countries, notably China and India, reaffirmed their outright opposition to reducing their greenhouse gas emissions. Then Indian Prime Minister Atal Bihari Vajpayee pointed out that per capita emissions from his country are an order of magnitude below those of the developed countries (Vajpayee 2002). He added that developing countries will continue to increase their emissions – and ought to so that millions of poor people can be lifted out of poverty. China has consistently taken an identical position, and in the run-up to the 13th conference of the parties at the end of 2007 Chinese officials affirmed this. In the words of China's Vice Foreign Minister, Zhang Yesui, "Climate change is caused mainly by developed countries. . . . They should have the main responsibility for climate change and to reduce emissions" (McDonald 2007). This position was reaffirmed by China and other developing countries in the region as they participated in negotiations in early 2008 toward reaching agreement on a successor to the Kyoto Protocol.

Consequently, much attention has focused on *adaptation* measures, through transfers of funds and technology to developing countries to help them cope with the effects of climate change (Harris 2002a, 2003b). The result has been an alliance of sorts between the United States and some large developing countries. By shifting the focus of the climate talks to adaptation, and away from mitigation, both sides can avoid doing what they dread the most: reducing their greenhouse gas emissions. The poor countries can get more money and technology on preferential terms – assuming the agreements are carried through – and they would not be required to stop using cheap forms of energy as they develop. This seems a fair outcome because poor countries will be able to take advantage of aid from the Global Environment Facility and other funding mechanisms set up under the climate change convention, as well as funding and technology transfers through the Kyoto Protocol's Clean Development Mechanism, which allows industry in developed countries to implement emissions cuts in developing countries.

The upshot is that climate change has not been prevented and climate change will bring the most suffering to those least responsible for it, many of them living in East Asia. It is important to bear in mind that developing countries in East Asia have similar short-

term economic concerns – and domestic interests lobbying governments – which oppose greenhouse gas cuts found in the developed countries. But in addition to these interests resisting more concerted action to reduce national greenhouse emissions, they have major concerns about justice and equity. Indeed, as Japan's former ambassador for international economic and global environmental affairs has argued, assertions by the United States and some other developed countries that implementing the Kyoto Protocol to the UNFCCC will be too costly for them "could lend weight to the argument advanced by some developing countries that they are too poor to take action" (Asakai 2001).

All countries in East Asia have signed and ratified the UNFCCC. The convention calls on all of them, including the developing countries, to inventory their emissions, in addition to undertaking their 'common' responsibility to work toward addressing climate change. In many ways the developing countries of East Asia are doing this, and they are becoming more energy efficient because in so doing they derive many domestic benefits (i.e. increased energy security, reduced local environmental pollution, etc.). However, they continue to have low per capita emissions relative to the developed countries, and most of them remain relatively poor. As a consequence, they continue to refuse mandatory emissions limitations, and certainly they will not accept mandatory emissions *reductions*. China's concerns about injustices associated with climate change are indicative of the views of many developing countries, including those of East Asia (Kobayashi 2003). It wholeheartedly opposes new developing country commitments and continually demands greater action from the developed world. Even Japan supports the notion of common but differentiated responsibility because the developed countries have caused the problem and because their per capita emissions are twenty times those of the poor countries. From the Japanese perspective, it is "not right to expect developing countries to assume the same level of obligation" (Asakai 2001).

One practical manifestation of what the developing countries want, apart from not being required to reduce their greenhouse gas emissions, is increased development aid. Most developing countries of East Asia view the climate change regime as a potential source of funds and technology to assist with their sustainable development and to improve their energy security. International financial institutions, such as the World Bank, have many programmes in place to assist the developing countries in the region with, for example, energy conservation and efficiency. Japan is important in this respect, for it is a source of much of the funding (Asuka-Zhang 2003). It provides assistance to reduce emissions from energy production, which not only reduces greenhouse gases but also reduces emissions that affect Japan directly (e.g. acid rain), and its bilateral assistance is viewed more broadly by the government as a way to engage countries of the region, to show its leadership among them, and to promote the interests of Japanese industry with facilities in the region or that wish to export their environmental technologies (Asakai 2001). China has benefited greatly from the Clean Development Mechanism (Michaelowa/Asuka-Zhang/Krause/Grimm/Koch 2003). In 2006 China alone received $ 3 billion of the mechanisms $ 4.8 billion payout (Chen 2007), and by October 2007 China had 885 greenhouse gas-reduction projects garnering $ 15 billion for Chinese companies.[6]

This is not surprising because, among the countries of East Asia, China is the most important for efforts to address climate change. Its greenhouse gas emissions, particularly CO_2, will increase dramatically in coming decades, and it soon will (if it has not already) overtake the United States to be the number-one national source of greenhouse gas pollution (Netherlands Environmental Assessment Agency 2007). Nevertheless, it is important to point out where most of the blame for past emissions and observed climate change really lies: with the United States and other large developed countries, whose per capita emissions far exceed those of China and other developing countries – and indeed all countries of East Asia (if not all cities and regions within those countries).

84.4 Conclusion

Increasing knowledge of the uncertainty and adversity that will result from climate change has raised awareness and concern among East Asian countries. Climate change poses challenges for economic development and will likely harm human and international security in the region. All things being equal, one would expect this knowledge to lead to very concerted action by East Asian countries to do all that is possible to mitigate climate change. However, domestic and international politics, and even ethics, inter-

6 See: Associated Press, 2007: "Beijing won't budge on emissions despite spewing 58pc of increased carbon", in: *South China Morning Post* (10 November): A6.

vene. Concerns about justice and equity often override or obscure the concerns and considerations regarding the likely dangers and difficulties posed for all countries in the region. Strong concerns about international justice, issues that are inherent in climate change and related international politics, mean that worries about the impacts of climate change are not easily translated into national action by most East Asian countries. Indeed, governments and even many people may be willing to endure the ravages of climate change rather than join in or succumb to what they perceive to be unjust international demands for them to reduce their greenhouse gas pollution. At most they can be expected to demand help to *adapt* to the impacts of climate change, as they have been doing in ongoing international negotiations toward a post-Kyoto Protocol agreement that would simultaneously address the problem of climate change and the problem of perceived and actual injustice in this context.

In other words, without perceived (and possibly actual) justice, strong action to join global efforts to cut greenhouse gas emissions within the region is much less likely. Thus, *both* the impacts of climate change *and* concerns about related questions of justice will continue to occupy policymakers in East Asia, and both will influence their attitudes toward the climate change regime and the degree to which it is implemented in the region. This points to the need for the developed world to do much more to take the lead – and to be *seen* to be taking the lead – in cutting the pollution causing climate change *before* expecting developing East Asia to do much more.

85 Strategies for Coping with Climate Change in Latin America: Perspective beyond 2012

Ricardo Zapata-Martí

85.1 Introduction

In Latin America and the developing Caribbean countries and island territories, coping with climate change is not yet part of the development agenda and takes in many countries a back seat in the government's priorities that are more closely associated with economic growth and competitiveness, the trade agenda, poverty alleviation, uneven income distribution, and social marginalization and exclusion. The clear synergies between sound environmental policies, sustainable development, and the attainment of the *Millennium Development Goals* (MDGs) are not clearly established, just as the link between a social policy agenda and national security is just beginning to assert itself.

The issues of climate change in many instances are seen as more of an imposition from the developed world and a constraint to fast growth associated with industrialization, the exploitation of natural resources and basic raw materials such as minerals, petroleum, and expansion of large-scale agricultural production linked with the extensive use of chemical fertilizers, pesticides, and genetically modified seeds and species. Only a few countries have generated policies and mechanisms to allow environmental goods as a source of income and participate in the emerging CO_2 sinking bonds and mitigation projects. Even the designation of natural habitats as environmentally protected areas or national parks is limited given the continent's vast expanse and huge biodiversity, and in many instances it has been through foreign investors or as part of nature-for-debt processes that these have been created.

In part this is understandable given the still limited world market for environmental goods and services and the still limited – albeit fast growing – contribution to overall greenhouse gas emissions. The soon to expire Kyoto protocol has not provided sufficient incentive for the region's government and private sector investors to realize the potential that climate change mitigation can have as a means to increase the value of the region's natural capital. [1] The region has numerous examples where forest cover has been consistently reduced associated to investments on fossil energy resources exploration, the expansion of agriculture through extensive plantations and cattle farming, aggravating the deforestation directly caused by wood exploitation of its very rich and fast reducing forest cover.[2]

According to ECLAC (2009) in recent years there has been an increase in per capita emissions in almost all the countries of the region. The main contributing sectors are agriculture, change in land use, and energy consumption with about a third each. Emissions of industrial processes and waste represent less than 10 per cent. Nevertheless, emissions of *greenhouse gases* (GHG) in Latin America remain within the range of 12 per cent (including land-use change) but to remain at those levels it is clear that the region will need to invest in clean technologies and revert land-use changes to a greater extent than it is doing at present. By the same token the increasing cost of adaptation is not being incorporated in the region's development policies, thus increasing the vulnerability of both its productive and social investments.

1 At the United Nations Climate Change Conference in Bali in December of 2007, the 192 Parties to the UNFCCC agreed to launch negotiations on an agreement to step up international action on climate change in the period beyond 2012, when the first phase of the Kyoto protocol expires. The new agreement is based on four pillars: mitigation, adaptation, technology and finance, and is to be concluded in Copenhagen in 2009.

2 For an updated general description of desertification in Latin America see the WAFLA webpage; at: <http://www.wafla.com/>. For an interesting perspective on deforestation in Latin America see; Southgate and Runge (1990).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_85, © Springer-Verlag Berlin Heidelberg 2011

A brief review of current environmental strategies and policies related to climate change describes a development profile in which sustainability is mostly a declarative principle. The discussion in Latin America and the Caribbean focused on the environmental impact of climate change, and it is only very recently that the economic implications have been addressed.[3] ECLAC (2009) has bridged the environmental and economic analysis, offering for the first time an analysis of relevant updated information till the end of 2008. This review highlights relevant economic aspects of climate change and its regional implications, as well as their link with major economic areas of concern such as international trade, fiscal implications, and additional restrictions to a rapid development growth that is not linked to an equally rapid growth in carbon consumption and greenhouse gas emissions. In 2009, climate change is beginning to be viewed as a development handicap as natural resource losses or management to adapt to the negative impacts of climate change. This publication argues that at the regional level climate change adaptation and mitigation pose an opportunity for a better quality development which will require investments in technological research and mobilize resources to access technologies that will allow for the mitigation of environmentally negative externalities of the current development process. It stresses the importance of attracting economic policy-makers and management to these issues, recognizing that the climate change adaptation and mitigation governance are still lacking. This derives from a lack of attention that climate change poses unforeseen pressures on government expenditure coupled with revenue losses.

85.2 Intra-regional Differences in Impact and Policies

There are intra-regional differences between South and Central America and between continental countries and small island states. This is mostly due to the increased consciousness of small island economies that longer and stronger hurricane seasons are linked to sea temperatures as a contributing factor, and that this is due to greenhouse gas emissions over which they have little control, and the fact that their small territories makes them extremely vulnerable. This smallness also implies that their potential contribution to mitigation is very limited both because they do not have a huge potential for gas sinks or for diversification of activities in order to reduce their vulnerability. These territories' footprints – given their remoteness and their economic sources of income linked to transport such as tourism or export of agricultural products or basic commodities – are also linked to the development of technologies that lie beyond their realm. This is not the case of larger continental territories where the potential for gas sinks is in some cases quite large. In those countries afforestation or avoided deforestation have a larger potential, and they also have a wider scope of sources of economic activity that they may diversify. A challenge for these countries is to reduce their use of non-renewable fuels, reduce their dependence on basic raw minerals and commodities and increase the value added in their productive processes, strengthen the value chain in their economies while improving their production processes by expanding clean production techniques. In Central America these strategies may be accelerated by joint regional cooperation and horizontal and vertical integration of these chains and processes.

Since the 1980's, several countries in the region have begun to adapt their legal and institutional frameworks to the new paradigm of sustainable development. All nations included the principle of environmental protection in their constitutional law, albeit to varied levels. In 14 countries, the new constitutions promulgated during the past 25 years contain environmental provisions that were inspired by ideas shaped in world *fora*. Others amended existing constitutions to incorporate environmental regulations.

Latin America and the Caribbean supported the environment agenda since the first UN Conference on the Environment and Development in Rio de Janeiro (1992) and in 2008 at a meeting in Brazil the 'Post 2012 Climate Change Framework' was discussed, and the need for a consensus on proposals on biofuels and forestry to be presented to the G8 leaders.[4] The movement from discussion and advocacy to actual policy formulation and political commitment from decision-makers, though, has not necessarily been translated into concrete actions and policies or into significant investments – either public or private – and the link between environmental concerns and

3 For a review of past regional positions see: IDB (2005, 2004). The latter report investigates the current state of the region's national institutional capacities in the area of climate change policy and the Kyoto protocol's Clean Development Mechanism. In particular, it assesses the role of the Designated National Authority

conservation and climate change has seldom been explicit.

Many countries have established general environmental legal frameworks while also trying to deal with natural resource conservation, concentrating in specific areas such as water resources, mineral resources, marine and land areas, hunting and fishing, forestry resources, and pollution hazards, as in the case of tourism, use and control of chemical products, pesticides, and coping with air pollution in large urban areas. These efforts, though, have not been linked perspectives of climate change so, despite the fact that these countries have developed national environmental plans and strategies, they are not seen as intrinsically linked or harmonized with adaptation or mitigation strategies in face of climate change. During the 1980's and 1990's, many Latin American and Caribbean countries created new environmental institutions with different status within governmental ministries, commissions, and councils. In some cases these were carved out of, or combined with, or reorganized within existing institutions. Pioneering cases at the ministerial level were Mexico, Costa Rica, Honduras, and Nicaragua although their effectiveness over time has been erratic and limited. Chile, Ecuador, Guatemala, and Peru among others created commissions (Gligo 1997) that had neither the resources nor the political clout for major change.

85.3 Discrepancy between Laws and Implementation

Based on this institutional development many rules and regulations emerged on specific environmental issues, such as mandatory environmental impact assessments for all projects and a requirement for the approval of investments, construction or industrial development and their control of hazardous wastes. In some cases environmental crimes were legally established regarding water pollution, deforestation, and fire control. The protection of natural resources with regulations on the use and access to natural resources in production processes, both industrial and otherwise, has also been legislated. Most prevalent are laws or regulation for the protection of human health from harmful environmental effects (UNEP 1993). Insufficient resources for monitoring, uneven legal practice and several exceptions have plagued the effectiveness of these legal provisions. A notable exception is the Brazilian Environmental Crimes Law of 1998.

Although laws regulating the use of natural resources often include provisions to punish non-compliance (Orozco/Acuña 1997); in many cases they do not include criminal or administrative sanctions. The root cause for this inefficient application of existing laws and regulations is not only a lack of resources and capacities to monitor compliance, but systematic implementation may have negative economic effects for the private sector and fiscal revenues. In Nicaragua pollution from domestic, industrial, and agricultural sewage is regulated but none of the rules can be properly enforced (Dourojeanni 1991).

This was stressed in the report on *Climate Change in Latin America and the Caribbean 2006* (UNEP; SEMARNAT 2006), which states that there is a "lack of information regarding how to approach adaptation" and that, in spite of the growing body of evidence, a perception prevails among policy-makers of "uncertainty regarding the interaction between climate change and other pressures." In most cases there is only a short-term planning horizon and what the report calls a "lack of mechanisms for public participation... The region has made great progress in terms of civil defence measures to deal with the disasters arising from change, but it has not done so in the area of adaptation." The impact of climate change is seen in the growing intensity and frequency of hurricanes in the Caribbean, changes in rainfall patterns, increased water levels in rivers in Argentina and Brazil, and the shrinking of glaciers in the extreme southern region of Patagonia and the Andes Mountains (Cevallos, Diego 2006).

4 On 20–21 February 2008 over 100 legislators from the G8 countries and the five larger emerging economies (Brazil, China, India, Mexico, and South Africa) gathered in Brasilia to participate in a major international forum on climate change, the GLOBE G8+5 Legislators Forum. Participating lawmakers discussed a 'Post 2012 Climate Change Framework' and a potential agreement on proposals on biofuels and forestry was sought. These initiatives developed by the G8+5 Legislators in consultation with business leaders and international experts. The papers presented touched on adaptation, market mechanisms, technology transfer, and energy efficiency. The GLOBE G8+5 Climate Change Dialogue, a unique informal initiative, was launched after the G8 Gleneagles Summit in 2005. With its broad political, international institution, and private sector support, it has successfully influenced the G8+5 governments.

85.4 Areas Where Policies Could Advance the Agenda

There are several policies the region could consider, linking adaptation, mitigation and risk reduction in facing an increase in extreme weather events. This could include measures to help communities cope with climate risks by improving human capital and better living conditions. Among these are:[5]

- *Better housing for poor people* in hazardous zones, such as flood plains, adaptation of construction techniques to local climatic conditions, culture and traditions, better use of local materials and reduced dependence on imported techniques, models and resources.
- *Improved sanitation and greater access to clean water* in poor neighbourhoods, and more efficient use of water in key areas, reduction of pollution of water sources and creation of new sources of income for the population. An urgent problem in most urban areas is waste disposal, where the economic potential is rarely considered, e.g. through conversion in energy, recycling of materials and reduction of the pollution of soil, air, and water. Upscaling has suffered from lacking technological proposals, and relied on government funding.
- *Early warning systems* combined with public education on potential hazards has been very limited and relied more on technology than on community participation. This implied little adaptation to local conditions and insufficient education on what to do with warning messages. Such warning and monitoring mechanisms could also be a crucial source of knowledge of climate indicators and their evolution over time. There is a lack of historical meteorological and climate information at the local scale.
- *Preventive actions prior to a warning* and appropriate responses when a warning is issued. Prevention should move from preparations for emergency response to an involvement of community organizations, social networks, social groups, among them women, and community design, including land-use zoning and construction techniques that are coherent with local conditions and cultures.
- *Better building codes and strict enforcement thereof* then are not to be seen as externally imposed but internally generated.
- *Better management of resources during emergencies* as part of an adaptation process, by using local providers, having necessary stockpiles, and offering an opportunity for intra-regional trade and cooperation and reducing reliance on external resources.
- *Public education programmes* should be expanded from preparedness and alert for sudden events, which are well developed in several countries, particularly in those affected by the yearly hurricane season. There is a need to prepare the population and agricultural producers for slow onset hazards, such as drought and hazards associated with changing rain patterns causing seasonal dryness leading to wildfires. Current policies often ignore a need for changing traditional planting practices associated with pre-planting burning and promoting more organic, energy efficient agri-culture, and adaptation to seasonally changing patterns, as for the recurrent El Niño/La Niña events. These cyclical events have increased return periods and cause major damage and losses through record flooding in some areas, extended drought and dryness in others, and thus aggravate climate extremes.
- *Improved weather and climate forecasting* from short to seasonal time horizons should become part of public awareness programmes with an institutional strengthening of chronically underfunded climate agencies. These institutions should strengthen their technological base and their monitoring equipment and stations should be modernized. In some countries an overlap of institutional responsibility often leads to a duplication of activities in areas where large irrigation programmes, hydroelectricity generation, and river basin commissions exist, leaving large parts of remote, less developed and more vulnerable national territories hardly monitored.
- *Partnerships among forecasters*, intermediary organizations and users to facilitate delivery, interpretation, and application of forecasts to manage climate risks. Here is a large potential for intra-regional cooperation and for reducing reliance on external sources of information which are often insufficient for local forecasting or prevention of flash flooding and preventable damage from landslides and avalanches. These agencies in large mountainous areas, as the Andes, should monitor

5 This section is based on: SEI, IUCN and IISD (2001); cited in: Simms and Reid (2006).

the dynamics of the evolution of glaciers that are rapidly shrinking in extension and volume, a major cause of climatic variations that affect the yearly cycles of rainy and dry seasons.

- *Better coastal zone planning guidelines* that recognize the flood mitigation potential of mangroves and natural wetlands should be seen both as a desirable environmental conservation practice and a risk prevention tool, increasing resilience to sea surges. Damages in coastal areas were often linked to reduced native green cover, mangrove depletion due to expanding beach surfaces and tourist structures, such as 'tropical' gardens, extended grass cover replacing native flora for golf courses, etc.
- *Watershed management and river basin monitoring*, control and restoration are an increased concern given the recent disasters due to siltation and reduction of watersheds to contain floods. This is frequently linked to a lacking integrated basin management due to deforestation, leading to a depletion of natural sources and increasing vulnerability to sudden unseasonably high rainfall that leads to landslides, debris moving downstream and causing major flooding. This is further aggravated when the normal flow is diminished by changes in the natural course, reduction of the natural coastal environment by activities such as fish ponds, tourist developments, or inappropriately built marinas and seawalls in port structures. Additionally, when these courses flow into the sea the water flow may be slowed by storm surges, increased sea level rise and changing climate patterns.

Two recent issues call for specific attention: the use of clean production techniques and a trend to promote the use of biofuels which are potentially useful in reducing the region's carbon footprint but pose equity issues and competition for use of resources.

85.5 Negative Impacts from Extreme Events

The cumulative negative impact of extreme weather events illustrates the potential impact of climate change (table 85.1).

According to CRED data for 1970 to 2008, economic damages and losses are above US$ 121,234 million, since it counts damages but not losses[6], the total affected population numbers 187,129,174 (what is larger than the primarily affected people of ECLAC[7]) and the persons killed are 265,238. CRED's database

Table 85.1: ECLAC assessments of natural hazards in Latin America and the Caribbean (1970-2008). **Source:** Zapata Martí (2005).

Period	Affected Population		Total damage and losses
	Deaths	Primarily affected persons	(millions US$, 2007 value)
1970-80	38,042	4,229,260	95,293.10
1981-90	34,202	5,442,500	115,787.02
1991-2000	32,365	2,718,452	25,027.37
2001-2008	9,400	34,505,278	58,194.79
1972-2008	114,009	46,895,490	294,302.28
Yearly average	3,167	1,302,652	8,175.06
Meteorological or climatic	49,639	39,574,403	164,125.2
Percentage of climatic of total	43.5	84.4	55.8

(figures 85.1, 85.2) covers all reported events while ECLAC is mostly based on actual assessments.

These differences do not change the observed trend for all disasters (figures 85.3, 85.4) and for climate-related or meteorological ones. For ELAC the economic impact has grown faster, what is consistent with global trends (CRED, reinsurance companies).

6 According to ECLAC's assessment, based on a stock-flow analysis, *damages* are a partial or total destruction of assets, stocks, inventories, etc. at replacement costs, while *losses* are economic flows affected as a consequence of the first. They are added to describe the total impact to document the required post-disaster resource mobilization to rebuild damaged capital and for additional investment required to rehabilitate incomes, production, and other economic flows. Both amounts cover a disaster's economic impact as certain events (e.g. drought) have minimum physical destruction and mostly cause subsequent losses. The same applies to epidemics since deaths, medical treatment and epidemiological control as well as economic flows affected by labour losses or decline in economic demand due to a drop in tourism and transport flows in affected areas are not derived from physical or capital damage.

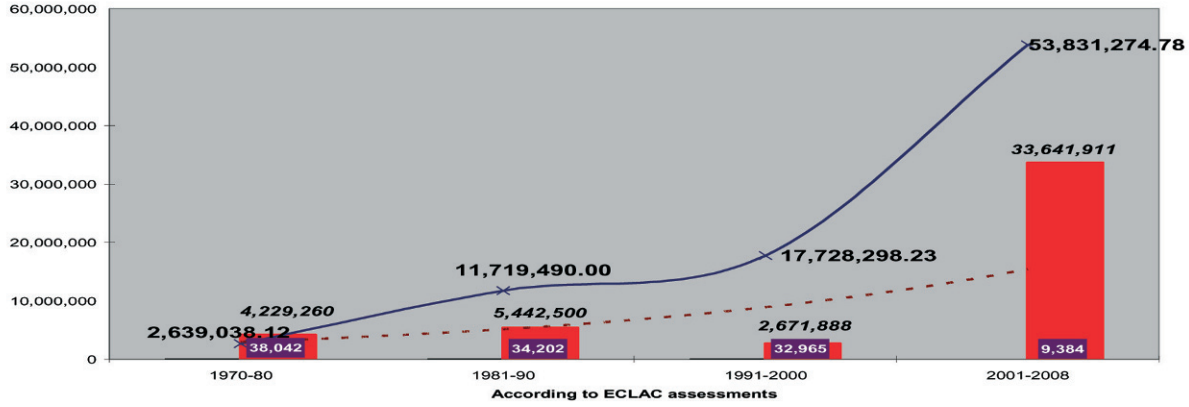

Figure 85.2: Evolution of climatic/meteorological events in Latin America and the Caribbean (1972-2008). **Source:** EM-DAT: The OFDA/CRED International Disaster Database, Université Catholique de Louvain, Brussels, Belgium; at: <www.emdat.be>.

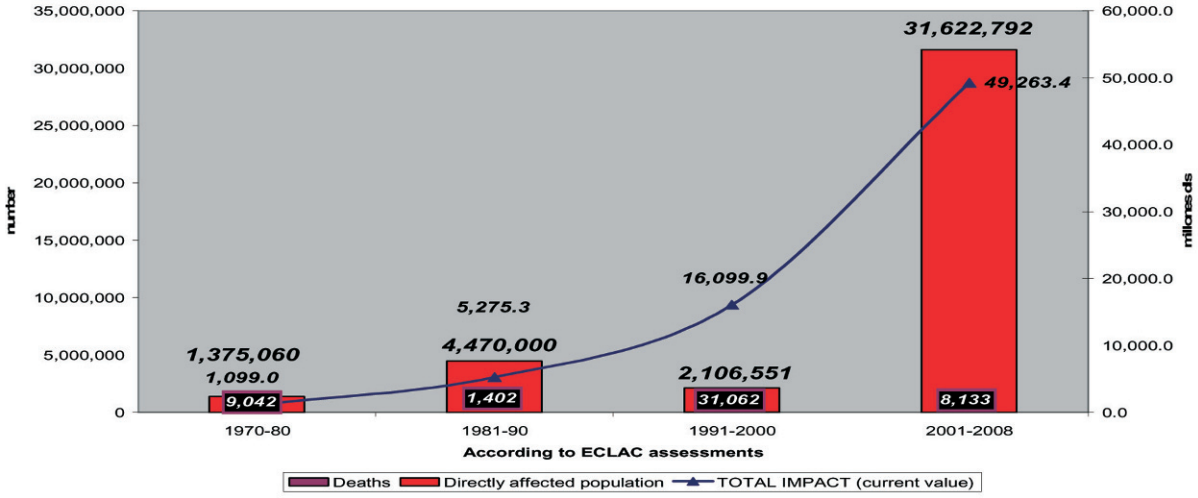

Several other negative impacts can already be observed for the Amazon (box 85.1). Charmaine Heslop-Thomas (University of West Indies, Jamaica) claimed in 2005 that dengue-carrying mosquitoes are appearing at higher altitudes leading to a significant increase in dengue fever, especially in El Niño years. Julia García Vargas (CONAM, Peru) addressed fears of a 'permanent' El Niño as sea surface temperatures remain high.

According to the fourth IPCC (2007) assessment report these long-term trends (1900–2005) have been observed in precipitation amounts over various regions. Significantly increased precipitation was observed in the eastern part of North and South America, in northern Europe and north and central Asia.

> For the next two decades, a warming of about 0.2°C per decade is projected for a range of SRES emission scenarios. Even if the concentrations of all greenhouse gases and aerosols had been kept constant at year 2000 levels, a further warming of about 0.1°C per decade would be expected. ... Since IPCC's first report in 1990, assessed projections have suggested global average temperature increases between about 0.15°C and 0.3°C per decade for 1990 to 2005. This can now be compared with observed values of about 0.2°C per decade, strengthening confidence in near-term projections (IPCC 2007: 5).

The IPCC (2007a) reviewed the quantifiable impacts at the sectoral and regional level, and concluded for Latin America and the Caribbean:

Figure 85.3: Global trend of disaster impact for fatalities and economic damage. Number of people reported killed by natural disasters (1975-2008). **Source:** EM-DAT: The OFDA/CRED International Disaster Database, Université Catholique de Louvain, Brussels, Belgium; at: <www.emdat.be>.

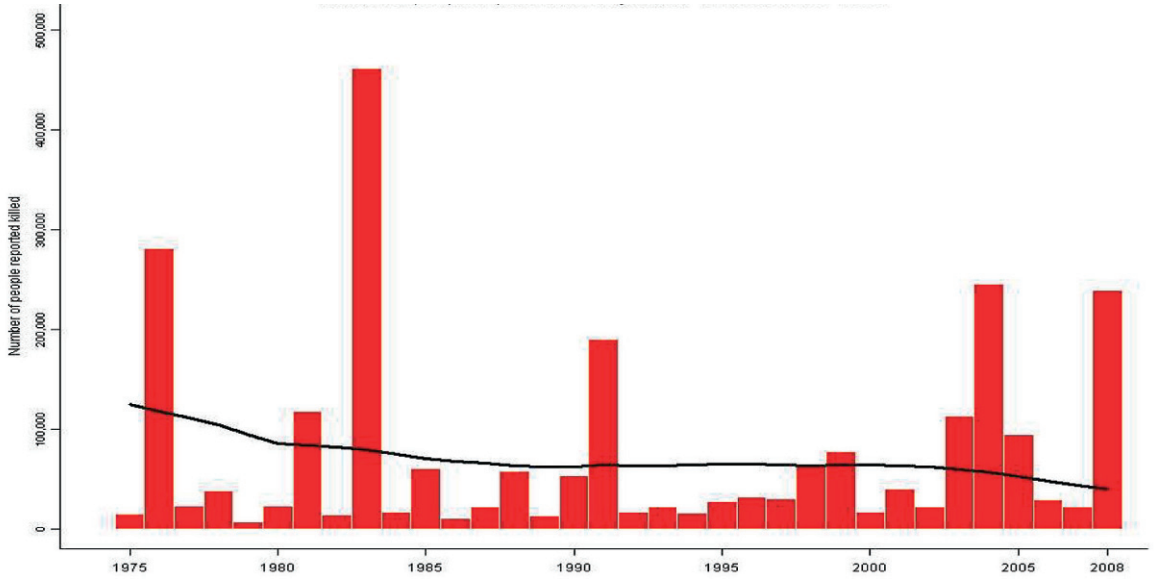

Figure 85.4: Estimated economic damage (US$ billion) caused by reported natural disasters (1975-2008). **Source:** EM-DAT: The OFDA/CRED International Disaster Database, Université Catholique de Louvain, Brussels, Belgium; at: <www.emdat.be>.

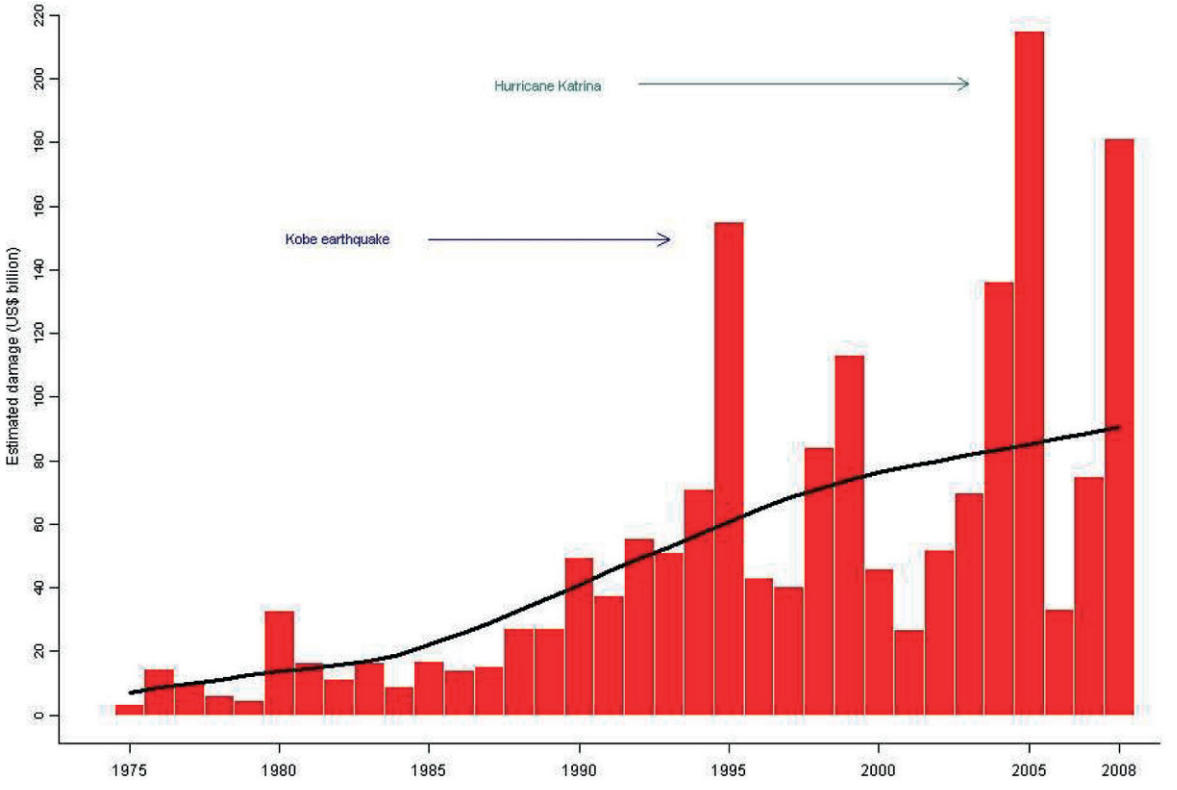


The annual mean warming is likely to be similar to the global mean warming in southern South America but larger than the global mean warming in the rest of the area. Annual precipitation is likely to decrease in most

Box 85.1: The destruction of the Amazon: a glaring example of the region's dilemma: concern on principle, little actions on the ground. **Source**: WWW (2007).

Climate change could speed up the large-scale destruction of the Amazon rainforest and bring the 'point of no return' much closer than previously thought. According to a study published by World Wildlife Fund (WWF 2007) almost 60 per cent of the region's forests could be wiped out or severely damaged by 2030, as a result of climate change and deforestation. The damage could release somewhere between 55.5bn–96.9bn tons of carbon dioxide into the atmosphere from the Amazon's forests and speed up global warming. Trends in agriculture and livestock expansion, fire, drought and logging could severely damage 55 per cent of the Amazon rainforest by 2030. Climate change could speed up the process of destruction by reducing rainfall by as much as 10 per cent by 2030, damaging an extra 4 per cent of the forests during that time. By the end of the century, global warming is likely to reduce rainfall by 20 per cent in eastern Amazonia, pushing up temperatures by more than 2 °C and causing forest fires. Destroying almost 60 per cent of tropical rainforest by 2030 would do away with one of the key stabilizers of the global climate system. Such damage could have a knock-on effect on rainfall in places such as Central America and India, and would also destroy livelihoods for indigenous people and some 80 per cent of habitats for animal species in the region. The 'point of no return', in which extensive degradation of the rainforest occurs and conservation prospects are greatly reduced, is just 15-25 years away - much sooner than some models suggest.

of Central America and in the southern Andes, although changes in atmospheric circulation may induce large local variability in precipitation response in mountainous areas. Winter precipitation in Tierra del Fuego and summer precipitation in south-eastern South America is likely to increase. It is uncertain how annual and seasonal mean rainfall will change over northern South America, including the Amazon forest. However, there is qualitative consistency among the simulations in some areas (rainfall increasing in Ecuador and northern Peru, and decreasing at the northern tip of the continent and in southern Northeast Brazil).

The IPCC addressed climate change impacts in Latin America and the Caribbean:

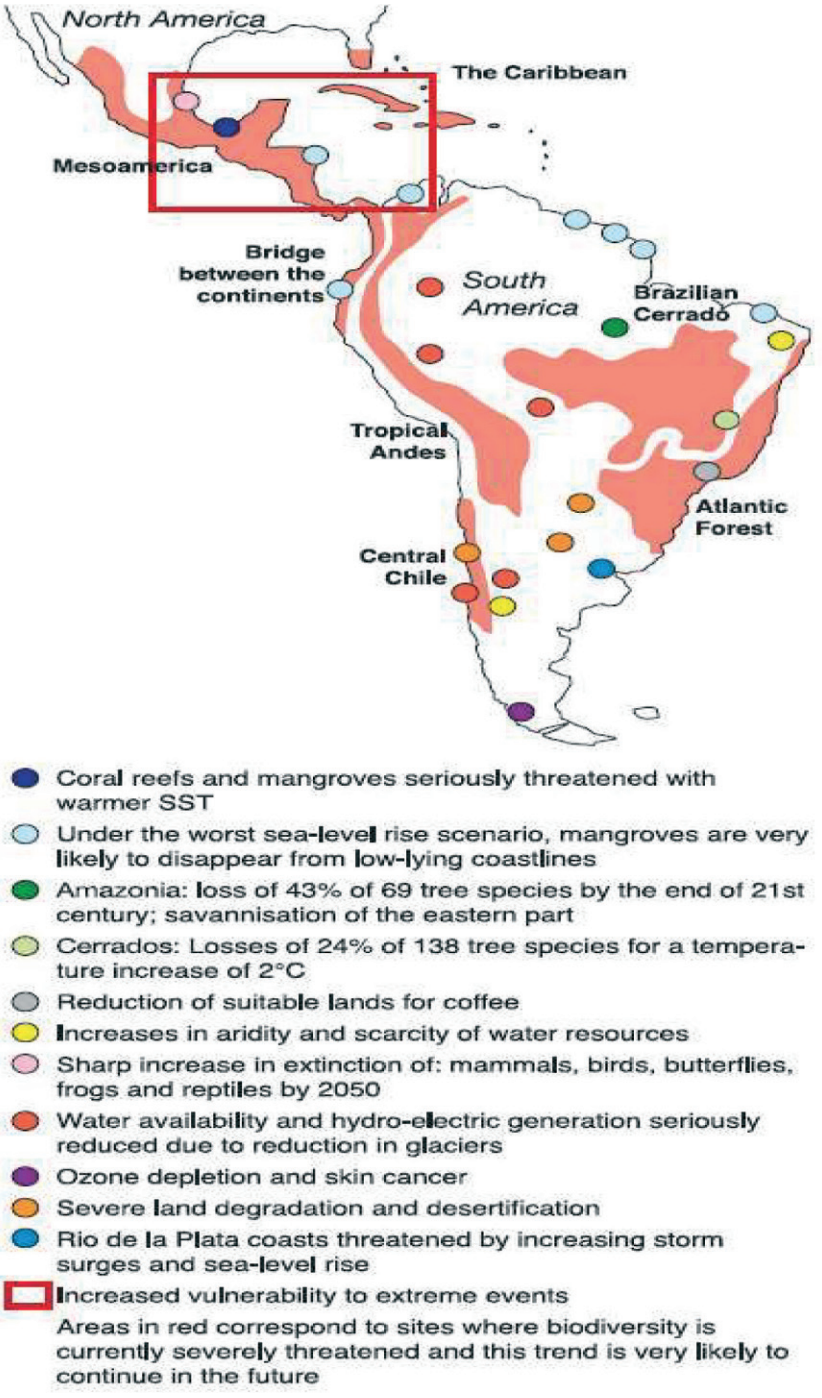
- By 2060 there is expected to be a loss in agriculture and in energy. Without adaptation, this loss could equal 1.3 per cent of the entire region's GDP. Such estimation is conservative. When all climate disasters are considered, the estimated loss is from 2 to 6 times as much (IPCC 2007: 583–611).
- Given the importance of agriculture to most of the region, climate change will have an adverse impact upon employment and trade (IPCC 2007: 583–611).
- Maize (corn) production in the Andean countries (AC), and Mexico and the Central American (MA) countries could decrease. Keith Wiebe questions whether Belize, Guyana, and Venezuela even have begun to consider seriously issues of food security (Wiebe 2002: 27–30).
- Coastal sectors (i.e. biodiversity, fisheries, tourism, and infrastructure) that are highly vulnerable to floods, sea level rise (SLR), and windstorms will very likely be damaged. The most vulnerable countries to SLR and storm surges during tropical storms and hurricanes are those of the Caribbean, Central America, Argentina, Ecuador, Mexico, Peru, Uruguay and Venezuela (IPCC 2007: 583–611).
- A large fraction of the population living west of the tropical Andes will be affected by the melting of the glaciers between 2010 and 2050. People at risk of water supply for human consumption, hydro-power and agriculture are estimated to reach about 37 million in 2020 and 50 million in 2050. Shortages are expected in Central Chile, Patagonia, Mexico, Central America, most of the Caribbean, Venezuela, the Guyanas, and Amazonian and Northeast Brazil. Particularly affected will be the cities of La Paz, Lima, and Quito (IPCC 2007: 583–611).
- Under climate change scenarios mitigation investments in safe drinking water are estimated to amount to $16,500 million (2000) during the period 2000-2015 (IPCC 2007: 583–611).

Other recent reports (Stern 2006; Nagy 2006) provide additional details. Although many case studies were carried out in the region and ongoing research will produce new evidence, Latin American governments and their delegations at climate change negotiations still lack a strategic approach to use this scientific evidence (figure 85.5).

85.6 Some Positive Actions

There are some interesting examples where climate change options and environmental degradation can generate positive initiatives instead of a negative downward cycle.

Figure 85.5: Climate change impacts in Latin America and the Caribbean. **Source:** IPCC (2007a: 606).



- According to the *Proyecto de Desarrollo Forestal*, only four percent of the Andean forests are still standing in Ecuador (DFC 2001). Progressio has been working with Ecuadorian NGOs in this region, helping 21 native Kichwa communities for 10 years. There are no irrigation systems in this area. In the case of Ecuador, one tonne of carbon costs US$0.79 cents, whilst in Holland it is US$8.04. The Dutch company FACE therefore markets carbon from Ecuador.
- Tearfund's partner MOPAWI (Mosquitia Pawisa) works in the region of La Mosquitia in eastern Honduras in several areas to facilitate an integrated sustainable development and for a conser-

Box 85.2: Progress in climate change adaptation in the Caribbean community. **Source**: Donna McRae Smith, Project Officer, CARICOM (year)..

The Caribbean community is deeply committed to the implementation of adaptation and mitigation measures to minimize the effects of climate change on the region's sustainable development. Governments, as well as the private sector, are involved in such efforts. The region is making commendable progress through ... training programmes, ... sustainable tourism and initiatives in renewable energy.

In 2002 the CARICOM Heads of Government established the Caribbean Community Climate Change Centre in Belize ... [that] coordinates its climate change activities [and] provides a range of services and products relating to research, impact assessment, response strategies and systematic observation of climate change in the region.

The CARICOM governments ... [initiated] ... the *Caribbean Planning for Adaptation to Global Climate Change* (CPACC) with the support of the *Global Environment Facility* (GEF) ... in association with the University of the West Indies and the CARICOM Secretariat. The *Mainstreaming Adaptation to Climate Change* (MACC) project is being implemented by the Caribbean Community Climate Change Centre.

The *Caribbean Environment Network* (CEN) Project, an initiative of the *Caribbean Environmental Programme* (CEP) was implemented during 1996-1999 to improve environmental quality and coastal and marine natural resource protection, by promoting the use of environmentally sound practices in the tourism industry. This project conducted training workshops and developed training manuals for a number of areas including *Improved Training and Public Awareness on Caribbean Coastal Tourism* and *Manual for Sand Dune Management in the Wider Caribbean*.

Desalination plants were constructed in Antigua and Barbuda and Barbados. In some CARICOM states, such as St. Vincent and the Grenadines, building codes require cisterns to be constructed for water capture and storage. At the regional level, the *Caribbean Environmental Health Institute* (CEHI) is encouraging member countries to practice Integrated Water Resource Management. The *Integrated Watershed and Coastal Area Management* (IWCAM) project was approved by GEF in May 2004.

The private sector is also very actively involved in energy conservation schemes. The *Caribbean Alliance for Sustainable Tourism* (CAST) assists hotels in conducting energy audits, and advocates incentives for the promotion of energy efficient technology, the development of standards and building codes and the provision of attractive interest rates for the purchase of energy efficient technology.

Other sustainable energy initiatives are ongoing in the region. With assistance from the *Global Sustainable Energy Islands Initiative* (GSEII), St. Lucia has adopted a National Sustainable Energy Plan, establishing aggressive targets for renewable and energy efficiency, and setting the stage for significant changes in the energy sector. Grenada and Dominica are developing similar plans.

Another major initiative is the *Regional Special Programme for Food Security* (RSPFS) which is spearheaded by the *Food and Agricultural Organization* (FAO) in collaboration with the CARICOM Secretariat with support from ... Italy. This project involves the CARICOM member states, and the Dominican Republic. A key aim ... is to address constraints related to increasing trade, increasing small farmer productivity, and improving food policy, food insecurity information and linkages between food product development and promotion and food and health related issues.

In October 2007, the Climate Change Centre signed a Memorandum of Understanding with the UK government to facilitate a comprehensive *Caribbean Regional Climate Change Strategy* [that] will provide the Caribbean community with a coherent and cohesive policy framework and implementation plan to guide its efforts.

Adaptation efforts in the region so far, have focused primarily on capacity building for adaptation. However, ... the adaptation activities ... [reflect] the Region's sustainable development agenda, namely the implementation of the *Barbados Programme of Action* (BPoA) and the ... *Mauritius Strategy of Implementation*. There is ... a need ... for ... a mechanism which would ... feed ... climate change adaptation issues into the sustainable development agenda.

vation of biodiversity. Thorny issues are property rights, deforestation, and forest management and ownership by indigenous people. Alternative forest concession policies and trade and environmental issues in forest production are also analysed. This introduces into the agenda the distinction between public goods and private rights (Tearfund 2005).

In a case study on the Caribbean, Donna McRae Smith documented progress on climate change adaptation in the Caribbean community (box 85.2).

The problem is one of upscaling from pilot experiences into general practice and large macro projects. Generating appropriate strategies for coping with climate change leads directly to a discussion of public goods and how these are valued in societies where market regulation and legislation are insufficient given weak institutions, lack of transparency and discretion in their application. The region's governments perceive their responsibility as different from that of industrialized developed countries.

Table 85.2: Mexico: Emissions of CO_2 ($MtCO_2$) based on IPCC categories (1990-2002). **Source:** National Ecology Institute (2006

Type of emission	1990	1992	1994	1996	1998	2000	2002
1. Energy	312,027	321,836	342,900	349,129	394,129	398,627	389,497
Fossil fuels consumption	279,864	291,046	308,932	311,197	351,760	356,796	350,414
Other emissions	32,164	30,790	33,968	38,233	42,369	41,831	39,082
2. Industrial processes	32,456	32,878	39,248	42,774	50,973	55,851	52,102
3. Agriculture	47,428	46,049	45,504	44,077	45,445	45,527	46,146
4. Waste disposal	33,357	36,935	46,862	52,895	62,656	63,220	65,584
Total without land-use change and forestry (LULUCF)	425,269	437,698	474,514	489,176	553,203	563,225	553,328

85.7 Public Goods, Market Mechanisms, and Compensation

The region is no major player in the emissions game. It is mostly concerned with the costs of adaptation to an externally generated process that requires at least concessionary cooperation resources if not actual compensation for the impact suffered:

> Latin-American and Caribbean countries only produce around five per cent of global emissions, but we are in the front row facing the consequences of climate change and suffering the impacts of the phenomenon such as the recent storms Noel and Olga. These storms took over 100 lives in the Dominican Republic and generated losses of around US$ 800 millions...We have a shared responsibility with all the countries of the planet, but not to the same degree. ... There is an ecological and historical debt towards our countries and this has to be reflected in a new agreement that provides not only clean technology, but the necessary adaptation funding (Ramírez Tejada 2008).

Some countries are adopting pioneering climate strange strategies with quantitative goals, establish concrete thresholds, and set timelines for them. Mexico's strategy – although not yet clearly funded – establishes goals for emission reductions, reforestation, energy efficiency, and for using the clean development mechanisms. An ever more ambitious strategy was adopted by Costa Rica setting a time frame to become 'carbon neutral'[8] (box 85.3).

In 2007, Mexico adopted a national climate change strategy (table 85.2).

This strategy recognizes that actions for reducing GHG emissions will not be sustainable without clear economic signals. The social costs of emissions produced by different economic agents can become economic opportunities through cooperation agreements with external actors with mandatory emissions reductions targets under the international climate change regime.

> For Mexico, the establishment of an integrated national scheme for emissions trading can be aspired to in the medium term, through a realistic, step by step process involving the strengthening of national capacities. The principle of progressive action employed in this strategy sets out the possibility of increasing by phases both the

Box 85.3: Costa Rica: A commitment to Carbon neutrality. **Source**: National Geographic; at: <http://news.nationalgeographic.com/news/2008/03/080307-costa-rica.html> (Costa Rica Aims to Be 1st Carbon-Neutral Country Stefan Lovgren in San Jose, Costa Rica, for National Geographic News, March 7, 2008) and <http://www.costaricaneutral.org/.>

Costa Rica, along with Norway and New Zealand, began fleshing out some ... pioneering plans and strategies they are developing in order to achieve climate neutrality in their own countries. Costa Rica has placed climate change at the top of its agenda arguing that a climate neutral economy is also a competitive one. Its aim is to achieve the neutrality goal by 2021 to coincide with the country's 200th anniversary of independence. The country has a series of loans and grants in place, providing financial support that pays landowners who manage forests for their carbon sequestration and storage alongside management for water production, biodiversity and scenic beauty. In 2007 Costa Rica planted more than five million trees or 1.25 per person making it the highest per capita planting in the world. Other elements of the strategy include increasing the percentage of renewable energy generation to well over 90 per cent and action on energy efficiency including energy saving appliances.

8 The entire UN system has also pledged to work towards climate neutrality under the leadership of Ban Ki-moon across all its offices and operations globally.

> number of participating sectors and the value of the carbon being traded. The scheme would operate with controlled carbon prices, set low, initially, which would be subject to periodic review until reaching equilibrium with international market prices. The phased deployment of this scheme would allow for its adaptive management to take advantage of opportunities arising from international negotiations on the climate change regime, thereby allowing optimum dividends for promoting cleaner development.[9]

What this entails in terms of costs of negative impacts to be faced or investments to be made to adapt and mitigate is a matter of ongoing research. ECLAC is conducting a series of sub regional (Caribbean and Central America) and national studies for the South American countries. From this research it is evident that coping mechanisms are scant and actual strategies both for the ongoing negotiations leading to the post Kyoto successor agreement and for national policies formulation neither have sufficient scientific nor economic foundation. Concluded studies deal with Mexico and (still unpublished) Brazil.[10] A study on the economics of climate change in Mexico[11] concludes that the expected impacts by 2100 will be at least three times higher than the cost to reduce emissions by half. Under one of the scenarios considered – with an annual discount rate of 4 per cent – the climatic impacts would reach on average 6.22 per cent of GDP while the mitigation costs to reduce emissions by 50 per cent would represent between 0.70 per cent and 2.21 per cent of GDP, estimating respectively a cost of 10 to 30 dollars per carbon/ton.

Based on this preliminary data the author concludes that it is necessary to intervene in the market to introduce appropriate signals that will make it profitable to individuals, communities, and entrepreneurs to comply with regulations and find attractive investment opportunities in adaptation and mitigation projects. According to the UNFCCC's Executive Secretary, Yvo de Boer,

> ...the world can build on experience with the emerging carbon market over the last couple of years, in particular the *Clean Development Mechanism* (CDM). This mechanism supports sustainable development and adaptation in developing countries.

At the UN Climate Change Conference in Bali (2007), it was agreed to launch the Kyoto Protocol's Adaptation Fund with financial resources coming from the CDM, this allows the development of new, innovative financial instruments. As de Boer indicated:

> In order to address climate change, we need a cleverly designed financial architecture, a plan that will spur green, low-carbon economic growth worldwide and enhanced adaptation, particularly in developing countries. ...We need a new climate change Marshall Plan that will reshape the world's future economy and redirect investment flows into a sustainable future. ... It needs to be expanded because it can unleash significant financial flows from the North for green economic growth in the South.

So the ultimate solution should be an appropriate use of laws and regulations, the use of the market to give appropriate value and signals to the goods that are publicly shared but insufficiently paid for by society, and new fiscal and economic instruments for the new additional financial and technical tools to operate

> because markets do not guarantee equal geographical distribution, do not provide support for national policies and do not provide financing for expensive mitigation options, such as carbon capture and storage.[12]

If such change of perspective does not change the region's situation by 2012, then continued declarations and political statements and small-scale discontinuous actions will occur, mostly led by external actors or impelled by extra regional global policies. This would be, once again, a missed opportunity to generate a regional, endogenously supported dynamic process that should include technological research and development, leading processes adopted and implemented at the community level.

This study was coordinated by Luís Miguel Galindo Paliza, researcher at the Universidad Nacional Autónoma de México (UNAM), at the request of the Ministry of Finance and Public Credit (Secretaría de Hacienda y Crédito Público, SHCP) and the Ministry for the Environment and Natural Resources (Secretaría de Medio Ambiente y Recursos Naturales, SEMARNAT), with the collaboration of the Mario Molina Center, the National Ecology Institute (INE), and the Atmospheric Studies Center at UNAM. Funding was provided by the United Kingdom and the InterAmerican Development Bank. Technical support was given by the World Bank and ECLAC.

12 De Boer, op.cit., *Sixteenth Meeting of the Forum of Ministers of Latin America and the Caribbean* (Santo Domingo, Dominican Republic, 30 January–1 February), United Nations Framework Convention on Climate Change (UNFCCC)

A key message that emerges from the current situation is that there are still too few activities taken by Latin American and Caribbean countries and states to reduce the growth of their greenhouse gas emissions. Not only is there an observable trend to increase the use of fossil fuel – with coal growing faster than natural gas – but there are too few efforts to counter the rapid land-use change due to pasture, cattle farming, and crop expansion. Given the fragility of the tropical and subtropical forests and the intrusion into coastal mangroves and wetlands, also associated with urbanization and tourism, the rate of deforestation is proof of the ongoing stresses on the environment in addition to the aggravating carbon footprint in the region. Although there are some important new initiatives, such as Mexico's announced reforestation programme, the current trend will not be reversed in the short run.

Recent publications from ECLAC and the World Bank (Fajnzylber 2009)[13] indicate the region has not been actively involved in the international context, continuing the trend under the current Kyoto protocol where the region assumed no commitments (2008–2012). Ongoing negotiations require from major emerging economies and larger developing countries a more active role in adopting goals and voluntary quantitative commitments for a number of indicators, such as per capita income, emission levels, and focusing on some high-emission sectors such as cement, iron, automotive, paper mills, irrespectively whether the plants are in developed or developing countries. Noncompliance with commitments for clean technology and emission reduction processes may lead to trade barriers for imports and transportation of non-complying merchandises. These considerations need a push for compensatory mechanisms, technical cooperation for technology transfer and adaptation and specific funds for adaptation and mitigation.

86 Politics of Equity and Justice in Climate Change Negotiations in North-South Relations

Ariel Macaspac Penetrante

86.1 Introduction[1]

A hardening of the front lines between developed and developing countries occurred during the COP15 meeting in Copenhagen with both sides criticizing the other for taking the climate as hostage. The G77 chief negotiator Lumumba Di-Aping compared the behaviour of developed countries to the holocaust. Several countries, particularly the poorer nations, protested blackmailing when they were coerced to sign the Copenhagen Accord, because without signing they would have been unable to access adaptation funds from richer nations. Particularly the United States was blamed for the failure of the talks because President Obama "demanded concessions while offering nothing".[2] Furthermore, Denmark was highly criticized for convening a meeting of only 26 nations in the last two days of the conference that led to the Copenhagen Accord. Khor argues that it undermined the UN's multilateral and democratic process of climate change negotiations.[3] On the other side, developing countries with emerging economies like China and India were criticized for cooperating at Copenhagen to thwart attempts at establishing legally binding targets for carbon emissions, in order to protect their economic growth. In addition, African countries were criticized by *The Australian* for their behaviour in turning COP15 into "a platform for demands that the world improve the continent's standard of living" which is out of place in environmental talks such as the meeting in Copenhagen. The same newspaper commented the comparison of the potential impact of climate change on Africans to the holocaust through the G77 chief negotiator Lumumba Di-Aping as "inane and offensive" and "demonstrates how the conference process was corrupted". The newspaper criticized as well the opposition of Sudan, Nicaragua, Cuba, Venezuela, Bolivia, and Tuvalu to "Obama's agreement" as a "demonstration how Copenhagen was about old-fashioned anti-Americanism, not the environment".

Clearly, the negotiation deadlock can be referred to the incompatibility of the behaviour between developed and developing countries which maintained the distrust between both sides. The lack of trust refers to structural faults in the international system that hinders any substantial outcome through negotiations. Furthermore, the UN as a multilateral negotiation system is increasingly perceived as being incapable to produce a sustainable, comprehensive and yet focused agreement that will effectively address climate change. The entanglement of climate change in North-South relations seems to have legitimized 'non-multilateral' approaches such as the de facto closed door negotiations on the Copenhagen Accord leading to the marginalization of non-major players in the climate change context. Some major players felt that the bargaining table must be downsized if a substantial agreement is to be achieved. The North-South divide is now blamed as the cause of the current deadlock in the negotiation process. The international system seems to have no formula to bridge the gap between North and South in the climate change negotiations.

However, the North-South divide has not been the object of conflict but rather a result of existing incompatibilities in the international system. There is a need to conceptualize the divide in such a way that the dynamics and drivers behind it can be understood.

1 The views presented in this paper do not necessarily reflect the views of IIASA staff, visitors, or National Member Organizations.

This chapter focuses on the politics derived from the contesting notions of equity and justice and how through such notions the implicit and latent decisions are determined. How was the North-South divide reinvigorated as a political axis and what are its implications for the negotiation process? How should this divide be addressed in future negotiations to benefit from the situation? Understanding the divide is a necessity in the strategic facilitation of the divide as a point of departure for conflictual relations. The North-South relations reflect the outcome of an identity-building process according to which decisions and behaviour are determined by identity narratives. This chapter conceptualizes the North-South divide in the climate change negotiation context through conflict analysis, where the triggers and reasons for the incompatibilities of this behaviour will be assessed, as well as their impact on the negotiation process. Understanding the divide as a conflict between 'identity groups' offers a guiding framework for the value system that determines actions of a collective group, and this leads to insights on how these 'values' can be reframed to strategically facilitate the negotiation process. This chapter introduces the 'identity contestation model' to illustrate the dynamics leading to incompatibilities in North-South relations. This model seeks to explain the diverging identity-building processes between two sides that contribute to the maintenance of the divide.

The assumption that the North-South divide points to several contesting lines in the international system builds on a theoretical framework according to which conflict manifests itself due to incompatibilities in the behaviour of developed and developing countries (86.2). This section tries to answer the question how the insufficiently conceptualized divide leads to misleading assumptions that the divide is itself delaying the negotiation process and therefore 'non-multilateral' approaches, such as the way the 'Copenhagen Accord' was reached, are legitimized. Section 86.3 suggests reframing the perception of the divide and to use the opportunities this situation provides. This reframing of the perception requires an analysis of the divide from the negotiation perspective particularly focusing on coalitions and leadership. Finally, the opportunities that could be obtained from the proper reframing of the North-South divide will be discussed in the conclusions (86.4). Such missed opportunities could be useful in pushing the process forward with the goal of a sustainable outcome for facing and coping with climate change.

86.2 Catching a Slippery Fish: The Elusive Concept of the North-South Divide

The international system is dynamic in its nature. It is constantly evolving and changing. This changing of conditions at the bargaining table represents challenges that will be addressed. What are these conditions? How do these conditions determine the 'rules of the game' at the bargaining table and therefore determine the outcome of the bargaining? Nevertheless, such desired outcomes can only be found when negotiating parties would first be able to reach a consensus on the agenda (goal) and later on another consensus on the procedure. A consensus between states implies a 'win-win' situation in which the proposed agreement involves a situation better than the status quo. No country will sign any agreement that will make itself net losers, even though this will mean the collapse of the environment, particularly when the environment remains a 'public good'. However, it should be noted that the negotiation occurs in a dynamic setting which influences strategies of actors. For instance, a win-win situation might change easily to a win-lose situation. Furthermore, a currently win-lose situation might be perceived a win-win if there will be a prospect that, in the next few years, the reached agreement will be favourable. In this regard, the perception of a win-win situation and the attitude that is determined by this perception can be changed.

In recent years, climate change has gained more attention from the public and this led to the transformation of the climate change issue from 'low politics' to 'high politics' particularly when it became evident that climate change is horizontally interlinked with other 'high politics' issues such as trade, economics, and security. Policy-makers recognized the threats to human well-being in general (Cowie 2007). Climate change impacts threaten national security and therefore have the potential to undermine the legitimacy of any state that fails to address it (Penetrante 2010). However, this transformation leads to its securitization and therefore to the increase of the complexity of the climate change issue.

The transformation leads to the expansion of the bargaining table when it comes to the number of negotiating parties striving for participation. Particularly for the developing countries, whose interest are perceived not adequately met in other multilateral negotiations such as the Doha rounds, which are exploring other platforms to voice their positions. The climate change negotiations are not anymore merely address-

ing climate change, but to push forward the nexus of 'climate change' and 'sustainable development' as an agenda item (Najam 2004: 1).

The *World Summit on Sustainable Development* (WSSD) in Johannesburg in 2002 reaffirmed the necessity to establish more coherence between trade and environment policy. However, the South remains generally suspicious of environmental issues "seeping into trade deliberations" (Najam 2004: 2) because of the general distrust that the outcome will be used by developed countries to establish further trade barriers and disguised protectionism. In the same sense, the South is suspicious of any climate change related commitments that might hinder their economic development.

Thus, a 'technical formula' based on scientific expertise will be subordinated to a 'political formula' (Penetrante 2010). Getting it done no longer means only to get it right (Zartman 2003) but now rather to get it 'accepted'. The climate change negotiations, like other negotiations, seek to produce a formula for agreement on the resolution of the problem. However, producing a formula for an agreement requires a consensus on goals which was reached in Copenhagen when the parties agreed on the 2 °C target for the maximum temperature increase. Although the 'Copenhagen Accord' is not legally binding, it sets a norm and provides a framework for further negotiations (Sjöstedt/Penetrante 2010). A formula for agreement on the resolution of the climate change problem requires a consensus on goals to enable the translation of these goals into acceptable details for implementation (Zartman/Berman 1982). Contrary to the proposal of Timothy Wirth (2010: xxxv), using a formula to allocate a reduction is a promising approach for avoiding decisions based simply on politics and power. Any formula will be subject to bargaining involving politics and power, and therefore will be inevitably exposed to politicizing and power-wrestling. Posner and Sunstein (2010: 344–345) asked, "if the North is to give financial assistance to the South, how great should this assistance be? If the South is to agree on targets, how ambitious should these targets be?" The relationship between climate change and questions of justice and fairness remains complex, and consists of additional dilemmas and challenges.

86.2.1 The North-South Divide Continues – A New Old Paradigm

The North-South divide initially represented the concept about the geographical division that is represented by the socio-economic gap that exists between the developed (North) and developing (South) countries (Hayes/Smith 1993; White 1993; Zartman 1987). It comprises the development gap between countries as described by the *Human Development Index* (HDI) and exemplified by Walter Rostow's model of development (2000). This divide was regarded as somewhat outdated, deceased, discredited, and misleading (Hardt/Negri 2000; Harris 1986; Hoogvelt 1997; Sebenius 1991; van Evera 1990) particularly in the 1990's. Nigel Harris (1986) for instance announced the disappearance of the Third World as an economic reality and ideological representation. The divide is now obsolete, because there is "no clear identification between rich and poor, have-and-have-nots, industrialized and non-industrialized" (Harris 1986: 200–202). Therefore, assumptions formulated within the premise of the North-South divide are seen as rather misleading.

This can be true, but looking from the negotiation perspective, as this chapter argues, the divide came back to the international system and determines bargaining; nevertheless, it has changed its profile. The divide in the climate change context is not anymore primarily based on the formal criteria of development to distinguish membership, but rather on identity narratives and related cognitive processes. How the countries behave depends on how they identify themselves.

As box 86.1 and box 86.2 illustrate, there are differences between the concept of the North-South divide in the trade domain and the concept of the North-South divide in the climate change context. The so-called 'threshold countries' which have formally satisfied the criteria of development and with per capita emissions above the average of EU-27 have resisted and have continuously refused formal obligations in reducing emissions. Countries such as China, Argentina, India, Indonesia, Saudi Arabia, Mexico, South Korea, South Africa, and Turkey behave as if they are still developing countries in the climate change negotiations even though they are now members of at least one of the following 'coalitions' of developed countries of the G20 (Brazil, Argentina, China, India, Indonesia, Mexico, Turkey, South Africa, and South Korea serving as G20 chair for 2010) or OECD (Mexico and South Korea).

Some of the threshold countries, such as China, have joined the G-77 coalition. Some of these countries have formally joined the North; however, they exercise 'permissive connivance' to the South, such as South Korea and Singapore. This behaviour leads to the assumption that the climate change context pro-

Box 86.1: The North in International Climate Change Negotiations. **Source**: Compiled by the author.

The 'North' in the climate change context has a different profile compared to the trade domain. The *United Nations Framework Convention on Climate Change* (UNFCCC) has classified parties as Annex I (industrialized countries and economies in transition), Annex II countries (developed countries which pay for costs of developing countries) and developing countries. Annex I countries, which have ratified the Kyoto protocol, have committed to reductions of emission levels with 1990 as baseline. Annex II countries are a sub-group of Annex I and comprise the OECD members, excluding economies in transition which are mainly the countries of the former Warsaw Pact. These countries pay for costs of developing counties. The convention has provided the possibility for developing countries to volunteer to become Annex I countries when they are sufficiently developed. Furthermore, Annex II countries can be removed from the list upon request. However, the UNFCCC distinction between developed (Annex I and II countries) and developing (non-Annex countries) does not always reflect the development status of countries. The so-called 'threshold countries' such as South Korea, Singapore, Israel, and Saudi Arabia are countries with higher per capita income, but are not listed in the list due to political considerations. Interestingly, Mexico and South Korea are members of the OECD, and Brazil, Argentina, China, India, Indonesia, Mexico, Turkey, South Africa, and South Korea are members of the G20 which is the block of the leading industrialized nations of the world. Furthermore, there are other 'political groups' among the developed countries which follow different preferences and expectations on the outcome of the negotiations. The so-called 'Kyoto light' countries which consist of the United States, Australia, Japan, and Canada push for an agreement that is for them politically viable. Another forum that could later develop to another political group is the *Asia-Pacific Economic Cooperation* (APEC), which consists of both developed and developing countries, met in November 2009 to come up with a common agenda for COP15 but they could not reach any substantial agreement and ended up lowering the expectation for Copenhagen.

Although APEC is perceived as dominated by developed countries such as the United States, Japan, Canada and Australia, it provided a representative glimpse of the succeeding COP15 meeting through a political barometer leading to 'more realistic' expectations in Copenhagen. The APEC summit tried to reach a consensus on emission targets but failed.

duced 'issue coalitions' according to which the decision over membership either to the North or to the South is determined by the issue and not by the formal criteria of development. The North-South divide in the climate change context is therefore a state of mind. If there will be no North-South divide, then it is something that will be eventually invented. Coalitions operate within the premise of the divide – e.g. G77 and China, G20, EU, etc. The divide has entered the sphere of the climate change negotiations particularly because of the horizontal inter-linkages between climate change and other negotiated issues – such as security, trade, and economics.

The North-South divide determines coalitions, hinders any effective comprehensive leadership, and leads to the bargaining of issues that are supposed to be merely means of achieving the goal of emission abatement and now becoming issues on which states are negotiating. The divide has moved the attention of negotiating parties to 'side-effects' by enlarging the bargaining table. It has established trade-offs to move across the divide and not across individual countries. On the other hand, the divide is identified as a legitimizing factor in reducing the multilateral bargaining process to 'closed-door meetings' that only involve major players. The divide motivates bilateralism for efficiency deliberations (Penetrante 2010). Particularly in the COP15, there has been a strong sense that efficiency suffers with the increase of participation of more actors. The North-South divide is regarded as a stumbling block in reaching a sustainable agreement.

The next subsection offers a conceptualization of the North-South divide, how it determines behaviour and decision-making, and what it means for the climate change negotiations.

86.2.2 Identity Politics Leading to Conflict – A Concept of the North-South Divide

The North-South divide was reinvigorated as a political axis in the climate change negotiations when it became clear that the participation of the so-called 'South' on the one hand became a precondition for the participation of the 'North' (Penetrante 2010). For instance, President George W. Bush Jr. announced during his term that the United States will not return to the negotiation table unless developing countries had also formally accepted the same responsibilities as the countries in the North in formulating mitigation targets. On the other hand, developing countries – particularly those with emerging economies such as China, India, and Brazil – have discovered resources not only to determine the agenda of the talks, but also more importantly to set the framework for talks

Box 86.2: The South in International Climate Change Negotiations. **Source**: Compiled by the author.

Although the North-South concept has been regarded as outdated, deceased, discredited and misleading (Hardt/Negri 2000; Harris 1986; Hoogvelt 1997; Sebenius 1991; van Evera 1990), it is increasingly receiving attention from experts, because it seems to gain more relevance in recent climate talks. The 'South' as an identity does not refer only to the formal criteria of development, but on how the countries historically perceive themselves. In the climate change context, countries from the South refer to the historical animosities of the North, leading to the question whether the South's identity is formed by referring to the South's experience of 'victimhood'. The identity of the South has been determined by the consciousness of trauma and victimhood that leads to claims for recognition (86.2.2). Recognition means to be able to participate in social interactions as peers (Fraser 2003). Like the North, it refers to the value of justice and fairness. To talk about the South in terms of countries lacking development is rather misleading, because many of the developing countries have a rich population with similar standards and in some cases have higher aggregated income than some developed countries. Furthermore, some threshold countries still act as developing countries such as South Korea that threatened in 1997 that it will rather leave the OECD than take binding obligations. This development calls for a 'utility-based' understanding of identity politics. In the climate change context, the South consists of developing countries without quantitative reduction obligations and to a significant extent 'receivers' of the adaptation fund. In the climate change negotiations, the South is represented by the so-called G77 and China which consists of more than 130 countries and China, and functions as the 'negotiation vehicle' of the majority of all countries narrating their real and imagined marginalization in the international system. The G77 and China serves as a forum for coordinating positions among member countries to increase negotiation leverage. The group is rather process-oriented through its long-term planning approach according to which the group seeks to influence the agenda and norm-setting processes that will eventually lead to the desired outcome. The group is complimented by other groups that act within the South premise such as AOSIS, BASIC, and for some years OPEC which focus more on specific issues and seek to determine measures to forward specific issues in the negotiation process, thus complimenting the G77 and China. Furthermore, in the last decade a regional approach has been pursued such as the African countries coordinating positions among themselves, the Caribbean countries rallying together, and Southeast Asian nations using existing regional forums to forward the climate change issue. This has been interpreted in the North as a sign of fragmentation of the South due to its diversity. However, this is again misleading, because the South is in this logic as fragmented as the North is, which themselves has maintained several forums such as the G5, G20, EU, the Economic Forum, NAFTA, etc. The diversity of interests within the South is obvious; however, process-wise the South is a force to reckon with, because the group still shares common narratives and values.

and even delay the process through issue-specific negative power. Developing countries have come to form or revive existing coalitions such as the 'G77 and China' that could match and actually challenge the resources and knowledge of the developed world. Developing countries are not anymore willing to remain in the back seat.

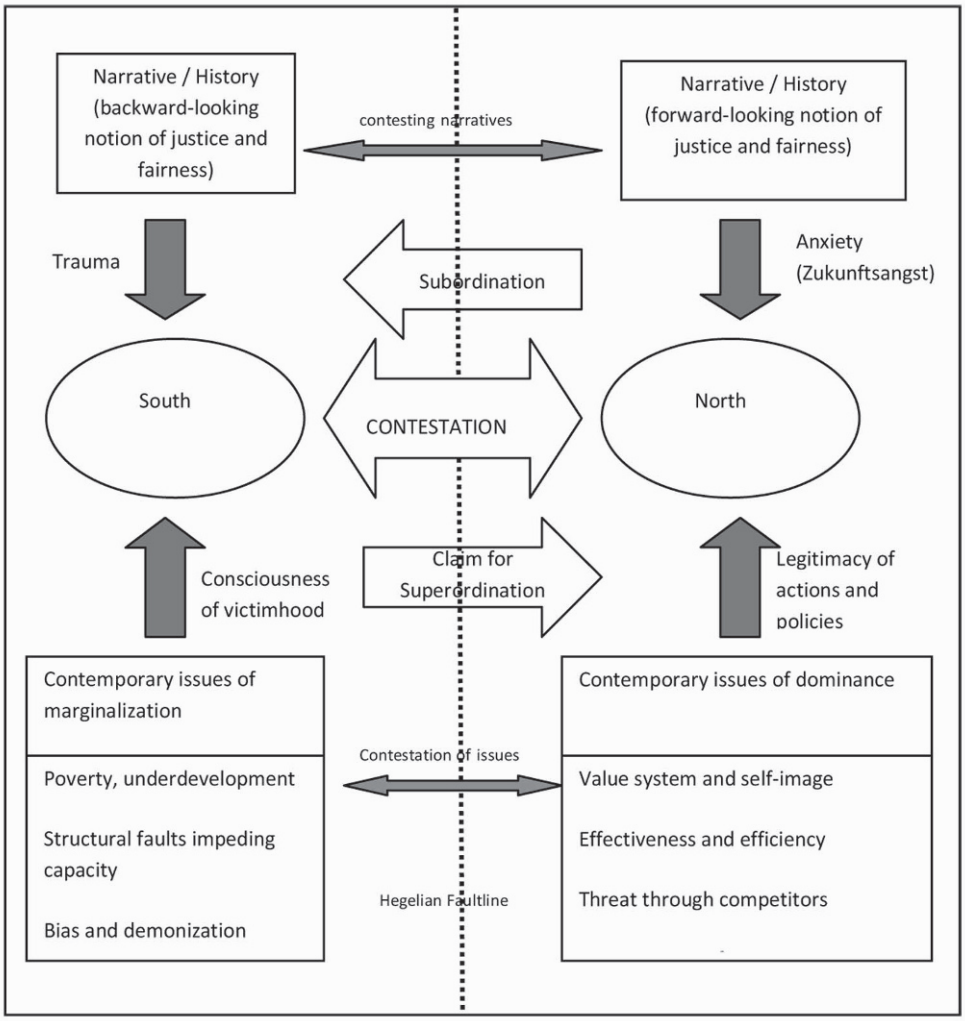
Understanding the dynamics within the premise of the North-South divide is a necessity in the strategic facilitation of the conflict between developed and developing countries. Figure 86.1 illustrates a model of the contesting identity-building processes that contain incompatibilities that should be addressed. Any outcome of any negotiation process will be determined by trade-offs across the divide reflecting the notion that where one goes depends on where one is coming from (Munton/Castle 1992; Cutler/Zacher 1992). As shown in the figure, there are several dynamics that sum up the North-South relations.

The North and the South are divided by the 'Hegelian fault line' in which the South finds itself to be in opposition to the North. This opposition was the point of departure for the identity-building process. The Hegelian fault line summarizes the conflict between the two sides. The selection from the pool of past experiences of misrecognition (trauma) legitimizes claims for full participation in the social interactions – claim of recognition (Fraser 2003). However, this claim for recognition is perceived as a 'threat' by the North, because it sees the South as potential competitors that will lessen their privilege in the current setting, if such a claim is to be granted.

According to Anstey (2006), perceptions of 'relative deprivation' or `unfair discrimination' offer fertile grounds for mobilization purposes. The struggle for recognition is conceptualized by Hegel (1977) which according to him is a circumstance where full participation is not only assumed, but actually implemented. The figure suggests that to overcome the Hegelian fault line, there is a need to move from the master-slave dialectic to full partnership.

Furthermore, particularly in the climate change negotiations, the 'weakness' of the South (based on resource-based power) is paradoxically translated into

Figure 86.1: Dynamics of identity contestation in the North-South divide. **Source:** Author.



'strength' (based on negative power, that is to delay the process). This new setting, combined with the unprecedented "assertiveness" of the South, motivated by the South's vulnerability to the adverse effects of climate change, implies a changing negotiation table. The leaked Danish text was harshly criticized by the majority of developing countries. A similar situation has happened in past negotiations such as the original text on trade and services during the GATT negotiations, which, however, did not face loud opposition from developing countries. It was a common practice that major countries determine the agenda and substance of agreements during negotiations. However, that has changed in the climate change context.

The North-South divide in the climate change context has found relevance through contesting narratives on notions of justice and fairness (Penetrante 2010). The boundary between the North and the South has been determined by positions about who should shoulder the costs of confronting climate change, both mitigation and adaptation measures. Any effective facilitation of the climate change negotiations needs to address the diverging understanding of the two sides what makes a measure just and fair (chap. 89 by Kanie/Nishimoto/Hijioka/Kameyama). As Zartman (2003: 34) states, "relevant principles of justice [are] likely to be loose, contentious, tentative, and fluctuating".

The North pursues a 'forward-looking' notion of justice and fairness. It should be noted that using the term forward-looking does not imply a positive evaluation of such a notion. It is merely the time reference of where justice and fairness are derived. According to the North, present generations should not be punished for 'crimes' they did not commit and 'crimes' that were no crimes when the actions in question

were carried out by earlier generations (Caney 2009). The forward-looking notion of justice furthermore involves the principle of intergenerational justice and fairness. The assumption that future generations of developing countries will be anyway better off in the future and in some cases will even surpass the affluence of those from developed countries, any measure that would further favour these generations will lead to distortion of a sound competition between those future generations from developed and (formerly) developing countries (Posner/Sunstein 2010; Meyer 2004). It is perceived unfair for present and future generations that mandatory cuts would be required by developed countries and not by major emitters in the developing world such as India, China and Brazil, which is the case under the Kyoto Protocol.

A just and fair measure must be based on emissions and not on the developmental status of a country. Developing countries, particularly those with emerging economies, must adopt substantial mitigation targets of their own (Buchner/Lehman 2005; Gardiner 2004). Polluters must pay – both developed and developing countries. Australia (2008: 11, 31) notes that by 2050, the per capita emissions for China is expected to be similar to those of the developed countries today. For instance, the United States 2050 per capita emission will be 23.3 tons CO_2 which is slightly higher than the 22.2 tons per capita emission of China. The behaviour and the decisions of the North are then based on 'anxiety on the future' (Zukunftsangst) that giving in today could lead to disadvantages for their future generations. The idea of giving advantages to increasingly formidable competitors is "politically toxic in many developed countries" (Wirth 2010: xxxvii).

These narratives support contemporary policies of dominance. For instance, moral values are used as a basis of arguments for intervention in the developing world. The narratives promote furthermore a relativization of 'coercive' policies such as the use of 'carrots and sticks', which both imply a disposition of superiority. 'Carrots' are built within the assumption that developed countries are the 'generous donors' and therefore can use such soft measures to pursue their own interests. 'Carrots' imply that one has something that the other needs and 'blackmailing' can change the behaviour of the other actor pointing out to dependence. 'Sticks' are built within the assumption that violent measures are legitimate when they serve the purpose and can lead to the desired end. Both carrots and sticks are legitimized by such narratives. Both policies of 'carrots and sticks' are measures that maintain dominance through the subordination of the other. Measures of subordination can be manifested for instance in COP15 when 'closed-door meetings' were held and developing countries coerced to sign the 'Copenhagen Accord' to avail funds, limiting the bargaining table to major players and therefore marginalizing the majority of the developing countries for the sake of effectiveness and efficiency.

In contrast, the discourse of the South consists of narratives on historical atrocities of developed countries to the environment. The North 'owes' from the South the environmental space it has contaminated in the last hundred years, therefore, there should be a scheme of compensation for the developing countries particularly because they are more vulnerable to the adverse effects of climate change (IPCC 2001; UNFCCC 2007e).

The decisions and behaviour of developing countries are based on the counterpart of 'Zukunftsangst' of the North and that is of 'trauma'. The identity of the South is in cognitive terms maintained by trauma (Alexander 2004). Trauma occurs when members of the collectivity feel that they have been "subjected to a horrendous event that leaves indelible marks upon their group consciousness, marking their memories forever and changing their future identity in fundamental and irrevocable ways" (Alexander 2004: 1). The trauma supports the consciousness of 'victimhood', which is first formulated during the process of understanding the contemporary issues of marginalization and calls for social responsibility of those who caused the trauma to stop the marginalization and to provide compensational measures. The consciousness of victimhood is arising from contemporary issues of marginalization, which are supported by historical narratives leading to the mobilization of countries to rally behind a coalition. There exists a general suspicion on the behaviour of the developed countries. The South then learns to resist subordination and pursues claims for subordination either through rhetoric or through delaying the process. The South maintains distrust, because of past experiences. For instance, only Scandinavian countries are sending the agreed 0.7 per cent of their GDP as *Official Development Assistance* (ODA) to developing countries. Furthermore, although the majority of developed countries do not meet their ODA obligations, they intend to classify climate funds as ODA, which implies a further reduction of development assistance for the least developed countries. It is distrustful of an approaching developed country expressing its intention to enhance capacity, but de facto calls for more dependency. For

instance, the inclusion of the IMF and the World Bank in the climate change context is perceived by most developing countries as an increase of the influence of developed countries in the context.

Figure 86.1 illustrates the diffuse dynamics of contestation between the North and the South. For instance, although both developed and developing countries speak of justice and fairness, it seems that there are still some existing gaps between their understanding of what justice and fairness mean. These gaps must be linked, if not reconciled. Understanding these dynamics enables the proper and strategic designing of facilitation measures.

86.3 The North-South Divide from the Negotiation Perspective

Gunnar Sjöstedt (1993: vii) agrees with Robert H. Pry (1993: vii–xii) who points out that international negotiations on environmental issues is a relatively recent phenomenon. The 1972 UN conference on the environment held in Stockholm has been a major landmark. This conference set the agenda for the negotiations and cooperation concerning environmental problems over the following decades (Sjöstedt 1993: 1). It also set the UN multilateral system as the procedure on how to address environmental problems. The 1992 *UN Conference on the Environment and Development* (UNCED) in Rio de Janeiro was intended to produce a new approach on the environment for the 1990's and beyond. However, in the last two decades, it became apparent that due to the inter-issue linkages environmental issues are not to be contained in one domain and will be affected by other multilateral negotiations such as the Doha trade negotiations in 2001 that have placed a limited set of trade and environmental issues on the negotiating agenda. The inter-institutional linkages call for long-term relationships between institutions leading to more constraints and more reasons for distrust on the part of developing countries.

Environmental negotiations, such as the climate change negotiations, are part of a larger process of international relations, capable of changing the relationship among nations through cooperation and joint problem-solving (Sjöstedt 1993: 4). This results in a necessity of increasing the awareness of the importance of negotiations and of the analysis of climate change through the negotiation perspective. Every negotiation has its own features, depending on the issues, actors, structure, intended outcome, and processes involved. These features also depend on power sources and power perceptions that determine strategies and the 'yes/no threshold' in the international system. As discussed in the earlier subsection, problem-solving will eventually lead to a resurfacing of incompatibilities due to diverging interests and needs of the negotiating parties. Complexities and uncertainties of negotiations on climate change represent the "different aspects of the social and political lives of nations – sovereignty, borders, the decision-making process, and the level of economic development" (Sjöstedt 1993: 7).

The development in Copenhagen in December 2009 formalized the goal for further negotiation beyond the Kyoto protocol. The 2 °C consensus will define the logical structure of further bargaining, particularly when it comes to implementation measures that would include burden-sharing in forms of emission cuts. Parties differ previously widely in terms of goals and therefore inevitably, there were widely different perceptions of the issues in conflict. Countries have varying national conditions, such as constraints through national legislation like in the United States or dependency on coal like Australia and China. Some countries do not find it difficult to commit to binding regulations, because their current emissions are not statistically significant, while some are on the verge of industrialization. Varying goals are preconditioned by varying national priorities. The next step after the 2 °C consensus (as a goal) is to find a consensus on the implementation or on the procedure how to fairly distribute the costs of facing climate change. From the negotiation perspective, there are several steps that could be taken – some more politically brilliant, some more politically blatant, to get parties to agree on what the conflict is about and to get the way towards its successful resolution or management. Reaching an agreement on the implementation of the goal of reducing the average increase of temperature to 2 °C will be bargained in a way that it will reflect power, power asymmetries, coalition-building processes, trade-offs, bargaining rules, and procedures. The North-South divide as a premise points out to the conflict areas between groups in the international system as well as to the complexities and uncertainties brought by the multilateral nature of negotiation (Zartman 1994).

86.3.1 Coalitions and North-South Relations

Coalitions are built according to the interests of negotiating parties and these interests are formulated

Box 86.3: Coalitions within the North-South Premise. **Source**: The author.

Coalition-building is an integral element of a multilateral system (Hampson/Hart 1995; Potzer/Mannix/Neale 1995; Raiffa 1982; Zartman 1994) to pursue individual interests by building a community with like-minded negotiating parties. Membership to a coalition requires identification with the group based on interests. In the climate change context, coalitions are built to serve as leverage in negotiating at the bargaining table. Interestingly, the majority of the coalitions reflect the North-South premise, because of the common interests among countries that belong to one side. Nevertheless, it should be noted, that aside from process coalitions, coalitions are also established along issues. For instance, BASIC members (Brazil, South Africa, India and China) felt that they have more in common and therefore they have decided to form a block, however, without posing a competition to the G77 and China as these countries continue to cooperate with other countries within the larger group. The United States seems to have formed a coalition with Canada, Japan and Australia, which calls for an alternative approach due to national stakes.

In the view of this author the so-called 'threshold countries' can act as facilitators between developed and developing countries. The political context of climate change negotiations aggravates any form of leadership (86.3.2). However, there is still no visible coalition among these (historically-speaking) developing countries that have reached economic development. Their membership to both the G20 and close collaboration with the G77 put them in the position to understand both sides and therefore are less biased and thus more credible. This proposed coalition should not assume leadership, because it will not have the political resources to do so, but rather to act as facilitators in the process.

within the North-South premise. Coalition-building is an integral element of a multilateral system (Hampson/Hart 1995; Polzer/Mannix/Neale 1995; Raiffa 1982; Zartman 1994) and gives rise to a number of strategies. Najam (1994, 1995), Sauvant (1981) and Weiss (1986) argue that developing countries do negotiate as a collective in most global negotiations such as in climate change. Coalitions refer to the "collective elaboration" that Moscovici (1963) describes in his social representation theory. He points to a community with a stock of shared values, ideas, beliefs, practices that function as orientation for behaviour and communication. As Polzer, Mannix and Neale (1998) argue, coalitions do not only affect the resource pool available to states, particularly smaller states, however, these resource pools are linked with compatible interests.

This section focuses on the coalition-building process within the developing countries which does not imply the lack of a similar process among the developed countries. The inter-linkage of trade and environment has induced the spillover of the G77 coalition from the trade to the climate change domain. The G77 as the main coalition of developing countries was *de jure* joined by China as well as de facto by Brazil and South Africa. The South identity has determined the negotiation positions as well as strategies of the group influencing the negotiating structure. Identity defines the frame of reference for motivations and actions of the group members (box 86.3).

Furthermore, there are other 'issue coalitions' that move within the premise of the South identity such as the *Alliance of Small Island States* (AOSIS) and the *Small Island Developing States* (SIDS). From the negotiation perspective, coalition-building is a dynamic process in which different variations of coalitions are found. In this case, states assume multiple memberships depending on a specific issue. The complexity of the climate change context leads to several constellations of alliances designed to maximize influence on the outcomes. The AOSIS as a coalition functions as an ad hoc lobby and negotiating voice for SIDS within the UN system particularly in global climate change negotiations. Although AOSIS is mostly composed of developing countries, it is not seen as an alternative to the G77 and China coalition. Aside from Palau which withdrew from the G77 in 2004, 27 of its 43 members and observers are still members of the G77 and China coalition.

The AOSIS is an issue coalition in a complex context which confirms multiple memberships in several coalitions without compromising a state membership in another coalition, particularly because the 'G77 and China' is more a 'process coalition' than an issue coalition. Issue-coalitions have their own tactics (Zartman 2003: 35) and own time frame. Other existing similar issue coalitions such as Brazil-South Africa-India-China (BASIC) block (Vidal 2010) and OPEC are not to be evaluated as indications of fragmentation of the South, but rather of issue-specific accommodation in a multilateral system. Fragmentation implies competition which is not the case between these coalitions among developing countries.

86.3.2 Leadership and North-South Relations

The divide points to the impediments in assuming effective leadership. Andresen (2010) proposes that identifying potential leaders can facilitate the negotiation process. He enumerated different types of leadership, as categorized by Underdal (1991, 1994) and Young (1991, 1998): intellectual leadership, instrumental or entrepreneurial leadership, power-based or structural leadership, and directional leadership. As shown in Copenhagen, although there were some expectations, any form of leadership was not really possible. Developed countries, particularly the United States, were expected to lead because of their contribution to the concentration of GHGs in the atmosphere. Leadership requires both the actual capacity and resources to lead, and the legitimacy to assume this role. Intellectual leadership refers to the intellectual capacity to shape the perspective of those who participate in institutional bargaining (Young 1991).

In Copenhagen, countries such as those belonging to the *European Union* (EU) tried to reframe the perspective of developing countries particularly in convincing that environmental policies must not necessarily hinder development – mitigation is not the opposite of sustainable development. However, the potential intellectual leadership of the EU is somewhat undermined by contradicting policies of union members, such as the reduction of government subsidies to the solar energy industry in Germany. Related to this is the potential directional leadership of the EU in which a directional leader sets up good examples on how to deal with an issue (Gupta/Grubb 2000). Although the EU is seen as the only possible directional leader, its potential is undermined by distrust among the developing countries, particularly when it comes to fulfilling the 'polluter pays' principle in which European countries are not prepared to contribute an amount perceived appropriate by developing countries.

Power-based or structural leadership is to some extent fulfilled by major countries like the *United States* (USA) and the EU. However, without a consensus of goal, threats, and promises between these countries, a coherent leadership seems impossible. Without knowing what is actually desired as an outcome leaves no room for power-based or structural leadership. Furthermore, without a consensus between major countries, particularly between the USA and the EU, what the outcome should look like, there can be no strategic sharing of resources that can be promised, particularly in the climate change context, when no single actor has the resource to engage in the promise-making process. Instrumental or entrepreneurial leadership refers to bringing in ideas on the agenda to reach common goals. As mentioned above, with the absence of a consensus on goals as was the case before Copenhagen and the existence of several diverging and partly competing goals, instrumental leadership is as well impeded.

86.4 Reaching a Global Deal through Negotiation – Reframing the North-South Divide at the Bargaining Table

Reframing the North-South divide is a precondition for reaching any global deal through negotiations. At the COP15 in Copenhagen, the divide was identified as the major stumbling block for reaching any agreement. The application of the conceptual framework introduced above points to the divide as understood in the operational way. The divide in the climate change context points to the positions of actors. From these positions, coalitions are established as part of the calculation of states how to achieve their interests. Positions are manifestations of interests (Fischer/Ury 1981). The agenda of the COP15 to establish a Post-Kyoto mitigation mechanism was conducive to position-taking which is from the negotiation perspective a legitimate phase of a long-term bargaining process. What was `unprecedented` at the COP15 was the assertiveness of the developing countries. This assertiveness combined with the negative power to delay the process was rather perceived as obstruction. The upcoming COP meeting in Mexico is expected to remain a 'hostage' of developing countries particularly with the lack of prospect of any procedure to overcome this divide. This chapter argues that a 'win-win' situation is not impossible at all. However, such a 'win-win' situation requires the following: flexibility at the bargaining table, and the strategic facilitation between conflicting actors.

86.4.1 Flexibility at the Bargaining Table – Bilateralism vs. Multilateralism

Bargaining is the consensual procedure to reach an agreement in the climate change context. As Rubinstein (1992) argues, bargaining is the situation where actors exchange terms on the agreement. However, as the COP15 shows, even though negotiation itself was not contested as being legitimate, the modus of the

negotiations was highly contested. Multiparty negotiations connote multilateral bargaining processes, in which countries negotiate with each of the players in the game. Although power asymmetry exists, states are regarded as equal partners. Multilateralism as a mode of negotiations involves "complex social interactions because of multiple sets of preferences" (Pozer/Mannix/Neale 1998: 42) that must be considered in designing a global agreement. This complexity motivates some actors to leave the framework and pursue alternative modes particularly when these actors perceive more efficiency in the alternative framework.

At COP15 and the events leading to this conference, some major countries such as the United States preferred the bilateral modus of negotiation, not particularly with the intention to isolate the majority of the countries, but to reduce complexity and herewith increase efficiency. For instance, the increasing frustration on the slowness of the agreement-making process led to the exclusion of the majority of the (developing) countries in drafting the Accord. Multilateralism was more or less sacrificed in exchange for efficiency. Furthermore, prior to the COP15, the United States and China reached a bilateral agreement to expand cooperation on climate change, energy, and the environment. Nevertheless, the tendency to switch to a bilateral modus of negotiation is perceived to undermine the United Nations as the international multilateral framework to reach an agreement. Bilateral agreements do not only tend to exclude the majority of countries, they also increase distrust among those excluded countries, because of the perception of a lack of transparency.

This chapter argues that the usage of the bilateral modus of negotiation in a multilateral framework requires a more pragmatic discourse. Flexibility on which modus or on which modus-mix expands the so-called *Zones of Possible Agreement* (ZOPA), which in turn provides more resources to make a 'win-win' situation more likely (Lewicki/Minton/Saunders 1999). The combination of bilateral and multilateral modi, however, faces opposition from those who felt that the previously agreed procedure of multilateral negotiations is being disregarded, particularly when those excluded have stakes on the outcome The North-South divide points to the need of starting a comprehensive discourse to enable a paradigm shift. For the upcoming COP16 in Mexico, bilateral agreements for instance between the United States and China, as well as bilateral agreements between members of specific coalitions such as the G77 are necessary for the reason that some of their interests are perceived to be only reachable through bilateral means.

86.4.2 Strategic Facilitation: The Role of Threshold States

This chapter argues that the climate change negotiations are not conducive to leadership (86.3.2). The North-South divide points to the lack of coherence in the international system when it comes to expectations in the outcome of the negotiation process. The diverging interests of countries are manifested as packages representing the different coalitions such as the G77 and G20. These coalitions imply contesting values, norms, practices, and interests between coalitions which are used as reference for identity. Leadership, however, requires a `supra-identity´, which still does not exist in the climate change context. For instance, the memory of past injustices maintains distrust to the intentions of developed countries. Leadership is impeded through contesting notions on goals and understanding of terms such as justice and fairness. Furthermore, the lack of coherence for instance among developed countries on their emission targets does not signal good examples.

This chapter argues that facilitators or mediators are needed. In Copenhagen, the Danish government acted as chair, however, not facilitative, but rather evaluative (Riskin 1994; 1996) when it drafted its own text. Future chairs could take one step backward and assume of role of mediators. In a simulation of the COP15 in the *International Institute for Applied Systems Analysis* (IIASA) in Laxenburg, Austria in 2009, the Danish government was assigned the role of mediator. The participants of the simulation mediated 'in concerto' (between G77 and China group and the G20, as well as between individual states). The facilitators strategically assumed control of the procedure in which a basis of trust and a basis of efficiency were established, because the countries could concentrate their resources in negotiating the substance, and not negotiating their understanding of procedural justice. Shuttle diplomacy proved to be effective to establish communication channels between actors. However, for the chair to effectively conduct shuttle diplomacy, it must have an overview about the interests of states. For this, it is important for the facilitator to profile interests.

Aside from the chair, the threshold states, such as South Korea and Mexico, can contribute to the facilitation of the negotiation process. Such threshold states which are members of multiple coalitions can

limit the negative externalities. The decisions made by major countries have both positive and negative effects for those countries that were excluded in the decision-making for the 'reason of efficiency'. The threshold states, although pursuing their own interests, can bridge the gap between coalitions, because their interests, values, norms, and practices reflect elements of both groups. For instance, South Korea, although it belongs to the OECD, behaves in particular contexts as a developing country. The multiple membership of these threshold countries lead to 'cross-externality' according to which externalities are now coming from both sides. Decisions made by developing countries have effects on developed countries and vice versa, which facilitates the establishment of a `grand coalition´. Functioning as core in the new grand coalition, threshold states could facilitate cooperation.

In allowing countries to take positions without moral sanctions being imposed on them, their positions could be heard. From positions, interests were derived. Coming from the interests, solutions were easier to be found. The assertiveness of the developing countries in the COP meetings is highly criticized as purely position-taking and therefore detrimental to the agreement-making process. However, as this chapter argues, position-taking is an important part of the bargaining process. Unless the developing countries perceive that they could voice out their positions (interests), there can be no moving forward in the climate change negotiations.

86.5 Conclusion: Managing Entanglement – Opportunities through Strategic Facilitation

The North-South divide has been perceived as a major stumbling block in reaching agreements to confront climate change. Politics is demonized and blamed for failures that experts propose moving away from the North-South paradigm (La Viña 1997: 189). La Viña proposes the reconsideration and rejection of the North-South divide, because negotiations within this premise will always begin with political rhetoric about the inequality in the international economy, about historical responsibility, about the need for radical restructuring of the international political and economic system, about the predisposition for suspicion of environmental issues (Najam 2004: 5), and the negotiation usually ends up with either deadlocks or unsatisfactory compromises over the core issues that have been raised. The South usually easily slips back into a defensive, risk minimizing strategy (Najam 2004: 5) and ends up in frustration for both sides. However, it should be noted that such behaviour expresses positions that are raised to pursue interests. While positions are non-compatible, interests do not necessarily debar each other. Politics as understood in the climate change negotiation context is a social reality and coping with it represents a more practical approach.

Carefully conceptualizing the North-South divide can lead to the proper understanding of the divide as an indicator and not the cause of the delay in reaching a sustainable outcome through negotiations. Reframing the divide as the reference to the structural deficiencies and not as the problem itself enables parties to address the root causes and to promote sensitivity for the needs of the other side through the exchange of perspectives. The divide is not the conflict object, but rather an indicator of the dilemmas that have plagued the international system in the context of climate change. Reframing the divide as the point of departure of the analysis of the system enables the identification of opportunities for achieving a more sustainable, focused, and yet comprehensive outcome. For instance, the divide serves as a point of reference in coalition-building. Coalitions are established on the basis of common interests, which make the negotiation process less uncertain. The divide reflects a basic function of a multilateral process which requires the building of a like-minded community of negotiating parties. Coalitions do not only serve as a 'negotiation vehicle' (Penetrante 2010) enabling the expansion of resources to pursue interests through cooperation among like-minded actors, they also serve as a channel to moderate extreme views or positions through the various deliberation rounds within coalitions before engaging talks in the international stage. Coalitions bundle interests into packages, decreasing complexity of negotiations. The divide points to the necessity of more facilitators and less of leaders in the bargaining process if a more pragmatic approach is to be pursued. It would mean for instance a chair not drafting a text, but rather a chair that mediates between groups.

The constructive usage of the North-South framing enables a future-oriented conflict management, because the divide points to the issues that must be accommodated to allow future cooperation. It sets the norm and calls for a North-South partnership. As Zartman (2003) explains, discussing the future actually means reconciling two rights, not re-addressing ancient wrong.

87 Climate Change: Long-Term Security Implications for China and the International Community

Yu Hongyuan and Paul J. Smith

87.1 Introduction[1]

Climate change has emerged as one of the top security challenges of the early 21st century (Brauch 2009; chap. 41 by Bauer; chap. 42 by Scheffran; chap. 88 by Ohta). UN Secretary-General Ban Ki-Moon stated that "climate change is altering the geopolitical landscape," as manifested by increased competition over Arctic resources, increased intra-state and interstate migration and rising sea levels.[2] Similarly, U.S. Senator John Kerry argued that "global climate change poses a real and present danger of environmental destruction and human dislocation on a scale that we've never seen."[3]

Climate change poses a security challenge on a number of levels: the individual (human) level, the state level and the level of the international system. On the individual level, the *United Nations Development Programme* (UNDP) asserted in 2007 that "climate change is the defining human development issue of our generation. ... Climate change threatens to erode human freedom and limit choice" (UNDP 2007–2008: 1). With regard to impacts on the state and governance, the United Kingdom, in its *National Security Strategy* described climate change as "potentially the greatest challenge to global stability and security, and therefore to national security" (UK 2008: 18).

Addressing some of the international security aspects of climate change, the United States' based Center for Naval Analyses described in a 2007 report some of the long-term security implications of climate change when it noted: "Climate change acts as a threat multiplier for instability in some of the most volatile regions of the world" (CNA 1007: 6). Thus, states or regions already experiencing various social or governance challenges would be further compromised by some of the anticipated effects of climate change.

China is central to regional and global efforts to fight global warming and climate change. Any successful international effort to mitigate threats to human and national security posed by climate change must inevitably include China.[4] With a population exceeding 1.3 billion, China's economy is one of the world's largest and fastest growing. Consequently, China is experiencing widespread and often acute environmental challenges with severe local, national and regional consequences.[5] It already produces vast amounts of *greenhouse gases* (GHGs). In 2007, the Netherlands Environmental Assessment Agency asserted that due to China's low energy efficiency, the country's emissions had surpassed the US and are now ranked number one globally.[6] In addition, according to an IEA (2007) report: "Carbon dioxide emissions in China could rise to over 11 bn tonnes in 2030, compared with 8 bn tonnes in the US, about 4.5

1 The views presented here are the authors' own and do not reflect the positions of their respective governments or institutions.

bn tonnes in Europe (OECD countries), and just over 2 bn tonnes in India."[7]

Since the 1990's, China has paid increasing attention to environmental protection and the growing hazards posed by climate change (Schreurs 2009; Barnett 2009). In its 2008 White Paper on climate change, the Chinese government acknowledged that "China is one of the countries most susceptible to the adverse effects of climate change, mainly in the fields of agriculture, livestock breeding, forestry, natural ecosystems, water resources, and coastal zones."[8] However, China is still a developing country and in global environmental governance, it has not committed to any immediate concrete responsibility for reducing GHGs, according to the 'no regret' principle. During debates held in the UN General Assembly in November 2007, China's Liu Zhiyong stated that with regard to climate change "the principle of common but differentiated responsibilities should be observed." Moreover, Liu argued that developed countries "should meet their emissions reduction targets" while developing countries "should adopt positive measures to control their greenhouse gas emissions to the extent possible."[9]

China's current development route is based on a high growth-oriented, unsustainable, resource constrained economic model, and it faces the crucial need to promote development while joining the global struggle against climate change. Thus, as China contributes to global economic growth, it simultaneously assumes a role of being one of the largest environmental polluters in the world.

China is also important in the climate change debate because it is a leading member of the developing world that influences international environmental negotiations. If China continues in its unfettered pursuit of an energy-intensive and growth-oriented development model, its moral reputation – including its carefully-promoted "peaceful and benign rise" narrative – may become severely damaged. With these considerations in mind, this chapter examines possible consequences of climate change for the Asia Pacific region, and particularly for China (87.2), it then reviews China's climate change diplomacy and its principles (87.3), it discusses empirical findings for international and domestic implications for China and global climate change (87.4) and finally it discusses Chinese initiatives beyond 2012 (87.5).

87.2 Security Challenges of Climate Change for the Asia-Pacific Region and China

87.2.1 The Scientific Basis: IPCC Assessments

Since 1988, the world's governments began to seriously consider problems of global warming and resulting climate change.[10] It is now generally accepted that global warming is substantially influenced by human activities (IPCC 2001, 2007). Global warming in turn is causing climate change, which is resulting in rising sea levels, droughts, floods and other extreme weather events, spread of pests, harm to natural ecosystems and species, and other adverse consequences. In its Fourth Assessment Report, the IPCC (2007, 2007a, 2007b, 2007c) concluded that billions of people could face shortages of food and water and increased risk of flooding as a result of climate change.[11] Nearly all regions, including Europe, Africa, Asia and America, are anticipated to be negatively affected by some future impacts of climate change and these will pose challenges to many economic sectors (IPCC 2007a: 8–9). The 2007 IPCC synthesis report shows,

> In Asia, available fresh water will decrease by mid-century. Coastal mega-deltas will be at risk from flooding due to rising seas. Mortality due to diseases associated with floods and droughts will increase (IPCC 2007a: 8-9).

According to the Fourth Assessment Report of the IPCC,

8 [Information Office of China's State Council]: "'Full text' of China's policies, actions for addressing climate change", in: *BBC Monitoring Asia Pacific-Political*, 30 October 2008.

9 Transcripts of remarks by Amb. Liu Zhiyong to the United Nations General Assembly, 62nd Session, 20 November 2007 (A/C.2/62/SR.16): p. 14 (accessed from UN website, 21 September 2009).

10 Some of these ideas rely on Harris (2003: 3–18, 2003a: 19–39, 2002: 130–149). This chapter uses 'global warming' to refer to the enhanced greenhouse effect.

11 See: IPCC WGII (2007a: 2–6): "Many natural systems are being affected by regional climate changes. It is likely that anthropogenic warming has had a discernible influence on many physical and biological systems with observational evidence from all continents and most oceans showing temperature rises. Climate changes in many physical and biological systems are linked to anthropogenic warming".

> Future climate change is likely to affect agriculture, risk of hunger and water resource scarcity with enhanced climate variability and more rapid melting of glaciers (medium confidence). Climate change is likely to affect forest expansion and migration, and exacerbate threats to biodiversity resulting from land use/cover change and population pressure in most of Asia (medium confidence). Future climate change is likely to continue to adversely affect human health in Asia. Multiple stresses in Asia will be compounded further due to climate change. Water and agriculture sectors are likely to be most sensitive to climate change-induced impacts in Asia (IPCC 2007a: 471–473).

87.2.2 International Perspectives on the Security Dimensions of Climate Change and their Relevance for China

In June 2008, the U.S. National Intelligence Council issued a report that addressed the global security implications of climate change. Among other things, the report asserted that "climate change could threaten domestic stability in some states, potentially contributing to intra- or, less likely, interstate conflict, particularly over access to increasingly scarce water resources."[12] The report also looked at the likely impacts of climate change on specific regions. Regarding Asia, the NIC concluded that:

> In parts of Asia, extreme weather events are more frequent and severe and intense rains and floods come more often. Droughts have intensified and/or affected more areas in Central, South and Southeast Asia. Tropical storms are more frequent in the South China Sea, and the Bay of Bengal is experiencing fewer but more intense storms.[13]

A subsequent U.S. government assessment predicted the possibility of interstate conflict over water resources, such as in the Himalayan region – the water source for a number of river systems in China, Pakistan, India and Bangladesh (National Intelligence Council 2008: 66). Many of the severe consequences from climate change predicted for the Asia-Pacific region will also affect China. China may see greater weather extremes, including droughts in the north and floods in the south, and increased incidence of infectious disease, including malaria and dengue fever (Nielsen/McElroy 1998: 4–25). Hotter weather – including periodic heat-waves – will increase human mortality as indicated by historical studies from China showing a strong correlation between peak summer temperatures and death rates (Johnson/Li/Jiang/Taylor 2003). Among other prominent impacts are those to agriculture, forests and water resources (China Climate Change Country Study 1999: 107–201).

Food security in China is also likely to be threatened by long-term climate change. A separate U.S. intelligence assessment focusing exclusively on climate change impacts on China concluded that by 2030, "overall crop productivity in China could decrease by as much as 5–10 per cent if no action is taken" (National Intelligence Council 2009: 21–22). In the second half of the 21st century, the results will likely be more severe, resulting in substantial reductions in the yield of rice, maize and wheat of up to 37 per cent (National Intelligence Council 2009: 21–22).

87.2.3 Chinese Official Political and Academic Assessments of the Long-term Security Implications for China

Similar to many Western assessments regarding the security implications of climate change, Chinese official documents also acknowledge such risks. For example, in the foreword of its White Paper on *China's Policies and Actions for Addressing Climate Change*, the Information Office of China's State Council acknowledged that

> as a developing country with a large population, a relatively low level of economic development, a complex climate and a fragile eco-environment, China is vulnerable to the adverse effects of climate change, which has brought substantial threats to the natural ecosystems as well as economic and social development of the country.[14]

One of the Chinese government's primary concerns is the possibility of an increased incidence of natural disasters that may be linked to climate change. In its most recent disaster prevention White Paper, issued in May 2009, the government asserted that "China is one of the countries in the world that suffers the most natural disasters," some of which are tied to extreme weather events.[15] Moreover, such "extreme weather phenomena are increasing along with global climate

12 Statement by Thomas Fingar, Deputy Director of National Intelligence for Analysis and Chairman of the U.S. National Intelligence Council, U.S. House Permanent Select Committee on Intelligence, U.S. House Select Committee on Energy Independence and Global Warming, 25 June 2008.

13 *Ibid.*: 5.

14 [Information Office of China's State Council]: "'Full text' of China's policies, actions for addressing climate change", in: *BBC Monitoring Asia Pacific-Political*, 30 October 2008.

changes."[16] China anticipates increased disaster risks that may be tied to increased flooding, droughts, heat waves, forest and grassland fires and insect infestation, among other effects.[17] In addition, according to the Chinese Government, climate change "will also produce far-reaching impacts on society, economy and other fields, and cause huge losses to the national economy."[18]

Food security, which is often characterized as a national security issue in China, may be undermined by climate change. Yin Chengjie, vice chairman of the Agriculture and Rural Affairs Committee of the *National People's Congress* (NPC), recently stated that the government must remain focused on food security in the long run "because grain is not only a commodity, but also a strategic material for a country of 1.3 billion people."[19] Nevertheless, according to the Chinese White Paper "climate change has already produced visible adverse effects on China's agriculture and livestock-raising sectors."[20] In the long-term, the government expects the overall future impact of climate change on the country's agricultural sector (including livestock breeding) to be "mainly adverse."[21]

Along with its impact on food security, climate change is also likely to undermine water security throughout China, which is already acknowledged as being a major ecological concern in the country (chap. 57 by Gao/Hu). The White Paper asserts that "climate change has already caused changes in the distribution of water resources all over China" and more ominously it predicts that "future climate change will have a great impact on the temporal and spatial distribution of water resources" in a number of ways.[22] Moreover, climate change will likely intensify the drought trend in northern China.[23]

Sea-level rise linked to climate change is also expected to have profound and pernicious consequences for China. The Chinese *Climate Change White Paper* asserts that the country has witnessed an increasing trend of sea-level rise during the past 30 years, "which has caused seawater intrusion, soil salinization and coastal erosion" among other effects.[24] The government also fears that continued sea-level rise "will undermine the capacity of public drainage facilities in coastal cities, and impair the functions of harbours."[25]

87.3 Projections of China's Energy Consumption by 2030

In 2006, China overtook the United States to become the largest CO_2 emitter in the world. By 2020 China's average per capita energy consumption is expected to match the current global average, meaning that China alone will account for almost one third of the world's total GHG emissions between 1990 and 2020 (Harris/Yu 2005). Thus, China clearly matters when it comes to global efforts to mitigate climate change. Without substantial efforts on the part of China to limit future carbon emissions, any measures undertaken by other countries to address the climate change question will be negated – hence, the importance of China's approach to climate change and its role in international negotiations.

87.3.1 China's Economic Development and Projections Until 2020 and 2030

Carbon emissions from developing countries have been growing rapidly. In its *World Energy Outlook 2006*, the International Energy Agency pointed out that the economies and population of developing countries were growing faster than those of the wealthier nations, "shifting the centre of gravity of global energy demand." It estimated that more than 70 per cent of the increase in global primary energy demand between now and 2030 would come from developing countries.[26]

25 *Ibid*.

As one of the world's major economic powers, China is vital to regional and global efforts to fight global warming particularly in the Post-Kyoto climate negotiation era. Due to its high economic development and low energy efficiency, in the early 1990's China became the second largest source of GHGs, and recently (2006) it reached the number one spot according to a Netherlands environmental agency.[27] By 2020 China's average per capita energy consumption will match the current global average, meaning that China alone will account for almost one-third of the world's total GHG emissions between 1990 and 2020 (Harris/Yu 2005). As the general amount increases, we should also see that the emissions intensity of carbon dioxide related to China's average GDP will begin to decrease. According to the International Energy Agency, China's average emissions intensity related to GDP is 5.47 kg CO_2/dollar (prices of 2000).

In 2004, the ratio fell to 2.76 kg CO_2/dollar, dropping 49.5 per cent. Meanwhile, the average level globally dropped 12.6 per cent and for members of the *Organization for Economic Cooperation and Development* (OECD) by 16.1 per cent within a two to three year timeframe. The national average GDP energy consumption dropped 1.79 per cent from 2005 to 2006, and also dropped 3.66 per cent from 2006 to 2007. China's economy has managed to flourish despite the limitations in energy supply. Moreover, the former and current leadership all recognize the imperative of balancing the environment and energy consumption.

Premier Wen Jiabao stressed that energy use per unit of GDP must be reduced by 20 per cent from 2005 to 2010. Under these new circumstances, the Chinese government is shifting from the past development principle of "fast and healthy growth" to "healthy and fast growth."[28] With these objectives in mind, the Chinese government has issued its *Energy Conservation Law* (1997) and the *Renewable Energy Law of the People's Republic of China* (2005).

87.3.2 Western Projections of China's Energy Consumption

China's role in contributing to climate change is related to its energy-intensive economic structure. China's transition from a light manufacturing economy to one featuring more energy-intensive industries—including iron, steel, cement, chemicals and aluminium—is a major factor behind this trend. China accounts for about 35 per cent of world steel production and about 50 per cent of the world's production of cement. These industries and associated activities are "laying a foundation for ... a consumption-led Chinese energy challenge down the road."[29] Chinese consumers' increasing tendency to purchase automobiles and air conditioners, among other products, is establishing the basis for China's future energy challenge.[30]

Based on current projections, therefore, fossil fuels are expected to remain a key part of China's energy mix, with oil playing an increasingly prominent role. According to the IEA's (2007: 79) projections, global oil demand is expected to grow by 1.3 per cent a year, from 83.7 million barrels per day in 2005 to 98.5 million barrels per day in 2015, and 116.3 million barrels per day in 2030. Roughly 42 per cent of this increased demand will come from India and China, while China will account "for the biggest increase in oil demand in absolute terms of any country or region" (IEA 2007: 79).

In the future, the expansion of China's transportation sector is expected to sharply increase the country's demand for oil. By the year 2030, automobile ownership is predicted to increase from 27 million

30 This paragraph relies on: "Transcript of remarks by Mr. Trevor Houser, Director, Energy and Climate Practice, Rhodium Group, Session One of a Council on Foreign Relations Symposium on China and Climate Change and Findings of CFR's Independent Task Force on Climate Change, Subject: Chinese Energy and Climate Strategy", in: *Federal News Service,* 24 June 24 2008; at: <http://www.cfr.org/publication/16630/symposium_on_china_and_climate_change_session_one.html> (5 October 2007.).

cars in 2004 to 400 million by 2030 (US DOD 2008: 10). Consequently, oil consumption in China is expected to rise from about 7.58 million barrels of oil per day currently to 10–12 million barrels per day by the year 2015, the majority of which is expected to be imported (US DOD 2008: 10). Currently, China imports 53 per cent of the oil that is consumed (US DOD 2008: 10).

Similar to oil, the demand for coal is also projected to rise from 4,154 *million tons of coal equivalent* (Mtce of 2005) to 7,173 Mtce in 2030, with demand from China and India accounting for three-quarters of the projected increase to 2030. Coal is the basis of China's power generation infrastructure; eighty per cent of the electricity generated in China can be linked to coal, which is also tied to approximately 80 per cent of all of China's CO_2 emissions (US DOD 2008: 10).

Most Western experts believe that for the foreseeable future – at least 30 years – this fundamental reliance on coal will remain, if not increase dramatically (IEA 2007). By 2030, coal will constitute 63 per cent of China's energy demand mix (IEA 2007). The dominant role of coal in China's energy mix complicates China's ability to achieve certain abatement objectives. As the Chinese government articulated in its 2008 White Paper: "[China's] coal-dominated energy mix cannot be substantially changed in the near future, thus making the control of greenhouse gas emissions rather difficult."[31]

87.3.3 China's Long-term Economic and Energy Projections and Planning

China has strengthened its laws, regulations, policies, systems and management mechanisms to actively address climate change, and has also created a strong institutional, policy and market environment for low-carbon development of enterprises. Since the 8th Five-year Plan (1991–1995), global climate change has been a priority in plans for the state energy plan. According to its 11th Five-year Programme, China will accelerate the pace of building a resource-efficient and environmentally-friendly society, and promote the harmonization of economic development with its population, resources, and the environment. China issued its *National Action Plan on Climate Change* in June 2007, in which the Chinese government established the following goals to 2010: 1) to reduce energy consumption by 20 per cent; 2) to increase the share of renewables (including large-scale hydropower) to 10 per cent of primary energy supply; 3) to increase coal-bed methane production to 10 bn cubic meters a year; and 4) to promote nuclear power development.[32]

In view of its industrial structure and capacity, China carried out industrial upgrades, eliminated outdated production capacities, and focused on energy efficiency. More importantly, a range of tools has been used to help establish the market mechanism and industrial systems, such as encouraging technical innovation, promoting legislation, changing consumption patterns and establishing a carbon market. At the same time, China has also adjusted its trade policy by restricting the export of high energy consumption products and by expanding the import of manufactured goods. Technological innovation is the most important long-term strategy to deal with climate change.

At the technical level, Chinese science and technology have provided some good tools to address climate change. China is vigorously developing energy-saving and energy efficient technologies, renewable energy and new energy technologies, and clean coal. Other technologies China is exploring and utilizing include advanced nuclear energy, carbon capture and storage, bio-sequestration and carbon sequestration. The development of each energy technology may cost as much as one trillion U.S. dollars each.

China has also emphasized public education to enhance awareness on the low-carbon issue. Experience has shown that effective social participation is the basis for a transition to a low-carbon economy. Low-carbon consumption needs to become part of social consciousness, and China needs to guide people in ways to save energy and reduce carbon emissions. China is encouraging government and social organizations to participate in its emerging low-carbon economy. Through their economies of scale, they can promote the transition to environmental protection at a relatively low cost. China also aims to promote the concept of low-carbon lifestyles for individual citizens, to ensure that the low-carbon transition is universal. In China, low-carbon living is still hampered by a lack of social infrastructure. China has therefore continued to strengthen civic education to avoid a high-carbon lifestyle in the future.

31 Xinhua News Agency: "China National Action Plan on Climate Change"; at: <[http://news.xinhuanet.com/politics/2007-06/04/content_6196300.htm> (3 March 2008).

32 *Ibid.*

In addition to its current (and projected increase) reliance on fossil fuels, China – as noted above – is also expanding the renewable and alternative categories of its overall energy mix. The 2008 White Paper seeks to raise the proportion of renewable energy sources (wind, solar and hydropower) to 10 per cent (total consumption) of the overall energy mix by the year 2010. Recent initiatives by the Chinese government – including calls to substantially expand solar and wind power capacity – suggest that this goal will be achieved or exceeded.[33] The Chinese government also announced plans to expand nuclear energy (doubling its original goal), with the ultimate objective of achieving a capacity of 70 gigawatts by the year 2020.[34]

87.4 China's Domestic Climate Change Policy

Recognizing the increasing challenge posed by climate change – and China's central role within this issue – the Chinese government has responded by engaging in 'climate change diplomacy' that operates on several levels. Broadly speaking, China's climate change diplomacy has sought to further several goals, namely, to protect China's sovereignty and national interests; to acquire foreign aid and technical assistance; to promote China's economic growth based on a *Scientific Outlook on Development*; and to enhance its role as a responsible great power and as the leader of the developing world (Economy 1998: 264). To cope with these agendas, China has responded incrementally towards growing external influences, particularly to the requirements of the *United Nations Framework Convention on Climate Change* (UNFCCC).

China's energy intensity – defined as the "ratio of energy consumption to a measure of the demand for services"[35] – is only a fifth of that of the European Union. But China is seeking to find a model that will allow it to resolve the conflicts between energy consumption and environmental degradation. As noted earlier, China is developing a diverse mix of energy resources, and is putting in place a system that will supply stable, economical and clean energy. China is also working hard to develop a recycling economy so that it will garner the highest possible economic and social benefits with the lowest possible energy consumption.

First, China has consistently pursued the goal of relying on its domestic resources and constantly increasing the domestic supply of energy. China is not only a major energy consuming country, but also a major energy producer. Since the 1990's, China has obtained more than 90 per cent of its energy from domestic sources (93 per cent in 2005) and the potential of its domestic energy supply is still great.[36] From 1980 to 2001, on average, China's GDP growth rates have been around 10 per cent, with approximately a five per cent growth rate in energy consumption.

China's economy has managed to thrive despite limitations in energy supplies and the recognition by former and current leaders that China must seek to balance environmental concerns with energy priorities. Deng Xiaoping pointed out that energy efficiency was essential to achieving economic goals in China. Recent external assessments suggest that China is already more energy efficient than many of its counterparts in the developing world. However, this assessment also indicated that China's energy use has grown much faster than its GDP since the end of 2001, putting China's development goals and global climate change struggles in jeopardy.[37]

Second, as part of the national law building process, after the 1992 Earth Summit, the Chinese government devised a national sustainable development plan based on the summit's "Agenda 21" objectives. As part of its implementation, the government adopted – as described earlier – the *Energy Conservation Law* (1997) and the *Renewable Energy Law of the People's Republic of China* (2005). Since the Eighth Five-year plan (1991–1995); global climate change has been listed as a priority for the state energy plan. With the 11th Five-Year programme (2005–2010), China has accelerated the pace of building a resource-efficient and environmentally-friendly society, and has promoted a harmonization of economic development with its population, resources, and its environment. This will ideally reduce energy consumption per unit of GDP by some 20 per cent by the end of the 11th FYP period

37 Interview of Hongyuan Yu with Mark Levine of the Lawrence Berkeley National Laboratory on 27 July 2007.

in 2010. Furthermore, China issued its *National Action Plan on Climate Change* in June 2007, and its government has selected these goals to be achieved by 2010:

1. Reducing energy consumption by 20 per cent;
2. Increasing the share of renewable energy (including large-scale hydropower) to 10 per cent of its primary energy mix;
3. Increasing coal-bed methane production to 10 billion cubic metres a year; and
4. Promoting nuclear power development.[38]

Third, in terms of institution-building, to specifically address the issue of climate change, in 1998 the State Council of the Chinese government created the *National Coordination Committee for Climate Change* (NCCCC). The committee was given responsibility for coordinating and formulating various policies related to climate change. In 2007, the Chinese government set up a national leading group for climate change headed by Premier Wen Jiabao, Vice Premier Zeng Peiyan and State Councillor Tang Jiaxuan. While encouraging and pursuing economic development, the government has simultaneously adopted various measures to cope with climate change and to improve the ecological environment in line with the country's national sustainable development strategy. China has also appointed a special representative for climate change negotiations within the Ministry of Foreign Affairs.

87.4.1 China's Climate Diplomacy Practice

The development of the UNFCCC requires an active involvement of China which plays a proactive role in the so-called 'China + G77' negotiation bloc. Three stages in this regime building process may be distinguished:

1. Prior to 1992 before the *United Nations Framework Convention on Climate Change* (UNFCC) was signed: This stage focused on international consensus-building to create the foundations of a climate change regime.
2. Between the 1992 Rio Summit and the 1997 Kyoto Conference: This stage focused on the adoption of legally binding goals for reducing GHG emissions relying on three flexible Kyoto mechanisms: CDM, JI and ET.
3. Since the 1997 Kyoto conference: This stage focused on the implementation and ratification of Kyoto Protocol.

Table 87.1: Chronological development of the international climate regime.

1992	Earth Summit in Rio de Janeiro: Over 150 countries adopt the UNFCCC and are committed to achieving a "stabilization of GHG concentrations in the atmosphere at a level that would prevent dangerous interference with the climate system."
1994	Entry into force of the UNFCCC.
1995	First Conference of the Parties (COP 1) in Berlin: Adoption of the Berlin Mandate with 'Common but differential responsibilities' for developing countries (China + Group of 77)
1997	At COP 3 in Kyoto: Over 160 countries sign the Kyoto Protocol. Industrialized signatories commit to binding GHG reductions of a global average of 5.1 per cent below 1990 levels for the period of 2008-2012.
1998	COP 4, Buenos Aires: Parties set deadline to decide on Kyoto rules on the implementation of reducing of GHG in developing countries.
2001	COP7, Marrakech: 165 nations endorse the Marrakech consensus and adoptguidelines for implementing the Kyoto Protocol.
2002	The Second World Summit on Sustainable Development in Johannesburg in September 2002. COP8, New Delhi: China ratified the Kyoto protocol.
2005	COP11 and MOP1Montreal: The Kyoto protocol enters into force. The Montreal Action Plan extends the Kyoto Protocol beyond its 2012 expiration date and to negotiate deeper cuts in GHG emissions.
2007	COP-13 and MOP-3, Bali: The negotiation focuses on the post 2012 framework on GHG reduction and adopts the Bali Plan of Action
2009	COP-15 and MOP-5, Copenhagen: prospective adoption of the post 2012 climate change regime.

Since the 1990's, China has been actively involved in the foundation, negotiations and implementation of the UNFCCC and its Kyoto Protocol. During the first stage, from 1990 to mid-1992, China worked with other countries to draft and negotiate the UNFCCC. China made an important contribution to the consen-

38 Xinhua News Agency: "China National Action Plan on Climate Change", 7 June, 2007; at: <http://news.xinhuanet.com/politics/2007-06/04/content_6196300.htm> (13 September 2008).

sus on the principle of "common but differentiated responsibilities" which allowed the UNFCCC to enter into force in 1994. The convention was adopted in principle by China on 9 May 1992 and it was formally opened for signature at the *UN Conference on Environment and Development* (UNCED) in June 1992 in Rio de Janeiro, where it was signed by 155 countries, including China.[39] China's National People's Congress ratified the UNFCCC in November 1994.

The greatest subsequent challenges for China in the conferences of the parties to the UNFCCC were the Kyoto Protocol and the so-called three flexible mechanisms for its implementation, such as the *Clean Development Mechanism* (CDM), the *Joint Implementation* (JI, whereby countries with legal reduction obligations (Annex I countries) can offset their emissions with projects in other countries) and *International Emissions Trading Schemes* (IETS) (Cooper 1998: 66–80). The EU urged China and other developing countries to join this environment trading system.

The third stage covers the period since late 1997, when the parties to the UNFCCC approved the Kyoto Protocol, up to the present. During this period, Chinese diplomacy has focused on two issues: 1) on how to improve international environmental trading mechanisms and 2) on preventing the Kyoto Protocol from becoming a failure due to its rejection by the U.S. Government. At the *World Summit on Sustainable Development* (WSSD) in Johannesburg in 2002 former Chinese Prime Minister Zhu Rongji transmitted the Chinese ratification of the Kyoto Protocol.[40] China has shown great interest in the flexibility mechanisms. Chinese president Hu Jintao argued in the 2007 at the APEC Summit that:

The UNFCCC and its Kyoto Protocol constitute the legal basis of international cooperation on climate change and are the most authoritative, universal and comprehensive international frameworks for the issue.[41]

China's approach to the UNFCCC can be understood in the context of five important stages between COP8 (2002 in New Delhi) and COP12 (2006 in Nairobi):

- First, the UNFCCC provides a fundamental and effective framework for international cooperation in response to this growing phenomenon. What is particularly significant for China is the enshrinement within the Convention of the 'principle of common but differentiated responsibilities'.
- Second, China argues that climate change countermeasures should be implemented within the framework and spirit of 'sustainable development'.
- Third, the role of technology in combating climate change should be emphasized.
- Fourth, equal consideration should be given to mitigation and adaptation.
- Fifth, the international community should adopt concrete measures to mitigate climate change.[42]

At the 2007 APEC Summit, Chinese President Hu Jintao put forward four proposals for tackling climate change:

1. Cooperation is indispensable for global efforts to tackle climate change;
2. Efforts are needed to pursue sustainable development, as climate change is ultimately a development issue and it can only be addressed in the course of sustainable development;
3. The United Nations Framework Convention on Climate Change should be upheld as the core mechanism for addressing climate change. The Convention and its Kyoto Protocol provide the legal foundation for international cooperation on climate change and are the "most authoritative, universal and comprehensive international framework for the issue;"[43]
4. Major efforts should be pursued to promote technological innovation as a means of mitigating climate change.[44]

39 UNFCCC: "Issues: A Brief History of the Climate Change Process" (Bonn: UNFCCC Secretariat); at: <http://www.UNFCCC.int/cop7/briefhistory.html> (12 November 2006).

40 Jiang Weixin, "Presentation in the Cop8", in: *Renmin Ribao*, 11 November 2002. Elizabeth Economy (1998: 264) argues that "China took a significant step forward at the UN World Summit on Sustainable Development in Johannesburg when it announced that it had ratified the Kyoto Protocol to curb greenhouse gas emissions."

87.4.2 Principles of China's Climate Diplomacy

China's substantial GHG emission rate, which now ranks first in the world, makes the effectiveness of the UNFCCC heavily dependent on concrete and tangible action on the part of China. Moreover, other developing countries (G 77 + China) hope that China will assume a leadership role in protecting their interests in negotiating the UNFCCC. The perceived and actual differences between developing and developed countries in their economic development levels and political objectives have created a serious divergence over the means and priorities needed to reduce GHG emissions. This has led to the principle of 'common but differentiated' development becoming the collective philosophy of China + G77.[45] As a result, certain interactions between China and the UNFCCC members and secretariat have occurred.

First, China joined with other developing countries to demand that developed countries should reduce their GHG emissions. It also rejected most market-based international mechanisms for emission reductions advocated by developed countries, and demanded assistance for developing countries' climate change programmes (Linnerooth 1999: 59). In its 2008 White Paper, the Chinese government argued that "developed countries should be responsible for their accumulative emissions and current high per-capita emissions and take the lead in reducing emissions, in addition to providing financial support and transferring technologies to developing countries."[46]

In particular, China has joined with India in reiterating its outright rejection of GHG emission cuts for developing countries, arguing that increased emissions are required for developing countries to lift their populations out of poverty. Despite the nominal self-positioning of China in the so-called "developing gang," interestingly, there was an instance of spontaneous cooperation between the US, China and developing countries in the UNFCCC negotiations. Specifically, China agreed with the US that employing adaptation measures – transfers of funds and technology from developed to developing countries to help them cope with climate change – was the preferred way to address the problem. As such, China joined the US in dismissing some developing countries' agendas that were designed to channel as many resources as possible from the rich to the poor.

China is increasingly aware of its dual status as a developing country and a major contributor to global environmental challenges. In the past, partly due to national pride, China resisted linking financial and technical assistance from developed countries to climate change control. But now it has demanded the transfer of funds from the West on non-commercial and preferential terms, and promised to channel such resources to contribute to the battle against international climate change. As a result, China has become the largest recipient of environmental aid from the World Bank, and receives substantial amounts of environmental aid from other international funding agencies. Indeed, most of China's environmental budget already comes from abroad (Economy 1998: 278).

China is also receiving environmental technological assistance from overseas, such as that offered by the United Nations' CDM (Japan Environmental Council year: 106). It is therefore impossible for China, after receiving all this funding, to behave in any way differently from the expectations of the UNFCCC. China's current participation in international environmental institutions and processes has increased noticeably. China has signed a wide range of treaties and declarations, developed extensive linkages with scientific and environmental policy communities around the world, and hosted a variety of international conferences and workshops on the environment. These gestures have paved the way for China to allow the UNFCCC to play a larger role in its domestic bureaucratic and policy coordination concerning climate change.

87.4.3 The Focal Points of China's Climate Diplomacy

Recognizing the important international political significance of its climate change posture, the Chinese Government had adopted a climate change strategy that consists of three basic tenets. First, the UNFCCC and its Kyoto Protocol serve as the basis and the mandate of the Bali Roadmap plays a central role. Within this framework exists the principle of "common but differentiated responsibilities," which China adheres to strongly. Second, China subscribes to the principle of "equitable development and technology transfers," which is embedded in the fundamental notion that developed countries have certain responsibilities to provide technology and assistance (economic or oth-

erwise) to developing countries that are only beginning to enjoy the fruits of economic prosperity. Third, any long-term approach to the challenge of climate change will require appropriate strategies in terms of mitigation and adaptation.

87.4.3.1 Principle of 'Common but Differential Responsibilities'

The principle of 'Common but Differentiated Responsibilities' is the global consensus within the UNFCCC, which has evolved into an international legal norm that allows "different responsibilities among different groups of parties" (Stone 2004: 279). Essentially, under the Kyoto Protocol to the FCCC, developed countries (Annex I) must (as a group) reduce greenhouse gas emissions by 5.1 per cent or more below 1990 levels during the 2008–2012 time frame. The non-Annex I countries (i.e. developing countries) do not have any quantitative obligations (Stone 2004: 279).

China and other developing countries' adherence to this standard reflects, as many politicians and legal analysts have noted, a basic structural shortcoming within the Kyoto Protocol regime to the extent that developing countries are, in essence, excluded from universal abatement obligations. This is particularly problematic because, as one legal analyst has noted: "[D]eveloping countries will be responsible for half the world's emissions by 2020 or earlier" (Gerber 2008: 333). Nevertheless, Chinese leaders contend that each person in the US now emits more than five tons of carbon per year, while in China the figure is only one ton per year. Since the start of the industrial revolution, the US and Europe account for more than 50 per cent of the total, accumulated global emissions over two centuries, while China accounts for less than eight per cent. The 50 least developed countries have together contributed less than 0.5 per cent of global cumulative emissions over 200 years."[47]

Developed countries, in general, argue that China and other developing countries must immediately take action to reduce carbon emissions; otherwise, international environmental cooperation, particularly regarding climate change, will be unsuccessful. For example, by 2006, carbon emissions in developing countries were 44 per cent over 1990 levels, and 71 per cent over 1986 levels. In 1998, the EU successfully persuaded certain Latin American countries to reduce GHG emissions, which led to the creation of the 'Buenos Aires Plan of Action' which imposed greater pressures on China. At the COP8 in New Delhi in late 2002, China joined with India in reiterating its outright rejection of GHG emissions cuts for developing countries proposed by the EU, arguing instead that increased emissions would be required to eradicate poverty in their respective societies.

87.4.3.2 Equitable Development and Technology Transfers

For China, the largest developing country, global warming issues are intimately linked to efforts to modernize the economy and the associated energy strategy necessary to bring about such modernization. However, according to Professor Pan Jiahua, developed countries' resource and energy use is excessive and wasteful, particularly in comparison to the use in developing countries. China and other developing countries only struggle to satisfy their basic needs, which can be characterized as industrialization, urbanization and maintenance of a basic and reasonable physical life.

Developing countries contend that it is their inalienable right to develop their economies, to improve living standards and to enjoy the same living standards of people in developed countries. Of the world's 6.5 billion people, only one-third enjoys regular access to electricity. In addition, one third – roughly two billion people – lack access to modern energy services and live on less than $2 per day.[48] Furthermore, the global dilemma between energy and environment should be solved through international coordination, cooperation and mutual assistance in clean energy development. Developing countries are deeply dissatisfied with developed countries in this respect because the latter refuse to pay necessary regard to the constraints imposed by developing countries' lack of development.

Wealthy countries, for instance, place a low priority on technology transfers, and insist on the high price of intellectual property rights of these technologies. Since its inception, the *Global Environment Facility* (GEF) has promoted technology transfers, grants, and loans from the developed world for reduc-

47 "CO_2 emissions increasing faster than expected", in: *M2 Presswire*, 22 May 2007.

48 According to International Energy Agency data, the per capita total primary energy supply of the U.S. was more than six times higher than China's and nearly 15 times that of India's in 2004; the per capita emissions of carbon dioxide by these countries followed a similar pattern.

ing carbon emissions through a series of projects in developing countries. However, since its launch in 1991, the GEF has only allocated about $ 4 billion in grants.[49]

Through CDM mechanisms, industrialized countries could also meet part of their obligations for reducing emissions under the Kyoto Protocol by receiving credits for investing in projects that reduce carbon emissions in developing countries. However, developed countries could also adopt a more ambitious programme of transferring advanced clean energy technologies to the developing world. China has joined with other developing countries to demand that developed countries provide non- commercial technology assistance to developing countries to help them cope with climate change and cultivate low-carbon emission economies.

However, developed countries have insisted on using commercial approaches to facilitate transfer of technology. One 'middle way' alternative would be funding of joint research centres involving China and foreign countries, such as the United States. Such centres, employing scientists and engineers from both countries, could focus on breakthrough technologies (for GHG abatement purposes) that could be distributed globally on a largely non-market basis.

87.4.3.3 Adaptation and Mitigation for Climate Change

Among developed countries, the EU and its member states place more emphasis on mitigation than on adaptation in climate change negotiations. In early 2007, the EU decided to cut greenhouse gas emissions by 20 per cent by 2020 from their 1990 levels and by 30 per cent if other industrialized nations join in. The EU also agreed to back collective cuts of 60 per cent to 80 per cent by 2050 compared with 1990 levels.[50] However, a new alliance emerged between the United States, China and many developing countries, such as India and members of OPEC. According to the logic underpinning this alliance, if China decreased its GHG emissions by 10–20 per cent, the country's GDP would decrease by 2 per cent. By contrast, if the per capita income increased by 5.1 per cent, the GHG emissions would also increase by 1.29 per cent (Zhang 1996). Thus, China agreed with the United States that *adaptation* measures – defined broadly as transfers of funds and technology from developed to developing countries to help the latter cope with the consequences of climate change – were the preferred ways to address the problem.

87.4.4 From Climate Diplomacy to Chinese Policy Implementations

With regard to addressing climate change concerns and in preparation for the upcoming Copenhagen negotiations, China is facing a complicated set of negotiations, especially when considering its energy consumption patterns (and resultant GHG emissions). Moreover, emerging economies (such as China) have become the key stakeholders in Bali Roadmap and Post-Kyoto negotiations. The success (or lack thereof) of their negotiations will influence the future of global stability, particularly as the effects of climate change continue to manifest and become more severe. It has often been argued that China should clarify its climate diplomatic position in order to pursue more understanding and support from the developed world and the international community.

However, by shifting the focus of climate talks to adaptation, and away from mitigation, both the rich and poor countries can avoid doing what they have sought to avoid the most: demanding that entrenched economic interests reduce their GHG emissions. Ironically, China has been sceptical regarding the practicality of imposing a global carbon tax (a proposal supported by the EU) as a mitigation measure from which revenue could be used to finance technological transfers. As is well known, higher trade dependence would result in a sharing of the burden associated with China's energy-intensive industries and resulting carbon emissions. In 2005, China's GDP was 18,670 billion RMB, and its exports of goods and services were roughly 6,858 billion RMB. In 2006, China's GDP was 21,438 billion RMB, and its exports of goods and services at 8,396 billion RMB.[51] Thus, the global carbon tax proposed by the EU would likely damage China's economic development.

87.5 Conclusion: Chinese Initiatives Beyond 2012

China's response to global warming and climate change has a number of social, political and economic implications (Barnett 2009; Schreurs 2009; chap. 28 by Heberer/Senz; chap. 57 by Gao/Hu; chap. 36 by Shen; chap. 15 by Zhao). First, it is clear that China has proactively addressed the challenge in multiple ways, in the policy, legal and technical front. Such actions suggest that fellow Asia-Pacific countries can not only benefit from China's growth, but also the larger consequences of China's balanced development model. A number of wealthy countries, including the United States, have been unable to implement adequate measures to facilitate GHG emission reduction. Many of these countries have sought only to adopt incremental measures domestically while avoiding international obligations to substantially limit GHG emissions.

Despite this reality, China has decided to move forward using its dual status as a developing country (with rights to and needs for development) and its growing role as a major contributor to global environmental problems (such as GHG emissions) to acquire substantial influence in international environmental negotiations. To be sure, China is well-positioned to leap frog into a clean energy development path. In the longer term, however, China could show true leadership on climate change in the developing world by adopting a concerted transition to an economy that produces fewer carbon emissions. Such a choice would be greatly facilitated (and expedited) with financial and technical aid from developed countries. Nevertheless, even in the absence of such aid, it is clear that the Chinese government should integrate climate change into its development policy. Otherwise, collective action against global warming and climate change will likely fail.

Lastly, another important factor in the future of China's climate change policy is its ongoing dialogue and cooperation with the United States. Based on total quantity of GHG emissions, China and the United States are two of the world's most important countries in terms of climate change. The American Energy Secretary Steven Chu stated recently that "what the U.S. and China do in the coming decades will help shape the fate of the world."[52] For years, both countries have used the other – particularly allegations of the other's lack of progress or sincerity regarding greenhouse gas emissions abatement – as a justification for delaying or avoiding difficult policy choices.

Recently, the Obama administration has sought to obtain specific abatement guarantees from China, partially as a way of pre-empting opposition to its own abatement proposals within the U.S. Congress. However, China has resisted such specific targets, while at the same time accusing the United States of failing to adopt meaningful GHG abatement targets. Nevertheless, the U.S. and China have still agreed – under the aegis of the U.S.-China Memorandum of Understanding to Enhance Cooperation in Climate Change, Energy and the Environment – to engage in an "ongoing dialogue on what both countries are doing to reduce emissions and to advance international climate negotiations."[53]

In the longer-term, however, a sustained U.S.-China dialogue on climate change may provide the foundation for scientific advances in clean energy technology that would have global implications. In July 2009, the United States and China announced the establishment of a clean energy research centre in China, reflecting a pro-technology policy preference among many American and Chinese officials. A senior U.S. official stated that "clean energy is the solution [and] the transformation to a low carbon economy in our country [US] and China, and ultimately globally, is the only way to solve this problem."[54]

On a recent trip to China, a senior U.S. Department of Energy official, David Sandalow, expressed surprise by the speed and depth of Chinese research into clean-energy technologies. "It is clear the Chinese are investing heavily in clean energy, and intend to be world-class players in clean-energy technologies in the decades ahead."[55] Both China and the United States are slowly positioning themselves for the challenges and opportunities associated with the major energy transition period that lies ahead.

U.S. Energy Secretary Chu provided one of the more optimistic assessments when he stated that "through clean energy, we can create new jobs and

new industries and vitalize our economy."[56] Through mutual confidence and ongoing dialogue, China and the United States are positioned to serve as potential leaders in the field of clean energy and GHG abatement in the years and decades ahead.

88 Japanese Climate Change Policy: Moving Beyond the Kyoto Process

Hiroshi Ohta

88.1 Introduction

Despite its potential to become a leader in international negotiations on climate change, Japan has not played an assertive role in this field since the third *conference of the parties* (COP 3) of the *United Nations Framework Convention on Climate Change* (UNFCCC) held in Kyoto in 1997. Focusing on Japanese climate change mitigation policy, this study uses the process-tracing method to examine the reasons why Japan relinquished its leadership and initiative internationally. Since overcoming severe pollution problems in the 1960's and 1970's, Japan has maintained a technological lead in pollution-abatement and energy-efficient technologies. This chapter demonstrates how unfavourable marginal abatement costs in comparison with those of EU member states and the United States have dictated a regression in Japan's climate change policy discourse. A lack of strong and stable political leadership on climate change through this period has also allowed well-organized economic interests and the economy ministry to solidify an industry-oriented policy coalition. With the advent of the new Democratic Party of Japan-led administration in September 2009, however, Japan has begun to move back into its natural position as a vital force in international climate change negotiations.

Political change has finally come to Japan, and with it a new dynamic on climate change policy. Prime Minister Yukio Hatoyama, at the UN Summit on Climate Change on 22 September 2009, pledged that Japan would reduce *greenhouse gas* (GHG) emissions by 25 per cent by 2020 from the 1990 level if all major emitters also commit to ambitious reduction targets. In order to promote a broader cooperation, he proposed the 'Hatoyama Initiative', an international scheme for the provision of additional technological and financial support for developing countries while assuring developing countries' "measurable, reportable, and verifiable" emission reduction targets.[1]

As the world's second largest economy, Japan has sought a proper position in international society through its contributions to the provision of international public goods. Japan overcame severe environmental pollution problems in the 1960's and 1970's and weathered two oil crises in the 1970's. In surmounting these problems and crises, Japan has developed pollution-abatement and energy-efficient technologies. Regarding mitigation of climate change, it has maintained a technological lead, for instance, in developing and commercializing hybrid cars and solar panels. In tandem with these efforts, Japan has had a strong domestic political incentive to play a leading role in non-military issues like global climate change due to the 'no-war clause' in its constitution, which renounces war as the sovereign right of a nation and prohibits the threat or use of armed forces even in the settlement of international disputes. As expected by many observers in the world, Japan, jointly with European countries, has taken the lead during negotiations for the UNFCCC and it did host the Kyoto Conference (COP 3) in 1997 and contribute to the adoption of the *Kyoto Protocol* (KP). However, since that time it has been reluctant to grasp the initiative once more. Rather, by assigning itself the role of a mediator between the United States and the European Union, it has become increasingly allied with those countries that remain cautious on international negotiations on climate change.

Under President Barack H. Obama and his 'Green New Deal', the United States is now moving, although not yet fully joined by Congress, with the EU toward the front lines of the battle to arrest global climate change. Is Hatoyama's commitment to climate change a mere reaction to evolving changes in international

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_88, © Springer-Verlag Berlin Heidelberg 2011

relations on climate change? Or does it reflect an undercurrent of domestic changes within Japanese society? If so, why has Japan been so reluctant to take a leadership role in climate change negotiations despite the technological lead it holds that could generate economic gain, vigorous public support, and the strong political incentive, as mentioned above? What kind of political will is necessary to overcome resistance from the forces intent on maintaining the status quo?

This chapter attempts to answer these questions by analysing the domestic process of Japanese foreign policy making on climate change, focusing on the policy discourse for achieving the Kyoto target (88.3), international cooperation toward ratification of the Kyoto Protocol (88.4), and international negotiations beyond the Kyoto process (88.6).[2] The scientific discourse in Japan on this subject is also briefly discussed (88.5). This study employs the process-tracing method, giving a detailed account of the important decision-making processes and describing the core elements of climate-change policy discourse (George/Bennett 2005).

88.2 The Analytical Framework

Numerous studies have been done on the domestic sources of foreign policy or on the interaction between international relations and domestic politics. Putnam's 'two-level games' (1988), Gourevitch's 'second image reversed' (1978), and Milner's 'domestic interest-based' explanations (1997) are just a few.

The analytical framework for this study of the interaction between international and domestic politics combines the two-level game approach with an emphasis on domestic-factor based explanations. Government negotiators work out a tentative agreement, which each country's constituents must decide to ratify or not. Thus, the domestic political discourse of international negotiation is of crucial importance. Domestic politics includes "[political] parties, social classes, interest groups (both economic and noneconomic), legislators, and even public opinion and elections, not simply executive officials and institutional arrangements" (Putnam 1988: 432). The intersection of domestic politics and international negotiation is the "win-set" which is defined "for a given Level II (domestic) constituency as the set of all possible Level I (international) agreements that would 'win' – that is, gain the necessary majority among the constituents – when simply voted up or down" (Putnam 1988: 437). In Japan, however, since the process of ratification of international agreements is more or less automatic, one can afford to be less concerned about domestic constituents during international negotiations. Instead, special attention must be given to the following factors that influence the state's behaviour during international negotiations on climate change.

From the perspective of the domestic sources of international negotiations, the degree of ecological vulnerability and the cost of climate-change mitigation are the main factors that determine state behaviour (Sprinz/Weiss 2001). The higher a state's ecological vulnerability and the lower the mitigation costs the more likely a state is to become a 'pusher' or 'lead' state in international negotiations. Contrarily, the lower its ecological vulnerability and the higher its mitigation costs, the more likely a state is to become a 'dragger' or 'veto' state. If both ecological vulnerability and mitigation costs are high, the state may become an 'intermediate' (between pusher and dragger), or what is called a 'support' state. If ecological vulnerability is low and mitigation costs are high, a state would become a 'bystander' or a 'swing' state.[3] Japan is ecologically quite vulnerable since it is surrounded by the sea, often suffers from severe seasonal floods, and is occasionally hit by damaging typhoons. The mitigation costs for Japan are very high because it has already achieved high standards of energy efficiency. This means that one unit of CO_2 emission reductions is relatively more expensive in Japan than in other OECD countries. According to this domestic interest-based explanation, thus, Japan is likely to become an 'intermediate' or 'support' state in negotiations on the climate change regime.

The explanation, however, requires elaboration of the domestic sources of Japanese international negotiation positions beyond a mere analysis of cost-benefit positions. For instance, perceptions of mitigation costs may differ between energy-intensive industries and 'green' industries, between the economy and trade ministry and the environment ministry, or between the business sector and the environmental

2 On Japan's domestic politics and diplomacy on the *UN Framework Convention on Climate Change* (UNFCCC) and on the Kyoto Protocol, please see this author's previous studies (Ohta 2009, 2005a, 2005b, 2000, 1995).

3 The terms 'pusher', 'intermediate', 'bystander' and 'dragger' are used by Sprinz and Vaahtoranta (1994) and the terms 'lead', 'support', 'swing' and 'veto' are used by Porter and Brown (2000).

NGO sector. In the absence of strong political leadership in the promotion of climate change policy, the voices of well-organized and well-funded industrial and business associations that tend to exaggerate mitigation costs can drown out those of environmental NGOs in influencing the governmental policy-making process. If, however, Japanese environmental NGOs were well organized and well financed, they would be able to balance perceptions of high mitigation costs with an awareness of the long-term benefits of precautionary measures. In this way, Japan's perception of high mitigation costs could be shifted to relatively low costs, thereby transferring Japanese behaviour from that of an 'intermediate' or 'support' state to that of a 'pusher' or 'leader' in international negotiations.

Within the purview of the hypotheses mentioned above, Japan's domestic politics of adoption and ratification of the *Kyoto Protocol* and of post-Kyoto negotiations can be explained by five variables and two parameters. The five explanatory variables include political leadership, bureaucratic politics, the business (or private) sector, environmental NGOs and public opinion polls. The relative strength of each variable determines the size of win-sets, which in turn influences Japan's negotiation positions, as pusher and leader or intermediate and supporter. Political leadership or equivalent power, including the presence or absence of policy entrepreneurs (or policy brokers) (Walker 1974, 1981; Kingdom 1984) or influential 'greenish' politicians and/or 'greened' political parties, is influential in determining the size of the win-set. It is presumed that the more influential the politicians or political party playing the role of policy broker, the more likely it is that the win-set will become larger. Bureaucratic politics, in turn, hinge on relative strength or the presence or absence of political leadership. For example, strong political leadership may make it possible for turf wars between bureaucrats in the economic and environmental agencies to be overcome and policies furthered for the sake of the environment.

The business sector and environmental NGOs are another integral element determining the size of the win-set. Neither bureaucrats from the *Ministry of Economy, Trade and Industry* (METI) and from the *Ministry of Environment* (MOE) nor politicians can ignore the pressures from business and environmental NGOs. While pressure from the business sector generally leads to the smaller size of the win-set, pressures from environmental NGOs backed by strong support from public opinion polls can support widening the win-set for international negotiations insofar as the government is active in promoting international agreements on climate change. In the former case, Japan may call for weak emission reductions, while in the latter case, for strong emission reductions.

Domestic or international political, economic, and ideational contexts act as parameters, or intervening variables, promoting or discouraging action or inaction in Japan's climate change diplomacy. For instance, Japan's bubble economy and the Asian financial crisis of 1997 activated and deactivated environmental policy-making processes, respectively. Advancements in scientific knowledge or assessment of global climate change, moreover, have great potential to further accelerate policy developments. The so-called epistemic community may again play a significant role in the promotion of international negotiations, as it normally acts as a principal agent in identifying these problems (Haas 1990; Adler/Haas 1992).

In sum, Japan's reluctance since COP 3 to take a leadership role in international negotiations stemmed from its estimation of the high mitigation costs it would have to bear resulting from the stronger clout gained by the energy-intensive industries and in the absence of a strong counterbalancing political leadership. From September 2009, with the advent of a new administration that has pledged to promote the country's role in international negotiations on climate change, Japan is now shifting gears to move from an intermediate or support state to a pusher or leader state.

88.3 How to Achieve the Kyoto Targets

After the *Kyoto Protocol* was adopted in December 1997, on 19 June 1998, the Japanese government established the *Guideline for Measures to Prevent Global Warming: Measures towards 2010 to Prevent Global Warming* (Global Warming Prevention Headquarters 1998). This policy programme counts, above all, on the role of forests in absorbing CO_2, supported through additional activities such as forest management suggested in Article 3.4 of the *Protocol*. With regard to forestry activities, the proposed 'essential measures' to prevent global warming aimed at the reduction of 3.7 per cent out of 6 per cent, or an assigned target for Japan. The policy to reduce domestic GHG emission by 2.5 per cent consists of energy conservation, introduction of new energy and more construction of nuclear power plants "with rigid nuclear safety measures." However, the *Guideline* estimated a 2 per cent GHG increase due to the emissions of

CFC-alternative gases. Therefore, Japan would have to rely on the Kyoto mechanism to the extent to which it could gain credits equivalent to 1.8 per cent of emissions reduction.

This initial policy was amended in March 2002 when accord on the detailed legal documents of the *Protocol* was reached in November 2001 at COP 7. The path to conclusion of the detailed rules for the *Kyoto Protocol* was not easy. A full agreement was not reached at COP 6, held in The Hague in November 2000, so COP 6 was reconvened in Bonn in July 2001 (IISD 2000). Three months before the second session of COP 6, the declaration of the new Bush administration that the United States would not ratify the *Kyoto Protocol* was tantamount to a sentence of death to the document. However, U.S. abandonment of international cooperation inadvertently united the rest of the world and induced the EU, during the resumed session of COP 6, to make a large concession to Japan and the Russian Federation, particularly on the role of forests for their role in sequestration of CO_2 (Hamanaka 2006). In the end, the EU succeeded in achieving political agreement on the key features of the *Kyoto Protocol* such as a flexible (or Kyoto) mechanism and on special funds for the most vulnerable developing countries. The prospect for revitalizing the *Protocol* came in sight at COP 7 in November 2001, when the detailed legal aspects of the *Protocol* were finalized in the Marrakesh accord.

Having obtained more leeway for carbon sinks,[4] the Japanese government began to prepare for ratification of the *Kyoto Protocol*. About one month after EU ratification, the Japanese government finalized its process of ratification on 4 June 2002. In March, prior to ratification, it had also adopted a new policy guideline to alleviate global warming. The special feature of the new guideline is its step-by-step method. There were to be three steps in this policy scheme. During the first period between 2002 and 2004, the government would entrust voluntary reduction efforts to industry. During the second period between 2005 and 2007, the government would review the performance of current policies and, if necessary, introduce legal institutional reforms, including the introduction of an environment tax. Finally, Japan would keep to its international commitment of a 6 per cent reduction (Global Warming Prevention Headquarters 2002). The largest emitter within Japan, which accounts for roughly 60 per cent of the entire CO_2 emissions, is the manufacturing industry. Whereas CO_2 emissions from the manufacturing sector during 1990 and 1999 increased by just 1 per cent, during the same period the household sector increased by 17 per cent and even the transportation sector by 23 per cent. As of 2002, Japan as a whole faced a 7.6 per cent increase in GHG emissions relative to the 1990 level; therefore, it has to reduce emissions by about 14 per cent during the first commitment period of 2008–2012[5]. Under these circumstances, the policy objective of the new policy guidelines, namely, "7 per cent reduction by industry, 2 per cent by households and 17 per cent by transportation,"[6] would be quite difficult, if not impossible to achieve.

To the current trend across different sectors within Japan regarding emissions must be added the new dimension of distributional justice. How to allocate emissions reductions among different industries is a vital issue for some industries, even if utilization of the Kyoto mechanism promises to generate new commercial activities. While some eco-businesses may be able to grasp the opportunity to invent energy saving technologies and use them to open up new markets, others may suffer from the emission regulations. Possible losers are the raw materials industries such as steel, chemical, paper, and cement industries.[7] In addition, some environmental NGOs have begun to stir up the policy debate regarding a carbon tax. The tax would become a legal instrument for distributing reduction costs and responsibilities among the manufacturing, transportation, and household sectors (Tansozei kenkyukai 2002).[8]

Environmental NGOs have good reasons for encouraging policy-makers to seriously discuss the introduction of a carbon tax. As a tool for relatively universal burden sharing, a consumption tax could correct excessive dependence on fossil fuels (CO_2 emissions of the transportation and household sectors are in-

4 Japan's ceiling for forest sequestration of CO_2 as a part of domestic efforts to reduce greenhouse gases was raised to 13 million carbon tons, which in turn enabled Japan to rely on carbon sinks for 3.9 per cent (up from 3.7 per cent) of its target of 6 per cent below the level of 1990 during the period between 2008 and 2012.

5 Japan's GHG emissions in 2005 increased by 7.8 per cent relative to the level of 1990 (Global Warming Prevention Headquarters 2007: 5).

6 Global Warming Prevention Headquarters (2007: 5).

7 "Shosha to haisha" ("Winners and Losers"), *Nikkei ekoloji* (*Nikkei Ecology*), July 2002: 24–37.

8 Carbon Tax Study Group, *An Institutional Design Proposal toward the Early Introduction of Carbon Tax for Promoting Measures to Arrest Global Warming*, 31 March 2002.

creasing more rapidly than for the industrial sector). As for the period between 1990 and 2002, CO_2 emissions increased for all sectors except industry: transportation by 20.4 per cent, commercial by 36.7 per cent, and residential by 28.8 per cent, respectively.

Japanese environmental NGOs are also critical of Japanese government policy, particularly its heavy reliance on nuclear power, innovative technologies, and carbon sinks. The EU and most developing countries were also hoping for more assertive Japanese leadership in mitigating climate change. Japanese leadership could be a crucial force since a country like Japan, which has already achieved the highest rate of energy efficiency among the developed countries, can become a role model for the rest of the world. Nevertheless, the short-term costs of implementing measures for alleviating climate change loom disproportionately large for Japan in comparison with other industrial countries. What, then, would be the rationale for Japan in mitigating climate change should it wish to assume such a role? What have been the major policy discourses on climate change?

88.4 Domestic Climate Change Policy Discourse: Relative Gain versus Absolute Gain

After the Sixth Conference of the Parties (COP 6) to the UNFCCC of November 2000, policy contests in Japan between the *Minister of the Environment* (MOE) and the *Minister of Economy, Trade and Industry* (METI) gradually became more noticeable, particularly over the issues of introducing an environmental tax and emissions trading. There are no clear policy guidelines for the utilization of the Kyoto mechanisms, such as for assigning specific GHG reductions targets to each industry. METI and the energy intensive industries have been unwilling to adopt a policy for a 'cap-and-trade' emissions reduction system, agreeing only to voluntary reduction efforts advocated by Nippon Keidanren (Japan Federation of Economic Organizations). Moreover, METI has not been fully supportive of the idea of imposing an environmental tax. In 2003 when the MOE made public its interim draft report and solicited public views on proposed policies including an environmental tax, the then METI vice-minister criticized the proposal. He stated that it was too early to talk about such a policy in concrete terms and opined that there were other policy options for the arrest of global warming.[9] Shun'ichi Suzuki, then environment minister, countered this argument by stating that the timing was not at all too early, for, should the 2004 policy review arrive at the conclusion that additional measures to arrest global warming were necessary, it would by then be too late to start an inquiry into the introduction of an environmental tax as an economic policy measure.[10]

The MOE policy draft on a carbon (or global warming) tax aiming at its introduction in 2005, was presented in July 2003 to the special committee of the Central Environmental Council, an MOE policy advisory body.[11] The proposed 'global warming tax' was a new category of taxation levied according to the carbon content of fossil fuels such as coal and oil. The imposition of the carbon tax sought a simplification through 'upstream imposition', where the number of taxpayers is small. Referring to the current oil tax and taxes on volatile oils such as benzene and naphtha, the global warming tax would be imposed on importers of crude oil and the manufacturers of petroleum-related products. Taking international competitiveness into consideration, tax reduction measures would be applied to the steel, cement, and other industries, which consume vast quantities of petroleum-based energy.

If a new global warming tax were introduced, even at a modest rate of taxation of 3,400 yen per ton of carbon, it could generate substantial revenue (about 950 billion yen according to the MOE's trial calculation) that could be used to subsidize the implementation of climate change policy (Chuo Kankyo Shingikai 2003: 7). Allocation of this new revenue would be a matter of great interest to all concerned ministries such as Ministry of Agriculture, Forestry and Fisheries, Ministry of Land, Infrastructure and Transport and even METI.[12] In the end, a policy coalition backing the new taxation may attain a majority within policy-making circles, unless a strong drive emerges leading to the utilization of the market system to establish a 'cap and trade' emissions trading system in Japan. However, no global environmental tax has been introduced by the government until October 2009.

On the other hand, the interim report of METI's Industrial Structure Council of July 2003, entitled "Perspectives and Actions to Construct a Future Sustainable Framework on Climate Change", represents the ministry's stance on global climate change (METI

9 *Jiji tsushin sha* (Jiji Press) and *Kyodo tsushin sha* (Kyodo News Service), 17 July 2003.

10 *Jiji tsushin sha* (Jiji Press), 22 July 2003.

11 *Kyodo Tsushin Sha* (Kyodo News Service), 18 July 2003.

2003). While admitting the difficulties for Japan to achieve the emissions reduction target stipulated in the Kyoto Protocol because Japan has already achieved high energy efficiency, the METI report promises government efforts to implement various measures steadily under the new national programme to arrest global warming in a step-by-step approach. Along with recognition of the nature and value of a stable global climate as indispensable to the global public good, the METI report emphasizes the significance of technological breakthroughs in order to cope with the long-term challenge of arresting global warming. For instance, it declares that alternative energy sources (including nuclear energy) capable of replacing fossil fuels and energy-conserving technologies are keys to success even more effective than state-of-the-art technologies. In addition, the dissemination of appropriate existing technologies to developing countries is also essential for successful international efforts to tackle the long-term challenge.

The report also stresses the importance of creating a new international framework in which both the United States (the world's largest GHG emitter), and developing countries (emerging major-GHG emitters), take responsibility for reducing emissions. Accordingly, a truly meaningful climate regime beyond 2012 must take into account each country's energy supply and demand structure. This implies stress on cost effectiveness in the adoption of various policy measures. Reflecting differences in energy supply-and-demand structures, the marginal costs of GHG reductions differ greatly from country to country, from region to region, or from sector to sector. Therefore, it has been suggested that future agreement on the allocation of responsibilities among states must be made fair and just by taking into consideration the different marginal costs of reducing greenhouse gases.

In Japan, both ministries of the environment and the economy regard a stable global climate system as an international public good based on the latest scientific knowledge. For instance, on 28 April 2005, the Cabinet adopted the "Programme for Achieving the Kyoto Target" (hereafter, the 2005 Programme) (Government of Japan 2005) after reviewing the achievements of the 2002 Guideline and incorporating various existing policy measures into climate change policy. The 2005 Programme refers to scientific findings presented in the Third Assessment Report of the Intergovernmental Panel on Climate Change (IPCC) while reporting the increase of Japan's mean temperature by one degree Celsius during the 20th century together with distinctive ecological changes that occurred in Japan (Government of Japan 2005: 1–2). Both ministries recognize Japan's responsibility to mitigate global warming and are willing to help the most vulnerable developing countries to adapt to adverse the consequences of climate change.

While agreeing on the importance of technology, another MOE policy report stresses the absolute gain of global climate change mitigation. A policy report delivered during COP 9 in Milan presented seven points for basic consideration of a climate regime beyond 2012 (Global Environment Committee 2003). This interim report calls, for instance, for continuous progress to meet the ultimate objective of achieving a stabilization of greenhouse gases in the atmosphere "at a level that would prevent dangerous anthropogenic interference with the climate system" (Article 2 of the UNFCCC), bringing the Kyoto Protocol into effect, and achieving global participation including the United States and developing countries. This report goes on to focus on the importance of ensuring equity based on the principle of *common but differentiated responsibilities* (CBDR) (Article 3.1 of the UNFCCC). In order to ensure equity between developed and developing countries based on the CBDR principle, the report calls on the leadership of developed countries to combat climate change and, at the same time, seeks special consideration for the circumstances of developing countries that lack capabilities for addressing climate change. It also calls for taking into consideration different circumstances among developed countries and among developing countries for more equitable burden sharing toward a climate regime beyond 2012.

The policy debate between the MOE and METI reflects international negotiations. Policy-makers concerned with the relative gains and losses involved in order to avoid placing their country in an unfavoura-

12 The budget for the Guideline to Prevent Global Warming in the fiscal year of 2003 was about 1.32 trillion yen in total. The largest amount of about 390 billion yen was allocated to forestry related projects such as forest environment conservation projects. The second largest share of about 320 billion yen was for measures to promote nuclear energy. The third largest amount of about 200 billion yen was allocated to the provision of waste treatment facilities, non-energy source CO_2 and methane emissions reductions through the improvement of water drainage systems in rural communities and the like. In addition, about 126 billion yen were allocated for the establishment of an environmentally friendly transportation system, and about 122 billion for the development of new energy sources (Chuo Kankyo Shingikai 2003: 11).

ble position vis-à-vis other countries (Barrett 2003; Grieco 1990). Although Japan is firmly committed to the reduction of GHG emissions, concerns with the absolute gains of global climate change mitigation are now being contested more overtly than previously by gain-and-loss-concerned industries. All in all, despite some different policy preferences between the MOE and METI, both remained in step with the Japanese government position of supporting the Kyoto Protocol based on sound climate change science.

88.5 Scientific Discourse on Climate Change in Japan

It is not an easy task to trace the scientific discourse on climate change in Japan. It is difficult to identify a clear and united Japanese epistemic community which exerts influence on the climate change policy-making process. The most influential research institutions regarding climate change are two MOE extra-departmental research bodies – the *National Institute of Environmental Studies* (NIES) and the *Institute for Global Environmental Strategies* (IGES), and two METI-affiliated bodies – the *New Energy and Industrial Technology Development Organizatio*n (NEDO) and the *Global Industrial and Social Progress Research Institute* (GISPRI). Other academic associations, including Science Council of Japan, the Japan Weather Association, the Japanese Forest Society, as well as the Society for Environmental Economics and Policy Studies, all endorse IPCC scientific research and findings and the members of these academic communities collaborate with the government in furthering the IPCC's research and peer-reviewing activities. In fact, major governmental policy papers like the 2002 Guideline and the 2005 Programme, endorse the IPCC assessment reports, referring to its major findings. In this context, rather than to attempting to trace the climate change discourse within an authoritative scientific community, it may be more meaningful to ask how IPCC assessments have been treated in Japan's mass media.

One interesting study does just that. Applying the framing analysis approach (Pan/Kosicki 1993), Asayama and Ishii analyze how three major Japanese newspapers portray the IPCC in framing the public debate – including the scientific discourse – on climate change issues (Asayama/Ishii 2009). The three major newspapers are *Asahi*, *Mainichi*, and *Yomiuri Shimbun* (newspapers), whose subscriptions together reach 22 million households, representing 42.5 per cent of all households. According to the Asayama-Ishii analysis during the period from 1988 to 2007, based on reading about 1,206 articles, the IPCC was portrayed as a 'value-free', 'apolitical', and 'rational' scientific assessment body which sounds the alarm for society about the dire consequences of anthropogenic global warming.

Asayama and Ishii emphasize that the Japanese media, including the three major newspapers, share the same information from the concerned ministries. The information from the IPCC is no exception. In Japan, the *Ministry of Education, Culture, Sports, Science and Technology* (MEXT) and the Japan Meteorological Agency are in charge of subjects dealt with under Working Group I (WG I: physical scientific assessments) of the IPCC; MOE is in charge of WG II (impacts, adaptation and vulnerability); and METI is in charge of WG III (mitigation of climate change). Since Japanese scientists and technicians are closely working with the concerned governmental departments, no serious scientific debate is being carried out among scientists and policy-makers in Japan. Thus, Asayama and Ishii suggest, on the contrary, the danger of the 'scientific monopoly' of the IPCC. The physical, social and economic assessments of the IPCC reports and the impact of climate change are in fact not necessarily 'purely' scientific and 'absolutely' free from political bias. The mass media tends to accept the IPCC assessments uncritically and its projection of the IPCC images as an 'impeccably' scientific and 'apolitical' authority could even be harmful to a sound public debate on the issues of climate change, lacking a more broad-based view of the social and political aspects of the IPCC assessments.

In sum, it is fair to conclude that, at least before the recent regime change in Japan, the scientific debate on climate change exerted little influence on the Japanese climate change policy-making processes.

88.6 Japan's Domestic Politics and Diplomacy Beyond the Kyoto Process

Recent Japanese climate change policy has been reactive and lacklustre, as the domestic political climate has been stormy and changeable since the 65-month coalition government led by Prime Minister Junichiro Koizumi ended. The successive administrations led by Shintaro Abe, Yasuo Fukuda, and Taro Aso were all short-lived and unstable, plagued by political scandals, parliamentary impasses, and internal party political

turmoil. These administrations, which came to power without general elections, also suffered from low approval ratings.

After formation of the Abe Cabinet on 26 September 2006, the government pursued a conservative political agenda, inheriting from the previous Koizumi Cabinet a more than two thirds majority in the House of Representatives (the Lower House) and the majority at the House of Councillors (the Upper House). The conservative agenda included the National Referendum Law (enacted on 14 May 2007), which established for the first time procedures for initiating revisions to the Japanese Constitution promulgated in 1946 (known as the 'Peace Constitution').

The Abe administration also showed interest in the issues of global climate change. Abe was eager to create a new framework beyond the Kyoto process in which the entire world would participate in emissions reductions. In May 2007, he announced the new climate change initiative 'Cool Earth 50'. The proposal has three pillars.

- The first pillar sets forth a long-term strategy for reduction of GHG emissions globally. It proposes a long-term target for reducing global GHG emissions to half from the current level by 2050 as a common global goal. The proposed solutions include the establishment of innovative technologies, the creation of a 'low carbon society', and a national campaign for energy conservation.[13]
- The second pillar is composed of three principles for establishing an international framework to address global warming beyond the Kyoto process. The first principle calls on all major emitters' participation in an international framework beyond 2012. The second principle stresses the importance of the flexibility and diversity of a new framework, taking different circumstances of each country into consideration. Thirdly, such a framework should be able to cope with both environmental protection and economic growth by fully utilizing energy conservation technologies and other best-available technologies. Concrete measures to realize these three principles include the creation of a new financial mechanism for developing countries, the dissemination of energy conservation technology throughout the world, and promotion of the safe and peaceful use of nuclear power with the provision of assistance such as infrastructure development for developing countries.[14]
- The third pillar of 'Cool Earth 50' is a national campaign for achieving the Kyoto Protocol target. This policy proposal expresses the Japanese government's determination to achieve its Kyoto commitment to reducing GHG emissions by 6 per cent. The government planned to promote its initiatives and urge municipalities and major business entities to accelerate their actions for emissions reduction. A national campaign called for efforts and creative ideas for reducing GHG emissions by one kilogramme per person per day while making 'Cool Biz' (casual dress, without tie and jacket, for men) the standard practice in summer.[15]

Despite the role that Abe played in getting the statement of "considering seriously . . . at least a halving of global emissions by 2050" into the communiqué of the Heiligendamm G8 summit, his sudden resignation left that policy line to drift without a leader. Various cases of political corruption by Abe's Cabinet appointees including the involvement of three ministers of *Agriculture, Forestry and Fisheries* (MAFF) in political funding scandals took a heavy toll on the Cabinet and substantially lowered its approval ratings. The heaviest blow to his Cabinet, however, was the crushing defeat to the LDP, Abe's party, in the election of the Upper House on 29 July 2007. As the result of this election the ruling coalition parties of the LDP and the Clean Government Party (New Komeito) lost substantially, whereas the DPJ significantly increased its seats so as to make it the leading party in the Upper House.[16] Although Abe did not immediately resign, taking responsibility for this historic electoral defeat, he later gave up his post after reshuffling his Cabinet. After a brief political vacuum, the LDP chose Yasuo Fukuda as its new party leader (and prime minister), who was not such a strong political leader as Koizumi. Without a strong leadership Japan could hardly be expected to play a significant role in the negotiations at COP 13 in 2007 in Bali. Japan took sides with the United States and developing countries in opposing

16 *Kyodo Tsushin News*; at: <http://topics.kyodo.co.jp/feature38/> (16 December 2007).

the introduction of mid-term numerical targets in the so-called 'Bali roadmap' [*Bali Action Plan* (UNFCCC 2007d)]. Germany, on the other hand, proposed a reduction of greenhouse gas emissions by 40 per cent compared to the 1990 levels by 2020 (Gabriel 2007). This was a more ambitious target than the EU's proposal of 20 per cent reduction by 2020.[17] The final text of the *Bali Action Plan*, however, lacks any binding commitments; instead the delegates from 187 countries agreed to conclude a new accord in 2009 that will require "deep cuts in global emissions" (UNFCCC 2007d).

During the Bali Conference (COP 13), one of the Japanese governmental side events demonstrated the clear influence of established and energy-intensive Japanese industries such as steel, cement, transportation, and electric power.[18] These industries constitute the core of Nippon Keidanren, the umbrella organization for major Japanese industries and businesses. The preponderance of the METI and energy-intensive industries policy alliance permeated the process of the G8 Toyako Summit in July 2008. The Japanese government did not press the G8 leaders to negotiate numerical targets for a mid-term scheme with persuasive arguments for the sectoral approach to emission reductions as a viable policy option. Critics and environmental NGOs consider the G8 Toyako Summit a failure since it did not result in agreement on the establishment of mid- and long-term numerical targets. The government sought to give a good account of itself by declaring that all major GHG emitters, including the United States, China, India, Brazil and Mexico, recognized the need for substantial emissions reductions by 2050. But this is like saying 'a miss is as good as a mile'. The outcome of the G8 Toyako Summit did not generate the desired tailwind for the international community, especially, for COP 15 in December 2009 in Copenhagen, where an international framework beyond the Kyoto process will be decided on.

Within a year, Prime Minister Fukuda, who suffered from low approval ratings, gridlock in the Diet, and economic recession, abruptly resigned his position on 1 September 2008, again creating a power vacuum. Taro Aso defeated four candidates to become LDP President in the party's election. He was elected prime minister on 24 September 2008 thanks to the Koizumi-era legacy of a ruling coalition of a two thirds majority in the Lower House. Aso's main mission was to win the next general election expected held a few months later. However, soon after taking office, mainly because of various political gaffes, inconsistency, as well as halting and incoherent responses to the global economic recession, Aso suffered from chronically low approval ratings. He has also lacked leadership qualities. He did not manage to dissolve the Diet while the LDP had the upper hand over the DPJ before his term as prime minister expired in September 2009. He was forced instead to plunge into the 'suicidal' general elections of 30 August 2009 in the wake of major LDP defeats in the 12 July 2009 Tokyo Metropolitan Assembly elections, which is often taken as a barometer of the outcome of general elections.

Against the backdrop of Japan's unstable domestic political atmosphere, on 10 June 2009 Aso announced Japan's climate change policy for the mid-term target. According to this new policy, by 2020 Japan will reduce GHG emissions by 15 per cent from the 2005 level. This target is one per cent more 'ambitious' than the 14 per cent reduction, a strong candidate as a mid-term target among the six reduction targets deliberated in government decision-making procedures. The final governmental decision of a 15 per cent reduction target from the 2005 level fell far short of the IPCC reference point for a mid-term target: that is, between 25 and 40 per cent in GHG reductions from the 1990's levels referred to in the Bali Action Plan. Aso defended the figure, emphasizing that the Japanese plan excludes purchase of emissions credits from abroad and forest sequestration of carbon dioxide, both of which are included in the EU plans calling for a 20 per cent reduction below the 1990 levels.[19] The Japanese government also considered it crucial to ensure the United States participa-

17 Communication from the Commission, "Limiting Global Climate Change to 2 degree Celsius: The way ahead for 2020 and beyond" [COM (2007) 2 final]; at: <http://europa.eu/cgi-bin/etal.pl> (5 December 2007).

18 A Japanese governmental side event entitled "Road to Hokkaido Toyako Summit: Message from Japan as a G8 Host Country in 2008," held on 10 December 2007 at COP 13, was composed of panelists representing all energy-intensive industries endorsed by MOFA's Ambassador for Global Environmental Problems and MOE's Vice Minister of Global Environmental Affairs. The proposed policy outlined a bottom-up approach under a voluntary reduction scheme differing according to each industrial sector.

19 "Greenhouse Gas Reduction," in: *The Japan Times Weekly Online*, 20 June 2009; at: <http://www.japantimes.co. jp/weekly/ed/ed20090620a2.htm> (18 July 2009).

Table 88.1: Six options for Japan's mid-term target. **Source:** Naikaku kanbo (Cabinet Secretariat, 17 April 2009).

	Main Features	Reduction in 2020	
		Above/below 1990 (per cent)	Above/below 2005 (per cent)
Case 1	Spontaneous renewal of machinery/equipment based on existing technologies according to *Long-term Energy Demand and Supply Outlook* – Japan's reduction goal comparable to U.S. and EU goals (in terms of marginal abatement cost)	+4	-4
Case 2	Equivalent of Japan's share of 25 per cent reduction (below 1990) of developed countries' total average reduction rate allocated on a basis of equal marginal abatement cost	-5 ~ +1	-12 ~ -6
Case 3	Revision of *Long-term Energy Demand and Supply Outlook* (with voluntary maximum possible introduction of optimally energy-efficient new machinery and equipment)	-7	-14
Case 4	Equivalent of Japan's share of 25 per cent reduction (below 1990) of developed countries' total average reduction rate allocated on the basis of equal cost as a percentage of the GDP	-17 ~ -8	-23 ~-13
Case 5	Stepped-up or mandatory introduction of new machinery and equipment (with all new machinery and equipment introduced being optimally energy-efficient, and mandatory partial replacement of existing machinery and equipment)	-15	-22 ~ -21
Case 6	A single common reduction rate (25 per cent reduction below 1990 levels) for all developed countries with a mandatory replacement of all machinery and equipment with optimally energy-efficient new machinery and equipment	-25	-30

tion in mid- and long-term commitments to GHG emission reductions. The US government now refers to a 14 per cent reduction below the 2005 level, so, as maintained by environment minister Tetsuo Saito, the Japanese government coordinated with the U.S. in setting its own mid-term target.[20] In any case, if the Kyoto Protocol's 1990 benchmark is applied to Japan's 15 per cent mid-term reduction target from the 2005 level, it is equivalent to only 8 per cent reduction below the 1990 level.[21] Environmental NGOs, such as the *World Wildlife Fund* (WWF), immediately criticized the Japanese mid-term target, arguing that it "completely lacks ambition," declaring that Japan will stand in the way of global climate change negotiations in Copenhagen in December 2009.[22]

The domestic policy discourse has to be taken into account to understand the Japanese policy options, particularly the debates over the six options for Japan's mid-term targets. In February 2008 the "Informal Gathering for the Discussion on Issues of Global Warming" (Chikyu Ondanka Mondai Kondankai: hereafter Kondankai), which deals with various issues regarding a low-carbon society, was established under the aegis of the Cabinet Secretariat. The Kondankai established the Mid-term Target Committee in October 2008 to scrutinize various mid-term reduction targets and generate policy proposals for the government. The Mid-term Target Committee conducted scientific studies and analysis of policy options and proposed six options for Japan's mid-term targets on 14 April 2009 and the Kondankai collected public comments about these targets as of 16 May 2009. The six mid-term targets are: -4 per cent (case 1), -12 to -6 per cent (case 2), -14 per cent (case 3), -23~ -13 per cent (case 4), -22~-21 per cent (case 5) and -30 per cent (case 6) below the 2005 level (table 88.1).

As represented in the position announced by Nippon Keidanren (2009), the energy-intensive industries and their labour unions responded to the invitation to public comments by selecting option one (case 1), the

20 Eric Johnston, "Saito Defends Midterm Plan for Greenhouse Gas Reduction", in: *The Japan Times*, 25 June 2009.

21 "Greenhouse Gas Reduction", in: *The Japan Times Weekly*, 20 June 2009.

22 WWF, "Japan's Emission Reduction Target Makes Global Agreement Harder", 11 June 2009; at: <http://www.ecoseed.org/index.php/general-news/features/in-depth/2715> (18 July 2009).

option that was chosen by 74.4 per cent of about 10,000 public comments. The main reasons for this choice include the maintenance of international competitiveness, setting up fair and equitable mid-term targets comparable to those of the EU, the U.S., and others, and the need to scrutinize the feasibility of the mid-term targets so as not to place a heavy burden on the Japanese economy (Naikaku kanbo 24 May 2009a: 2–3). Needless to say, environmental NGOs, representing about 13 per cent of the respondents, favoured option six (case 6). These respondents considered substantial reductions as a scientific imperative. They also pointed out that ambitious targets are necessary for Japan to take a leadership role in the promotion of developing countries' participation in GHG emissions reductions so as not to leave an excessive burden to future generations (Naikaku kanbo 24 May 2009a: 2–3).

Besides soliciting public comments, the Kondankai also conducted a public opinion poll on mid-term targets.[23] 15.3 per cent of the respondents favoured -4 per cent below the 2005 level (case 1), and 4.9 per cent chose -30 per cent (case 6). The most appealing option was the 14 per cent reduction option (case 3) chosen by 45.4 per cent of the respondents. It should be mentioned that 13.5 per cent opted for -21 per cent. The government decision on the mid-term target mentioned above thus reflected the result of this public opinion poll.

88.7 Conclusion

Recent international negotiations over mid- and long-term reduction targets have been bogged down over the distribution of burden sharing – over who's use is to be reduced by how much. Individual country concerns for cost-benefit calculations began to dominate the domestic and international policy discourses. In Japan the argument that marginal abatement costs would be relatively high compared with those in the EU and the United States has dictated the climate change policy discourse. The lack of strong and stable political leadership has allowed the relatively well-organized economic interests and the economy ministry to solidify their policy coalition. Thus, despite its natural position as a vital force in climate change negotiations, Japan has relinquished both its leadership and its initiative. Instead, it has withdrawn into the role of an 'intermediate' and 'supportive' state.

Japan's political landscape changed dramatically with the landslide victory of the DPJ in the general elections of 30 August 2009, resulting in forming the ruling coalition government with the *Socialist Democratic Party of Japan* (SDPJ) and Kokumin Shinto (People's New Party).[24] As is argued in this chapter, strong political leadership is the key for Japan to advocate an ambitious mid-term GHG emission reduction target. Prime Minister Hatoyama refers to "the introduction of a domestic emission trading mechanism, a feed-in tariff as well as a consideration of a global warming tax" in Japan's statement at the UN Climate Change Summit in September 2009.[25] However, there are already strong voices of dissent rising within Japan against Hatoyama's DPJ 25 per cent reduction target. One such voice attacks the premise of Japan's DPJ leadership in promoting international cooperation by proclaiming an ambitious mid-term target since developing countries are demanding that developed countries assume a 40 per cent mid-term reduction and that the prospect of the passage of a similar bill to the Waxman-Markey bill at the US Senate on climate change is not bright.[26]

The Hatoyama administration policy discourse may introduce different domestic and international policy priorities. What kinds of policy networks will emerge with a new administration among the various bureaucratic branches and business and industry associations? How open will the new government be to the general public? How attentive will it be to the scientific community and environmental NGOs? These questions are beyond the scope of this chapter, but it should at least be noted that the main slogan of the DPJ is to break down the entrenched structures of vested interests that plague Japanese politics.

23 This survey was conducted from 5 May to 17 May and obtained 1,222 valid answers out of 4,000 people above 20 years old selected according to simple random sampling.

24 Although the DPJ obtained 308 electoral seats out of 480 at the Lower House, it has not held the majority at the Upper House, where the DPJ needs to maintain a policy alliance relationship with the SDPJ and Kokumin Shinto.

89 Implications of Equity Considerations and Emission Reduction Targets: Lessons from the Case of Japan's Mid-Term Target

Norichika Kanie, Hiromi Nishimoto, Yasuaki Hijioka and Yasuko Kameyama

89.1 Introduction[1]

Unlike in the Kyoto Protocol, emission reduction targets for individual countries in the 'Copenhagen Accord' contain a list of pledges without international negotiation. As a result, whether or not international negotiations on QERLOs (*Quantified emission reduction and limitation objectives*) can actually be adopted in a post-2012 climate change governance architecture remains uncertain. However, after the COP15 of the *United Nations Framework Convention on Climate Change* (UNFCCC) in Copenhagen, it is clear that several countries are concerned about a situation where only they would have to take on the 'extra burden' of reducing GHG emissions, implying additional costs compared with their economic competitors. The business and industrial sectors are particularly concerned about an agreement with unbalanced QERLOs between and among developed countries and emerging economies. Thus, many pledges on emission reduction targets under the 'Copenhagen Accord' were made under the condition that they are only bound to their commitment if others adopt comparable (or equal) emission reduction obligations.

A key question is what a comparable effort means? In other words, what could be the criteria for measuring equal emission reduction targets? Given the current economical, social, and political inequity in the world as well as different interests of nation states, such an issue may never result in a consensus as a result of international negotiations. But it would still be useful to learn that there are different ways of defining 'equity', and that implications of the difference may sometimes lead to a larger difference in concrete target numbers than existing studies have argued. Therefore, policy analyses should pay more careful attention to the concepts and processes of numerical calculation of equity and fairness, as spaces for value judgements exist in there but tend to be overlooked in the science policy interface.

This chapter addresses the Japanese case of mid-term target setting to show how the calculation results differ if alternative equity criteria and formula are used (89.2, 89.3). It then identifies problems associated with the allocation issue and draws some lessons for international negotiations on QERLOs for the post-Copenhagen period (89.4).

89.2 Approaches to Allocate GHG Emission Reductions

Before reviewing the Japanese case an overview on approaches to allocate GHG emission reductions is appropriate. The allocation of GHG emission reductions among countries was discussed in the negotiations prior to and after the Kyoto conference (1997). It is also referred to as the emission (reduction) differentiation or the 'burden-sharing' issue. The reference to "common but differentiated responsibility" has served as the principle for the differentiation in the *United Nations Framework Convention on Climate Change* (UNFCCC), but translating this principle into concrete national emission reduction targets by numbers has been a challenge, both methodologically and politically.

Conceptual allocation principles for GHG emission reductions could be categorized using three

broad criteria: a) the combination approach; b) responsibility, capability, or ability; and c) efficiency or the potential to mitigate.[2] The responsibility criteria focus on the extent to which each country is responsible for climate change. The Brazilian proposal, or the historical responsibility approach, allocates national emission limitation objectives by focusing on each country's historical responsibility for the global temperature increase (La Rovere/de Macedo/ Baumert 2002).[3] It is also based on the 'polluter-pays principle'.

Although the original proposal was first presented during the Kyoto negotiations – but was not adopted to decide the final allocation formula due to its complex methodology for determining the responsibility for each developed country – the main element survived, and its scientific investigation continued within the *Subsidiary Body for Scientific and Technological Advice* (SBSTA).[4]

Under this calculation, countries that industrialized earlier, such as the United Kingdom, would face higher emission reduction allocation targets than others, such as rival developed countries that developed later, e.g. the United States and Japan. But there has always been a methodological question when to start the calculation, how to mirror the carbon cycle in the model, including land-use changes, the reliability of data for the past 100 years, as well as the question of whether the emitters may be accused when they were unconscious about the consequences of their actions. In the negotiation process, Brazil and China still consider the historical responsibility as the criteria for emission reduction allocation targets after the year 2012.

Another approach focuses on the per capita emissions. Although currently the figures on emissions per capita differ between developed and developing countries, this approach dictates that they should be equalized eventually. This approach stems from the idea that the Earth's atmosphere is a global commons, and all humans are equally entitled to use it. An approach called 'contraction and convergence' (C&C) represents this approach, although some variations exist (Aslam 2002; WBGU 2003; den Elzen/Meinshausen 2006). In this approach, countries commit to converge their per capita emissions in a certain year, such as 2050 or 2100, towards which the global emission profile contracts. Future projections of population and emissions depend on the path drawn, and therefore any calculation inevitably contains uncertainty, but these data are rather popularly used and well developed compared to other data. In the negotiations, the majority of countries from the 'G77+China', but e.g. also Switzerland, support C&C as an allocation criterion. There are still other examples of allocation approaches focusing on responsibility, such as absolute emissions or their trends.[5]

The capability, or ability, to pay is an allocation approach focusing on the economic aspect of climate change. The absolute amount of the *gross domestic product* (GDP) could be a criterion under this approach. Some others focus on per capita GDP. Although positions are not yet finalized, New Zealand and Canada argue that costs relative to GDP could possibly be an allocation criterion, while Canada also points to loss of effectiveness (income decline). Still another calculation focuses on the *human development index* (HDI) as a source of presenting the ability to pay, or using a combination of these criteria. Jacoby, Schmalensee and Wing (1999) applied the ability approach to argue that the parties to the UNFCC only enter the emission reduction phase once they have exceeded a certain level of per capita welfare, called the welfare 'trigger'. Otherwise, they would follow their reference emissions (unconstrained no-policy emissions).

The third criterion focuses on the efficiency of actions to reduce emissions in terms of economic activity. This can also be called the potential to mitigate.[6] Approaches that stem from this criterion focus on the emission reduction potential. A typical example of this approach is a Japanese proposal to equalize the *marginal abatement costs* (MAC) of emissions among industrialized countries, thereby keeping the allocation fair in terms of economic competitiveness across countries (Hanaoka/Hibino/Miyashita/Akashi/ Mat-

3 The original Brazilian Proposal during the Kyoto negotiations included other elements such as the Clean Development Fund (CDF), but we focus here on the element of the differentiation aspect of the proposal. For more detailed account of the Brazilian Proposal, see La Rovere, de Macedo and Baumert (2002).

suoka/Fujino/Kainuma 2006; Akimoto/Sano 2008). The calculation of MAC requires careful modelling, and currently it is difficult to calculate the domestic emissions of all countries for the long term, such as up to 2050. Therefore, this approach can only be used for medium-term emission allocations, and not for long-term target-setting for individual countries. Another way of translating the efficiency of emission reductions into a calculation formula uses the emissions per GDP. Although this does not guarantee to limit GHG emissions, it secures economic activity while paying attention to GHG emissions. The same could be applied to emissions per unit of production.

As these three criteria do not represent a comprehensive translation of the concept into a quantified calculation, and a conceptual principle such as 'common but differentiated responsibility' would entail a few different aspects, combinations of approaches have also been proposed, such as the 'Triptych approach'. It was first presented in early 1997 at a workshop held in Zeist, The Netherlands, prior to the Kyoto Conference, and was used for internal European Union emission reduction allocations for the Kyoto target. It was a combination of an EU-wide abatement target and a proposal for an internal emission allocation mechanism.

Its main characteristic was its sectoral approach, but it used different criteria for each sector. Each member state was divided into three sectors: the domestic sector, the energy-intensive export sector, and the electricity generation sector. An emission reduction target for each country was then set by adding up the potential for emission reduction in each sector. For example, a per capita convergence approach was applied to the domestic sector, while an efficiency criterion was applied to the energy-intensive sector, and a tailor-made approach considering national circumstances was applied to the electricity sector (Gupta/Jepma/Blok 1998; Phylipsen/Bode/Blok/Merkus/Metz 1997). It was further developed after Kyoto, and version seven of this approach now expands to a global scope and more than three sectors (den Elzen/Höhne/Moltmann 2008).

A similar combination approach includes multi-sector convergence. This multi-stage approach is another kind, whereby countries are divided into four or five categories depending on their level of economic development, and any emission reduction commitment would be enhanced once across the threshold. The commitments vary from business-as-usual, to emissions per GDP, to per capita emissions convergence.[7]

An interesting attempt was made by den Elzen, Höhne, Brouns, Winkler and Ott (2007), in which explicit attempts were made to translate the qualitative approach of beyond-Kyoto architecture into a quantitative multi-stage approach. The three criteria described earlier were used here. Cumulative per capita emissions of fossil carbon dioxide (CO_2) over the period from 1990 to 2000 were used as a proxy for responsibility criteria in the original approach, which is then translated into cumulative energy CO_2 emissions per capita from 1990 onwards divided by the number of years summed up. In order to secure an equal weighting potential to mitigate emissions, a weighting of one third was used. The *human development index* (HDI) and the GDP were used as capacity indicators, which were then translated for calculations into GDP in purchase-power parities per capita with a weighting of one-third. Finally, the potential to mitigate was expressed in the original proposal as the intensity of emissions and emissions per capita, which was translated into energy GHG emissions per GDP and all GHG emissions per capita, both with a weighting of one-sixth (den Elzen/Höhne/ Brouns/Winkler/Ott 2007).

On the practical side, the *European Community* (EC) communication addressed to the Copenhagen negotiations of 28 January 2009, also applies a multi-criteria combination approach. It includes per capita GDP as an ability criterion, per GDP emissions as an efficiency criterion, the emission trend between 1990 and 2005 as a responsibility criterion, and the population trend between 1990 and 2005.

Using different criteria results in different emission reduction allocations for individual countries. The commonly cited figure of a 25 to 40 per cent GHG emission reduction for developed countries to meet the 450 *parts per million* (ppm) CO_2-equivalent atmospheric GHG concentration stabilization level, which was presented in box 13.7 of the report of Working Group Three in the IPCC's Fourth Assessment Report, is also based on a review of the results of calculations made by allocation schemes applying these different criteria (Metz/Davidson/Bosch/Dave/Meyer 2007; den Elzen/Höhne 2008). The range of a 25 to

Table 89.1: Climate change targets for an international agreement and for Japan as of March 2010. **Source:** Compiled by the authors.

	International agreement	Japan
Ultimate goal	2 Copenhagen Accord (2009) and G8 (2009)	
Long-term global	Global 50% reduction by 2050 (G8:2007/2008)	2007 May: PM Abe (LDP) – 50% by 2050
Long-term national (AI)		2008 January: PM Fukuda (LDP) 60-80% reduction – 80% by 2050
Mid-term global (AI)	[25-40% AI / Substantial deviation from BAU NAI mentioned in LCA-KP]	
Mid-term National	Copenhagen Accord Pledge	2009 Sep: PM Hatoyama (DP) – 25% in 2020 from 1990 level (2009 June PM Aso (LDP): -15% from 2005 level (-8% from 1990)
Short-term global	KP 5.2% for AI	KP 5.2% for AI
Short-term national	KP binding	KP -6% from 1990 level

40 per cent reduction relies partly on the use of different allocation formulas. Those used for its background papers that produced this figure are a) C&C, *common-but-differentiated convergence* (CDC),[8] b) the multi-stage Triptych approach, c) equal improvement of emissions per GDP, and d) minor variations of these. However, they also argue that the allocation formula, which comes from different conceptual assumptions, is less important than are model assumptions and emissions stabilization levels and paths in determining QERLOs for a particular year. These authors challenge this argument by introducing the case of Japan, and they argue that allocation concepts and forms also matter to a great deal.

89.3 Allocating GHG Emissions: The Case of Setting Japan's Mid-Term Targets

Different allocation principles produce different consequences for each country's emission allocations; sometimes the large differences also have political and economic consequences. Therefore, a careful and discreet consideration is necessary when a principle is translated into a calculation formula, because they do not necessarily correspond one by one, and there remains room for different interpretations. Although an existing study argues that what matters more is the global emissions reduction path rather than allocation schemes (Criqui/Kitous/Berk/den Elzen/Eickhout/Lucas/van Vuuren/Kouvaritakis/Vanregemorter 2003), allocation schemes do matter for some cases, and such a difference is more than marginal in the contest of the international negotiation process, because countries make equity arguments in international negotiations based on the allocation criteria on which their arguments rely. In this section the introduction of Japan's mid-term target-setting process in spring of 2009 is discussed.[9]

In autumn 2008 the Cabinet Office of the Japanese government launched a process to review mid-term targets for Japan for 2020. In this process approaches to equitable GHG emission reduction allocations among countries were referred to, as part of preparations for the upcoming Copenhagen negotiations. As is shown in table 89.1, long-term, mid-term, and short-term targets for GHG emission reduction had gradually been set at various levels, but Japan was missing a mid-term target, which had been considered as one of the key issues to be discussed in Copenhagen.

The mid-term target committee meetings were held seven times between 25 November 2009 and 14 April 2009, and detailed calculation was tasked out in a sub-committee.[10] The then-ruling government led by the *Liberal Democratic Party* (LDP) put the efficiency

8 CDC is an application of C&C in which developing countries can increase emissions up to the level of average global emissions, and then reduce emissions to the convergence level taking the same period as the developed countries.

9 In August 2009 there was a change in Japanese government. Consequently, the medium-term target was changed to a 25 per cent reduction of GHGs in 2020 from 1990 levels. Note that this case study deals mainly with the target-setting of the former administration that set a target of an 8 per cent reduction in 2020 from 1990 levels (15 per cent from 2005 levels).

criterion at the heart of the allocation principle. The equal mitigation potential was evaluated by means of *marginal abatement cost* (MAC), but equal per GDP abatement cost was also calculated in addition as a 'side story' to the main calculation. Calculations were made by a few research institutes that are usually working with the ministry of economy, trade and industry (METI), and the ministry of environment. As the meetings carried on, it was clarified that differences in data and assumptions set by different institutes led to different results. They tried to consolidate them, where relevant. However, some of the gaps were originated from different requirements and supports made by different ministries and some of the gaps remained in existence, although they were made clear as much as possible. The result of the calculation is shown in table 89.2. These are calculated by emulating the domestic emission reduction potential, provided that the same amount of money would be spent on mitigation actions in each country. In other words, they disregard the global GHG emission reduction path for the longer term, and just look at a point in time, in this case, for 2020. In this sense, this approach is not one of resource allocation, but a bottom-up calculation of an economically feasible action by each country. The resulting numbers were slightly different from a research institution to the other, but it looked pretty much the same as is shown in table 89.2.

Table 89.2: GHG emission reductions by countries and regions by 2020. **Source:** The result of the analysis was made based on the AIM/Enduse [Global] Model; at: <http:// www.kantei.go.jp/jp/singi/tikyuu/kaisai/dai07tyuuki/07gijisidai.html> (14 April 2009).

	Japan	USA	EU25	Russia	Annex I
Equalize MAC	−5%	−24%	−27%	−32%	−25%
Equalize cost per GDP	−17%	−18%	−31%	−31%	−25%

The authors believe that taking such an approach alone is problematic taking into consideration the objective of UNFCCC as set out in its Article 2, because the Earth's climate is considered a global commons and, the allocation of benefits, responsibilities, and involuntary risks between countries and actors is required for proper management. The more general, interdisciplinary notion of allocation advanced here refers to the allocation of resources and rights among individuals and groups within and between societies, and such a concept is often opposed to conventional economic theory, where allocation is broadly understood as an allocation of input factors for production processes.

We therefore re-evaluate the allocation used for the Japanese government's calculation, using other criteria on the basis of the different idea of allocation. The assumption for the Japanese government study was a 25 per cent emission reduction for Annex I (developed) countries, so our calculation also used this condition. Three allocation formulas were employed, which were also applied in some of the background papers used to create the information in box 13.7 in the IPCC's Fourth Assessment Report. For the responsibility criterion, the authors used the C&C formula as a proxy to this principle, with converging years of 2050, 2075, and 2100.[11]

In addition, the authors employed another formula on efficiency criteria. As opposed to MAC, we used an equal improvement of the emissions per GDP throughout the world. In other words, an equal emission intensity improvement rate is applied in this calculation. In all cases, they estimated a condition of halving global GHG emissions by 2050 from the 1990 level, as this is Japan's and the G8 target, which also includes Japan, and the Kyoto Protocol's reference year emissions were applied for these calculations. All calculation results are shown relative to emission reductions against the 1990 levels.[12] The result of the calculation is shown in table 89.2.

10 See at: <http://www.env.go.jp/earth/ondanka/mid-target/exam_prog.html>.

11 *Contraction and Convergence* (C&C) is explained as follows. "Contraction refers to the 'full-term event' in which the future global total of *greenhouse gas* [GHG] emissions from human sources is shrunk over time in a measured way to near zero-emissions within a specified time-frame. The example shows 90 per cent by 2100. Calculating future emissions contraction on the basis of concentrations and sink evidence is a non-random way of responding to the objective of the UNFCCC. Convergence refers to the full international sharing of the emissions contraction-event, where the 'emissions-entitlements' for all countries result from them converging on the declining global per capita average of emissions arising under the contraction rate chosen. Converging at a rate to be agreed – the example shows 2030 – is a non-random way of responding to the principle of 'equity' in the UNFCCC, whilst still meeting its objective." Source at: <http://www.gci.org.uk/>.

Table 89.3: Emission allocations by 2020 based on different formulas. **Source:** The authors.

		Japan	USA	EU25	Russia	AnnexI	Non AnnexI	World
C&C (year of convergence)	2050	–16%	–13%	–26%	–46%	–25%	74%	14%
	2075	–20%	–9%	–28%	–48%	–25%	74%	14%
	2100	–21%	–8%	–28%	–49%	–25%	74%	14%
Equal emissions improvement per GDP		–30%	–19%	–33%	–21%	–25%	74%	14%

89.4 Discussion

The above exercise shows that even if the emission reduction rate for developed countries (Annex I) as a group is the same 25 per cent from the 1990 level, the allocation principle and formula change the required amount of emission reductions for individual countries within Annex I countries. For example, Japan's reduction by efficiency criteria, using MAC calculation, is –5 per cent, whereas C&C with converging year 2010 shows –16 per cent in the same year. Similarly, the reduction for the US is –24 per cent in the former case, but it is –13 per cent in the latter.

The cause of such a rather large difference has three levels. One level is a difference in the allocation principle, whether it takes responsibility, capability, or efficiency. The second level is a difference in the allocation formula under the same allocation principle, and the other is a different calculation criteria used under the same allocation formula, such as the difference in the year of convergence.

The gap between the conceptual principle and the quantified allocation formula used to materialize the principle, in terms of the numbers, exists partly because most if not all of the principles employed in the international regimes are established as a result of international negotiations in the form of a consensus document. In a sense, this blurred nature of the overarching principle is the very reason why such principles were agreed upon by a consensus of more than 190 countries, but it leaves space for different interpretations, and triggers the use of different allocation formulas, as well. This is also a space where value judgments may intervene, and thus a space where political and policy interpretations may come into place.

In the calculation used to produce Japan's mid-term target, there are differences in the reduction targets derived from calculating *marginal abatement cost* (MAC) and calculating *equal emissions improvement* (EEI) per GDP, even though both are considered to represent the efficiency criterion, or the potential to mitigate. In particular, Japan's target for MAC is -5 per cent, while it is –30 per cent for EEI. For the USA and EU, –24 per cent and –27 per cent for MAC respectively, whereas –19 per cent and –33 per cent for EEI. This means that the allocation formula, or the way the allocation principle is translated into a formula, matters greatly, as does the allocation principle.

In the case of Japan's mid-term target setting process, the government commissioned the Committee to apply specific calculation methods that would represent the most favourable results for Japan compared to its economic rivals. The cabinet, then, led by LDP, chose the MAC calculation formula as the main method of allocation calculation without a wide and deep discussion prior to its adoption. When the LDP was defeated in August 2009 in the general elections the *Democratic Party of Japan* (DPJ) took over. Soon after taking office, in September 2009 the new Prime Minister Hatoyama announced as the new mid-term target for Japan a 25 per cent reduction in 2020 based on the 1990 level, as the DPJ had promised during the election campaign, which is far more ambitious than the prior one. Since the announcement of the new target, it seems that the new government has not followed the same calculation formula as the former cabinet to legitimate the new target. Even when verifying the domestic feasibility of the target, they asked to recalculate the former ones under their guidance.

This process shows that there is a space for political interpretation of the equity and fairness calculation. Without a political interpretation, there is space

12 As total global emissions in 2020 are estimated to be 14% above 1990 levels, this falls into the range of scenarios below 450 ppm of CO_2-equivalent in Box 13.7 of the IPCC AR4. This allocation can also be considered as being relevant for the same scenario category (see den Elzen, Höhne and Moltmann 2008).

for an exercise requiring other scientific disciplines, such as ethics and qualitative research. The calculation itself could be a rigorous and science-based one, but it is also a task of science to reveal the extent to which science can deal with, and to which it can not. This exercise in Japan contributed to clarify this point.

In addition, MAC deals only with allocation among Annex I countries, partly due to limited data availability. In contrast, although total Annex I reductions are the same 25 per cent as with the MAC case, EEI allows calculations to be done for non-Annex I countries. The implication of using this allocation calculation scheme is that it requires more emission reductions for many developing countries whose emission intensity is currently very low. At this point, one may wonder about the feasibility of applying solely efficiency criteria in allocation of global common goods which principle is set under the norm of "common but differentiated responsibility" (Art 2,x of the UNFCCC). This is the point where a shift is needed from quantitative work to qualitative considerations.

Another difference exists within the same allocation formula, but it is still possible to use different criteria in calculating things such as benchmarks or baselines that may end up with varying results. Our calculation for C&C shows that, due to different future predictions, the converging year to realize equal per capita emissions between 2050, 2075, or 2100 resulted in different targets for Annex I countries in 2020, as presented in table 89.3. Different converging years imply a different reduction path for each country. This difference also has implications for the allocation principle. The question is, which year should we realize equalized rights to use the Earth's atmosphere, given the current unequal allocation? Should it be 2050, 2075, or 2100? As environmental governance is also a matter of equity between the current and future generations, allocations in the current and near-term has also implications for the burdens of future generations. Such a notion may not be considered if only the efficiency criterion was used.

89.5 Conclusion

The case study of allocation schemes focusing on Japanese mid-term targets has shown that different equity criteria and different calculation formula would lead to largely different QERLOs for individual countries. This is true if different principles are employed for calculations, but is also true even if they are calculated with the same principle, but different formula for calculation were used. Thus, the model assumptions and emissions stabilization levels and paths are important factors in determining QERLOs, as existing studies argue, but the authors would like to raise more attention to implications of different allocation principles and formulas.

Importantly, this is a space for political intervention. In the end it is up to policy-makers, and not to scientists, to determine which allocation formula would be useful for deciding on the political target. However, more attention should be paid to a space where value judgements can intervene even though it looks like rigorous science at a first glance. Such a problem can be solved by employing other study discipline(s), but often collaboration at this level is neglected. Sometimes differences in resulting numbers are large enough to make different perceptions regarding implications of what consists of equal and comparable efforts. The issue is particularly important in the context of post-Copenhagen international negotiations, as Copenhagen did not deal with the allocation of emissions. Should there be any step forward to go beyond pledges of targets as set out in the Copenhagen Accord, the allocation issue may reappear. Then, national interests will enter into this issue, and therefore a careful calculation, or a simpler calculation formula, would be required.

Even if it is impossible to reach the consensus on equity criteria for QERLOs calculations by international negotiations, it is still important for science to present comparability in terms of various criteria. In the end it is the role of politics that determines national emission reduction targets either at international or national levels, but presenting a menu to politics is included in roles of policy-oriented science. The allocation of emission rights in climate change governance cannot be fully appraised without employing integrated interdisciplinary approaches. In order to identify a long-term global emissions path to reach certain stabilization levels, such as 450 or 500 parts per million of CO_2 equivalent, or placing an upper limit on temperature increase, such as a two-degrees Celsius above pre-industrial levels, a dynamic optimization model may be required.[13] Only then can global differentiation schemes be calculated. Such schemes involve the consideration of both a long-term and short-term institutional framework on climate change, as well as social and political feasibility, data availabil-

13 See e.g., Eickhout, den Elzen and van Vuuren (2003); Höhne (2006); Hijioka, Masui, Takahashi, Matsuoka and Harasawa (2006).

ity, and considerations of ethical aspects (Kanie 2008). One of the most important and difficult challenges here is the way to translate equity considerations into numerical calculations. Gaps exist between institutional architectures, allocation principles, and allocation formulas. A challenge for future research is to fill in these gaps.

Because of the solid interaction between science and policy in contemporary environmental governance research, limits to data availability and manoeuvrability constrain the governance architecture in return. As den Elzen stated, "the current methodology does not quantify the effect of qualitative commitments such as obligatory *sustainable development policies and measures* (SD-PAMs), sectoral CDMs, and non-binding targets of the proposal, as this requires more detailed, disaggregated, sectoral energy modelling" (Den Elzen/Michel/Höhne/Brouns/Winkler/Ott 2007: 188). The same is applied to more diffused governance architectures. A combination of national targets and private agreements remains an option for a possible future climate governance architecture.[14]

In fact, it is argued that the best institutional design for managing complex problems such as climate change is a loose, decentralized, and dense network of institutions and actors that are able to relay information and provide sufficient redundancies in the performance of functions, so that the inactivity of one institution does not jeopardize the entire system. Emerging environmental governance agencies beyond the state seem to confirm this observation. The experience of the Copenhagen conference has also indicated that an institutional arrangement beyond nation states may be an option for the post-2012 period. Sector-based cross national arrangements, possibly with partnerships with the multilateral process, appear to be an option in this regard.

Should these be effectively dealt with in an allocation methodology, then the numerical impact of the institutional architecture, including those qualitative mechanisms, can be presented to negotiators and policy-makers, who tend to prefer a strong numerical backbone before introducing new mechanisms. The final deal may be made politically, but numbers interacting with norms, principles, and narratives make up the foundations of the architectural design.

90 Land-use and Flood Risk Changes in Coastal Areas of South-eastern Spain

Juan M. Quiñonero-Rubio, Francisco López-Bermúdez, Francisco Alonso-Sarría and Francisco J. Gomariz-Castillo

90.1 Introduction

Flash floods are a major natural hazard in the south-east of Spain. A semi-arid climate along with severe droughts with extreme rainfall events are the cause for a scarce vegetation cover. For geological reasons, the steep slopes near the sea have generated this situation (Romero Díaz/Maurandi Guirado 2000; Camarasa Belmonte 2002). Human occupation in this area was scarce and the land use limited to some dry land cultivations. But during the last 25 years, two new trends have increased the human risk from natural flood hazards.

- *Firstly* the availability of groundwater for irrigation initiated an explosive increase of newly cultivated and irrigated areas, thus reducing the soil infiltration capacity;
- *Secondly* the tourist and property boom have increased the residential occupation near the sea in many '*ramblas*' (ephemeral channels in Spanish) (Torres Alfonsea 2002).

Land use describes the activities carried out by humans in the landscape (Koomen/ Stillwell/Bakema/ Scholten 2007). The changes of land use have an impact on economic, social and cultural activities, as well as those related to the safety of the population, since natural processes govern any human activity, although it is well known that current generations are the first that can degrade the environment and ecosystems where humankind has survived since its origin.

These anthropogenic changes affect various fields of the Earth and social sciences, such as climate change, desertification, alteration of the hydrological cycle, diversion of sea currents in areas close to the shore by the construction of ports, change and degradation of plant cover, degradation of soil fertility by overexploitation, change of the generation of runoff flows, soil erosion (López Bermúdez 1996), and so on.

The response of the water flow to the geomorphologic characteristics of a basin is obvious, but land-use may represent an important factor in the dynamics of surface water, since discharge flow varies between land-use types. In addition, some uses are associated with an increased risk to the public.

Population growth contributes to a process of intensification and expansion of human activities and therefore of land occupation. This process has produced changes in the Earth's surface that have in many cases profoundly changed land use (Barbera/ López Bermúdez/Romero Díaz 1997; Goldewijk/Ramankutty 2004). This chapter studies these changes in the dynamics of surface runoff due to changes in land use in recent decades.

Two documents on management of flood risks must be taken into account at the national and European level:

- The Basic Guidelines for Planning of Civil Defence against Flood Risk (1995);
- Directive of the European Commission and the Council on the assessment and management of flood risks (2007).

Both documents, which entered into force in 1995 and 2007, aim at the prevention and management of flood risks, for which they offer procedures for action. They also refer to the division of responsibilities among different territorial entities to safeguard the health and welfare of the population and prevent damage to property. Territorial studies are a common tool and in Spain they are assigned to the autonomous regions, including weather forecasting, hydrological studies, land use, and geological and geomorphologic features of each territorial entity.

Since these tasks aim at the management of flooding events, one of their premises has been the crea-

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_90, © Springer-Verlag Berlin Heidelberg 2011

tion of a database identifying where the problem spots are and providing a classification of areas in terms of levels of risk related to different return periods of flows, as well as mapping the geological and associated geomorphologic risks at varying scales, but always adapted to the magnitude of the phenomenon and as accurately as possible (Alonso 2002). In this study land use is taken into account, but land-use change and its effects on hydrological processes are not addressed. These studies are also related to the directives and guidelines for spatial planning with a purely legal management, to obtain economic returns, and often they are not very concerned about the environment and are inefficient regarding population safety (CARM 2007).

This chapter goes a step further and establishes a timescale for hydrological studies, determining how changes in land use during several decades may have impacts on the flow of several non-gauged streams *(ramblas)* located near the southern littoral of the Region of Murcia in the south-east of Spain. It is necessary to use hydrological models that adapt well to

the area. New information technologies are indispensable to obtain high quality precise results, thus *Geographic Information Systems* (GIS) as well as satellite and aerial images were used.

90.2 Spain and Flood Risk in the Region of Murcia

The database created by the CRED (*Centre for Research on Epidemiology Disasters*) EMDAT (*International Emergency Disaster Database*) shows that among the ten major natural disasters in Spain, seven were floods. The economic damages and people affected from floods are behind droughts. There were 21 floods from 1953 to 2007 with 742,300 affected people where 1,279 people died; followed by wind storms with 15 events with 60,412 affected people and 132 dead people.

Research by the CCS (*Consortium of Insurance Compensation*) and the IGME (*Geological and Mining Institute of Spain*) (2004) analysed the consequences of the risks and losses associated with disasters derived from earthquakes and floods in Spain. This research offers much information on the value of the loss, amounting to 0.1 per cent of the national GDP for the period 1987–2001 (with 2002 as the year of reference), whereof floods represent 98 per cent. The most affected provinces were Valencia, Málaga, Barcelona, Guipúzcoa, Alicante, and Huelva. Estimates for the next 30 years project a reduction of losses from floods by 7 per cent.

In the Region of Murcia historical records (figures 90.3, 90.4) exist on large and persistent river floods that affected different spots and were caused either by the Segura River or one of its tributaries (e.g. the River Guadalentín, currently regulated) or were caused by *ramblas* that pose complex challenges for risk management and prevention. Thus, the annual distribution of these phenomena can be assessed, most of which occurred in September and October (figure 90.5; Romero Díaz/Maurandi Guirado 2000).

The shock caused by natural disasters led to initiatives for action against river floods. The local bodies opted for the principle of prevention relying almost exclusively on the massive execution of civil works (river bed course rectification, retaining of dams and channels). These works are carried out in the main river beds and require on some occasions monumental works to regulate the river beds to reduce the risk

Figure 90.3: Historical floods of the Segura Basin. **Source:** Regional Atlas of Murcia (2008).

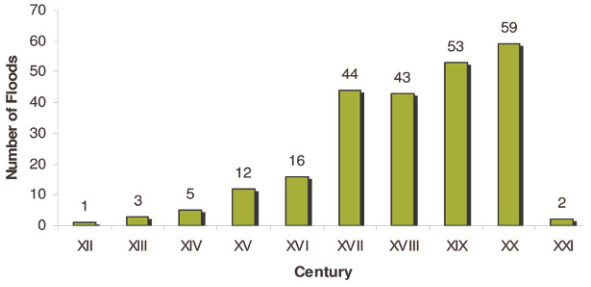

Figure 90.4: Floods of the Segura River in the XX Century **Source:** Regional Atlas of Murcia (2008).

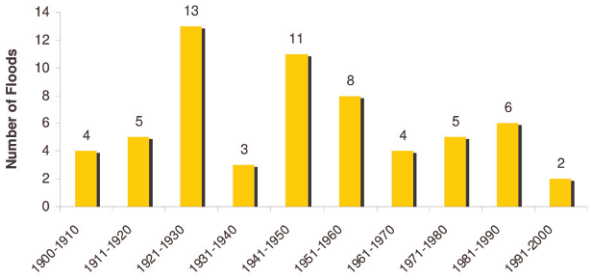

Figure 90.5: Flood annual destruction in the basin of the Segura River. **Source:** Regional Atlas of Murcia (2008).

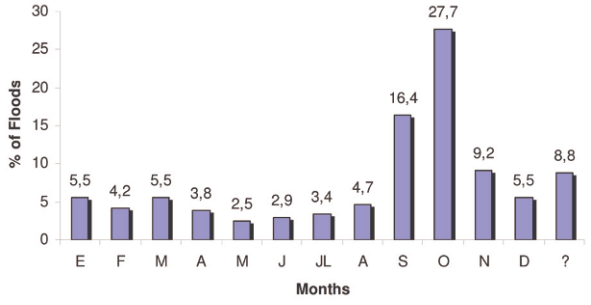

of floods. A second aim addresses problems of water resource management.

The population is highly vulnerable. On numerous occasions, these works are not the solution to avoid events like the Santa Teresa flood in Murcia. On 15 October 1879 the flow of the Segura River reached 2000 m^3/s in the city of Murcia devastating everything also in the neighbouring town of Orihuela. The entire country mobilized to help the flood victims. Another example is the severe flood suffered by the town of Cartagena on 29 September 1919 with the overflow of the *Rambla de Benipila*. Water in the town centre peaked at three metres. The consequences of both events were catastrophic in terms of

Figure 90.6: he centre of Cartagena city during the flood of 29 September 1919. **Source:** <http://www.cartagenaantigua.es>. The photo is in the public domain.

casualties, home loss, socio-economic consequences, and the number of people affected.

90.3 Study Area

The study area is the southern part of the Region of Murcia (figure 90.7) and is located in the south-south-east of the Guadalentín River basin along the Mediterranean Sea. In this territory are the southern foothills of the Cordilleras Béticas mountain ranges (Sierra de las Moreras, 431 m; Mayorales, 689 m; Lomo de Bas, 641 m; Carrasquilla, 785 m; and Almenara, 881 m) that are of Tertiary origin and derived from the Alpine orogeny and arranged in concentric arcs that open to the sea and subdivide the coastal strip. Among the elevations of this rugged landscape, there are several Neogene-quaternary basins where wadis develop. This hydro-geomorphologic system in the Mediterranean was selected for this study (Rosselló 1986; López Bermúdez/Conesa/ Alonso Sarría 1998).

The region has a semi-arid Mediterranean climate, with a marked dry season during the summer months, and two rainfall maxima in spring and autumn, which represent more than 70 per cent of the annual rainfall. In general, these are concentrated in a few hours due to their intensity and torrential character. Minimum rainfall occurs in winter. Only some meteorological observatories throughout the study area have records of annual precipitation above 250 mm. The area is warm with an annual average of 19 °C, with peaks above 40 °C in the summer and a minimum of 9–11 °C depending on altitude and exposure. The climate is the driest in Europe and extends to the Cabo de Gata in the province of Almería (Vilá 1971; Geiger 1973; Font Tullot 1989; López Bermúdez 1999).

This combination of topographic, geographic, and climatic factors leads to a unique variety of vegetation species. This diversity spans from an open scrubland dominated by esparto, thyme and lentisc, becoming denser with altitude, to pine forests in the higher elevations, often due to reforestation, but also tamarisk, oleander, palms and carob on the beds of numerous wadis, some of them coming from an ancient human use.

The most populated areas are near the city of Cartagena in the eastern sector, Mazarrón and Puerto de Mazarrón in the central sector and Águilas, the main urban community in the western sector. In addi-

Figure 90.7: Study area in Murcia. **Source**: This map was designed by the authors.

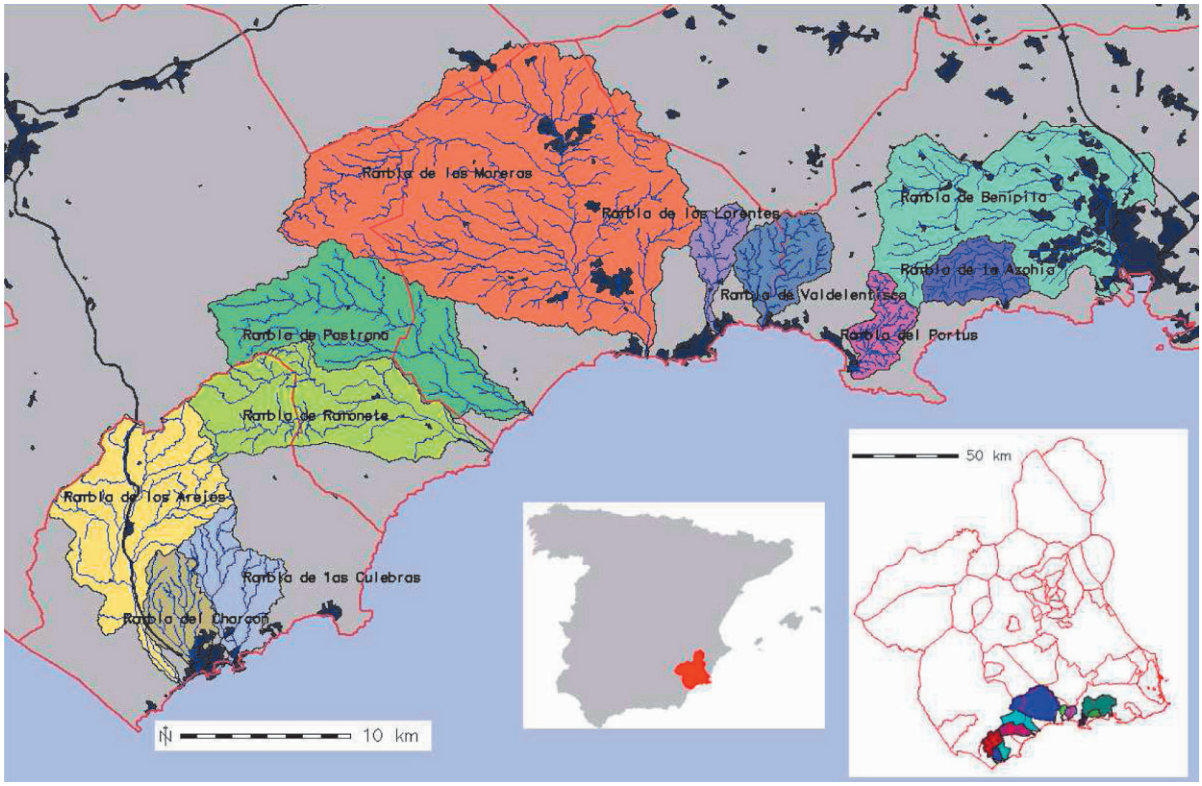

Figure 90.8: Typical vegetation environment of the area. **Source**: Photo by Juan M. Quiñonero-Rubio.

tion, there are several small villages along the coast. These communities are affected by the hydrological dynamics of wadis due to the overflows and floods they cause.

90.3.1 Risks linked to Land-Use Changes

The first settlers in this zone lived close to the river beds, as they offered suitable areas for agriculture and cattle, which directly exposed the population and their principal activities to hydrologic risks. Stone walls and terrace farming in river beds were usual measures that alleviated the harmful effects of floods, but their effectiveness was low in major events.

The population has increasingly been exposed to flood risk as demographic developments required a territorial expansion of economic activities and also favoured building of new homes due to great technological advances, especially during the last decades. Thus, losses are more substantial and disasters more frequent. Great transformations occurred in this region during the last decades that match these processes:

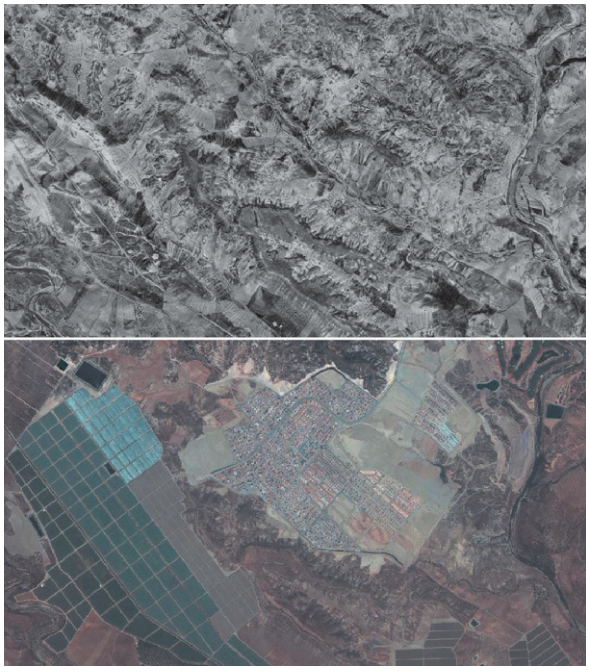
- Increase of the artificial presence of new constructions on the surface;
- Transformation of agriculture with the spread of new irrigation techniques;
- Changes in forest ecosystems with hydrologic consequences, not only for increasing flood risks but also for the loss of the ecosystem itself;
- Decline of wet areas and endorreic zones due to the first two developments.

The growth in housing and intensive farming in this region constitute the main risk factors for the people.

The increase in the number of houses since 1996 has been spectacular, especially the growth that occurred during the last three decades. But the number of people remained practically constant; it also declined in small clusters or it suffered a slow evolution which does not match the vast construction of houses. Many houses located in this part of Murcia are secondary dwellings (not permanently occupied), resorts, and apartments destined for tourists that are used especially during summer, what affects the vulnerability of the population from flood risks, since the non-permanency throughout the year implies that a major part of the damages will affect goods and not people. This differs for *camping areas* that are usually next to riverbeds.

A clear example are the resorts – e.g. in the Saladillo area where housing increased by about 2,500 per cent – that changed from an almost uninhabited area to a population of 800 inhabitants within a short time (Pérez Morales 2008). This implies environmental changes, exposition of houses in areas of water convergence and modification of the surfaces and of the direction of the runoffs. The city of Águilas experienced a moderate change with an urban growth rate of 361.4 per cent and 117.8 per cent for the population (data from National Statistics Institute; at: <http://www.ine.es>).

Figure 90.9: New urban area close to Mazarrón city (images from 1956 [top] and 2005 [below])
Source: Regional Ministry of Spatial Planning.



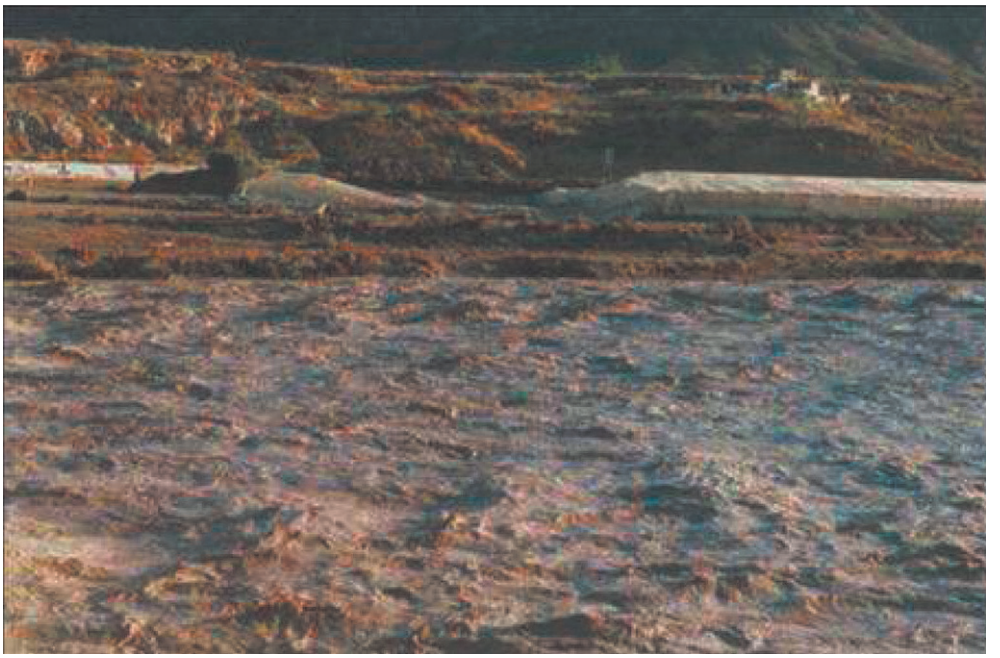
The new urban expansion along the coastline is associated with an intense real state speculation, which resulted in a progressive decline of agricultural areas. Thus, these areas are not available any longer for farming, which poses additional risks besides the growth of economic activity and population.

90.3.2 Consequences of Flood Risk for Spatial Planning

The western sector of Águilas is a clear example. It was previously a terraced area which used the water coming from the ramblas Majadas and Peñaranda-Labradorcico. Now it is part of the urban setting and is highly vulnerable when it rains heavily. An event in October 1989 showed the limited awareness for the risks of imminent floods in urban planning. The river burst its banks and a flood wave grew rapidly and further increased due to the narrowing of the drainage system. This provoked an increase of the height of the water of up to one metre in some parts of the city (*La Verdad*, 17 October 1989). Estimates by the Regional

Figure 90.10: Old salt flats (1956, left) and new urban expansion. (2007, right) **Source:** Regional Ministry of Spatial Planning.

Figure 90.11: Rambla de las Moreras Flood in September 1989. **Source:** High School of Mazarrón "Felipe II".



Agricultural Ministry referred to 567 houses affected and total losses of 7.5 million Euros.

All actions to avoid such events were inadequate. In May 2006 the city was affected by a new flood. Marina de Cope, an agricultural area close to Águilas, was chosen for a housing project for tourists which was classified as an *Action of Regional Interest* with an extension of 2,116 hectares for 9,000 houses and 20,000 hotel beds. An analysis of 2004 on the flood risks generated by this project was only a mere artificial drainage systems when heavy rainfall in the description which did not include all possible risks that may occur in the future (Pérez Morales 2008).

In the municipality of Mazarrón, urban growth occurred in areas of natural drainage or in endorheic areas. The most extreme example of an area affected by frequent floods is the so-called *Urbanización Bahía de Puerto de Mazarrón*. This cluster of houses was built on an area used by the Romans as *salt works* (figure 90.10). The orographic situation of these houses makes it difficult to evacuate all water through area leads to floods.

Figure 90.12: Flood of Rambla de las Moreras in September 1989 during the flood close to Bolnuevo village (left) after the flood in the campsite (right). **Source:** High School of Mazarrón "Felipe II".

The most significant event was the flood of 7 September 1989 in the *Rambla de las Moreras* (Mazarrón), whose disastrous effects were caused by poor land-use planning. There was more than 100 mm of rainfall in just over an hour that resulted in a runoff with an estimated flow peak of 500 m^3/s. The narrowing of the stream bed due to an artificial channelling in the village of Bolnuevo generated a flood wave of several metres that destroyed the urban infrastructure, greenhouses, and a campsite that were located in the ephemeral channel flood-plain and in its delta (figures 90.11; 90.12) at the Mediterranean Sea. Two persons died and economic damages amounted to several million Euros (Rodríguez Estrella/López Bermúdez/Navarro Hervás/Albacete 1992; López Bermúdez/Gomariz 2006). This was another example of bad land use or territorial management. But today the campsite remains in the same place.

The major activities carried out focus on this basin shown above. However, the urban expansion resulted in new risks since the clusters invaded the mouths of the main riverbeds of adjacent basins such as Lorentes, Valdelentisco, Ramonete, etc. In the future, heavy rainfalls may produce new risky situations for the people in this area.

90.4 A Simulation of the Study Area

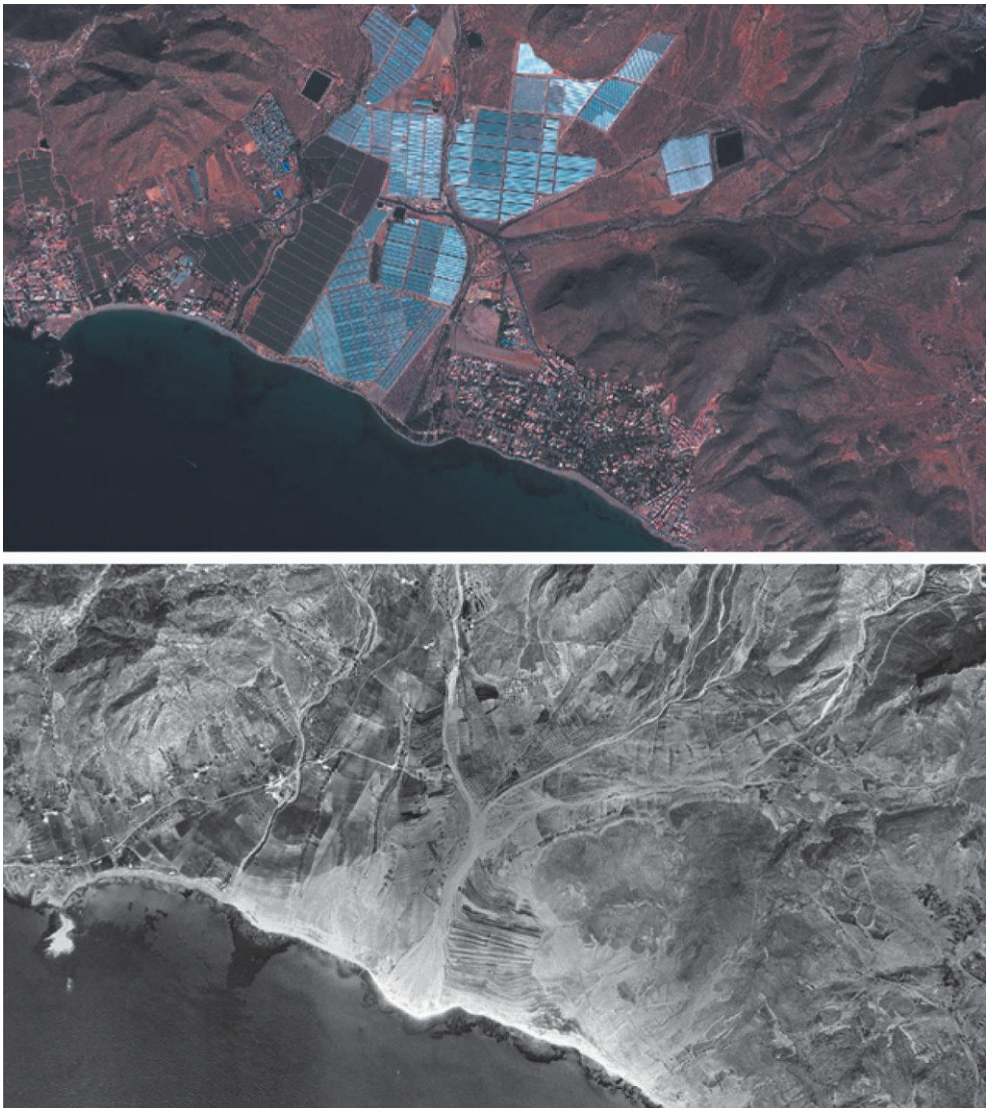
This study used a *Geomorphologic Unit Hydrograph* (GUH) (Iturbe 1993) to analyse the increase in risks that has taken place during the past 25 years by modelling three different stages using land-use maps that were generated with remote sensing images. Drainage networks are extracted from a Digital Elevation Model by GIS (Burrough/McDonnell 1998) techniques using GRASS software and HEC-RAS, developed by the *US Army Corps of Engineers* (USACE 2000; 2008; McCuen/Richard 1982) to predict for different scenarios the depth flow generated on inhabited zones.

A simple aggregated hydrological model was used to analyse how land-use changes can alter the potential flood hazard for high return periods. This specific model is based on well known models recommended and used by the Spanish hydrological and weather authorities (Ferrer Polo 2000; Santamaría Arias/Parrilla Alcaide 1999). For this chapter a simple and robust modelling approach is used instead of more sophisticated ones, assuming that the trends discovered with such a model will be consistent with those estimated with other models and with reality (Chow/Maidment/Mays 1999; Olivera/ Maidment 1999). GRASS GIS (Neteller/Mitasova 2002) has been used for the spatial side of the implementation (Crawley 2005).

Dangerous spots covered in the study rely on the work of INUAMA (2001), and were selected based on these criteria: a) they are located (or not) in the streams and its mouth or close to it; and b) they were selected based on population and the main land-use types.

For the generation of flood risk maps the assessment of risk of the DIHMA methodology (1997) was applied, which takes into account both the probability of occurrence of flooding at the levels reached, assuming for this study the proposed interval for storm return periods of 500 years (low frequency of flooding) and low depths, resulting in the so-called 'low risk' of flooding. Table 90.1 shows the evolution of the runoff parameters; *Qp* stands for runoff peak and *Qt* for total runoff. The general trend is towards a slight decrease in those parameters, except for *Ram-*

Figure 90.13: Land-use changes in a water outlet area of the coast of Mazarrón (2005 (top) and 1956 (bottom)). **Source:** Regional Ministry of Spatial Planning.



bla del Charcón and *Rambla de los Arejos* where an increase in total runoff and peak can be assumed.

After an analysis of the selected spots for the return period of 500 years, minimal differences in the flows were observed that were calculated in the hydrological modelling stages for land-use changes, what is apparent in the area for the resulting water table.

Different performances of the modelled problem spots were distinguished on the basis of the measures taken to prevent floods:

- *Channels regulated* by containment measures, usually an artificial canalization with stone walls and clean and hardened river beds. In most cases the sizing was correct, showing the mouth of the Rambla del Portús where it can be seen that neither in 1977 nor in 2000, the characteristic water level for a return period of 500 years overflows the channelling, with the exception of a point located on the left wall, where water was overflowing and affected the camping.
- *Unregulated channels*. In this case, as in the previous ones, differences of land use in the basin barely affect the water sheets resulting from a return period of 500 years. However, contrary to what happens in the above-mentioned spots, in this case overflows seriously affect human uses in each of the periods in question.

7	Charcón	671.33	789.81	789.81	1.81	1.97	1.97
8	Arejos	964.42	1146.24	1146.24	5.69	6.27	6.27
9	Portús	423.27	399.75	399.75	1.41	1.36	1.36
10	Culebras	927.50	927.50	927.50	2.47	2.47	2.47
11	Valdelentisco	724.93	686.13	686.13	2.15	2.08	2.08

90.5 Conclusions

- The land-use changes did not affect the flow of the wadi studied and if there is any change it has been of limited hydrological significance.
- The simulated peak flows do not pose a high risk for the current population in the area, although in the past they have occurred when human activities have triggered major disasters. The construction of new barriers to defend against floods is more effective than those in previous decades but is no solution.
- Based on these results, the geomorphology of the ephemeral channels has set an effective drainage system. It is recommended not to change these channels so as to permit the water to flow freely without creating problems for the safety of the population.
- Spatial planning in the flood areas is presently producing good results, although it is always possible

to observe in situ some spots that should be studied in the future.

- The new spatial planning based on massive tourism and intensive agriculture is a real economic fact but the surfaces for these activities must be located in the correct areas. The vulnerability of the population is growing if this situation remains.
- Past floods are the best examples of possible future situations.

91 Monitoring Conflict Risk: The Contribution of Globally Used Indicator Systems

Jochen Jesinghaus

91.1 Introduction: Indicators Are No Toys for Statisticians[1]

No Prime Minister in the World will sleep well when the rate of GDP growth is below zero. The risk to lose the next elections is just too high. In richer countries, this holds also true for bad unemployment and inflation rates. Another example how indicators drive politics: There would be no Kyoto Protocol if our statistical offices had not the indicator 'CO_2 emissions per capita' in their pockets. At the right place, in the right moment, and under certain conditions, indicators play an overwhelmingly powerful role in politics, and may indeed decide the fate of governments. Could indicators play a role in preventing conflicts?

In the following, the author will try to formulate how an indicator system intended to help reducing the risk of violent conflicts should look like. The goal formulation, an indicator system intended to help reducing the risk of violent conflicts, is certainly ambitious – is it credible to picture a warlord in the heart of Africa who looks at these indicators and then says, "ok, you convinced me, from now on I will settle my disputes peacefully?"

A more desirable and realistic scenario would be a political environment in which warlords simply do not thrive, thanks to efforts by all actors involved to exploit resources in a fair and sustainable way, and to seek dialogue instead of confrontation. This implies understanding the root causes of non-sustainable behaviour, and it implies creating a situation where options to reduce or eliminate such causes are being discussed by those who have the power to negotiate solutions. To name some of these actors (in the heart of Africa, or in the mountains of Central Asia, etc.): The government, opposition parties, civil society, warlords, UN troops, the donor community.

While the media do not appear in this list as 'direct' actors, they do have a crucial role, as *media*tors, in enforcing dialogue among the political actors. For example, in April 2008, a Chinese ship loaded with weapons had trouble with the media. A headline from a Pakistani online service:

'Zimbabwe silence may be Mbeki's demise': South African President Thabo Mbeki's failure to criticize neighbouring Zimbabwe leader Robert Mugabe has weakened his international stature, analysts said. ... human rights groups have reported an upsurge in violence by pro-Mugabe militias and the military. ... Mbeki rival Jacob Zuma ... denounced Zimbabwe's 'police state' during a European tour in which he met Britain's Prime Minister Gordon Brown.[2]

The same day, the *Financial Times* comments:

> 'No guns for Mugabe': Beijing had no need of more bad publicity ahead of the Olympic Games and on Thursday said the ship [the An Yue Jiang], which was carrying enough bullets to start a civil war, was heading home. ... Human rights activists, church groups and unions across southern Africa have shown solidarity with long-suffering Zimbabweans by campaigning to bar the An Yue Jiang from African shores.[3]

World-wide, in the UK and in Pakistan, people with access to newspapers and/or the internet learnt something about the role of the following actors: R. Mugabe, T. Mbeki, human rights and church groups, J. Zuma, the Trade Unions, G. Brown, and the Chinese government. At the time of writing this article, Mr. Mugabe is still President – but the whole world is watching the news from Zimbabwe, and is debating

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_91, © Springer-Verlag Berlin Heidelberg 2011

how to cure the African disease, i.e. greed and corruption of governments.

While there might be situations where secrecy helps to advance a good cause, as a general rule transparency enforced by the media helps to push the actors towards the negotiation table. Of course, a ship full of weapons for a government that just rigged the elections is a simple case, so one would not need any indicators for explaining what are the stakes here. But most conflict situations are far more complex, and require a thorough analysis.

In the following, the author will present a practical example of an indicator system created from existing data sets, discuss its messages, and draw lessons for a more elaborate system aimed at enhancing a societal debate on policy priorities, inter alia with regard to resolve tensions through dialogue rather than armed conflict.

91.2 An Indicator System for Communicating Conflict Risk

Indicator systems can help to provide political actors and stakeholders with a good analytical basis for negotiations – and the media are the vehicle to transport such indicators, and thus their underlying issues, into the debate. To illustrate how such a system could be designed, a 'strawman' framework will be presented here, focusing on three dimensions/elements related to conflict risk in developing countries: a) the quality of institutions; b) socio-economic development; and c) the natural environment.

As a working title for the strawman, the author chose "*Sustainable Development Index*" (SDI) – a name that is far from being innovative but certainly rings a bell for the audience; the 'bell' is, by the way, a required feature for any indicator system that is supposed to be used by the media: An indicator system should *not* be innovative; it should rather reflect and present, using simple and easy-to-understand means, facts and figures that relate to the already existing mental setups, 'world views', of a majority of potential users. There is currently no other world view as broadly accepted as 'sustainable development', and it should not be too difficult to convince the citizen that *sustainable development* (SD) requires a functioning government, money in the wallet, and a thorough look at the mid- and long-term risks of overstretching nature's patience.

For each of the three dimensions (quality of institutions, socio-economic development, and the natural environment), a database is required – more precisely, a set of figures that have the necessary *properties* for being fed into difficult and complex political negotiations, for example: being scientifically sound, robust and politically relevant official statistics. Given that a lot of detail will be needed, such figures should lend themselves to *aggregation*, so that the actors at the negotiation table will not get lost in piles of spreadsheets containing data cemeteries. Several 'indicator sets' exist already. UNDP's Office for Development Studies has found 178 aggregated indicator sets, among them are: [4]

- 31: *Disaster Risk Index* (DRI)
- 91. Human Rights Commitment Index
- 97. Index of Human Insecurity
- 105: *International Country Risk Guide* (ICRG) Ratings - Composite Risk Rating
- 113: Least Secure Countries
- 162: The Observer Human Rights Index
- 177: World Military Expenditures and Arms Transfers rankings

And then there is No. 89, the *Human Development Index* (HDI), one of a handful in the list that are well-known to the media – although in a "Google contest", even the HDI would have no chance against GDP and unemployment. For the purpose of the 'strawman', these three indicator sets are used:

91.2.1 Quality of Institutions

The *Failed States Index* (FSI by Foreign Policy and Fund for Peace[5]) is a comprehensive dataset examining the ability of states to manage their own business:

> Because it is crucial to closely monitor weak states – their progress, their deterioration, and their ability to withstand challenges – the Fund for Peace ... and Foreign Policy ... ranked 177 states in order of their vulnerability to violent internal conflict and societal deterioration. To do so, we examined more than 30,000 publicly available sources, collected from May to

4 Romina Bandura, UNDP Office of Development Studies: "A Survey of Composite Indices Measuring Country Performance: 2008 update" (personal communication from Ms Bandura, June 2008).

5 See: Foreign Policy: "The Failed States Index 2009"; at: <http://www.foreignpolicy.com/articles/2009/06/22/the_2009_failed_states_index> (21 September 2009); Fund for Peace: "Failed States Index 2009", at: <http://www.fundforpeace.org/web/index.php?option=com_content&task=view&id=391&Itemid=549 (21 September 2009).

December 2007, to form the basis of the index's scores." [6]

The indicators used are:

- *Social Indicators*: I-1. Mounting demographic pressures, I-2. Massive movement of refugees or internally displaced persons creating complex humanitarian emergencies, I-3. legacy of vengeance-seeking group, grievance or group paranoia, I-4. Chronic and sustained human flight;
- *Economic Indicators*: I-5. Uneven economic development along group lines, I-6 sharp and/or severe economic decline;
- *Political Indicators:* I-7. Criminalization and/or delegitimization of the state, I-8. Progressive deterioration of public services, I-9. Suspension or arbitrary application of the rule of law and widespread violation of human rights, I-10. Security apparatus operates as a 'state within a state', I-11. Rise of factionalized elites, I-12. Intervention of other states or external political actors.

91.2.2 Socio-economic Development

The *Millennium Development Goals* (MDG) dashboard uses over 60 MDG indicators elaborated by the UN system in the wake of the 2000 Millennium Summit to calculate overall scores of 'MDG performance' for all countries of the world. Its structure reflects the eight MD Goals agreed in 2000 by 189 Heads of State and Government [7]:

- Goal 1: Eradicate extreme poverty and hunger
- Goal 2: Achieve universal primary education
- Goal 3: Promote gender equality and empower women
- Goal 4: Reduce child mortality
- Goal 5: Improve maternal health
- Goal 6: Combat HIV/AIDS, malaria and other diseases
- Goal 7: Ensure environmental sustainability
- Goal 8: Develop a Global Partnership for Development [8]

91.2.3 Natural Environment

The 'Environmental Performance Index' [9] is the latest of a series of environmental indices, elaborated by Yale and Columbia university that was presented in 2006 (as a 'pilot') and 2008 at the Davos World Economic Forum. It contains a total of 25 indicators, structured by six major themes:

- Environmental health (with sub-themes burden of disease, water, and air pollution)
- Air pollution (ecosystems)
- Water resources (ecosystems)
- Biodiversity and habitat
- Productive natural resources
- Climate change.

91.3 A First Look at the 'Strawman'

To make the 'strawman' look more realistic, real data for real countries will be used from now on. To avoid showing boring spreadsheets, a simple code of shades will be used in the following: darker means better, lighter means worse than others in the same group. For the current context, Africa was chosen as the peer group to compare with. For the current context, Africa was chosen as the peer group.

Here are the results for Tanzania (figure 91.1):

- First, the *FSI* portrays Tanzania as a country with a medium risk of state failure. Refugees and IDP (internally displaced persons) require specific attention, though.
- Second, the socio-economic performance measured through the MDG lens highlights Tanzania's good education system by assigning a dark green. Hunger and poverty seem to be more serious than in the rest of Africa; a closer look at the data reveals that the World Bank's headcount, per cent of people living with one US$ per day, pulls down the score, together with a high share (44 per cent) of malnourished adults – the latter contrasted by a better-than-average child malnutrition score of 22 per cent, as compared to over 40 per cent in Sudan and Madagascar. Tanzania's red spot, however, is the Maternal Mortality Ratio (MMR): 1500

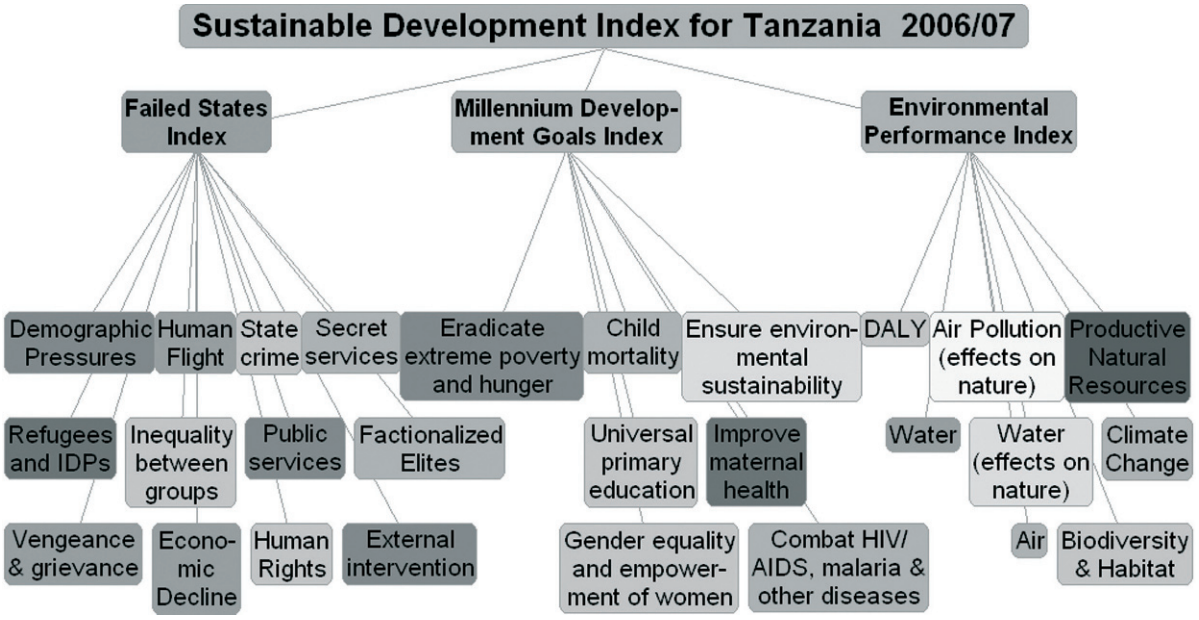
7 See "Road Map towards the Implementation of the United Nations Millennium Declaration (A/56/326)", Annex, point 5: "The proposed formulation of the eight goals, 18 targets and more than 40 indicators". In 2007, the indicator set was revised, following UN Resolution GA 60/1, "2005 World Summit Outcome".

8 The MDG dashboard; at: <http://esl.jrc.it/dc/>, holds data for Goal 8, "Global Partnership", but for the purpose of this paper, we will concentrate on the first seven dimensions designed to measure development progress.

9 Environmental Performance Index 2008, at: <http://epi.yale.edu/Home> (21 September 2009).

Figure 91.1: Sustainable Development Index for Tanzania (2006/2007). **Source:** The author.



deaths per 100,000 live births, almost twice as high as in the neighbouring countries Uganda (880) and Zambia (750)[10]

- Third and finally, the *Environmental Performance Index* (EPI) shows a rather mixed picture – excellent for air pollution, even for Sub-Saharan Africa standards, a yellow for water quality, and a red spot for 'productive natural resources'. Further investigation identifies two culprits for this low score: the *Marine Trophic Index* (MTI) promoted by the *Convention on Biological Diversity* (CBD), which

  > is used to measure the degree to which countries are 'fishing down the food chain', i.e., catching smaller and smaller fish ... It is considered to be a measure of overall ecosystem health and stability, but also serves as a proxy measure for overfishing;[11]

  and *pesticides*:

  > The Pesticide Regulation indicator is based on national participation in the Rotterdam Convention, which controls trade restriction and regulations for toxic chemicals, and the Stockholm convention, which bans the use of Persistent Organic Pollutants.[12]

The need for pesticide regulations in Sub-Saharan Africa might be worth a debate, but to move on, here the respective results for Senegal (figure 91.2):

- First, the *FSI* shows Senegal as a low risk country. Observers should keep an eye on demographic pressures, in particular on refugees and IDP's, and should not overlook the activities of the secret services – but overall, on risk of state failure Senegal scores a lot better than Tanzania.
- Second, Senegal's *MDG* indicators look better on poverty but only marginally better on maternal health – the *Maternal Mortality Ratio* (MMR) is under 700. However, contraceptive use (a component of the maternal health index) is half as high as in Tanzania, and this low level of protection against sexually transmitted diseases might contribute to Senegal's HIV/AIDS problem.
- Finally, Senegal's *Environmental Performance Index* (EPI) looks pretty similar to the Tanzanian one, with a slightly lower score on biodiversity but better water quality. Again, the 'natural resources' indicator is strongly pulled down by the *Marine Trophic Index* (MTI) and pesticides. As mentioned earlier, these valuations are calculated against the peer group 'Africa', and there are quite a number of countries in this group with excellent

10 "Data derived from the direct sisterhood method adjusted estimates: The direct sisterhood method is a variant of the sisterhood method- a survey-based technique that obtains information by interviewing respondents on the survival of all their adult sisters"; MDG Dashboard, based on; at: <http://mdgs.un.org/unsd/mdg/SeriesDetail.aspx?srid=553>.

scores for MTI (Tunisia, Cameroon) and pesticides (Burundi, Rep. of Congo, Sudan, Benin, Egypt and Morocco), so the question may be allowed why the governments of Senegal and Tanzania have another pesticide strategy than the rest of Africa.

91.4 Observations on the 'Strawman'

As a philosophical concept, sustainable development is great for election campaign speeches and late night talk shows, but for decision-making it needs quantification – they need to know what are the priorities for action, at a given point in time and space. Do the twenty-seven indicators shown above offer enough substance for informed debates on policy priorities?–

91.4.1 Function of the Goal Sustainable Development

The focus of this chapter shifted slowly from 'monitoring conflict risk' to the seemingly banal alternative 'sustainable development'. There are good reasons for this shift, but they need some elaboration. While it is desirable and important to know the truth about conflict risk, it would be even more desirable if governments acted to avoid tensions and prevent violent conflicts. The challenge is to find a good compromise between the academic desire to *measure* things correctly, and the need to exert (media) pressure on those who can *change* things[13]. There is no lack academic initiatives to *measure* conflict risk; to quote one initiative claiming comprehensiveness,

> *Facts on International Relations and Security Trends:* The FIRST system offers researchers, politicians and the media an authoritative and structured factual reference system on international relations and security trends. It contains high-quality, up-to-date and clearly documented information in areas such as: conflicts, arms transfers and military expenditure, hard facts on states and international organizations, economic and social statistics, chronologies ... data in FIRST is provided by the following [16] organizations. [14]

For a post doc working on conflict risk, FIRST is as valuable as Eurostat for the general statistician. Another example: The European Commission's *Joint Research Centre* features a specialized Support to External Security unit [15] that claimed in a paper on conflict risk assessment:

> we hypothetized that a number of widely used structural indicators might be strongly correlated with the risk of armed conflict in a country. Our study findings were that despite widespread discussion in academic papers, the most commonly used academic indicators [GDP growth, ODA, FDI etc]... did not unequivocally emerge

13 See Figure 5.2., "Policy cycle in a media society using an SDI", in: Hak, Moldan and Dahl (2007: 86).
14 See at: <http://first.sipri.org/ (7.12.2009).
15 See for the full source; at: <http://ipsc.jrc.ec.europa.eu/research.php?unit=2>.

after regression analysis as causal factors (Burnley/Buda/Kayitakire 2007).

There is considerable man- and institutional power behind this paper, but it is *research*, and as such very different from publications that hit, for example, the BBC headlines because Italy finds herself three ranks below Botswana in the *Transparency International's Corruption Perception Index*:[16] "An independent organization which produced an annual 'corruption index' reckons that Italy is more corrupt than the African state of Botswana, and Greece is more corrupt than Namibia." [17]

It is necessary to distinguish clearly between the kind of information that flows into research papers and into the secret 'crisis rooms', and public information that is able to influence ordinary citizens to the extent that they threaten to send the government onto the opposition benches.

To spur a political debate, messages must be simple and straightforward, to the taste of journalists. However, to launch a good political debate, TI's Corruption Perception Index is not the ideal tool. Certainly, it points to an important phenomenon, but if it were to become a really powerful indicator such as GDP growth, it would detract attention from other, equally important issues. Pushing a society on a sustainable path to prosperity requires complex information served in a simple format. The FIRST integrated database system mentioned above, for example, is public, and contains rich information from many respected international organizations specialized in conflict research, but selling it as "a free-of-charge service for politicians, journalists, *researchers* and the interested public" is wishful thinking. Besides researchers all other users want something more digestable, something simpler.

Simple messages are not possible without research. Even a seemingly primitive indicator like 'CO_2 emissions per capita' builds on a huge body of scientific literature on climate change. How many tonnes of paper on climate change would a researcher find in a medium-sized specialized library? And yet, climate change politics, i.e. the Kyoto process, is largely driven by one single figure, CO_2 emissions,[18] thus acknowledging that many years of research have led to the 'simple' conclusion that reducing greenhouse gases is *the* top priority.

Likewise, intensive research on the roots of conflict will come to the 'simple' conclusion that we should work on a number of variables that can be influenced by politics. Above, a total of twenty-seven indicators were presented in a sustainable development framework; and it would be easy for any conflict researcher to dismantle this framework in a few minutes, by demonstrating that many of the variables have nothing to do with conflict risk. And yet, there is a precise reason why the author chose SD to analyse conflict risk: because sustainable development is *mainstream*, i.e. it is a policy framework that is accepted by, and familiar to, a broad range of stakeholders, from Greenpeace to industry associations, and from trade unions to religions.

But conflict risk also seems to be mainstream, at first sight: A Google phrase search for 'conflict risk' yields an impressive 49,400 hits,[19] demonstrating that many authors write about, and are familiar with, the notion of conflict risk. However, 'Gross Domestic Product' yields 5 Million hits, and the abbreviation GDP arrives at over 57 Millions – this is 'real' mainstream...! Given that the Bretton Woods' 'GDP is good for you' ideology is not so helpful in this context, [20] the author chose 'Sustainable Development' (with 'only' 25 million hits) as the mainstream vehicle to transport conflict risk messages.

One might argue that being mainstream is not a goal in itself, and certainly not a guarantee for quality. For example, the *Failed States Index* (FSI) shown above is a high quality effort to present crucial vari-

17 "Analysis: How corrupt is Europe?", in: *BBC News Europe*, 15 January 2002; at: <http://news.bbc.co.uk/1/hi/world/europe/1762447.stm> (August 2008).

18 Only recently governments have recognized the need to use a more comprehensive measure, the so-called "Kyoto basket" of several greenhouse gases, condensed to a greenhouse gas index by weighting individual gases (CO_2, CH_4, N_2O, CFCs and others) with their respective greenhouse warming potentials.

19 All Google searches done on 29 September 2009.

20 The European Parliament organized in November 2007 the "Beyond GDP" conference in order to demonstrate that societal progress should not measured as GDP growth; at: <http://www.beyond-gdp.eu/>. OECD promotes the same line through the "Measuring Societal Progress" initiative; at: <http://www.oecd.org/dataoecd/52/19/42536811.pdf>; and most recently, the *Commission on the Measurement of Economic Performance and Social Progress* established by President Sarkozy comes to the same conclusion: that GDP is inadequate to measure progress; see at: <http://www.stiglitz-sen-fitoussi.fr/documents/rapport_anglais.pdf> (28 September 2009).

ables in a carefully constructed framework; however, it is too specialized to attract the attention of researchers and NGOs, and therefore could never exert the political pressure that is necessary to change Ms. or Mr. Prime Minister's behaviour. It requires a mainstream index à la GDP, strong enough to hit the headlines, in order to feed messages into a public political debate. Including the FSI as one of three components into a *sustainable development index* (SDI) is a smart way to promote it from a specialists' tool to a mainstream indicator.

91.4.2 Dimensions of Sustainable Development

Sustainable development is vague enough to accommodate a range of operationalizations. Again, there is a mainstream interpretation: 'SD equals economy plus social plus environmental issues'. Industry, for example, has adopted this three pillar model as the 'triple bottom line',[21] i.e. an extension of traditional economic measures of corporate performance taking account of social and environmental values.

Many claim that *culture* should be added as an essential fourth pillar of SD; [22] however, the United Nations SD indicator list, drafted in the wake of the 1992 UNCED, featured already a fourth dimension called 'institutional indicators',[23] which might well include cultural aspects. In recent years, the term 'institutions' has been replaced by 'good governance'. While it is difficult to find evidence for any formalized consensus, there seems to be a widespread feeling that SD is a 3+1 model, with economic, social, environmental plus governance elements.

The 'strawman' takes account of this line of argument but clusters economic and social aspects under 'MDG performance'. This may seem an arbitrary decision, but it is pretty obvious that, in the non-OECD World, policy has adopted the MDG framework for measuring *poverty* and *development* – synonyms for *economic* and *social* performance. Again, we need to balance the quest for analytical clarity with the need to talk the customer's language. The only alternative to the MDG set would have been the UN CSD Sustainable Development indicators set, which is nicely split into economic and social SD indicators but almost unknown outside environmental expert circles.[24]

Taking account of these choices and arguments, the author opted for a three-pillar sustainable development framework composed of governance, socio-economic development, and environmental elements.

91.4.3 The Right Indicators

The choice of the indicator sets was driven by pragmatic compromises between the need to be analytically and scientifically sound, and politically acceptable.

- The *Failed States Index* (FSI) covers important governance issues but has, in contrast to broad general governance indicator sets,[25] a specific focus on conflict-related aspects; furthermore, it is one of a several databases that are available for a sufficient number of countries and for more than one year.
- There is no real alternative to the *Millennium Development Goals* (MDG) indicator set when dealing with socio-economic issues in developing countries. Legitimated by the Millennium Declaration, a document endorsed by almost every Head of State in the World, this indicator set has become a de-facto standard for measuring 'development' in a broad sense – but not by

21 The term was coined in 1998 by John Elkington (1999).

22 See, e.g. on 'culture': "The Fourth Pillar of Sustainable Development" by the Creative City Network of Canada; at: <http://www.creativecity.ca/news/special-edition-3/culture-fourth-pillar.html> (August 2008). According to Council of Europe: "Sustainable developent requires ... also protecting the diversity and vitality of the worlds' many cultures"; at: <http://www.coe.int/t/dg4/culture-heritage/Topics/dev_en.asp> (August 2008). See also Keith Nurse (June 2006) for the Commonwealth Secretariat on "Culture as the Fourth Pillar of Sustainable Development"; at: <http://www.fao.org/sard/common/ecg/2700/en/Cultureas4thPillarSD.pdf> (August 2008). "Culture, politics, governance" as fourth pillar of a "fairly traditional four-pillar model of Sustainable Development", was discussed at the OECD-JRC conference on "Measuring Wellbeing and Societal Progress", Milano, 19–21 June 2006: The Follow-Up; at: <http://crell.jrc.ec.europa.eu/Well-being/WB_Summary_JRC.pdf> (August 2008).

23 The 1997 Eurostat publication "Indicators of Sustainable Development" contained 9 economic, 14 social, 21 environmental and 2 institutional indicators taken from the then official UN DESA list.

24 There is also no regular data collection for the UN CSD set. The last database was built in 2000 by John O'Connor, the former Head of the World Bank's environmental indicator programme, for the "From Rio to Jo'burg Dashboard"; at: <http://esl.jrc.it/envind/dashbrds.htm>.

25 The World Bank Institute's detailed indicator set falls into this category.

accident it excludes governance aspects, which gives the opportunity to highlight them in their own 'pillar' through the FSI.

- The *Environmental Performance Index* (EPI) is by far the best-known environmental index, due to the promotion by the World Economic Forum, and its solid academic background provided by the universities of Yale and Columbia. There is no real alternative to this set.[26]

All three sets have in common that the data are *really* available and not buried in badly maintained databases in not-so-accessible formats, but rather ready for download in handy spreadsheets, and part of an institutional setting that ensures regular updating of the data.

It is debatable whether one should take these indicators 'as is', i.e. as provided by the owners of the datasets, or whether omissions and/or additions are meaningful. The author believes that unless there is a compelling reason, the sets should *not* be modified. First, because it would be arrogant to think that the authors personal modifications would lead to a better result than many man-years of teamwork performed by specialists; second, even if the result was better, it would trigger a loss of ownership. Imagine that a future Sustainable Development Index became widely accepted by the media, and journalists would interview the makers of FSI, EPI and the MDG indicators set. If the SDI used their original sets, their reaction would be a sensation of proudness and ownership, and a renewed commitment to make it even better. If the SDI picked the cherries only, thus dismissing the conceptual efforts the teams put into these sets, the reaction might well be to call the lawyers and see how this abuse of data could be stopped.

And yet, the 'strawman' features one significant modification: MD Goal 8, "Global Partnership", has been deliberately left out. It is unlikely, though, that this omission would trigger harsh reactions, because it is generally felt that Goal 8 is less relevant for developing countries, since it focuses on donor countries' commitment to development, in particular regarding ODA and trade policies.[27] The author did not eliminate MD Goal 7, "Ensure environmental sustainability". Although one might argue that the environment is already present through the EPI, there are two good reasons *not* to exclude Goal 7:

1. One should maintain the consistency of the MDG set (and there is *no* general feeling that Goal 7 is less relevant to DCs – on the contrary);
2. Several of the Goal 7 indicators are social indicators in disguise, such as access to clean water and sanitation, and the percentage of slum dwellers; they are important but not yet covered in the EPI.

Considering these arguments, the question whether the 'right' indicators are chosen can be answered that a good compromise was reached between having perfect indicators and those that are available at a sufficient level of consistency and coherence, and provided by reliable initiatives.

91.4.4 Right Weights

Many indicator experts will claim that the question is irrelevant because one should not weight at all: Aggregation is misleading, obfuscates the facts, makes us lose valuable detailed information, is scientifically unsound, etc.; this debate cannot be solved here, but a few words are necessary to avoid the impression that the author is unaware of this debate.[28]

An example may illustrate the complexity: On behalf of the 27 heads of government of the European Union, a group of a dozen really senior researchers had been asked to write a report on the current situation, future trends and priorities of developing countries; and that they had been required to base their analysis on the available facts and figures, i.e. the roughly 100 variables underlying the 27 indicators of our strawman, for each of the 140+ countries. At one page per indicator and country, the report will have 100 x 140 = 14,000 pages – no problem for a powerful printer.

26 The EPI has been criticized for its idiosyncratic way of calculating the climate change score – which sees the United States in the green range, well ahead of, for example, Swaziland, Botswana, Djibouti and Guyana. While the EPI disqualifies therefore for judging EU environmental policies (having a strong stance on climate change issues), the choice of indicators such as 'CO_2 per electricity generation' and 'industrial carbon intensity' gives roughly the right message to poor nations' governments: 'Don't let your economies depend on oil imports'.

27 Unfortunately, Goal 8 also contains a handful of indicators that do not fit into this logic, such as 'telephone lines per 100 population', 'cellular subscribers' and 'internet users'. Besides this political argument, a much more explicit and elaborated the Commitment to Development Index is available at the Center for Global Development, Washington.

28 For the mathematically literate: see Nardo, Saisana, Saltelli and Tarantola (9 August 2005).

The trouble starts when the heads of government ask for an executive summary. Even if we assume that they are willing to read a dozen pages, we are still stuck with a substantial problem: How to condense 14,000 pages into only twelve? There is a pragmatic solution: Each of the twelve experts picks the three indicators and the three countries s/he knows something about, and writes one page highlighting the winners and losers. The problem of this 'solution' is that it insults the institutions that developed the other 64 indicators, and the people of the 104 countries that could not be covered by the analysis.

To avoid such political trouble, the group of senior researchers will be given a reasonable budget, so that they can put at work twelve groups of junior researchers to produce a thousand pages each. Of course, the seniors will ask for twelve 'sub-executive summaries'. Then, the final executive summary will *seem* to cover everything, will use plenty of phrases such as 'the economic situation in the Sahel zone is characterized by...' or 'the education system in Eastern Africa continues to be more efficient than elsewhere', and manage to arrive at the conclusions at page 11. What the authors definitely will *not* include is a description of the indicators used for assessing the overall 'economic situation' and the performance of 'the education system', let alone explain how they weighted different aspects of *economy* and *education* ...

The SDI strawman *mimics* the production of an executive summary, but it makes all choices and assumptions explicit. Of course, the same people who would silently accept the black box of a traditional executive summary are often the first to attack the explicit and transparent weightings used in a *Sustainable Development Index* (SDI). The ideological dispute on aggregation will continue, so at this point the author limits himself to one statement: Saying 'Thou shalt not aggregate my indicator batteries' is equivalent to telling a head of government 'There is no executive summary, you have to read all 14,000 pages'. Which leaves the reader with the rather trivial but unanswered question at the top, 'Are these the *right* weights?'

For both levels, equal weights were chosen; this means the scores of the 12 FSI indicators are multiplied by 8.33 per cent to arrive at the FSI score, to which MDG (7 x 14.3 per cent) and EPI (8 x 12.5 per cent) scores are added. Finally, the sum of the three sub-index scores is divided by three. Admittedly, choosing equal weights is a straightforward but arbitrary decision. Here are some alternatives:

- *Reduce the complexity* of reality: Instead of arguing about the relative weight of climate change vs. biodiversity, of child vs. maternal mortality, etc., just take GDP per capita. The problem is that many experts dislike this alternative, precisely because it assigns *very* unequal weights: 100 per cent to GDP, 0 per cent to all other aspects of development and conflict risk.
- Find some *magic formula*: Run the data through a statistical package, and pick a method that calculates the weights for the user. Here, the problem is that only statisticians will understand what has been done, and several of them will claim they know a much better formula that produces, unfortunately, completely different results.
- Let *experts decide:* Pick one-hundred conflict risk and sustainable development experts, give them the list of indicators and run a simple *budget allocation process* (BAP):

  > You are an expert for state failure and conflict risk. Here are 12 indicators related to your field of expertise. You have a budget of 100 points. How would you distribute these 100 points on the 12 indicators, in view of calculating an index that truly reflects the importance of each indicator in reducing the risk of violent conflicts?

That looks complicated, but this system works surprisingly well: The weights obtained are usually very near to one's plausible expectations, and in addition the survey creates a group of 100 experts who have participated in defining the weights. They develop a sense of ownership and are thus often willing to promote 'their preference' in conferences. However, the problem of the BAP is to find the panel experts: There are 140+ developing countries, so in order to be politically correct and to guarantee world-wide acceptance, one should at least find one expert per country. To ensure qualified replies to the survey, this person should be specialized in all 27 issues covered by the strawman.

While the latter alternative works in principle, it is evident that considerable manpower and a lot of time would be needed to set up such an expert survey. This is an alternative beyond the scope of a strawman. To conclude: equal weights are not the 'right' weights, but they are probably a lot more 'right' than those obtained by the first two alternatives outlined above. Furthermore, they give one clear message:

"Here are 27 measurable issues that may play a role in reducing the risk of conflicts, and in heading towards Sustainable Development. In the absence of clearly defined political priorities, we consider each of them *equally* important." This does not dissolve us

from the obligation to perform some statistical checks: A global *sensitivity analysis* (Saltelli/Ratto/Andres/Campolongo/Cariboni/Gatelli/Saisana/Tarantola 2008) identifies which indicators and which other elements of the calculation have the strongest influence on the final results, i.e. on those rankings that journalist *like* and politicians with low scores *hate*; sensitivity analysis helps to identify indicators that must be improved or replaced. It should be coupled with *robustness analysis*, i.e. the question whether weaknesses in the data can make the preferred index so volatile that it becomes unusable for judging conflict risk and SD performance? As a rule of thumb, indices with many components are more robust than those with a handful of indicators – little errors tend to compensate each other. Since the 27 indicators of the strawman are all indices themselves (for example, over 50 indicators are needed to calculate the seven MDG scores), they are probably robust enough to stand a political blow by somebody who dislikes the outcome.

91.4.5 Correct Data

With rare exceptions, neither official statistical services nor private institutions provide error margins for their data; getting reliable information on the quality and correctness of data used is almost impossible. It is an open secret that poor developing countries do not have the resources to provide reliable data, but partners in development cooperation have learned to live with this problem, and are trying to improve the consistency and reliability with various means, such as modelling, statistical plausibility checks, and coordination with partner countries, e.g. through the Paris 21 *Statistical Capacity Building Initiative*.[29]

Instead of asking for correct and precise data here and now, one should approach this question processwise: If incorrect data are being publicly used, and if experts openly criticize such data, then chances are high that the owners of such data will improve them. The internet is full of databases that nobody seriously uses, and a closer look at them usually reveals plenty of fairly obvious errors. Those databases instead that are used by a large number of experts and scientists tend to be well maintained, with footnotes flagging those problems that could not yet be eliminated, such as breaks in time series and similar methodological changes. In particular, those limited sets of indicators that are being used for calculating indices, such as the FSI and EPI, undergo thorough checking, and face strong criticism from the expert community if something goes wrong. The same applies to the United Nations MDG database: although not flagged for aggregation, it is used by a broad range of development experts, and therefore enjoys the kind of feedback that helps eliminating the errors.

The three datasets FSI, MDG and EPI have deliberately been chosen because of their public availability, and the commitment of the institutions behind to keep them public. There is no better mechanism than public access and user feedback to ensure that databases are being improved and maintained for many years to come.

Finally, the strawman, or a more elaborated 'SDI pilot', should not be seen as 'the' best available measure for describing conflict risk and SD, but rather as an invitation to discuss:

- whether the weights are correctly assigned,
- whether the right indicators have been chosen,
- whether the data are correct,
- what is missing in the picture.

91.4.6 The SD Index as a Conflict Prevention Tool

The *Sustainable Development Index* (SDI) seems to work, in the sense that the rankings obtained reflect well-known patterns; as in most country rankings, the Scandinavians are on top, Afghanistan, Somalia and Sub-Saharan Africa are at the bottom. So there are no big surprises. It is very important to recall that the objective of publishing such an index is not to *describe* 'reality' in all its facets. Finding the true level of conflict risk, and its key determinants, is a task that will keep a number of research disciplines, including economics, game theory, sociology and psychology, busy forever.

The goal of the SD index is rather to *change* reality, by using figures that are as 'true' as possible, and by exploiting the mechanisms of a media society: The hunger of journalists to get the headlines, the habit of voters to believe their messages, the fear of ministers to lose their posts. Scoring rank 99 among 200 countries is not particularly exciting; but losing three positions on a close neighbouring country does trigger debates, especially if the 'culprits' can be named and shamed.

This mechanism works best in a democracy with a free press; but even in more closed societies, opinion leaders have access to such information, and will use it. The availability of a detailed country profile for public debate is healthy for *any* society. However,

29 See at: <http://www.paris21.org/betterworld/goals.htm>.

apart from journalists, and ordinary citizens, there is another group of actors that deserves attention: investors.

Imagine you would have a Million Euros on your bank account, and were looking for a more profitable location to invest this money. You have two alternatives: First, a bank in Switzerland, offering an interest rate of 5 per cent; second, a bank in Somalia, offering 10 per cent. As *homo economicus*, you would of course take the higher offer – provided your friends and family would allow you to do so...

In real life, people invest in high risk countries only if they can expect, *on average*, a hefty profit. Risk aversion plays a strong role: The fear to lose is much higher than the joy to gain. Therefore, even if the expected profit (corrected for the probability of losing all our property) is twice as high as in Switzerland, we would rather not invest in Somalia. We might change our mind at 50 per cent, though – but this implies that poor Somalis have to work for much lower salaries than they deserve. To illustrate the argument with a simplified example: When producing a pair of shoes with a market value of 50€ in Switzerland, 5€ would go to the investor, 45€ to the worker; when producing an identical pair in Somalia, 45€ would go to the 'greedy' foreign investor, only 5€ to the Somali. There is surprisingly little research on this mechanism[30], but it is evident that insecure countries pay a high price.[31]

Would investors consult the SDI, or would they rather rely on Moody's?[32] Big investors have to justify their decisions in front of shareholders and the general public. While they may be inclined to trust a private specialized reliable black box more than a public not-so-specialized SDI, public opinion might force them to look also at a transparent SDI that takes into account human rights, democracy and other Western values, as well as country performance on education and health. The debate on economic ethics in the context of the Beijing Olympic Games shows that pure economic performance considerations should be balanced against the risk to lose a reputation. Overall, an investor finds in the SDI many relevant aspects: Confidence in the institutions, respect for human rights and democracy, education and health, respect for the environment, they all complete the picture and are able to give hints how sustainable an investment in country X would be.

91.5 Conclusions

Conflict risk needs monitoring. Researchers try to identify, by studying present and historic data and their correlations, what are the key variables promoting conflicts. Such information is certainly valuable for political decision-making, but it tends to be most useful for *understanding* conflicts, i.e. for their ex-post analysis.

The *Sustainable Development Index* (SDI) presented here is radically different from the researcher's approach. It starts from the assumption that conflicts will not thrive in a political climate that is driven by a transparent societal dialogue on a country's strengths, weaknesses, opportunities and threats. The SDI takes therefore a broad inclusive approach aimed at triggering informed debates between a country's government, opposition and civil society about the political priorities that have to be addressed in order to achieve sustainable development. The key idea is that societies which openly debate their tensions and conflicts can eventually resolve them before they escalate to violence. A detailed SD Index would be a good vehicle to promote such debate, but in order to succeed, it must be *more* attractive to the media and their audience than the current main policy guidance indicator, the rate of GDP growth. Acceptance of any new

30 The literature focuses on the 'risk premium' defined as the difference between returns from government bonds and 'risky'stocks, *for a given country*; see e.g. Mehra and Prescott (1985: 145–161). Comparisons *between countries* are difficult to find (but there are some, see next footnote), although analysts are aware of the phenomenon; see Ambrose Evans-Pritchard: "Georgia a reminder of 'Russia risk' premium ... This geostrategic earthquake comes at a moment when global funds are already starting to have serious doubts about the wisdom of sinking any more money into Vladimir Putin's Russia", in: *The Telegraph*, 12 August 2008.

31 In addition, the presence of big money tends to directly decrease the risk of violent conflict: "There is no evidence that the Russians intended to hit the [Baku-Tbilisi-Ceyhan pipeline], which is 30 per cent-owned by BP .. The BTC pipeline cost $3bn (£1.5bn) to build"; see at: <http://www.telegraph.co.uk/money/main.jhtml?xml=/money/2008/08/17/ccgeorg117.xml> (1 September 2008). It would be naïve to believe that British Petrol invests a billion dollars without political guarantees from the most relevant actors in the region.

32 Both Aswath Damodaran; at: <http://www1.worldbank.org/finance/assets/images/Equity_Risk_Premiums.pdf > (1 September 2008) and Allan Huang; at: <http://www.sjsu.edu/faculty/watkins/econ202/risk.htm> (1 September 2008) base their per-country risk premiums on Moody's information.

indicators is difficult to achieve, given that economic growth is still an overwhelmingly dominant political goal, and that GDP has been its yardstick for so many years. However, a carefully designed Sustainable Development Index that is not only technically sound but also resonates with the political interests of citizens might have a chance to make GDP history, and to enable a societal debate on real priorities, including the need to manage conflicts peacefully.

Part IX Towards an Improved Early Warning of Conflicts and Hazards

92 Networking Disaster and Conflict Early Warning in Response to Climate Change

Patrick Meier

92.1 Introduction

Can *Disaster and Conflict Early Warning* (D/CEW) systems be networked to untangle the multiple but interdependent crises that characterize complex emergencies, particularly in response to climate change? In other words, can continuous information gathering identify the socio-ecological ingredients of complex crises before they escalate into widespread violence? And if so, can early warning methodologies based on events-data analysis provide the common platform to network D/CEW for early response?

The purpose of this chapter is to explore these questions from the perspective of a scholar-practitioner engaged in the development of field-based conflict reduction systems. The questions posed will be addressed using the case-study method. To this end, the *Conflict Early Warning and Response Network* (CEWARN) in the Horn of Africa serves as the primary case study.

After highlighting the confluence of climate change and complex emergencies (92.2), I briefly review the perennial conflicts between nomads and resident farmers in the Sahel Zone, both in West and in East Africa (92.3). This is followed by a presentation of CEWARN as an operational methodology being adapted to network D/CEW (92.4). The next section outlines how networked warning systems can remain effective in response to climate change (92.5), while the final section ties the above analysis to people-centered early response (92.6).

92.2 Climate Crises and Isolated Responses

The occurrence of 'natural' disasters amid complex political crises is increasingly widespread: over 140 natural disasters have occurred alongside complex political crises between 2001 and 2006 alone (UN 2006). "The dramatic increase in major disasters witnessed in the last 50 years [also] provides worrying evidence of this trend, [and] if climate change produces more flooding, heat waves, droughts and storms, this pace may accelerate" (UN 2004a: 27). In fact, average worldwide losses from natural disasters have been increasing exponentially since 1960 (Munich Re 2005). To make matters worse, where conflicts already exist, "the threat of climate change is likely to exacerbate, rather than ameliorate matters because of uncertainty about the amount of future resources that it engenders" (IPCC 2001a: 225; IPCC 2007: 14). At the same time, political crises and armed conflicts indirectly exacerbate the impact of natural disasters by exhausting coping mechanisms and response capacities (Brauch 2002). Indeed, human-driven "environmental degradation has enhanced the destructive potential of natural disasters and in some cases hastened their occurrence" (UN 2004a: 27).

In this rush of feedback loops, "the catastrophic risks are magnified by the fact that some risks are positively correlated" (Posner 2004: 89), which implies that "regional climate change, as with other causes of environmental degradation, could make armed conflict more likely" (Purvis/Busby 2004: 68), with "more people on the move, internally and across borders, [seeking] livelihoods away from stressed areas" (Walker 2006: 2). During the last decade, for example, an estimated 188 million people per year worldwide were affected by natural disasters, more than 6 times the 31 million annually affected by armed conflict (Purvis/Busby 2004). The *International Panel on Climate Change* (IPCC) warns that "migration of populations affected by extreme events or average changes in the distribution of resources might increase the risks of political instabilities and conflicts" (IPCC 2001: 85; IPCC 2007a: 12). At present, an estimated 25 million people per year are fleeing temporarily from weather-related disasters and global warming is projected to increase this number at least eight-fold

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_92, © Springer-Verlag Berlin Heidelberg 2011

to some 200 million before 2050 (Myers 2002: 609). Ethnic compositions usually in flux may solidify around local resource- and identity-based conflicts as a result. The most recent drought and famine in the Horn of Africa in year is unfortunately yet another data point on this grim scatter plot since it had an immediate impact on the fluid relationships between pastoral groups. To be sure, "the ethnic composition of countries can be altered [or sharpened] by migration. This is one of the most widely cited conflict-generating effects of climate change in the literature" (Nordås/Gleditsch 2005: 18).

There is little doubt that climate change will spawn new ecological crises across Africa (Bättig/Wild/Imboden 2007) but these needn't become complex political emergencies unless perilously managed – perhaps deliberately so – by outdated strategies of war and diplomacy (Sachs 2006). Clearly then, "study[ing] the linkages between human insecurity and conflict and between humanitarian crises and conflict is vital," but these linkages "have not been as widely studied as the political and military factors that lie behind [them]" (Lacina/Gleditsch 2005: 149–150). More effective cross-disciplinary research is desperately needed to bridge the archipelago of disaster studies (Hewitt 1983a). To be sure, partitioning the general study of disasters from other fields, and partitioning specialties within disaster studies from other specialties, "creates a patchwork of isolated approaches rather than what we need: a coherent, comprehensive, and connected view" (Email by Ilan Kelman, 18 January 2007).

These isolated approaches may explain why the disaster management and conflict prevention communities hardly collaborate. Indeed, they opine that disaster and conflict early warning systems "are logically different" (Schmeidl/Jenkins 1999: 474) even though "both types of disasters have commonly led to massive internal and external displacements of people" (Ryan 1992: 166), and many such disasters, "whether man-made or natural, are interlinked, and disaster-prone regions, countries or groups are vulnerable to any kind of disasters" (Kuroda 1992: 217). In other words, "despite the different origins of disasters, they share many common elements" (Helbing/Ammoser/Kühnert 2006: 332). Moreover, there are obvious functional parallels in risk assessments, monitoring and warning, dissemination and communication, response capability and impact evaluation. These analogous functions have real operational consequences for implementing organizations and stakeholders (Brauch 2003f; Brauch/Oswald 2006).

Still, the two communities are not engaged in either joint dialogue or scientific research. This is ironic given repeated concerns that *disaster early warning* (DEW) systems are too narrowly focused on meteorological and agricultural information at the expense of socio-political indicators (Maxwell/Watkins 2003; UN 2006; Dynes 1998), while *conflict early warning* (CEW) systems are being urged to integrate environmental change indicators into their analyses (Brauch/Oswald 2006; Meier 2006). These converging trends suggest that D/CEW do share the same functional logic: early detection and early response.

92.3 Pastoral Conflict

In Genesis: "Cain said to his brother Abel; And when they were in the field, Cain rose up against his brother Able and killed him (...)." The reader will notice that what Cain actually said to Abel is omitted in the passage. One respected interpretation gives a plausible explanation: Cain and Abel had divided the world between them and Cain owned all the land and "became a tiller of soil," while Abel took possession of the livestock and "became the keeper of sheep." According to this religious commentary, Cain told Abel to get his livestock off his brother's land and this triggered the first violent conflict over resources. Pastoral conflict is certainly as old as civilization itself but is it merely a coincidence that "many of today's major conflicts are fought in pastoral regions – places such as Somalia, Afghanistan, Sudan and Palestine?" (Nori/Switzer/Crawford 2005: 3). To be sure, pastoralists are often dubbed the "climate change canaries" – the people most likely to become the first victims of world climate change according to a recently commissioned report (Christian Aid 2006: 3).

The relationship between violent conflict and pastoral groups is by no means a new one. Krati and Swift (1999) argue that a certain level of conflict is endemic to many pastoral areas. Resource-related conflicts are widespread in pastoral ecosystems and may fuel conflict as more people compete for fewer resources (Blench 1996; Klare 2001, Homer-Dixon 2001, 1995; Suhrke 1996). This necessarily presents tensions between nomadic peoples and more sedentary farmers. However, Turner (2004) argues that the source of farmer-herder conflicts in the Sahel goes beyond resource related competition. He asserts that "the complex relationships between political interests, moralities and resource access" are what "underlie these conflicts (Turner 2004: 863). Clearly, pastoral conflict

is part of a much larger literature that spans the world, it's history and questions the vary nature of human beings (McCabe 2004: 81). Since this chapter's focus is specifically on herder-herder conflicts, we turn our attention to the causes of such conflicts.

Pastoral conflict takes different forms. "Local-level conflicts over natural resources, of which livestock raiding is one specific form, are endemic in Africa's pastoral and agro-pastoral systems" (Hendrickson/Mearns/Armon 1998: 189). To be sure, raiding has been characteristic of the people living in East and West Africa for much of the twentieth century. Raiding is very much linked to pastoral traditions, which provide a right of passage for young men. Cattle give status and are used as dowry in marriage. To this end, raiding was based on clear principles of reciprocity. For example, elders from the attacking group would often notify their enemy of the approaching raid.

These days, cattle raiding and theft are thought to be the result of more complex cross-scale dynamics. Hendrickson, Mearns and Armon (1998) argue that raiding has been transformed "from a quasi-cultural practice with important livelihood-enhancing functions, into a more predatory activity," which "occurs on a very large scale, is extremely violent and is sponsored by actors from outside the pastoral sector with criminal motives" (Hendrickson/Mearns/Armon 1998: 186). It is abundantly clear that environmental factors are not the sole cause of pastoral conflicts. In seeking to identify the causes of environmental conflicts, "political ecologists follow a mode of explanation that evaluates the influence of variables acting at a number of scales, each nested within another, with local decisions influenced by regional policies, which are in turn directed by global politics and economics" (Robbins 2005: 11).

To be sure, a pastoral system represents a complex form of natural resource management, which Pratt et al. (1997) define as the direct interaction between three systems: 1) the ecosystem; 2) the social system and 3) the geopolitical system. This interaction occurs at multiple geographical and temporal scales with the interplay between endogenous and exogenous causal factors adding further complexity to the dynamic that episodically is punctuated by violent conflict.

Evidently, identifying all the possible causes of pastoral conflict poses a Herculean task and remains beyond the scope of this chapter. However, we would be remiss if we ignored other plausible causes of pastoral conflict altogether since a strict resource-scarcity approach to understanding pastoral conflict can undermine legitimate claims that socio-economic and political factors also influence the control, use and vulnerability that result from natural resource management. What follows is therefore a a very brief summary of the literature on pastoral conflict in the Horn of Africa's Karamoja Cluster and is not meant to serve as an exhaustive or comprehensive assessment.

The causes of conflict are often divided into two distinct categories – structural and proximate causes. The former are generally long-term social, economic, political and environmental processes that provide a permissive environment for violent conflict even though they only change slowly with time while the latter include more direct and immediate causes of violent conflict. Structural and proximate causes of conflict in the Karamoja Cluster can be further divided into those that are endogenous or internal to the cluster and those that are external the region.

Clearly, these categories are fluid and their borders porous. Causes and consequences of conflict tend to merge in certain circumstances with some indicators appearing both as causes and consequences (Oxfam 2004: 17). We therefore identify plausible indicators of conflict based on the loose definition of structural and proximate categories from the perspective of the three systems identified above by Pratt et al. (1997): the ecosystem, social system and global system.

92.4 CEWARN and Methodology

Established in 2003, the *Inter-Governmental Authority on Development's* (IGAD) *Conflict Early Warning and Response Network* (CEWARN) in the Horn of Africa uses events-data analysis to monitor and anticipate pastoral conflict (box 92.1). In 2005, the author helped to initiate CEWARN's collaboration with IGAD's *Climate Prediction and Assessment Center* (ICPAC) in order to network the D/CEW systems. The focus on pastoral conflict and climate change in the Horn's cross border regions is salient since similar ecological ingredients were present in the Sudan during the 1980's. Indeed, "is it merely a coincidence that many of today's major conflicts are fought in pastoral regions – places such as Somalia, Afghanistan, Sudan and Palestine?" (Nori/Switzer/Crawford 2005: 3).

Box 92.1: Facts on the CEWARN Project. **Sources**: Meier year; CEWARN website, AT. <add URL>.

CEWARN was initiated by IGAD and became operational in June 2003. Its participating Member States have been: Djibouti, Eritrea, Ethiopia, Kenya, Sudan and Kenya. Its mandate is to prevent cross-border pastoral conflict. Its geographical coverage: The Karamoja and Somali Clusters in the Horn of Africa. Its Methodology: Incident and situation reporting, event-data and baseline analysis. Important links are; <www.cewarn.org> and: <www.iss. co. za/af/regorg/unity_to_union/pdfs/igad/Protocol. pdf>.

Pastoral conflict is considered inherent to many pastoral ecosystems (Krati/Swift Box 1999). Indeed, "local-level conflicts over natural resources, of which livestock raiding is one specific form, are endemic in Africa's pastoral and agro-pastoral systems" (Hendrickson/ Mearns/Armon 1996: 189). Pastoral groups inhabit a mercurial ecological system, which can hardly be ignored as having a potential influence on pastoral conflict and beyond. Little wonder then that pastoralists have been dubbed the "climate change canaries" according to a recently commissioned report, which suggests that pastoralists in the Horn of Africa are likely to be the first people wiped out by climate change.[1]

Swisspeace and *Virtual Research Associates* (VRA) were invited by IGAD to develop and operationalize an appropriate methodology for CEWARN.[2] The project's specific focus on pastoral conflict necessitated a customized approach since "preventive action requires a degree of specificity which usually does not flow from global [or macro] indicators" (Ryan 1992: 170). VRA therefore proposed and developed a fully customized approach that went beyond Swisspeace's event-logging methodology (Bond/Meier 2005, 2006). In 2007, CEWARN field monitors use fully customized surveys to report from more than twenty locations along the borders of Ethiopia, Kenya, Somalia and Uganda –collectively known as the Karamoja and Somali Clusters (figure 92.1). Instead of event-logging, CEWARN integrates two types of complementary, standardized and structured surveys: 'incident reports' and 'situation reports'.

Incident Reports (IncReps) are surveys used to document specific incidents of pastoral conflict that CEWARN seeks to prevent. Local area experts from Ethiopia, Kenya and Uganda identified these incidents during a series of indicator workshops. IncReps are used to record '*who did what to who, where, when* and *how*', when these incidents occur. IncReps also document the consequences of individual incidents. In addition, each report includes measures for quality control and a short textual description or narrative of the incident, which provides the context for subsequent interpretation. Like Swisspeace's event-logging approach, Incident Reports are completed episodically, that is, when incidents occur. However, "everyone knows at least since David Hume that we have no reason to believe that the association of events provides a basis for inferring the presence of a causal relation" (Waltz 2000: 9). Furthermore, since the purpose of early warning is to anticipate these incidents *before* they occur, this retroactive approach misses the point. Early warning analysis must move beyond the event-logging approach to context-based, forward-looking methodologies that monitor precursors to peace and conflict.

Figure 92.1: The dotted area represents the Karamoja and Somali Clusters that have been monitored by CEWARN. **Source:** This map was prepared by this author.

1 Christian Aid, 2006; "Life on the Edge of Climate Change: The Plight of Pastoralists in Northern Africa"; at: <www.christian-aid.org.uk/indepth/0611climatechange 2/kenya_climatechange.pdf>.

2 The author was previously a consultant to FAST, VRA and IGAD between 2003–2006, but all information included in the chapter is publicly available.

This explains why CEWARN uses *Situation Reports* (SitReps). The purpose of SitReps is to monitor situational processes that render the likelihood of those incidents both more *and* less likely. In other words, SitReps use a weighted scale to monitor both precursors and mitigating processes associated with pastoral conflict incidents. Relevant situational processes were identified and 'unpacked' into discrete events by local area experts with extensive knowledge of pastoral livelihoods. In other words, precursors and mitigating factors were translated into physically observable indicators. It is important to note that SitReps monitor a wide range of events. These include events associated with communal relations, civil society activities, economic activity, governance and media, natural resource use and disasters, safety and security, and social services. Like IncReps, each Situation Report includes contextual descriptions of evolving situations. Unlike IncReps, they are completed on an episodic basis, currently weekly; thus ensuring that processes are monitored systematically.

By complementing these two types of surveys, CEWARN can empirically verify which precursors of pastoral conflict (documented in SitReps) are most closely correlated with subsequent pastoral conflict incidents (tracked in IncReps). Furthermore, by monitoring precursors of conflict (and not just outcomes), CEWARN may be in a position to respond to an increasing frequency of precursor events *before* these translate into irreversible incidents – such as the body counts documented in IncReps. In other words, developing SitRep baselines of precursor events is tantamount to monitoring social vulnerability and needs, while baselines of mitigating factors quantify changes in social resilience since they focus on "what is already in place: resources and adaptive capacities" (O'Brien/O'Keefe/Rose/Wisner 2006: 71).

Box 92.2: CEWARN Reports along with the aggregated data are available on-line at: <www.cewarn.org> for the time period from April 2004 to August 2006 (update).

Bond and Meier (2006) describe an early success story at CEWARN: "In July 2003 a field reporter submitted a report of a pre-raid blessing. This kind of a report is considered a signal or trigger for acute conflict in the near term, as a raid typically follows the blessing. Upon reviewing this field report, a CEWARN staff member in Addis called the country coordinator responsible for quality control in that area, and he in turn called the field monitor. Several telephone discussions later, the local police agency in the area was informed of the impending raid. The police responded by holding a previously scheduled training exercise in proximity to the two parties identified by the field reporter. The bottom line is that no raid occurred" (Bond/Meier 2006: 132). However, it should be noted that this success was not due to CEWARN's analysis of incident and situation reports (i.e., academic analysis) but rather through a process akin to signals intelligence. Also telling is the fact that only a handful of other potential success anecdotes have surfaced. This may suggest that an institutionalized, bureaucratic approach to early warning may have serious limitations.

Using a data-driven approach to humanitarian reporting means that the information collected is amenable to statistical and geospatial analyses. Indeed, the data collected using Incident and Situation Reports can be used in baseline or time-series analysis to identify trends and anticipate subtle changes in vulnerability that may lead to complex emergencies crises. Such changes or inflections in baselines may signify a deviation from the 'norm' which may indicate the need for early response. To be sure, "understanding structural causes [or processes] and recognizing the events and actions that lead to conflict should highlight potential moments and fields for intervention" (van de Goor/Verstegen 1999: 4).

Baseline analysis is thus "the fundamental building block of a rational information system" since "proper baseline data make it possible to identify the most critical information types for early warning" (Maxwell/Watkins 2003: 76, 87). Moreover, baselines analysis permits the testing of counterfactuals, which is "an essential tool because the concrete event is too complex to subsume under causal generalizations or theoretical laws" (Griffin 1993: 1101). At the same time, textual descriptions or narratives included in the Incident and Situation Reports provide the necessary context to interpret and comprehend change. "Events, then, are our points of access to structuring and narratives are how we describe, reconstitute and comprehend events" (Griffin 1993: 1098). The bottom line is that the use of both Incident and Situation Reports produces more reliable baselines.

This approach may then provide an advanced warning of impending incidents directly relevant to pastoral conflict, thus rendering systematic conflict prevention more than a hypothetical possibility. In addition, by monitoring mitigating processes, CEWARN can identify the "causes of resilience" or local knowledge and coping mechanisms employed by indigenous stakeholders when confronted with stressful situations produced by conflict and/or environmental change (Walker 1992). Information on the drivers of resilience is invaluable since recognized trends in coping mechanisms can serve to guide and inform early response and capacity building with respect to livelihoods (Meier/Zambiras 2006). The section that follows outlines how conflict systems networked with disaster systems can be adapted to inform prevention and mitigation strategies in response to climate change.

92.5 Networking Early Warning for Climate Change

Taking a multi-hazard approach by monitoring both events and the situations that lead to them is a critical component of a robust early warning and response system, particularly within the context of climate change (Reid 2006; Maxwell/Watkins 2003). This is because "disasters triggered by environmental phenomena do not cause political change, rather they act as catalysts that put into motion potentially provocative social *processes* at multiple social levels" (Pelling/Dill 2006: 4). Put differently, there is a subtle but fundamental difference between disasters [processes] and hazards [events], a distinction that Jean-Jacques Rousseau first articulated some two hundred years ago after Portugal was shaken by an earthquake in 1755.[3] In a letter to Voltaire one year later, Rousseau notes that, "nature had not built the houses which collapsed and suggested that Lisbon's high population density contributed to the toll" (Kelman 2007).

In other words, natural events are hazards and exogenous while disasters are the result of endogenous social processes (Oliver-Smith 1986; Glantz 1994; Hewitt 1995; Cardona 2004).[4] As Rousseau added in his note to Voltaire, "an earthquake occurring in wilderness would not be important to society" (Kelman 2007). That is, a hazard need not turn to disaster since the latter is strictly a product of social processes (O'Keefe/Westgate/Wisner 1976; Lewis 1988; Kelman 2007). And so, while disasters were traditionally perceived as "sudden and short lived events, there is now a tendency to look upon disasters in African countries in particular, as continuous processes of gradual deterioration and growing vulnerability," which has important "implications on the way the response to disasters ought to be made" (cited in Rupesinghe 1988: 219). But before we turn to the issue of response, what does the important distinction between events and processes mean for early warning?

In *The Poverty of Historicism* (1944), the Karl Popper distinguished between two kinds of predictions: "We may predict (*a*) the coming of a typhoon [event], a prediction which may be of the greatest practical value because it may enable people to take shelter in time; but we may also predict (*b*) that if a certain shelter is to stand up to a typhoon, it must be constructed [process] in a certain way" (Popper 2002: 38). A typhoon, like an earthquake, is certainly a hazard, but it need not lead to disaster if shelters are appropriately built since this process culminates in minimizing social vulnerability. In contemporary disaster research, "it is generally accepted among environmental geographers that there is no such thing as a natural disaster. In every phase and aspect of a disaster – causes, vulnerability, preparedness, results and response, and reconstruction – the contours of disaster and the difference between who lives and who dies is to a greater or lesser extent a social calculus" (Kelman 2007).

The vulnerability or resilience of a given system is not simply the outcome of future events since vulnerability is the complex product of past political, economic and social processes (O'Keefe/Westgate/Wisner 1976). "The role of vulnerability as a causal factor in disaster losses tends to be less well understood, however. The idea that disasters can be managed by identifying and managing specific risk factors is only recently becoming widely recognized" (Dilley/Chen/Deichman/Lerner-Lam/Arnold with Agwe/Buys/Kjekstad/Yetman 2005: 19). This explains why past "discussions with regard to early warning systems

3 This event triggered earthquake research in Europe and also served as the focus for various publications, ranging from Kant's (year) essay about the causes of earthquakes to Voltaire's "Poème sur le désastre de Lisbonne" (Jentsch/Kantz/Albeverio 2006).

4 The endogeneity argument holds for society as a whole, but not necessarily for specific communities, countries, or regions. All disasters result from social processes, but many disasters result from social processes external to the community, which experiences the disaster.

have emanated from a concern with the early prediction and reporting of events [instead of processes] which could lead to social disasters" (Rupesinghe 1988: 224).

Consider an hourglass or sand clock as an illustration of vulnerability-as-causality. Grains of sand sifting through the narrowest point of the hourglass represent individual events or natural hazards. Over time a sand pile starts to form, which represents the evolution of society or the connectedness of a social network. Occasionally, a grain of sand falls on the pile and an avalanche or disaster follows.[5] Why does the avalanche occur? One might ascribe the cause of the avalanche to one grain of sand, i.e., a single event. On the other hand, a systems approach to vulnerability analysis would associate the avalanche with the pile's increasing slope and to the connectedness (or population density) of the grains constituting the pile since these factors render the structure increasingly vulnerable to falling grains. Left on its own, the sand pile's stability, or the social network, becomes increasingly critical or vulnerable.[6]

From this perspective, "all disasters are slow onset when realistically and locally related to conditions of susceptibility" (Lewis 1988: 4). A hazard event might be rapid-onset, but the disaster, requiring much more than a hazard, is a long-term process, not a one-off event. We must therefore "reduce as much as we can the force of the underlying tectonic stresses in order to lower the risk of synchronous failure – that is, of catastrophic collapse that cascades across boundaries between technological, social and ecological systems" (Homer-Dixon 2006: 281).

Unlike the clock's lifeless grains of sand, human beings can minimize their vulnerability to exogenous shocks through disaster preparedness, mitigation and adaptation. In doing so, individuals can 'flatten' the structure of the sand pile into a less hierarchical system and thereby shift or diffuse the risk of an avalanche.[7] In conflict prevention terms, this means structural prevention, which typically focuses on local livelihoods and local capacity building. Early warning should thus seek to monitor both the falling grains *and* the vulnerability of the sand pile to determine the risk and magnitude of an avalanche. In more formalistic language, a dual approach is important because it is not always clear *a priori* whether a disaster is due to a strong exogenous, to the internal dynamics of the system or a combination of both (Sornette 2006). As the disaster management community has learned, in "support[ing] good decision-making, the issue is not one of being able to predict the unpredictable. Rather, the fundamental question is that, given that we cannot have reliable predictions of future outcomes, how can we prevent excessive hazard levels today and in the future in a cost-effective manner?" (Chadná/Motchanova/Obersteiner 2006: 296). To this end, risk is often defined as the product of hazard, exposure[8] and vulnerability (some divide this product by resilience which is a function of knowledge and capacity):

$$\text{Risk} = (\text{Hazard} \times \text{Exposure} \times \text{Vulnerability}) / \text{Resilience}$$

This explains why a simple event- or hazard-logging approach to D/CEW is sub-optimal.[9] D/CEW systems should systematically focus on both events *and* processes in order to calculate and forecast both the risk of a typhoon and the resilience of a shelter. This requires cross-disciplinary collaboration between "geologists, seismologists, meteorologists and other scientists who can monitor and predict hazards, while social scientists are brought in to explain people's behavior in response to risk and disaster and to develop early warning mechanisms and disaster preparedness schemes" (Hillhorst 2004: 52). In other words, close cross-disciplinary collaboration between the D/CEW communities from both the Global North and South is critical, as is the participation of local stakeholders.

5 Note that this analogy is more than simply conceptual; the distribution of avalanches in sand piles with respect to frequency and magnitude follows a power law, i.e., frequency and magnitude are inversely proportional. The distribution of fatalities resulting from natural disasters and armed conflict also follows a power law (see Meier/Spagat/Becerra/Restrepo 2006).

6 This is an ordinary process in complex systems called self-organized criticality.

7 The author realizes that social and physical systems are not closed, as the hourglass analogy would suggest. In addition, within the context of climate change, avalanches in the sand pile have a feedback effect on the frequency and magnitude of the falling sand. In other words, human-induced climate change "emphasizes the mutuality of hazard and vulnerability to disaster due to complex interactions between nature and society" (Hilhorst 2004: 53).

8 This parameter is particularly salient in face of climate change since exposure times are increasing while recovery times between disasters are being reduced (Walker 2006; Maxwell/Watkins 2003).

9 Earthquake physicists do not only document where and when earthquake events take place, they focus predominantly on the composition of fault processes (Stein 2005).

If event-data analysis is to be used as a platform to network D/CEW, then ecological causes of conflict need to "be concrete events specific to concrete situations" (Vayda/ Walters 1999: 171). In this respect, "if the object of explanation is truly to be environmental change," the methodology used to network early warning within the context of climate change might be characterized as an event-focused approach to ecological study, or "event ecology" (Lees/Bates 1984: 78). This method focuses first and foremost on "the environmental events or changes that we want to explain and then work[s] backward in time and outward in space so as to enable us to construct the chains of causes and effects leading to these events or change" (Vayda/Walters 1999: 169).

Event ecology is compatible with an events-data approach to CEW since the latter already uses data-driven analysis as a framework for reporting and analysis. An integrated events-data approach to disasters, conflicts and climate change may therefore provide an appropriate platform upon which to network D/CEW. However, given the importance of monitoring processes, this platform must not be limited to basic event-logging but should instead adopt the 'incident' and 'situation reporting' methodology developed by CEWARN. Furthermore, relevant ecological processes relevant to violent conflict should be identified in collaboration with local stakeholders and the climate scientists at ICPAC. These can then be networked into CEWARN's SitReps as discrete observations that serve as precursors or mitigating factors to pastoral conflict. In other words, contrary to recent recommendations that DEW should focus more on social and political indicators, the author maintains that D/CEW systems should maintain their individual comparative advantages and simply collaborate by 'trading' raw data in real-time.

With this in mind, a recent pilot study has demonstrated empirically the added value that closer collaboration between the D/CEW communities can offer.[10] Given pressing concerns over the implications of climate change for pastoral conflict in the Horn of Africa, the author drew on geo-referenced "event ecology data" from the *Livestock Early Warning System* (LEWS), the *Malaria Early Warning System* (MEWS) and IGAD's *Climate Prediction and Assessment Center* (ICPAC) to create baselines for forage, rainfall and vegetation availability respectively. By using *geographic information system* (GIS) data, these baselines or time-series were comparable to CEWARN's conflict baselines in both time and space. This study would *not* have been possible without CEWARN monitoring both events *and* processes.

Meier, Bond and Bond (2007) have demonstrated the potential added value of D/CEW by linking CEWARN with LEWS and MEWS by drawing on GIS data and analysis. Their preliminary findings, based on several multivariate regressions, suggest that the availability of vegetation is directly proportional to the social triggers of pastoral conflict with a two-to-three month lag. In other words, the correlation between high vegetation and high conflict triggers appears to be statistically significant at the 95 per cent confidence level, which may at first seem counterintuitive (Meier/Bond/Bond 2007). One of the advantages of networking disaster and conflict early warning systems is that results can be interpreted in an integrated manner. This can illuminate the influence of intervening factors. Upon further cross-disciplinary research, the key to explaining the results lay in raiding tactics. Indeed, as grasses grow tall, pastoralists seeking to raid cattle gain cover and therefore the advantage of surprise. Given that ICPAC provides high-resolution vegetation forecasts several months in advance, systematically integrating this ecological indicator (and others) into CEWARN's analysis is long overdue. An integrated approach may become even more pressing given the impact climate change is expected to have on pastoral societies worldwide. This warrants closer institutional collaboration between conflict and disaster early warning systems. However, such collaboration should not be limited to early warning only, but must also include early response.

92.6 In Response to Early Warning

The process of decision-making in the context of early warning is fraught with organizational barriers (Campbell/Meier 2007). That said, the disaster management community has made more progress in identifying and tackling these barriers than the conflict prevention community. They have also been in the business of early warning for longer than those engaged in conflict early warning. However, the two communities rarely share lessons learned and best practices (Brauch/Oswald 2006; Meier 2006), which may explain why conflict early warning systems continue to be 'wired' vertically – that is, early warning information is centralized and transmitted hierarchically (Barrs 2006).

10 For a detailed cross-disciplinary analysis of early response form a complex systems perspective, see Meier (2007).

Why are these systems vertically wired in the first place? Because first generation conflict early warning systems were designed with Western interests in mind – to control and remain abreast of escalating violence well beyond their own borders. Admittedly, "the social process of prediction, whether of physical or social events, is to secure a measure of control" (Rupesinghe 1988: 217). This explains why CEW is still largely an "exercise in understanding how what is happening over there comes be known [and controlled] by us over here" (Adelman 1998: 2). These centralized systems reflect the hierarchical power structures that already exist in international relations. They rarely recognize that "a democratic flow of information is the first condition for a democratic and open system of warning and resolution" (Rupesinghe 1988: 221). Indeed, a democratic approach to local early response for civilian networks in zones of conflict does not figure prominently since conventional systems take a hierarchical and egocentric view of early warning. In fact, local at risk communities often remain completely unaware that formal warning systems even exist (Barrs 2006), which means they exclude the real stakeholders even though "humanitarian early warning is [allegedly] based on protecting the interest of others who are at risk" (Schmeidl/Jenkins 1999: 482).

The central question is who controls or owns the information? Put differently, it is "not only timeliness and effectiveness, but also the question of whose interests are to be served," that matter in early response.[11] Furthermore, even though CEWARN is headquartered in Addis Ababa and not in Berne, the initiative still remains too hierarchical for early warning information to be customized to meet the *demands* of the end users. Some have described this using the analogy of planning food for a dinner party. "We not only need to know how many people are coming but who is coming, the time of the day, and the season. Without such knowledge, we may prepare the perfect dinner for the wrong set of people" (Krummenacher/Schmeidl 2001: 6).

However, the real stakeholders – the communities at risk – may not actually be on the guest list in the first place. As consumers of early warning information, we buy expensive alerts, flashy bulletins and colorful reports. Our early warnings are e-mailed around the world in the blink of eye but "rarely touch the ground where the killing happens. They fly through cyberspace, high over the victim's heads. People at risk on the ground might never learn that the *demarches* we write on their behalf even exist" (Barrs 2006: 2). And so, the rhetoric labels the communities at risk as "the intended beneficiaries; but, in practice they [are] not the real clients of early warning activities" (Stephen 2004: 106). From the perspective of vertically wired early warning systems, "we [the West] are the rescuers; aid does not start until we arrive" (Barrs 2006: 1). Unfortunately, we rarely arrive – Darfur being just one tragic example among dozens of "neglected crises" in addition to numerous so-called "forgotten emergencies" (World Disaster Report 2006).

The trouble with CEWARN and similar systems such as FAST is that they are designed to trigger a response from the outside. When early warning is targeted vertically, "that is from the informants to their headquarters – there must be an onus upon the headquarters to act. There is little point in investing in warning system if one then ignores the warnings!" (Walker 1992: 102). To be clear, "early warning should not be an end in itself. ... The real issue is not detecting the developing situation, but reacting to it" (Kuroda 1992: 217). Accountability and incentives to react, however, are often a function of scale. That is, communities at risk 'on the ground', are more likely to respond to conflict than a bureaucratic organization situated several thousand miles away. The limited ability to operate at the scale that generates a manageable or self-organized incentive structures for early response is another drawback of centralized early warning systems.

The field of disaster management has recognized that incentive structures are more likely to reside with the local communities themselves. The UN Global Survey of Early Warning Systems (2006: 2) defines the purpose of people-centred early warning systems for natural disasters as follows: "to empower individuals and communities threatened by hazards to act in sufficient time and in an appropriate manner so as to reduce the possibility of personal injury, loss of life, damage to property and the environment, and loss of livelihoods." This explains why "increasing attention is now paid to the capacity of disaster-affected communities to 'bounce back' or to recover with little or no external assistance following a disaster" (Manyena 2006: 433). To this end, people-centered early warning in the context of conflict prevention would "seek to inculcate a situational or security awareness within high-risk communities as it builds on local capacities to address and reduce their vulnerabilities in a sustainable way, which differs from the traditionally more 're-

11 Email exchange with Professor George Kent, 3 February 2007.

mote' and 'vertical' monitoring" (Bond/Meier 2006: 130).

Although the conflict prevention community has yet to embrace a new discourse let alone a people-centred approach, nonviolent social movements may be the closest parallel to people-centred warning systems for natural disasters. Indeed, lessons learned in disaster early warning systems suggest that, "the usefulness of this [people-centred] approach lies not so much in predicting ..., but in building up a strong partnership between local community and the relief agency" (Walker 1992: 103). Similarly, "prevent[ing] violent conflict requires not merely identifying causes and testing policy instruments but building a [social and] political movement" since "the framework for response is inherently political, and the task of advocacy for such response cannot be separated from the analytical tasks of warning" (Rubin 2002: 37–38, 147).

Why then are CEW and nonviolent movements erroneously assumed to be conceptually and operationally distinct in the practice of conflict prevention? Isn't communication central to both early warning and nonviolent action? Indeed, and some of the most successful nonviolent campaigns detailed in numerous case studies turned on the ability to get accurate, timely information (Ackerman/Kruegler 1994). The literature on military history also demonstrates that "success in counter-guerrilla operations almost invariably goes to the force which receives timely [local] information" (Thompson 2002: 52).

Reliable people-centred early warning is also vital when conducting manoeuvres of defensive dispersion within the context of strategic nonviolence. Tactical evasion is a central component of strategic nonviolence: people must be capable of concealment and dispersion. However, getting out of harm's way and preparing people for the worst effects of violence requires sound intelligence and timely strategic estimates (Helvey 2002). To be sure, a realistic appreciation of impending violence based on people-centred early warning makes it possible to motivate civilian groups to respond early in conceiving plans for evasive action and protection. At-risk communities can, for example, "learn what dispersed and hidden livelihoods look like. They can be shown how they might dismantle their village homes and build temporary huts near their fields as the Vietnamese sometimes did in the face of American airpower. Or use crop colors and canopies that are less noticeable from the air, as Salvadoran peasants sometimes planted" (Barrs 2006: 7). In sum, indigenous strategies have almost always been the predicate for successful resistance to oppression (Merriman/DuVall 2007).

Box 92.3: Overview of case studies on people-centred early warning systems.

There are very few case studies available that assess the implementation of a people-centered approach to conflict early warning. However, two are worth noting here. The first is the "Early Warning for Violence Project" developed by the Foundation for International Tolerance. The project started in June 2005 with participation of IFES, UNDP, OSCE, and the Swiss and US governments. From the start of the project a nation-wide network of monitors was established who reported about all cases of socio-political violence and tensions that could lead to violence. Initially, there was a special focus on conflicts related to the presidential and local elections. Analysis and recommendations were made public through a weekly bulletin and regular briefings. The project administered an emergency fund to which organizations could apply for small grants for urgent conflict intervention. Mediation activities and round tables were organized. From January 2006, only the early warning component was continued, until the end of the first phase in May 2006. In the current project phase, there is an equal focus on early warning and on early response. The project has resumed publication of its weekly bulletin and will also undertake thematic researches. It's revised early response strategy is focused on offering consultancy, training, problem-solving workshops, and mediation to individuals, organizations and state bodies. The project is closely working with a network of interveners.

The second project is more recent and based in Timor-Leste. The country's only national NGO, BELUN, is launching a new project to enhance security and community resilience in Timor-Leste through the establishment of an early warning and response system. Unlike the typical one-directional hierarchical warning systems that exist, BELUN has recognized that a two-pronged approach to conflict early warning and response is required – a national level and a community level. The vast majority of early warning projects mistakenly assume that one methodology – usually highly academic and quantitative – can address and respond to the needs of both sets of stakeholders. This is far from being the case and BELUN is therefore combining incident and situation field reporting for national-level stakeholders with preparedness and contingency planning at the community level. This very much reflects the people-centred approach taken in the

context of disaster management. Instead of preparing for possible flooding or earthquakes, local communities draw on existing capacities for conflict management with additional training by BELUN. This encourages local communities to identify threats of violence ahead of time but more importantly this approach creates a space for communities to develop action-oriented scenarios for early response. The first phase of the project was completed in February 2007. BELUN's early warning project holds great promise and may soon become a model for developing people-centred conflict early warning and response networks.

Unlike highly technical and hierarchical early warning systems, nonviolent social actions are more effective in responding to conflict since they recognize the inherently political nature of armed conflict. According to the nonviolence literature, the organizational template most useful in responding to repressive environments is a community-based network rather than a hierarchical structure since networks are more likely to innovate tactically and weather repression (Stephan 2006; Allen Nan 2006). Indeed, "networks are more flexible and effective than hierarchies in responsiveness to changing conditions: new information is more easily disseminated, interpreted, and acted on without the constraint of passing information or searching for resources up and down a hierarchy" (Ibarra 1992: 169). This explains why "nonviolent action is non-institutional; it operates *outside* the bounds of the institutionalized political channels" (Kurt 2003: 705). The operational parallels between strategic nonviolence and would-be people-centred conflict early warning systems are striking and the commonalities merit further exploration.

92.7 Conclusion

The initiative to network CEWARN and ICPAC revealed that certain environmental factors influence conflict behaviour via the role of tactics. Understanding the role of intervening factors is critical for early response, and the use of events-data – only when complemented with situation reporting – can serve to untangle the multiple but interde-pendent crises that characterize complex emergencies, especially within the context of climate change. At the same time, the fact that tactics and the environment play a role in pastoral conflicts is already well known to local stakeholders (box 92.4).

This explains the need for people-centred early warning, which in no way excludes the competent use of rigorous analysis or the parallel pursuit of more technical initiatives. Indeed, traditional coping mechanisms depend on the ability to anticipate hazard patterns, which are increasingly erratic with the advent of climate change. This means technological systems are also needed. In other words, both hierarchical and people-centered systems have distinct comparative advantages. Therein lies the added value of networking formal disaster and conflict warning systems such as CEWARN and ICPAC. To this end, a multi-track approach to early warning is perhaps the most prudent strategy to manage the conflation of conflict and climate change.

This exercise should not be an end in itself, however. Pathways for technology transfer need to be identified and community-based protocols implemented to mitigate the impact of environmental conflict and create alternative futures (Pattie 2006; Corbacioglu 2006). This means promoting traditional knowledge systems for risk reduction and blending high technology with indigenous settings (Pattie 2006; Abramovitz 2001). The added value of centralized and technological early warning systems should therefore be strictly judged on their empowerment of local people-centred systems. Put differently, formal early warning systems should seek not to supplant but instead aim to support local and informal warning systems, much akin to those operational in nonviolent movements. As the literature on strategic nonviolence clearly demonstrates, early warning works and saves lives. The most versatile and successful organizational templates in this respect are decentralized, horizontal networks. This stands in stark contrast to the typically hierarchical and centralized conflict early warning systems such as CEWARN and FAST that continue to demonstrate little to no return on investment in terms of successful early responses.

Box 92.4: Observed and projected demographic and climate change in the IGAD region. The data should be broken down for the IGAD countries. **Source**: <http://hdr.undp.org/en/statistics/data/>.

Population (millions)	1975	2005	2015	Annual Growth rate 2005-2015
Ethiopia	34.2	79	101	2.8
Kenya	13.5	35.6	46.2	3.2
Sudan	16.8	36.9	45.6	2.6
Uganda	10.9	28.9	40	3.3
Total/Average	75.4	180.4	232.8	2.975

According to the most recent global warming models produced in August 2007, there are indications for an upward trend in rainfall over much of Kenya, Uganda, and southern Somalia. Wet extremes are projected to increase during both rainy seasons. In general, the simulations project a positive shift in the whole rainfall distribution over most of east Africa during both rainy seasons. While this means more surface water for pastoralists, flash floods and flooding in general can lead to mass cross-border displacement as well as shortages in forage availability.

In terms of other strategies and recommendations, further studies on local human adaptability in decentralized settings as well as self-adaptation in dynamic disaster environments may also shed light on new principles for early warning and response. To this end, a promising avenue might be the development of new protocols and principles based on self-organizing and adaptable systems. To be sure, social systems evolve and adapt, which explains why "in a world where centralized modes of risk management lose effecttiveness, we also see tendencies toward increased cross-sectional complexity, increased effective participation by people, broadening liability on international scales and a move towards a 'claim culture'" (Chadná/Motchanova/Obersteiner 2006: 317). However, responding to this claim culture with more hierarchical early warning systems is unlikely to render at-risk communities more resilient to global environmental change and security threats. Ultimately, what is required is a less egocentric approach to early warning and response – one that seeks "the proper balance between the need for external assistance and the capacity of local people to deal with the situation" (Bankoff / Hilhorst 2004: 33).

93 Vulnerability Assessment in Sri Lanka in the Context of Tsunami Early Warning

Juan Carlos Villagrán de León

93.1 Introduction

The tsunami of 26 December 2004 was a catastrophic disaster where fatalities could have been minimized if there had been an early warning system in operation and people in coastal areas would have been aware how to respond effectively to such a warning. The event caused over 250,000 fatalities, more than half of them in the Aceh province of Indonesia alone, and many others in countries as far away as Africa.[1]

In Sri Lanka, over 34,000 fatalities were reported by the *National Disaster Management Centre* (NDMC), the agency in charge of coordinating the response efforts. Material losses included the destruction of public and private infrastructure, segments of important telecommunication and energy networks, as well as train and road infrastructure. As a consequence, the country experienced a disruption in processes and services which are part of the framework of development.[2] Table 93.1 presents a summary of impacts due to a variety of natural events based on the OFDA-CRED database on Sri Lanka (1957–2007) highlighting the impacts of the tsunami.

While it is important to recognize that not all these losses could have been avoided with the use of an early warning system, the question remains whether fatalities and injuries could have been far greater should the tsunami have taken place on a weekday, when markets are extremely crowded and schools are in full operation, congregating large numbers of children in each facility.

Unfortunately for Sri Lanka and for many other countries, tsunamis were totally out of the picture in the framework of disaster preparedness prior to this event. The 2003 floods and landslides which provoked disasters in urban and rural communities of several provinces of Sri Lanka prompted the NDMC to set up a programme focusing on disaster preparedness in the five most affected districts at that time (table 93.2).

1 The *Centre of Research on the Epidemiology of Disasters* (CRED) database provides information on the impacts at the level of countries in terms of numbers of people killed, injured, affected, as well as economic losses for this and other events. Munich-Re Foundation (2004) reported data on insured and non-insured losses. Within the *United Nations Organizations* [UNO], several of its agencies published reports documenting impacts at the national level. UNDP-BCPR maintains a web page with documents related to rapid impact assessments and situation reports which emerged in the days and weeks following the tsunami for many countries affected by the tsunami. In addition, the *Asian Development Bank* (ADB) carried assessments of the impacts of the tsunami in several of the countries which were impacted by this event to define a strategy to support reconstruction and recovery efforts. For a detailed survey of impacts on infrastructure related to the tsunami see: Iwan (2006) .

2 Data on casualties and injuries within Sri Lanka, like in the case of other countries impacted by the tsunami, were initially gathered and reported by the national agency in charge of disasters. In the case of Sri Lanka, the *National Disaster Management Centre* (NDMC) took this role through an information centre established for that purpose. Impacts in terms of people killed or affected can also be found on the database maintained by CRED. A more comprehensive survey of impacts was carried out by the Department of Census and Statistics of Sri Lanka in 2005. Data are reported at the national, provincial, district, and division level on a variety of topics. In the context of the *United Nations* (UN), the *International Labour Organization* (ILO) carried out a rapid assessment of the impacts of the tsunami on livelihoods in affected regions of this country. The *United Nations Environment Programme* (UNEP) conducted an assessment of the impacts to the environment. However, there are discrepancies in the numerical data reported by some agencies due to the way in which surveys were conducted.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_93, © Springer-Verlag Berlin Heidelberg 2011

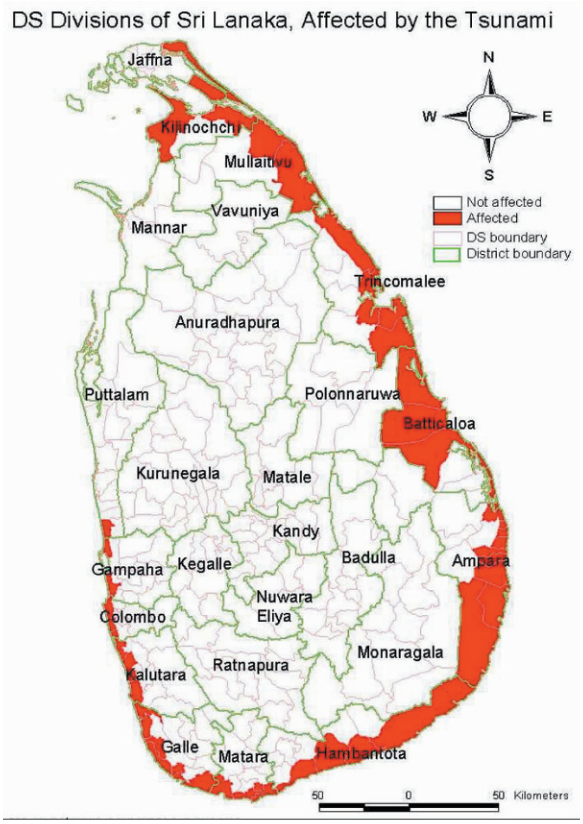

Figure 93.1: Coastal regions of Sri Lanka affected by the 26 December 2004 tsunami. **Source**: Sri Lanka, Department of Census and Statistics, public domain, permission is granted.

With the support of the *United Nations Development Programme* (UNDP), the NDMC promoted the establishment of inter-institutional Disaster Management Committees at the district level, and the subsequent elaboration of emergency and early warning plans. Unfortunately, tsunamis were not considered in such plans prior to the 26 December 2004 tsunami. In fact, in the District of Galle, one of the five districts selected by the NDMC for this programme, the *Asian Disaster Preparedness Centre* (ADRC 2005) conducted a perception survey on tsunami awareness which concluded that 94 per cent of the residents had very little knowledge regarding tsunamis. Thus, even if a warning would have reached the coastal population, people would probably not know how to react to such a warning.

A parallel survey conducted in the Nias district in Indonesia by ADRC (2006) concluded that 56.6 per cent of the residents had no prior knowledge about tsunamis, and 26 per cent had very limited knowledge about tsunamis at all. Belonging to the class of very infrequent events, tsunamis have been neglected over decades in most efforts focusing on disaster preparedness. In Latin America, a similar trend would surely take place with respect to the term 'tsunami', as the more traditional term is 'maremoto' (seaquake).

The tsunami revealed the vulnerability of people, infrastructure, processes, and services in many coastal cities along the Indian Ocean. With over a quarter of a million people killed, in particular more children and elderly than adults; the tsunami destroyed thousands of houses which were not built to stand the direct impact of such a wave, and disrupted lifelines and services provided by both the government and the private sector. As such, the tsunami displayed the physical, social, economic, and environmental dimensions vulnerability of urban and rural areas along the coastlines of those countries which were impacted. In the context of people, the event manifested gender and age-related differential aspects with respect to the social dimension of vulnerability. Such differential aspects of vulnerability need to be highlighted and linked to early warning practices.

The chapter stresses two important issues: the need to recognize differential vulnerabilities related to age and gender characteristics of the population, and the need to use such information to develop effective warning strategies which reach such vulnerable groups in order to improve the degree of preparedness of coastal communities and minimize loss of lives.

After introducing a risk model (93.2), the chapter begins with a discussion focusing on such gender and age-related aspects which depict the differential character of social vulnerability (93.3), and then assesses the exposure of vulnerable groups to the tsunami hazards using as a practical example the coastal city of Galle in Sri Lanka to deduce public warning strategies (93.4). It concludes with a discussion regarding the shift from risk assessment to early warning (93.5) and other types of vulnerabilities in early warning (93.6), and a few concluding remarks (93.7)

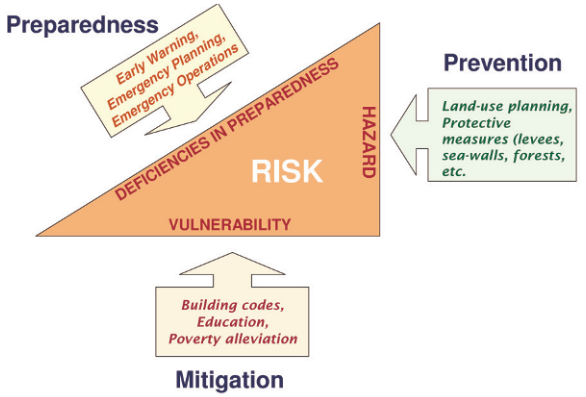
93.2 Linking the Elements: The Risk Model

As stated by the *Platform for the Promotion of Early Warning of the International Strategy for Disaster Reduction* (PPEW-ISDR 2006), an effective tsunami early warning system needs to incorporate four elements:

- Prior knowledge of risks faced by communities;
- Technical monitoring and warning service for these risks;
- Dissemination of understandable warnings to those at risk;
- Knowledge and preparedness to act.

While the second and third elements have usually been addressed in traditional early warning systems, the first and fourth components emerge when analysing gaps in such existing systems particularly after events which display their weaknesses.

Figure 93.2: Risk as the integration of Hazard, Vulnerability, and Deficiencies in Preparedness; and the elements of risk management: Prevention, Mitigation, and Preparedness. **Source**: The author.



Since 2001, the author (Villagrán 2001) has proposed a model to represent risk in terms of three components: *hazard*, *vulnerability*, and *deficiencies in preparedness* (figure 93.2). The explicit incorporation of *deficiencies in preparedness* is based on the fact that in some cases vulnerabilities cannot be reduced, but losses can be avoided or reduced if preparedness measures are in place. This is particularly essential in the case of vulnerable groups of people which could be saved, should an efficient early warning system be operational.

Risk management would comprise the set of measures which tend to reduce existing risks and those measures which should inhibit the generation or enhancement of such risks. In this context, *Prevention* focuses on a variety of measures to minimize the exposure to the hazard, or those which are aimed at modifying the dynamics of such hazards. *Mitigation* focuses on the set of measures aimed at reducing vulnerability and the factors which may enhance it. As expected, *Preparedness* encompasses the measures aimed to improve the capacity of the community to reduce the impacts related to specific events through early warning, for example.

One typical measure within the context of preparedness is an early warning system. According to the *International Strategy for Disaster Reduction of the United Nations* (UN-ISDR), early warning is defined as "the provision of timely and effective information, through identified institutions, that allows individuals exposed to a hazard to take action to avoid or reduce their risk and prepare for effective response" (UN-ISDR 2004). Considering such a definition, an effective response to a warning should imply that governments, the private sector, and people should carry out the necessary tasks to minimize the impact and hence potential losses associated to the forecasted event, in particular, evacuation of population to safe areas prior to the event. While the destruction of infrastructure cannot be avoided through the operation of an early warning system, such a system could indeed be employed to minimize the number of fatalities and injuries, and reduce to a minimum the disruption in processes and services.

However, it is important to recognize the fact that existing early warning systems have a particular weakness: "warnings may fail to reach those who must take action and may be understood or address their concerns". As stated by ISDR in its *Global Survey of Early Warning Systems* (UNISDR 2006), existing early warning systems have been developed with a strategy to generate and issue warnings in a reliable fashion, rather than to empower those at risk who need such warnings to take evasive action.

Basher (2006) expanded the notion of 'people-centred' early warning, stating that risk assessment should focus on identifying vulnerable groups of people, determining their degree of exposure to the hazard, and identifying warning strategies to allow such groups to take evasive action should an event manifest itself. This notion of 'people-centred' early warning was brought forward during the Second International Early Warning Conference held in Bonn in 2003 and again, under the term 'last-mile' in the Third Interna-

tional Early Warning Conference, again held in Bonn in 2006.

93.3 Vulnerable Groups

If the goal of a tsunami early warning system is to minimize the number of fatalities and injuries, then a starting point in the identification of vulnerable groups should be the assessment of the impacts of the tsunami in terms of mortality. According to Birkmann, Fernando, and Hettige (2006), children in the youngest age group (0 to 10 years old) and adults over 40 years old could be considered as highly vulnerable when looking at the mortality rates in the coastal cities of Galle and Batticaloa in Sri Lanka (see also chap. 69 by Marre/Renaud). Similarly, these authors argue that women are more vulnerable than men, based on mortality rates by gender. A similar study carried out in coastal areas of the Ampara district in Sri Lanka by Nishikiori, Abe, Costa, Dharmaratne, Kunii and Moji (2006) confirms the fact that children in the youngest age group are highly vulnerable, as well as elderly people fifty years old or more. In addition, this study confirms that women are by far more vulnerable than men (Ariyabandu/Fonseka 2009). Similar results have been published by Guha-Sapir, Parry, Degomme, Joshi and Saulina Arnold (2006) in a mortality survey in Tamil Nadu, India. Interestingly, the results from this coastal region in India point out that the ratio of fatalities to injuries is large in the case of children and small in the case of adults. These results stem from the fact that a higher number of children were killed by the tsunami than the number of children injured, whereas an opposite trend was found in the case of adults. These results were confirmed in Indonesia by Doocy, Rofi, Burnham and Robinson (2006) in a survey in Aceh where the highest mortality rate was found among the youngest children (age 0–10 years old), and elderly people over 70 years old. In addition, these researchers found that casualties among women were larger than among men, but such differences would disappear in the case of infants, and for the elderly over 70 years old.

Higher mortality in the case of children can be explained on physiological differences. In the case of children, their small mass means they can be thrown around by the tsunami rather easily and they lack the strength to hold on to objects such as trees in such a case. Table 93.3 displays data gathered by the Department of Census and Statistics of Sri Lanka (2005) regarding dead and missing persons related to nine districts which were affected by the tsunami in terms of age groups and differentiated by gender. The fifth column represents the total number of fatalities by age group regardless of sex, and the data in the last column is obtained by dividing this fifth column by the number of years which the respective age-group spans (for example, the age-group 0 to 4 spans 5 years, whereas the age-group 199329 spans 11 years. As no data is available for the last age group, a symbolic figure of 40 years was considered).

In the case of gender, column 4 (table 93.3) displays the ratio of females to males which were killed by the tsunami according to age group. As this column indicates, mortality is higher for women than for men, and in terms of age groups, the data allows for the conclusion that women in the age-group 19–29 display the highest ratio.

As stated by OXFAM (2005), and by Neumayer and Plümper (2007), higher mortality can be attributed to women than to men on the basis of physiological and social patterns. As in the case of children, these authors state that women have less strength and less inertia than men. In addition, learned skills are different for men and women, particularly in the context of swimming and climbing trees. These activities are usually taught to boys and not to girls. Finally, these authors argue that social roles play a difference as portrayed in many societies: women are expected

to look after and protect the children in the house, care for the elderly, and guard the valuables of the family within the household. This traditional division of labour would force women to spend substantial amounts of time inside houses which could collapse in case of the tsunami, due to structural vulnerability. In the particular case of Sri Lanka and India, another social aspect which could contribute to higher mortality in the case of women when compared to men is the traditional use of '*saris*', traditional clothes with long tails which could hamper running and swimming, and can even get tangled with heavy objects, leading women to death by drowning.

In addition to these results, it is likely that tsunamis may provoke fatalities in places where vast amounts of people can congregate, such as public markets, churches or cinemas, as well as in the case of those people with permanent or temporary incapacities to move, particularly patients in hospitals. Therefore, for early warning, it is imperative to find places where such vulnerable groups congregate and to tailor warnings accordingly. Thus, the most vulnerable groups are:

- *People with permanent or temporary incapacity to move*. This group comprises patients undergoing treatment in hospitals or women on maternity leave, especially those who have given birth recently, are confined to bed, and permanently handicapped people (in wheelchairs, with crutches) as well as infants.
- *Children* who because of their small size and reduced strength have difficulties to survive inside a tsunami wave.
- *Women who may have less strength than men to cope with the tsunami wave,* and may also lack the swimming skills of men in such a case or may die trying to save the children or an elderly person within their households, as well as trying to secure their valuables at home.
- *Elderly people* of both sexes in the age group above sixty years. As in the case of children the vulnerability would stem from their lack of strength to survive the impact of a wave, and their decaying state of health, which enhances their vulnerability in case of trauma.

93.4 Linking Vulnerable Groups to Hazardous Areas

Having identified the vulnerable groups, the next step is to identify places where these people meet. Schools for example are locations where children congregate, and thus they constitute a setting where there is a high amount of vulnerability during the days of the year in which the education process takes place. Children's homes or orphanages constitute another setting with a high vulnerability. In the case of homes for the elderly there exists high vulnerability. For women the identification of such places is more difficult, however, one can identify certain facilities such as schools for nurses where large numbers of female students who are enrolled in such academic programmes may congregate; hospitals where vast numbers of nurses may also congregate, as well as some commercial areas where women may congregate either to sell or purchase products of various kinds. In this context, it is important to recognize the fact that vulnerable groups of people may congregate in such places at particular times of the day and in selected months of the year, although in the case of elderly homes and hospitals one should not expect such a variation throughout the year.

The tsunami also manifested the fact that places where many people meet could constitute sources of fatalities. In Sri Lanka the tsunami overturned a train full of people killing over one thousand passengers who could not evacuate quickly from the train carriages. Other places where vast amounts of people can congregate are the main train stations and main bus stands, commercial streets and public markets, government buildings, churches and religious temples, cinemas, technical, vocational schools, universities and auditoria, as well as sports facilities including stadiums.

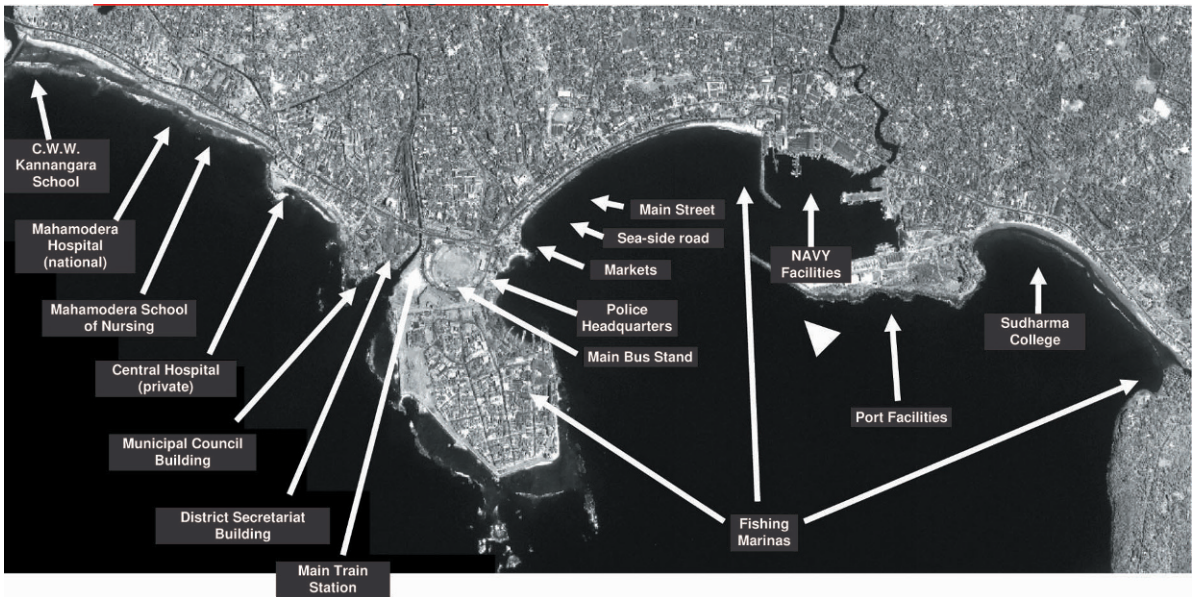
Two activities where people assemble in coastal areas are fishing and tourism. Local fishing communities usually congregate around fishing marinas and tourists prefer hotels next to the ocean shores and public beaches. Particular seasons of the year are more attractive, boosting the tourism population. This applies particularly to southern Europe that experiences a massive flux of tourists from northern Europe during the summer months.

While such vulnerable groups may be found in any part of a city, it is the combination of such vulnerable groups, places of high exposure to tsunamis, and lack of preparedness in terms of weak or non-existing early warning systems that constitute the high risk areas, which when the tsunami manifests itself turn such areas into disasters. Therefore, one should consider that high risk areas could be defined as places next to the ocean which concentrate vulnerable groups where there are no measures in place to reduce the impacts

Table 93.4: High risk areas within the city of Galle. **Source**: The author.

Hospitals	Schools	Densely concentrated areas during business hours	Government Buildings	Other
Mahamodera hospital	Mahamodera school of nursing	Public bus station Main train station	District Secretariat Municipal Council	Fish, fruit, vegetable markets
Central Hospital (private)	C.W.W. Kannagara Suddharma College	Main street Sea-side street Road to Colombo Road to Matara	Navy port facilities Police Headquarters Prison	Neighbourhoods located by the ocean shore. 3 fishing marinas

Figure 93.3: Satellite image of the central part of the City of Galle, Sri Lanka and of the coastal area indicating places where vulnerable groups may congregate. **Source:** Satellite image by GeoEye through European Space Imaging. Copyright: GeoEye, all rights reserved.



through preparedness. The identification and assessment of such areas would then be employed to design strategies regarding how to ensure that warnings reach such areas as quickly as possible so that evacuation to safe areas can be carried out prior to the arrival of a tsunami.

An exercise along these lines of identification of high risk places was carried out in the city of Galle in Sri Lanka (Villagrán 2008). The high hazard area in relation to tsunamis was defined as the buffer area spanning from the shore to one hundred metres inland. While this is an arbitrary choice, there is as yet no scientifically developed hazard map that could be used at this time for this city. Critical facilities in this high hazard area include the large Mahamodera national hospital with a capacity of 215 beds for patients in a multi-storey building and a small private hospital, the School of Nursing which hosts about one thousand female student nurses, two schools in which there are over 1,340 children registered, several streets which host large commercial areas, the main bus and train stations, as well as three fishing marinas where local fishermen congregate, and two public fish and vegetable markets (table 93.4). Figure 93.3 presents a view of the coastal area of the city of Galle, along with the location of these facilities.

The 26 December tsunami provoked considerable damages to the two hospitals; it destroyed the main bus station, damaged the nursing school and the two colleges, destroyed the fish market, severely affected the vegetable market, and damaged all government facilities listed above.

In addition, it destroyed practically all boats and fishing gear in the fishing marinas, and killed many fishermen. In terms of housing, the tsunami destroyed or damaged over 1,500 houses located next to or very close to the shore, and damaged over 100 businesses located in the coastal streets, ruining merchandize of

various kinds, as the flood level rose to the roof of such businesses. In terms of population, the tsunami killed 767 persons, and injured nearly 1,000 people as reported by a local staff member of UNDP supporting efforts on disaster preparedness at the time of the tsunami.

93.5 From Risk Assessment to Early Warning

Having identified the main risk areas, the next step in the design of an early warning system would constitute the elaboration of an early warning plan which contains the following elements:

- Strategies to ensure that warnings reach highly vulnerable groups in the identified places;
- Identification of safe areas for evacuation of people, particularly in the case of vulnerable groups, and procedures for their evacuation to such safe areas;
- Posting of signs related to evacuation routes, safe areas, and meeting points to facilitate the evacuation process in case of a real event;
- An awareness campaign so that people in high risk areas take note of the early warning system and what to do in case a warning is issued; as well as exercises and drills to identify deficiencies and gaps in early warning plans and to reinforce the awareness campaign;
- Periodic testing through drills to sustain the early warning effort.

A plan outlining such elements has been prepared by the author for the District-level Disaster Management Committee of Galle (Villagrán 2006a), as part of a project conducted by UNU-EHS in Sri Lanka within the Tsunami Flash Appeal Programme coordinated by the *Platform for the Promotion of Early Warning of the International Strategy for Disaster Reduction*.

93.6 Other Types of Vulnerabilities in Early Warning

As has been stated, an effective early warning system should include the capability of a community to minimize impacts based on an anticipated response to a warning. An impact assessment provoked by the tsunami in Galle allows identifying additional vulnerable elements and processes which could benefit from an early warning.

Lifelines: Due to its physical nature, water can be contaminated when coming into contact with the tsunami surge. Renaud (2006) referred to the short- and long-term problems which people experienced in rural areas with respect to the contamination of open wells. If such wells could be closed temporarily once a warning has been issued, contamination by debris would be minimized, event though the infiltration of salinity in the soil may generate some long-term problems. For electricity a timely warning can allow the electrical company to shut down power in transmission lines to avoid short circuits due to the high conductivity of the tsunami surge, should it come in contact with live transformers.

Transportation: For transportation, the tsunami provoked damage or destruction of motor vehicles of many types. In this context, an efficient early warning plan would include evacuation routes for people and for motor vehicles along separate roads, so that the exposure of such vehicles to the tsunami wave is reduced to a minimum.

Health processes: While there are no documented cases in the literature, surely a tsunami may disrupt many types of activities in hospitals, in particular surgeries. It is to be expected that an effective warning strategy would be for planned surgeries to be delayed temporarily until the situation after the tsunami has returned to a normal state to avoid complications during such surgeries and other medical procedures in case of a tsunami.

Critical information and paperwork: In Galle the municipality lost critical records (birth records) and other vital information stored in computers or on paper, as the information in hard disks and on paper was completely damaged when coming in contact with the tsunami surge. A similar situation was experienced at the head office of the police department since the building is located right on the coast. Commercial businesses also lost substantial amounts of money as credit vouchers were kept in a paper format. Paper is highly vulnerable when it comes in contact with the tsunami surge. When a warning is issued and effective response measures are in place, the loss of such valuable information can be reduced to a minimum without too much effort.

93.7 Conclusions

The 26 December 2004 tsunami showed the capacity of such events to trigger a major disaster with high fatalities, as well as the interruption of many processes

and services which are essential for any community. The tsunami demonstrated both the vulnerability of people, infrastructure, processes, products, information, and services; as well as the need for an early warning system to minimize the number of fatalities and injuries inflicted by such a tsunami in coastal populations. The assessment of the impacts of the tsunami in terms of mortality and in terms of vulnerability provides an insight into potential measures which can be put in place to minimize the impact of such events in the future.

Research conducted in Sri Lanka, India, and Indonesia has permitted the linkage of mortality rates to differential conditions of vulnerability in terms of age and gender by various groups, allowing for the conclusion that children and the elderly are the most vulnerable groups when it comes to tsunamis and the fact that in general, women are more vulnerable than men. The information gathered on such groups within the coastal city of Galle in Sri Lanka has allowed for the identification of high risk areas in this city, as well as a strategy to promote an efficient and timely early warning when considering as a starting point such vulnerable groups in the design of an early warning plan.

The need to go beyond just the issuing of warning in case of a tsunami through mass media such as radio and television is imperative if lives are to be saved. In the context of effective early warning as defined by PPEW, risk assessment needs to provide information on those who are at risk, so that warnings reach them with sufficient anticipation to allow for an evacuation to a safe place. In addition, it is important for the risk assessment to include the component of deficiencies in preparedness, so that capabilities to react to such warnings are enhanced. Only then will such early warning systems be able to span the proposed 'end-to-end' strategies and reach those who are located in the 'last, but most important mile'.

94 Political Geoecology for the Anthropocene

Hans Günter Brauch, Simon Dalby and Úrsula Oswald Spring

94.1 Introduction: Hypothesis and Goal of this Chapter[1]

This chapter argues that a fundamental change in earth history is under way which requires a rethinking of the relationship between humankind and nature, including the political realm and international relations, that makes geopolitical approaches in the Hobbesian tradition obsolete. The Nobel laureate Paul Crutzen coined for this new period of earth history the term 'Anthropocene' (Crutzen 2002 and preface essay).[2]

During the Anthropocene our thinking on peace and security must be reconsidered. This implies a fundamental shift in the concept of security that is increasingly being influenced by human interventions into the earth system. In the Anthropocene the nature of the threat for the survival of humankind is changing from 'them' (neighbour country, coalition of states, competing military, social and ideological systems) to 'us', i.e. to our lifestyle and consumption of fossil sources of energy that has resulted in major increases of greenhouse gases since 1750 (of which 2/3 has occurred during the past five decades). However, if 'we' are the threat it is impossible to fight a war against ourselves. To cope with this threat to human well-being, survival and security a radical change in our thinking on international relations and security is needed. This new threat is global in nature and does not respect national borders or political systems, nor does it discriminate between the 'good' and the 'bad'.

The old spatializations of international political, strategic and economic relations as 'geopolitics', 'geostrategy' and 'geoeconomy' have been primarily power- and interest-based and were partially ideologically legitimated. Many of these spatializations trace at least some of their ideas back to the writings of Thomas Hobbes, famous for his theories of Leviathan and assumptions of perpetual war as the human condition in the absence of some overarching authority. While Hobbes was more concerned with civil wars than international relations, the assumption of anarchical relations between states is frequently simply called Hobbesian. These scientific and political approaches are unable to cope with the new environmental security threats, challenges, vulnerabilities and risks posed by issues of global environmental change during the Anthropocene in the 21st century.

Instead of these Hobbesian spatializations of international political, strategic and economic relations that have totally ignored the environmental dimension and issues of global environmental change, a new concept of a '*political geoecology*' is developed by introducing, scoping and contextualizing a new research paradigm and policy vision and contrasting this with the traditional Hobbesian debates on geopolitics and geo-strategy that legitimized many national strategies with political, economic and military means.

In the tradition of conceptual theory the authors argue that geopolitics, geo-strategy and geo-economics have understood space as 'territory' as a component of national sovereignty and have left the environment out. But several approaches from the natural sciences, such as Lovelock's (1979, 1988, 1992, 1998, 2006, 2009) 'Gaia hypothesis', Edward O. Wilson's (1998) 'consilience', Huggett's (1995) 'geoecology', and the approach of an 'earth systems analysis'[3] have left politics out.

The specific goal of this chapter is to conceptually merge these four approaches by bringing politics, and

1 This chapter builds on two previous joint chapters by Dalby, Brauch and Oswald Spring (2009) and Oswald Spring, Brauch and Dalby (2009) and on previous studies by Brauch (2001a, 2003, 2003a, 2008a), Dalby (2002b, 2003, 2007, 2009, 2009a) and Oswald Spring (2001, 2008, 2008b, 2008c). From the perspective of three disciplines (political science, geography, socio-environmental anthropology) and from three national vantage points (Germany, Canada, Mexico) the authors develop a joint research and policy perspective for a new security policy in the Anthropocene from a gender perspective.

2 See Paul Crutzen's webpage at: <http://www.mpch-mainz.mpg.de/~air/anthropocene/Text.html>.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_94, © Springer-Verlag Berlin Heidelberg 2011

especially peace-building and widened security issues in, by developing a 'security policy for the Anthropocene' (Dalby 2009, 2009b) and outlining a policy vision for the 21st century that aims at a sustainable peace (Brauch/Oswald Spring 2009a; Oswald 2009) by combining the needed 'security policy for the Anthropocene' with proposals for a "science for global sustainability" (Clark/Crutzen/Schellnhuber 2004, 2005). This outline of a new transdisciplinary research field is highly policy relevant and may help to express the urgency of proactive political strategies with non-military means and tools (MA 2005; Leemans 2009).

This chapter, in addressing the spatial dimension of human and environmental security in the Anthropocene, calls for a shift away from the Hobbesian or power- and force-related concepts of geopolitics, geostrategy and geoeconomics, which have legitimized foreign and in some cases even military actions towards the new concept of 'political geoecology'.

The next part contextualizes the new security dangers in the Anthropocene due to anthropogenic interventions into the earth system from 1750 to the present with an outlook until 2100 (94.2). Then the spatial or 'geo' approaches with regard to geopolitics, geostrategy and geoeconomy are reviewed that are inappropriate for addressing the new security dangers and concerns of the Anthropocene era in the 21st century (94.3). Part 4 discusses the *geoecology* approach from physical geography and systems perspectives on global environmental change, the *earth systems analysis* (ESA) of the *Earth Systems Science Partnership* (ESSP) for the multiple linkages among the four global environmental change programmes: WCRP, IGBP, IHDP and Diversitas. Only IHDP addressed the political, and its GECHS programme, the security dimensions of earth systems change (94.4). Part 5 compares different approaches bringing 'ecology' into the scientific discourse on geopolitics and a 'political dimension' into geoecology given the security impacts of global environmental change in the Anthropocene. This concept leads to a broadening from state- to human-centred concerns as well as from top-down to bottom-up policy processes (94.5).

Part 6 introduces political geoecology as a new concept for research and teaching that links the approaches in physical and human geography with those of the social sciences. This requires introducing a political dimension (94.6). Part 7 moves from anticipatory knowledge to proactive action from a policy vision of a political geoecology that offers guidelines for cooperative environmental policy in the Anthropocene era (94.7). Finally, part 8 summarizes the key conceptual messages of the new features of political geoecology, bringing 'geo' approaches into the political realm (94.8).

94.2 Multiple Challenges of the Anthropocene from GEC

In the Anthropocene, global environmental change, represented by an environmental quartet (Brauch/Oswald Spring 2009; Oswald Spring/Brauch 2009) of global, regional and local climate change, land degradation and desertification, water scarcity and drought, pollution and stress of air, water and soil, and biodiversity loss, poses multiple dangers for international, national and human security (Brauch 2009a; chap vy by Bauer; yz by Scheffran). These dimensions of environmental change are all linked together in various ways and at various scales, and although they happen in specific places, the key point in thinking about matters in terms of 'geoecology' is the important point that these things are linked into the global biosphere; hence the designation 'geo'.

The anthropocene emphasizes that there are human causes to the disruptions of ecosystems, and hence these are matters that are decided by humans, although frequently decisions are made in the absence of clear understandings of the consequences of human actions. But now, as science pieces together the big puzzles of how parts of the biosphere fit together, it is clear that human actions have consequences for ecologies in numerous places. Thus 'political' geoecology adds a political dimension to 'geoecology'.

The term geoecology is a concept that has been used in Germany since 1968 (Troll) in physical geography (Müller 1983; Wein 1985; Hütter/Reinirkens 1993; Stüdemann 2008). Geoecology was also introduced as an interdisciplinary natural science by Huggett (1995) and Blumenstein, Schachtzabel, Barsch, Bork, and Küppers (2000). Huggett (1995) defined geoecology as the study of the "structure and function of geoecosystems" in different scales. In his 1995 book, he developed the framework for thinking about geoecology in three parts:

> Part I introduces geoecological systems, their nature, hierarchical structure, and ideas about their interdependence and integrity. ... Part II explores internal or 'ecological' interactions between geoecosystems and

3 See Schellnhuber and Wenzel (1998); Steffen, Sanderson, Tyson, Jäger, Matson, Moore, Oldfield, Richardson, Schellnhuber, Turner and Wasson (2004).

> their near-surface environment, ... looking at the influence of climate, altitude, topography, insularity, and substrate. Part III prospects the role of external factors, both geological and cosmic, as agencies disturbing the dynamics of the geoecosystems.

Huggett (1995: 229ff.) listed among the ecological disturbances: wind, fire and grazing, and analysed changing disturbance regimes as well as the causes of geophysical hazards (local, regional and global disturbances from volcanic activities), cosmic disturbances from meteor activities while anthropogenic interventions were ignored. Clearly there are long term effects on the earth's climate of sun spot cycles and the long cycles of fluctuation in the earth's orbit have consequences for the amount of sunlight driving natural systems, as also macro-scale changes in the arrangements of the continents, glacial periods and other long term climate fluctuations, but these are beyond the scale of Huggett's concerns.

For Blumenstein, Schachtzabel, and Bork (2000: 9) geoecology is "an environmentally-oriented, interdisciplinary natural science that defines structures, functions and modes of action within geosystems or between them and their environment". Geoecology draws both on the spatial sciences (geography, cartography, landscape and regional planning) and on the natural sciences, but it excludes the effects of environmental degradation on environmental stress and their outcomes. They called for an integration of legal, social science and economic aspects but ignored the political dimension.

A German encyclopaedia of the geosciences (Rolli 2000: 283) pointed to the linkage between bioecology (biosystem) and geoecology (geosystem), and an encyclopaedia of geography (Buttschardt 2002: 28-29) referred to its task to contribute to an ecological development in all parts of society by research, planning, advice, administration, policy and laws. From a US perspective:

> The terms 'landscape ecology' and 'geoecology' were coined by Carl Troll to describe the field of study deriving from the linkage of physical geography and ecology. ... Contemporary applications of landscape ecology in the United States typically emphasize biological concerns, but modern problems in the analysis of landscape structure and dynamics and in landscape management, especially those involving the influence of human land use patterns, require a more integrated 'geoecological' approach (should be integrated). [4]

According to Richard Huggett's definition geoecology combines geography with ecology:

> Geoecology seeks to understand how landscape mosaics are created and how they change. Three mechanisms are primarily responsible for creating landscape mosaics: substrate heterogeneity, natural disturbance, and human disturbance. Substrate heterogeneity includes the distribution of hills and valleys, of wet spots and dry spots, of different rock types, and of different soil types. Natural disturbance is caused by physical agents (wind, running water, fire) and by biological agents (burrowing animals, grazing animals, pests, and pathogens). Human disturbance arises through such activities as ploughing, forest clearance, mining, quarrying, road building, and city building. Biological and ecological processes usually modify the landscape mosaics created by these mechanisms. ... The trend is now to study a much wider range of landscape units.[5]

More recently, Stüdemann (2008: 9) defined geoecology as a holistic science whose objects are "geoecosystems and the images of all spatial and temporal structures of the geosphere. They are analysed with inventory process and structure analyses regarding systems stability and change and defined for an action maxim". But in this approach the political dimension is limited to environmental planning reflecting the requirements of sustainable development. It introduces landscape and geoecology into the development of environment policy, law and education and implementation strategies on the global level. But as other geoecological approaches, Stüdemann (2008) lacks a specific political dimension in his horizontal widening of the theoretical scope of geoecology including sustainability goals.

In Latin America political geoecology started as a scientific concept in 1979 when the State University of Moscow initiated a master's degree in Cuba, where almost all countries from the subcontinent participated. Beside human ecology a strong emphasis was given to the ecological system approach. In 1978, in Mexico a group started with an interdisciplinary research about food system, ecosystem, socio-cultural and political systems (SAS 1986; Oswald Spring/Flores 1985), analysing systematically fourteen ongoing development processes within a frame of regional and global dependency and negative repercussion in life quality and the environment. In 1998 the Latin American Centre of Social Ecology (*Centro Latino Americano de Eco-*

4 See the paper by Hugh DeForest Safford: "Geoecology: Historical Roots and Contemporary Practice," presented at the 2002 Denver Annual convention of the Geological Society of the US, at: <http://gsa.confex.com/gsa/2002AM/finalprogram/abstract_42211.htm>.

5 See Richard Huggett: "Geoecology", in: Hancock, Paul; Skinner, Brian J., 2000: T*he Oxford Companion to the Earth* (Oxford. Oxford University Press), at: <http://www.encyclopedia.com/doc/1O112-geoecology.html>.

logía Social: CLAES 1999) integrated geoecology with policy, with a strong emphasis on economic equality. This Centre supported strongly the World Social Forum in Porto Alegre, and in 2006 they founded the *Centre for Development, Economy, Ecology and Equity* (D3E) in Latin America, where geoecology and human ecology were key themes. During the Earth Summit in Rio de Janeiro (1992) the precautionary principle was systematically introduced into the geoecological thinking in Latin America (Cafferatta 2004).

Brazil with the biggest biodiversity in the world, thanks to the Amazon, was always concerned about the foreign interests in its almost uncontrollable and wide territory, and therefore together with an approach on sustainability, the green lung of the world was always considered in the limited geopolitical interests, independently from ecological concerns (López 2009; Proença/Diniz 2008, 2009). But also the war against cocaine in Colombia, later involving Bolivia, Peru and Mexico widened the political geoecology to a military concern of the whole region, involving also the USA (Tickner/Mason 2008, 2009).

While there is no precise agreed definition of 'geoecology', the concept suggests the importance of interlinked formulations that understand dynamic ecological systems over a variety of scales while not breaking the science down into the traditional compartments of biology, chemistry, geology, etc. But the human dimension of geoecology isn't always so clear, not least because so many sciences have separated the human from the natural. Other formulations have started with the human parts of the global ecosystem and tried to work towards the ecological sciences.

In contrast, *human ecology* focuses on the interactions between human beings and the environment addressing the linkages between human activities and their impact in space as well as the anthropogenically-induced human environment by analysing societal, economic and physical environmental variables. *Social ecology* "integrates the study of human and natural ecosystems through the attempt to understand the relationships between culture and nature". Its proponents argue that "environmental problems result from social attitudes and practices, therefore the former must be solved by focusing on and changing the latter" (Pepper 2002: 484). According to the School of Social Ecology at the UC – Irvine:

> Social Ecology faculty apply scientific methods to the study of a wide array of recurring social, behavioural, and environmental problems and specialize in conducting research 'with considerations of use' in society. ... While the field of ecology focuses on the relationships between organisms and their environments, social ecology is concerned with the relationships between human populations and their environments.[6]

The original division between a geographic and a social human ecology was replaced by a holistic human ecology approach (Douglas 2002: 2–11). Sack (1980, 1996), Bennett (1985) and Orme (1985) proposed that geographers should "adopt an integrated (human-ecology) approach to spatial analysis in the human and physical environments" (Faniran 1995: 931). Douglas (2002: 3) argued that

> the extension of ecology from the study of plants and animals in specific habitats to the study of interactions between people, other organisms and their environment requires the inclusion of social processes and introduced the concept of human ecology. Early in the 21st century, several varieties of human ecology have emerged. For some, it is primarily concerned with people's interactions with the built environment, while others consider it to be about how the human being, as an organism, responds to environmental stresses and changes and thus suffers disease or retains good health. A third view examines the way society and communities can manage their surroundings to achieve a better life while not over-exploiting natural resources. Whatever the precise definition of human ecology, it is the analysis of the interplay of social life, from politics to industry ... with the biogeochemical, water and energy circulations that maintain all life on earth. Its analysis requires an integrated science that looks at the world as it really is.

This holistic approach includes an analysis of human drivers of global environmental change such as land cover and land use change, industrial metabolism and their interlinkages, as well as of the causes and consequences by addressing decision systems and cultural attitudes, the patterns and consequences of global environmental change and the feedbacks in the society. Social anthropology and psychology deepened through the theory of social representation into the cultural nature of human beings and their environment, where beside geopolitical power struggles also equity concerns within the identity processes were analysed (Flores 2001; chap. 66 by Flores/Wagner). But despite these attempts, and important formulations such as "social nature" that increasingly inform geographical scholarship (Castree/Braun 2001), the divisions between the physical and human sciences frequently remain. Interesting attempts by ecologists

6 See University of California, Irvine, School of Social Ecology; at: <http://socialecology.uci.edu/about> (9 September 2009).

to think about the transformation of systems, both natural and human, don't necessarily connect with the geoecology framework either (Gunderson/Holling 2002), even when explicitly linking globalization to ecology and security (Pirages/DeGeest 2004).

Given all these difficulties, Brauch (2003, 2003a) argued that a *political geoecology* is needed that combines the divergent approaches of 'geoecology', 'social ecology' and 'human ecology' by addressing the regional implications of global change and its potential outcomes: disasters, environmentally-induced migration, crises, and conflicts from a human security perspective on the environmental security dimension. Such a wider *political geoecology* must combine the complex causes and interactions of key factors of regional environmental change with environmental stress, natural disasters, distress migration, crises, and conflicts. Relying on the results of the natural sciences, *political geoecology* should also use methods of political science and international relations. These complex nature-human interactions have been addressed in the PEISOR model (Brauch 2005, 2005a, 2009a; Brauch/Oswald Spring 2009c).

This new approach requires an interdisciplinary discourse on global change and its regional impacts for environmental security and conflict avoidance that was suggested by Wilson (1998, 1998a) with the term 'consilience'. This term refers to the interlocking of causal explanations across disciplines. Wilson (1998: 197) correctly noted that the social sciences, in their efforts to predict alternative courses of actions, have in most cases ignored the natural sciences, and too often they relied on historical precedents. His call for a 'unity of knowledge' requires transdisciplinary cooperation among scientists.

Such thinking has precedent in the work of the French historian Braudel (1949, 1966, 1969, 1972) who has distinguished three historical times of events, conjunctures and structures.

> Historians have over the years grown accustomed to describing this contradiction in terms of structure and conjuncture, the former denoting long-term, the latter short-term realities. Clearly there are different kinds of structure just as there are different kinds of conjunctures, and the duration of either structure or conjuncture may in turn vary (Braudel 1972: 16).

For a political geoecology approach all three historical times matter, especially the structural dimension of "la longue durée" (Braudel 1969: 41–83) that addresses humankind "in its relationship to the environment, a history in which the change is slow, a history of constant repetition, ever-recurring cycles" (Braudel 1972: 20). Besides this structural history where geoecological developments and global environmental change impact, Braudel (1972: 20–21) referred to the "histoire de conjunctures" as the social history of groups and groupings with "slow but perceptible rhythms", and to "l'histoire évènementielle", the traditional history of individual men, of surface disturbances of brief, rapid, nervous fluctuations.

Inspired by Braudel's history of structures, Brauch (2001a: 53–54) applied this structural perspective to present and future environmental determinants posed by climate change, desertification and water stress that determine and constrain the range of options available for policy-makers. Clearly the Anthropocene now suggests that Braudel's assumptions about "ever-recurring cycles" in the environment are now no longer the case; historical lessons from the past may be of limited use, although the framework for analysis retains its utility. In particular this is clear in the literature in history linking the world system to environmental change (Hornborg/McNeill/Martínez-Alier 2007). Thus, the suggested approach of a *political geoecology* combines four components:

a.) a sensitivity for Braudel's three historical times or for three temporal dimensions;
b.) the three features of the notion of 'policy' (field), 'politics' (process) and 'polity' (legal structures, institutional framework):
c.) with the reference to 'geo' the specific spatialization that is delinked from the Hobbesian tradition of the notions of 'geopolitics', 'geostrategy' and 'geoeconomics';
d.) reflecting research on the environment from i) physical geography (*geoecology*), and ii) other natural sciences (e.g. physics, chemistry) on *earth systems science*, as well as iii) from a wider and holistic *social* and *human ecology* approaches.

However, the 'spatial' approaches of globalization, new regionalism and geopolitics were mostly delinked from the discourse on a reconceptualization of security (Brauch 2008a, 2008c, 2009, 2009d). So far many writers on the 'Anthropocene' in geography (Ehlers/Kraft 2006; Ehlers 2008) and in the natural sciences (Crutzen/Stoermer 2000, Crutzen 2002, 2006) have not discussed its ramifications for security; this debate is just emerging (Dalby 2007, 2007a, 2008, 2009; Brauch/Oswald Spring 2009, 2009a). Questions of the specific conditions and challenges posed during the Anthropocene require a fundamental rethinking of security.[7]

94.3 'Geo' Approaches to the Spatial Effects of GEC

Before this emerging discourse on the securitization of GEC is taken up, a brief review of the debates on the spatial approaches in international relations is appropriate. Global environmental change encompasses "a full range of globally significant issues relating to both natural and human-induced changes in Earth's environment, as well as their socio-economic drivers". According to Munn (2002: xi) "human-induced perturbations in the environment are increasingly becoming large and are potentially coming to dominate the natural workings of the complex and independent global system that sustains the Earth". Furthermore, "humans and their global environment are no longer independent. They are ever-increasingly becoming interdependent components of a single global system".

Some of these themes have appeared in earlier discussions of the environmental dimensions of global politics, and in the discussions of geopolitics in particular, but as this chapter makes clear, the sheer scale of the changes in the last half century now require a substantial update of these earlier theories and a recognition that humanity has effectively taken its fate into its own hands, even if much scholarly analysis has yet to understand matters in this way. The spatial categories of politics are especially important because, while administration is still understood in these terms, the ecological context we now live in makes many of them redundant in terms of how security now needs to be understood.

94.3.1 Spatial Approaches in International Relations

Both the old and the new approaches of geopolitics and the related issue areas of geostrategy, geoeconomics, and geo-culture have addressed issues of international politics from a perspective of political geography where spatial categories are essential. Since the end of the Cold War, geopolitical considerations within geography in particular experienced a renaissance with the emergence of new scholarly journals.[8]

Two phases of geopolitical thinking can be distinguished: the old primarily German and Swedish school of *Geopolitik*[9] and the British and American approaches to *geopolitics* and *geostrategy*,[10] and the recent revival of geopolitics in the UK and the US[11], of *géopolitique* in France[12] and its impact on the renewed thinking on *Geopolitica* in Italy[13] and Spain[14], as well as in Cuba, Brazil, Mexico, Argentina, and other countries in Latin America[15] in the 1990's, of *Geopolitik* in Germany,[16] and in Israel[17] the postmodern approaches to *critical geopolitics*[18] in the tradition of the deconstructivist schools and other *new* approaches partly provoked as a geopolitical response to the globalization challenge.[19]

After World War II, in many German political dictionaries and international relations textbooks, *geo-*

politics did not exist.[20] The term '*Geopolitik*' (1899) was originally coined by Rudolf Kjellén (1864–1922) while the related concepts of a political geography were fully developed by Friedrich Ratzel (1844–1904) and Karl Haushofer (1869–1945).

Geopolitik refers to a scientific approach between geography, law, history and the social sciences that analyses interdependencies between political factors and space focusing on the impact of geographical or spatial factors on political phenomena. Prior to World War II, this school of thought had some impact on Japan, Italy, Spain but also on the US, Brazil, Chile and Argentina.[21]

Ratzel's laws on the 'spatial growth of states' were highly deterministic while Haushofer's concept of 'Lebensraum' (living space and movable borders) was adopted by the Nazis to justify German expansionism. After 1945, these concepts were not used among professional geographers "because of its association with Nazi policies and ideas of environmental determinism from which geographers were in retreat" (Agnew 1993: 349).

In Great Britain in the early 20th century, *geopolitics* was popularized by Halford Mackinder (1861–1947)[22] who focused on the *heartland* as the seat of power and the *inner* (running across the Mediterranean region) and *outer crescent*. In the United States Alfred Mahan (1840–1914)[23] in his writings on naval power became an early proponent of geopolitical and geostrategic thinking while Nicholas Spykman (1893–1943) was influenced by both.[24]

These old conceptual and political debates in Germany, in the UK and in the USA influenced the political and strategic debates in the USA since World War II when realist notions gradually replaced the idealist and Wilsonian worldview that was influential after World War I.

In this early discourse, the environmental dimension and ecological considerations were lacking. However, the relevance of climatic factors on human history were already addressed by the American geographer Ellsworth Huntington (1915, 2001) who argued that the geographical-physical conditions, which are determined mainly by the climate and climate changes, decide the character of the people, as well as their history.

Since the 1930's, this determinist paradigm "was replaced by the anthropogenic model, which placed all blame for the emergence and collapse of civilizations (including the improvement and degradation of the natural systems supporting them, such as water, soil, and vegetation) on human malpractice".[25]

However, the impact of the Sahelian droughts (1968–1984) on people in Africa, and the growing influence of paleo-environmental research began to "bring an increasing number of geographers, archaeologists, and historians to start shifting the blame back from man to climate changes and other natural causes".[26] This neo-deterministic paradigm "emphasizes the dynamic interaction between the natural environment as decided by the geographical position, climate, water, soil, vegetation, etc. and the human society supported by that environment. This interaction oscillates within the endurance capacity of both systems dictated by their sustainability, as well as by the flexibility of the natural system and the agility of the human mind" (Issar/Zohar 2009: 119–120).[27] But this discourse among climate historians did not discuss se-

19 The debate on geopolitical topics and problems as well as on the use of the geopolitical approach exists also in many countries in Asia and Africa and in other parts of the world. See the bibliography compiled by the *Centre for Geopolitical Studies* in Geneva; at: <http://www.exploringgeopolitics.org/Education_Books_Bibliography_Geopolitical_Thought_Analysis_Critical_Geopolitics.html>; see also Dalby (2010).

25 Representatives of the anthropogenic school are: Woolley and Lawrence (1936); Albright (1949), Glueck (1968); Lowdermilk (1946); Worster (1982); Evenari, Shannon and Tadmor (1971).

26 The major representatives of this school are: Carpenter (1966); Braudel (1972); Le Roy Laudrie (1971); Lamb (1977, 1982, 1985); Issar (1990); Angelakis and Issar (1996); Issar and Brown (1998); Brown (2001); Yoshino, Domrös, Annick, Douguédroit, Paszyñski and Nkemdirin (2006, 1997); Issar (2003); Issar and Zohar (2004, 2007, 2009).

27 The neo-deterministic paradigm is obvious in the work of: Dalfes, Kukla and Weiss (1997); Issar (2003); Issar and Zohar (2004, 2007, 2009).

curity issues. Thus, these two approaches by geographers in the early 20th century remained unrelated.

94.3.2 The Hobbesian Obsession of Geostrategy

After World War I, with the emergence of international relations as a new sub discipline of political science, at least in the USA, idealist conceptualizations of international relations in the Wilsonian tradition prevailed, while in the UK Carr (1939) expressed realist notions. During and after World War II, realist thinkers (Morgenthau 1948; Niebuhr 1949; Hertz 1959) represented the mainstream that stressed the US national interest and US national security concerns. In the post World War II period Mackinder's heartland model fell into disrepute, and geopolitics, without an explicit continuity, acquired two new meanings:[28]

> 1) as a synonym for geostrategy in the pursuit of particular diplomatic and military goals and 2) as the equivalent of political geography, in the sense of a real variation in political phenomena at all scales, including the global. The more classical usage returned to prominence in US debates over international politics in the late 1970's and early 1980's. ... Soviet desire for warm-water ports and oil deposits in the Middle East, and the key role of the US Navy in denying the world's sea-lanes to the Soviet Union. From this perspective the United States and the Soviet Union were seen as successor states to, respectively, Britain's nineteenth century maritime empire and French and German attempts to assemble an overwhelming 'continental bloc' (Agnew 1993: 349).

Since the late 1970's, and especially during the 1980's, there was a renaissance of geostrategic and geopolitical thinking among US and UK civilian and military strategists (Gray 1977, 1986, 1988, 1992, 1994, 1999, 2005) that were influenced by Mahan, and in 1990's, there was a revival of political geography with a focus on nuclear geopolitics and on geoeconomics. Influenced by Mackinder and Spykman, Cohen (1963, 1991, 1991a, 1993) applied geopolitical categories for the analysis of world politics and zones of influence, and the basic differences between conservative *continental* and liberal trade oriented *maritime* powers. After the Cold War he introduced the term of 'gateway regions' that link up the economic and political transfer between neighbouring geopolitical and geostrategic regions. Cohen (1991: 552) argued:

> Geographers today have an unparalleled opportunity to dispel geopolitical illiteracy by focusing on the 'geo' of geopolitics. ... while the 'geo' accounts for the spatial dimension, the 'politics' in geopolitics is the exercise of power that derives from and seeks to control economic, social and cultural forces. ... The 'geo' in geopolitical analysis starts with spatial structure. ... The structure is hierarchical.

From a different perspective, O'Loughlin and Heske (1991: 37) argued: "It is time to reclaim the geopolitical theme from the hijackers in the strategic community" and – influenced by the new French school – suggested to convert "a discipline for war to a discipline for peace".[29]

However, the renewed attractiveness of geopolitical thinking in Europe and North America after the end of the Cold War has only partly been influenced by the old German and Anglo-Saxon roots, it was rather stimulated by a completely distinct school of political thinking on *geopolitique* in France influenced by *Yves Lacoste*, his centre for geopolitical research and analysis (CRAG) at Paris University VIII, and the journal *Hérodote*.[30]

94.3.3 Revival of Geopolitics in France

The work of Lacoste was a result of analysing problems of the violent process of decolonization. For him geography is a social discourse "a mode representing the world", and a strategic form of knowledge that by "the structuring of knowledge relating to space, is a strategic knowledge, a power" that is needed both for warfare but also for territorial administration and government (Ó Tuathail 1996: 162–163). For Lacoste (1984: 214) the theses of Mackinder and Mahan "rest more on historical evocations than on rigorous strategic thinking, based as they are on grandiose geographical metaphors of Land and the Sea" lacking scientific value. He called for a repoliticization of the geographic discipline and he stressed the necessity

> to exhaustively document the complex spatial relationships that is to be found in international relations. Geographers must think of space as something that is 'textured, extremely varied and very complex'. Only ... a 'sensitive analysis of the articulation between them will make geographical reasoning worthwhile and enable geographers to arm themselves better against the

29 O'Loughlin (1994); Nester (1995); Wiarda (1996); Simon and Dodds (1998); Dodds and Atkinson (2000).

30 Hérodote (1976ff.); Gallois (1990); Lacoste (1990, 1993, 1997); Raffestin (1995); Chauprade (1999); Claval (1996); Defarges (1994); Laïdi (1998).

influence of ideological assumptions' (Ó Tuathail 1996: 166).

Nevertheless, Ó Tuathail (1996: 167–168) – from the perspective of critical geopolitics – argued that Lacoste's work falls "back into the very ideological system of epistemology he wished to challenge" and that it is "a polemical argument against its (ab)use by the military", that he leaves "the epistemological infrastructure of geography/geopolitics intact", and that it "ultimately fails to specify a detailed way how geographical knowledge functions strategically as a form of power/knowledge". For Lacoste (1997), the state and nation remain the key actors and concepts of politics and international relations.

In a review of the new attractiveness of *géopolitique* in France, Dussouy (2000: 507–519) distinguished between: a) the geopolitics of the state, and b) of the international system. Lacoste (1996: 3–8) has applied a wide concept of *géopolitique* that covers everything "what refers to rivalries between different types of power on territories that may be of different dimensions", thus focusing not only on inter-state but also on intra-state conflicts. For Dussouy (2000: 515–519, 1998) the geopolitical space "is a system of material and immaterial or symbolic spaces in which each space has its own organizational logic, its own structure" (Dussouy 2000: 515–516). He argues that the analysis of different spaces and that the structuring of each space often reflects a dialectics of homogenization and fragmentation with respect to heterogeneities. For example, the geoeconomic space and the diplomatic international space produces both a global homogenization (market, production, consumption patterns) and a dual polarization between North and South and an internal polarization within multinational enterprises. He defines the international system as a configuration of spaces and actors that act in the pursuit of their interests under the influence of the socially imaginary. In conclusion, Dussouy argues that interdependencies of territories and networks in a regional framework may be best suited to permit a coexistence of the unsolvable problems of geography and history with the forces of a homogenization within macro systems.

Many French studies have analysed the German and Anglo-Saxon roots of geopolitics (Defarges 1994; Claval 1996; Raffestin 1995; Chauprade 1999) by contrasting the geopolitics of maritime and continental powers, discussing the relations between geopolitics and war and geoeconomy and the specific *géopolitique* of France (Defargues 1994), the evolution of geopolitical thought in history, especially during fascism in Germany, Italy, and Spain (Raffestin 1995), focusing on the methods, and on permanent and changing geopolitical factors (Chauprade 1999) or dealing with the relationship between geopolitics and (nuclear) geostrategy (Claval 1996).

94.3.4 Revival of Geopolitics in Italy and in Germany

In Italy, in the 1990's the renaissance of *Geopolitica*[31] (Petersen 2000: 481–505, 1993) was very much influenced by the French debate, especially by Lacoste (1993), Defargues (1996), Claval (1996a), and Lorot (1997) whose books were translated into Italian. Since 1993, the journal *Limes*, and Carlo Jean (1995)[32], a retired general, played a leading role in spreading geopolitical concepts in Italy.[33]

Until the 1990's, in Germany geopolitical approaches were ignored after efforts in the 1950's to reintroduce the pre-Nazi geopolitical thought failed.[34] In the early 1990's, a few experts called for new geopolitical considerations (Palaschewski 1989, 1992; Brill 1993, 1994) while others focused on Haushofer (Ebeling 1994). In 1994 a conference reviewed theoretical designs on the political space and the journal '*WeltTrends*' devoted an issue on '*Geopolitik*' with contributions by Lacoste and Taylor.[35] In autumn 1997 and 1998, two conferences reviewed the old thinking on *Geopolitik* from 1890–1945 and new approaches since 1945.[36]

---

31 The first debate in the late 1930's was nearly exclusively influenced by the German debate by Haushofer, Ratzel, Maull et al., see Petersen (2000: 486–487). From 1939–1942 the journal *Geopolitica* was published in Milan by Roletto. From the mid 1940's until the 1980's, geopolitics had virtually disappeared.

32 Based on French and Anglo-Saxon publications, Carlo Jean analysed world politics from geopolitical, geostrategic and geoeconomic perspectives. See also the conference volume edited by Ferro (1993).

33 Among the challenges are: disintegration of Italy, the emergence of a Franco-German community, a stop to European unity and a Balkanization of Europe while among the opportunities are: the dynamics and vitality of the Italian economic system, the cultural heritage, the role of the Catholic Church and the role of Italian emigration around the globe.

34 See: Grabowsky (1960); Schöller (1961); Matern (1978); Kost (1988); Schultz (1989); Sandner (1994: 12–14); Buck (1996); Sprengel (1996); Faßler (1996); Brill (1998).

35 See *WeltTrends* No. 4 (1994): on the Hannover Conference: 177–181; and the articles by Lacoste (1994: 21–24); by Taylor (1994: 25–38); on *Hérodote* (1994: 150–152).

In this context, von Bredow in analysing 'international politics' as a 'spatial order', briefly addressed the impact of globalization on the loss of the spatial dimension and argued that it is not the spatial aspect of international relations that is being challenged but the territorial principle and national sovereignty due to the removal of the boundaries between the domestic and foreign space. Only few authors (Clark 1997; Menzel 1998) have addressed the opposite tendencies of globalization and fragmentation in the post-Cold War world.

94.3.5 The Geopolitical Tradition in Latin America

The classical geopolitical discussion in Sweden, Germany, and the UK as well as the new debates on geopolitics, geostrategy and geoeconomy in the USA, the UK, and France had a lasting impact on the conceptual discussion of the military in Latin America (Zea/Magallón 1999). Kelly (1997) reviewed the geopolitical assumptions of their foreign and domestic policies and actions by pointing to

> the influence of geopolitical theories originating in the ... German Realpolitik, 'scientific', organic-state schools on the thinking of Southern Cone military men and their civilian allies. The old school of organic concepts does not offer a serious theory of international relations or a satisfactory basis for policy; the military regimes were discredited largely because of the national security rationale for brutal repression at home. ... Kelly identifies ... three basic approaches to geopolitics: as the impact on foreign security policies of geographic features, such as locations, distances, terrain, climate, and resources; as the relationship between power politics and geography; and as a deterministic organic-state imperative (the original school of geopolitics identified above). These perceptions have collectively influenced the thinking and actions of both military and civilian policy-makers. [37]

In Brazil during the military rule, the geopolitical debate of the military focused on the national security state. Thus, it was a reflection of the Hobbesian obsession based on power politics and in many cases it directly legitimated the rule of the military regimes.

94.3.6 Contemporary Discourses of Critical Geopolitics

In the Anglo-American world, some geographers questioned whether a geopolitical ordering of the world into 'strategic regions', 'spheres of influence', 'buffer zones', and 'strategic locations' existed (Agnew 1993: 349).

> Rather, geopolitics could be viewed as any discourse about geographically defined interests including particular models privileging fixed geographical 'facts' about the world. From this point of view geopolitics did not disappear after World War II or when moral rhetoric replaced *Realpolitik* in the pronouncements of politicians. It is implicit in the practice of foreign policy. In line with this dynamic conception of geopolitics, as the world political economy changes the criteria used for ordering the world geographically change.

Beyond the geostrategic and geopolitical reasoning in the realistic tradition of power politics, a new school of '*critical geopolitics*' evolved in the framework of late modern or postmodern and deconstructivist approaches to international relations (Ashley 1984, 1988, Derrida 1981, Der Derian 1992). While geographers have long been interested in how geographical concepts work, Hartshorne (1950), influenced by Foucault (1980) and Lacoste (1976) the new critical approaches focused on geopolitics as a discourse and as a form of power and knowledge interpreting hegemonial power as rule writers. Critical geopolitics focused on the geopolitics of imperialism, the logics of American foreign policy, and how intellectuals of statecraft constructed geographical arguments to legitimate power (Ó Tuathail 1989, 1996; Ó Tuathail/Agnew 1992; Ó Tuathail/Dalby/Routledge 1998; Dalby 1991). On Ó Tuathail's version of *critical geopolitics* (1996), Agnew (2000: 96–98) noted:

> From the outset, the terms of geopolitics are situated in a set of discourses about statehood, state sovereignty, and the geographical divisions of the world upon which

36 See Diekmann, Krüger and Schoeps (2000), 2 volumes with a review of the debates on political geography in Germany and since 1990 also in France and Italy. Only two specialists of international relations are represented: von Bredow (2000: 433–452) and Fröhlich (2000: 559–590). The volumes ignore the new debate on *critical geopolitics* while the US geostrategic debate is covered. Among the 26 contributions one focuses on imperial, cultural and political borders, on frontiers and on anthropogenic research on political borders, border conflicts and border regions in the context of globalization and regionalization (Heller 2000: 325–350).

37 See the review of Kelly's survey of the geopolitical thinking in Latin America by G. Pope Atkins, University of Texas, Austin, in: *Journal of Interamerican Studies and World Affairs*, Summer 1998; at: <http://findarticles.com/p/articles/mi_qa3688/is_199807/ai_n8793265/?tag=content;col1>.

> the practices of international relations depend for their meaning and significance. ... Ó Tuathail sees the mapping of the world by academic theorists and political practitioners as involving a 'geo-graphing' in which meaning is never completely mapped, even as this is the claim all make. The goal of the book is to analyse the ways in which conventional geopolitical writing can be called into question or 'displaced' from its intellectual and political pedestal. Three main approaches ... are taken to task. The first is to open up traditional terminology of geopolitics by exposing it as anything other than self-evident and innocent. ... a second approach is to define geopolitics as a type of 'governmentability'. ... The third and most important approach explores the techniques of 'seeing' that make global political mapping possible. ... Overall, the three-pronged attack displaces the logic of geopolitics by pointing how it is discursively produced. Geopolitics does not simply 'happen'.

Other geography authors have focused on issues of economics, identity, and nationalism in global cities (Scott 1998; Agnew 1998; Herb/Kaplan 1999). David Newman (1999: 1–2) summarizes the factors that contributed to its renaissance:

> The collapse of the Soviet Union and the territorial reordering of Central and Eastern Europe, together with the impact of globalization and supra-national processes on what is traditionally seen as the Westphalian compartmentalization of the world into sovereign states, has raised a host of new questions concerning the nature of the world political map. The study of these topics has assisted in the re-legitimization of Geopolitics as an academic sub-discipline.

On the international scene, a reassessment of the geopolitical writings of Ratzel occurred at a meeting held in Trieste in December 1997 on 'Europe between Political Geography and Geopolitics' (Antonsich/Kolossov/Pagnini 2001), and a subsequent meeting in Israel in January 1998 focused on 'Geopolitics and Globalization in a Postmodern World'.[38] Newman (1999: 3–5) identified as key themes of the contemporary study of geopolitics:

- Globalization and the changing function of state sovereignty. ...
- The deterritorialization of the state and the associated changing roles and functions of international boundaries. ...
- The study of geographical texts, narratives and traditions. ...
- The geopolitical imagination. The relative location of a state in the global system. ...
- The 'reterritorialization' of the state and the emergence of new ethnic national and territorial identities. As globalization and boundary permeability affect the state at one end of the spectrum, so too do the emergence of new states and the associated creation of new boundaries affect the lower end of the system. ... Geopolitics should focus on the geographic differentiation of these processes, along a continuum from deterritorialization to reterritorialization and the way in which globalization affects different state activities unevenly.

Geopolitics or 'politics within a space' and globalization 'politics beyond space and borders' point to two extremes that are relevant for the analysis of the referent objects of security. Through both theoretical perspectives of '*géopolitique*' and '*globalization*' different features of the present political reality may be perceived and evaluated. But now the global environmental changes in the Anthropocene mean that all these matters have to be updated to take the new circumstances into account.

94.3.7 Bringing the Environment into the Geopolitical Discourse

The debate on *global environmental change* (GEC) and climate change (Issar/Zohar 2004, 2007, 2008, 2009) triggered new proposals for a spatialization of environmental issues with concepts such as: *ecological geopolitics* (Dalby 2000, 2002a, 2002b) and a *political geoecology* (Brauch 2003, 2003a, 2009a). This is important because the effects of climate change do not distinguish national borders but the specific impacts differ due to the socio-economic status of the affected countries and the degree of social vulnerability of its affected people (IPCC 1990, 1990a, 1996, 1996a, 1998, 2001, 2001a, 2007, 2007a, 2007c). The securitization of climate change started in the early 21st century (Brauch 2002, 2005a, 2007, 2007f, 2009a; chap. 42 by Scheffran). It did so in part by extending the earlier 1990's discussion of environmental security, although it seems that in at least some cases the earlier discussion has been overlooked and some of the lessons lost in the process (Floyd 2008). Clearly the focus in the early part of the twenty-first century focuses more explicitly on the theme of security broadly understood, than on the 1990's debate specifically about conflict (Detratz/Betsill 2009; Trombetta 2008)

Climate change is discussed as an issue of environmental and US national security[39], of international

38 Newman (1998); Kimmerling (1983); Biger (1990); Sucharow (1999); Bernstein (2000); Shilhav (1985).

and human security[40, 41], reflecting contemporary strategic concerns (Dyer 2008; Dupont 2008). The German Advisory Council on Global Change (WBGU 2007, 2008) in a report on *Climate Change as a Security Risk* discussed "climate change as a threat to international security" due to four climate-induced conflict constellations (chap. 41 by Bauer). This report used an extended security concept that included the securitization of environmental dangers including the risks associated with climate change, however, its referent object focused on the nation state.

International relations analyses of globalization, new regionalism, and geopolitics have mostly ignored both the environmental dimension and the securitization of climate change and desertification. According to Alker and Haas (1993), thinking on global environmental change and politics could develop into either a reworking of classical *geopolitics* or a new focus on *ecopolitics*. For Dalby (2000: 90) this ecopolitical analysis of the global environment requires thinking beyond "the state and the conceptual tools of contemporary neoliberal scholarship", but also beyond the spatializations of political processes (globalization, regionalism, geopolitics) with the state or non-state economic actors as major points of reference. To understand "politics and ecology as processes in motion, rather than as stable entities", requires according to Dalby (2000: 98), "a more sophisticated political ecology that understands environmental change as a series of complex social processes in specific geographical contexts". Dalby (2000: 99) concludes that the post-Cold War context permits a discussion of environmental security issues beyond geopolitical rivalry. Thus, environmental change should be incorporated into models of conflicts, geopolitical assumptions must be debated, and "ecopolitical considerations require that ecology and environmental history be taken seriously" (Dalby 1998b).

While Dalby (2000) approached *eco-geopolitics* from critical geopolitics (1998) and did so specifically to challenge the framing of environmental matters in terms of national security, Brauch (2003, 2003a) argued that a *political geoecology* is needed that combines the regional implications of global change and its potential outcomes: disasters, environmentally-induced migration, crises, and conflicts, and Oswald (2008a; chap. 72) insisted on the triggering factors and focused on social vulnerability. This approach requires an interdisciplinary discourse on global change and its impacts for security and conflict avoidance. As Trombetta (2008) notes adding climate into the discussion explicitly challenges the traditional meanings of security. It does so precisely because the new geopolitical context of the Anthropocene requires a forward looking, anticipatory understanding of security, not the old one that emphasizes monitoring borders, providing insurance or cleaning up after a disaster.

Traditional geopolitics frequently suggested that the environment in some ways determined or at least dramatically shaped human actions. The arguments were demolished by the middle of the 20th century (Sprout/Sprout 1965), but they are remarkably persistent in the popular discourse and elsewhere in political thinking (Kearns 2009). They have re-emerged in June 2009 when Robert Kaplan (2009) rearticulated Halford Mackinder's classic geopolitical text on the 'pivot of history' from 1904 in the pages of Foreign Policy magazine. Kaplan tries to use the Mackinder notions of nature being the ultimate arbiter to suggest that geopolitical rivalry in Asia is coming, regardless of what anyone in the West can do about it. This determinist argumentation ignores human-induced changes to the biosphere (Dalby 2009, 2009a). Returning to an old theme of geographically clashing spaces, suggesting that such clashes are inevitable because they are an objective given condition of the planet ignores change and redirects attention away from looming changes to focus on military and naval rivalries (Morrissey 2009), not the transformation of local and regional ecosystems and the large scale impacts of climate change.

Both the term geoecology and the notion of the Anthropocene suggest that the old assumptions of the environment determining human fate are no longer tenable, because carbon fuel use have already changed environmental conditions. Old fashioned geopolitics diverts attention from these new circumstances, and as such it is a distraction from the tasks at hand which conjures up an inappropriate geography to suggest the inevitability of conflict precisely when large scale cooperation is needed to deal with the changes that

41 See the GECHS workshop on climate change and human security at: <http://www.cicero.uio.no/humsec/list_participants.html>; Barnett and Adger (2005); at: <http://www.cicero.uio.no/humsec/papers/Barnett&Adger.pdf>.

are already in motion due to profligate use of carbon fuels and the numerous other changes.

Political geoecology suggests a much more explicit focus on ecology, on the big scale in particular in terms of geo, and also a clear indication that human choices are shaping the world of the future. The recognition of the significance of our actions is only now registering in many parts of the world as the debate about climate change suggests to people the profound choices that our predecessors and ourselves have made in shaping the future condition of the biosphere. This terminology suggests the most important theme for all concerned about security in the 21st century, the inapplicability of traditional geopolitical notions of an external environment for discussions of human security in the future.

94.4 New Spatial Approaches in the Anthropocene: Geoecology and Earth System Analysis or Science

94.4.1 Combining Human, Social, and Geoecology

The analysis of the security impacts of global environmental change in the Anthropocene requires the knowledge produced by both the *geoecology* programmes that are located in physical geography, earth system science and numerous other disciplines, and by *social ecology* and *human ecology* approaches combining scientific efforts in geography, sociology, psychology and political science.

In trying to encapsulate numerous ecological processes, Huggett (1995, 2000) used the term geoecology to emphasize the importance of earth system processes, and the necessity of thinking carefully about the interactions of *pedosphere* (soils), *biosphere* (living things), *atmosphere* (air), *lithosphere* (minerals) and *hydrosphere* (water). All these 'spheres' matter in current thinking, but all are being changed by human activities. Climate change is obviously about the atmosphere, but what's changing the composition of the atmosphere is really a matter of extracting carbon from the lithosphere. Likewise the artificial use of nitrogen fertilizer is changing the pedosphere directly, while converting land to use for farming directly changes the pedosphere and the biosphere. When water is diverted to irrigate these fields the hydrosphere too is changed. Linking this to the term political makes it clear that humanity is actively changing the various 'spheres' that make up the geoecology of our planet.

The sheer scale of the human remaking of ecosystems requires that we now think about these matters at the global scale (MA 2005; UNEP 2007; IPCC 2007; Leemans 2009). Synthesizing these themes, the largest of scales has not been an easy scientific task, but in the last couple of decades putting the pieces together to understand the processes driving geoecology at a planetary scale have coalesced into a new perspective on humanity and the environment.

> The interactions between environmental change and human societies have a long and complex history, spanning many millennia. They vary greatly through time and from place to place. Despite these spatial and temporal differences, in recent years a global perspective has begun to emerge that forms the framework for a growing body of research within the environmental sciences. Crucial to the emergence of this perspective has been the dawning awareness of two fundamental aspects of the nature of the planet. The first is that the Earth itself is a single system, within which the biosphere is an active essential component. In terms of a sporting analogy, life is a player, not a spectator. Second, human activities are now so pervasive and profound in their consequences that they affect the Earth at a global scale in complex, interactive and accelerating ways; humans now have the capacity to alter the Earth System in ways that threaten the very processes and components, both biotic and abiotic, upon which humans depend (IGBP 2001: 4).

94.4.2 Earth System Science Perspectives on GEC

During the 1990's, *Earth Systems Science* (ESS) gradually emerged from research on *global environmental change* (GEC). According to Ehlers and Krafft (2001: 3–4): "global change research ... started off as climate research and the climate research community contributed the first scientific breakthroughs in the understanding of climate variability stimulating further research". This triggered the interest of "geologists, hydrologists, biologists as well as representatives of the terrestrial and marine geo-sciences" who focused on the "biogeochemical impacts and processes in both marine and terrestrial environments". Many new insights were achieved within research in the contexts of the *World Climate Research Programme* (WCRP, see chap. 78 by Church/Asrar/Busalacchi/Arndt) and the *International Geosphere-Biosphere Programme* (IGBP, see chap. 77 by Noone/Nobre/Seitzinger).

With the creation of the *Human Dimensions of GEC Programme* (HDP) in 1989 that became the *International Human Dimensions of GEC Programme* (IHDP) the social sciences joined the community addressing psychological, cultural, economic, historical and political factors. During the initial phase, Ehlers and Krafft (2001: 11) noted during the initial phase of global change research (1985–2000) a "hesitance of social scientists to participate more actively in the promising and future-oriented endeavours of this new and huge research field" as they appeared "to be neither interested nor knowledgeable about GEC research". But also the natural sciences would have to reflect on the interpretative questions posed by social scientists who often preferred bottom-up or inductive approaches compared with the top-down or deductive modelling of many natural scientists. In identifying pathways towards sustainable development, Clark, Jäger, van Eijndhoven (2000: 2) stressed the need to reduce uncertainties:

> Efforts to manage humanity's interactions with the global environment ... will almost certainly be partial, contentious, and prone to failure. But the management of global environmental risk is also what an increasing number of political leaders, advocacy groups, scientific experts, and international organizations find themselves doing, not uncommonly with the best of motivations and the greatest trepidation.

Ehlers and Krafft (2001: 13–14) also referred to the debate on a new social contract between scientists and society, where the former offer "socially robust knowledge" (Gibbons 1999: C 84) and they stressed that the "grand challenges" of GEC research "can only be addressed through cooperation and interaction of both natural and social sciences". The need for integrative research on global change was taken up by Grunwald (2001: 23–24) who distinguished four levels of integration with regard to research on a) economic sectors, b) on the classic disciplines between the natural and social sciences, c) cultural predispositions, and d) on the dimensions of sustainability.

In *Earth System Science in the Anthropocene*, Ehlers and Krafft (2006: 7) provide a context of the emerging debates on global change research and Earth Systems Science, especially since 1990 that focuses on the "human role in the transformation not only of the earth's surface but of the earth and climate system", where "human-driven changes cause multiple effects that cascade through the earth system in a complex way".[42] But in none of these contributions, the relevant policy areas, the political process and institutions were analysed and – except for one chapter on food security (Zingel 2006) – the security impacts of GEC were not addressed.

From the vantage point of physics and climate impact research, the *Earth Systems Analysis* (ESA; Schellnhuber/Wenzel 1998) or *Earth Systems Analysis for Sustainability* (Schellnhuber/Crutzen/Clark/Claussen/Held 2004; Schellnhuber/Crutzen/Clark/Hunt 2005) and the *Earth Systems Science Partnership* (ESSP; chap. 74 by Leemans/Rice/Henderson-Sellers/Noone) have evolved since the 1990's as a new "scientific enterprise that tries to perceive the earth as a whole, a unique system which is to be analysed with methods ranging from nonlinear dynamics to macroeconomic modelling".[43] Schellnhuber and Wenzel (1998: vii) called *Earth System Analysis* (ESA)[44] a "science in *statu nascendi*" that combines the object "Earth System" with the method of "Systems Analysis".[45]According to both authors: It is a science as it has

1. a genuine *subject*, namely the total Earth in the sense of a fragile and 'gullible' dynamic system,

42 Ehlers and Krafft (2006) addressed four key themes: 1) "The Anthropocene"; 2) "Global Change and Human Security"; 3) "Interface between Nature and Society" and 4) "The Scientific Challenges for Anthropogenic Research in the 21st Century." Only one chapter addressed the security dimension for "food security in South Asia" (Zingel 2006: 229ff.) but without any reference to the debate on a reconceptualization of security.

43 See the back cover of Schellnhuber and Wenzel (1998).

44 The ESA concept has framed the programme of several multi-, inter- and transdisciplinary university departments and research programmes. At Enschede (Netherlands) the International Institute for Geoinformation Science and Earth Observation has a Department on *Earth System Analysis* <http://www.itc.nl/Pub/Home/Organisation/Introduction-Scientific-departments/ESA> that "concentrates on a number of societal issues and problem areas, including: i) earth resources management, exploration and exploitation; ii) land (soil) degradation; and iii) natural hazards and disasters; geo-environmental hazards. ... The department's activities include: a) spatio-temporal modelling for an improved understanding of earth systems and processes; b) development of methods, techniques and tools for the assessment and monitoring of these earth systems and processes; and c) earth and land resource information provision for planning and decision-making on the multi-functional use of space. ... ESA provides and applies relevant geo-information for an improved understanding of earth surface and subsurface processes in space and time, for the sustainable use of earth resources and the mitigation of natural and man-induced disasters.

2. a genuine *methodology*, namely transdisciplinary systems analysis based on, i.a. planetary monitoring, global modelling and simulation,
3. a genuine *purpose*, namely the satisfactory (or at least tolerable) coevolution of the ecosphere and the anthroposphere (*vulgo*: Sustainable Development) in the times of global change and beyond.

The ESA concept evolved from the inauguration of the scientific Advisory Board of the *Potsdam Institute for Climate Change Impact Research* (PIK) in 1994. In his introduction Schellnhuber (1998) offered the conceptual and formal framework in which he associated the 'scope of the challenge' with that of geo-cybernetics, or "the managed coevolution of nature and humanity". He defined as the task of *Earth System Analysis*:

> The scientific investigation of how the infinitely interrelated complex of ecosphere and anthroposphere responds as a whole to major perturbations, and how these reactions might be favourably influenced by wise global management. ... The ... Earth System Analysis clearly ought to be: i) interdisciplinary, ii) international, and iii) inter-objective. ... Its main task is to provide tools for managing Global Change in order to secure an *acceptable long-term coevolution of nature and civilization*. In other ... words, Earth System Analysis should yield a good deal of the information and methods required for defining and materializing 'Sustainable Development' (Schellnhuber 1998: 6–9).

The 'Integrated Earth System' concept was taken up by the *International Geosphere Biosphere Programme* (IGBP) in its study on *Global Change and the Earth System* that outlined a research agenda to meet the future challenges that is based on the following two key observations on the earth system functioning:

> First, that the Earth itself is a single system within which the biosphere is an active, essential component. Secondly, that human activities are now so pervasive and profound in their complex, interactive and apparently accelerating ways; humans now have the capacity to alter the Earth System in ways that threaten the very processes and components, both biotic and abiotic, on which the human species depends (Steffen/Sanderson/Tyson/Jäger/Matson/Moore/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004: 1).

The Dahlem workshop on *Earth System Analysis for Sustainability* in May 2003 carried the discussion further (Schellnhuber/Crutzen/Clark/Claussen/Held 2004). According to Clark, Crutzen and Schellnhuber (2004: 1, 2005): "we live today in ... the 'Anthropocene' – a new geologic epoch in which humankind has emerged as a globally significant – and potentially intelligent – force capable of reshaping the face of the planet" (Crutzen 2002). The recognition of the role of humans as global transformers of the earth has gradually evolved since Alexander von Humboldt (1808) and was systematically developed by the Russian geochemist, Vernadsky (1926, 1998) in his lectures on the 'biosphere' delivered at the Sorbonne in the 1920's.

Clark, Crutzen and Schellnhuber (2004: 2, 2005) argued that "the last half century witnessed an accelerating program of scientific studies (e.g. Thomas 1956; Steffen/Sanderson/Tyson/Jäger/Matson/Moore/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004) that have broadened and deepened our understanding of what Turner, Clark, Kates, Mathews and Richards (1990) have convincingly characterized as an 'Earth transformed by human action'". In response to the gradual understanding of the anthropogenic contribution to GEC and climate change in the Anthropocene the normative concept of 'sustainable development' (Brundtland 1987) has been adopted in Rio de Janeiro in 1992 at UNCED and become a key policy goal of UN Secretary-General Kofi Annan's *Millennium Report* (UN 2000), and at the *World Summit on Sustainable Development* (WSSD) in Johannesburg (2002) where "the need for harnessing science and technology in support of efforts to achieve the goal of environmentally sustainable human development in the Anthropocene was generally recognized" (Clark/Crutzen/Schellnhuber 2004: 3, 2005).

At the Dahlem Conference in May 2003 these three scientists assessed the state of this transformation and called for an 'earth system science' (ESS) that requires a second Copernican revolution or a new scientific paradigm of a 'science for global sustainability'. The Amsterdam Declaration (2001) that established the *Earth System Science Partnership* (ESSP) contributed to a comprehensive earth system science research programme by formulating 23 basic analytical, normative, operational, and strategic questions (chap. 74 by Leemans/Rice/Henderson-Sellers/Noone).[46] Clark, Crutzen, and Schellnhuber (2004: 19, 2005) argued that efforts to synthesize the work on the resil-

45 For an overview of systems theory see Mesjasz (2008, 2008a, 2008b). For a recent assessment of systems theories with a special focus on issues of complexity, steering of structures vs. structural steering, as well as on concepts of negotiation and application from the perspective of geographers see Egner, Ratter and Dikau (2008).

ience of ecological systems and on the vulnerability of social systems

> have highlighted the importance of incorporating multiple stresses, teleconnections, explicit pathways of exposure, the possibility of threshold responses, explicit treatment of scale, and attention to the components of adaptive capacity in frameworks for the analysis of vulnerability and resilience (Turner/Kasperson/Matson et al. 2003). ... Needed now for management is problem-driven research that utilizes these conceptual vulnerability/resilience framework to illuminate the kinds, rates, and magnitudes of specific disturbances beyond which the 'ability of society to advance human well-being' can no longer be sustained.

However, all these conceptual as well as research and educational scientific efforts have left out the key component for the transformation of knowledge into action: *Politik* in its triple meaning of *policy* (field), *politics* (process) and *polity* (legal and institutional framework). Thus, the discourse on the reconceptualization of security in the Anthropocene has not yet reached the multidisciplinary global change community in the natural sciences.

However, a proactive security policy in the Anthropocene that addresses the *Global Challenges for Leviathan* (Cerutti 2007) must be science- and knowledge-based, and requires a different knowledge from what national intelligence agencies and the military establishment have offered policy-makers, and it calls also for different goals, strategies, and means than traditional security experts trained in the Hobbesian tradition of security studies can offer.

Such a new security policy in and for the Anthropocene necessitates for the new security dangers posed by GEC a new policy framework that integrates both the experience of past nature-human interactions as well as the scenario- and model-based projections of the probable societal outcomes of future trends. This emerging security policy makes a conceptual thinking for a new peace policy in the early 21st century necessary that combines the goals of 'sustainable development' with a 'sustainable peace' to cope with the 'survival dilemma' of humankind (Brauch 2008b; Oswald Spring 2008; Brauch/Oswald Spring 2009a).

Earth System Analysis for Sustainability (Schellnhuber/Crutzen/Clark/Claussen/Held 2004) uses an integrated systems approach to provide a panoramic view of planetary dynamics since the inception of life some four billion years ago and to identify principles for responsible management of the global environment in the future. Perceiving our planet as a single entity with hyper complex, often unpredictable behaviour, the authors use *Earth System Analysis* to study global changes past and future. They explore the question of whether the unprecedented human-originated changes transforming the ecosphere today will end a 10,000-year period of climate stability. *Earth System Analysis for Sustainability* (Schellnhuber/Crutzen/Clark/Claussen/Held 2004) analyses the driving forces behind global change and uses this knowledge to propose principles for global stewardship.

With so many interconnections and the growing realization that the scale of human activities is having widespread repercussions, and in ways that are not necessarily predictable, questions of how to synthesize the findings in numerous human and social sciences inevitably emerge. But from the review of the geoecology and earth systems in this sections five key findings emerge that are crucial to understanding the new context for thinking seriously about human security in the future.

First, a generation after James Lovelock (1979, 1988, 1995, 2006, 2009) suggested as much in his formulation of the Gaia hypothesis, earth system thinking notes the crucial, and relatively new, realization that life partly regulates the biosphere; it is an active part of the multiple processes that shape our world. Life is not, as it has frequently been understood to be until recently, a mere addition to a planet of oceans, atmosphere and rocks. It has actively changed the biosphere, nowhere more clearly than in producing the oxygen that is key to the life of most life forms. Thus environment cannot now be understood as something outside of life, or as the given context for humanity. The key separation that most of modern life has assumed, of humanity separate in importance senses from nature on the big scale, no longer makes any scientific sense.

Second, the important point is that the sheer scale of human activities is already now adding a new dimension to these earth processes. More than just climate change: "Human activities are significantly influencing the functioning of the Earth System in many areas; anthropogenic changes are clearly identi-

46 Thereof four are relevant for security studies, as e.g. 7: Which are the most vulnerable regions under global change? 8. How are abrupt and extreme events processed through nature-society interactions? 14. What are the most appropriate methodologies for integrating natural science and social science knowledge? and 23. What is the structure of an effective and efficient system of global environment and development institutions?

fiable beyond natural variability and are equal to some of the great forces of nature in their extent and impact" (Steffen/Sanderson/Tyson/Jäger/Matson/Moore/Oldfield/Richardson/Schellnhuber/Turner/Wasson 2004: 4). Where the first finding suggests that life itself changes its context; that what we have called environment is substantially a product of life itself, now this second finding makes it clear that humanity as the now dominant form of life on earth, has become a major factor in shaping the context of life itself.

The third key finding notes that the various changes to the earth system intersect and may do so in ways that have 'cascading' effects. Changes in one part may have effects that influence others, which in turn, knock on effects elsewhere. Thus analysis has to try to understand these interconnections while also seeing the potential for 'cascades' as whole sequences of change are set in motion. The sheer complexity of ecological systems makes this difficult to predict, and analytical science that narrows a focus to examining a small part of life in detail has to be complemented by synthetic work that puts the particular parts back into the larger context. Change doesn't necessarily happen in simple patterns, nor does change of one factor necessarily cause a similar change in others.

Fourth, systems frequently have thresholds with potential instabilities, which when they are crossed cause abrupt changes. This finding emphasizes the importance of learning where the thresholds in ecological systems are so that dramatic changes do not come as surprises and in many cases so that policies can be put in place to prevent crossing the threshold in the first place. Humankind learned about one crucial threshold by accident in the 1980's when it was discovered that previously unknown chemical processes were seriously damaging the stratospheric ozone layer and endangering that crucial layer which blocks incoming ultraviolet 'B' radiation from the sun. The damage to this crucial ecological layer came as an entirely unintended consequence of humanity's production of chlorofluorocarbons. These chemicals had been thought to be benign, but they turned out to be both potent greenhouse gases and, when they broke down in the stratosphere over the poles in winter, key to removing the ozone from the upper atmosphere. Where the thresholds for rapid climate change may be we cannot yet be sure (Schneider 2004), but the recent rapid melting of ice at the poles is clear indication that we may already have crossed at least some important thresholds.

Finally, and probably the most important finding, is that the changes that we have already caused in the biosphere have pushed some of the key ecological processes of the planet out of the range for which we have detailed knowledge from the past. Over the last six hundred thousand years, detailed records of temperature and the composition of atmospheric gases show fluctuation within a fairly narrow range. Carbon dioxide and methane in particular are fairly closely correlated with temperature through this period that includes a series of ice ages. Reduced greenhouse gases coincide with ice ages, slightly higher concentrations with the warmer so-called interglacial periods; the most recent one of which has provided the relatively stable climatic conditions that allowed the emergence of human civilization. Nowhere in that period of recorded geological history is there any record of methane and carbon dioxide levels at current levels. There is no parallel situation that we might draw lessons from; in the scientific terms of the International Geosphere Biosphere Program (IGBP 2001) authors, we are in a 'no-analogue state'. Precisely because we are in this situation, and don't know exactly what is coming, the necessity to prepare to deal with a broad range of contingencies is clear.

If we do not think ahead then we may face the perilous fate that, thirty years after he published the 'Gaia hypothesis', James Lovelock (2009: 33) warned might befall us:

> We have enjoyed twelve thousand years of climate peace since the last shift from the glacial age to an interglacial one. Before long, we may face planet wide devastation worse even than unrestricted nuclear war between superpowers. The climate war could kill nearly all of us and leave the few survivors living a Stone Age existence.

Lovelock's dramatic "final warning" here in *The Vanishing Face of Gaia* addresses the security dimension of GEC, even though he avoids using the term.

94.4.3 Bringing Security Into the Ecological Discourse on GEC

The point about the Anthropocene is that humanity, and in particular the urban carbon fuelled industrial part of humanity, is making the biosphere increasingly artificial. We are a new forcing mechanism in the biosphere, shaping and changing many ecological processes while introducing new materials and geographies into the system. We are literally making our future by changing ecological and material arrangements for our immediate convenience. This is a very different set of circumstances from those depicted in the determinist literature of traditional geopolitics. We are increasingly shaping nature, but we have no

choice but to adapt to the new circumstances we are making. Getting this contextualization of the human condition right in our political thinking is key to intelligent planning and policies for the future. Hence the utility of phrasing matters in terms of 'political geoecology'. We are shaping the earth, literally producing nature as a consequence of our industrial metabolism, a metabolism that has very uneven geographical results as development transforms our political spaces and natural circumstances simultaneously (Smith 2009).

Traditional geopolitical thinking with its themes of environmental determinism in the 19th century and early 20th century frequently operated to both obscure social processes and simultaneously pin the blame for disaster on the supposedly cruelty and fickleness of a stingy and unreliable nature. The famines that Mike Davis (2001) acidly calls the late Victorian holocausts were blamed on unreliable weather, not the disruptions caused by imperial political economy and the social and economic dislocations as traditional systems were integrated into the expanding global grain trade. Speculation and the failure of imperial administrators to manage food supplies or provide for those people in their charge was evaded by the attribution of cause to rainfall, temperature fluctuations, and the like. This was supported by the early data from the new network of meteorological monitoring stations being established by Europeans around the world in the late 19th century. Meteorology, and in part the data which were much later to be interpreted in terms of the *El Niño Southern Oscillation* (ENSO) climate pattern, provided the alibi for imperial neglect. Millions died, the environment got the blame.

Now *earth system science* (ESS) makes it clear that the environment is not out there beyond our control determining our fate. Today one billion people suffer from hunger, during 2009 100 million more due to speculation and biofuels production from grains (IFPRI 2009). The environment is an increasingly artificial entity whose processes we are remaking without usually realizing that this is in fact what we are doing. More so than that, the crucial insight in earth system science is that life is a key component of the biosphere, not a late addition to a pre-given system of atmosphere, land, and water. Life is a player, not a spectator, as the IGBP (2001) authors reminded us. For much of earth's history life has been removing carbon from the atmosphere, making limestone from skeletons of sea creatures, coal, petroleum and gas from the buried remains of terrestrial life forms. What's new about the Anthropocene is that humanity has been reversing this process, literally turning rocks into air every time we use our vehicles or ship goods around the world. Globalization is a physical process in addition to a cultural or economic one. That crucial point needs to be incorporated into our thinking. The Anthropocene emphasizes that there is a new form of life transforming things; industrial urban humanity fuelled by those fossil fuels.

This is important because it is now clear that we can no longer use the environment as an alibi for our inactions or unsustainable actions on many things. In the Anthropocene we are disrupting many natural processes, turning forests into fields, wetlands into solid land for building, migration routes are being blocked, many species extirpated either directly by hunting or frequently simply by destroying their habitat as our resource extraction spread to all corners of the planet. In the process the ecological services these systems used to provide are being changed or lost (UNEP 2007). So too is the ability of natural systems to adapt and change; resilience to reorganize and recover after disruption works only within thresholds, and many of those thresholds may be crossed without humanity knowing they even exist (MA 2005).

From this it follows that a focus on the politics of what we are making is crucial for thinking about the future. Our environments are increasingly artificial; there is no longer a plausible case to be made that the environment determines our fate in general, even if it appears that way to people going hungry or thirsty. Clearly we are increasingly making the circumstances of our own existence, making decisions about how we all will live in the future. In short, this is a very political exercise in which power is used to shape the human context. But this is not a context given by political boundaries however much themes of sovereignty and security are expressed and practised in terms of spaces and supposed autonomies.

Globalization has made it clear that the economies of the planet are interconnected in many ways; earth system science now makes it clear that a geopolitical model of the human condition that starts with separate bits of territory and assumes that this is what determines our modes of life is completely misleading, and dangerously so. Especially so when security is invoked in these terms to maintain the privileges of the powerful by excluding the demands of the poor and marginal. Erecting boundaries and barriers to migration and blaming the poor for their fate is not new, but now it is clear that the circumstances which may set the poor in motion are more our doing than theirs. This is a very unsettling thought, but it is the

unavoidable conclusion that derives from considering the political geoecology of living in the Anthropocene.

It is important to understand vulnerability as a two-fold process, or as Leichenko and O'Brien (2008) put it, a matter of 'double exposure'. People's circumstances are increasingly artificial in the sense that they depend on technology, trade, and manufactured materials for food, water, shelter and clothing. But they are also increasingly subject to storms, droughts, and other disruptions precisely because the technology, trade, and artificial places they live in are at least indirectly now disrupting weather systems. Thinking about vulnerability and the manner in which institutions provide safety and protection, the rationale for security in the first place, now requires that these new circumstances be worked into the thinking. Linking security with environmental change makes this new context of humanity the starting point for analysis (Brklacich/Bohle 2006).

94.5 From Ecological Geopolitics to Political Geoecology

The two discourses on the spatialization of international relations and security as well as on the nature-human interactions have two major deficits:

- the discourse on geopolitics, geostrategy and geoeconomics in the social sciences has been dominated by the Hobbesian pessimism and ignoring environmental concerns and issues of global environmental change as dangers for security and survival;
- the newly emerging research in the natural sciences on Lovelock's Gaia hypothesis, on geoecology in geography, and on *Earth Systems Analysis* (ESA) or *Earth Systems Science* (ESS) has so far to a large extent ignored the political dimension of transforming this new systemic knowledge into proactive policy initiatives.

94.5.1 Bringing the Environment into Security Discourse

Critical geopolitics tackles some of the most basic assumptions used to structure the political discourse. It challenges the taken for granted specifications of the world, its divisions into states, blocs, territories, North and South, rich and poor, and so on justified by discrimination processes (chap. 72 by Oswald Spring). Emphasizing that most geographical categories used in politics are social constructions, rather than the given context for discussion, critical geopolitics then examines the political identities that inhabit the world designated in terms of regions, states, nationalities, etc. (O'Tuathail/Dalby/Routledge 1998). National histories, and the claims to territory which usually unproblematically support the expressions of national pride, turn out to be much more contentious than conventional accounts suggest. The apparently obvious designation of 'Europe' turns out to be highly disputed through history (Heffernan 1998), a matter that is obvious to anyone reflecting on the current debates about what it means to be European, but complexities that are obscured in so much political discussion when security is invoked (Kuus 2007). Even naming continents, seemingly the most natural of all geographical categories, turns out to be a complicated matter of cartographic controversy and change through history (Lewis/Wigen 1998).

On the smaller scale nation states are usually the product of political and power struggle rather than the natural outgrowth of some inevitable process (Agnew 2007). Identities and territories are invoked in the logics of national security too, specifying the context for struggle and rivalry by using apparently unproblematic geographical specifications of the world to structure their discourse. How social representations (chap. 66 by Flores/Wagner) justify fears of strangers, and how threats and dangers work their way through popular culture has also become a matter for scholarly analysis, and it links geographical categories directly to matters of culture and the specification of secure spaces and places and those that are deemed threatening (Pain/Smith 2008; Ingram/Dodds 2009).

At the very largest of scale, that of the planet, contemporary geopolitics looks at how the world is imagined, divided up, and specified in the discourse of contemporary politics (Agnew 2003). Much of this concerns how the world is viewed from the capital cities of the North, the places where rivalries among the great powers for access to cheap natural resources are a preoccupation. How and where dangers originate, and what threatens the metropoles of the global system, is a long-standing geopolitical theme directly connected to matters of inter-imperial rivalry (Kearns 2009) and superpower behaviour. But now too, as environmental matters come to the fore, critical geopolitics asks how climate and other 'environmental' dangers and threats are specified in geographical terms (Dalby 2002b). Where the dangers lie, what their source of threat to whom where, is the theme of

much of the environmental security discussion of the last couple of decades. But upon closer investigation much of this discourse still draws unreflectively on formulations from earlier times, colonial and imperial assumptions of dangerous peripheral places threatening the populations at the centre of empire, but affecting also the survival of the periphery (hunger, illnesses, disasters, urban slums).

More dangerous in terms of thinking intelligently about ecological transformation is the link between old-fashioned geopolitical thinking and environmental determinism[47]. Long discredited in the scholarly literature, not least because it was so obviously wrong in many cases and besmirched with racist themes, the arguments that environments determine human behaviour are powerful in so far as they can be used to suggest that human behaviour is shaped and determined by forces beyond human control. Linked to the ideas of Thomas Malthus, and his articulation of eighteenth century European fears of the collapse of civilization due to the depredations of impoverished populations, the arguments that scarcity is a matter of nature, not economy, and that the Third World is a matter of environment rather than of the history of colonization and resource extraction, provide powerful support for suggestions that the rivalries of great powers are the only terms in which security can be understood. Rearticulated forcibly by Robert Kaplan once again in 2009, where he explicitly drew on Halford Mackinder's 1904 formulations of "the pivot of history" to interpret the political possibilities of the next few decades, these suggestions conveniently reprise the imperial administrator's view of the world, not the ecological scientists nor the historian's nor the geographer's view (Dalby 2009). If environment determines the fate of particular places, then all that can be done is to manage the chaos to ensure that the peoples of the metropoles, the only people who matter to the Robert Kaplan's of this world, do not suffer from the disruptions that are inevitable.

While no serious scholar doubts that environmental matters constrain human societies in numerous ways, as the world system historians have recently begun to investigate in a fairly systematic way (Hornburg/McNeill/Martínez-Alier 2007) the assumptions that environment necessarily causes polities to behave in particular ways is a different matter. Arguments that states inevitably have to expand or die, the organicist geopolitics of the nineteenth century, legitimates war-fighting and conquest, and in so far as such arguments suggest the inevitability of warfare then they link a misunderstood notion of the environment to a competitive notion of national security. Although not much commented upon, nor even noticed it seems, this mode of thinking persisted through much of the Cold War in terms of the arguments about Soviet foreign policy. In the 1970's prominent 'hawks' in Washington dusted off Friedrich Ratzel's figures of nineteenth century Russian agricultural production and used these figures to suggest that the long-term pattern of Russian expansion, followed through by the Soviet Union, subsequently was driven initially by stingy and unproductive agricultural lands and the search for better food supplies to the south (Dalby 1990). This was linked directly to the nuclear containment strategies of the Reagan administration.

Even if determinist arguments, and their Malthusian variations in particular, once had some merit, what is clear now is that the current changes set in motion are as a result of abundance, and changes wrought by the rapidly expanding global economy. Climate change is a matter of greenhouse activities and massive land clearance, not a matter of scarcity implicit in nature. But this does not stop journalists repeatedly arguing that water wars are inevitable, food will run out, and starving millions will be set in motion, triggering security problems caused by environmental factors (Kaplan 1994). There is nothing inevitable about this formulation; it is not the only way to think about global politics. As the science of global change and the detailed social science arguments elsewhere in this volume make clear, it doesn't have to be the case that environmental change necessarily causes conflict. Even Jared Diamond (2005), frequently criticized for his supposed determinism, argues in his big book on environmental *Collapse*, that we can use these histories to think our way out of the difficulties our present circumstances present.

Alker and Haas (1993) draw a crucial distinction between geopolitics and ecopolitics as frameworks for thinking about environmental change on the largest scale. Geopolitics draws, they argue from organicist notions of the state, from metaphors of competition drawn ostensibly from Darwin, and from assumptions that states were inevitably in competition. Coupled to territorial specifications of states

47 New threats are linked also to the justification of military bases with destruction of environment in other countries (Viesca) or Kissinger with the food power policy in 1972, when the USA became the most important grain exporter of the world and was able through subsidies, food prices, and market restriction to control emerging power interests in several countries.

and their powers this leads to an understanding of politics as competitive struggles between territorial states. While clearly the era of territorial aggrandizement ended in the 1940's; the United Nations and the norms of non-intervention and fixed boundaries have nearly entirely superseded conquest as the *modus vivendi* for state behaviour (Jackson 2000), the assumptions of competitive states and territorial struggle have remained a powerful interpretive framework for contemporary politics. In particular this notion of competitive spaces undergirded much of the Cold War rivalry; in that case it was competition between blocs, large parts of the globe tied into competing territorial entities. Since the Cold War such tropes have continued to structure the narratives of geopolitics. Now competition is understood in terms of rivalries over trade, control of financial flows, military capabilities and prestige, if less so about territorial conquest. It is still premised on clashing territorial entities, even in Samuel Huntington's (1993, 1996) infamous arguments about the clash of civilizations.

In this view, starting with territorial blocs in rivalry as the key focus, and the provider of security, climate change is somehow natural, beyond control, the cause of numerous difficulties that need to be managed, but pretty much outside any effective control. Among the arguments concerning the security implications of climate change are fears of migration, climate refugees being one prominent argument for the need for military preparation to deal with the national security consequences of change (Smith 2007; Busby 2008). The presupposition behind such thinking is once again the assumption of territorial states as the key to political life, and the exceedingly odd assumption that people are normally fixed in place rather than in motion. Given the rapid changes in the human condition, and the movement of people from rural to urban parts of the planet, migration is the human condition these days. Understanding that this is being accelerated by environmental changes in many places is important. Some of these migration attempts do run up against state boundaries that impede movement. But viewed from the migrant's perspective, it is precisely these barriers that prevent them getting access to shelter, livelihood, food, and medical attention. It is precisely the imposition of geopolitical modes of rule that may endanger their lives. But viewed from the metropoles, it is precisely these migrants who are the security problem because of the social disruptions that supposedly follow from their arrival.

In contrast, ecopolitics is a framework in which the earth is understood as a single dynamic system, one where interconnections between places and peoples are part of a larger ecological story (Alker/Haas 1993). Precisely because of a focus on competition between states and the priority given to economic development to fuel the war machines of the superpowers, ecological matters were downplayed through the period of the Cold War. But these matters cannot be addressed by assuming that what is most important in politics is the rivalries of the great powers. The appropriation of resources to fuel the rivalry is part of the cause of the dramatic environmental changes that are now the cause of so much concern, especially with the issue of climate change. But even when environmental matters do make it onto the political agendas of the big powers' old habits of 'imperial' behaviour, and how they are reported in media discussions of these events, are very persistent. In 1992 when the world's political leadership met in Rio de Janeiro to discuss the fate of the planet, a huge meeting to tackle numerous environmental themes, it was reported in the *New York Times* in terms of international prestige and the activities of the leaders at the event, not in terms of the ecological matters needing attention (Dalby 1996).

Now however, such modes of thinking are increasingly untenable precisely because the ecopolitical mode of thinking turns out to be the one supported by the science that studies environmental change. The shift in focus in earth system science makes it clear that humanity is not the hapless victim of a determining nature. Earth system science now makes it clear that life is not simply an afterthought on a planet of rocks, air and oceans. Life has shaped all three quite fundamentally. Life makes soils and has made the atmosphere one that is oxygen rich. Life has, over the long course of hundreds of millions of years, made the materials that fossil fuels. Now the latest dominant form of life on the planet, industrial humanity, is reversing this process of lithogenesis by turning those rocks back into air, and in the process setting numerous other ecological processes into motion, only most obviously the phenomenon that we now call climate change.

This transformation is key to the reason why earth system scientists now say we are living in the Anthropocene, the new geological era marked by this new transformation of the planet's surface systems by a new form of life. Thus, we need a very different formulation of security, one that is based on the insights that we are well on the way to transforming the biosphere such that it operates in a new way (Dalby 2009). Understanding ourselves as having taken our

fate into our own hands, albeit inadvertently, is key to thinking about how to slow climate changes (mitigation) to facilitate adaptation to the new circumstances we are creating. The old notions of environmental determinism, organicist models of states, and the focus on rivalries and territorial actions are completely inappropriate intellectual and political tools for grappling with the ecological context within which we now have to think about security.

Neither do the traditional frameworks have anything useful to say about the artificial ecologies of the cities and megacities where the majority of human beings now dwell. These are new ecologies, ones dependent on long commodity chains and infrastructure that has replumbed and rewired much of the planet to feed, fuel, and supply these cities. The supplies of food, fuel, biofuels, building supplies, not to mention automobiles and endless electronic gadgets, cross national frontiers, linking the world together in a global economy that provides urban dwellers the necessities for this increasingly artificial existence. Disruptions to this system are the new context for thinking about human insecurity (Graham 2010). Determinist arguments connected to discussions of territorial rivalries are simply inappropriate starting points for a serious discussion of security in the Anthropocene. Worse than this, they are a dangerous distraction from thinking through the ecological connections that are the key to providing security in the new circumstances of the Anthropocene.

Friedrich Ratzel's geopolitics with his 'evolutionism' and 'diffusionism' influenced the consolidation of political anthropology. He sustained theoretically the understanding of primitive organizational structures that must evolve to complex systems to get modernized. The justification of colonization was linked to the "vacío imaginario"[48] ('imaginary void', Macías Zapata 2004) explaining the expulsion of indigenous populations from fertile land to marginal zones (zonas de refugio, Aguirre Beltrán/Pozo 1991) by powerful interests, first the conqueror, later landlords, and today multinational corporations (MNC). On the other side, the critical anthropology supported social movements in their struggle for urban land, peasants for new agricultural extensions, and the displaced people due to modernization projects for creating a new livelihood. Recently, the combination of ecological anthropology with geopolitics opened the field for bottom-up approaches, but also for the integration of complex social failures such as drug trafficking linked to environmental forced migrants related to human trafficking, pornography, arms trade, and prostitution gangs (Oswald Spring 2009c). Another approach was related to the overexploitation of groundwater in drylands for cash crops, biofuels creating biodiversity loss and water scarcity, expulsion of people from their livelihood, but also the rise of new illnesses linked to the overuse of agrochemicals and unhealthy productive processes in the 'maquila'.[49]

In Latin America, the analysis of the implication of the Free Trade Agreement of the Americas and the support of opposition movements was analysed by anthropologists, such as the proposal of the Plan Puebla Panamá with the Mesoamerican Corridor promoted by the World Bank and the Mexican and Central American governments, where huge displacements of people are planned, due to the construction of more than 80 big dams. The interconnection of electricity among the whole region is the first step for the control of land and resources in the hands of multinational elites, and the expulsion and displacement of the indigenous and peasants from their ancestral land. Guerrilla movements and opposition are temporarily stopping the process, but the repression of leaders and the criminalization of social movements are the new arms to impose a hegemonic way to dispossess the poor and to concentrate the wealth in a few hands.

94.5.2 Introducing the Political Dimension into the Research on Nature-Human Interactions

A major shortcoming of the multiple approaches on geoecology and earth systems analysis or science, and of the research programmes and university degrees that have been set up during the past three decades in many parts of the world, is that the key "action" aspect necessary for the realization of a Copernican revolution towards a sustainability science has been lack-

48 This Spanish term does not refer to the Latin legal term 'terra nullius' which means empty land, or to land to whom no-one has a legal title. It is communal land that was in use and that was taken away from the original users, which were not linked to a personal system of ownership but to a collective one and therefore their collective rights were destroyed.

49 The Spanish term 'maquila' refers to an enterprise that imports materials and equipment without paying customs for assembly or manufacturing and then re-exports the final product by using the cheap labour force in Mexico and Central America.

ing. The transformation of knowledge into action with regard to scientific schools, social movements, and political forces and institutions that translate the new knowledge of a sustainability science into policies that aim at proactive security policies has been slow to emerge. What is clearly needed is the goal of achieving a policy vision of a sustainable peace that is based on economic strategies of sustainable development. However, this requires a fundamental change in our action-oriented thinking where a mere reference to intellectual traditions is not sufficient.

The non-linear and possibly chaotic challenges in the Earth System that may trigger multiple tipping points in the global climate would have severe policy and security implications that cannot be attributed to a specific enemy against whom military forces can be employed. In Lovelock's *Vanishing Face of Gaia* as well as in work documented by Lenton, Held, Kriegler, Hall, Lucht, Rahmstorf and Schellnhuber (2008) it is clear that we may be close to important tipping points in the earth system. This suggests that we are close to key transitions in the earth system, threshold points where the earth system will change in unpredictable but potentially disastrous ways, at least as far as humanity is concerned.

Thinking about such changes emphasizes the point that the traditional geostrategic views of Cold War policy-makers are irrelevant to contemporary times. The assumption of clashing states and geopolitical blocs that were key to Cold War security thinking are completely irrelevant if solutions to problems of ecological change are to be considered. Earth system analyses make it clear that the appropriate geopolitical premises for thinking are now about humanity collectively living in a small biosphere that we are destabilizing. Assuming that we are still living in separate territorial boxes struggling to control, or at least dominate what happens in other territorial boxes, is precisely the wrong set of geopolitical assumptions to now formulate appropriate security policies. Our geographical context has changed; security thinking needs to catch up.

The additional danger is that should disastrous disruptions of part of the earth system happen shortly the traditional mindsets, locked into an inappropriate and outdated geography would once again invoke the priorities of "national security" to try to protect particular states from "external" disruptions. This, in so far as it undercuts international cooperative efforts is both inappropriate policy and counterproductive both because it is ineffective, and because it perpetuates practices that are violent and unhelpful.

94.5.3 Towards a New Political Geoecology

The suggested new concept of a *political geoecology* should, by bringing the environment into the spatializations of international politics and security, as well as by introducing a political and economic dimension into the discourses on geoecology and earth systems analyses (ESA) or science (ESS), overcome these dangers. Thus, *political geoecology* combines three components:

- the '*political*' dimension of the transformation of complex knowledge into innovative and proactive action:
- the spatial of '*geo*' contextualization of this new knowledge and action;
- the *ecological* focus on the human-nature interface during the Anthropocene that combines the approaches of geo-, social, human and political ecology.

Thus, below the new concept of a *political geoecology* will be used in a wider sense than it is being used in the more narrow approach of geoecologists so far.

Two aspects in overcoming this dual deficit will be discussed below with regard to the actors of the needed proactive policy response and the role of new transdisciplinary knowledge that reflects Wilson's (1998) plea for 'consilience' and anticipatory learning as a precondition for perceiving a need for proactive policies as suggested by the *Millennium Ecosystem Assessment* (MA 2005) and many other recent international reports (UNEP 2007).

94.5.3.1 Actors, Processes, and Levels of Analysis of Political Geoecology

The classic geopolitical and geostrategic approaches were state-centred with the nation state as the key referent object and in the security realm posing the main threat to the well-being and survival of one's own country, but also as the single protector that controls the means and the decision on their employment.

Due to modern weapons (Herz 1959), the subsequent growth of satellite communications, monitoring and transparency (Deudney 1983), and more recently the other processes of globalization, national sovereignty has been disconnected from its image in terms of Westphalian boxes. Sovereignty has also been progressively undermined by the activities and effects of actions by non-state actors, both transnational corporations but also less 'visible' organized crime cartels and terrorist networks. However, with the observed and projected increase in the number and intensity of

hydro-meteorological extreme events, a new category of threats for human survival is evolving for which neither another state or alliance nor a criminal actor can be held responsible. This new quality of the danger to our well-being, security, and survival in the Anthropocene necessitates a new conceptual thinking that overcomes the Hobbesian obsession that has been guiding geopolitical and geostrategic worldviews and mindsets that so far have resisted adapting to the triple reasons that have triggered a reconceptualization of security: a) the end of the Cold War, b) the impact of globalization, and c) the impact of GEC in the Anthropocene era.

In the Anthropocene, a single nation state or a military alliance cannot protect its citizens or allies anymore against the impacts of GEC, neither with its adopted military and political strategies nor with its military means: armed forces and weapons. This insight undermines a fundamental rationale and function of the nation state as a protector of its people. If as a result of the projected sea level rise, countries lose important parts of their highly urbanized coastal land, or if due to the impact of a tipping point in the climate system the Gulf Stream in the North Atlantic is shut off, the most modern navies, armies, and air forces offer no protection although they might be used for evacuation and rescue missions.

With the social construction of the new knowledge on the changing human-nature interface scientists have acquired a new role not only to create new knowledge on the complexities of the earth system but also to communicate it to both the citizens and to the actors in the states, as well as in the society and in the economic sector. As the potential of the nation state in guaranteeing protection of its people against these new challenges may be rapidly declining, the need for an empowerment of its people is rapidly rising to create public awareness and to build a culture of resilience by diverse self-organization.

If 'we' – a part of the human species through our lifestyles, productive and consumptive patterns – 'are the threat', how are the actors: states, societies and economic community reacting to these new threats? In the Anthropocene human security – by countering the multiple causes of GEC and their impacts – can be achieved not any more with military means of the state but by the individual decisions of citizens to reduce energy consumption by efficiency improvements and by a radical switch from fossil to renewable energy sources.

However, on behalf of globalized trade, finance and communication systems, the state still plays a major role by creating legal and institutional frameworks ('polity') that encourage both the society and the economic sector to use the inducements and to avoid the punishment by increasing taxation. As national and human security against these new environmental security dangers cannot be guaranteed any longer by the military and by justice and home affairs, new policy fields become increasingly security relevant: science, technology, education, the environment but also sustainable development cooperation, negotiation processes and international agreements.

Thus, coping with both the causes and the impacts of global environmental and climate change requires both global strategies, policies, measures and guidelines as well as national, regional and local human action for adaptation, mitigation and resilience-building. This also requires new top-down policies that create frameworks and space for bottom-up initiatives.

Recently, Bolivia, one of the poorest countries in Latin America, has become a success story for improving integral sustainable development. Bottom-up indigenous movements changed the power relations among different stakeholders. These processes require a scaling up from the state's legal and economic frame, where social movements and small businesses can offer space for an economy of solidarity. *Multinational corporations* (MNC) may support a process of ethical business, where micro-credits can be linked to micro-insurance in seriously affected regions, thus permitting the victims a faster recovery and resilience-building (Oswald Spring 2008, 2009c). These bottom-up efforts are normally very labour intensive but the reinforcement from top-down facilitates the organization and consolidation process, finally benefiting both the state and the poor people with dignified livelihoods.

A *political ecology* approach must take into account the research in international environmental governance. According to the WSSD Plan of Implementation, "good governance, within each country and at the international level, is essential for sustainable development". UNEP's work to support a coherent structure of international environmental governance has been greatly enhanced by the *Global Ministerial Environment Forum* (GMEF).[50] According to the *World Resources Institute* (WRI):[51]

50 See at: <http://www.unep.org/IEG/>.

51 See at: <http://www.wri.org/publication/content/8542> (10 September 2009)

> The current system of international environmental governance consists of three basic elements. One component is a collection of intergovernmental organizations [UNEP, UNDP] ... and other specialized UN agencies and commissions with a variety of other international organizations, such as the World Bank and the World Trade Organization (WTO). A second element ... is the framework of international environmental law that has evolved over the last century or so. ... A third element is financing mechanisms to build capacity to carry out treaty commitments, to supplement national efforts toward sustainable development in poorer countries, and to support the UN agencies and treaty secretariats that coordinate and carry out environmental efforts (GEF).

However, none of these three elements deals with security issues. In the scientific realm several research networks[52], programmes and projects (e.g. at UNU[53], The Free University of Amsterdam[54], Yale University[55]) have contributed to the analysis of global environmental governance, however, nearly all exclude analysing its linkage to specific security concepts and policies in the Anthropocene and a bottom-up approach oriented to consolidate the resilience-building and survival of the vulnerable. IHDP's core project has defined 'Earth system governance' as:

> the interrelated and increasingly integrated system of formal and informal rules, rule-making systems, and actor-networks at all levels of human society (from local to global) that are set up to steer societies towards preventing, mitigating, and adapting to global and local environmental change and, in particular, earth system transformation, within the normative context of sustainable development. The notion of governance refers here to forms of steering that are less hierarchical than traditional governmental policy-making (even though most modern governance arrangements will also include some degree of hierarchy), rather decentralized, open to self-organization, and inclusive of non-state actors that range from industry and non-governmental organizations to scientists, indigenous communities, city governments and international organizations.

However; its science plan does not directly address 'security' among its analytical problems (architecture, agency, adaptiveness, accountability, allocation and access) and crosscutting themes of power, knowledge, norms and scale or in its first four case studies on the water, food, the climate, and the global economic system.[56]

In their structure for a new international governance they pointed to the key sectoral interactions between and among three major groups, that is, government (state), private sector (economy) and civil society based on the nine universal principles embodied in the UN's Global Compact, among them human and labour rights and these three environmental principles: i) precautionary principle; ii) environmental responsibility, and iii) environmental friendly technology. But they also avoided considering the new security dimension of global, national, and local environmental governance in the Anthropocene.

94.5.3.2 Role of Innovative Knowledge and Anticipatory Learning

Environmental stress and climate-induced natural hazards often cause extreme impacts: forced migration, domestic crises and low-level conflicts that may be resolved by the state in cooperation with societal groups and the business community. These three actors are influenced by their use of knowledge in facing and coping with the social challenges posed by *Global Environmental Change* (GEC) for international, national, environmental and human security. A better understanding of these complex nature-societal interactions empowers societal, economic and state actors to respond to these challenges by preventing that extreme societal outcomes lead to violent conflict. Instead, proactive strategies that link top-down and bottom-up initiatives may assist societies to face and cope with the social challenges of global change.

In this regard the role of modern and traditional knowledge[57] matters for the 'policy response' in different nature-society relationships, or 'pressure response models' such as those suggested by OECD, UN-CSD, EEA and in the PEISOR model (chap. 47 by Brauch/Oswald Spring).

> The boundary between research-based knowledge and decision-making is not hard and fixed, but rather semi-permeable, moveable and negotiated (Jasanoff 2003;

52 The "Earth System Governance Project" builds on the former IHDP project on the *Institutional Dimensions of Global Environmental Change* (IDGEC); see at: <http://www.earthsystem governance.org/>.

53 See UNU-IAS; at: <http://www.ias.unu.edu/binaries/NYPrepComReport3.pdf>; Green (2005); Rechkemmer (2006).

54 See: Biermann, Siebenhüner and Schreyögg (2009).

55 See at: <http://environmentalgovernance.org/about/> (10 September 2009) on the Global Environmental Governance Project of The College of William and Mary and the Yale Center for Environmental Law and Policy.

56 Its first project report refers repeatedly to food security and peripherally at human and environmental security; see: Biermann, Betsill, Gupta, Kanie, Lebel, Liverman, Schroeder and Siebenhüner (2009).

> Jasanoff/Wynne 1998). Earth system governance thus requires a reflexive and carefully designed approach to organize and utilize some boundary functions, like mediation or translation ... (Cash/Clark/Alcock/Dickson/Eckley/Guston/Jager/Mitchell 2003, Guston 2001). Some research suggests that boundary organizations do best when they are dually accountable to both the research and policy communities. In some situations, the two community views may not be very accurate: there are policy savvy and connected researchers, scientifically literate policy-makers or well-informed stakeholder groups (Van Kerkhoff/Lebel 2006).
>
> Science is not free from politics or politics from science (Mitchell 2002). Competing knowledge claims may be sorted out through joint fact-finding, assessment or validation exercises (Cash 2000; Karl/Susskind/Wallace 2007) and action strategies. Knowledge is pertinent also in the role of scientific assessments in earth system governance. Research suggests that assessments that are perceived by all key stakeholders to be legitimate, credible and salient, are those that have the most influence (Mitchell/Clark/Cash/Dickson 2006). Assessments that are overly driven by science easily become trapped by their framing of the issue (Rayner 2003). Tacit, practice-based, experiential and research-based knowledge may be complementary and usefully hybridized (Forsyth 1998, 2003), but they can also be pitted against each other and against other systems of belief.[58]

Since 2000 climate change has been 'securitized' and the links between climate change and conflicts are being addressed in scientific studies and policy declarations. This new knowledge challenges the traditional narrow conceptualization of security as a state-centred, power-based and interest-centred concept, and has contributed to the development of an environmental dimension of human security where 'freedom from hazard impacts' has been suggested as a fourth pillar as well as to a shift from a 'security dilemma' to a 'survival dilemma'. A proactive policy response to the social challenges of global change requires a joint international and human security approach that integrates traditional and modern knowledge and aims at both top-down and bottom-up policy responses in facing and coping with the potentially extreme and violent societal outcomes of GEC.

The Cold War has convincingly demonstrated that individual 'events', whether as the outcome of policy decisions by policy-makers, societal leaders or the business community, cannot be predicted. The other, the temporal dimensions of Braudel's historical analysis (of long-term 'structures' and medium-term 'conjunctures'), can be better predicted and have been projected in the past as both determinants and constraints on policy actions. But the emerging debate on tipping points of the climate system has also pointed to the limitations of linear projections of demographic and climatic trends, once they cross an unknown 'threshold'. While neither the unpredictable chaotic interactions of the geophysical systems of the human-nature interface can be foreseen, even less so the specific human response to such surprising events can be predicted or modelled. Both traditional knowledge, based on thousands of years of communicated experience, as well as modern narrow disciplinary scientific knowledge will be challenged by the societal impacts of potential tipping points in the climate system.

Thus, in the Anthropocene period of earth and human history, earth systems science research can address potential geophysical constellations, while the social sciences can point to probable and possible conflict constellations, but both will remain unable to predict if, when, and how these constellations may or will become reality. The societal impacts of the linear, exponential or chaotic developments in the global climate system can even less be predicted or projected. Past historical developments on the human-nature interface and their catastrophic consequences have contributed to the decline of the collapse of high civilizations and forced peoples to move.

To sensitize the people on the effects of potential catastrophes, the results of earth systems sciences should be communicated through the media and the education process. This may also contribute to a readiness for anticipatory learning. Learning is a bottom-up process. It is human beings that learn, not states. But the policy-makers as the representatives of the people must allocate resources to foster the development of new knowledge, and respond proactively to action-oriented knowledge by adopting strategies, policies and measures, and implementing them.

---

57 Hess and Ostrom (2007: 7–8) in following Davenport and Prusak (1998: 6) wrote: "knowledge derives from information as information derives from data". They used the term knowledge by referring "to all types of understanding gained through experience or study, whether indigenous, scientific, scholarly, or otherwise non-academic". Knowledge is both a constitutive force of society and a commodity; it is both a human need and an economic good, both a common and also a private good. "Acquiring and discovering knowledge is both a social process and a deeply personal process."

58 See the lengthy discussion of scientific knowledge by the IHDP core project on global environmental governance; <http://www.earthsystemgovernance.org/publications/2009/Earth-System-Governance_Science-Plan.pdf>.

There is also a fundamental difference in the production, dissemination, and access to knowledge for understanding the causes of these new security dangers, and on the needed policy responses. While military knowledge often relies on classified intelligence collected, processed, and assessed by intelligence services that are beyond the reach of the citizens, the new scientific knowledge is open to everybody but must be understandable from the elementary to the advance levels, and disseminated by journalists and responsible media.

94.6 Political Geoecology as a New Field of Research and Education

The new concept of a political geoecology focuses on the linkages or transmitters of translating knowledge into action. It aims at a conceptual integration of two research approaches in the social and natural sciences that requires an integrative approach to address the biophysical and societal causes and impacts of nature-human interaction in the Anthropocene. The most important point of all is the simple one implicit in the use of the term Anthropocene; the context for thinking about security has been changed by our actions. Knowledge has to be recontextualized if it is to be useful for policy, research, education, and political action.

94.6.1 Areas for Research on Political Geoecology

The new security dangers posed by GEC in the Anthropocene pose a dual challenge for scientific endeavours and political action. In science transdisciplinary approaches are needed that address the linkage themes of several disciplines both within the natural (geoecology, ESA, ESS) and the social sciences (political science, law, economics, anthropology, sociology, psychology) and between both reflecting Wilson's (1998) call for 'consilience'.

Scientific research programmes, academic courses and degrees in geoecology and on earth systems science should incorporate a policy dimension that goes beyond the legal and institutional framework (*polity*). This requires also that the knowledge assessment, e.g. by the IPCC, should be expanded beyond the narrow focus on assessing only the peer-reviewed scientific findings in the natural (on causes and impacts) and engineering sciences (on adaptation and mitigation) by including the findings of the social sciences on the linkages between the nature-human interactions and their societal outcomes, i.e. as migration, crises, and conflicts.

In foreign and international politics, *learning* of key decision-makers has often been in response to severe political, economic, and military crises[59]. But *anticipatory learning* and *forward looking* strategies are more ambitious. They require that both analysts and decision-makers foresee challenges that may have an impact on *future governments* and generations, and that may require unpopular decisions today to avoid crisis events in the future. With regard to 'sustainable development' *anticipatory learning* requires the formulation and *implementation of sustainable policies* with respect to industry (pollution), water management, soil preservation, agriculture etc. in all countries. Anticipatory learning as a tool of crisis prevention (Burton 1990; 1990a; Burton/Dukes 1990, 1990a) is far more ambitious and difficult than the requirements of *crisis management* as a centrepiece of national emergency planning.[60]

As national priority areas for upgrading crisis management, several major tasks exist: a) a wider *innovative risk assessment;* b) a better integration of national *regulation and design* into international structures, and c) an intensive planning and preparedness involving large-scale operations and transcending the civil-military divide as well as the management of uncertainty and complexity, whereby the knowledge production in social science research and transfer to operating units is crucial (Hart/Stern/Sundelius, 1998: 219–21).

But during the Anthropocene, past experiences may be of limited relevance and policy guidance, especially with regard to the security dangers posed by GEC and by the unpredictable potential tipping points in the global environmental system. Traditional worldviews often filter out new information, especially from other schools of thought and disciplines,

59 For example, during the final phase of the Cold War, for Gorbachev and Shevardnadze *learning* was an instrument of domestic crisis management responding to complex challenges in an innovative way beyond traditional patterns (Grunberg and Risse-Kappen 1992: 104–46; Stein 1994: 155–83; Levy 1994: 279–312).

60 Hart, Stern, and Sundelius (1998: 207–8) argue that learning from past experience remains an important building block for efforts to cope with future crises (Stern, 1997: 69–86). From past successes in crisis prevention, they point to three obstacles: a) the *problem of complacency* that excludes the unconventional challenges; b) the *vulnerability paradox*; and c) the *balance between prevention, adaptation and resilience.*

and may thus be resistant to learning. Booth (1979, 1987: 39–66) argued that 'old mindsets' often have distorted the assessment of 'new challenges'. These mindsets[61] include ethnocentrism, realism, neoliberal free-market dominance, ideological fundamentalism, and strategic reductionism.

Thus, *anticipatory learning* requires that both analysts and policy-makers foresee the negative impacts and the socio-economic consequences of the global environmental change that can pose a *survival dilemma* in the decades to come. *Anticipatory learning* remains the domain of long-range and interdisciplinary discourses, and to a more limited extent of foreign policy planning staffs of national governments. As these long-term *structural challenges* do not require urgent responses, sufficient time exists for the establishment of conceptually focused and policy-oriented *epistemic communities* with gender and regional balances.

Joint North-South *anticipatory learning requires* as a debate on longer-term development for the well-being, security, and survival of humankind, and a mutual understanding of their relevance. Further, a multidisciplinary search for complex strategies is needed to cope both with the root causes and their effects and the socio-economic implications of global environmental change. This anticipatory learning must be on four different levels: a) across the boundaries of scientific disciplines; b) across the North-South cultural and political divide; c) beyond the glass ceiling of gender discrimination, and d) between conceptually oriented academics and action oriented decision-makers. The policy relevant task of this undertaking must mitigate, prevent, and avoid these crises from occurring.

94.6.2 Areas for Political Initiatives on Political Geoecology and Organized Civil Society

In the political realm, a horizontal interdepartmental or interministerial cooperation within governments and between different international organizations is needed to overcome the lack of coordination. Initiatives for action on the security dimension of the nature-human interface are needed on behalf of the state as well as by societal and economic actors to set up the political agenda-setting, with a prioritization of goals and the allocation of resources for adaptation, mitigation, and resilience-building. This new socially constructed knowledge that has emerged during the past three decades affects all three features of the political dimension of *policy*, *politics*, and *polity* that are outlined below (table 94.1).

Socially constructed knowledge of earth systems science on the nature-human interface of global environmental change issues may create the basis for proactive policies if the societal forces overcome the interest-based and ideology-driven worldviews and mindsets that are often determined by past experiences and short-term political and profit interests.

94.7 From Anticipatory Knowledge to Proactive Action: Towards a Policy Vision of a Political Geoecology

Anticipatory knowledge deals with the structural and conjunctural dimensions of time addressing longer-term structural trends (e.g. demography, climate change, etc.), while future events as the outcome of specific circumstances, challenges, conditions, human actors and their decisions may be anticipated (as a possibility) but not predicted (with a probability).[62]

The suggested *political geoecology* should introduce into research, teaching, and education on earth systems science and analysis a political dimension that helps to translate and disseminate new scientific knowledge that will affect and constrain the range of political options available to policy-makers in the Anthropocene during the 21st century to initiate a process of anticipatory learning to address the causes, effects, impacts, and possible societal outcomes of global environmental change.

Anticipatory learning is the necessary precondition for proactive strategies, policies, and measures to face and cope with the possible extreme societal outcomes by supporting efforts to build local resilience by the peoples most likely to be affected most severely who often lack the knowledge on these complex

61 The dominance of 'old mindsets' in the Administration of George W. Bush challenged the thesis of anthropogenic contribution to global climate change and tried to block the implementation of the Kyoto Protocol and significant progress towards legally binding international obligations towards a progressive decarbonization of the economy. Thus, established theoretical or ideological worldviews and mindsets of policy-makers have been major constraints and obstacles to any anticipatory learning and proactive policy strategies.

62 One specific case has been the failure of the social sciences to predict and to foresee the end of the Cold War (Gaddis 1992/1993) with the symbol of the fall of the Berlin Wall on 9 November 1989.

Table 94.1: Political dimensions of nature-human interactions on the security dangers posed by global environmental change. **Source:** The authors.

	Three political dimensions		
Actors/level of analysis	**Policy**	**Politics**	**Polity**
Definition	Field of analysis and action, e.g. environment and sustainable development with a sustainable peace policy	Political process of actors (stages of policy formulation, decision and implementation)	Legal and institutional framework for policies and for the political process
Object of action: nature-human interaction and global environmental change (GEC)	Knowledge creation (basic and applied research) and dissemination (teaching, training, education)	Process of political agenda-setting, formulation, adoption, legitimation, funding and implementation (sometimes against the opposition of interest groups)	• Adoption of Agenda 21, • UN Framework Convention on Climate Change (UNFCC). • UN Convention on Biodiversity (CBD) • UN Convention to Combat Desertification (UNCCD) • National laws of implementation and establishment of national bodies
Security Linkages (international, national, community, human, environmental, gender, water, etc.)	• Disaster preparedness, planning and response • Internal displacement and migration • Humanitarian assistance [international, national and human scales]	• World of states (G-8, G-5, G-20, G-77) • Societal world (social movements, business communities, trade unions)	• UNOCHA • UNISDR • EU-ECHO • OAS, AU, LAS, OSCE • NATO
State	A system of priorities, goals and guidance, and their implementation with sanctions for non-compliance	Process of articulation of goals, strategies, policies and measures at the local, national, regional and global level	Laws implementing global frameworks or setting the framework for policy implementation and proactive policies, scaling up and down (glocal)
Society	Family, local communities, ethnic tribes, religious communities, social movements and NGOs all forming civil society	Transparent political process of actors identifying challenges, formulating goals, adopting and implementing environmental, economic and security policies	The legal and institutional framework for policies that set the goals and boundaries for the political process
Economic sector (policy instruments, role of the business community in politics)	• Support of technology developments • Regulation and taxation • Scientific and technological innovation and its application	Dual role: • opposition, obstacle, constraint for political action • promotion of new technologies (green economy)	Technological innovation creates political opportunities for coping with the physical and social impacts of GEC
Knowledge (as a precondition for anticipatory learning and proactive policies).	Areas of science, technology and education policy and of its transmission via scientific and popular media	Science offer basis for anticipatory knowledge, for innovative, proactive strategies, policies and measures	Factors influencing and being affected by processes of global environmental change

interactions, and even more the economic resources to adapt and to mitigate against environmental change.

This requires a fundamental paradigm shift also in the strategic and in the security debate. For the environmental security dangers posed by anthropogenic

GEC the answers of the prevailing power-based realist worldview and of the mindset of military strategic thinkers, policy-makers and their advisers will rapidly become obsolete. If we – as human beings and as the human species represented by humankind – are the threat, then totally different answers are needed for coping with these new rapidly emerging environmental dangers.

Besides the linear projections assessed by the IPCC in the available climate modelling, the reference to tipping points in the Earth and climate system makes rapid and totally different proactive policies inevitable to reduce the probability that such tipping points occur, such as the shutoff of the Gulf Stream in the North Atlantic, the depletion of the glaciers in the Andes and in the Himalayas, and their negative impact on the water security in the megapolises of Latin America (Mexico City, Lima, La Paz) and Asia (Beijing, New Delhi, Calcutta, Dhaka, etc.).

From a security perspective the societal impacts of these possible tipping points in the climate system may confront humankind in this new millennium with revolutionary social changes far more severe than the extreme weather events during the 1780's and 1840's that have triggered in Europe the revolutions of 1789 and 1848[63] or in Mexico the revolution in 1910 and independence in 1810 (Sánchez/Oswald Spring/Díaz/Cerano/Inzunza/López/Villanueva 2010).

The global economic and banking crisis has once more illustrated the prevailing political structure and behaviour that 4.3 trillion US dollars (IMF 2009) are not too high to bail out and to maintain the existing speculative banking system with minor constraints by the community of states, while for the bold and long-term decisions the dominance of short-term interests still prevails likewise in democracies and in non-democratic states.[64] Even the EU countries (chap. 83 by Egenhofer/Behrens/Georgiev) and also the new US administration by President Obama have fallen victim to this dominance of interest-based short-term perspectives to stay in power as a member of a parliament, as a government or as a president.

Clark, Crutzen, and Schellnhuber (2004, 2005) have called for a 'Copernican revolution' towards a sustainability science, even if that language isn't used it is clear that a fundamental paradigm shift in political and strategic thinking on security is needed during this century to move from future-oriented rhetoric to bold policy decisions (chap. 95 by Oswald Spring/Brauch). This requires overcoming the shortcomings and constraints of classical approaches to geopolitics, geostrategy and geoeconomics. In October 2007, in the *Potsdam Memorandum* the participating Nobel Laureates argued that "a great transformation is needed to respond to the immense threat to our planet. This transformation must begin immediately".

The employment of military force will not enable future policy-makers to deal with the challenges humankind will face during the Anthropocene because environmental security difficulties are caused by the modern industrial mode of life, and the benefits and consequences are unevenly spread, and numerous political issues of responsibility haunt discussions of climate change. Climate change presents numerous challenges to equity both at present and in relation to future generations (Roberts/Parks 2007; Vanderheiden 2008).[65] The historical and present emitted GHG should finance the adaptation of EFM of people within their countries or the region the affected consider adequate for establishing a new livelihood. This is not the normal political discussion concerning security or refugees, but such formulations are consistent with new thinking that is now needed in light of earth systems analyses of the Anthropocene.

For the new environmental dangers posed by GEC, the security policy in the Anthropocene must drop the Hobbesian obsession and move towards a more pragmatic Grotian vision of international relations that stresses multilateral cooperation, early and proactive action aiming at a policy vision of a sustainable peace where the cooperative implementation of sustainable policies becomes the core for a new peace strategy in the Anthropocene. This cannot be enforced from the top down, rather it has to be requested, accepted, and implemented from the bottom up by civil society in close cooperation with the economic sector where the state represented by the governments from the national level down to the local level has to become a major catalyst and allocator of

63 Drew (2000); Weiss and Bradley (2001); Webster (2002); Demarest, Rice and Rice (2004); Gill (2000); Zhang, Cheng, Edwards, Chen, Wang, Yang, Liu, Tan, Wang, Liu, An, Dai, Zhou, Zhang, Jia, Jin, and Johnson (2008).

64 In many oligarchic states regime security has been the upmost goal, while in many democratic societies the dependence on short-term economic interests seems to prevail that remains unchallenged by the media that partly depend on the same economic interests for advertisements.

65 See at: <http://climatecongress.ku.dk/speakers/schellnhuber-plenaryspeaker-12march2009.pdf/>.

resources to implement a 'sustainability revolution'. In short, force is irrelevant for the solution. The employment of force may make the needed solutions even more difficult and takes away scarce and crucial resources. In this needed sustainable transformation the involvement of societal actors becomes inevitable.

Thinking on and conceptualizing a new 'political geoecology for the Anthropocene' is just a modest contribution to the change in prevailing worldviews and mindsets in international relations focused on 'international peace and security'. Indeed, as our conclusions suggest here, the Anthropocene makes the point about establishing conditions of respect for treaties and laws ever more important, because these conditions are now increasingly of our own making, in both the infrastructure that powers society and, on the large scale, shapes the condition of the biosphere for future generations.

94.8 Conclusions

In terms of traditional notions of security, and the application of violence to control spaces, and not only borders, the earth system analysis suggests that this is simply inappropriate for dealing with global environmental change and human security. More so than this the assumption that security is a spatial strategy, one of dominating and controlling an external environment, is also now clearly an inappropriate categorization of things. The environment is not external to the human enterprise; it is the increasingly artificial context that allows us to live our lives. Commodities from the other side of the planet, the highways and railways that bring us food and all the material things of living are not constrained by national frontiers. Moving these things and building the farms and factories that make the material conditions of our life are an ecological process too. We are not on the Earth; we are part of the earth, once one starts to think in ecological rather than environmental terms.

This is not primarily a philosophical point, although it does challenge the key categories of modern thinking fundamentally (Walker 2006), but rather it is the key underpinning to new notions of security in the Anthropocene. Obviously, wars between states cannot be fought over climate change, nor conducted easily over other modes of ecological change, but numerous people can suffer and die as a result of these transformations unless we think seriously about how ecological structure are to be provided to secure humanity. Floods and famines are increasingly anthropogenically-induced events, not only in terms of ecological disruptions and the political economies of scarcities in crisis situations, but also in terms of the infrastructure that is essential to providing the materials for life for most of us. Vulnerabilities are not solely a matter of economic and social entitlements and their disruption, although these things matter as much now as they did in early famine events, but they are also about the contexts in which we live, and the connections through social and ecological systems that link us to the processes of life.

In these terms security is common for all of us because we are all connected albeit in ways that are not frequently obvious. We are not geographically separate from many of our peers. And if these fellow humans are forced to migrate in search of a livelihood, whether because of slow environmental changes or rapid onset disasters, our security is involved. But how that response happens is crucial. International aid efforts are frequent in the face of disaster, but in terms of their ability to prevent and cope they are frequently inadequate, mostly absent, and often too late.

One obvious lesson from recent disasters is that state capacities have been undermined after a generation of neo-conservative policies and a neo-liberal economic model that prioritizes economic 'efficiency' or accumulation for a few over all else. But as has become clear, efficiency frequently removes duplication and redundancy in complex systems. It's precisely these redundancies that provide the resiliency to systems in crisis. State capacities to help and provide for citizens have been stripped in the interests of efficiency; now as the global economic crisis of 2008 and 2009 has made clear, states have to intervene and do so cooperatively in the face of disruptions. The lessons of cooperation are key to thinking about the larger crisis of changing the material circumstances in the Anthropocene. Habits of cooperation and aid are what are going to be needed; geopolitical rivalries are not the solution to the novel circumstances, however tempting such strategies may be to political elites more concerned to remain in control than assist the citizens in their charge.

Viewing disasters in terms of ecology suggests another key lesson too. Systems change, adapt, and learn new modes of functioning under crisis. Cities are dynamic systems, not collections of bricks and cement. The innovative efforts of the marginal young men in Mumbai during its huge flood in 2005, the men Hollywood subsequently made known to the rest of the world as 'slumdogs', stepped into the absence of official state emergency services (Dalby 2009). Im-

provization saved many lives, suggesting that security in adversity is not a matter of official provision in many cases. Adaptation in these circumstances wasn't about planning; it was about generosity and practical assistance.

Likewise, in many parts of the world people are already trying numerous new ideas to deal with ecological changes, but coping strategies are frequently asset stripping exercises where things are sold until destitution arrives. This is not security; it is a downward spiral. Here matters traditionally understood as development are key, and the global political economy, in particular the dominance of the West in matters of food trading and the downward trends in many food crops, has made the lot of marginal people even more difficult. These people are frequently subject to a double exposure, vulnerable to both the economic forces of globalization and the ecological disruptions of global change (Leichenko/O'Brien 2008). Thinking clearly about this as the context of insecurity precludes policy responses in terms of traditional modes of geopolitics; it is the flows and connections that matter, not the sovereign spaces of state mappings. Political geoecology shifts this understanding of the contexts of danger, and does so by putting interconnections at the heart of the analysis, rather than using the spatial abstractions of earlier modes of thinking. Rethinking context is what both the earth system science and the formulation of political geoecology require. It is essential to rethinking security in the new times in which we now live.

This leads us to three policy relevant conclusions. A strategy aiming at the realization of the approach of a political geoecology requires scholars and policymakers to shift from looking backward to looking forward, to move from confrontative or power-focused and national interest-based to global cooperative negotiation-focused concepts, and from reactive to proactive concepts of action, from aid to justice, equity and solidarity.

In this new context of the Anthropocene, security can no longer be understood in the traditional geopolitical thinking in terms of using force to prevent external depredations. Ecological thinking, and the recognition that we are literally making our future, requires us to look to vulnerabilities, and to the multiple causes and reinforcing processes of these vulnerabilities in particular places. But rescuing people and picking up the pieces after a crash, dealing with emergencies and using exceptional measures in extraordinary times, while sometimes necessary, fails to grapple with the terms and conditions of insecurity, for the marginal rural populations of the planet obviously, but also as hurricanes, heat waves, etc. in particular demonstrate, for the residents of metropolitan places too.

Security now needs to be thought of in terms of what we are making (Dalby 2009). Building schools with proper seismic structures in earthquake zones, ensuring bridges are big enough to survive large floods and ensuring that pipelines[66] don't rupture in extreme weather, are the kind of policies that help mitigate hazards and stop severe events turning into disasters. But the other side of this argument is also crucial; building things that don't cause ecological disruption is also now necessary. Houses without furnaces simultaneously reduce ecological disruptions if they don't emit greenhouse gases and are not vulnerable to disruptions of fuel supplies either. Agricultural and forestry plantation have to be ecologically diverse so as to better adapt to changing climate and overcome all the dangers of monocultures. Windmills and solar panels likewise reduce emissions and are not dependent on long supply lines for fuel (Sachs/Santarius 2007), but support a decentralized sustainability.

But the poor and the marginal, while they too may benefit from technological innovations, are vulnerable in economic development all the time, not just to immediate shocks from extreme events. Without economic options they have little flexibility in the face of disruptions; this key theme, of poverty as vulnerability is now emphasized as the implications of disrupted subsistence systems are focused on in the increasing literature on adaptation to climate change (Adger/Lorenzoni/O'Brien 2009). The precise terms and conditions of interconnection are of course what international trading negotiations are about; but clearly over the last few decades winning the game of competition by writing the rules has not benefited the marginal producers. As such their insecurity remains, now exacerbated by the unpredictable ecological changes set in motion both by local strategies for coping, and now by GEC.

With their proposed 'political geoecology for the Anthropocene' the authors want to launch a debate among scientists of the natural and the social sciences. While the old geopolitical and geostrategic research and policy debates have left the 'environment out' and have become obsolete, the new research pro-

66 Alternative energy would substitute pipelines and a decentralized energy network would reduce the necessity of huge amounts of investment in the hands of multinational enterprises.

grammes in physical geography on 'geoecology' as well as the multidisciplinary programmes on 'earth systems science' (ESS) and on 'earth systems analysis' (ESA) have so far left 'politics out', as the fields, processes, institutions, and legal frameworks that are needed for the implementation of sustainable development.

However, the call for a new fourth green revolution requires a long-term global cooperative political strategy in a multilateral context at which the proposed perspective of 'political geoecology for the Anthropocene' aims at. It also requires a rethinking and adaptation of the key goals of the United Nations Charter "to maintain international peace and security" to reflect these new challenges humankind is facing in the 21st century and to develop a new strategy for a sustainable peace based on a gradual decarbonization of the global economy in order to cope with the impacts global environmental change is posing.

The proposed new approach of a political geoecology combines the necessary *political orientation*, with a *spatial focus* that combines different scales – from the local, regional, national, continental, and to the global by implementing the many visions, perspectives and programmes for a sustainable development into action in order to prevent that both the linear projections of 'dangerous climate change' and the possible tipping points in the earth system become reality. Securitization implies that policy-makers upgrade the dangers posed by global environmental change to issues 'of utmost importance' that 'require extraordinary measures'.

However, this new securitization must overcome the narrow focus on 'national security'. If humankind and humans poses these new security dangers, then the traditional military strategies, policies, measures, and tools will gradually become obsolete. These new security dangers do not distinguish among countries and they cannot be countered by military superiority, they cannot be addressed by weapons of mass destruction, nor can they be prevented by any sophisticated missile defence systems or intercontinental missiles.

The new security policy in the Anthropocene to cope with the dangers posed by GEC requires primarily non-military instruments. It requires a gradual reallocation of scarce resources for technological innovations for strategies of adaptation and mitigation with the impacts of GEC and global and regional climate change. This requires foremost a change of thinking of nationalist and fundamentalist ideologies in order "to save succeeding generations from the scourge of war" but also "to promote social progress and better standards of life in larger freedom", and finally "to establish conditions under which justice and respect for the obligations arising from treaties and other sources of international law can be maintained". Technical solutions are bound to fail if a comprehensive political strategy for a progressive global green economy, but also a change in human lifestyles and social responsibility, is lacking.

95 Coping with Global Environmental Change – Sustainability Revolution and Sustainable Peace

Úrsula Oswald Spring and Hans Günter Brauch

95.1 Introduction: Focus and Hypothesis

In the Anthropocene era of earth and human history we are confronted with opposite :

- *Business-as-usual* in a Hobbesian world where economic and strategic interests and behaviour prevail leading to a major crisis of humankind, in inter-state relations and destroying the Earth as the habitat for humans and ecosystems putting the survival of the vulnerable at risk (see the 'market first' and 'security first' scenarios of UNEP 2007).[1]
- The need for a *transformation* of global cultural, environmental, economic (productive and consumptive patterns) and political (with regard to human and interstate) relations (see the 'sustainability first' scenario of UNEP 2007).

Both visions refer to totally different coping strategies with *Global Environmental Change* (GEC):

- In the first vision of business-as-usual *cornucopian perspectives* prevail that suggest primarily technical fixes (such as geo-engineering, increase in energy efficiency or renewables), defence of economic, strategic and national interests with adaptation strategies that are in the interest of and affordable for the 'top billion' of OECD countries in a new geopolitical framework, possibly based on a condominium of a few major countries.
- In the alternative vision of a comprehensive transformation a *sustainable perspective* has to be developed and implemented into effective new strategies and policies with different goals and means based on global equity and social justice.

The consequences of both opposite scientific visions and competitive policy perspectives are:

- The vision of *business-as-usual* with minimal reactive adaptation[2] and mitigation[3] strategies will most

1 The *International Geosphere-Biosphere Programme* (IGBP) in its analysis of *Global Change and the Earth System* (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner II/Wasson 2004: 286) defined the *Business-as-usual* approach as: "This strategy is built around the belief that no explicit measures need to be taken with respect to global change, either to attempt to slow or prevent it or to adapt to it." In their interpretation this approach is based on these assumptions: "(i) threats to the global environment are overstated or misrepresented by green organizations and sometimes even by the scientific community; (ii) the Earth System is more robust towards perturbations that most people, including many scientists, believe; (iii) the existing market-oriented economic system will be able to solve any environmental problems, including global-scale ones; and (iv) resources that might be used to mitigate global change would be better spent on more pressing problems, such as provision of clean water, improvement of public sanitation systems in the developing world, etc." This strategy involves "taking great risks".

2 The IGBP diagnosis argued that the "the business-as-usual is not appropriate to deal with global change" and that different adaptation and mitigation strategies are needed. It suggested that "serious research questions, both biophysical and socio-cultural, remain to be considered before informed and reasonable interventions in the functioning of the Earth System may be contemplated, if ever" (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner II/Wasson 2004: 286–293).

3 The mitigation approach tries "to diminish or eliminate the problem itself rather than react to it". By taking off pressure on the Earth System, "mitigation represents an attempt to manage human activities and not the functioning of the Earth System itself, with the aim to allow the System to function in a more natural way" (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner II /Wasson 2004: 289–291).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_95, © Springer-Verlag Berlin Heidelberg 2011

likely increase the probability of a 'dangerous climate change' (Schellnhuber/Cramer/Nakicenovic/Wigley/Yohe 2006) or catastrophic GEC with both linear and chaotic changes in the climate system and their socio-political consequences that represent a high-risk approach.

- To avoid these consequences the alternative vision and sustainability perspective requires a change in *culture* (thinking on the human-nature interface), *worldviews* (thinking on the systems of rule, e.g. democracy vs. autocracy and on domestic priorities and policies as well as on interstate relations in the world), *mindsets* (strategic perspectives of policy-makers) and new forms of national and global *governance*.

This alternative vision refers to the need for a "new paradigm for global sustainability" (Clark/Crutzen/Schellnhuber 2004)[4], for a "transition to [a] much more sustainable global society" (Raskin/Banuri/Gallopin/Gutman/Hammond/Kates/Swart 2002), aimed at peace, freedom, material well-being and environmental health. Changes in technology and management systems alone will not be sufficient, but "significant changes in governance, institutions and value systems" are needed, resulting in a fourth major transformation after "the stone age, early civilization and the modern era". These alternative strategies should be "more integrated, more long-term in outlook, more attuned to the natural dynamics of the Earth System and more visionary" (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner II/Wasson 2004: 291–293). These many changes suggested above by natural scientists require a 'Fourth Green Revolution'.[5]

After briefly introducing the four key concepts of an alternative vision (95.2) and reviewing the dangers humankind is facing in the Anthropocene (95.3), the argument is further developed by moving from the vision of business-as-usual towards a vision for a global sustainable transformation (95.4). This is followed by a discussion of policy strategies for coping with GEC by distinguishing between both visions, the business-as-usual and the sustainability vision (95.5). To assist the transition towards a sustainable transformation, a brief analysis of specific threats posed by GEC (95.5.1), an assessment of the failure of COP15 (95.5.2.) is offered that broadens the scope to national and international obstacles in adopting and implementing such a strategy (95.5.3) that are needed to link sustainable development with sustainable peace (95.5.4) and a discussion of non-military means (95.5.5) for achieving the goals of sustainable development, security, and peace in the Anthropocene (95.6) concludes this discussion.

95.2 Four Key Concepts of an Alternative Vision

The four key concepts in this alternative vision of a new 'Fourth Green Revolution' are a radical change in *culture*[6], *worldview*, *mindset* and *participative governance* in the thinking and action on sustainability laying out an alternative development path with a total transformation of productive and consumptive

4 The IGBP report suggested that the future management of the Earth System will rely on "a mix of current and more visionary approaches implemented by an imperfect and only partially efficient decision-making system based on an evolving, but never complete knowledge base. ... In these conditions; adaptive management is the only way forward", which they defined as "an interactive process of learning by doing and doing based on learning" that are based on imperfect information (Steffen/Sanderson/Tyson/Jäger/Matson/Moore III/Oldfield/Richardson/Schellnhuber/Turner II/Wasson 2004: 295–299).

5 After the agricultural, industrial and the technological-communication revolution this 'Fourth Green Revolution' goes further than the new Copernican revolution proposed by Clark, Crutzen and Schellnhuber (2004). Besides a paradigm shift, this 'Fourth Green Revolution' requires a deep cultural change which should include overcoming the present consumer society. This implies to significantly reduce the global demand for natural resources and industrial products and to increase the supply of goods to satisfy basic human needs through green productive processes. Instead of mitigating against pollution at the 'end of the tube', pollution itself must be avoided. This Fourth Green Revolution includes a change of 'habitus' (Bourdieu 1972, 1980, 1980a, 1997) and a transformation of existing social relations and identities. This also requires to eliminate the exploitation of nature and human beings by small elites. Furthermore, it is necessary to care about humans and ecosystems and to overcome vulnerabilities by reinforcing environmental services.

6 Any of the three former revolutions implied a cultural reorganization of the whole productive system, the social relations, and the representations and identity processes inherent to these changes: the agricultural revolution produced stable human settlements, the industrial revolution the consolidation of urban areas, and the technological and communication revolution the globalization process with a glocal (global and local) restructuring of networks and nodes.

processes aiming at equity, social justice, and solidarity with the most vulnerable and marginal people and the poorest countries.

95.2.1 Culture

Culture is a globally organized way of life based on values, norms, beliefs, institutions and productive processes including the development of science and technology. Culture is transmitted from generation to generation by formal and informal processes. Therefore culture is a learning process which includes acculturation and enculturation processes. Cultural products are shared by the members of a society and they link people together who live and think in ways that can bring about identity patterns and social representations (chap. 66 by Flores/Wagner). As a constant practice that is culturally and mutually constructed and transformed through social interaction, language, thought and beliefs are creating symbols and symbolic meanings. Culture is therefore not based on natural laws but socially constructed, where interests are able to maintain and reinforce structures of power and mechanisms of control. Finally, culture is so deeply internalized that it is perceived by the people as natural. They take it for granted and defend their cultural habitus[7] against other beliefs and different power structures, often against their proper interests. Thus, culture can be understood as the sum of learned behaviour and a collective programming of the mind, where the present globalization is widening the number of people belonging to the dominant culture. These people consider that the present global tradition was transmitted from generation to generation and they often forget a critical understanding or that culture is a socially constructed category.

Cultural differences manifest themselves in different ways and in differing levels of depth. Symbols represent the most superficial and values the deepest manifestations of culture, gods and goddesses, heroes and rituals are located in between. Boudon and Bourricaud (1989) argued that cultural expectations are reinforced by the media, governments, religious institutions and educational systems, but also by internet and by other modern communication systems that are disseminating the present 'American' or 'Western way of life' of a consumerist society. Different cultural approaches may be identified by clusters.

Hofstede (1997) analysed the cultural awareness and the extent of global involvement within enterprises. His different layers could also be used for the analysis of the globalization process of the dominant culture, where transnational enterprises and their powerful interests are linked to formal institutions and dominant governments, creating a culture of the 'top billion'.

Boas's (1932, 1940) cultural anthropology allows us to understand that the other five billion – the excluded – are also aspiring to form part of the top billion. He believed in the psychic unity of humankind and in the universality of culture and therefore his emphasis was oriented to overcome the local context and cultural diversity by achieving one sole universal culture, based on occidental, patriarchal, exclusive and violent elements with a hierarchal power structure and one sole worldview and mindset.

Later, Talcott Parson (1937, 1951) developed the structural functionalism of social actions, where the behavioural system of biological needs, individual characteristics of the personality system, the patterns of units of social interaction of a social system have created social status and role patterns and the cultural system of norms and values that is regulating social actions symbolically for a complex functioning structure of society. This pragmatic liberal-pluralist tradition was criticized by the Frankfurt School and by Althusser, but especially by the critical neocolonialst analysis (César 1972; Fanon 1969) and the dependency theory in Latin America (Marino 1974; Faletto 1983; dos Santos 1968), and it was further reinforced by the epistemological studies of feminists (Harding 1988, 1991; Reardon 1996; Mies 1998; Longino 1990).

These critical studies analysed the perception and the cognition process that legitimized the deep and often unconscious structures of beliefs and behaviour. These reflections permitted also to understand the complex relationship between the natural and the human systems, their interdependence, but also the progressive destruction of the natural system by an irrational human exploitation. Therefore, individual and social actors, institutions, regimes, and worldviews require a fundamental change to adapt to the present conditions, where the cornucopian view does not permit the survival of the complex biological-human system. Thus, this radical cultural change is related to overcome an anthropogenically dominated worldview and to return to a dynamic understanding of the complex interrelations between nature and humankind and to analyse the boundary processes between differ-

7 As Bourdieu (1977) argued his understanding of habitus is "a socialized subjectivity".

ent disciplines, but also between the natural and the human system.

Culture represents the accumulation of material and immaterial processes humankind has been able to create. It includes systems of knowledge and understanding, experiences, attitudes, social representations, identities and meanings. Within the communication process culture has been changing and thus the suggested 'Fourth Green Revolution' responds to established hierarchies, beliefs, values, notions of importance, space and time, division of labour, and to the establishment of new roles. This alternative model must also alter social and spatial relations, the concept of universe and nature, the material possessions of objects and acquired knowledge. In a broader sense, cultivated behaviour that is socially transmitted and controlled must be changed into care for nature and humans. This green revolution conveys also the symbolic communication of this paradigm shift, where the *anthropos* is no longer in the centre of the universe but the dynamic interrelationship between humans and nature. As a collective memory of the mind, a sustainable culture may also transform worldviews and mindsets along with deeply rooted habits, which are understood as social representations (Flores 2001), behaviour and beliefs.

95.2.2 Worldview

The *worldview* concept evolved from the German term 'Weltanschauung' that refers to a wide world perception and to a framework of ideas and beliefs through which an individual interprets the world and interacts with it. A comprehensive worldview includes the fundamental cognitive orientation of a society, its values, emotions, and ethics through which a society or a group interprets the world in which it interacts (Palmer 1996: 114). Hiebert (2008) suggested that worldview is the fundamental cognitive, affective, and evaluative presupposition a group of people makes about the nature of things, and which they use to order their lives. The 'construction of integrating worldviews' begins from fragments of worldviews offered to us by different scientific disciplines and various systems of knowledge to which different perspectives contribute in the world's cultures. According to Aerts, Apostel, De Moor, Hellemans, Maex, Van Belle and Van der Veken (1994), a worldview should comprise seven elements: 1. an *ontology* (descriptive world model); 2. an *explanation*; 3. a *futurology*; 4. *values*; 5. a *praxeology* or a theory of action on how we should attain our goals; 6. an *epistemology*, or a theory of knowledge on what is true and false; and 7. an *etiology* or a constructed worldview with an account of its own building blocks, origins and construction. Krell ([1]2000, [2]2003, [3]2004, [4]2009) used this concept for distinguishing among several macro-theoretical approaches in international relations.

95.2.3 Mindset

The concept of *mindset* includes a fixed mental attitude or disposition that predetermines a person's responses to and interpretations of situations by referring to different patterns of perceiving and reasoning. Fisher ([2]1997) used it as 'cultural lenses' that filter our view of and reaction to the world. With regard to the 'Fourth Green Revolution' this concept refers to a discussion of a post-carbon society, where solidarity, equity, and social justice are the key drivers instead of the maximization of profits and the destruction of the Earth without thinking of the next generations or of the collapse of ecosystems.

95.2.4 Governance

Weiss and Thakur (forthcoming), defined global governance as "the complex of formal and informal institutions, mechanisms, relationships, and processes between and among states, markets, citizens and organizations, both inter- and non-governmental, through which collective interests on the global plane are articulated, rights and obligations are established, and differences are mediated". The concept has been widely used in international relations and in international environment policy since the 1990's, and several specific research centres, projects, and programmes were set up[8]. In the context of the 'Fourth Green Revolution' participative governance is needed combining processes of policy initiation and adoption (bottom-up) and the implementation of the required fundamental transformations (top down). This requires peaceful negotiation processes based on diversity and tolerance.

As these four concepts show, all dominant paradigms have been socially constructed, but are deeply involved in the complex process of civilization of global society; therefore a mere 'paradigm shift' is not

8 Rosenau and Czempiel (1992, [2]1995); Rosenau (1999); see the global governance project in the context of the IHDP: Biermann, Betsill, Gupta. Kanie, Lebel, Liverman, Schroeder and Siebenhüner (2009); Biermann, Siebenhüner and Schreyögg (2009).

enough. One shortcoming of the debate in the natural sciences so far has been that the political dimension and the emerging thinking in the social sciences, e.g. the postmodern approaches in philosophy, sociology, in political science and specifically in the programmes on peace, security, development and environment have not been taken up in the discourses in the natural sciences while their conceptual suggestions are only gradually being considered in the debate in the social science communities on GEC, on natural hazards and security (chap. 1 by Brauch/Oswald Spring).

An isolated approach from the natural or social science alone will not be able to develop the required revolutionary changes in thinking and policy (Held/Hervey 2009).[9] Therefore, we need a 'Fourth Green Revolution' where material and immaterial processes, beliefs and behaviours are changed, including power relations and control mechanisms. The transformation in the thinking on the human intervention into the Earth System must be accompanied by fundamental changes in the cultural, social, and political systems.

95.3 Dangers Humankind is Facing in the Anthropocene

Since the 1970's, scientists have gradually socially constructed new diagnoses of the dangers to human well-being, livelihood, and security:

- From the perspective of the natural sciences the focus has turned to human interventions into the Earth System during the Anthropocene and their physical impacts on the climate system (temperature rise, precipitation change, sea-level rise and increase in number and intensity of natural hazards), the hydrological cycle, the ecosystems and on the land.[10]
- From the perspective of the social sciences (human geography, economics, political science, sociology, law, etc.) the focus has shifted from perspectives of exploiting nature for human prosperity based on unequal accumulation and distribution patterns using economic and military power towards more complex systems' analyses on the human-nature interactions and their inherent risks using modern energy, transportation, and communication systems which have increased greenhouse gases and thus became a major cause of anthropogenic climate change.

From the perspective of the humanities (culture, philosophy, anthropology, psychology, etc.) the focus has shifted to new lifestyles (from rural to urban contexts, from extended to small families), dependency structures (from the family and local community networks to socio-political institutions), and changes in norms, values, preferences and behaviour.

An outcome of these new socio-cultural constructions of reality have been different scientific research results and insights based on new theories and empirical assessments on the human predicament with a gradually evolving understanding of the social impacts of the severe interventions of human activities into the Earth System that may fundamentally undermine the very basis of human life on Earth. These multiple new scientific results have been referred to before as the first stage of a *scientization* of *global environmental change* (GEC) issues.

Partly based on these scientific findings, concerned citizens, social movements, NGOs as well as governments and international organizations have placed in the 1970's environmental pollution, drought and desertification and later ozone depletion and since the late 1980's also global environmental issues such as climate change, water degradation and biodiversity loss on the local, national, and global political agenda. This agenda-setting resulted in the creation of a new policy field with an institutionalization at the national (ministries, agencies) and international level (programmes such as UNEP, financial instruments, such as GEF and conventions creating new environ-

9 Held and Hervey (2009: 14f.) suggested as elements of a global deal in combating climate change that it should be "broadly inclusive, multi-faceted, state-centric and sustainable". Held and Hervey (2009: 5, 10, 17) pointed to various deficiencies in democratic systems facing climate change, such as a) *short-termism* (electoral cycle); b) *self-referring decision-making* (reliance on local constituencies); c) *interest-group concentration* that often paralyzes and prevents bold decisions; and d) *weak multilateralism* with a limited compliance with environmental regimes. They suggested guiding principles for governance and policy at the level of the nation-state (broadening and deepening of the deliberative process, transformation of private preferences, active involvement of citizenry, leadership overcoming narrow interests) and at the global level (promotion of inclusive, broadly representative global decision-making process, assistance for developing countries, broader mandate of GEF, increase of status and responsibility of UNEP).

10 See the preface essay by Müller, Lotze-Campen, Huber, Popp, Svirejeva-Hopkins, Krause and Schellnhuber; chap. 77 by Noone, Nobre and Seitzinger; chap. 74 by Leemans, Rice, Henderson-Sellers and Noone.

mental processes and regimes, such as UNFCC etc.), which has been conceptualized as a process of *politicization*.

Due to both the social construction of these new threats and their perception by a global audience, some policy-makers have stressed the sense of urgency and thus upgraded these new environmental dangers as issues of 'utmost importance' that require 'extraordinary political means' in both facing and coping with global climate change, water scarcity and degradation (Oswald Spring/Brauch 2009b), as well as desertification (Brauch/Oswald Spring 2009 and chap. 47; Oswald Spring/Brauch 2009). This process in framing these dangers and concerns in a human, national or international context has been referred to as '*securitization*' (Wæver 1995, 2008; Buzan/Wæver/de Wilde 1998).

The analysis of the linkages within the climate system has focused first on linear interactions resulting in modelling and projections of physical impacting on economic sectors (agriculture, industry, habitat, health, etc.), ecosystems or bioms (coastal, marine, forests, deserts, etc.) and geographic regions (Africa, Asia, Latin America, Arctic, etc.) that may trigger extreme societal outcomes (BMU 2002; WBGU 2008; Brauch 2009a).

Since the early 21st century the scientific attention has shifted to chaotic processes such as a nonlinear and abrupt climate change (NAS 2001). Once linear processes cross certain thresholds they may result in fundamental contextual changes, as, for example, the shutoff of the Gulf Stream, the collapse of the Amazon rain forest, the ENSO cycle or the change of the Indian monsoon. These chaotic changes have recently been conceptualized as 'tipping points'[11] in the climate system that may fundamentally change the linear projections. Their socio-political and cultural impacts have not yet been addressed and may pose major uncertainties for the survival of several civilizations and also for global security.

95.4 Moving from a Business-as-Usual Towards a Global Vision of Sustainable Transformation

From the vision of *business-as-usual* in a Hobbesian world the dangers posed by GEC have been addressed as new national and military security threats. From the prevailing geopolitical and geostrategic mindset of policy-makers and of the institutions of the national security state[12] their traditional priorities, strategies, and hard military instruments are often applied to these fundamentally different and new security dangers and concerns.

This mode of thinking was first expressed – with regard to the U.S. national security impacts of abrupt climate change – in a study funded by the Pentagon by Schwartz and Randall (2004) that applied the dominant geostrategic thinking to a fundamentally different threat environment where the security dangers are not any longer represented by the other (nation or ideology, etc.) but by one's own 'way of life' and the inherent risks it entails, expressed by the unlimited right to consume the limited natural resources.

The prevailing Hobbesian mindset of the political and military elites applies power concepts, strategic rationales, and military instruments (armed forces, weapons, intelligence) for dealing with a new and fundamentally different security danger that it is not any longer 'them' (China, India, Russia, Brazil, South Africa, the developing countries, and the new rapidly rising GHG emitters) that poses the threat but 'us' due to our fuel-intensive mode of production and consumption patterns where the externality of the costs have been ignored far too long.

11 For Lenton, Held, Kriegler, Hall, Lucht, Ramsdorf, and Schellnhuber (2008: 1186) the term 'tipping point' has been used in discussions of global change "to describe a variety of phenomena, including the appearance of a positive feedback, reversible phase transitions, phase transitions with hysteresis effects, and bifurcations where the transition is smooth but the future path of the system depends on the noise at a critical point". They offered "a formal definition, introducing the term 'tipping element' to describe subsystems of the Earth System that are at least subcontinental in scale and can be switched – under certain circumstances – into a qualitatively different state by small perturbations. The tipping point is the corresponding critical point – in forcing and a feature of the system – at which the future state of the system is qualitatively altered".

12 See Hogan (1998); Nelson-Pallmeyer (1992): refers to its seven features: 1) the military is the highest authority; 2) political democracy and democratic elections are viewed with suspicion, contempt, or in terms of political expediency; 3) the military and related sectors wield substantial political and economic power; 4) its obsession with enemies; 5) the enemies of the state are cunning and ruthless why any means used to destroy or control these enemies are justified; 6) restricts public debate and limits popular participation through secrecy or intimidation; and 7) the church is expected to mobilize its financial, ideological, and theological resources in service to the National Security State.

The rapidly progressing 'militarization' of climate change in the context of the national security discourses (chap. 1 by Brauch/Oswald Spring) that are often instrumentalized for adjusting the national security apparatus to new tasks by creating new military missions and larger budgets – an approach that totally obfuscates the fact that this security threat cannot be solved with military means but requires a fundamental transformation of the economic system and of human values and aspirations, as well as an adaptation of political processes.

This emerging scientific discourse and interest-driven policy debate that frames GEC solely as national security dangers and concerns aims at stabilizing the hegemonic position of the one remaining superpower, and of the dominance of multinational corporations. This is also reflected in proposals to address the challenges posed by climate change outside the UN system by a condominium of a few leading countries without binding legal obligations.[13]

While from the perspective of major industrialized countries no price was too high to bailout the consequences of the global financial crises since 2008, at COP 15 in Copenhagen, many of those countries that referred to climate change as a major new threat to international security were neither ready and willing to treat climate change as an issue of 'utmost importance' nor to commit even less than one per cent of their bailout costs of the global financial crisis for a global fund to assist developing countries in coping with the impacts of global climate change.[14]

The same policy response has applied to the food crisis since 2007 when major industrialized countries were unwilling in November 2009 to commit significant food-aid and financial resources to counter the hunger of 1 billion people.[15] Many of the same countries have used food crops for biofuels, creating an artificial scarcity of food commodities that resulted in major food price hikes (partly due to speculation). They have also spent much more in subsidizing ethanol and biodiesel than would have been needed to launch a strategy for combating hunger.[16]

However, from a human security perspective on GEC the focus has shifted from the states and international organizations to humankind and human beings as referent objects of security. The people have become the primary victims of the global financial crisis and who were the first to lose their employment, income, and livelihood. It will also be the people who will become the primary victim of the physical effects of GEC and their social repercussions. As a result of the reconceptualization of security the focus has widened from the narrow political and military focus to include the economic, social, and environmental security dimensions. Many chapters in this handbook have applied the human security perspective to this extended scope (chap. 74–96 in Brauch/Oswald Spring/Grin/Mesjasz/Kameri-Mbote/Behera/Chourou/Krummenacher 2009).

From the alternative vision of a need for the transformation of global cultural, environmental, economic, and political relations, both scientists and policy-makers have repeatedly declared to shift towards a sustainable development perspective (Brundtland

13 See for the debate in the USA immediately after the failure of COP 15 in Copenhagen: Lisa Friedman: "Negotiations: Some climate experts seek alternative to U.N. process", in: *ClimateWire*, 21 December 2009; at: <http://www.eenews.net/public/climatewire/print/2009/12/21/1>; Suzanne Goldenberg and John Vidal: "UN should be sidelined in future climate talks, says Obama official", in: *The Guardian*, 14 January 2010; at: <http://www.guardian.co.uk/environment/2010/jan/14/climate-talks-un-sidelined>.

14 In 2009, the estimates of the total costs of economic bailout have reached 25 trillion US$ (see: *Wall Street Journal*, 28 October 2009; at: <http://247wallst.com/2008/10/28/financial-crisi/>). The requests for financial aid to developing countries by 2020 that were discussed at COP 15 in Copenhagen amounted to 100 billion US$, OECD countries were unable to commit for a major challenge to the security and survival of humankind in this century. US Secretary of State indicated in December 2009 at COP 15 in Copenhagen that the USA would join a $100 billion aid package for developing countries by 2020 and the EU promised short-term finance for developing countries of $30 billion up to 2012 and $100 billion by 2020 while African countries called for financial means of $200 billion a year by 2020 for technology transfer and capacity building, besides US$67 billion a year for adaptation against climate change. See Fred Oluoch-Ojiwah: "The Road to Copenhagen Did Not Pass Through Africa", in: *The New Times* (Ruanda), 5 January 2010; at: <http://allafrica.com/stories/201001050069.html>.

15 Subejo: "Lesson learned from World Food Security Summit 2009", in: *The Jakarta Post*, 6 December 2009; at: <http://www.thejakartapost.com/news/2009/12/06/lesson-learned-world-food-security-summit-2009.html>; "Wealthy countries' leaders lack the political will to commit to solving these problems. There was no increase in financial commitments to eradicate hunger, as developed nations would not agree to allocate the hoped for US$44 billion in agricultural aid per year."

16 See Rudaheranwa (2009). The EU support for Ethanol in 2006 was 1,282 million Euros and for biodiesel was 2,437 million Euros.

1987; Annan 2000, 2005). However, the adopted declaratory politics during the past two decades has so far only marginally been implemented into policy activities that transform economic processes according to these goals.

From a sustainability perspective, natural scientists suggested to shift towards an *Earth Systems Science* (ESS) that requires many human-induced changes oriented at global sustainability by advancing sectoral wisdom, aiming at a stewardship of the Earth System and moving towards a new paradigm for global sustainability.[17]

From the perspective of the technical disciplines, many institutions and authors – from both North and South – have suggested a total transformation of the energy system by enhancing efficiency and replacing fossil fuels with renewables, thus creating new sustainable production, production lines, and jobs.[18] Others suggested a gradual dematerialization and decarbonization of the production, transportation, and consumption processes.[19] Based on these proposals some economists in the North suggested a new global and green deal (Stern 2009; Calvo 2009); while others called for a transformation of the terms of trade, a different debt policy (chap. 5 by Mesjasz; Jubilee 2000, 1998) and fundamental reforms of the global financial system with enhanced national and international control mechanisms. While the massive economic growth based on cheap fossil energy was the major cause of pollution and global warming, it did not overcome underdevelopment and poverty, and has so far contributed very little to the achievement of the MDGs.

Furthermore, sociologists (Giddens 2009) and political scientists (Held/Harvey 2009) called for new global governance systems or a new geopolitics of climate change. These multiple initiatives for a transformation of the global economic system of production, services and consumption, a needed sharing of knowledge and technology, will create many new and additional employment opportunities for the rapidly growing population both in the South and in the North.
