The population of the Gaza Strip experiences severe water quality and quantity problems. These include: a) intrusion of sea water, and of saline water from deeper saline strata into the *Gaza Coastal Aquifer System* (GCAS); b) high levels of water pollution (high concentrations of chloride, nitrate and other chemicals); c) biological and chemical contamination, due to untreated sewage and the heavy use of pesticides and fertilizers in agriculture which penetrate into the GCAS; d) return flows from intensive irrigation; and e) over-extraction of water from the GCAS. This is in addition to the rapid population growth, the high level of poverty, the spread of diseases, and the scarcity of water resources. All these problems are beyond the capacity of the Gaza Strip's inhabitants. These problems have caused not only environmental hazards but also profound risks to peace, stability, and sustainable development (Kelly/Homer-Dixon 1998; Brauch 2003; Salem/Isaac 2007). These problems have already resulted in 'environmental migration', in addition to the 'political and economical migrations' the Gaza Strip has experienced for a long time.

Qahman and Zhou (2001) predicted that by the year 2015, the sea water intrusion will be 2,300 m (2.3 km) in the upper part of the GCAS and 2,800 m (2.8 km) in the GCAS's lower part. The poor quality of water supply in the Gaza Strip is such a major concern for its people that it is seriously affecting their quality of life and, thus, exposes them to severe health risks (Alfarra/Lubad 2004; Bohannon 2006; IRIN 2006; Salem/Isaac 2007; Abu Heen/Tubail/Abu El-Naeem 2008).

These problems have already contributed to a serious deterioration of the local environment. The projected climate change impacts for the Gaza Strip during the next 30 to 100 years will be significant. Considerable attention should be paid to problems of SLR, sea water intrusion, and water contamination and their impacts on environmental migration, poverty, hunger and health problems, as well as on instability in this small and very densely populated area.

Scenarios of the *United Nations Environment Programme* (UNEP) indicated that a 50 cm rise in sea level could displace millions of Egyptians living close to the Mediterranean shoreline by the year 2050.[9] As the Gaza Strip is a natural extension of the Egyptian coastal shores on the Mediterranean, it will be affected by the SLR in a similar way. To give a rough estimate of the SLR for the Gaza Strip, the empirical equation given by El Raey (2007) is used (table 23.4).

Table 23.4 shows that for the last century, the sea level rose about 20 cm, and it will rise another 23 cm

9 See FoEME (2007); El Raey, Nasr, Frihy, Desouki and Dewidar (1995); El Raey, Fouda and Nasr (1997); El Raey, Dewidar and El Hattab (1999); Agrawala, Moehner, El Raey, Conway, van Aalst, Hagenstad and Smith (2004); El Raey (2007); chap. 45 by El Raey.

until the end of this century. Over the 185 years from 1915 to 2100, the sea level in the Gaza Strip rose or may rise by at least 43 cm, or about 0.23 cm/yr. These values correspond with the findings of UNEP for the global SLR by 2 cm in the 18th, by 6 cm in the 19th, and 19 cm in the 20th century (UNEP 2009; IRIN 2009a).

According to recent publications the SLR may accelerate. When the ice melted at the end of the last ice age 10,000 years ago, the sea level rose by between 70 and 130 cm per century (UNEP 2009). Recent studies argued that if the atmospheric CO_2 concentrations were not kept below 350 part per million (ppm), the results could be disastrous (Hansen/Sato/Kharecha/Beerling/Masson-Delmotte/Pagani/Raymo/Royer/Zachos 2008). The current level of CO_2 concentration in the atmosphere is 385 ppm. If it exceeds 450 ppm, it could lead to a catastrophic SLR. The EU has set a target to stabilize the atmospheric GHG concentration at 550 ppm by the year 2035 (TGG 2008). Hansen argued that the EU target of 550 ppm should be reduced to 350 ppm if "humanity wishes to pre-

Table 23.4: Calculated Sea-Level Rise (SLR) for the Gaza Strip's Region during the Period of 1915-2100 (based on the El Raey's (2007) empirical equation for the Port Said Area in Egypt: *Y = 0.2314X - 442.7, where Y is SLR in cm and X is year.*).

590 – 710	3.2 – 4.0	2020 – 2060	0.6 – 2.4

serve a planet similar to that on which civilization developed" (Pilkington 2008). Table 23.5 shows the SLR for the next 50 years due to increases in global mean temperature.

Studies on the SLR in the Gaza Strip are urgently needed, especially after Israel's 21 day invasion in 2008/2009, which also caused huge damages to the environment (Bergstein 2009; Falk 2009; IRIN 2009b, 2009c; Kloosterman 2009; Mitchell 2009; Salem 2009b, 2009c).

23.5.3 Water Scarcity and Transboundary Aquifer Systems

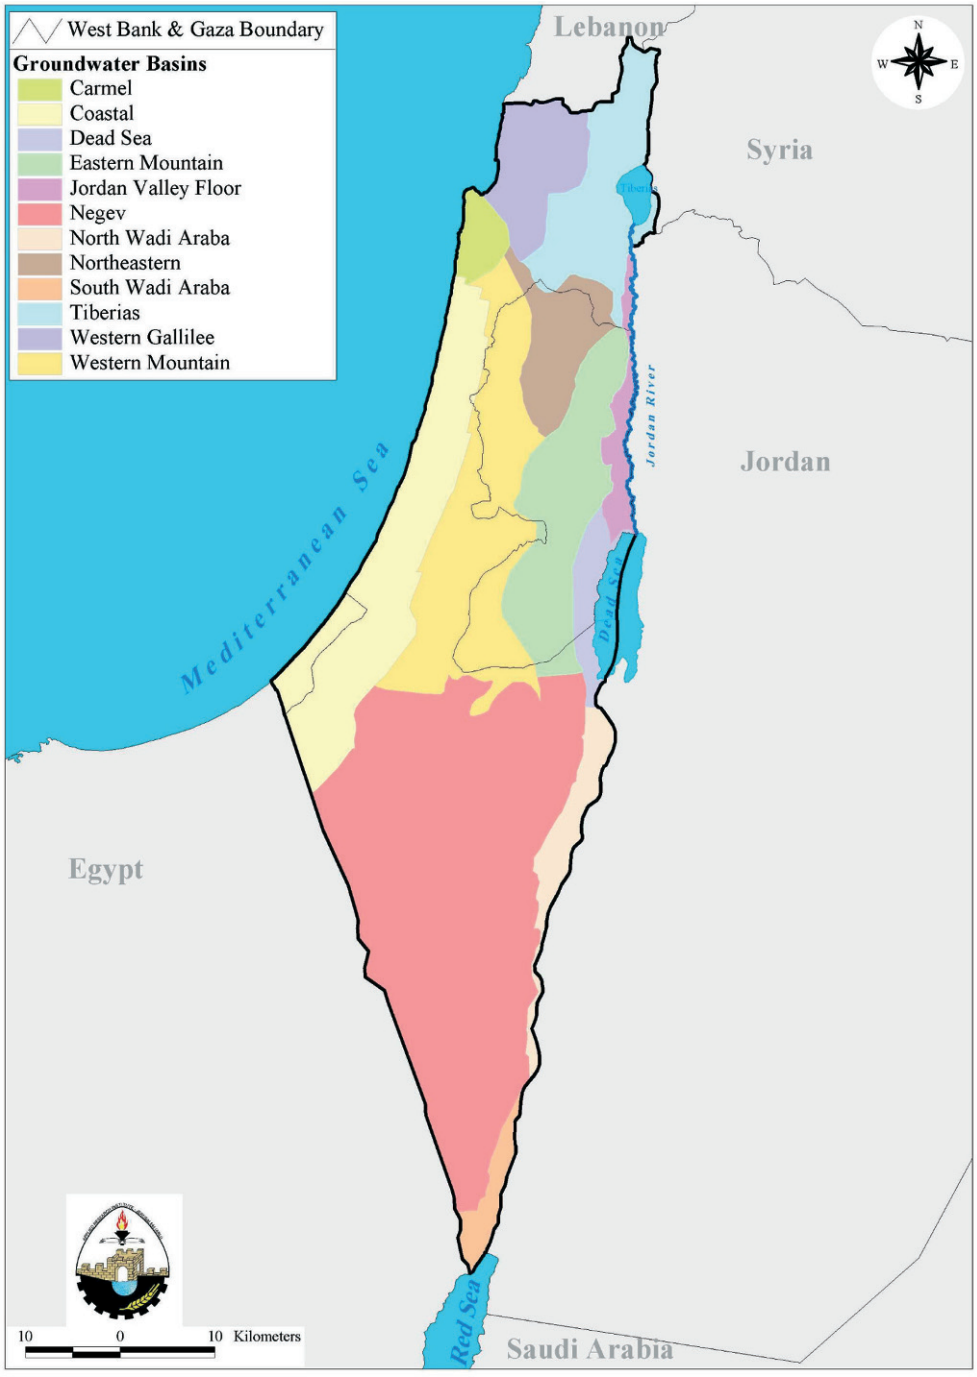
During the 5th World Water Forum in Istanbul in March 2009, Koïchiro Matsuura, Director of UNESCO, said, "that unless we change our behaviour towards fresh water we will face a major water crisis. Water is the principal medium through which climate change will affect economic, social, and environmental conditions" (IRIN 2009d).

Historical Palestine (HP) includes 11 groundwater aquifer systems (figure 23.4) of which three are in the West Bank: the *Western* (WAS), *North-Eastern* (NEAS), and the *Eastern Aquifer Systems* (EAS) which all comprise the *Mountain Aquifer Basin* (MAB), as well as the *Gaza Coastal Aquifer System* (GCAS) under the Gaza Strip (figure 23.4, 23.5). These four aquifer systems are extensively used by Israel and the 200 Jewish settlements in the OPT (Salem/Isaac 2007). The Palestinians have severely suffered from huge water shortages (for domestic, agricultural and industrial needs). The Palestinians are only allowed to use 15 per cent of their own water. As Israel controls the water in these aquifer systems, the impacts of climate change will double in the OPT, given the severe water shortages and Israeli denials of Palestinian water rights.

Independent research by Palestinians is urgently needed to acquire detailed knowledge on the aquifer systems in the OPT, their recharge and discharge areas, the status of wells penetrating them, and their delineation, as well as on the flow of pollutants within these aquifer systems.

The *Western Aquifer System* (WAS) is the largest system, with a safe yield of 365 million cubic metres/year (MCM/yr), of which 40 MCM is brackish water. Eighty per cent of its recharge area is in the West Bank, whereas 80 per cent of its storage area is in Israel. The water flows towards the coastal plain in the west (figure 23.5), making it a shared basin for Israelis and Palestinians. Water in this WAS is mainly of good quality and is largely used for municipal supply. Israelis have exploited this system through 300 deep wells in the west of the Green Line, as well as through the deep wells drilled by *Mekorot* in the West Bank (Salem/Isaac 2007). Palestinians consume only about 7.5 per cent of this water. They extract their water from 138 wells, including 120

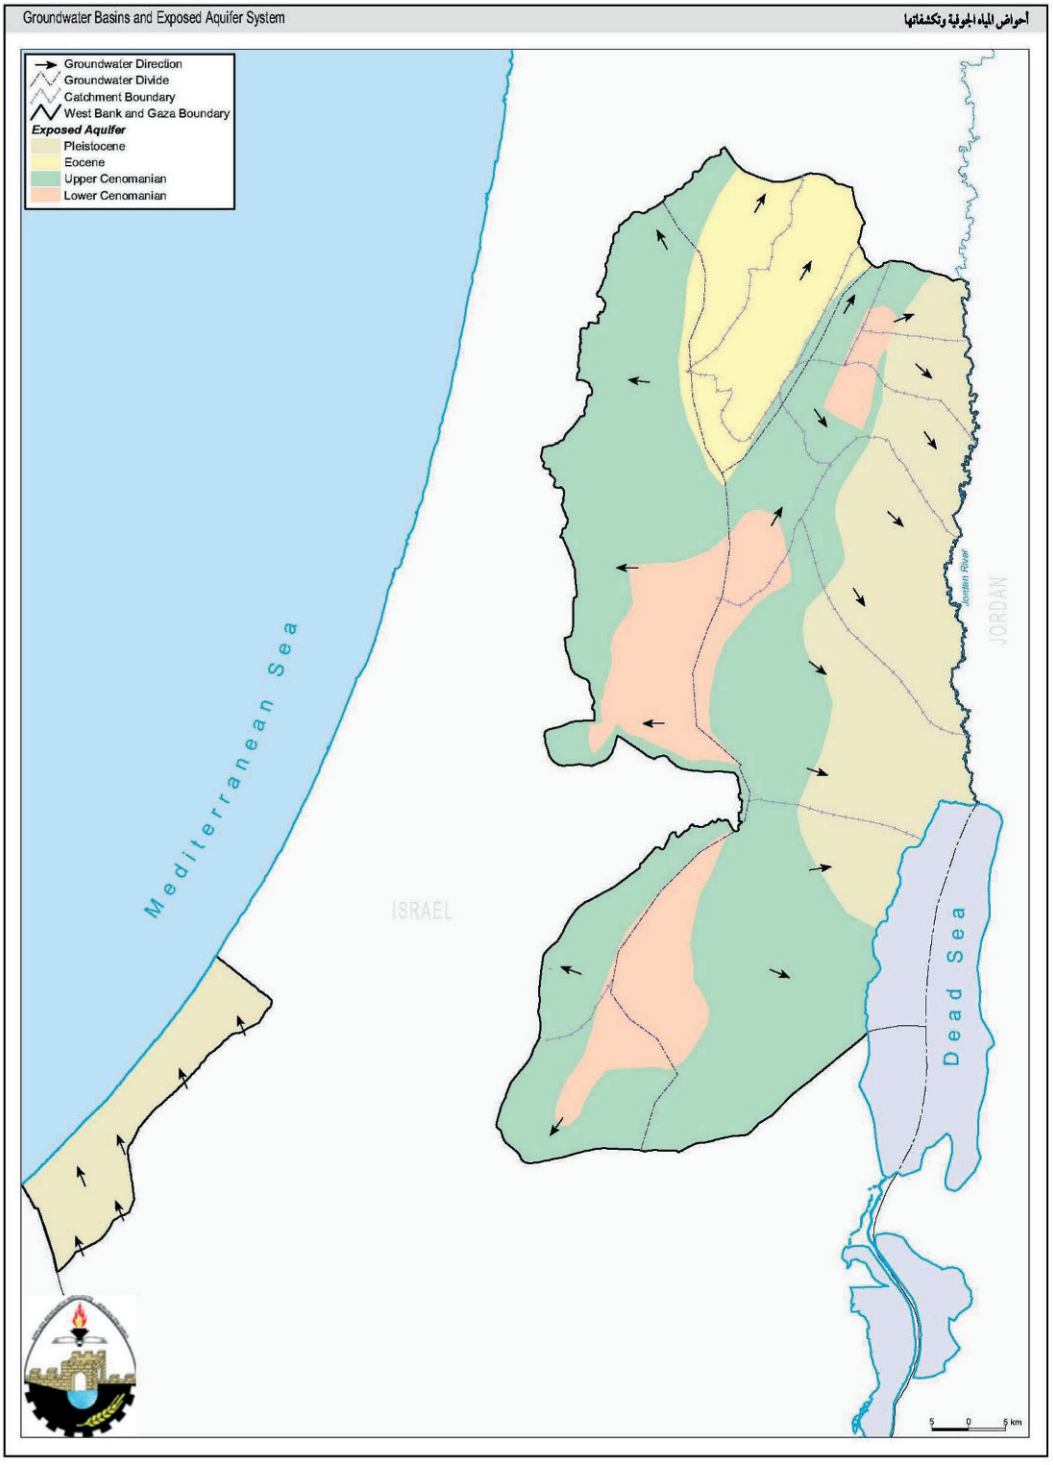
Figure 23.4: The Aquifer Systems in Historical Palestine (including Israel and the OPT). **Source:** Salem and Isaac (2007).



wells for irrigation use and 18 wells for domestic use in Qalqilya, Tulkarm, and western Nablus (figure 23.2). There are 35 springs with an average flow of approximately 0.1 l/s (360 l/hr). Many of these wells are beyond the reach of Palestinian communities as they are isolated behind the ISW.

The *North-Eastern Aquifer System* (N-EAS) has an annual safe yield of 145 MCM, of which 70 MCM is brackish water. Palestinians in the Jenin district and eastern Nablus (figure 23.2) consume only about 18 per cent for both irrigation and domestic purposes. There are 86 Palestinian wells, including 78 for irrigation and 8 for domestic use. The general groundwater

Figure 23.5: The Aquifer Systems in the Occupied West Bank and Gaza Strip. **Source:** Salem and Isaac (2007).



flow in this aquifer system is towards the natural springs in the north and north-east (figure 23.5).

The *Eastern Aquifer System* (EAS) has an annual safe yield of 175 MCM, of which 70 MCM is brackish water. This EAS lies entirely in the West Bank and was exclusively used by Palestinian villagers and farmers until 1967 (Salem/Isaac 2007). Then Israel expanded its control and tapped it to supply Jewish settlements

in the West Bank. Seventy-nine springs, with an average discharge of more than 0.1 l/s (360 l/hr), provide 90 per cent of the total annual spring discharge in the West Bank. There are 122 Palestinian wells drilled in this system, including 109 for irrigation and 13 for domestic use. The groundwater flows towards the Jordan Valley and the Dead Sea (figure 23.5).

The *Gaza Coastal Aquifer System* (GCAS) is the sole water source for Palestinians in the Gaza Strip (figure 23.5), providing it with 96 per cent of its needs. This aquifer system is a continuation of the shallow sandy/sandstone Coastal Aquifer used by Israel (figure 23.4). Over 4,000 wells penetrate the GCAS with depths ranging from 25 to 30 metres. The annual safe yield of this system is 55 MCM. It has been overused with more than 120 MCM annually. As a result, the groundwater table fell below sea level, and saline water has intruded the aquifer system in many areas.

23.5.4 Water Scarcity, Climate Change Coping Strategies for the Jordan River Basin (JRB), and Water Conflict

The study of the impacts of climate change for water scarcity, biodiversity, agriculture, ecosystems, irrigation, desertification, etc. requires multidisciplinary scientific knowledge based on *in situ* and remote sensing measurements, monitoring and experiments, socio-economic data, and modelling from conventional and non-conventional methods of water management and of their ecological and socio-economic implications.

While Historical Palestine and Jordan have one of the lowest per capita water supplies worldwide, the water demand has rapidly increased due to population growth and economic development. These conditions have further deteriorated due to the political conflict. Climate projections for the Eastern Mediterranean refer to increased aridity, which has started during the past few decades with lower precipitation and higher evaporation rates. Temperature increases and prolonged droughts have severely reduced the surface-water and groundwater supplies.

The *Upper Catchment of the Jordan River* (UCJR) is a valley (80 km long and 15–30 km wide), covering approximately 1,600 km^2. The flow into the UCJR is continuous throughout the year, with an average yield of about 500 MCM annually, all of which is taken by Israel, contributing about 25 per cent of Israel's total water budget (Salem/Isaac 2007). Since 1967, the OPT has not benefited from the JRB's waters. Most groundwater resources in the region are transboundary, requiring strategies for sustainable water management based on regional collaboration.

Research on climate change impacts for the JRB and other regional transboundary water resources requires comprehensive analyses on: a) the range of environmental stresses and their effects; b) the resilience of regional ecosystems; c) the adaptive capacity of regional socio-economic systems to changes in the hydrological cycle and water resources; d) the interactions of agriculture and irrigation with water resources and regional atmospheric processes; and e) the extreme events (droughts, heatwaves, floods, etc.). The studies of the *Global Change of the Water Cycle* (GLOWA) on the JRB (Part I, II), focusing on the Upper and Lower Catchments of the Jordan River, indicated that an increase in average temperature of 0.75°C and a decrease in rainfall will take place in the JRB during the period from 2007 to 2045 (GLOWA 2007).

The water resources available to Palestinians in the OPT are, per capita, among the lowest in the world (Salem/Isaac 2007). The Israeli per capita consumption for domestic and agricultural uses is 254 *cubic metres per year* (m^3/yr), while the Palestinian per capita consumption for both domestic and agricultural uses is only 81 m^3/yr, or less than one third of the Israeli per capita consumption. The Israelis take about 60 per cent of their water needs from the JRB, more than 25 per cent from the *Mountain Aquifer Basin* (MAB), and the rest from desalination and water treatment plants, water harvesting, and fossil water in the Negev Aquifer System (figure 23.4). A study referred to high rates of radioactive elements (radium isotopes) in the fossil groundwater aquifers in the Middle East. The study on the Disi Aquifer System in southern Jordan concluded that the findings raise concerns about the safety of this and similar non-renewable groundwater aquifer systems, exacerbating the already severe water crisis in the Middle East (Vengosh/Herschfeld/Vinson/Dwyer/Raanan/Rimawi/Al-Zoubi/Akkawi/Marie/Haquin/Zaarur/Ganor 2009).

Most of the Israeli water consumption (75 per cent) goes to irrigated agriculture (Isaac/Selby 1996; Salem/Isaac 2007), though this sector contributes less than five per cent to the Israeli GDP, and only two per cent of the Israeli labour (including support service) is employed in this sector (IMA 2004). Almost half of Israel's cultivated land is irrigated, and about 70 per cent of the land cultivated by Israeli settlers in the West Bank is irrigated. By contrast, only 6 per cent of the Palestinian land is irrigated and the rest is rain-fed,

although agriculture is more important to the Palestinians and more central to their economy than to the Israelis, as it contributed about 11 per cent to the Palestinian GDP in the year 2004 (Attaya 2005) and more than 26 per cent to employment in the OPT (HighBeam 2007).

Since June 1967, Israel imposed several military orders to control the Palestinian water resources, including the Order No. 92 of 15 August 1967 (JMCC 1995), stating that the water is to be considered a strategic resource and all new wells must be approved by the Israeli military where both Israelis and Palestinians are purportedly given equal consideration. While Israel and its settlers consume more than 85 per cent of the Palestinian water resources, Israel has granted only a few wells to the Palestinians (Isaac/Salem 2007). Many other military orders followed, extending a complete Israeli military control over Palestinian water resources, including the three West Bank aquifer systems of the MAB, the JRB and its tributaries, Lake Tiberias, and the Syrian Golan Heights. The Palestinian water and fishing rights in Lake Tiberias are unquestionable, based on the fact that the Palestinians are riparians with the privilege of equitable utilization.

While the Palestinians are not allowed to drill new wells or rehabilitate old ones, Israel drilled deep wells in the four aquifer systems (WAS, N-EAS, EAS, and GCAS; figure 23.4) under the OPT. This means that the old shallow Palestinian wells dry up, leaving the Palestinian population without water, especially in hot summers and during drought. The Palestinians have no choice but to buy their water from *Mekorot* that extracts it from the four aquifer systems under the West Bank.

Israel takes about 60 per cent of the surface water (685 MCM/yr) of the Jordan River, while Jordan receives 23 per cent (263 MCM/yr), Syria 11 per cent (126 MCM/yr), and Lebanon only 0.3 per cent (3.4 (MCM/yr), and the rest (5.7 per cent or 65 MCM/yr) flows into the Dead Sea.

Currently the Palestinians in the OPT receive nothing from the JRB. Until their water rights in the JRB were taken away by the Israelis, the Palestinians had used this water for centuries and they extracted 30 MCM/yr for domestic and agricultural purposes. Israel claims prior usage of the MAB (Shuval 2007), but denies the Palestinians' prior use of the Jordan River's waters. Palestinians have used the MAB's waters for centuries. They used the natural springs that are recharged from the WAS, and they had a few deep wells penetrating that system, long before Israel was established in 1948. With the construction of the ISW, Israel has surrounded important Palestinian water resources, including many springs and wells owned by Palestinians.

It is estimated that 70 per cent of the recharge area of the Western Aquifer System has been or will be isolated between the ISW and the Green Line (figure 23.2). In the northern part of the West Bank, the ISW acts as a concrete dam, trapping water and preventing it from flowing west and thus causing flooding in nearby areas. Furthermore, while the 200 Israeli settlements in the West Bank always receive water, the Palestinians in the West Bank may get water once or twice a month. About 25 per cent of the West Bank's Palestinian population are still not connected to the water network. Bringing water to these people is still a decision of Israel, according to the 1993 Oslo Agreement that divided the West Bank into 'Area A', 'Area B', and 'Area C', each of which has certain jurisdictions (Salem 2009a).

Article 6 of the *UN Convention on the Law of the Non-Navigational Uses of International Watercourses* (1997) on 'Factors Relevant to Equitable and Reasonable Utilization' states the following factors should be considered in water conflicts (UN 2005b; Salem/Isaac 2007):

> 1) the geography of the basin, including the drainage areas; 2) the hydrology of the basin, including the contribution of water by each basin (if more than one); 3) the climate affecting the basin; 4) the past utilization of the basin's water; 5) the economic and social needs of each of the basin's riparians; 6) the population dependent on the basin's water, with regard to each of the basin's riparians; 7) the comparative costs of alternative means that satisfy the economic and social needs of the basin's riparians; 8) the availability of other water resources; 9) the avoidance of unnecessary waste in the utilization of the basin's water; 10) the practicability of compensation to one or more of the basin's riparians, as a means of adjusting conflicts among users; and 11) the degree to which the needs of a riparian of the basin may be satisfied, without causing substantial injury to any of the basin's riparians.

Israel bases its claims on the fourth point (Shuval 2007), while ignoring the other 10 points that do not give Israel a favourable treatment regarding the water resources in Historical Palestine. Israel has ignored (Shuval 2007) the vast history of the prior Palestinian use and current needs, as well as the Palestinian shares of the water resources in the region. In this case, Israel has violated the Hague Resolutions of 1907 (IHL 1907) and the Fourth Geneva Convention of 1949 (IHL 1949), and many other international

treaties, by controlling and exploiting the water resources far beyond what is allocated to Israel. Israel has ignored the water agreements signed with the Palestinian leadership in 1993 and 1995, according to the Oslo Peace Agreements, whereby Israel should acknowledge the Palestinians' immediate needs of 28.6 MCM/yr and future needs of 70–80 MCM/yr (Palestine Facts 2009).

Israel argues that huge extraction of water from the Jordan River is supported by international law (Shuval 2007), basing its claims on a draft proposal called the *Johnston Plan* (JP) which they negotiated with their Arab neighbours in 1956 (Elmusa 1997). Israel considered the JP as a de facto law and invoked it on occasions. The JP called for the *West Ghor Canal* (WGC) to supply the West Bank with 250 MCM/yr to meet the needs of the Palestinians. While the WGC was never built and the JP was never enacted due to the political conflict, the Palestinian water rights in the JRB still remain. Before Israel was established in 1948, the Jewish Agency ignored the *Ionides Plan* (IP) of 1939 which outlined a realistic assessment of water resources in the region (Elmusa 1997; Isaac/Salem 2007).

But Israel has never been interested in solving the water conflict with the Palestinians with respect to their water rights based on international law. Instead, Israel has been concerned about giving the Palestinians the minimum of what they need. Accordingly, Israel has always addressed the concerns of the Palestinian people in the OPT in terms of *water needs but not water rights* (Rouyer 2003).

While denying the Palestinians their water rights, Israel suggested water quantities for Palestinians from non-conventional sources, such as desalinization, water treatment, and water imports from Turkey. To find a common ground for a lasting peace, the allocation of waters among Palestinians and Israelis in *Historical Palestine* (HP) should be equally shared, and Israel needs to do its part to demonstrate that it has genuine peace aspirations with its neighbours.

A proposal has been made, based on international law, to solve the water conflict between Israel and Palestine fairly and peacefully, where the population size is considered (Salem/Isaac 2007; Isaac/Salem 2007). Under this proposal, the annual renewable amount of water in HP, which is about 2086 MCM/yr, should be equally shared, whereby the Palestinians in the OPT would get 698 MCM/yr instead of the 238 MCM/yr presently allocated to them. The Israelis would get 1,388 MCM/yr instead of the 1,959 MCM/yr they currently use. Accordingly, the per capita share would be 241 m^3/yr for both Palestinians and Israelis, instead of the 81 m^3/yr and 254 m^3/yr, which are presently consumed per person, respectively, in the OPT and Israel (including the illegal Jewish settlements in the OPT). A joint management structure would have to be agreed upon by both sides for the monitoring and compliance with these quotas, to assure protection of the water resources and a periodic reallocation, based on climatic and demographic changes.

This proposal reflects equity, which is essential for sustaining peace, stability, security and development. It offers the best way for resolving the water rights issue. It introduces an integrated water management scheme that will expedite resolving water conflicts not only between the Israelis and the Palestinians, but also among the Israelis, Jordanians, Syrians and Lebanese. The proposal encourages regional and international water cooperation. Such an initiative for a fair solution of the water conflict between Israelis and Palestinians and in the Middle East needs cooperation with other international bodies, such as the *Quartet* (UN, EU, USA, and Russia).

During the Euro-Mediterranean Ministerial Conference on Water in 2008 at the Dead Sea, in Jordan, the ministers decided to identify the different stages and the most suitable framework needed to strengthen the coordination of existing networks of information and expertise on water in an independent and neutral way (EuroMed 2008a). The ministers avoided any reference to the water conflicts in the Middle East.

23.5.5 Red Sea-Dead Sea Conveyance Project and Climate Change

The Dead Sea is the lowest body of water on the Earth's surface (421 m below sea level). Its water has the highest salinity and density of sea water. Its shores are the natural borders of Historical Palestine (OPT and Israel) on the west, and of Jordan on the east (figures 23.1, 23.5).

The goal of the proposed *Conveyance between the Red Sea and the Dead Sea* (figure 23.6) is to restore the considerable decline of the Dead Sea water level that dropped since the 1970's by more than 25 m. This negative water balance is due to the diversion of water from the catchment area of the Dead Sea by Israel, Jordan, and Syria (Bromberg 2008). This results in a loss of huge amounts of water that should be discharged in the Dead Sea. It is also due to the water mismanagement policies and strategies of upstream countries, and due to Israeli and Jor-

danian pumping of the Dead Sea water into evaporation ponds to produce salt. Thus, the Dead Sea Basin, a unique natural heritage (habitat for wildlife), a global cultural, archaeological and religious site, a natural clinic for many illnesses, and a tourist resort, is threatened with disappearing (Salem 2009d).

During the *World Summit on Sustainable Development* (WSSD) in Johannesburg in 2002, Israel and Jordan announced their interest to save the Dead Sea by constructing the *Red Sea-Dead Sea Conveyance* (RSDSC) that would pipe water from the Red Sea to the Dead Sea. The proposed RSDSC would be located in the Wadi Araba (Arava) between the Gulf of Aqaba and the Dead Sea (figure 23.6). The RSDSC would be between 180 and 200 km long, and it would transfer two billion cubic metres of salt water per year (BCM/yr), of which about 850 million cubic metres (MCM/yr) would be desalinated, and the huge amounts of salt from the desalination process would be left behind and dumped into the Dead Sea (Salem 2009d).

The difference in the water level between the Red Sea and the Dead Sea of about 590 m would be used for power generation. This includes the natural difference of water levels between both seas (about 420 m) and the height (about 170 m) to which the Red Sea water must be pumped. The power would be used for running the desalination plant(s) as part of the project. Although the RSDSC project (figure 23.6) may have some positive impacts, it would form a real hazard due to its environmental impacts and its possible contributions to climate change.

The RSDSC project would be one of the biggest projects in the region to restore the Dead Sea, to generate power, to provide fresh water to neighbouring nations, to establish development projects, to build new cities and rehabilitation centres, to create jobs, and to activate the peace process in the region. However, critics on both sides of the Dead Sea argue that this project fails to address the root cause of the depletion of the Dead Sea, which may have serious negative side effects.

The RSDSC would cross the Araba (Arava) Valley, a highly active seismic area, where many earthquakes and a steady micro-seismic activity along the fault in the Jordan Rift Valley have been documented (El-Atrash/Salem/Isaac 2008; Salem 2009d). Geologists, seismologists and earthquake engineers predicted that (given the 1–10 mm annual slip rate) the Dead Sea fault could trigger fatal earthquakes of 7.0 in magnitude every 200 years (Klinger/Avouac/Dorbath/Abu Karaki/Tisnerat 2000; El-Atrash/Salem/Isaac 2008; Salem 2009d), where the hydropower facilities and the desalination plant(s) would be highly vulnerable. Some argue that the large amount of explosives needed for the construction of the RSDSC and the large quantities of sea water that will be transported through the RSDSC could lead to strong seismic activities, as the Earth crust in the project's area is thinner than elsewhere. Furthermore, hundreds of sinkholes have already emerged along the shores of the Dead Sea and, hence, large areas are subsiding (Closson 2005; Salem 2009d).

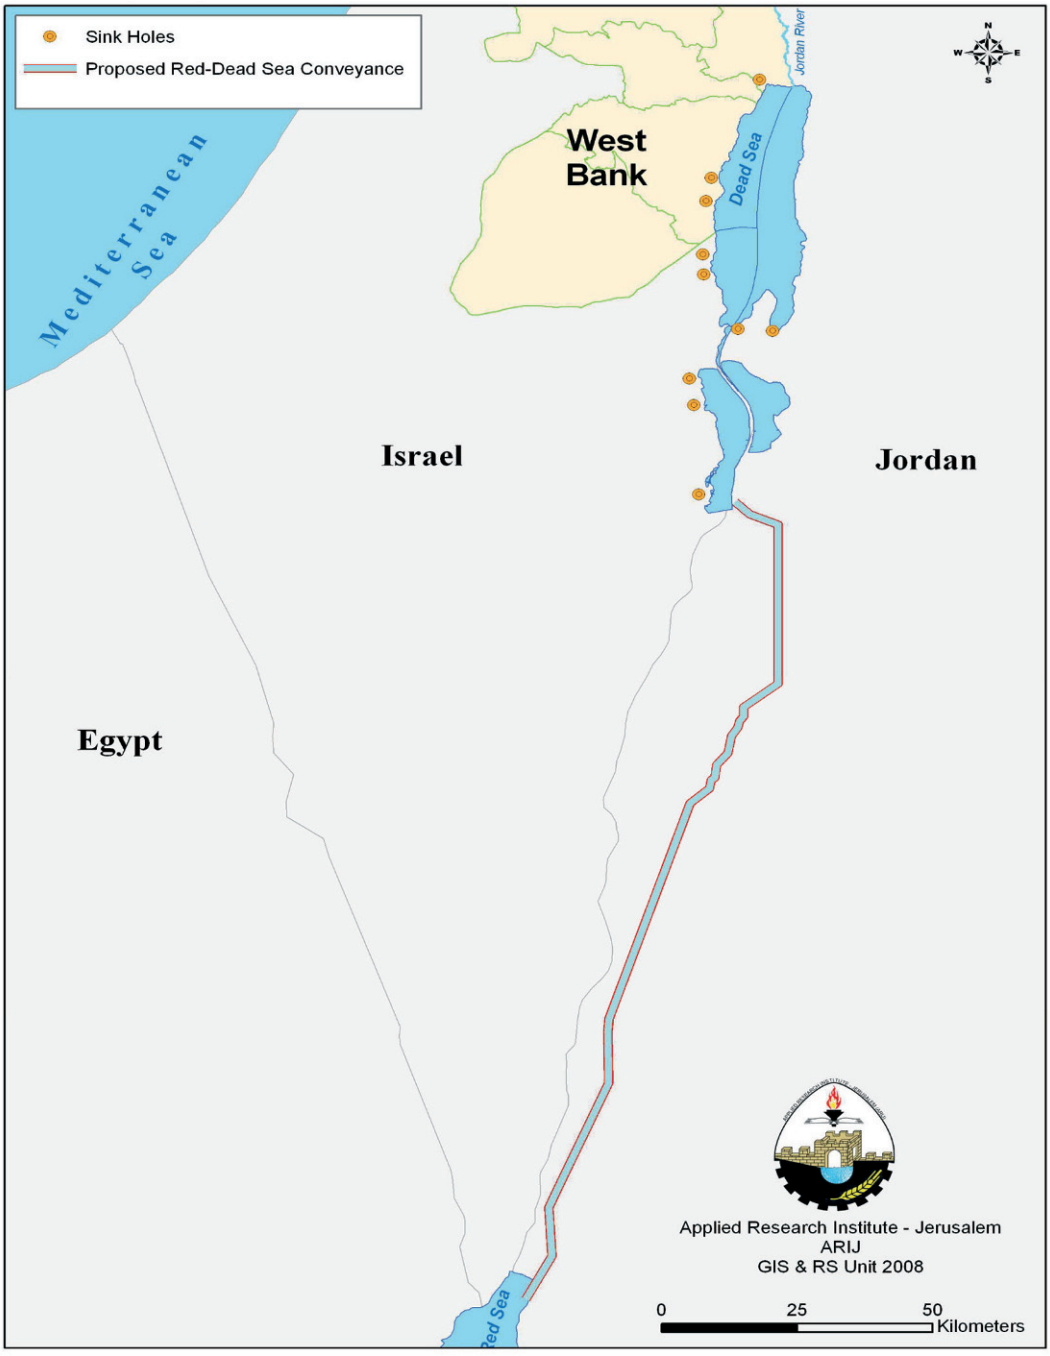
Besides these potential seismic hazards, the huge intakes of saline water from the Red Sea may have unwanted and unpredicted implications for the marine ecosystem of the Red Sea that has some of the most beautiful coral reefs in the world. The RSDSC project will place the fragile coral reefs of the Jordanian city of Aqaba and the Israeli city of Eilat at risk (Bromberg 2008). The Dead Sea itself is already a severely disturbed ecosystem due to anthropogenic interventions in its water balance, and, thus, this mega project would have negative impacts on the fragile ecosystem of the Dead Sea.

Mixing the waters of the Red Sea and the Dead Sea would have considerable negative environmental impacts that would affect the chemical and biological characteristics of both seas, and would affect tourism and the salt industries. Experiments by a team of scientists from the Geological Survey of Israel have shown that mixing the water from both seas could lead to blooms of algae, to precipitation of gypsum, and to turning the water red (Gavrieli/Bein/Oren 2005; Shafy 2007; Salem 2009d). Environmentalists argued that the waters of the Red and Dead Seas may not mix well and may damage the fragile ecosystem of the Dead Sea, and could kill the delicate micro-organisms of the Dead Sea and harm its appeal to tourists.

The inflow of sea water and the brine from desalination into the Dead Sea will have major impacts on the Dead Sea's limnology, geochemistry and biology. During the filling stage, relatively diluted surface water may emerge and the rate of evaporation may increase. Dilution of the surface water may result in microbial blooming of unknown duration. Once the target level would be reached, the inflow would be outbalanced by evaporation, and salinity of the surface water would increase, due to the accumulation of salt.

Gidon Bromberg of *Friends of the Earth – Middle East* (FoEME) warned that mixing water from the Red Sea with the unique chemical soup of the Dead Sea could create a natural disaster:

Figure 23.6: The Proposed Red Sea-Dead Sea Conveyance (RSDSC). **Source:** El-Atrash, Salem and Isaac (2008).



The Dead Sea's [natural] mix of bromide, potash, magnesium and salt is like no other body of water on the planet. By bringing in [the Dead Sea], the marine [Red Sea] water, this composition will be changed. There is concern about algae growth and we could see the sea change from deep blue to red and brown and the different waters could separate (TimesOnLine, 13 September 2006).

The proposed RSDSC would cross the *Eastern Aquifer System* (EAS), what may increase the probability of a groundwater contamination due to leakage or sudden overflows of the non-treated sea water with high saltwater concentrations to be transported through the RSDSC.

Some environmentalists claim that the RSDSC is driven by the Israeli and Jordanian construction com-

panies' interest in such a mega project. "The RSDSC is not the only solution to the water problem, neither is it going to undo the mismanagement of the Jordan's water resources", Dureid Mahasneh, the Secretary General of the Jordan Valley Authority, explained. He added, "Re-exporting water in the form of watermelons and tomatoes is part of the Jordan's mismanagement that also has to stop" (El-Shamayleh 2007). Gidon Bromberg (2008) suggested alternatives for the RSDSC Project:

> Our vision is based on water sharing, water conservation technologies, sustainable agriculture and sustainable tourism. The Peres [Israeli President Shimon Peres]-Tshuva [Israeli billionaire Yitzhak Tshuva]-World Bank (WB) vision may lead to ecological disaster.

According to the *World Wildlife Foundation* (WWF), extracting salt from sea water to make it drinkable is the wrong way to handle global water shortages that could also exacerbate climate change (WWF 2007), as desalination uses large amounts of energy, emits greenhouse gases, and destroys marine life in some coastal areas. Pumping two *billion cubic metres* (BCM) of saline water out of the Red Sea could alter water temperatures in the Red Sea Gulf. The rate of building these desalination plants seems to be growing exponentially. If that continues, greenhouse gas emissions would accelerate and increase climate change dramatically (WWF 2007).

It is argued that the construction of huge desalination plants on both sides of the proposed RSDSC would produce huge amounts of CO_2 and other GHG emissions that would contribute to a temperature increase in the region above the present high temperatures that usually reach up to 50°C during the summer months. The higher evaporation rates could result in greater humidity. All these changes, possibly resulting from desalination plants and the huge RSDSC project, may contribute to a change in the regional climate that would further deteriorate the present conditions in the region with water scarcity, water, air and soil pollution, and damage to the ecosystems.

23.5.6 Deforestation, Desertification, and Land Degradation: Causes and Effects on Climate Change

Land-use change is related to climate change both as a cause for and as a possible effect of climate change (Dale 1997). Trees are a carbon sink. Thus, cutting millions of trees (as Israel does in the OPT) reduces the potential for absorbing CO_2. Desertification and land degradation may contribute to changes in the local climate and may become irreversible due to climate change.

23.5.6.1 Deforestation

Deforestation causes up to 30 per cent of global GHG emissions (Johnson 2008). Due to the deforestation and the land-use changes in the Amazon, Brazil has become a major GHG emitter (Manneh 2008). Accordingly, some groups have suggested that stopping deforestation should be included in the post 2012-Kyoto Climate Change Agreement (GCA 2007; Hmaidan 2008).

According to the *Arab Group for the Protection of Nature* (APN), Israel has cut about 1.4 million trees in the OPT between 2001 and 2005 (APN 2005), of which 1.1 million disappeared between 2001 and 2003, including 263,000 olive trees, 356,000 citrus trees, 113,000 forest trees, 69,000 stone fruit trees, 51,000 grape vines, 18,000 banana trees, 23,000 palm trees, and 251,471 other trees (Abdelrahman 2005). For example, to build the Jewish settlement of Jabal Abu Ghnaim (or Har Homa), Israel has cut more than 60,000 pine trees between 1997 and 2007 (figure 23.7).

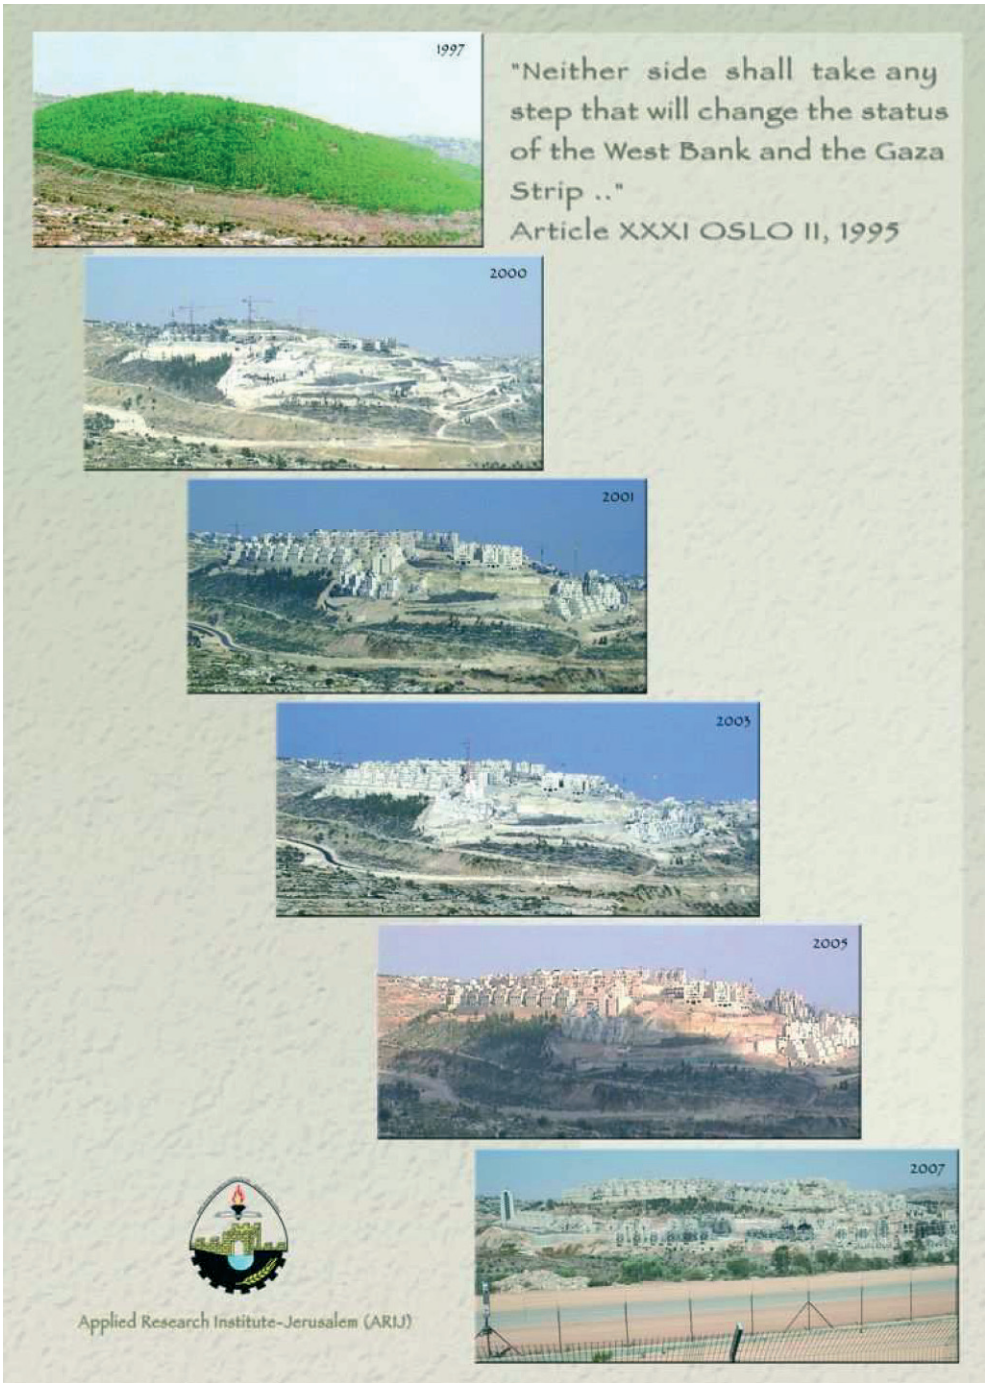
23.5.6.2 Desertification

Land degradation and desertification have also contributed to changes in the climate of the OPT, whose biodiversity has seriously declined since 1967 (Salem 2008a), on which no accurate figures are available. According to a study by CAMRE, ACSAD and UNEP (2004), the desertification in Palestine is mainly due to the practices and activities of the Israeli occupation authorities. Other factors include the overexploitation of the water resources, confiscation of the agricultural land, and the increase of the level of salinity. These factors have led to the decrease of agricultural production, drying up of water resources, disappearance of wildlife, deterioration of rangelands, and encroachment of sand dunes (UNEP 2004). The Palestinian lands suffer from the consequences of desertification that resulted in a decrease in the fertility of arable lands.

23.5.6.3 Land (Soil) Degradation

Soils are degraded due to many factors, including erosion, acidication and salinization. In the OPT, the major causes are soil erosion from water and wind, and *in situ* soil deterioration, due to chemical and physical soil degradation. Incorrect agricultural management

Figure 23.7: The Israeli Settlement of Jabal Abu Ghneim (Har Homa) in the West Bank, as developed in a 10-year period (1997-2007): **Source:** ARIJ (2007, 2008).



due to water scarcity, uncontrolled domestic and industrial dumping sites, and the heavy use of fertilizers and pesticides are important reasons behind the *in situ* soil deterioration in the West Bank (Salem 2008a). The Israeli occupation has increased the pressure on the land that Palestinians retain access to, encouraging overgrazing and intensive farming practices, besides creating a difficult environment for planning and implementing sustainable land-management schemes.

Anthropogenic soil degradation in the OPT includes political and socio-economic factors and exist-

ing land-use practices, whereas the natural causes include changes in precipitation intensity and temperatures. These natural factors are a response to air and water transport of soil particles. However, the anthropogenic factors are more tangible due to Israeli activities in the OPT that have contributed to the destruction of the Palestinian environment (Twite 2003; Salem 2009c). "There is no Palestinian environmental problem without bearing on Israelis, and no Israeli problem without consequences for Palestinians" (Twite 1998).

The misuse of arable lands by Palestinians has led to the destruction of the natural land's cover that stabilizes the soil cover. The prevailing rain-fed agriculture in the dry and semi-dry regions in the OPT has contributed to the destabilization of the soil cover, which causes deterioration of the soil particles. This has led to a decline in the fertility rates of arable lands, where the affected particles lost much of their ability to absorb the rainfall, leaving them susceptible to percolate to the underneath soil layers. The cultivation of lands in dry periods has made the surface soil more susceptible to air erosion. The loss of balance between the major elements of the surrounding environment (plants, animals, soils, water, etc.), due to the unsustainable use of natural resources by humans, has caused decreases in the quality of soils.

23.5.7 Reducing Climate Change Impacts with Renewable Energy

Most of the electrical energy consumed by Palestinians in the OPT is imported from Israel through the *Jerusalem District Electricity Company* (JDEC). There is one electric power plant in the Gaza Strip, which has been repeatedly damaged through Israeli air strikes and land incursions. This power plant generates about 40 per cent of the Gaza Strip's electricity, and the rest is imported from Israel and Egypt. While the percentage of households in the OPT which are connected to the *Public Electricity Network* (PEN) reached 99.4 per cent in January 2005 (PCBS 2006), there are still many localities with 10,000's of Palestinians without electricity as some localities are far from the PEN and connecting them would be costly; and as it is difficult for some localities to get electricity because they are close to Israeli settlements or military bases.

Compared with other Middle Eastern countries, the cost of electricity in the OPT is high and higher than in Israel (Salem 2007). The cost for industrial and commercial purposes is higher than for domestic use. The electricity cost for domestic use is about 14 US cent/kwh, while it is about 18 US cent/kwh for industrial and commercial uses according to the JDEC's tariff of 2007.

The average electricity consumption per household was 227 kwh in July 2006, 264 kwh in July 2005, but 380 kwh in July 1999 (PCBS 2007). It reached 332 kwh in the middle of the West Bank and did not exceed 196 kwh in the north. The average was about 240 kwh in urban localities, 190 kwh in rural areas, and 230 kwh in refugee camps. The overall average per capita electricity consumption in the OPT in July 2006 was 35.8 kwh (PCBS 2007).

The OPT is behind many other countries in using *Renewable Energy Sources* (RES), such as solar, wind, and biogas. Research projects are needed to pursue these objectives (Salem 2008d):

- to assess the opportunities for cost-effective *Renewable Energy Technologies* (RET) to be primarily used in rural areas and remote villages in the OPT which have no electricity;
- to assess their effectiveness through better knowledge of social and end-user behaviour;
- to assess the society's acceptability for clean and efficient RET;
- to measure the impact of electrification on socio-economic development in rural areas; and
- to enable parts of the society to widen their knowledge and expertise on RET, which will help Palestinians to build capacities and improve their way of life.

By embracing the RES the Palestinian society may move towards a cleaner environment. This could be done in collaboration with local, regional and international academic, industrial and other institutions. This is particularly important due to the high prices of fossil fuels many Palestinians cannot afford due to the unstable political and economic situation in the OPT.

Research projects on RES in the OPT will contribute to partnerships with different stakeholders, particularly the EU within the *Union for the Mediterranean* (UM). On 3–4 November 2008, ministers from *European and MENA* countries agreed in Marseille on launching a *Mediterranean Solar Plan* (MSP) and a *Euro-Mediterranean Climate Change Framework* (EMCCF), in support of regional efforts to combat climate change (EuroMed 2008b). Such an initiative could become a cornerstone for a clean environment and for programmes that will encourage using RES in the OPT. This will enhance the multiple relationships (economical, political, social, environmental, etc.)

between the OPT and the EU and other international organizations (Salem 2008d).

As the MENA region has increasingly been affected by the impacts of climate change, Palestinian policy-makers should be highly concerned about its impacts on the environment in Palestine. As this region has been negatively affected by rapid variations in temperatures, rates of low precipitation and high evaporation, hot summers, cold winters, and by desertification and deforestation, using RES should become an excellent option to gradually eliminate the dependence of the Palestinian people on fossil fuels (Salem 2008d).

Developing RET, particularly solar and wind technologies, would enable Palestinians to produce their own electricity. This is particularly important, as this system would require low maintenance and could be used for long periods of time, and would create jobs. It would enable Palestinians to gradually reduce their dependence on imports of fuels and electricity from Israel. As some Palestinian localities still have no access to the *Regional Electricity Grid* (REG), this has forced some Palestinians to leave their homes and move to other places that have electricity. Thus, international donors should support the Palestinians in using RET to help them overcome the hardships they have been facing for a long time.

23.6 Conclusions

Israel, the OPT, and Jordan have been and will be affected by climate change impacts. According to UNEP (2003): "The Middle East is a meeting point of many escalating environmental threats. This is particularly the case in the Occupied Palestinian Territories. Long-term environmental degradation has occurred over recent decades. In an already densely populated area, there are additional problems of scarcity of water resources and land, rapid population growth, a long-lasting refugee situation, climate change, desertification, and land degradation."

As climate-induced resource scarcity could escalate existing conflicts, violence and political turmoil, the Euro-Mediterranean Partnership suggested integrating the climate change dimension into water resource management (EuroMed 2008c). Unless adequate and urgent actions are taken to reduce vulnerability to climate change, the region will be exposed to large economic and social risks, which will put further pressures on groundwater that has been used beyond the aquifers' recharge potential (EuroMed 2008a, 2008b, 2008c).

Besides the political instability, the impacts of climate change will intensify in the Eastern Mediterranean, with more pressure on the OPT, what is due to the following reasons:

- Water scarcity contributes to deteriorating health and socio-economic conditions besides high rates of poverty and unemployment.
- As precipitation has been projected to decline further, more conflicts may occur in the Middle East besides the existing tensions and past wars.
- Geopolitics has so far prevented joint initiatives in addressing regional climate change impacts. The Israeli Segregation Wall (ISW) and settlements in the OPT have increased the pressure on the limited natural resources that may have impact on local changes in climate. These activities have resulted in deforestation, land degradation, desertification, a decline or loss of biodiversity and of water resources.
- The possible construction of mega projects, such as the Red Sea-Dead Sea Conveyance will cause huge ecological and environmental damage that may have impact on climate change.
- Given its high population density and growth, the Gaza Strip is extremely vulnerable to climate change impacts, due to sea-level rise, sea-water intrusion and water shortages, besides many other socio-political and socio-economic problems. Under present political conditions adaptation to combat climate change in the Gaza Strip is not feasible, and, therefore, mitigation measures are urgently needed.

In the Eastern Mediterranean region, political circumstances have been the main cause that efforts to address the causes and impacts of climate change are widely lacking (Brauch 2009b). As long as a peaceful resolution of the Middle East conflict is missing, the Eastern Mediterranean region will severely suffer from climate change impacts. Technical initiatives were suggested to develop and use renewable energy technologies in the region, especially solar energy.

On 22 May 2008, Prince Hassan Bin Talal of Jordan, in a speech to the *United Nations General Assembly*, addressed the linkages among global instability, climate change, and human security (Bin Talal 2008):

> Rising temperatures and extreme climate patterns are also having an enormous impact on human security. Many people, especially the poor in some of the world's

most crowded and marginally productive areas are affected by: a lack of water for drinking and irrigation; a decline in agricultural production; increased resource scarcity; loss of supportive wildlife; widespread diseases from mosquitoes and other pests; declining health; economic losses caused by hurricanes, tornadoes and cyclones; volatility in economic output and trade; and increasing poverty.

The harmful impact of these climate extremes on human livelihoods and living conditions, combined with heightened competition for scarce resources, has triggered disputes over territory, food and water supplies, social and cultural traditions, and tribal and religious differences. Fundamental and unresolved issues of territoriality, identity and movement of peoples lead to sectarian and ethnic violence, armed conflict, mass migration and the spread of infectious diseases. ... The health, well-being and rights of those who are forced to leave their homes and communities through external disruptions must be given particular attention. We usually think of migrants and refugees fleeing political conflict, but increasingly there are also victims of the menacing effects of global warming. We are currently witnessing many instances of this kind of temperature-driven civil strife and social displacement in parts of Central Asia, the Middle East, Africa and Latin America.

24 Progressive Development of the Water Resources of Israel and Palestine to Mitigate the Negative Impact of Global Warming

Arie S. Issar

24.1 Introduction[1]

For the last three decades, the author has been investigating the impact of climate changes on the hydrological cycle, past, present and future, worldwide, in the Middle East and in particular on the water resources of the Israeli and Palestinian territories.[2] These investigations have been based on analyses of the impact of climate change on the hydrological cycle and human settlements, from the time human beings arrived in the Middle East from Africa, to the present. The general conclusion was that warm periods in the past caused droughts and famine. As the present warming process is gaining momentum beyond past records, the impact may surpass that of the past, namely, its negative effects may mean a severe reduction in the water resources of these countries.

As the standard of living rises in Israel and hopefully, will also rise in the Palestinian and neighbouring populations, the demand for water per capita will also increase. These trends raise the question of whether the conventional policy of 'sustainable development' will allow for the increasing demand for water in this region.[3] In other words, the question is whether this ideal goal can be maintained in a region undergoing a simultaneous process of diminishing natural water resources and increasing demand. As the answer is negative, the question then becomes: Should widespread and profound changes in the natural environment be effected in order to avoid a crisis in the water supply system? Such changes, among others, are the drying up of the summer flow of springs, by pumping and lowering the groundwater table, in order to prepare an empty volume of storage for recharge by winter rains; the reuse of reclaimed sewage for irrigation as well as recharge to ground water, thereby reducing the quality of the water in the sub-surface; the introduction of desalination projects, of either sea water or brackish ground water, for purposes additional to irrigation; the mining of fossil water, etc.

These actions, which are indispensable for sustaining standards of living, if not the basic existence of human societies in this region which is in the process of drying up, interfere with the natural hydrologic systems. Nevertheless, this interference should be carried out in the framework of a regional long-term master plan. The need for such a plan led the author to suggest a new conceptual model, 'progressive development', as a replacement for the sustainable development model in regions that are drying up.

24.1.1 The Progressive Development Model Should Replace Sustainable Development in Regions Where Water Resources Are Drying Up

The principle aims of 'progressive development' are to bring about a gradual change in natural and human environments that will enable survival in the face of deteriorating climatic conditions, and to guarantee progress towards safer and higher standards of living. The most important aspect of the conceptual model of 'progressive development' is its multi-dimensional holistic approach, which aims to manage the long-term impact of each of the above-mentioned steps on

1 The author would like to thank Prof. Yehuda Bachmat, the former head of the Hydrological Service of Israel, for his corrections, remarks and suggestions. The English editing by Ms. Marcia Ruth is gratefully acknowledged. After introducing the changes suggested by the reviewers, the English was re-edited by Camille Vainstein and is hereby acknowledged.

3 The Brundtland Commission (1987) report on *Our Common Future* defines sustainable development as development that meets the needs of the present without compromising the ability of future generations to meet their own needs.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_24, © Springer-Verlag Berlin Heidelberg 2011

water resources and on natural and human environments. In the first stage, such management will involve planning the steps needed to ensure water supply to a growing population while helping it progress towards a higher standard of living, despite the drying-up of natural water resources. This progress is dependent on the promotion of standards of education for both male and female populations, from the very young to adolescents, from kindergarten to the university level, in the technical as well as natural sciences.

Progressive development will not be restricted, however, to technical and general education. It will simultaneously target the full development of all natural water resources in the region described in the introduction, the most negative action from a sustainable development point of view being the exploitation of one-time reserves, by either allowing the controlled advance of the sea or connate water interface, or utilizing fossil water reserves.

The stages for fulfilling these aims are the following:

1. On the basis of a preliminary survey, prepare a regional development plan, starting with the exploitation of the most available and low-cost water resources, and progressing, stage by stage, to more costly resources and advanced methods of exploitation.
2. Construct an infra-structure consisting of an extension service and schooling for the population involved in the project, covering technical as well as cultural aspects.
3. Promote demonstration projects by the local inhabitants, backed by an advisory team.
4. Promote the settling of the nomad population by offering them a piece of land and a water resource on which they can continue raising their livestock while ensuring their water and food supply without having to move from one place to another.
5. Move to more advanced and sophisticated stages once the basic supply of water and food has been guaranteed.
6. Promote local industry for the supply of equipment, spare parts, etc.

These steps will guarantee that while the one-time reserves are being consumed, the economy of the region is progressing to a level that will enable the construction of more sophisticated projects in order to produce new income resources to replace the consumed ones. One such project might be the desalination of brackish water existing below the fresh-water fossil aquifers.

Generally speaking, projects should be designed and carried out as integral components of a comprehensive plan of regional development preceded by research into the hydrology, soil and ecology of the region, and followed up by monitoring and re-assessment procedures. Special emphasis should be placed on monitoring programmes as a part of management planning to avoid irreversible salination damage to the soil and water resources (Issar 2008, 2009).

24.2 Impact of Global Warming on Water Resources of the Middle East

In connection with the international effort to evaluate the impact of the global climate change on the hydrological cycle of the world, the author was invited in 1981 by the Division of Water Sciences of UNESCO to join a working group set up in the framework of the *International Hydrologic Programme Project* (IHP IIc). Its main objective was to assess 'the impact of climate variations on water management systems and related socio-economic systems'. Based on his previous investigations, the author suggested making use of all available data on past climate changes, proxy as well as historical documents, available in the Middle East, and investigating these changes' impact on the availability of water resources in this region. The results could then be used to correlate such impacts with changes in other regions on a global scale and later, to forecast the future, based on the assumption that the past is the key to the future.

The suggestion of a worldwide survey, starting with an investigation of the Middle East, was adopted and sponsored by UNESCO. It involved a survey of available data, which included visits to research centres all over the world.[4] This survey confirmed the working hypothesis that pre-historic as well as historical climate changes observed in the Middle East can be correlated with major changes in various regions of the globe. The correlations were presented in a report

4 This survey included the Institute of Geography of the Chinese Academy of Science in Beijing, the Department of Geography of the Universities of Tokyo and Tsukuba in Japan, the University of Arizona at Tucson, the Free University of Amsterdam, as well as the Departments of Geology at the University of Madrid and at the University of Perugia, Italy.

to UNESCO (Issar 1995, 2003). The author's conclusions were presented at two international conferences in Heraklion, Crete (Greece) sponsored by NATO (Angelakis/Issar 1996) and in Sede Boker (Israel) sponsored by UNESCO (Issar/Brown 1998).

A more focused advanced study was carried out on the influence of climate changes on water resources throughout history and thus on the environment of the Middle East. The emphasis on this region took into consideration that it is the root of Western Civilization and rich in archaeological remains and ancient documentation. This research was initially based on new proxy data, such as Dead Sea levels, the isotopic composition of stalagmite rings of the Soreq Cave near Jerusalem, among others, pollen ratios in the Sea of Galilee lake-bottom deposits, and humidity data in the drainage basin of Lake Van, Turkey. The major conclusion was that rather severe climate changes had indeed influenced the proto-history and history of the region. During cold periods, the climates were humid and the desert flourished and was settled. The warm periods, on the other hand, spelled out dryness, desertification, and the migration of populations from regions that were drying up into the fertile belts along the big rivers (Issar/Zohar 2004, 2007, 2007a).

Combining the results of these investigations, the forecast can be made that global change will result in a decline in the average precipitation in the Middle East, and most probably will lead to years of drought.[5] These will have a negative effect on the economy, which – in many countries of the region – still very much depends on rain-fed agriculture. It is beyond the scope of this chapter to discuss the reasons for the phases of global warming and cooling in the past. Nevertheless, it is important to emphasize that the human factor has been negligible for most, if not all desertification phenomena in the Middle East, which were a result of warm climates.

At present the world, including the Middle East, is undergoing a process of warming. The IPCC (2007) concluded that global warming is accelerating due to human activity, which results in increasing the production of *greenhouse gases* (GHG) due to the burning of fossil fuels. These gases include *carbon dioxide* (CO_2), the major GHG that has risen from 279 parts per million (ppm) in the atmosphere in the pre-industrial period (1750) to 384 ppm in 2007. Simultaneously, a longer term (from 1900 to 2005) declining precipitation trend has been observed in the semi-arid regions of the Sahel and in the Mediterranean-type climate of the Mediterranean region and southern Africa. Linked to higher temperatures, more intense and longer periods of drought have been observed, particularly in the tropics and subtropics. Computerized models predict that even if the emission of GHG and other contributors to the warming process were held constant at the level of the year 2000, warming would continue, due to the slow reaction of the oceans, in the next two decades at a rate of 0.1 °C per decade. A decrease in precipitation of up to 20 per cent is likely to occur in most subtropical regions. In general, mid-range scenarios predict severe droughts and floods, more intense hurricanes and cyclones, decreasing fresh-water and food supplies, increasing spread of diseases, and rising sea levels that could displace hundreds of millions of people worldwide. According to records of the *World Meteorological Organization* (WMO),[6] the year 2006 was estimated to be the sixth warmest year since observations started in 1880. Thus, the predictions which were based on the proxy data of the past have been confirmed by present-day observations (IPCC 2007, 2007a, 2007b, 2007c[7]).

Recent computerized mathematical modelling of future precipitation in the Eastern Mediterranean due climate warming, by Alpert, Krichak, Shafir, Haim and Osetinsky (2008) and Kitoh, Yatagai and Alpert (2008), based on the observation that the average temperature over the Mediterranean area has increased by 1.5 to 4 °C during the past 100 years, predict that temperatures towards the end of the 21st century may increase by about 4 to 6 °C over northern Israel. Processing of climatic data shows that precipitation over most of the Mediterranean region has followed a dominant negative trend during the past 50 years and that there is a tendency toward extreme events. The models predict that the standard deviation of the average annual precipitation will continue to be high, showing a trend toward both drier and wetter years in the future. The impact of these forecasts on the water resources of the Middle East will be a series of dry years followed by a series of wet

5 This does not apply to Egypt, which gets its water from the Nile that is fed by rains coming from the Indian Ocean.

6 See: "2006 Was the Sixth Warmest Year Ever", in: *ENS (Environment News Service)* staff report, 3 January 2007.

7 See Israel's *First National Communication on Climate Change* (2000). In this present author's opinion this report fails to mention the impact of climate changes on the water resources of Israel during history.

years. Such a trend necessitates the storing of water, which requires adequate storage capacity. This issue is discussed further on.

In ancient periods, the prediction of changes from good to bad years led to the storage of food. As the consumption of water was mainly for drinking, the storage of water for dry years was not vital, except for the watering of herds. However, today the problem is not only food but water for many other purposes beyond the supply for drinking and domestic use. In a semi-arid region like the Middle East, the problem extends to water needed for irrigation. The negative impact of such a deficiency due to decreasing precipitation in this region will become more severe as the population, particularly the Palestinian population, continues to grow at a high rate. This is due to modern medicine, which has reduced infant mortality on the one hand, and increased life expectancy on the other.

This chapter focuses on measures to mitigate the impact of diminishing water resources resulting from global climate change. This will be considered in the framework of the conceptual model of 'progressive development', while the population increase will be dealt with as an important but secondary factor to the diminishing resources.

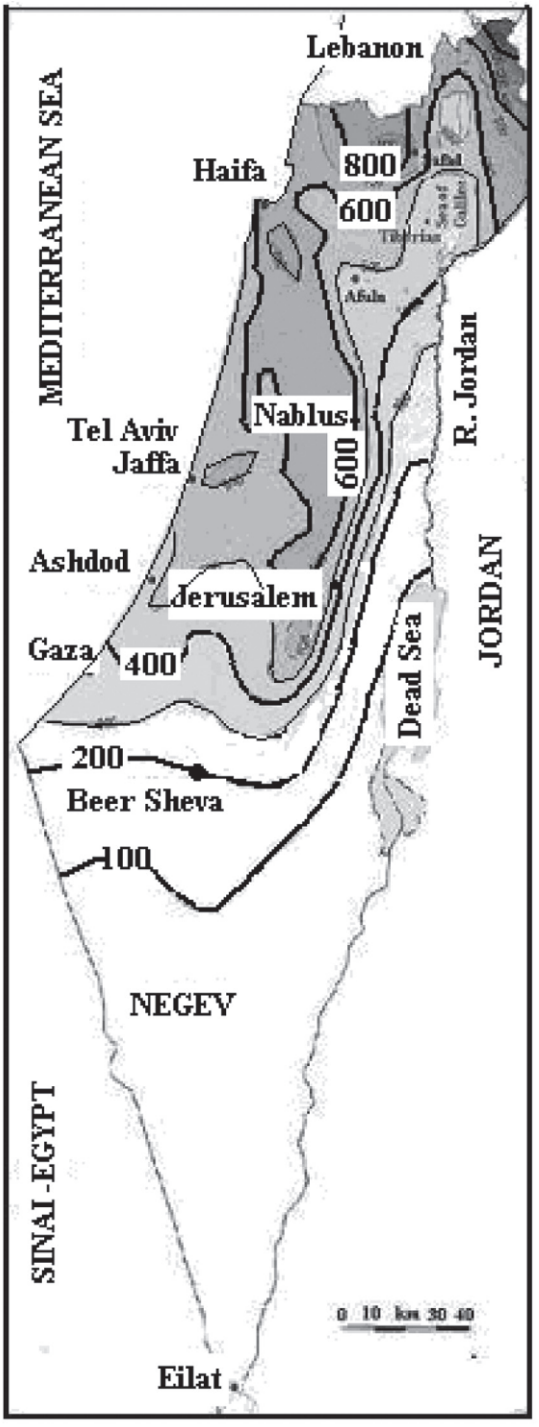
24.3 The Present State of Water Resources

24.3.1 Water Resources of Israel

The development of the water resources in Israel has been dictated by various factors, the most important of which is its geographical location along the margin of the Arabian-Saharan desert belt: as a consequence, its southern part is arid, while its northern part is rather humid (figure 24.1) but is susceptible to abrupt variations in the amount of precipitation from years of excessive precipitation to years of severe drought. Moreover, the climate is seasonal. Thus, precipitation is limited to the colder winter season from November to February, while the summer months are hot and dry. The second factor has been the need to meet the demand of a rapidly growing population due to immigration and natural growth since the establishment of the State of Israel in 1948.

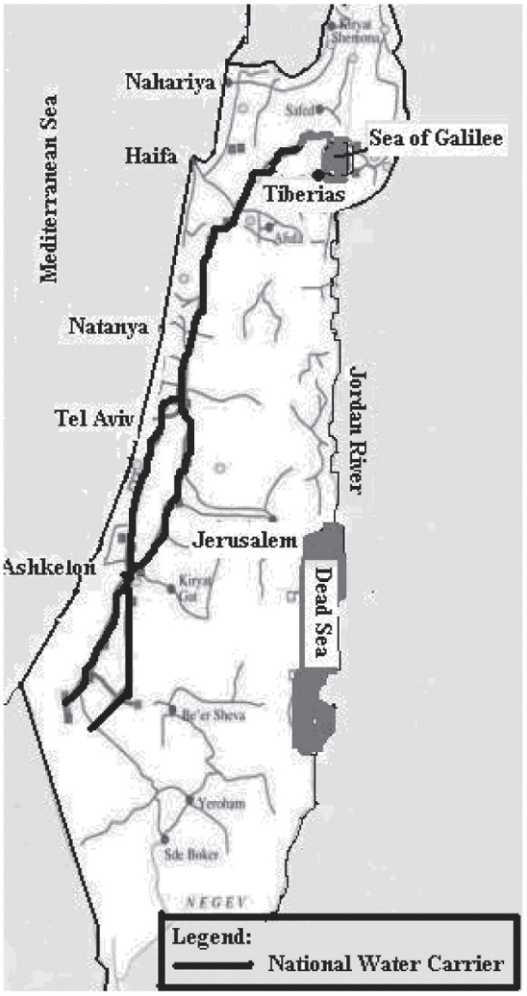
While precipitation is abundant in the northern part of Israel, land resources are rather limited there. On the other hand, there is a relative abundance of land in the south where precipitation is low. Thus one

Figure 24.1: Precipitation map of Israel and Palestine. **Source:** Based on the map in the Israel Atlas (1995: 27).



of the first endeavours undertaken by the government of Israel, immediately after the state was established, was to reduce the natural water deficiency in its southern part. This was done, in the 1950's, by planning

Figure 24.2: National Water Carrier, Israel. **Source:** Based on Mekorot's Major Water Plants Map, Mekorot, Israel National Water Co.



and constructing the National Water Carrier, which brought water from the Sea of Galilee to the Negev – the southern arid part of Israel (figure 24.2).

At the same time a National Water Law was adopted (1959) which declared that "all water resources in the country are [in the] public domain, are owned by the state for the benefit of the people and the development of the country." Prior to its approval, the law recognized the water rights of private people and organizations, and it therefore allowed them to use the quantities they were already using.

The total quantity of the annual natural replenishment of the water resources of Israel and the Palestinian territories amounts to an average 1,555 *million cubic metres* (MCM), of which 650 MCM come from the Sea of Galilee catchment areas, about 135 MCM from the Cretaceous carbonate aquifers of the Western Galilee and Carmel mountains, and about 450 MCM from the aquifers building the central part of the country. To the Coastal Plain aquifer, built of Quaternary age sandstones, about 250 MCM is recharged annually. The mean annual replenishment of water of the Negev is about 70 MCM.

In addition to the supply from the National Water Carrier, Israel gets its supply from the western watershed of the Central Mountain aquifer and from the Coastal Plain aquifer. The western Central Mountain aquifer is also called The Yarkon-Taninim basin due to the Yarkon River, fed by the springs of Rosh Haayin in the central part of the basin, and the Taninim stream, fed by the Taninim Springs in the northern part of the basin. The recharge zone of the Rosh Haayin-Yarkon system extends over an area of about 1,400 km^3. In historical times, the springs emerged over an area of 25 hectares and their annual discharge was about 220 MCM. Due to the big storage capacity of the aquifer, the hydrograph of the springs was rather flat, ranging from about 15 MCM/month during the winter months to 9 MCM/month during the summer. In the early 1950s, there was a need to enlarge the supply of water to the new and old urban centres of central Israel as well as to the new settlements of the Jewish refugees from North Africa, Iraq and Syria in the arid lands of the northern Negev. This led to the decision to make full use of the water of these springs for urban supply as well as for irrigation of the lands, which before the War of Independence were partly occupied by Arab settlements living mainly on rain-fed agriculture and partly desolate sand dunes.

This task was accomplished by drilling a series of wells in the central western foothills area of the Judean mountains. A pipeline was laid parallel to these to convey the water to the Negev. The project was launched in 1952 and started to function in 1955. It enabled the establishment of about 75 settlements, altogether 6,000 farms irrigating about 15,000 hectares. Part of the economy of the settlers in this region was based on rain-fed field crops, yet these failed every few years due to the occurrence of drought. Later on this project was integrated into the above-mentioned National Water Plan of Israel. The pumping brought about a cessation of the Yarkon springs and the drying up of the Yarkon River, especially due to a few dry years during the late 1950's and early 1960's. It was only in 1964, which was a good year for rain, that the springs recuperated and the river flowed. Nevertheless, because of the intense urbanization of the entire region, which forms the northern suburbs of Tel Aviv,

the quality of the Yarkon River water deteriorated, due to the drying up of the springs and uncontrolled flow of sewage. In 1988, the Yarkon River Authority was established. The entire area from the springs to the sea became a national park, the rehabilitation of which depended on fresh water coming from various sources: either the springs' flow in wet years or the National Water Carrier, or reclaimed sewage and warm sea water discharged from an electrical power station. The yield of the Taninim springs, originally about 100 MCM per year (Y) of brackish water, declined to about 10 MCM/Y.

The Coastal Plain aquifer is recharged by rain falling on its outcrops and to some extent by floods coming from the mountains. It is also fed by a return flow from irrigation and leakage from sewage systems. The annual natural recharge (including the flow from the east), as calculated by the Hydrological Service of Israel, amounts to an average of about 250 MCM (with a standard deviation of 68 MCM). About 30 MCM is recharged annually due to infiltration from irrigation and about 140 MCM/Y is recharged artificially, 87 per cent of which is reclaimed sewage, and about 30 MCM/Y flows into the aquifer from the east. An average of 420 MCM is pumped out annually and an average 30 MCM flows to the sea (Hydrological Survey of Israel 2007). The average salinity of the water in this aquifer in Israel has risen from 100 mg Cl /l during the 1930's to 205 mg Cl /l at present, and is rising at a rate of 2 mg/l annually. This is mainly due to return flow from irrigation, recharge by reclaimed sewage and inflow of brackish ground water from the east. Nitrates have increased from an average of 10 mg/l in the 1930's to about 62 mg/l at present, and are rising at an annual rate of 0.7 mg/l.

The total annual consumption of water in Israel reached 1,959 MCM in 2006, of which 737 MCM was for domestic use, about 114 MCM was used by the industry and a total 1,128 MCM was used by the agricultural sector. Due to innovative methods of irrigation and advanced agronomy, about 50 per cent of this quantity was second-grade water, either reclaimed sewage or brackish water (Shani 2008).

As the average annual replenishment is about 1.5 *billion cubic metres* (BCM), while the annual total consumption is about 2 BCM, the annual deficit is 500 MCM. Moreover, there is an accumulated deficit of more than 2 BCM. In addition to the quantitative deficit, there is an ongoing process of deterioration of water quality. In order to deal with the deficit and deterioration, a national endeavour was undertaken to develop second-grade water sources, namely reclaiming waste water as well as intercepting runoff, mainly for artificial recharge. In 2005, desalination of brackish and sea water began. The quantities of desalinized brackish and sea water in Israel in 2008 reached 145 MCM/Y. The plants under construction will bring the total supply in 2009 to 160 MCM/Y, while according to the Water Authority of the State of Israel (Shani 2008) it is anticipated that the plants under planning will supply in the year 2013 the total amount of about 500 MCM/Y.

In parallel, water-conservation measures were undertaken to promote the efficient use of water in the agricultural sector by introducing advanced methods of irrigation such as drip irrigation, micro-sprinklers, and computerized automatic *fertigation* (irrigation + fertilization). These measures brought the average quantity of water needed for irrigation to about 5,000 m^3/hectare, compared with about 9,000 m^3/hectare in 1975. Thus while the output by the agricultural sector has increased 12-fold, the total water used for irrigation has remained almost constant.

The urban sector has applied control and conservation efforts such as monitoring municipal water systems, and installing water metres for every household. At the same time, special measures to reduce water for the irrigation of urban parks have been taken, including the planting of drought-resistant plants and watering at night to reduce evaporation and transpiration.

According to the figures of the Israeli Ministry of the Environment, some 450 MCM of wastewater are produced in Israel per year, some 96 per cent of which is collected in central sewage systems. About 63 per cent, i.e. 283 MCM/Y, is adequately treated and reclaimed, while about 36 per cent, i.e. 160 MCM/Y, is either untreated or inadequately treated and still used for irrigation of plantations. Only a small quantity is still directed to cesspools or flow to the sea.

However, despite these measures, there is a general diminishing trend in available water resources due to re-occurring dry years, which in the author's opinion are due to global warming. An increase in the salinity of the ground water has been observed in many wells due to a return flow from irrigation and the influx of pollutants from human activity.

24.3.2 Palestinian Territories

The main source of fresh water in the Palestinian territories is from ground water. The four main basins are the mountain cretaceous and Eocene aquifers in the central mountain region, and the Gaza Coastal

Plain aquifer. The western part of the Mountain aquifer underlies the two states, with 68 per cent of its recharge in the Palestinian territories. In the West Bank, Palestinians now control, and consume, approximately 125 MCM/Y, while the Palestinians in Gaza consume around 103 MCM/Y. The per capita consumption of water in Palestinian territories for irrigation amounts to between 106 m^3 in the West Bank to 172 m^3 in the Gaza Strip (UN document A/46/263, annex, table 1). The average urban daily per capita consumption in the West Bank is about 50 l/day (about 18 m^3/Y), while in Gaza it is 78 l/day on average (about 28 m^3/Y). Water quality is poor, with high nitrate and chloride concentrations. In both regions, system losses are high – about 40 per cent of the supply. Palestinian per capita water consumption has risen from 86 m^3/Y in 1967 to 100 m^3/Y currently. Palestinian use of water in the West Bank is limited to 17 per cent of the total water in the aquifers. Israel uses the remaining 83 per cent either for its settler population in the West Bank or for pumping from the shared aquifers for consumption in Israel or for sale back to the Palestinian utilities. Palestinian allocations from wells are restricted, with rare approvals for new wells or for increasing outputs from existing wells dug before 1967. As a result, Palestinian annual water extraction has actually dropped by about 10 per cent, from 120 MCM to 98 MCM, since the mid-1990's. This is despite the fact that 10 to 14 per cent of the Palestinian *gross domestic product* (GDP) comes from agriculture, as opposed to 2 to 3 per cent of Israel's GDP. Only 10 per cent of Palestinian agriculture uses irrigation; the rest is rain-fed. The Gaza Strip relies on wells that are increasingly become saline (World Bank 2008d: 51).

In the West Bank and Gaza Strip, in 1996 agricultural water use was about 7150 m^3/Y per hectare, much of it for drip irrigation and greenhouse agriculture (Stanhill 1992). In the Gaza Strip, the only water source is the Coastal Plain aquifer built of Quaternary sands and sandstones. The average annual recharge is estimated to be 50 to 80 MCM, including return from irrigation and leakage from sewage facilities, while the annual utilization is more than double, i.e. between 120 and 160 MCM. Thus, the present overall annual deficit is on the order of 90 MCM. This quantity will undoubtedly increase with a rise in per capita consumption. In addition, approximately 44 per cent of the wells show nitrate concentrations higher than 90 mg/l (Melloul/Collin 1994). This situation is expected to worsen due to the high annual population growth rate which according to the 2007 census of The Palestinian Central Bureau of Statistics has reached 2.6 per cent in the last decade (not yet published, cited by the World Bank 2008b: 18).

24.4 Anticipated Water Demand by the Year 2020

According to The World Bank AAA Program report (World Bank 2006) on Israel, based on the estimates of Israel's Water Commission (2002), by the year 2020 the total annual agricultural water demand in Israel (8.6 million inhabitants utilizing 1,330 MCM/Y for domestic needs) will reach 1,300 MCM, of which 600 MCM will be fresh water. Future agricultural demand by the Palestinians may reach 415 MCM/Y (Alatout 2000). Thus, in the year 2020, the total Palestinian and Israeli water demand for agriculture may reach 1,770 MCM. Taking into account that part of this will come from reclaimed sewage water, which when fully exploited in both countries may reach 830 MCM/Y, and that an annual amount of about 530 MCM can be supplied from natural resources, there will still be an unmet annual demand of about 400 MCM for agriculture. These projections are based on the assumption of no major deterioration in climate. When future climate change impacts on precipitation are included, the natural water supply could decline by 25 per cent of its present average. This would increase the agricultural water demand deficit by the year 2020 to 500 MCM/Y for both Israel and Palestine.

During the last decade, agriculture was the largest sector of the Palestinian economy, generating over 22 per cent of the GDP of the West Bank and Gaza Strip and providing employment to over 15 per cent of the population (Butterfield/Isaac/Kubursi/Spencer 2000). Taking into account that by the year 2020 agriculture may still be an important source of income for the Palestinians, the drying up of the climate due to the ongoing increase in global temperatures will have a severe negative impact on Palestine's economy. At the same time, Israel's above-mentioned desalination plants may cover the urban consumption, even in dry years, while in extreme dry years the supply to agriculture may be reduced, without causing severe damage to Israel's economy. However, it is assumed that in such years, Israel will be ready to increase the Palestinians' share of the ground-water resources. This increase will be at the cost of the flow of springs, not to speak of the one-time reserves. Thus, this increase must be in the framework of a general development

programme, not only of water resources, but also of the efficiency of agriculture and irrigation methods. In order to ensure that these steps will not lead to a dead end if the dryness continues, it is suggested that the policy of 'progressive development' be applied, as discussed above (24.1.1), in order to mitigate the impact of increasing aridity.

24.5 Applying the Policy of 'Progressive Development' to Mitigate the Impact of Water Scarcity

In fact, the principles of 'progressive development' were applied through a policy of 'trial, error and innovation' during the development of Israel's agriculture and water supply system, both rural and national. This policy involved the stage-by-stage integrated development of the various water resources, starting from deep drilling and intensive utilization of the ground-water resources, which brought about utilization of the one-time ground-water reservoirs, the use of aquifers containing brackish water, and irrigation by treated effluents. At the same time, the application of advanced economizing irrigation methods, as well as other advanced agricultural methods, which conserved water and provided a higher income per cubic meter of water were introduced. The lessons learnt served as a practical field experiment on which the theoretical program of 'progressive development' is based.

In the case of the Middle East, one needs to bear in mind that all major surface and sub-surface water resources are trans-boundary and that the riparian and upper basin users are inter-dependent. Thus the impact of increasing water demand, deteriorating water quality, etc. needs to be investigated on a regional basis. It is beyond the scope of this chapter to suggest a master plan for the water supply of the Middle East, let alone for Israel and Palestine, despite the fact that the future need for such a master plan is beyond question.

A master plan for Israel's water needs for 2002–2010 does, in fact, exist (State of Israel 2002). This master plan is being updated by Israel's Water Authority (2007, 2008) for the period beyond 2010, taking declining climate conditions into account. In the 2002 plan, climate change was not included as the impact of this factor was not yet obvious.[8] In the topical master plan (2002), the solutions for satisfying future demand concentrate on water conservation, replacement of fresh water with effluents and desalination of brackish water (which will reach 50 MCM/Y of fresh water in 2010). By the year 2010, desalination and water imports (of about 50 MCM/Y from Anatolia) were projected to reach 500 MCM/Y. In addition, by 2010 the amount of treated effluents was planned to reach 230 MCM/Y, from which about 33 per cent, i.e. about 115 MCM/Y, would be upgraded from the secondary to the tertiary level. The 'first level' of treatment includes only the deposition of solid components in depositional basins, while in the 'secondary level', the effluents undergo biological treatment in anaerobic oxidation ponds, or bio-mechanical separation of the organic materials. In the tertiary treatment, the effluents are filtered and chlorinated.

With regard to the Palestinian territory, the Israeli master plan forecasts a supply of 115 MCM/Y from the Israeli system based on signed agreements, in addition to the water available to the Palestinians from their own resources. No official master plan by the Palestinian Authorities is available. The one available projection was prepared by the Committee on Sustainable Water Supplies in the Middle East (1999): it does not take future climate change into account but it emphasizes sustainable development.

The following section focuses on non-conventional solutions, in the framework of a working plan for 'progressive development'. Such a plan reflects the water conflict between Israelis and Palestinians, which will become even more severe due to population growth and the decrease in precipitation due to global warming.[9]

24.5.1 The Mountain Aquifer

The western Mountain aquifer is the main issue of controversy between Israel and the Palestinians, as about 80 per cent of the recharge of this aquifer is over the Palestinian territories. Yet because of the geological structure, the water is not stored under the recharge zones but flows to the west where it is stored in the sub-surface of the foothills region. While the Palestinians claim that the water belongs to them because it is recharged in their territory, the Israelis claim that they were the first to tap into and develop this source.

---

8 Personal note by Y. Dreizin, chief planner of Israel's Water Commission.

9 This dilemma has also been stressed by Brauch (2004, 2006a, 2007). The argument has been partly taken up by Freimuth, Bromberg, Mehyar, Al Kahteeb (2007).

Moreover, due to the semi-arid character of the region, in dry years the aquifer in the mountain region may be exhausted as there is not enough storage capacity there. This controversy could potentially become worse if indeed, as envisaged by the author, global warming causes a decline in average precipitation. This will decrease the flow of the perched local springs and also diminish quantities of water collected by the Palestinians into cisterns. These springs and cisterns are their source of drinking water and are also used for the irrigation of vegetable plots, for both domestic and marketing purposes.

The negative impact of the diminishing precipitation will particularly affect the eastern and southern parts of the mountain region belonging to the Palestinians. The eastern region will be affected because it is situated in the rain shadow while the southern region borders the desert. Thus in these regions, where the present precipitation averages 350 mm/Y, an approximate 20 per cent reduction will reduce the average to less than 300 mm/Y, which is below the minimum needed for the rain-fed fruit plantations upon which many Palestinian farmers depend. Thus, the main problem to be faced is storage, which is available on the Israeli side.

Discussing this issue at an Israeli-Palestinian meeting, the author suggested regarding this problem as an argument between two neighbours that he experienced in his childhood in Jerusalem, where the source for drinking water was collection from a domed plastered roof into a cistern in the yard. Thus, while the upstairs neighbour claimed that the water belonged to him, as he owned the roof and looked after its annual plastering and white-washing, the neighbour who owned the yard in which the cistern was located also claimed ownership of the water. The only solution was the cooperative use of water resources, where each neighbour would get water according to his/her needs.

Yet here enters the problem of defining need. While the Israelis will claim that their need is according to their per capita domestic demand of about 100 m^3/Y, while for irrigation they only need 5,000 m^3/Y per hectare, the latter partly supplied by reclaimed effluents, the Palestinians will claim that they need only 50 m^3/Y per capita, but 7,150 m^3/Y per hectare for irrigation. These arguments represent only the tip of the iceberg of conflicting demands, where the main issue is the chasm between an advanced society adapted to a high standard of living and manufacture, and a traditional society adhering to an ancient way of life and production.

To reach an agreement, the Israelis must reduce their domestic demand via water-conservation measures, and satisfy part of that demand with second-grade water resources. The Palestinians must improve their irrigation methods, treat their effluents and reuse their waste water for irrigation. The latter measure is essential and will have an additional positive effect in curtailing contamination of the Mountain aquifer.

Additional non-conventional sources are discussed next, which have not been utilized to date and which will have to be developed mutually by Israeli and Palestinian authorities.

24.5.1.1 Management of the Flow of Springs and Streams

In semi-arid regions like the Middle East, where precipitation falls only during the cold winter season, two types of springs exist, seasonal and perennial. The difference is in the volume of storage feeding the spring. The seasonal springs, which depend on a local perched aquifer that is relatively limited in area and thickness, flow mainly during the wet season and part of the dry season. In a good year, they may flow the whole year, but their flow during the dry summer season keeps diminishing, until the winter when they recuperate. The perennial springs, fed by an aquifer whose storage exceeds the quantity of outflow during the dry season, will flow during this entire season, diminishing only at the end, and then recovering its maximum flow during the wet season. The bigger the volume of storage, the more flat the flow hydrograph will be. The flow of such springs, either seasonal or perennial, is controlled by drilling into the feeding aquifer and utilizing the storage during the dry summer, by lowering the water table. Such a management policy may cause the total drying up of the natural spring and its efficient utilization by pumping. In this case, the stream, which was fed by the spring, will dry up if not artificially fed by the pumping wells. Thus, use of the aquifer storage is much more efficient, but the drying up of the springs, if not taken into consideration and controlled, may have a negative impact on the natural environment. This flow may be artificially renewed by treated effluents.

The most salient issue is the management of the Rosh-Haayin springs, the source of the Yarkon River and Taninim springs and stream, both outlets of the western Mountain aquifer. The same policy can be applied to efficiently utilize the springs emerging from the eastern part of the Mountain aquifer, namely the ground-water flow towards the rift valley, by wells

drilled in the mountainous region. The sub-surface flow towards the north-east and east is on the order of 240 MCM/Y, from which about 140 MCM/Y flows towards the north-east, i.e. the valleys of Esdarelon and Beit Shean, while about 100 MCM/Y flows eastward. The north-eastern flow is almost totally utilized by wells drilled along the fault lines bordering the mountains (Rosenthal/Mandel 1985). As some of the springs are brackish due to the up-flow of saline water from depth, the over-utilization of these wells has brought about a slow increase in salinity in some of them (Rosenthal 1988). From the flow towards the east, about 80 MCM/Y flows towards the springs flowing directly towards the Dead Sea, from which about 15 MCM/Y is pumped in the mountain region. It is estimated that about 50 MCM/Y can still be utilized in the mountain and foothill regions from the flow of the springs along the western border of the rift valley.

24.5.1.2 Desalinization of Brackish Fossil Ground Water in the Mountain Region

An investigation of data from the oil-exploration wells drilled in the central mountain region (Greitzer/Issar 2001) showed that underlying most of the mountainous region, there exists an additional aquifer in the layers of the Kurnub Group. The water in these layers is brackish. The layers in the south-eastern part of the anticlinorium consist of sands and sandstones, but towards the centre and north, the facies change into shale and limestone. The shale layers may divide the aquifer into sub-aquifers. It is assumed that the regime of flow is decided by the geological structure and thus is more or less in the direction of that of the limestone-dolomite aquifer of the Judea Group overlying it. The Kurnub Group aquifer outcrops over an area of about 40 km^2 at the peaks of the anticlines. However, as the thickness is rather limited (around 200 m) and part of the section is composed of shale, the recharge is limited as well. No direct measurements have been performed but considering that these areas also coincide with the areas of maximum precipitation, reaching about 600 mm/Y, the annual recharge is estimated to be about 5 to 8 MCM. Some recharge may take place by leakage from the overlying Judean Limestone aquifer, which has a higher water table. This recharge, the quantity of which is unknown, is estimated to take place along the fault zones. The aquifer in the mountain area extends over 2,400 km^2 with an average thickness estimated at no more than 100 m. From the interpretation of the oil-exploration well logs, the salinity of the water is on the order of 1,000 to 5,000 mg Cl/l. The lower salinities are found around the outcrops and increase towards the synclinal areas and towards depth. The stored quantity is about 7.2 BCM, as estimated according to the abovementioned data, taking into account an effective storativity[10] of 3 per cent. It was calculated that by pumping about 30 MCM, the water table will drop by 0.5 m/Y. Taking into account a thickness of about 100 m, the supply can last about 200 years, or about 60 MCM/Y for 100 years. An investigation in the Beer Sheva region, which will be discussed later, showed that when the supply of fresh water is needed for an urban centre located far from the sea, the local desalination of brackish ground water is more economical than importing desalinized sea water. As any addition to the supply of water to Israeli-Palestinian populations will have to come from the desalination of sea water, the supply to the urban centres of the mountain region of partially desalinized water from the Kurnub Group aquifer should be investigated in more detail.

24.5.2 Turning the Coastal Plain Aquifer into a Storage Reservoir of Second-grade Water

As the demand for fresh water increases and precipitation decreases, it is clear that the water supply from natural resources for irrigation will have to be drastically reduced by the year 2020 (and even totally eliminated during dry years), and that a major portion of the urban demand of the Israeli and Palestinian populations will have to be met by the desalination of brackish and sea water. At the same time, the increased demand for agriculture will be made mainly by the Palestinian population, and for this purpose the use of reclaimed sewage will increase. Considering these general assumptions, the three main problems to be dealt with are:

1. The storage of surplus of water during years when precipitation is above average;
2. The storage of fresh water from desalinization plants (either brackish ground water or sea water) which, in order to ensure their economic profit,

10 Storativity is the percentage of volume of the aquifer which can be filled with water, while 'effective storativity' is the percentage of this which can be pumped out (minus the water which remains due to hygroscopic forces).

will also have to operate in periods of low demand such as the winter season;
3. The storage of reclaimed sewage in general and particularly during the winter months, when supply exceeds the seasonal demand for irrigation.

Examining the various aquifers from the point of view of storage, it seems clear that the greatest potential for further augmentation of storage is in the Coastal Plain. This is due to the fact that the sandstone layers from which this aquifer is built have a high storativity coefficient (average 10 per cent), due to their high porosity. At the same time, the velocity of flow in the sandstones is relatively low due to a low permeability coefficient (K = 1 m/day). On the other hand, the high permeability of the limestone aquifer (K = 100 m/day) causes recharged water to flow to the outlets in a rather short time. Another fact to be considered is that in the eastern part of the Coastal Plain, a large volume of the aquiferous layers is unsaturated and can be recharged artificially, providing additional storage. The shifting of the recharge and storage areas to the east is a prerequisite to meeting future storage requirements, which should reach about five times that of the present. Today, this is being carried out in a densely populated region while the demand for, and cost of land are on the rise. Moreover the location of the present sub-surface storage field of treated sewage in the central Coastal Plain (the Shafdan) is at a rather small distance from the sea. This area is underlain by confining layers, which limit the inflow of the recharged water to the deeper aquifer and thus cause water to flow to the sea. If use of this storage field continues and the quantity stored is increased, these losses will become even more pronounced.

These are the basic assumptions concerning desalination and agricultural use. They, as well as the hydro-geological characteristics of the Coastal Plain, must be taken into account in planning for the storage of reclaimed sewage and flood water. Once Israel and the Palestinian Authority collaborate, they will jointly be able to close the gap between supply and demand. In the first place, the Coastal Plain aquifer will have to become joint storage for Israel and the Palestinian Authority. Once the recharge of reclaimed sewage and storage areas have shifted from the western part of the region to its eastern part, it will also be possible to recharge and store the flood water coming from the Palestinian territory. At the same time, Israel will have to plan anew its recharge areas for its reclaimed sewage and flood water. Due to paleo-environmental conditions which existed during the Quaternary period, all the riverbeds crossing the Coastal Plain are underlain by thick layers of clay. Moreover, adequate natural sites for storage dams are very rare in the central and western parts of the Coastal Plain. These conditions dictate that the best places for storage and later gradual recharge by floods are in the eastern parts of this region, close to the foothills.

In the vicinity of the coast, clay layers exist in the sub-surface which divide the aquifer into sub-aquifers. These sub-aquifers can be used to store the desalinized sea water during periods of low demand, since in order to be economical, the operation of the desalinization plants has to be continuous.

As part of the new cooperative planning, storage in the section of the Coastal Plain under-lying the Gaza Strip should follow a similar policy. This will enable recovery of the over-pumped aquifer below the Gaza Strip. This can only be done once the gap between supply and demand in this region has been supplied from Israel and from local desalinization projects. On the whole, the total quantity of water recharged annually to the Coastal Plain aquifer would be on the order of 600 MCM. The quality of this water supply would be as follows:

1. One-third recharged from precipitation, infiltration from urban runoff and returning irrigation water, containing about 300 mg Cl /l.
2. Another third, coming from the winter flow of the Jordan River, diverted above the Sea of Galilee to the Israeli National Carrier, containing about 100 mg Cl/l.
3. One-third, coming from reclaimed wastewater, containing an average 400 mg Cl/l.
4. An additional quantity, not yet estimated, will come from the desalinization plants during periods of low demand.

All this would eventually combine to give an average water quality of about 250–270 mg Cl/l.

24.5.3 Utilization of a One-time Reserve from Fossil Aquifers

Studies by the author and his colleagues (Issar/Bein/Michaeli 1972; Nativ/Bachmat/Issar 1987; Issar/Nativ 1988; Tsur/Park/Issar 1989; Issar 1994) have shown that a few hundred million cubic metres per year may be pumped from the Nubian Sandstone aquifers underlying the Negev and the Sinai. This pumping is guaranteed for at least the coming century. The actual quantity and duration would be a function of management policies and various economic factors. In principal, however, such a project is technically feasible, and

the water is of adequate quality. Although this water source is not replenishable, it may be regarded as any other non-replenishable resource (e.g. oil, coal, iron ore). In other words, the evaluation of whether or not to use it should be based on socio-economic considerations aimed at encouraging settlement of the empty desert regions in order to relieve the population density in the overcrowded Coastal Plain area, as well as the settling of the Bedouin population. The latter issue is one of the principles of the paradigm of 'progressive development'. The drying up of the desert boundary region of Israel, a process which has already begun and where most of the Bedouins reside, will bring about this process anyway. It is thus advisable to do it in the framework of a general plan.

24.5.4 Desalinization of Sea Water and Greening of the Desert

As discussed earlier, natural recharge of the water resources of Israel and Palestine is not sufficient to fulfil the present, let alone future demands of the growing population. Israel has begun the desalinization of sea water and in 2013 the plan is to reach the amount of 500 MCM/Y. This target amount was set without taking into consideration the future negative impact of climate change. Thus, as the desalinization of brackish and sea water is the only solution for the future, it is suggested to increase the target volume of desalinization according to the forecasted 20 to 30 per cent reduction in precipitation, which will thus have to reach the volume of 650 MCM/Y in 2013.

The desalinization of sea water, as well as brackish water, necessitates the input of energy. Until economically and environmentally friendly resources such as wind mills, solar photovoltaic cells (Brauch 2006a, 2007; Faiman 2009; Trieb/Krewitz/May 2009) and the like are developed, most of this energy will have to come from conventional sources, i.e. fossil fuels. In order to compensate for this, plantations for sequestering atmospheric CO_2 can be planted in the desert. Preliminary projects involving the planting of olive and date palm trees in the Negev Desert, utilizing fossil brackish water, have proven successful both agriculturally and economically (chapt. 48 by Safriel). However, this combination, although an important issue, is beyond the scope of this chapter.

24.6 Conclusions

The impact of accelerating global warming on the natural and human environments of the arid and semi-arid zones in general, the Middle East in particular, has been projected to be negative. The drying up of the climate and thus of the water resources raises some doubt as to whether the principles of sustainable development will be able to avert the forthcoming crises, especially in developing societies, in these countries. A desire to avoid the impact of such crises brought the author to suggest the new policy of 'progressive development', which entails the comprehensive development of soil and water resources, including one-time water reserves and marginal land resources. Such projects will include deep drilling and pumping, modern irrigation and agricultural methods. In parallel to the investments in the development of natural resources, efforts will be made to advance the human resources, via both technical and cultural education.

25 Jerusalem: Where To? In Search for Hidden Opportunities

Mohammed S. Dajani Daoudi and Ashraf M. Dajani

Two women came before King Solomon, each claiming that a newly-born baby was hers. The judgment of Solomon was to have the baby sliced in two and each be given a half. "Let it be neither thine nor mine, but divide it!" As the sword was drawn to carry out the order, one of the women agreed with the verdict whereas the other rushed forward to save the baby, exclaiming, "Oh my Lord, give her the baby, but please do not slay it". Observing these reactions, King Solomon judged the later women to be the true mother and ordered that she should have the child.

25.1 Introduction

This chapter addresses one of several major obstacles to the Israeli-Palestinian peace process the dispute over Jerusalem - a complex controversial issue, which seems insoluble and the search for any hidden opportunities it may contain has proved elusive. The model proposed reflects the potential for shifting the political discourse in the holy land from the persistent conflict to address the common threats, challenges, vulnerabilities and risks both Palestinians and Israelis face and experience to various degrees. It explores the hidden opportunities for Jerusalem as a sustainable city on which all sides are proud and which all parties can co-exist and co-develop based on equality of opportunities and mutual respect and not on control and power. The search for viable solutions to the future status of Jerusalem is the focus of this chapter. It attempts to deal with future concerns about Jerusalem, and to discuss how they may be alleviated. By exploring ways of achieving a balance between national interests, religious beliefs, political demands, and international legality, it enters the thorny field encompassing the political, religious, legal, and economic agendas of both Palestinians and Israelis dealing with the future of Jerusalem as well as their psychic adoration of the city. The key goal of this chapter is not to offer answers as much as to provide a milieu or setting that may be conducive to thinking in terms of problem solution. This objective is usually lost when emotions overcome rationality. Palestinians and Israelis often get so immersed in their national pursuit to win all that the windows of opportunities and promises escape attention.

25.2 Significance of the Jerusalem Issue

The significance of the Jerusalem issue stems from its universal religious importance for the three great monotheistic faiths: Christian, Muslim, and Jewish who for centuries have been competing for its soil. It also stems from the assorted colourful mosaic of peoples living in it and the rich culture, traditions and customs surrounding it. The ancient Greeks called Jerusalem 'The Navel of the world'. The sources of Muslim[1], Christian[2], Jewish[3] and joint Israeli and Palestinian[4] attachment to Jerusalem are deep and complex; both have infused different ingredients of spiritualism, politics, religion, nationalism, history, and patriotism to demand unquestioned loyalty to the

1 There are many sources on Jerusalem by Muslim, Arab or Palestinian authors, among them are: Arafeh, Rahman (1992); Albin (1990); Asali (1989); Bin Talal (1979); Boudreault and Salaam (1992); Cattan (2000); Mattar (1994); Musallam (1996); Karmi (1996); Sabbah (1990).

2 There are many sources on Jerusalem by Christian or other authors, among them are: Armstrong (1996); Ellis (1999); Hodgkins (1996); O'Mahony, Gunner and Hintuan (1995); Peters (1985); Sinclair (1995); Whitbeck (2000).

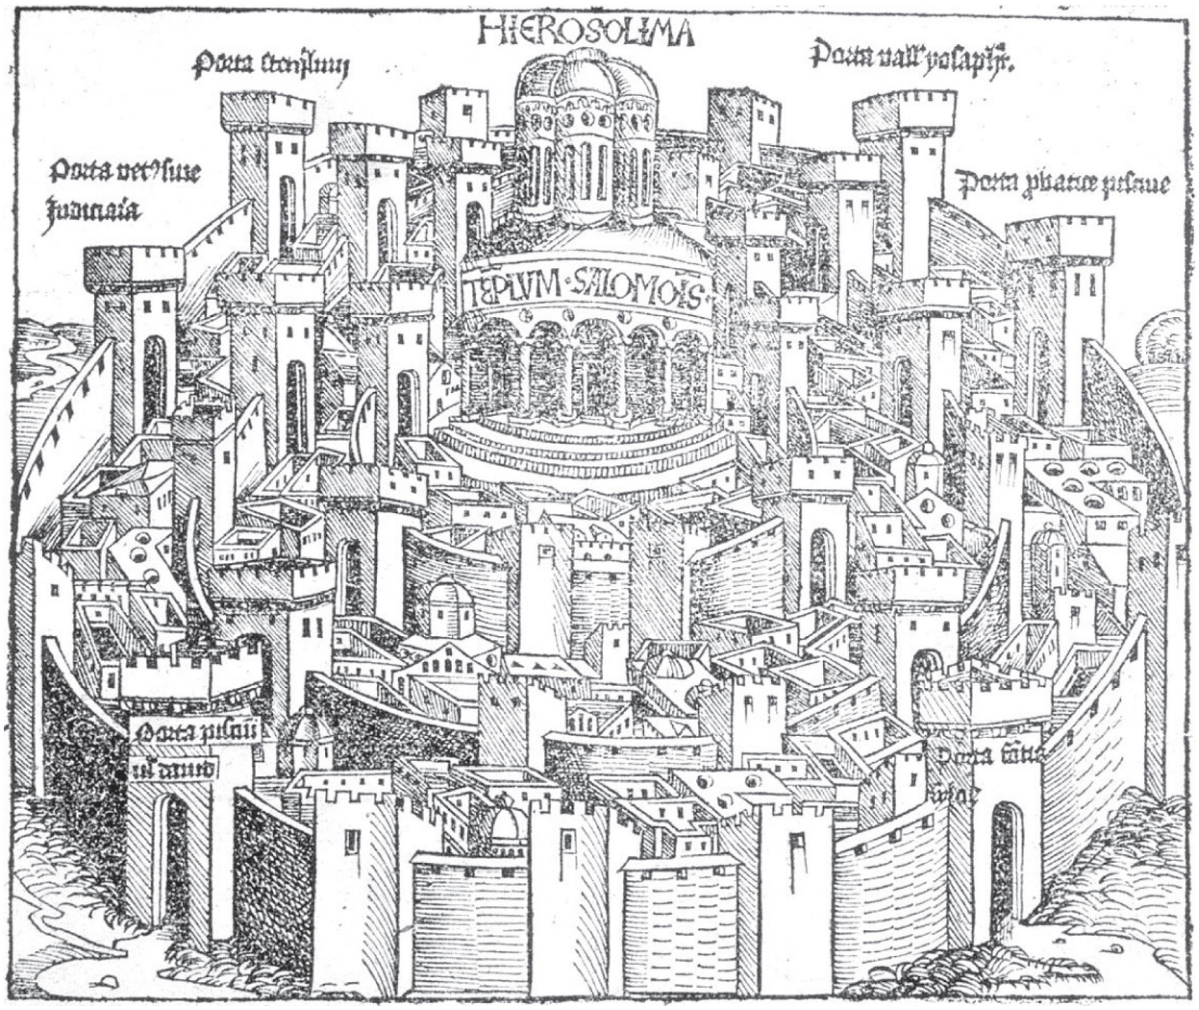
Figure 25.1: Map of Jerusalem. **Source:** Hartmann Schedel (1440-1514); Hierosolima (Jerusalem) Liber cronicarum, Nuremberg/Nürnberg 1493 Woodcut, 19.0 x 22.3 cm - Kyram Collection; at: <http://commons.wikimedia.org/wiki/File:Hartmann-schedel-hierosolima-1493_2-BW-1147x965.jpg>. This map is in the public domain.



cause of maintaining and holding on to absolute sole political and religious sovereignty over the holy city.

Muslims, Christians and Jews share many identical values and beliefs such as the oneness of God, the need for total submission to the will of God, as well as the similar differentiation between good and evil. In Islam, the antecedent of the other two religions, many of the individuals, events, stories, and places sacred to Jews and Christians are similarly sacred to Muslims. The Holy Quran states:

> Say: We believe in Allah and that which is revealed to us; in what was revealed to Abraham, Ishmael, Isaac, Jacob, and the tribes; to Moses and Jesus and the other prophets by their Lord. We make no distinction amongst any of them, and to God we submit ourselves. [Baqara Sura; verse 136]

Many Jews believe that God promised the holy land to the descendants of Abraham, Isaac, and Jacob. According to the Jewish *Tanakh*, God made a covenant with Abraham, saying to him: "I assign the land you sojourn in, to you and your offspring to come, all the land of Canaan, as an everlasting holding. I will be their God" (Bereishit/Genesis 17:7–8).

3 There are many sources on Jerusalem by Jewish or Israeli authors, among them are: Ahimeir (1983); Amirav (1992); Baskin (1994); Beckerman (1996); Benvenisti (1976, 1983, 1989, 1996); Blum (1974); Chazan (1991); Cohen (1977); Elon (1995); Feintuch (1987); Friedland and Hecht (1996); Gold (1995); Lapidoth and Hirsch (1994); Romann and Weingrod (1991).

4 And there several joint publications by Israeli and Palestinian authors on Jerusalem: Amirav and Siniora (1991–1992); Nusseibeh and Heller (1991); Nusseibeh and Maoz (1991).

Figure 25.2: Jerusalem as pictured in the 6th-century Madaba mosaic map. **Source**: Photo by Hans Günter Brauch (Germany). Printed with permission.

Jewish attachment to Jerusalem dates to the 10th century BC when David captured the city and declared the city the capital and religious centre of Israel. King Solomon, who followed him, enlarged the city and erected the temple, which transformed the city into a permanent centre of the Jewish religion. When the Babylonian King Nebuchadnezzar II (562–630 BC) captured the city in 586 BC, he exiled the Jews and destroyed their temple. Nevertheless, Jerusalem remained to the Jewish diasporas the spiritual centre. The Jews returned and rebuilt the city after the Persian exile, but it was destroyed by Trajan about 70 AD. The centrality of Jerusalem in Jewish life is reflected in the vow uttered by Jews on religious occasions, 'Next year in Jerusalem'. The Jews consider the City 'uniquely holy', and assert that Jerusalem has always been the heart and soul of Judaism and the Jewish nation: "And the Torah shall be disseminated from Zion, and the word of the Lord from Jerusalem" (Isaiah 2: 3).

The times Jesus of Nazareth spent in Jerusalem and his crucifixion, burial, and resurrection makes the city most sacred to Christianity. Christian attachment to Jerusalem is reflected in the various names for the city contained in the Bible, such as the 'city of righteousness', the 'faithful city', the 'city of God', the 'holy city', and the 'city of truth'. The book of Psalms says: "Pray for the peace of Jerusalem" (Psalms 122: 6); "Praise God O Jerusalem, laud your God O Zion" (Psalms 147: 12).

For Muslims, Jerusalem is the third most holy city in Islam, next to Mecca and Al-Madinah. The Muslim heritage in Jerusalem is reflected in the Holy Quran as well as in the sayings of Prophet Muhammed. Jerusalem has had an important spiritual meaning for Muslims, not only for being the first Qibla but also for the mystical experience of the prophet's ascendance to heaven as recited in the Quran:

> In the name of Allah, most gracious, most merciful: Glorified be he who carried his servant [Prophet Muhammed] by night from the inviolable place of wor-

> ship [The Sacred Mosque in Mecca] to the farthest distant place of worship [Haram el-Sherif in Jerusalem] the precincts whereof we have blessed, that we might show him some of our tokens. [Surat al Israa', Chapter 17, Verse 1]

Prophet Muhammed is quoted to have said: "Pilgrimage is restricted to only three mosques: Al-Haram al-Sharif, in Mecca, my Mosque, in Al-Madinah, and Al-Aqsa Mosque, in Jerusalem." He asserted that the Muslim who starts procedure for pilgrimage or *umra* from Al-Aqsa Mosque shall have all his/her sins forgiven. "Jerusalem is the land of the ingathering, go to it and worship in it, for one prayer therein is equivalent to 1,000 acts of worship elsewhere."

To yield political sovereignty over Jerusalem would be to the Israelis a betrayal of their history, heritage, tradition, and sacrifices. On the other hand, to yield political sovereignty over their holy city, which they call 'pearl of the cities', would be to all Muslims, a betrayal of their religion, history, identity, heritage, and tradition.

25.3 Concept of Sustainable Conflict Resolution

The most perplexing question to answer on the future status of Jerusalem is: Is a sustainable resolution for the Arab-Israeli or Muslim-Jewish conflict over Jerusalem elusive or can it be achieved? If a 'sustainable resolution' to the Jerusalem issue is achievable, the persisting dilemma remains: How best can it be achieved, and will there be good will to implement it by all parties concerned? Here, the term 'sustainable resolution' refers to a solution to the conflict that satisfies the basic needs and aspirations of the present generation without compromising the ability of future generations to meet their basic needs, demands, and aspirations.

This definition contains three key concepts and ideas: conflict resolution, psychological needs satisfaction, and future collective aspirations. The concept 'conflict resolution' proposes a durable peace without any residues for future conflict. It includes the satisfaction of minimal political and national demands. The term 'needs' introduces the idea of distribution of resources: meeting the basic needs of all and extending to all the opportunity to satisfy their longing for a better secure prosperous life. The third concept of 'future collective aspirations' means that we have a moral duty to look after the city of Jerusalem in terms of physical and environmental status, and to pass it on in durable political, administrative, and organizational order to future generations. It suggests that whatever solution to the conflict reached today must continue to be acceptable, relevant and workable in the future – embodying ideals and conditions that future generations will be happy to live with. Its sustainability would stem from its success to meet and satisfy religious, social, economic, and political demands and efficiency measures. Should one party impose unacceptable terms on the other today, then this would, no doubt, constitute a potential seed recipe for a future conflict. Sustainable resolution implies resolving the conflict both for moral and practical reasons.

At least there are eight basic assumptions required to achieve a sustainable peaceful solution. Both peoples:

1. Respect and recognize the right of each other to live, work, and move freely within the borders of the city of Jerusalem.
2. Recognize the right of others, Christians, Muslims, and Jews, to have free access to their holy shrines to practice their faith.
3. Value the need to protect the unique spiritual, religious and cultural diversity of the city of Jerusalem.
4. Appreciate that joint planning, coordination and cooperation between the *de facto* present Palestinian and Israeli sectors of the city of Jerusalem is vital to overcome the economic, technological and educational gap between them.
5. Acknowledge the need to alleviate the religious, cultural, and social enmity between both communities on a gradual and continuous process.
6. Seek to ensure order, security and peaceful coexistence for all the inhabitants of the city of Jerusalem.
7. Call for fostering good will among all residents of the city of Jerusalem.
8. Encourage the development of peaceful relations among residents.

25.4 City Borders

A sustainable resolution of the Jerusalem issue requires the concise allocation of territory over which the Palestinians and Israelis exercise political and administrative authority. *The Webster's New World Dictionary* defines the word 'border' as "a dividing line between two countries, states, etc., or the land along it." The Arabic Dictionary, *Lisan al-Arab*, defines borders as "a means of separation between two objects,

Figure 25.3: Map of Jerusalem. **Source:** The Palestinian Academic Society for the Study of International Affairs (PASSIA); at: <http://www.sacred-destinations.com/israel/images/maps/jerusalem-nc-passia-org.gif>.

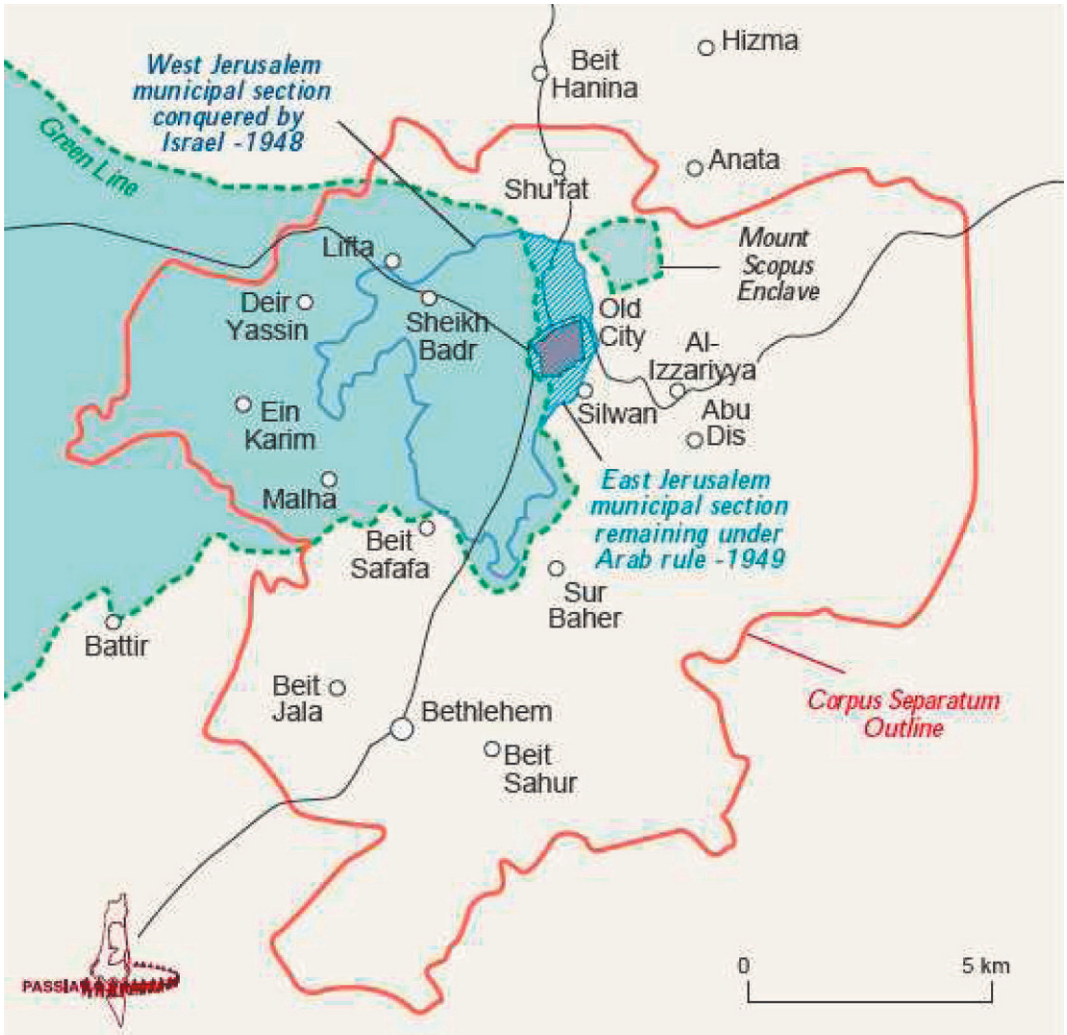
in order that one does not mix with the other, or does not transgress on the other." In our context, it is the second meaning that is of interest. The importance of good demarcation of borders stems from the famous expression: 'Good borders make good neighbours. Bad borders are often the source of tension and conflict'.

The major difficulty facing the question of addressing the city boundary of Jerusalem is that the boundary pillars, which marked the boundary lines, had subsequently been demolished and erased. However, the issue of borders may be discussed on the following six levels by distinguishing between geographical (25.4.1), *de jure* (25.4.2), *de facto* (25.4.3), *status quo* (25.4.4), administrative (25.4.5) and municipal borders (25.4.6).

25.4.1 Geographical Borders

Jerusalem is situated at the top of mountains, on the crest of the ridge that forms the watershed partition line between the foothills to the west and the desert

Figure 25.4: Jerusalem and the Corpus Separatum proposed in 1947. **Source:** Palestinian Academic Society for the Study of International Affairs (PASSIA); at: <http://www.passia.org/palestine_facts/MAPS/images/jer_maps/UNPartition.pdf>.



to the east. The geographical location determined to a large extent the area of the city, its boundaries, and the direction in which it expanded throughout the ages. The city began on a hill and later extended to the north, and in the course of time expanded in the direction of Mount Zion and the western and northern hills. Jerusalem's topography influenced the alignment of the city's boundaries on all sides (figure 25.4).

25.4.2 *De Jure* Borders

The Council of the League of Nations approved on July 24, 1922 the mandate for Palestine entrusted to Great Britain. The mandatory instrument gave Britain the authority with regard to all holy places and religious foundations, with the express injunction that they should be administered according to religious law, existing rights, and public order.

In 1947 the *United Nations Special Committee on Palestine* (UNSCOP) recommended Jerusalem to be internationalized. The United Nations General Assembly adopted on 29 November 1947 Resolution 181 entitled "Plan of partition with economic union" that envisaged Jerusalem as an international city. It was the first international document delimiting the boundary of the city of Jerusalem.

The resolution stated:

[Part II. Boundaries

A. The City of Jerusalem

> The boundaries of the City of Jerusalem are as defined in the recommendations on the City of Jerusalem (See Part III. Section B below)
>
> Part III. City of Jerusalem
>
> A. Special Regime
>
> The City of Jerusalem shall be established as a *corpus separatum* under a special international regime and shall be administered by the United Nations. The Trusteeship Council shall be designated to discharge the responsibilities of the Administering Authority on behalf of the United Nations.
>
> B. Boundaries of the City
>
> The City of Jerusalem shall include the present municipality of Jerusalem plus the surrounding villages and towns. The most eastern shall be Abu Dis; the most southern, Bethlehem; the most western, Ein Karim (including also the built-up area of Mosta); and the most northern Shu'fat.]

The UN General Assembly reaffirmed on 11 December 1948 that the city should be "under effective UN control." The United Nations declared that Jerusalem must remain an international zone, but Israel refused to demilitarize her zone and Jordan refused to consent to the concept of Jerusalem as an international city.

The UN Security Council and General Assembly took firm resolutions throughout the years rejecting Israeli attempts to annex Jerusalem or to change its status. Both bodies adopted resolutions which condemned "Israel's continued occupation of Jerusalem," and asserting that such measures "violates the Charter of the United Nations, the principles of international law and the relevant resolutions of the United Nations." These resolutions affirmed that the acquisition of territory by force is inadmissible under the Charter of the United Nations and the principles of international law and hinders the achievement of a comprehensive peace. The UN General Assembly also determined that "the decision of Israel to impose its laws, jurisdiction and administration on the Holy City of Jerusalem is illegal and therefore null and void and has no validity whatsoever." Furthermore, it adopted resolutions which confirmed that "all legislative and administrative measures and actions taken by Israel, which purport to alter the status of Jerusalem, including expropriation of land and properties thereon, are invalid and cannot change that status."

Official policies of the United States, the European Union, Russia, Japan, the Arab League and the rest of the international community in general held that Israel should not unilaterally change the status of Jerusalem, nor claim West Jerusalem or United Jerusalem as its capital. For many years, Israel had been anxious to see the American Embassy moved from Tel Aviv to Jerusalem. "Committed as it was to the UN Palestine partition resolution of 1947, the United States initially resisted Israel's requests because Jerusalem and its adjacent area had been designated as an international, UN-controlled territory. Later, Israel's annexation of Arab East Jerusalem further reinforced America's unwillingness to move its embassy to Israel's capital" (Lenczowski year: 269) .

The 'Venice Declaration on the Middle East' adopted by the European Council on June 13, 1980 affirmed a similar position on Jerusalem:

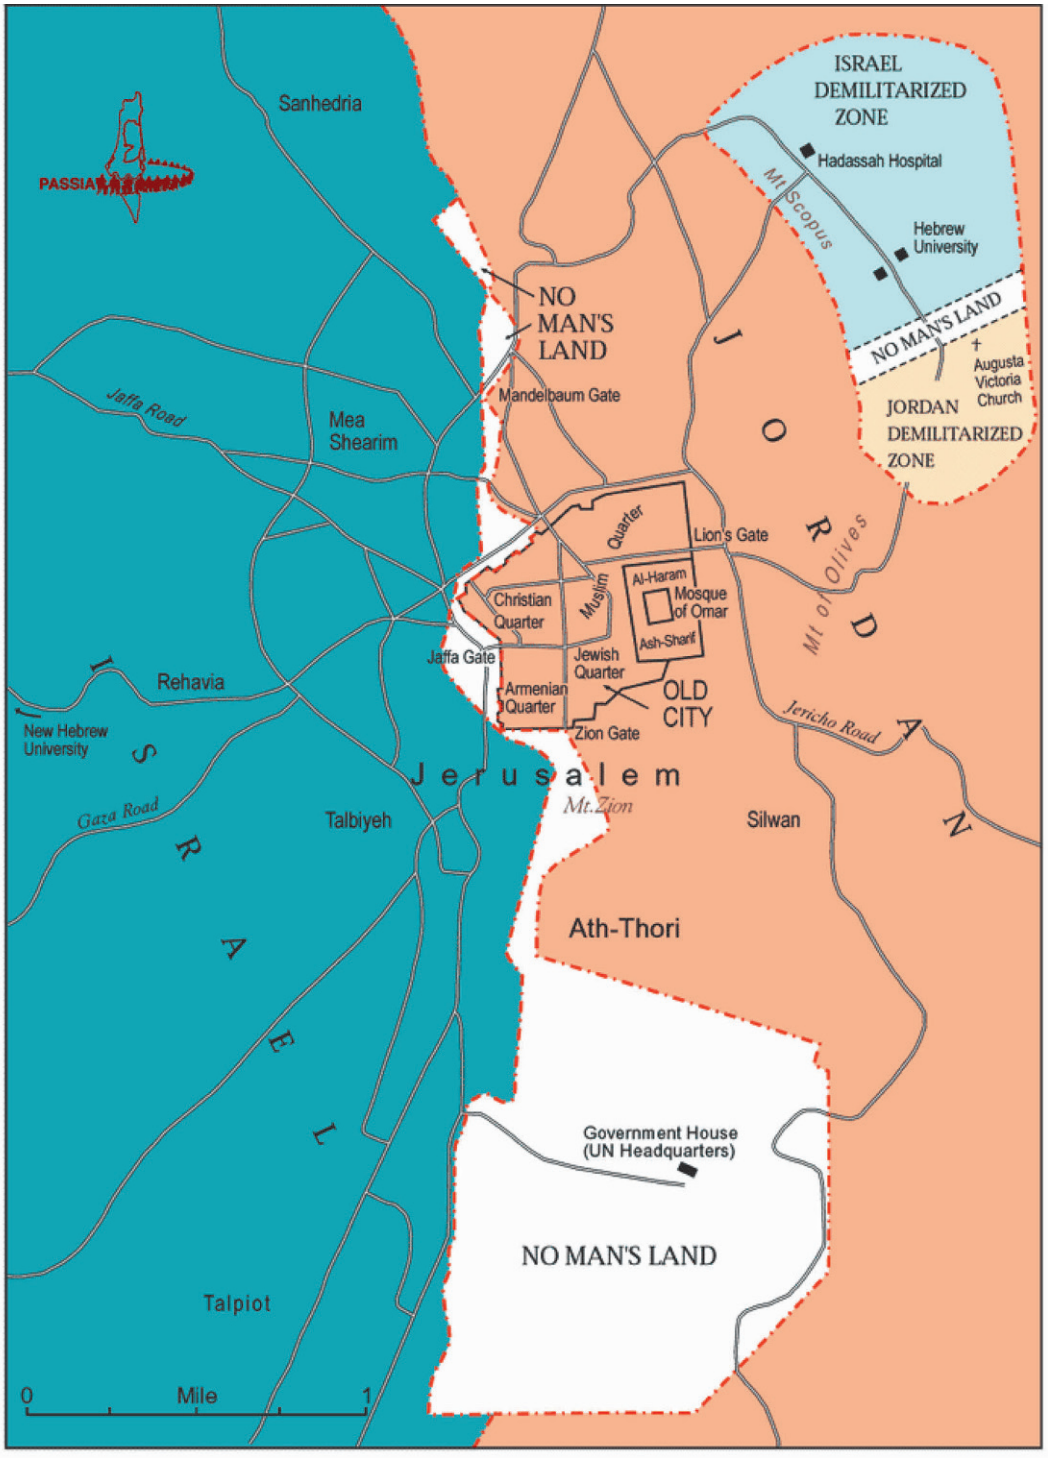
> The Nine recognize the special importance of the role played by the question of Jerusalem for all the parties concerned. The Nine stress that they will not accept any unilateral initiative designed to change the status of Jerusalem and that any agreement on the city's status should guarantee freedom of access for everyone to the Holy Places.

The following shows the *de jure* status of Jerusalem as reflected by the principles of international law and the Charter of the United Nations:

1. The acquisition of territory by force, as well as, all legal, legislative and administrative actions and measures taken by the occupier (Israel) to annex occupied territories (Jerusalem), to impose its sovereignty and jurisdiction, to alter its status either by expropriation of land and properties, or by the transfer of population and imposition of Israeli legislation, violates the principles of international law. It contradicts The Hague Agreement of 1907, the Stimson Doctrine of 1932, and Declaration of Lima of 1938. It is inadmissible under the 1945 UN Charter. Thus, Israel's continued occupation of the city of Jerusalem [West sector occupied in 1948 and East Sector occupied in 1967], is in violation of the international law, UN Charter and the relevant UN resolutions.
2. Israeli unilateral measures to alter the status of Jerusalem are totally null and void since they contradict the principles of international law.
3. Any transfer of diplomatic missions by members of the United Nations to the city of Jerusalem is considered in violation of international law and UN resolutions.

Although resolutions by the UN General Assembly are not legally binding to member states, yet they do carry moral power since they reflect the will of the international community. States applying to membership of the UN organization pledge to abide by UN

Figure 25.5: Partitioned Jerusalem (1948-1967). **Source:** Palestinian Academic Society for the Study of International Affairs (PASSIA); at: <http://www.passia.org/palestine_facts/MAPS/images/jer_maps/PartitionedJerusalem.html>.



resolutions once they become members. Here, one should not forget that the legal rationality for the existence of the State of Israel is based on the 1947 UN Partition Resolution.

25.4.3 *De Facto* Borders

In 1948, more than 30,000 Palestinians fled from their homes or were forced to flee from West Jerusalem, leaving in the process more than 10,000 fully furnished homes. Jerusalem was divided into an Arab and Israeli sector, and on 1 December 1948, Jordan established its administration in Arab Jerusalem and that area of the city became territorially demarcated by the armistice line that has been in effect since 1949. The Israel-Jordan Armistice Agreement of 3 April 1949 finalized the physical partition of Jerusalem and left the city divided into two parts with barbed wires and cement barriers cutting across it. The Israeli sector included the Western and Southern parts of the new city. The city was extended westward and Jerusalem became the administrative centre of Israel.

In 1949, a number of Israel's ministries were moved from Tel Aviv to Jerusalem and in December of that year the Knesset met in Jerusalem for the first time. In January 1950, Israel proclaimed Jerusalem as its capital. All government offices moved there except the ministry of foreign affairs, which remained in Tel Aviv to keep in touch with foreign diplomats whose

governments refused to officially recognize Jerusalem as the capital of Israel.

On 24 April 1950 Jordan officially annexed the West Bank, including East Jerusalem, which created a political boundary between the two sectors of the city. In 1966, 190,000 persons resided in Jewish Jerusalem and 60,000 resided in Arab Jerusalem. In June 1967 the boundary line was eradicated and in the aftermath of the war, Israel formally united the two sectors. The barriers, cement walls, blocks and barbed wires that had divided the city were removed. Israeli leaders declared that this act was permanent and non-negotiable.

On the basis of an amendment to the 1948 'Law and Administration Ordinance' adopted by the Knesset, the Government of Israel decreed on 28 June 1967 that Israeli law, jurisdiction and administration applied to a 70 square kilometre area east of the 1948 armistice line. In addition to the old city and the municipal area of Arab Jerusalem, this area included some villages that had previously enjoyed independent status. In July 1967, the Arab municipality of Jerusalem was dismantled and East Jerusalem annexed. In his letter to President Jimmy Carter, the Prime Minister of Israel, Menachem Begin, stated that "Jerusalem is one city, indivisible, the capital of the State of Israel. Thus shall it remain for all generations to come."

Palestinians view the borders of the city of Jerusalem to include the area east of the demarcation line of 1949. They consider that there is a need to review the present status of the districts and villages located outside the borders of the 1967 municipality of Jerusalem.

The *de facto* situation on the ground is that in the aftermath of the 1948 war, Israel had full control and occupation of the 'new Jerusalem'; and in the aftermath of the 1967 war, Israel had full control and occupation of united Jerusalem. However, according to international law, occupation and control as a result of the use of force do not necessarily result in legal legitimacy. Furthermore, the operation of diplomatic missions from Jerusalem as a result of the *de facto* situation does not imply the *de jure* recognition of Israeli sovereignty over united Jerusalem.

25.4.4 *Status Quo* Borders

The *status quo* borders refer to the psychological boundaries that separate the Arab East sector of Jerusalem from the Jewish West sector of the city. Three key factors determine psychological boundaries: a) perception; b) a sense of belonging; and c) emotional affiliation. When East Jerusalem was under Arab sovereignty, Palestinians took good care of their city. However, when the Arab part of the city fell under Israeli occupation, the Israelis never felt that the East sector of the city belonged to them. The Municipality of Jerusalem neglects to develop the Arab Jerusalem sector in par with the Jewish Jerusalem as a general policy.

Since the early days of their occupation of Arab Jerusalem in 1967, the Israelis erected a *cordon sanitaire* around the Arab sector of Jerusalem. Palestinians were granted Israeli blue identity cards as residents of Jerusalem while some remained Jordanian nationals. The Israeli law was imposed but the Palestinian Arab curriculum was in use in the municipal and private high schools in the Arab sector of Jerusalem.

In the Israeli political rhetoric, Jerusalem was one united city not to be redivided. However, in their psyche as well as in their day-to-day practice, two cities existed. One neglected Arab ghetto in which Palestinians resided under tremendous social, political, legal, and economic pressures, in addition to poor health, educational and sanitary conditions; the other in which Israelis resided was a flourishing modern style well-maintained beautiful clean city. High in the clouds, Jerusalem's universal spirit roamed with no borders.

No doubt, there is a growing high degree of national polarization affecting daily activities in the city of Jerusalem where two main focal identities exist – a national Arab/Israeli focal identity, and a religious Moslem-Christian/Jewish identity. The Arab national identity used to attract Palestinians from the West Bank and the Gaza Strip for their prayers, shopping, business, commerce, and entertainment. Similarly, the Jewish focal identity attracted Jews for similar reasons. Both are dominantly inhabited by their respective constituencies. Residency in each is highly segregated while commerce, labour and trade are moderately so depending on the political temperature. While some Palestinian Jerusalemites walk to the Jewish sector for shopping, many seek work opportunities there. Few Jews shop in the Arab sector while none seeks job opportunities there. Palestinian Arabs, who between 1948 and 1967 formed the absolute majority of the population of East Jerusalem, became a minority in their own city. In 1967, the demographic balance was 70/30 per cent while today it is 66/34 per cent.

Figure 25.7: Israeli Settlements and Palestinian Neighbourhoods in East Jerusalem (2000). **Source**: Palestinian Academic Society for the Study of International Affairs (PASSIA); at: <http://www.passia.org/palestine_facts/MAPS/images/jer_maps/Settlements.html>.

25.4.5 Administrative Borders

The administrative borders mark the municipal boundaries of the city of Jerusalem. While the political, cultural and psychological borders separating Arab Jerusalem from Israeli Jerusalem were beyond Israel's power to erase by law or force, the administrative line marking the borders of separation between both sectors of Jerusalem was erased. However, Palestinians define the geographical boundaries for the Jerusalem administrative district as they were during the period 1948–1967.

According to the Jordanian regulation 125 issued based on Article 120 of the Jordanian constitution, the district of Jerusalem included the following cities, villages and tribes:

i. a. The district of Jerusalem comprised 36 cities, villages and tribes.

b Jericho: 6 cities, villages and tribes

c. Bethlehem: 15 cities, villages and tribes

ii. a. Sub-district of Ramallah which comprised 9 cities, villages and tribes.

b. Nahiet al-Nabi Saleh: 9 cities, villages and tribes

c. Nahiet Deir Kadis: 9 cities, villages and tribes

Accordingly, the Arab municipality of Jerusalem under Jordanian authority (1951–1967) included the following localities:

1. The City centre and its environs which include the Old City, Musrarah, the American Colony, Salah ed-Din Street, Bab al-Zahra, al-Thouri, Al-Tur, Sowaneh, Wadi el-Joz, Sheikh Jarah, Silwan, Ras el-Amoud, Shufat, Beit Hanina, Kufr Aqab, Sur Bahir, Um Tuba. Israel excluded the following three localities from the Jordanian municipal boundaries of Jerusalem: (1) Beit Safafa, which was annexed to the Bethlehem district; (2) Gilo Settlement, which was annexed to Ramallah district; (3) Jerusalem Airport near Qalandia, which was annexed to the Ramallah district.

Israeli settlements were constructed in this Arab territory on confiscated land, among them: Neve Ya'acov, Pisgat Ze'ev, Ma'alot Dafna, Giva'at Hameftar, Giva'at Hamatos, Ramot, French Hill, Talbiot, Rekhes, Atarot Industrial Zone, Gilo, Har Choma, and Ramat Eshkol.

25.4.6 Municipal Borders

In 1967, the municipal boundaries of East Jerusalem were enlarged 10.5 times of its original size from 6.5 km^2 to 70.5 km^2. The municipal boundaries of the city of Jerusalem reflected the political geography of the city from the Israeli perspective, rather than its urban structure. In an effort to maintain and preserve its power position in Jerusalem. Israel consistently manipulated the city boundaries for its own advantage to meet its political and religious ambitions. The Israeli Government tended to distort the popular constituency of Jerusalem by implementing the American practice of gerrymandering, i.e. redrawing congressional districts to favour the interests of the political party or persons in power.

The Israeli Municipality of Jerusalem copied skilfully the science of gerrymandering in drawing the map of the united city of Jerusalem. Gerrymandering aimed to keep the Arab heavily populated neighbourhoods such as Al-Ram outside the borders of the city while including the unpopulated areas under full Israeli control and thus corrupting the districting process. Gerrymandering took advantage of the ethnic and religious distinction of Jewish and Muslim/Christian constituencies. The municipal boundaries were drawn in a zig-zag manner in order to include as much as possible of the unpopulated land and to exclude as much as possible the Palestinian populated suburbs of Jerusalem.

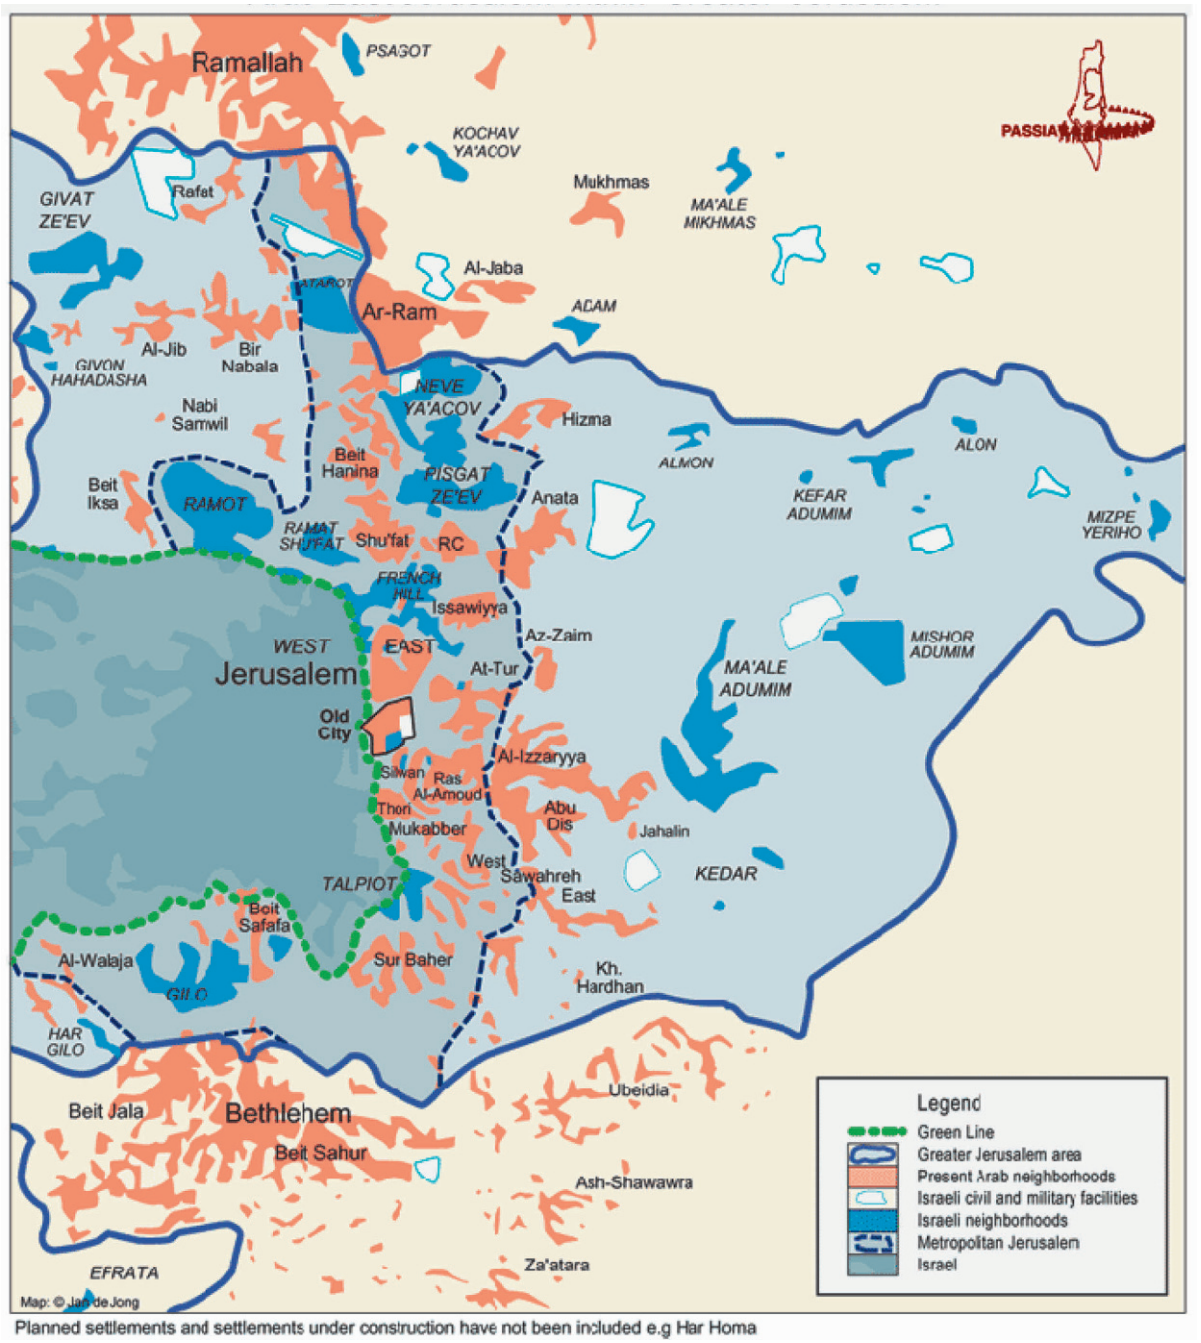
Were the Arab neighbourhoods on the periphery of the city of Jerusalem included when the boundaries of the city were extended, then the percentages of the Palestinian residents would have risen in equity with the increase in the size of the municipal area. However, Arab neighbourhoods on the periphery of the city were excluded when the boundaries of the city were extended. The skilful art of gerrymandering succeeded in lowering the percentage of Palestinians living within the municipal boundaries of the city, making them a one-third minority in comparison with the two-third Jewish majority.

One result of this gerrymandering distortion is that the interests of Palestinian residents of the city have been largely curtailed and neglected as they were discriminated against by the Israeli Municipality of Jerusalem in almost everything from education to health to taxing abuses and even to garbage collection.

In addition to the 1967 municipal borders and the localities annexed to it since 1967, the future borders of Arab Jerusalem should include the following heavily populated Arab localities. Many of these places were part of the Jordanian district of Jerusalem in the pre-1967 period: Issawiyeh, Eizariya, Abu Dis, Dahiet al-Barid, al-Ram, Qalandia, Beir Nabala, al-Jib, Beit Iksa, Beit Sourik, Qubaiba, Beit Anan, Beit Ijza, Katana, Mikhmas, Beit Safafa, Anata, Beit Duqqu, Hizma, Jaba', Nabi Samuel, Judeira, Rafat, Bidu. Israeli settlements constructed on confiscated Arab land such as Ma'ale Adumim, Qidar, Site, Giv'at Binyamin, Mishor Adumim, Kefar Adumim, A'lmon, Kokhav Ya'acov, Giva'at Haradar, Ramot Allon, Giv'on Hadasha, Giva'at Ze'ev, Nahal Anatot are subject to negotiations to determine their future status (figure 25.7).

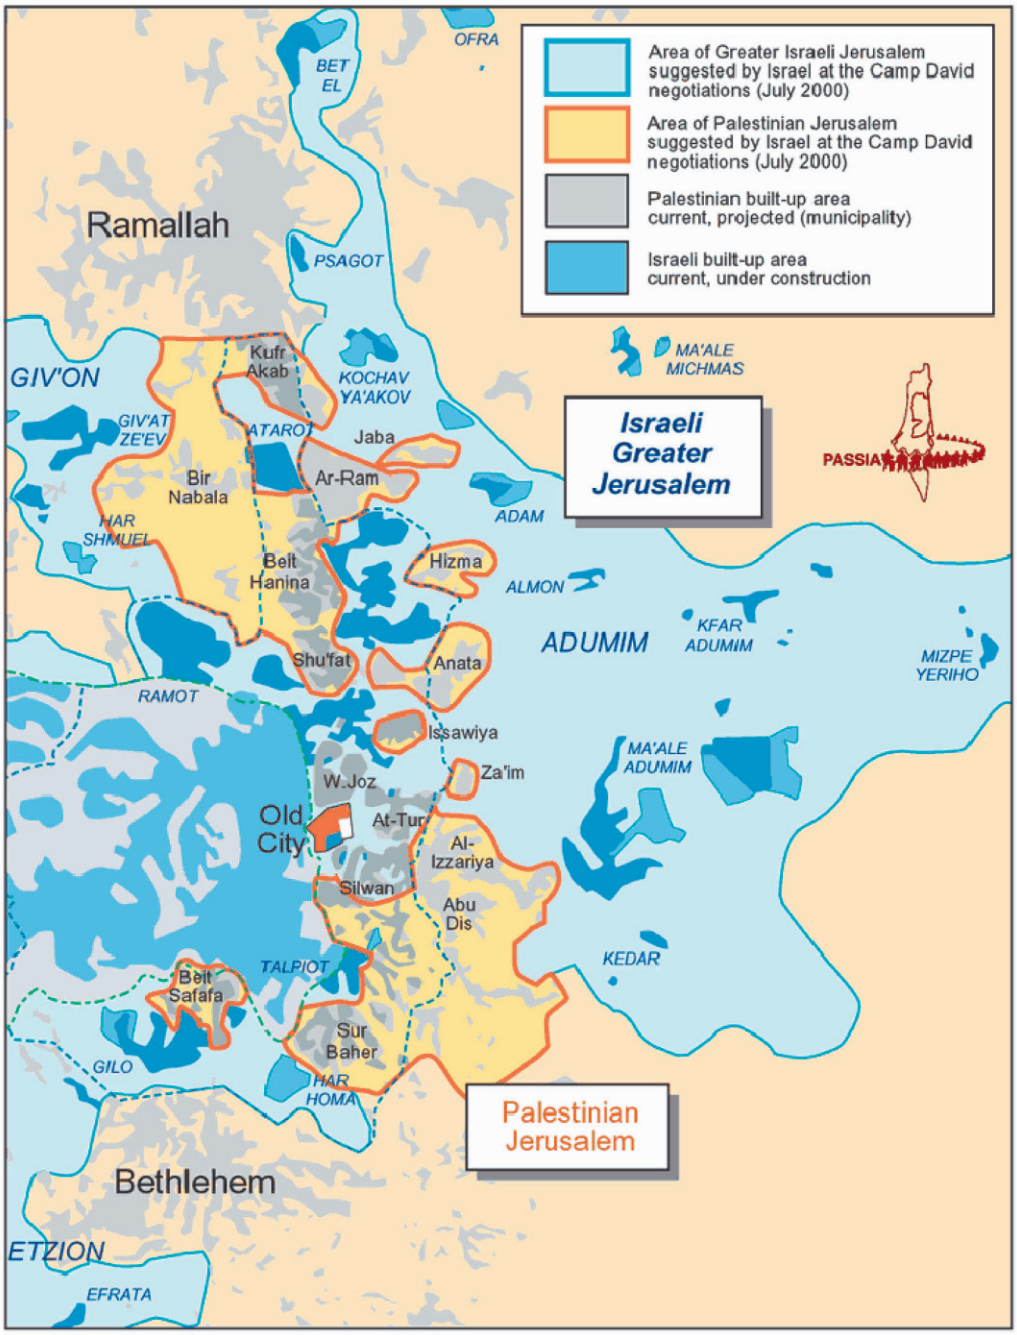
Without having a fair part of the city votes, it is difficult for Palestinian candidates to get elected to the Israeli municipal council. Two suggestions were proposed to bring some justice to the equation. Former

Figure 25.8: Arab East Jerusalem with 'Greater' Jerusalem. **Source:** Palestinian Academic Society for the Study of International Affairs (PASSIA).



Mayor of Jerusalem Teddy Kollek suggested after he left office the idea of 'occasional concessions'; others suggested 'equitable representation.' However, when drawing the municipal boundaries of the two sectors of the city, the following three principles should be adopted: compactness; homogeneity of popular interests; and equality of populations.

Figure 25.9: Projection of the Israeli Proposal for Jerusalem's Final Status, Camp David, July 2000. **Source**: Palestinian Academic Society for the Study of International Affairs (PASSIA); at: <http://www.passia.org/palestine_facts/MAPS/images/jer_maps/Jlem_camp_david.html>.



25.5 Models Proposed for the Future of Jerusalem

There is one question that preoccupies all those concerned about the future of Jerusalem. What is the most practical and useful model for power sharing and division of responsibilities for the future City of Jerusalem? These three models had been proposed for the future of the City:

Figure 25.10: Expanding Jewish settlements in East Jerusalem. **Source:** © Philippe Rekacewicz, Le Monde Diplomatique (February 2000); at: <http://mondediplo.com/IMG/arton2066.jpg>. Reprinted with permission of the author.

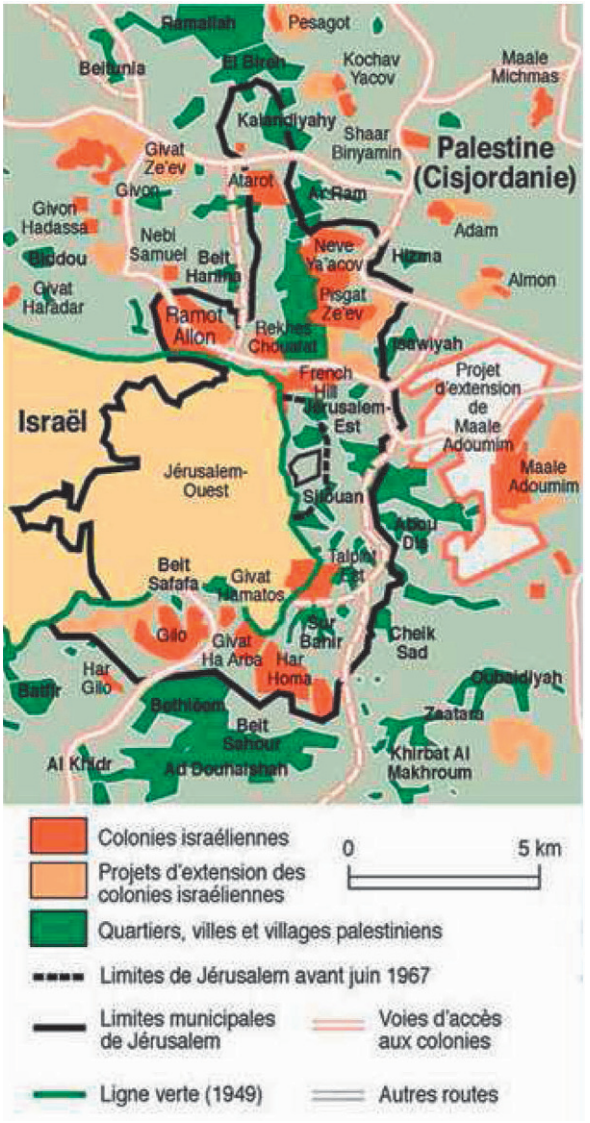


Figure 25.11: Mapping the Conflict. Israeli proposals made at the Camp David talks in July 2000. **Source:** © Philippe Rekacewicz, Le Monde Diplomatique (February 2000); at: < http://mondediplo.com/maps/mappingtheconflict200109>. Reprinted with permission of the author.

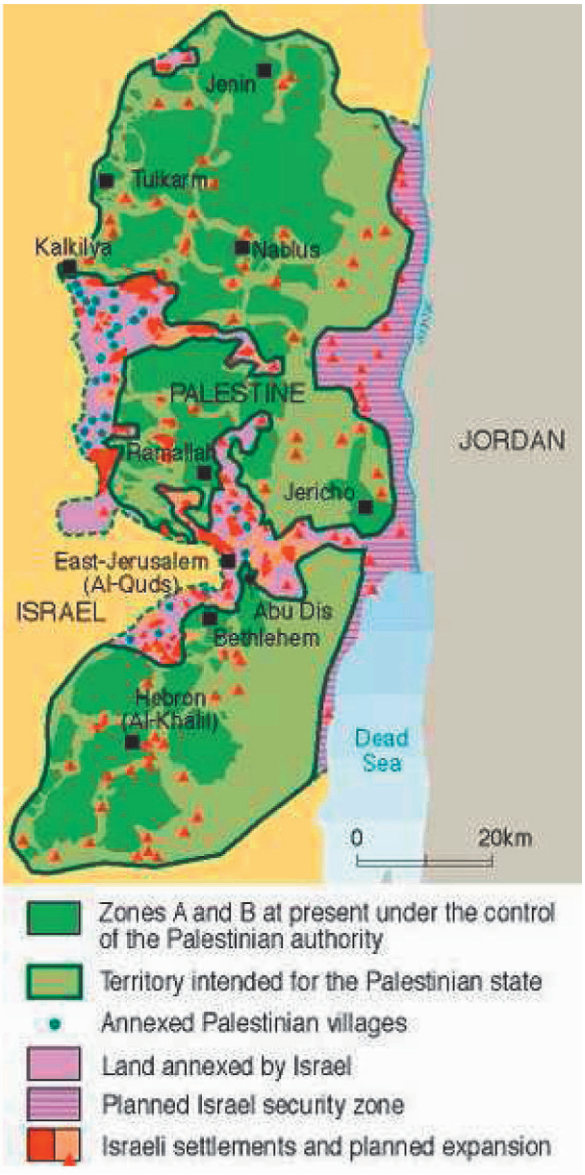

- Model I (International): An international united city; or a bi-national undivided condominium city;
- Model II (Israeli): One national united city;
- Model III (Palestinian): Two national divided cities; or a bi-national twin politically separate but geographically undivided city.

25.5.1 International Model

The first model of an international united city of Jerusalem is not new. Britain, France and Russia initially conceived it in the Sykes-Picot Agreement of 1916. The United Nations again suggested the concept of Jerusalem as a separate area *(corpus separatum)* in its Partition Plan of 1947 (figure 25.5). In December 1949, the UN General Assembly restated its intention to establish an 'international regime' in Jerusalem, which would provide adequate protection for the holy

places. However, the plan for internationalizing Jerusalem presented by Count Folke Bernadotte, the UN mediator in Palestine, was never approved by the United Nations and the international community withdrew this proposal given the strong opposition from both Israelis and Arabs.

Another model is that of a bi-national undivided *condominium* city. Condominium is a Latin term formed of two words: *con*, meaning together, and *dominium*, meaning ownership, thus 'joint ownership'. It also means joint administration over a given territory or unit in a multi-unit structure. It implies joint sovereignty by two or more nations and refers to 'a regime in which two or more states control a particular area on a basis of equality and in accordance with a specific arrangements to which they have agreed'. Precedents of condominiums are Chandigarh, the joint undivided capital of two neighbouring Indian states, Sudan, a condominium of Britain and Egypt for half a century prior to its independence in 1956. Then there are the New Hebrides Islands in the South Pacific, now the independent nation of Vanuatu, which during colonial times were under the joint undivided sovereignty of Britain and France. Finally, there is the example of Andorra, a tiny republic in the Pyrenees between France and Spain, which was under the joint French and Spanish undivided sovereignty.

The British journalist Michael Adams proposed the 'condominium' model in 1968 as a way to reconcile Arab-Israeli competing claims for sovereignty over Jerusalem. A number of scholars have adopted this model, among them John V. Whitbeck, a Paris-based international lawyer. Its main points include a joint sovereignty over an undivided city, i.e. "the city would be a condominium of Israel and Palestine." In the context of a two-state solution, united Jerusalem would form an undivided part of both states and constitute the capital for both states. An umbrella municipal council and local district councils would administer the city; a borough system modelled on the French-style *arrondissements* 'could bring municipal government closer to the different communities in the city'.

The advantages of this model are: 1) The City of Jerusalem would remain undivided; 2) Both Palestinians and Israelis would have a say in the future of Jerusalem; 3) Both Palestinians and Israelis would name the city as their national capital; 4) Both Palestinians and Israelis would jointly own and jointly govern the territory of united Jerusalem, but with dual administrative and legal arrangements. The weakness of the model lies in its impracticality in terms of implementation.

The 'condominium' model for Jerusalem distinguishes between political sovereignty over one city and functional sovereignty pertaining to the municipal administration of two cities: one Arab and the other Israeli. The scheme implies either a joint Israeli-Palestinian shared sovereignty over the united city of Jerusalem, which Israel strongly rejects, or a joint Israeli and Palestinian shared sovereignty over 'ambiguous' certain areas of Arab Jerusalem, which the Palestinians strongly reject.

In late December 2000, US President Bill Clinton proposed Jerusalem would "encompass the internationally recognized capitals of two states - Israel & Palestine," with Palestinians having some "form of sovereignty over Haram al-Sherif as well as over Arab neighborhoods in East Jerusalem....Israel would annex the giant settlement blocs adjoining Jerusalem." An "international presence" would monitor enforcement of agreement. The Clinton Plan divided the city into a checkerboard of different sovereignties.

25.5.2 Israeli Model of One National United City

The concept of the city of Jerusalem as 'one city united and undivided under Israel's full sovereignty' is the official Israeli policy on Jerusalem. In the aftermath of its occupation of East Jerusalem in June 1967, Israel formally annexed the Arab sector of Jerusalem and enlarged the municipal area of the city more than ten times its original size. Israel succeeded in the *Camp David Framework for Peace in the Middle East* (1978) on the principles governing a comprehensive peace settlement to place occupied Jerusalem totally outside the scope of the powers and responsibilities of the projected 'self-governing' authority.

In its 1996 election platform, the Likud outlined its position on Jerusalem as follows: "United and undivided Jerusalem is the capital of the State of Israel. Activities which undermine the status of Jerusalem will be banned, and therefore the PLO and Palestinian Authority institutions in the city, including the Orient House, will be closed."

After the election of Prime Minister Benjamin Netanyahu the guidelines of the Israeli government on Jerusalem were: "Jerusalem, the capital of Israel, is one city, whole and united, and will remain forever under Israel's sovereignty... The Government will prevent any action which is counter to Israel's exclusive sovereignty over the city." Likewise, in its 1996 elec-

Figure 25.12: Arab Jerusalem Airport in 1962. **Source**: Photo from the personal photo archive of the Dajani family.

tion platform, the Israeli Labour Party claimed: "Jerusalem, the capital of the State of Israel and the focal point of the Jewish people, will remain undivided, under Israeli sovereignty." Various Israeli experts, such as former Mayor of Jerusalem, Teddy Kollek, political geographer Saul Cohen, Mapam Party leader Ya'akov Hazan, and many others, proposed a number of plans for the city, which reiterated the Israeli official line of advocating Jerusalem as "one city united and undivided under absolute Israeli sovereignty." Israeli policies viewed Palestinian presence in Arab East Jerusalem as purely functional; the city would be divided into boroughs in which the Arabs will be guaranteed some social, cultural and educational autonomy.

The main characteristics of the Israeli model are the following:

1. It keeps the city of Jerusalem united under Israel's full control and assigns the sovereignty over the entire city exclusively to the Israelis, and thus allows the continuation of the domination of one people over another in defiance of international law. In addressing the Jordanian Parliament on 23 November 1993, late King Hussein of Jordan reflected Arab views when he asserted: "A just and comprehensive peace will not be realized until Jerusalem becomes a city of peace and its occupied Arab land is returned to its owners. ... A full settlement is impossible as long as Israel demands sole sovereignty over Jerusalem."
2. It enjoys general support from the Israeli public.
3. It allows Israeli political national considerations to remain the cardinal cornerstone with regard to future planning and development of the united city.
4. It promotes a city government structure that taxes one segment of the population (Palestinian Arabs) much more while spending much less in response to its needs.
5. It advocates a process of local government system, which allocates public resource among the various services and functions in a manner that would benefit one segment of the community (Jews) more than others (Muslims and Christians). It is a system in which political and religious factors make an important difference in determining the level of services delivered and the manner of their distribution (who gets what?).
6. It lacks support of the Palestinians as it only grants them purely 'functional sovereignty' rather than 'political sovereignty' over Arab Jerusalem while retaining Israel's political sovereignty over the united city. Moreover, it grants Palestinian residents of Arab neighbourhoods in Jerusalem a special status within the framework of the municipal government that will only allow them to have a

minimum say in the responsibility of the administration of their lives in the city.
7. It contradicts the spirit and letter of the Oslo Accords signed by Israel with the PLO and the Jordan-Israel Peace Agreement, which stipulated that permanent status negotiations should include Jerusalem among other issues. Thus Israel's claim of exclusive sovereignty over Jerusalem pre-empts any genuine future negotiations on the status of the city.

25.5.3 Palestinian Model of Two National Units

Since its establishment in 1964, the *Palestine Liberation Organization* (PLO) adopted a firm policy aiming at the establishment of a political, religious, spiritual and administrative capital in al-Quds al-Sharif, (the holy) city of Jerusalem for a Palestinian state. The proclamation of independence announced by the *Palestine National Council* (PNC), meeting in Algiers on 15 November 1988, called for the establishment of the Palestinian state with Jerusalem as its capital. Consequently, the *Palestinian National Authority* (PNA) continued carrying this banner.

The official Palestinian position on Jerusalem may be summarized as follows:

1. Arab Jerusalem is an integral part of the Palestinian Territories occupied in 1967. Therefore, UN Security Council Res. 242 of 22 November 1967, and Res. 338 of 22 October 1973 that called for Israeli withdrawal from all Arab territories (including Jerusalem) occupied in the 1967 war, should be implemented.
2. The main aim of the Palestinian people is the establishment of the state of Palestine with al-Quds al-Sharif (the holy city of Jerusalem) as its capital.
3. The Israeli unilateral decision to annex Arab Jerusalem and enjoy full exclusive political sovereignty over Jerusalem is totally denied and categorically rejected.
4. Palestinians in the Palestinian Territories, including Jerusalem, have the right and desire for self-rule and self-determination in accordance with international law and the basic principles of democracy.
5. There should be no separation between political sovereignty over Jerusalem and the custodianship over the holy places in the City.
6. There should be a guaranteed freedom of worship at the holy places for all faiths.
7. A removal of all Israeli settlements built in Arab Jerusalem since 1967.
8. The Jerusalem of the future should be an umbrella city for two capitals, one Palestinian in East Jerusalem, the other Israeli in West Jerusalem.
9. There should be free access between the two capitals within the city, which will remain functionally united.
10. Cultural, social, and economic ties should be established between both communities living in the city.
11. No one party should impose its will on the other, or dictate its views regarding the future status of the city.
12. Jerusalem's diversity and its multicultural character must be maintained in any future settlement.

The alternative model is that of a bi-national twin 'separate and undivided' city. *Webster's New Collegiate Dictionary* (1987) defines 'twin' as "made-up of two similar, related, or connected members or parts; paired in a close or necessary relationship; having or consisting of two identical units; being one of a pair." This relates to the future model of Jerusalem as the concept of a twin city – separate and undivided – as proposed by many Palestinian scholars and international experts as an imaginative durable solution for the Jerusalem issue that would realize both Palestinian and Israeli aspirations. Professor Walid Khalidi (1988) of Harvard University proposed these ten points as a solution for the future status of Jerusalem:

1. East Jerusalem would be the capital of Palestine, with its own municipality in the extended municipal borders of 1967; West Jerusalem would be the capital of Israel.
2. The borders between West and East Jerusalem would follow the 1967 lines, but be open both ways – 'sovereignty without walls' – subject to agreed security arrangements.
3. The Jewish quarter in the old city, the Wailing Wall plaza, and the Jewish cemetery on the mount of Olives would have extraterritoriality.
4. An agreed number of Jewish residences of East Jerusalem would remain, as Israeli citizens, with their own boroughs within the Palestinian municipality of East Jerusalem.
5. Each religion would be in exclusive charge of its own holy places and institutions, but an ecumenical council with a rotating chairmanship would promote interfaith harmony.
6. Central structures with rotating chairmanships would exist at both an interministerial and an

Figure 25.13: Dome of the Rock, Christian churches, and Jewish cemetery outside the wall. Holy Sites of Muslims, Jews and Christians in Jerusalem. **Source**: Photo by Úrsula Oswald Spring (Mexico). Printed with permission.

intermunicipal level to address the political and infrastructural issues respectively between East and West Jerusalem.
7. Land acquired by Israel but not built upon in East Jerusalem would be returned to the Palestinians.
8. The choice of compensation or return would be accorded to Palestinian Jerusalemites.
9. Jewish colonies outside the extended 1967 municipal borders would be addressed in the final status negotiations on the settlements in the West Bank.
10. There would be an agreed transitional period.

Professor Sari Nusseibeh (1991), President of Al-Quds University, proposed the following 'mixture of separation and integration' in which Palestinians and Israelis have 'separate sovereignty' over Jerusalem:

1. The Palestinians will have sovereignty over eastern Jerusalem and the Israeli over western Jerusalem in an undivided city.
2. Jerusalem would have an extended and joint municipal government, or joint function of two separate municipal governments, which would operate both sectors, such as sewage, fire-fighting, street lighting, tourist aid and facilities, public health, whose enjoyment by the citizens and benefit is non-exclusive.
3. Matters such as the culture, political and religious affairs would be operated by two separate municipal governments.
4. Jerusalem would be the seat of two capitals and systems of government.
5. The city would have its own single court of law, supervised by a judiciary body whose members are seconded respectively by the two states and whose legal framework is adjusted to address the unique states and dealings of the city's Israeli and Palestinian residents.
6. The outlying metropolitan borderline endowing the city with a special status to be enhanced.
7. The porosity of the city borders should allow the free movement of capital, goods, and persons, to make it possible for residents, whatever their nationality, and wherever they reside, to move freely.
8. The city is to be declared a violence-free and demilitarized zone, a sanctified area that provides free access to all pilgrims and visitors at all times.
9. To introduce an honorary role for a distinguished international public figure to be appointed as UN representative with a special Jerusalem title.
10. To adopt a massive renovation programme in the Old City.

25.6 Proposed Troika Model for Jerusalem

Previous proposed models reflect the interests of one community at the expense of the other. Each demands exclusive sovereignty rights over Jerusalem as a united city or as a divided city. In the scheme where the united city is internationalized, the Israeli and Palestinian sovereignty claims over the city are ignored and thus the model is rejected. In the scheme where the city remains united under Israeli control, Palestinian sovereignty claims are ignored. In the scheme where there is joint sovereignty, the interests of the international community are ignored. Thus, we are proposing a model, which meets the requirement of what has been earlier defined as a 'sustainable resolution' since it aims to fulfil the needs, demands, hopes, and aspirations of the three major players, namely, the Israelis, the Palestinians, and the international community – Jews, Moslems, and Christians.

Our proposal aims to overcome the political hurdles and to provide political attractiveness that makes it promising for all three monotheist religions for which Jerusalem is a holy city. In this context, 'Jerusalem' is composed of the one square kilometre area that falls inside the walls of the Old City. We suggest for a future settlement that the walled Old City be declared a *corpus separatum* subject to a 'special status troika regime', and that the rest of the city of Jerusalem would be divided to two sectors – West/Israeli and East/Palestinian. The arrangements to be determined for the administration of the city would take the interests of all the inhabitants into account including those of the Jewish, Christian, and Muslim communities. East Jerusalem excluding the Old City would be under Palestinian sovereignty; while West Jerusalem would fall under Israeli sovereignty. Those who lost properties in consequence to the 1948 conflict would receive compensation for it.

The 'special troika status' of the Old City of Jerusalem have the following advantages:

1. It meets the claims of both Palestinian and Israeli to Jerusalem as the capital of their nations;
2. It resolves the thorny issues of sovereignty as it bestows sovereignty rights related to governmental matters to each state in the sector where it has the major population weight;
3. It takes into account the desires of both the Palestinians and Israelis to have each community take responsibility of dispensing with functional needs of residents in their respective sector of the city;
4. It has the potential to enjoy support from the international community;
5. It satisfies the needs for identity and recognition for both antagonists;
6. It places emphasis on urban considerations and human needs as the cardinal cornerstone with regard to city planning and development rather than religious zeal, politics and nationalism;
7. It meets the requirements of international law and UN resolutions;
8. It allows the city to become fully accessible to the international, regional, and local communities; and,
9. It provides peace, prosperity, and security to the city, its inhabitants and visitors.

This model fulfils the symbolic, religious, spiritual and psychological needs of both Israelis and Palestinians. While the Israeli and Palestinian sole claims to Jerusalem are exclusive claims to the total city, this plan reflects a limited realistic and practical inclusive future plan for the city.

25.6.1 Sovereignty

In searching for a practical, realistic, and pragmatic answer for the future of Jerusalem, the major element in this complex formula of sovereignty must be de-emphasized. Attempts to resolve the Jerusalem issue in the past have failed because they have invariably hinged on the question of sovereignty and nationalism since these claims were mutually exclusive and diametrically opposed. Jean Bodin (1530–1596) in his theory of sovereignty defined the term as, "the absolute and perpetual power of a republic." *A Concise Dictionary of Law* (1991) defines sovereignty as: "Supreme authority in a state. In any state, sovereignty is vested in the institution, person or body having the ultimate authority to impose law on everyone else in the state and the power to alter any pre-existing law. How and by whom the authority is exercised varies according to the political nature of the state."

The rising tide of democratic ideals in the 19th and 20th centuries caused political thinkers to re-evaluate the concept and demand it to be replaced with other concepts that were more fitting with the new spirit of the century. New developments in the law of the sea led to the emergence of the concept of functional sovereignty, i.e. "situations in which the State has sovereign powers to undertake only certain activities in a specific sea area." (Source year: page) Similarly, a more flexible attitude to the concept of sovereignty is required. Here, the traditional concept of sovereignty,

as an 'all-embracing and indivisible quality', needs to be revised. In this particular case, the idea of sovereignty ought to be fragmented and the notion of divided sovereignty or fragmented sovereignty should be introduced and developed to become a divided triple sovereignty. While shared sovereignty and scattered sovereignty refer to territorial sovereignty on the vertical and horizontal level, 'an absolute indivisible sovereignty', fragmented sovereignty deals with distribution of authority and power in the city of Jerusalem into various horizontal components. It calls for the division of sovereignty in theory and practice among three different components to be divided among three entities i.e. to have sovereignty vested in three bodies, a governing body, an administrative body, and a religious body.

- *Spiritual sovereignty (to include religious sovereignty)*: The ultimate source of authority in the walled Old City of Jerusalem, as King Hussein of Jordan emphasized, should be for God and for God alone. It is within those walls that the religious sites which Jews, Christians, and Moslems revere. No state, institution, person or body should have ultimate control over the Old City exclusively.
- *Governance Sovereignty*: General governance sovereignty over the Old City of Jerusalem would be vested in an umbrella: a *Troika Governance Council*. The Troika will be formed from three equal constituencies: members representing both, the State of Israel and the State of Palestine, and members selected by the Security Council of the United Nations.

The city of Jerusalem would be comprised of three entities: Arab East Jerusalem (*al-Quds*); Israeli West Jerusalem (*Yerushalayim*); the walled Old City (*Yerushalayim/al-Quds*) with three separate municipal entities. Palestine would practice direct sovereignty over Arab East Jerusalem and shall declare it its religious and political capital. The State of Israel would practice direct sovereignty over of Israeli West Jerusalem and shall declare it its religious and political capital. The state of Palestine would recognize the governance sovereignty of the state of Israel over West Jerusalem and recognize it as its religious and political capital. In reciprocation, the State of Israel would recognize the governance sovereignty of the State of Palestine over East Jerusalem and recognize it as its religious and political capital. Governance sovereignty would encompass executive, legislative, and judicial jurisdiction in the assigned territories for each state outside the walled city. Both states of Israel and Palestine would recognize the special troika status of the Old City as 'holy status' under God's sovereignty and international auspices.

- *Spiritual Sovereignty*: As the holy city of God, the spiritual sovereignty over the Old City of Jerusalem will be for God and for God alone.
- *Religious Sovereignty* over the Walled Old City of Jerusalem will be vested in a Troika Council formed from the three faiths, Muslim, Christian and Jewish. Religious Sovereignty would not encompass legislative and judicial powers in the area within the walled city.
- *Administrative Sovereignty*: The *Troika Administrative Council* would have broad powers over administrative matters for the Old City of Jerusalem. Administrative sovereignty would encompass the power and authority to administer the municipal affairs of the city. It would include functional sovereignty. The Troika would enjoy extensive powers of supervision over the functioning of the subsidiary units. The Troika would be entrusted with the responsibility of providing common services for the subsidiary units.
- *Arab/Israeli Jerusalem Municipal Council*. An elected *Municipal Council* would manage the Arab East Jerusalem. And a similar Israeli council would manage West Jerusalem. Both would retain a general coordinating authority and specific controlling joint powers in certain spheres. Both would have the powers to provide specific functional city needs. Members of each municipality including both mayors would be elected by taxpayers that had habitually resided in the city. The powers of each *Municipal Council* would include education, health, social services, sewage, water supply, electricity, garbage collection, fire protection, local transport, communications, parks and recreational facilities.
- *Subsidiary Units*. The locally elected subsidiary municipal units would enjoy powers of local government and administration. Each subsidiary unit would have a micro-municipal status and would enjoy autonomy in the day-to-day administration of its affairs in certain areas such as education, health, sports etc. The basis for the division of subsidiary units within the boundaries of each municipality would be geographical.

25.6.2 Borders

The sad memories of conflict over borders among nations provide strong motivation to exert all efforts to obliterate borders in general and to belittle their significance. As the Berlin Wall failed to prevent people from crossing over to West Berlin, a similar wall around Jerusalem is not preventing Palestinians living outside the municipal boundaries of the city from crossing over to East Jerusalem. Any borders constructed around Jerusalem to prevent people and goods from entering will be a denial of human rights to access religious holy places for prayers and seeking God; some Palestinians living in the West Bank, whether Moslems or Christians, slip by them on their holy feasts to perform their prayers in their holy sites. Thus there should be no physical borders dividing the twin city of Jerusalem and the Old City. However, for functional purposes, a municipal border will demarcate the boundaries of Arab East Jerusalem and Israeli West Jerusalem.

The municipal boundaries of Arab Jerusalem would include as a core the pre-1967 Jordanian boundaries excluding the Old City, the localities officially added to it since 1967, as well as those Palestinian localities, which should have been included within these boundaries but were excluded for political reasons. In addition, the future boundaries would be extended to meet the acute housing, economic and social demands of the Palestinians. Municipal boundaries of Israeli Jerusalem would comprise mainly West Jerusalem, west of the walls whose population is Jewish. A further expansion of the Eastern and Western sectors of the city is recommended, not affecting the Jewish-Arab population mix as much as to accommodate the social and economic needs of the residents of close neighbourhoods and to balance the geographical distribution of the urban structure of the city.

25.6.3 Urban Planning and Future Development

The idea of administering a city under separate functional sovereignties is feasible, possible and practical. New residential, commercial and industrial development would continue in the city and in its surrounding areas. Some face lifting would be undertaken in all sections of the central city, and the physical infrastructure of the city (water and sewage systems, streets, alleys, buildings) which are experiencing deterioration today, would be renovated and perhaps replaced due to their age and long-deferred maintenance. The train would become one of the predominant modes of transportation, with public transit continuing to play a significant role, more so in the Jewish sector than in the Arab sector of the city.

The process of developing Jerusalem as a sustainable city of the future will involve a major cultural change, which for many would mean a change in lifestyle where public transportation, car-pooling, and taxi services would prevail. Restrictions on modern-style high rise buildings would be more strictly enforced in the centre of the city and less so in the periphery. The movement of the people of Jerusalem to suburbia and the fringes of the city would be encouraged to relieve the core city of further high density, condensed and highly populated cells. Crime and drugs are not expected to constitute serious problems because of the smaller proportion of the type of entertainment centres located inside the city that breeds crime and violence (gambling, casinos, sex clubs, etc.) and the strict enforcement of law and order. Improvement in community relations between the two communities would be enhanced. Housing within the boundaries of the city would remain in short supply. Unrest and feelings of insecurity among Palestinians will diminish as Israeli policies and programmes to evacuate and deport them outside the city are expected to cease.

The main activities in each sector of Jerusalem would focus on cultural, educational, touristic, technological, and commercial aspects. The residents of Jerusalem would work mainly in jobs, such as education, tourism, health, engineering, law, commerce, trade, handicraft, photography, and as gold and silver smiths. The mainstay of the economy would be tourism, diaspora investments in the economy, trade, education, banking, and construction. Artistic crafts would play an important role in the beautification of the city.

Significant changes would occur in the existing governance pattern, with the Palestinians having their say in the administration and management of the Arab sector of the city, and with Israelis having their say in the administration and management of the Jewish sector of the city. Joint public decision-making in matters of delivery of services would become highly decentralized. Local district and village elected municipal councils would intervene more effectively in community affairs. A fragmented process of policy formulation would be created to encourage local action. Coordination among the joint municipal units, single municipal units, and local village councils would increase and become an effective tool of governmental

machinery. There will be no restrictions on the movement of people and goods between both sectors of the City. Rights, immunities and privileges of religious denominations and religious institutions with respect to the Holy Places would be preserved, and free access to Holy Places would be protected.

25.6.4 Management of the Old City

The management basis for governing the Old City would have to be a trilateral Palestinian, Israeli and International Governance Council of Jerusalem (Troika) that should be given the following general authorities, functions and responsibilities within the walled area of Jerusalem: a) protecting the holy places, religious buildings and sites; b) supervising and regulating public services within its boundaries; c) taking all necessary measures and precautions to protect people and property from danger due to malicious incidents that would arise due to violence and terrorism; d) designing strategies and establishing plans for the protection of inhabitants from outside dangers (civil defence); e) taking all measures to prevent damages caused by natural disasters and catastrophes then provide relief for victims of earthquakes and other natural disasters; f) taking precaution to prevent public hazards and fires, control fuel combustible material, regulate its sale and storage, operate and maintain vehicles and appliances for extinguishing big fires; g) adopting legislation for residency laws and regulations to grant immigration and residency permits within boundaries of the walled city; and h) implementing laws for environmental protection.

25.6.5 Healing, Confidence and Trust Building Measures

Healing, conciliation, trust and confidence-building measures reflecting the new spirit of peace and cooperation between the Palestinian and Israeli communities, Moslems, Christians, and Jews, would be undertaken to create a healthy peaceful, prosperous, and secure environment. Joint educational, cultural, economic and social activities may be organized to enhance the spirit of living together and to undermine the spirit of living separately apart. Both sides would refrain from making any activity or taking any measures that may infringe on the rights or interests of the other or touch his sensitivity.

25.7 Concluding Remarks

In recent times, many solutions to the Jerusalem problem have been suggested. These many proposals failed to lead to a breakthrough because they promoted exclusive national agendas. The wealth of proposals reflected different maximum positions that never led to an agreement based on mutual respect and common interests. The arguments on the future of Jerusalem should drift from focusing on the doomed maximal win-lose resolution scenarios towards taking a more positive attitude of mutual win-win often painful compromise scenarios. Here, it must be recognized that such sacrifices by the people on both sides of the conflict would not go unrewarded. Although it took military force to tear down the walls which divided Jerusalem, it will surely take profound moral power and deep human commitment to bridge the chasm between Moslems and Jews on Jerusalem. Nevertheless, this should not stop the people in Jerusalem from aspiring to achieve a dream of a Jerusalem sailing in peace beyond the troubled horizons of the 20th century into the rainbow of the 21st century. Thus, the enduring question persists: Will the balance tilt away from a vision of sorrow and death to a vision of life and festivity?

While religion and nationalism based on power have often contributed to hate, violence, and wars, the very goals of the three monotheist religions of the sons of Abraham addressing peace would suggest a shift towards mutual compromise from the maximalist dreams to the small realistic hopes. By referring to a different notion of religions as forbearers of peace and cooperation, and of mutual trust and respect, a solution of the religious aspect could possibly open a different avenue that is hardly present where the Hobbesian vision of the old testament seems to prevail by a thinking on tooth by tooth, action and counteraction as the tragic events in Gaza have shown once more, the impossibility for peace without painful sacrifices. This proposal aims to overcome this fundamental obstacle and could open a different road to peace.

No doubt, the outcome of the peace process will depend on the path that Palestinians and Israelis take in their negotiations on the future of Jerusalem. According to our optimistic scenario the Jerusalem of tomorrow would look much different from the Jerusalem of today.

There is still a very wide religious, political, emotional and psychological divide between Palestinian and Israeli views on Jerusalem, what makes it ex-

Figure 25.14: Al-Haram Sharif and Wall of Mourning: Holy Sites of Jews and Muslims in Jerusalem. **Source**: Photo by Úrsula Oswald Spring (Mexico). Printed with permission.

tremely painful to have both to make historic concessions on the city of Jerusalem. John Whitbeck (2000: 52) had observed: "The future status of Jerusalem is a bit like death. Everyone knows that it is at the end of the road, but virtually no one wants to talk about it because no one can see any solution or happy ending." Similarly, Meron Benvenisti (1996: 11) wrote: "Jerusalem is an enigma without a solution." This chapter takes the optimistic view that should there be good will to reach a win-win solution, there will be a way to achieve this solution.

Perhaps in the complex elements of religion, culture, psychology, and rationality hides the window of opportunity, which might lead to an imaginative solution *sui generis*. An emotional appeal is voiced to awaken the creative spirit of the decision-makers to strive to build bridges of cooperation and understanding for the sake of future generations – our children and our grandchildren. Jerusalem in this case may become what the Camp David 'framework' declared as a goal of Arab-Israeli peace: 'a model for coexistence and cooperation among nations' – an oasis of peace in a troubled sea of conflict.

The good city is the place where one finds home at the end of a long journey. The future city of Jerusalem, should a sustainable resolution be achieved, would be just to the extent that it would offer its residents the missed opportunities of enjoying its beauty and charm.

Under conditions of peace, the urban future of the city of Jerusalem holds many promising prospects. There would be a period ahead where peace would provide an impetus for both communities to expand their capacities and potentials to promote the city's responsiveness to human civilized needs. At a time when many old cities are in trouble, Jerusalem would be one city, which would have the potential to cope with the challenges of the 21st century.

Cooperation of Moslems, Christians, and Jews would tilt the balance towards a more optimistic vision as it would bridge the gap between the two divergent and conflicting views on the future of Jerusalem. It would offer fresh opportunities for imaginative solutions for the problems over Jerusalem. This would help bring the two peoples together, as well as, deepen and strengthen the cooperative spirit between them, leading inevitably to a solid and sustainable peace.

We do believe that citizens could help shape the future of their society by having faith that the future

of Jerusalem will see the fulfilment of Herman Kahn's (1979) technological optimism, which held that technological advances would assure sufficient resources to sustain rapid economic expansion for another 200 years. The future is what humans make of it. As human beings we certainly can shape the future of our society. We do have control over our destiny and so we should design a better future for Jerusalem.

We close with the famous words of Robert Kennedy: "Some men see things as they are and ask 'why' I dream of things that never were and ask 'why not'!" All those who fell in love with the city of Jerusalem should dream of things that never were and ask 'why not'. The dream is creating a joint future for present and future generations by jumping out of the perennial cycle of conflict, hate, despair and violence to an oasis of peace, harmony, tranquillity, and security. No doubt, the fruit of peace would bring a period of prosperity, tranquillity, and coexistence which Jerusalem dearly deserves.

26 Global Climate Change Impacts for the Mediterranean in the 21st Century: Challenges for Human and Environmental Security

Hans Günter Brauch

26.1 Introduction[1]

There is no generally accepted definition of the Mediterranean nor are there any common criteria of the Mediterranean Sea, its space, region, climate or way of life. It is a 'sea' whose shores combine the three continents: Europe, Africa and Asia. There is a consensus that it is a 'region' that once has been a centre of the world that was the cradle of several high civilizations and of three monotheistic religions of Jews, Christians and Muslims.[2]

This chapter focuses on the global environmental and climate change that has been projected in the scientific literature and – under certain assumptions - on the probable societal, economic and political and economic impacts for the Mediterranean region and on the possible – primarily environmental and human – security impacts these may pose for the Mediterranean region by 2020, 2050 and possibly by the end of the 21st century.

However, this analysis faces major scientific and methodological constraints:

- The models of climatologists on future changes in temperature, sea-level rise, precipitation and of the number and intensity of hydro-meteorological hazards are based on different assumptions on future GHG emissions.
- So far, in IPCC publications no joint assessment of the Mediterranean region has been conducted, rather this tricontinental region has been analysed in the context of Southern Europe, North Africa and West Asia. The projected future trends are more detailed for Europe compared with North Africa and in the Eastern Mediterranean. Thus, the quality of the projections for these three subregions is rather uneven.
- The awareness of these global environmental challenges, the political commitment of the elites and the economic, political and administrative coping capacity have differed significantly between Mediterranean EU and non-EU countries in South-Eastern Europe as well as riparian countries in North Africa and in the Eastern Mediterranean.
- The analysis of these *global environmental change* (GEC) and *global climate change* (GCC) challenges and of their possible socio-political impacts has been rather fragmented.
- The scientific discourse and the policy debate on their possible implications for international or regional; national but also for the environmental, human as well as water, soil, food, health and energy security is just starting.[3]
- There are several possible political frameworks for the scientific and policy debate on the security im-

1 This chapter builds on previous publications by this author that focused primarily on the Mediterranean space and the political frameworks (Brauch 2001, 2001a, 2003), on confidence and security building measures (Brauch 1994, 1994a, 2000, 2000a, 2000b), on natural hazards (Brauch 2002d, 2003c), on regional environmental challenges (Brauch 1998), on the socio-political impacts of climate change (Brauch 2006c, 2007f, 2009a, 2009c, 2010), on desertification (Brauch 2006d, 2006e, 2006f; Brauch/Oswald 2009), migration (Brauch 1997b, 1997d, 1998a, 2000/2001, 2008, 2010) and on renewable energy policy (Brauch 1994, 1997, 1997c, 2001b).

plications of GEC and climate change issues: the UN context (Brauch 2001, 2003), the OSCE framework (Wohlfeld/Abela 2000; Wohlfeld 2008; Maas/Briggs/Cheterian/Fritzsche/Lee/Paskal/Tänzler/Carius 2010), the NATO dialogue (De Santis 2003; Bin 2008; Winrow 2000) and the Euro-Mediterranean Partnership (Brauch/Marquina/Biad 2000) that was relaunched as the *Union for the Mediterranean* (UfM) on 13 July 2008.

This chapter will address the following key research questions: What have been the GHG emissions and the climate policy commitments of the Mediterranean riparian countries? What are the projected climate change impacts in Southern Europe, in North Africa and in the Eastern Mediterranean? What are possible societal, economic and political impacts of climate change in the Mediterranean region? Which dangers and concerns may be posed by both the physical and societal impacts of GEC and climate change for international, national, environmental and human security? Which are possible options for proactive coping strategies and which political frameworks and actors may prepare, adopt and implement both reactive and proactive coping strategies.

After a brief discussion of the regional focus on the Mediterranean and its subregions (26.2), the available knowledge on the projected physical (26.3) and societal (26.4) impacts of climate change will be reviewed. Then, past migration trends within the Mediterranean region will be assessed and the possible impact of GEC and GCC on future migration trends during the 21st century will be analysed (26.5). This will be followed by a brief discussion whether the potential impacts of GEC and GCC may lead to conflicts (26.6) and by a systematic analysis as to whether these developments may pose specific security dangers and concerns during the 21st century (26.7) and finally which proactive strategies (26.8) are foreseeable for coping in cooperative and peaceful ways with these developments.

26.2 Mediterranean Region: Southern Europe, North Africa and the Eastern Mediterranean

For millennia, the Mediterranean has been a unique geographical space but – except for the Roman Empire – it has been a divided region politically, economically and culturally. Most authors agree that the 'Mediterranean' is characterized by both *unity* and *diversity*, by periods of cooperation and conflict, of tolerance and violent conflicts, by intensive cultural exchange and cultural clashes, of close economic cooperation, interdependence but also by exploitation, unequal exchange and dependence. These contradictions challenge any uncritical application of social science concepts and approaches.[4]

After a brief discussion of the different spatial regionalization of the Mediterranean (26.2.1), the *greenhouse gas* (GHG) emissions and the legal commitments as well as their implementation will be reviewed for the Mediterranean EU countries (26.2.2), the South-Eastern European non-EU Mediterranean countries (26.2.3), for the North African countries (26.2.4) and for the Eastern Mediterranean countries (26.2.5).

26.2.1 Definitions of the Mediterranean

The definitions of the Mediterranean have differed for a) various time periods, b) scientific disciplines, c) based on the conceptual lenses of the scientist that are influenced by national perceptions and traditions, and d) according to specific purposes and goals of the analyst. In order to avoid a total confusion both definitional and conceptual clarity are essential. A consensus exists that the Mediterranean is a 'sea', a 'space' and possibly a 'region' with narrow, medium and wider boundaries. Based on this differentiation of the Mediterranean Sea or basin, space and region three geographic concepts have been generally used:

a) the *narrow concept* of the Blue Plan of the administrative units with a Mediterranean coastline, of the watershed or of the cultivation areas of the olive;
b) the *medium concept* of a Mediterranean perspective that includes all countries with Mediterranean coastlines plus Portugal and Jordan;
c) the *wide concept* of the Mediterranean that includes the Black Sea, the Red Sea and the Per-

sian/Arab Gulf region, recognizing the ecological, cultural and economic similarities.

In addition a fourth political concept of the Euro-Mediterranean region is extensively being used in the policy debate that comprises the member countries of the *Barcelona Process* (BP) and of the expanded *Union for the Mediterranean* (UfM) that replaced the *Euro-Mediterranean Partnership* (EMP, figure 26.1).

Geographers like Wagner (2001) pointed to regional features of *unity* (climate, ecology, vegetation, agriculture, urban culture, traditional economy, one-sided industrialization, emigration, tourism, similar social attitude, interaction of historic, cultural and economic activities) and historical *diversity* due to demography, migration, religion, ethnicity, colonialism and particularism. The contemporary spatial differences emerged from natural and economic differences within the region due to increasing ecological risks, growing economic distances, different demographic patterns, social change, cultural and religious identities, fundamentally different political systems, and impacts from outside due to globalization (processes of economic deregulation, free trade, modest movements towards political liberalization, Westernization, global economic integration) and the regional differentiation is still stronger than trends towards unity.

According to King (1997: 1) only few geographical texts treat the Mediterranean "as a relatively homogeneous regional unit". He believes that defining the Mediterranean is impossible while *Mediterranean identity* is a powerful concept. "The Mediterranean is a sea, a climate, a landscape, a way of life." King, Cori and Vallega (2001: 1–17) reviewed definitions of the Mediterranean based on ecological and physical-geographic criteria (certain species of plants, crops and wildlife), and by geographers and meteorologists who stress the specific climate. The term *Mediterraneanism* (Durell 1956, 1962, 1969; Houston 1964; King 1997) refers to the close interaction between the physical and human realms influenced by the climate, the sea, the land, the vegetation, the long tradition of urban life and the resources offered by the Mediterranean environment "with links to diet, history, landscape, farming systems and ways of life" (King/Cori/Vallega 2001: 4). King referred to aspects of *unity* (climate, ecology, cultural traditions, economy, and strategic location for transporting hydrocarbons) and *diversity* (heterogeneous political regimes, coexistence and confrontations of religions and cultures, economic division) in the modern Mediterranean.

Major unifying elements are: a) common ecological features (climate landscape) and a shared environmental responsibility, that is challenged by urbanization, demography, tourism that have contributed to an 'environmental crisis' (Thornes 2001), b) a common history (Braudel 1972), c) a distinct Mediterranean economy, and d) relatively homogeneous cultures. Beyond this classic dichotomy (unity vs. diversity), King, Cori and Vallega (2001: 4–11) discussed several subdivisions of the Basin: the *North* vs. the *South* in economic, cultural and religious terms, the *Western* vs. the *Eastern* Mediterranean divided by the channel between Sicily and Tunisia; and the division into four land-based sub-regions: a) the *north-west* (EU countries) with low fertility; b) the *south-west* (Maghreb) with high demographic pressures; c) the *south-east* (Mashreq, Gulf countries, Israel) with the Middle East conflict, and d) the *north-east* (Turkey, post Yugoslav states, Albania) with ethnic and religious conflicts, or the juxtaposition of the *First, Second* and *Third Worlds*. Brunett (1995) referred to seven models of the Mediterranean: 1) the closed basin; 2) the straits model; 3) the lake model; 4) the bridge or isthmus model; 5) the hostile barrier or frontier model; 6) the focal model of poles of development; and 7) the model of zones of uneven development. For King, Cori and Vallega (2001: 11) "the Mediterranean is a plural space of overlapping and hazy boundaries and complex economic, political, socio-demographic, cultural and environmental relations."

While the geographical space remained unchanged for millennia, during the past 5,000 years of human history the spaces of rule were in a permanent flux. Different political spatializations due to functional cooperation in different issue areas have emerged since 1990. Empirically, cooperation in the Mediterranean may be analysed for different *actors* (states, economic, societal organizations) at several *levels of analysis* (international, state, and sub-state) for *degrees of intensity* (organizations, regimes, dialogues) and *issue areas*: security and military, political, economic and environmental. The existing institutions of cooperation in the narrow, medium and wide Mediterranean space point to different institutional boundaries (table 26.1).

Anderson (2001: 18–27) analysed the Mediterranean as "a geopolitical fracture zone", arguing that the old East-West divide "has been replaced by a fracture zone between North and South", across the Mediterranean. From his geopolitical perspective, Anderson listed as key issues of a 'macro-political agenda': migration, non-proliferation, terrorism and international debt as sources and consequences of conflicts.

Among the "deep-seated causes of insecurity", he mentioned the different demographic structures on either side of the Mediterranean and concludes: "The Mediterranean is to Europe what the Rio Grande is to the United States." Ragioneri (2000: 81–82) argued that the Mediterranean area can hardly be defined as a region based on cultural and political homogeneity, economic exchange and institutional integration. Rather, Europe and the *Middle East and North Africa* (MENA) could be defined as two different "security complexes" (Buzan 1991: 190) that affect each other and are connected by Russia and Turkey.

These two assessments illustrate how authors with different worldviews and mindsets come to contrasting assessments of the fundamental security issues in the Mediterranean area. But both agree that during the 1990's, in security, political and economic terms the Mediterranean region has been highly fragmented. Since 1995, the Euro-Mediterranean partnership and since 2008 the UfM have been a channel for an increasing cooperation on different issue areas.

The oldest and only truly pan-Mediterranean regime emerged from the Convention for the Protection of the Marine Environment and Coastal Region of the Mediterranean (*Barcelona Convention*) of 16 February 1976 that entered into force on 12 February 1978.[5] This environmental *Barcelona regime* is based on several related protocols, and an amendment to the Convention adopted on 10 June 1995. Major steps have been the development of the *Mediterranean Action Plan* (MAP),[6] of the *Blue Plan*, the setting up as one of nine *Regional Seas Programmes*, of the UNEP *Co-ordinating Unit for the Mediterranean Action Plan* (MEDU) in 1982 in Athens, and finally in 1995 the establishment of the *Mediterranean Committee on Sustainable Development*. It was the first regional environmental regime that evolved from the first global environmental summit in *Stockholm* in June 1972.

Between the EEC, EC and EU and its Mediterranean partners four stages may be distinguished: a) the emerging relationship (1958–79); b) the protocol period (1979–89) and c) the MEDA period (1995–2006) with so far three budget cycles MEDA I (1996-1999), and MEDA II (2000–2004), MEDA III (2005–2006) and since 2006 as part of the European Neighbourhood and Partnership Instrument.

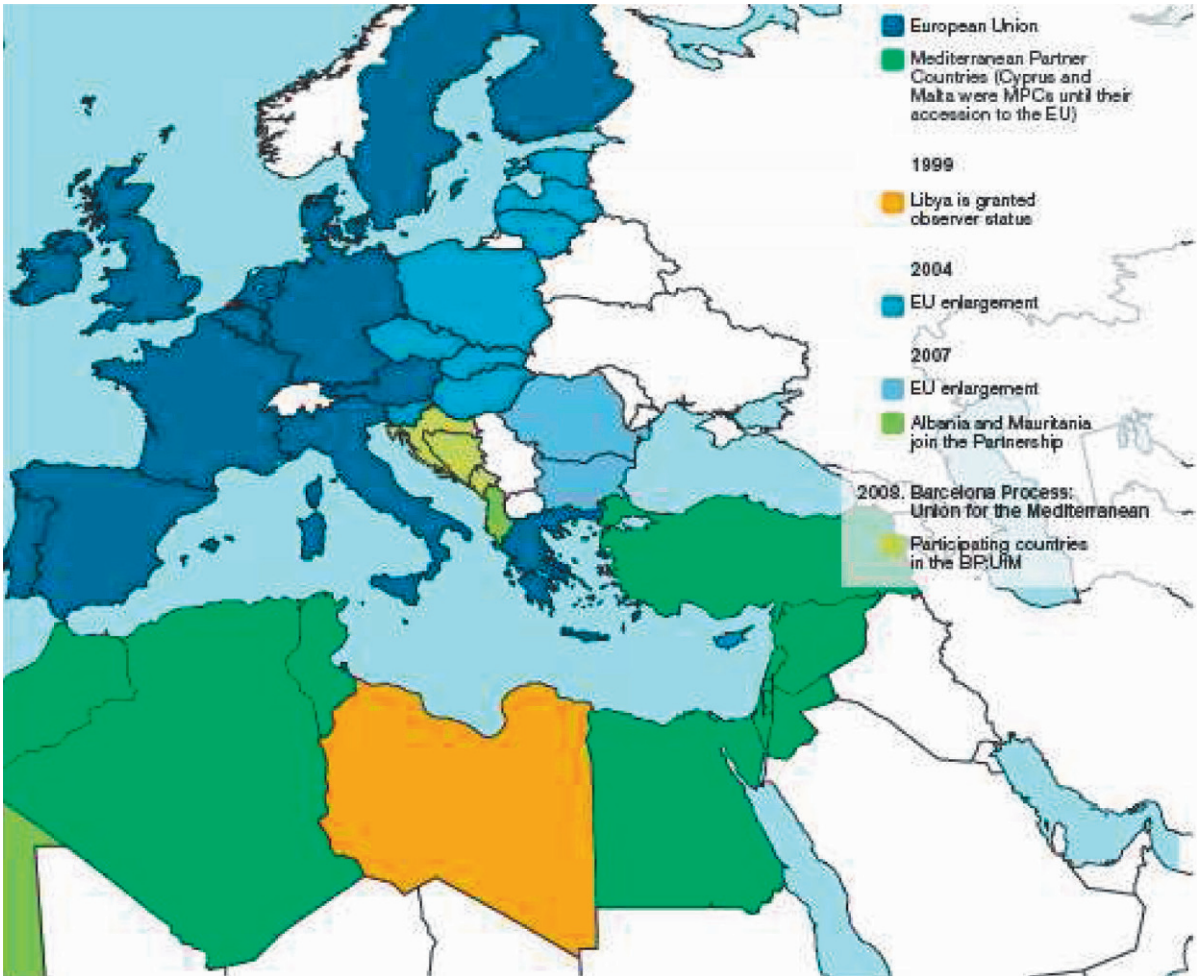
After the relaunch of the EMP on 13 July 2008 in Paris as the *Union for the Mediterranean* (UfM, table 26.2) a joint secretariat was established in Barcelona. The UfM has identified these six priority projects for: a) the de-pollution of the Mediterranean Sea; b) the establishment of maritime and land highways; c) civil protection initiatives to combat natural and man-made disasters; d) a Mediterranean solar energy plan; e) the inauguration of the Euro-Mediterranean University in Slovenia; and f) the Mediterranean Business Development Initiative focusing on micro-, small- and medium-sized enterprises. Of these the first, third and the fourth are directly related to environmental and the latter two to GEC impacts and coping efforts (Brauch 2010).

While for the analysis of the physical and societal impacts of GCC, the IPCC distinguishes among the three continents: Europe, Africa and Asia, for the analysis of the political framework for coping strategies four sub-regions will be distinguished (table 26.3).

5 The text of the Barcelona Convention is at: <http://www.unep.ch/regionalseas/regions/med/t_barcel.htm>.

6 For details on the MAP see at: <http://www.unepmap.org/>.

Figure 26.1: Member Countries of the Union for the Mediterranean (November 2009). **Source:** Brauch (2010: 21) that was provided by the IE in Barcelona.



In May 2010 only 25 (except Malta and Cyprus) of the 27 *European Union* (EU) countries had quantitative reduction obligations under the Kyoto Protocol (1997).

The riparian states of these four sub-regions of the Mediterranean may be distinguished with regard to their degree of environmental and social vulnerability, and with regard to their political and economic capability for coping with the impacts of GEC and GCC (table 26.4).

26.2.2 Southern Europe and EU Mediterranean Countries

Of the eight EU Mediterranean countries, all have ratified the UNFCCC (1992) and the *Kyoto Protocol* (KP) and six had quantitative reduction obligations under the KP. Three of these six countries were permitted as part of the internal EU arrangement to increase their emissions by 15 per cent (Spain), by 25 per cent (Greece) and by 27 per cent (Portugal) until 2012 with regard to 1990 as the base year. Among these six countries only France and Greece fulfilled their obligations, while the performance of Spain, Portugal and Italy failed to achieve their reduction targets (table 26.5). Six Mediterranean EU countries submitted all four national communications required by the UNFCCC secretariat, Malta only the first and Cyprus so far none. In 2005 the GHG emissions per person ranged from 6.5 tons in Malta to 11.5 tons in Greece.

26.2.3 South-Eastern European Countries

All South-eastern European countries have ratified the UNFCCC and the KP but only Croatia, as an Annex 1 state under UNFCCC, has reduction obligations it failed to meet by the end of 2007. Croatia submitted only the first and fourth national communication

a) In November 2009 Serbia and the Former Yugoslav Republic of Macedonia did not participate in the UfM.

26.2.4 North Africa

While all five North African countries have signed and ratified the UNFCCC and the KP, none has reduction obligations. Four countries submitted so far only the first of four national communications to the UNFCCC Secretariat. Thus, climate change issues seem to have only a low political priority for the governments in North Africa. Here the subregional variation in GHG emissions ranged in 2005 from 1.6 tons per person in Morocco to 8.3 in Libya.

Table 26.7: Emission reduction obligations of East Mediterranean countries. **Sources:** See table 26.5.

26.2.5 Eastern Mediterranean Countries

Of the seven countries in the region, the *Occupied Palestinian Territory* (OPT) is no sovereign state and therefore can be no party to the UNFCCC and to the KP. Of all Mediterranean countries Turkey had the worst performance by increasing its GHG emissions by 119 per cent from 1990 to 2007. The GHG emissions per person varied from 2.7 tons/person for Syria to 11.5 for Israel.

The UNFCCC Secretariat supplied a detailed overview on the changes in the emissions of all Annex I countries under the UNFCCC from 1990 (as the base year) to 2007 without or with land use changes and forestry) that show slight variations in the performance of state members.

26.3 Projected Physical Impacts of Climate Change

The IPCC did not systematically assess the climate change impacts in the Mediterranean.[7] Its fourth *Assessment Report* (AR4) reviewed the literature for Southern Europe; North Africa and West Asia (IPCC 2007, 2007a, 2007b) and its Synthesis report (IPCC 2007c: 50) concluded that

> in Southern Europe, climate change is projected to worsen conditions (high temperatures and drought) in a region already vulnerable to climate variability, and to reduce water availability, hydropower potential, summer tourism and, in general, crop productivity. Climate

7 The SAR (IPCC 1996a) dealt in more detail with the impacts, adaptation options and assessment of mitigation options. In the IPCC's (1998) *Regional Impacts* study, Mediterranean issues are covered under Africa, Europe and the Middle East and arid Asia. In the TAR (IPCC 2001a), the African chapter reviewed climate change impacts on water, food security, natural resource management, human health, settlements, infrastructure and desertification (IPCC 2001a: 525). The Asian chapter dealt with physical and ecological features, scenarios for future climate change and key variables for sensitivity and adaptability. The European chapter offered an overview of future European climate change scenarios (IPCC 2001a: 653).

> change is also projected to increase the health risks due to heat waves and the frequency of wildfires.

The IPCC (2007c: 50) noted that Africa will be most severely affected "because of low adaptive capacity and projected climate change impacts" and "new studies confirm that Africa is one of the most vulnerable continents because of the range of projected impacts, multiple stresses and low adaptive capacity".

However, no systematic and integrated scientific assessment exists of the physical climate change impacts for the Mediterranean and especially for the *Middle East and North Africa* (MENA) region. Several research projects, conferences and publications have covered selected impacts.[8] The conference report of a regional seminar organized by the Plan Bleu Regional Activity Centre in October 2008 on climate change in the Mediterranean considered it "essential to develop a Mediterranean ocean-atmosphere regional climate model, taking into account the change in sea surface temperature".[9] The conference report further suggested that priority should be given to "adaptation and emissions reduction" and that the Mediterranean countries "should continue to develop advanced interdisciplinary research programmes". The consensus among the participating experts was that the "resolution of the models should be in the range of 1 to 2 km within the ten years", and that "the refining of the models should be accompanied by the production of more qualitative climate change monitoring indicators".

The Copenhagen Climate Science Conference of March 2009 concluded for the global level that "many key climate indicators are already moving beyond the patterns of natural variability within which contemporary society and economy have developed and thrived", and its authors warned that "with unabated emissions, many trends in climate will likely accelerate, leading to an increasing risk of abrupt or irreversible climatic shifts". Thus, the climate change impacts may be much more severe for the Mediterranean region than the assessments of the IPCC and the Blue Plan have indicated that will be reviewed below.

26.3.1 Observed and Projected Temperature Increases

Depending on the assumptions of the global circulation models assessed by the IPCC (2007; 2007c) the level of increase in greenhouse gas emissions and the temperature increase differ widely. There is a wide consensus among climatologists that a global increase in temperature of 2°C is virtually certain, of up to 4°C is possible and up to 6°C cannot be excluded if business-as-usual trends continue. As COP 15 in Copenhagen failed to agree on binding constraints on GHG emissions, the possibility of a "dangerous climate change" (Schellnhuber/Cramer/Nakicenovic/Wigley/Yohe 2006) may be more likely during this century if no stringent reduction measures are agreed and also implemented in the near future.

On GHG emissions per capita there is a clear differentiation among the northern and the southern Mediterranean countries. The European chapter foresaw that for the Mediterranean due to rising temperature (IPCC 2001a: 651) and declining summer precipitation (IPCC 2001a: 652) the risk of forest fires may increase further. The risk of severe water shortages in the Mediterranean would also have severe effects on freshwater ecosystems in the region (IPCC 2001a: 666).

The UNEP-MAP (2009) report on the *State of the Environment and Development in the Mediterranean* noted that "over the 20th century and with a clear acceleration since 1970, South-Western Europe (the Iberian Peninsula, South of France) recorded an increase in temperature of almost 2°C. The same increase can also be noticed for the North of Africa". On future trends, the UNEP-MAP (2009) report claimed:

> By the end of the century, the average annual temperature increase is likely to be between 2.2°C and 5.1°C for 2080–2099, compared with 1980–1999. The probability of temperatures rising by between 3 and 4°C is estimated at 50 per cent. The expected rise in surface temperature varies from one region to the next – in the Sub-Saharan regions it could well be as much as 4°C in summer. On the other hand, on the northern shores, the rise is likely to be more marked in winter, at around 3°C. Nonetheless, this overall rise in temperature could

8 See the Report of the Regional Seminar on Climate Change in the Mediterranean, Plan Bleu Regional Activity Centre, Le Pharo, Marseilles (France) 22–23 October 2008; UNEP-MAP (2009: 13–28).

9 It referred to three major projects: a) the CIRCLE MED research initiative on water management in coastal sectors; b) the CIRCE project on physical impacts of climate change on the environment, their implications for society, the economy and the adaptation strategies; see at: <http://www.circeproject.eu/>; c) the SESAME project (Southernmost European Seas: Evaluation and Modelling of Ecosystem Change) on how the changes in hydro-climate characteristics have influenced the evolution of the zooplankton over the last 50 years in the northern Mediterranean region. See also the ENSEMBLE project; at: <http://ensembles-eu.metoffice.com>.

> well hide some local falls in temperature relating to changes in air mass. ... The greatest rises in temperature ... are likely to be recorded in the Mashreq (Palestinian Territories, Jordan, Lebanon, Syria and Iraq). Higher temperatures should thus produce summers with an increasing number of very hot days.

These projections referred to by the IPCC (2007) and by UNEP's MAP (2009) apply not only to the increase in temperature but also to projected changes in precipitation.

26.3.2 Observed and Projected Precipitation Changes

The Mediterranean and especially the MENA area is one of the most water scarce regions of the world. The water availability per capita in the Maghreb countries declined significantly between 1960 and 1990 and it has been projected to decline further until 2025 (Berkoff 1994: 68; Jellali/Jebali 1994: 150; chap. 20 by Chourou). The third IPCC Report (2001a: 651) foresaw for the Mediterranean an increase in the variability of water flows with summer flows reduced and in coastal areas, the risks of flooding and erosion will increase substantially (IPCC 2001a: 652):

> Southern Europe will be more adversely affected than Northern Europe. ... In particular, the Mediterranean region appears likely to be adversely affected [... e.g. by] increased variability of river flow; increased flood risk; decreased summer runoff and recharge of aquifers; and reduced reliability of public water supply, power generation, and irrigation. Increased fire hazards affecting populated regions and forests and heat stress on humans, crops and livestock may occur. ... There is greater vulnerability, in general, in Southern than in Northern Europe (IPCC 2001a: 680).

According to the *IPCC Synthesis Report* (2007c: 30), from 1900 to 2005 trends have been observed in precipitation amount in many large regions that "precipitation declined in the Sahel, the Mediterranean...." According to the IPCC (2007c: 50) "in Southern Europe, climate change is projected to worsen conditions". Furthermore, changes in precipitation and temperature lead to changes in runoff and water availability that is projected to

> decrease by 10 to 30 per cent over some dry regions at mid-latitudes and dry tropics, due to decreases in rainfall and higher rates of evapotranspiration. There is also high confidence that many semi-arid areas (e.g. the Mediterranean Basin, western United States, Southern Africa and north-eastern Brazil) will suffer a decrease in water resources due to climate change. Drought-affected areas are projected to increase in extent, with the potential for adverse impacts on multiple sectors, e.g. agriculture, water supply, energy production and health. Regionally, large increases in irrigation water demand as a result of climate changes are projected (IPCC 2007c: 49).

In addition climate change will affect "Mediterranean-type ecosystems because of reduction in rainfall". Working Group II of the IPCC referred to the following water availability and droughts during the 2020's, 2050's and 2070's. Around the Mediterranean the hydropower potential "is expected to decline ... by 20 to 50 per cent" (IPCC 2007a: 743). The chapter on Africa in the IPCC's AR4 (2007a: 443) has only few references to the Mediterranean that reinforce the claims in the European chapter, especially "with the SRES A1B emissions scenario and for 2080–2099, mean annual rainfall is very likely to decrease along the Mediterranean coast (by 20 per cent), extending into the northern Sahara and along the west coast to 15°N" (Christensen/Hewitson/Busuioc/Chen/Gao/Held/Jones/Koli/Kwon/Laprise/Rueda/Mearns/Menéndez/Räisänen/Rinke/Sarr/Whetton 2007). This chapter noted specifically the increased water scarcity:

> in North Africa, considering that estimates for the average annual growth of the population are the world's highest: 2.9 per cent for the period 1990–2002. The Water Exploitation Index is high in several countries in the subregion: >50 per cent for Tunisia, Algeria, Morocco and Sudan, and >90 per cent for Egypt and Libya (Gueye/Bzioul/Johnson 2005). Until recently, these countries have adopted a supply-oriented approach to managing their water resources (IPCC 2007a: 441–441).

This is repeated in the chapter on Asia that stated on water scarcity (IPCC 2007a: 477):

> In arid Central and West Asia, changes in climate and its variability continue to challenge the ability of countries in the arid and semi-arid region to meet the growing demands for water (Abu-Taleb 2000; UNEP 2002; Bou-Zeid/El-Fadel 2002; Ragab/Prudhomme 2002). Decreasing precipitation and increasing temperature commonly associated with ENSO have been reported to increase water shortage, particularly in parts of Asia where water resources are already under stress from growing water demands and inefficiencies in water use (Manton/Della-Marta/Haylock/Hennessy/Nicholls/Chambers/Daw 2001).

This assessment was reinforced by the UNEP-MAP (2009: 13) report on the *State of the Environment and Development in the Mediterranean* noting that "rainfall ... has ... diminished in Southern Europe. In the Mediterranean, some regions to the south have recorded a 20 per cent drop in rainfall. The trend is less even as far as North Africa is concerned."

In the MENA water is extremely scarce. Since 1960, the water per person has dropped and population growth will reduce the water available for irrigated agriculture and the amount of food produced (chap. 50 by Galil). In the 21st century, MENA countries will be confronted with physical, technical and economic constraints. Depending on growth rates, water conservation and efficiency improvements, the water demand in North Africa may fluctuate.

By the year 2000, in North Africa about 63 to 79 per cent of the fresh water was used for agriculture. Only in Algeria this share was 47 to 63 per cent and the share of domestic use was 15 to 30 per cent, while it was below 15 per cent for the other four countries. In all five North African countries between 0 to 16 per cent of the water was used for industrial purposes. In Southern Europe only in Spain and Greece 63 to 79 per cent of the water was used for agriculture, in Italy this share was 31 to 47 per cent and in France it was below 16 per cent.

According to the scenarios of the Acacia project in South Europe precipitation will decline until 2020 in summer in parts of Central Spain by 13–14 per cent and in the northern part of Greece by 10 per cent. Up to 2050 the projected precipitation decline in summer will drop in Greece by 14–20 per cent, in South France by 13–15 per cent and along the Spanish Mediterranean coast by 21–23 per cent. By the year 2080 the decline in summer precipitation in Greece will be between 18–27 per cent, in South France between 17–20 per cent and in Spain between 27–42 per cent. According to the A-2 scenario of the Acacia project a decline of summer precipitation is projected for Spain amounting to 51–73 per cent and to Greece by 41–52 per cent (Parry 2005). According to the data of the Acacia project for parts of the Atlas mountain region in North Africa precipitation may decline in summer until 2020 by 20–25 per cent, until 2050 by 31–49 per cent, and by 2090 by 47–75 per cent.[10]

According to the Blue Plan (Benoit/Comeau 2005: 87) in Morocco 5.7 million people had no direct access to drinking water and 9.1 million lacked access to appropriate sanitary installations. In Algeria the equivalent share was 3.3 million for drinking water and 3.0 million for sanitary units, in Tunisia 1.9 and 1.5 million, in Egypt 1.98 and 1.32 million and in Libya 1.7 or 0.18 million respectively. In Southern Europe in the early 1990's the renewable water supply per person and year was the lowest in Spain and Italy while Portugal had sufficient precipitation. In Mediterranean Spain from 2000 to 2025 the share of the used water will increase from 50 to 75 per cent to above 75 per cent while it was below 25 per cent for Portugal, France, Italy and Greece. In Egypt and Libya the water use will remain above 75 per cent, while it is projected to rise in Mediterranean Morocco from 25 to 50 per cent in the year 2000 to 50 to 75 percent by the year 2025 and along the Algerian Mediterranean coast from below 25 per cent to 25 to 50 per cent (Benoit/Comeau 2005: 87).

During the 21st century, climate change may have significant impacts on precipitation, soil erosion and desertification in the Mediterranean. These climate-related factors will have a significant impact on agricultural prospects: on the availability of arable land and on yields.

26.3.3 Observed and Projected Sea-level Rise

The population in coastal cities of the Mediterranean region has grown between 1950 and 2000 from 25 to 70 million and it has been projected to rise up to 90 million by 2025. In Southern Europe the coastal population doubled between 1950 and 2000 from 20 to 40 million and it will probably stabilize at this level by 2030, while it is projected to rise in the MENA region from 40 to 50 million between the year 2000 and 2030. This will most seriously affect the deltas of the major rivers, most particularly the Nile Delta.

The UNEP-MAP report (2009: 17) noted "between January 1993 and June 2006 ... an obvious east-west differentiation, with a clear trend towards a sea-level rise in the Eastern Mediterranean". The projections on the average sea-level rise have been disputed in the preparation of the IPCC's AR4, which could only agree on an average global increase during the 21st century of 18–59 cm. Rahmstorf referred to recent studies of an observed average increase of the sea level by 1.6 mm/year between 1961 and 2003 and 2.5 mm/year between 2003–2008.[11] Depending on the

10 Carlo Buontempo reminded the author that "this is a common problem when looking at drought in the Mediterranean. An even large percentage decrease in summer precipitation for any Mediterranean country may not be as negative as it sounds as long as winter precipitation doesn't change much. The average number of rainy days in July for the central Mediterranean is 1.2. A reduction of even 50 per cent would only mean few less hours of rain per month."

11 Stefan Rahmstorf: "Sea Level Rise", Copenhagen Climate Science Conference, 10–12 March 2009; at: <http://climatecongress.ku.dk/speakers/stefanrahmstorf-plenaryspeaker-10march2009.pdf/>.

achieved GHG stabilization level and an increase of global mean temperature between 2°C and 4°C, according to the IPCC chairman Pachauri[12] the global sea level may rise between 0.4 and 2.4 metres until 2100. In the Nile Delta, according to Sherif and Singh (1999; WBGU 2006: 45) "an increase of 50 cm would imply that the salty water would intrude about 9 km into coastal aquifers". Without protective countermeasures a sea-level rise of 50 cm would affect in the administrative districts of Alexandria and Port Said about "1.5 million people" (El-Raey/Dewidar/El-Hattab 1999; El-Raey 1991, 1993, 1994, 2000; see chap. 45; WBGU 2006: 48).

26.3.4 Observed and Projected Climate-Related Hazards

The IPCC's Working Group II referred to climate-related natural hazards such as droughts, forest fires and heatwaves as well as storms, floods and landslides. The chapter on Europe (IPCC 2007a: 543) noted that "warmer, drier conditions will lead to more frequent and prolonged droughts, as well as to a longer fire season and increased fire risk, particularly in the Mediterranean region". Beniston, Stephenson, Christensen, Ferro, Frei, Goyette, Halsnaes, Holt, Jylhä, Koffi, Palutikof, Schöll, Semmler and Woth (2007) estimated "that Mediterranean droughts would start earlier in the year and last longer" (IPCC 2007a: 548). Polemio and Casarano (2004) claimed that the Mediterranean "may experience an increase in dry periods by the late 21st century". Further, "the regions most prone to an increase in drought risk are the Mediterranean (Portugal, Spain) [Döll 2002; Donevska/Dodeva 2004]" (IPCC 2007a: 750). This will have severe impacts for agriculture as the crop productivity is likely to "decrease along the Mediterranean and in South-eastern Europe" (IPCC 2007a: 743).

> In particular, in the European Mediterranean region, increases in the frequency of extreme climate events during specific crop development stages (e.g., heat stress during flowering period, rainy days during sowing time), together with higher rainfall intensity and longer dry spells, are likely to reduce the yield of summer crops (e.g., sunflower). Climate change will modify other processes on agricultural land (IPCC 2007a: 755).

The number, intensity and duration of extreme weather events (heatwaves, summer drought, floods in winter) will also increase. Up to 2025 the Blue Plan expects that climate change will lead to an "intensification of extreme weather events". The danger of droughts has increased in this region during the past three decades and it is projected to further rise until 2050 and 2080 (table 26.9).[13]

According to the *IPCC Synthesis Report* "Climate change is expected to magnify regional differences in Europe's natural resources and assets. Negative impacts will include increased risk of inland flash floods and more frequent coastal flooding and increased erosion (due to storminess and sea-level rise)" (IPCC 2007c: 50).

These four physical effects of anthropogenic climate change, of an increase in temperature, a change in precipitation, rise in sea level and changes in the number and intensity of climate-related hazards have triggered and may cause societal impacts in the Mediterranean region.

26.4 Projected Societal Impacts of Climate Change

The major human-induced challenge both for the governability of the states and for the survivability of the MENA countries will remain the projected population growth, urbanization and the emergence of urban conglomerations for this region (UNPD 2001a, 2002, 2008; preface essay by Zlotnik).

26.4.1 Growing Demand: Populations Growth and Urbanization

Besides the projected physical effects of climate change, population growth in the MENA region will be a major factor that determines the demand for water, soil and food during the 21st century. Table 26.10 focuses on Mediterranean countries for 1850 to 2005 with a projection up to 2050. Since 1950 until 2005, the population of 11 countries in North Africa and in the Eastern Mediterranean increased from 72 to 266

12 R. Pachauri, keynote speech, conference of German Foreign Ministry in Freiburg, 6–7 November 2008 on "Climate Change as a Security Threat"; at: <http://www.freiburg-konferenz.de/downloads/R.K.Pachauri.pdf>.

13 This author's expert study for the WBGU (Brauch 2007f) and a more recent report refers also in detail to issues of soil erosion, degradation and desertification (Brauch 2010) as well as on water scarcity and on the impact of water scarcity and soil infertility on a decline of agricultural crop yield and a drop in the self-sufficiency of the MENA countries with cereals and its impacts on food insecurity in the MENA region.

Table 26.9: Impact of climate change on water availability, drought and flood occurrence in Europe for various time slices and under various scenarios based on the ECHAM4 and HadCM3 models. **Source:** IPCC (2007a: 550).

Time slice	Water availability and droughts	Floods
2020's	Increase in annual runoff in Northern Europe by up to 15 per cent and decrease in the south by up to 23 per cent.[a] Decrease in summer flow.[b]	Increasing risk of winter flood in Northern Europe, of flash flooding across all of Europe. Risk of snow-melt flood shifts from spring to winter.[c]
2050's	Decrease in annual runoff by 20-30 per cent in South-eastern Europe.*	
2070's	Increase in annual runoff in the north by up to 30 per cent and decrease by up to 36 per cent in the south.[a] Decrease in summer low flow by up to 80 per cent.[d, b] Decreasing drought risk in Northern Europe, increasing drought risk in Western and Southern Europe. Today's 100-year droughts return every 50 years (or less) in Southern and South-eastern Europe (Portugal, all Mediterranean countries, Hungary, Romania, Bulgaria, Moldova, Ukraine, Southern Russia).[c]	Today's 100-year floods occur more frequently in Northern and North-eastern Europe (Sweden, Finland, Northern Russia), in Ireland, in central and eastern Europe (Poland, alpine rivers), in Atlantic parts of Southern Europe (Spain, Portugal), and less frequently in large parts of Southern Europe.[c]

[a)] Alcamo, Floerke and Maerker (2007); [b)] Santos, Forbes and Moita (2002); [c)] Lehner, Döll, Alcamo, Henrichs and Kaspar (2006); [d)] Arnell (2004).

million and is projected to grow until 2050 by an additional 148 million people. While from 1950 to 2050 the population for eight Mediterranean EU countries is projected to increase by 66 million, the comparable figure for the MENA states has been an increase by 342.239 million (UNPD 2009, table 26.10). However, the possible migration from Turkey and the MENA region to the EU countries will partly counter the projected aging of the European Mediterranean countries.

The urbanization trends between Southern Europe and North Africa have differed between 1950 and 2005. While in Southern Europe the relative urban population will still grow and the rural population will decline, in North Africa the rural population will stabilize while nearly all projected population growth will be in the cities (table 26.11). This rapid and often chaotic urbanization has resulted in rapidly growing megacities where the people are highly socially vulnerable to natural hazards (table 26.12).

These population growth and urbanization trends pose different demands for water and food.

26.4.2 Growing Demand for Food Imports in the MENA

In North Africa the agricultural land is limited by the Sahara, in Egypt to 2.6 per cent, in Libya to 1.2 per cent, in Tunisia to 10.0 per cent, in Algeria to 3 per cent and in Morocco to 20 per cent. Morocco has about 8.4 million ha agricultural land, Algeria more than 7.5 million ha and Tunisia more than 4.6 million ha. The overuse of the land as a consequence of the intensification of agricultural methods has eroded the soils. Salinization and water erosion are partly a result of the deforestation and of the change in the use of fertile land (chap. 30 by Chourou; chap. 50 by Galil).

While the North may adapt to declining precipitation more easily with a slightly growing population, for the countries on the southern and eastern shore the declining precipitation will require major efforts that will affect the water available for irrigation and food production (chap. 21 by Hayek/Al Hmoud; chap. 22 by Haddad; chap. 23 by Salem; chap. 24 by Issar). Self-sufficiency in cereals will drop in MENA countries and the need for food imports or 'virtual water' will rise. In reaction to a region-wide economic crisis in the mid-1980's Algeria, Morocco and Tunisia launched agricultural reforms to reduce their food imports and food subsidies that contributed to increases in foreign debt.

However, with the increasing global and regional demand in the MENA countries for rising food imports the food prices may rise further as will be the financial resources needed to pay for these imports. While the Maghreb region and the Levant supported their population for millennia, their environment was transformed by human activities, especially by deforestation, land clearance and overgrazing. The rapid population growth in the 20th century put the environment under serious stress. In Morocco between 1987 and 1991, the cropland increased from 4.4 to 5.4

Table 26.10: Population growth of eight South European EU, six South-east European and 11 Mediterranean partner countries (in million). **Source:** UNPD (2009a): *World Population Prospects: The 2008 Revision*; at: <http://esa.un.org/unpp/p2k0data.asp>; McEvedy/Jones (1978) for 1850, 1900; for projections to 2050: UNPD (2009).

c) Southern Europe includes these countries: Albania, Andorra, Bosnia Herzegovina, Croatia, Gibraltar, Greece, The Holy See, Italy, Malta, Montenegro, Portugal, San Marino, Serbia, Slovenia, Spain and The Former Yugoslav Republic of Macedonia

million ha primarily by extending to marginal rangeland (200 mm rain). This contributed to overgrazing in poorer land and increased the potential for soil erosion. The same development can also be observed in Algeria. Swearingen (1996: 89) concluded that the "agricultural policies implemented during the 1980's have substantially increased the risk of drought in North Africa". The major reason is the strife for self-sufficiency in food. It is difficult to imagine any agricultural technology capable of sustaining such a large population, given the region's limited and deteriorating resource base.

The solution to the Maghreb's shortfall in food production ultimately lies in population control (World Bank 1988). In the 21st century, many Southern and Eastern Mediterranean countries will be affected by two negatively reinforcing trends: the continued high population growth in an area that cannot produce enough food (chap. 50 by Galil). The projected *global* climate change will make the *regional* challenges of population growth, urbanization, pollution, desertification, water and food scarcity more severe. All MENA countries must spend more for importing cereals and for making potable water available to their people, to tourists and for irrigation. Due to oil exports all countries but Morocco gained assets to pay for these imports. However, this source of foreign income is limited.

A recent report on environment and security issues in the southern Mediterranean region briefly discusses the "pressures on water, agriculture, desertification" but it does not meet systematic requirement

of an authoritative IPCC assessment (MEDSEC 2009; chap. 47 by Brauch/Oswald Spring).

26.4.3 Need for a Pan-Mediterranean Assessment on the Physical Effects and Societal Impacts of Climate Change

The Mediterranean faces a major contradiction: The longer-term common environmental challenges are confronted with highly fragmented security, political and economic spaces. In the 21st century two pan-Mediterranean political 'spaces' exist: a) the environmental regime of the *Barcelona Convention* (1976), of the *Mediterranean Action Plan* (MAP) and of the Blue Plan, and b) the emerging political regime of the *Barcelona Declaration* (1995) and of the *Union for the Mediterranean* (UfM; 13 July 2008). While the *Barcelona Declaration* and the UfM reflect different attitudes of North and South, the *Barcelona Convention* refers to the common Mediterranean space that will be affected by environmental factors.

The *Mediterranean climate* implies complex interactions between global climate change and regional implications that will negatively reinforce ongoing processes of desertification (chap. 48 by Safriel; chap. 50 by Galil; chap. 53 by Mainguet/Dumas/Kabiri/Rémini; chap. 55 by Gómez/López-Bermúdez/Quiñonero Rubio). There are common non-military environmental challenges affecting the whole Mediterranean that will have socio-economic and political consequences that may affect the Euro-Mediterranean region.

A common long-term scientific agenda is needed to develop an early warning system for common challenges and concerns. Both climate change and desertification may constrain the supply side for water and food. For the analysis of population policy and urbanization national policies set the framework. While for the analysis of 'environmental security' issues only an environmental spatialization of the Mediterranean applies, for a policy of avoiding conflicts emerging from medium-term implications of long-term structural causes, early and joint action by the countries participating in the wider Euro-Mediterranean space of the Barcelona or the BP/UfM framework is needed.

The most likely societal, national and international impact of climate change in close interaction with the other five trends has been and will continue to be migration, primarily of the young generation from rural areas to the national urban centres (urbanization), distress, political and economic migration from the Sahel zone and Sub-Saharan Africa to North Africa or from South, Central and West Asia to Turkey, and labour migration from MENA countries and the Balkans to the EU that may be *pushed* by socio-economic and environmental conditions and *pulled* by the attractiveness of the North and by existing networks. Due to population decline in European countries, labour migrants will be needed to satisfy future manpower demand in all sectors of the economy.

So far no specific climate impact analyses that were assessed by the IPCC exist for the Mediterranean. Based on the reviewed available scientific evidence, the MENA countries will be confronted until 2050 with three structural challenges of population growth, desertification and climate change. The specific short-term interaction of these structural factors with short-term political events and medium-term socio-economic changes cannot be predicted. But based on past evidence it may be concluded that the interaction of these factors could intensify the domestic socio-economic and political crises in these countries.

On the global level, the first four assessment reports of the IPCC have evaluated the peer-reviewed scientific literature on the multiple impacts of global climate change, most particularly on fresh water resources and their management (IPCC 2007a: 173–210), on ecosystems, their properties, goods and services (IPCC 2007a: 211–272), on food, fibre and forest products (IPCC 2007a: 273–314), on coastal systems and low-lying areas (IPCC 2007a: 315–356), on industry, settlement and society (IPCC 2007a: 357–390), and on human health (IPCC 2007a: 391–432).

On the regional Mediterranean level various studies of the UNEP-MAP and of the Blue Plan reviewed the impacts beyond the requirements of the IPCC assessments. The report of the regional seminar of the Blue Plan on climate change in the Mediterranean (2008) addressed the impact on the environment and on human health, most particularly the vulnerability of Mediterranean coasts that are to take the more drastic sea-level rise into account. This report also addressed the migration of ecological niches and the shift of invasive species in the Mediterranean, the risks of spreading infectious diseases and the health impacts of heatwaves, such as the one of August 2003, when between 35,000 and 70,000 people died in Central and Southern Europe. Another focus was on the discussion of the impact on natural resources, especially on water resources, on natural risks and on forests as well as on anthropogenic activities (fisheries, tourism, agriculture, energy needs).

Table 26.13: Cereal balance for MENA countries. **Source:** Bruinsma (2003).

	Demand				Production	Trade	Self sufficiency rate %	Growth rates, % p.a.			
	Per capita (kg)		Total (million tons)						Demand	Production	Population
	Food	Total	Food	Total

2030	205	367	130	232	131	-102	56	'95/97-2030	1.8	1.3	1.7

26.4.4 Declining Supply: Soil, Water and Food

The UNEP MAP (2009: 17–21) analysis listed among the major climate change impacts "water availability, biodiversity and the economic activities on which they depend" and the implications of these projected changes on fisheries, on risk-prone forests also due to increase in the number and intensity of forest fires, tourism and on human health. These recent reports as well as the previous extensive studies of the Blue Plan (Grenon/Batisse 1989, 1989a; Benoit/Comeau 2005) did not discuss the implications of climate change on crop yields and food production as well as on the declining self-sufficiency rates in cereals for the MENA region countries (Brauch 2007f).

According to FAO analyses the cereal imports to the MENA region rose between 1964–1966 and 1995–1997 from 5 to 43 million tons, thus during drought years the balance of payment were negatively affected and foreign indebtedness increased. Given the projected increase in the need of cereal imports from 1995 to 2030 by about 150 per cent, this situation may become dramatic, especially when grain prices rise and the income form oil and gas exports will gradually decline or totally drop (as has already been the case in Tunisia, and may occur in this decade probably in Egypt and until 2050 probably also in Algeria).

Between 1964/1966 and 1997/1998 the self sufficiency rate in cereals in the MENA region has declined from 86 to 65 per cent and until 2030 it is projected to drop to 56 per cent. This deficit has been balanced by food imports or "virtual water" (Allan 2003, 2009). The food demand has grown much faster than the agricultural production and population growth (table 26.13; figure 26.2).

According to figure 26.2 until 2020 the crop yield may increase for France, Spain, and Portugal as well as for Morocco, Algeria and Egypt by 0 to 2.5 per cent, but it may decline for Italy and Libya by 0–2.5 per cent and for Greece by 2.5 to 5 per cent. For 2050 for Italy, Morocco and Tunisia a decline has been projected of 0 to 2.5 per cent and for 2080 the crop yields may decline by 2.5 to 5 per cent for all five North African countries. If one assumes for 2080 a CO_2 stabilization at 550 and 750 ppmv then the yields may decline by 0 to 2.5 per cent or more (figure 26.2).

Martin Parry (2005) pointed to the consequences of climate change for agriculture in Europe:

- It will be hotter in the North, drier in the South, flash floods will increase and the frequency of extremely hot days and of heatwaves.
- There will be more agricultural benefits in the North and more damages in the South.
- Water scarcity and heatwaves will rise in the South, more flooding in the North, in central Europe and in mountainous regions.
- Environmental problems will rise (desertification in the South; soil exhaustion in the North).
- Climate change problems should be mainstreamed into European development and environment (directives for water, combating desertification).
- Europe will experience less negative impacts than other continents and it will have to increase agricultural production to maintain global food security during this century.

Do these physical impacts of climate change pose objective security dangers, directly or indirectly through the effects on the human system, or are these effects perceived as subjective security concerns by the Mediterranean states and by those countries par-

ticipating in the Barcelona process and in the new UfM?[14] Two societal effects are most prominent that may also pose additional security threats, challenges, vulnerabilities or risks for security: migration and possible low-level conflicts.

26.5 Migration Trends and Future Migration Scenarios

So far international organizations and demographers specializing in migration issues have only peripherally addressed environmental causes of migration while environmental specialists have discussed conceptual issues of defining environmental and climate-related push factors often ignoring the work of demographers. A recently formed *Climate Change, Environment and Migration Alliance* (CCEMA) tries to bridge the gap of both communities.[15]

Migration covers different features of people's movements from a) rural to urban livelihoods (*urbanization*), b) temporary '*internal displacements*' due to a natural hazard, conflict or a complex emergency or c) permanent internal, regional or international South-North migration. Such migration may be *forced* (often due to push factors) or *voluntary* (often due to pull factors). Environmental factors due to GEC (water scarcity, soil degradation, climate change) may force people to leave their homes and traditional livelihoods to survive or to have better prospects for life and economic and human well-being.

The *International Association for the Study of Forced Migration* (IASFM) listed under forced migration these types: a) conflict-induced displacement, b) development-induced displacement, c) disaster-induced

displacement. It also distinguished these forced migrants as: i) refugees, ii) asylum seekers, iii) internally displaced persons, iv) development displaces; v) environmental and disaster displacees, vi) smuggled people, and vii) trafficked people. The fifth group is "sometimes referred to as 'environmental refugees' or 'disaster refugees' ... This category includes people displaced as a result of natural disasters (floods, volcanoes, landslides, earthquakes), environmental change (deforestation, desertification, land degradation, global warming) and human-made disasters (industrial accidents, radioactivity)".[16]

This 'environmentally-induced migration' has resulted in 'distress migrants', some have called 'environmental refugees' (El-Hinnawi 1985). Castles (2001) in his review of the debate on "Environmental Change and Forced Migration" concluded that "we clearly need a much broader approach, which recognizes the complex causes and the global dimensions of the crises that force people to flee their homes".[17] The report on the UNHCR/IOM/RPG (1996) symposium distinguished these types of environmentally-induced population movements:

- Acute onset movements, with and without the possibility of return;
- Slow onset movement, with and without the possibility of return due to the natural conditions of the area;
- Slow onset movement with predictability (for example, displacement caused by large-scale development projects) with no possibility of return because of human activities.

This Report suggested the term 'environmentally displaced persons' it defined as: "Persons who are displaced within their country or habitual residence or who have crossed an international border and for whom environmental degradation, deterioration or destruction is a major cause of their displacement, although not necessarily the sole one." Flintan (2001) listed among the main causes of environmental migration: a) human-induced environmental change (including land degradation, desertification), b) environmental catastrophes and/or natural disasters, c) military and political upheavals and d) socio-economic factors.[18]

To summarize, there seems to be an emerging consensus that soil degradation, erosion, desertification and drought contribute to distress migration. Disasters cause, trigger or contribute to migration, while migration may intensify disasters due to a high social vulnerability. No detailed data exist to quantify the environmental or climate-induced causes of migration.

Policy-oriented discussions have addressed conceptual issues of environmentally and climate-induced migration and the methodological issues of migration statistics in the Euro-Mediterranean, the Arab world and for the MENA region.[19] Despite these efforts environmental causes for migration have not been systematically covered in most recent migration statistics:

- *Trends in International Migrant Stock: The 2008 Revision* (UNPD 2009b);[20]
- *International Migration Report 2006: A Global Assessment* (UNPD 2009);[21]
- *2008 Global Trends: Refugees, Asylum-seekers, Returnees, Internally Displaced and Stateless Persons*;[22]
- *Trends in International Migration* (e.g. OECD, SOPEMI 2008, 2009).[23]

No major statistical source (UN, OECD, and IOM) has included a category of 'environmental refugees',

'environmental migrants' and 'environmentally-induced migration' or 'climate migrants' in their database. Thus, no reliable global statistics exist on environmentally triggered migration due to land degradation, desertification, drought or famine. Nevertheless, as many case studies by political scientists, social anthropologists or ethnologists have shown, issues reacted to global environmental change (due to natural and human-made causes) are new causes of migration while migration has also become a cause of environmental change.

While the percentage of the international migrants of the world population has grown from 2.1 per cent in 1975 to 3.0 per cent in 2005, the percentage of refugees of international migrants grew from 2.9 per cent in 1960 to 11.90 in 1985 and 1990 and has since then fallen to 7.1 per cent in 2005. A report of the *Global Commission on International Migration* (GCIM) on: *Migration in an interconnected world: New directions for action* as well as a report by the UN General Assembly on migration and development of 18 May 2006 for the high level meeting on this theme in mid-September 2006 did not mention environmental factors as a driver for migration. The GCIM commissioned some 50 research papers that focused on 8 thematic projects and regional studies but none dealt with environmental causes of migration. The third project on: "Irregular migration, state security and human security" examined:

> the use and adequacy of terms such as 'irregular migrants/migration', 'illegal migrants/migration,' 'undocumented migrants/migration' and 'unauthorized migrants/migration', and examines the potential for consistent and/or alternative terminology to be used in relation to the different phenomena commonly described in this manner.

While many studies were published on environmental refugees (El-Hinnawi 1985; Bächler 1994; Myers 1995) or more recently on climate migrants (IOM 2009, 2009a; Warner/Erhart 2009) and on the need to develop a legal regime (WBGU 2008; Biermann/Boas 2008), still no systematic and detailed statistical studies exist that permit a quantification of the environmentally triggered migration across the Mediterranean Sea. There are, however, case studies on specific events that have forced people to leave their livelihood in some countries (EACHFOR project).

From 1950 to 2000 a fundamental shift has occurred in the migration patterns of the Western Mediterranean countries that include besides Spain, Portugal, France and Italy also five small states (Andorra, The Holy See, Malta, Monaco, San Marino) and Gibraltar (Zlotnik 2003). From 1950 to 1970 there was a net emigration from Spain, Portugal and Italy but since 1970 there was a net inflow of migrants of a million during the 1970's and two million during the 1990's. However, the emigration from the Southern Mediterranean (North Africa) has steadily increased between 1950 and 1980, temporary declined during the 1980's and during the 1990's returned to the level of the 1980's (Zlotnik 2003: 599).

The rapidly increasing irregular migration from the Maghreb and Sub-Saharan Africa already poses manifold national, political, societal but also human security threats and challenges both for the recipient countries and for the migrants as well. For the source countries migration may reduce the potential for domestic protests among the hopeless and increase the prospects of remittances for those family members staying at home. However, for some recipient countries that are confronted with an emerging humanitarian catastrophe, the irregular South-North migration has become a major challenge for their national and internal security.

In Spain and Italy a significant increase in immigration has occurred during the past decade. In Spain the number of immigrants has increased from 299,953 (1975) to 4,790,074 (2005) or sixteen fold in 30 years (table 26.14). During the past decade, the migrant population has increased from 1 million to 4.8 million people or from 2.5 per cent to 11.1 per cent of the total population. At the same time the number of refugees remained stable at about 5,500 people. Between 2000 and 2005 Spain had an average annual net migration inflow of 405,000 migrants. As a result the Spanish population rose from 39,921,000 (in 1995) to 40,717,000 (in 2000) and 43,064,000 (in 2005).

This increase in statistically recorded immigrants in Spain and Italy are reflected in the changes in the UN population projections for both countries between the 2000 and the 2008 revisions. While the medium variant of the UN population projection (revision of 2000) projected a significant population decline for Spain (-9.6 million) and Italy (-14.6 million) between 2005 and 2050, the medium variant of the 2004 revision projected for Spain an increase of 1.8 million and for Italy a decline of 6.8 million. The 2008 revision projected for Spain a population growth of 8.2 million and for Italy a decline of 1.58 million people.

Thus, immigration has become a major political but also security challenge for the Spanish government and society. While this immigration cannot be interpreted as a direct outcome of environmental or

desertification factors, nevertheless, the inflow has increased from those countries in North and Sub-Saharan Africa that are victims to desertification. It may be difficult to quantify the number of migrants that have left their homes and countries due to environmental causes, among them soil erosion, desertification, severe drought and famine.

Between 1950 and 1989 the net immigration to Middle and Western Europe was 14.61 million persons. In 1991 about 64 per cent of the 15.9 million foreigners in the then 12 EU states came from Non EU-states and of these alone 5.011 million came from five Non-EU Mediterranean countries: Turkey (2.248 million), Morocco (1.053 million), Yugoslavia (785,000), Algeria (641,000) and Tunisia (241,000; see table 26.15).

Which causes have contributed to this significant increase in migration? Two major reasons for migration are distinguished in the literature, so-called *pull factors* (e.g. the recruitment of foreign workers, economic disparity between South and North, family networks, etc.) and *push factors* (wars, violent domestic conflicts, economic hardship, hunger, poverty and environmental catastrophes). During the 21st century two push factors will increase in urgency, population growth (table 26.11) that will increase the demand for scarce resources, especially for soil, water and food, and the impacts of global environmental change, such as climate change, soil erosion and desertification, decline in precipitation and increase in evaporation what will reduce the water available per person dramatically.

These environmental 'root causes' often cannot at all or easily be changed by political decisions or by political decision-makers. Root or structural causes point to the third temporal level of policy analysis referred to by Braudel (1969, 19972) as "histoire du longue durée". From a Braudelian vantage point the *independent and intervening variables* of international migration can be classified in three groups of determining or root causes: a) *structural* or long-term factors, b) the *socio-economic* or medium-term factors and c) the *political* or short-term factors. According to Braudel's 'structures du longue durée' especially 'environmental conditions', and particularly two anthropogenically generated processes of environmental degradation are crucial: *regional desertification* and *global climate change*.

While in the past *population growth* was *the major cause of internal and international migration* from North Africa to Europe, the second *long-term root cause* is environmental degradation that will increase in urgency during the 21st century. Figure 26.3 outlines the possible impact of two long-term causes on the projected migration from North Africa to Western Europe up to the year 2020 or 2030 (medium-term) and up to 2050 or 2100 (long-term). If a *short-term reactive* migration policy of the EU states is to be avoided, these *root causes* must be addressed. These trends may possibly still be avoided if they become tasks of a cooperative effort and if they are successfully implemented in their respective countries.

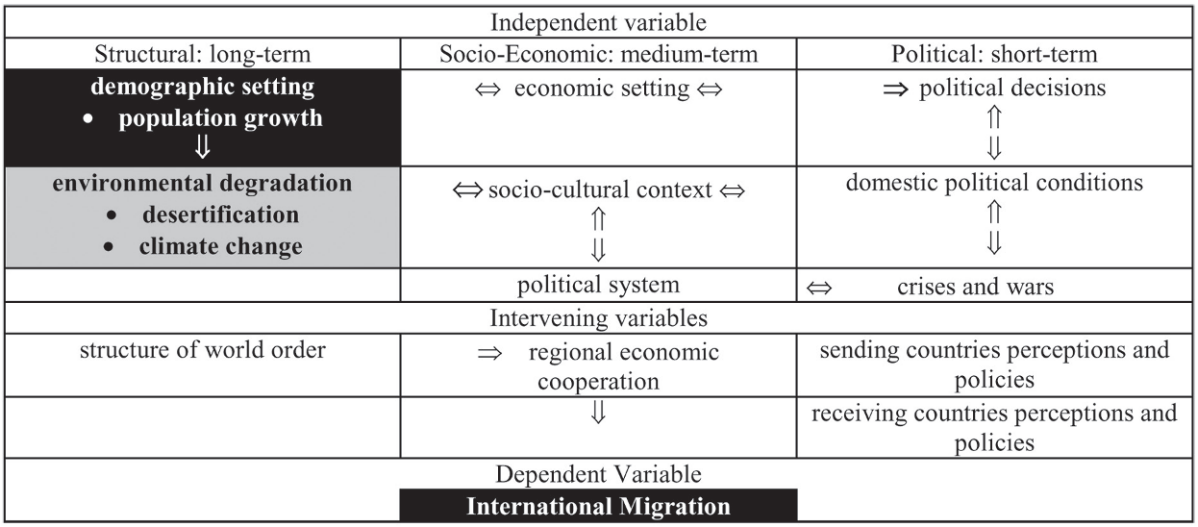
The projected population growth for the MENA region will increase the pressure on the environment. Due to the rural exodus and urbanization the ecological consequences will increase the pollution of the air and the contamination of soil and water and the health problems in large cities and 'bidonvilles' (Grenon/Batisse 1989, 1989a; Brauch 1998). Poverty and high unemployment rates among the young will also increase what may contribute to a political radicalization. With the population growth the demand for drinking water rose and for agriculture to feed the growing population. The extension of the agricultural areas and the overexploitation of the poor soil have already increased the ecological stress and contributed to an extension of soil erosion (chap. 47 by Brauch/Oswald Spring).

Several North African countries experienced major food protests. In Morocco droughts and the increase of food prices have resulted in 1984 and 1990 in bread riots that were repressed by force (Seddon 1986, 1988; Benjelloun 2005). While the trends of a growing demand for water soil and food can be projected for the MENA region based on a continuing population growth and urbanization, the decline in precipitation and in crop yields can also be foreseen based on different climate models. However, it is impossible to predict how the governments and unknown policy-makers will respond to these challenges and whether they will result in a drastic increase of migration and transmigration, and whether this will lead to conflicts within and between MENA countries and with the EU's Mediterranean countries. Many claimed that the Mediterranean has become the major demographic and economic dividing line, much deeper and extreme than the Rio Grande between the US and Mexico. Many experts have predicted that the migration pressure from the MENA to the EU will rise.

Given the many conceptual, theoretical and empirical problems and especially the statistical difficulties to assess the environmental and climate-induced rural-urban migration (urbanization), internal displacement and intraregional as well as intercontinental migration in general and for the Mediterranean region in particular, a discussion on future environmentally and GEC-induced migration pressures up to 2020 and 2050 or until the end of the 21st century remains highly speculative. Globally the number of estimated environmental migrants referred to by Myers (1995), humanitarian and environmental NGOs, by national governments (NIC 2008) and international organizations have varied "between 50 million and 350 million" (IOM 2007, 2009, 2009a). However, as no systematic and reliable data on environmentally and climate-induced migration exist it is impossible to offer any detailed estimates of the scope of this future migration both globally but also regionally for the Mediterranean region.

Figure 26.3: Framework for a causal analysis of migration dynamics**. Source:** Brauch (2000/2001: 111).



26.6 Conflicts in the Mediterranean

So far no specific climate impact analyses based on the climate models of the IPCC exist for North Africa. Based on the present scientific evidence – reviewed above – it may be assumed that the North African region will be confronted until 2050 with three structural challenges beyond the control of political leaders: population growth, desertification and climate change. The interaction of these structural factors with short-term political events and medium-term socio-economic changes cannot be predicted. Nevertheless based on past evidence – e.g. of severe droughts, environmental degradation, migration, domestic conflicts and interstate wars which were observed in the Sahel – it may be concluded that the interaction of these factors could intensify the domestic socio-economic and political crises in these affected countries.

Several studies assumed a correlation between high population growth and the likelihood of interstate conflicts, while others saw a causal relationship between environmental scarcity (e.g. of water and food) and environmental degradation (of air, soil, water) and domestic violence and interstate wars. Other authors have claimed a direct causal relationship between environmental degradation (pollution, desertification and climate change) and an increased pressure to migration. Both domestic and international violent conflicts have been major 'push factors' for migration. The migration pressure from North Africa to Western Europe may further be exacerbated by the 'pull factors' of existing family networks and the attractiveness of the North or the lack of competitiveness of the South.

26.6.1 Past Conflicts in the Euro-Mediterranean Region

Pfetsch (2003) offered an overview of the conflicts in the Mediterranean (1945–2001) where he distinguished among four regional conflict clusters that cover "three quarters (90) of the 121 conflicts" he counted for this 46 year period:

1. *Conflicts in the Middle East with Israel and its neighbouring Arab countries* with 35 conflicts that count for 42 per cent of the total weighted conflict occurrence in the Mediterranean.
2. *Colonial and post-colonial conflicts in the Maghreb countries* with 30 conflicts.
3. *Conflicts between and within Greece and Turkey* with 14 conflicts. Another complex of conflicts arises between Greece and Turkey over Cyprus and the Aegean Sea.
4. *Conflicts resulting from the dismemberment of Yugoslavia* with 11 rather severe conflicts.

Most conflicts in the reviewed period were severe crises (53), crises (28), latent conflicts (20) and wars (19). With regard to the intensity of conflicts, Pfetsch (2003: 151–152) concluded that

> the Mediterranean region is also fragmented in politics and conflict behaviour. ... Environmental conflicts are difficult to assess by quantitative empirical research. Some of them are included in the categories of resource and water. The map of political conflicts shows four

> sub-regional clusters of conflicts. Each of these sub-regions can be linked to the determining factors of stress/challenge, security/support and the capability to manage conflicts that contribute to explain the rather conflict laden region.

During the past nine years (2002 to May 2010) the Middle East conflict re-emerged after the collapse of the peace process, while the Greek-Turkish conflict declined, and in the post-Yugoslav space Bosnia and Kosovo became two quasi protectorates of the EU. During the first decade of the 21st century in no single case environmental reasons triggered a major violent conflict in the Mediterranean region.

The paper by the High Representative and the European Commission to the European Council of 14 March 2008 on *Climate Change and International Security* noted on the Middle East that water systems "are already under intense stress" and that "roughly two-thirds of the Arab world depends on sources outside their borders for water" (EU 2008). The report argues that "existing tensions over access to water are almost certain to intensify in this region leading to further political instability with detrimental implications for Europe's energy security and other interests". Due to the projected decline in water supply "a significant drop in crop yields is projected", especially for "Turkey, Iraq, Syria and Saudi Arabia and thus affect stability in a vitally strategic region for Europe" (EU 2008).

In its *Report on the Implementation of the European Security Strategy – Providing Security in a Changing World* the European Council (11 December 2008) referred to the previous report that claimed "climate change is a 'threat multiplier'", and it stated that "natural disasters, environmental degradation and competition for resources exacerbate conflict, ... with humanitarian, health, political and security consequences, including greater migration". The EU report stated that the Mediterranean

> still poses complex challenges, such as insufficient political reform and illegal migration. ... The ENP has reinforced reforms originally started under the Barcelona process in 1995, but regional conflict, combined with rising radicalism, continues to sow instability. The EU has been central to efforts towards a settlement in the Middle East ... In Lebanon, Member States provide the backbone of the UNIFIL peacekeeping mission (EU 2008a).

A scoping paper on "Regional Security Implications of Climate Change" in a synopsis of the policy-focused reports offered this assessment on the MENA region (Maas/Tänzler 2009: 4) pointing to "water and food scarcity, resulting in decreasing employment opportunities and potential economic downturns". This report argued that "climate change is likely to worsen divisions, particularly those running along social divisions and unequal wealth distribution and resource access". Further, "sudden food shortages may trigger violent riots and – if left unaddressed – could destabilize states and increase public support for extremist groups offering viable alternatives". They point to security implications of climate change: "when the combination of converging climate and socio-economic trends will reach critical thresholds, catalysing processes that lead to state fragility" that may lead to future food riots:

> The global food crisis in 2008 witnessed riots in the Maghreb region. With agricultural production likely to decrease in the region, dependency on food imports will increase and the impact of price hikes will be felt more drastically. In the future, riots could increase in size and scope. Popular discontent could be channelled by extremist groups, which in turn could result in further repressive actions by governments.

The Middle East has been one of the most conflict-prone regions due to the unresolved Israeli-Palestinian conflict and the crises in Iraq, over the Iranian nuclear programme and with the 30 years war in Afghanistan. Water scarcity will rise due to population growth and climate change and may intensify local water conflicts. During the Israeli-Palestinian peace process of the 1990's the water question has remained unresolved (Shuval/Dweik 2007; see chap. 21 by Hayek/Al Hmond; chap. 22 by Haddad; chap. 23 by Salem; chap. 24 by Issar). So far technical efforts on joint water management had no spillover on peace building (Jägerskop 2009; Selby 2009).

26.6.2 Discussion of Four Conflict Scenarios

In its report on *Climate Change as a Security Risk*, the German Advisory Council on Global Change (WBGU 2008) argued that if states fail to act early and proactively climate change may trigger "numerous conflicts between and within countries over the distribution of resources, especially water and land, over the management of migration, or over compensation payments between the countries mainly responsible for climate change and those countries most affected by its destructive effects". The report argued that "climate changes amplifies mechanisms which lead to insecurity and violence" affecting specifically countries in transition, those with weak governance structures, and poor countries affected by resource scarcity (land, water, food) and often with high population growth. These local or national conflicts may spill over and

destabilize neighbouring countries "through refugee flows, arms trafficking or combatant withdrawal". The social impacts of climate change can thus transcend borders and expand "the geographical extent of crisis and conflict regions".[24]

To address the possible linkages between climate change and conflict, the WBGU identified "four conflict constellations in which critical developments can be anticipated as a result of climate change and which may occur with similar characteristics in different regions of the world". These 'conflict constellations' were "defined as typical causal linkages at the interface of environment and society, whose dynamic can lead to social destabilization and, in the end, to violence". All four are relevant for the Mediterranean and the MENA region, the WBGU referred to as one of the major 'environmental hotspots'.

26.6.2.1 Conflict Constellation 1: Climate-induced Degradation of Water

The MENA region is already a region with high water scarcity and severe droughts. Due to the projected population growth and the precipitation decline, the access to safe drinking water and to green water for agriculture will decline. "This dynamic", the WBGU argues "triggers distributional conflicts and poses major challenges to water management systems in the countries concerned". Both in the MENA region and in the Nile River Basin "the countries which will suffer the greatest water stress are generally those which already lack the political and institutional framework necessary for the adaptation of water and crisis management systems. This could overstretch existing conflict resolution mechanisms, ultimately leading to destabilization and violence".

Due to the 95 per cent dependence of Egypt on the water of the Nile, the future division of its water can be a cause of survival and conflict for Egypt and the Nile riparian countries (Adly/Ahmed 2009; Kameri-Mbote/Kindiki 2009). For the Eastern Mediterranean the following conflicts on the access, control and distribution of water resources exist that have repeatedly resulted in political conflicts but in no 'water war':

- The Turkish GAP project has repeatedly resulted in conflicts with Syria and Iraq (Scheumann 2003: Aydin/Ereker 2009; Kapur/Kapur/Akca/Eswaran/Aydin 2009);
- The conflict between Israel and its neighbours on the water of the Jordan is not resolved (Dombrowsky 2003; Shuvall/Dweik 2007; Hayek 2009; Selby 2009; Jägerskog 2009; Newman 2009; Dajani 2009);
- The conflict between Israel and Syria on the control of the water resources of the occupied Golan Heights and between Israel and Lebanon on the Litany River is unresolved;
- The question of the access to the ground of the common aquifer water between Israel and the Palestinian Authority is still to be solved (chap. 24 by Issar and chap. 23 by Salem).

These interrelated water questions require a political solution of the Middle East conflict. The question of the drinking water may be solved as part of a comprehensive multilateral cooperation strategy and by new technologies, e.g. by using solar energy for the desalination of brackish and sea water. However, the massive desalination of sea water for agricultural purposes, especially for food production, may not yet be cost-effective. Thus, exporting surplus solar energy to Europe and importing cereals as virtual water may be more efficient in the near and medium future (Brauch 1994, 1997, 2000, 2000a, 2007, 2007a, 2010).

26.6.2.2 Conflict Constellation 2: Climate-induced Decline in Food Production

The second conflict constellation of a 'Climate-induced Decline in Food Production' is most pertinent for the MENA region, where the self-sufficiency rate in food and especially cereals has been declining rapidly since the 1960's and it is projected by the FAO to drop rapidly until 2030 and 2050 due to population growth and the physical effects of climate change. Climate change and bio-energy development will affect food security in its "four dimensions – availability, accessibility, stability and utilization". Globally, with a global warming of 2–4°C, a drop in agricultural productivity is anticipated worldwide WBGU 2008: 94–95).

> This trend will be substantially reinforced by desertification, soil salinization or water scarcity. In ... North Africa ..., the areas suitable for agriculture are already largely exploited. This may well trigger regional food crises and further undermine the economic performance of weak and unstable states, thereby encouraging

24 WBGU press release: "Report 'Climate Change as a Security Risk' - Climate change threatens international stability and security", Berlin, 6 June 2007; at: <http://www.wbgu.de/wbgu_jg2007_presse_engl.html>. The full report is for download at: <http://www.wbgu.de/wbgu_jg2007_engl.pdf>.

> or exacerbating destabilization, the collapse of social systems, and violent conflicts (WBGU 2008: 2).

This situation will become even more dramatic in the 10 countries in the Nile River Basin that are already severely affected by a vicious circle of repeated droughts, hunger and famine and that connect the militarily strong downstream country Egypt with the less powerful upstream countries which are already seriously affected (Brauch 2002, 2007f).

In the MENA the self-sufficiency rate with cereals has continuously declined since the 1950's due to the high population growth, the increase in meat consumption per person and due to observed climate change impacts, according to FAO projections the demand for imports of cereals will increase significantly until 2030 (FAO 2003). In these hyper-, semi- and arid regions of the MENA (chap. 50 by Galil) it will be impossible with traditional means to produce the food needed for its growing population. New methods for the economic use of the drylands are needed to enhance soil, water and food security (chap. 54 by García Lorca; chap 48 by Safriel; Brauch/Oswald Spring 2009; Brauch 2010).

26.6.2.3 Conflict Constellation 3: Climate-induced Increase in Drought and Flood

This third conflict constellation has also severely affected the Mediterranean region that has been confronted with drought throughout history. When the precipitation comes in autumn, it often comes in intensive flash floods causing a high number of casualties, affecting people and producing economic damages in many MENA countries due to the higher degree of social vulnerability (Brauch 2003, 2003a, 2010; chap. 90 by Quiñonero-Rubio/López-Bermúdez/Alonso-Sarría/Gomariz-Castillo). Both on the global and regional Mediterranean level an increase of the number and intensity of natural hazards has been projected that may affect "many cities and industrial regions in coastal zones". However, in the Mediterranean these extreme weather events may be less likely to become a direct trigger of violent conflicts.

For millenia, the MENA region has been vulnerable to severe and repeated droughts that were often instrumental for the collapse of civilizations (in Egypt, Mesopotamia, Asia Minor) and for triggering a massive movement of people. Very intensive flash floods have also hit many countries in the Western and Eastern Mediterranean and have caused human fatalities and economic damage. But due to the different level of social vulnerability and resilience the human death toll was much higher in the MENA countries than in South Europe.

26.6.2.4 Conflict Constellation 4: Climate-induced Increase in Migration

Migration from the MENA region to the European Union has already become a major issue of domestic or internal security and of the intergovernmental policy coordination on justice and home affairs. In some cases, massive environmentally-induced migration has increased

> the likelihood of conflict in transit and target regions. It can be assumed that the number of environmental migrants will substantially rise in future due to the impacts of climate change. ... The increase in drought, soil degradation and growing water scarcity in combination with high population growth, unstable institutions, poverty or a high level of dependency on agriculture means that there is a particularly significant risk of environmental migration occurring and increasing in scale (WBGU 2008: 3).

Transboundary environmental migration prevails as south-south migration, but Europe will face increased migratory pressure from Africa, West and South Asia most at risk from climate change. Figure 26.3 shows the present main migration roots between and via the MENA countries to the European Union.

Throughout history massive peoples' movements have occurred as a result of the natural variability of the climate primarily in cold periods (in climate pessima), e.g. in Europe between the fifth and eighth century AD. Even though the environmentally forced migration cannot be quantified it has become a reality that will become more urgent due to climate change, water scarcity, degradation and stress as well as due to soil degradation, desertification and drought. Elsewhere, this author has distinguished between five migration scenarios in the framework of the environmental dimension of human security and five on the environmental dimension of national security (Brauch 2007f).

The EU paper on "Climate Change and International Security" (2008) referred ten times to environmentally- and climate-induced migration issues that may pose security dangers. It claimed that "desertification could trigger a vicious circle of degradation, migration and conflicts over territory and borders that threatens the political stability of countries and regions". It listed 'environmentally-induced migration' among the seven security threats posed by climate change:

Box 26.1: Documents adopted by the EU on climate change and security (March 2008-November 2009). **Source**: European Commission: "Joint progress report and follow-up recommendations on climate change and international security (CCIS) to the Council" (25 November 2009); at: <http://register.consilium.europa.eu/pdf/en/ 09/st16/st16645.en09.pdf>.

- "White paper - Adapting to climate change: towards a European framework for action" April 2009 (European Council, 16645/09, 25 November 2009).

Since 2008, the European Commission and its member states commissioned various studies and held many consultations that are documented in the joint progress report of 25 November 2009.

> Those parts of the populations that already suffer from poor health conditions, unemployment or social exclusion are rendered more vulnerable to the effects of climate change, which could amplify or trigger migration within and between countries. The UN predicts that there will be millions of 'environmental' migrants by 2020 with climate change as one of the major drivers of this phenomenon. Some countries that are extremely vulnerable to climate change are already calling for international recognition of such environmentally-induced migration. Such migration may increase conflicts in transit and destination areas. Europe must expect substantially increased migratory pressure (EU 2008: page)

In the framework of the EU's multilateral leadership to promote global climate security, the EU paper suggested among the three key actions to "consider environmentally-triggered additional migratory stress in the further development of a comprehensive European migration policy, in liaison with all relevant international bodies" (Raleigh/Jordan/Salehyan 2008).

26.7 Security Challenges Posed by Global Climate Change

These four conflict constellations indicate causal pathways that the projected physical effects of climate change in the Mediterranean and specifically in the MENA countries may pose severe security dangers and concerns during this century. However, it is impossible to predict if and when they will result in violent conflicts or whether they can be avoided by proactive and cooperative policy decisions within this region. The likely increase in human insecurity does not necessarily pose national and international security problems. In extraordinary cases they result in conflicts over scarce water, fertile soils and access to affordable food that may under certain conditions and in some cases escalate to violence.

26.7.1 Impacts of Climate Change for Mediterranean Security

In its implementation paper (EU 2008a) of the *European Security Strategy* (EU 2003) the 27 countries of the European Council concluded that "natural disasters, environmental degradation and competition for resources exacerbate conflict, especially in situations of poverty and population growth, with humanitarian, health, political and security consequences, including greater migration". The European Council noted that "climate change can also lead to disputes over trade routes, maritime zones and resources previously inaccessible". In the "Joint progress report and follow-up recommendations on *climate change and international security* (CCIS) to the Council" (25 November 2009) it was acknowledged that "CCIS has become a standard item on the agenda of third party meetings in the Mediterranean and Middle East Region at all levels and in a variety of bi- and multilateral formats". Since 14 March 2008 (S113/08), the European Union bodies adopted various documents on the linkage between climate change and international security that are relevant for the Mediterranean and the MENA regions (box 26.1).

However, these concerns have not yet been mainstreamed into the eight priority projects of the Union of the Mediterranean. During the third Euro-Mediter-

ranean ministerial conference on the environment on 20 November 2006, its Cairo Declaration only once referred to climate change welcoming an EU initiative for a "Communication establishing an environment strategy for the Mediterranean that outlines the approach of the European Commission regarding its environmental cooperation in the region for the coming years across a range of sectors such as climate change, desertification and biodiversity". Among the key pillars of the EU's environmental policy for the Mediterranean in the framework of activities of Horizon 2020 among its four key priorities: a) projects to reduce the most significant pollution sources; b) capacity-building measures to help neighbouring countries create national environmental administrations; c) using the Commission's research budget to develop and share knowledge of environmental issues; and d) developing indicators to monitor the success of Horizon 2020, climate change has not been specifically emphasized. The timetable of Horizon 2020 for the first phase (2007–2013) does not even once refer to climate change.

The Communication from the Commission to the Council and the European Parliament - Establishing an Environment Strategy for the Mediterranean (SEC(2006)1082/*COM/2006/0475 final) of 2006 only once referred to climate change in the framework of ongoing and completed research under the 5th and 6th Research Framework Programmes "addressing water issues under the EU Water Initiative's Mediterranean component and those covering accidental marine pollution, marine and coastal research and climate change impacts". Furthermore, "global environmental threats such as climate change and biodiversity loss" are identified in this Communication within a thematic programme for sustainable management of natural resources.

A literature synopsis for the DG External Relations on regional security implications of climate change (Maas/Tänzler 2009: 4) reviewed recent reports on the six target regions mentioned in the Commission Report, of which the MENA region is of special interest:

> In the Middle East and North Africa, climate change impacts will converge with socio-economic processes leading to water and food scarcity, resulting in decreasing employment opportunities and potential economic downturns. ... Climate change is likely to worsen divisions, particularly those running along social divisions and unequal wealth distribution and resource access. Crisis events such as sudden food shortages may trigger violent riots and – if left unaddressed – could destabilize states and increase public support for extremist groups offering viable alternatives. Given the geopolitical currents in MENA, this could have global repercussions.

This synopsis argued that "the two major sources of wealth, income and employment in the MENA region, oil and agriculture, will diminish", and that "climate change will likely decrease agricultural output due to heat stress and reduced available water". The unresolved water disputes and the high sensitivity to food price hikes resulted in violent conflicts in North Africa since the 1970's and most recently in 2008. While climate change impacts in the Mediterranean have been so far no major concern of EU environment policy, especially in the framework of the EMP and the UfM, the discussion on the security implications of climate change pertaining to the Euro-Mediterranean region have increasingly become a concern for the DG on External Relations that launched the EU roadmap process on the security impacts of climate change.

26.7.2 Assessment of Security Impacts from Different Security Perspectives

Besides migration, the physical and societal effects of climate change may pose many other security dangers for the Mediterranean region. These may be analysed from the perspective of international and Mediterranean security in the framework of the UfM, of the national security of riparian Mediterranean countries with regard to source, transition and host countries as well as for the affected human beings (human security). Last but not least, the above physical effects and their impacts on human systems produce also various environmental security impacts for the region, the states and the peoples.

So far water scarcity and degradation have not been the sole cause of any violent international conflict within the Mediterranean space and in the MENA region. It is unlikely that in the foreseeable future climate change will become the only cause of any war. Thus, the dramatizing references to water or climate wars have been misleading. Rather, climate change may become a 'threat multiplier' (EU 2008; UNSG 2009) that may intensify already existing conflicts in the four conflict clusters and within the conflict constellations referred to above.

However, climate change poses very severe security threats, challenges as well as many vulnerabilities and risks for coastal and delta regions, especially for Egypt where the homes and livelihoods of millions of people living in the Nile Delta will be threatened (chap. 45 by El Raey). The Nile is the key to Egypt's

survival. Any plans by the nine other riparian states to use more water of the Nile provoked nervous Egyptian reactions. Since the 1990's the *Nile Basin Initiative* (NBI) has become a focal point of regional cooperation on water issues among the 10 Nile countries. Until 2050, in the ten Nile countries population has been projected to increase from 280.8 million in 2000 by 575 million to 855.6 million by 2050 (UNPD 2001). Thus, the competition for water and the struggle for survival for millions of people will increase (Adly/Ahmed 2009: 643).

Thus Egypt will be confronted with severe human catastrophes that may be foreseen for the upstream Nile countries. Whether the severe challenges for distributing the water can be resolved peacefully, as the NBI aims at, whether in addition to the existing civil wars along the ethnic divide new types of conflicts, such as environmental conflicts or clashes with migrants fighting for their own survival may be added, cannot be predicted. However, these structural factors are distressing and conflict-prone constellations on the North-South axis may not be avoided. Whether the NBI can mitigate these trends will partly depend on the willingness of both donor and recipient countries to implement the needed strategy for survival. Migration from upstream Nile countries in Sub-Saharan Africa into Egypt will increase within the next decades. Thus, migration from Egypt to Europe may become a problem in the 21st century, especially due to the efforts of Sub-Saharan Africans to migrate first to Egypt and then from there to EU countries.

None of these challenges are of a military nature and none can be solved by military means or military forces. These non-military challenges posed by the struggle for survival of distress migrants at the individual, family or clan level will require short-term catastrophe relief (food aid, water supply, etc.) and in the long-term complex and interrelated counterstrategies of climate change and reproductive health. The best long-term mitigation efforts for all industrialized countries will be effective strategies of reducing GHG emissions, and to assist the countries that will be hit most but that lack the means for mitigating climate change impacts. This requires, development strategies that address the causes that may lead to the catastrophic projections.

The UN Secretary-General (UNSG 2009) noted that climate change will have many negative economic impacts. The most obvious trends are: the demand for the scarce water, soil and food will grow rapidly while the supply will decline due to climate change and its impact on declining crop yields. The water and food scarcity can be overcome by 'virtual water' or food imports that will impact negatively on the balance of payments of MENA countries.

Rising food prices directly affect the poor people in the MENA countries that are spending a large proportion of their earnings on purchasing food and water for drinking. Repeatedly droughts and increases of the global food commodity prices have resulted in mass protests and in some cases in food riots in several MENA countries to which the governments responded either by increasing the subsidies to maintain supply at stable prices or by repressing these protests by force which has resulted in several cases in human casualties.

Climate change will also pose manifold threats to environmental and human security by directly threatening the livelihood of human beings and thus also affecting their human security (chap. 2 by Brauch). Two major alternatives exist for a policy response: a) to postpone decisions and to wait until this challenge will become most urgent or b) to anticipate these challenges and to act proactively with the goal to reduce both the projected human victims and economic damages, what will be more cost effective (Stern 2006, 2009).

26.8 Proactive Policies for Coping with Climate Impacts

Both the EU and the UN debate on climate change impacts for security has followed the latter track, calling for early action to minimize the projected impacts by multilateral cooperation. Also the joint British and German approach on the linkages between climate change and security has pursued a proactive approach. However, preventive security considerations require complex transformation strategies that will offer the people in the hyper-, semi- and arid regions who face water stress, soil erosion, desertification and drought a perspective for survival in the drylands to counter the environmentally-induced pressure for migration.

One of several possible transformation strategies addresses the widely unused technical solar energy potential in the countries in the sunbelt of the MENA region. Plans for the exploitation of solar thermal electricity generation in the desert region are just being developed (e.g. the DESERTEC Industrial Initiative)[25] and within one or two decades an economy of scale

25 See for details at: <http://www.desertec.org/en/news>.

may be gradually developing (Trieb/Krewitt/May 2009). The large-scale use of concentrated solar photovoltaic power generation may offer another medium-term alternative (Faiman 2009). Once such an 'economy of scale' has been achieved, solar desalination plants may use either energy source thus avoiding the rising costs of oil and gas and the proliferation danger associated with the transfer of technologies for the peaceful use of nuclear energy.

The use of alternative and renewable energy sources may create new livelihoods and sources of income for millions of people living in drylands (chap. 47 by Brauch/Oswald Spring and chap 48 by Safriel) and thus create a new basis for human, social and economic but possibly also for national and international security. It may somewhat relieve the pressure on the access and control over the fossil sources of energy and provide the states with alternative sources of revenue, also for those fossil energy exporters whose reserves will be depleted within the next few decades.

In the long run (e.g. by 2020–2050) a common and joint strategy will be needed that offers for these countries new economic perspectives, e.g. as an exporter of energy based on renewable energies, such as fuel cells, hydrogen from solar energy. However, such a vision requires already now a scientific and technical cooperation in the energy sector, in manufacturing and in the area of electric engineering (Brauch 2010). Thus, a longer-term oriented cooperative and strategic rethinking is needed beyond declaratory and symbolic policies and the schemes offered by the neo-liberal concepts of globalization. The latter schemes may intensify the pressure to migrate from the South and increase the costs for the European Union to cope with its consequences. Thus, in the 21st century the migration issue will remain both a major cause of action for the European Union and its intensity an indicator of the success or failure of a cooperative problem solution.

26.8.1 Launching a Mediterranean Environmental and Human Security Initiative (MEH-SEC) in the UfM Framework

Within the Union for the Mediterranean or the OSCE a new *Mediterranean Human and Environmental Security Initiative* (MEH-SEC) could be launched to address the manifold challenges posed by global environmental and climate change for the security in the Euro-Mediterranean region. This MEH-SEC Initiative may combine the regional soft security approach of the Barcelona process and of the Union for the Mediterranean with ideas of the "human security doctrine for the European Union" (2004) and the environmental security approach of the *Madrid Declaration on Environment and Security* of the OSCE (2007).

According to the *Intergovernmental Panel of Climate Change* (IPCC 2007) the Mediterranean will be affected most by global climate change getting hotter and drier. The policy messages of the Scientific Climate Conference of Copenhagen in March 2009 were even more dramatic that the "climate system is already moving beyond the patterns of natural variability" and "temperature rises above 2 °C will be very difficult ... to cope with, and will increase the level of climate disruption through the rest of the century". A sea-level rise of 1 metre during this century puts Mediterranean coastal zones and millions of people living in deltas at risk.

The Mediterranean is already severely affected by climate change, water stress, desertification and land degradation. The number and intensity of droughts, forest fires, storms and flash floods has increased in Spain, Greece, Turkey and in many MENA states. The trends of projected climate change impacts, hydro-meteorological hazards and their effects on declining crop yields and food supply in the MENA pose challenges for international, regional, national and human security. The European Council has acknowledged that climate change will severely affect the Middle East.

In December 2008, the European Council adopted a report on the implementation of the *European Security Strategy* of 2003 noting that "natural disasters, environmental degradation and competition for resources exacerbate conflict, especially in situations of poverty and population growth, with humanitarian, health, political and security consequences, including greater migration". The EU stressed that "we have enhanced our conflict prevention and crisis management, but need to improve analysis and early warning capabilities".

At the Paris Summit of 13 July 2008 that launched the Union for the Mediterranean the states shared "the conviction that this initiative can play an important role in addressing ... climate change and desertification, with the view of promoting sustainable development". The representatives of the 43 participating governments stressed: "the importance of strengthening food security, especially taking into account the consequences of climate change on food crops". They adopted, among others, two policy initiatives on civil protection dealing with both geophysical and man-

made natural disasters and launched the Mediterranean Solar Plan.

The Marseille Meeting of the Euro-Mediterranean Ministers of Foreign Affairs in November 2008 agreed that "climate change could adversely affect the environment and human activities in the Mediterranean". The ministers "recalled the need to intensify co-operation on climate change through the establishment of a Euro-Mediterranean Climate Change Network to provide the forum for the sharing of information and experience ... to build relationships ... in support of regional efforts to combat climate change". The Horizon 2020 Steering Group addresses "questions of mitigation/adaptation to climate change, biodiversity protection and conservation of the Mediterranean seabed". But these policy declarations lack a sense of urgency.

Since the 1990's, migration across the Mediterranean was for many European partners a 'hidden' driver for the Barcelona process and it has remained so for the new Union for the Mediterranean. But many reactive policy measures could neither turn the tide nor did they address the root causes why millions of people are on the move. There is a need for a proactive securitization of climate change in the Mediterranean in terms of international, national, environmental and human security. This security threat has been posed by human energy consumption since the Industrial Revolution, especially since the 1950's.

The solutions for achieving climate, water and soil security in the 21st century are not offered by the military but by the ingenuity of scientists and the willingness of political elites to establish policy frameworks for a proactive coping with the projected climate change impacts, thus avoiding potential violent conflicts. The Mediterranean is a fault line of political, economic, societal and environmental insecurity that pushes or pulls hundreds of thousands of distress migrants to Europe. A more ambitious, forward looking strategy for an economic co-development across the Mediterranean is needed in the framework of a 'survival pact' (26.8.6) that requires a long-term strategy of political and economic cooperation on commodities that are crucial for human and economic survival. Thus, a North-South strategy of confidence and partnership-building measures and projects is needed to achieve this longer-term goal.

Such a long-term initiative requires a sense of urgency on the mind of policy-makers. This idea requires a strategy that is delinked from the Middle East conflict. A policy framework for promoting such a long-term strategy could be a new *Mediterranean Environmental and Human Security Initiative* (MEH-SEC), modelled after the ENVSEC initiative of OSCE, UNDP, UNEP, with NATO as an observer, for Central Asia, the Caucasus and the Balkans. This MEH-SEC initiative should include besides the OSCE, UNDP, UNEP, FAO, WMO, IPCC also the Secretariat of the UfM to avoid policy competition and guarantee funding.

Within the framework of this MEH-SEC initiative all relevant conceptual activities of the different DGs of the European Commission and the Council dealing with the Mediterranean region and addressing human and environmental security dangers and concerns should be horizontally coordinated with a clear policy goal to develop an integrated strategy for addressing the security implications of regional climate change, desertification and water stress as well as the direct humanitarian effects due to increased climate related hazards and mutual needs for an uninterrupted supply for food and sustainable energy.

The MEH-SEC Initiative should develop a joint policy agenda that enables proactive policies for coping with *short-term effects* (natural hazards such as drought, heatwaves, forest fires, as well as flash floods), *medium-term impacts* (on precipitation, water stress, desertification, agriculture through declining crop yields, climate induced people's movements) and coping with *long-term consequences* (sea-level rise in deltas and coastal regions) of climate change in the Euro-Mediterranean region by developing joint adaptation and mitigation capacities.

26.8.2 Assessing Climate Change Impacts in the Mediterranean

The first four IPCC assessment reports (1990a, 1995a, 2001, 2007) dealt with climate change impacts only in the context of Africa, Asia and Europe. Therefore, no integrated research assessment exists for the whole Mediterranean region that addresses the huge knowledge gaps for many MENA countries, compared with higher resolution models and more detailed climate change impact studies for Europe as a whole.

In 28 October 2009 the European Union became an observer of the *Intergovernmental Panel on Climate Change* (IPCC) what permits representatives of the European Commission to introduce proposals. After consultation with the 43 member states of the UfM, the *European Commission* may propose a special report of the IPCC's three working groups on assessing:

- The *physical basis of climate change research* for the whole Mediterranean region thus combining South Europe, North Africa and the Middle East;
- The *impacts and vulnerabilities* of different sectors of human activity to climate change;
- The national efforts for adaptation and mitigation against short-, medium- and long-term physical impacts and societal consequences of climate change.

As no similar systematic regional assessment exists for the Mediterranean region, such a report could become an important policy instrument for addressing knowledge gaps, research needs, thus enhancing European research activities and fostering research cooperation with partners from the Euro-Mediterranean region. At the same time it would offer an independent scientific assessment of the outcome of many cooperative research projects on climate change in the Mediterranean. The scope of this independent science assessment should not be limited to the physical effects but should include the research on the societal effects and on the possible security implications during this century.

26.8.3 Environmental and Climate-induced Migration and Developing Alternative Livelihoods for People in Drylands

There are a few research institutes and projects that address migration issues with a regional focus on the Mediterranean but none deals in a systematic way with issues of environmentally- and climate-induced migration within the Euro-Mediterranean region.

Since 2004 Philippe Fargue has directed at the European University Institute in Florence the Euro-Mediterranean *Consortium for Applied Research on International Migration* (CARIM). Its Mediterranean migration reports (2005, 2006–2007, 2008–2009) address the demographic, economic, legal, political and social dimensions of migration but they do not analyse environmental factors that may cause, trigger or affect migration. The *Mediterranean Migration Observatory* (MMO) at Panteion University of Athens focuses primarily on Greece.

Two symposia at Almería (1994, 2006) addressed the linkage between desertification and migration. At the second Almería Symposium (2006) various proposals were made for establishing an international research centre on the linkages between soil erosion, desertification and migration in the Euro-Mediterranean context, for developing alternative livelihoods for people in drylands by using sustainable renewable energies. As desertification and migration had its greatest impact in Spain, it was suggested to set up such a research body in Almería to analyse these linkages in cooperation with the *Plataforma Solar de Almería* (PSA) in Almería, a leading research centre on solar thermal technology development.

The transformation of Almería from a poor province of labour emigration to a region of immigration due to the small-scale plastic agriculture (chap. 54 by Garcia Lorca) could be an ideal location for a Euro-Mediterranean training centre on creating small-scale alternative livelihoods in drylands and for developing knowledge for small-scale solar thermal installations for desalination of brackish and salty water in cooperation with the existing PSA.

26.8.4 Civil Protection in the Euro-Mediterranean Region

At the initiative of Italy civil protection was added as an area of cooperation among disaster response agencies with the goal "to build the Euro-Mediterranean Area for Civil Protection by progressively integrating the Southern partners into the European Civil Protection Mechanism". Civil protection has been made a priority area of the UfM that aims at the *Prevention, Preparedness and Response to Natural and Man-made Disasters Programme* (PPRD) to enhance the collaboration between civil protection institutions in EU member states and Mediterranean Partner countries in the field of training and on the operational level.

Within the European Union, civil protection gradually evolved as a new "functional security" area (Ekengren 2008) among the EU member states that was coordinated by the DG Environment in response to various natural hazards (earthquake in Turkey in 1999; Elbe flood in Germany, 2002; forest fires in Greece and Spain). With the solidarity clause of the Lisbon Treaty, this new task was further upgraded. Various international crises resulted in the creation of new EU agencies, such as the *Centre for Disease Prevention and Control* and the *European Maritime Safety Agency* (EMSA).

Building on present and planned activities and depending on the interest of the partner institutions from MENA countries, the cooperation on civil protection in the Euro-Mediterranean could be gradually expanded to facilitate joint research, capacity-building and training of civil protection officials and practitioners to enhance the monitoring of droughts and the

early warning of impending hydro-meteorological hazards.

Gradually the focus should expand from short-term disaster response, to disaster preparedness and disaster prevention activities with regard to rapid disaster response for rapid onset disasters such as earthquakes, volcano eruptions and tsunamis and hydro-meteorological events (storms, floods, forest fires) and slow onset extreme events (droughts) and long-term changes (sea-level rise). A goal should be to reduce the high social vulnerability of the poorest people in the MENA countries by improved early warning systems and technical and administrative capabilities and capacities that permit a rapid response.

The activities on civil protection may result at a later stage in the establishment of joint training centres in Southern Europe, North Africa and in the Near and Middle East that could benefit from a research centre monitoring droughts, forest fires and sea-level rise based on the most modern methods and the assessment of best practice in rapid disaster response to encourage improvements in the effectiveness of national disaster response forces and to ensure effective cooperation with outside rescue and assistance teams.

To move from disaster preparedness to disaster prevention requires a long-term institutionalization to monitor, analyse and assess in a systematic way the changes in the number and intensity of natural climate-related hazards in the Euro-Mediterranean region. This requires the active involvement of meteorologists, weather experts, agricultural specialists who can advise farmers in their adaptation to drought and landscape and city planners in the development of adaptation and mitigation measures to flash floods, landslides and water and wind erosion of agricultural land.

As the number and intensity of hydro-meteorological hazards in the Euro-Mediterranean region has significantly increased since 1950 and most particularly since 1975 (Brauch 2003, 2003c) and is projected to increase further during this century resulting, e.g. in more frequent heatwaves such as the one of August 2003, this requires a preparedness of the social and medical system of all countries (e.g. doctors, hospitals, etc.).

In moving from disaster response to disaster prevention a wide variety of national and international agencies, humanitarian assistance organizations and the research community would have to be involved in the MENA region. This functional cooperation among practitioners, public officials, assistance teams and experts from many different professions and scientific disciplines may be able to enhance the performance to the benefit of the affected people, reducing social vulnerability and the number of killed and affected, and the economic damage.

26.8.5 Mediterranean Solar Plan and Desertec Industrial Initiative

Several Arab countries in the MENA highly rely on the export of fossil energy sources (oil, gas); while a few other countries have already shifted from oil and gas exporting to importing countries or totally rely on imports of fossil fuels. Due to their geographic location in the sun-belt they have very high solar intensity especially in the deserts. For many decades visionary natural scientists have suggested to use this technical potential for a sustainable energy generation to reduce the emissions from the burning of hydrocarbons (Trieb/Krewitt/May 2009; Faiman 2009; Nitsch/Staiß 1997; Knies/Czisch/Brauch 1999; Brauch 1994, 1997, 1997c, 2000, 2010).

As long as oil and gas were relatively cheap there was no economic incentive for the coastal regions and sun intensive drylands to invest in the development of various renewable energy sources, especially in wind power and in solar (thermal, photovoltaic and solar concentration technologies) energy for the generation of electricity and hydrogen and for the desalination of brackish and seawater for both 'blue' (drinking) and green (agricultural) water.

Since the 1990' senergy system specialists of the DLR in Stuttgart have suggested to supply a part of Germany's electricity demand by importing electricity from solar energy installations from Southern Spain and from the Sahara Desert via long-distance *high-voltage direct currents* (HVDC). These conceptual ideas were developed further in three research projects funded by the German Federal Ministry on the Environment, Nature Protection and Nuclear Safety (Trieb/Krewitt/May 2009).

These conceptual and technical ideas resulted in the *Trans-Mediterranean Renewable Energy Cooperation* (TREC) concept that was endorsed by the Club of Rome under the leadership of HRH Prince Hassan bin Talal (foreword by HRH Prince Hassan bin Talal). Since 2003 the experts involved in the TREC project have developed the DESERTEC concept. On 13 July 2008 with the establishment of the UfM the EU Solar Plan was chosen as one of six key projects and developed further during the meeting of the foreign minis-

ters of the 43 participating countries in November 2008.

For two decades the Spanish research establishment CIEMAT and the energy department of DLR have closely cooperated in the development of solar thermal technologies and since 2006 they are being built in different locations of Andalusia (Seville, Granada). Based on previous activities in the Euro-Mediterranean region,[26] the EU and the *Union for the Mediterranean* (UfM) may create a long-term cooperative framework where the development of sustainable energy sources will aim at achieving simultaneously various policy goals by:

- Reducing the greenhouse gas emissions in the energy and transport sectors by developing first a political framework for a long-term Euro-Mediterranean survival pact that links two essential commodities, a sustainable food and energy production.
- Sharing renewable energy technologies with countries in the EU-MENA region by building centres of excellence but also establishing technical training centres to create a local expertise to install and maintain renewable energy systems thus creating an economy of scale.
- Focusing these activities initially on countries that lack fossil fuels (Morocco, Jordan) or whose reserves are rapidly declining (Tunisia, Egypt) but also increasingly on those countries (e.g. Algeria, Libya) that rely primarily on fossil exports to assist them in the mid- and long-term transformation of their energy system.
- Taking the severe water scarcity in the Nile River Basin into account that will become more severe due to the dual impact of continued high population growth rates and the impacts of climate change.
- Helping Egypt to reduce its high dependence (ca. 95 per cent) on the water resources of the river Nile with the gradual build-up of desalination plants based on renewable energy sources thus reducing one of the causes that may lead to conflict.

Such a sustainable development initiative may not only reduce the probability of violent domestic or regional conflicts on the access and control of water and food but by developing alternative livelihoods for people living in the drylands of the MENA region the environmentally-induced migration pressure may also be reduced. This may also create a political framework within the UfM building on the technical activities within the EU Solar Plan by creating a stable economic and geopolitical environment that facilitates the massive investments foreseen in the framework of the *Desertec Industrial Initiative* (Dii).

26.8.5.1 Mediterranean Solar Plan (MSP)

During the Spanish EU Presidency a MSP Strategy Paper[27] was considered in February 2010 and a conference was held in Valencia on the MSP on 11–12 May 2010 after a meeting by the European Investment Bank on 10 May 2010 on "Energy in the Mediterranean Region: the challenges ahead". [28] The MSP Strategy Paper outlined the goals and referred to two comple-

26 A Strategy Paper on the *Mediterranean Solar Plan* (MSP) <http://ec.europa.eu/energy/international/international_cooperation/doc/2010_02_10_mediterranean_solar_plan_strategy_paper.pdf> listed earlier initiatives on the Euro-Mediterranean energy co-operation contained in the "Priority Action Plan" (2008–2013): "A series of programmes supported by the European Union directly aim at integrating the Maghreb and Mashrek energy markets (e.g. MED-EMIP2, MEDREG3 projects) and at co-operation in the field of energy efficiency and renewable energy (MED-ENEC project 4). These projects also closely collaborate with the *Regional Centre for Renewable Energy and Energy Efficiency* (RCREEE) based in Cairo. Additionally, EU Member States together with UfM Partner Countries support a number of relevant initiatives, such as the *Mediterranean Renewable Energy Centre* (MEDREC) based in Tunis as the focal point of the MEDREP Initiative. Other regional initiatives such as the *Mediterranean Energy Observatory* (OME) or MEDELEC have also provided a very important contribution."

27 See at: <http://ec.europa.eu/energy/international/international_cooperation/doc/2010_02_10_mediterranean_solar_plan_strategy_paper.pdf>.

28 The Spanish EU Presidency held a Conference on the Mediterranean Solar Plan, Valencia, 11–12 May, 2010; at: <http://www.mediterraneansolarplan-conference.es//index.php/idmenu.1034>; and on 10 May 2010, the *European Investment Bank* (EIB) hosted a conference focusing on solutions to the energy challenge being faced by the Mediterranean Region, where the EIB presented new instruments for boosting energy efficiency, discussed how to integrate the Mediterranean's potentially large renewable capacity into the national and international grids, and announced the results of the FEMIP Trust Fund Study on the Mediterranean Solar Plan. See at: <http://www.eib.org/attachments/valence-programme-en.pdf>. However, the Euro-Mediterranean Summit that was planned for 7 June 2010 was postponed on 20 May 2010 to November 2010 to commemorate the 15th anniversary of the Barcelona Process.

mentary targets: "(i) developing 20 GW of new renewable energy production capacities and (ii) achieving significant energy savings around the Mediterranean by 2020, thus addressing both supply and demand". These goals include the transfer of know-how and technology, including activities on education, training, research and developing and local manufacturing capacities in cooperation with the existing institutions, such as *Mediterranean Association of National Energy Agencies* (MEDENER), the *Mediterranean Energy Observatory* (OME), the *Regional Centre for Renewable Energies and Energy Efficiency* (RCREEE) in Cairo and the *Mediterranean Renewable Energy Centre* (MEDREC) in Tunis. The partners of the MSP also aim at creating favourable framework conditions (regulatory framework on investments, for know-how and technology transfer and for electricity transmission). During the preparatory stage (2008–2009) meetings were held on 22 November 2008 in Paris, on 21 October 2008 in Seville and on 28 and 29 October 2008 in Berlin. Among the goals that were considered in spring 2009 in the framework of the EU's Mediterranean Solar Plan are:

- Expansion of renewable energy systems for electricity generation (wind, CSP, PV) and grid infrastructure with a perspective of exporting "green electricity" to Europe;
- Creation of an appropriate framework conditions to secure stable investments and a sustainable development;
- Development of the Master Plan Study and approval of first projects.

In February 2009, a German official[29] listed among the most urgent tasks the development of 1) projects (criteria, next steps); 2) master plan study (terms of reference, responsibilities, realization); 3) discussion about new elements of MSP (on efficiency, infrastructure, technology transfer); and 4) strategy paper (finalizing and distribution). A German technical expert distinguished two phases of the MSP.[30] The work on the *Master Plan Study* started in early 2009 to outline "concrete steps for the development of: a) solar thermal power plants: b) solar photovoltaic, c) other renewable energy installations, d) export of electricity to the EU along with local energy needs, e.g. for water desalination". One key goal is to develop a road map for the implementation of the Mediterranean Solar Plan.

As an outcome of the first ministerial meeting on sustainable development programmes on 25 June 2009 in Paris it was announced to organize: a) technical workshops on environment, transport, energy and sustainable urban development and b) an energy workshop about MSP with participants from 22 UfM member states, the EC and US representatives, plus multilateral and national financial institutions. Furthermore, MSP documents were released and it was announced that the KfW, EIB and AfD earmarked about 5 billion euros for renewable energy and energy efficiency projects for the next 5 years.[31] A conference of experts in November 2009 addressed the obstacles but also the business opportunities due to public-private partnerships.[32]

Based on the Strategy Paper an Action Plan will be set up to launch the first projects during 2010–2011, to improve the framework conditions and to secure and develop adapted financial mechanisms with the World Bank and the EIB. During the second deployment phase (2011–2020) the 20 GW target is to be reached as part of a master plan with a roadmap for implementation to be presented in 2011 that should develop a strategy including these elements:

- Site selection issues and local industrial capabilities and renewable energy market development in the countries of the Mediterranean region;
- Initiatives in the field of solar and other renewable energies for power generation and energy efficiency in the Mediterranean countries and potential synergy measures to make the best possible use

29 Ralf Christmann, Division Research and Development in the Field of Renewable Energies, BMU: *Union for the Mediterranean – Mediterranean Solar Plan*; at: <http://www.erec.org/fileadmin/erec_docs/Events_Documents/EUSEW_MSP_13_Feb_2009/MSP_Ralf_Christmann-panel_2.pdf>. He referred to these governmental tasks: a) keeping the momentum for achieving the goal; b) keeping continuity for the MSP development; c) enhancing active involvement; d) diversifying work and responsibilities; e) bringing transparency into the process and results; and f) ensuring broad backing and acceptance.

32 Manon Malhère: "Mediterranean Solar Plan - Project faces strategic and financial problems", in: *Europolitics*, 20 October 2009; at: <http://www.europolitics.info/sectorial-policies/project-faces-strategic-and-financial-problems-art251878-14.html>.

of existing efforts, notably regarding energy efficiency initiatives;
- Progress of legislative and regulatory reforms, institutional and administrative conditions, as well as other relevant infrastructure and electricity sector issues for a phased development of solar and other renewable technologies in the Southern Mediterranean countries;
- Suitable mechanisms for financing (including appropriate support and import-export schemes, concessional financing and carbon finance and other innovative financing schemes) along with the most cost-effective solutions to ensure active private sector involvement, taking into account results from existing or coming publications, such as the Commission's "Communication on financing low carbon technologies" and the FEMIP study on the economic conditions regarding the Mediterranean Solar Plan contracted by the EIB;
- Address the specific issue of transmission infrastructures to EU countries, taking stock of existing bilateral agreements and the ongoing involvement of transmission system operators, and proposing, in particular, specific electricity grid infrastructure projects that could be of common priority in the Euro-Mediterranean context for establishing an effective green electricity import-export framework and could be addressed in the framework of the *Trans-European Networks* (TEN) initiative;
- Relevant conditions for the improvement of energy efficiency in the most energy intensive sectors such as buildings, household appliances, industry and transport, including financial and economic aspects;
- Identify further needs for technical assistance and capacity-building in the fields of renewable energy production, energy efficiency and technology cooperation and transfer. Synergies with the *International Renewable Energy Agency* IRENA could be suitable for this purpose.

These activities on the governmental level provide a policy framework for activities of economic consortia, such as the DESERTEC Industrial Initiative (Dii), that aim to install thermal energy plants in the Sahara Desert for an estimated cost of €400 billion.

26.8.5.2 DESERTEC: From Vision to Reality

The DESERTEC concept gradually evolved during the past decade within the framework of the Club of Rome and the DESERTEC Foundation[33] stimulated by three research projects funded by the German Environment Ministry (BMU) on *Trans-Mediterranean Renewable Energy Cooperation* (TREC) that aim at:

> the perspective of a sustainable supply of electricity for Europe (EU), the Middle East (ME) and North Africa (NA) up to the year 2050. ... A close cooperation between EU and MENA for market introduction of renewable energy and interconnection of electricity grids by high-voltage direct-current transmission are keys for economic and physical survival of the whole region. ... The challenge of future electricity supply is to find a mix of available technologies and resources that is capable of satisfying not only the criterion of 'power on demand', but all the other criteria for sustainability too.[34]

The DESERTEC Foundation is to contribute to the realization of this concept and it works "for creating a global alliance to ensure security of energy supplies, to promote economic development, and to stabilize the world's climate". The *Desertec Industrial Initiative* (Dii) was launched on 13 July 2009 in Munich with the goal: "to analyse and develop the technical, economic, political, social and ecological framework for carbon-free power generation in the deserts of North Africa". Among its key goals are

> the drafting of concrete business plans and associated financing concepts, and the initiating of industrial preparations for building a large number of networked solar thermal power plants distributed throughout the MENA region. The aim is to produce sufficient power to meet around 15 per cent of Europe's electricity requirements and a substantial portion of the power needs of the producer countries. All of the Dii's activities will be aimed at developing viable investment plans within three years of its establishment. ... Besides the business opportunities for the companies, there are other economic, ecological and social potentials:
>
> - Greater energy security in the EU-MENA countries;
> - Growth and development opportunities for the MENA region as a result of substantial private investment;
> - Safeguarding the future water supply in the MENA countries by utilizing excess energy in seawater desalination plants;

33 On 26 April 2010, there was a leadership change in the DESERTEC Foundation; see at: <http://www. desertec.org/en/press/press-releases/100426-01-leadership-changes-within-the-desertec-foundation/>. Gerhard Knies, the chair of the Supervisory Board became Chairman of the Board of Trustees of the Foundation and was succeeded by Max Schön, an entrepreneur and chair of the German section of the Club of Rome. Ms. Katrin-Susanne Richter and the entrepreneur Thiemo Gropp became Directors of the DESERTEC Foundation.

34 See summary of the DESERTEC project; at: <http://www.desertec.org/en/concept/summary/>.

- Reducing carbon-dioxide emissions and thus making a significant contribution to achieving the climate change targets of the European Union and the German Federal Government.[35]

On 31 October 2009 the Desertec GmbH (limited liability company) was established that plans to cooperate with the MSP and the World Bank's *Clean Technology Fund* (CTF). [36]

Dii has already generated much interest in several MENA countries, including in Morocco, which plans to produce 2,000 megawatts (MW) per year of solar power by 2020; Jordan wants to produce 7 per cent of its energy requirements through renewable sources by 2015; Abu Dhabi 7 per cent by 2020, and Kuwait 5 per cent by 2020. Egypt has announced a goal of 20 per cent renewable power by 2020. Algeria is completing the world's first operational *integrated solar combined cycle* (ISCC) power station with a 150 MW plant at Hassi R'Mel. Egypt's solar thermal installation in Kuraymat that will be completed by the end of 2010 will have a generation capacity of 150 megawatts (MW), with 20 MW coming from the solar array. The project is expected to generate 852 GWh of electricity per year, with solar accounting for 4 per cent of the total. The solar components were supplied by Flagsol from Germany and all construction was undertaken in cooperation with Egyptian construction firm Orascom. With the CSP project Shams, the Abu Dhabi Future Energy Company will concentrate sun rays on a receiver filled with molten salt. Large solar projects are also underway in Saudi Arabia, Kuwait and Tunisia. [37] Besides the deserts of the USA and Mexico, of South America, Southern Africa and Australia, the MENA region offers the best technical potential for CSP (figure 26.4). To achieve the goal of a global 50 per cent reduction of GHG, or up to 80 per cent for most OECD countries by 2050 requires major political initiatives aiming at a 'Fourth Green Revolution' (chap. 95 by Oswald Spring/Brauch) with a major decarbonization and dematerialization of the economy.

In May 2010, both initiatives, the *Mediterranean Solar Plan* (MSP) of the UfM and the Dii of the private sector could become conceptual components of a far more ambitious *EU-MENA Survival Pact* that may link two essential commodities, food or 'virtual water' and sustainable solar energy or 'virtual sun' (Brauch 2002b).

26.8.6 Developing a EU-MENA Survival Pact

The concept of a 'survival pact' outlines an interregional perspective of sustainable co-development by linking these two commodities, where both partners either have a surplus or are in need. Both commodities are indispensable for human survival and for the economy. This proposal suggests an inter-regional framework for a strategy of sustainable co-development for the Mediterranean where the economic gap between North and South has widened. For no other contact region is the complementarity of both commodities as obvious. The growing demand for food (especially for cereals) in the South can be satisfied by importing food as 'virtual water'. In the North, the demand for energy can be satisfied by importing both hydrocarbons (oil and gas) and in the future also renewable sources of energy, e.g. electricity and hydrogen or the 'virtual sun', as part of a mutual sustainable development scheme.

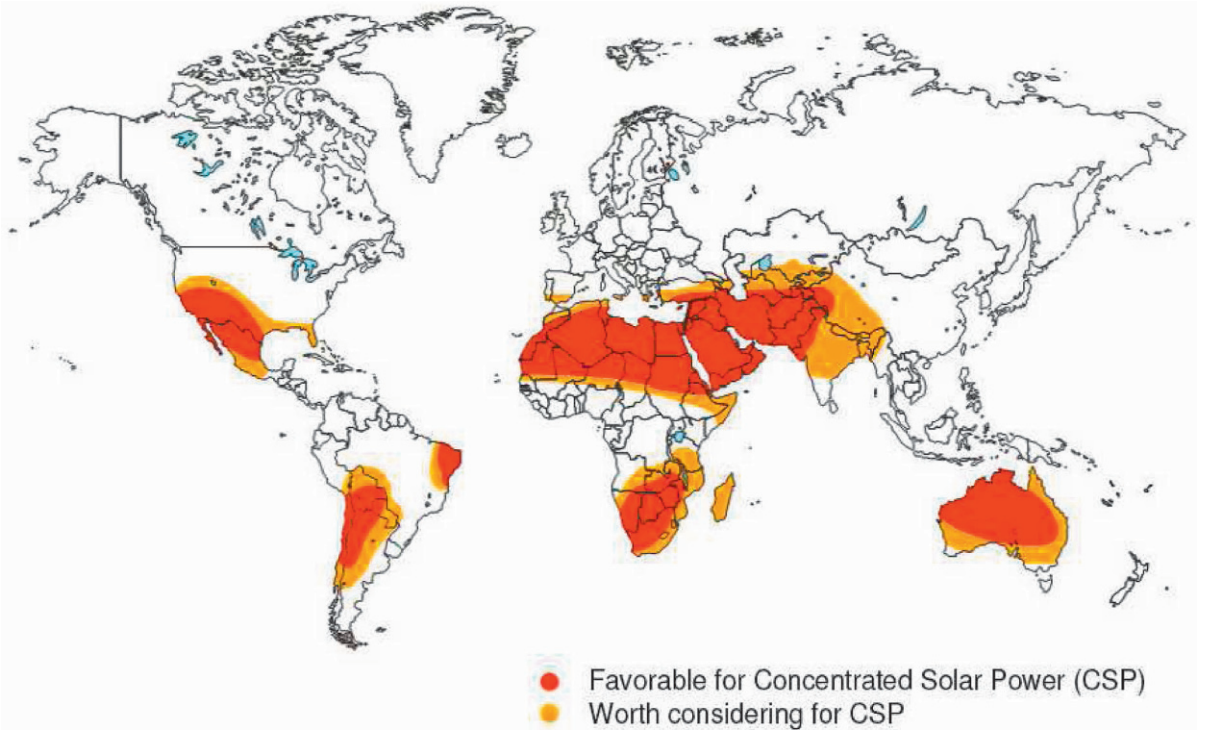
However, this perspective requires a fundamental change in political thinking by overcoming notions of food self-sufficiency (in terms of food security) in the

35 Press release – Munich, 13 July 2009: "12 companies plan establishment of a Desertec Industrial Initiative"; at: <http://www.desertec.org/fileadmin/downloads/press/09-07-13_PM_DII_english.pdf>; 30 October 2009: "Joint venture DII established and ready to take up work"; at: <http://www.desertec.org/en/press/press-releases/091030-01-formation-dii-gmbh/>.

36 The *Desertec Industrial Initiative* (Dii) "is a private-sector initiative" that seeks "all forms of collaboration with leading or complementary international political and institutional initiatives such as the *Mediterranean Solar Plan* (MSP) or the World Bank's *Clean Technology Fund* (CTF) that, like us, are devoted to developing the markets for large-scale sustainable energy production and transmission. See at: <http://www.dii-eumena.com/home/about-us.html>. In late April 2010, 17 companies from eight countries were among the shareholders of Dii: ABB, Abengoa Solar, Cevital, DESERTEC Foundation, Deutsche Bank, Enel Green Power, E.ON, HSH Nordbank, MAN Solar Millennium, Munich Re, M+W Group, NAREVA Holding, Red Eléctrica de España, RWE, Saint-Gobain Solar, SCHOTT Solar and Siemens, and 15 additional companies were associate members: 3M Deutschland; Bilfinger Berger, Commerzbank, Evonik Industries, First Solar, FLABEG, IBM Deutschland, Italgen, AEFER Isoliertechnik, Lahmeyer International, Morgan Stanley Bank AG, Nur Energie, OMV, Schoeller Renewables and TERNA ENERGY. See at: <http://www.dii-eumena.com/media/press-releases.html>.

37 Cam McGrath: "Oil-rich Gulf states look to the sun – Feature", in: *Earth Times*, 27 April 2010; at: <http://www.earthtimes.org/articles/show/320699,oil-rich-gulf-states-look-to-the-sun–feature.html>.

Figure 26.4: The best regions for *Concentrated Solar Power* (CSP). **Source**: Jonathan Walters, World Bank: "MENA Concentrated Solar Power", presentation for the Conference on the Mediterranean Solar Plan, Valencia, 11-12 May 2010; at: <http://www.mediterraneansolarplan-conference.es/uploads/documentos/documentos_onathan_Walters_World_Bank_9769228b.pdf>.



South and for energy supply security in the North. It necessitates a complex interregional interdependence between the agricultural and energy sectors of the EU and of MENA countries. The concept of a 'survival pact' requires a long-term strategy of political and economic cooperation on commodities that are crucial for human and economic survival. No such perspective is realistic without a level of mutual trust and confidence among its partners.

'Virtual sun' is the sun embedded in forms of renewable energy that can satisfy the energy demand (desalination of water) and can be exported to the North as electricity via long-distance cables (from Morocco to Spain and from Tunisia to Italy) and as hydrogen in existing gas pipelines. The MENA countries have a high potential for solar energy both as solar thermal (CSP) and photovoltaic. A major constraint in the North has been the thinking in terms of energy supply security since the oil shocks of the 1970's and 1980's that energy can be used as a weapon to 'strangulate' the economies of the North.

Solar electricity for solar home systems, solar village systems, or as part of hybrid energy systems can satisfy the rapidly growing electricity needs of the MENA countries by using their largest renewable source - the sun. It would thus extend the lifespan of available fossil energy reserves that have been projected to decline during the next 10 to 50 years.

The MEH-SEC Initiative suggested above could offer a political mechanism that involves besides the 43 countries of the UfM also relevant UN institutions (e.g. UNEP, UNDP, WMO). The proposal of a Euro-Mediterranean survival pact offers a long-term strategic perspective to cope with the multiple security implications in a proactive way by outlining a strategy of a long-term economic interdependence by making it impossible that either side could use energy or food as a weapon and by moving jointly towards a sustainable development path.

26.9 Conclusions

This chapter has compiled and summarized the best available scientific knowledge on the physical climate change impacts for the Mediterranean and the *Middle East and North Africa* (MENA) region; it reviewed the evidence on the possible societal impacts forcing people to move (push factors) or following the pull

factors of migration across the Mediterranean from North and Sub-Saharan Africa as well as from West and South Asia to Europe and discussed the high relevance of the WBGU's four conflict constellations for this environmental hotspot. Thus, the impacts of GEC and GCC in the Mediterranean and MENA regions may result in increased human, environmental (Chourou 2009), energy (Selim 2009) and climate (WBGU 2008; Brauch 2010; Issar 2010 and chap. 24; chap. 23 by Salem) as well as national and regional insecurity if business-as-usual policies prevail and proactive political strategies, policies and measures are not undertaken.

The water scarce but energy rich MENA region does not only control the largest oil and gas reserves, it has also the best conditions for the use of concentrated solar power, relying on solar thermal and wind power (Dii) but also on concentrated solar photovoltaic (Faiman 2009). The Mediterranean Solar Plan and the Desertec Industrial Initiative are indications of a political willingness by the 27 EU countries and a consortium of major industrial, energy consuming and renewable energy producing companies from the EU-MENA regions as well as financial institutions that have the economic potential to bring about a 'Fourth Green Revolution' during this century and thus to counter the possible consequences of the increased competition for access to and control of the hydrocarbon resources that may lead to future 'resource wars' (Klare 2001, 2001a) in the MENA region. Shifting from hydrocarbons to renewables in the countries of the sunbelt avoids the proliferation potential associated with the build-up of peaceful nuclear energy that is linked to the Iranian nuclear project.

The Mediterranean Solar Plan and the Dii are two bold schemes that may become catalysts for a major energy transformation in the EU-MENA region that must be embedded in a long-term oriented cooperative strategy for a sustainable peace between Europe and the Arab world based on mutual respect, cooperation relying on trust and common interests. If these complementary visions should gradually be implemented on the ground starting in 2011 they must be combined with determined and closely coordinated European and US efforts to resolve the Middle East conflict that has partly paralysed the Barcelona process since 1995 and that has also created obstacles for the UfM that could be the political framework for the realization of a trans-Mediterranean sustainable economic co-development. Both the MSP and the Dii may also become major 'partnership building projects' (Brauch 2000) linking Europe with the regions of North Africa and the Middle East.

This requires both mutual respect but also confidence and trust among the adherents of the three monotheist religions of Jews, Christians and Muslims. If they should succeed to create a few hundred thousands if not millions of new jobs and alternative livelihoods for the people in the EU-MENA region, especially for the qualified young generation, during this century then these visions – if they lead to new policies on the ground – may also reduce the pressure for forced migration that may be expected from the projected impacts of GEC and GCC.

Thus, the resolution of one of the most persistent conflicts of the past 60 years may be closely linked to efforts to move towards a 'Fourth Green Revolution', by implementing strategies, policies and measures aiming at transitions towards sustainable development (Grin/Rotmanns/Schot 2010) that aim at the longing of humankind for peaceful relations among states and for sustainable or progressive development (Issar 2010, also chap. 24), or for strategies of a sustainable peace (Brauch/Oswald Spring 2009) that conceptually combine both goals. However, for the realization of these bold plans and initiatives, a decoupling from the Middle East conflict is essential to avoid that setbacks continue to paralyse the Euro-Mediterranean cooperation.

27 Global Environmental Change and Conflict Potential in Central Asia

Jenniver Sehring and Ernst Giese

27.1 Introduction

The aim of this chapter is an assessment of the impact of *global environmental change* (GEC) on stability and security in Central Asia. Security thereby is not only understood as the non-appearance of interstate conflicts but also as the ability of states to manage economic and social crises and thereby to prevent violent conflicts and to guarantee human security as defined by the UNDP (WBGU 2007: 19–24) Therefore, in its conceptualization of the link between environment and security, this analysis follows the definition of security and conflicts of the WBGU.[1] The evolving research question is if and how global environmental change might increase security risks in the region – risks of violent conflicts between states, but also risks for the survival of the population leading to destabilization. Before this question is assessed, a review of the current situation regarding conflicts is appropriate.

The conflict potential in Central Asia is grounded in the internal situation of the states as well as in the difficult interstate relations. Internally, the conflict potential is often related to the general situation in the poor, authoritarian, and partly politically unstable states with weak governance structures, Islamic underground groups, and organized crime as well as to the relatively new borders that left considerable minorities of each country in neighbouring states. Here also the huge social differences play a role. Already during Soviet times the republics of Middle Asia as well as the Autonomous Region Xinjiang in China, had been the poorest regions in the respective states. Following independence, a small rich social class evolved which mainly stemmed from the former Soviet *nomenklatura* and controls the political and economic institutions. It maintains its influence through clientele networks. Patronage, nepotism, and corruption are widespread; not only in the political sphere but also in the socio-economic realm where they even determine access to basic resources such as education, health care, or agricultural inputs (Cummings 2002; Heathershaw/Toresjen 2005; Berg 2004). Cooperation between the states is – though announced in numerous agreements and declarations – still a difficult task. In those cases where they have been somewhat successful, as with the *Shanghai Cooperation Organization* (SCO), Russia or China are involved, but there is no successful 'purely Central Asian' cooperation (Seidelmann/Giese 2004; Allison 2004, 2007; Jackson 2007).

Since independence in 1991, several tensions with sometimes violent incidents between ethnic and political groups happened, especially in the following 'hot spots':

- the Fergana Valley, the most densely populated area in Central Asia, divided between Kyrgyzstan, Tajikistan, and Uzbekistan; social protests and ethnic tension erupted in the Eastern part (Namangan and Andizhan, Uzbekistan), Osh (Kyrgyzstan); it is also met by tensions along the new frontiers and by activities of militant Islamic groups.
- A conflict between poor Southern Kyrgyzstan and the Northern part of the country, which is richer and more secularized, together with a penetration of politics with persons connected to organized crime.
- Tajikistan, which experienced a civil war and still is characterized by fragile statehood and strong regional identities.
- The delta area of the Amu Darya where the interests of Uzbekistan and Turkmenistan on water distribution are in conflict (Tashaus, Turkmenistan and Khorezm, Uzbekistan)

1 This article is based on a more detailed background study of the two authors for the WBGU (Giese/Sehring 2006). We thank the WBGU for granting the copyright for the English version.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_27, © Springer-Verlag Berlin Heidelberg 2011

Figure 27.1: Central Asia: Hydrographic and political overview. **Source:** The authors compilation.

- General instability in Northern Afghanistan in the border regions to Tajikistan, Uzbekistan, and Turkmenistan;
- Xinjiang, with the Kazakh and Kyrgyz autonomous districts in the upper Ili valley, the city of Kashi and the Western part of the Tarim basin as centres of the Uigurs and the capital Urumchi, which is dominated by Han Chinese (Giese/Sehring/Trouchine 2007).

Where violent incidents occurred, this mostly happened on a local level and was connected to access to key resources such as land and water and rooted in socio-economic disparities. It was hence not only a result of environmental degradation but also of political and economic factors. Will this situation be reinforced by environmental changes due to climate change? Will existing environmental crises such as water scarcity and soil degradation aggravate and lead to conflicts? Will poverty raise and threaten human security? The basis for the following analysis are the data of the 2007 report of the *Intergovernmental Panel on Climate Change* (IPCC 2007) and of own analyses of climate change in Central Asia (Giese/Mossig 2004; Giese/Mossig/Rybski/Bunde 2007).

27.2 General Geographical Conditions

For the purpose of this analysis, Central Asia comprises the area of the five former Soviet republics Turkmenistan, Uzbekistan, Tajikistan, Kyrgyzstan, and Kazakhstan as well as the Autonomous Region of Xinjiang in China (figure 27.1).[2] The region is characterized by mighty mountain ranges and huge basins without outlets. The ranges of Tien Shan, Pamir-Alai, Hindukush, Karakorum, Kunlun, and Altyn-Tagh are broadly above 4000 m and reach peaks up to 7000 m. The extreme difference in elevation is one reason for the frequent occurrence of mass movements (mudslides, landslides, etc) in certain areas of Central Asia, e.g. in the Fergana Valley or the Northern Tien Shan.

The Central Asian mountain complex is the biggest mass elevation world wide. This has two consequences that are climatologically relevant: First, the mainly east-west stretching ranges are a barrier to all south-north or north-south airstreams. It influences thereby precipitation patterns. Secondly, it impacts on

2 This definition is oriented at the former territory of Turkestan. In hydrographic or cultural and historical respect, other framings are possible, e.g. including Northern Afghanistan or Mongolia. See Machatschek (1921); Hambly (1966); Olzscha/Cleinow (1942); Stadelbauer (2004).

temperature (Blüthgen/Weischet 1980: 617; Haffner 1997: 307ff.): It is considered to be one of the main reasons (besides the location in the interior of the Asian continent) for the disproportionally high increase in air temperature in Central Asia.

The big arid inland drainage basins in Central Asia are the Aral Sea Basin, the Ili-Balkhash Basin, the Fergana Basin, the Issyk-kul Basin, Dzhungarian Basin, Turfan-Hami Basin, and Tarim Basin. All rivers from the mountain ranges – the biggest ones are the Amu Darya, Syr Darya, Ili and Tarim – drain in these basins, flowing into lakes without outlet or drying up before. All major rivers are transboundary crossing two or more states (Giese/Sehring/ Trouchine 2004; Kipping 2009; Rakel 2009; Wunderer 2009; Martius/ Froebrich/Nuppenau 2009).

Due to its location inside the Asian continent and its orographic structure, a highly continental climate prevails in the lowlands of the basins that are also extremely arid. Deserts and semi deserts are widespread, covering more than 50 per cent of the basin area. Consequently, only limited land is available for agriculture – in most countries of the region less than 10 per cent of the territory is arable land and even only 1.8 per cent in Xinjiang. More than 90 per cent of these areas are cultivated by irrigated agriculture, which is the prime water consumer.

Precipitation in the lowlands of Central Asia does not exceed annually 150–200 mm (in spring and summer). Precipitation increases – depending on exposure of the mountain range – with an elevation to 400 mm or even 600 mm per year. In the forelands of the mountains, which serve as water accumulator and water dispenser for rivers flowing into the arid basins, agriculture is therefore possible in the foothills and along the rivers.

Climate in Central Asia is not only arid, but also continental. It is not unusual that the annual variation of mean monthly temperature exceeds 25 °C (e.g. Almaty: -5.5 °C in January, +24 °C in July; Kazalinsk: -9.2 °C in January, +27.2 °C in July). Summers are very hot and winters very cold. In winter therefore is a strong need for energy, which cannot be met in parts of Kyrgyzstan and Tajikistan (Giese/Sehring 2007).

Scarcity of natural resources is a general characteristic in Central Asia. The shortage of arable land was already mentioned. Also water, while not scarce physically, appears to be short due to its extensive usage in agriculture, where demand exceeds available resources. One consequence is the well-known disaster of the drying up of the Aral Sea (Giese 1998; Micklin 2006; Sehring 2007, 2009). The scarcity of land and water is significant as agriculture – and especially irrigated agriculture – is an important economic sector, fundamental for the survival of a majority of the population. The following analysis focuses on the conflict potential arising from questions of resource access that might become influenced by the regional impacts of global climate change.

27.3 Impact of Global Environmental Change

27.3.1 Water

The scarcity of freshwater resources is the most pressing current as well as prospective environmental problem. As all major rivers in Central Asia are transboundary and water is a key resource in agriculture, this has enormous conflict potential on the national as well as on the international level. The share of irrigated cropland of the total area under cultivation is about 36 per cent in Northern Afghanistan, 75 per cent in Kyrgyzstan, 84 per cent in Tajikistan, 89 per cent in Uzbekistan, and 100 per cent in Turkmenistan (Ahmad/Wasiq 2004: 18; Bucknell/ Klytchnikova/ Lampietti/Lundell/Scatasta/Thurman 2003: 3).

Agriculture counts for more than 90 per cent of water use in Central Asia. A second usage is hydropower production, which is of increasing importance for the mountain states (Kyrgyzstan and Tajikistan). Since the 1960's, numerous reservoirs have been built in order to enhance the regulation of the rivers and produce hydro power. Examples are the Toktogul reservoir at the Naryn river in Kyrgyzstan, which allows the multi-year regulation of the Syr Darya, and the Nurek reservoir at the Vaksh, which is the main tributary to the Amu Darya. The working regime of hydro power production is opposite to that of the regulation for irrigation of water delivery (water discharge in winter when peak in energy needs vs. water discharge in summer when peak in irrigation water needs). While the downstream states Kazakhstan, Turkmenistan, and Uzbekistan need water especially for irrigated agriculture, the upstream states Kyrgyzstan and Tajikistan are interested in hydropower production (Giese/Sehring 2007).

The spatial distribution of water resources in Central Asia is highly unequal. The major part of renewable surface water is formed in the mountain regions of Tajikistan, Kyrgyzstan, and Afghanistan. In the Aral Sea basin, which covers most part of Central Asia, 43 per cent of annual discharge originates in Tajikistan,

Table 27.1: Water formation and usage in Central Asia. **Source:** Giese/Sehring (2007: 484).

State	Discharge formation			Usage	
	Amu Darya	Syr Darya	Total Aral Sea basin	Amu Darya	Syr Darya
Tajikistan	62,90	2,70	43,40	17,92	9,07
Kyrgyzstan	2,00	74,20	25,10	1,03	0,85
Afghanistan and Iran	27,20	–	18,60	?	–
Uzbekistan	6,00	16,60	9,60	41,76	51,76
Turkmenistan	1,90	-	1,20	39,29	-
Kazakhstan	–	6,50	2,10	–	38,32
Total	100	100	100	100	100,00

24 per cent in Kyrgyzstan, and approximately 19 per cent in Afghanistan. These states use only about 17 per cent of the water, while downstream Kazakhstan, Uzbekistan, and Turkmenistan use 83 per cent. These usage patterns are guaranteed in a quota system that was established in the 1980's by the Soviet Union and is still valid today. China is involved as an upstream state of the Ili (flowing into Kazakhstan) as well as a downstream state of the Tarim (whose main tributary is the Aksu from Kyrgyzstan).

Since the 1960's, the whole region is hit by an increasing scarcity of freshwater and degradation of the quality of drinking as well as irrigation water. The regions at the middle and lower reaches of the big streams are hit hardest: at the Amu Darya (Uzbekistan and Turkmenistan), Syr Darya (Kazakhstan), Ili (Kazakhstan), and Tarim (Xinjiang/PRC). The quantitative and qualitative water problems are mainly anthropogenic. As already mentioned, irrigated agriculture is the main water consumer. Since the 1950's, especially the water-intense cotton cultivation was massively extended. Today, the total irrigated area in the former Soviet parts of Central Asia exceeds 8 mio. ha. Water consumption increased from about 60,000 mio. m^3 in 1960 to almost 105,000 mio. m^3 in 1999. On the Chinese side, the government conducted a similar land reclamation policy in Xinjiang.

Water consumption did not only increase because of the expansion of the irrigated area, but also because of the low degree of efficiency in usage. Experts estimate that the usage coefficient is only about 40–60 per cent. The reasons are inadequate infrastructure (earthern instead of concrete-lined channels with high infiltration rate), open channels with high evaporation rate), mismanagement (outdated irrigation techniques with high water consumption and high evaporation rate on the fields), and salinization of fields due to decade-long cotton monoculture (need for additional irrigation in winter for desalinization).

While infrastructural and management reasons could be solved by technical improvements, also climate change plays a role and makes less water needs in the future unrealistic. According to time series analysis, global warming is stronger in Central Asia than on the global average. While on global average, mean annual temperature increased by 1.8 °C/100 years from 1970/72 to 2000, in Central Asia it increased by 3.1 °C to 4.8 °C/100 years (Giese/Mossig 2004: 33–35). The model calculations of the IPCC (2007) indicate an increase of mean annual temperature in Central Asia by 3.2 °C to 4.1 °C until the end of the 21st century (2.7 °C on average). A consequence is that evaporation rates further increase and hence even more water is needed.

A related long term problem of climate change is the melting of glaciers. Its consequence is the irretrievable loss of the freshwater resources stored in the ice of the glaciers. Since the 1970's, the melting processes became more intense due to the warming (Dikikh 2004: 27–28; Giese/Mossig 2004: 1–4).

Kuzmichenok (2003) developed several scenarios on the future development of the glaciers in the Kyrgyz part of the Tien Shan. Given an increase of summer temperatures by 5 °C/100 years and constant precipitation rates, he projects that by 2050 about 20 per cent of the glaciers, mainly smaller ones, will have disappeared and the total volume of glaciers will be reduced by 32 per cent. The results of Dikikh's (2004) calculations concerning the Kungey- and Terskey-Alatau are similar: Given summer temperature increases in the same pace as in the past 20 years (+1.5 to +2.0 °C), he forecasts a loss in volume of 38 per cent until 2025 for the Northern exposed glaciers and even 73 per cent for those exposed to the South.

In the short and middle term, discharge in the glacier-fed rivers will increase during the summer months. In the long term, however, discharge will decrease and partially the inflow of glacier water will stop completely. And for some rivers, the share of glacier water for the total discharge is immense - so e.g. up to 53 per cent in the rivers of the Terskey- and Kungey-Alatau of the Northern Tien Shan, which flow into the Issyk-kul basin. In summer, the share of glacier water can even reach 69–87 per cent (Dikikh 2004: 37). Micklin (2006: 564) estimates that the flow of the Amu Darya will reduce by 7–10 per cent in the next 50 years. These developments can have disastrous effects in those downstream areas that already today face shortages.

The increasing water scarcity already led to conflicts of interest concerning water usage between the states. The most important conflict constellations are:

- at the Syr Darya and his main tributary Naryn between Kyrgyzstan on the one side and Kazakhstan and Uzbekistan on the other side about water discharge from the Toktogul reservoir in Tajikistan;
- at the Vaksh, one of the main tributaries of the Amu Darya, between Tajikistan on the one side and Uzbekistan and Turkmenistan on the other side about the construction of the Rogun and several other dams;
- at the Amu Darya between Uzbekistan and Turkmenistan because of the Karakum canal, which diverts water from the Amu Darya into Turkmenistan, the usage of the Tuyamuyun reservoir, and the construction of the Golden Century reservoir in Turkmenistan;
- at the Ili between China and Kazakhstan about water usage in China
- at the Sary Dzhas/Aksu, main tributaries of the Tarim, between China and Kyrgyzstan about dam construction plans in Kyrgyzstan (Giese/Sehring/Trouchine 2004).

The question, in how far there is a threat that these conflicts of interests can lead to violent conflicts, has to be assessed differently for each case. It depends highly on the general relationship among the concerned states. As the relationship between Kazakhstan and Kyrgyzstan is quite close, it was possible to come to an agreement concerning the Chuy and Talas rivers, which flow from Kyrgyzstan to Kazakhstan (see: <www.talaschu.org>). Uzbekistan, on the other hand, has tense relations with almost all neighbouring states. Most conflict potential is definitely between Kyrgyzstan and Uzbekistan on the Syr Darya and between Uzbekistan and Tajikistan on the Amu Darya.

The potential of conflicts is hence not rooted in environmental degradation and climate change alone, but in its connection and interaction with economic and political tensions. This is also evident on the local level in rural regions. In all Central Asian countries (besides Kazakhstan) more than half of the population lives in rural areas, where often water and land is scarce compared to usage requests. Water shortage can destroy the harvest and sufficient and timely water supply is hence of crucial importance for the majority of the rural population that depends on subsistence agriculture. Local quarrels on water distribution time and again lead to affrays. Unauthorized water withdrawal is frequent and is not sanctioned by the state - partly because lack of implementation rules and knowledge of these by local courts and water agencies, partly because informal networks protect against sanctioning, partly because officials tolerate the withdrawal (Sehring 2009). Conflicts evolve when environmental degradation and scarcity of resources coincides with unequal access to land and water, demographic pressure, forced migration, economic crisis, or political marginalization.

Due to global environmental change and projected population growth (UN 2007), water shortage will increase in the long term and it therefore can be expected that current problems and conflicts will intensify. Violent conflicts seem to be more likely on the local than on the international level. However, local conflicts in border regions can easily get an international dimension.

The problem-solving capacity is weak as administrative structures in the water sector in all countries are characterized by hierarchical patterns, lack of horizontal coordination, sectoral fragmentation, overlapping competencies, competition among agencies for scarce financial allotments, lack of experience in policy formulation, movement of qualified labour, lack of transparency, accountability, and participation.

Concerning the transboundary water management at the Amu and Syr Darya, in 1992 the *Interstate Commission for Water Coordination* (ICWC) was established. Later it was subordinated to the *International Fund for Saving the Aral Sea* (IFAS). Its task is to control regulation, usage and protection of the water resources and to administer the water distribution among the states. However, decisions of the ICWC and IFAS respectively are often not adequately implemented. Reasons are a lack of competencies and legal base on the side of the ICWC, conflicting interests

and mutual mistrust of the states, and lack of capacities. Additionally, China and Afghanistan are not incorporated in its structure. Furthermore, freshwater disputes do not only involve the Central Asian republics, but also several competing regional powers, namely Russia, China, and Iran, which are involved as investors in dam construction projects (Giese/Sehring 2007). A necessary precondition for successful cooperation, however, is the political will of the elites and the overcoming of the mutual mistrust that characterizes current relations between the Central Asian states.

27.3.2 Sand and Dust Storms

A large part of the basins are covered by sand and salt (*solonchak*) deserts. These lowlands are due to atmospheric circulation and soil conditions especially predestined for the formation of sand and dust storms. The silted areas of dried-up lakes (Aral, Lop-nor) recently accomplished these areas. In the Turanian lowlands around the Aral Sea, such nourishing areas for dust and sand storms are capturing about 70 per cent of the total area (Zolotokrylin 1996: 48). This leads in certain regions of the lowland basins to the appearance of sand and dust storms in spring and early summer (April to June) and dusty winds in winter. Sand and dust storms do not occur area-wide, but are spatially concentrated. The following areas are especially affectted:

1. The eastern and north-eastern Aral Sea region (Kyzyl-Orda province in Kazakhstan);
2. the Southern Aral region (Karakelpakestan in Uzbekistan);
3. the foreland of the Kopet-dag (central Karakum, Turkmenistan);
4. in the Tarim basin the Northern and Southern border areas of the Taklamakan desert as well as the eastern border area, where the two sand deserts Taklamakan and Kuluk threaten to coalesce;
5. the Ebinur-region (Northern Xinjiang).

The reasons for the sand and dust storms in Central Asia are manifold. They are natural (atmospheric circulation, soil condition) as well as anthropogenic. Major factors are the existence of sufficiently big nourishing areas and the occurrence of strong winds. The last 30 to 40 years saw several changes that lead to the probability of a stronger occurrence of sand and dust storms in the future:

1. The climate in the arid lowlands of Central Asia is characterized by an increasing warming and aridization since the 1970's (see above). The consequences are on the one hand an intensification of circulation processes and on the other hand an intensification of evaporation processes, which leads to a further drying of the surface soil. Both promote the formation of sand storms.
2. Simultaneously to the temperature warming, there is a declining trend of annual precipitation in the central lowland basins in Central Asia.
3. Of major significance for the occurrence of sand and dust storms is also the deletion of desert vegetation and of the protective riparian and gallery forests along the rivers. It is partly a result of the land reclamation campaigns that were conducted in the 1950's on the Soviet as well as the Chinese side. It also affects desert shrubs that are important for the fixation of dunes and drifting sands. They are used as fuel by the population and are damaged by game bite. Their loss often leads to sand drifts. The increasing sand drifts since the 1950's affect arable land as well as settlements and infrastructure. An area especially hit by sanding are the middle and lower reaches of the Tarim river in Xinjiang (PRC). At the middle reach, the silted area increased from 917.6 km² in 1960 to 948.3 km² in 1998, this is 7.3 per cent (Song/Fan/Lei 2000: 381). Even stronger is said to be the sanding at the lower reaches. Between Korla and Lop-Nor the silted area is reported to have increased from 12 per cent to 52 per cent of the total area. The meteorological station Yuli at the lower Tarim recorded on average 42 days per year with sand storms in the 1960's, in the 1990's already 110 days per year were registered.
4. A strong impact on sand storms certainly also have the drying-up processes of the huge inland lakes such as the Aral Sea, the Lop-nor or the Kara-bogaz-bay at the Caspian Sea and the drying-up of delta regions of big rivers (Amu Darya, Syr Darya, Tarim, Ili). They led to an increase in nourishing areas for sand and dust storms. Around the Aral Sea the number of sand and dust storms increased from on average on 10 days per year until 1966 to 20 days and in some coastal regions of the Aral Sea even 50 days per year in the mid-1990's (Zolotokrylin 1996). This is especially significant due to the health risks of these storms. Of the Aral Sea alone, more than 54,000 km² of seabed were exposed. This exposed seabed consists of 75 per cent of salt-crust and 35 of sandy sediments

(Opp 2007: 97). The areas without vegetation are now a nourishing area for sand and dust storms. Satellite images show their expansion up to 500 km away from the Aral Sea (Orlovsky/Orlovsky 2001). Similar processes can be observed in other inland lakes and smaller salt pans. The former seabeds are now covered by sand and solonchak deserts, so that the sand storms are infiltrated by salt particles.

Concerning the general question on the conflict potential, sand and dust storms are significant for two reasons:

1. They are highly dangerous to health as they are interspersed with saline particles, so that the population of the affected regions suffers disproportionally highly from respiratory and lung diseases.
2. They cause processes of sanding and sand drifts, so that arable land (which is already scarce in Central Asia) gets lost, infrastructure and settlements are destroyed and droves killed.

Sand and dust storms hence affect human security and may sharpen conflicts on already scarce land resources.

27.3.3 Geo-hazards: Mass Movements

Geo-hazards such as mass movements (land slides, mud and boulder slides, avalanches, etc.) are frequent in Central Asia. Most affected are the mountain regions and the outskirts of the mountains at the Tienshan, especially the forelands of Kyrgyzskii and Zailiyskii Alatau as well as the Fergana valley. In these areas lives a considerable part of the population; also important cities such as Bishkek (800,000 inhabitants) and Almaty (1.5 mio inhabitants) are located there.

The Southern proximity of Almaty are among the most threatened regions worldwide (Schröder/Eidam 2007: 115). In 1921, Almaty was covered by a huge mud and boulder slide from the Zailiyskii Alatau. Similar, though not as strong, slides occurred in 1947, 1950, 1956, 1963, 1973, and 1977. In August 1977, a mud and boulder slide of 6 Mio. m^3 reached Almaty. Again and again mass movements bury villages or part of them, every year people have to be resettled. In 2003, the settlement Kashka-Suu in the Ala Archa valley South of Bishkek was completely destroyed by a mud slide.

Sudden mass movements are in general caused by a concurrence of several factors such as high precipitation and earth quakes. So do frequent land and mudslides in short time as in the Fergana valley only occur when larger masses of loose material in steep locations get oversaturated during snowmelt or during strong summer precipitation and then are shaken by earthquakes (Schröder/Eidam 2007: 115). Central Asia is among the areas of the world most hit by seismic activity and therefore also a region affected by geo-hazards. This is because two tectonic plates, the Indian and the Eurasian one, which drift with high speed (4 cm/year) and force against each other, cause earthquakes which then provoke land and slope slides. That earthquakes provoke mass movements is proven by the fact that the strong mass movements in the Fergana valley mostly occur along tectonic rupture zones (Roessner/Wetzel/Kaufmann/Kornus/Lehner/Reinartz/Mueller 2000; Wetzel/Roessner/Sarnagoev 2000).

The major reason for the instability of slopes is often water. The factor that finally initiates land and mud slides are mainly heavy rainfalls as well as the snowmelt in spring and early summer. They lead to increased soil saturation and undercutting by groundwater. The risen frequency of land slides and avalanches in recent time is related to global warming, due to which heavy rainfalls have increased and snowmelt processes got more intense. But there is also another effect of climate change that fosters especially avalanches: Due to the temperature increase in Central Asia since the 1970's (Giese/Mossig 2004; Giese/Mossig/Rybski/ Bunde 2007), the surface of permafrost soil in altitudes above 3000 metre has melted (Schröder/Eidam 2007: 117). As a result, much of the before frozen material lost its cohesion. Therefore big avalanches are also observed in valleys that were not at risk before, steep hillsides considered save until recently are now perceived as avalanche formation zones (Schröder/Eidam 2007: 118). Given the continuing global warming it can be anticipated that periglacial permafrost soil will further thaw and the occurrence of avalanches will increase.

While since the 1960's protection dams against mass movements have been built, these are not sufficient to protect all settlements at risk, especially not in the 'new' areas of avalanches. The described geo-hazards do not only threaten the human security of the affected population. As was described, it is especially the Fergana valley that is faced with an increase in mass movements (figure 27.2). And this is a region that already is considered to dispose over a high conflict potential with tensions on access to land and water resources (which already incidentally led to violence), dense population, border disputes, Islamic underground movements, and drug trafficking. This is one reason why it is already addressed by many con-

Figure 27.2: Impact of climate change on environmental risks in the Fergana valley, Uzbekistan. **Source:** Viktor Novikov/Philippe Rakacewicz (UNEP/GRID/Arenal 2005); at: <http://maps.grida.no/go/graphic/climate_change_and_natural_disaster_impacts_in_the_ferghana_valley>. Permission has been granted by the copyright holders.

flict prevention programmes (Heathershaw/Torjesen 2005). Natural hazards can destabilize this region easily. Additionally, as the Fergana valley is shared by Kyrgyzstan, Tajikistan, and Uzbekistan, local conflicts quickly get an international dimension.

27.3.4 Salinization

Salinization of land plots is one of the most serious bottlenecks in agricultural production. It dramatically increased during the last decades. In Kyrgyzstan at

least 12 per cent, in Tajikistan 16 per cent, in Kazakhstan 33 per cent, in Uzbekistan 50 per cent, and in Turkmenistan 96 per cent of the irrigated area are affected by salinization (Bucknall/Klytchnikova/Lampietti/Lundell/Scatasta/Thurman 2003: 9). It is also a problem in Xinjiang, where along the Tarim 35–41 per cent of the land plots are salinized (Giese/Mamatkanov/Wang 2005: 28). As a result, irrigated areas have to be abandoned and new land has to be reclaimed.

Reasons for salinization are mainly the irrigation system and irrigation practices. They are often not adapted to the natural conditions (especially to the soil which is often loamy soil with low hydraulic permeability). Furthermore, the high water amounts used for irrigation of rice and cotton are not met by enough capacities of drainage systems, which are sometimes completely missing (Giese 1998: 70ff.; Betke 1998: 139–141; Giese/Mamatkanov/Wang 2005: 28f.). Other reasons are the enormous use of fertilizers that became necessary due to the decade-long monoculture (cotton and rice), which leached out the soils, and the re-usage of irrigation water that is already enriched with residuals of fertilizers, pesticides, and herbicides.

Beside these economic and technical reasons there are also climatic factors. Sand and dust storms transport the salts from the dried-up sea beds and deposit them partly on the fields. Partly the particles in the winds are absorbed by rains and on this way also reach the soils. The salt concentration in the precipitation in the Aral Sea area has risen sixfold alone from 1968/69 to 1979/80 (Murzaev 1991: 28). According to Razakov (Giese 1998: 69), in the oases of the lower Amu Darya each year 240 kg dry and 180 kg liquid salts per ha precipitate. A big part of these salts are sulphates and chlorides that are especially harmful for plant growth. If the frequency and intensity of salt and dust storms increase with global change, increased salinization can be expected leading to the loss of arable land. Arable land is already scarce. If land availability further decreases, it might lead to instability especially in poor and densely populated rural regions such as the Fergana valley. Here conflicts about land access questions already occurred in the early 1990's and are interrelated with political instability. But also in other regions the conflict potential is high.

27.4 General Assessment of Conflict Potential due to Global Change

While oil and gas resources in the region are economically important, for a majority of the population living on subsistence agriculture, water and land are key resources. Both are not only scarce compared to demand, but also distributed spatially unevenly. And these are the two resources that are most affected by global environmental change: water as well as land resources will get scarcer due to increasing evaporation, salinization as well as damage by sand and dust storms.

This situation already led to tensions on the local as well as the interstate level in the past. Where violent incidents occurred, this mostly happened on a local level and was connected to access to key resources such as land and water and rooted in socio-economic disparities. It was hence not only a result of environmental degradation but also of political and economic factors. With soil degradation and climate change, the productivity of arable land decreases while water demand simultaneously increases, hence both resources become relatively scarcer. The negative socio-economic consequences of the environmental change hit primarily the poor parts of the population. Rural population commonly is excluded from the economic development in the capitals and depends on subsistence production. Access to sufficient and qualitative satisfactory water and land is therefore crucial and the lack of access a security risk.

Until now environmental degradation was not a direct cause for violent conflicts in Central Asia. However, it interacts with existing social, economic, and political tensions. On the local level, violent incidents occur when degradation goes along with lack of access to or unjust distribution of land and water, population density, forced migration, refugee movements, economic crises, or ethnic tensions. The safety hazard is hence not solely environmental degradation enforced by global climate change, but its interaction with societal and socio-economic deficiencies. The security implications of the disastrous environmental situation in Central Asia are addressed by numerous programmes of international and non-governmental organizations. Since 2002 the Fergana valley is one of the main foci of the *Environment and Security Initiative (EnvSec)* of UNDP, UNEP, OSCE and NATO (Cheterian 2009).

The internal stability of the Central Asian states was unsettled in the last years by civil war (Tajikistan), Islamic militants (Uzbekistan), organized crime (Kyr-

gyzstan), and civil unrest (Uzbekistan, Kyrgyzstan). All political systems, even the initially more democratic Kyrgyzstan and Kazakhstan, can be classified as authoritarian regimes, with Turkmenistan and Uzbekistan as most repressive states. They are characterized by increasing social inequality, strong subnational identities, and neo-patrimonial ruling patterns. All these features prevent political responsiveness to the needs and demands of the population. This comes along with the fact that those regions that are especially affected by (future) environmental degradation are also politically and economically marginalized such as the Fergana valley in Uzbekistan, the Aral Sea area in Kazakhstan and Uzbekistan and Xinjiang in PRC. Their problems have no priority for the political leadership. Governments give priority to economic development rather than to ecological considerations. This can lead to unrest, particularly when problems are instrumenttalized. This assessment is also made by UNDP (2003a: 3): "Environmentally triggered or heightened tensions arise at sub-state level and in already marginalized and remote areas."

The capacities of the national agencies to deal with the environmental problems and their consequences are rather weak – concerning the development of adequate policies as well as the implementation of international agreements and national reform programmes. On the regional level, since the end of the Soviet Union the states in rhetoric strive to establish cooperative structures. In practice, most efforts failed due to mutual mistrust and prevalence of national interests. However, the transboundary character of many environmental problems requires international cooperation, especially in water management. The failure of joint management on this level might have a worsening effect on existing problems and can lead to further conflicts. Due to the general unstable situation in Central Asia, the lack of good governance on the national level, and of cooperation on the regional level it is unlikely that the capacity for environmental problem-solving and adaptation to climate change will increase in the near future.

27.5 Conclusion

This analysis has shown that global climate change has serious impacts on the environment in Central Asia. It affects the availability of land and water resources and tends to increase the occurrence of sand and dust storms as well as of land and mud slides. While land and water resources might not be financially as significant as gas and oil resources, they are crucial for agriculture, which is the major sector in the region and for the survival of the rural population which is dependent of subsistence agriculture. A further degradation and shortage of resources might increase the conflict potential as questions of resource access are closely related to social and economic disparities and can easily be politically instrumentalized. The weak governance structures in the concerned states and the lack of public participation limit the adaptive capacities and the development of adequate strategies.

It should therefore be obvious that any effort to mitigate the impact of global environmental change in Central Asia and reduce the conflict potential has to built on a two-fold strategy: technical assistance in environmental issues as well as support for governance reforms to enhance the adaptive capacity of the concerned societies.

28 Impact of Environmental Change on Stability and Conflict Potentials in China

Thomas Heberer and Anja D. Senz

28.1 Introduction

During the last decades China has faced serious environmental degradations due to extensive economic development. In particular China's large emissions of greenhouse gases have raised international concerns about the environmental situation in China. The country faces a large amount of international criticisms due to its poor environmental performance and is perceived as one of the most polluted countries in the world. The 2008 Environmental Performance Index Report of Yale University, which evaluates indicators like people's health, air and water pollution, ranks China as 104 of 149 countries. According to the World Bank, the majority of the world's most polluted cities are located in China (Klein 2004: 21).

Without doubt, China has serious environmental problems (Economy 2006). While China spends 1 per cent of its GDP on environmental preservation, pollution and environmental degradation annually amount to 8 to 13 per cent of GDP (Dupont 2001: 52).[1] Hence, environmental costs are as high as annual economic growth. The deteriorated environmental situation causes many domestic socio-political problems (Jun 2000). According to official data, 510,000 conflicts on environmental pollution occurred in China in 2005, of which 70 per cent occurred in the countryside, because rural areas suffer especially under heavy environmental degradation (Yan 2005: 184). A rapid loss of arable farm land, declining soil quality, air and water pollution, water scarcity and droughts especially in northern China, but also a rapidly decreasing groundwater level in the North and a large acid rain belt in the South are negatively affecting the people's livelihood and human security[2] in general. The already high rate of domestic migration may even more be aggravated by the effects of climate change. If the projected sea level rise impacts on the prosperous East coast up to 90 million people could be forced to resettle. According to some estimates climate change could reduce China's economic capacities by 20 per cent until 2050 and be related to new resource conflicts (Heberer/Senz 2007b).

Environmental challenges are therefore sensitive national political issues and taken seriously by the Chinese central government, as the growing amount of protests and conflicts caused by environmental degradation and climate change could challenge political stability. With rising expenditure for environmental protection[3] and the adoption of a policy framework including modern environmental laws, the central government demonstrates its emphasis on this issue (OECD 2007; Yan 2005; Abigail 1998). But in many ways China still lacks effective institutions to implement policies and laws. Therefore central policies often do not have the expected effects at the local level.

This chapter explores the relationship between environmental challenges and regime stability. We argue that the central government tries to preserve regime stability by enhancing system legitimacy. An important basis of system legitimacy is the demonstration of administrative performance, but in an institutionally fragmented administrative structure often such policies cannot effectively be implemented. Therefore, even if environmental issues are taken seriously by the

1 See, e.g. *Shanghai Daily*, 6 June 2006; at: <www.chinadaily.com.cn/China/2006-06/06/content_609350.htm> (12 June 2006).

2 Human security refers to a holistic approach of security in the context of sustainability, food security, health, employment, education, poverty reduction, etc. and does not limit security to violent conflicts among states (Mushakoji 2001).

3 Expenditures for environmental protection have recently considerably increased. In 2008, they reached 100 billion yuan (News Office of the State Council 2006).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_28, © Springer-Verlag Berlin Heidelberg 2011

central government, these measures may not convincingly be implemented at the local level. Hence, with regard to environmental policies and administrative performance it has been difficult for the Chinese system to cope with environmental challenges. Inadequate capacities of political and socio-economic system and at the institutional level may provoke further domestic conflicts and could lead to political instability in the long run.

28.2 Argument, Theoretical Approach and Database

The Chinese political system has been characterized as a fragmented authoritarianism, because the party state is not a homogeneous entity but a complex structure of different interrelated actors operating at different administrative levels (Lieberthal 1992: 1). However, from a theoretical perspective authoritarian regimes are fragile, mainly because of weak legitimacy and over-dependence on coercion (Nathan 2003: 6). But research shows that the legitimacy of the Chinese party state is not as weak as the theory suggests (Heberer/Schubert 2008).

Using Fritz Scharpf's concept of legitimacy, the authors distinguish analytically between input and output legitimacy. Output legitimacy refers to effective policies that serve general public interests and meet the criteria of distributive justice. In this regard, states produce effective outcomes like in the environmental field by "achieving the goals that citizens collectively care about" (Scharpf 1997: 19). Therefore, output legitimacy is concerned with common interests and the degree to which a state is able to implement policies responding to the needs of its citizens. Input legitimacy means integration of citizens by political participation and is strongly related to the idea that problems are solved cooperatively by a contribution of all affected actors. Obviously the Chinese party state lacks an input-oriented legitimacy with free elections and a transparent democratic political process. The input has certainly increased for instance due to responsibility contracts for local officials, the internet and the media, environmental NGOs, local parliaments, etc. Concurrently, in generating legitimacy the Chinese party state relies primarily on what is called output legitimacy. Accordingly, this chapter links legitimacy primarily to the output of the state and to a policy that is strongly oriented at finding solutions for environmental problems. In this regard, efforts of the party state to ensure stability by enhancing output legitimacy are based on achieving minimum standards of environmental protection. However, administrative constraints make it difficult to meet these standards.

In this chapter the term stability is closely related to the political system. Political systems interact with their environment, they influence and are also influenced by the context. Processes of change or crises in the system's environment can cause dynamics and may even induce major disturbance that could spawn socio-political instabilities. Stabilization means that in the case of such disturbances or 'malfunctions' a system is capable of returning to a state of balance. Stability may be defined both structurally and functionally in relation to the system, i.e. as political performance. Efficiency, output legitimacy, and order may be classified as factors for generating stability. Influenced by Parson's system theory and Gabriel Almond, Wolfgang Merkel defined a functional, action-oriented political concept of stability. He sees one of the requirements for stability in that the "inner construction of the multi-stranded interrelationships between structures and actors [must] be laid out in such a way that both are able to solve the tasks required by the environment (economy, society, international political arena)" (Merkel 1999: 57–58). If stability is understood as a "process of dynamic equilibrium", in which a system is to be situated, for Merkel it is primarily a matter of the system's adaptability and of determining the conditions which would allow or impede such adaptive flexibility (Merkel 1999: 58). Accordingly, the concept of stability is not tied to perpetuation and persistence, but rather to change: there is no stability without adaptation. Thus, stability may be understood as an adaptive process rather than a static situation.

As an effect of the economic reforms since the late 1970's the Chinese system has undergone rapid changes that affected not only economic but also political as well as social and cultural issues. During this rapid development socio-political stability has always been crucial to Chinese leaders. According to the central government reform policies are to serve the stability of the system and gaining legitimacy is seen as a way to reinforce stability.

Currently, the political leadership pursues a two-fold strategy to generate legitimacy. On the one hand output legitimacy shall be gained through enhanced administrative efficiency and responsiveness to local demands. Top-down pressure on local authorities via financial means, career promotion and institutional constraints are major tools to achieve this objective.

On the other hand the party state tries to win the support of the population for central policies.

Chinese surveys illustrate that large sections of the population expect that the state tackles environmental problems and improves their environment and ecology (Wong 2003). Thus, the authoritarian system does not only try to convince the people of certain policies but to integrate the people by input institutions like local hearings, opinion polls, space for NGO activities and local offices where complaints and petitions can be submitted. Here the impression is conveyed to the population that the people can influence decisions and in this way input legitimacy can be strengthened to a certain degree. However, far more important is the fact that with these input institutions information can be gained on the performance of local administrations and local officials can also be monitored with the support of the population. Such information is useful to improve administrative performance and thus serves output legitimacy. It is precisely this two-sided approach in serving output legitimacy which can be used to explain the relative stability of the state in contemporary China.

To assess the output legitimacy of the central state this chapter will first briefly discuss the relationship between environmental degradation and the risk of socio-political instability (28.3). Then China's environmental policies, and in particular its modes of governance on the central-local relationship and the steering capacity of the central state are examined and efforts of the central state and problems with the implementation of environmental policies are addressed (28.4). Finally, the public awareness and environmental protests are analysed as mechanisms that are employed by the central state to put pressure on the local administration (28.5). On environmental policies different interests between the central leadership in Beijing and the local governments can be observed. It is argued that the central government is interested to ensure stability and an effective implementation of policies, while local governments are more concerned with economic growth (28.6). Moreover, due to certain institutional incentives local officials often conceive environmental protection as a contradiction to economic success (Heberer/Senz 2008). Besides this, the fragmented political system offers sufficient institutional space for different actors to express their own concerns. Finally the policy output regarding environmental policies and the output legitimacy of the Chinese party state are assessed (28.7).

This chapter relies on findings of two research projects on "Environmental administration and the environmental implementation gap in China" that were conducted in six counties and cities in the Northwest (Shihezi/Xinjiang) Northeast (Yingkou/Liaoning), East (Shouguang/Shandong), Southeast (Xiamen/Fujian and Deqing/Zhejiang) and South China (Nanfeng/Jiangxi) between 2007 and 2009. The first project focused on urban areas, the second on rural areas. In-depth interviews with environmental experts, administrative personnel of local bureaus concerned with environmental issues, grassroots officials in townships and villages, environmental NGOs, journalists, and ordinary citizens in China have been conducted. Further, a large amount of Chinese material has been analysed. This includes academic books and articles as well as local newspapers and official documents.

28.3 Environmental Degradation and Risks of Socio-political Instability

In Chinese history the downfall of dynasties has often been triggered by natural disasters. The emperor, so the popular interpretation, had lost the mandate of heaven (Gernet 1988). In the light of this tradition, environmental degradation and an increasing amount of natural disasters as a result of climate change could currently also challenge the legitimacy of the Chinese government. Therefore, an awareness of the Chinese government for a fast and effective crisis management as well as the respective demand of the population is likely.

But social challenges could turn into threats for socio-political instability if environmentally-induced disturbance of relevant parts of the society erupts in large protests.[4] Here not only the sheer size of protests might be a relevant fact. Even more important could be the reason for these protests. If such protests are no singular events triggered by a certain cause, but based on a popular assumption of severe general governmental failures, the Chinese authoritarian regime would face a challenge with the potential of destabilizing the country and questioning the authority of the regime. Thus, the environmental crisis might turn into a challenge to stability, if followed by the population's

4 As relevant parts of the society the authors consider social groups that are capable to articulate their interests and gain recognition due to the sheer size or their access to the public arena. Those groups in China could be the rural population (peasants), migrants, the urban elite and the emerging middle class.

principal loss of confidence in the modes of governance (crisis of legitimacy) or the diminishing ability of the government or the leading elite to maintain power (either by repression or financial compensation for environmental damage).

Another potential threat to stability is the malfunction of state institutions, caused by the absolute amount of environmentally provoked challenges, which bind financial, technical and administrative resources of the system and drastically reduce the political scope of action. Thus, an interconnection between stability and environmental issues in China could occur if pollution, natural disasters or other effects of climate change would cause a massive curtailing of basic needs for relevant parts of the population. Access to potable water, clean edibles or health care might not be guaranteed in the future and could lead to conflicts between different sections of society. Several areas of the systems' tension can be identified with regard to environmental degradation, climate change and human security (Heberer/Senz 2007b):

a.) *Socio-political disparities and poverty*: Environmental degradation could intensify current income disparities as well as poverty. In particular, the livelihood of the rural population is endangered by massive environmental degradation. If in the future more peasants depend on social welfare this will further bind financial resources.
b.) *Health:* Prior to the reforms launched in 1978, the entire population had access to at least basic health care. Currently, large sections of the rural population are underserved with health care. Given an increase of diseases caused by pollution and a higher demand for health care in cases of natural disasters caused by climate change, this could become a major challenge for China. Again, this could bind financial resources that cannot be invested elsewhere.
c.) *Ethnic and religious factors*: China is a multiethnic state, but many ethnic minorities are not well integrated into the Chinese state. In addition, the areas of ethnic minorities are in particular exposed to an exploration of resources that cause massive environmental damage. Further environmental challenges could aggravate the situation in the ethnic areas and result in ethnic conflicts (Heberer 2001).

Socio-political stability will depend in particular on the ability of the government to control and channel resources and to handle environmentally-induced conflicts efficiently. Stability in terms of system' equilibrium will therefore depend on the existence of a balanced relationship between steering capacities of the state, its social acceptance and the available (material) resources. In particular assuring the access to resources is an important base for China's further economic development, and both – economic development and growth – are needed to assure the working abilities of the political system (Heberer/Senz 2007a; Ding 2002).

Finally, in case of China's instability even regional conflicts might occur, which could be caused by the rivalry for resources, cross-border migration, pollution affecting neighbouring countries or the regional spread of infectious diseases. In general, environmentally-induced conflicts will only turn into threats to stability and regional security if the willingness and ability of the Chinese government to act cooperatively and conflict managing is not convincing anymore for other actors involved.

28.4 China's Environmental Policies

In 1972, prior to the economic reforms, China already faced major ecological problems. This fact alerted the government to care more about environmental issues. In the following years China established institutions for environmental protection, integrated an environmental agenda into its five-year plans and even into its constitution (Bechert 1995: 22). Laws to protect the environment have been enacted and international standards for environmental measurements have been implemented. Since 2006 the expenditure for environmental protection are officially included in the central level budget (News Office of the State Council 2006). In 1998, China established a central authority for environmental protection, the State Environmental Protection Administration (SEPA) which in 2008 has been upgraded to a ministry. In 2008 the Chinese government also launched a 600 billion US$ programme for climate and environmental protection. Hence, compared with other developing countries China started its environmental policies quite early and has relatively well established environmental institutions.

In addition, the Chinese government treats the concept of sustainable development favourably and supports water and wind energy as well as other renewable energies. China aims to increase the use of solar, wind and hydro power from currently 8 per cent of its total energy supply to 15 per cent by 2020. Furthermore, the government plans to include an

evaluation of environmental degradation into the calculation of its GDP (green GDP) (Lincoln 2004: 7/8).

In the international field, China has signed all major environmental agreements (Montreal Protocol, UN Framework Convention on Climate Change, UN Convention on Biological Diversity, and the UN Convention to Combat Desertification). Beijing supports the United Nations and the creation of a UN environmental organization. But China has so far opposed, like the US during the Bush Administration, any binding limitations of its CO_2 emissions. Its political leadership recognizes the common global responsibility for the climate, but stresses the particular responsibility of 'developed countries'. Therefore, China has ratified the Kyoto Protocol, but as a 'developing country' it did not sign any binding obligations (Lewis 2007/08).

As our own research in several Chinese regions between 2007 and 2009 indicates, especially in the big cities, the pressure of the central government to protect the environment has been increasing and the attitude of local governments towards environmental issues is changing. The implementation of environmental regulations is closely controlled and published in the internet.

In recent years the central government has allocated large financial resources for building waste water sewage plants, waste incinerating plants, energy and water saving, the technical retrofitting of plants and for enhancement of renewable energies (biogas, solar energy, wind power, etc.). All counties and cities are entitled to apply for funding. In the rural areas the gigantic nation-wide programme "Constructing new villages" shall provide a new infrastructure in rural areas: afforestation programmes, waste disposal in villages, concreting of rural roads, piped water and modern lavatories for each rural household, establishment of biogas facilities where the necessary conditions are existing, etc. are part of this programme. It is also considered to improve environmental and living conditions in rural areas. For the various packages the central state, the provinces, the prefectures, cities, and counties have to share funding. In more prosperous areas like in the Zhejiang province in 2009 this programme was rather advanced, whereas in poorer areas like in the Jiangxi province it was estimated that ten to fifteen years were needed to implement it.

Certainly, this very progress should not hide the fact that the environmental situation across China remains precarious. Yet, this progress also illustrates that the will of the central state to tackle environmental problems has increased. It may be hoped that these effects will be sustainable, the more as many local governments conceive environmental protection merely as a policy enforced from above and are often disregarding local peculiarities.

28.5 Chinese Administrative Capacity Between Local Leeway and Steering by the Central State

To understand environmental policies of the party state, it is necessary to understand that the party state does not have a centralist but a fragmented structure (Lieberthal 1992). Accordingly, China is not controlled by a small cluster of politicians at the highest echelons of the party state. Today a lot of different actors with diverse concerns are involved in policy formulation and decision-making. While the ministry of commerce i.e. tries to foster economic development, the ministry for the environment wants to ensure that environmental laws are observed. Those different and sometimes contradicting preferences can not only be found at the centre but in particular at the lower levels of the government. Provinces, cities, counties, townships and even villages claim local characteristics and convey different concerns and standards. The Party and state are therefore split into many different actors with different aims or priorities with the result that orders cannot anymore be issued top down like in the Mao era. This means that policy implementation often has to be coordinated and negotiated among many actors at different levels within the party-state's structure, with contingent results.

Accordingly, China's political system is characterized by both a horizontal and a vertical fragmentation of power and the involvement of a multitude of actors with various self-interests. Structures of that kind complicate a countrywide implementation of policies, laws, and minimal standards or frequently thwart national endeavours in the sphere of environmental protection. In this respect China is facing major institutional challenges.Thus, the further fate of the political system will depend on the successful coping with those challenges to find solutions for the most urgent (environmental) problems. Nevertheless, in offering space for a locally bounded test of approaches to solve particular problems this fragmented system certainly has specific advantages, as it is flexible enough to enable institutional learning, importing ideas and concepts, and implement certain problem solutions which have proved successful in other regions or countries (Heberer 2008). If the central state would

insist that all localities across China had to implement a unique environmental policy this would on the one hand negatively affect local economic development, when e.g. local enterprises were forced to close and accordingly unemployment would rise, on the other hand evoke strong local opposition or even instability.

The policy of liberalization since the 1980's has significantly widened the room of provinces and municipalities to manoeuvre and bargain. The consequence of the process of decentralization is that local authorities frequently pursue policies diverging from those of the centre and do not follow directives of the higher echelons. Under conditions of an authoritarian system this reinforces selfish and arbitrary political decision-making of local authorities and causes problems to the effective implementation of environmental policies.

So, decentralization and devolution (i.e. the transfer of decision-making power to lower levels) has spawned a double identity of local governments. Whereas in the Mao era they had to a large extent been merely agents of the central state today they are also local economic principals and thus advocates of local interests. Consequently, they enjoy a wider room in implementing, non- or partly implementing policies of the centre and concentrate upon the protection and promotion of local social and economic interests (Ting 2006).

Part of this fragmented system is a so called implementation gap (Chan/Wong/Cheung/Lo 1995), which means a discrepancy between decisions made in Beijing and the realization at the local levels. This implementation gap can be well observed in the field of environmental policies: Even though the Centre passes and enacts laws and regulations, many cities and counties violate the laws under the pretext of local economic development. In general decentralization has transferred decision-making capacities to the local level permitting them to accomplish their own 'local experiments'. Therefore some counties for instance, follow orders from above, while others ignore them or even develop their own 'local models'.

What are the main reasons that local authorities do not or only in a limited way implement environmental laws or policies of the centre? Several reasons can be identified according to the field research of the authors:

a.) *institutional deficits*: Decentralization reinforced the power of local authorities thus spawning a fragmentation of state power. There are no institutional means (e.g. legal remedies) to sanction deviance in a satisfying way;

b.) *one-sided policy preferences*: The Centre strongly emphasizes two issues: first, economic growth and second, preserving stability. All other issues are of secondary relevance. They only gain priority if a policy field becomes more prominent by virtue of domestic economic and social pressure or by international pressure. Accordingly, local officials know that in the case of environmental damages or mining accidents they have little to fear as long as no major social unrests appear. Minor protests can easily be suppressed, because the media are not permitted to raise open concerns or criticisms. Moreover, in assessing the performance of local officials only the two issues mentioned above (economic growth and preserving stability) are crucial. All developments that affect those issues negatively are directly sanctioned by the centre;

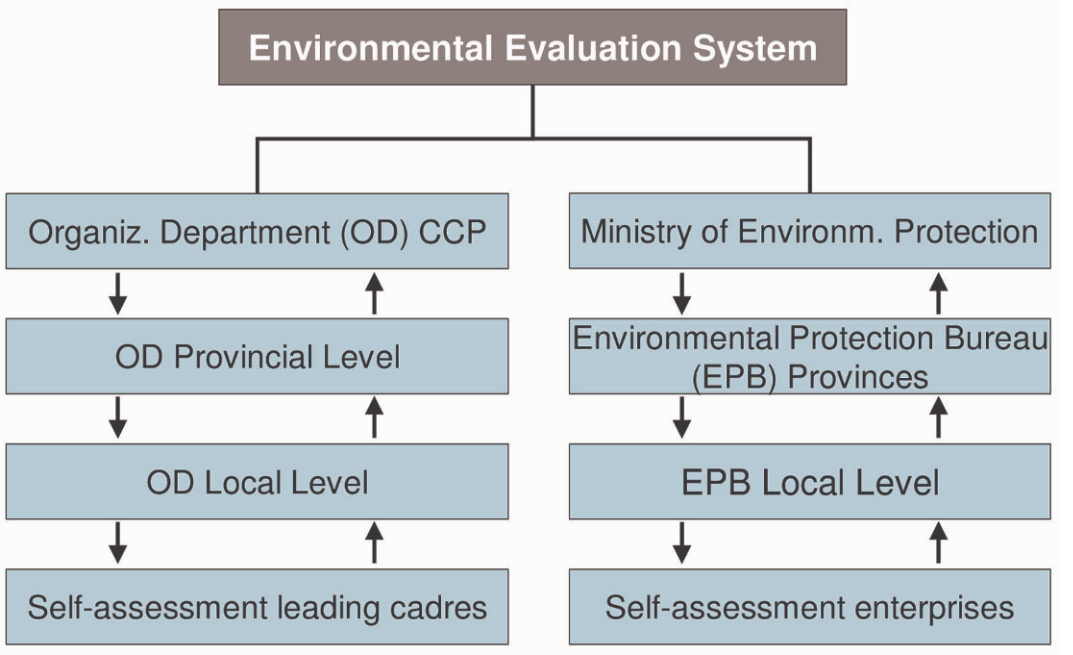
c.) *lack of financial resources* for implementing environmental policies;

d.) *local-level clientelism, i.e. local networks*: mighty coalitions of local officials with entrepreneurs or certain social groups directly or indirectly participate in an issue (e.g. in an enterprise contaminating environment, unsafe mines) and oppose the implementation of central policies in the name of 'local stability' or 'economic development'. According to their perspective closing enterprises could result in an increasing unemployment rate and accordingly cause social unrest. Moreover, the local state would lose tax income, entrepreneurs their profits – and officials their sinecures and additional incomes;

e.) *corruption and local-level state capture*, i.e. influencing local policies, rules and regulations in the interest of local enterprises and entrepreneurs;

f.) *incorrect reports* to higher authorities or officials which do not reflect the real situation, i.e. double realities in 'reporting'. Local officials report 'politically correct' to higher authorities, but those reports do not describe correctly the current situation; thus, the higher authorities are not informed about the real situation in a given locality. Zhao Shukai displayed how cadres at the district, county, township and village level form coalitions if cadres from higher echelons (the Centre or the province) arrive for inspections. Top officials arriving in a region are observed and every aspect they are interested in to evaluate will be rearranged in order to make sure that the real situation is covered (Zhao 2006: 25). A good example is the extreme pollution of Lake Taihu in South China. Shortly before the pollution was publicly

Figure 28.1: Environmental evaluation system in China. **Source:** The authors' survey of 2007.



announced the city of Yixing, the main polluter of Lake Taihu, had been chosen as a "model for environmental protection" – obviously without knowing the actual local situation.

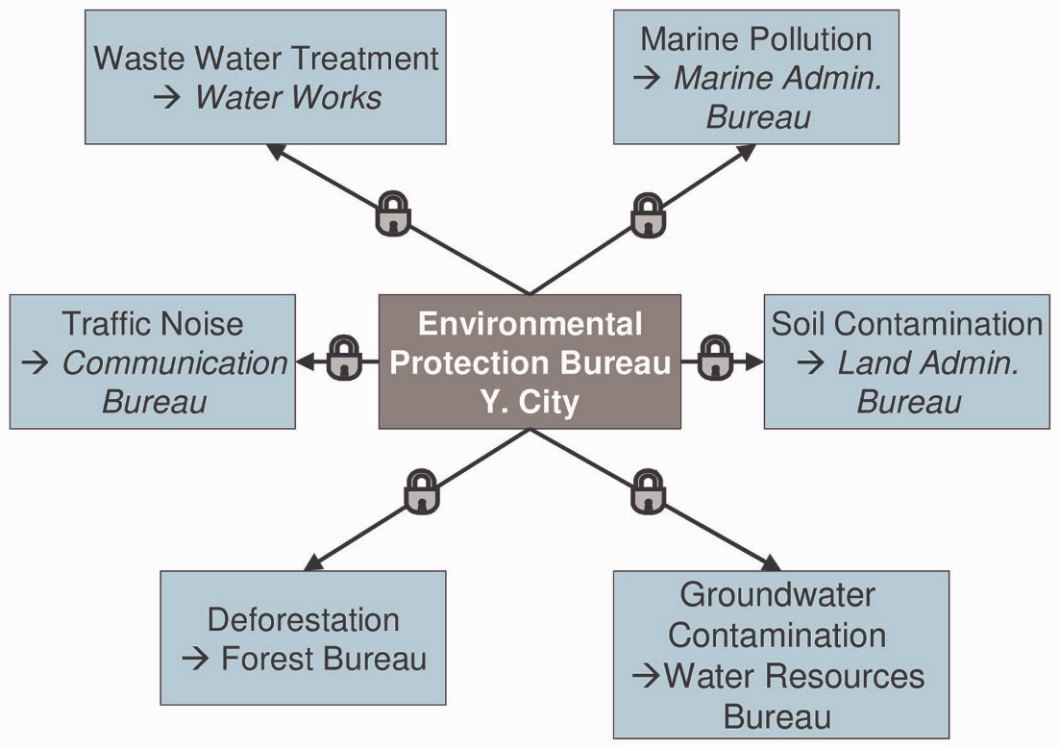
A lack of understanding of the Chinese implementation gap in the Western literature often leads to the notion that the central state is responsible for all grievances and deficits in China. Even if the central level issues general policies, it is overcharged with controlling the implementation of such policies in the 2,862 counties. Therefore some 'hard' policies are issued – such as economic development, stability, increase of local level income and birth control – and their adherence is checked rigorously. 'Soft issues', currently for instance environmental protection, efforts are made to control central regulations, but institutional and legal instruments are too weak to guarantee their implementation. In this regard political fragmentation and implementation gaps in several policy fields of minor relevance are accepted by the government as part of a process of pluralization.

However, the central government tries to improve governance. In recent years a cadres 'responsibility system' and an evaluation system for cadres' and enterprises at the local level have been established. Contracts of higher administrative levels with local officials determine the most relevant tasks of policy implementation at the local level. It is argued that this has enhanced environmental governance (Lo/Tang 2007). Officially, the organizational departments of the Communist Party have been entrusted to monitor the performance of cadres and the implementation of the contract tasks. Regarding environmental issues the local *Environmental Protection Bureaus* (EPB) should concurrently monitor the environmental performance of enterprises on a yearly basis. Our own investigations in China in 2007 revealed, conversely, that currently a genuine evaluation process does not exist, because the responsible departments are understaffed and therefore the evaluation in many locations is primarily based on self-statements of the offices or officials concerned (figure 28.1). Furthermore, there are 'hard' contracts for issues related to economic growth and social stability and 'soft' contracts for environmental issues. The former are strongly related to an official's advancement and reward and have to be implemented under any circumstances, the latter should be implemented and are not related to promotion and remuneration. Therefore the incentives to implement environmental issues are rather weak.

Three structural problems at least aggravate an effective implementation of environmental policies:

1. *Coordination problems*: At the local level environmental tasks are highly fragmented. Different offices are responsible for different issue areas (figure 28.2). The core problem is that those fields are not linked to each other and that no clear-cut (positive) coordination exists. The various offices

Figure 28.2: Problems of Environmental Governance in China: Fragmentation. **Source:** The authors' survey of 2007.

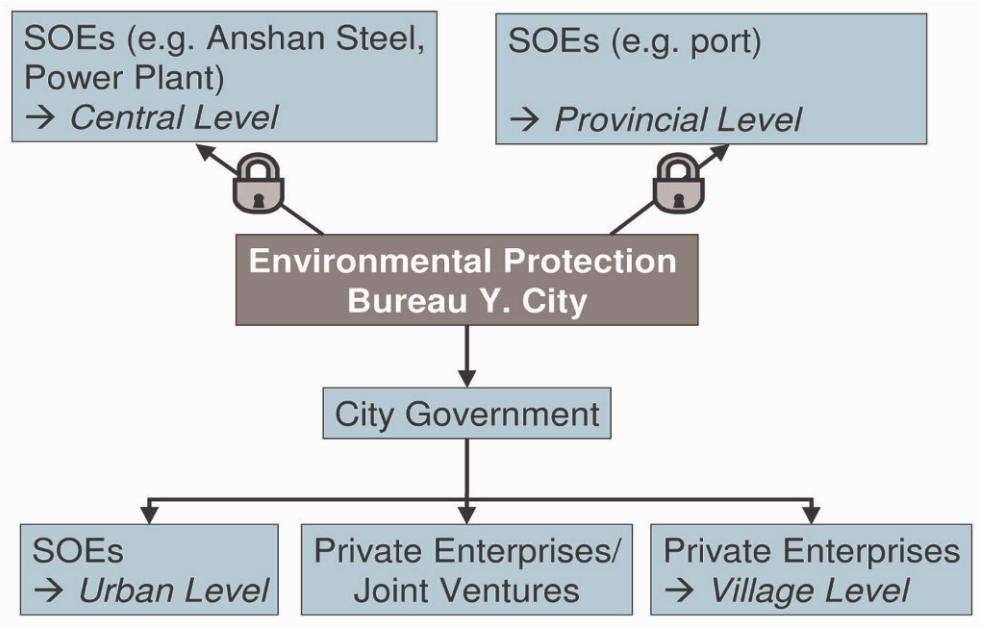


are not well informed on each other's activities. Due to the lack of a clear-cut division of labour, overlapping responsibilities, and an asymmetric information structure, the coordination of environmental policies among the various authorities are seriously impaired. The various offices are simply not interested in any cooperation because they conceive themselves to be 'local kingdoms' competing with each other for funding, income, prestige and power.

2. *Territoriality*: Regarding environmental responsibilities strong boundaries exist between administrative entities, i.e. counties, municipalities, prefectures or cities discharge waste water in rivers so that downstream areas are negatively affected. Cooperation beyond territorial borders is virtually non-existent and no respective regulating body exists. Due to this multiplicity of territorial structures in China administration and problem solution is much more complicated than in other countries.
3. *Hierarchization of Ownership Structures*. Complex ownership structures make the territorial administrative structure even more complicated. Enterprises can be located in a city but administered by higher levels, i.e. the central or provincial level. Hence, local governments and the *Environmental Protection Bureaus* (EPBs) do not have access to those enterprises, i.e. *State Owned Enterprises* (SOEs). In this highly fragmented and hierarchical structure a monitoring of major environmental polluters is often simply not possible (figure 28.3).

This example from Y. city in Northeast China illustrates this problem: Here, a branch of the state-owned Anshan Steel Company was the biggest polluter in town. As this enterprise is under the administration of the State Council and therefore much higher in the hierarchy than the government of Y. city, let alone the local EPB, this bureau is not permitted to monitor or supervise this enterprise. The second largest polluter is the local sea port. It is administered by the provincial government and the EPB has no access to the port area. The enterprises under the local government as well as the joint ventures and private businesses are protected by the local government, as they are the biggest source of tax income and employment. In order to enrich the local peasants the Y. government even protects the polluting village enterprises against inspections by the local EPB. As the EPB has a lower standing in the local hierarchy, its power and monitoring capacity is limited to very narrow domains.

Figure 28.3: Problems of Environmental Governance: Hierarchy. **Source:** The authors' survey of 2007.



28.6 Environmental Awareness and Environmental Protests

Our field research has revealed that generally speaking the environmental awareness has increased. The media are concerned with ecological issues almost on a daily basis. Furthermore, in recent years Chinese surveys have proven that particularly young, well-educated and urban professionals increasingly give priority to environmental protection. The internet, meanwhile one of the most salient sources of information in urban space, contributes to elucidate environmental damages, its consequences and alternatives. Particularly NGOs as well as an increasing number of environmental organizations among students display more general interest in ecological issues. Already in 2006 such organizations existed at 176 universities in 26 provinces (Stalley/Yang 2006: 335).

Meanwhile urban inhabitants increasingly perceive ecological problems as severe. Chinese surveys reveal that urban citizens expect greater government efforts in tackling environmental issues. Yet, only a minority, particularly younger and better educated people living in the better-off parts of the country, are aware of the negative impact of their own behaviour and know how to contribute to improving environmental conditions. Therefore, since the late 1990's the Chinese government is fostering education programmes concerning environmental protection and sustainable development in educational institutions. But an understanding and insight in the regional and global dimensions of environmental problems is still widely lacking.

Despite some improvements even Chinese surveys reveal that the environmental awareness among both the Chinese population and the authorities is not yet well developed. According to Chinese sociologists in 2008 merely 1.8 per cent of the respondents (out of 7,135 people surveyed) held the opinion that environmental pollution is belonging to the most severe problems for China. While in this regard the urban-rural variety was small there were interesting regional differences: 17.0 per cent in the Eastern part of China were convinced that environmental damage was a serious problem, compared with 9.1 per cent in Central China and only 8.1 per cent in the poorer Western part of the country (Li/Li 2009: 25). Likewise surveys by social scientists illustrate that the environmental awareness among students and university graduates has grown. Stalley and Yang have argued that many students perceive environment protection as a central task and that the awareness of Chinese university students does not fall behind that of students in other countries. The majority of the respondents were even of the opinion that environmental problems would mitigate in the years to come (53.4 per cent), while

merely 21.0 per cent expected a further deterioration (Stalley/Yang 2006).

City and county governments are forced by higher echelons to increasingly attach greater weight to environmental protection. The norms and targets of the centre and the provinces became much stricter, particularly in the more developed regions. But the cities often relocate environmentally polluting industries and channel off waste water into rural areas. Therefore protests among the rural population is currently on the rise (in the year 2005 already 70 per cent of all cases). More and more information on the consequences of environmental damage and pollution (e.g. via the internet, the media, and environmental NGOs) are likely to increase environmental protests in the near future in both urban and rural areas, particularly where local governments disregard environment protection.

Usually, peaceful protests are not very advantageous and laws are so far hardly formally enforceable. Therefore, the rural population often turns to specific forms of protest. In May 2007, for instance, a larger group of peasants from Anhui province kneeled before the State Environment Protection Office in Peking in order to achieve an investigation into the massive environmental pollution in their hometown. More than ten years the peasants had patiently submitted their concern to various offices. Several times prefecture and province governments had dispatched investigation teams to their hometown without any result (Wang 2009: 90).

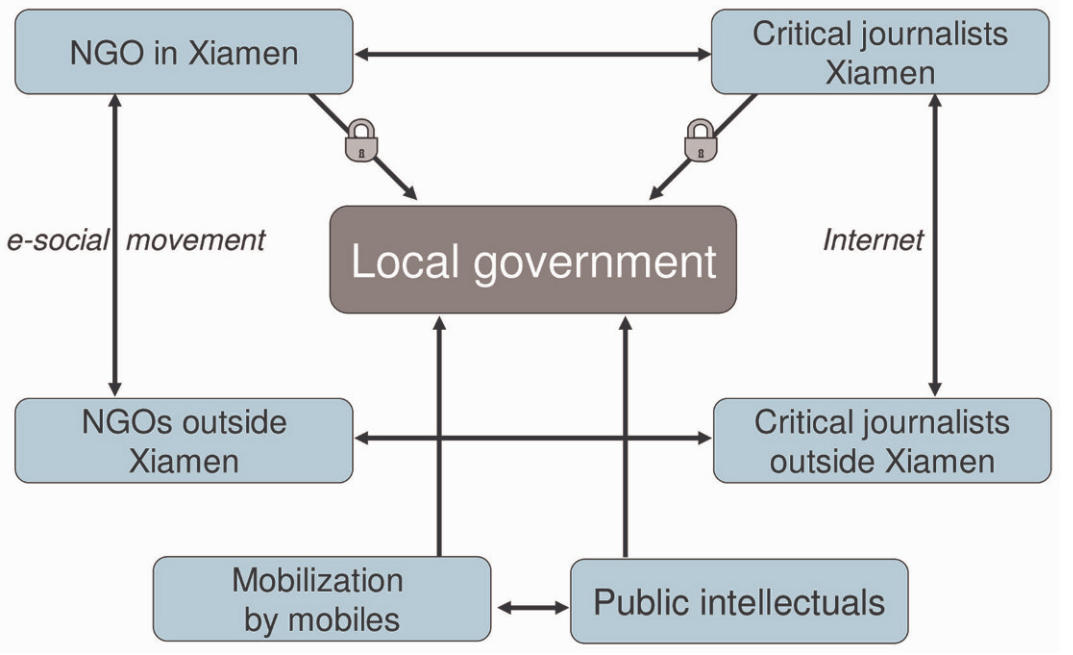
So far there are only few opportunities to take legal action. Although meanwhile in some provinces environment courts and an environment police force does exist, the majority of provinces have not yet established such institutions. Moreover, as a rule higher courts refuse to accept lawsuits of individuals or NGOs by pointing out that they were already overburdened. This conflicts with the national environment law which explicitly stipulates lawsuits by individuals or group of citizens. Chinese surveys display, however, that the argument of higher courts is pleaded. Even months after establishing environmental chambers, the environment courts for instance in Kunming (Yunnan Province) or Wuxi (Jiangxi Province) had not yet received a single lawsuit. The reason is that individual citizens or NGOs are reluctant to turn to the law as they are afraid of reprisals by local authorities or enterprises or because they have to spend large amounts of money for lawyers and court fees (Wang 2009: 90/91).

Another problem is that due to institutional weaknesses no checks and balances and no efficient monitoring system for environmental protection exists. Furthermore, the local *Environmental Protection Bureaus* (EPBs), parliaments, media, and the legal system do not play a noteworthy role.

Meanwhile, several international NGOs are operating and a small environmental movement is developing that can be understood as a basis for the development of Chinese environmental NGOs, too. But local NGOs in most cities are weak and depend on local authorities. Often such NGOs are even intimidated or attacked by local authorities, which are pursuing goals contrary to environmental protection and standards. As long as this small environmental movement does not challenge the party state but rather turns against local violations of policies and laws, the central state is willing to support it. Yet, in the case that it commences to challenge the authorities or even the political system the central state will suppress such activities very rapidly. Under these conditions, NGOs and the environmental movement emerge only in large cities or regions with enormous acute ecological crises and remain fragmented and locally orientated. While NGOs are often hampered by the local state, the central state needs environmental organizations, because he lacks both information on local problems and the ability to enforce environmental policies by institutional means. If environmental activists do not confront the party state and challenge its authority but denounce local violations, the central state tolerates and makes use of them in order to put pressure on local administrations. Such pressure is to improve local administrative performance and foster output legitimacy of the party state.

An interesting case of new forms of protests of citizens was the public opposition against the settlement of the PX factory in the Eastern coastal city of Xiamen. PX stands for para-xylene, which is said to cause cancer. In May 2007, the city government had announced the construction of this factory. This event immediately caused protests by scientists and ordinary citizens. At first well-known intellectuals criticized the project and provided information on it via the internet. In the internet the project was heavily discussed; citizens then informed each other by using their mobiles (SMS) and invited to protest demonstrations. For many weeks tens of thousands of people demonstrated peacefully. Local NGOs refrained from attending but spread information and critiques via the internet throughout the country. Even local journalists provided information to outside reporters. This inter-

Figure 28.4: New forms of protest: The PX factory case in Xiamen. **Source:** Authors' own survey 2007.



action of intellectuals, critical journalists, NGO networks and citizens as well as the public protests finally forced the local government to renounce the project.

28.7 Conclusion

Undoubtedly, an ambivalent situation exists in China. On the one hand international and domestic pressure grows to cope with environmental issues and to implement stricter environmental policies by the state. The central state is interested to implement better environmental policies in order to reinforce legitimacy and secure stability. On the other hand there is still a gap in implementing central environment policies at the local level. A rather low level of environmental awareness prevails in local authorities and within the population. Local authorities often give preference to economic development and economic growth and they avoid the closing down of enterprises which could increase unemployment and therefore negatively affect social stability. Ultimately the central state is responsible as both economic growth and preserving socio-political stability gain top priority in national politics thus often assigning the environment a subordinate role.

Yet, with a rising environmental awareness among Chinese citizens the central state will have to change its policies. Environmental and climate protection are likely to become the third priority in national politics. The upgrading of the *State Environmental Protection Agency* (SEPA) to a ministry, a stricter enforcement of environmental regulations and the establishment of a broad variety of environmental funding programmes illustrate that the significance of environmental issues is rising. It also seems that the central state uses local requests for stricter environment protection, e.g. from NGOs, as a mechanism to put pressure on local authorities.

By strengthening environmental policies, the party state also attempts to reinforce its output legitimacy and, in doing so, to preserve socio-political stability. An interest in maintaining stability presupposes a collective benefit for the actors involved. Both interests and benefits are ensured on different levels: a) on the part of the citizens by improving environment and ecology; b) on the part of the state by ensuring environmental protection, guaranteeing environmental standards, and installing tools for monitoring local authorities and policy implementation (e.g. through evaluations, cadres' responsibility systems, etc.). The current institutional change in environmental governance is not occurring as a bottom-up process triggered by a civil society but as a top-down process driven by the authoritarian state.

By a policy of fostering, monitoring and improving the environment and ecology, the party state attempts to generate output legitimacy at the local level. "Administrative capacity", the party daily *Renmin Ribao* [People's Daily] wrote in March 2005, "is a central

component of the Party's leadership capacity [*zhizheng nengli*]." It went on to claim that measures to strengthen this capacity would need to focus on the aspect of a "serving government" [*fuwuxing zhengfu*], so that the people will be pleased with the government even on environmental issues. Good governance including the improvement of the environment, good public services as well as continual stability even under difficult circumstances would also need to be ensured (Xu 2005).

To sum up, the environmental policy output of the central government has noticeably increased. It has also intensified its pressure on local governments and pays more attention to environmental issues. Furthermore, local environmental protests are not always and automatically oppressed but used to enforce better local environmental protection. The central state even contributes to strengthening the awareness of the people by disseminating information and knowledge on environmental issues through the media and the educational system. The media report on environmental issues and problems on a daily basis. In newspapers, television and broadcast there are special programmes where people can complain and in each city or county environmental 'hotlines' (*green 110*) are available. Moreover, particularly the internet contributes to enhancing and spreading information on environmental problems and issues. And knowledge is a salient factor to enhancing the environmental awareness of the population.

But due to institutional constraints, e.g. the minor role of the legal system, media control and especially the implementation gap between central policies, laws, decisions and their local implementation have the effect that the level of environmental output legitimacy is still low. And in the case that environmental policies should negatively impact upon those domains which bring most legitimacy to the central and local state (like GDP growth, employment, and social stability) this impact would negatively affect the general output legitimacy of the party state.

Undoubtedly, the implementation gap increasingly challenges the accountability of local authorities and compromises the legitimacy of both the local and the central state. Additionally, stability is affected where local authorities disregard environmental issues, albeit the Chinese case proves that stability at the local level could erode without having a direct impact upon the central government. Presumably the rising awareness of the urban middle classes might evoke social pressure that could spawn the state to endorse that environmental protection also becomes a top priority of Chinese politics.

29 The Vulnerability of Cities to Disasters and Climate Change: A Conceptual Framework

Mark Pelling

29.1 Introduction

This chapter offers a conceptual overview to help unpack human vulnerability to natural disaster and climate change in the city. Vulnerability and its components are interpreted as applications of wider debates on social justice that emphasize the human dimension of security – the meeting of basic needs and human rights (Anand/Gasper 2007). But vulnerability is more than this; at its core is the interaction of social and environmental systems so that human security has to be seen within a socio-ecological lens. This positioning is felt most clearly on the ground where projects aimed at reducing vulnerability overlap comprehensively with those for sustainable development (UNDP 2004).

Human vulnerability to both hydro-meteorological and geophysical hazards has generic and hazard specific attributes and can lay latent or unrecognized until manifest through a disaster. One of the primary – but still challenging – aims of vulnerability research, recently extended by the climate change community, is to identify and act to reduce vulnerability before it is revealed through disaster loss. Human vulnerability can be disaggregated into constituent elements including social vulnerability (health, livelihoods, and social well-being) as explored in part IV of this volume, and physical vulnerability (buildings and critical infrastructure), and is the product of social governance processes acting across scales and through time.

This chapter starts by asking what a city is and what we seek to protect within cities when we study vulnerability (29.2), and it then examines six elements shaping human vulnerability to climate change in cities (29.3).

29.2 Competing Visions of Urban Risk

What do we mean by urban vulnerability? Who asks this question has a great influence on the answer. This is because different actors with varying stakes in the city differ on the primary purpose and driving forces behind urbanization and what a successful or sustainable city might look like. Five conceptualizations of the city are compared in table 29.1. Each vision leads to the identification of a specific set of vulnerable objects. This in turn leads to the identification of key strategies for managing vulnerability in the city. The dominant literature base with which each vision is associated is also noted.

The predominant conceptualization of the city is as a motor for economic growth. Economic development is assumed to trickle down to reach the poor, so that the poor as well as the rich rely upon the safety of physical assets, critical infrastructure and financial or business systems. Academic work has tended to come from business management or insurance sectors and to provide technical rather than socially critical input (Castillo 2004). Some work has explored the vulnerability of cities as nodes in globalized networks and flows of capital (Vale/Campanella 2005). Connection to global flows can provide resilience to global capital, while at the same time magnifying the vulnerability of places as they are exposed to contagion effects from other networked places and the potential flight of global capital (Klein 2007).

A similarly top-down, comprehensive view is taken by those who see them as integrated systems of consumption and production. Here cities are often presented as organisms consuming raw materials from the hinterland and producing wealth and waste. Such systems rest on the safety of critical life support systems – transport networks, communications, potable water, sanitation, and drainage (Pelling 2003a). When these systems are damaged by disaster local direct losses can magnify quickly as the movement of people, goods, and information around and through the city is disrupted. The earthquake that hit the port city of Kobe, Japan in 1995 cut trade routes from Japan

Table 29.1: Diversity in the conceptualization of urban vulnerability. **Source:** The author.

Vision of the city	Vulnerable objects	Pathways for managing vulnerability	Literature
An engine for economic growth	Physical assets and economic infrastructure	Insurance, business continuity planning	Macroeconomics and business continuity
An organism or integrated system linking consumption and production	Critical/life-support infrastructure	Mega-projects connecting urban and rural environmental systems	Political-ecology, systems theory
A source of livelihoods	The urban poor, households, livelihood tools	Extending and meeting entitlements to basic needs	Livelihoods analysis
A stock of accumulated assets	Housing and critical/life-support infrastructure	Safe construction and land-use planning	Engineering and urban planning
A political and cultural arena	Political freedoms, cultural and intellectual vitality	Inclusive politics and the protection of human rights	Discourse analysis

with repercussions across Southeast Asia (UNCRD 1995).

Cities can also be seen as an aggregation of multiple components. The most common use of this perspective is to see cities as a collection of individuals all seeking to secure and hoping to improve their livelihood status. Most at risk in this conceptualization are the urban poor – the homeless, those living in shelters without legal tenure or renting. Safety in this vision of the city is built through the extension of individuals' entitlements to basic needs, through which livelihoods can be built and protected in the face of disaster risk. Livelihoods analysis, initially applied to rural vulnerability analysis has proven a successful tool for analysing the production of vulnerability and resilience particularly amongst the poor (Moser 1998).

Cities are also an outcome of the historical aggregation of physical assets – even relatively young cities are given form and have their physical vulnerability shaped by land-use and building standards. Risk is most graphic in those cities where the majority of the urban population lives or works in buildings that are not disaster resistant. A review of health service infrastructure in Latin America and the Caribbean found that around half of all hospitals are sited in high-risk areas. Perhaps not surprisingly, this report also found that over the 1980's and 1990's, 100 hospitals and 650 health centres have been destroyed in disasters (Conchesco 2003).

A final vision of the city sees it as a place of political, cultural, and intellectual interaction – as a stage or theatre where different beliefs or sets of values come into contact. Disasters can damage or destroy cultural assets, including architecturally significant buildings, urban landscapes, and artworks housed in urban centres. During the '*Jahrhundertflut*' (most intense flood in a century) of August 2002 that affected the Czech Republic, Germany and Hungary, the world heritage towns of esky Krumlov and Prague were damaged and galleries of international importance in Dresden and Prague were flooded. Disaster response can threaten cultural, political, and intellectual freedom. The two most effective ways of managing risk are *autocratic command and control* (which limits freedoms) and *inclusive governance* (which opens political freedoms). The former is the most common response from liberal and authoritarian governments alike (Pelling/Dill 2006). A notable exception was the response to the Mexico City earthquake in 1985 when strong civil society composed of new allegiances between workers and liberal intellectuals forced open and maintained new political space which transformed the reconstruction process and post-disaster political life in the city (Pelling 2003).

Part of the challenge of understanding urban risk is to explore the ways in which these varied and sometimes conflicting visions of the city lead to competing discursive and material constructions of vulnerability and policy for its reduction. As table 29.1 shows, a holistic view is made difficult because of the segmented division of policy in urban governance with each vision being promoted by particular policy sectors and actors, each under the control of different professions and administrative structures (Warmsler 2006) and at times built on incompatible theoretical foundations. Horizontal diversity, produced by policy sectors, is compounded by vertical diversity, produced by different levels of governance. Neighbourhood committees sit within local governments and these within municipalities that in turn liase with national line ministries.

Similar connections across scale from the local to the global can be found in civil society and the private sector.

Scale can also generate conflict. Ways of measuring vulnerability and subsequent policy interventions differ by scale. For example, city level vulnerability assessment and management may cause (planned or unplanned) damage to the assets and livelihoods used by local actors at risk so that local vulnerability is increased while city level vulnerability is reduced (Adger/Arnell/Tompkins 2005). Thus, for any one way of seeing the city or of constructing its vulnerability there are multiple stakeholders whose ways of measuring and acting on vulnerability are dictated by the sector and scale of their responsibilities. Individual policy actors may be engaged in activity at multiple scales but nonetheless policy tends to be enacted at specific scaler levels, this is especially so in cities with multiple levels of government.

The study of urban vulnerability is not the first time a research agenda has been challenged by diversity and scale. Work on sustainable urbanization in the 1990's was faced with the same task when trying to bring together the environmental, social, and economic elements of sustainable development with local and global agendas of change (Drakakis-Smith 1996). In their urban environmental transition model, McGranahan, Jacobi, Songsore, Surjadi and Kjellén (2001) showed how development gains, rather than reducing net environmental risk, tend to push hazard from one place or time to another. Sanitation systems can protect the urban poor from environmental health concerns, but without treatment sewerage can generate pollution for downstream residents and ecosystems. At a larger scale, urban industrialization and high carbon consumption systems provide one route for safety form environmental and social hazards but are the world's largest contributor of greenhouse gas emissions generating risk for the future and disproportionately for those people with least ability to cope – often the economically poor and politically marginalized.

Two observations from the sustainable urbanization agenda have particular resonance for research on vulnerability and resilience in cities. The first is that local actions can make profound contributions to the lives of the most vulnerable (Pugh 1996). Scaling-up or reproducing innovations from local or neighbourhood level to city-wide programmes requires support from local or municipal government. The centrality of local or municipal government in managing risk in the city is a starting point for the second observation, that urban governance should be the focus for research and policy aiming to understand and manage risk (Satterthwaite 1998).

Recognizing that governance is central to any enquiry on vulnerability and disaster risk in the city is important analytically because it can be used for the study of generic as well as hazard specific vulnerability. Hazard specific vulnerability assesses vulnerability in relation to a known hazard type – a past event or future scenario. Generic vulnerability assessment focuses on the vulnerability of human systems without any specific hazard type defined, and is particularly useful in urban contexts where hazards are varied, multiple and overlapping, and in an era of climate change where future hazards increasingly depart from historic records in their distribution, severity, and frequency. Building adaptation into urban governance requires responsive and flexible decision-making models.

Governance is also central to understanding the interaction of disaster risks in the city. As McGrenahan, Jacobi, Songsore, Surjadi and Kjellén (2001) have shown us, disaster risk is neither static nor isolated. Table 29.2 presents urban disaster risk as a continuum from everyday to small and large disasters. This includes technological and natural hazards and the potential for compound natural-technological events where one hazard triggers another. Everyday disasters are felt at the individual level and are caused by environmental health hazards, including inadequate sanitation or access to potable water or dangerous road use; they are the largest cause of premature mortality and injury in the city. Small and large disasters are caused by natural and technological hazards and differ in their scale of impact. The distinction is arbitrary but follows that used by the *Centre for Research on the Epidemiology of Disasters, Emergency Events Database* (EMDAT: <http://www.em-dat.net/>) allowing analysis of larger events. Very few countries or cities undertake systematic collection of small or large disaster data. This is a major challenge to comparative or historical analysis and has played a part in the lack of support given to mitigating small disasters, which are rendered invisible to city authorities and humanitarians through this lack of data.

Everyday hazards are typically studied and managed apart from small and large disasters, but each kind of disaster risk and associated vulnerability interact with each other. The ratchet effect of vulnerability describes the erosion of capacity following exposure to hazard (Chambers 1989). This can be seen where those individuals or households already weakened by

Table 29.2: The continuum of urban disaster risk.

	Everyday disaster	Small disaster	Large disaster
Frequency of exposure	Everyday or continuous	Frequent, can be seasonal	Infrequent
Scale of impact	Individuals	Less than 10 killed or 100 injured, no call for external assistance, no state of emergency	10 or more killed, 100 or more injured, external assistance required or a state of emergency
Impact on all premature death and serious injury	Main cause of premature death and serious injury in aggregate	Under-reported but considered to be significant	Can be catastrophic in particular places and times
Hazard types	Environmental health hazards including air pollution and traffic accidents	Localized natural or technological hazards	Major natural or technological hazards
Established, formal risk managers	Public health and critical infrastructure providers	Local emergency and recovery agencies	Local and external emergency, recovery and reconstruction agencies

disease or injury (perhaps forced to live in more hazardous conditions as household incomes are reduced) are less able to withstand the impacts of small or large disasters. Disasters that destroy environmental health infrastructure or local primary health clinics will have a long-term impact on local and city-wide vulnerability to everyday disaster. Food security and urban drought have the potential to cross from one classification to another, moving from being recognized as everyday to small and large disasters. There is little research on vulnerability to either type of urban disaster in the literature, creating a gap in knowledge that becomes more urgent under climate change and the continuing failure of cities to meet the basic needs and entitlements of the poor to sufficient nutrition and clear drinking water.

29.3 Urban Poverty and Vulnerability to Disasters and Climate Change

This section focuses on six overlapping aspects of vulnerability. Each aspect is relevant to understanding vulnerability to natural disasters and acts as a foundation for exploring vulnerability to extreme events associated with climate change (table 29.3). Climate change is felt in cities through increasing variability and extremes in temperature, precipitation, wind, and through sea-level rise. Cities magnify some hazards such as extreme temperatures through the heat island effect or the consequences of sea-level rise and flooding in cities affected by subsidence. Because urban residents and economies are connected into global financial and trade systems they are also exposed to climate change related shocks being felt across the globe. The 2008 global food crisis demonstrates this interconnectivity with a combination of changes in local planting regimes, increasing global demand, the failure of key regional harvests, and instability in the global financial systems resulting in price rises and increased hunger and malnutrition for the poorest. Locally, this fed back into the political system through violent protests, for example in Cameroon, Egypt, Haiti, Indonesia, Mexico, Morocco, Pakistan, Senegal, and Yemen (FAO 2008a). The following discussion equates climate change risk with extreme events and interprets larger systemic crises as global root causes for human vulnerability.

There is some tension between the application of terms within the disaster risk and climate change community (ISDR 2006). Within the disasters community mitigation describes interventions aimed at reducing local hazard. While a similar definition is used in climate change, the global orientation of the discourse has meant mitigation has come to be applied to reducing climate risk through controlling greenhouse gas emissions. Local actions to reduce subsequent hazard are described as adaptations. So climate change adaptation includes mitigation and vulnerability reduction efforts as conceived by the disasters community. Climate adaptation has come to replace coping as the term of choice in international development discourse. Where they are used together coping has come to signify the application of short-term and tried and tested responses to threat or loss, adaptation refers to more fundamental systems changes and suggests a novel departure from established routines of living with risk. In the following discussion ability

Table 29.3: Six aspects of human vulnerability to climate change. **Source:** Based on Satterthwaite, Huq, Pelling, Reid and Lankao (2008).

Exposure	Hazard mitigation	Early warning	Resistance	Resilience	Adaptation
Who lives and works in places most exposed to hazard?	Who lives or works in places where hazards are least contained?	Who lives or works in places where there is least capacity to avoid impacts before they arrive?	Who is least able to bare the physical impacts of hazard?	Who is least able to cope with the impacts and losses caused by a disaster?	Who is least able to change in order to reduce risk through exposure, mitigation, early warning, resistance or resilience?

to respond to threat and loss are included within an overall vulnerability framework. This reflects dominant conceptualizations of vulnerability which see it as an outcome of interactions between exposure to hazard, sensitivity to loss, and capacity to cope with/adapt to threat or loss. In this respect while individual formulations may differ in favoured terminology, the climate change and disaster risk communities agree.

The separation of the six aspects of vulnerability in the following discussion is heuristic. On the ground there are many policies or spontaneous actions that impact on multiple aspects simultaneously or through trade-offs where reduction of vulnerability in one area may generate vulnerability elsewhere, to another hazard type or for another actor. For example, investing in household retrofitting to protect a dwelling from strong winds may increase the resistance of the building in the long-term, but in the short-term, the household will have fewer resources to adapt to shocks from other hazard sources, for example a food price increase associated with global markets and climatic extremes.

29.3.1 Exposure

Exposure to urban hazards including those associated with climate change is a function of the location of residence or work. In theory this should be an outcome of land-use planning, but with more than 50 per cent of the population of many urban settlements living outside the formal sector, scope for planning is severely limited. Within already constructed settlements controlling exposure requires expensive retrofitting of buildings, or urban redevelopment and rehousing schemes to move people to less exposed locations. Unless undertaken with great care relocation can easily disrupt social and economic networks that sustain low-income households (UN-HABITAT 2007).

In cities that are expanding rapidly there is an opportunity to plan hazard exposure out of the city. However, there are few cases where this is being done. More often expansion of small and medium sized settlements or in the fringes of larger cities is unplanned or does not take hazard into account. The result is that urban expansion continues to bring new sources of hazard into the city as hill slopes, floodplains, and coastal wetlands are developed, exposing more not fewer people to risk.

Rapid urban growth can also expose the less poor living in the formal sector. This is especially so where the pace of expansion exceeds the ability of local governments to regulate construction, or where the demand for housing is given political priority over vulnerability management. In the UK, many have warned that extensive contemporary public housing development on the floodplain of the Thames is generating future hazard exposure and vulnerability (Lavery/Donovan 2005).

29.3.1.1 Hazard Mitigation

Exposure to hazard is mitigated by physical infrastructure. There is no shortage of technical ability and know-how including engineered drains, dams, river defences, sea walls and slope stabilization, however, the uncertainty imposed by climate change means that existing infrastructure and planning guidelines may not be able to cope with growing extremes in weather events (World Federation of Engineering Organizations 1999). Even without the uncertainty of climate change dominant political and economic concerns mean that many infrastructure projects were not built to disaster resistant standards leading to human exposure. This is an important element of urban risk showing that mitigation is not simply a technical exercise but a political one as well. A review of World Bank lending during the period 1984–2005 found that of 197 completed mitigation projects, 26 per cent showed flaws in design, and half had been damaged by a subsequent event (World Bank 2006b).

Mitigation can protect the exposed from direct hazard impacts and can also aim to limit indirect and systemic losses. Where disaster losses are contained by mitigation this can also help prevent or limit indirect losses caused by knock-on consequences of disruption of critical infrastructure and systemic losses when the urban economy is distorted following disaster shocks or the demand for goods during reconstruction. The wider impacts of climate change – for example on global commodity process – are beyond the scope of local or urban mitigation but show how international mitigation for climate change affects local vulnerability.

Successful urban mitigation brings together top-down and bottom-up strategies, large-scale civil engineering works with local adjustments such as hazard mapping and collective action to contain hazards through the construction of dams, drains, and revetments (UN-HABITAT 2007). A good example of this is the Naga City programme in the Philippines, which has integrated disaster risk reduction into urban planning, through the formation of disaster management standards and training of urban professionals and local stakeholders, and also established governance mechanisms to bring together neighbourhood level and city level planning (see: Asian Urban Disaster Mitigation Programme; at: <http://www.adpc.net/AUDMP/Phi.html>).

29.3.1.2 Early Warning and Evacuation

When a hazard exceeds mitigation capacity, early warning and evacuation can still prevent human loss. Experience from recent disasters, even from high-income countries (such as the US during Hurricane Katrina) emphasizes the challenges in extending early warning and evacuation to the urban poor (IFRC 2006).

Most state controlled early warning systems are oriented towards national security. This works well for large hazards – such as tropical storms, sea-surges, and for major urban areas which are important for the national economy and political stability. Less well covered are small and medium urban centres that have to rely on relaying national level warnings or develop stand alone early warning systems that can translate national alerts for local conditions. Thus, one challenge that prevents early warning from getting to those at risk is a lack of fit between national and local information needs. There has been much investment in city level early warning systems for geophysical hazards, for example through the *Earthquakes and Megacities Initiative* (<http://www.emi-megacities.org/>), but less work on developing systems that are locally relevant for hydro-meteorological hazards.

Where local early warning exists this has been shown to add value to national early warning. During Hurricane Mitch, the La Masica municipality, Honduras was protected by a community-based early warning system that proved more resilient than high-tech alternatives (IFRC 2005). Neighbourhood early warning systems are particularly useful not only in providing resilience through overlapping capacity and local control but because through this greater awareness of hazard and trust in warning is generated. Maintaining local early warning and hazard monitoring services for infrequent hazards is challenging because of limited finances and competing local priorities.

In short, the greatest challenge is not to increase the technical capacity of national early warning systems but to devise ways of translating available scientific information into forms that are useful for local populations at risk. This requires more investment in local early warning systems but also in innovative information dissemination strategies, such as the use of mobile phone networks to broadcast warnings (see chap. 93 Villagrán).

29.3.1.3 Resistance

Resistance describes openness to impact (and is referred to as susceptibility in the climate change literature). Both resistance and resilience share similar root causes and on the ground are often difficult to distinguish. This also means that interventions aimed at reducing susceptibility and a lack of resistance can also build capacity for resilience.

In people, resistance is shaped by physical and psychological health and indicated by age, gender, physical ability, and psychological state (Wisner/Blaikie/Cannon/Davis 2004). Higher impacts are associated with the very young or old, being a woman, disabled or injured. Women may suffer high losses (Enarson/Morrow 1998). Women and orphans can also lose out during reconstruction as assets are transferred away, often to male relatives (UN-HABITAT 2004). But demographic characteristics shaping resistance are not linear or necessarily cumulative, for example age can bring experience or social respect and so added individual security.

In property, resistance is indicated by design quality and standards of maintenance. Most cities have detailed design standards, which need to keep pace with the changing hazard profile of climate change. The main challenge is a failure to implement these standards (UNDP 2004). In the formal sector this weak-

ness is linked to cost-cutting, corruption, and the high demand for dwellings in rapidly expanding cities. Losses to the Marmara earthquake, Turkey in 1999 were predominantly felt by aspiring middle-income families who had purchased recently built flats constructed without applying basic construction guidelines. This disaster has led to a revision in regulation as well as planning laws in Turkey (Özerdem/Jacoby 2006; see chap. 38 by Gencer; 37 Tekeli Yeşil).

Most of the urban poor live in informal housing or in rental accommodation in the formal sector. Both housing sectors have very low resistance to natural hazard shock. Short term financial needs mean that few dwellings built in the informal sector consider natural hazard standards. As settlements mature and incomes grow there is scope for retrofitting, but this is more expensive than building safe dwellings. Those living in rental accommodation often have little knowledge of the standards used in construction. For the urban poor, lack of maintenance by landlords (both state and private sector) of basic services and high density living can generate its own health risks aggravating risk associated with the building's poor resilience to climate shocks (Pelling 2003).

Livelihoods can also be analysed in terms of resistance. For the urban more than the rural poor, the dwelling is a key productive asset. High levels of commodification in the urban economy make repairing and replacing the dwelling more challenging so that livelihoods can be disrupted should a dwelling be damaged or lost following a climate shock.

The most vulnerable are those who experience a triple burden of inadequate housing, human and livelihood frailty. As hazards associated with climate change become more frequent and severe the number of exposed people and places without sufficient resistance to withstand impacts will increase.

29.3.1.4 Resilience

Resilience describes the capacity of an individual, social group or physical structure to cope with and survive the impacts of a climate shock or stress. For poor households, a low level of assets relative to loss makes coping difficult as these are destroyed or sacrificed for survival. The range of coping strategies employed by households is described in figure 29.1.

Coping is presented as unfolding in a series of steps, with the potential for a return to pre-disaster livelihoods and social life. However, as external stresses, including disaster impacts, make resources scarcer the household finds it harder to return and over time can descend closer to economic and social collapse. The further down the coping staircase a household descends, the harder it is to recoup losses and emerge from coping to getting by and improving welfare.

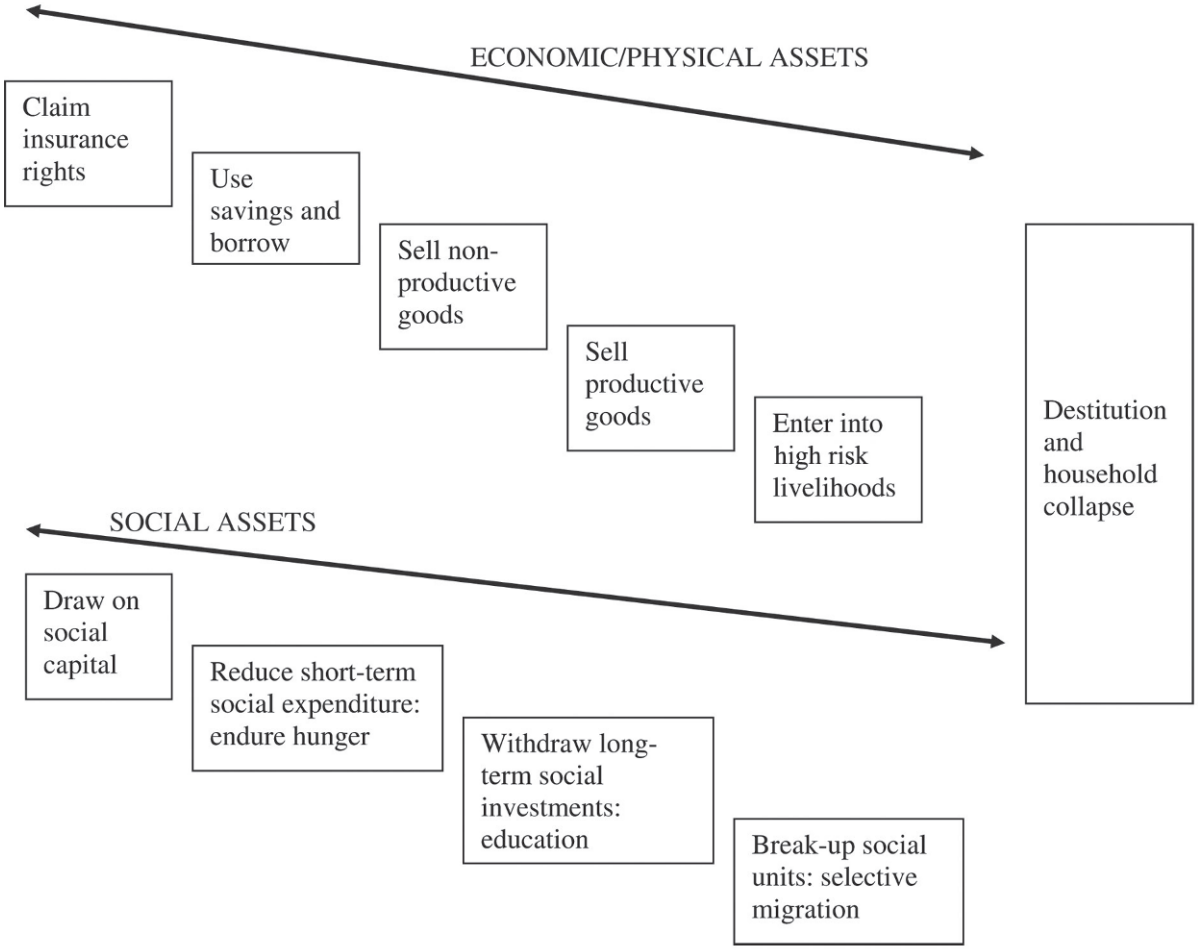
Economic and physical assets can be protected when losses are covered by insurance. For the poor this is seldom an option forcing households to cope by expending savings (which can act as an informal insurance mechanism), selling non-productive and productive goods. A last resort before destitution may be for household members to enter into exploitative livelihoods, the poor are vulnerable to engaging in work that jeopardizes their human rights and is dangerous with long hours of labour providing minimal return, and illegal or socially unacceptable activities including child labour and the sex industry.

Social assets can be protected if they are embedded in strong ties of social capital. Social capital is strengthened when used so those communities and individuals with stocks of social capital may build resilience when coping is successful. Where social capital is weak this can also impact directly on livelihood recovery. Following Hurricane Mitch widespread looting, on top of disaster losses, has been used to explain the slow rate of formal labour market re-entry, especially for women in Nicaragua and Honduras (Delany/Shrader 2000).

Where households suffer economic impact and have limited social capital three coping mechanisms have been identified. The order presented in figure 29.1 shows a continuum of severity rather than a chronology of deployment. Final choices are an outcome of household cultural context and households can jump from one element to any other and in both directions as indicated by the double headed arrows. The temporary withdrawing of children from school is common during times of stress, this cuts costs and provides scope for children to contribute to the household economy. Over the short-term reducing expenditure on food or medicine can help preserve the household economy even if it undermines social assets. Finally, before the household collapse children may be sent to live with relatives. This is socially acceptable and common in the English-speaking Caribbean, for example.

- Figure 29.1 identifies the primacy of economic resources and of social capital in determining whether a household will cope with the impacts of disaster shocks. Interventions by the state and civil society actors can support poor households at risk of slipping down the coping slope and build resil-

Figure 29.1: The coping slope: coping and erosion of household sustainability. **Source:** The author.



ience into the city through social policy. Key interventions and target populations include:

- Land and property tenure documentation before disaster and after disaster for widows and orphans to prevent loss of physical assets. This should be applied to the informal as well as formal sector.
- Extending insurance mechanisms to the urban poor through micro-insurance schemes.
- Supporting local social capital building through community development programming.
- Make health care and education zero cost for the urban poor to maximize access post-disaster.
- Provide flexible education to allow students to integrate work and study.
- Provide short-term and low or zero interest loans to slow down the drift into debt and the selling of assets.

Support for those whose households do collapse is a core component of reducing urban vulnerability. In contrast to rural disasters the majority do not gravitate towards shelters and refugee camps but are redistributed across the city, perhaps moving to different neighbourhoods or migrating to different settlements (Shelter Centre 1982). This is a dislocating experience serving to erode further the social and economic capital stocks of the most vulnerable. The homeless and those with marginal livelihoods are at risk from even minor subsequent shocks.

29.3.1.5 Adaptation

Adaptation in response to any aspect of vulnerability can target material or institutional change (Pelling/High 2005). The former includes using better building standards the latter changes in decision-making structures and governance. Adaptation can also be hazard specific or generic, responding to background stresses and opportunities of life in the city that in turn shape household assets and capacity for climate change hazard risk management.

Adaptation requires information to identify a potential future hazard or cause of vulnerability, information to identify an alternative mode of working or living that can reduce vulnerability, and the social/political will and resources to make a change. Proactive adaptation where hazards are infrequent but large is difficult. Will to change is often lacking even if scientific evidence of the threat exists. Here the best chance for adaptation is immediately following disaster events. To have the best chance of taking this opportunity, local actors need to be organized before disaster.

Proactive adaptation is preferable to post event adaptation. Work comparing prevention with humanitarian response shows the former is cheaper as well as saving human loss (DFID 2005). Given the lack of experience with building adaptation into urban planning, a good place to start is with disaster risk reduction activities (Sperling/Szekely 2005; Schipper/Pelling 2006). This includes an array of practical measures that enhance each stage of vulnerability identified in table 29.3. UN-HABITAT (2007) has documented examples of local, proactive risk reduction including:

- Participatory disaster risk assessment;
- Micro-finance and micro-insurance;
- Local early warning;
- Local mitigation including raising dwellings, clearing drains, slope stabilization, building bridges and walkways.

Local government led initiatives include:

- Land tenure regularization and upgrading of settlements;
- Relocation of settlements at high risk;
- Land-use planning to inform new construction;
- Updating and implementing building codes for disaster resistant housing and places of work;
- Protecting critical infrastructure; and
- Improving early warning systems.

City governments, line ministries, and civil society organizations can help provide an institutional environment that supports adaptation by the vulnerable – an agenda for progressive change in governance which is itself an adaptation, and perhaps the most fundamental one. The starting point for providing a supporting environment is legislation that recognizes the basic needs and human rights of the urban poor. Perhaps most important here is a right to secure housing and to safe places of work. Granting the poor rights of tenure to land can stimulate local actions to invest in upgrading the dwelling and can also help local government and civil society actors invest in social infrastructure to support mitigation and resilience and reduce hazard exposure.

City government can also directly invest resources to enable adaptive action through providing skills for the most vulnerable, including women, those with the most precarious livelihoods, and socially isolated groups such as recent migrants. Following the Gujarat earthquake in India a variety of projects helped to train local craftsmen in earthquake resistant building technique and then employ them in reconstruction programmes providing human and financial resources for the local economy. SEWA (2001) combined this with an emphasis on female employment and community led planning.

29.4 Conclusion

The aim of this chapter has been to outline the predominant forces shaping human vulnerability, particularly of the urban poor, to natural disasters and to use this as an entry point for exploring vulnerability to climate change. Discussions of vulnerability are necessarily political with different visions of the city leading to particular priorities for protection and potentially to competing interests and approaches for vulnerability reduction. From the perspective of the urban poor, climate change associated hazards are just one of a range of threats faced everyday and through small and large disaster events. This calls for an integrated meta-theoretical frame, and one that retains a focus on power asymmetries in driving the social distribution of vulnerability. Political economy can provide this level of analysis but is less good at revealing the mechanisms and networks through which information – and power – flows in shaping risk. For this reason it is argued that political economy needs to be nuanced with approaches from systems and complexity theory (Pelling 2003c).

This chapter presented a framework for unpacking the different aspects of vulnerability around the themes of exposure, mitigation, early warning and evacuation, resilience, resistance and adaptation, aspects that overlap on the ground but open different opportunities for policy intervention. Most important is the role of adaptation, which can operate across each of the former themes but yet is usefully separated to enable focused conceptual debate.

Across this analysis of urban vulnerability and adaptation the most important determinant of risk has

been governance and within this the role of local or municipal government acting to coordinate between sectors, scales, and areas of professional responsibility. In many cities, realizing the potential for local government to reduce risk is one of the biggest challenges in confronting urban vulnerability. It is likely that in searching for what makes urban systems better able to adapt to the uncertainties of climate change – including indirect economic as well as direct impacts through extreme events – adaptive management within inclusive governance will be key.

Adaptive management is not yet understood well, but can draw on research into social learning (Pelling/High/Dearing/Smith 2008) that identifies the need for clear communication, horizontal decision-making, flexibility in setting and meeting goals, and the need to build personal and professional trust so that information can move quickly across administrative systems. There is a danger that the high levels of trust found in adaptive management systems can lead to closed social circuits, and undermine equity and efficiency. It is because of this that adaptive management needs to be set alongside inclusive governance. Inclusiveness has been shown to enhance human and systems safety when support for local actors has been networked through civil society associations, and there is much support for this from the international community. Still, unless municipal government is put at the heart of vulnerability reduction, policy and analyses to understand the causes for urban disaster risk under climate change will be incomplete.

30 Vulnerability to Natural Hazards: Case Study on Landslide Risks in La Paz

Fabien Nathan

30.1 Introduction[1, 2]

Before the 1980's the study of risks and disasters was mainly focused on the features of hazards and on post-disaster reactions. Natural disasters were seen as the only result of natural forces: geophysical, hydro-meteorological or biological hazards. Pre-disaster intervention was reduced to engineering techniques (construction of dikes, contention walls, etc.); risk management was reduced to disaster management: emergency warnings, search and rescue operations with command and control schemes. This has dramatically changed since more than 25 years, partly triggered by a shift in the dominant paradigm. This chapter will briefly examine how this happened.

Historically, there were early attempts in human ecology by the Chicago School, since the end of the 19th century, to examine the relationships between man and nature, and the interaction between society and environmental hazards (Dewey 1938; MacIver 1931; Mileti 1999). Another starting point of social sciences' studies of disasters can be traced back to the study of Samuel Prince (1920) that raised pertinent theoretical questions about crises and social change but that have not been taken up until World War II. Then most researches focused on the psychological study of stress situations and behaviour in times of crisis and disasters, mainly war. These studies were generally driven by a Western vision, led by U.S. agencies (Lepointe 1984). It continued during the 1950's with the cold war. This situation of the field changed in the 1960's with the establishment of the Disaster Research Center[3] founded in 1963 by E.L. Quarantelly, Russell L. Dynes, and J. Eugene Haas (Dynes/Haas/Quarantelli 1967). They laid the foundation for the sociological study of disasters (Oyola-Yemaiel/Wilson 2006). At the same time, Gilbert White founded the human geography study of hazards and hazards management (White/Haas 1975; Burton/Kates/White 1993, 1977), and in 1976 he established the Natural Hazards Research and Application Information Center at the University of Boulder, Colorado.[4] These centres, researchers and studies initiated the multiplication of the hazard and disaster research in the world and its progressive widening. But behind these multiple approaches, Oliver-Smith (1986a) noted the creation of an "academic research consensus" dominated by sociology and geography, dividing into two branches: behaviourist and environmental. The first one puts the emphasis on individual and collective behaviour in disaster situations and the second one considers disasters as extremes of the geophysical process, minimizing the role of social factors.

For a long time, hazard and disaster studies have thus remained caught into a technicist paradigm with a post-disaster focus, attributing natural causes to natural disasters and considering disasters more than risks. But since the mid 1970's, this view was questioned, firstly by researchers working in the South who began to rethink the dominant explanations, putting the emphasis on the role of the social context in disasters, and criticizing the prevailing views on dis-

1 This chapter is based on the author's PhD research on *The Social Regulation of Disaster Risks. Study in the Western Peripheral Neighbourhoods of the City of La Paz, Bolivia*, under the supervision of Prof. Milbert that was defended in September 2009 at the IHEID, Geneva. More information at: <http://www.nccr-north-south.unibe.ch/Person/person.asp?contextID=&Context=NCCR&refTitle=the%20NCCR%20North-South&ID=709> and <http://www.afes-press.de/html/download_nathan.html> (papers available for download). Some results are available in Nathan (2008, 2009, 2009a, 2009b), the latter on the link between vulnerability and security.

2 For a complete attempt to understand the genesis, structure and logic of the field of global risk management, see Nathan (2004).

aster management. At the same time in the 1970's and 1980's, the world took progressive awareness of the devastating effects of multiplying disasters, and the necessity of a different response. Indeed, these years were marked by a dramatic raise of big disasters, such as the 1970 cyclone and tidal wave in Bangladesh (with 300,000 deaths), the 1976 Tangshan earthquake (China, with 290,000 deaths), the Armero eruption in 1985 (Colombia, with 25,000 deaths), and the great famines affecting the Sahel region in the 1970's and 1980's that had a big impact on public opinion and researchers (Meillassoux 1973), etc. The governments were spending increasing amounts of money to finance an emergency state that was becoming almost permanent. This explains the growing recognition that emergency assistance is not enough.

The creation of the *United Nations Disaster Relief Organization* (UNDRO) in 1971 that was replaced in 1992 by the *Department of Humanitarian Affairs* (DHA) to coordinate help and to promote also the study, prevention and pre-disaster planning is part of this change. The real paradigm shift was theorized among others by Cuny (1983), Hewitt (1983b), Watts (1983) and Oliver-Smith (1986). They put the emphasis on risks and discovered what is now considered as axiomatic in risk studies: vulnerability is the key to understand disasters, and there is no such thing as "natural disasters" (O'Keefe/Westgate/Wisner 1976).

This was followed by the *La Red* group[5] in the 1990's, emphasizing the concepts of *socio-natural disasters* (Fernandez 1996), *popular mitigation* (Maskrey 1993), risk management, etc. The famous book *At Risk* (Blaikie/Cannon/Davis/Wisner 1994) also brought some of the main theoretical insights and remains a major reference. Consequently, the field of questions, domains and disciplines concerned by the study of hazards, risks and disasters became enormous. Risk analysis now counts with thousands of publications in all directions, from history (Dourlens/Galland/Theys/Vidal-Naquet 1991) to econometrics (Mechler 2003), post-modern sociology (Beck 1992), conflict theory (Stallings 1988), political ecology (Bohle/Fünfgeld 2007), urban vulnerability analysis (Pelling 2003) etc. In turn, some major moves in the international world occurred in the 1990's, like the creation of the *United Nations International Decade for Natural Disaster Reduction* (IDNDR), ancestor of the current *International Strategy for Disaster Reduction* (UN/ISDR).[6] This gave birth to the Yokohama conference and Strategy[7] in 1994 that was updated in Kobe in 2005.[8]

The shift towards the study of what is happening *before* the occurrence of disasters is now widely recognized and understood through the rapid rise and triumph of the concept of vulnerability (Varley 1994; Bankoff/Frerks/Hilhorst 2004; Birkmann 2006; Cannon 2006; Villagrán de León 2006; Bererra/Peltier 2009). It is now so widely employed in many different fields that confusion sometimes arises around this notion. Security and international studies should better integrate these concepts and try to establish more bridges with risk and disaster studies (Nathan 2009). It has been noticed that one still lacks a robust theory of vulnerability (Kasperson/Kasperson 2001). It is essential to define these concepts, their usefulness and how they may be applied to better understand risks and disasters.

Therefore, this chapter explores the central concept of vulnerability (Nathan 2009a), as this is the absolute key to the understanding of risks, and ultimately why disasters happen. It will be done through a brief analysis of the literature but also how to best apply vulnerability analysis to a concrete case study on landslides in the city of La Paz, Bolivia. The chapter will first present what is vulnerability, how it can best be defined (30.2), what are the most useful existing frameworks for analysis (30.3), and how they can be combined and one of them applied to the case study (30.4). A new and simple method will be offered to analyse vulnerability at the household level.

30.2 Definitions and Conceptual Precision

30.2.1 Vulnerability as a Component of Risk

Vulnerability has emerged from a notion of everyday language to a more elaborated scientific concept. There are so many uses of vulnerability (Brutschin 2002) that it is very difficult to formulate a synthesis. Each author, institution or report has proposed its own, usually adapted to a specific context: research in hazards, climate change, food security, social sciences, psychology, health, etc. But generally it is possible to distinguish two types of definitions and their variants:

5 See for details at: <http://www.desenredando.org>.
6 See for details at: <http://www.unisdr.org>.
7 See for details at: <http://www.unisdr.org/eng/about_isdr/bd-yokohama-strat-eng.htm>.
8 See for details at: <http://www.unisdr.org/eng/hfa/hfa.htm>.

- *vulnerability as susceptibility*: a set of conditions, that raise the susceptibility of a community to the impact of a damaging phenomenon.
- *vulnerability as capacity*: the manner in which an exposed unit can anticipate, cope with and recover from hazard impacts.

Following Chambers' (1983) three categories of vulnerability, Hans-Georg Bohle (2001) has theorized this distinction as respectively *external* and *internal vulnerability*. The first one is representing the 'exposure', whereas the internal side represents 'coping', each side having its own theories to apply to. Many definitions combine both aspects, defining vulnerability as a compound that aggregates *negative* aspects (potentiality of having damages, incapacity to anticipate, resist, or cope) and *positive* aspects (capacity to cope, resist, recover). One of the most used in hazards and disaster research has been developed by Blaikie and colleagues:

> By 'vulnerability' we mean the characteristics of a person or group in terms of their capacity to anticipate, cope with, resist, and recover from the impact of a natural hazard. It involves a combination of factors that determine the degree to which someone's life and livelihood is put at risk by a discrete and identifiable event in nature or in society (Blaikie/Cannon/Davis/Wisner 1994: 9).

Or even more clearly,

> vulnerability is a measure of a person or group's exposure to the effects of a natural hazard, including the degree to which they can recover from the impact of that event (Blaikie/Cannon/Davis/Wisner 1994: 57).

Cannon, Twigg and Rowell (2003) has summed up both approaches of vulnerability and capacity:

> The first conceives of them being the two ends of a spectrum, so that people who have a high degree of vulnerability are low in capacity (and vice versa). (...) The second perceives them as two distinct (or only partly inter-related) sets of factors (Cannon/Twigg/Rowell 2003: 4).

This chapter stresses the positive aspects in vulnerability definitions in order to avoid confusion: vulnerability is by essence negative, or we need to radically change its meaning. Vulnerability would then be both a susceptibility to undergo damages by specific hazards, and an *in*capacity to anticipate, cope, resist, or recover. On the contrary, capacities are not part of vulnerability but to reduce it, thus contributing to its opposite, resistance and resilience.

There is also a tendency to use vulnerability independently from the context, like 'vulnerable people' in general. It is emphasized that vulnerability in the absolute does not exist. It is both context-dependent and subject-dependent: *one* is vulnerable *to something*, in a given place and at a given time. There is a 'stake', i.e. someone or something is threatened, and there is a 'threat', i.e. a hazard, like a storm, an earthquake, etc. For instance, the people living in the Pacific coast in December 2004 were vulnerable to tsunamis, which created the conditions of the possibility of this disaster. They were at risk of a disaster triggered by a tsunami hazard.

One can define risk as a probability of undergoing damages by one or several hazards, and a disaster as a 'realized' risk, i.e. a social disruption provoked by the impact(s) of one or several hazards exceeding the capacities to cope by the affected society/people. Risk is a virtual and latent potentiality, and disaster is more concrete, observable, a sensible phenomenon, although it is also a question of appreciation (Perry/Quarantelli 2005).

The hazard alone is not able to 'convert' a risk into a disaster. For example, a heavy rain or an earthquake is not necessarily disastrous or a damage-generator. There must be specific conditions of vulnerability: the presence of populations, animals, ecosystems or valued objects (stakes) in hazardous areas (D'Ercole 1994); and some properties which render the damages possible: a certain fragility and incapacity to resist, face or cope. That is what the concept is covering. Vulnerability is thus a component of risk, the latter being the encounter of a hazard with vulnerable stakes. Risk as a probability of damages is closely related to hazards occurrence and severity, but at least as significantly to numerous other components: the *vulnerability* of the exposed unit, its *capacity* to anticipate, resist (*resistance* or *robustness*, see Van der Leeuw 2001), face the adverse consequences of the impact (*coping*, see Smit/Wandel 2006; Gallopin 2006), and adapt to come back to a functionally acceptable state (*resilience*, see Janssen/Ostrom 2006; Holling 1973; for a new framework on social resilience, see Obrist/Pfeiffer/Henley 2010). Many formalizations have been attempted, usually with poor results. It begun with R = H + V (Blaikie/Cannon/Davis/Wisner (1994, 2004) where R means risk, H hazard and V vulnerability) and was rapidly replaced by R = V x H in order to show the *combination* between hazards and vulnerabilities that shape risk (UN/ISDR 2002, 2004). As some scholars have argued that societies also have capacities to lessen risk, the variable C for coping appeared, as in UN/ISDR

(2002 :24): R = H x V/C. Others (ZEF 2002: 11) have tried V = H - C (coping).

What can be said is that risk is a function of hazard, vulnerability, resistance and resilience, the first two being multipliers of risk, and the last ones divisors: R = f (H, V / Resistance, Resilience). Between a hazard and its social translation into a disaster, there is thus a society at risk, more or less vulnerable, capable, resistant, or resilient. It is sometimes argued that capacities are part of resilience or resistance, and that resilience and resistance are the inverse of vulnerability: V = f(1/Rtce+Rlce). These conceptions and formalizations are defining risk as a state. It is now known that risk is an ongoing process shaped by all its components, and should be analysed synchronically but also diachronically (Oliver-Smith 1999). This is the same for vulnerability.

30.2.2 Definition

To sum up, vulnerability can be described on the one side as a *propensity to undergo damages*, i.e. a state of fragility that raises the susceptibility of the stake to suffer the impact of a damaging phenomenon. On the other side, vulnerability is the incapacity to anticipate, cope with, resist to, adapt to, and recover from hazards. Vulnerable units are either non-resistant, i.e. incapable of withstanding the shock (without adapting); and/or non-resilient, i.e. incapable of absorbing the shock and adapting back to a (functionally) acceptable state.

At the global level, the rise of the number and severity of disasters is more important than the increase of the hazards themselves (UN/ISDR 2004). This means that the vulnerability of the human societies has risen, i.e. they are more disaster-prone; their arrangements and organization favour the transformation of hazards into disasters. This shows the extreme importance of a good understanding of vulnerability. If all the pre-disaster conditions not directly related to the hazards can now be analysed through vulnerability, one could object that the concept is too broad, encompasses everything, and would therefore be unusable for analytical purposes. This is not so: even though it is very broad, complex and dynamic, it can be sliced to render the analysis possible, before reconstructing the entire puzzle in a more dynamic and relational way. For that purpose some frameworks are suggested to analyse vulnerability.

30.3 The Frameworks

This section reviews five of the most useful frameworks proposed in the literature to analyse vulnerability. Generally there are two types of approaches on vulnerability. In the debates they are often opposed or seen as contradictory. Some people work with a concept of vulnerability that is precise and varies according to the context, in particular the hazard related to it. Vulnerability to floods is different from vulnerability to droughts or earthquakes. Others prefer a more general concept, applicable to all hazards, sometimes called *baseline vulnerability*. It deals with general fragility factors that do not depend on the hazard and act as a general context: if they are present, the person or household is vulnerable, in general. Both approaches generally do not match very well with each other.

It seems in reality that the real division resides in the relationship to the hazard(s). Seen in that way the two approaches are complementary. On the one hand, the 'single-hazard-related vulnerability approaches' describe a vulnerability that is different according to the hazard. The protective measures, exposure factors or fragilities in relation to a hurricane are distinct to those related to a landslide. The 'single-type-of-hazards-related analyses', in turn describe vulnerability to one broad type of hazards, comprising several hazards of that type: vulnerability to natural hazards, or industrial, etc. These types of approaches ('single-hazard-related' or 'single-type-of-hazard-related' vulnerability assessments) comprise the classical analyses of vulnerability and those of the literature on risk management.

On the other hand, the 'multi-types-of-hazards-related vulnerability analyses', without necessarily conceptualizing it that way, analyse vulnerability to multiple types of hazards at the same time: natural hazards, social hazards (poverty, survival, violence...), etc., trying to understand the strategies and aspirations of the individuals, households and communities in their struggle for life. One finds here the literature focused on livelihoods, households, poverty reduction, access to assets, human security, etc.

It seems that both approaches are complementary, and that they can be applied simultaneously: first, consider the specific vulnerabilities according to the hazards, and then replace them in the general context of the social strategies of the actors in the face of adversity.

Below the main frameworks of qualitative vulnerability assessment will be reviewed. Table 30.1. gives an

Table 30.1: Overview of the main frameworks to analyse vulnerability. **Source:** The author.

Framework	Scale-analysed unit	Relationship to hazard(s)	Advantages	Limits
1. Analytical slicing	Works at all scales, but mostly used as general holistic analysis	Related to one or one type of hazards	Serves as a remainder of all broad dimensions that should be taken into account	Not relational nor dynamic; too linear; redundancies inevitable; does not provide any interpretation
2. Five components	Household centred, but includes upper levels	Related to multiple types of hazards	Comprehensive and articulate; relational between dimensions and scales; reflects people's priority on livelihoods; intermediary between pure analysis and proposal of interpretation	Does not relate enough with exposure factors; difficult to scale up
3. Vulnerability and capacity assesments (VCAs)	mainly community level	more related to one or one type of hazards	Insists on capacities and resilience factors; people- and practical-oriented, but serves also for research	Too simplistic; too much separated from the upper levels; too separated from power and governance analysis; lack of historical dimension; purely analytical
4. Livelihood	household level	related to multiple types of hazards (natural, social, etc.)	people- and practical-oriented; emphasis on the assets people have or need	vulnerability mixed with hazards and considered as a 'context', not a dynamic process; simplistic action theory (agency considered but not structure); too economically-driven; lack of power and governance analysis; lack of historical dimension; impossible to scale-up
5. Pressure and Release	general, holistic	Related to one or one type of hazards	causal, dynamic, obliges to trace back the root causes and have an interdisciplinary, holistic understanding	Categories too vague; does not help to explain the links between them; lack of methodology to apply it.

overview of their scales, advantages and limits, and table 30.2. analyses their commonalities and differences.

Below the frameworks will be examined one by one.

30.3.1 Assessing Vulnerability through Analytical Slicing

The first model for the analysis of vulnerability to natural hazards is a decomposition in analytical parts (Nathan 2009). It is a inspired by Bohle (2001) and Wilches-Chaux (1993).Vulnerability has two sides in interaction: the exposure (a), and a series of insufficient capacities (b):

a.) Exposure refers to the following features:

1. *physical exposure*: presence and density of the people, habitat, networks, ecosystems, goods and services in risk zones, defining potential losses or damages, both human and non-human (stakes).
2. *socio-ecological exposure*: human-induced ecosystemic perturbations aggravating the natural

Table 30.2: Commonalities and differences among five frameworks. **Source:** The author.

Scale	Scope	Contradictions and possible combinations	What is still lacking
• 1 and 5 are general • 2, 3 and 4 are mainly household-oriented • 2 and 5 allow cross-scale analysis • 1, 3 and 4 are single-scale	• 1, 3 and 5 are purely analytical and theoretically neutral tools that need to be nourished by interpretational content. • 2 and 4 propose a middle-range interpretation • 2, 3 and 4 give methodological hints to help application; 1 and 5 not.	• 1, 2, 3 and 5 are basically compatible: within the broad 5. • may enter all dimensions of 1 that include both vulnerabilities and capacities, and can be eventually regrouped into the five categories of framework 2 to provide a beginning of interpretation, at a general level. • Some parts of framework 4 may enter into the analysis (e.g. capitals as capacities) but the underlying theory of action is not really compatible with 2 and difficult to upscale to 5.	All frameworks fail to present a more advanced combination between the analysis (what dimensions need to be taken into account) and interpretation (how to explain the construction and current existence of vulnerability in a given setting).

hazard (deforestation, land degradation, street pavement, some engineering practices, climate change, etc.).

b.) Insufficient capacities to prevent, prepare for, face and cope with hazards and disasters

1. *physical weakness*: insufficient capacity of an individual or an asset to resist or recover from a hazard's impact.
2. *juridical-legal*: inadequate state of the legislative and judiciary regulations to prevent, mitigate, prepare for, face and recover from disasters.
3. *institutional*: inadequate state of the institutional disposals, at all levels, to prevent, mitigate, prepare for, face and recover from disasters.
4. *technical*: technical factors impeding to prevent, prepare for, face and cope with hazards and disasters such as: inadequate knowledge and/or use of risk management techniques.
5. *political*: political factors impeding to prevent, prepare for, face and cope with hazards and disasters.
6. *socio-economic*: social and economical elements which raise the susceptibility of undergoing disasters and lower the capacities of self-protection, such as: socio-spatial segregation, inequalities of wealth and of access to the security disposals, misery, anomia and social disorganization, poor social position and social isolation of exposed people, existence of higher social hazards undergone by people, etc.
7. *psychological and cultural*: psychological and cultural factors impeding to prevent, prepare for, face and cope with hazards and disasters such as: inadequate security paradigm or risk perceptions; cultural anomia or weakness; attachment to risk zones or risky behaviour, non-willingness or incapacity to protect oneself.

The overall vulnerability (Wilches-Chaux 1993) of someone, a community or a society is a mix of some or all of these dimensions. Almost all of these vulnerabilities include an informational dimension: lack of information, bad information, misinterpretations, etc. (White/Kates/Burton 2001). They are also generally both collective and individual, so the model can be applied at all levels (societal analysis as well as household-centred or individual analysis). This is a neutral, purely analytical framework that serves to remind about the main dimensions that should be taken into account in synchronic vulnerability analysis. However, it does not help to draw connections between the categories or study of the genesis of vulnerability.

30.3.2 Terry Cannon's Five Components of Vulnerability

A more articulate classification of vulnerability components has been elaborated by Terry Cannon (2006). It reflects people's priority on livelihoods and constitutes an intermediary level between pure analysis and interpretation, as it gives a vision of the importance for the household of broader structures such as social protection, the governance system, and the like.

- *Livelihood and its resilience*: assets and income earning activities;
- *Base-line status*: initial well-being: health (physical and mental), nutrition;
- *Self-protection*: quality of house construction and location;
- *Social Protection*: adequacy of building controls; large-scale measures;
- *Governance*: power system, rights, status of civil society.

The degree to which a household is vulnerable depends on its livelihoods (assets and income earning activities), initial well-being (health and nutrition), self-protection (quality of house construction and location), the social protection provided by society, and its governance structures (power system, rights, etc.). This analysis takes into account different social dimensions and levels of analysis: the individual vs. the household level and its relation to broader social structures. It is more relational and very informative. But the application is mainly a household-centred one and it remains difficult to upscale.

30.3.3 Vulnerability and Capacity Assessment Models

The second dimension of vulnerability is a series of insufficient capacities. It is generally not a binary matter of presence or absence of a capacity, but more of a degree in which people are *not capable enough* to resist or recover properly. Therefore the analysis should not be purely pathogenic, but seriously consider the capacities, abilities to cope, i.e. the elements lowering the vulnerability and contributing to *resistance* and *resilience*. It is increasingly recognized that risk analysis must encompass an analysis of vulnerability and capacity.

Field workers, unsatisfied with usual mitigation methods, proposed a tool called *vulnerability and capacity assessment* (VCA), but its application by social scientists is still in its infancy. They consider vulnerability as being predictive and applicable, as for example Cannon, Twigg and Rowell (2003: 4): "Vulnerability should involve a predictive quality: it is supposedly a way of conceptualizing what may happen to an identifiable population under conditions of particular risks and hazards. Precisely because it should be predictive, [vulnerability assessment] should be capable of directing development aid institutions." The first comprehensive attempt to propose a VCA, by Anderson and Woodrow (1989: 12), proposed a matrix of vulnerabilities and capacities with three categories:

- *Physical and material*: "What productive resources, skills and hazards exist? ...What made the people affected by disaster physically vulnerable: was it their economic activities ..., geographic location ... or poverty/lack of resources?"
- *social and organizational*: "What are the relations and organizations among people. ... What [was] the social structure (...) before the disaster and how well did it serve the people when disaster struck? ... What impact do disasters have on social organization?"
- *motivational and attitudinal*: "How does the community view its ability to create change. What are people's beliefs and motivations, and how disasters affect them?"

This matrix is both a conceptual tool and a tool to guide practical assessments in communities. For Cannon, Twigg and Rowell (2003: 10), it should be completed by five factors: "disaggregation by gender, disaggregation by other differences (e.g. economic status), changes over time, interaction between categories, and different scales or levels of application (e,g, village or national levels)." Strangely enough, they oppose vulnerability to needs:

"Vulnerabilities refer to the *long-term factors* which affect the ability of a community to respond to events or which make it susceptible to calamities. Needs, as used in disaster context, refer to immediate requirements for survival or recovery from a calamity" (Anderson/Woodrow 1989: 10).

Other attempts are being developed to create practical tools for community leaders or NGOs to assess vulnerabilities and capacities[9] that are useful mostly for practitioners. These types of VCA have the advantage of being very practical, operational, by insisting on skills and capacities of the exposed or affected people that are usually underestimated or misunderstood by risk managers. It also insists on the social and cultural aspects, as the OXFAM methodology does: "vulnerability is quite explicitly seen as a social phenomenon that is related to level of exposure to risk ..., in combination with a range of factors ...

9 See for example the Community based Vulnerability and Capacity Assessment (VCA) in Central America <http://www.proventionconsortium.org/?pageid=32&projectid=9> or Guidelines for vulnerability and capacity assessment (VCA), IFRC at: <http://www.ifrc.org/what/disasters/dp/planning/vcaguidelines.asp>.

that affect people's ability to cope with their exposure" (Cannon/Twigg/Rowell 2003: 36). On the other hand, it is very simplistic and too much separated from the upper levels. It is also very separated from the power and governance analysis. To sum up, it is more a practical tool than a framework for researchers.

30.3.4 Livelihood Approaches

30.3.4.1 Sustainable Livelihood

A whole area in disaster research is developing around (*sustainable) livelihoods* (SL), considering "vulnerabilities, of all kinds, as part of the context in which livelihoods are shaped" (Twigg 2001: 8). This approach is well known (De Haan/Zoomers 2005; Carney/Drinkwater/ Rusinow/Neefjes/Wanmali/Singh 1999) and close to human security-based approaches and Amartya Sen's concepts of capabilities and entitlements (Sen 1999). It originated in a work done by Chambers and Conway (1992: 1) who defined it as follows:

> a livelihood comprises the capabilities, assets (stores, resources, claims and access) and activities required for a means of living: a livelihood is sustainable which can cope with and recover from stress and shocks, maintain or enhance its capabilities and assets, and provide sustainable livelihood opportunities for the next generation; and which contributes net benefits to other livelihoods at the local and global levels and in the long and short term.

The aim of the model is both analytical and normative: "The SL approach seeks to understand the many factors influencing people's choice of livelihood strategy and then to reinforce the positive aspects ... and mitigate the constraints" (Twigg 2001: 12).

This framework may be summarized in the following manner (Solesbury 2003): a *vulnerability context*, in relation to some *transforming social structures and processes*, and a series of *livelihood assets* (equivalent to capacities, both material and social) determine some *livelihood strategies*, to end up with *livelihood outcomes* (food security, income, reduced vulnerability, etc.). Categories of vulnerability are *trends* (large-scale social, economical, technological and political), *shocks* (health, natural, economic, conflict, crop) and *seasonality*. Capacities are resumed in *five capitals*: a) *human* (skills, knowledge, health), b) *social* (relations), c) *natural* (resources), d) *physical* (infrastructures to support livelihoods), and e) *financial*. "Transforming structures and processes" are institutions that, from a sociological perspective, determine the livelihoods, the possible strategies, etc.

The five capitals remind the reader of Pierre Bourdieu's (1983; 2002) four capitals, but in a quite modified version; another underlying theory is institutionalism, as the analysis of the role of "transforming social structures and processes" on livelihoods is a simplified institutional socio-economy. The discussion on capitals (Bebbington 1999; Moser 1998) has resulted in thousands of publications, especially on social capital (Wisner 2002a). The capitals are viewed as assets people need to make a living and cope with adversity (Glavovic/Scheyvens/Overton 2002). One of the main concepts in this discussion is access, remarkably paved by Penchansky and Thomas (1981), although still little followed.

This kind of explanation is nothing more than an attempt to explain actor's strategies around livelihoods, something that sociology has tried for more than a century. But this has the advantage of proposing an alternative view on disasters and security, considering "the significance of hazards and their impact ... in the vulnerability/livelihoods equation" (Twigg 2001: 16). Indeed, "vulnerable people and victims of disasters, without using theory, will always place the disaster in the context of their daily struggle to earn a living and feed their families. They can also articulate these issues clearly, if they are given a chance" (Twigg 2001: 16).

The framework is nevertheless limited by several elements: vulnerability is somehow mixed with hazards ('trends, shocks, seasonality') and considered as a 'context', not as a dynamic process linked to the household; the action theory proposed is very simplistic (agency is considered but not structure); it is also too economically-driven and lacks a power and governance analysis, and a historical dimension. Finally, it is impossible to scale-up.

30.3.4.2 The Access Model

Blaikie, Cannon, Davis and Wisner (1994: 48) have developed a model of disaster risk centred around the household level and livelihoods: the *access model*, which is quite similar to the SL model and obviously served as a basis for it. Access refers to "the ability ... to use resources which are directly required to secure a livelihood." [10]

As access to resources is essential to maintain livelihoods, less access means an increased vulnerability. In short, an individual or a production unit have spe-

10 It is close to Amartya Sen's *entitlements theory* developed in his studies of famines (Sen 1984).

cific resources and assets, material and immaterial, determining a specific access level and further economic opportunities and decisions that are also influenced by structures of domination. These decisions lead to livelihoods, a household budget, and further choices, which in turn lead to an outcome: changes in the access profile.

In the second edition of *At risk* (Blaikie/Cannon/Davis/Wisner 2004), the authors take into account the critiques made to them in almost a decade (e.g. Haghebaert 2001) as well as theoretical developments in order to present a more sophisticated model. It now comprises the different temporal dimensions that lead to the 'unfolding' of the disaster, among them the time of the hazards, of the household activities, strategies and opportunities, the seasonality, the temporal development of the political, class and domination structures, the times of the emergency phase and coping strategies, etc. This reflects the historical dimension of vulnerability, hazards and disasters, and to take into account the transformations of the household analysed but also of what is external to it in a dynamic way.

However, the framework seems difficult to apply and the authors do not really propose a methodology for that. Another constraint is that even if it takes the social structures into account, the model remains mainly economic. Even if an interesting discussion on needs is proposed to analyse coping, it remains difficult to understand with this model all non-economic determinants of household vulnerability, and how the structures of domination really operate at the household level. The authors' 'Pressure and Release' framework, complementary to the access one, insists more on these structural aspects.

30.3.5 Pressure and Release Model

This famous and widely reproduced *pressure and release* (PAR) model is based on the idea that "... an explanation of [a] disaster requires us to trace a progression that connects the impact of a hazard on people through a series of levels of social factors that generate vulnerability" (Blaikie/Cannon/Davis/Wisner 1994: 22). It is the only framework of disaster risk and vulnerability that clearly distinguishes between the different causal levels. It is also one of the most ambitious ones, allowing a real social science analysis.

In the framework, the disaster is crunched between the hazards on the one side, and the "progression of vulnerability" on the other. Vulnerability starts from "root causes", a "set of well-established, widespread processes within a society and the world economy, [which] reflect the distribution of power." These political and economical ideologies and systems translate into activities and processes called "dynamic pressures," which are "macro forces" (e.g. urbanization, debt repayment schedules, etc.) and incapacities (a series of lacks). These pressures, in turn, create the "unsafe conditions" which express the vulnerability to hazards of a specific population (exposure of buildings, specific groups, livelihoods; lack of local institutions; endemic diseases, etc.). In short, "the unsafe location is linked [to] a series of dynamic pressures that can be traced back to root causes" (Blaikie/Cannon/Davis/Wisner 1994: 23).[11]

The great merit of this framework is to recognize that the deepest causal factors "may ultimately be quite remote from the disaster event itself" (Blaikie/Cannon/Davis/Wisner 1994: 22), therefore operating a breech with common sense and allowing to construct a scientific object, with a "chain of explanation." It also reminds researchers, that risk and vulnerability are processes that develop through time, thus necessitating to make synchronic as well as diachronic analyses to trace its genesis.

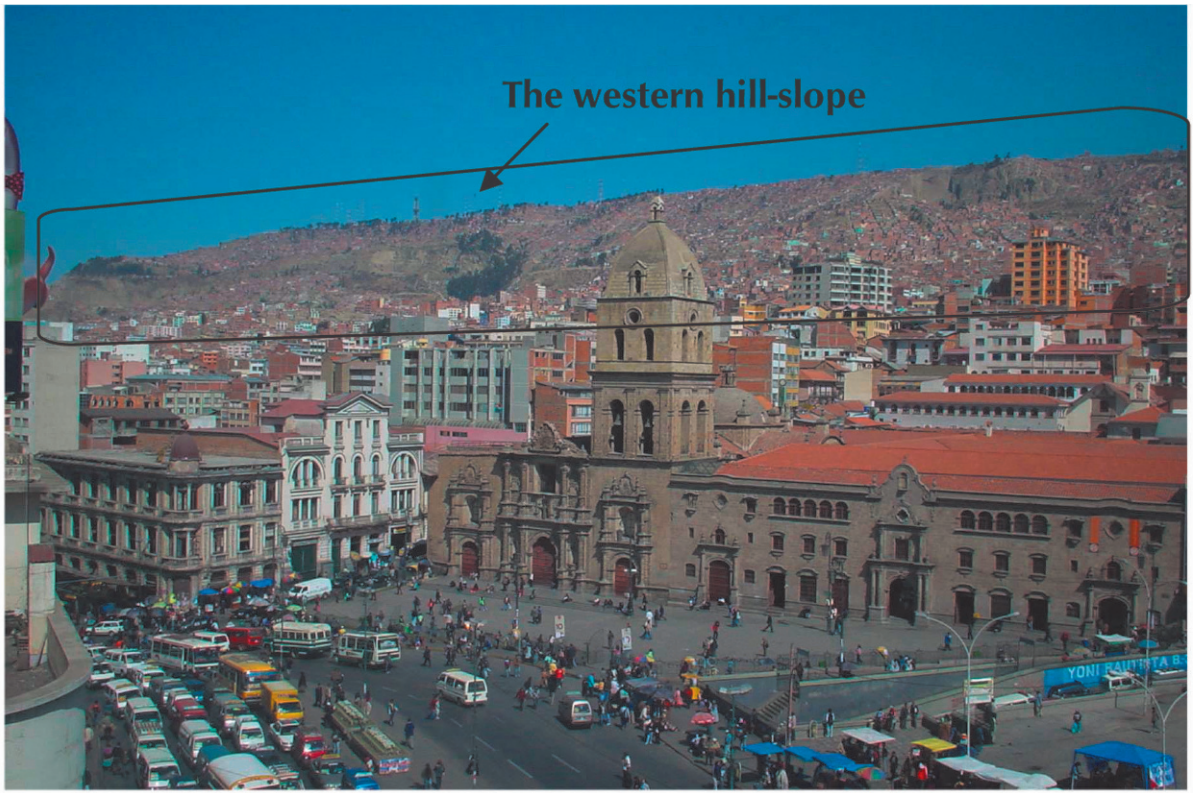
Only with such a 'grand' analysis is it possible to identify and correct the determinants of disaster risk which lead to human insecurity. The authors postulate that it is possible to inverse the progression of vulnerability by addressing root causes, reducing pressures and achieving safe conditions.

30.4 Application to the Case of Landslides in La Paz

The city of La Paz (figure 30.1), Bolivia, is situated in the Andean Mountains, between 2,800 and 4,000 meters high. More than 500,000 people live in the hill slopes surrounding the city centre, many of them in poverty and precarious conditions.

11 The 'Pressure-State-Response' Framework of OECD (2003) is probably inspired by this framework, driven by the need to show in a simple manner human-environment interactions. It is not really focused on disaster issues but more on the ecological services and consequences of human actions on it, and ultimately on society. The human actions exert a pressure on the natural environment which reacts to these pressures by qualitative and quantitative changes. In the face of that situation, human societies elaborate societal responses (mitigation, protection, etc.).

Figure 30.1: The western hill slope viewed from the city centre. **Source:** Photo of the author.



Many of the people live in slopes of more than 50 per cent and are highly exposed to hazards like landslides, mudslides, land/debris fall, and the collapse of their house because of the instability of the soils due to many subterranean rivers. The neighbourhoods are densely populated and composed of adobe houses (made of mud) or red brick houses built without expert advise and generally by the owner himself (figures 30.2, 30.3 and 30.4)

The fact that thousands of poor people are relegated into the peripheral zones of the city at risk is a well-known phenomenon in many cities of the South. What is more place-specific is the history of risk and the progression of vulnerability in La Paz. It all started by the choice of the location of the city by the Spanish colonizers, but the risk really became massive since the 1970's and 1980's, when the migrants from the countryside were pushed into the cities, in Bolivia and elsewhere, and in particular towards the city of La Paz. This has occurred mainly because of the growing difficulty to make a living in the countryside, and after 1985 the brutal neoliberal adjustment expelled thousands of workers out of their jobs, worsened the living conditions, and pushed people into the informal urban economy. Yet the peculiar topography of the city leaves very few habitable spaces that were rapidly taken by those who could afford it. Thus, the poor migrants had no choice but to buy or invade the remaining lands, those most unstable: the hill slopes. Risk was the price to pay for them to be able to live in the city. At the same time, the authorities were incapable or unwilling to plan and control these massive population movements, and let the greediest speculate with lands. Until now there are very few restrictions of control of the market of urban landownership in La Paz, and everybody knows that the norms of land use remain largely unenforced. The people in unplanned and unrecognized neighbourhoods would progressively gain the legalization of the neighbourhoods, with increasing consolidation (more public services) and enhancements. However, the problem of the exposition of considerable amounts of people to natural or socio-natural hazards remains difficult to solve, resulting in frequent small to medium-scale disasters (from minor damages to more than 30 deaths in a row). There are also a myriad of other factors that contribute to vulnerability, be them physical, legal, institutional, technical, political, socio-economic, psychological and cultural, at all scales: individual, house-

hold, community, municipality, etc. That is why it is a good example to test the frameworks and see how they can be used and combined.

Combining the 'analytical slicing' with the 'Pressure and Release' framework provides a general idea of the vulnerability of the city of La Paz and its inhab-

Figure 30.4: Views of some exposed neighbourhoods in La Paz, western hill slope. **Source:** Photo of the author.

itants to landslides hazards (table 30.3). An additional dimension may be added between the dynamic pressures and the root causes, if we stick to the definition of the latter as the root processes that deal with the distribution of power within a society. Indeed, there may be an intermediary level of analysis, like migration, socio-spatial segregation or misery that is causal to the dynamic pressures but not really constituting the root processes of the political economy. We also choose to leave the 'root causes' as well as some of the causes as question marks, because although it is fascinating to do, analysing that goes beyond the scope of this chapter and deals with the Bolivian society's overall political economy. The reader will notice some redundancies, like 'misery' or 'migration' as causes appearing several times, which is normal: misery can be one of the cause of a physical incapacity to cope (e.g. poor health) as well as a lack of worry for disaster risks, because of the law of adaptation of the expectations to chances Bourdieu had revealed (Bourdieu 1992). Migration from the countryside can also be one of the causes of a lack of knowledge of the hazards in urban setting, as well as of an inappropriate construction technique, imported from another context where these abilities are well adapted.

The table offers a causal progression of vulnerability from the right to the left, for each type of vulnerability - those who pertain to the exposure and those who constitute the insufficient capacities to prevent, prepare for, face and cope with hazards and disasters.

Each line represents a type of vulnerability; the columns represent the progression of this vulnerability to landslides in La Paz, from the existing unsafe conditions to their root causes, going through the dynamic social pressures that lead to the existing vulnerability. It is important to understand that vulnerability is a complex compound of mainly socio-economic and organizational aspects that derive from social causes quite remote from the disaster but that is leading to an increased and effective vulnerability. These vulnerability types and their causes are related to each other and must be analysed in a dynamic way. Some causes that ultimately contribute to vulnerability to landslides in La Paz, as shown in table 30.3, are misery, lack of resources, socio-spatial segregation, migration, scientism and technicism, absence of care by powers for certain social sectors, etc. They are the causes of the pressures that lead to exposure and the incapacity to prevent disasters or cope with them. In turn, explaining their root causes would require another type of political economy analysis.

As the results of the application of the above framework are very general, it is important to combine it with other methods which allow understanding the process of the construction of risk and vulnerability closer from the people exposed, at the

Table 30.3: Some dynamic factors of vulnerability to landslides in La Paz, Bolivia. **Source:** Compiled by the author.

Progression of Vulnerability —— Types of Vulnerability	Unsafe Conditions	Dynamic Pressures	Causes	Root Causes
		Exposure		
Physical Exposure	Presence of houses, people and goods in landslides areas	Settlement in hazardous zones	Socio-spatial segregation	?
Socio-ecological Exposure	Perturbed ecosystems in La Paz	Deforestation; Inadequate water management and waste management; Destabilizing of soils	Migration; Lack of technical knowledge; Lack of ecological management	?
Insufficient capacities to prevent, prepare for, face and cope with hazards and disasters				
Physical	Physical incapacity to resist or cope with impacts	Diseases; Impossibility to cure oneself; Bad quality of housing	Misery ; Cultural mistrust	?
Juridical legal	Inadequate legal system for prevention and mitigation	Non-application of norms for land use planning; Absence of compliance and control mechanisms	Disorganization; Lack of human and financial resources for effective application	?
Institutional	Lack of an overall and coherent organizational risk management system in the city of La Paz	Confusion, lack of coordination between risk management organization; Lack of overall prevention strategy	Scientism; Technicism; Lack of resources	?
Technical	Bad use of risk management techniques: construction without contention walls and with bad foundations, lack of drainage of water, weakening and destabilization of soils for construction, bad state of canalizations for water management	Lack of ecological management; Lack of technical knowledge; Autoconstruction	Migration; Lack of resources of individuals and organizations	?
Political	Lack of integral risk management policies in La Paz	Weakness of political powers and instability; clientelism, lack of long-term vision	?	?
Socio-economical	Misery: very low income which hardly allows a minimal alimentation; malnutrition of children; extreme isolation: lack of social capital and solidarity; impossibility to sell the house and have access to credit. unemployment and informal economy; job instability	Economic crisis; Unequal structure of landownership; Vertical structure of power; Differences of power among neighbourhoods	?	?
Psychological and cultural	Underestimation of risk; Lack of preoccupation of risk and disasters; Wrong beliefs: that the soil is stable for example; Resignation	Existence of more important social hazards: unemployment, livelihoods, violence; lack of education in risk and risk management; lack of trust in existing institutions and organizations; massive unemployment	Misery; Absence of care by powers; lack of resources for education; high tolerance to risk; Migration	?

household level. In his field study the author used among others a methodology that is partially inspired by the livelihood framework, partially by Terry Cannon's classification, but above all adapted to the specific research needs. It will be shared here because it may be applied to other contexts, although it may be developed much further. The author used an interview guide that was used for the heads (male, female or both together) of the households at risk, working only with people highly exposed (quasi independent variable) in order to understand their perceptions, their trajectory, their vulnerability and capacity to cope, and the way they manage risks in their daily living (dependent variables). This allows to see how the big structures that may act as causes or root causes in table 30.1. (e.g. the state of landownership, neoliberal policies that led to a microeconomic crisis, etc.) are transformed, lived, experienced or embedded at the individual/household level. For example, it shows how people are somehow forced to settle in risk zones, why, how they cope, what is their current grade of vulnerability, what are their household strategies, their social position, etc. The interview guide tries to inform eleven elements: a general self-presentation of the family, its trajectory, conditions of habitat, how they perceive the neighbourhood and what are its main problems, the economy of the household, its health, its relationships with friends and relatives, the relations with organizations, risk perception, past emergencies and risk management in their daily living. If conducted properly, this offers the researcher a general picture of the household, not only of its perceptions but also some objective elements of its situation. The qualitative analysis and interpretation of each category gives rich ethnographic data, and this allows to conclude with a general interpretation of the interview, including the following information: understanding of the reasons of exposure-taking and the trajectory that led to it; general situation of the household and social position, the habitat, some elements of exposure, the perception of risk and lay risk management, the cultural, social and economic capitals available, and if relevant the governance issues related to the neighbourhood (this should also be gathered by other means, like participant observation and interviews with key informants). This permits conclusions on the state of the household's self-protection and social protection that contribute to vulnerability or resilience, and thus qualify and understand closely the people's vulnerability in the field.

One example of analysis and interpretation of an interview we realized is the following (skipping the analysis of the 11 categories above-mentioned):

A and B[12] live in a tiny adobe house, on a rocky headland eroded from below and above the precipice. Their young children are wearing second-hand clothes and do not seem to be in good health. One of them is coughing. The room where the parents and their four children use to sleep is minusculous, humid, and only comprises two small beds. The ground is made of clay and the ceiling is made of distended cloth.

A and B form a family of migrants from the Altiplano who came to settle in La Paz since a decade because of the difficulty to live in the countryside. They live in a house that was donated by the father of A, who had bought there a long time ago in prevision for the future of his children, when the hill slope was still empty land. Their material conditions are very harsh, living in misery without being able to satisfy their vital needs (food, health, basic services, housing). Their exposure to landslides is very high, living in an adobe house sensible to humidity, victims of water infiltrations and having cracks in the walls, without real rainwater drainage nor sanitation, just above the precipice on an eroded rock, etc. Their cultural capital is very weak (primary school, strong peasant accent in Spanish) and their social capital reduced to the minimum (meetings of the neighbourhood's organization, few relations with neighbours). In other terms, they cannot count on anyone to help, moreover their position within the neighbourhood seems weak (symbolic capital very low), and they do not feel legitimate to seize the existing institutions. Their economic capital and their income are largely insufficient because of A's lack of a regular and secure job, the fact that he gets very low income when he manages to get paid, and the absence of protection and respect for labour legislation.

In contrast, their perception of the hazard, of the exposure, of risk and of the solutions is extremely precise, conscious and developed, though without having the means to cope, which contributes to their despair. They know that their house will, sooner or later, fall, but they are incapable of moving, reinforce or protect the house, or obtain protective measures from the authorities or from the neighbourhood leaders. The few measures of self-protection they take during the rainy season are insignificant when compared to the magnitude of the problem.

12 A stands for the name of the husband and B of his wife.

Figure 30.5: Some exposed houses in La Paz, western hill slope. **Source**: Photo of the author.

Their social protection is almost non-existent: they are not well taken into account by the community leaders or by the authorities; they have no health protection, pension or social benefits; the precariousness at work is absolute, etc. The children are victims of that state, without possibility to get treatment when ill, and with few possibilities of social promotion. The family's vulnerability, as much to the natural as to the socio-economical hazards, is thus maximal.

30.5 Conclusion

The chapter focused on the notion of vulnerability in order to clarify its meaning, its uses and the models for qualitative analysis. It was replaced in the history of the discipline and this showed that although it is now widely used, the paradigm shift that accompanied its appearance and proliferation is recent, and science still lacks a more developed theory and methodology for vulnerability analysis. The author reviewed the compatibility and differences among major frameworks and concluded that there are two framework types and that there is a compatibility among many of them. But the real challenge is their application in concrete case studies. Almost no methodological insight is provided to achieve a practical application, apart from the VCA analyses that were designed from the start for practitioners. In moving towards this direction, the author proposed two ways of applying the frameworks in a creative manner to the case of landslide risks in the city of La Paz, Bolivia. The first was deliberately at a general scale, i.e. at the level of the city or society. It focuses primarily on vulnerabilities more than on capacities. The second is a personal simplistic but practical way of evaluating qualitatively the vulnerability and assets or capacities of exposed households based on semi-directive interviews and life stories with family leaders. The author used it in his PhD research (Nathan 2009b) and it provided interesting results: not only rich ethnographic data, but also a possibility to understand people's vulnerability close to them. Policy recommendations may arise, especially from the latter methodology. In the case of La Paz as in many other cases, understanding the exposed people's priorities and situation is essential for an integral risk management (Cannon 2008, Gaillard 2008, Nathan 2008), as any purely top-down proposal would fail. For example, risk for many people is just a supplementary price to pay for the people to be able to live within the city,

Figure 30.6: : Some exposed houses in La Paz, western hill slope. **Source**: Photo of the author.

benefit from a minimum of public services, and be relatively close to points of the city where informal employment is exercised. One solution could be a kind of people-centred resettlement of the most exposed people at the neighbourhood level, working with social organizations that are very strong in Bolivia, in conditions that put the beneficiaries' priorities and livelihoods at the centre. This could be accompanied by mitigation measures for those who remain exposed, like forestation schemes, waste management, water management, capacity building, community early warning, etc. A synergy between local authorities, the central government and the people could arise around such a project.[13]

13 A feasibility study of the pilot-project has been conducted. For more information, please contact the author at: <nathan.Ffbien@gmail.com>.

31 Revealing the Impact of Small Disasters to the Economic and Social Development

Mabel C. Marulanda, Omar D. Cardona and Alex H. Barbat

31.1 Introduction

The effects of natural hazard events of small or moderate size are not considered by many people as 'disasters', although they share the same origins and causes of large and extensive effects. The impact of these events cannot be underestimated, because in general terms, they typify the disaster risk problem of a city, region or country. This chapter does not debate risk regarding to extreme events with a long return period, but insular, real and daily risk that multiple communities are exposed to in rural areas and in small and large cities. The most of these disasters are the result of socio-ecological processes associated with environmental deterioration and are associated with persistent small hazard events such as landslides, avalanches, flooding, storms, and also lower scale earthquakes and volcanic eruptions.

The analysis of small disasters illustrates how frequent small disasters, usually as a result of climate variability, increase difficulties for local development and entail a serious problem for the development of a country as a whole. These disasters, contrary to the extreme and extraordinary events, are very often not visible at the national level and their effects are not relevant from a macro-economic point of view. Small disasters usually affect the livelihoods of poor people in rural areas and small municipalities, perpetuating their level of poverty and human insecurity as factors of social vulnerability. In urban centres small and moderate disasters occur in those city zones that historically had the greatest degree of vulnerability.

At present, climate change impacts cause worry to several scientists and some politicians. Particularly the effects related to risk and human insecurity are increasing (UNFCCC 2007; UNDP 1994). However, the risk is growing not only from hazards due to climate variability that are exacerbated by climate change. There are also other risk factors that must be seen with the same thoroughness as the 'vulnerability' conditions and the need of 'adaptive capacity' to the action of the natural hazard events (IPCC 2007; Manuel-Navarrete/Gómez/Gallopin 2007). These are risk factors that have not been perceived well enough due to the lack of systematized information. For this reason, this chapter presents data that illustrate the increase of 'small disasters' or 'invisible disasters'. They are a result of climate variability and the vulnerability increasing from an economic, social, and environmental perspective. These figures illustrate, from a new perspective, that climate change implies a serious problem for disaster risk not only related to the potential of future extreme events but also small and frequent disasters that destroy the livelihoods of the poorest and deepen their incapacity of adaptation, perpetuating their vulnerability and poverty.

From the beginning of 1990's, some researchers in Latin America posed the hypothesis that the effects of small and moderate events, accumulated over time, could be equivalent and even bigger than the impact of big disasters. This hypothesis can be verified through analyses of the losses and damage reported in the DesInventar; database developed by the *Social Network for Disaster Prevention in Latin America* (La RED) and used in this research to evaluate the impact of small disasters This database has been useful to evaluate the number of events, the effects in terms of deaths, injuries, crops and housing destruction, the economic costs, and their comparison to the impact of extreme disasters.

The chapter presents the results of the evaluation of the proneness of Colombia to small scale and chronic disasters, and the type of impact they have for local development, and the country from an aggregated perspective. This analysis detected the spatial variability and dispersion of vulnerability and risk in the country as a result of events that rarely enter the international or even national disaster databases, but which pose an accumulative development problem for

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_31, © Springer-Verlag Berlin Heidelberg 2011

local areas and, given their overall probable impacts, for the country as a whole.

The empirical work made in Colombia to reveal the impact of small disasters in the country is treated in three sections. In the first, the database of small disasters used is described to identify the strengths and weaknesses of the available data and how that information was prepared for this research (31.2). In the second, a conceptual framework regarding the impact of small disasters is presented to characterize the risk associated to this type of disasters (31.3). In addition, in this section, a quantification of their effects and their economic costs are presented to illustrate their relevance due to their accumulated impact and recurrence. The third section presents the conclusions of the study (31.4). They are not only concerning the specific case of Colombia but also other developing countries. Accordingly, new risk concepts have been issued (ISDR 2009): The concept of 'intensive risk' to refer to the concentrated risk manifesting infrequently in specific locations, and the concept of 'extensive risk' to refer to the diffuse risk manifesting frequently over wide territories.

31.2 The DesInventar Disaster Database

DesInventar[1] offers simultaneously a database to elaborate a historical inventory of disasters and a methodology for their analysis. It consists of a software that allows to gather, systematize, organize, and consult information recorded in the system both from a spatial and temporal point of view, and an information capture and analysis methodology that especially emphasizes these aspects:

- *DesInventar* analyses disasters as a set of adverse impacts on lives, goods, infrastructure, and social relations caused by the interaction of socio-environmental and anthropogenic phenomena in given vulnerability conditions. It includes from those disasters very few effects (i.e. destruction of a house or five affected people because of crop loss caused by a frost) until those with large effects (such as the Quindío earthquake in Colombia, 1999).
- Disasters materialize in communities and their environment. The scale of resolution of the observation of disasters affect the vision and understanding of them, therefore they should associate with various spatial scales, both to perceive small and 'invisible' disasters as an expression of daily risk construction, and to decompose those disasters that affect large areas with multiple and different effects that are singular for each affected community.
- Information that record the exposition, vulnerabilities, and risks conditions at all scales must be constructed as variables and indicators that should be as much as possible homogeneous both in terms of effects and in trigger effects. There should be a common language aiming at a compromise between rigorous definitions and the comparability of data at a continental scale.
- The resolution of the inventory offers information for the municipality or territorial level comparable with other countries. A local or regional inventory with a more detailed resolution can be made. This information is also gathered with a lower resolution (e.g. for a department or country).

DesInventar Colombia has been initiated, and maintained, refined and updated as a part of the Project *DesInventar* of La RED by the *Observatorio Sismológico del Sur Occidente* (OSSO) since 1994. It records information from 1914 to 2002, with a total of 23,386 entries. The information used and analysed in this chapter covers a 32-year period (1971–2002) and are based on 19,202 entries. In the databse *DesInventar*/Colombia, as in other existent disaster databases, the information compiled does not pretend to shape the universe of disasters that historically have occurred. In the best case, it is a wide sample of disasters, limited by the characteristics of the information and its sources, permanently subjected to debugs and complements and, therefore, it is not free of errors.

With regard to the sources three significant aspects can be distinguished in the case of Colombia:

a.) Until 1995, the principal source of database were newspaper archives, with an emphasis on national newspapers (*El Tiempo* and *El Espectador*) and, in some cases regional papers (*La Patria of Manizales*, *El Colombiano of Medellín* and *Cali's*). Irrespective of the quality of the information there is a bias in gathering information that privileges

1 Detailed information on the conception, methodology and use of *DesInventar* is at: <www.desinventar.org>, especially on the methodology and the user manual. The work by LA RED-OSSO for UNDP-ISDR on: "Comparative analysis of disaster database EmDat-DesInventar" of January 2003 may also be consulted at: <www.desenredando.org>.

Antioquía, the coffee-growing zone, the Valle del Cauca and Bogotá/Cundinamarca, compared with other regions of the country. For other regions only cases are recorded that were reported in national newspapers ignoring the regional press. This implies that the quality of the recorded information on the regions is unequal.

b.) Since 1995, the main source has been provided by *Disaster Prevention and Attention Directorate of Interior Ministry* (DPAD), and has been complemented with information from the media. As the DPAD does not register 'all events' but only those which require national support, this information coverage is probably more significant for small and medium municipalities and for those departments with few resources (Costa Atlántica, Caquetá, Meta, Arauca, Casanare and Santanderes) than for big cities and the rest of the country, although press information contribute to reduce that slant.

c.) Information on national territories (e.g. Orinoquía and Amazonia with few inhabitants and very far from the national centre) is practically inexistent for this period.

d.) Due to the origin of information and representatives of sources, information on regional capitals and intermediate cities (bigger than 100,000 inhabitants in the census of 1993) is more complete than for the remaining municipalities).

In summary, weaknesses and problems with the data have been recognized and to some extent corrected or compensated for, as to be discussed on the next section. On the other hand, different factors must be considered for an appropriate analysis:

a.) It is important to have available strong or robust variables such as: type of the event that caused a disaster; date of occurrence and geographical location of the event. There are other less robust variables but useful for an analysis like number of dead people, number of destroyed and affected houses, and number of casualties and affected people as it results from the comparison with other databases, such as EmDat/DesInventar (La RED/OSSO 2003), that provide data on. The affected crop hectares can be also aggregated.

b.) In quantitative terms these less robust variables may present different problems (additional or generic 'prejudgment' of newspaper information) that require a permanent assessment of data and their analysis:

- The data from journalists often do not come from proven sources (and often contrast this information with other official sources of fire brigades, the red cross, civil defence, and 'technical and scientific' such as by Ingeominas (Colombian Institute of Geosciences and Mines) that produced studies or from other newspaper archives).
- Official sources that 'inflate' data due to certain political interests (e.g. the 'lathe operation' of the government (1994–1998) at the Atlantic Coast), are difficult to correct but may be compared with other non official sources.
- Errors in data compilations.

c.) Furthermore, not all entries contain the same information due to the type of damages (e.g. if there is no damage to houses but to bridges), or no quantification of them (a 'lot of damaged houses'), probably if the original information only includes certain variables and not others (e.g. logically, damaged houses must have a corresponding number of casualties or affected people, although they do not belong to anybody and nobody lives there, and it does not always appear).

d.) Particularly the affected people often include high numbers that in 99 per cent of cases refer to the inclusion of the affected population that stayed one or two hours, or one or two days without supply of basic services (e.g. two million people lacked electricity in Bogotá).

e.) From a spatial perspective, as the information is organized by municipalities, three problems may occur: a) some records are taken at regional level and municipality is not defined; b) some records are taken at a lower municipal level (commune, road); and c) some municipal divisions change and it is not possible to know which records correspond to which municipality.

31.2.1 Preparation of the Database

Information was compiled based on 19,202 records for 1971–2002 reflecting limitations mentioned above. After a validation of the data based on these criteria these variables were analysed:

1. For affected people, data from a suspension of public services (1,500,000 affected people in Medellín due to a power blackout for two hours, for example) were excluded.
2. A value for affected people was given to entries on destroyed or affected houses. These estimates

tried to be conservative assuming that only one family lived in each destroyed or affected house.

3. Given the disparity of criteria for differentiating between casualties and affected people, it was assumed that both cases (except for those referred to above) were about direct effects of diverse scales or intensity and therefore they were integrated in one variable.
4. Other detected problems dealt with the geographical location of an event and computation errors were corrected.
5. The used database includes an assessment and complementation by La RED/OSSO. This has been useful not only for this study but also for other ongoing research with the *Inter-American Institute for Weather Change* (IAI) and the *Programme of Disaster Risk Management Indicators* of the *Institute of Environmental Studies of the Inter-American Development Bank* (IDB-IDEA).

After the database was updated and adjusted the information was analysed to confirm the relevance of small and moderate disasters and their accumulated impact compared with extreme events from 1970 to 2002, and for all municipalities where effects of the impact of local disasters were recorded. A hypothesis is that the effects from small and moderate events, accumulated over time, could be equivalent and even bigger than the impact of big disasters (La RED). This hypothesis can be verified through analyses of the losses and damage reported in the *DesInventar* database. However, some requirements are desirable, namely:

a.) Information in available records is incomplete. The sources of information do not always include damage or loss values. In many entries some variables are only expressed qualitatively (e.g. approximately 35 per cent). In some cases numbers are recorded, but in other cases only general effects were noted).
b.) As the information on the entries is not homogeneous, only damages and loss categories are considered for the number of deaths, affected (injured) people, destroyed houses and the number of affected crop hectares.
c.) These data cannot be considered as definitive; they are approximated, and only compare effects with reported damage and losses of big disasters.
d.) This analysis has focused only on small and moderate events excluding figures on big disasters.
e.) Given the type of information, analysis of damage and loss accumulation from small and moderate events is compiled for the national level.

Throughout these 32 years Colombia was affected by several local events that oscillated between small and moderate (table 31.1).

Table 31.1: Number of small and medium disasters in Colombia (1971-2002). **Source:** *DesInventar* database, La RED (2004).

Period	Number of events	Percentage of total
1971-1980	5,226	27.2
1981-1990	5,405	28.1
1991-2000	7,063	36.8
2001-2002	1,508	7.9
1971-2002	**19,202**	**100**

31.3 Small and Moderate Disasters

Disaster implies loss and damage and subsequent impacts that the affected community is unable to absorb or to cushion the effects and recover using its own resources and reserves. The concepts of vulnerability, or predisposition to be affected, and resilience, or capacity of recovery and adaptive behaviour, enter to play an important role due to their significant relation with the possible occurrence of disasters. Hence, disaster is a social context or process, triggered by a natural, technological or anthropogenic phenomenon, which in interaction with a susceptible medium causes intense alterations in the normal functioning of the community. Regarding disasters some processes require special attention. These include population growth, rapid urban development, international financial pressures, degradation of the earth, global warming, and environmental change and war. To take but a limited number of examples, urbanization processes have been an important factor in damage caused by earthquakes in urban areas; population increase helps to explain increases in the number of persons affected by floods and prolonged droughts; and deforestation increases the chances of flooding and landslides (Wisner/Blaikie/Cannon/Davis 1994; Birkmann 2006). Adhering to the hypothesis that the lack of development and vulnerability are correlated, and considering that the lack of capacity to cope, recover, and adapt is

also a factor of vulnerability, particularly taking into account the climate variability and change, Cardona (chap. 3) suggests that vulnerability originates in physical fragility or exposure; the social, economic, and ecological fragility; and the lack of resilience or ability to cope and recover. Seen from this human or social perspective, any understanding of vulnerability also requires careful consideration of the factors or contexts that contribute to human and livelihood vulnerability: the security or insecurity of buildings, infrastructure, and environment; the nature of institutions and social organizations; the levels of income and welfare, etc. These explicatory factors do then become a fundamental part of the equation and understanding of human or social vulnerability.

Risk regarding small disasters usually is not considered as relevant, nevertheless small disasters are a social and environmental problem with big implications. These events are primarily related to persistent hazards such as landslides, avalanches, floods, forest fires, droughts, and so on resulting from socio-ecological processes associated with climate variability and environment deterioration that affect, in a chronic way, the most fragile socio-economical low-income population in rural as well as in urban areas. In general, small and frequent disasters prevent the sustainability of local human development and they reveal in which areas of urban centres the vulnerability is growing and where new hazards or the exacerbation of the already existing hazards are occurring due to inadequate environmental, social, and economic processes.

Taking into account the abovementioned and the report of Marulanda/Cardona (2006) the concept of *intensive risk* refers to concentrated risk manifesting infrequently in specific locations and the concept of *extensive risk* refers to diffuse risk manifesting frequently over wide territories (Maskrey 2008). Global disaster databases and risk indexes reflect principally patterns of *intensive risk* given that *extensive risk* is largely invisible from a global level of observation. *Extensive risk* patterns only become visible from a national level of observation and a higher resolution, and thus have consistently been ignored. Due to this invisibility *extensive risk* has not been a driver of disaster risk reduction, which has focused primarily on saving lives and mitigating against major economic loss. A central hypothesis of the ongoing *2009 ISDR Global Assessment Report on Disaster Risk Reduction* is that whereas mortality and economic loss risks tend to be *intensive*, asset risks in sectors such as housing and agriculture are more *extensive* in character and have pervasive, negative impacts on the livelihoods and lives of poor urban and rural populations. Through testing this hypothesis the Global Assessment Report will make the case for strategies to address *extensive risk* to become central to both disaster and poverty reduction, as well as to climate change adaptation.

Small and moderate disaster analysis, and the definition of large events, create diverse methodological problems, especially two: a) the problem of a threshold from which a disaster is considered as large, and b) given the effects of an event (e.g. an earthquake) on different territorial units, which of these effects should be included or excluded in an analysis of small and moderate disasters, given the singular impacts registered in each unit (i.e. a municipality alone[2]). Without pretending to have an answer to these two problems, the analysis should be inclined to exclude from the database the information of effects related to large disasters. Taking into account the preparation of the database and the difficulties to identify all potential wrong data by a detailed analysis and, particularly, the shortcomings due to several disputed figures of affected people and affected hectares of crops, an outlier (or an extreme value) identification process defining arbitrary thresholds was applied. Although the direct selection of large disasters is an acceptable procedure, the definition of a large disaster is a problem if a systematic approach is attempted. The process of identification of outliers[3] detected the extreme main effects of large hazard events, but their small or moderate effects were considered and the selection should be based on the size of the effects and not because the effects were made by a 'recognized' hazard event.

31.3.1 Effects Caused by Small and Moderate Disasters

In Colombia, for the period from 1971 to 2002, the emergency database (EM-DAT) by the Centre of Epi-

2 The *DesInventar* database contains the information of effects by municipality and not by event.

3 Outliers are obtained using statistical and data mining techniques. Criteria for extreme values were chosen, taking into account when the value in each case could be considered as very large. This means, that the effects in a municipality are considered extreme when they are usually visible or notable at the national level. The values considered as extremes are the following: *Dead people*: more than 500 people; *Injured people*: more than 1,500 people; *Affected houses*: more than 4,500 houses; *Destroyed houses*: more than 2,500 houses; and *Destroyed crop hectares*: more than 80,000 hectares.

Table 31.2: Gross figures of effects as a result of small and moderate disasters. **Source:** *DesInventar* database, La RED (2004).

Period	Deaths	Affected	Destroyed houses	Affected houses	Damaged crop hectares
1971-1980	2,964	204,393	18,588	16,604	327,497
1981-1990	3,812	608,180	19,754	16,044	738,743
1991-2000	2,394	871,374	50,465	163,051	964,450
2001-2002	305	61,584	4,353	21,376	144,023
1971-2002	9,475	1,745,531	93,160	217,075	2,174,713

Table 31.3: Effects per local event on average. **Source**: DesInventar database, La RED (2004).

Period	Death	Affected	Destroyed houses	Affected houses	Damage crop hectares
1971-1980	0.57	39.11	3.56	3.18	62.67
1981-1990	0.71	112.52	3.65	2.97	136.68
1991-2000	0.34	123.37	7.14	23.09	136.55
2001-2002	0.20	40.84	2.89	14.18	95.51
1971-2002	0.49	90.90	4.85	11.30	113.25

demiology of Disasters of the Catholic University of Louvain (chap. 40 by Guha-Sapir), lists at present 97 events that fulfil at least one of these criteria: a) 10 or more dead people; b) at least 100 affected people; c) emergency state has been declared; and, d) international assistance has been required. Summarizing, it is about events that in some way have attracted the attention of authorities or news reports. That is, it deals with visible disasters. However, beyond these notable disasters, there are hundreds, even thousands of events that occurred in the same period which were not listed in these statistics of international organizations on this subject. According to the *DesInventar* database in Colombia more than 19,000 events occurred during the same period. This number of events contrasts considerably with 97 events listed by the EM-DAT disaster database. Therefore, a gross assessment of damages and losses caused by small and moderate events in Colombia from 1971 to 2002 using the *DesInventar* indicates that they have not been marginal. Table 31.2 shows that close to 9,500 dead people, almost 2 million affected people, 93,000 destroyed houses and 217,000 affected houses, as well as close to 2 million destroyed crop hectares were the result of an accumulation of this type of disasters.

During the 1990's, there is both an accumulation trend of larger number of effects and greater records of occurred small disasters. In this period, with exception of the number of death people, the largest damages and losses occurred. They have been much bigger than the average registered by local events during the 32 years studied, as is illustrated by table 31.3.

In table 31.3, the last line shows the overall average values for the whole studied period. The losses and damages related to death people, affected people and destroyed crop hectares of decade 1981–1990 were above average of the period of 32 years, while for the period between 1971 and 1980 only the number of death people by event were above the average of the whole period. A comparison of annual averages for the three decades and for 2001–2002 shows that the latter offers very high values for only two years against periods of ten years.

As the quality of data are similar since the 1970's, the trend towards an increase in the amount of damage and losses by small disasters throughout these years can only be explained by two factors: *first*, the growing of the intensity and recurrence of hazard events; *second*, the increasing vulnerability and volume of exposed elements. The rise of hazard events is detected particularly in some hydrographic basins resulting from the environmental degradation and perhaps due to the gradients of climate variability (i.e. climate change). Taking the growing population and urbanization during the past 40 years into account, a growth in the volume of exposed elements and in their vulnerability can be observed. In any case, it can be argued that the increase and accumulation of risks in Colombia are consequences of rising natural and socio-natural hazard events that are due to the devel-

opment model the country has implemented and maybe due to climate change.

In comparative terms, the accumulation of damage and losses induced by small disasters during the whole period is notable. If they are compared with the biggest disasters Colombia suffered during the past 32 years – i.e. the Nevado del Ruíz volcanic eruption in 1985 and the Quindío earthquake in 1999 – the figures cannot be undervalued as shown in table 31.4.

Table 31.4: Comparison between the effects due to small and extreme disasters**: Sources:** *DesInventar* database, La RED (2004), and report on small disasters for National Department of Planning, ERN-Colombia (2005).

Type of damages and losses	Nevado del Ruíz eruption (1985)	Quindío Earthquake (1999)	Small disasters (1971-2002)
Deaths of people	24,442	1,862	9,475
Affected people	232,546	160,336	1,745,531
Destroyed houses	5,402	35,949	93,160
Affected houses	NA	43,422	217,075
Damage of crop hectares	11,000	NA	2,174,713

Although the number of deaths in the volcanic disaster of 1985 represents an extraordinary event that exceeded predictions of any specialist at that time, the accumulation of deaths caused by small disasters over time also tend to be an elevated figure. It represents 38.8 per cent of the deaths that occurred in Armero and Chinchina through the volcanic eruption. The number of affected people from small disasters is 7.5 times those of large disasters, and this amounts to almost 11 times the figure of the Quindío earthquake of 1999 which severely affected the whole coffee-growing region. Taking the total of destroyed houses into account, the figure for small disasters represents more than 2.5 times the total of destroyed houses in the Quindío earthquake and more than 17 times the destroyed houses in Armero and Chinchina. The houses affected by small disasters are 5 times as high as those for the Quindío earthquake.

31.3.2 Economic Cost of Small and Moderate Disasters

In terms of economic cost the recorded losses from small and moderate local events are very significant. If two categories of economic losses (damaged houses and crop hectares) are considered, the total amount accumulated for 32 years of study exceeds 1,650 million dollars according to table 31.5 of this total, 35.1 per cent corresponds to the amount of destroyed and affected houses and the other part (64.9 per cent) corresponds to the amount of damage from crop hectares.

Table 31.5: Estimated cost of losses and damage caused by small disasters, in 1,000 US$. **Source:** Based on the methodology of the IDB-IDEA Programme of Indicators, IDEA (2005a/b).

Period	Losses in houses	Losses in crops	Total
1971-1980	68,217.00	98,249.10	166,466.10
1981-1990	78,424.50	295,497.20	373,921.70
1991-2000	385,892.33	578,669.70	964,562.03
2001-2002	47,127.42	100,816.45	147,943.87
1971-2002	579,661.25	1,073,232.45	1,652,893.70

This approximation is useful for estimating the magnitude of losses and to make general comparisons.[4] Although in the case of affected crops overestimates are possible due to the valuation of errors or to the difficulty of estimating the real surface affected, it can easily be observed that losses in the agricultural sector are very important, although they are hardly visible.

These are hypothetical values and they neither correspond with real reconstruction expenditures nor to any coverage of losses made by the government. The value of any destroyed house is assumed as the average cost of a social housing unit according to the ex-

4 Methodology proposed by the Risk Indicators Project IDB-IDEA was applied for calculation of losses caused by small disasters. In the case of houses, the total of destroyed houses plus affected houses, where 4 affected houses correspond to a destroyed house has been considered. Estimation of loss is made assuming reconstruction a social interest house (average number of square meters by value of square metre constructed of this type of construction in each period) and without the cost of land. For the case of the loss estimation of crops, it was obtained based on the average cost of the typical hectares of crops in the flooded zones by total number of affected hectares.

isting standards in each country (number of square meters) during the period of analysis. And, the value per square meter of social housing is equivalent to one legally established minimum salary during the same time period. On the other hand, it is proposed that the value of one hectare of crops be calculated on the basis of the weighted average price of usually affected crop areas, taking into account expert opinion in the country at the time of analysis. In most of cases, neither any formal reconstruction programme was made nor any government loans or subsides for reconstruction or recovering have been paid to the affected people. Although these estimates are not accurate, the figures refer to the magnitude of a problem that is worrying and often overlooked. Most affected people come from low-income communities with scarce resources that do not receive any recovery aid from the government when this type of events occurs. In addition, they are recurrently affected by these small disasters at the local level, losing their livelihoods. While this chronic situation may not be relevant from a macroeconomic point of view, it perpetuates their poverty and the underdevelopment of the country. This is a worrying situation as the adaptive strategies of low-income communities are less effective and unsuccessful at present, and because disaster resilience is now diminished to cope with the effects of climate change and climate variability.

Based on the data in tables 31.2 and 31.5 it can be clearly observed that the losses have grown over time in a different way if they are compared with the respective number of events. Thus, between the 1970's and 1980's the number of events grew only by 3.42 per cent but the losses occurred had an unexpected increase of 224.6 per cent. Whereas the increase of events from the 1980's to 1990's was 130.68 per cent, the losses had an extraordinary growth of 257.96 per cent. The importance of these figures expressed in monetary terms can also be seen if the average cost of each recorded event is considered. The average cost for each event for the decade of 1971 to 1980 amounted to US$ 31,853, for the period from 1981 to 1990 it was US$ 69,181, and for 1991 to 2000 it was US$ 136,566.

A comparative analysis of losses caused by small events and some of the recognized extreme disasters with the massive destruction that have occurred in Colombia is useful to assess the impact that small and moderate events have had over time. According to figures of table 31.6, the material losses in current million US$ caused by small disasters during 32 years are 6.7 times the losses caused by the Nevado del Ruíz volcanic disaster in 1985. Even the aggregated losses during the decade (1981–1990) due to small disasters are 1.5 times the losses caused by the same disaster in Armero and Chinchina.

Table 31.6: Losses of extreme hazard events, in current million dollars and in percentage of GDP. **Source:** Extreme events, report on small disasters for National Department of Planning, ERN-Colombia (2005).

Events	Estimated losses	Costs of rehabilitation
Eruption of Ruíz Volcano (1985) Armero	246.05 (0.70)	359.95 (1.02)
Coffee Region Earthquake (1999) Quindío	1,590.81 (1.88)	856.72 (1.01)
Small and moderate events (1971-2002)	1,652.89	NA

NA: It means not available data, but, in most cases, direct investments from State have not been made.

The total of losses from small local events surpassed the material losses caused by the Quindío earthquake in 1999 when the figures of destroyed houses and crop hectares are considered. This means that approximately for every 30 years, the losses from small disasters to housing and agriculture are similar to the losses produced by a large event such as the Quindío disaster. The big difference between the extreme and small disasters mentioned above is that in the first case, any programme of reconstruction has been implemented and significant investments have been made to aid the affected people, whereas in the second case no formal rehabilitation or reconstruction activities have been implemented. This means that people affected by small disasters only in some cases received humanitarian aid but in all cases they did not receive any substantial post-disaster aid for recovery and development.

Nowadays estimates of the economic impact of disasters are very common taking aggregated macroeconomic variables into account, such as the *gross domestic product* (GDP). This has been the approach of the International Financial Institutions as well as of the banks and agencies as the *Economic Commission for Latin America and the Caribbean* (ECLAC). Although it is recognized that the economic losses do not correspond to the real impact of disasters, the economic losses expressed as a percentage of national and sectoral GDP's are certainly useful to illustrate the relevance of small disasters and their impact for

Table 31.7: Accumulated losses of small disasters in million US$ and percentage of the agricultural GDP. **Source:** For the estimate the GDP of the last year of each period was taken using data by the Word Bank (2003).

Period	Losses in crops in current (constant) US$	GDP agricultural sector in current (constant) US$	Losses in sectoral GDP (percentage)
1971-1980	98,25 (172.64)	6,466 (11,352)	1,52
1981-1990	295,50 (689.50)	6,539 (15,257)	4,52
1991-2000	578,67 (758.38)	10,330 (13,358)	5.60
2001-2002	100,82 (138.80)	10,103 (13,909)	1.00
1971-2002	1,073.24 (1,759.32)	(13.909)	(12.65)

Table 31.8: Accumulated losses from small disasters in million US$ and percentage of construction GDP. **Source:** For estimates, the GDP was taken of the last year of each period using data of the Word Bank (2003).

Period	Losses in housing in current (constant) US$	GDP construction sector in current (constant) US$	Losses in sectoral GDP (%)
1971-1980	68.22 (119.87)	1,607.20 (2,824.11)	4.25
1981-1990	78,42 (182.98)	1,993.10 (4,650.58)	3.95
1991-2000	385.89 (505.73)	3,058.10 (4,007.80)	12.62
2001-2002	47.13 (64.88)	3,184.95 (4,354.89)	1.48
1971-2002	579.66 (873.47)	(4.354.89)	(19.92)

Table 31.9: Accumulated losses of small disasters in million US$ and percentage of GDP of Colombia. **Source:** For estimates, the GDP was taken of the last year of each period using data of the Word Bank (2003).

Period	Losses [crops+houses] current (constant) US$	National GDP in current (constant) US$	Participation of losses in per cent of national GDP
1971-1980	166.47 (264.81)	33,400 (53,180)	0,50
1981-1990	373.92 (688.05)	40,274 (74,108)	0,93
1991-2000	964.56 (1,129.24)	83,220 (96,652)	1,16
2001-2002	147.95 (175.94)	84,002 (99,893)	0,18
1971-2002	1,652.89 (2,249.03)	(99,893)	(2.25)

the national economy. In the agriculture sector, for example, small disasters recorded elevated amounts of losses. Table 31.7 shows accumulated losses for the period 1971–1980 that were equivalent to 1.52 per cent of the agricultural GDP for 1980. Furthermore, the impact of small disasters was more significant for the 1980's because the total amount of losses in the sector represented 4.52 per cent of the agricultural GDP for 1990; and it was greater (5.6 per cent) for the 1990's. Losses in the sector have been equivalent to 12.65 per cent of sectoral GDP, constant prices, for the period of 32 years. It is important to say the agriculture is one of the most important sectors of the country's economy.

Table 31.8 shows losses due to the destruction of housing by small disasters in terms of GDP for the construction sector. The amount of losses is considerably smaller than recorded in the agricultural sector, but the impact on the sectoral GDP is quite larger. During the 1970's the losses were equivalent to 4.25 per cent of the construction GDP. In the 1980's it was 3.95 per cent and in the 1990's losses rose to 12.62 per cent. In accumulative terms, damages for housing during the 32 years represented 19.92 % of GDP, at constant prices, in the construction sector. This is another important sector of the economy and employment source in Colombia.

Finally, at an aggregated level, the impact of small disasters has been significant. According to table 31.9, the total of losses for the construction and agricultural sector caused by small disasters during the period of 32 years represents 2.25 per cent of the national GDP for 2002, in constant prices. This is significant taking into account that losses caused by the

Quindío earthquake represented 1.88 per cent of the national GDP of 1999.

Given these figures for small disasters, it is difficult to refer to disasters without any impacts; furthermore among the estimated losses the cost of damage for the infrastructure (i.e. lifelines, facilities, roads, bridges, etc.) and for productive sectors (industry, commerce, electricity and others) were not included.

These figures are not only significant in quantitative terms but they offer evidence that confirms the hypothesis that recurrent and accumulated effects of damage and losses by small disasters can be equivalent and in many cases even larger than by those caused by extreme disasters, whose correlation or simultaneousness of effects are very visible. Even though these small disasters continue to remain 'invisible' and they are not considered as events of concern. The data that were given above illustrate the relevance of these disasters, because they indeed represent a worrying risk situation that exists in all Latin American countries.

31.4 Conclusions

The experience with the application of *DesInventar* for other Latin American and Caribbean countries has given extremely positive results when a wide view is used of the type of events that most frequently appear in these countries. So far the Colombian case study represents the most complete effort to apply this tool and the deepest analysis because it has not only allowed to describe the frequent types of disasters affecting the country, but also to identify in some cases their causes and effects, the high priority attention zones, and the impact small disasters have caused for the economy of specific sectors and at the national level as well.

Small disasters are usually not very relevant from macroeconomic perspective because they are usually not important for contingent liabilities and for fiscal sustainability of a country; this is the reason why they are very often ignored. However, small disasters are certainly relevant from social and microeconomic point of view and; therefore, they should not be ignored by the policy makers and planners.

The main objective of this chapter has been to analyse the results of an evaluation of the proneness of Colombia to small scale and chronic disasters, and the type of impact they have on the local development and for the country from an aggregated perspective. This analysis has detected the spatial variability and dispersion of risk due to events that are rarely recorded in international or national disaster databases, but which pose serious and accumulative development problems for local areas given their probable overall impacts for the country as a whole. In addition, the growing number of small disasters and their effects illustrate that the adaptive strategies of poor communities are less effective now as result of the recurrent destruction of their livelihoods, and due to the reduction of human settlements disaster resilience. Most of these disasters are the result of socio-ecological processes associated with the environmental deterioration and are associated with persistent small events such as landslides, avalanches, flooding, storms, and also lower-scale earthquakes and volcanic eruptions.

With these results it is possible to stress that extreme disasters not necessarily determine the history of disasters. Until now in Colombia the recent history has been dominated by big disasters such as those caused by the Popayan earthquake (1983), the Nevado del Ruíz eruption (1985), the Tierradentro (Paez) earthquake (1994) and the Quindío earthquake (1999). By accepting the relevance of their effects on the population and the economy as a whole, it must also be recognized that each year many small and moderate disasters, that individually do not cause high damages and losses, affect the population and the diverse economic sectors due to their frequency and their accumulated impact over time.

The outcomes of this analysis has been useful for economic analysts and sectoral decision-makers responsible for urban policy development, because they can detect not only the potential impact of extreme events but also the persistence and accumulation of effects of small and local disasters. This stimulates the consideration of risk problems in territorial planning at the local level, the intervention and protection of hydrographic basins, the protection of ecosystems, and the implementation of resource transfer and collective insurance programmes to cover the losses of poor communities. This research reveals that the aggregated impact of small disasters as well as the impact of extreme events also leads to a fiscal exposure and contingent liability for the government to compensate housing and to recover the livelihoods of the poorest people.

32 Climate Change, Natural Hazards and Coastal Ecosystems in Latin-America: A Framework for Analysis

Carmen Lacambra and Kaveh Zahedi

32.1 Introduction[1]

According to the *Intergovernmental Panel on Climate Change* (IPCC), the warming of global climate is now unequivocal. Over the last 100 years (1906–2005), global temperature has increased by 0.74 °C. Global sea level has risen by 17 cm during the 20th century (Rosenzweig/Casassa 2007: 92). Estimates for projected global temperature increases from the 1980's to the end of the 21st century range from 1.8 °C (1.1–2.9 °C) to 4 °C (2.4–6.4 °C) (assuming no additional mitigation measures apart from those already in place in 2000). Global average sea level is expected to rise by 18 to 59 cm by the end of the 21st century (Rosenzweig/Casassa 2007: 92).

As a result of climate change and sea-level rise coasts are projected to be exposed to increasing risks, including coastal erosion. Coastal ecosystems – defined in this chapter as mangrove forests and coral reefs – will be negatively affected. Many millions more people worldwide are projected to be flooded every year (Rosenzweig/Casassa 2007: 109).

Densely-populated and low-lying coastal communities like those in much of Latin America where adaptive capacity is relatively low and which already face other challenges such as tropical storms or local coastal subsidence, are especially at risk (Magrin/Gay Garcia 2007: 599).

At the same time coastal ecosystems can potentially provide an important service in helping coastal communities adapt to a changing climate and rising sea levels. Although the coastal defences provided by these ecosystems have long been acknowledged (Lacambra/Moeller/Spencer 2008b), there is not enough information available on the conditions and thresholds needed for coastal ecosystems to adequately protect coastal areas. Furthermore most of the information available has been derived from experiments and observation in Asia, while the potential role of coastal ecosystems as coastal defences in Latin America has been largely overlooked.

This chapter provides an overview of climate change, natural hazards and the role of ecosystems in adapting to these in Latin America, focussing on seven tropical continental Latin-America countries: El Salvador, Nicaragua, Costa Rica, Panama, Colombia, Venezuela and Ecuador.[2] It begins with an overview of the natural disasters and their consequences (32.2). This is followed by a brief analysis of the state of coastal ecosystems, specifically mangrove forests and coral reefs, the services they provide to coastal societies, and the impacts of natural hazards and climate change on these ecosystems (32.3). It then reviews existing assessments of vulnerability to climate change and natural hazards (32.4). In conclusion, a framework is proposed for the analysis of how coastal ecosystems respond to, cope with and react to climate change and natural hazards and of the potential role such ecosystems can play in helping coastal communities adapt to the consequences of climate change and increased natural hazards (32.5). Preliminary conclusions are then presented from the application of the framework in the seven Latin-America countries (32.6). Although the proposed framework is best applied at the local level, this chapter provides a regional integrated overview of the topics described above and their interrelationship to highlight the importance of including the natural environmental perspective in vulnerability assessments (32.7).

1 The authors wish to thank UNEP-WCMC for providing the ecosystems distribution data and Dr. Iris Muller, Dr Tom Spencer, Mario Palacios, Martha Vides and the anonymous reviewers of this chapter for their thoughtful comments and contributions.

2 These countries were selected due to their geographical position, presence of the selected coastal ecosystems and their diverse coastal geomorphology.

32.2 Natural Disasters in Coastal Tropical Latin America

The IPCC reports that future tropical cyclones (typhoons and hurricanes) are likely to become more intense, with larger peak wind speeds and more heavy rainfall (Rosenzweig/Casassa 2007: 109), leading to greater waves and further floods both from the sea intrusion and freshwater channels. In Latin America the expected increases in *sea-level rise* (SLR), weather and climatic variability and extremes are very likely to affect coastal areas. Adverse impacts would be observed including on low-lying areas, coastal morphology, mangroves (e.g., in Ecuador, Colombia and Venezuela), availability of drinking water (e.g. on the Pacific coast of Costa Rica and Ecuador) (Magrin/Gay Garcia 2007: 583). In order to understand the consequences of increased intensity and possibly frequency of climatic events, it is important to understand current and historical consequences of similar events considering the ability of coastal systems to react to such events.

Tropical Latin America and the Wider Caribbean are regions with a high propensity to natural climate and non-climatic extreme events. Hurricanes, floods, tsunamis, earthquakes, and volcanic eruptions have all been a common feature in the region since records begun. Table 32.1 shows the proportion of natural disasters occurred in coastal areas in the seven selected countries and table 32.2 lists the most common climate related natural disasters along the Caribbean and Pacific coasts of the seven selected countries. Figure 32.1 and 32.2 show the countries of scope and the distribution of population, ecosystems and natural disasters reported along the coastal areas.

Most of the recorded events (table 32.2 and figure 32.2) refer to the late 20th century. It is important to note that an increment in numbers of records could in part explain the increasing incidence of reported events and similarly when comparing between countries a greater number of records could also be related to a greater national capacity to report events rather than to a larger number of events *per se*.

Nevertheless even considering only recent years where records are more reliable (due to the construction of databases and improved measurement techniques), natural disasters have become more frequent. During the past 30 years there have been over 30 disasters per year in the Wider Caribbean region (which includes the selected countries with the exception of Ecuador) causing 226,000 fatalities. That is 7,500 deaths per year and at an annual average cost of

Figure 32.2: Distribution of population, coastal ecosystems and natural disasters reported along the seven selected countries. (Features are not represented in scale). **Sources:** Population (ESRI); events (developed by the authors from DesInventar and own research for the years 1498-2000); mangrove forest (UNEP-WCMC 1997) and coral reefs (UNEP-WCMC 2003).

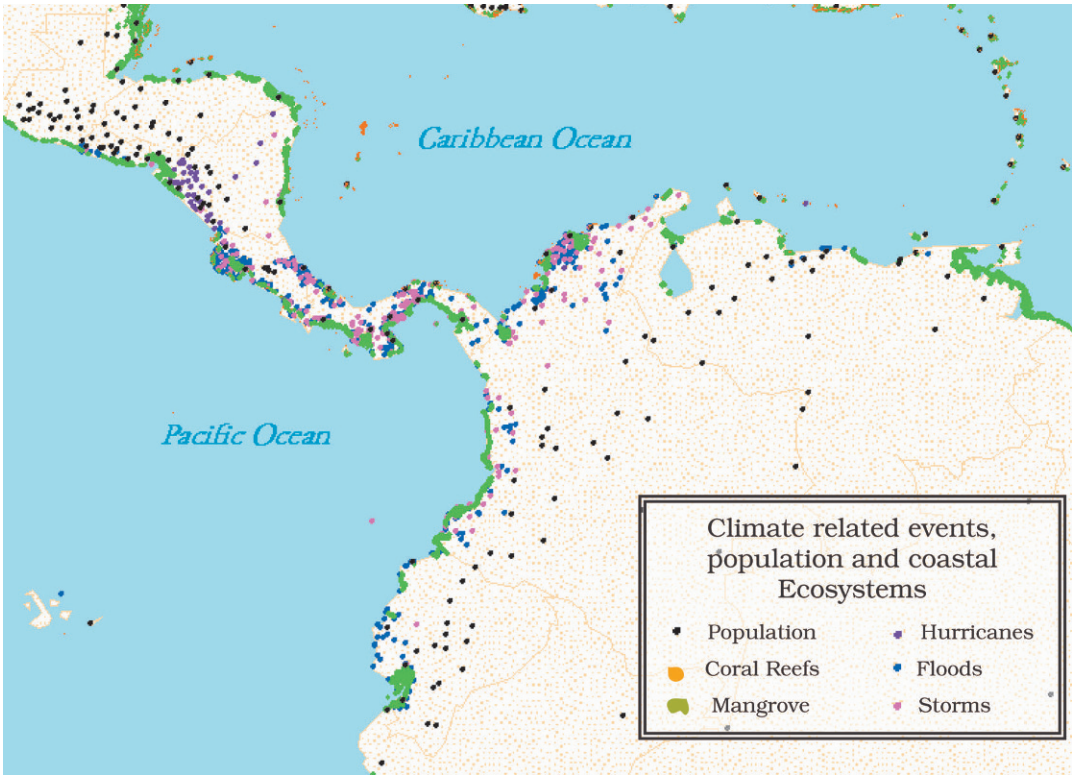

Table 32.1: Number of Natural Disasters reported in the seven selected countries since 1498 until 2002. **Sources:** Lacambra/Möller/Spencer, 2008: 89 and based on the DesInventar database, version 2005 and literature review.

Country	National events	Coastal events*	Coastal municipalities	Selected events	% of total in coastal areas
EL Salvador	955	450	102	80	8
Nicaragua	146	73	49	49	33.5
Costa Rica	5569	2021	1787	1679	30
Panama	2456	2456	2076	1086	44
Colombia	17569	9921	3337	3032	17
Venezuela	795	777	245	154	19
Ecuador	2458	1387	1122	571	23
Total	29948	17085	8718	6651	22

Legend: *National events* include all events despite their origin reported for each country. *Coastal events** include all those events in the 1st order of administrative division. *Coastal municipalities* include those events at the 2nd order administrative division. *Selected events* include those events in coastal municipalities that are of natural origin. *Percentage in coastal areas* refers to the proportion of natural events reported in coastal municipalities with respect to the national reports.

a DesInventar is a public database produced with support of UNDP, La Red and maintained by the Observatorio Sismológico del Sur-Occidente (OSSO). DesInventar (2005): <http://www.desinventar.org/desinventar .html> (7 December 2005).

Caribbean	249	306	43339	48.6
Total	512			

between $700 million and $3.3 billion US dollars (Chaveriat 2000: 10).

Table 32.3 summarizes the consequences of climatic and non-climatic events along the coasts of the selected countries. With the projected increase of the number and intensity of such events due to climate change, Latin American countries are highly vulnerable to these extreme weather events and related natural disasters. Some countries have made efforts to adapt, particularly through conservation of key ecosystems, strategies for flood, drought and coastal management. However, the effectiveness of these efforts is outweighed by a lack of basic information, observation and monitoring systems; lack of capacity-building and appropriate political, institutional and technological frameworks; low income; and settlements in vulnerable areas (Magrin/Gay Garcia 2007: 583).

32.3 Coastal Ecosystems

Sea level rise as a consequence of climate change and the projected increase of extreme climatic events will have a severe impact on the region's coastal zones. The ability of coastal ecosystems to adapt to a changing climate and rising sea levels depends not only on their physical and geomorphologic conditions but also on the level of intactness or degradation of the ecosystem (Invemar 2003; Gilman 2004: 10; Ellison 2004: 34).

Several studies have stated that ecosystems act as coastal defences (UNEP-WCMC 2006: 14; Sudmeier-

Explanation: Ellison/Farnsworth (1996) with estimates for 1990. (a) Figures in this column correspond to the first record reported by FAO (2003a). For each country different figures are shown in parenthesis; references that were consulted by FAO (2003a) include for Salvador (Cueva 1961); Costa Rica (FAO/UNEP 1978); Nicaragua (Direna 1983); Panama (Maci-FAO 1969); Colombia (IGAC 1966); Venezuela (Mac 1961); Ecuador (Clirsen N.d.). The total regional figure refers to the Wider Caribbean Region and to Latin America.

Rieux/Masundire/Rizvi/Rietbergen 2006: 1, 8, 14, 37; Burke/Maidens 2005: 56). It is therefore important to consider the ecosystem services of coastal protection provided by coastal ecosystems as part of the adaptation strategies to climate change.[3] This section presents a brief analysis of the distribution and state of coastal ecosystems (mangrove forests and coral reefs) in the countries of scope, the ecosystem services they provide and how consequences of climate change are likely to affect them.

32.3.1 Mangroves (Distribution, State, Uses and Services)

The area of mangrove forests along the shorelines of the seven selected countries is estimated to range from 11,821 to 21,307 km^2 (table 32.4).

There are some discrepancies among these figures due to both inaccuracies and the use of different methodologies, which do not allow a detailed comparison of the different estimates. But there is a clear trend indicating that the distribution of mangrove forests has decreased substantially over the past 40 years. Reliable area estimates have only been produced since the early 1980's; there are, however, estimates from the 1970's and 1960's that enable us to observe a massive loss of mangroves in the region, particularly in Venezuela and Panama (Ellison/Farnsworth 1996: 551).

Mangroves have been exploited for several purposes since pre-colonial times: building material, fuel and food sources (either by cultivation or extracting), fishing gear construction, utensils construction and associated to important fisheries. Extraction remained and increased with the colonization period,

3 Ecosystem services were defined by the *Millennium Ecosystem Assessment* (MA 2003: 49) as: "Ecosystem services are the benefits people obtain from ecosystems." Coastal ecosystem services and their interactions have been studied by Moberg/Rönnbäck (2003: 30); Turner/Brouwer/Georgiou/Bateman (2000); Adey (2000); Ewel/Twilley/Eong Ong (1998) among others, considering the importance of biodiversity, of specific species relationships, of species richness and resilience and, the need of proper restoration.

Figure 32.6: Deteriorated mangrove in Cartagena (Colombia). **Source:** Archive El Universal (September 2008).

vast areas of mangroves were also cut for tannin production until the 1950's (Lugo 2002: 10; Ellison/Farnsworth 1996: 552; Majluf 2002: 19).

The clearance of mangroves for shrimp cultivation has become one of the greatest threats to the ecosystem globally. Within the region, Ecuador has successfully created an industry out of it; during the 1990's the country's revenues from shrimp exports were second, only after oil (Lugo 2002: 10). There are also examples on the sustainable use of mangroves in the wider Caribbean region, particularly in Trinidad, Venezuela, Puerto Rico and Florida (Lugo 2002: 10; Ellison/Farnsworth 1996: 558).

Historically mangroves have been seen as dumping grounds or reclamation areas for rural and urban development. Several cities along the Caribbean and Pacific coasts developed on mangrove areas including the greatest coastal cities in the region: Cartagena, Guayaquil and Maracaibo (Lugo 2002; Alvarez-Leon/Polania 1996; PNUMA 2005). Nowadays mangroves

Table 32.5: Status of coral reefs in Central and South America. **Source:** Modified from Wilkinson (2004).

Region	Coral reef area (km^2)	Destroyed reefs (%)	Reefs recovered and destroyed in 1998 (%)	Reefs in a critical-stage(%)	Reefs at a threatened stage (%)	Reefs at a low or no threat level
Central America	4,630	10	NA	24	19	47
South Tropical America	5,120	15	NA	36	13	36
TOTAL	284,803	20	6.4/16	24	26	30

are still claimed for habitat purposes. Consequences of human activities can be summarized in area loss and changes in hydrological and soil conditions (Figures 32.4, 32.5, 32.6 show different mangroves along the Colombian Caribbean coast.

There are also studies on the economic value of mangroves and their use for coastal protection in Asia and reports on the protection role for communities in Bangladesh and India, but not for the Latin American region. Castiblanco (2002: 39) valuated mangrove forest along the Pacific region of Colombia adding up to 50000 $US dollars per hectare; however the study did not include their role as natural coastal defences.

32.3.2 Coral Reefs (Distribution, State, Uses and Services)

Estimates of global coral reef area vary between 255,000 km^2 (Spalding/Grenfell, 1997: 226) and 284,300 km^2 (Spalding/Ravilious/Green 2001; UNEP-WCMC 2006: 7). Majluf (2002: 14) reports that 26 per cent of global corals are concentrated in Latin America and the Caribbean region.

Although there are still some healthy coral reef communities, the majority of them are under serious risk. According to Bryant, Burke, McManus and Spalding (1998: 21) and UNEP (2000: 44) 29 per cent of the reefs areas in Latin America and the Caribbean region are at considerable risk. Gardner, Côté, Gill, Grant and Watkinson (2003: 958) report a reduction of 80 per cent of hard coral cover in the Caribbean region, 10–50 per cent of which has occurred during the past three decades.

Over-fishing threatens more than 60 per cent of the region's reefs. Additionally, coral populations in the Caribbean have been affected by a series of diseases since 1983. Diseases have affected all coral reef communities but seem to be more intense in those areas where corals are affected by pollution and sedimentation. Estimates of up to 35 per cent of the reefs in Latin American and Wider Caribbean region are affected by pollution and sedimentation; the latter is particularly common in both the Pacific and the Caribbean coasts and enhanced by deforestation (Spalding 2004; Burke/Maidens 2005: 27; Wilkinson 2004: 460).

Coral reefs have been used since pre-colonial times as sources of food and utensils. Nowadays, many communities in the region continue depending on fisheries, crafts, industrial and recreational activities. In some locations, because of the volume of material on sale, such activities may have an important impact on the reefs (Spalding 2004). Recently corals have been harvested and are now reproduced artificially for pharmaceutical companies that have found anti-inflammatories, inmunodepresents, antiviral and other chemical components in different reef species from the Caribbean (Spalding 2004). Burke and Maidens (2005) reports land filling in Panama and Wilkinson (2004: 482) reports the exploitation of reefs at the Pacific coast in Salvador for cement production.

Coral reefs are natural breakwaters to ocean waves and mangrove forests disperse the energy of arriving waves; however this protection capability depends on each ecosystem status and ecological and physical characteristics (Kabdali/Turker 2002: 153). Cesar, Burke and Pet-Soede (2003: 10) calculated the value of coastal protection by coral reefs along the Wider Caribbean coast, excluding the USA, at approximately 1.3 billion US dollars. Adding fisheries, tourism and recreation and the value of biodiversity figures reached almost 4.0 billion US dollars. The value of coral reefs for coastal protection was also estimated by Burke and Maidens (2005: 14) who gave a similar figure of 700–2.200 million US dollars per year and including the entire Wider Caribbean Region estimates of up to 420 millions of US dollars of annual losses were calculated as a consequence of the coral degradation in the region.

32.3.3 Impact of Natural Hazards and Climate Change on Coastal Ecosystems

The impacts of natural hazards were examined as part of the coastal ecosystems' dynamics[4] and of damages and responses to hurricane impacts.[5] The damage to corals varies with the orientation and position of the substratum and the size and characteristics of exposed corals.[6] Lugo, Rogers and Nixon (1999: 106) conclude that highly structured coastal ecosystems can develop in spite of the constant destructive action of hurricanes. For Rogers, Suchanek and Pecora (1982: 542) the intensity, type, and duration of the stress influences the impact to reefs and their recovery times.

The effects of hurricanes Allen (1981), Hugo (1990), Andrew (1992), and Mitch (1998) on ecosystems were reported in greater detail, most of such reports were on Florida.[7] In summary, the broad consequences of impacts to coastal ecosystems described in these studies include: a) for corals: bleaching, breaking, rooting out and burying; and b) for mangroves: defoliation, tree breaking, detached vegetation, sedimentation, massive tree mortality, delayed mortality, species turnover, change soil characteristics, selective pressure on organisms, siltation.

Hurricanes are the most recurrent cause reported to explain massive mangrove mortalities worldwide; however, other causes include tsunamis, floods, impoundment, runoff diversion, subsidence, hyper-salinity, frosts and pollution (Jimenez/Lugo/Cintron 1985: 179). All of which, with the exception of tsunamis and pollution, can directly or indirectly be related to consequences of climate change.

The impacts on the Mesoamerican reefs have been concentrated mostly on anthropogenic disturbances. Although natural hazards are considered, these events and their impacts have not been a main topic of concern so far. Hurricanes can temporarily cause dramatic sea level rise. In 1961, hurricane Hattie swept Belize with winds up to 320 km/h and destroying reefs that took more than 20 years to recover (Stoddart 1974). However, the strength and altitude of waves are not the only hazard for reefs; rains associated with hurricanes and storms lead to an increase of the sedimentation in areas close to the river mouths (Burke /Maidens 2005: 36).

Coral reef bleaching has been used as a direct indicator of climate change impact on living environments, as the increase of bleaching events has been related to rising sea surface temperature. However, not all thermal related stresses can be attributed to climate change. Changes in sea temperature are also attributed to the El Niño event and seasonal changes. [8] Regarding sea level rise as a consequence of climate change, studies report more concerns related to the pressure of human impacts on the ecosystems rather than from climate change as such. Healthy and undisturbed reefs would have a greater chance to cope and adapt to a greater depth and to reduced light conditions. Although there are adaptation models, still there are other major pressures that would not allow reefs to migrate (Walling/Creary-Chevannes 2005; Vides/Sierra Correa 2003; Wilkinson 2004: 468; IDEAM 2001). In summary, some of the projected consequences of climate change on coral reefs include: decrease in growth as a consequence of higher temperatures, bleaching and more physical damage caused by more intense and frequent storms (Hoegh-Guldberg 1999; Wilkinson 2004; Buddemeier/Kleypas/Aronson 2004: 14; Burke/Maidens 2005: 33).

Nevertheless most scientific information available on the impacts of hurricanes on mangrove forests has been based on three events: Mitch, George, Joan and Andrew. Hurricanes Mitch and Joan were the only ones impacting on Central America and mangroves in both coasts were impacted in different ways by them. Coral reefs in San Blas in Panama and Bahia Chengue in Colombia were impacted by hurricanes Allen (1980) and Lenny (1999) respectively (Lacambra/Moeller/Spencer 2008b: 11). At the global level and in particular for this region key questions regarding the processes and capacity of coastal ecosystems to absorb forces that are a product of natural events still remain valid and there is still much research needed.

32.4 Vulnerability and Climate Change

Coastal areas will be under more pressure from the combination of increasing climatic events and rising sea level on the one hand, and growing populations and demand for resources on the other. Without integrated policies involving land planning in accordance with local physical dynamics, prevention and attention to disasters and climate change, consequences of climatic events (tables 32.1, 32.2, 32.3) are likely to increase; resulting on greater damage to human populations and their livelihoods and to ecosystem services previously described which are not yet fully valued and understood.

For this reason it is important to take into consideration both the national strategies to address climate change in order to understand priorities and capabilities as well as the impacts of climate change in coastal areas. Policies and national strategies are described at the end of this section. Impacts of climate change in coastal areas have been assessed through vulnerability assessments only at the local level, in very specific areas and often disintegrated to other events[9].

Climate change will have an influence on natural climatic events in the region and to understand its potential damage on population, infrastructure and natural environment it is important to also understand current processes and dynamics and the different ways they can be affected as well as their coping capabilities: "As climatic changes occur, natural resource management techniques can be applied to increase the resilience of ecosystems, key uncertainties exist that limit our ability to project climate change impacts on ecosystems."[10]

It is not the aim of this chapter to present a discussion on the different concepts and approaches to vulnerability in the region, but rather to contribute to those approaches from an environmental perspective considering the physical processes involved in natural events along coastal areas and historical changes in the landscape, either natural or man-made. Table 32.6 presents 20 parameters/indicators most commonly used to measure a coastal community or a region's vulnerability to climate change, natural hazards, and poverty.

Among them are only seven indicators that are related to the natural environment and to the geomorphologic dynamics of a region. From those seven indicators, only 3 have been used in the region: erosion, dependence on the environment and protected areas.

9 According to the IPCC "vulnerability is the degree to which a system is susceptible to, and unable to cope with, adverse effects of climate change, including climate variability and extremes". "Vulnerability is a function of the character, magnitude, and rate of climate change and variation to which a system is exposed, its sensitivity, and its adaptive capacity" (IPCC 2007c: 883).

None of which really reflect the systems' resilience[11], nor their vulnerability or capacity to cope either with climate change or any of the natural events. The natural environment has not been considered in many territorial and landscape planning initiatives despite the region's dependence on this environment.

Thanks to La Red[12] and its publications, there is a regional platform for information exchange that is increasingly being used by a greater multidisciplinary audience. This platform has allowed researchers and policy-makers access to disaster management analyses, concepts, statistics and impacts of disasters on the society across Latin America.

Natural events have normally been analysed independently, and possible interrelations between events have not been considered. At the national and local level there are some initiatives mostly related to the El Nino phenomena. Some national institutions involved with disaster prevention and attention were created to attend affected populations during El Niño years and encourage research on this event. The ENSO affects both the Pacific and the Caribbean coast, despite the fact that most of the published information seems to be targeted at the Pacific Ocean. However, analyses integrating land use changes over time with historical or recent climatic events in coastal areas remain still scarce. Recently Nicaragua, Colombia and Panama have included risk assessments as part of their coastal municipalities territorial planning. All initiatives originated from national environmental authorities. Al-

11 Resilience as defined by the IPCC: *The ability of a social or ecological system to absorb disturbances while retaining the same basic structure and ways of functioning, the capacity for self-organization, and the capacity to adapt to stress and change*. IPCC (2007c: 880).

12 La Red is a network of professionals working on social studies in natural disasters prevention in Latin America since 1992. <http://www.desenredando.org/>.

though these are still pilot initiatives the aim is to implement such plans nationally.

32.5 Framework for Analysis

Climate events and natural hazards are part of the region's physical dynamics; however, unstable institutions and economies, concentration of people in vulnerable areas and the lack of planning mechanisms, increase even more the region's susceptibility to natural disasters and the consequences of climate change (Cardona 2003; Chang 2004: 22; Lavell 1999; PNUMA 2005).

The IPCC reports a great uncertainty regarding climate change and its impacts on the region and recognized the need for integrative vulnerability studies for preserving biodiversity and ecosystem services already pressured by changes in land use (Fischlin/Midgley/Price/Leemans/Gopal/Turley/Rounsevell/Dube/Tarazona/Velichko 2007), coastal areas are particularly in need of this type of analysis.

Considering the above, the proposed framework aims to provide a tool that assesses coastal areas' vulnerability to the impacts of climate change related to SLR and changes on climatic events intensity and frequency, at the local level. The model has been constructed from an environmental perspective acknowledging the interrelations between the environment and communities surrounding it or/and depending on it. Furthermore the model has been built considering the existing information in the region.

The authors acknowledge the existence, value and accuracy of coastal vulnerability frameworks used globally and in the region such as by Szlafsztein (2007) in Brazil; by Ortiz Perez and Mendez Linares (2006) in Mexico; by Klein and Nicholls (1999) and Kaiser (2006) at the global level. The proposed framework integrates these results. This type of information is feeding it and the way it integrates them and the historical analysis contributes to the existing knowledge.

Components of vulnerability are broad and interrelated. To ease data gathering and understand some interrelations this model classifies the impacts and responses in different components and for each one a series of indicators and parameters have been proposed. For description purposes, the components of vulnerability in this approach are: human-cultural, economy, policy, bio-physical and infrastructure. As an environmental perspective, the environmental component is much more developed than any other one; however, the same approach can be applied and branches developed for the other components as well.

The natural environment provides goods and services to communities transforming it and using it according to their needs, social structure, traditions, and economic activities. At the same time communities create social networks, institutions and policies that regulate exploitation and uses of the natural environment, among other activities within a society. Hence despite the apparent division on the components there is constant feedback and interrelation between them.

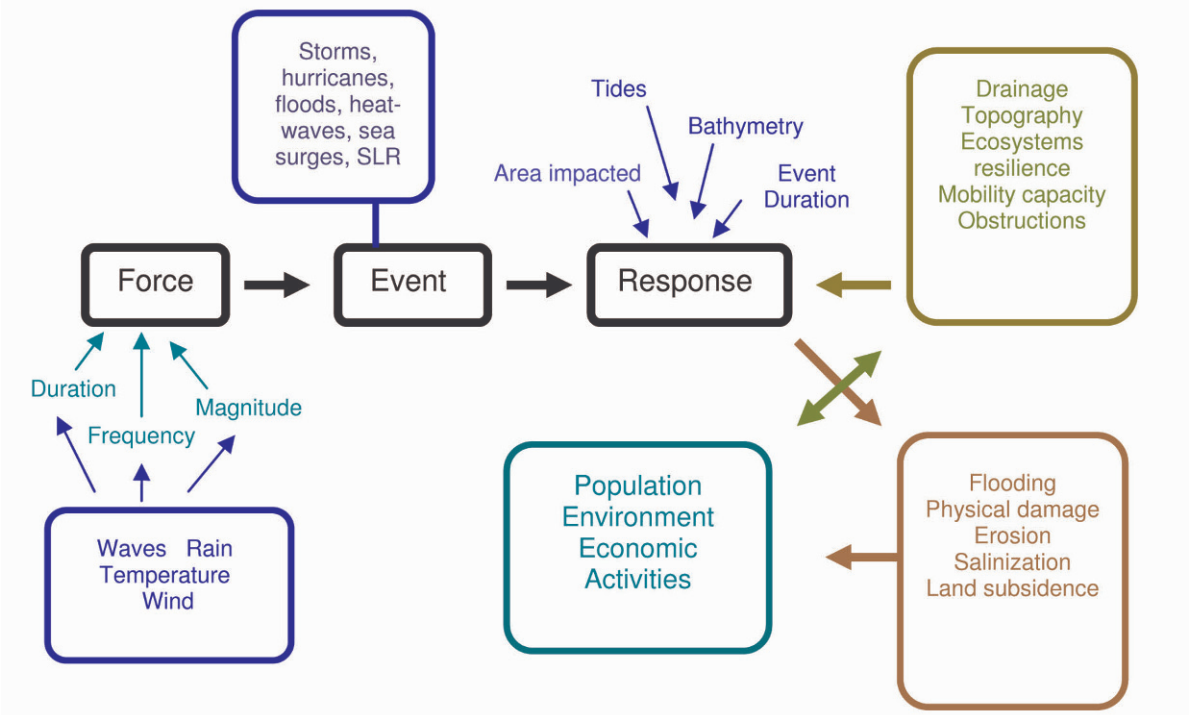
Perhaps regionally the most important consequences of climate change in coastal areas are sea level rise and its consequences and the change on frequency and intensity of natural disasters (Magrin/Gay Garcia 2007). If at the moment the physical dynamics of natural disasters are poorly understood within the region, the possibility to address more frequent and more intense events in the future is smaller. The same reasoning is applied to each natural system's capacity to respond (natural or man-made). There is an intrinsic capacity to resist natural forces in each system; if their current capacity to respond to actual events is unknown it will be further more difficult to plan for prevention for the short and long term.

This approach is based on the FER (*Force Event Response*) model, described in figure 32.7. It is a summarized representation of the forces affecting coastal areas, with or without climate change and of the potential consequences from the geophysical perspective. One force or the sum of them, originates natural events that become hazards and potential disasters. Despite of the origin of this force being a hurricane, a storm, severe rains etc, the system is having an impact upon which it will respond, as illustrated by Holling's (2001: 5) resilience model.

Depending on the characteristics of the system there can be no response, a complete change, and a temporal change. In the coastal areas the consequences of the forces of these natural events are flooding, physical damage, erosion, saline intrusion and land subsidence. These consequences will have an effect on human communities inhabiting coastal areas as well as on any activities developed there. However, as coastal areas have been transformed the impact of such forces does not only depend on an area's biogeophysical dynamics but also on those transformations.

In figure 32.8 these relationships are simplified in terms of information gathering. Each component has intrinsic capabilities independent of the occurrence of

Figure 32.7: Force Event Reponses (FER) applied to climate related events in coastal areas. **Source:** Modified from Lacambra/Moeller/Spencer (2008:84).



The Force Event Response (FER) diagram represents the different forces impacting on the coastal areas in the region, together with possible responses and physical and natural characteristics that will influence these responses. Impacting forces and responses vary with each event. This particular FER represents those forces influenced by climate change.

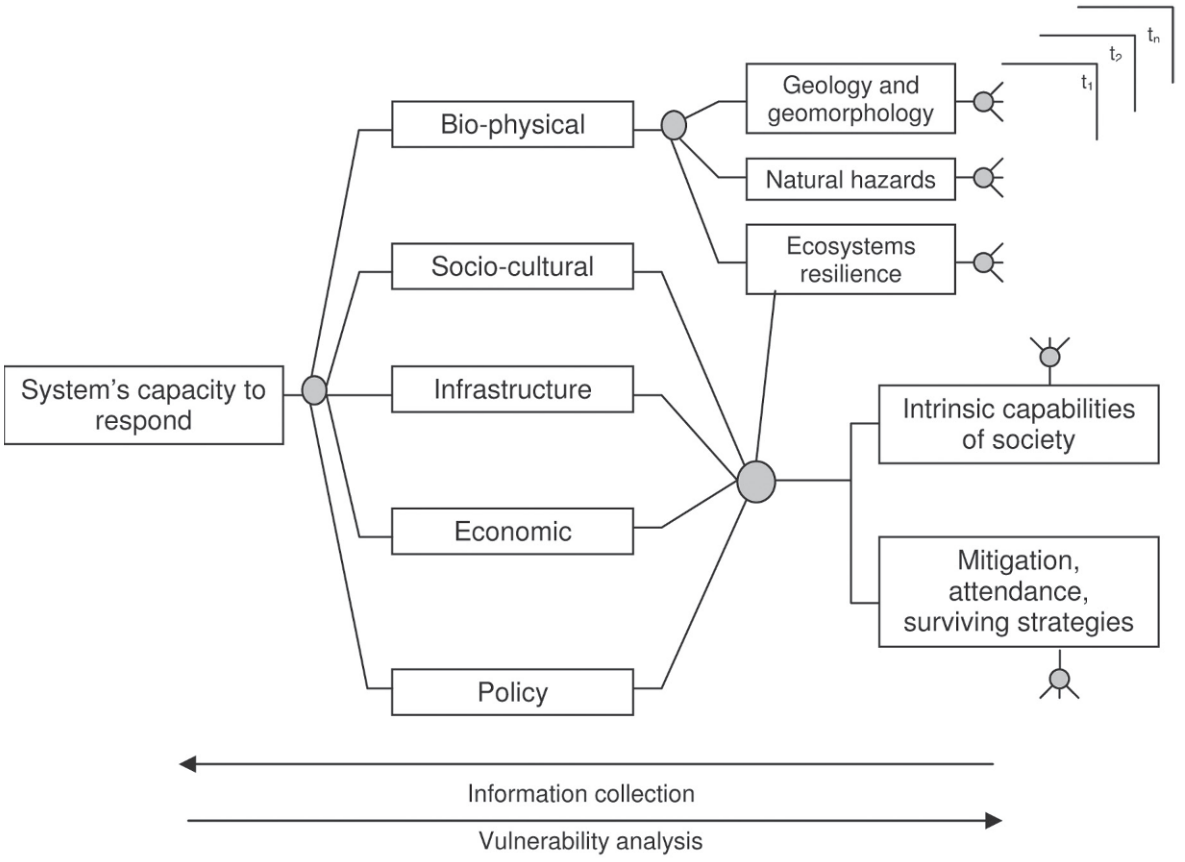
climate change and disasters that make the system more or less vulnerable. Also each component has a series of strategies to mitigate or to respond to each particular event. Biophysical responses to natural events have been classified into four categories: drainage, topography, the system's mobility capacity (migration) and ecosystems resilience. There are other physical characteristics on the impacted area, and related to each event that also influence on the responses: area, natural hazards, frequency, duration, bathymetry, and tides.

Parameters related to the ecosystem's resilience have been selected according to the ecosystem's intrinsic capacity to defend itself. The ecosystem's health for it determines its capacity to respond, defend and recover from an event and pressures on the ecosystems affect the intrinsic defence and health of these ecosystems.

It is at the local level that an integral vulnerability assessment considering ecological and physical variables is addressed. This is due to the type of indicators used and their change through time which are normally particular to each area. Each locality's development, economic activities, population distribution and governance policies (in relation to ecosystems, planning and disasters/risk) is considered. In order to establish the present vulnerability in each particular site, and for it to be comparable to the site itself, the same parameters are applied to different stages of development in history in the assessed area. The model applied to the same site in different historical settings allows identifying current and past drivers of vulnerability and its changes through time.

The model has already been validated at the local level in two study sites on Cartagena in the Caribbean and on Tumaco in the Pacific coast, both in Colombia. Because information from different disciplines and qualitative and quantitative information are treated in the same way the application of the framework requires expert knowledge of the area, ground proofing of information and holds a certain degree of subjectivity. However, it represents a good tool to understand the factors influencing an area's vulnerability. It allows the user to distinguish between those fac-

Figure 32.8: Decision tree, information collecting and vulnerability assessment. **Source:** The authors.



tors that are directly related to the natural events and those that are linked to the communities inhabiting such areas. The strength of the method is that it uses simple, basic information and expert knowledge from the area, as well as the processes (physical and human related) that have contributed to a site's vulnerability through time. The method introduced here can be used for several periods in history, covering centuries, decades or years. For the particular case studies applied, much of the change has been attributed to the past 50 years, perhaps if more detailed information existed for the other periods (1500's, 1800's and early 1900's) changes within each period could be as noticeable as those reported recently.

32.6 Preliminary Results

The primary conclusions here have resulted from a broad scale integrated analysis using the framework. Far from disagreeing with current approaches to climate change in the 7 countries analysed the authors' view is that these strategies should be complemented with climate change impact assessments. It is at the local level that climate change consequences will be felt and planning mechanisms ought to be aware of the possible consequences of climate change in order to provide feasible solutions to local communities. Other relevant facts summarized in table 32.8 and resulting from the integrated analysis have been outlined below:

- More than 30 per cent of the regional population inhabits coastal areas directly exposed to extreme climatic events.
- Approximately 70 per cent of coastal population in the region is rural or inhabits towns or cities smaller than 1 million people.
- These coastal areas represent 13,242 km of shoreline or roughly 45 per cent of the 7 countries' perimeters. They also report 25 per cent of events, most of which are
- related to floods resulting from rain, storms, or rains upland causing floods in coastal areas.
- Almost 85 per cent of the reported events (a total of 5,588 events) occurred between 1980 and 2004.

68 per cent of the reported events that are related to climatic factors have occurred during the past 25 years. 93 per cent of deaths have been caused by climatic events, but less than 7 per cent of climate related events reported deaths. Non-catastrophic events such as rains and floods caused by severe or long rainy seasons have caused almost 90 per cent of victims in the coastal areas.

- The most commonly reported effects of climate-related events are injuries and loss of life, as well as damage to crops, houses and infrastructure.
- The increase in population and urbanization during the past 30 years along coastal areas has contributed to an increase in reported events. However, the increase in reporting can also be the result of improved recording methods on such events.
- 90 per cent of reported natural disasters are related to climatic events.
- Floods account for 50 per cent of the events reported in coastal areas, while deforestation along river basins directly impacts on floods in lowland areas. With greater precipitation and less forest cover, coastal floods are likely to be more frequent.
- Considering that approximately 70 per cent of the coastal population within the 7 selected countries is rural or inhabiting towns and small cities with less than 1 million people[13] and, despite the fact that the natural environment supports and provides livelihoods to these coastal communities, the damages it suffers as a consequence of extreme events are very rarely reported; nor are direct damages, such as those damages to the services the ecosystems might provide (source of food, water and shelter).

32.7 Conclusions

There is a need to understand the regional consequences of climate change at the bio-geophysical level in coastal areas, in particular considering that natural events related with climate will be more frequent and more intense. Although countries have produced policies for disaster prevention, understanding of the physical forces driving these events and their relationship with the landscape and the natural ecosystems does not seem to occur. Understanding of these dynamics as well as other coastal dynamics will lead to a better implementation of current policies and a more rapid adaptation to climate change.

Among the issues needed far greater attention are directed to the following problems:

- More policy analysis is needed on how best to address the consequences of climate change in coastal areas, especially as an integral part of *Coastal Zone Management* (CZM) strategies.
- There is a need to understand the physical processes involved with coastal events, their interrelationship with climate change and the role of natural ecosystems, and to integrate that information with corresponding policy; i.e. independent of climate change, adequate land planning is required for preventing natural disasters.
- Although consequences of sea level rise have been accounted for at the local level in all seven countries, there seems to be a lack of integration between climate change policies and policies on natural disasters, between climate change and ecosystem policies and between environmental and

13 This figure has been calculated from the National Populations Census, considering those coastal cities with population greater than 1 million people and that are directly impacted by coastal hazards.

natural-disasters-related policies, at least in coastal zones. Confronting climate change requires a more integrated and cross-cutting policy approach than on any policy issue in the recent past.

- All seven countries are highly diverse countries and promote and protect their biodiversity through their respective environmental authorities. While ecosystems and the biodiversity they contain have been acknowledged as an important issue, the services provided by such ecosystems are not well known. There is a need to enhance research on the services provided by coastal ecosystems and integrate it with vulnerability analysis on coastal areas.
- There is a need for research on the regional, national and local resilience of coastal ecosystems to the different natural events. While there are studies in other regions of the world, the region's geomorphology, oceanography, climate and natural environment are different and could produce equally different results.
- The inclusion of environmental indicators in vulnerability analysis, for coastal hazards, is a good tool to understand past events; how they have modelled the current landscape; and how the natural environment can protect against some forces of climatic events or ameliorate such forces before they reach populations.
- There is a need to include the impact of natural events in coastal areas into climate change research and policies. There is a regional need to elaborate SLR assessments at the national level with updated information that takes into account the coastal dynamics of each particular site.

Despite the uses and services provided by coastal ecosystems and the various initiatives for their protection, mangroves and coral reefs are being degraded at great speed. If these coastal ecosystems are not in a good condition, they might not be able to respond to climate change and its impacts and to help the region's coastal communities protect themselves and adapt to a changing climate.

33 Flood Loss Redistribution in a Third World Megacity: The Case of Mumbai

Monalisa Chatterjee

33.1 Introduction[1]

Loss redistribution[2] is an embedded coping[3] mechanism that plays a significant role in sustaining low income populations during times of crisis. Mumbai provides evidence of existing and emerging loss redistribution practices that may be representative of slums in many other Third World mega cities. In Mumbai slum, populations typically have access to more than one method of loss redistribution, depending on a variety of socio-economic factors, to assist in the recovery process after floods. The study identifies these socio- economic factors that impact the type and number of sources available to affected households and in turn also serve as an indicator of resilience in these communities.

Loss redistribution is widely believed to be one of the primary strategies used by members of poor societies to cope with the effects of natural hazards like flooding (White/Burton/Kates 1978). However, apart from anecdotal evidence (and limited case studies in which hazard loss is not the main focus), little is known about the salience, structure, function and varieties of this strategy as it is actually practiced (Basu 1997; Baydas/Bahloul 1995; Goetz/Gupta 1996; Sumarto/Suryahadi/Pritchett 2003; Zeller/Sharma 2000). The main objective of this chapter is to identify and analyse examples of contemporary flood loss redistribution networks in slums of Mumbai, India.[4] This will: (1) add to the growing body of research on the role of social capital in human sustainability; and (2) permit an assessment of the potential of these informal networks for broader use, perhaps in formal systems of flood vulnerability reduction and flood hazard management.

The main hypothesis guiding the research is that individual poor households affected by floods have access to a wide range of alternative support networks that provide important – though often overlooked - cushions against hazard impacts. This chapter is based on decades of research by geographers on vulnerability and human adjustment to environmental perturbations where research suggests that humans choose suitable coping measures influenced by such factors as social structure, past experiences, available resources, pools of information, cultural preferences, and individual capabilities of members, among others (Blaikie/Cannon/Davis/Wisner 1994; Mitchell 1989a; White/Burton/Kates 1978; Wisner 1998). These adjustments span a wide range of choices from the structural to the behavioural, from the anticipatory to the reactive, and from those that are employed by private individuals to those that can only be practiced collectively by governments, businesses or civil organizations (Mitchell 2008).

The initial section of the chapter (33.2) provides background information about flood loss redistribution in the context of natural hazards research. This is followed by a discussion on monsoon-related flood problems, urbanization and vulnerability of poor populations in Mumbai, India (33.3). Interim findings on flood loss redistribution among slum dwellers are outlined (33.4) and results are elaborated (33.5). These provide the basis for more general conclusions based on the research completed to date (33.6).

1 The author is grateful to Prof. James K. Mitchell for his valuable inputs and suggestions.

2 Loss redistribution is a process by which losses suffered by affected population is shared by local, regional and global societies. It has its formal and informal forms. Ability to redistribute losses reflects the capacity to cope, recover and adapt for specific communities.

3 Coping is a capacity to respond and recover from something stressful, e.g. disaster.

4 It forms part of a doctoral dissertation on 'Urban Flood Loss Sharing and Redistribution Mechanisms among the Impoverished Industrial Population of Mumbai' Department of Geography, Rutgers University.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_33, © Springer-Verlag Berlin Heidelberg 2011

33.2 Loss Redistribution and Hazard Risk

Capabilities in loss redistribution have been a strong factor in defining vulnerabilities for different communities in developed and developing countries. In the United States, human adjustments to floods by loss redistribution were introduced in the 1940's when White (1945) and later others (Kates/Burton 1986a, 1986b) shifted attention from engineered methods of controlling floods to land use planning and effective adjustments by people living in floodplains. This perspective emphasized the rational behaviour of affected individuals in reducing losses by better land use and redistribution policies. However, in a developing country context this approach is altered as rational behaviour among affected households is constrained by socio-political, economic and cultural factors (Robbins 2004; Smith 2002). Under the influence of structural forces and its impact on entitlement (Oliver-Smith 2004), hazard vulnerability and resilience in communities of developing countries is a function of economic, socio-political, infrastructural, ecological and personal assets (Bohle, 2001). Here resources rely on the social, political and economic networks of support and loss sharing (Nathan 2009) and studies show that access to various social networks also plays a significant role in developing people's self perception of their vulnerability (Dershem/Gzirishvili 1998). Redistribution of hazard losses can be part of a formal risk mitigation system like flood insurance in the United States (Burby 2001) or a more informal embedded system where losses are shared among interlinked (Baydas/Bahloul 1995) and interdependent communities (Basu 1997).

In developing countries of Latin America, South East and South Asia, low income communities show increasing reliance on the transfer of resources by means of remittances (Adams 1998; Woodruff/Zenteno 2007; Yang 2007). Furthermore, remittances are used by receiving households, especially in urban communities, as insurance against sudden fluctuations of income and related shocks (Yang/Choi 2007).

Urbanization isolates populations as people migrate away from their social setting and relocate themselves in different physical, social and economic environments (Blaikie/Cannon/Davis/Wisner 1994; Keyder 2005; McGranahan/Jacobi/Songsore/Surjadi/Kjellen 2001; Wisner 2003). In the city new migrants, especially the poor, do not reproduce traditional social and economic associations from their rural places of origin, that can be used for support in the event of a disaster (Pelling 2003; Wisner 2003). Although, the process of building social capital in the neighbourhood begins as soon as the migrants move into the settlements, nascent forms of associations are rarely enough to permit adequate disaster recovery, especially when whole neighbourhoods are equally affected. Under such circumstances, slum dwellers – who are the most vulnerable of all exposed groups – make and maintain different types of safety and recovery support networks. These networks are often layered and complex, requiring considerable attention, skills and resources if they are to function effectively (Alexander 1978). When floods threaten or occur, affected populations employ such networks to draw on sources of assistance that are structurally, geographically, socially and economically separated from them. In places like Mumbai, the overall vulnerability or resilience of flood-affected populations depends significantly on their capacity to manage these network affiliations (Moser 1998).

In some rural post-flood situations it has been found that low-income households rely disproportionately on their employers for credit needed to recover from losses. This arrangement is often recurrent and is acceptable to both parties because the entitlement offered by the lender is economically valuable to the employer[5] (Basu 1997). Similar arrangements have been observed in cities where displaced slum inhabitants do not have access to other traditional forms of support. This adds a new layer to the traditional mix of basic social, political and religious arrangements that are found in India. These bridging and linking aspects (Sumarto/Suryahadi/Pritchett 2003) serve to bring population groups of separate social classes and background into direct association (Mitchell 2006). Moreover, in places that are exposed to forces of globalization, individuals can take advantage of new linkages to expand their access to resources permanently, thereby increasing opportunities for safe and sustainable development (Roberts 2005; Sen 1981).

Contemporary global change research interest is to understand how structural forces affect and alter the concept of vulnerability and human security in societies of different regions and distinguish specific communities that benefit and suffer from its impact (Brauch 2005a; IHDP 2005). Furthermore, identification of marginalized communities excluded from

5 Skilled workers offer entitlements like working extra hours, working at subsidized rates. These are economically viable only for employers and not for any other financial or private institutions.

Box 33.1: Mumbai Facts. **Source:** Risbud (2003); Arunachalamn (2005); Gupta (2007).

Total Area = 437.71 km^2
Number of Wards = 24
Total Population = 16,360,000 (2001)
Expected Population = 25,000,000 (2025)
Rate of Increase = 3.7 per cent
Total Slum Population = 54–65 per cent of total population
Topography = Linear central bowl or depression with low lines of hills on either side
Annual Rainfall = 2300 mm (90 per cent in Monsoon season between June – August)
Flood Frequency = Parts of Mumbai are inundated every year
Reasons for Flooding = Low ground levels, dilapidated drains, obstructions of utilities, encroachments along '*Nallas*' (drains), slums along outfalls, increase in runoff coefficients, loss of holding ponds, siltation of drains

emerging layers and networks of safety provide social locations that need strong institutional and state interventions to prevent consequences of discriminations (Chari/Gupta, 2003) and ensure basic provisions of human security.

33.3 Monsoon Floods and Vulnerability in Mumbai

Mumbai is a flood prone mega-city that has fifty four per cent (Risbud 2003) of its population in the informal economy. An event in the recent past illustrates the consequences of excessive monsoon rainfall on such a city. On 26 July 2005, Mumbai and its surrounding areas received up to 940 mm of rain followed by 700 mm during the next two days. This downpour, which was considerably larger than those experienced in any day of the monsoon period in the past hundred years (Arunachalam 2005), resulted in 672 deaths in Mumbai with at least 300 more in surrounding areas (Government of Maharashtra 2005). In addition there was extensive loss of property especially among the inhabitants of low-income communities, many of whom lost all their possessions. Moreover, there was widespread damage to transport and communication systems within the city, as well as public buildings including schools, offices, storehouses of medicines, grains, etc. Commercial activities for the entire city were disrupted for more than seven days. Many observers attributed these problems to haphazard and unprecedented growth of the city into marginal locations that are more severely affected by out of the ordinary natural processes (Mehta[6] 2005; Nariman[7] 2005; Sachdeva[8] 2005; Sekhar[9] 2005). Monsoons in the following years, though of lesser intensity, also reflect the effect of continuous growth and haphazard construction without taking into account the risk of floods in the future (Bhagat/Guha/Chattopadhyay 2006).

Mumbai is representative of many fast-growing and transforming large cities in developping countries like Sao Paulo, Dhaka, Mexico City, Delhi, Jakarta, Shanghai, Seoul, Lagos, etc. (Dawson/Edwards 2004) where low income settlements primarily house the informal sector of the city. In addition to growing informal settlements Mumbai is also witnessing the process of extensive informalization of work and polarized occupation distribution of workers where the division of high and low income classes are further widening (Sita/Bhagat 2007). Mumbai therefore provides a suitable example to analyze the emerging trends of vulnerability and human security in a mega-city that is restructuring away from dependence on industry and towards investment in services.

Vulnerability to hazards in Mumbai is largely a product of the lack of access by poor populations to much-needed affordable low-income housing in the city and suburban areas and lack of participation by these same populations in the making of public decisions about urban development. The impacts of international neo-liberal trends in philosophies of economic investment (e.g. increased private risk-taking, decreased collective welfare payments) have been markedly evident since the 1990's, affecting then mainstream economic sectors like the city's textile industries and typical industrial workers (Rao 2006). Those industries are in severe decline and centrally located industrial and workers' residential areas are now being redeveloped as commercial and high-income residential zones to support the rapidly growing service sector. The final land rezoning decision for the last

1800 acres available for redevelopment in central Mumbai remains to be taken (Correa 2006). However, it is already clear that textile workers and other conventional industrial workers have lost the battle to retain their jobs and homes to opponents comprising a coalition of builders, landowners, and development authorities for the city and state (D'monte 2006). Disintegration of the city's old industries and the advent of a service economy have set the scene for the removal of existing workers. Like everyday incoming immigrants they are being relocated to peripheral residential settlements that lack adequate infrastructure and basic facilities. The global land market has driven up the value of land in central Mumbai to the point where such displacements have the effect of redistributing both the fading middle-income populations and the growing low-income populations. In other words, the levels and locus of flood vulnerability are being shifted to new sites in Mumbai. Here globalization has an immediate effect on the distribution of vulnerability because communities that are not involved in - and hence not connected to - the global system, are excluded from the benefits of the existing local support network. Furthermore, the growing visibility and influence of native *marathi* speaking populations of Maharashtra in Mumbai (Appadurai 2001) has further isolated others from existing support networks. As a result even more disadvantaged sub-communities are segregated within the larger slum settlements that are already generally deprived.

In 2005, floods in Mumbai opened up several public debates about problems of urban planning and development, but very little was done to reduce losses borne by low-income communities. During preliminary fieldwork (in July and August 2005) it was observed that immediate and random distribution of relief in the form of food, water, and medicines is the only assistance the low-income population received at the individual level. Populations that were included in existing local religious, political and social communities had priority for access to relief. This method of disaster assistance had two main disadvantages. First, it increased the dependency of poor communities on municipal authorities and non-governmental organizations that often performed in an erratic manner. Second, alternative larger, more effective and more sustainable networks of protection, that might otherwise have been employed, were not made sufficient use of. As a consequence, flooded local communities received haphazard and usually inadequate attention triggered by political connections and mass media publicity rather than actual need. This conclusion is substantiated by research on similar cases in other developing countries (Bankoff/Frerks/Hilhorst 2004; Pelling 2003).

Since the reliability of the public support system after floods in Mumbai is inconsistent and somewhat limited to providing immediate relief, marginal populations of the city's informal economy are increasingly dependent on ad hoc arrangements that help recovery. These arrangements are individually developed and maintained unlike institutionalized formal support systems. Securing the means to recover was already a serious problem for low income populations before the destruction of the local industries. Now, with large numbers of workers being forced to migrate to the peripheral shantytowns, the inadequacies of this system are being reproduced in a far wider spread of places. Repercussions for the formal sector of society are also increasing.

33.4 Flood Loss Redistribution Measures Practiced by the Slum Population

The analysis of loss redistribution by slum dwellers in Mumbai shows that the flood loss redistribution system of the low income population living in cities of developing countries is a set of diversified and multiple layered complex arrangements. Furthermore, the study confirms that although this system is an effective method of empowerment and loss reduction for slum households in general, there are marginalized population groups left out of these support networks due to internal (cultural, social and political) discriminations or external (labour demands, skill, type of industry) exclusions.

Surveyed respondents comprised workers in the following industries: manufacturing; chemical and pharmaceuticals; engineering goods; printing, packaging and transportation, and construction.[10] The pool of respondents ranged from permanent employees to casual labourers hired as daily wage earners (table 33.1).

On average each household had access to approximately five (4.8) sources of emergency economic assistance in form of monetary support for damage coverage, bonuses, allowances, easy loans, etc. Table

10 Employers have been classified on the basis of markets, for example, industries and factories that produced goods for the international markets have been classified as 'internationally connected' employers.

I. Questionnaire Surveys – 50 Households randomly selected in two flood affected slumsSections in Questionnaire – (For this paper, results from section 1, 6 and 7 are analyzed and presented. Each section contained categorical and open-ended enquiries)
(1) Socio economic cultural profile of the respondents
(2) Characteristics of flood vulnerability including physical vulnerability, infrastruc-ture availability, access to basic amenities
(3) Flood impact, extent of losses, and type of direct and indirect losses
(4) Methods adopted by individuals to immediately survive from floods
(5) Government, NGO and other institutional support or aid and relief received
(6) Access to formal and informal financial facilities, sources of credit and loans
(7) Specific loss sharing mechanisms adopted and sources applied to reduce losses
(8) Awareness and perceptions about insurance coverage for flood losses, insights into the idea of suitable products to redistribute flood risks.

II. Ethnographic study of selected settlements was used to understand and evaluate lifestyle, resources and attitude of slum dwellers about their vulnerability, potential risk from recurrent floods, their perception on the causes of these losses and responsibility for dealing with it.

III. Analysis: Data are grouped by evolving themes and cross-tabulated to develop typologies of practices, processes, choices and opinions. Chi Square tests are used to identify relations between different social, economic and mitigation variables.

a This chapter presents some results of the fieldwork conducted in 2007 in Mumbai.

Total	33	11	3	3	50

33.2 below demonstrates that all 50 households had at least one source of economic assistance (rank 1). The great majority (80 per cent) could draw on up to five sources simultaneously (rank 5). After floods, employers and money lenders are the leading sources of financial help, followed by family members, informal establishments and friends.

It is noteworthy that formal banks and neighbours are the least approached sources after floods as 98 per cent and 92 per cent of households' surveyed chose not to rank them as options. First options of economic support selected by respondents are employers (30 per cent), family members (24 per cent) and local traders (22 per cent). Accepted alternatives that are ranked second are again employers for 26 per cent of respondents, however, family members and local traders are replaced by money lenders (16 per cent) and religious organizations (14 per cent). Employers remain a prominent source of help even as the third option for 22 per cent of surveyed households followed by informal establishments (16 per cent). As the fourth and fifth option, informal establishments turn into an important source. At rank 5 means like arrangements with money lender (28 per cent), family members (22 per cent) are observed to be other leading options of support. Almost two third of the population have used friends as sources of economic assistance, however, friends are not prominent in any specific ranks but are more or less present as a preference in all ranks.

33.5 Findings and Discussion

Collected data clearly indicate that the flood loss redistribution system for slum residents is multiple layered and spatially complex; the same household often has access to several different types of financial support concomitantly and vulnerable populations can avail themselves of assistance from networks at many overlapping spatial scales; these can involve communities that are geographically, socially and economically separate from them. Jewellery shop owners who exchange cash for pawned items and storekeepers who provide goods and credit both are part of exclusively local networks. Networks of self-help groups, religious organizations and informal establishments are local or city wide. Family members and employers are part of networks that can be local, metropolitan or global in scope. Therefore loss redistribution strategies of slum dwellers are affected by internal, local and regional, national and global factors.

The impact of structural forces is evident in the role of employers and deserves further comment. In the contemporary era of global economic restructuring, employers at the city, national and global level have become significant providers of emergency support for Mumbai's hazard affected slum dwellers. This is partly due to the growing ease with which skilled individuals can access easy loans, information and support networks that permit them to leave present employers and set up their own businesses. The indirect impact of globalization in Mumbai therefore has made skilled workers a valuable asset for employers. As a result employers are careful to supply support to their employees to ensure minimum attrition. This inclination, however, is particularly noticeable in the case of permanent workers (with or without contracts) (table 33.3). Cross tabulation of employment type and employer-provided economic assistance shows that employers are the most preferred source of support for 31 per cent of the survey respondents. The statistical relationship (Chi Square test[11]) between employee type and employer-provided economic assistance is also highly significant (^{2}<*0.00*).

Neo-liberal economic policies probably also play a role in encouraging employer-provided emergency support. Employers seem to prefer assisting individual workers to absorb the costs of flooding because this relieves employers of responsibilities to protect entire communities at risk. Moreover, in a mobile labour market, factory owners who are unable to support and retain workers might otherwise be subject to the indirect impacts of the flood hazard (Basu 1997). For the employer, therefore, advancing financial assistance or easy loans to the worker is a form of insurance to assure that the future income is not affected. Hence a common arrangement adopted in Mumbai is

11 The Chi Square test is used in this study to examine if two variables are independent or related. A chi-square probability of 0.05 or less is commonly interpreted as a justification for rejecting the zero hypothesis that the variables are unrelated.

Temporary	1	4	3	2	0	1	11
Total	4	15	13	12	5	1	50

to work additional hours for the employers in lieu of the support forwarded after floods. Approximately 70 per cent of the workers surveyed affirmed working extra hours after floods. However, working extra hours in some cases is not a formal repayment of the loan but a gesture of gratitude and assurance for future support. Among the surveyed population only 63 per cent of the respondents that worked extra hours claimed to have made a formal (written or verbal) contract for financial support and repayment of loan. For the 37 per cent respondents that worked extra hours the arrangement is a matter of understanding between the 'malik' (employer) and the worker. In the later case, workers are more likely to be exploited because the number of extra hours worked could be worth more than the support provided. Furthermore, working extra hours for future aid is also an investment without having the means to claim a repayment because getting support in the future is not in the workers' control but is dependent on the attitude of individual employers.

The practice of seeking assistance from employers appears to be confined to employees of companies that produce goods for non-local markets. Respondents who work in factories that produce local goods for local markets do not get significant economic assistance from their employers. One possible reason for this inconsistency is that local employers do not hire skilled workers and therefore do not need to support them during emergencies to keep them available for later employment. Another reason might be that locally situated employers cannot call on extra-local resources; after suffering flood losses they do not have the means to assist their employees.

The other prominent group that provides economic assistance to slum population is the immediate or extended family living near or abroad. Family members living in other parts of the city are the foremost sources of support for slum inhabitants. This is for two reasons. First, those family members are not likely to be so affected by flooding. Second, because they live relatively nearby these relatives can be contacted quickly in the event of a flood. Applying to and getting support from them is both faster (due to proximity) and more straightforward (because of their heightened awareness) than with other potential sources of support. Furthermore, the relationships with relatives that live in the same city are not only likely to be semi-continuous, they are easier to maintain and available for quick activation when needed. Although there is no clear evidence to show, if these appeals are primarily horizontal (i.e. between siblings or cousins) or vertical (i.e. between generations and those related by marriage), an apparent dependency exists between new migrants and relatives who have been living in the city for some years. Chi square tests show that the association between years of residence and reliance on economic assistance from family members is highly significant for this dataset ($^2 < 0.00$). New migrants are more likely to be located near water bodies and therefore are more at risk from floods in the monsoon. Furthermore, since they are recent settlers they do not have a well-developed aid network to approach and consequently are reliant on older family members in the city or back in the villages. Older migrants (living in the city for more than 20 years) also show a degree of dependence on family members. Often this involves horizontal exchange but where it is vertical, the flow of resources is from younger family members (e.g. people working in the Middle East) to older relatives in Mumbai.

Although employers, family members and local traders dominate the informal loss redistribution system, other agents have also been significant for certain types of marginal populations. Inherent social and cultural factors are important influence on the effectiveness of these sources. For instance, religious organizations are an important source of aid to small ghettos of religious minorities within larger slum settlements (table 33.4). Table 33.2 shows religious organ-

Table 33.4: Economic assistance from religious organization categorized by religion of affected households. **Source:** The author's primary fieldwork in Mumbai in 2007.

Religion of respondent and economic assistance from religious organization	Economic assistance source religious organization ranks (0-4)					Total
	0	1	2	3	4	
Christian	3	0	4	0	1	8
Hindu	29	0	0	0	4	33
Muslim	4	1	3	0	1	9
Total	36	1	7	0	6	50

izations ranked as second and fourth sources by seven and six households respectively. Chi square tests of variables like the religion of the household surveyed and financial assistance from a religious organization are highly significant with $^2< 0.00$. Table 33.4 illustrates a relationship where religious organizations are higher ranked support sources for minority groups of Muslim (44 per cent) and Christian (50 per cent) households. For Hindu households however, it is an additional source of support for only 12 per cent of surveyed households. Religious organizations are most effective at the ward and city level because such associations need to be continuously nourished if they are to be useful. As a result it is noted that 72 per cent of respondents did not avail support from religious organizations.

Informal establishments are in a special category as members need to participate in them for a long period of time before they can approach the members with requests for support. Continuing contribution to the financial pool with other members of the group is essential to be able to use informal networks. Participating in informal arrangements provides extra remuneration and therefore is a common practice among slum dwellers. Collected data indicates that informal establishments provide acceptable sources of loss redistribution and 33 households have used them for additional support after floods. However, they are not the chief network of support for any family. The chi square test shows that religion ($^2<0.00$) and years of residence in the present place ($^2<0.00$) signify an association with the use of informal establishments for support after floods. The results therefore suggest that the cultural and socio economic characteristics of individual households, like religion and the number of years they have been living in the present address, affect their ability of using support from informal establishments to recover after floods.

Self-help groups are the first source of support for 3 families in the survey (table 33.2). Here the financial arrangements among members of the group are more formal in nature because the money is openly accounted for and the affected population is entitled to support simply by joining the association. This offers some advantages because members can claim support first and contribute later, which is the reverse of practice for members in informal establishments.

Results from the study show that both internal and external agencies are important components of the flood loss redistribution system. However, all sources of support are not equally influenced by local and global forces. Type of loss redistribution is reflected in the kind of arrangements observed between the affected and supporting members. Table 33.5 explains the type of arrangements organized by scale. For instance, local traders and money lenders are dominant sources in the local loop of assistance whereas employers and family members are more prominent as the wider circles of support. This distinction further highlights the emerging impact of local and global forces on flood loss redistribution. It also demonstrates the co-existence of traditional and contemporary mechanisms where flood victims use two different types of safety networks simultaneously. Because of the diversity in cultural, social, political and economic groups found in cities the range of alternatives is more complex for urban dwellers than for rural residents. Table 33.5 shows that the transaction is more likely to change from informal to the formal as the victims begin to draw on non-local sources of support. However, a considerable amount of flexibility exists even in the formal circles where both formal and informal arrangements can be made with different types of employees.

Emerging trends show that individuals in slums of cities like Mumbai are connected on many levels with expanding sources of support. The urban environment provides an enhanced degree of complexity in networks which are utilized by affected low income households simultaneously to redistribute their losses. The growing presence of employers in the flood redistribution of slum dwellers illustrates the gradual pen-

etration of private sector commercial institutions into what was formerly a support system that relied mainly on intimate bonds among kin and loosely organized involvement by government or community organizations.

Having access to multiple sources of flood loss redistribution was observed to be directly related to coping and recovery among the affected households. Ethnographic study of the surveyed households demonstrated that households with diversified loss redistribution had regained their prior lifestyle, i.e. had required household assets, children studying in private schools, etc. Furthermore, many of these households were able to adopt structural adjustments like raising the foundation of their rooms, adding a higher platform or second floor to their house to ensure against future losses from floods. While households with access to fewer networks of loss redistribution absorbed the losses by themselves, and therefore were living in degenerated conditions. Type and number of loss redistribution sources were observed to play an important role in defining resilience among slum dwellers of Mumbai.

33.6 Conclusion

In developing countries like India there exist various layers of post-disaster coping strategies and adjustments to hazard and its impact, though the type and mix is somewhat different from those of the more developed world. Among others, observed loss-redistribution adjustments include: resource transfers from family (Morduch 1999); cash or in-kind advances from employers in return for overtime work or extra labour (Basu 1997); community lending and saving organizations (Baydas/Bahloul 1995); social support from community networks (Dershem/Gzirishvili 1998); income diversification (Dercon 2005); and credit from money lenders (Lapenu 2002). All of these loss redistribution measures are operating in Mumbai, often in complex combinations and under the influence of external and internal forces. Indeed, hazard vulnerability in Mumbai is defined by the degree of access to several support networks. Membership in fewer networks adds another layer of complexities that increases the household's vulnerability (Moser 1998) to suffer excessively from floods. Conversely, for industrial workers and their families, who live in the slum neighbourhoods of Mumbai, resilience is aided by participation in a range of support networks as well as by the possession of labour skills for which there is a high demand.

The types of support provided by employers to permanent and skilled employees living in Mumbai's slum settlements operate at 'soft locations' (Marcuse/Kempen 2000) within the flood redistributive system where a more structured and formal mechanism of flood loss adjustment, involving employers and workers, might be infused. However, this study also reveals that semi-skilled temporary or seasonal and daily casual workers cannot presently take advantage of this soft location. Their exclusion from the existing informal support system renders unskilled labourers more vulnerable than skilled workers. Perhaps there are possibilities for assisting the unskilled by promoting self-help groups under the broader banner of micro-finance schemes. While self-help groups assisted only a small pool (16 per cent) of households surveyed, they were the most preferred choice for unskilled workers. More effort might be directed towards improving awareness and knowledge of this alternative among slum dwellers.

Adjustments to flood losses are typically mixes of proactive and voluntary, reactive and compelled steps

(Mitchell 2007). In the case of slum populations in Mumbai it might seem that lack of resources and expediency ensure that reactive and compelled adjustments dominate the available alternatives. However, many of the arrangements that are activated in the wake of flooding depend heavily on the existence of pre-existing relations between victims and organizations or individuals in the community, that are cultivated before the flood event. In these cases the line between proactive and reactive adjustments is difficult to draw. Proactive and voluntary methods comprise making and maintaining arrangements with employers, family members; establishing informal arrangements of money investments; participating in religious communities, self help groups, and other such mechanisms of income diversification. Reactive and compelled options are borrowing from the local trader and money lenders, etc. Flood loss redistribution systems can broadly incorporate three types of societal bodies; (1) family and kin; (2) community (including social, political and religious population groups), and (3) formal (mainly economic) organizations comprising employers, banks, and other financial institutions. In Mumbai these groups are interwoven in a complex mode rather than being separate. For example, private financial institutions (e.g. local traders, money lenders) are part of a flood-affected household's immediate intimate community and family members (e.g. siblings and offspring, working in Dubai) who support slum dwellers are a part of a globe-spanning community.

Cities have heterogeneous populations with different cultural, socio-political and economic attributes that classify vulnerability differently for particular communities. Coping with natural and anthropogenic disasters exacerbated by global change processes therefore needs multiple alternatives and layers of support that will provide effective and variegated methods of loss reduction and human development for populations with different characteristics and constraints. In this case the unskilled workers, new migrants and socially or religiously unconnected households represent the marginalized population that remain outside most networks of useful loss sharing and are perennially affected by hazard events. Policy interventions from state and urban development organizations therefore need to target such specific groups to provide options for recovery and lasting security to slum dwellers in cities of developing countries.

34 Coping with Water- and Wastewater-related Risks in Megacity Delhi

Reena Singh

34.1 Introduction[1]

Megacities are not only concentrations of people, enterprises, growth and opportunities, but also nodes of inadequacies, crises, shocks, and vulnerabilities which are marked by complex socio-ecological processes as well as exceptional dynamisms of formal and informal settings. There has been phenomenal growth of megacities[2] in the recent past which accommodate about 10 per cent of the world's urban population (UNFPA 2007: 10). These are highly dynamic urban centres and their maintenance thereof relies upon chains of consumption that pull in resources like water, food, and power on one hand and generates huge volumes of waste on the other (Pelling 2007a: 1). Apart from being threatened by consequences of external events, megacities are also generators of hazardous consequences themselves and as such are 'victim and culprit' at the same time (Kraas 2007: 13). Today megacities are subjected to increasing risk and vulnerability due to overcrowded living conditions, infrastructural stress, escalating inequality, social segregation, conflicts, as well as failure of government to adequately care for environmental and social well-being.

Undersupply of basic infrastructure is affecting the large urban population and living with infrastructural stress is increasingly becoming a common urban characteristic. Consequently, urban citizens are frequent victims of denial of 'rights to basic services'; inadequate provisions of water, sewerage and sanitation threatens their security against harmful exposures which translates into hazardous environmental and health implications through specific patterns of vulnerability, of physical, socio-economic, and political origins. Therefore, providing quantitatively and qualitatively adequate basic services to all becomes a major responsibility of good urban governance and a prerequisite to ensure environmental and health security.

There is a broad consensus globally that health is central for human security and development. Human security in a broader sense also encompasses deprivation from: good governance, access to basic services, health care and basic human rights, as well as impoverishment, pollution, illiteracy, and exposures to other maladies (Ogata/Sen 2003: 6). Increasing infrastructural stress and ill-designed urban regulation are making cities huge centres of harmful perturbations posing enormous threats to environment and public health securities. Disadvantaged social groups are continuously exposed to the day-to-day crisis of access to food, water, and sanitation. They are compelled to spend time and money in securing food and water, managing their own waste, and treating themselves against avoidable water-related illnesses like diarrhoea, dysentery, cholera, malaria, dengue, etc.

In this context the main objective of the following case study on Delhi is to analyse potential risks related to water and sewerage; causes of defencelessness threatening environmental and human health security in this regard, and further to explore the coping strategies and adaptation measures in response to the prevailing situation of multiple stresses that enable urban citizens to continue to live with risk. This chapter focuses specifically on problem areas relevant for development policies and on structural and non-struc-

1 This chapter represents a part of the author's PhD thesis entitled "Wastewater Problems and Social Vulnerability in Megacity Delhi/India" that was submitted to the Faculty of Mathematics and Natural Sciences, Department of Geography, University of Cologne, Germany in September 2008.

2 "The United Nations (UN) coined the term megacities in the 1970's to designate all urban agglomerations with a population of 8 million or more. In the 1990's, the UN raised the population threshold to 10 million, following the practice of institutions such as the Asian Development Bank. The UN estimates that there are 19 megacities in the world at the beginning of the 21st century" (Brockerhoff 2000: 10).

Box 34.1: Different forms of settlement colonies in Delhi. **Source**: Batra (2005: 2-3).

Planned/Approved colonies: These are colonies that are approved by the zonal agencies and form part of the Master Plan of Delhi.
Slums: These are settlements that are notified as per provisions of Section 3 of the Slum Areas (Improvement and Clearance) Act, 1956 as too dilapidated or suffering from other disadvantages in terms of ventilation, etc.
Unauthorized colonies: These are colonies created on land that is not meant for residential use.
Regularized unauthorized colonies: These are unauthorized colonies which are regularized by government agencies.
Urban/Urbanized Villages: These are villages that having been overrun by the city of Delhi are now, by notification of the Delhi Government urban development department, declared as urbanized villages.
Jhuggi Jhompri (JJ) clusters: These are normally shanty constructions made by migrant workers in Delhi, largely on government agency land or 'encroached' land. In a number of documents JJ clusters are also referred to as squatter settlements.
Resettlement colonies: The term is often used loosely (and incorrectly) to cover also relocated colonies. These colonies tend to be better off than JJ relocation colonies e.g. plot sizes etc. are usually larger. Some of the resettlement colonies now have the same standards as other planned colony.

tural solutions aiming at a reduction of social defencelessness and strengthening resilience.

34.2 Megacity Delhi: Statement of the Problem

Delhi is one of the fastest growing megacities in the world. It supports a population of about 14.1 million (tenfold more than it was originally planned for), making it the sixth largest city in the world and second largest city in India, next only to Mumbai (United Nations 2004: 7). Only within the last decade its population has increased by 46 per cent. Thereof 45 per cent was natural growth and 55 per cent was due to net immigration (Govt. of NCT of Delhi 2002: 32). Much of this immigration is poverty-induced as a large number of poor villagers, particularly from the neighbouring states, come to the capital in search of job opportunities (Chakrabarti 2002: 5). Delhi's multifaceted development and economic growth has always attracted a large number of migrants leading to unplanned mushrooming of illegal residential colonies at unfavourable locations for accommodating the huge influx of people. This is one of the reasons why Delhi's urban scenario has become complex and difficult to be managed by the limited capabilities of the local bodies. About 45 per cent of Delhi's population is residing in some form of unplanned/informal settlements (Batra 2005: 2). Apart from the planned/approved colonies and informal slums, there exist various other forms of settlements in Delhi (box 34.1).

The city itself is affected by a high degree of fragmentation between upper class quarters and squatter settlements of the urban poor, attesting strong heterogeneity within close proximity. Such steep social gradients resulted in physical and social boundaries, and different types of access to water and sewerage have developed. Many problems hindering an equitable supply are due to the complexities pertaining to such close coexistence of formal and informal settlement quarters, as well as to technical and legal constraints in providing the unplanned/informal quarters with proper water and sewer connections at the household premises.

According to the 2003 data Delhi generated 3,267 *million litres per day* (MLD) of wastewater including 218 MLD from industrial sources. The corresponding treatment capacity during the same year was 2,330 MLD but the actually utilized capacity was only 1,478 MLD (CPCB 2004: 1). This wide gap between the wastewater generation and the actual wastewater treatment exists even today. Wastewater generated from domestic, commercial, and industrial sources enter the same sewer system without segregation. Moreover, to a large extent the main trunk sewer is either not functioning at all or working only partially due to the damaged and silted sewers (Controller and Auditor General of India 2004: 102). Additionally, Delhi receives about 89 per cent of total rainfall only during the monsoon months of June-September (IMD 2005: 1). The dilapidated and silted drainage system of the city is further burdened with additional storm water causing severe problems of monsoon flooding and inundation of low-lying areas.

The government has augmented the water supply, upgraded the treatment capacity, expanded and rehabilitated sewers, provided community sanitation, and invested heavily in upgrading the water quality in the 23 km stretch of river Yamuna crossing the city (Centre for Science and Environment 2005: 1). But in reality all such endeavours have yielded only limited re-

Table 34.1: Trends in population growth, water, and sewerage in Delhi. **Source**: CPCB (2004: 14).

Years	Population (Lakhs =100,000)	Population (million)	Water Requirement (MGD)	Water Available (MGD)	Sewage Generation (MGD)	Sewage Treatment Capacity (MGD)
1961	26.59	2.659	211	77	169	67
1971	40.66	4.066	324	173	259	97
1981	62.20	6.220	495	252	396	130
1991	93.70	9.370	749	469	599	250
2001	137.80	13.780	1096	650	877	497
2011	182.00	18.200	1468	919	1174	814

sults as the social communities continue to be exposed to water and wastewater hazards and grapple with the inadequacies of the water system's infrastructure. Thus, the government has been unsuccessful to grant basic rights to safe water and adequate sewerage to all even after decades of planning.

Sewerage contamination of water supply is a major cause for increasing waterborne diseases like diarrhoea, dysentery, typhoid, etc. which forms the most common illness of adults and children in the city. Moreover, puddles of stagnant wastewater form breading ground for disease carrying vectors (mosquitoes, flies, etc.), which is quantifiably attributable to consumption of contaminated water, open drainage, open defecation, and unsafe garbage disposal. Delhi also suffers a huge burden of vector-borne diseases like malaria and dengue fever. According to data reported by a small sample of 22 index hospitals under the Municipal Corporation of Delhi 77,355 cases of gastroenteritis, 1,784 cases of cholera, and more than 900 cases of malaria were reported in a 12-month period (Jan-Dec 2004)[3]. In 2006, there was an outbreak of dengue in Delhi where 2,950 cases and 65 deaths were reported (Agarwal/Srivastava/Choudhary/Kaushik 2007: xii). The same health report indicates that the prevalence of these diseases is almost double amongst the urban poor compared to those of urban rich, what only shows the defencelessness of the urban poor against the health insecurities and their incapability to cope with them.

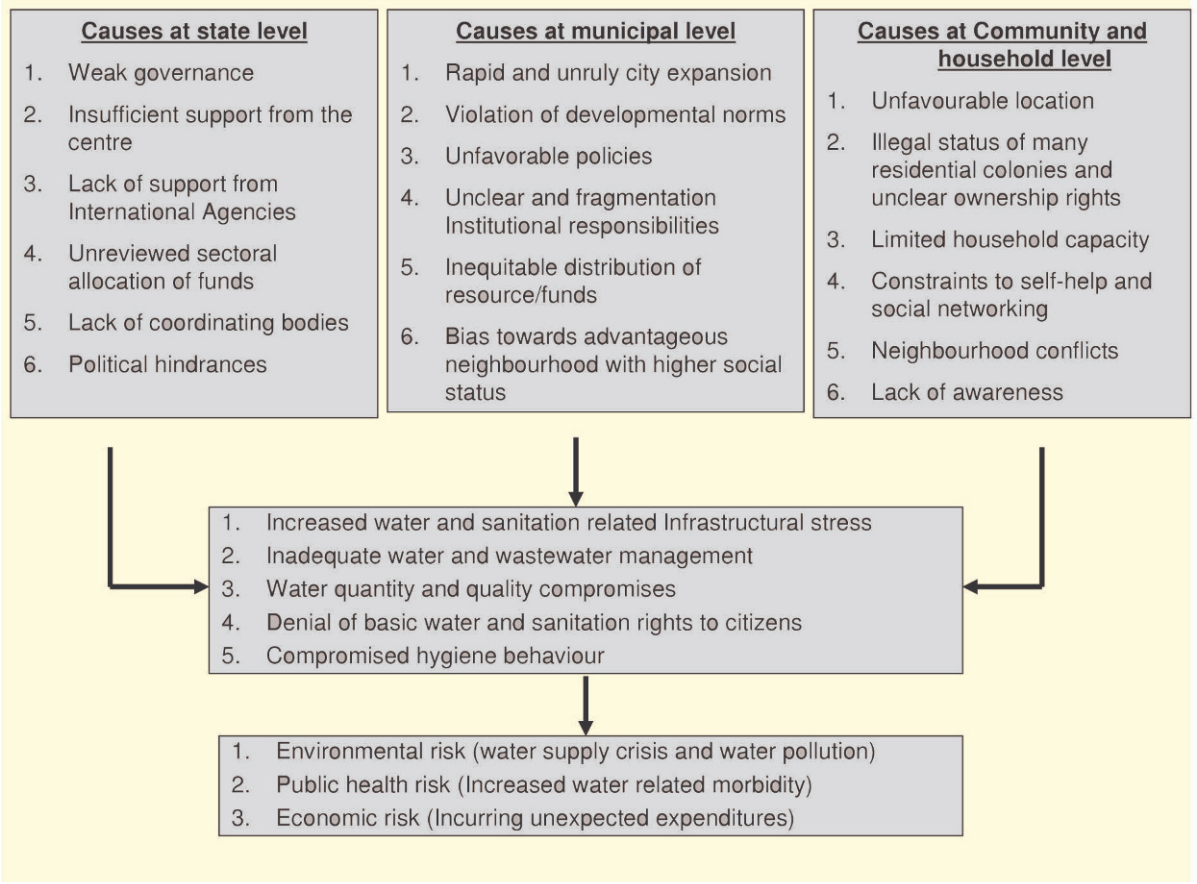
34.3 Causes for Water and Sewerage Inadequacies in Delhi

Urbanization has increased rapidly in Delhi, a settlement of about 9.2 lakhs (920.000) in 1947, increased to 137.8 lakhs (13.78 million) in 2001, 153 lakhs (15.3 million) in 2005, and is estimated to reach 182 lakhs (18.2 million) by 2011. On the other hand the status of water and sewerage in the city has continued to deteriorate as water requirement has increased to 1,468 million gallons per day (MGD) without a corresponding increase in the water availability options. Moreover, the increased generation of wastewater has not been matched with an augmentation of the sewerage treatment capacity (table 34.1). The existing sewerage treatment capacity is also under-utilized because of deficiency in the sewerage network including insufficient coverage, ageing and damaged sewer lines and siltation. Therefore, only a part of the generated wastewater are actually collected and effectively treated while the balance enters the open drains and finally joins the river Yamuna, which form drinking water source for downstream communities.

Since the city has been expanding in a haphazard manner planning has not been very successful. The frequent violation of developmental norms has left large areas still poor and unserviced with basic amenities. The continued population growth, immigration, and scarcity of suitable habitation compel people to settle in unfavourable areas, and unresponsive utilities combine to create a water supply crisis as well as wastewater disposal and sanitation deficiencies. Moreover, improvements in water supply, sewerage, and sanitation have merely meant increasing physical coverage whereas the quality of provided services is highly substandard and its maintenance is grossly neglected. The conventional way of piped supply and sewers are neither affordable to poor communities nor easily accessible without high government subsi-

3 Bureau of Health Intelligence, Health Department under Municipal Corporation of Delhi: Data as reported by 22 Index hospitals of Delhi.

Figure 34.1: Causes and Implications of Inadequate Water and Sewerage in Urban Areas **Source**: Designed by the author, adapted from UN Habitat (2003: 103).



dies and support. Thereby, a lack of access to safe water supply and sewerage can be indirectly related to poor governance reflected through an inability of the government to invest in water system and sanitation improvements.

There is a significant inequality in the regional distribution of basic services particularly water, sewerage, and sanitation services depending on the social and legal status of the respective colonies (CPCB 2004: 24; Zérah 2000: 68). The increasing demand confronting the water system infrastructure by growing urban populations, skewed distribution of basic amenities, and biased investment towards affluent zones has resulted in numerous islands of informal and unserviced settlement areas within the city, with unhealthy living conditions. Present policies do not outline any scope for provisions of sewers in squatter and illegal settlement quarters. Large proportions of unauthorized areas cannot be provided with individual piped water supply and sanitation because of the problem of legality pertaining to their land ownership rights. Thereby, only about half of the population is legally connected to water and sewerage while large parts of the unserved population either remain unconnected or make illegal provisions, and are therefore subjected to compromised hygiene.

In the national capital territory of Delhi, water supply and wastewater service go together and are a public responsibility. The *Delhi Jal Board* (DJB) is responsible for production and distribution of drinking water, treatment and disposal of wastewater, as well as water quality control in Delhi (Ruet/Saravanan/Zérah, 2002: 127). Furthermore, there are several other authorities engaged in the development and maintenance of water supply and sewerage and water pollution monitoring in the city, namely, the *Delhi Development Authority* (DDA), the *Municipal Corporation of Delhi* (MCD), the *Delhi Cantonment Board* (DCB), and the *New Delhi Municipal Corporation* (NDMC). Conflicting priorities of different authorities and lack of a common action plan affects delivery of services for the city in general. In addition,

the administrative zones, water supply zones, and sewerage zones do not match, which again leads to planning and organizational problems which further hinder the provision and maintenance of water and sanitation services for all.

When the city economy is developing at a good rate of 12.6 per cent, which is higher than the national economic growth (Govt. of NCT of Delhi, 2006: 8), it should be rather easy to expand the basic infrastructure facilities and maintain them in good standard. But, multiple causes like inequitable infrastructural expansion depending on the socio-legal status of the locality, un-reviewed investments, and various political, institutional, and social-economic problems constrain the equal infrastructural provision and access by all urbanites. A range of causes simultaneously exists at the state, municipal, and community levels leading to inadequacies of basic services and social defencelessness which are finally reflected as environment degradation and on the social communities as health burdens and other allied costs in terms of time and effort involved for managing their own water needs and waste disposal and protecting themselves against hazardous environmental exposures (figure 34.1).

34.4 Risks Associated with Improper Management of Water and Wastewater

Risk in human terms is "a situation in which human values (including humans themselves) are at stake and where the outcome is uncertain" (Jaeger/Renn/Rosa/Webler 2001: 17). Today many risks are eco-centric, i.e. they are linked to environmental problems or related to environmental conditions (Jaeger/Renn/Rosa/Webler 2001: 9), "to be at risk is to be under threat of harm" (Pelling 2003: 5) by unfavourable consequences. The improper management of wastewater creates hazardous conditions, water pollution and environmental degradation, exposure to which is regarded as a matter of risk that threatens the ecosystem and human health security, and indirectly threatens the economy.

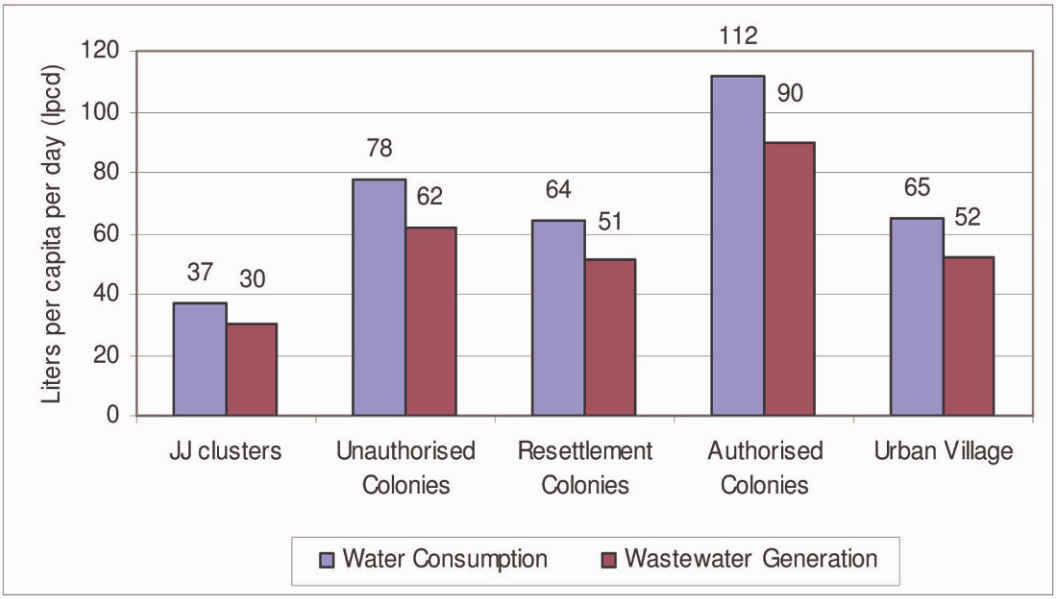
Even if the water and sanitation services are not officially provided by the state, under whose jurisdiction one is residing, still each living human being somehow obtains drinking water and also disposes of wastewater (Solo 1999: 118) though, not in an environmentally safe and hygienic manner. Health is significantly compromised at lower levels of water and sewerage services. Apart from improved hygiene behaviour, public health gains and household security is derived from provisions of qualitatively safe and quantitatively sufficient volumes of water and access of adequate sewerage for all. Further health improvements may also occur at higher levels of service associated with drinking water quality control and improved sanitation at the household as an effect of improved socio-economic status, better social capital, and good city governance.

With optimal levels of water and sewerage services where piped water supply and wastewater disposal facility exists in the household, health risks were observed to be low due to fewer chances of wastewater exposure. When the level of access is insufficient, i.e. only to the very basic ones, and no proper maintenance is undertaken, an exposure to wastewater takes place most of the time and thus keeps the community at high health risks. Even a basic access to sewerage and sanitation facilities with a regular maintenance reduces the chances of wastewater exposure. Low health risk is only attained with an optimal access to water and sewerage facilities in households.

There are numerous sources of water catering to the needs of various residential colonies in Delhi. Shortage of piped water is compensated with groundwater accessible through hand pumps. In addition people also relied on water tanker services. The *Delhi Jal Board* (DJB) provides free water tankers while the private water tankers charge a high price. Results of a household survey[4] (figure 34.2) shows that the JJ clusters which are settlements without sewerage are currently using only 37 *litres per capita per day* (lpcd) of water, whereas unauthorized colonies also without sewerage facilities are using 78 lpcd, even more than the resettlement colonies (64 lpcd), which are somehow networked with sewer systems although not of a

4 A comprehensive household survey was conducted by the author and V. Selbach, with the help of students from the University of Delhi (who were carefully trained to administer the designed questionnaire), during the years 2005 and 2006. Purposive-random sampling techniques were applied to choose the respondent household from various kinds of colonies using the Delhi Eicher map and satellite images. Preference was given to involve the household (wherever possible) within close proximity to canals, water and sewer pipes, open drains, hand pumps, etc. Adequate representation of socio-economic hierarchies was also kept in mind. Key informants of the households were interviewed, including both male and female participants. In total, seven test sites were chosen from three different locational settings and 696 households were interviewed covering a population of 4,358 persons.

Figure 34.2: The average volume of water used and wastewater generated (lpcd). **Source:** Own household survey, 2005-2006, N = 696.



desired quality. This explains the private arrangements of water supply sorted by unauthorized colonies due to the comparatively higher water purchasing power of the residents there than those of the resettlement colonies. Normally, 80 per cent of the water supplied results in wastewater. Therefore, usage of water without proper provision for wastewater collection network like in informal colonies leads to huge volumes of uncollected sewage flowing in open drains and canals to enter the river Yamuna and other water bodies

Untapped as well as insufficiently treated sewerage joining the river Yamuna led to higher quantity of ammonia in the water which was declared to be beyond treatable limits.[5] Since the river provides a source of drinking water for the people living downstream, the water quality criteria of the river needs to be maintained as a high priority. But the extent of environmental imbalance is so severe that the water quality of the Yamuna which should ideally be fit for bathing, swimming, and recreation actually is unfit even for agricultural purposes (SulabhEnvis, 2003: 7).

Freshwater lines, which often run close to drains, are frequently affected by the 'siphon-effect', which is the intake of contaminated wastewater into the freshwater system due to a decrease in pressure (Krafft/Wolf/Aggarwal 2003: 23) causing numerous leakages and resulting in contaminated water supply for end users. The groundwater quality in various parts of the city is also precarious. Harmful pollutants seep into the groundwater from a variety of sources including irrigation, septic tanks, sewage, injection wells, sewage percolation via cesspools and unlined drains, solid waste disposal, and an accumulation of industrial wastewater on land, etc. Residents were continuously warned not to consume groundwater through red painted hand pumps in areas where the *Delhi Jal Board* (DJB) had diagnosed the water to be of unsafe quality. About 77 per cent of the surveyed households reported water quality problems in terms of yellowish colour and bad odour. But only 35 per cent of the households used some means for water purification like boiling of water or using water filters and aqua guards for drinking water.

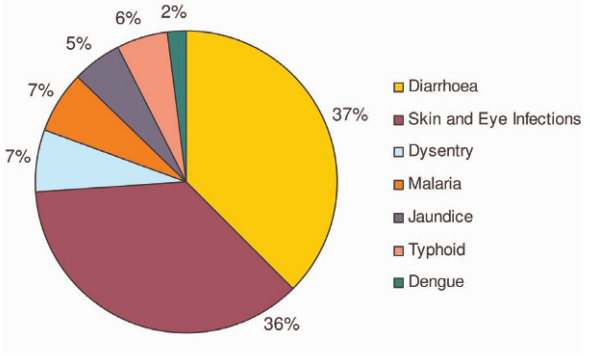
Open defecation and public washing was also commonly carried out by marginalized groups in localities deprived of public facilities. In such case, puddles of wastewater lying in the open were unavoidable to be contacted by them during the course of their everyday spatial mobility in and around the area. Narrow and unmetalled lanes of surveyed unauthorized colonies and JJ clusters were in pathetic condition due to all time stagnation of flooded wastewater – even during the non-monsoon period. Nearness of open drains, frequent drain overflows, taking to public washing, and open defecation are all means of directly getting into physical contact with wastewater. In some cases children fell into these open drains while playing

5 Times News Network: "Ammonia hits water treatment", in: *Times of India-Delhi (*14 November 2007): 3.

and lost their life. This further reiterates the interlinkages between increasing human insecurity due to a poor water system related to the infrastructural development in the city.

No primarily epidemiological study was conducted and thus no attempt was made to establish a relationship between these diseases and wastewater nuisance. Commonly reported illnesses documented that waterborne and water-related diseases exist all year round, but they rose considerably when the monsoon started. Apart from fever and cold, which were extensively reported from all kinds of localities as a regular phenomenon, diarrhoea, vomiting, dysentery, malaria, dengue, jaundice, as well as skin and eye infections were also common diseases prevalent among the surveyed communities. Diarrhoea and dysentery alone contributed to about half of the total disease burden (figure 34.3).

Figure 34.3: Burden of waterborne and water-related diseases. **Source:** Own household survey 2005-2006, N = 696.



However, morbidity differed across the types of colonies and the level of vulnerability. JJ clusters, unauthorized, and resettlement colonies report about 75 per cent of the total morbidity, whereas authorized colonies and urban villages had only one-forth of the total reported morbidity. Water-borne diarrhoea infection was common, more so amongst the social communities where piped water supply was served, which can be attributed to sewage leakages into the water pipes. Skin irritation, rashes, and eye infections like allergic and infectious conjunctivitis which is caused due to direct contact with infectious pathogens (viral or bacterial) were also highly reported from those localities where exposure to raw sewage was unavoidable and hygiene behaviour was compromised due to the quantitative and qualitative supply crisis, primarily in informal quarters.

The direct economic burden due to water, sanitation, and hygiene-related health implications acts further as a decrementing factor on household finances that was already difficult for the marginalized poor families to endure. Per capita expenditure on the treatment of water-related diseases on an average ranged between 160–180 INR[6] annually for each person, which could be largely avoided by households if the required standard of hygiene is maintained. In the case of households having large families, the percentage of household income spent on treatment would increase enormously. Residents of the authorized colonies spent the maximum of about 220 INR, which was largely because they had the preference and financial capability to avail of private practitioners, whereas residents of informal quarters with lower household income preferred to go to the public health clinics for these ailments. Nevertheless, water- and sanitation-related health implications were posing an increasing economic risk for urban citizens.

When families are impoverished, e.g. residents of JJ clusters who were largely daily wage earners or domestic helpers, and their household earning was less than 2,000 INR monthly, even a marginal unexpected increase in household expenditure would be a pressure on the family. Taking an average family size of six members, household annual expenditure on water-related minor health ailments and managing their wastes for lower income families (earning < 2,000 INR) was ranging between 5–8 per cent of household income and only about 0.5–1.5 per cent of household income for higher income families (earning >10,000 INR). In addition, there was a loss of working days when workers suffered from various ailments which indirectly led to an economic loss for the family, particularly if the earning member of the family was sick. The intention here is to hint at the additional economic burden which is largely avoidable by (1) combating environmental degradation, (2) extending an efficient water and sewerage system, and (3) achieving a reduction in water-related morbidity.

34.5 Coping and Adaptation as Components of a Resilient System

Human societies are in a constant process of responding and adapting to their changing environment surrounding as well as influencing them. Adaptation in

6 1 USD = 39.88 INR (rates at 2008.02.28, 17:08:30 UTC).

the context of the human dimension refers to the actions which the human community (at a different scale) takes in order to better cope with, manage or adjust to changing conditions, stress, and hazard risk (Smith/Wandel 2006: 282). Studies on various aspects of social vulnerability have shown that 'living with risk' needs to be based on coping strategies and adaptation techniques, and any vulnerability assessment needs to serve as a means of improving human capacities to respond and actively manage the risks (Bohle 2006: 189). These aspects clearly indicate the importance of effective responses towards strengthening defences against risks of varying nature (sudden events as well as continuous stresses) and in doing so enhancing resilience building. Apart from other aspects like good governance, diverse option availability and accessibility, awareness, education and communication at city level, local coping strategies are considered to be key factors in determining a community's resilience (Davis/Haghebaert/Peppiatt, 2004: 8).

Resilience is surely not just absence of vulnerability. It refers directly to the ability to function with the spectrum of uncertainties associated with the dynamics of a megacity system and indirectly to the capacity of people, communities, agencies, infrastructure "in the first place to prevent and mitigate losses and then secondly, if damage does occur, to maintain normal living conditions as far as possible and manage recovery from the impact" (Buckle/Mars/Smale 2000: 13). In this respect residents of a megacity system become more vulnerable if the prevailing socio-political structure restricts their capability to respond effectively towards prevailing risks.

The relation between vulnerability and resilience is rightly expressed in the terms "vulnerability comes from loss of resilience" (Holling 1995: 24) and "resilience depends on, among other things, the effectiveness of the risk response and the capability to respond in the future" (Alwang/Siegel/Jørgensen 2001: 10). Although the response capacity is clearly an attribute of the system as a whole that exists prior to the event (sudden shocks as well as continuous stresses), it gets operational or functional only when the event strikes or the stress exceeds tolerance. At a higher scale, a city itself is a complex adaptive system wherein the system is responding to the constant changes taking place.

Slow changes over time get absorbed within the coping thresholds[7] in the case of human society and get rectified to some extent by the self-correcting mechanisms for the environment. Since humans are constantly exposed to environmental changes and stresses, they are continuously coping and adapting to them, but once the threshold of coping and adaptation capacity is crossed hazardous outbreak strikes, calls for further responses, and again the process of coping and adaptation restarts. Although there are limits to the thresholds, "they are not necessarily fixed" (Yohe/Tol 2002: 26).

Adaptation and coping capacity also prepares the system for future risks and stresses, but in cases when stresses or changes exceed the thresholds of endurance capacity, hazardous outbreaks or unavoidable events strike (e.g. an outbreak of dengue fever or diarrhoea). These are occasions which again call for the coping capacity to get operational; actors need to adapt and learn from the experience, modify their preventive as well as coping responses, and strengthen their capabilities, which would presumably increase the threshold to a higher level. Good governance, education awareness, and communication are required elements for strengthening resilience.

34.6 Responses to Water and Wastewater Problems

Response and adaptation as well as mitigation efforts towards water and wastewater problems or any other forms of risks, hazards, or period of threats are all important coping measures to achieve human, environmental, livelihood, and health security. Response exists even before the occurrence of an event (as preventive strategies) and operates after the event (as coping and adaptation strategies). Human responses heavily depend on their prior experience, awareness about the severity of consequences, their perception of the problem, as well as their social and material capabilities to cope with the situation. People use their own capabilities, skills, talents, knowledge, and technologies to deal with the crisis situation, which might not necessarily be sudden extreme events. Even in everyday life, people's knowledge and their level of understanding play an important role in perceiving risks, and in turn it moulds their decision-making and actions (Hauger/de Boye/Geldof/Mikkelsen 2003: 12).

In this study, water supply and wastewater disposal related risks were understood by people only as health hazards. Aesthetic degradation due to wastewa-

7 A threshold is defined as a point between alternate regimes in ecological or social-ecological systems (Resilience Alliance and SFI 2004: 1).

ter nuisance and related long-term threats were not considered as a risk to their social well-being; more so by social communities of poor economic strata. In the absence of adequate water and sewer facilities, social groups chose various adaptation and coping strategies depending on their capabilities, perception, and available options. Their responses ranged from emotion driven 'doing nothing' to adoption of action oriented preventive, adaptive and coping measures for dealing with water and sewerage problems depending on family particularities, and available resources at the household level.

34.6.1 Preventive Responses

Social community and institutions, based on their previous experience, may start responding to anticipated events even before they occur. Adoption of preventive measures, precautions, and similar strategies to minimize the impact are categorized as preventive responses. These responses are strategies which help building the coping capabilities of the social communities.

The residents of certain surveyed localities, being aware of the grim infrastructural and water system related problems in their immediate neighbourhood, took precautions by elevating the entrance of their houses to prevent wastewater overflows and floods from entering their households. They covered open drains with stone slabs and got the windows and doors netted in order to safeguard against mosquito problems, etc. They try to adopt preventive behaviour like restricting their water consumption, purifying the drinking water, etc.

34.6.2 Adaptive Responses

Adaptive responses are actions and strategies undertaken after the event has occurred. The social community and environment adjust to the changes and get gradually adapted to the new system. This is more on a long-term basis, e.g. the continuation of living in unhygienic surroundings without feeling bothered is also seen as a 'situational adaptation'. Adaptation was about facing the fact that infrastructural inadequacy was inevitable at the given socio-political situation; it involved acceptance of the condition and making changes accordingly to strike a harmony.

It was repeatedly noticed in the study area that communities which frequently faced wastewater and sanitation problems in their households had somehow adapted to this prevailing situation and were not much bothered, or at least they denied to be grossly affected by the uncertainty and irregularity of its maintenance. They were no longer bothered to see or get exposed to puddles of wastewater and day-long lying garbage and filth. They seemed to have mentally accepted the prevailing pathetic sanitation condition of their neighbourhood and remained satisfied as long as they could maintain their household premises clean.

Adaptive responses also include activities which would strengthen people's capabilities to endure future shocks of at least similar nature, e.g. by the installation of sewer pipes of larger diameter, having alternative arrangements for water supply, having access to multiple relying options, etc.

34.6.3 Coping Responses

Coping responses refer to the process of managing crisis circumstances and seeking to minimize, reduce or tolerate stress. They may include short-term and temporary actions too which are needed to manage the hazardous event or stresses. Coping responses get operationalized particularly after the event strikes and may need short- as well as long-term measures to reduce its impact immediately, as well as for future occurrences, e.g. flooding due to sewer blockage which needed to be cleaned either by sewer staff of the city municipality or by private cleaners immediately, and also called for proper maintenance of the sewer lines regularly. The water crisis was augmented by buying tankers of water or getting water from other places, etc.

These responses also include activities undertaken by organized social groups such as the Resident's Welfare Associations (RWAs) of the residential colony for restoring normalcy as well as reducing implications. Apart from other activities such actions may comprise of measures for developing economic and social safety networks and providing a forum for communication; facilitate learning from each others experiences.

Human response falls simultaneously into more than one category as they are not mutually exclusive. Kind of social responses and some commonly practised measures at household levels for managing water- and wastewater-related problems in different residential colonies surveyed are listed in table 34.2.

Table 34.2: Household strategies for managing the water and wastewater problem in different residential colonies: Delhi. **Source:** Own household survey 2005-2006.

Type of colony	Measures taken for wastewater disposal problems
JJ cluster	• Illegally connect to the water and sewer network. • Get water from distant sources or from other colonies having piped water supply. • Cover the open drains by stone slabs. • Channel the household wastewater to the ditch and manually empty it into the nearby drain. • Spread oil on stagnant water to avoid the breeding of mosquitoes.
Resettlement	• Store water for use during short supply period. • Buy water from water vendors. • Spray oil or disinfectants on stagnant water. • Clean the drains individually. • Report to local political leader who would approach the Municipal Corporation office and get the work done.
Authorized	• Resident Welfare Association usually looks after the maintenance of water and sewer system. • Use motor pumps to draw water also buy water and use individual water filters. • In case of sewer problem complain to the Municipal Corporation office or employ a private cleaner.
Unauthorized	• Disposal into on-site septic tanks. • Channel the household wastewater to the open drains. • Raise entrance to the house. • Reuse the water to minimize the disposal and reduce water demand. • Clean individually.
Urban Village	• Use boring pumps to withdraw groundwater. • Clean individually or hire private cleaners. • Mostly try to take precautions while going out of the house.

34.7 Constraints to Effective Responding.

A common explanation for the inadequacies of the water system infrastructure in Delhi is the very rapid population growth, which overwhelms the capacity of the local authority to improve and extend provision. But many rapidly growing cities in Latin America and Europe have nonetheless managed to improve water and sanitation provision with improved governance and institutional efficiency in the management system (UN-Habitat 2003). Urban system resilience is greatly enhanced by an efficient institutional structure and a beneficial relationship between the municipal and national government (Solway 1994; Pelling 2003: 81) and an involvement of all stakeholders.

A weak institutional organization coupled with poor urban governance have led to numerous obstacles which have directly hindered an efficient management and adequate infrastructural access on one hand and indirectly threatened human health and environmental security on the other. Under such circumstances at the city level social communities even if they have the potentials to help themselves find it increasingly difficult to deal with the problem of securing health and livelihood security as they are faced with numerous economic, political and legal constraints acting as limiting factors to their developmental attempts.

The worsening problem of water system management and inadequate sanitation in Delhi attests that current governmental actions have been highly inadequate in alleviating the situation. Years of planning and infrastructural upgrading have also failed to achieve declared goals and the developmental results have not benefited all social communities equally. The manifold managerial, governance, and resource constraints for effective responses, and a failure to provide an adequate water and sewerage disposal facility for all can be summarized at the institutional and community level (table 34.3).

Table 34.3: Constraints for improving water and sewerage services. **Source:** Own findings.

Institutional Level	Community Level
1. Multiple agencies-in-charge	1. 'Illegal' status of the colonies
2. Fragmented and unclear departmental responsibility	2. Financial incapability
3. Lack of managerial coordination and accountability	3. Over-dependence upon the government
4. Underqualified operating and maintenance staff	4. Lacking civic responsibility
5. Improper financial management	5. Prevailing local politics
6. Unstable managerial positions	6. Lack of information and awareness
7. Undue political influences	7. Lack of cooperation and social networking
8. General apathy towards people's grievances	8. Burden of other household problems

34.8 Conclusion and Discussion

An effective response has always proven to reduce potential risks and decrease the need for serious action. Since the water- and wastewater-related hazards can be considerably eliminated and avoided, timely responses to the risk are needed that can prevent potential environmental- and health-related emergencies in the future. Moreover, they can also be helpful in reducing financial burden for the household by directly saving time spent on wastewater- and sanitation-related hassles for useful economic activities and also through reduced expenditure on water-related illness by improved sanitation and hygiene conditions.

It is clear from this discussion that in fast growing urban areas institutions for water, wastewater, and sanitation issues are increasingly getting complex. Various institutional legal and social constraints have hindered effective responses towards the management of problems related to sewerage and sanitation services for a large number of poor people. Effective actions to reduce water- and wastewater-related risk by an efficient response needs to be taken at the national, regional, community as well as household level, and further linked to each other. All these actions need to be within a time-bound framework. There are multiple factors in play which need to be taken into consideration while planning for urban settings which implies looking for integrated solutions at an affordable price.

Despite governmental responses with new plans and policies, the water system infrastructure has remained highly inadequate. The government of a megacity, like Delhi, must plan and design the provision of basic service to cater adequately to the huge 'illegal' population of informal quarters as well. Future efforts and policies must aim at overcoming the obstacles and expanding *private sector participation* (PSP) to improve efficiency and performance management as well as improve public information systems and transparency of these operations. Moreover, encouragement of the private sector financing and higher cost recovery would provide a stronger financial base and lessen the burden on the scarce public funds.

Based on their perception and capabilities households act to reduce the implications of wastewater nuisance by taking up precautionary actions where possible and endure the unavoidable circumstances when these household measures fail. Local measures are capable of providing preventions for a short time but the long-term structural solution to the problems is beyond the capabilities of a household, which urgently require a need-based effective response from the civic agencies to be executed with proper coordination at the community, zone, and state level.

Actions at the household and community level are important and highly required but unless there is a strong political will to remove the root causes of infrastructural inadequacies and hindrances to effective responses, the currently unplanned actions would continue to be superficial and all planned interventions and agendas would only show unsatisfactorily limited results. People's involvement at all levels – from planning to implementation – can be helpful in building trust and making the provision and maintenance of water- and sanitation-related basic services 'everyone's business'.

35 Politics of Displacement and Vulnerability

Nanda Kishor

The intricacies in the development of a country are leading to several debates which are worth mentioning and run through the whole process of public policy. Among these, the politics of development, the politics of displacement and inequalities along with vulnerability take a primordial position. Although the present work does not deal with all concepts involved in development and displacement in detail, it does deal with key issues which have changed the lives of millions who have borne the brunt of the development of the country and accepted the sacrifice of their belongings and putting themselves in the position of the vulnerable.

35.1 Introduction

India is a country with multiple diversities and cultures. The country has gone through different phases since its independence. She had to face the wrath of colonial rule for very long time, and this paralyzed the growth of the country severely. It is often argued (Sen 1996) that outside India, the reforms have been fairly universally welcomed, but they have been, since their inception, the subject of severe debate within India. The controversies have been extensive, and the arguments on each side are quite firm and forceful. The path which was chosen after independence to pursue development appeared astoundingly humanitarian and progressive, but to the dismay of the people, it did not allow the country to progress the way she wanted to. This chapter critically reviews the concept of development, at the cost of people, the politics of development and it also shows the risks involved in such unplanned development plans leading to different vulnerabilities.

The term 'development' envisages a battery of changes – changes for the betterment of the community. It involves the notion of progress, growth, improvement, and welfare of the collective. 'Development' has to be an innovative process leading to the structural transformation of social systems. The development is multifaceted and it is not always progressive as it is supposed to be by its definition. Sometimes, "both history and daily experiences teach us that development processes, be they spontaneous or induced, bring not just benefits. True development is undoubtedly beneficial to very many people. But development changes the status quo and such change usually entails social disruption and undesirable consequences for some population segments" (Cernea 1996: 1515). This chapter analyses for three typical cases displacement due to unplanned development taken up by the Government of the State of Andhra Pradesh (India) in its capital Hyderabad.

Hyderabad is one of the six metropolitan cities and is located in the Deccan Plateau in south India. It is the capital city of the province called Andhra Pradesh with a population of 3.829753 million people (2001 census of India).[1] It is situated at an altitude of 536 metres above sea level on the eastern side of India. The city is one of the fastest growing cities with respect to information and technology.

35.2 The Politics of Development

The concept, 'politics of development' is crucial for the understanding of the complexity of the concept of displacement. The highest numbers of displacements in the country are 'development-induced displacements'. So displacement cannot be studied in isolation and without controlling aspects of development the undercurrents of all paths of devastating development may not be understood. In explaining how 'politics' has entered into development Adrian Leftwich (2000: 4) argued to locate politics in development, "the central and dominant variable determining not only the conception and shape of development, but developmental failure or success in all human so-

1 See at: <http://www.censusindia.gov.in/Tables_Published/A-Series/A-Series_links/t_00_005.aspx>.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_35, © Springer-Verlag Berlin Heidelberg 2011

cieties, is their politics." To put it in more appropriate words, politics is not simply important, but it is crucial for both understanding and promoting development. It shapes and in turn influences by the character, structure, and capacity of the state. But the question why states are so political and development is also made political arises. The answer is clear in all the activities of conflict, cooperation, negotiation involved in the use, production and distribution of resources, whether material or ideal, whether at local, national or international levels, or public domains have politics as an inherent component. This definition almost makes the concept very clear and gives a perfect platform for further arguments.

The meticulous answer by Government agencies on the unplanned developments in India use concepts like globalization and its pressure on all countries to grow stronger, and take a leap in their development so as to compete with other countries in the world. But, even the so-called globalization failed to produce any results in making India grow stronger, especially with regard to the marginalized sections of its society who have remained poor for generations. Joseph Stiglitz (2002: 5) argues that "those who vilify globalization too often overlook its benefits. But the proponents of globalization have been, if anything, even more unbalanced. To them, globalization is progress; developing countries must accept it, if they are to grow and to fight poverty effectively. But to many in the developing world, globalization has not brought the promised economic benefits. A growing divide between the haves and have-nots has left increasing numbers in the Third World in dire poverty, living on less than a dollar a day." Also in India the poor have remained poorer and the rich are becoming richer. Development does not serve those who sacrifice for the sake of development and India's development pattern documents this.

35.3 Politics of Displacement

After many debates many scholars (Cernea 1986, 1995, 1996, 1998, 1999; Goyal 1996; De wet 2001; Mathur 1995; Thukral 1996; Kothari 1996) agree that displacement is a political process. This offers a platform for the following argument. It is essential to know what exactly displacement means and what is involved in it. Walter Fernanades (1995: 280) defined displacement as

> an unequal struggle for the control of the natural resources and the powerful minority will continue to appropriate most of them to their own benefit. This process of the further impoverishment of the marginalized sections and transfer of their resources will continue, unless the weak organize themselves to resist this onslaught.

This definition explains what displacement is, who does it and for whom, the impact of such an action, and what has to be done to overcome this problem. Chris De Wet (2001: 1638) described what displacement is all about. "Displacement is a move which is effectively permanent, in the sense that the area where people used to live has been transformed by the intervention, and there is no going back." Displacement with resettlement should be distinguished from resettlement, where people may simply have to go out of the way and make provision for themselves, and which should perhaps be termed 'expulsion'.

Table 35.1: Global distribution of projects by the type of development. **Source:** World Bank (1990).

Type of Displacement	Projects with Resettlement		People Displaced	
	Number	%	Number	%
Dams	39	26.6	1,233,000	62.8
Transportation	36	24.7	3,11,000	15.8
Water supply, sewerage	18	12.3	59,000	3.0
Thermal(including mining)	15	10.3	94,000	4.8
Urban infrastructure	12	8.2	73,000	3.7
Irrigation, canals	7	4.8	71,000	3.6
Environmental protection	5	3.4	74,000	3.8
Industry	4	2.7	2,000	0.1
Forestry	2	1.4	45,000	2.3
Other	8	5.5	1,000	0
TOTAL	146	100	1,963,000	100

Unfortunately, dam-related displacement was identified with all other development-related displacements and this error has influenced the provisions for rehabilitation (Dhagmawar/De/Verma 2003). Smitu Kothari (1996) argues that efforts at minimizing displacement or improving resettlement will only be marginal, palliative, and temporary if they are not conceptualized in a wider socio-political context. Planners and administrators invariably capitalize on and manipulate the relatively weaker socio-economic and political

position most people are facing. Their numbers are underestimated, they are treated indifferently and only minimal cash compensation, if at all, is paid. There is an extraordinary unwillingness to grant them clear rights, such as security of tenure on alternative developed land sites.

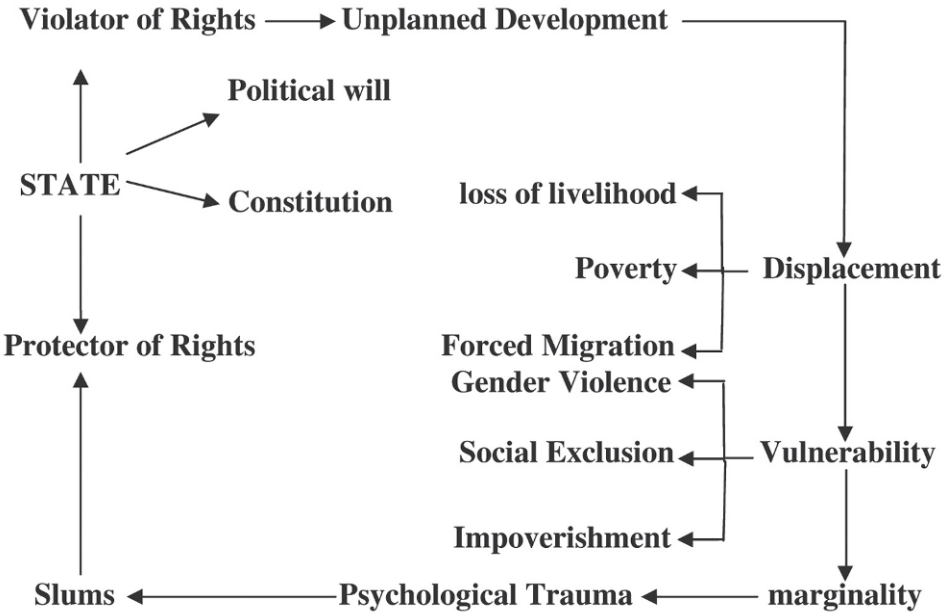
The problem is a negation of the participation by the people in the process of planning and implementation. Equal participation is a main component of democracy. Democracy is not only a desirable feature of development, but a necessary feature as well. The forced displacement of populations caused by many infrastructural development programmes epitomizes one category of disruptive changes that may occur as by-products of economic growth (Cernea 1996). It is interesting to note the public policy responses to forced displacement, the magnitude, social content (discontent) and severity of the adverse effects.

The social analysis has to delve beneath the ethnographic surface in order to identify the macro processes and the local matters that must be addressed by development planners. Later this analysis should be used in both academic and applied forms to enable the displaced to get justice. The law permitting the acquisition of land must be examined in a more meticulous way as the whole process of displacement starts with the failure of the standards of the *Land Acquisition Act* of the government of India.

35.4 Land Acquisition Act and its Coercive Aspect

Each displacement in the state has been arbitrary and can even be termed as forced eviction. The top-down approach has not been changed into a bottom-up ap-

Figure 35.1: Role of the state in development, displacement and the consequences of displacement. **Source:** Based on primary data compiled by the author.



proach. Most of the educated among of victims of development and displacement are not even aware that this *Land Acquisition Act* exists, with which land acquisition must comply. This draconian law is more than one hundred years old. In 1894 the first ever land acquisition act was formulated under the British rule and it has remained the base for the present act. The latest land acquisitions in Hyderabad documents the usage of this act. The information issued to the farmers and others for the acquisition and compensation of their land is entitled 'Land Acquisition Act of 1894 under the section 12 (2) - Form no. 9'. Whereas the Land Acquisition Act of 1894 categorically states that "any person or agency obstructing the process of acquisition on conviction before a magistrate is liable to imprisonment, for any term not exceeding one month, or to fine not exceeding five hundred rupees or both." The act ignores the resettlement question. Indeed, this is the starting point for the history of unplanned displacements in India. There have been a few amendments to this act in the year 1984 and later also but the basic structure remains unchanged. This law is still kept as an asset by the government as it offers a simple way of acquiring land without any big hurdle. The growing pace of development under 'liberalization' has increased the intensity of such displacements to the extent that communities living in their traditional settings are getting displaced with the loss of their traditional sources of livelihood. Once displaced, the people affected by such a project are pushed into an open-market situation as individuals and must compete for their survival in a hostile new environment. A majority of them are lost in this new race of development. There have been several national resettlement and rehabilitation policies which are not mandatory to any province in the country but remain as a base and are allowed to have their own resettlement and rehabilitation policies.

Empirical evidences give us a clear picture of the displacements and its vulgarity. Three cases are not sufficient to generalize about displacement in India, but the history of displacement and vulnerability allows drawing generalizations where the trauma and the risk which the people have gone through and go through only varies in degree.

Figure 35.1 above points to certain causes and the consequences of displacement through several different factors along with models like those on impoverishment (Cernea 1996, 1998; Mahapatra 1999). However, it does not show all those factors leading to and happening after displacement as there are a number of vulnerability risks. It shows how the state as a violator of the people's rights initiates unplanned development leading to displacement. This displacement has three major consequences: a) a loss of livelihood, b) poverty, and c) forced migration, and these three consequences lead to vulnerability along with gender violence, social exclusion, and risks of impoverishment. All these factors together contribute to marginality and through the psychological trauma the people

are pushed to set up new slums or to join the existing slums and again appeal to the government to protect their rights by recognizing them as coming from the slums. This whole process of accepting and recognizing which remains with the state and the state's decision remains with the political will by invoking the rights of the citizens which are constitutionally recognized. The process continues as the state again comes up with an unplanned development and, being a protector of the rights, it turns out to be the violator of these very rights. It is a vicious circle in which the citizens are totally vulnerable as the state has been using coercive methods to carry out involuntary displacements. Most of these factors are explained below in the section dedicated to adverse consequences of displacement and vulnerability issues.

First three cases will be introduced and then the adverse consequences will be discussed. These three cases were chosen to justify the concepts of displacement of people with land titles and the displacement of people without such land titles. The empirical work was carried out through a stratified proportionate random sampling with a diachronic method of assessment (pre-displacement and post resettlement). Focused group discussions were held as part of the work along with case study method, and finally, a triangulation method was adopted to crosscheck the available data.

35.4.1 Project of Multi Modal Transport System

The first case addresses the *Multi Modal Transport System* (MMTS) in Hyderabad in the year 2002. There was a place called Nirankari Nagar near Lakdikapool[2] behind the Ranga Reddy District collector office (figure 35.2). The place comes under the survey No. 2, Block L, Ward no. 83 covering 21,820 square metres in the Greater Hyderabad Municipal Corporation. The people were residing in this locality for the past thirty to thirty-five years. All of them belonged either to the Scheduled Caste (marginalized groups in India) or to backward classes including Muslims. The land belonged to the South Central Railway and it wanted to have the MMTS project at the advice of the state government of Andhra Pradesh with the approval by the Government of India. The MMTS project was of utmost importance among all government projects in the city. Due to the traffic havoc and scarcity of buses in the city, the government had planned for an alternative with railways. The politics for this project had started long back but the people were not aware of the project until the regional newspaper *Eenadu* reported that this locality would be displaced for the project when there was less than 90 days to start the acquisition process. Although the land did not belong to them, the inhabitants of the locality pleaded with the authorities, asking them to stop the displacement as they had resided in the locality for more than thirty years. As all plans had already been made it was just a mandatory function for the authorities to give the required notification before land acquisition. The people thought the last resort could be approaching the courts as they had invested all their earning in constructing their houses.

When the people of the locality resisted leaving the locality, the authorities considered playing different politics. The people of the locality were asked to find a place to stay wherever they wished in the city, but on the condition that all 398 families would have to be resettled in the same place. After all efforts failed to relocate them to a common place, the people returned to the authorities resisting against their displacement. The role played by the politicians at different stages is very significant. While the then ruling *Telugu Desam Party* (TDP is a regional party) remained silent on this issue as the project was initiated by the party, the National Congress Party as the opposition did not undertake any effort to come to the rescue of the people. The leader of the Congress Party, Mr. Janardhan Reddy was not very happy with these people as they had not voted for them. The national *Bharatiya Janata Party* (BJP) sent a representative, Mr. Bandaru Dattatreya, the then Railway Minister for State of the Government of India, but he could not do much besides consoling the people and assuring them that no arbitrary action would succeed. Then the BJP was the ruling party in the central government and it was supported by the TDP as a coalition partner. The political parties of the Left did not help either. The threat of losing power made the minister not to take any progressive measure. The Mayor of the city, Mr. Teegala Krishna Reddy, wanted to visit the place after hearing about the protest. But the authorities, like the Revenue Department officials, convinced the Mayor that there were no problems with regard to the displacement.

The government took arbitrary measures and lodged a false complaint against the leader of the locality and arrested him. Policemen forcefully evacuated the people and cleared the locality by destroying

2 This is an area in Hyderabad the first case study dealt with. The displaced people were living in the place that belonged to the South Central Railway of India.

all structures which were built during several years of hardship and hope. The government moved all members to a place called NTR Nagar for resettlement and allotted them small houses which were already built for another purpose, but it did not keep any promise ranging from providing rice, money, and a feast. Although the locality from where the people were displaced was declared a slum by the *Municipal Corporation of Hyderabad* (MCH) and was receiving funds for the development of the slums from the World Bank and Asian Development Bank, these funds were never used and never reached the people. The argument of the displaced was that they were paying for all amenities provided by the government. But in turn the government never gave them proper facilities and finally put them in a place which is far away from their working place. The consequences of this displacement leading to vulnerability are dealt with more elaborately below.

35.4.2 Information and Technology (IT) Park at Cyberabad

The second case is an illustration of how capitalist forces can be the worst agencies to the poor in disguise. Within the city of Hyderabad there is a part called Cyberabad that has become the hub of information and technology. A large number of economic migrants from Andhra Pradesh and Karnataka had settled in a place called Manikonda. There were 439 families living by cutting stones, working in construction and as drivers. After IT companies like Microsoft, Wipro, Infosys and Polaris settled in this part, there was much construction. All 439 families were involved in construction for these companies. The land issue was disputed when the *Andhra Pradesh Industrial and Investment Corporation* (APIICL) extended the land for the IT companies, and one occasion which served as a platform to acquire this land was a visit of the CEO of Microsoft, Mr. Bill Gates, in 2004. When he visited the city the government proposed to evacuate all families and to use the place for more IT companies. As the people were all informal dwellers, they were requested to vacate the place within a month. This is the time when the politics of displacement sneaked in; the authorities used the *divide and rule* method. One of the leaders of the locality called Tirupati was taken to the IT minister, Mr. Sabita Indra Reddy, and wooed with gifts and assured of full support that he required. The leader convinced a large number of the people that they had all come to the city with nothing but that the government was ready to give them a house and proper resettlement. This convinced many people and most of them followed this leader to get displaced and resettled. The major hurdle against the government was solved more easily than the authorities expected.

Another reality of forced eviction followed and the people were sent to a village ten kilometres away to a place called Indra Reddy Nagar, but to the dismay of the displaced, the host community did not allow the displaced to enter their village. Although the land belonged to the government it could not do much. The people in the nearby village were upset that some outsiders were being given free land. This gave rise to a violence of a different kind and the host community began to intimidate the displacees, with the women being worst hit, as will be discussed below in dealing with vulnerability and gender. Due to the pressure from academic groups, the government took some steps to get houses built for them, but to the consternation of the people, during this process the government came up with another infrastructure project of the *Outer Ring Road* (ORR) for the city. Thus, the people were pushed into multiple displacements and had to move again to a semi forest opposite to the first allotted place of resettlement.

35.4.3 International Airport Project

The third case refers to the International Airport Project, the most devastating and one of the biggest displacements in Hyderabad. The government of Andhra Pradesh, under the leadership of former Chief Minister Chandra Babu Naidu of the Telugu Desam Party (TDP), had proposed the plan for an International Airport in the year 2000, but it had not received any assurance as new leaders took over in Andhra Pradesh after the elections. The TDP lost the elections and the Congress Party came to power in 2004 and instantaneously got the approval of the Central Government of India that was also led by the Congress Party, and started the work. Both the IT park in Cyberabad and the International Airport projects were launched under the same legislator, Mrs. Sabita Indra Reddy. Although a formal announcement was made about the land acquisition, just fifteen days before the actual date of displacement the people of the four villages were informed. This short notice came as a shock as there were a number of ceremonies planned for several months already in this locality. The people approached the legislator, Mrs. S. I. Reddy, for additional time to complete all ceremonies in the village. The legislator, Mrs.

Figure 35.2: The three sites of displacement in the mega city of Hyderabad: 1) MMTS station Lakdikapool; 2) Cyberabad Info Tech park; and 3) the International Airport. **Source:** Corporate Infobase Ltd. and Municipal Corporation of Hyderabad; at: <http://www.ghmc.gov.in/hyd/hydmap.asp>.

S. I. Reddy granted fifteen more days and promised proper compensation and resettlement to all affected people as they had land titles. She also explained the inevitability of having such a project and made it clear that the project was certain to happen. When these processes were going on, the people were in a di-

lemma, whether to move from the place or to stay there and protest. After the given time, the authorities came with the police forces and asked the people to vacate. On 13 May 2004, more than 500 Special Police Forces involuntarily displaced the people and they were moved in lorries like animals, and the land was forcefully acquired.

The Government of Andhra Pradesh acquired 5,480 acres of land for this project and more than eleven villages were affected either fully or partially (Reddy 2006). Out of the 5,480 acres of land 3,400 acres belonged to private owners who have land titles (Pattas), the other 1,600 acres were considered as government land that had been occupied by the local people, especially by the people belonging to the Schedule caste and other backward classes for agricultural purposes fifty or sixty years ago. The people of these villages were dependent on the flora and on agricultural crops. Although compensation was provided to these people, it was negligible. The categorization of the land for compensation remained dubious and no justifications were given by the concerned authorities. The compensation was far below market values. Adding to the wound of displacement the people who had been living on the assigned lands were in troubled waters as the compensation scheme was pathetic for them. Although the people were organized in the *Shamshabad International Airport Land Loser's Welfare Association* (SIALLWEL) it could not bring any pressure on the government. People received 250 square yards as compensation to build houses. Several demands were submitted to the land acquisition officer, one was to employ one person from a family in the construction of the airport which was agreed but never became a reality.

35.4.4 Adverse Consequence of Displacement Leading to Vulnerability

Displacement by nature itself will lead to vulnerability, and if it is in the urban arena the agony cannot appropriately be explained. Vulnerability can be explained according to Kasperson (2001: 7) as: "the degree to which an exposure unit is susceptible to harm due to exposure to a perturbation or stress, and the ability (or lack thereof) of the exposure unit to cope, recover, or fundamentally adapt (become a new system or become extinct)." This is the same situation faced by all the displacees of all three crucial cases. The number of people displaced and loss of all or part of their productive assets, employment, and loss of livelihoods are immesurable as it just does not involve the measurable assets but also involves pyschological trauma.

The many stories from the field refer to an extreme level of psychological and physical trauma. In the NTR Nagar (1st resettlement colony) when a boy named Salim was asked what he wanted to become in the future, he replied that he wanted to become a doctor and treat his fellow residents, but his dreams were shattered and now he is without school and the family is no more capable of assisting him as he has 6 older sisters waiting to be married off. Another case of a boy called Tofique Ahmed is more depressing. After the displacement his father lost his job and later ended up as an alcohol addict and died in an accident close to the new locality, currently the boy is 16 years old and is responsible for his family. He works with a construction group doing manual labour. He has managed to enrol two of his sisters in a Madarasa for their education by sacrificing his own. A girl Sailaja was a top student in her previous school and she had dreams to become a civil servant but as the new locality had no school she was forced to do household work.

The vulnerability level at the Indra Reddy Nagar resettlement colony is the worst in all three resettlements. The people were residing without even a proper shelter. They were displaced in 2004 and were doomed to remain without proper housing facilities until May 2005. Their huts were so small that a person could not stand and it was built with small wooden sticks and leaves. The worst part was that, during the summer when throughout Andhra Pradesh it rained incessantly, their belongings got washed away along with the huts and the people had to take shelter in one of the buildings in the vicinity which were under construction. As the people had tapped the power from the electric poles directly many of the children were electrocuted. In one such incident a boy called Ravi passed away and he was the only son of the family. The resettlement colony made people extremely vulnerable during the nights. The resettlement colony is so far away from the city and it is surrounded by a small forest where snakes would sneak through the houses and were seen on the small roads of the colony. There are several incidents where elderly people and children got bitten by the snakes.

In the International Airport resettlement colony the agony of the people has been unimaginable. Adding to the shock, several elderly people passed away with cardiac arrests as they lost everything, at the expense of mere compensation. The system exposed them to extreme stress, crises, and shocks at the dis-

placement site of the International Airport area. One person, Mr. Krishna, who is the president of the *Shamshabad Mandal Differently Abled Peoples Association*, lost his father due to cardiac arrest when the displacement took place, and his mother also passed away within two months due to the separation from her husband as it came as a shock for her. Mr. J Narasimha lost both parents due to the shock of losing the land of their livelihood. There are hundreds of examples which are depressing and each case documents the autocratic way used by the government and yet again failing to keep the promises it made to the people.

35.4.5 Human Rights Abuse, Human Security Approach and A Gender Perspective

The displacement has caused several vulnerabilities including cultural alienation, dispossession of land resources, human rights abuse, and lowering of living standards. Due to its crosscutting nature no social or equity and distribution analysis can proceed without a discussion of gender. Thus, a growing constituency of policymakers, social advisers, and gender scholars address gender mainstreaming and 'engendering' activities. They use gender conceptually and practically to approach a whole array of issues ranging from forced migration to development cooperation and health. Here the process will be reviewed which led to the mainstreaming of gender in national development, at least at the de jure level. The tragedy of displacement due to development projects is compounded because the affected bear the cost without sharing the benefits. In the case of women, of course they had even lesser access, as mere passive recipients in fallouts.

There is an attempt to link human security issues and other societal, economic, and development challenges India is currently experiencing due to globalization and privatization. The individual and their interests are under threat from the state behaving in a coercive manner to suppress the freedom of its people by working for vested economic and political interests. According to the human security concept there is a need for protection from "sudden and hurtful disruptions in patterns of daily life" (UNDP 1994: 22). This aspect of daily life further identified some core elements which reflect the basic needs of human security: economic, food, health, environmental, personal, community, and political security (UNDP 1994: 23–25). The concepts of human security, peace, and development can be related in a more cohesive manner. Human security is formulated on the premise of rights and entitlements that were articulated and adopted in the *Universal Declaration on Human Rights* (UDHR)[3]. The UDHR states that the basic socio-political and economic conditions should be guaranteed to every human being, and that "every one has the right to life, liberty and security of the person" (Art. 3, UDHR).

The Commission on Human Security, chaired by Nobel laureate Amartya Sen and Sadako Ogata (CHS 2003), calls for an integration of policy responses to address the interconnectivity of threats to human security. The report focused on human security issues in the light of democratic principles and development dealing with the security in protecting the people from violent conflict, encouraging fair trade, and markets to benefit the extremely poor, ensuring universal access to basic education and healthcare facilities. Its greatest strength is its focus on larger socio-economic and political threats.

These threats are noticed in all three case studies on Hyderabad that noted five human rights challenges. The Indian Constitution provides certain rights which are not respected but abused by some government agencies. These rights define the situation as the right a) to development and self-determination, b) to participation, c) to life and livelihood, d) as the right of vulnerable groups, and e) as the right to remedy arising from development-induced displacement. The Indian Constitution also mentions some rights explicitly or implicitly among the fundamental rights (Art. 19, 21, 29, 31), as guiding principles of state policy (38, 41, 46, 47, 48A), as special provisions relating to certain classes (Art. 330, 342), and as right to constitutional remedies (Art. 32). If the government is to seriously address problems of the *resettlement and rehabilitation* (R&R) process, it must introduce a rights-based approach to the respective national policy.

Only in the past few decades a gender perspective has been offered by scholars (Vandana Shiva 1993; Ganguly Thukral 1996, Goyal 1996; Cernea 1997; Vasudha 1998) and different organizations working on women's issues. The adoption of the convention on the elimination of all forms of discrimination against women in 1979 was an important step in addressing the imbalances in gender-related issues. The UN (2002) issued a report on Women, Peace and Security

3 United Nations, 1948: *Universal Declaration of Human Rights*. General Assembly Resolution 217A (III), UN Doc A/810 at 71 (New York: United Nations); at: <http://www.udhr.org>.

based on Security Council resolution 1325 adopted in 2000. The study acknowledges that more has to be done to achieve the expected goal.

Vandana Shiva (1993) argued that women's underdevelopment was not due to insufficient and inadequate participation, but due to their enforced and asymmetric participation whereby they bore the cost but were excluded from the benefits. This refers to a different set of ideas on the process of displacement and resettlement of women where women have been neglected in the policy process. The authorities in charge of the relocation did not understand the problems of women in adjusting to the new locality. Since, even under normal circumstances, society has yet to treat women equally, the displaced women will need additional attention to cope with the changed circumstances until they can become equals. The traumas of displacements are directly connected with the rights of women and their civil liberties. There is a need to maintain the social rights of all those who are vulnerable, but the required attention has so far not been granted. Úrsula Oswald Spring (2006) argued that

> human rights and its phases of development do not guarantee minimal life conditions, but reinforce the individualization process increasing social vulnerability. On the contrary, social rights reinforce networks and create within diverse cultural contexts and cosmovisions options for resilience building, reduction of social vulnerability, self reliance and peaceful conflict resolutions.

The women need time to adjust to the new community and all communities are not safe for women. For example, men in resettlement colonies do not have toilet facilities, so, they go out to the field but it is not easy for women to do the same during the daytime. There are other examples to document that women are worst hit in any developmental project. A shocking and disgraceful situation occurred at the Indra Reddy Nagar resettlement colony. Uma was pregnant and when it was raining heavily in Andhra Pradesh during the summer, due to the unhealthy conditions at the resettlement colony she got sick at night, and as the colony had no transportation facility or health centre Uma passed away without proper medical care, along with the child.

The future of the women and children has been taken for granted by the authorities. The children who are displaced have no proper education and the utter poverty has made them vulnerable at one level and on the other hand there are instances of children becoming anti-social elements by indulging in theft and other crimes. Due to the burden some parents have even sold their children and there are instances that a girl was sold for a low price like a commodity. Women trafficking and child abuse have been other major factors of vulnerability.[4] The women are mere passive recipients. First of all children and women are vulnerable in the family during post displacement situations. Thus, there is a necessity to emphasize education.

35.5 Conclusion

The debate on resettlement and rehabilitation cannot occur in isolation. Many decisions of this generation will affect the needs of coming generations and this generation is not entitled to transfer a devastated future to coming generations for which every citizen will be blamed and held responsible.

- *First*, involuntary displacement is a phenomenon which should be understood in a humane way. An experience is required to asses the best way. The human security issues involved in development and displacement must be understood by the agencies involved in the process. Human rights abuses must end as well as the vulnerability this causes and to the risks involved in such projects.
- *Secondly*, there is a growing consensus among policymakers and the academic community on the overwhelming exposure and risk of impoverishment and on rights to protection and assistance. In reality, however, a bewildering array of motives for development-induced displacement prevails. The members of civil society should take the responsibility and make sure that the marginalized people are not harassed, and that their rights are not abused. The civil society has to respond positively and make it possible that a more egalitarian society may emerge.
- *Third*, the absence of (and inability to enforce) legal frameworks is a major factor of concern, there is a growing attention to the (human) rights and entitlements of those displaced as a consequence of conflict and development, although there is little consensus on appropriate institutional responses. The resettlement of internally displaced people has, until recently, been treated as a peripheral issue, the reasons for this are varied and interconnected – including the absence of international attention, the marginal status and the lacking

4 In a previous volume of this book series these issues have been analysed for other countries by Truong (2009) and Perpinian/Villareal/Oswald Spring (2009).

'voice' of the displaced, and the limited attention devoted to the subject by social scientists and other disciplines. This mindset has to change and the world must respond in a more cohesive manner and practice solidarity with the displaced communities.

- *Lastly*, the development-induced displacements leading to social, economic and political vulnerability, and moving to psychological trauma must be given a pause and any development should be egalitarian, only then a country can progress towards the right direction and build a conducive and healthy environment for everyone to live in. This is the responsibility of every human being who is concerned about the world.

36 Linking Oriental and Western Thinking to Mitigate Flood Risk

Xiaomeng Shen

"水能载舟，亦能覆舟" (魏征，580-643)

"Water can carry a boat or sink it." (Wei Zheng, 580-643).

36.1 Introduction

This famous quote by the Chinese Prime Minister Wei Zheng of the Tang Dynasty (618–907) uses the characteristics of water as a metaphor to describe the relationship between a ruler and his/her people. People are symbolized by water which can be utilized and be beneficial for the ruler; the ruler is symbolized by the boat which relies on the water to carry it. However, water can be an ambivalent double cross. Once the harmony between the water and the boat is disturbed, water brings destruction.

This relationship can be transferred to the relationship between water and human beings. Water is indispensable for human life as it does not only provide natural resource services essential for the development of human civilization, but also nurtures intellectual inspiration. Philosophers such as Confucius (551 BC–479 BC) meditated on the source of life and exclaimed: 'Water, ah water!' trying to find the fundamental principles of life (Allan 1997: 31). Maybe the Chinese have conferred a unique meaning to water in the intellectual domain; however, it is not only the Chinese who have shown a propensity towards water in the course of history. Pohl (1993) pointed out the significance of the natural event of flooding on human civilizations: "The frightening as well as fruitful floods of Euphrates and Tigris in Mesopotamia, and the floods of the Nile in Egypt or of the Yangtze and the Huanghe in China have greatly influenced the development of mankind" (Pohl 2003: 196). Wittfogel even contends that the need for irrigation and flood protection is a decisive factor which laid the foundation of a societal form (Wittfogel 1955: 44–45).

Despite the environmental services and intellectual inspiration that water and flood events provide for humankind, the power of water is also manifested in destruction. Floods often have great negative impacts on human well-being. They cause loss of human life, economic damage, damages to ecosystems, aggravate human health problems, and damage historical and cultural sites. In the last decade of the 20th century floods killed 100,000 worldwide and affected over 1.4 billion people (Jonkman 2005: 151–152). According to Munich Re, about one third of all reported damages and one third of all economic losses are flood-related. Over the last few decades there have been more casualties due to flooding than caused by all other natural catastrophes together (Kron 2003: 80). During the period from January 1975 to June 2002, freshwater flood events are reported to have killed 176,864 people and affected 2.27 billion according to the International Disaster Database (EM-DAT) of CRED (Jonkman 2005: 158).

Less developed countries are especially affected by floods. According to CRED data, among the ten most deadly floods since 1931 China is listed seven times (table 36.1), and among the floods that affected most people since 1989, China is listed even nine times (table 36.2). Among the top ten most important flood disasters for the period from 1900 to 2009 (sorted by economic damage costs at the national level), China has been listed four times (table 36.3). According to another source of the five floods with highest casualties since 1978, China is listed twice (table 36.4; Jonkman 2005: 158). Flood mitigation is gaining more and more importance, posing an ever challenging task.

What are the major discourses in the international flood risk management community? How do the Chinese flood experts and managers perceive and cope with flood risk? Can different cultures learn from each other's experiences, based on the link between

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_36, © Springer-Verlag Berlin Heidelberg 2011

their thinking? This chapter endeavours to examine the flood risk management strategies in China by conducting a case study in Wuhan, China and explore the potential of mutual learning within the global community in order to better cope with risk and disaster. Section 36.2 will discuss the main discourses on flood risk management. The field site chosen for the case study and research design will be elaborated upon in 36.3. Then research results will be presented (36.4), followed by discussion and conclusion (36.5).

Venezuela, Flash flood	15 December 1999	30,000
Bangladesh, –	July 1974	28,700

36.2 Flood Mitigation

Currently, there are two main discourses on flood disasters. The dominant view considers floods to be a natural disaster. The alternative discourse sees flood disasters as being jointly produced by the interaction of the physical hazard and social vulnerabilities. The latter discourse brings to the fore social relations, structures, institutions, and governance as well as political processes in understanding flood disasters (Lebel/Nikitina/Manuta 2006: 3; Dixit 2003: 166; Stefanovic 2003: 231; Few 2003: 47). As a consequence of differences in perspectives within these discourses, the implications for flood mitigation strategies are different as well.

Table 36.2: Overview of the ten flood events with most affected people. **Source:** UniversitÈ Catholique de Louvain, Brussels, Belgium, EM-DAT: The OFDA/CRED International Disaster Database; Created on: 2 June 2009. Data version: v12.07; at: <www.em-dat.net>.

Country	Date	No. Total Affected
People's Republic of China, general flood	01.07.1998	238,973,000
People's Republic of China, general flood	01.06.1991	210,232,227
People's Republic of China, general flood	30.06.1996	154,634,000
People's Republic of China, general flood	23.06.2003	150,146,000
India, –	08.07.1993	128,000,000
People's Republic of China, general flood	15.05.1995	114,470,249
People's Republic of China, general flood	15.06.2007	105,004,000
People's Republic of China, general flood	23.06.1999	101,024,000
People's Republic of China, –	14.07.1989	100,010,000
People's Republic of China, flash flood	08.06.2002	80,035,257

If the first approach is applied, the focus is on physical events. The implication for mitigation is the prediction of their magnitude and occurrence using hydrological and meteorological science. Technical measures such as dykes and dams are solutions to alleviate floods. However, these technical measures only intensify flood problems and this approach largely ignores the mitigation potential during the normal time between two flood events (Dixit 2003: 166). This hazard-led approach does not involve the affected people in the decision-making about mitigation. Instead, mitigation is carried out in a bureaucratic manner through a top-down approach (Dixit 2003: 166).

Certainly, short-term reductionist strategies have their place at certain times and within certain scales. However, numerous studies revealed that disasters are not only the outcome of natural hazards, but also of socio-economic structures and political processes that make individuals and families vulnerable (Lebel/Nikitina/Manuta 2006: 3; Wisner/Blaikie/Cannon/Davis 2004: 216; Dixit 2003: 166). This perspective is la-

Italy, flash flood	14.10.2000	8,000,000
People's Republic of China, general flood	23.06.2003	7,890,000

belled as the 'alternative approach' which focuses on how social systems operate to make people vulnerable to disasters. This approach recognizes the fact that natural hazards do occur, but vulnerability is equally important for the outcome of a disaster (Dixit 2003: 166).

Due to asymmetric socio-economic relationships, for instance, those families which have no access to basic resources, such as land, food, and education are particularly vulnerable. "Disasters are the unresolved problems of societies during 'normal' times, and these problems affect the way people are impacted by disasters" (Dixit 2003: 168; Wisner/Blaikie/Cannon/Davis 2004: 206). Lebel, Nikitina and Manuta (2006: 3) pointed out that viewing disaster solely as a technical problem ignores the importance of participation and transparency, and conceals the politics of shifting risk to already vulnerable groups.

Yet, public participation in flood mitigation has not been widely practised; instead the public are treated as irrelevant to the technical exercise of assessing and managing risk and designing institutional responses. Despite the knowledge and promotion of community-based flood disaster management by international agencies, national agencies remain sceptical about its implementation. Reason for this scepticism lies in the fact that this approach requires "addressing fundamental issues of governance and social justice that may undermine positions of authority" (Lebel/Nikitina/Manuta 2006: 3–4).

Whilst public participation in river basin management is strongly advocated by the scientific community[1], case studies in many Asian areas such as Nepal, Vietnam, and Thailand among others show that the dominant response to flood mitigation has been hierarchical and guided by the motivation to control both water and people through states. Consequently, flood mitigation is translated into structural measures which have been proven to be insufficient (Dixit 2003: 174; Lebel/Nikitina/Manuta 2006: 4). Dixit concludes: "that the appropriate response to flooding lies in providing unhindered drainage is an intellectual blind spot because of the political-economic incentives of structural flood control measure" (Dixit 2003: 174).

Lebel, Nikitina and Manuta often observed in their case studies 'risk redistribution' instead of risk mitigation. The interventions reduce risks for one group while increasing them for another. The study describes a common phenomenon of risk redistribution in order to protect major cities. For instance, the protection of the central business district of Bangkok frequently put the surrounding suburbs and upstream districts or farmlands at risk. Due to a lack of prior involvement of the farmers and compensation mechanism serious conflict was provoked (Lebel/Bach/Garden/Bui/Subsin/Le/Nguyen 2008: 3). At the same time, the information made available to the urban population emphasizes structural measures which protect the interests of local elites in urban areas. The social and environmental impacts of such measures on affected areas are not mentioned (Lebel/Bach/Garden/Bui/Subsin/Le/Nguyen 2008: 4).

In addition, the reliance on structural measures leads to crisis driven management, since engineering measures could fail. Simultaneously, more building and investments behind the dykes are generated due to the structural protection, in return, more people

1 See: Jansky (2002: 58); Wisner/Blaikie/Cannon/Davis (2004: 239); Lebel/Nikitina/Manuta (2006: 4); Dixit (2003: 169); Bradbury (1989: 394); Tierney/Lindell/Perry (2001: 201); and Krasovskaia/Gottschalk/Berg/Mcerlain/Ngu/Geissler (2006: 9).

Table 36.4: Overview of the five freshwater flood events with most people killed. **Source:** Jonkman (2005: 158).

Country	Year	Month	Day	Killed	Total affected	Description
Venezuela	1999	12	19	30,000	483,635	flash and river floods and landslides around Caracas and other areas
Afghanistan	1988	6		6,345	166,831	floods in Badakhshan, Baghlan, Heart, Kabul, Jouzjan, Samangan, Takhar provinces
China	1980	6		6,200	67,000	floods in Sichuan, Anhui, Hubei
India	1978	7		3,800	32,000,000	floods in north and northeast India
China	1998	8	6	3,656	238,973,000	river floods combined with storms and landslides in Hubei, Hunan, Sichuan, Jiangxi, Fujian, Guanxi Prov.

and assets are at risk (Lebel/Bach/Garden/Bui/Subsin/Le/Nguyen 2008: 5).

The flood events in the past decade have triggered a rethinking process about mitigation strategies. Especially those flood events in the developed world such as the Elbe flood in 2002 in Germany led to the collapse of confidence in engineered flood prevention in these countries (Wisner/Blaikie/Cannon/Davis 2004: 201). Cutter believes that the ideology of conquering and taming nature, rather than living in harmony with it, was and still is the driving force in the production of the physical vulnerability of the metropolitan area.[2] As a result of the rethinking of the past flood mitigation strategies, the thought of enabling rivers to flow freely and the approach of 'living with floods' arose in the last decades (Wisner/Blaikie/Cannon/Davis 2004: 201–203).

However, this 'new' approach is not completely new. During the Chinese Western Han Dynasty (206 BC–24 AC) flood disasters occurred frequently in the Huanghe River Basin. From 39 BC to 11 AC there was a flood disaster every seven years due to dyke breaches. The most affected area at that time was Jizhou (today's Heibei Province and the south-west of Shandong Province) which was back then already densely populated. The economy in the area was prosperous and the density of townships was the highest in China. Yet, the economy was often severely affected by flood disasters. Thus, the Emperor called for flood mitigation strategies among the officials and scholars (Tan/Wang/Zhou 2005: 49).

One of the most famous strategies was recommended by one of the government officials, Jia Rang. He proposed three different approaches which he categorized into best, moderate, and worst practices. He considered the first approach as the best approach whose core dictates that human being "should not compete with water for land". He suggested relocating the people living between the Taihang Mountain and the dyke along the northern river bank of the Yellow River so that the river could flow freely. The worst practice would be to build dykes and fight against floods. He argued that it was not feasible only to renovate and build dykes, but that, on the contrary, structural measures were not only costly but also detrimental to flood management. Thus, he considered this approach to be the most unfeasible one. The moderate approach which combines dyke building and the creation of retention areas was considered to be the most practicable approach (Tan/Wang/Zhou 2005: 49).

Although Jia Rang's flood mitigation strategy of allowing rivers to flow freely has become a canonical work in the Chinese flood management history, neither his best practice nor his moderate approach have ever been seriously undertaken (Tan/Wang/Zhou 2005: 49). Already in early China of the Western Han period, Jia Rang's opponents argued that his best policy was not applicable due to the advanced economic development and population density.

Today, two thousand years later, Western academics and flood managers have reinvented Jia Rang's thought. At the same time, the Chinese water management authority at the national level has also started to advocate the 'new' idea of 'leaving flood space to flow'. Still, despite the growing understanding of disasters, loss of life and property from flood disasters remains unacceptably high and is increasing in affected countries, including China (table 36.3).

Thus, to investigate how Chinese institutions manage flood risk and how they shape their mitigation strategies according to their conception of risk seems to be a feasible start for understanding the challenges in flood mitigation in China. The next section will elaborate the case study design for researching the

risk perception of flood managers and their current flood mitigation strategies in Wuhan, China.

36.3 Research Method

36.3.1 Field Site

The study was conducted in the city of Wuhan in China. Wuhan is located in the middle reach of the Yangtze River. Sub-tropical monsoon dominates the climate. Yearly rainfall is 1,205 mm. As the provincial capital, Wuhan is the political, economic, and cultural centre of Hubei Province as well as the intersection of water, air, and land transportation. Wuhan is one of the most important economic zones in the Yangtze River Basin (figure 36.1). The GDP of the city of Wuhan was 259 billion Yuan in 2006 and per capita GDP was about US$ 3,790[3].

Altogether Wuhan was flooded more than 50 times in the last 800 years. The magnitude of the flood events in 1996, 1998, and 1999 are comparable to the most severe flood event in 1954 (Xu/Rao/Mao/Zhao 2003: 1). According to Fan (2000: 3) 1,183 firms had to interrupt their production during the Great Flood of 1998 and direct economic loss mounted to ca. 4.4 billion Euros, which was 4.8 per cent of the total GDP in the year 1997 in China (Fan 2000: 3).

36.3.2 Research Design

The qualitative social research methods applied in this research include semi-structural interviewing, informal interviewing, field observation, and documentary analysis. Semi-structural expert interviewing was the principal method of data collection in this study. The structured approach systematically asks each informant the same or thematically similar questions (Bernard 2006: 385). This enables comparison between cases and makes coding and analysis of data easier. This approach is especially applicable to research which involves high-level bureaucrats and elite members of a community who have time constraints (Bernard 2006: 212; Kelle 1999: 63). Since this research focuses on how flood experts and managers construe their risk conception and shape coping strategies accordingly, this specific qualitative method is applied.

Informal interviewing and field observation serve to provide additional information to triangulate with the data collected through more formal structured interviews. Documentary analysis includes newspaper articles, official websites, and governmental documents which provide information on how flood risk is perceived by flood experts and managers to complement and triangulate with the other data sources.

During the field work data collection was carried out in 2 phases. The first field phase took place between the end of August and the middle of October

3 See: "Wuhan Tongji Shuju", in: <http://www.whtj.gov.cn/documents/whsq2007/index.htm> (25 October 2007): 1–2 of 5.

2005. In this field phase a bottom-up strategy was applied, since the researcher mainly interviewed the river basin and local flood managers in Wuhan. After analysing the data collected, a second field phase was carried out between November and December 2006 in order to generate additional data to fill 'data gaps'. Here, further interviews were conducted with interviewees at river basin and national level, as well as NGOs. Altogether 35 semi-structured expert interviews were conducted.

The research subjects cover government officials of different agencies such as the flood protection and related agencies, environmental agency, representatives of NGOs such as conservationists' union, as well as the military. Interviewees at different management levels for flood protection were invited to attend the discussion with the researcher, since flood protection in China is arranged in a hierarchical way and all management levels from the central to the local government are involved in flood protection. This includes the national, river basin, and local levels.

36.4 Research Results and Analysis

The research results of the case study in Wuhan have revealed distinctive features of the hazard-led technical approach of the flood risk mitigation strategies which were elaborated above (36.2). These features are mainly shown through the perception of flood risk as an objectively calculable fact, the consequently rationalistic approach and risk distribution without public participation in the decision-making process.

According to the interviewees (in 2005/2006) flooding is a calculable and controllable natural event which requires technical solutions such as technical forecast and probability modelling. One interviewee stated: "Flood management is simple. Namely, we better hydrologically forecast and build more and better dykes. Don't you know the Chinese saying, 'once water comes, one stops it with earth'" (Interview, 2005)?

Dyke construction as a major coping strategy is based on the ideology of altering nature for the benefit of man – a typical Maoist ideology evolved during the Chinese Cultural Revolution. Especially at the local level many interviewees cited Mao's idea of conquering nature and fighting the flood: "We can not allow the flood to do whatever it wants. Like Mao said, we have to build dams and dykes and fight against the flood" (Interview, 2005).

In addition, risk managers believe that the dykes and reservoirs would guarantee them a bright political career like Yu (also Dayu, meaning the Great Yu), the famous King of the old once had. Dayu is a household name in China and the myth about how he coped with flood disasters has left its imprint in China's flood management approach. The official website of the Chinese Ministry of Water Resources published a series of articles on China's water management history to celebrate the World Water Day. One article states, "The Great Yu is the symbol of the spirit of the Chinese nation. The significance of Great Yu's water management is a part and parcel of the long Chinese history and it is also the peak of our civilization"[4]. Dayu was the first successful flood manager in recorded history for water management. Yu's method is to channel water to the sea following the 'way of water'. Mencius elaborates the 'way of water' as taking advantage of its natural tendency to flow downward and yield to obstacles. Thus, Yu controlled water by following water's natural inclination (Allan 1997: 40).

However, today this myth is conferred with different meanings: "The management approach of the Great Yu reveals a vivid picture of how our ancestors *fought* against floods. It also reflects the *unyielding fighting* spirit of our people in the course of *conquering* nature. His fearless spirit of *fighting* floods and his great achievement of water governance has been praised and handed down over generations. This spirit provides people with courage to *fight* flood disasters".[5]

Coupled with the belief that man can shape nature and control nature as well as the meaning of flood management for a political career, the eagerness of engineered flood measures among the flood managers seems to be a logical consequence. The dyke is not only a functional protection measure, but has also monumental symbolic for the politicians: "The Great Wall running thousands of miles and built on water has been constructed based on the 'concept of harmony between man and water'; it has become a monument in the heart of the people living along the river."[6]

This fighting spirit and the western rationalistic ideology, which was brought to China during the New Cultural Movement at the beginning of the 20th cen-

tury (Hu/Aer/Qiong 2005), seem to reinforce each other, thus, *scientism* has assumed an unshakable position in flood mitigation strategies. Baum observed that one of the characteristics of modern Chinese culture is the propensity to idealize science, to reify and universalize its precepts, thereby elevating it from a method of inquiry to the status of canonical dogma (Baum 1982: 1172). Scientific evidence is instrumentalized to justify reductionist engineered flood mitigation strategies as one interview states: "The most important thing in flood protection is to base our measures on solid scientific calculation" (Interview, 2005). Another interviewee even understands science as an instrument to create harmony between man and nature: "Science shall deepen the harmony between man and nature in relation to flood protection" (Interview, 2006).

As Beck states, the discussion in the western world on environmental destruction is only or at least dominantly based on a natural science paradigm. It is largely misconceived that all problems also have a social, cultural, and political meaning. Beck calls it the "*technocratic and naturalistic*" approach. However, this approach is blind to power and distribution structures, bureaucracy, current valid norms, and rationalities (Beck 1986: 33). This description of the technocratic approach in the western world coincides with the statement of Chinese water management officials. Decision-making based on 'scientific evidence' is a strong feature of decision-making in Wuhan and among other management levels.

Rayner contends that a hierarchical culture formalizes risk like all the other themes (Rayner 1992). This behaviour pattern is eminent among the interviewees in water management. When asked about what could be done to reduce flood risk in Wuhan, flood managers often have a very similar response as follows: "Flood risk reduction is just to relocate flood water in different retention areas; decide which reservoir will be used for what purposes; to implement the emergency plans for flood management; consultation to the higher leaders; to collect information of dangerous situations and respond to it..." (Interview, 2006)

Science seems to be entirely neutral to assess risks and therefore free from any moral judgement. At the same time science becomes also a strong instrument to justify the government's behaviour in assessing, managing risk, and their decision-making. Furthermore, science is also an instrument to stabilize authority, because experts always know better and it is the expert who has access to science and acts accordingly.

While many western scholars strongly advocate the approach of 'taking the naturalness out of natural disaster', Chinese water authorities still emphasize the 'naturalness' of a natural disaster and therefore support their risk management strategy using a 'pure' scientific paradigm.

Engineered flood protection supported and justified by scientism leads to *risk externalization* in urban areas which rank high in terms of population and economic considerations, since risk distribution priority is clearly defined according to criteria of population density and economic status (Li 1999: 34). Flood risk in the city of Wuhan is assigned to the retention areas located close to the city (see figure 36.2).

One of the most frequently used retention areas is Dujiatai with a total population of 256,200 according to the statistics of 2004.[7] The city area of Wuhan is protected by dykes. Dykes, as a result of development of technology, are not only used for the function of protection, but also as an instrument to channel risks. This risk distribution approach is perceived to be the most rational way to distribute risk and whose acceptance of stakeholders is not questioned: "The safety of the city of Wuhan should certainly be guaranteed with all means. The other areas can take more risks. Flooding one or two counties in a rural area is not a big deal. We have to take a certain risk and we can calculate risks and see which region can take which risk" (Interview, 2005).

Externalizing risk distribution jeopardizes both the city of Wuhan where inhabitants and local managers completely rely on transporting risk to other areas and the retention areas which are not flooded on a regular basis, for people living in these areas are often not aware of the risks they are facing. Especially in retention areas such as Dongxihu which has never been put into use since its construction in 1957.[8] "Local people living in retention areas are often not aware that they are living within a retention area which can be flooded in case of severe flood events to ensure the safety of more important protection objects" (Interview, 2005). Thus, risk distribution has become an ever challenging and risky undertaking.

However, this externalizing risk distribution is again justified by the cultural tradition. One interviewee argues: "In China it is not like in western countries, that people risk living in flood prone areas in or-

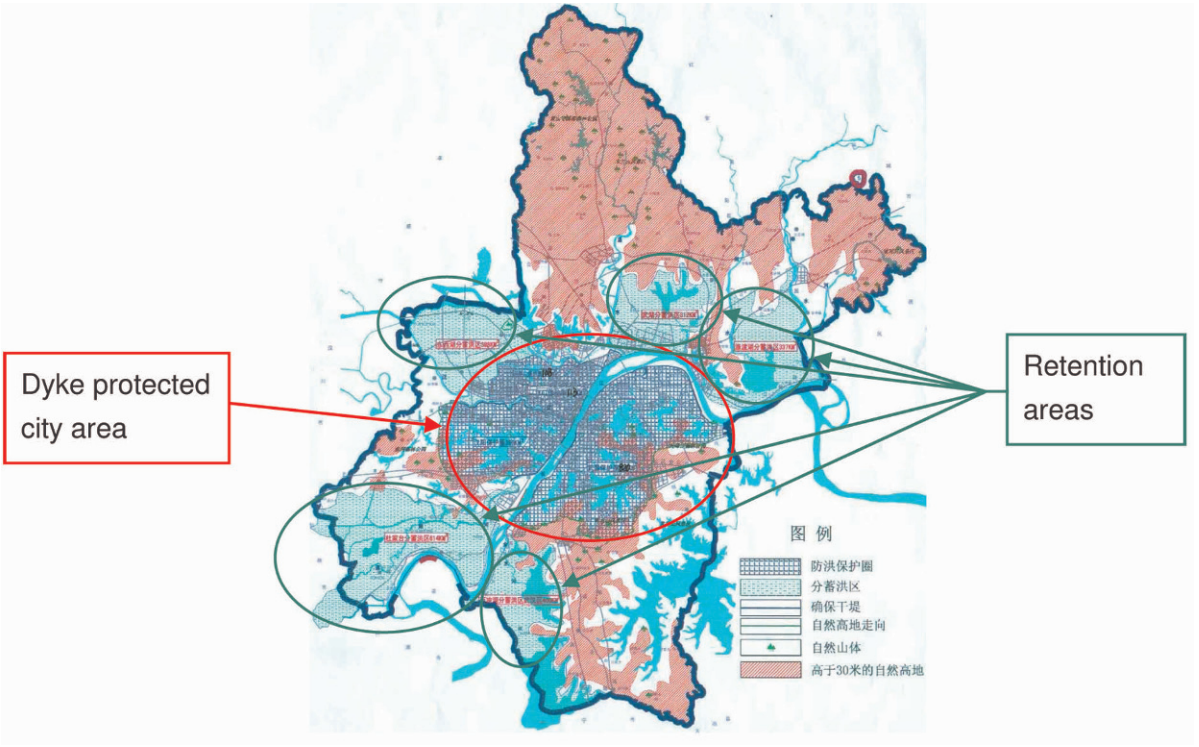
8 See: <http://www.chinawater.com.cn/cwrn/cwrn.htm> (30 January 2008): 1–7 of 11.

Figure 36.2: Retention areas in Wuhan. **Source:** Wuhan Chengshi Guihuaju (2003).



der to make more money due to the cheap real estate prices. If they are flooded, they require financial aid paid by all tax payers. In China people have to live in retention areas, otherwise they can not make a living at all. This is like a family with 2 sons: if one son gets a better land protected by dykes, another son has to farm in high risk locations. Once a flood occurs, the son with safer land is obliged to help the son living in a high risk area. The same applies for people in retention areas. Once a disaster occurs and their land has to be flooded, then they will get help from all over the country. This is our culture" (Interview, 2006).

The dilemma here is that this principle functions well if everyone obeys this cultural rule. But in reality the interests of affected people are far from being protected through moral obligation. Without legal enforcement a compensation mechanism solely based on and enforced by a moral code is not ensured. Consensus of affected people on being exposed to urban flood risk is highly hypothetical. Only *public participation* involving affected people into the decision-making process can ensure that their interests are represented properly. However, some local managers seem to be at a loss as to how to respond to public participation when confronted with this topic (field observation, 2005/2006). This shows that public participation is indeed a new concept to many local flood managers. They are more used to the traditional way of coping with flood which focuses on crisis driven top-down management during flooding events.

Other water managers perceive public participation to be a new concept of decision-making which is not completely in line with the traditional Chinese culture. The flood managers in Wuhan who are very sceptical about this approach argue: "We don't have too much public participation in our country. This is due to our thousand-year-old culture. People are willing to be guided and led. The relationship between people and government is a relationship of leading and being led. People don't want to make their own decisions. They have been used to it since thousands of years" (Interview, 2005).

36.5 Discussion and Conclusion

The flood risk management approach in Wuhan is hazard-led and focuses on emergency management. This approach largely ignores the interests of vulnerable social groups in rural areas and the externalization of flood risk from urban agglomeration to rural regions increases the vulnerability of these social groups which affirms the research results of the previous studies in other countries (36.2). Chinese flood man-

agement at the national level has realized this problem, yet, a compensation law to ensure social justice is still embryonic. Moreover, this approach is deeply embedded in the traditional Chinese flood management ideology and justified by the scientist paradigm; thus, a depoliticization of risk becomes a logical consequence of this practice.

Doubtlessly, the integrated flood mitigation approach is widely accepted and advocated by international communities. Yet, the implementation of such an approach depends on fundamental values and beliefs of a society as well as the social relations each society prefers. Especially viewing risk as a social process requires extensive public participation which is one of the most important categories for good governance according to democratic principles. It enhances policy efficiency and legitimacy, when citizens and other institutions have a chance to influence how rules are formulated and implemented (Van Ginkel/Court/Barrett 2001: 18). However, countries such as China have a completely different value system and worldview. It appears that a political and cultural change is needed to adopt the Western democracy-based management approach. Yet, any such change can only take place ideally from within. If the purpose of culture research is to find out features of certain existing cultures and adapt or formulate one's own policy accordingly to work with but not against this culture, it is beneficial to improve hazard management. However, the intention to change or form a new risk culture through a culture study is doomed to fail, for any cultural change takes place during a very long period. And organizational culture particularly is very resistant to change (Johnson 1991).

In addition, the desirability of western modernity in countries like China is questionable. Although western modernity is in the process of successfully projecting its self image upon the rest of the world, it manifests limits in radically different societies (Deuchars 2004: 203). It removes from the story the richness of cultural diversity and space and place specificity (Deuchars 2004: 205). Deuchars contends: "All known societies do order their world to confront the dangers perceived there, however, and so to privilege one form of risk management as being universally superior is a form of conceit" (Deuchars 2004: 203).

Yet, the existence of commonalities across national and cultural borders can serve as the key to transferability of different practice and thinking. The Chinese Yin-Yang principle as an essential part of the Chinese traditional cultural heritage is based on a pluralistic approach. It encompasses both active and passive approaches which seem to have found an echo in the western rethinking process about flood management. Balance and stability, according to this principle, can only be reached by combining both passive (non-structural) and active (engineered) measures. Jia Rang's flood mitigation strategy followed such a tradition. The link between the ancient Chinese wisdom and the novel western (re)thinking appears to be a key to facilitate this political and cultural change.

37 Preparation for an Earthquake in the Megacity Istanbul

Sıdıka Tekeli Yeşil

37.1 Introduction[1]

This chapter addresses the importance of involving and ensuring the active participation of individuals and communities in disaster mitigation and preparedness activities[2]. The key question of this chapter is: What are the factors affecting action regarding mitigation of damage due to earthquakes and earthquake preparedness at the individual level in Istanbul? The chapter is based on the literature review carried out by the author for a study in Istanbul[3].

After brief information on the process of taking action regarding disaster mitigation and preparedness (37.2), the megacity of Istanbul will be reviewed as an example (37.3), looking at the factors affecting the way its residents practise preparedness and mitigation activities (37.4). In conclusion some recommendations will be put forward (37.5).

The impact of natural hazards has increased in severity in recent decades due to the growing vulnerability[4] of populations through, *inter alia*, rapid population growth, urbanization, environmental degradation, poverty, and social inequalities (Wisner/Adams 2002: 15–17; Arnold 2002: 6–7; Brauch 2005). It is therefore becoming vital that pre-disaster activities should be undertaken at both the community and individual level to mitigate the consequences of disasters and sustain the population's resilience. To be effective and successful, efforts to improve mitigation activities and preparedness at governmental, sectoral, and institutional levels should be supported by corresponding efforts at the community and individual levels. For example, land-use strategies or the application of building codes do not mean much if they are not observed (as often happens), and early warning systems are useless if the people do not know what to do or are unprepared for such situations.

The opposite is also true: governments should support individual and community disaster preparation efforts. For example, first aid training could be provided for volunteers and cheap credits given to house-owners to strengthen the construction of their homes. This is why disaster risk reduction was described in the context of the *International Strategy for Disaster Risk Reduction* (ISDR) as a shared responsibility between governments, communities, and individuals (ISDR 2004: 13). Additionally, in many disasters the victims and local people are the first to respond, especially where search and rescue activities are concerned. They can also be isolated or unreachable in the early phases of disasters and thus have no option but to cope with the situation by themselves. Their involvement and active participation in any kind of mitigation and preparedness activities are therefore essential for coping successfully with natural disasters.

1 The author is grateful to Necati Dedeoğlu, Director of the Public Health Department, Akdeniz University Medical Faculty; Marcel Tanner, Director, Swiss Tropical Institute; and Charlotte Braun-Fahlaender, Director a. i., Institute of Social and Preventive Medicine, University of Basel for their helpful input.

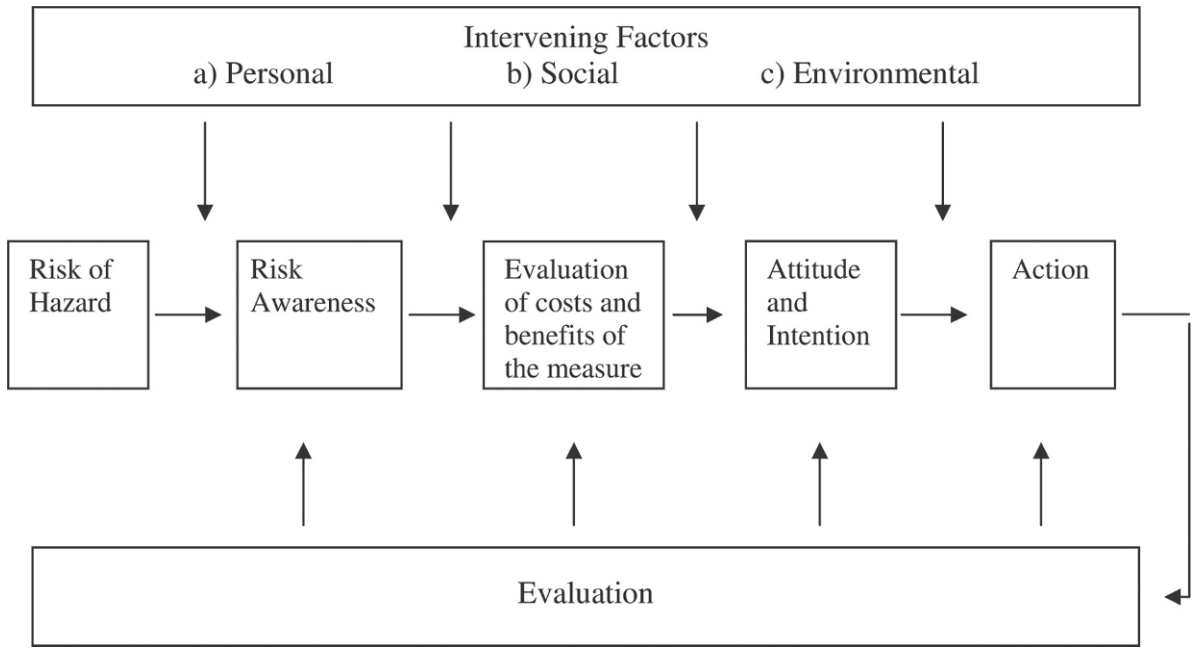
2 Preparedness comprises activities designed to minimize loss of life and damage, to organize the temporary removal of people and property from a threatened location, facilitate timely and effective rescue, relief, and rehabilitation, while mitigation comprises measures taken in advance of a disaster aimed at decreasing or eliminating its impact on society and the environment (Wisner/Adams, 2002: 13).

3 PhD project at the University of Basel/Switzerland: "Factors affecting the process of taking action at individual level regarding mitigation and preparedness for an earthquake in Istanbul."

4 The term 'vulnerability' explains "the characteristics of a person or group and their situation that influence their capacity to anticipate, cope with, resist and recover from the impact of a natural hazard" (Wisner/Blaikie/Cannon/Davis 2004: 11); and "a function of susceptibility (the factors that allow a hazard to cause a disaster) and resilience (the ability to withstand the damage caused by emergencies and disasters and then to recover)" (Wisner/Adams 2002: 13).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_37, © Springer-Verlag Berlin Heidelberg 2011

Figure 37.1: Conceptual Framework for the Process of Taking Action on Disaster Mitigation and Preparedness. **Source**: The author.



Getting the cooperation of individuals and communities is not easy. Studies in various countries with different economic and social backgrounds have shown that people tend to be uninterested in and unwilling to take action for preparedness and to reduce their risks.[5] Many social, economic, personal, environmental factors underlie this situation. 'Freedom from hazard impact' can only be achieved when people who are vulnerable to such hazards and disasters (which are often intensified by associated societal threats, challenges, vulnerabilities, and risks) receive better warning of them and are prepared and protected against their impact (Brauch 2005: 41). While many studies focus on understanding the susceptibilities of populations, an equal understanding of the characteristics of resilience in a population is also important in maintaining this freedom and mitigating the consequences of hazards.

37.2 Factors Affecting Individual Preparedness

A conceptual framework on the process of taking precautions at the individual level was developed and applied in the data collection and analysis. This framework is based on theories and models which were used in epidemiological studies to understand risky and protective health behaviour and activities, e.g. on the 'Health Belief Model' (Schwarzer 1991; Becker 1974; Strecher/Rosenstock 1997); on Ajzen and Fishbein's (1980, 1991) 'Theory of Reasoned Action and Theory of Planned Behaviour'; and Rogers' (1975) 'Protection Motivation Theory', and inspired by DeJoy's (1996) model for 'Workplace Self-protective Behaviour'. These models and theories were applied to various preventive and life style behaviours, e.g. to vaccination, smoking, seat belt use, safe sex practices, and exercise (DeJoy, 1996: 62), and all contribute to understanding this behaviour which equals the behaviour on disaster preparedness.

This framework presents a five-step process and shows that where there is a hazard risk, awareness of this risk is the prerequisite of taking action. *Risk of hazard* is the risk of a hazard occurring and involves the type, severity, frequency, and impact of it. *Risk awareness* includes perception and knowledge of the risk, its consequences, and how to cope with it, which

5 See: Tekeli-Yeşil/Tanner/Brauen-Fahrlaender/Dedeoğlu (2007: 102); Dedeoğlu (2005: 273); Inelmen/Işeri Say/Kabasakal (2004: 150); Shaw/Shiwaku/Kobayashi/Kobayashi (2004: 48); Anderson-Berry (2003: 229); Paton (2003: 210); Fişek/Yeniçeri/Müderrisoğlu/Özkarar (2003: 59–60); Kasapoğlu/Ecevit (2001: 15); Kleindorfer/Kunreuther (1999: 727); Larsson/Enander (1997: 11); Hurnen/McClure (1997); Lehman/Taylor (1987: 551–552).

are determined by the availability of reliable and accessible information. These factors have an important influence on the process of taking action to prepare for disasters and mitigate their effects.[6] Although they present high correlations with taking such action, these factors do not, however, automatically guarantee better preparedness at the personal level or mitigation of the effects of disasters (Johnston/Bebbington/Lai/Houghton/Paton 1999: 123; Paton 2003: 210; Chan 1995: 304).

The next step is the *evaluation of costs and benefits*. When deciding whether to prepare for hazards, a person weighs the physical, psychological, and economic costs of taking action against the probable benefits to life and property in the future, and evaluates whether the input can bring greater and/or similar benefits if invested in another area, much as economists do when considering the opportunity cost of an intervention or an investment. According to the results of this evaluation, the sequence might continue with person's *attitudes* towards and *intentions* regarding taking action for mitigation and preparedness, followed by the action taken. Sometimes, as a consequence of a disaster or some other development, the action concerned may be followed by an evaluation applied to all or some of these steps.

The process of *taking action* cannot be considered only in the context of a hazard. A serious of social, personal, and environmental factors is also crucial in this process. This is why intervening factors have been included in the framework. Each step and the transition phases can be positively or negatively influenced by intervening personal, social or environmental factors. Eventual elements of these intervening factors are as follows:

a.) *Personal factors:* previous experience with a disaster (Weinstein 1989: 46, Johston/Bebbington/Lai/Houghton/Paton 1999: 120, Anderson-Berry 2003: 219); availability of resources, such as time, skill, financial and physical resources (Mamun 1996: 71; Chan 1995: 291); demographic characteristics such as age, cohabitation, the presence of a child in the household, type of residence, e.g. ownership or rent (Larsson/Enander, 1997: 17); unrealistic optimism (Weinstein 1989: 44; Burger/Palmer 1992: 42); denial (Lehman/Taylor 1987: 551; personal beliefs such as outcome expectancy, such as perceptions of whether individual action will effectively mitigate or reduce a problem (Lindell/Whitney 2000: 18–19; Rohrmann 2000), and perception of hazards as controllable or uncontrollable (Slovic/Fischof/Lichtenstein 2001: 117; Rohrmann 2000); fatalism, helplessness (Mamun 1996: 69) of the hazard (Renn/Wiliams/Kasperson/Kasperson/Slovic 1992: 156); transfer of responsibility to others, e.g. to the state, government or local authorities (Inelmen/Işeri Say/Kabasakal 2004: 149; Paton 2003: 214; Johnston/Benton 1998); world views (Slovic 2001: 402–403).

b.) *Social factors:* socio-economic status, social class (Burningham/Field/Trush 2008: 220); social network (Anderson-Berry 2003: 227; Paton/Millar/Johnston 2001: 163); sense of community (Paton 2003: 213; social support and interaction (Mileti/Fitzpatrick 1992: 399); cultural phenomena (Kasapoğlu/Ecevit 2004, Bontempo/Bottom/Weber 1997: 480, 486); lack of trust (Inelmen/Işeri Say/Kabasakal 2004: 146) media coverage (Renn/Wiliams/Kasperson/Kasperson/Slovic 1992: 156).

c.) *Environmental factors* mainly related to the phenomenon: frequency of occurrence; normalization bias (Paton 2003: 211, Becker/Smith/Johnston/Munro 2001); imaginably and potential for catastrophe (Slovic/Fischof/Lichtenstein 2001: 107, 117); characteristics and impact of the hazard agent, such as speed of onset, scope, and duration of the impact (Lindell 1994: 320–321); location (Lindell/Prater 2000: 326).

37.3 Megacities and Vulnerabilities of their Residents in Relation to Natural Disasters

The global urban population was 46.7 per cent of the total world population in 2000 and is estimated to rise to 59.9 per cent in 2030 (UN 2006, 2007). Nowadays, urban areas are at the highest risk of disaster since they are places where nearly all factors that make populations more vulnerable are seen or experienced. These factors include high population concentration and densities, in some cases uncontrolled spatial expansion and severe infrastructural deficits, high concentration of industrial production, insufficient housing provision, ecological degradation, and in some cases extreme socio-economic disparities and high immigration rates (Kraas 2003/4: 9). Furthermore, the most crowded cities of the world are lo-

6 See: Johnston/Bebbington/Lai/Houghton/Paton (1999: 1229); Lindell/Whitney (2000: 23); Mileti/Fitzpatrick (1992: 394); Weinstein/Sandman (1992: 73); Mamun (1996: 69); Ronan/Johnston/Daly/Fairley, (2001); Dedeoğlu (2005: 273); Kasapoğlu/Ecevit (2001: 92).

cated in areas that are at extremely high risk of natural disasters (ISDR 2004: 59). As more people move each year to urban areas, it is clear that special attention should be given to the development of projects on urban preparedness.

Disasters in urban settlements can also have positive consequences for awareness. Özerdem and Barakat (2000: 433) mentioned the urban-rural dichotomy when pointing out that even though there have been many earthquakes in Turkey[7], it was only after the 1999 earthquake that earthquake safety and disaster management began to be taken seriously due to the large number of urban areas affected, and as victims were mainly urban dwellers.

An investigation into earthquake preparedness in Istanbul would benefit other cities, even for other types of disasters, since megacities have more in common with each other than with their own hinterlands (Kraas 2003/4: 9) In addition, although all hazard events are unique and their consequences may differ depending on many factors, the similarities in the human response to hazards means that the results could also have general relevance for other hazards. The suggestion is that the methods and findings are not applicable to all cities and all types of natural hazards, but the common aspects in human response and the living circumstances are noteworthy.

37.4 The Case of Istanbul

The social, demographic, and economic characteristics of Istanbul can be summarized briefly as follows. The 2007 general census showed that 12,573,836 people were living in Istanbul; the population density was 2,420 people per km^2; 89 per cent of the people were living in urban areas, 70 per cent of the population was between 15 and 64 years of age.[8] The annual population growth rate was 3.3 per cent and the unemployment rate was 12.7 per cent (IBB 2001). The high population growth rate in Istanbul is mostly due to migration of low-income groups from other parts of Turkey for employment opportunities. This situation produces many problems which increase the vulnerability of the population, such as overcrowding, inadequate infrastructure and services, environmental degradation, and informal settlements (the *gecekondu,* which are makeshift one story houses built illegally on government land, on the outskirts of the city). Since *gecekondus* are constructed without regard to building codes and regulations, the structures are weak and susceptible to hazards. Unfortunately one fifth of the Istanbul population lives in the *gecekondu* (Keleş/Geray, 1995: 141). There are approximately 2,714,462 buildings in Istanbul, of which only 32 per cent are insured against earthquake risk[9] even though insurance has been compulsory since the end of 1999.

On 17 August and 12 November 1999, the Marmara region, where Istanbul is located, was shaken by two severe earthquakes with magnitudes of 7.4 and 7.2 respectively on the Richter scale, which cost nearly 18,000 lives and did severe damage to buildings, economic life, and infrastructure (Sayıştay Bakanlığı 2002/3: 13). Some authors have estimated that there is a 62 per cent probability (± 15 per cent) of an earthquake of a magnitude of approximately 7 on the Richter scale before 2030 in the vicinity of Istanbul (Parsons/Toda/Stein/Barka/Dietrich 2000: 661). During the 1999 earthquakes Istanbul, except for the Avcılar district, was not affected as badly as other cities in the Marmara region, mainly due to the distance from the epicentre of the earthquakes.

The province of Istanbul consists of 1 metropolitan municipality and 32 district municipalities; 13 of the latter are located on the first degree (highest) earthquake risk zone, 17 are located on the second degree earthquake risk zone, 2 located on the third degree earthquake risk zone, and only 2 sub-districts (non-urban) on the fourth degree earthquake risk zone (Istanbul Valiliği Afet Yönetim Merkezi 2005).

37.4.1 Individual Preparedness in Istanbul

Fortunately, increasing numbers of studies about human responses to hazards and individual and community preparedness are being undertaken as more scientists and institutions in different disciplines have begun to deal with these issues. There is still, however, a limited number of studies at national and international levels. Below, findings are offered from a few studies on individual and community preparedness in Istanbul.

7 Between 1902 to 1998 and the two earthquakes in 1999, 129 earthquakes in Turkey caused damages, such as the loss of housing stock, and of these 92 resulted in fatalities ranging from 1 to 3,959 deaths; at: <http://angora.deprem.gov.tr/raporen.htm> (7 February 2008).

8 TUIK [Türkiye İstatistik Kurumu: Turkish Statistical Institute], at: http://www.turkstat.gov.tr (7 February 2008).

9 DASK [Doğal Afet Sigorta Kurumu: Turkish Catastrophe Insurance Pool], at: <http://www.dask. gov.tr/ istatistik21.html> (29 October 2008).

The consequences of a predicted earthquake in Istanbul would be severe, as well as its socio-economic consequences. One scenario projects between 30,000–40,000 casualties and more than 120,000 injured people needing hospitalization (BU 2003: 81). The 1999 earthquake in Turkey and the experience in the rest of the world have shown that most minor and medium injuries are caused by non-structural elements and building contents, e.g. by glass and furniture (Petal 2000: 2–3; Noji 1997: 157) Furthermore, almost all victims were either rescued by local people (neighbours, family members) or saved themselves (Dedeoğlu/Erengin/Pala 2000: 365; WHO 1999: 11). These two findings clearly highlight that individual preparedness plays a critical role and that there are many things that individuals and the community can do to prevent or mitigate the consequences of earthquakes, even with small-scale investments. Although there are many promising mitigation and preparedness programmes which have been conducted since the 1999 earthquakes, the situation in Istanbul on earthquake preparedness at the individual and community level is inadequate.

The level of awareness of the predicted earthquake among the inhabitants of Istanbul is quite high. In the study of Fişek/Yeniçeri/Müderrisoğlu/Özkarar (2003: 25) respondents gave a realistic appraisal of the risk they face in terms of the security of their zones.[10] In the same study, 75 per cent of the respondents gave relevant answers to the question what an earthquake is and 62 per cent saw the construction as the real source of danger. Many inhabitants of Istanbul had experienced earthquakes before (Bay Aytekin 2006: 26; IBB 2002: 126) and had a high perception of the risk of a predicted earthquake. According to studies conducted in different districts of Istanbul, over 50 per cent of the respondents perceived a high risk about a predicted earthquake: 68.8 per cent (Kalaça/Bay Aytekin/Çalı 2007: 405); 52.5 per cent (Işeri Say/Inelmen/Kabasakal 2005: 12); 58.3 per cent (IBB 2002: 46); 58.1 per cent (T.C.[11] Başbakanlık PUB 2005: 16). However, risk perception declines when the question is referred from the city to the individual level. (Işeri Say/Inelmen/Kabasakal 2005: 12).

In the study of Bay Aytekin (2006: 34) 26 per cent of the respondents thought that there is nothing to be done individually against earthquakes. Structural safety was the most commonly mentioned measure (67 per cent) as a way to mitigate the damage from an earthquake among the respondents of the study of Fişek/Yeniçeri/Müderrisoğlu/Özkarar (2003: 53). Despite the people's high perception of risk, very few mitigation or preparedness activities were undertaken (Inelmen/Işeri Say/Kabasakal 2004: 150; Kalaça/Bay Aytekin/Çalı 2007: 405; Fişek/Yeniçeri/Müderrisoğlu/Özkarar 2003: 60; IBB 2002: 33–43). More than 10 per cent of the respondents had not taken any such measures. According to Kalaça, Bay Aytekin and Çalı (2007: 405) and Işeri Say, Inelmen and Kabasakal (2005: 13) 12.9 per cent and 16.7 per cent, respectively, of the respondents had taken no measures for earthquake preparedness, even though earthquakes had been often a theme of daily conversation (IBB 2002: 10–11; T.C. Başbakanlık PUB 2005: 17).

The most common mitigation and preparedness activities undertaken were learning how to behave during an earthquake; having an earthquake bag/kit; fixing high furniture and equipment; obtaining an earthquake insurance (Kalaça/Bay Aytekin/Çalı 2007: 405; Fişek/Yeniçeri/Müderrisoğlu/Özkarar 2003: 60; IBB 2002: 33–43).

37.4.2 Factors Affecting Individuals in Taking Mitigation and Preparedness Actions in Istanbul

The 1999 Marmara earthquakes, which killed over 18,000 people, showed the need for action to prepare for an earthquake in the city of Istanbul. The need to mitigate damage and for preparedness activities was only acknowledged after these deadly earthquakes. (Tekeli-Yeşil/Tanner/Brauen-Fahrlaender/Dedeoğlu 2007: 102; Balamir 2001: 229; Karancı/Akşit 2000: 413). The findings of various studies showed that the

10 High risk districts in earthquake zones or the site dependent intensity distribution of a scenario earthquake provided by related governmental or municipality departments and universities and open to the public knowledge. For detailed information about risk zones or high risk areas see: Afet Işleri Genel Müdürlüğü Deprem Aratrma Dairesi [General Directorate of Disaster Affairs, Earthquake Research Department]; at: <http://www.deprem.gov.tr>; Istanbul Metropolitan Municipality; at: <http://www.ibb.gov.tr/trTR/SubSites/IstanbulVeDeprem/> and BU: Earthquake Risk Assessment for the Istanbul Metropolitan Area Final Report (2003).

11 Risk perception for a destructive earthquake in Istanbul in 2–5 years or later was 58.1 per cent; and within the coming three months or in a year was 13.5 per cent.

following are important factors in undertaking mitigation and preparedness activities in Istanbul.

1. *Higher socio-economic level* (Kalaça/Bay Aytekin/Çalı 2007: 405; Fişek/Yeniçeri/Müderrisoğlu/Özkarar 2003: 62–66). In both studies respondents with a high income or a high socio-economic level had a significantly higher completed prevention score or had taken more precautions than other groups.
2. *Educational level*: According to Bay Aytekin (2006: 34) a higher education level of the respondents influenced significantly their positive attitudes towards preparedness, as well as on taking more precautions.
3. Istanbul citizens living in a district with *relatively high risk*[10] (Kalaça/Bay Aytekin/Çalı 2007: 405) gave a realistic appraisal of the risk they face on the security of their zones. Respondents living in higher risk areas had taken more precautions.
4. *High perception of risk*, where the risk is perceived as a threat to the person or the family (Kalaça/Bay Aytekin/Çalı 2007: 405). However, high risk perception was not followed by action (Fişek/Yeniçeri/Müderrisoğlu/Özkarar 2003: 57, 66).
5. *Trust*: Two studies (T.C. Başbakanlık PUB 2005: 33–37; Öncüler 2002: 6–7) of people's decisions on retrofitting buildings against earthquakes showed that trust (in the institutions that plan, apply, and control retrofitting projects) was an important determinant for decision-making for mitigation of damage. Green (2008: 363–368) discussed distrust of a construction process especially among residents of *gecekondu* districts. She argued that additional to the root causes of unauthorized housing – poverty, macro-economic instability, urban migration, and hierarchical social relation – distrust promotes self-built, unauthorized construction. Because these people perceived self-built houses as being more, rather than less earthquake resistant, as they are constructed by themselves and not by someone interested in profit. Inelmen, Işeri, Say and Kabasakal (2004: 146) discussed the lack of trust in various information sources. Their study and other studies (IBB 2002: 119) showed that scientists and university institutions were the most trusted sources of information on earthquakes.
6. *Experience with an earthquake*: Previous experience with a major earthquake, losing a close relative or friend and participating in solidarity activities during the 1999 earthquakes, were found as significant factors by Kalaça/Bay Aytekin/Çalı (2007: 405).
7. *Fatalism*: Almost all studies noted the existence of fatalism that was no significant factor for taking precautions. However, the study by Inelmen, Işeri Say and Kabasakal (2004: 144) claimed that it was a key factor for not joining disaster preparedness organizations.

In multi-storey buildings with many apartments, group dynamics (T.C. Başbakanlık PUB, 2005: 27) and home-ownership (Kalaça/Bay Aytekin/and 2007: 405; Fişek/Yeniçeri/Müderrisoğlu/Özkarar 2003: 63) were important factors for implementing mitigation and preparedness measures. Öncüler's (2002: 6–7) research showed that the average willingness to pay for earthquake mitigation measures increased when a building nearby was improved. The reduction in damage due to mitigation was another factor. The respondents were more likely to pay for a mitigation activity that offered 'zero damage'. But positive attitudes towards mitigation and preparedness did not necessarily result in such measures being taken (Fişek/Yeniçeri/Müderrisoğlu/Özkarar 2003: 25).

37.5 Conclusion

The impacts of hazards are not just geological, meteorological or hydrological events, they do not only leave economic damage or casualties behind them, and disaster management is not just a technical matter. There are human and social issues around hazards which must also be well understood. Disasters cannot be managed only with technical measures such as an increase in the number of search and rescue personal and ambulances. A wise and effective measure is to educate the communities and individuals for the pre- and post-disaster stages, and maintain their active participation in mitigation and preparedness activities (Tekeli-Yeşil 2007: 192–193). As megacities are seen as hotspots of risk,[12] special attention should be paid to them. By understanding their vulnerable aspects, it is important to determine and use the opportunities they provide.

As noted above (37.4, 37.4.1), in the near future an earthquake is expected in Istanbul with effects beyond those of the earthquakes in 1999. According to

12 See the press release on "Megacities – Mega Hot Spots", by the Institute for Environment and Human Security of the United Nations University in Bonn; at: <http://www.ehs.unu.edu/article:365>.

the conceptual framework (37.2), based on the cited studies, the risk of an earthquake in Istanbul is quite well known by the inhabitants and leads to a high risk perception and moderate awareness. If individuals personalize their actual risk, their high perception of risk can lead them to undertake activities to prepare better for this hazard; otherwise it is no guarantee for critical earthquake awareness or for further activities. But despite an increase in awareness, there is little progress towards taking action.

The studies presented above have shown that there is some awareness within the community but not enough to trigger protective practices. Even if there is little information on evaluation of costs and benefits of physical, and economic aspects of taking individual action; home-owners see more benefit in taking measures on mitigating damage. The expected amount of reduction in damage due to mitigation is also an important factor in this step. Even if the attitudes for mitigation and preparedness measures are optimistic; studies show that they do not necessarily lead to action. According to the framework, possible factors for the disruption between awareness and the following steps are the intervening personal, social, and environmental factors.

Findings from the studies mentioned above and from other studies conducted in other parts of Turkey (Dedeoğlu 2005: 273; Kasapoğlu/Ecevit 2001: 61–62) as well as studies from around the world (Larsson/Enander, 1997: 17; Chan 1995: 292; Lindell/Prater 2000: 327) indicate that socio-economic and educational levels play a significant role in individual preparedness, and are influencing almost all steps of the process.

Living in a high-risk area and experience with a high magnitude earthquake seem to be motivating intervening factors. Past experience of disasters can be a starting point for many people, especially when they have had direct experience, such as participating in rescue or solidarity activities after the event. The lack of trust in the construction sector and information sources is acting as a constraining factor in undertaking precautions. Due to the higher trust people have in scientists and university institutions, they can be seen as potential actors to transmit the appropriate messages of mitigation and preparedness programmes. Findings about group dynamics and positive effects of a building nearby that had been strengthened, indicate the role of social interaction, which can also be helpful in persuading people to adopt precautions. Fatalism does not seem to play as important a role in disaster preparation as might be expected, however, this issue needs further explanation (Tekeli Yeşil/Dedeoğlu/Tanner/Braun-Fahrlaender/Obrist 2008: 12).

Based on the reviewed literature (37.2), it can be assumed that there should be additional key factors instrumental for the gap between awareness and action among citizens of Istanbul. Except the location (living in a high-risk area) there is no information on environmental factors, such as suddenness of onset, normalization bias, poor predictability, etc. Personal beliefs and perceptions on the probable outcome, on counter measures and where the hazard is seen as controllable or not, are also important factors that influence the process of taking action. But there is limited information on such personal factors. Furthermore, there may be additional social factors, due to the specific characteristics of Istanbul or cultural phenomena in the community. These points need further investigation.

In conclusion, the involvement and active participation of individuals in any kind of mitigation and preparedness activities is vital for coping successfully with natural disasters. Preparations for reducing damage from hazards are extremely important for a better disaster management. Individual preparedness for earthquakes and hazards are, however, complex processes, which are determined by many social, economic, environmental, and personal factors. Therefore it is important for disaster managers to identify barriers and motivations particular to their communities in order to communicate the risk successfully.

Finally, risk reduction is a community-based activity which involves the participation, power sharing, legislation, organization, and development planning. These factors mean that not much preparation can be expected in poor, powerless, marginal societies (Dedeoğlu 2006: 129). Preparing for disasters cannot be left with individuals alone: it is the duty of governments to increase the resilience and coping mechanisms of the population. Thus, for cities to become safer, individual activities regarding earthquake preparedness or other hazards should be supported by and integrated into governmental, institutional, and communal preparedness. In this context, disaster risk reduction has to be seen as a political, economic, and social issue, since disasters can only be coped with effectively if disaster management is successfully integrated into social and economic development.

38 Risk Management Strategies for the Predicted Earthquake Hazard in Istanbul

Ebru A. Gencer

38.1 Introduction

Istanbul, the largest and the most populated city in Turkey, lies at the crossroad between Europe and Asia. This natural setting that has created the potency of Istanbul's urban environment is, however, also a characteristic that threatens it. Located in an active earthquake zone, Istanbul's history has been interrupted many times by earthquakes; and today, history may repeat itself as scientists predict that in the near future the city will experience a major earthquake.

This chapter examines risk management[1] strategies for coping with the predicted earthquake hazard[2] in the metropolitan city of Istanbul. The chapter starts by explaining research questions and methods (38.2), and examines Istanbul's current earthquake hazard exposure and risk[3] (38.3). The chapter then continues by exploring the city's earthquake risk coping strategies (38.4), in addition to bringing in the results of the author's empirical research in Istanbul's local municipalities, depicting disparities and vulnerabilities[4] in this metropolitan city (38.5).

38.2 Research Questions and Methodology

This chapter is based on the author's doctoral dissertation, which examines the interplay between natural disasters, vulnerability, and sustainable development (Gencer 2007). As part of a larger framework, this chapter builds on to investigate how the sustainability of an urban environment shapes its vulnerability and disaster risk management. This chapter is primarily concerned with understanding how much impact natural disasters have on disaster risk management, as well as investigating factors that influence the adoption and the implementation of disaster risk reduction strategies in urban areas.

This study is based on a combination of secondary data gathering, field, and survey research. Local data collection and consultations included research at the Istanbul Governorship Disaster Management Center, the Geotechnical and Earthquake Investigation Department of the Istanbul Metropolitan Municipality, at the Master Planning Office of the Istanbul Metropolitan Municipality, the Department of Earthquake Engineering at Boğaziçi University Kandilli Observatory, at the Center for Disaster Management at Boğaziçi University, the Istanbul Branch of the Turkish Chamber of City Planners, the Istanbul Branch of

1 This chapter uses definitions given by the UN/ISDR (2004: 2) on the terms of disaster risk management, hazard, risk and vulnerability. It refers to the contemporary framework of disaster risk management, which gives emphasis to the proactive strategies of disaster risk reduction defined by the UN/ISDR (2004: 2–3) as "the conceptual framework of elements considered with the possibilities to minimize vulnerabilities and disaster risks through a society, to avoid (by prevention), or to limit (by mitigation and preparedness) the adverse impacts of hazards, within the broad context of sustainable development."

2 *Hazard* is an event, a condition, or a human activity, with a potential of causing a threat to people and to the physical environment, and that may result in a disaster. In most cases, its origin defines the hazard, such as natural or technological hazards (UN/ISDR (2004: 4–5).

3 *Risk* is the possibility of harmful consequences or expected losses resulting from interactions between natural or human-induced hazards and vulnerable conditions. In the field of hazard and disaster research, risk is commonly expressed as the product of hazard and vulnerability (UN/ISDR (2004: 6).

4 *Vulnerability* is the potential for loss (human, physical, economic, natural, or social) due to a hazardous event. It encompasses the conditions determined by physical, social, economic, and environmental factors or processes, which increase the susceptibility of a community to the impact of hazards (UN/ISDR (2004: 7).

the State Institute of Statistics, and the Istanbul Branch of the Ministry of Public Works and Settlement.

Field and survey research activities included development of a survey questionnaire to facilitate qualitative interviewing about disaster risk reduction activities carried out at local districts in Istanbul. A field research focused on observation of the urban context, as well as conducting interviews and collecting data in district municipalities in the city.[5] Data collection and interviews at this stage included research at Kadıköy, Zeytinburnu, and Avcılar Municipality.

38.3 Earthquake Hazard and Risk in the Istanbul Metropolitan Area

Turkey's unique location between two continents and three major plates – African, Eurasian, and Arabian – has caused major seismic events over the centuries. As the African and the Arabian plates move north towards the Eurasian Plate, the minor Anatolian plate is caused to move westward, resulting in a *strike-slip fault,*[6] known as *The North Anatolian Fault*, which is similar in length and movement to the San Andreas Fault in California (BU 2002: 87). The North Anatolian Fault extends from the Eastern Anatolian Region of Turkey to the western edge of the country, passing through the Sea of Marmara. Istanbul's seismic risk results from its location along this sea, under which tectonic plates move on one of the most active geologic boundaries in the world.

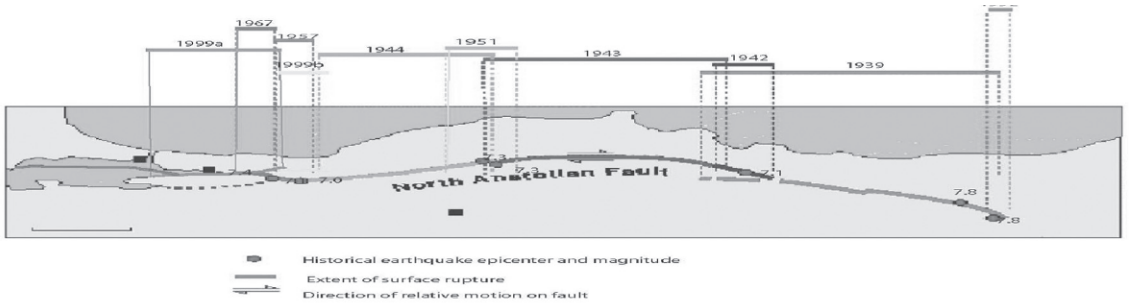
In recent years, an east-to-west progression of earthquakes along the North Anatolian Fault has increased Istanbul's earthquake risk. The first of the most recent major earthquakes, which are referred to as the Marmara earthquakes, occurred on 17 August 1999. The epicentre of the magnitude 7.4 earthquake was at Gölcük, south of Izmit, an industrial city that is located east of Istanbul. On 12 November 1999, a second earthquake with a magnitude 7.2 occurred in the region, near the town of Düzce.

The Marmara earthquakes were among the strongest earthquakes in Turkey, and they are considered to be the worst natural disaster in the Mediterranean region between 1975 and 2001 (Brauch 2003c). The losses from the two earthquakes were devastating: around 18,000 people lost their lives and 50,000 people were injured. In the two earthquakes, more than

5 Prior to the start of research, the author passed Columbia University's Human Subjects Protections Test and received a certificate for research. All interviews were conducted in a manner that respected federal regulations and responsibilities.

6 In strike-strip faults relative displacement of rocks is purely horizontal" (Bolt 2004: 357). In these faults, plates moving past each other horizontally lock together until tension builds to a release point. In the process, stress is released and placed on the neighbouring segments of the fault. These neighbouring segments are then more likely to rupture, resulting in progressive earthquakes along the fault (CU 2002: 123–124).

Figure 38.2: Historic Progression of Earthquakes on North Anatolian Fault. **Source:** Location of August 17, 1999 Turkish Earthquake; at: <http://www.usgs.gov>.



300,000 housing units and 46,000 business premises were damaged, and 320,000 people lost their jobs (Bibbee/Gonenc/Jacobs/Konvitz/Price 2000: 35). The extensive geographical area affected by the earthquake is considered "the industrial heartland of Turkey," with the most severely affected four cities (Kocaeli, Sakarya, Bolu and Yalova) contributing over 7 per cent of the country's GDP and 14 per cent of industrial value added at the time (Bibbee/Gonenc/Jacobs/Konvitz/Price 2000: 1). With the immediately surrounding cities of Bursa, Eskişehir, and Istanbul, the affected region had a share of 35 per cent of Turkey's GDP, stressing the risk of economic losses and significance of earthquake risk to Turkey's development. Direct and indirect economic losses from these two earthquakes were reported to be between five and twelve billion US dollars,[7] resulting in the world's highest relief cost between 1992 and 2003 (EQE 1999: 37). The immense damage of the Izmit earthquake pointed to the vulnerability of structures in Turkey. Post-earthquake inspections revealed that fault rupture, ground shaking, and soil liquefaction had caused structural damage that was intensified by poor construction quality.

Following the Marmara earthquake disasters and the heightened possibility of an earthquake in the Marmara Sea (due to the transfer of stress released by the Izmit earthquake), governmental, international, and academic organizations started working on depicting risk in the Istanbul metropolitan area. As an initial step, earthquake probability[8] calculations were performed for the Marmara fault. In 2000, Tom Parsons and his colleagues announced their calculations, and predicted the probability[9] of an earthquake of M. 7 or greater occurring near Istanbul within the next decade to be 32 +/-12 per cent, and in the next thirty years 62 +/-15 per cent (Parsons/ Toda/Stein/Barka/ Dieterich 2000: 1). Following this forecast, deterministic earthquake hazard assessments were undertaken in joint studies of the *Japan International Cooperation Agency* (JICA) and the *Istanbul Metropolitan Municipality* (IMM) (JICA/IMM/PCI/OYO 2002); and of the *American Red Cross* (ARC) and *Boğaziçi University* (BU 2002: 75). These studies concluded that the occurrence of a worst-case scenario earthquake with M 7.5 is considered "highly probable in the next 70 years" (Erdik/Siyahi/Şeşetyan/Demircioğlu/Akman 2003: 17). Following this diagnosis and the report of the newly founded National Earthquake Council, the Istanbul Metropolitan Municipality organized a consortium to provide risk assessment and vulnerability studies for an Earthquake Master Plan for Istanbul.

According to the site dependent deterministic intensity distribution maps presented in the *Istanbul Earthquake Master Plan* (BU/ITU/METU/YTU 2003), overall conditions lead to a likelihood of

7 The first number indicates the direct and the indirect losses that have been systematically compiled and reported to date in 2003 World Bank figures. The second numbers by OECD are suggested numbers reported by TUSIAD (Turkish Industrialist's and Businessmen's Association) as well as the numbers from Turkey's State Planning Organization (DPT).

8 There are two main approaches that are used in assessing an earthquake hazard: probabilistic and deterministic methods. Susan Cutter (2001: 24) explains that "[t]he *probabilistic approach* attempts to describe the integrated effects from all possible faults at an individual site." *Deterministic approach*, on the other hand, specifies a magnitude or level of ground shaking mostly for a single fault. This approach commonly represents a "worst case scenario," or the maximum risk the location and its residents are exposed to (Cutter 2001: 24).

9 In 2004, Tom Parsons (2004) of the USGS reassessed the hazard with improved Marmara Sea faulting and a new historical earthquake catalogue and recalculated that the 30-year probability of an earthquake at Istanbul is 41+/- 14 per cent.

strong ground motion on the southern part of Istanbul on the European side, along a portion of the coastline on the Asian side, and the Princes' Islands on the Marmara Sea. The northern areas of the city, due to their relatively large distance from the fault and more stable soils, are expected to have lower site-specific intensities resulting from the occurrence of a scenario earthquake (Erdik/Siyahi/Şeşetyan/Demircioğlu/Akman 2003). Unfortunately, the hazard exposed areas are also the areas where a large portion of Istanbul's development has taken place, which heightens the potential risk in the city.

Indeed, risk calculations performed for the predicted scenario earthquake present a bleak picture for Istanbul. As, due to deficiencies in design, quality of concrete as a construction material, and construction practices, the majority of the reinforced concrete building stock in Istanbul falls into an average vulnerability class C of the 1998 European Macro-Seismic Scale (EMS), intensity based vulnerability calculations for the Istanbul building inventory in 2000 expects more than 40,000 buildings (or about 5.5 per cent of the total building stock) to be damaged beyond repair, 77,000 thousand buildings (10.5 per cent) to be substantially-to-heavily damaged, and about 200,000

buildings (27 per cent) to be moderately damaged in a scenario earthquake (BU 2002: 243). Casualty calculations, based on both night and daytime population, and that were measured using HAZUS99[10] methodology and estimating a direct relationship between the structural damage and the number of casualties (Erdik/Siyahi/Şeşetyan/Demircioğlu/Akman 2003: 19), indicate that based on this building vulnerability, casualty levels in a scenario earthquake may vary between thirty to forty thousand people (BU 2002: 243). In addition to the potency of casualty, expected structural damages will also cause loss of settlement habitability. Analysis predicts about 600,000 households to be in need of shelters following a scenario earthquake in Istanbul, without adding the potential short-term needs of residents in moderately damaged houses (BU 2002: 213, 243).

In addition to buildings, other engineered urban structures, infrastructures, and lifelines are also vulnerable to the effects of earthquakes. Monetary losses from building damages in a worst-case scenario earthquake in Istanbul are estimated to be in the range of twelve billion US dollars (BU 2002: 243, 166). When secondary hazards, indirect economic losses, and social disruption are reflected in the damage assessment, broader dimensions of a scenario earthquake can be anticipated for the largest city in Turkey.

Furthermore, today, Istanbul's earthquake risk is enhanced by the socio-economic vulnerability of its population of over ten million inhabitants. The city is challenged by the volume and rate of internal migration flows. In addition to creating a big income divide, migration leads to illegal housing that is structurally unsafe, lacking in basic services, and located in hazardous areas prone to liquefaction and landslides. Indeed, in the 1990's, the rapidly growing migrant population had reached such levels that only 37 per cent of the population in Istanbul was born in the city (Sönmez 1996: 125). The new incoming populations are either unemployed, or working in temporary or low-skilled jobs and can not gain from Istanbul's economic progress. In fact, according to a survey of the State Institute of Statistics in 1994, in Istanbul, the top 20 per cent of the population with the highest income levels received 64 per cent of the total generated income in the city, whereas the bottom 20 per cent received only 4 per cent of it (Mortan 2000: 46). This polarization adds to the vulnerability of Istanbul's residents and stresses the need for a new risk management strategy.

38.4 Coping with the Hazard: Risk Management after the 1999 Marmara Earthquakes

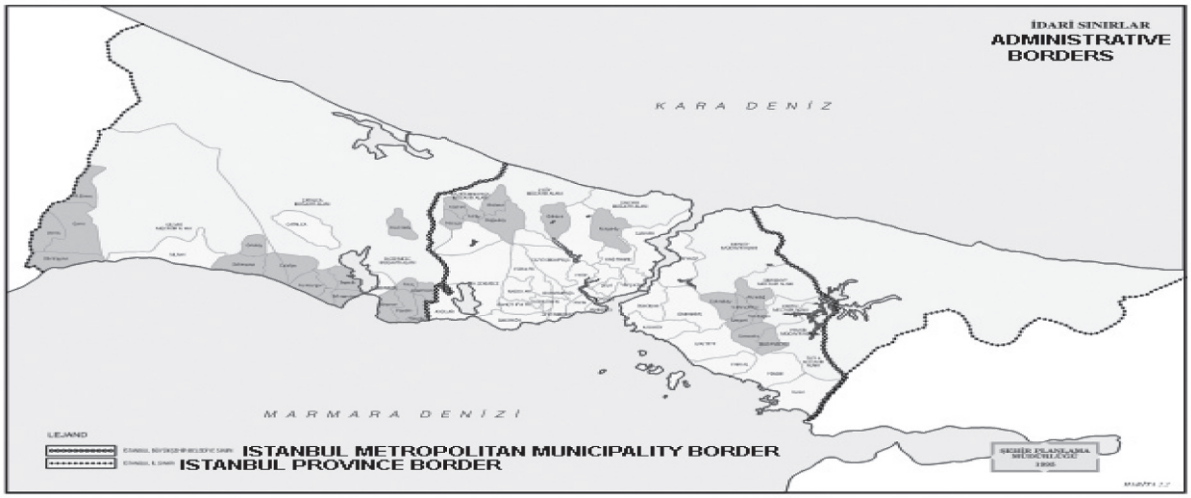
Following the two Marmara earthquakes, and the heightened possibility of a major earthquake in the Istanbul region, there has been a widespread acknowledgment of the significance of disaster preparedness in Turkey. This has been followed by a series of actions from international organizations, central and local governments, academic circles, and the public itself.

After the 1999 earthquakes two significant studies: *A Disaster Mitigation Basic Plan Including Seismic Microzonation* by JICA–IMM, and *Earthquake Risk Assessment of the Istanbul Metropolitan Area* by ARC–BU assessed the potential earthquake risk in Istanbul. Following these studies and the establishment of a *National Earthquake Council* and its *National Earthquake Strategy Report* in 2002, the Istanbul Metropolitan Municipality requested the preparation of the *Istanbul Earthquake Master Plan* (IEMP) by a consortium of four universities. This document laid the basis for identifying activities and responsible authorities, as well as preparing an action plan for disaster risk mitigation and management in Istanbul.

The current disaster management structure in Turkey has an abundance of central governmental agencies with a complicated arrangement of authorities. In addition, most of these organizations, as well as the laws and regulations related to disaster management, are focused on post-disaster actions rather than pre-disaster mitigation and preparedness. At the time of the 1999 earthquakes, the dominating laws on disasters were the 1958 *Law of Civil Defence* (7126 Sayılı Sivil Savunma Kanunu), and the 1959 *Law on Precautions and Aid Regarding all Types of Disasters that Impacts the Community* (7269 Sayılı Umumi Hayata Müessir Afetler Dolayısıyla Alınacak Tedbirlerle

10 HAZUS (Hazard US) is a loss estimation tool, developed by FEMA and the *National Institute for Building Sciences* (NIBS). This GIS-based loss estimation software has the capability of using both deterministic and probabilistic information. It uses four classes of information in order to calculate a probable maximum loss. These are: 1) Map-based analysis (e.g. potential ground shaking intensity); 2) Quantitative estimate of losses (e.g. direct recovery costs, casualties); 3) Functional losses (e.g. reconstruction of critical facilities); and 4) Extent of earthquake induced secondary hazards (e.g. distribution of fires, floods) (Cutter 2001: 29).

Figure 38.6: Istanbul Administration Map. **Source:** Istanbul Büyükşehir Belediyesi (IBB), 1995: *1/50.000 ölçekli İstanbul metropoliten alan alt bölge nazım plan raporu* [1/50,000 scaled Istanbul metropolitan area sub-region master plan report].

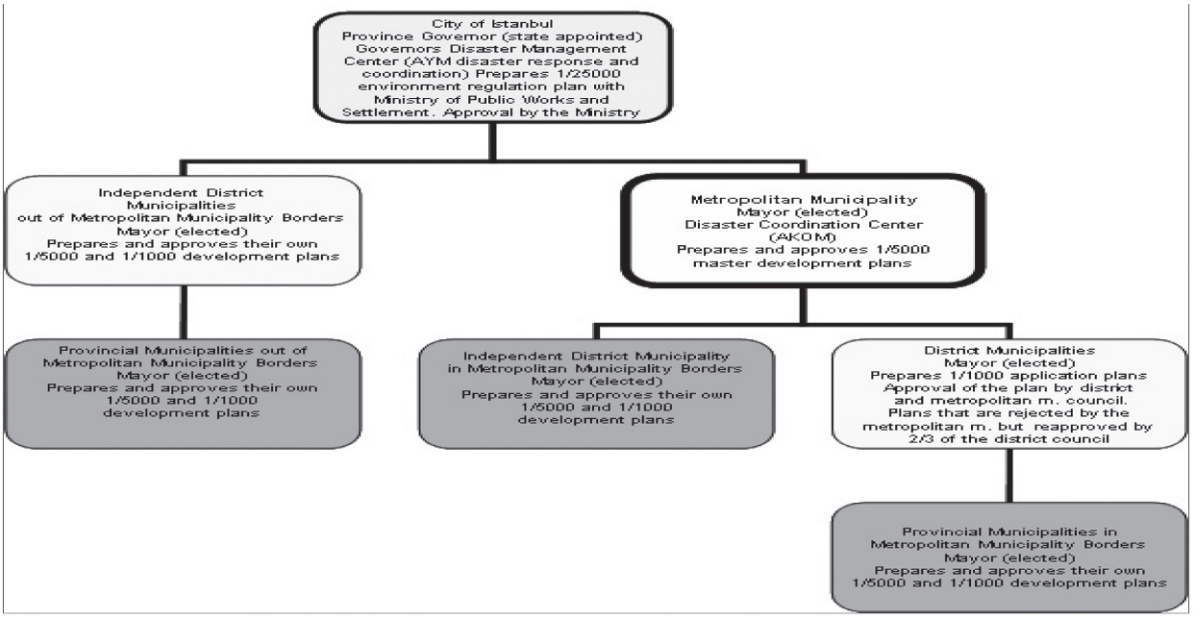


Yapılacak Yardımlara Dair Kanun). According to these laws, after the declaration of a disaster by the Ministry of Public Works and Settlements, authority is transferred to provincial and district governors, providing them with the "sole authority with powers of commanding all public and private and even military resources and means, property, all vehicles and manpower included" (Balamir 2001: 210). However, these laws contain only a few articles related to disaster preparedness and mitigation, such as those related to "dissemination of disaster related information to the general public," or "mandatory relocation of a whole neighbourhood because of eminent danger with the Council of Minister's decisions" (Kabasakal/Say/Inelmen/Yılmaz 2003: 220). The 1959 law and its by-law give authority to prepare and approve disaster area plans in district, provincial, and metropolitan municipalities to the Ministry of Public Works and Settlement, where a *General Directorate of Disaster Works* exists (Sağlam/Ökten/Şengezer/Dinçer/Demir/Koç/Gül/Evren/ Seçkin/Çekiç 2003: 420).

Immediately following the 1999 earthquakes, new revisions and decrees were added to the laws, and new agencies were established to support disaster management in Turkey. One of them is the *Directorate of Civil Defence* (Sivil Savunma Genel Müdürlüğü), under the Ministry of Internal Affairs and the Turkish Emergency Management Directorate (Türkiye Afet Yönetimi – TAY), responsible for organizing, training, and management of civil defence in disaster prone areas. In Istanbul, two disaster management agencies were established after the August 1999 earthquake. These are the *Governorship Disaster Management Centre* (Afet Yönetim Merkezi – AYM), and the *Metropolitan Municipality Disaster Coordination Centre* (Afet Koordinasyon Merkezi – AKOM). The Governorship Disaster Management Centre (AYM) aims to coordinate disaster management activities in the Province of Istanbul, and it is in the process of establishing district offices. Despite the fact that the provincial government has a higher authority in disaster management, it is financially more limited than the Metropolitan Municipality; therefore, it is in need of assistance by the central government, military, and other provinces. The Metropolitan Municipality Disaster Coordination Centre (AKOM) provides internal coordination between the organizations within the Metropolitan Municipality, and it does not have district offices. Both the Istanbul Metropolitan Municipality and the AKOM report to the Governorship on a monthly basis. This complicated disaster management structure of Istanbul is a result of its complicated administrative structure. Figure 38.6 explains the planning and disaster management authorities of the Province of Istanbul, the Metropolitan Municipality, and the District Municipalities, corresponding to Istanbul's administration map.

According to this complex administrative structure, at the time of the 1999 earthquakes, there were twenty-seven district municipalities, seventeen provincial municipalities, and one independent district municipality within the borders of the Istanbul Metropolitan Municipality. This situation created several problems both for the metropolitan municipality and

Figure 38.7: Istanbul Administration Chart. **Source:** Ebru Gencer, 2004: "Sustainable Planning for Disaster Mitigation in Istanbul", Paper presented at the ProVention Consortium Web Conference, World Bank Web Meetings, 2004.



the district municipalities located along the metropolitan city border, inhibiting the preparation of comprehensive plans, and giving full power to independent municipality districts.

An unprecedented change to this structure came in July 2004, as a special temporary decree was enacted for Istanbul and Izmit, enlarging the borders of the Istanbul Metropolitan Municipality to match that of the Province of Istanbul. With this decree, the four municipalities outside of the metropolitan municipality borders and the one independent district municipality within the borders of the metropolitan municipality were put under the authority of the Metropolitan Municipality (BB 2006).

This change in the administrative structure in Istanbul is one of several changes related to planning, urban administration, and risk mitigation that have been undertaken since 1999. Following the change in the administrative structure of Istanbul, a programme for a local administration reform has been undertaken by the central government, initiated in 2005 and supported by the UNDP and the European Commission. Simultaneous with the start of this programme, the World Bank provided a major loan for the development of the *Istanbul Seismic Risk Mitigation and Emergency Preparedness Project*, with the objective of improving the institutional and the technical capacity of the City of Istanbul for disaster management and emergency response, strengthening critical public facilities for earthquake resistance, and supporting measures for better enforcement of building codes and land use plans (World Bank 2005). Responsibility for the implementation of this project was given to a special unit established under the Governor's Office in Istanbul.

Meanwhile, as part of seismic assessment and rehabilitation projects, the Metropolitan Municipality of Istanbul followed up on micro-zoning projects of JICA, and prepared a 1/5000 scaled geological map of the area within the borders of the metropolitan city. Later, the Municipality initiated a pilot building assessment project in which trained civil engineers assessed buildings in one neighbourhood in Istanbul in order to provide specific measures, such as whether the buildings should be demolished, repaired, or strengthened in order to withstand a potential earthquake. This project was executed after the establishment of new regulations regarding construction practices. These regulations were the *Decree of Supervision of Construction Processes* (Yapı Denetimi Hakkında KHK) in April 2000, and the *Decree of Proficiency in Constructional Professions* (İnşaat Mesleklerinde Ehliyet KHK) in May 2000, both of which were transformed into the *Building Supervision Law* (Yapı Denetimi Kanunu) in July 2001 and the *Regulation on Structures to be Built in the Disaster Region* (Deprem Bölgelerinde Yapılacak Binalar Hakkında Yönetmelik) in March 2006.

According to these new regulations, building permits are to be signed by architects or civil engineers representing building control firms that have received government licenses. In addition, the Ministry of Reconstruction and Resettlement and the Ministry of Industry agreed to standardize building materials, and to 'discipline' those who do not obey the new standards with strong punishments[11].

In addition to regulations on construction practices, a *Decree on Compulsory Building Insurance* (Zorunlu Deprem Sigortası KHK) was introduced in December 1999. With this decree, the *Turkish Catastrophe Insurance Pool* (TCIP) was set up to implement compulsory earthquake insurance in Turkey. According to the 2004 World Bank reports, since the beginning of the programme, "insurance penetration for catastrophic coverage has more than tripled" in Turkey, making TCIP "the largest government insurance programme in the world, providing coverage to about 2 million Turkish homeowners (about 16 per cent of the eligible housing stock)" (Pusch 2004: 75). According to another report, "in Istanbul the programme achieved insurance penetration on the order of 30 per cent" (Gurenko/Lester/Mahul/Gonulal 2006: xiv). However, what these reports lack is the identification of residents who are able to purchase the obligatory insurance, as the author's study on district municipalities reveal, the number of residents purchasing insurance varies greatly depending on their socio-economic conditions.

A measure of the TCIP programme was to prohibit earthquake insurance eligibility of "buildings constructed after 27.12.1999 without any construction licence," in an attempt to support legal housing purchase in Turkey (TCIP: 4). For a similar reason, the government introduced a mortgage system, adding to the new housing credit systems issued by banks.[12] In both systems, the main idea is to provide earthquake-resistant and legal housing. However, the proposed mortgage system has contradictions with the newly issued construction laws, as it permits the eligibility of mortgage for housing at the project and construction level, which conflicts with the requirement of systematic control for building permits. Another consideration of the proposed law is that it does not impose a restriction on the age of buildings eligible for mortgage, even though new earthquake construction ordinances came into place only in 1999.

The mortgage law under discussion also provides funds for retrofitting. However, even though both the Municipality's pilot seismic rehabilitation project and other projects undertaken by academic circles have suggested the cost-effectiveness of retrofitting for the most common type of reinforced-concrete apartment structures in Istanbul (Smyth/Altay/Deodatis/ Erdik/ Franco/Gülkan/Kunreuther/Lu/Mete/Seeber/Yüzügüllü: 2004), there has not been a big interest in retrofitting from private home owners. This is partly because existing flat ownership laws require all residents to agree to building strengthening (Arpacı 2003). In addition, it is widely argued that retrofitting a single building will not be successful on lots with attached houses, or in lots where the required distance between buildings is insufficient, putting the risk of each building on its neighbour (Uyaroğlu 2005: 27). On the other hand, in a field survey measuring Turkish homeowner's willingness-to-pay for earthquake measures, it was found that "the role of group dynamics, trust and fairness" played a significant role in earthquake mitigation investment of Istanbul residents; and that the existence of a prior retrofitting of a neighbourhood building made a significant effect on neighbours (Öncüler 2002). Regardless of this analysis, instead of undergoing a retrofitting process, many Istanbul residents have taken steps either to relocate to newly built housing complexes in lower earthquake risk locations on the city outskirts, or to make arrangements with construction firms to demolish their existing buildings (which are usually not higher than six stories) and to rebuild taller ones, in exchange for new apartments.

In 2001, another legal coping strategy regarding the predicted earthquake hazard was introduced by the Ministry of Reconstruction and Resettlement with a draft bill on *Development and Urbanization* (İmar ve Şehirleşme Kanun Tasarısı Taslağı). The bill brought a new terminology to the existing planning documents with the introduction of *Disaster Maps* (Afet Haritaları), which were defined as: "Maps that are prepared in different types and scales, and compose a whole with their reports as one of the data groups that lay basis to planning, and identify all disaster dangers that can occur in planning areas, and include preventions and proposals related to the reduction of disaster losses and risks" (TCBB 2005: Article 3). In identifying planning principles, the draft bill explained that "in order to reduce disasters, disaster maps and risk administration reports are to be taken

as a principle in planning works" (TCBB 2005: Article 7).

However, even though the draft bill tried to incorporate disaster mitigation into the planning agenda, its language and complex definitions brought with it many criticisms by the *Turkish Chamber of Planners* (TMMOB SPO) and the *Istanbul Earthquake Master Plan* (IEMP) report team. Among many other reasons, the draft bill was criticized for not having conferred with the newly issued legislations, and for continuing to create a lack of public participation in the planning process (TMMOB SPO 2005; Sağlam/Öktен/Şengezer/Dinçer/Demir/Koç/Gül/Evren/Sekin/Çekiç 2003: 446–48).

38.5 Study on Risk Management at District Municipalities

This section introduces results of the author's research in district municipalities in Istanbul. The project aim was to investigate how the complex urban administration system in Istanbul influences disaster risk management, and to observe whether there are

disparities in the way the expected earthquake risk is managed in local districts. Three district municipalities – Kadıköy, Zeytinburnu, and Avcılar – within the borders of the Istanbul Metropolitan Municipality were selected for the purpose of this investigation, based on their proximity to the earthquake zone and differences in their socio-economic structures. In the selected municipalities, interviews were made to address an open-ended questionnaire comprised of twenty-six questions related to each municipality's and district residents' actions on disaster risk management.

38.5.1 Kadıköy

> "Even in such a sensitive municipality, we are also a unit under the department of the environment. The institutions do not have any law, and they are not up-to-date about this matter." M. Bilgin (Disaster Management Project) [Author's translation].

Project interviews revealed that Kadıköy[13] municipality was the most departmentalized municipality among the three project locations. Officials from several departments including the Static Bureau, Building Control Office and Planning Office, Ground and Concrete Test Laboratory, Disaster Management Project, Geographic Information Systems Office, Mapping Bureau, and Directorate of Accounting were interviewed for the project.

All interviews in the Kadıköy municipality indicated a clear awareness of the potential earthquake hazard, and significance given to the earthquake, despite the fact that the building stock in Kadıköy is estimated to be one of the least vulnerable in Istanbul. The Kadıköy municipality performed several new activities since the 1999 Izmit earthquake. It executed geological studies for the entire district after the 1999 Marmara earthquakes, according to the notice of the Directorate of Disaster Works in the Ministry of Development that demanded geological studies to prepare or to make changes in development plans in the 19 earthquake-prone cities in Turkey. At the time of the interviews in 2004, the municipality was waiting for the approval of these studies by the central government in order to continue with land-use planning. The Kadıköy Municipality had also prepared a Disaster Emergency Plan in which existing open spaces are proposed to be used for emergency and shelter. After the 1999 earthquake, the municipality established a concrete testing centre and a laboratory. Concrete studies have been performed as requested by Kadıköy's residents, and the highest number of requests was claimed by residents who live in alluvial

13 The district of Kadıköy has the highest GDP per capita of the three locations. It also has the highest education rates and lowest annual growth rate among the three districts.

Figure 38.10: Views from project districts: A 'gecekondu' (squatter housing) in Zeytinburnu, bracing (supporting structures with a wood member) in Kadıköy, and a building in Avcılar. **Source:** The photos were taken by the author in 2004.

soil along the Fenerbahçe canal. In addition to these requests, the Kadıköy Municipality plans to warn building owners, who live in other unsafe locations.

Soil studies are required to receive construction licences for new buildings. In addition, new building codes require the use of higher concrete levels (C20) in first degree earthquake areas**.** The Directorate of Development in the Kadıköy Municipality tracks the number of people who get construction permits; on the other hand they are also aware of those who build without getting permits as well. According to the Directorate of Research, Planning and Coordination, no requests for soil and concrete studies were received from informal settlement areas with low cultural education levels.

By 2002, about three years after the establishment of the compulsory earthquake insurance, 64 per cent of the residences in Kadıköy had joined the programme, accounting for the highest level of insured building stock in Istanbul. According to the office of Disaster Management, insurance purchase levels are low in neighbourhoods with low socio-cultural levels.

The Kadıköy Municipality has initiated a new project with the Chamber of Civil Engineers and Architects to train and give certificates to assistant contractors and foremen, with the future goal of not giving work permits to those without certificates. Another new development in this Municipality was the establishment of a Disaster Management Project Office, which educates volunteers through a project developed by the Kandilli Observatory and UNDP. The Municipality has also established a *Neighbourhood Disaster Volunteers Programme* that created a voluntary organization in twenty-eight neighbourhoods, to train and educate residents. The municipality directors are also sensitive to the education of their own staff, acquiring mostly those with either college or graduate degrees.

38.5.2 Zeytinburnu

> "The problem is that the damaged buildings are without construction licenses and are at odds with development plans. Out of 15,000 buildings, 2,000 of them were built illegally after 1980 amnesty laws. There are an additional 2,000 buildings that were pardoned by amnesty laws."
>
> B. Yıldırım (Civil Engineer) [Author's translation]

Interviews in the Zeytinburnu[14] Municipality revealed a different picture than that of Kadıköy. Zeytinburnu was selected for a pilot reconstruction project by the Metropolitan Municipality of Istanbul. This entailed all buildings in the neighbourhood to be examined at a sidewalk survey by trained engineers, and to be determined whether these buildings should be demolished, retrofitted, or have a change of use. As a result of this project, educational offices were opened in order to provide information to residents. However, the level of mitigation works that were executed prior to this pilot project was inadequate. After the 1999 earthquake, the municipality visited two thousand buildings and presented them with a brochure describing necessary steps to be taken in case of having received damages to their buildings. According to this brochure that was distributed in Zeytinburnu, moderately damaged buildings (with structural damage in beams) were to be strengthened by a specific time; otherwise they would be reconsidered as highly damaged buildings and demolished. However, this period is ex-

14 Zeytinburnu, the first squatter district of Istanbul has the highest density and lowest education rates of the three districts.

tended each year; and at the time of the interviews it was extended to the end of 2004.

According to the director of the building control office, most buildings suffered from steel corrosion and several building owners have implemented strengthening activities on their own. Despite this information, the municipality had no control over these buildings, as most of them were either squatter developments or did not have building permits. In addition, there was strong opposition to the input of the municipality from those who benefited from illegal construction, an opposition that came in the form of attacks to the municipality personnel. Only a small portion of Zeytinburnu residents requested soil studies after the earthquake and only 30 per cent of residences had purchased the compulsory earthquake insurance.

At the time of the 1999 earthquakes, Zeytinburnu Municipality had existing development plans that were prepared without geological studies. After the notice of the Ministry of Development, geological plans were prepared by Istanbul University, due to the lack of technical staff. These plans were superimposed on existing development plans. According to the final approved plans, no relocation was advised, however new zoning rules required the lowering of building heights in earthquake damaged areas. Even though, the Metropolitan Municipality's pilot project aimed at defining the type of transformative work on buildings suggest retrofitting at times, staff at Zeytinburnu Municipality oppose the idea of retrofitting, with the argument that it is expensive and that it can only change building static with 10 per cent improvement. The municipality personnel declare their priority to urban transformation, which can alter the appearance and economics of their district at large.

38.5.3 Avcılar

> There is a confusion of authority. Everybody considers the event from his/her point of view. This view brings distress to the project as well as consumption of time and efforts.
>
> S. Yalçınkaya, Chief Urban Planner [Author's translation]

After experiencing the heaviest destruction in Istanbul from the 1999 earthquake, Avcılar's[15] municipality has made significant changes to its urban planning activities. These changes are generally related to height restriction of buildings and to changes in land use, where settlement is not found suitable after geological studies. In addition, development plans for areas susceptible to landslides are now subject to the approval of the Ministry of Development's Disaster Management Office. Organizational change after the 1999 earthquake took place in the Directorate of Development and Planning, which is in charge of both planning and building control works. Expropriation works could not be easily undertaken due to limited financial resources and long duration of the planning phase. In such instances, planners propose a no-development zone. In upper-scaled plans, there is confusion about authority arising from politics involving the Metropolitan Municipality and the Ministries in charge of environment and development. In addition, the unresolved regional issues due to its location along the borderline of the metropolitan municipality, and neighbouring the independent municipality of Büyükçekmece and the provincial municipality of Esenyurt cause a chaotic situation in planning and earthquake preparedness in Avcılar.

In addition to these problems, Avcılar's municipality suffers from not having an adequate budget for risk management. There was no proper funding for residents that had endured the Izmit earthquake. Financial loans provided by the Ministry of Development were not sufficient enough for retrofitting of damaged buildings. Additionally, as the Ministry of Settlement was not responsible for identifying damages to industrial buildings, many business owners who had suffered from the 1999 earthquake or its indirect losses could not receive financial aid, thus leaving the district in a more vulnerable situation. But despite economic distress, all moderately damaged buildings have been retrofitted under the inspection of the Avcılar Municipality, and 49 per cent of Avcılar residences had purchased compulsory insurance by 2002.

38.5.4 Remark on the Result from Interviews

The interviews that were conducted at only three pilot project locations cannot sufficiently explain whether socio-cultural factors significantly influence the level of risk management activities in these districts in Istanbul. On the other hand, this investigation has exposed differences in levels in actions and strategies. A striking difference seems to arise from the organization of municipalities in these districts, and particularly from their budgetary allocations. In Turkey, the largest part of municipal budgets consists of income from taxes. In this case, it may be expected

15 The district of Avcılar has the highest annual growth rate of the three districts despite its poor soil conditions. It also has the lowest economic level of the three.

that municipalities with low income communities lack adequate income for acquiring experienced and specialized staff, and engage in risk management. In addition, the lacking authority or at times political calculations of local administrations prevent them from opposing and providing sustainable solutions to illegal constructions and settlements arising from migratory practices, leading to vulnerable communities.

38.6 Conclusion

This chapter examined risk management strategies in the earthquake prone city of Istanbul. After examining the hazard and risk profile of Istanbul, this study illustrated post-earthquake risk management in the city after the two Marmara earthquakes in August and November of 1999.

Both the local and the national government have taken many steps after the 1999 earthquake disasters to prepare for and to minimize the impact regarding an expected earthquake in Istanbul. Among them are the preparation of the comprehensive *Istanbul Earthquake Master Plan* (IEMP), the establishment of regulations that increase building construction quality, the imposition of construction control, and required mandatory earthquake insurance. On the other hand, investigations indicate challenges in the implementation of such risk management strategies in the current socio-economic and administrative circumstances of the polarized city, in which most residents neither have the means to upgrade, move, or insure in order to protect themselves. In addition to self-managed coping strategies, low-income groups have also been at a disadvantage from a complex urban administration system which has not provided a common public policy, and in which disparities have been witnessed in actions of risk reduction.

For a sustainable risk management in the metropolitan city of Istanbul, the ongoing legal reforms should provide a better administrative and planning system, where responsibilities are enhanced and clarified, decreasing confusion of authority by multiple agencies. They should be supported with a better financial model for local governments that will improve the current outdated budgetary system and help them with technical capacities to implement planning and development activities. Furthermore, for the success of risk management actions and policies in dynamic urban environments such as Istanbul, there should be a stronger ground for public participation, keeping in mind that there is no one solution to risk management, but that the larger framework should be tailored according to varying socio-economic and physical environments.

39 Urban Vulnerability to Climate Change and Natural Hazards in Nigeria

Adeniyi Sulaiman Gbadegesin, Felix Bayode Olorunfemi and Usman Adebimpe Raheem

39.1 Introduction[1]

Climate change and global warming have attained global dimensions with the recurrent discussions at the *United Nations* (UN) and in other international meetings. Global climate change, driven largely by anthropogenic activities, is a growing threat to human well-being in developing and industrialized nations alike. Significant harm from climate change is already occurring, and further damages are likely (Gwary 2008; Barnett/Adger 2007; CHGE 2005; IPCC 2001a). Extreme weather events resulting in hurricanes, windstorms, tornadoes, droughts, fires, floods and other weather-related hazards account for a large proportion of the increased losses from natural disasters over the last decades. More alarming even than the size of past losses is the trend for losses to increase. More than 1.5 million people died in the past two decades because of extreme climatic events, and more than ninety per cent of those deaths have occurred in developing countries (IFRC-RCS 2002; Munich Re 2003).

The devastating climate change impacts on life and property are most visible in urban centres where complex problems with the frequent breakdowns in services and a general lack of policy, programmes or funding exist. Indeed cities can be seen as crucibles of hazards that, without good management, generate extreme situations of vulnerability[2] and risk[3] for very large populations. In developing nations the problems are commonly associated with rapid growth, social inequalities, volatile flows of corporate investment, demographic change and environmental neglect. Natural disasters simply exacerbate existing social, physical and economic problems (Srinivashari 2007; Clarke/Munasinghe 1995).

The impacts of climate change will vary across cities as well as among households and sectors within cities. In this regard, scholars and practitioners concerned with urban development argue for the need to focus on the poor as they are more vulnerable due to their lack of access to infrastructure and their relative inability to hedge against risks (Mehrotra/Claudia/Natenzon/Omojola/Folorunsho/Rosenzweig/Rosenzweig 2009). UN Habitat (2008a, 2008b), the United Nations' agency for human settlements, as well as the International Institute for Environment and Development (Satterthwaite/Huq/Pelling/Reid/Romero Lankao 2007), among others, have articulated the need to focus attention on developing country cities due to several interrelated factors. Half the world's

1 Keywords: climate change, urban vulnerability, disasters, risk, Nigeria.

2 The term vulnerability has taken on a new and increased importance due to the greater scale of disasters. In general terms, it may be defined as the probability of a community exposed to a natural threat, given the degree of fragility of its elements (infrastructure, housing, productive activities, degree of organization, warning systems, political and institutional development), suffering human and material damages. The magnitude of such damage is, in turn related to the degree of vulnerability. According to Moor (2001: 1) cities as the most complex of human creations are more at great risk from their own multiple vulnerabilities. Points of urban vulnerabilities include their infrastructure systems, factories, telecommunications, transport, energy, food supplies, schools, offices etc.

3 Risk is defined as the probability of harmful consequences (ISDR 2002a), or expected losses (lives lost, persons injured, damage to property and/or the environment, livelihoods lost, disruption of economic activity or social systems) due to the interaction between humans, hazards and vulnerable conditions. Risk is therefore the possibility that a particular hazard might exploit a particular vulnerability (Nierkerk 2002: 4).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_39, © Springer-Verlag Berlin Heidelberg 2011

population is urban, and cities, which are the engines of economic growth, are extremely vulnerable to climate change. This is particularly so in developing countries as most coastal mega cities are located there and are home to rapidly growing population centres of the world (UN Habitat 2008a). The challenge posed by climate change for African cities is particularly alarming (UN Habitat 2008b).

According to Hardy and Pandiella (2009), the lack of attention to the risks faced by large sections of the urban population from extreme weather events puts many people at risk from the likely impacts of climate change, including storms, flooding, landslides, heat waves and drought, and overloaded water, drainage and energy supply systems. High levels of risk are particularly evident for those who want to inhabit dangerous sites and lack the resources and options to modify their vulnerability.

Indeed, the existing vulnerability and present and predicted climate change impacts on urban areas are particularly worrisome. According to Satterthwaite, Huq, Pelling, Reid and Romero Lankao (2007), the scale of devastation for urban populations and economies caused by extreme weather events documents these vulnerabilities. Worldwide, the number of people killed or seriously impacted by storms and floods rose rapidly as did the economic damage caused. A significant proportion of these impacts are in urban areas of low- and middle-income nations. Climate change has contributed to these hazards[4] and gives an apt description of the vulnerability of the urban populations to storms and floods whose frequency and intensity is likely to increase. It will cause other less dramatic stresses, such as heat waves and, for many urban areas, reductions in freshwater availability and sea-level rise for all coastal cities. Climate change provides an additional threat that adds to, interacts with, and can reinforce existing risks, placing additional strains on the livelihoods and coping strategies of the urban poor (IPCC 2001a).

The capacity to cope with climate variability and extreme weather events highly depends on the level of economic development. Livelihood sources of the poor are usually more climate-sensitive than those of the non-poor. Henderson (2004) revealed that this level of risk and vulnerability in urban areas of developing countries is attributable to socio-economic stress, aging and inadequate physical infrastructure. Most low-income urban dwellers face serious constraints in any possibility of moving to less dangerous sites, because of their need to be close to income-earning opportunities and due to lacking alternative, well-located, safer places.

A closer analysis of what transforms a natural event into a human and economic disaster[5] reveals that the fundamental problems of development that Nigeria, just as other developing countries, face are the same problems that contribute to its vulnerability to the catastrophic effects of natural hazards. The principal causes of vulnerability in developing countries include rapid and uncontrolled urbanization, widespread urban and rural poverty, degradation of the environment resulting from the mismanagement of natural resources, weak socio-economic infrastructure and inefficient public policies (Olorunfemi/Raheem 2006–2007; Olokesusi 2004).

Nigeria is particularly vulnerable to climate change impacts due to its geography, climate, vegetation, soils, economic structure, population and settlement,

4 A hazard as used in this context can be defined as a potentially damaging physical event, a phenomenon or human activity which may cause the loss or life or injury, property damage, social and economic disruption or environmental degradation. Hazards can include hidden conditions that may represent future threats and can have different origins. These include natural (geological, hydro meteorological and biological) and/or induced by human processes (environmental degradation and technological hazards) (ISDR 2002a: 24).

5 Disaster refers to an emergency caused by natural hazards or human-induced actions and resulting in a significant change in circumstances over a relatively short time period. A broad definition of disasters include *the fact that they are* dramatic, sudden, unscheduled events that are often accompanied by losses of human life, suffering and affliction to a society or a significant part of it, and a temporary breakdown of prevailing lifelines and systems. Such events cause considerable material damages and interrupt the normal functioning of an economy and of society in general (other types of natural events, such as droughts, take a long time to develop into a major disaster and may cause devastating effects in society as well) (Otero/Zapata Marti 1995). The intensity of disaster often represents the intersection of human and natural disaster. Conditions of poverty, poor housing, a lack of information about disaster risk, poor telecommunications, and inadequate physical infrastructures frequently exacerbate natural disasters such as floods. Although every nation is generally aware of their propensity for various kinds of human and natural disaster scenarios, their occurrence and consequences are often sudden, random and not well predicted. A disaster is a function of the risk process. It results from the combination of hazards, conditions of vulnerability and insufficient capacity or measures to reduce the potential negative consequences of risk (ISDR 2002a: 25).

Figure 39.1: Map of Nigeria. **Source:** <http://www.ciaonet.org/atlas/NG/map.html>. Permission to reproduce is needed

energy demands and agricultural activities. The location and size of, and the characteristic relief in Nigeria give rise to a variety of climates ranging from tropical maritime climate characterized by the rainforest along the coastal and southern part to the tropical hinterland climate associated with the Sahel in the north eastern part of the country. Nigeria has a population of about 140 million impacting on the physical environment through their various activities within an area of 923,000 square kilometres. Sixty per cent of the people live directly on the natural resource base as farmers, cattle rearers and fishermen while the informal sector constitutes the bulk of the urban population's economic activities. The technology adopted is rudimentary leading to low output and high levels of poverty.

Successful national economies depend on well-functioning and resilient urban centres. It is therefore crucial to secure the cities of Nigeria against vulnerability to climatic changes for them to become catalytic to national development goals. For most prosperous and well-governed cities, adaptation to the likely risks from climate change for the next few decades does not appear problematic. This has to do with adapting buildings and infrastructure to increasing risks; working with population groups and settlements most at risk to find solutions that serve them; and adequate disaster preparedness. In Nigeria, like other developing countries, one cannot adapt lacking infrastructure because the vulnerability of low-income urban dwellers to climate change is often ascribed to their poverty – but it is far more the result of failures and/or limitations in local governance to ensure that needed infrastructure is in place (figure 39.1).

Using a combination of secondary data gathering, field, and survey research, this chapter examines disaster risks in Nigerian cities, the major causes and patterns of the high vulnerability of these cities and the national framework for disaster management and funding. In line with a similar study by Gencer (2007, chap. 38) in Istanbul, it argues that a combination of urban poverty, unsustainable planning and development practices, and substandard urban management systems work together to add to the risk in these cit-

ies. The discussions in this chapter are based on the existing literature on the functional interrelationships between hazards, vulnerability and risk, and it links and extends the discussion to engage an understanding of disasters in Nigerian cities. It is revealed that the frequent disasters in which lives and livelihoods are destroyed are becoming a source of conflicts especially due to a perceived government inability to effectively address mitigation issues.

The chapter is divided into six sections. The next section (39.2) examines the phenomenal urban growth and development in Nigeria, then major causes of urban vulnerability are discussed (39.3) and the types and patterns of disasters in Nigeria are analysed (39.4). This is followed by a discussion of the institutional framework and funding mechanisms for disaster management (39.5). Finally, issues and challenges in disaster risk and urban management in Nigeria are discussed (39.6) while the last section (39.7) provides major conclusions.

39.2 Urban Growth and Development in Nigeria

Nigeria is a classic case of rapid urban population growth in Africa (table 39.1). Lagos, for example, has one of the fastest growth rates in the third world – between 5 and 8 per cent per annum, and so has become one of the 15 largest agglomerations in the third world. According to UN data (UN Habitat 2003), Lagos is expected to be the third most populous city in the world by 2015. The sheer magnitude of urban problems in Nigerian towns and cities and their seeming intractability have brought to the fore the very important issue of how to plan and manage these cities to make them liveable and sustainable.

As table 39.1 shows, the urban population in Nigeria is high and growing. For instance, the 10.2 per cent urban population in 1950 soared to 42.5 per cent in 2000 and may reach about 50 per cent in 2010. Indeed beginning from 2010, more than half of the Nigerian population will reside in cities of various sizes and the proportion may reach an unprecedented 75.4 per cent by 2050. The inevitable consequence is the fact that while cities were an exception in the ancient world of pre-industrial times, the reverse is rapidly becoming the case particularly since the industrial revolution (Ojo 1990).

Given this phenomenal growth in city size and population, and the attendant environmental management challenges, it is clear that most cities are fast exceeding their carrying capacities. Unfortunately, humanity, as at present, lacks the technology of detecting the critical point when this occurs.

Table 39.1: Total population of Nigeria in 1,000; development and projection of the percentage of urban population in Nigeria; urban population (1950-2050). **Source:** PD, UNDESA [Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat], 2007: *World Population Prospects: The 2006 Revision*; PD, UN DESA, 2008: *World Urbanization Prospects: The 2007 Revision*; at: <http://esa.un.org/unup> (13 August 2009).

Table 39.2 documents the proportion of cities with a population greater than 750,000 in 2007. The table shows that there are eleven Nigerian cities in this category. Lagos which consistently has the highest population since independence is also the third largest city in the world. It is important to note that its enormous population is located on the Atlantic Coast with attendant slum and informal settlement development. Thus many human homes are constructed on

marginal lands ñ parcels of land that are liable to flooding, erosion or slides. An important feature of Nigerian cities is their spatial distribution. Seven out of the eleven are located in the inland while only four are coastal cities. This is contrary to the notion that urban agglomerations are confined to the coasts of oceans and seas. In Nigeria, a significant proportion of cities are located in the hinterland. Thus, urban disasters are not confined to the coast but a widespread phenomenon with profound impacts on some cities located several kilometres off the Atlantic Coast.

The problems of urbanization in Nigeria are summed up in the prologue to the 2006 *National Urban Development Policy* (NUDP) according to which:

> the problems and challenges posed by the rapid rate of uncontrolled and unplanned urban growth are immense. Nigerian towns are growing without adequate planning. Millions of people live in sub-standard and sub-human environments plagued by slum, squalor and grossly inadequate social amenities. The result is manifested in growing overcrowding in homes and increasing pressure on infrastructural facilities and rapidly deteriorating environment. Low level of awareness on the part of the people, absence of effective advocacy and inappropriate programmes of development has further compounded the problems of urban growth and development (FMHUD 2006).

From the foregoing, rapid and uncontrolled urban growth and its associated problems have continued to overwhelm and outstrip the capacity of successive governments in Nigeria to tackle them, thus resulting in a situation where the supply, expansion and maintenance of services, utilities and physical infrastructure were terribly affected. Today's urban environment in Nigeria is at best described as unsustainable. This situation poses a serious challenge not only to urban administrators and planners, but also other professionals as well as urban residents in Nigeria.

The vast majority of the population in Nigeria, approximately 64 per cent, lived in rural areas, but the urban population is growing rapidly and has increased significantly from 19 per cent in 1963 to 36 per cent in 1991 (NPC 1998) and 46.2 per cent in 2005 (table 39.1). The most urbanized states in Nigeria are Lagos (93.7 per cent), Oyo (69.3 per cent), and Anambra (61.9 per cent) while the least urbanized are Jigawa (6.9 per cent), Taraba (10.4 per cent), Akwa Ibom (12.1 per cent) and Kebbi (12.4 per cent). The Southwest is the most urbanized region (table 39.3), with 20 per cent of Nigeria's 329 urban centres (with populations of over 20,000) located in the region (NPC 1998).

Due to a high rate of rural-urban migration, the overall population growth rate for Nigerian urban centres in 1991 was 4.5 per cent per annum compared to a rural growth rate of 1.70 per cent and a national rate of 2.8 per cent. Lagos, the commercial and industrial capital of Nigeria, with a projected population of 15.8 million, is projected to be the 12th most populous city in the world by 2015 (UN 2008: 10). The implications of these demographic trends for employment, the provision of food, housing and social services as well as the protection of the environment are staggering. As far back as 1981, approximately 58 per cent of the then 4.1 million inhabitants of Lagos were recorded to be residing in slums and informal settlements (Oberai 1993).

As is evident from table 39.4, while Nigeria is estimated to be at 42.5 per cent level of urbanization in 2000 (as compared with about 36 per cent for Ghana, 33.4 per cent for Kenya, 56.9 per cent for South Af-

** Medium Rank group: At least 25 per cent urban population but less than 40 per cent

*** Low rank group: less than 25 per cent urban population

rica, 57.4 per cent for Malaysia), this figure is expected to rise to 56.8 per cent by 2020 (UN 2008: 10). Lagos, for example, has one of the fastest rates of growth in the world – between 5 and 8 per cent per annum, and has become one of the 15 largest agglomerations in the world (Onibokun 2004).

The characteristics of the urban situation has led to a host of environmental, economic, political and social problems in most major urban centres, all of which have impacted negatively on the development of the nation (Olorunfemi/Raheem 2006–2007; Onibokun 2004).

39.3 Major Causes of Urban Vulnerability in Nigeria

Urbanization has both benefits and problems for humans and the environment. If well planned, urban centres generate economic growth and prosperity for themselves. However, if cities are not properly managed, they may generate major environmental problems that could impact negatively on development. Also, the structure and location of economic activities in and around cities affect the prevalence and severity of particular environmental problems. According to Leitmann (1994), this explains much of the variation in environmental issues between and within cities. The characteristics of the urban situation in Nigeria have led to environmental problems in most major urban centres which have negatively impacted on national development.

Urban environmental impacts stem from the use of resources, including land, water and energy; waste and waste water treatment and disposal practices; and, both industrial and domestic uses of chemicals (UNEP 1999). These problems already exist in Nigeria, and they are being compounded by other problems. According to the *National Urban Development Policy* (FMHUD 2006), the two most important factors determining the quality of the urban environment in Nigeria are the increasing concentration of population in the cities and their pervasive poverty. In general, main urban environmental issues include liquid and solid waste management, unplanned and blighted settlement, air pollution from increasing motor vehicle use (most of which are poorly maintained and use leaded fuel), water pollution, poor urban transportation, urban land degradation, lack of open spaces and poor management of the informal urban sector.

The urban areas of Nigeria are on the pathway of decay (Olorunfemi/Raheem 2008). Air pollution and environmental degradation from the poor refuse disposal are becoming the order of the day in Nigerian cities, while industrial activities which have given little concern to the sustainability of the environmental conditions are resulting in increasing levels of air, water and land pollution. In general, many Nigerian cities are reputed to be among the dirtiest, most unsanitary, least aesthetically pleasing, least safe and secure and most poorly governed cities in the world. Environmental degradation is noticeable everywhere with waste littering the roads (Mabogunje 1996). According to Olokesusi (1999), Nigerian urban settlements are afflicted with a growing list of problems, such as poor environmental quality, traffic congestion, quanti-

tatively and qualitatively inadequate housing, uncontrolled growth, inadequate building setback, poverty and encroachment on environmentally sensitive and marginal lands.

Nearly all cities and urban centres in Nigeria manifest glaring qualitative and quantitative deficiencies of housing, roads, municipal services and urban infrastructure. In 2000, access to water supply in urban areas stood at about 78 per cent, while sanitation access was 66 per cent (UN-Habitat 2003). As a result of rural - urban migration drift and rapid natural population increase, the cities and urban centres are congested. Homelessness, overcrowding and unemployment are serious problems contributing to urban poverty due to three reasons: a) the absence of physical development plans to serve as the basis for growth management; b) the weak local management capacity especially in development control and municipal management; and c) the inadequate consideration given to the integration of environmental and equity concerns into municipal management and development control.

Hitherto, local town planning authorities conceived of physical planning in a parochial and environmentally neutral way. Consequently, emphasis is not on growth management with sensitivity to environmental issues, but on the physical layout of human settlements and often an indiscriminate issuance of development permits without a legal basis. The problems of urban floods in Lagos, Ibadan and Benin are partly attributable to poor development control practices and environmental insensitivity. Since physical planning is often perceived by local town planners in terms of ad hoc physical solutions to human settlement problems, it has tended to accentuate the problem it is supposed to ameliorate (Izeogu 1986).

Also, the problem of solid waste disposal has become one of the most intractable environmental problems facing many cities in Nigeria. In recent years, there has been a phenomenal increase in the volume of waste generated daily due to many reasons including population growth, urbanization, industrialization and economic growth.

Most urban areas in Nigeria lack an effective system of refuse collection. As a result, most urban households resort to open dumping of refuse, although a few engage private refuse collectors or burn or bury solid waste. The common arrangement, in the very few urban communities where such a system is in place, is for waste management authorities to collect refuse from households and public containers on a regular basis. Unfortunately, the operation of waste management authorities is inefficient and ineffective as evidenced by mounds of decomposing rubbish that is fast becoming part of the regular landscape in urban areas. The management authorities often lack adequate manpower, equipment and operation funds in relation to the population they are mandated to serve. The reluctance of Nigerians to pay for waste disposal services, as well as relatively low cooperation between the state and *local government areas'* (LGAs) authorities in waste management further reduces the successful waste management agencies. The poor man-

agement of landfill sites is another challenge for waste management agencies.

39.4 Urban Vulnerability to Disasters in Nigeria

Addressing the challenges of evolving 21st century human settlement patterns demands a clear understanding of the vulnerabilities shaping such extreme events and also those factors that 'drive' everyday or 'chronic' environmental stresses. Importantly, there is a growing realization that more needs to be understood about how vulnerabilities – and their impacts – are configured by a range of causal mechanisms and how risks are shifted across the landscape differentially between groups of cities in the global periphery and emerging urban cores, and between rich and poor within individual cities (Bulkeley/Betsill 2003).

A major implication of uncontrolled urban growth in Nigeria is the increasing vulnerability of urban areas to disasters. According to Olokesusi (2004), a closer analysis of what transforms a natural event into a human and economic disaster reveals that the fundamental problems of development that Nigeria faces are the same problems that contribute to its vulnerability to the catastrophic effects of natural hazards. The principal causes of vulnerability in urban areas include rapid and uncontrolled urbanization, widespread urban and rural poverty, and degradation of the environment resulting from a mismanagement of natural resources, weak socio-economic infrastructure and inefficient public policies.

As shown in table 39.5, the *International Disaster Database* (EMDAT) identified 12 episodes of epidemic outbreak, 11 flood events and one drought between 1900 and 2009. These disasters also resulted in high human death tolls in many parts of the country and to say the least, a colossal loss of money and material. It must be noted that the information presented in the table is a modest expression of the disaster situation in Nigeria during the period under review. The data are also a reflection of the scale from which they was obtained. The local reality is such that there are pockets of natural hazards that were of disaster proportion in all parts of the country. A cursory look at tables 39.5 and 39.8 points to a commonality; namely the preponderance of environmental and ecological hazards over and above 'human hazards' like armed banditry and religious conflicts.

The vulnerability of frequent environmental emergencies in Nigeria is largely deter-mined by two variables: (a) the vulnerability of the elements at risk contained within them, that is, the ability of the built physical environment of buildings, site improvements; and infrastructure in them to withstand the stress imposed by natural hazards; (b) the hazards of their locations, or the extent to which they are subjected to environmental emergencies. Furthermore, the roots of urban vulnerability in Nigeria are human beings and their actions. For example, the urban population in the country has been growing at a rate of between 2–5 per cent per year since the 1990's (Olokesusi

2004). The environmental problems associated with uncontrolled expansion and poor management has increased the vulnerability of these cities to major disasters.

Large contingents of low-income migrants have settled on the poorest, most vulnerable land in cheap, dilapidated and over-crowded houses constructed on land subject to floods and landslides (figures 39.2 and 39.3). Poverty and lack of innovative approaches to urban management contribute to acute shortage of social infrastructure services in the urban areas in general, and in the low-income neighbourhoods in particular. The combination of the physical development on unsuitable lands such as wetlands, slopes, flood plains and other environmentally sensitive areas, and over-crowding, all exacerbate environmental degradation and vulnerability to environmental and anthropogenic hazards. Blocked drainage channels in urban areas worsen the externalities associated with flooding. For example, as shown in table 39.6, many residential buildings are built on unsuitable lands in the urban areas.

Nigeria is a disaster-prone country. In 2000/2001, more than 200,000 people were displaced by anthropogenic and environmental emergencies, including more than 1,000 deaths. Several homes, farm crops,

S/NO	State	Types of major disasters	Remark
8.	Abia	Rainstorm: soil erosion and market fires	Soil erosion is prevalence. Market fires frequent
9.	Adamawa	Armed banditry, flood, soil erosion	Soil erosion is a prevailing disaster
10.	Akwa Ibom	Flood, rainstorm and fire	Soil erosion is a prevailing disaster
11.	Anambra	Rainstorm and armed banditry and soil erosion	Soil erosion is a prevailing disaster
12.	Bauchi	Fire and windstorm, religious crisis	Armed banditry is rampant
13.	Bayelsa	Flood and coastal erosion, oil pollution	Oil pollution and youth restiveness are the commonest problem
14.	Benue	Communal clash and bush fire, flooding	Communal clashes and fire disasters are the commonest crises
15.	Borno	Desert encroachment, fire and flood	Desertification is the major problem
16.	Cross River	Fire disaster and oil pollution	Oil pollution is the major problem
17.	Delta	Flood, rainstorm, oil pollution, youth unrest	Oil pollution is the major problem and youth unrest
18.	Ebonyi	Soil erosion, bush fires	Soil erosion and bush fire are the commonest problem
19.	Edo	Flood and rainstorm, oil pollution and youth restiveness	Oil pollution and youth restiveness are the prevailing problems
20.	Enugu	Soil erosion, rainstorm and flood	Rainstorm and soil erosion are common
21.	Ekiti	Rainstorm, flood	Rainstorm and soil erosion are common
22.	Gombe	Desertification	Desertification and rainstorm are common
23.	Imo	Rain and windstorm, soil erosion	Soil erosion is the major problem in the area
24.	Jigawa	Flood, fire, windstorm and flood	Desertification is the major problem
25.	Kaduna	Fire, rainstorm, windstorm and communal clash, flood	Ethnic-religious clashes are the commonest problems in the area
26.	Kano	Flood, fire, windstorm and communal clashes, plane crash	Ethnic-religious clashes are the commonest problems in the area
27.	Katsina	Fire, windstorm and flood	Desertification is the major problem
28.	Kebbi	Fire, windstorm and flood	Desertification is the major problem
29.	Kogi	Flood, fire and rainstorm	Rainstorm and bush fires are the major problem
30.	Kwara	Flood, fire and rainstorm	Rainstorm and bush fires are the major problem
31.	Lagos	Bomb explosion, collapsed buildings, erosion, flooding, plane crash	Flooding is an annual event, armed banditry, communal clashes are very frequent and common in the area
32.	Nasarawa	Communal clashes and bush fires	Ethnic clashes is the major problem in the area
33.	Niger	Rainstorm, flooding	Flooding is common in the area
34.	Ogun	Flooding, ethnic clashes, plane crash	Flooding is common in the area
35.	Ondo	Rainstorm, erosion and communal clashes	Flooding is common in the area
36.	Osun	Rainstorm, communal clashes	Communal clashes are all too frequent
37.	Oyo	Flooding, rainstorm, erosion	Rainstorm and flooding
38.	Plateau	Communal clash, bush fire, erosion	Communal clashes and rainstorm

S/NO	State	Types of major disasters	Remark
39.	Rivers	Erosion, communal clash and oil pollution, flooding and plane crash	Youth restiveness and oil pollution are the main crises and are all too frequent
40.	Sokoto	Flood, quella birds, fire and flood and windstorm	Windstorm, drought
41.	Taraba	Ethno-communal clashes and bush fires	Communal clashes are very frequent
42.	Yobe	Fire, drought, fire and flood	Drought is common
43.	Zamfara	Flooding, religious crises	Occasional flooding is not uncommon
44.	FCT	Windstorm, fire, flooding	Market fires are frequent

Box 39.1: People under siege: "We are Dying". **Source**: TELL Magazine (19 April 2004: 49).

For nearly 10 years, residents of Baruwa, a suburb of Lagos, continue to live with debilitating effects of oil spillage. They could be mistaken for displaced persons from a war-ravaged town. With big jerry cans and large empty buckets, they march daily in search of water. Young men and women, even pregnant women trek kilometres in the heat of the afternoon sun. The scorch is tiring, the destination long. But people seem determined because water is life. Such is the daily lifestyle of inhabitants of Baruwa-Ipaja a Lagos suburb where potable water is scare. Not that Baruwa community is arid. The community is blessed with the where withal. In fact, Tell's investigation revealed that many houses in the community have deep wells where clean water is supposed to be fetched. But the water that flows from Baruwa's earth is polluted and reeks of petroleum products. The houses near the pipeline valve not only smell of petroleum but the product can be seen afloat the water from the well. Scientists have expressed fears that this situation could have a long-term impact on the health of hundreds of people in the community, since many of them still make use of water from the wells as a last resort.

country's environment and natural resources. In the Sudano-Sahelian states of Kano, Niger Bauchi and Sokoto, the situation is precarious due to sparse vegetation; hence, any unusually heavy rainfall results in severe floods and soil erosion. Table 39.7 reveals some of the major environmental problems in selected Nigerian cities. All these problems are projected to get worse due to climate change (Gworgwor 2008; Gwary 2008).

The available literature shows the existence of spatial differences in the nature of disasters in Nigeria. As revealed in table 39.8, while oil and gas pollution is largely a Niger Delta problem, drought and quella birds infestation occur in the Sudano-Sahelian states (e.g. in Kano, Sokoto, Katsina, Borno and Yobe). However, soil erosion, rainstorm and flood disasters are prevalent in virtually all states (NEMA 2002).

Disasters incidence and management in Nigeria are encapsulated in the two scenarios presented in boxes 39.1 and 39.2. While box 39.1 is a classical case of many disasters waiting to happen (creeping disasters) and which there is more or less no concern shown by responsible government agencies to address such, Box 39.2 reveals that many environmental emergencies in Nigeria that often result in major disasters are basically human-induced.

A common trend running through various disaster incidents has been incompetent or inadequate preparation, inadequate or inappropriate response to the disaster event, and an apparent failure to profit from the lessons of previous disasters.

An important dimension to some of the recent disaster incidents has been a wave of protests in some cities after the perceived inability of the government to respond urgently and adequately to the need of the affected and failure to take some mitigation measures to forestall or reduce the impacts of such incidents in the future. A case in point is the riot that broke out in the city of Ilorin after a heavy flooding in which lives were lost and properties destroyed. The riot stem from the fact that the people believed that the government did not provide enough relieve assistance and it did not come on time. Furthermore, the respective municipal authorities were seen as being insensitive to the frequent flooding in the city by not constructing drainages in most neighbourhoods and provide effective waste management services. This type of post disaster conflicts is fast becoming a frequent feature in many disaster prone cities and could threaten peace and stability of such cities and by extension become a threat to human security.

Box 39.2: Panic as Toxic Smoke Covers Lagos. **Source**: Vanguard (13 October 2005: 46).

A dense cloud of mysterious fumes enveloped much of Lagos metropolis, yesterday, triggering panic in many places and health concerns everywhere. The smoke was more noticeable at Ikeja, Oregun, Alausa, Alapere, Onipanu, Bariga, Maryland, Ojota, Ilupeju, Ikorodu and Monde in Ogun State, with residents complaining of eye irritation, difficulty in breathing, and stomach upset, among others. Till late afternoon, the affected area was thrown into a flux.

Governor Bola Tinubu of Lagos State ordered an immediate closure of all public and private schools, and appealed to companies and institutions to allow workers with respiratory infections go home immediately. Those affected by the smoke were also advised to go to designated government hospitals for treatment, while the State Ministry of Health dispatched ambulances and health personnel to the affected areas.

The smog is a type of large-scale pollution caused by chemical reactions between pollutants derived from different sources, primarily automobile exhaust and industrial emissions. The State *Environmental Protection Agency* (LASEPA) first attributed it to "a petroleum pipeline rupture between Mosimi and Atlas Cove Jetty" (Engr Rasheed Adebola, General Manager of Lagos state Environmental Protection Agency in a press statement). Preliminary laboratory analysis showed abnormal levels of sulphur dioxide (So_2) of up to 1,000 ppm.

Thus, anxiety, intense and almost palpable, swept the area as residents' minds went back to the Lake Nyos in South-Western Cameroon of 1987 when 'an ordinary gas' belched from the Lake killed hundreds of thousands in their sleep overnight.

39.5 Institutional Framework for Disaster Management and Funding in Nigeria

In response to the upsurge in disasters, the Federal Government of Nigeria through, Decree No. 12 of 1999, established the *National Federal Emergency Management Agency* (FEMA) as the apex public sector agency for emergency management. This legal instrument was fashioned after the *United States Emergency Management Agency* (U.S. NEMA) law. The enabling legislation contains concepts like co-ordinate, liaise, monitor and collect, etc. which presupposes that NEMA is a coordinating agency. Yet, the Director-General of the agency in his welcome address to a conference on emergency management noted that the management of any emergency no matter how small is the agency's responsibility (Markarfi 2004). This raises the fundamental question of which other units is NEMA liaising with or coordinating.

Although Nigeria has ratified the *United Nations Framework Convention for Climate Change* (UNFCCC), and is widely recognized to be vulnerable to climate change (Olokesusi 2004), much still needs to be done to develop local awareness, knowledge and expertise. Whereas, NEMA is structurally incapacitated, the situation is worse at the state and local levels. Although the 1999 NEMA Decree directs each state to have a fully equipped emergency management agency, this has not been realized. Furthermore, a National Disaster Response Plan was prepared about three years ago, it has not been put to use. In 2009, the Nigeriasat-1 satellite was gathering data on environmental conditions and resources, but what is of utmost concern is the application of such data for participatory and sustainable environmental emergency management.

Funding of disaster management programmes is presently a major responsibility of the Federal Government. The primary source of the financing of NEMA and its activities is a proportion of the Ecological Fund, a certain proportion of the oil revenue set aside to tackle environmental problems and emergencies. Between 1998 and 2004, about ₦82 billion accrued to this fund from which NEMA received its annual capital and recurrent budgetary allocations (table 39.9). Despite the Supreme Court's judgement on the constitutionality or otherwise of the 'Special Fund', deductions from the Federation Account, other tiers of government have not shown appreciable commitment towards disaster mitigation.

Although, it is true that under the current revenue allocation system, the lion's share goes to the Federal Government, it is an inalienable fact that disasters occur and could re-occur in all states of the federation with their attendant adverse economic, political, environmental and social impacts. Moreover, the entire pool of funds in the federation account and the proportion allocated to each tier of government are all subject to the vagaries of oil pricing in the global market. This is because Nigeria depends largely on oil revenue the price of which is not stable in the international oil market. Therefore, for a country striving strenuously to avoid these negative externalities, a comprehensive disaster mitigation financing policy and programme becomes imperative.

Available evidence further shows that apart from the budgetary releases to the *National Emergency Management Agency* (NEMA), there is little financial resource inflow directly and explicitly earmarked for

Table 39.9: Revenue Allocation to the Ecological Fund (1998–2006). **Sources**: Central Bank of Nigeria Statistical Bulletin (December 2003); CBN Annual Reports and Statement of Accounts for 2003 to 2006.

Year	(₦ billion*)	per cent of Total
1998	4.858	5.97
1999	9.125	11.22
2000	21.021	25.85
2001	25.491	31.35
2002	2.711	3.33
2003	0.000	0.00
2004	18.100	22.28
2005	19.234	20.05
2006	18.428	21.22
2007	19.285	20.56
Total	81.306	100.00

* 1 US$ currently exchanges for 150 Naira

Note: Before the 2003 Supreme Court Judgement, the Ecological Fund was deducted from the 'Special Fund' of the Federation Account, but it is now an item of distribution directly from the Federal Government's share of the Federation Account.

disaster reduction. Often the country bears the largest burden of disaster risks. This is due to a large use of *ex-post* financing strategies that do not transfer risk. The development challenge confronting the nation therefore makes it imperative for a transition away from excessive reliance on *ex-post* financing to disaster reduction through mitigation and risk transfer by using financial instruments. While this approach may be new to Nigeria, some countries have realized this transition through partnership arrangements with *International Financial Institutions* (IFIs) (Olokesusi 2004).

While the agency has succeeded in its advocacy and the coordination of emergency organizations during crises, it is finding it difficult to persuade operators of telecommunications in Nigeria to commence the implementation of 112 as the National Emergency Call numbers for quick access to assistance in distress situations. It has held meeting with the stakeholders but it seems some of the telephone operators are not willing to provide the toll free emergency call services which could link the public and response agencies. Such a service is provided in other countries free which are a link between the public and an emergency organization where distress alert calls can be received, processed and forwarded to the relevant response agencies.

To ensure a decentralized disaster management system, the Agency has made worthwhile efforts in providing some concrete structures to assist in the disaster management effort. Some of the structures include the creation of the following: The Agency establishment of zonal offices in the six geopolitical zones of the country namely (figure 39.4):

1. South West at Lagos,
2. South East at Enugu,
3. South South at Port Harcourt,
4. North East at Maiduguri,
5. North Central at Jos and
6. North West at Kaduna.

These zonal offices serve as focal points for NEMA to reach out easily to states, local government and communities within the zones where they are located.

At the state level, the State Emergency Management Committee (SEMC's) is responsible for coordinating disaster situations in their states and requesting† Federal assistance (NEMA) only when the level surpasses their capability. The efforts of NEMA in pursuing the establishment of SEMC's/Agencies in every state of the Federation and that of Local Governments Emergency Management Committees (LEMCs), have been yielding results, which can be visualized from the increasing number of already established committees in states and local government areas of the Federation. However, it is noteworthy that only 21 out of the 36 states in the country have an emergency management agency. These thus not augur well for emergency response and management in the country.

In addition, the agency has established *Disaster Response Units* (DRUs), a Nigerian Mission Control Centre (Cospas-Sarsat), *Emergency Response Teams* (ERTs), establishment of an Early Warning Unit (the Unit is composed of a *Geographic Information System* (GIS), remote sensing laboratory and a data bank).

39.6 Issues and Challenges in Disaster Risk and Urban Management in Nigeria

The management of urban environmental problems and those that are climate change related is a complicated business. The factors that cause managerial complexity are: (a) the frequently large number of

Figure 39.4: National Emergency Management Zonal Offices. **Source:** National Emergency Management Agency; at: <http://www.nema.gov.ng/zone.htm>.

actors per problem area; (b) cross-jurisdictional conflicts; (c) central-local conflicts; and (d) tension between forces for centralization and devolution of authority. Part of this managerial complexity can be attributed to the fact that there is often little relationship between the spatial scale or the nature of the urban environmental problems and the design of institutions or policies. Thus, the processes of planning and implementation can only address partial aspects of environmental problems; for example, there may be an ability to handle waste collection within municipal borders, but solid waste disposal is often a metro-level authority to plan, co-ordinate and execute a waste disposal programme, conflicts and suboptimal results are likely to occur. Similarly, urban environmental problems can be exacerbated when policies do not account for environmental factors. For example land use policies fail to prevent building in flood or earthquake-prone areas. Different measures taken by the government to improve the urban sector are highlighted in table 39.10.

One of the major goals of the new *National Policy on Urban Development* (FMHUD, 2006) is to improve the environmental situation in the urban areas. Specifically, the goal of the urban policy in the context of the environment is to make the urban environment in Nigeria safe, clean, healthy and aesthetically pleasing for all urban residents. To achieve this, according to the policy, the government will employ these strategies:

1. Encourage local planning and health authorities; as well as the local government environmental agency to exhibit greater vigilance in the discharge of their responsibilities;

Table 39.10: Categories of measures taken by governments in Nigeria on urban sector issues (2004). **Source:** Onibokun (2004) and compilations by the authors.

Legislation and Policy	Institution Building	Direct Action
In 1904, the *Cantonment Proclamations* led to the segregation of European Reservations from the Native Areas	In 1924, *Town Planning Committees* were established for the Northern and Southern Provinces to vet planning schemes and initiate new ones where necessary.	In 1974, the *Federal Government of Nigeria* (FGN) commissioned studies of twenty major urban centres in Nigeria to identify critical areas of urban infrastructure needs.
In 1914, *Ordinance No. 9* was enacted to empower the government to acquire land compulsorily for public reasons.	During the First National Development Plan period, *state-owned Housing Corporations* were created to provide planned residential and industrial estates.	From 1975 to 1980, the World Bank-Assisted Nigerian States Urban Development Programme was initiated.
In 1917, the *Road and Township Ordinance No. 29* provided for different grades of urban settlements, established broad physical layouts of towns and classified Nigerian towns into first, second and third class categories, with Lagos as the only first class town.	In 1992, the Urban Development Bank was established to focus on urban infrastructure and public utilities.	In 1985, the FGN, in collaboration with the World Bank, introduced the *Infrastructure Development Fund* (IDF) to finance urban development projects.
In 1928, *the Lagos Town Planning Act* created the *Lagos Executive Development Board* (LEDB) and the Board was empowered to carry out slum clearance, land reclamation, residential and industrial estates.	In 1979 the Federal Ministry for Housing, Urban Development and the Environment was created (it was scrapped in 1983).	In 1984, the monthly National *Clean-up Exercise* was introduced.
In 1946, *the Nigerian Town and Country Planning Ordinance No. 4* authorized Town Planning Authorities to prepare planning schemes. In 1978, FGN introduced the *Land Use Decree* (1978) as a regulatory tool to control the use of land and ensure equitable access to it by all Nigerians.	In 1992, Decree No. 3 of 1992 was enacted to establish the *National Housing Fund* as a source of funds for housing finance.	Between 1996 and 2002, the FGN, in collaboration with UNCHS and UNICEF, the *Sustainable Cities* Programme, the *Urban Basic Services* programme, *Community Upgrading* Programme, *Safer Cities* Programme and the *Campaign on Good Urban governance* were introduced.
In 1985, A National Housing Policy was adopted.	In the 1970's, the concept of *New Towns* was introduced, as a strategy for deconge-sting the major urban centres and creating new growth poles. This concept, for example, gave birth to the relocation of the Federal Capital from Lagos to Abuja.	From 1972 to 1975, the FGN planned to build 59,000 housing units over the federation. The number was subsequently increased to 202,000 units in 1997. The states also launched their housing programme each planning to build 4,000 between 1977 and 1980.
In 1986, the *Rolling Plan concept* was introduced.	In June 2003, a new Ministry of Housing and Urban Development was re-established.	
In 1988, a *National Policy on Environment* was enacted.		
In 1991, the *National Urban Development Policy* was prepared.		
In 1992, the *Nigerian Urban and Regional Planning Decree No. 88* of 1992 was adopted.		

Legislation and Policy	Institution Building	Direct Action
In 1996, *National Plan of Action* to guide human settlements development in the twenty-first century was prepared as part of the background papers for the Second United Nations Conference on Human Settlements (Habitat II).		
In 1998, the *Federal Environmental Protection Agency (FEPA)* was created under Decree No. 58		
In 1971, *the National Council of Housing was* adopted.		
In 2002, a new *Housing and Urban Development Policy* was scrapped.		

2. The government should protect and enact appropriate legislation to back up the various environmental protection conventions it has signed;
3. The government should promote co-operation among urban households to take interest in the maintenance of a high standard of the environment and to embark on campaigns to alert the public especially the urban poor to the increasing range of health hazards in the urban environment;
4. Ensure participation in promoting high environmental standards in our cities;
5. Enforce Development Control measures in order to reduce environmental hazards such as deforestation, oil spillage, desert encroachment, flooding and erosion;
6. Ensure greater coordination among different agencies involved with the environment at the local level such as the town planning authority, the local health board, the local education authority and the local works department.

On the other hand, the increasing frequency and intensity of disasters in Nigeria that will become more severe due to climate change would worsen the prospects for poverty eradication unless action is taken to become response-capable. This requires a focus on reducing vulnerability, achieving equitable growth and improving the governance and institutional context in which poor people live. Strategies to reduce vulnerability should be rooted in vulnerability analysis and greater understanding of both household-level and macro response options that are available to decrease the poor's exposure to disaster risk. Increasing the response-capability of Nigeria will require information on seasonal forecast to enable the preparedness to climate variability as well as longer-term climate prediction data to ensure that strategies to reduce vulnerability also reflect the underlying longer-term climate trends.

To effectively prepare for, manage and reduce the increasing incidents of disasters in Nigeria, therefore, two issues must be addressed. First, the issues involved in best practices for disaster planning and management. According to Quarantelli (1998) and Freeman, Martin, Linnerooth-Bayer, Warner, Level, Cardona and Kunreuther (2001), it is generally accepted that the best disaster planning and management implies to perceive disasters as different from accidents and minor emergencies, taking into consideration all four time phases of the planning process: mitigation, preparedness, response, and recovery, laying emphasis on the need for coordination both within and between organizations and segments of the community, rather than 'command and control'.

Secondly, there is a need to produce a set of guidelines for disaster management. Some important issues to be taken into consideration in disaster management include; the development of databases on various resources, skills and services required for relief at short notice, logistics, technological needs (i.e. a whole range of technical questions regarding buildings, rescue and relief needs to the resolved), self reliance (the lessons of community self help need to be put together), communication infrastructure, emergency preparedness and forecasting.

Climate change related risks pose even more daunting challenges. At the global level, the IPCC Working Group I identified four major aspects of climate change relevant to cities in its synthesis report (IPCC 2007c).

- First, heat waves are very likely to increase in frequency over most land areas.

- Second, heavy precipitation events are very likely to increase in frequency over most areas; available data suggest that a significant current increase in heavy rainfall events is already occurring in many regions. The resulting risk poses challenges to urban society, physical infrastructure, and water quantity and quality.
- Third, the area affected by drought is likely to increase. There is high confidence that many semi-arid areas will suffer a decrease in water resources due to climate change. Drought affected areas are projected to increase in extent, with the potential for adverse impacts on multiple sectors, including food production, water supply, energy supply and health.
- Fourth, it is likely that intense tropical cyclone activity will increase. It is also likely that there will be an increased incidence of extreme high sea level (excluding tsunamis). It is worth noting that all these four impact categories would have effects on one or more Nigerian cities because of its geography as pointed out in section one. Lagos, a coastal city for instance face many risks with respect to climate change (see box 39.3).

Box 39.3: Climate Change Risks and Response in the megacity of Lagos. **Source**: Mehrotra, Natenzon, Omojola, Folorunsho, Rosenzweig and Rosenzweig (2009).

Climate hazards: Sea level rise and coastal flooding;

Extreme events: Extreme precipitation May 1958, June 1962, July 1968, August 1998, November 1998; extreme temperature March 1988, March 1990, February 1998, March 1988, March 2001, March 2002, February 2003, March 2003, August 2004;

Vulnerability: very large population of slum dwellers living in coastal areas prone to storm surge and flooding; lack of adaptation planning and investment;

Adaptive capacity: lack of dedicated institutional support for climate risk reduction;

Response: Lagos State government is leading actor on climate change, which has been influenced by its membership in C40 Large Cities group; Initial studies of climate change risks but results have yet to inform ongoing and planned investments in infrastructure and slum upgrading.

Even more worrisome is the general sensitivity of the megacity of Lagos to climate change due to its flat topography and low elevation, high population, widespread poverty and weak institutional structures. Many more vulnerabilities stem from these characteristics including the high potential for backing up of water in drainage channels, inundation of roadways, and severe erosion. The barrier lagoon coastline in the western extremity, including the high value real estate at Victoria Island and Lekki in Lagos, could lose well over 584 and 602 square kilometres of land respectively from erosion, while inundation could completely submerge the entire Lekki barrier system (Awosika/French/Nicholls/Ibe 1993a; Awosika/ Ojo/ Ajayi 1993b). Further, the climate change associated risks for cities stem primarily from extreme events – implying that cities need to assess risks for droughts, floods, storms, and heat waves, in order to plan and implement adaptation strategies. However, gradual changes such as rise in mean temperature do affect cities in at least two significant ways: by increasing the frequency and intensity of extreme events and burdening the existing infrastructure (Mehrothra/Claudia/ Natenzon/Omojola/Folorunsho/Rosenzweig/Rosenzweig 2009).

There is therefore a need to study the vulnerability of each city in Nigeria to climate change in order to design appropriate mitigation and adaptation measures. This would reduce the risks currently faced by Nigerian cities to hazards associated with climatic events.

39.7 Conclusion

The Nigerian urban areas exhibit many characteristics associated with urban decay which makes them some of the most highly vulnerable cities in the world with frequent negative impacts of environmental emergencies and extreme weather events. Without major changes in the ways that governments and international agencies work in urban areas these impacts will rise.

Three initial lessons which were summarized in the study by Mehrotra, Claudia, Natenzon, Omojola, Folorunsho, Rosenzweig and Rosenzweig (2009) that included Lagos are very relevant for the Nigerian situation. First, a multidimensional approach to risk assessment is a prerequisite to effective urban development programmes that incorporate climate change responses. Second, mismatches between needs and responses are occurring with regard to who should mitigate, how much to adapt, and why. Cities need climate change risk assessments in order to decide for themselves what the right mix between mitigation and adaptation measures will be. Third, the vertically and

horizontally fragmented structure of urban governance is as much an opportunity as an obstacle for introducing responses to climate change.

The rationale for integrating adaptation into development strategies and practices into urban management in Nigeria is stressed by the fact that many interventions required to increase resilience to climatic changes generally benefit development objectives. Adaptation requires the development of human capital, strengthening of institutional systems, and sound management of public finances and natural resources. Such processes build the resilience of countries, communities, and households to all shocks and stresses, including climate variability and change, and are good development practices in them. Adaptations are successful if they reduce the vulnerability of poor communities and poor people to existing climate variability, while also building in the potential to anticipate and react to further changes in climate in the future. Adaptation to climate change requires local knowledge, competence and capacity within local governments. It needs households and community organizations with the knowledge and capacity to act. It also requires a willingness among local governments to work with lower-income groups. These are seriously lacking in Nigeria (Olorunfemi Felix Bayode, 2009).

All things considered, the long-term effects of disasters seriously affect the country's prospects for development. This calls into question at least two aspects related to a country's development strategy: first, an understanding that resources earmarked for preventing and mitigating the impact of natural phenomena are a very high-yield investment, both in economic, social and political terms in line with long-term growth (Coletta 2004). In a poor, disaster-prone country like Nigeria, cost-effective mitigation is important as well as new sources of funding for loss recovery from natural and other disasters which use recent developments in information technology and the emergence of new financial instruments and partnerships.

In conclusion, while an increasing rate of urbanization is inevitable in Nigeria, the circumstances under which the urban population is growing have wiped out most of the gains that should be associated with it. The context within which urbanization is taking place is creating a host of problems far beyond the managerial and fiscal capacity of the municipal governments. Thus, in resolving the environmental implications of rapid urbanization in Nigeria, there is a need to apply sound principles of environmental management through the integration of environmental planning into development. This is a challenge for urban planners and administrators in Nigeria.

40 Quantifying Global Environmental Change Impacts: Methods, Criteria and Definitions for Compiling Data on Hydro-meteorological Disasters

Debarati Guha-Sapir and Femke Vos

40.1 Introduction[1]

The world is confronted with the impact of natural disasters on human lives and livelihoods on a tremendous scale. These disasters affected 184 million people globally each year, on average, between 1980 and 2008, with a range of 28 million to 661 million. The annual loss of nearly 74,000 human lives occurred on average during this same period, with a range of 10,000 to 460,000. During 2008, 1 out of 31 persons worldwide was affected by natural disasters. Climate-related disasters caused 45,000 deaths each year and affected 178 million people, on average, between 1980 and 2008.

The risk of natural disasters involves three major elements: the exposure to hazards, frequency or severity of a hazard, and human vulnerability. Hazards are defined as "natural processes or phenomena occurring in the biosphere that may constitute a damaging event on human lives and livelihoods"[2] and are thus the natural events as such without their possible human or societal impact. Human vulnerability is comprised of susceptibility – the weakness of a system – and coping capacities – resources to deal with the negative impacts of hazardous events. A wider concept of vulnerability encompasses physical, social, economic, environmental and institutional features.[3] The approach required for measuring vulnerability depends on the type of hazard and both the socio-economic and cultural contexts.[4]

Natural disaster risk is strongly connected to human development processes, as disasters seriously hinder the development progress. At the same time, development processes and choices in governance can increase the risk of disasters. On one hand, development-linked factors responsible for increasing vulnerability to disasters are: rapid urbanization and migration, economic globalization, and climate change and environmental degradation. Furthermore, economic status, rural livelihoods, population size, social networks, changing epidemiology of diseases and armed conflict situations can all influence vulnerability to disasters. On the other hand, development can decrease disaster risk by reducing poverty and increasing community empowerment and resilience.[5]

Direct outcomes of natural disasters are the destruction or degradation of life, livelihoods and infrastructures. The impacts of disasters do not stop there, affecting social structures and education, economic investments, health systems, water and sanitation as well as the environment.[6]

1 The data upon which this report is based are maintained through the long-term support of the *US Agency for International Development's Office of Foreign Disaster Assistance* (OFDA-USAID). The authors would like to thank: David Hargitt for creating maps and proofreading; Laura Irvine and Ruwan Ratnayake for proofreading: Olivia D'Aoust for analytical design; and Regina Below and José Rodriguez-Llanes for their constructive remarks.

The Millennium Declaration recognizes the risk to development arising from disasters and calls on the global community to "intensify our collective efforts to reduce the number and effects of natural hazards and man-made disasters" (UN 2000a: 23). Disaster risk reduction can be defined as "action taken to reduce the risk of disasters and the adverse impacts of natural hazards, through systematic efforts to analyze and manage the causes of disasters, including avoidance of hazards, reduced social and economic vulnerability to hazards, and improved preparedness for adverse events." The *Hyogo Framework for Action* (HFA) provides the foundation for the implementation of disaster risk reduction.[7] One of the key activities of the HFA is identified as the development of various systems of indicators for disaster risk and vulnerability at national and sub-national scales. The aim of this activity is to aid decision-makers to assess the impact of disasters on social, economic and environmental conditions and disseminate the results to other decision-makers, the public and the populations at risk (UNISDR 2005: 7).

Much has been written on the above,[8] but a key component of effective policy for disaster risk reduction and disaster response is sound data that measure outcomes and provide quantifiable risk profiles of vulnerable communities. The *Centre for Research on the Epidemiology of Disasters* (CRED; box 40.1) provides standardized global disaster occurrence and loss data in their *Emergency Events Database* (EM-DAT). This is embedded in the overall goal of information dissemination for disaster management in order to enhance regional, national and local capacity to prepare for, respond to, and mitigate disaster events.

Other than CRED's EM-DAT, there are two different global disaster databases: *Munich Reinsurance Company's* (MünichRe) NatCat database[9] and *the Swiss Reinsurance Company's* (SwissRe) Sigma database[10]. EM-DAT is developed for scientific research with a development agenda, and while the overall structures of the three above mentioned databases are similar, their objectives differ, hereby influencing the information present in the databases. NatCat and Sigma are essentially designed to serve internal commercial policy and client insurance companies. Raw disaster data, as well as methodologies and criteria are not accessible to the public. However, their high quality data and sustainable resources allow regular analyses and publications that are available to be purchased by the public. Next to public availability, the main differences between data from the three databases derive from the definitions and thresholds used for the inclusion of disasters and the level of data entry (e.g. if disasters are entered per country or per event). Drought events are included in EM-DAT, while not monitored by NatCat or Sigma. Furthermore, EM-DAT also registers technological disasters (Guha-Sapir/Below 2002: 7).

The aim of this chapter is to display and analyse global disaster data held by CRED's EM-DAT database, the reference source for systematic global disaster data. Following this introduction, the chapter then sets out the methodological parameters that guide the recording of natural disaster events in EM-DAT (40.2). It also discusses challenges related to definitions, inclusion and exclusion criteria, as well as other potential ambiguities in disaster data collection. This is followed by a description of the trends and patterns of natural disasters recorded in EM-DAT (40.3.). It examines the absolute and relative distributions of not only the occurrence of natural disasters, but also the distribution over space (continents and countries) and time (long, medium and short term) of the victims of these disasters.

Box 40.1: About CRED. **Source**: CRED; at: <www.cred.be> (29 May 2009).

CRED has been active for over 30 years in the field of international disaster conflict and health studies, with research and training activities linking relief, rehabilitation and development. CRED provides an evidence base for the international community on the burden of disease and related health issues arising from disasters and conflicts. The Centre was established in 1973 in Brussels as a non-profit institution with international status under the Belgian law. It is located at the School of Public Health of the Catholic University of Louvain (*Université Catholique de Louvain* or UCL). CRED collaborates with the *World Health Organization* (WHO), the *United Nations Department of Humanitarian Affairs* (UN-DHA), the *European Union Humanitarian Office* (ECHO), the *International Federation of the Red Cross and Red Crescent Societies* (IFRC), the *Office of Foreign Disaster Assistance - United States Agency for International Development* (OFDA-USAID), and non-governmental agencies such as the *International Committee of the Red Cross* (ICRC).

The Centre works in four main areas: 1) natural disasters and their impact; 2) conflict and health studies; 3) database and information support; and 4) capacity building and training. By multi-partner and multi-country research projects, the health impacts of natural disasters are investigated. Examples are MICRODIS[a)], a 16-member research consortium funded by the European Commission, aiming at developing new methods and tools to measure the integrated health, social and economic impacts of natural disasters.

CRED's conflict and health research programme focuses on the way in which violence drives mortality, malnutrition, disease and disability, and otherwise disrupts human health. Funded by the European Commission, CRED is involved in MICROCON[b)], a micro-level and multidisciplinary approach to conflict, aiming at promoting the understanding of individual and group interactions leading to and resulting from violent mass conflicts.

The Centre provides an evidence base for disaster risk identification outcomes by maintaining an international *Emergency Events Database* (EM-DAT)[c)], funded by OFDA-USAID. In collaboration with the United States Department of State, Bureau of Population, Refugees, and Migration, CRED hosts the *Complex Emergencies database* (CE-DAT)[d)], a global database on complex humanitarian emergencies and conflict situations.

CRED's overall capacity building and training programmes enables individuals, communities and systems to strengthen their capabilities to plan, develop, implement and maintain effective health sector services during disasters, conflicts and other humanitarian emergencies. The *Assessing Public Health in Emergency Situations* (APHES) international summer course[e)], co-organized by CRED, UCL and the *Harvard Humanitarian Initiative* (HHI), focuses on quantitative epidemiological assessment tools and methods in the context of humanitarian emergencies.

40.2 EM-DAT: History, Methods and Contents

EM-DAT is a unique international reference database used by a wide variety of scientists, policy makers and operational organizations. This section provides an overview of the definitions, methods and limitations of the data collected in EM-DAT. Droughts are discussed as a particular example of methodological complexities in the compilation of disaster data.

40.2.1 History of EM-DAT

Based on the growing need for a comprehensive understanding of the human, economic and social impact of disasters, CRED has maintained EM-DAT since 1988, with the sponsorship of OFDA-USAID. EM-DAT was created with the initial support of WHO, *United Nations Disaster Relief Organization* (UNDRO) and the Belgian Government. The main objectives of the database are: to assist humanitarian action at both national and international levels, to rationalize decision-making for disaster preparedness, and to provide an objective basis for vulnerability assessment and priority setting. Based on historical dis-

aster data, characteristics of disaster risks can be determined and trends analyzed. EM-DAT contains essential core data on the occurrence and impacts of more than 18,000 natural and technological disasters in the world from 1900 to present. The database is compiled from various sources, including the *United Nations* (UN), governmental and non-governmental organizations, insurance companies, research institutes and press agencies. Table 40.1 shows the reporting sources of EM-DAT disasters. Within EM-DAT, strict methodology and standardization are applied, as well as an intensive validation procedure.

Table 40.1: Data sources for disasters registered in EM-DAT. This list is not exhaustive. **Source**: The authors.

Source Type	Source Information
United Nations	OCHA, IRIN, WFP, UNEP, WMO, WHO, FAO
US Government	FEMA, NOAA, OFDA, Smithsonian, CDC
National Governments	Governments, ADRC, CDERA
NGO & Humanitarian Organizations	IFRC
Reinsurance companies	Lloyd Casualty Week, MünichRe, SwissRe
Inter-Governmental Organizations	World Bank
Press	AFP, Reuters
Others	AirDisaster, Emergency Management
Specialized sources	USGS (earthquakes)
	DFO (floods)
	WHO (epidemics)

40.2.2 Definitions and Criteria

Several definitions are currently used to define a disaster. The World Bank's definition of an emergency, "an extraordinary event of limited duration such as a war, civil disturbance or natural disaster" that "seriously dislocates a country's economy,"[11] focuses on the economic impacts of a disaster. The definition promoted by WHO concentrates on the human aspects, describing a disaster as "any occurrence that causes damage, ecological disruption, loss of human life, or deterioration of health and health services on a scale sufficient to warrant an extraordinary response from outside the affected community or area" (WHO 2007: 9).

EM-DAT's definition for disasters includes all disaster types defined by the UN definition of disasters, which is "a serious disruption of the functioning of society, causing widespread human, material or environmental losses which exceed the ability of the affected people to cope using their own resources" (UN-DHA/IDNDR 1992: 27). Finally, the following definition is applied in the EM-DAT database: "a situation or event which overwhelms local capacity, necessitating a request to a national or international level for external assistance; an unforeseen and often sudden event that causes great damage, destruction and human suffering."

For a disaster to be entered into EM-DAT, at least one of the following criteria must be fulfilled:

- 10 or more people reported killed;
- 100 or more people reported affected;
- A declaration of a state of emergency;
- A call for international assistance.

In EM-DAT, the *number of persons killed* by a disaster is defined as "persons confirmed as dead and persons missing and presumed dead." The *number of persons injured* is defined as "people suffering from physical injuries, trauma or an illness requiring medical treatment as a direct result of a disaster." *Homeless people* are "people needing immediate assistance for shelter." *Affected people* are those who "require immediate assistance during a period of emergency, including displaced or evacuated people." The *total number of affected persons* is the sum of all injured, homeless, and affected people. The economic impact of a disaster usually consists of direct consequences on the local economy along with indirect consequences. In EM-DAT, the registered figures correspond to the value of the immediate damage at the time of the event and usually only to the direct damage, expressed in thousands of US$ (current value). Each disaster entry in EM-DAT consists of a set of fields that is universal for all entries in the database (table 40.2).

A data validation process allows for the comparison and selection of data compiled from different sources. An automatic error system alerts for suspect data (e.g. >10 per cent of the population killed). Economic loss data are cross-checked and completed with data from the MünichRe NatCat database (men-

11 See at: <http://go.worldbank.org/21P88LVQO0> (2 June 2009).

Table 40.2: Overview of main information fields included in the EM-DAT database. **Source**: The authors.

Field name	Content of field
DISNO	8-digit disaster ID composed of year + sequential number (e.g. 2008-0525)
Country	country(ies) of disaster occurrence
Disaster group	natural disasters or technological disasters
Disaster sub-group	geophysical, meteorological, hydrological, climatological and biological disasters
Disaster type and sub-type	description of the disaster according to a pre-defined classification
Date	start and end date of the disaster
People killed	number of people killed, including missing persons (official figures)
People injured	number of people injured
People homeless	number of people homeless
People affected	number of people affected
Total affected	sum of injured, homeless and affected people
Victims	sum of killed and total affected
Estimated damage	estimated economic damage in thousands of US$
Geographical information	location, latitude and longitude
Additional fields	e.g. scale of disaster, international status, aid contribution, affected sectors

tioned earlier). Validated data are uploaded to the EM-DAT website on a three-month interval.

An often used method to take into account the long-term impact of a multi-year disaster is by dividing the impact indicators by the number of years that the disaster persists. Only for the number of people reported affected, is the number repeated for each year during the disaster. The same applies for disasters that overlap at the end and beginning of a calendar year. The number of deaths is registered according to the year of onset of the disaster for sudden onset disasters only. Reported economic damages are attributed to the end year of the disaster.

40.2.3 Disasters: How Are They Classified?

CRED and MünichRe have recently led a collaborative initiative on a Disaster Category Classification for Operational Databases in order to create standardized terminology for global and regional databases on natural disasters for the use of comparing and exchanging disaster data (CRED/MunichRe 2008).[12] The definitions for geophysical, meteorological, hydrological, climatological and biological disasters are presented in table 40.3. In this chapter, the climatological, hydrological and meteorological events are defined as *hydro-meteorological* or *climate-related* disasters. Annex 1 and 2 provide a detailed overview of the natural disaster classification by sub-groups, as well as the definitions of natural disaster types.

Table 40.3: Definitions of the main disaster sub-groups as used in the EM-DAT database. **Source**: The authors.

Disaster Sub-group	Definition
Geophysical	events originating from solid earth
Meteorological	events caused by short-lived/small to meso scale atmospheric processes (in the spectrum from minutes to days)
Hydrological	events caused by deviations in the normal water cycle and/or overflow of bodies of water caused by wind set-up
Climatological	events caused by long-lived/meso to macro scale processes (in the spectrum from intra-seasonal to multi-decadal climate variability)
Biological	disaster caused by the exposure of living organisms to germs and toxic substances

40.2.4 Droughts – A Special Case

Droughts have always been among the most pervasive of all natural disasters. This assertion is substantiated by historical data collected and maintained in EM-DAT, which is widely cited in peer-reviewed literature, policy papers and international disaster reduction strategy documents. However, difficulties related to the slow-onset, spatially extensive, prolonged and complex nature of droughts have created inconsistencies concerning the identification of start and end dates. In addition, both the misattribution of drought-related losses, and problems reconciling multi-year and multi-country events within the EM-DAT database structure, have also presented challenges.

In earlier stages, all disasters were entered in EM-DAT by year and country, which meant that a new

12 See at: <http://www.emdat.be/Documents/CredCrunch/Cred%20Crunch%2013.pdf> (2 June 2009).

record and identification number was created for each country affected by a disaster. In cases of disasters involving several countries, multiple country-level disaster events were entered into the database. Similarly, if an event lasted more than one year, then the event had an individual entry for each year and the loss data were cumulative.

In addition to the temporal and spatial information, both multi-year and multi-country events also posed difficulties in documenting economic losses. Much of the available quantitative information about drought impacts is ambiguous as to the location and time period for which it is valid. Some statistics may be cumulative since the beginning of the drought, or may only refer to a specific location within a larger area. In the past, this would lead to over- or underestimation of the actual costs. Unlike other disaster types, no specialized dataset is currently available to cross-check drought statistics.

Drought-related famines pose their own documentation problems. As with droughts, they are often multi-country or multi-year events. A famine is not a hazard, but rather a disaster outcome and often a consequence of multiple natural and non-natural factors (e.g. drought, conflict and economic disruption). It is therefore difficult to identify the dominant causal factors that lead to famine and link them to the natural disasters included in EM-DAT.

Within this context, CRED, in collaboration with the *International Research Institute for Climate and Society* (IRI), which is a cooperative agreement between the *National Oceanic and Atmospheric Administration* (NOAA) Climate Program Office and Columbia University and part of the Earth Institute at Columbia University, undertook a comprehensive review of over 800 drought disasters and 76 famines from 1900–2004 recorded in EM-DAT against 1500 original sources, and assigned adjusted temporal information and loss data (Below/Grover-Kopec/Dilley 2007: 332). The review included the development and application of a standardized methodology designed to address four principal problems: 1) lack of a standard method for establishing attribution of drought-related losses; 2) inconsistencies in recording start and end dates; 3) problems created by multi-year droughts; and 4) the need to improve the handling of droughts that affect multiple countries. The outcome of this revision of the data was a decrease in the number of reported droughts by 56 per cent, an increase in the number of reported deaths by 20 per cent, and an increase in reported economic losses by 35 per cent.

40.2.5 Challenges of Disaster Data

Similar to all global datasets, there are limitations to the disaster data. The intent behind the reporting of disaster data by sources can differ, and data may not be specifically gathered for statistical purposes. Data collection methods are often not transparent, which hinders the evaluation of the data quality. Therefore, disaster statistics depend on the reporting sources to a large extent. There are also ambiguities in definitions or thresholds, as previously mentioned. The definition of people affected by disasters remains broad, which compromises the comparability of the data. The number of deaths due to a disaster may include missing people when not reported clearly, thereby inflating or deflating mortality figures. In certain areas, economic losses are loosely reported or missing, which is notably due to problems related to damage assessment. Although standard methods for assessing economic losses are under development by the *Economic Commission for Latin America and the Caribbean* (ECLAC), for example, there is not yet an internationally accepted method that can be used globally and across all disaster types. However, economic loss data are cross-checked with other specialized sources, like MunichRe. While no database can capture complete information on all events, numbers within EM-DAT provide insight into trends which can be used to appreciate the direction and comparative impact of different disasters. On a positive note, more consensus has been reached on definitions and thresholds in reported statistics in recent years.

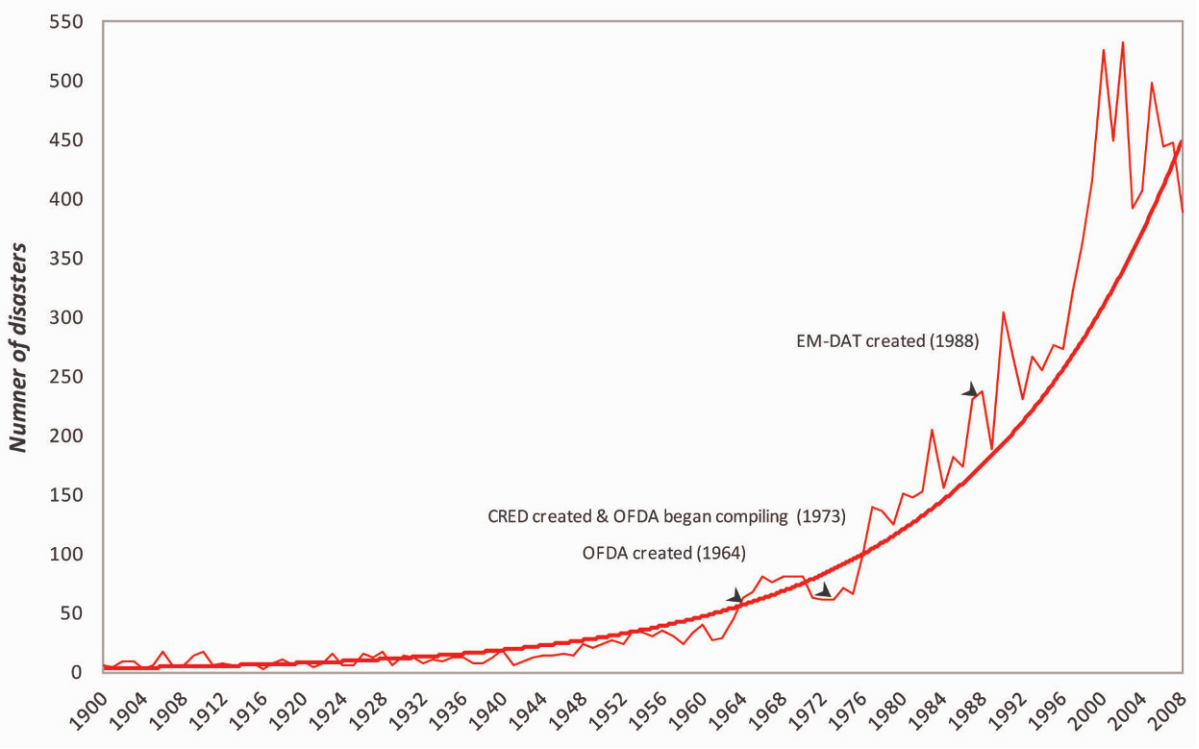
40.3 Patterns and Trends in Natural Disasters

This section describes the patterns and trends of natural disasters from three perspectives: long term trends from 1900 to 2008, an overview from 1980 to 2008 – a period when the reliability of disaster data has vastly improved – and the most recent disaster data in 2008 compared to previous years.

40.3.1 Interpretation of Long Term Trends of Natural Disasters

More than 11,000 natural disasters are registered in EM-DAT dating back to 1900. Of these, about 80 per cent occurred during the last 30 years. One of the main contributors to this apparent increase in natural disasters is related to better reporting due to the

Figure 40.1: Reported natural disaster occurrence in EM-DAT 1900-2008. **Source:** EM-DAT.



launch of both OFDA-USAID in 1964 and CRED in 1973.

Figure 40.1 might lead one to believe that disasters occur more frequently today than in earlier decades. However, reaching such a conclusion based only on this graph would be incorrect. When interpreting disaster data, one has to take into account the inherent complexity of disaster occurrence, human vulnerabilities, and statistical reporting and registering. Furthermore, the development of telecommunications and media, increased humanitarian funds and reinforced international cooperation have all contributed to a better reporting of disasters, particularly of smaller-scale disasters.

40.3.2 Patterns and Trends from 1980 to 2008

From 1980 onwards, data quality and coverage have improved substantially. Media coverage of world events expanded widely, and telecommunication costs decreased. Increased use of internet and email correspondence also made disaster reporting faster and of higher quality. Below, patterns and trends are reviewed using data since 1980.

40.3.2.1 Which Disaster Types Take the Lead? Overview from 1980 to 2008

From 1980 to 2008, hydrological (floods and wet mass movements; 38 per cent) and meteorological disasters (storms; 27 per cent) occurred most often, globally. Together, they represented 65 per cent of the total disaster occurrence during this period (figure 40.2). Floods and wet mass movements accounted for more than half of the total number of victims caused by natural disasters worldwide, whereas a third of the victims were caused by extreme temperatures, droughts and wildfires (figure 40.3). Economic damages were mostly due to meteorological disasters (39 per cent;). From 1980 to 2008, the number of reported natural disasters increased steadily, from more than 150 disasters in 1980 to almost 400 in 2008 (figure 40.5). Likewise, the total number of victims reported worldwide by natural disasters has increased. When looking at the human impact in more detail, it appears that, while the total number of affected persons increased, the number of people reported killed by natural disasters remained relatively stable (figure 40.6). Inherent to global disaster data statistics is the influence of the occurrence of major events and of annual monitoring of disasters, which distort the disaster picture in time. For example, a major peak in the

reported number of people killed occurred in 1983, reflecting the droughts in Ethiopia and Sudan. These droughts were multi-year events that started in 1983 and continued in the next years. The peak in 2004 was due to the Indian Ocean tsunami, the peak in 1991 was due to the Yangtze River floods in China, and the peak in 2008 was the joint consequence of cyclone Nargis in Myanmar and the earthquake in China. These two latter events will be discussed further. In reality, the numbers of people killed by disasters peak on a regular basis and may display an increasing trend once additional years of data can be added for analyses.

40.3.2.2 Focus on Climate-related Disasters: 1980 to 2008[13]

Hydro-meteorological disasters, also referred to as climate-related disasters, have had various impacts on human populations, depending on the type of the disaster and its geographical location. In recent years, floods of different types increased significantly all over the world. The industrialized countries saw unprecedented devastation and an increased frequency of floods, as had developing countries. The greatest increase of flooding, both in frequency and in severity, was in the Asian continent[14], ruining harvests and contaminating agricultural soil in large parts of deltaic regions such as the ones surrounding the Mekong River or the Gangetic plains. China also experienced spectacular floods over this period that destroyed millions of hectares of agricultural land and displaced more than a hundred million people. The effects of these floods were not only limited to the destruction and loss of agricultural produce of subsistence-farming families, but they also increasingly caused more direct fatalities than in the past. In addition to the increase in flooding, extreme temperature also affected Europe over the last decade. The largest number of heat and cold waves recorded in the European continent were responsible for nearly 90,000 direct fatalities (table 40.4). This has had a tremendous impact on the public consciousness of European citizens, contributing to the issue of climate extremes becoming a priority on the disaster preparedness agenda.

Figure 40.7 shows the reported economic damage costs of climate-related disasters from 1980 to 2008. Analysing data on the economic costs of climate-related disasters can be a misleading exercise when done on a global scale. This is largely due to the fact that higher property values and insurance penetration in wealthier countries distort damage assessment reports. For example, when economic costs of damage from a storm in Bangladesh are compared to a storm

13 See also the CRED CRUNCH quarterly newsletter on natural disasters in EM-DAT on floods at: <http://www.emdat.be/Documents/CredCrunch/Cred%20Crunch%2011.pdf>; on extreme temperatures at: <http://www.emdat.be/Documents/CredCrunch/Cred%20Crunch%209.pdf>; on droughts at: <http://www.emdat.be/Documents/CredCrunch/Cred%20Crunch%207.pdf>; and on storms at: <http://www.emdat.be/Documents/CredCrunch/Cred%20Crunch%203.pdf>

14 Composition of geographical regions is based on the United Nations Statistics Division's classification <http://unstats.un.org/unsd/methods/m49/m49regin.htm> (2 June 2009).

in Florida, the relative impact is not adequately captured. In developing countries most of the damages occur in the informal sector. This is not captured by the classic loss assessments. Neither are the costs of human lives lost included in these calculations. From the data that is available, from 1980 to 2008 the major economic impact was in the Americas with the main contribution originating in Northern America. However, Asia also presented high economic losses, mainly due to flooding as the frequency and severity has in-

creased in low-middle income countries such as China. Data on Africa reveal a crucial lack of reporting of natural disasters in general, and more particularly of economic losses due to disasters. Various countries in the African continent are often hit by droughts and floods, which are slow-onset disasters. These types of disasters can have impacts which are typically difficult to measure, since they affect many facets of life, livelihoods and economic structures over long periods of time.

Biological disasters, mainly comprised of epidemics and insect infestations, are another disaster subgroup in EM-DAT. Epidemics are defined as either an unusual increase in the number of cases of an existing infectious disease in the region or population of concern; or the appearance of an infection previously absent within a region (UN-DHA/IDNDR 1992: 35).

Figure 40.7: Average economic damage costs of hydro-meteorological disasters by continent from 1980 to 2008 (in million 2008 US$). **Source:** CRED, EM-DAT.

	Drought	Extreme temperature	Wildfire	Flood	Mass movement wet	Storm
Oceania	19657	241	1943	7107	0	12749
Europe	32035	18377	13277	121509	5119	105383
Asia	36813	24172	15559	323611	2438	195686
Americas	21945	19383	27988	101419	3586	574159
Africa	9300	78	442	6102	0	4963

The compilation of data on epidemics, besides the registration of occurrence, is a complex issue that CRED has not approached with as much thoroughness as other types of natural disasters. Part of the reason for this is the existence of other renowned epidemiological surveillance organizations, such as the WHO's Department of Communicable Disease Surveillance and Response and *Centres for Disease Control and Prevention's* (CDC) Centre for Infectious Diseases. Therefore, the analyses focuses next on the distributions and impacts of geophysical and climate-related disasters.

40.3.2.3 Where Do Natural Disasters Strike? Overview from 1980 to 2008

Figure 40.8 shows the spatial distribution of reported natural disasters by country. From 1980 to 2008, the most affected regions were Southern and South-Eastern Asia followed by Northern and South America. In particular, the United States (U.S.), Mexico, China, India, the Philippines, Indonesia, Bangladesh, Japan, Iran, Vietnam, Russia and Australia were prone to disasters. Figure 40.8 shows natural hazard boundaries, such as the Pacific's volcanic ring of fire, the cyclone and storm paths of Eastern Asia, the Eastern seaboard of Northern America and the tectonic plates.

As disasters are entered in the EM-DAT database by country and the criteria for inclusion are primarily based on the human impact of an event, countries covering large areas with large populations naturally present themselves as those with highest impacts. Below, these variables are accounted for and standardized to display a more realistic view of the effects of natural disasters (see 40.3.2.5).

From 1980 to 2008, Asia was the region most affected by natural disasters. More than 40 per cent of natural disasters occurred in this continent, accounting for almost 90 per cent of the total number of victims (figures 40.9 and 40.10). The Americas and Europe both had a significant share in reported disaster occurrence (26 per cent and 15 per cent respectively), yet together these two continents represented only 3.8 per cent of the total reported number of victims. Economic damage costs from 1980 to 2008 were mostly accounted for by Asia (44 per cent), followed by the Americas (38 per cent). Although the reported number of victims was relatively small, compared to the occurrence of natural disasters, in the Americas and Europe, the reported damage costs were high. On the other end of the scale, Africa accounted for 13 per cent of reported disaster occurrence and less than 1.5 per cent of global reported economic damage costs from natural disasters from 1980 to 2008.

40.3.2.4 Major Natural Disasters from 1980 to 2008

As table 40.5 and table 40.6 show, the most significant disasters in terms of people killed or affected from 1980 to 2008 have occurred in two continents of the developing world.

The two major droughts that led to famines in all Sahelian countries ranked high on the list with nearly half a million deaths registered due to drought. This is particularly notable as 'deaths due to droughts' are rare. These deaths are often attributed to infectious diseases and diarrhoea, but rarely to malnutrition or

'drought'. These registered figures are probably underestimations of the real mortality rate due to the drought-related famines in these years.

Table 40.5: Top 10 disasters by reported number of people killed from 1980 to 2008. **Source:** CRED, EM-DAT.

Disaster type	Year(s)	Country	N° deaths
Drought	1983-1984	Ethiopia	300 000
Tsunami	Dec 26 2004	Indonesia	165 708
Drought	1983-1985	Sudan	150 000
Storm	Apr-May 1991	Bangladesh	138 866
Storm	May 2/3 2008	Myanmar	138 366
Drought	1981-1985	Mozambique	100 000
Earthquake	May 12 2008	China	87 476
Earthquake	Oct 8 2005	Pakistan	73 338
Earthquake	Jun 21 1990	Iran	40 000
Tsunami	Dec 26 2004	Sri Lanka	35 399

Table 40.6: Top 10 disasters by total reported number of people affected (x1000) from 1980 to 2008. **Source:** CRED, EM-DAT.

Disaster type	Year(s)	Country	N° affected (x1000)
Drought	May-Aug 1987	India	300 000
Drought	Jul 2002	India	300 000
Flood	Jul-Aug 1998	China	238 973
Flood	Jun-Aug 1991	China	210 232
Flood	Jun-Jul 1996	China	154 634
Flood	Jun-Jul 2003	China	150 146
Flood	Jul 8-31 1993	India	128 000
Flood	May-Aug 1995	China	114 470
Flood	Jun-Jul 2007	China	105 004
Flood	Jun-Aug 1999	China	101 024

Tropical cyclone Brendan hit South-Eastern Bangladesh in 1991 with estimated wind speeds of up to 250 kilometres per hour. As often happens with storms, the heavy rainfall and associated flooding rather than wind strength caused most of the deaths and resulted in more than 15 million people affected.

The 2004 Tsunami that mainly affected Asia shows the enormous impact of this event in terms of the number of people killed. Cyclone Nargis, which hit Myanmar in May 2008, claimed over 138,000 lives, and is the third deadliest cyclone ever recorded in EM-DAT. The Sichuan earthquake is the third deadliest disaster in recent Chinese history with more than 87,000 people killed.

Among the top ten affected countries, India ranks first and second, again with droughts. The large and dense population of the country contributes to the high numbers of affected people by any natural event. The same holds true for China. Although the population density is not quite as high in some parts of China, like the Gobi Desert which is practically uninhabitable, a flood in an inhabited area immediately affects many people.

40.3.2.5 Standardizing Disaster Impact

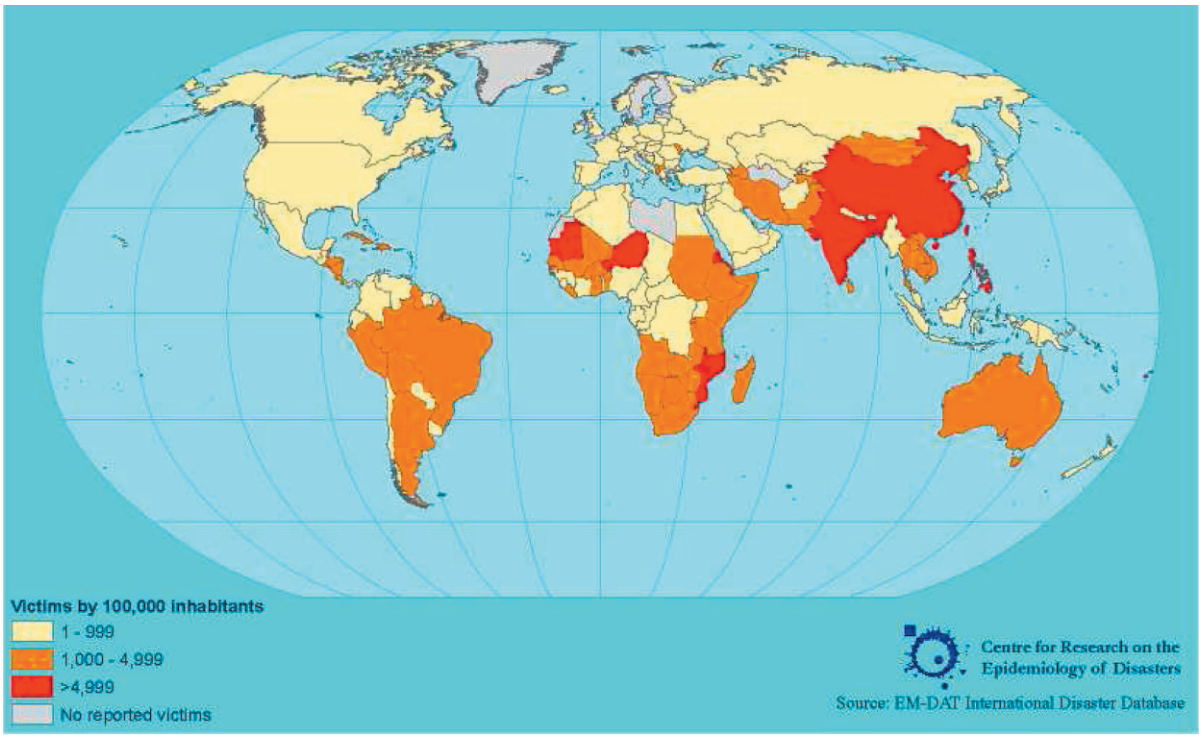
As mentioned before, absolute numbers, while they provide insights, require standardization to control for a variability between units of observation. The two main parameters that vary between countries and have a direct relationship with disasters and their impact are: population size and land surface. We present here the EM-DAT data standardized by these two variables. We are also aware that further refinements, such as excluding land surfaces that are non-inhabited, could also further change the rankings.

Countries in Southern and Eastern Asia, particularly Bangladesh, China and India, remain in the top rankings with a high proportion of the population affected by natural disasters. All have areas of high population density, especially in river basins, and are home to populations whose livelihoods often rely on agriculture. When floods occur, the number of affected communities quickly reach the hundred thousands, and in some cases, millions.

Several countries in Southern and Eastern Africa are added to this list, although they did not show in Figure 40.8 based on the ranking by disaster occurrence. In figure 40.12, Swaziland, Djibouti, Malawi and Mauritania are ranked in the highest category, together with Niger, Eritrea and Mozambique. The development burden of disasters where rates are more than 5,000 victims per 100,000 inhabitants can be crippling for many of these countries, especially those facing difficulties to maintain minimal growth.

The countries with the highest average number of victims per 100,000 inhabitants from 1980 to 2008 are: Swaziland (9,833), Bangladesh (9,434), Djibouti (8,869), China (7,079) and Malawi (6,935). Approximately 1 in every 7 to 10 persons was either reported killed or affected by natural disasters during this period. Inhabitants of certain small island states also had a large number of reported victims in this period, as was the case for Antigua and Barbuda (9,055), Vanuatu (6,221) and Samoa (6,080).

Figure 40.12: Number of reported victims of natural disasters by 100,000 inhabitants: 1980-2008. **Source:** CRED, EM-DAT.



Countries such as the U.S., Indonesia, Russia, or Japan, which in figure 40.8 of global disaster occurrence were placed in the highest category, are now placed in the lowest category in Figure 40.12, with the reported number of victims per hundred thousand inhabitants being 313 (U.S. and Indonesia), 151 (Russia) and 91 (Japan).

Looking at the number of natural disasters per 1,000 km² can also offer some interesting insights into which countries have a high incidence of disaster occurrence. Controlling for land surface, the most vulnerable countries, almost without exception, were the small island states. The top ranking countries in terms of numbers of disasters per 1,000 km² were Tokelau (245), Tuvalu (154), Bermuda (100), Montserrat (69) and Anguilla (56), all are small island states in the Pacific or the Caribbean.

Interestingly, countries such as the U.S., China and India, which ranked high in absolute number of disasters, by this indicator dropped to 0.06 disasters per 1,000 km² in China and the U.S., and 0.10 disasters per 1,000 km² in India.

Finally, table 40.7 lists the 10 most affected countries in terms of economic damage costs from natural disasters relative to country *Gross Domestic Products* (GDP) on average from 1980 to 2008. Here again, either small island states or small poor countries featured at the top 10 of the global ranking. Despite the enormous world attention frequently generated by disasters such as the Indian Ocean Tsunami in Indonesia, Sri Lanka, India and Thailand, or the Bam earthquake in Iran, the effects on the GDP of these countries tend to be relatively less significant. To get

Table 40.7: Top 10 countries average annual total economic damages as proportion of GDP from 1980 to 2008. **Source:** CRED, EM-DAT.

Country	Economic damage by GDP (%)
St. Lucia	29 %
St. Kitts & Nevis	13 %
Vanuata	11 %
Grenada	9 %
Tonga	4 %
EL Salvador	4 %
Honduras	4 %
Nicaragua	4 %
Maldives	3 %
Nepal	3 %

a useful perspective on the extent to which natural disasters affect a developing country's economy, a comparison relating it to GDP or another appropriate economic indicator is essential. Here we present only a rough idea of what the global ranking could look like if such a comparison was made.

The economic damage costs of natural disasters relative to the country's GDP reveals the economic consequences of disasters on a specific country. The bias in the economic data due to insurance coverage and property values has been mentioned earlier. There is an additional bias of disaster damage costs being reported more frequently for larger disasters, while small and medium disasters often do not provide an adequate loss assessment figure (chap. 31 by Marulanda/Cardona/Barbat). Therefore, these data tend to be underestimated, especially for developing countries (Guha-Sapir/D'Aoust/Vos/Hoyois 2009: i.p.).

40.3.3 Natural Disasters in the Short Term: Recent Trends

In 2008, immense human and economic losses due to natural disasters were reported. More than 235,000 people were killed, 214 million people affected and economic costs were over 190 billion US$. This section summarizes the natural disaster impacts in 2008 and compares the impact of the main disaster types in each continent to the previous years.

40.3.3.1 Natural Disaster Occurrence and Impact: 2008 Compared to 2000-2007

In 2008, 354 natural disasters were recorded in the EM-DAT database, which is less than the 2000–2007 yearly average of 397. The reported death toll in 2008 was over 3-fold the annual average of 2000–2007 (66,800), mainly caused by two major events: Cyclone Nargis in Myanmar and the Sichuan earthquake in China. Disaster costs in 2008 were more than twice the 82 billion US$ annual average of 2000–2007 and were mainly attributed to the Sichuan earthquake in China (85 billion US$) and hurricane Ike in the U.S. (30 billion US$).

In 2008, large populations were affected by few natural disasters. The earthquake and severe winter conditions in China affected a total of 122 million people. Droughts affected 14 million people in Africa and 12 million people in Asia. Severe weather conditions in the U.S. in May and June 2008 affected 11 million people. Figure 40.14 and figure 40.16 show the reported occurrence, total number of affected people and economic costs of global natural disasters in 2008.

Asia remained the most affected continent. Nine of the top 10 countries with the highest number of

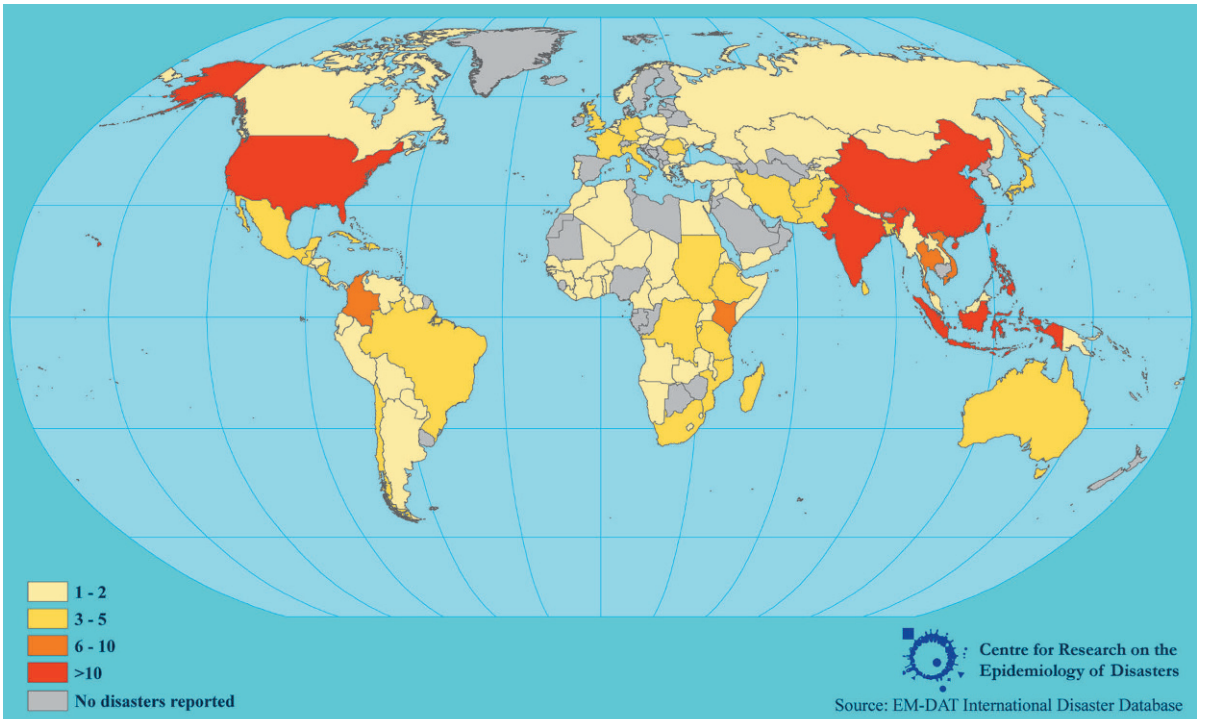
disaster-related deaths were in Asia. While China, the U.S., the Philippines and Indonesia reported the largest number of natural disasters, Djibouti, Tajikistan, Somalia and Eritrea topped the list of number of victims per 100,000 inhabitants.

Although less pronounced than in other years, 2008 continued the upward global trend in natural disaster occurrence observed over the last decade. As in previous years, hydrological and meteorological disasters were the main contributors to this pattern.

40.3.3.2 How are Disaster Types Distributed Today?

In 2008, geophysical disaster occurrence (32) increased compared to 2007 (26), but still remained far below the 2000–2007 annual average of 37 reported

Figure 40.14: Global map of reported number of natural disasters in 2008. **Source:** CRED, EM-DAT.



disasters (figure 40.13, table 40.8). The human impacts of these geophysical disasters in 2008 can be described as enormous, as they were multiplied by a factor 10 compared to the annual average over the last 8 years. This is not a steady increasing trend over the last years; rather it shows the impact of few single geophysical events with a major human impact, in particular the 2008 Sichuan earthquake in China that affected a total of 46 million people. Similar to the human impact, the economic damage costs of geophysical disasters were tremendous in 2008, also mostly due to the earthquake in China.

Meteorological disasters tend to show a cyclical pattern over the years, with major disasters occurring in some years and being absent in other years. Although the number of meteorological events increased slightly in 2008, the reported number of victims decreased when compared to the 2000–2007 annual average. Cyclone Nargis in Myanmar caused the most natural disaster-related deaths in 2008.

Despite the fact that hydrological disasters remained the most common disasters in 2008, their impact was relatively small compared to previous years. The number of hydrological disasters (178) was below the 2000–2007 annual average (196). The number of victims of hydrological disasters also decreased in 2008, whereas economic damage costs remained equal.

Although climatological disasters were less numerous in 2008 compared to the annual average of 2000–2007, the number of victims increased by 30 per cent. The occurrence of unusually costly climatological disasters marked 2008, with extreme winter conditions in China causing 21 billion US$ damages and wildfires in the U.S. causing 2 billion US$ damages.

40.3.3.3 Which Continents are Hit the Hardest?

In 2008, 40 per cent of all reported natural disasters occurred in Asia, which is approximately the same share as seen in the annual average of 2000–2007. More than 80 per cent of the reported victims of natural disasters in 2008 were from Asia, which is 10 per cent less than the average in previous years (table 40.8.). The economic costs in Asia increased greatly in 2008 compared to the annual average of 2000-2007. Asia's contribution to the total economic costs due to natural disasters almost doubled from 34 per cent in the period 2000–2007 to 62 per cent in 2008. The impact of natural disasters on (lower-) middle income countries, such as China, which was the largest contributor to economic losses in 2008, appears to be on the rise. As countries move up the development ladder, their economic vulnerability tends to increase. These countries in particular would benefit

Figure 40.15: Global map of reported number of people affected by natural disasters in 2008. **Source:** CRED EM-DAT.

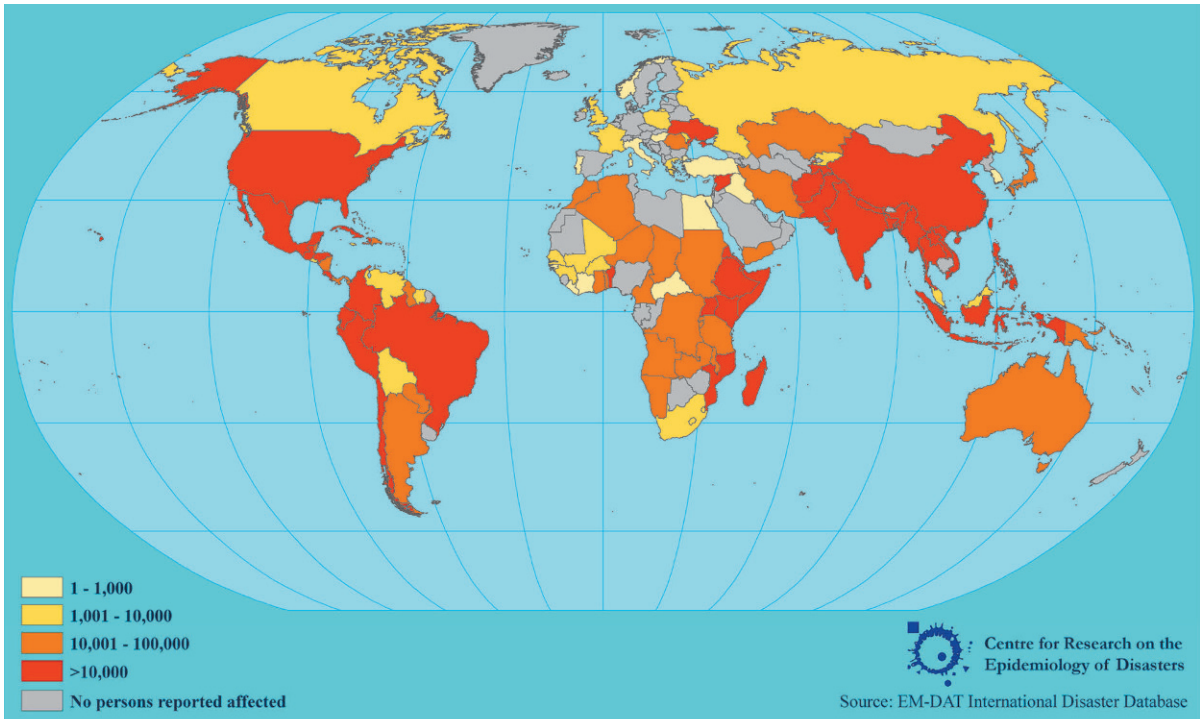


Figure 40.16: Global map of reported economic damage costs from natural disasters in 2008. **Source:** CRED, EM-DAT.

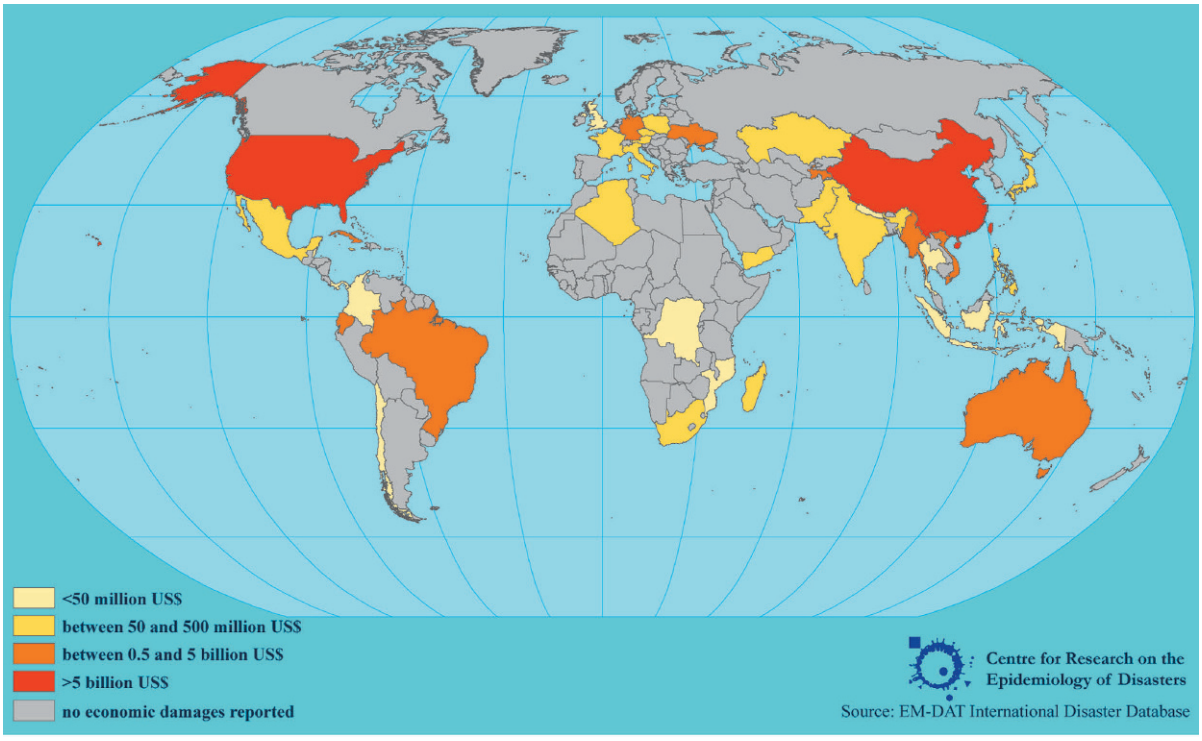

from disaster risk reduction measures in order to better protect development gains.

In the Americas, the number of reported natural disasters remained stable in 2008 compared to the annual average of 2000–2007. The Americas accounted

for more than 25 per cent of global natural disaster occurrence in 2008. A shift in disaster types was seen, as the occurrence of climatological disasters decreased from 15 per cent to 4 per cent and the occurrence of meteorological disasters increased from 36 per cent to 46 per cent of total reported natural disasters in this continent (2000–2007 average versus 2008). The Americas showed a 4-fold increase in the number of victims in 2008 compared to the previous years' average. Hydrological disasters caused the most victims in 2008 for this region (80 per cent), although the total number of hydrological disasters remained the same. These events resulted in increased economic damages in 2008 (4 per cent of total costs in 2000–2007 versus 19 per cent in 2008). Meteorological disasters contributed most to economic damage costs in the Americas in 2008 (78 per cent).

In 2008, Africa accounted for 20 per cent of global natural disaster occurrence. The continent showed a small decrease in reported natural disaster occurrence compared to the 2000–2007 annual average, mostly due to a decline in hydrological disasters. However, the number of victims increased. Climatological disasters were an important contributor to this increase, as Africa was hit by severe droughts. Data on Africa reveal a crucial lack in reporting of natural disasters in general, and more particularly of economic losses due to disasters. Africa accounted for less than 0.5 per cent of global reported economic costs from natural disasters in 2008, a share that is likely to be underestimated.

Compared to previous years, Europe showed the greatest decline in reported natural disaster occurrence among the five continents in 2008. Europe's share in disaster occurrence was 9 per cent in 2008, compared to 16 per cent during 2000–2007. This drop is mostly explained by a decrease in both reported hydrological and climatological disasters. Likewise, Europe experienced a decrease in victims, mostly seen for climatological and meteorological disasters. Europe's decrease in economic damage costs was mainly due to the impacts of hydrological and climatological disasters, which were smaller in 2008 compared to the annual average of 2000–2007. Economic damage costs due to natural disasters in Europe dropped from 16 per cent (2000–2007) to 2.5 per cent (2008) of worldwide damage costs. It is important to note that this does not reflect a decreasing trend in Europe; rather it reflects the impact of mega-disasters that happened in 2008 on other continents.

In 2008, Oceania was, as in previous years, mostly affected by hydrological and meteorological disasters. Hydrological disasters were responsible for over 85 per cent of total reported victims in Oceania in 2008 and also caused the highest economic losses. Because the continent covers many small islands, with the exception of Australia and New Zealand, natural disasters give rise to a relatively large human and economic impact when taking into consideration country surface, number of inhabitants and GDP (adapted from Rodriguez-Llanes/Vos/Below/Guha-Sapir 2009).

40.4 Conclusions and Recommendations

The disaster statistics presented in this chapter describe natural disaster occurrences and impacts in space and across time. By standardizing the data against population size and geographical area, global comparisons are made.

In conclusion, it is emphasized that for policy and preparedness to be effective, it is essential to base decision-making on systematic and scientific data for the occurrence and impacts of natural disasters. While disaster data on a global scale necessarily glosses over particularities and differences at local levels, it does provide an extremely useful view of overall trends and regional comparisons.

Secondly, these data indicate that climate-related disasters (principally floods and storms) constitute the largest proportion of the total disaster count in the past decade or more. Within this group, floods have been increasing in number and intensity in recent years. Furthermore, Southern and South-Eastern Asia display the highest vulnerability to increasing floods and their devastating impact.

Thirdly, while climate-related disasters such as floods, storms, heat and cold waves and droughts are on the rise, the current evidence is not conclusive regarding the main causes for this increase. While climate-related factors such as global warming may be a contributor to this increase, socio-economic vulnerabilities such as urbanization, land use and deforestation cannot be ignored as major potential causes for the rise in some of these climate-related disasters.

In conclusion, two recommendations are offered which are of high priority today, based on the authors' long involvement in natural disaster research and data analysis. Collecting data on a global level, while necessary and useful, is neither enough to change behaviour or policy at national and sub-

national levels, nor does it always provide the key insights necessary for preventing the impact of disasters. Therefore, building a field evidence base for the impact of natural disasters at micro-levels should be strengthened. These evidences should be drawn from well-designed scientific case studies in different parts of the world in different socio-economic settings, or cohort studies that follow vulnerable populations to measure their vulnerabilities in the short and long term. A critical mass of this type of research will build up an evidence base for policies that are drawn from realities rather than common stereotypes or theoretical hypotheses.

The second recommendation is of a more practical nature and relates to the development of operational risk profiles of communities exposed to disasters. Identifying exactly what makes a household or an individual more susceptible to trauma, injury and death when exposed to an acute natural disaster, will improve the quality and effectiveness of the local preparedness programmes.

Annex 2: Natural disaster (sub-)type definitions. **Source**: Compiled by the authors.

Disaster type	Disaster sub-type	Examples/ description	Definition
Earthquake	Ground shaking	Shaking and displacement of ground due to seismic waves; the earthquake itself without secondary effects.	An earthquake is the result of a sudden release of stored energy in the Earth's crust that creates seismic waves. They can be of tectonic or volcanic origin. At the Earth's surface they are felt as a shaking or displacement of the ground. The energy relea-sed in the hypocentre can be measured in different frequency ranges. Therefore there are different scales for measuring the magnitude of a quake according to a certain frequency range: a) surface wave magnitude (Ms); b) body wave magnitude (Mb); c) local magnitude (ML); d) moment magnitude.
	Tsunami	Waves advancing inland.	A tsunami is a series of waves caused by a rapid displacement of a body of water (ocean, lake). The waves are characterized by a very long wavelength and their amplitude is much smaller offshore. The impact on coastal areas can be very destructive as the waves advance inland and can extend over thousands of kilometres. Triggers of a tsunami can be: earthquakes, volcanic eruptions, mass movements, meteorite impacts or underwater explosions.
Volcano	Volcanic eruption	All volcanic activity, such as rock fall, ash fall, lava streams and gases.	Volcanic activity describes the transport of magma and/or gases to the Earth's surface which can be accompanied by tremors and eruptions. Depending on the composition, the magma eruptions can be phreatic, explosive or effusive and result in variations of rock fall, ash fall, lava streams, pyroclastic flow or emission of gases.
Mass movement (dry)	Subsidence	Downward motion of the Earth's surface relative to a datum (e.g. sea level).	Subsidence is the motion of the Earth's surface as it shifts downward relative to a datum. Subsidence (dry) can be the result of: geological faulting, isostatic rebound or human impact (e.g. mining, extraction of natural gas).
	Rockfall	Quantities of rock or stone falling freely from a cliff face.	Rockfall refers to quantities of rock or stone falling freely from a cliff face. It is caused by undercutting, weathering or permafrost degradation.
	Landslide	Any kind of moderate to rapid soil movement including lahar, mudslide and debris flow.	A landslide is the movement of soil or rock controlled by gravity and the speed of the movement usually ranges between slow and rapid. It can be superficial or deep, but the materials have to make up a mass that is a portion of the slope or the slope itself. The movement has to be downward and outward with a free face.
	Unspecified	Other hazards or losses	
Storm	Tropical cyclone	Cyclones in tropical areas, e.g. hurricanes, typhoons, tropical depressions, depending on its location.	A tropical cyclone is a non-frontal storm system that is characterized by a low pressure centre, spiral rain bands and strong winds. Usually it originates over tropical or sub-tropical waters and rotates clockwise in the Southern hemisphere and counter-clockwise in the Northern hemisphere. The system is fuelled by heat released when moist air rises and the water vapour it contains condenses ("warm core" storm system). Therefore the water temperature must be >27 °C. Depending on their location and strength, tropical cyclones are referred to as hurricane (Western Atlantic/Eastern Pacific), typhoon (Western Pacific), cyclone (Southern Pacific/Indian Ocean), tropical storm, and tropical depression (defined by wind speed; see Saffir-Simpson-Scale).

Disaster type	Disaster sub-type	Examples/ description	Definition
	Winter storm (extra-tropical cyclone)	Extra-tropical cyclones in spring, autumn or winter.	A winter storm emerges from an extra-tropical cyclone, a synoptic scale low pressure system that occurs in the middle latitudes of the Earth and is connected to fronts and horizontal gradients in temperature and dew point. A winter storm comes along with high wind speeds, gusts, thunderstorms, rain and often storm surges.
	Severe storm/ Tempest	Convective storm.	A severe storm is the result of convection and condensation in the lower atmosphere and the accompanying formation of a cumulonimbus cloud. A severe storm usually comes along with high winds, heavy precipitation (rain, sleet, hail), thunder and lightning.
	Hail storm	Storm with hailstones as dominant type of precipitation.	A hail storm is a type of storm that is characterized by hail as the dominant part of its precipitation. The size of the hailstones can vary between pea size (6mm) and softball size (112mm) and usually cause considerable damage.
	Lightning	Hazards/ losses caused by lightning stroke.	Lightning is an atmospheric discharge of electricity, which typically occurs during thunderstorms, and sometimes during volcanic eruptions or dust storms.
	Tornado	Other names for this weather phenomenon are twister, waterspout.	A tornado is a rotating column of air (vortex) that emerges out of the base of a cumulonimbus cloud and has contact to the Earth's surface. Typically it forms during a severe convective storm in so-called supercells and is often visible as a funnel-shaped cloud. Tornadoes are usually short-term, lasting on average <10 minutes. They can generate wind speeds above 400 km/h and are considered the most destructive weather phenomenon. The intensity of tornadoes is assessed using the Enhanced Fujita Scale.
	Local windstorm (orographic storm)	E.g. Katabatic winds Foehn, Mistral, Bora.	Local windstorm refers to strong winds caused by regional atmospheric phenomena that are typical for a certain area.
	Sandstorm/ Dust storm	E.g. desert storms.	A sandstorm/dust storm typically occurs in arid or semi-arid regions when high wind speeds causes the transportation of small particles like sand or fine clastic sediment by saltation and/or suspension.
	Snow storm/ Blizzard	Blizzard, ice and snow, often in Northern America.	A snowstorm refers to a storm, usually in the winter season, with large amounts of snow fall. If it is a severe snowstorm that meets certain criteria, such as strong winds, blowing snow or falling temperatures, it is called a blizzard.
Flood	General flood	Gradually rising inland floods (rivers, lakes, ground-water) due to high total depth of rainfall or snowmelt.	A general flood is caused when a body of water (river, lake) overflows its normal confines due to rising water levels. The term general flood additionally comprises the accumulation of water on the surface due to long-lasting rainfall (water logging) and the rise of the groundwater table above surface. Furthermore, inundation by melting snow and ice, backwater effects, and special causes such as the outburst of a glacial lake or the breaching of a dam are subsumed under the term general flood. General floods can be expected at certain locations (e.g. along rivers) with a significantly higher probability than at others.
	Flash flood	Rapid inland floods due to intense rainfall.	A flash flood describes sudden flooding with short duration. In sloped terrains the water flows rapidly with a high destruction potential. In flat terrains the rainwater cannot infiltrate into the ground or run off (due to small slope) as quickly as it falls. Flash floods typically are associated with thunderstorms. A flash flood can occur at virtually any place.

Disaster type	Disaster sub-type	Examples/ description	Definition
	Storm surge	Coastal flood on coasts and lake shores induced by wind.	A storm surge is the rise of the water level in the sea, an estuary or lake as result of strong wind driving the seawater towards the coast. This so-called wind setup is superimposed on the normal astronomical tide. The mean high water level can be exceeded by five and more metres. The areas threatened by storm surges are coastal lowlands.
	Glacier lake outburst flood/ Jökulhlaup	Flooding due to the outburst of a glacier lake.	A glacier lake outburst flood occurs when a lake - dammed by a glacier or a terminal moraine - fails. The outburst can be triggered by erosion, a critical water pressure, a mass movement, an earthquake or cryoseism. A jökulhlaup is a special type of a glacier lake outburst flood related to the outburst of an ice-dammed lake during a volcanic eruption.
Mass movement (wet)	Subsidence	Downward motion of the Earth's surface relative to a datum (e.g. the sea level).	Subsidence is the motion of the Earth's surface as it shifts downward relative to a datum (e.g. the sea level). Subsidence (wet) can be the result of: karst, changes in soil water saturation or permafrost degradation (thermokarst).
	Rockfall	Quantities of rock or stone falling freely from a cliff face.	Rockfall refers to quantities of rock or stone falling freely from a cliff face. It is caused by undercutting, weathering or permafrost degradation.
	Avalanche	Any kind of rapid snow/ice movement.	Avalanche describes a quantity of snow or ice that slides down a mountainside under the force of gravity. It occurs if the load on the upper snow layers exceeds the bonding forces of the entire mass of snow. It often gathers material that is underneath the snowpack like soil or rock (debris avalanche).
	Landslide	Any kind of moderate to rapid soil movement including lahar, mudslide or debris flow.	A landslide is the movement of soil or rock controlled by gravity with a speed of the movement usually ranging between slow and rapid. It can be superficial or deep, but the materials make up a mass that is a portion of the slope or the slope itself. The movement is downward and outward with a free face.
Extreme temperature	Heat wave	Heat waves like in central Europe 2003.	A heat wave is a prolonged period of excessively hot and sometimes also humid weather relative to normal climate patterns of a certain region.
	Cold wave/ frost	Damage caused by low temperatures.	A cold wave can be both a prolonged period of excessively cold weather and the sudden invasion of very cold air over a large area. Along with frost it can cause damage to agriculture, infrastructure or property.
	Winter storm (extreme winter conditions)	Damage caused by snow and ice.	Winter damage refers to damage to buildings, infrastructure, traffic (navigation) inflicted by snow and ice in the form of snow pressure, freezing rain or frozen waterways .
Drought	Drought	Long lasting event; triggered by lack of precipitation.	A drought is an extended period of time characterized by a deficiency in a region's water supply. It's a result of constantly below average precipitation and can lead to losses to agriculture and famine
Wildfire	Wildfire	Fire in forest or bush areas.	Wildfire describes an uncontrolled burning fire, usually in wild lands, which can cause damage to forestry, agriculture, infrastructure or buildings.
Epidemic			Either an unusual increase in the number of cases of an infectious disease, which already exists in the region or population concerned; or the appearance of an infection previously absent from a region.

Disaster type	Disaster sub-type	Examples/ description	Definition
	Viral infectious disease	E.g. Dengue fever, Ebola Hemorrhagic fever, Hepatitis, Lassa fever, Measles, Marburg Hemorrhagic fever, Viral meningitis, Poliomyelitis, West Nile disease, Yellow fever.	
	Bacterial infectious disease	E.g. Anthrax, Bacterial Meningitis, Botulism, Brucellosis, Cholera, Diphtheria, Leptospirosis, Plague, Typhoid fever.	
	Parasitic infectious disease	E.g. Chagas disease, Lalazar, Leishmaniasis, Malaria.	
	Fungal infectious disease	E.g. Candidiasis, Cryptococcodis.	
	Prion infectious disease	E.g. Bovine Spongiform encephalopathy, Creutzfeldt-Jakob.	
Insect infestation		Locust, Grasshopper or Worm	Pervasive influx and development of insects or parasites affecting humans, animals, crops or materials.
Animal stampede			

41 Stormy Weather: International Security in the Shadow of Climate Change

Steffen Bauer

41.1 Introduction[1]

As humankind approaches an increase of 1 °C in the average global temperature compared to the pre-industrialized era, ongoing climate change is already altering the natural systems that support human societies all around the world. Unless effectively mitigated in the near future, an unfettered climate change will drive global dynamics that could transform entire world regions. The radical changes of natural environments that are expected to follow from an unmitigated global warming would be without precedent in human history and it would thus be highly questionable if local authorities, national governments, regional organizations, and international agencies were capable of peacefully steering the resulting social and economic consequences. Indeed, if global average temperatures continue to rise beyond 2 or 3 °C this would imply a historical global experiment with unknown outcomes. The restriction of global warming and its effects should thus be a central concern of forward-looking world politics. As elaborated below, sustainable global development and international stability depend on the successful mitigation of climate change as well as on the effective management of its unavoidable consequences.

Alas, the political world – in its present state – is ill prepared to meet these challenges in a satisfactory manner. Without major breakthroughs in international climate negotiations, global efforts to cut greenhouse gas emissions will remain inadequate. Meaningful efforts to adapt to the already unavoidable consequences of climate change have only just begun to be addressed and may materialize too late, in particular with a view to the world's most vulnerable societies in small island developing states and least developed countries in tropical regions. While starting to take climate change seriously as an issue of 'high politics' the international community remains preoccupied with a bundle of established global issues such as terrorism, economic growth, financial stability, and global trade. Ultimately, the protagonists of world politics – by and large represented by the G-8+5 countries[2] – are concerned more with traditional intergovernmental relations and spheres of influence than with meaningful global governance. While this seems to be in line with short-term concerns for national sovereignty and security, it may prove self-defeating in the long term. In the following, this chapter will discuss why and how so.

To this end, *first* the specific threats will be outlined that ongoing climate change poses to stability and security at local, national, and regional levels and how these may eventually affect international security (41.2). *Second*, it will be discussed why these climate-induced security risks differ substantially from familiar types of conflicts that are driven by environmental degradation as well as how they are interdependent with distinct global trends that threaten international stability in their own right (41.3). *Finally*, it will be argued that current conceptualizations of international security are inadequate to meet the challenges of conflict and cooperation of the 21st century (41.4).

1 The author would like to thank Dirk Messner for substantive contributions to earlier versions of this chapter. Helpful comments by Hans Günter Brauch and three anonymous reviewers as well as editorial support by Michael Eichholz and Ina Gampfer are also gratefully acknowledged.

2 These are the United States, Japan, Germany, United Kingdom, France, Italy, Canada, and Russia (G-8) plus the so-called outreach countries Brazil, India, China, Mexico, and South Africa (G-5).

41.2 Climate Change as a Security Risk[3]

In November 2006, the then Secretary-General of the United Nations Kofi Annan urged the conference of parties to the United Nations Framework Convention on Climate Change to consider climate change as not merely an environmental issue, but as an all encompassing threat.[4] This was no trivial statement to make. Indeed, outside the environmentalist camp, the seriousness of climate change has been neglected for far too long.

The narrow perspective on one of the greatest global challenges of the 21st century is now gradually being overcome, it seems. Throughout 2007, this emergent paradigmatic shift (Brauch 2009a) was arguably helped by the quick succession of the assessment reports of three working groups of the *Intergovernmental Panel on Climate Change* (IPCC 2007, 2007a, 2007b) in February, March and May 2007,[5] the first ever deliberation of climate change by the United Nations Security Council (17 April 2007), the prioritization of climate change on the agenda of the Heiligendamm G-8 summit (June 2007), the United Nations General Assembly's High-level session on climate change which Annan's successor Ban Ki Moon convened in September, the dedication of the Human Development Report to "fighting climate change" (UNDP 2007) in virtual conjunction with the publication of the IPCC's synthesis report (IPCC 2007c) in November 2007, and not least by the announcement to award the Nobel Peace Prize to the IPCC and to former US Vice President Al Gore for their efforts to raise global awareness for both the causes and the consequences of global warming (October 2007) with the actual award ceremony following suit in December – accidentally in the middle of a dramatic world climate conference which convened in Nua Dusa, Bali (3–14 December 2007).[6]

The true significance of the resulting 'Bali Road Map', by which governments seek to arrive at a comprehensive and internationally binding climate agreement for the post-2012 period, can only be judged in the wake of the outcome of the meeting of the world climate conference which occurred in Copenhagen at the end of 2009.[7] It seems safe to say, however, that 2007 saw the arrival of global climate change at the highest levels of international politics, even as governments got distracted by the international financial crisis in 2008.

Also in 2007, the *German Advisory Council on Global Change* (WBGU) submitted to the federal government of Germany a flagship report which investigates and highlights the interlinkages between global warming, environmental degradation, and international security (WBGU 2007, 2008). It brings together the present state of knowledge and collates research findings on the causes of conflict and war, empirical evidence of conflicts triggered by environmental degradation and the projected consequences of climate change for people and societies. It concludes that emergent forms of large-scale environmental change that are driven by global warming may lead to a destabilization of societies and may overstretch the coping capacity of political and economic systems. Ultimately, climate change may thus generate violence and thereby confront an international system that is already under stress with profound additional challenges.

3 This chapter largely draws on the eponymous report of the German Advisory Council on Global Change (WBGU 2008); see also Bauer/Messner (2007).

4 United Nations Secretary-General Kofi Annan, Nairobi, 15 November 2006: UN Doc. SG/SM/10739; at: <http://www.un.org/News/Press/docs/2006/sgsm10739.doc.htm> (12 January 2009): "Climate change is not just an environmental issue, as too many people still believe. It is an all-encompassing threat. It is a threat to health, since a warmer world is one in which infectious diseases such as malaria and yellow fever will spread further and faster. It could imperil the world's food supply, as rising temperatures and prolonged drought render fertile areas unfit for grazing or crops. It could endanger the very ground on which nearly half the world's population live – coastal cities such as Lagos or Cape Town, which face inundation from sea levels rising as a result of melting icecaps and glaciers. All this and more lies ahead. Billion-dollar weather-related calamities. The destruction of vital ecosystems such as forests and coral reefs. Water supplies disappearing or tainted by saltwater intrusion. Climate change is also a threat to peace and security. Changing patterns of rainfall, for example, can heighten competition for resources, setting in motion potentially destabilizing tensions and migrations, especially in fragile states or volatile regions. There is evidence that some of this is already occurring; more could well be in the offing."

5 The respective reports are on: *The Physical Science Basis* (IPCC 2007); *Impacts, Adaptation and Vulnerability* (IPCC 2007a); and on: *Mitigation of Climate Change* (IPCC 2007b).

7 On negotiating the Bali Road Map and its significance; see also Müller (2008) and chap. 83 by Egenhofer, Behrens and Georgiev.

This fresh perspective on the environment-security nexus requires both a broadening of the timeframe under analysis and a reconsideration of established concepts of security. Anthropogenic climate change has only just begun and its impacts will cumulate and intensify over coming decades unless global warming is effectively mitigated. Large-scale disruptions pertaining to international security will need to be anticipated with a view to future decades. While familiar patterns of environmental conflicts clearly serve as a vantage point, they must not be expected to represent the challenges lying ahead.

Future conflicts about arable land, food resources, and access to freshwater may follow familiar patterns at local levels, but are likely to reach a new quality by way of magnitude and scale. Storm and flood disasters and drastic increases in environmentally forced migration can be expected to create additional stress and new conflict constellations. Not least, non-linear systemic feedbacks that might be activated once global warming reaches certain tipping points such as a dieback of the Amazon rainforest, a fundamental transformation of monsoon patterns, or a meltdown of continental ice sheets bear the potential to transform entire world regions and with unpredictable consequences for human civilization (IPCC 2007; Lenton/Held/Kriegler/Hall/Lucht/Ramstorf/Schellnhuber 2008; Lynas 2007; Schneider 2004; WBGU 2006, 2008).

The present pace of progress in international climate policy does not bode well for confining average global warming within a margin of 2 °C to 3 °C. Global greenhouse gas emissions are still increasing, despite noteworthy reductions in some countries. Unless the international community very soon reaches an effective global accord that ensures drastic reductions in global *greenhouse gas* (GHG) emissions, it seems all but probable that some of the systemic tipping points will be triggered even within this century.[8]

Even without such radical discontinuities in the Earth system, however, the four categories mentioned above – food security, freshwater availability, storm and flood disasters, and environmental displacement – that must be expected to gain significance in the foreseeable future, are likely to increasingly undermine human security in many regions of the world.[9] Thereby they will heighten susceptibility to social destabilization and, ultimately, violence. Accordingly, the WBGU (2007, 2008) has identified four distinct conflict constellations to explore the causal links between climate change and destabilization and the resulting threats to international security. These are introduced in the following.

41.2.1 Conflict Constellation 1: Climate-induced Fresh Water Scarcity

1.2 billion people are currently without access to safe drinking water, 2.6 billion without access to sanitation (UNDP 2006). The situation could worsen for hundreds of millions of people as climate change alters the variability of precipitation and the quantity of available water (IPCC 2007, 2007a). At the same time, demand for freshwater is increasing due to the world's growing population and its mounting aspirations. This dynamic triggers distributional conflicts and poses major challenges to water management systems in the countries concerned. For example, regions which depend on melt water from mountain glaciers – which are at risk from climate change – will require new water management strategies and infrastructures, as well as political efforts to avert national or even transboundary conflicts over the distribution of increasingly scarce water resources. The core problem generally is a lack of adaptive capacity to absorb changes in water supply and demand. However, the countries which will suffer the greatest water stress are generally those which already lack the political and institutional framework necessary for the adaptation of water and crisis management systems. This could overstretch existing conflict resolution mechanisms and may ultimately lead to destabilization and violence (WBGU 2008). Generally, the risk of violent

8 It is widely perceived that the single most important opportunity to reach a meaningful agreement to succeed the Kyoto Protocol in 2012 has been the 2009 world climate conference in Copenhagen.

9 On the concept of human security see UNDP (1994); Commission on Human Security (2003), see also Brauch (2005, 2005a, 2008a); Dalby (2002); Page/Redclift (2002) for discussions of human security in the context of environmental change. See also in this Hexagon Book Series the chapters by Barnett/Matthew/O'Brien (2008); Pachauri (2009); Steiner (2009); Gnacadja (2009); Zammit Cutajar (2009); Brauch (2009b); Fuentes/Brauch (2009); Abdus Sabur (2009); Werthes/Debiel (2009); Chourou (2009); Othman (2009); Poku/Sandkjær (2009); de Lombaerde/Norton (2009); Black/Swatuck (2009); Shinoda (2009); Schott (2009); Senghaas (2009); Nathan (2009); Wun'Gaeo (2009); Oswald Spring (2009); Truong (2009); Ariyabandu/Fonseka (2009); Tadjbakshsh (2009); Singh (2009); Schnabel/Krummenacher (2009).

conflict over water resources is estimated to be greater at an intrastate or local level than at an interstate level, particularly in weak and fragile states (Wolf/Kramer/Carius/Dabelko 2005).[10] Supply problems contribute to the risk of conflict. But, it is only in conjunction with adverse socio-economic constellations that they trigger violent conflict.

At an international level, a lack of institutional quality and stability of intergovernmental and international water regimes to control the use of shared water resources can be a key driver of transboundary water conflicts (Conca 2006; Scheumann/Neubert/Kipping 2008). Disputes over shared water resources can aggravate already tense relationships and may give rise to violent conflicts. More often, however, cooperative interaction over water use improves the relationship between the states involved (Wolf 2006). Indeed, historically the examples of cooperation between states over water resources have often proven instrumental in initiating cooperation under otherwise difficult circumstances, and have far outnumbered those of conflict escalation.[11]

Cooperative arrangements for the management of shared water resources are more likely to be concluded when economic advantages and other potential benefits of cooperation are foreseeable. This has been especially true for agreements over water infrastructure, e.g. dam building for shared power generation. On the other hand, few agreements have so far been made to promote adaptive responses to increasing regional water scarcity, i.e. agreements with an emphasis on burden-sharing rather than benefit-sharing (Klaphake/Voils 2006). Hence, it remains unclear to what extent benefit-sharing approaches can function to promote cooperation under conditions of increasing climate-induced water scarcity.

Whether or how this might lead to an occurrence of 'water wars' in the future remains debatable. Governments generally seem to be aware that there is little strategic or economic sense in waging wars if the aim is control over water resources outside their own borders. Yet, disputes over water could contribute to interstate violence in combination with other socio-economic factors that also relate to foreign affairs (UNDP 2006). In particular, where conflicts related to the overexploitation of water resources are paralleled by unsustainable land use patterns and soil degradation or where they become a driving force of migration.[12]

41.2.2 Conflict Constellation 2: Climate-induced Decline in Food Production

More than 923 million people worldwide are currently affected by food insecurity (FAO 2006; FAOSTAT 2006). This situation is the result of many interdependent causes.[13] It is likely to worsen in the future as food insecurity in many developing countries will be exacerbated as a result of climate change, even with a global temperature rise of just 2 °C (relative to 1990). If global warming rises beyond 2 °C, a drop in agricultural productivity is to be expected not only in the lower latitudes but worldwide (Battisti/Naylor 2009; IPCC 2007a). At regional levels, the risk of declining food production will be substantially reinforced by desertification, soil salinization, or water scarcity. In South Asia and North Africa, for example, the areas suitable for agriculture are already largely exploited. South of the Sahara changing rainfall patterns may reduce yields by up to 50 per cent by 2020 (Lal/Uphoff/Stewart/Hansen 2005; Dinar/Mendelsohn/Hassan/Benhin 2008). This may well trigger regional food crises and further undermine the economic performance of weak and unstable states, thereby encouraging or exacerbating destabilization, the collapse of social systems, and violent conflicts (Homer-Dixon/Boutwell/Rathjens 1993; de Soysa/Gleditsch/Gibson/Sollenberg/Westing 1999).

The adverse consequences of environmental change for regional food production are at the core of this conflict constellation. They are determined by the regional climate – temperature trends, precipitation patterns, extreme weather events – and the access to available natural resources, notably arable soil and fresh water. The impact of environmental changes on food production depends critically on the configuration of factors of regional agricultural production,

13 See i.a. Brüntrup (2008); Faaij (2008); von Braun (2007); von Koerber/Kretschmer/Prinz (2008).

which is basically a function of local agro-ecological conditions and sustainable land use. The viability of regional agricultural production is further determined by the adaptive capacity of agricultural systems to changing climatic conditions, for instance by crop selection, new breeds and varieties, or other yield-stabilizing techniques.

Competing demands and regional land use needs are also crucial, in particular if there is competition between food production and other land uses forms, notably biofuel crops or timber production (Faaij 2008; von Braun 2007; WBGU 2009). The more profitable these alternatives appear, the greater the danger that food production will be crowded out. This applies particularly to marginal agricultural regions with rising population density and may be exacerbated by increasing global demands for renewable energies. Utilization conflicts between different producer groups harbour the potential for outright conflict and violence. A danger that is evident already in the land-use competition between nomadic pastoralists and settled crop farmers in parts of Africa. The global rise in meat consumption is another factor that compounds land-use competition at regional and local levels (von Koerber/Kretschmer/Prinz 2008).

Of course, declining food production will not necessarily lead to a food crisis. This is largely determined by demographic development and economic factors. The higher a country's economic output and per-capita income, the more readily it can resort to agricultural imports to compensate for drops in production. Generally, high economic output also provides options for adequate transfers to affected groups and to thus mitigate the potential for conflict. Naturally, the impact of a decline in agricultural production will be more severely felt the greater the part played by agriculture in employment and value creation in the economy as a whole. This is typically the case in developing countries in which the export of agricultural products is a major source of foreign currency income. In the event of a noticeable economic downturn, these countries are more vulnerable than countries with a more diversified economy or higher levels of wealth and economic stability. Moreover, the quality of agricultural infrastructure (e.g. distribution of fertilizers and seeds, availability of loans), transport infrastructure, and effective institutions for disaster management are vital to prevent a destabilization in the event of a food crisis. Capacities for agricultural research also help to minimize the risk of food crisis by enabling forward-looking adaptation of the agricultural system (von Braun 2008).

Whether food crises eventually culminate in outbreaks of violence is ultimately determined by overarching societal factors, notably social and political stability, functional governance structures, and a resilient civil society. In this context, a particularly significant aspect regarding the potential for violence arising from food shortages is whether an affected country or region is prone to scapegoating. If, for instance, demagogues convince large social groups that certain ethnic minorities or religious groups are 'enemies within', the likelihood of violence increases dramatically.[14]

External factors, such as the regional and sectoral structures of global agricultural production and trade, need to be considered, too. If climate change gives rise to large-scale production failures, prices on world agricultural markets can easily exceed the financial capacities of highly indebted developing countries (WBGU 2009). In the extreme, worldwide food production could drop to a level that jeopardizes the nourishment of the world population, which would render it increasingly difficult to make up for regional shortfalls with imports even where the cash were available. A growing world population, changing patterns of consumption, and increasing global competition about the use of available land would amplify the problems resulting from any such scenario. Likewise, the interdependency of markets, e.g. for agrochemicals, fuels or machinery, may also have repercussions with global food security, which makes access to other countries' markets another key factor for political and economic decision-makers around the world. Multilateral framework conditions as governed by policies of the *International Monetary Fund* (IMF), the *World Trade Organization* (WTO) or regional development banks can have substantial influence over subsequent developments at regional and national levels (von Braun 2008; WBGU 2008).

41.2.3 Conflict Constellation 3: Climate-induced Increase in Storm and Flood Disasters

Climate change is likely to result in further sea-level rise, and more intensive storms and heavy precipitation. This will greatly increase the risk of natural disasters occurring in many cities and industrial regions in coastal zones. Those risks will be further amplified

14 See i.a. Bigagaza/Abong/Mukarubuga (2002); Diamond (2004); Gasana (2002); Hauge/Ellingsen (1998); Kaplan (1985); Percival/Homer-Dixon (2005).

by deforestation along the upper reaches of rivers, land subsidence in large urban areas, and the ever greater spatial concentration of populations and assets (UNEP 2002). Storm and flood disasters have already contributed to conflict in the past, especially during phases of domestic political tension, e.g. in Central America, India, and China. Conflicts are likely to occur more frequently in the future for two main reasons. Firstly, regions especially at risk from storm and flood disasters, such as Central America and Southern Africa, generally have weak economic and political capacities, which renders adaptation and crisis management much more difficult. Secondly, frequent storm and flood disasters along the densely populated coastal areas of India, Bangladesh, and China could cause major damage and trigger or intensify migration processes that will be hard to control.

Yet, climatic-meteorological mechanisms and rising sea levels are not the only factors that heighten the risks of disaster: deforestation in the upper reaches of rivers and land subsidence in major urban centres also contribute to this development. Moreover, the growing concentration of cities and settlements in coastal regions, the high proportion of economically weak population groups in developing and newly industrializing countries, and the particular vulnerability of the urban and industrial infrastructure are also reasons for concern. In many cities, land subsidence is perceived as a problem primarily because of the damages it inflicts on buildings and infrastructure. However, for coastal cities in particular, subsidence also implies a precarious rise in the relative sea level. The potential repercussions of such a rise in relative sea level were seen when New Orleans, where some districts are up to 3 metres below sea level, was hit by Hurricane Katrina. Although the special vulnerability of New Orleans does not automatically apply to every other coastal city, there are numerous cities, particularly in developing countries, in which major areas lie below or only narrowly above sea level.

The *International Strategy for Disaster Reduction* (ISDR) of the United Nations defines a disaster as "a serious disruption of the functioning of a community or a society causing widespread human, material, economic or environmental losses which exceed the ability of the affected community or society to cope using its own resources" (UNISDR 2006). From this definition it follows that natural disasters are usually associated with a temporary local collapse of state functions. The devastation of infrastructure blocks external consignments of relief, the water and energy supply is disrupted and the capacities of hospitals and physicians are overstretched. In situations like this, the scope of governments to act is often so heavily impeded that it virtually equals a total collapse of state functions, which can in turn often undermine political stability in several respects. At the same time, a population is never more reliant on public support than in the wake of a disaster. The call for external assistance in dealing with the direct consequences is part and parcel of almost all major natural disasters. Met with failure, this leads to frustration and dissatisfaction with the officials in charge, even more so if damages and casualties are not attributable purely to the physical forces of nature but to poorly implemented or inadequate policies and emergency measures (Drury/Olson 1998).[15] Local and regional security may be particularly at stake if a temporary breakdown of state functions is exploited by non-state actors in the pursuit of their own interests.[16]

Research on disaster impacts and political stability indicates three general mechanisms pertaining to the social and political outcomes of natural disasters:

1. an escalation of pre-existing internal conflicts;
2. conflicts resulting from social tensions that emerge within a power vacuum;
3. de-escalation of conflicts through relief operations and negotiations.[17]

41.2.4 Conflict Constellation 4: Environmentally-induced Migration

Changes in the environment as a consequence of climate change are expected to contribute to increased migration in the future. Migration, in turn, can greatly increase the likelihood of conflict in transit and target regions. It can be assumed that the number of environmentally displaced persons will substantially rise in the future due to the impacts of climate change, particularly in densely populated coastal areas affected by rising sea levels (WBGU 2006a)[18] and in dr-

15 See also Auf der Heide (2004); Fuentes (2003); O'Leary (2004).

16 These or similar issues contributed to political crises in Haiti (1954), East Pakistan (1970), Bangladesh (1974 and 1988), Bihar (1987), Orissa and West Bengal (1999), West Bengal (2000) and New Orleans (2005), see also WBGU (2008: fig. 3.2.4).

17 Examples including cooperation and assistance in spite of political tensions or ongoing conflicts include Turkey/Greece (1999), Iran/USA (2003), Sri Lanka/Tamil rebel movement LTTE (2004), Indonesia/Free Aceh Movement GAM (2004) and India/Pakistan (2005), see WBGU 2008 for details.

yland developing countries where recurring drought, desertification, and water scarcity are already severe (Bauer 2007, Leighton 2006). In combination with high population growth, weak institutions, high levels of poverty or dependency on agriculture further exacerbates the likelihood of environmentally induced migration, most of which typically occurs within national borders. However, transboundary environmental migration seems also likely to increase, mainly in the form of south-south migration. Yet, Europe and North America must also expect substantially increased migratory pressure from neighbouring regions with adverse environmental conditions. According to different estimates, some 150–200 million people might find themselves forced to abandon their homes by 2050 due to environmental changes caused by global warming (Myers 1993, 2002; Brown 2008a). While such estimates have a considerable margin of error and depend on underlying assumptions about population growth, economic development as well as the degree of climate change and subsequent environmental impacts, there is growing consensus regarding the general trend.[19] The consequences of global warming are likely to trigger migratory movements of an unprecedented scale, notably so in Asia and Africa (Biermann/Boas 2008).

At the international level, the questions of how to deal with growing migratory movements and which states will have to bear the costs of environmentally induced migration bears considerable conflict potential in its own right (Biermann/Boas 2008; Morton et al. 2008; WBGU 2008). While the recent past yields little evidence that large migration movements have been the cause of conflicts, there is evidence that migration can sometimes significantly increase the likelihood of conflict and that different types of migration involve different security risks (Goldstone 2002; Lohrmann 2000).

It stands to reason that the likelihood of conflict increases if environmentally displaced persons have to compete with the resident population for scarce resources such as land, water, accommodation, employment and basic social services, or even if immigrants are merely perceived as competitors. A competitive situation of this sort is particularly likely to arise in regions in which population growth is strong (Urdal 2005).[20] Moreover, the likelihood of ethnic conflict may increase if the arrival of migrants upsets the 'ethnic balance' in the region and thereby gives rise to xenophobia and violent confrontation or exacerbates pre-existing tensions (Homer-Dixon 1999; Lohrmann 2000). Recent research also highlights the relevance of a diaspora as a possible cause of conflict (Brauch 2006c). For instance, Collier and Hoeffler (2004) found a strong positive correlation between both susceptibility to repeated conflict and conflict intensity and the size of the diaspora abroad.

The actual impact of either of these factors depends considerably on the responses of the governments in charge, many of which are ill-prepared to cope with migration. This does not only refer to developing countries but has also been demonstrated in the industrialized world, for instance by Spain's periodic problems in dealing with West African boat people or by the difficulties encountered by the US government in catering for 1.3 million internally displaced persons after Hurricane Katrina in August 2005. Yet, the proliferation of environmental migrants mainly occurs in countries and regions with weak governance structures where political stability is easily shaken. Once an inflow of migrants overstretches the coping capacities, the likelihood of conflicts increases, in particular if affected countries are also prone to economic crises (Reuveny 2007; WBGU 2008).

41.2.5 Regional Distribution of Climate-induced Security Risks

While unmitigated climate change will eventually have adverse consequences for people all over the world, the eminent security risks that are expected to result from continued global warming will be unevenly spread. Resilience and vulnerability to changing environmental conditions vary considerably within societies but also across regions. Developing countries in Africa, Asia and South America, that typically have fewer capacities for adaptation at their disposal than developed countries, will be affected earlier and to a much higher degree. Arguably, small island develop-

18 In 1995 some 60 million people lived within the 1-metre elevation zone and 275 million within the 5-metre zone above mean sea level. Projections of population growth indicate that these figures will rise by the end of the 21st century to 130 million in the 1-metre zone and 410 million in the 5-metre zone; WBGU 2006.

19 See inter alia Biermann and Boas 2008; Brown 2008a; Jakobeit and Methmann 2007; Leighton 2006; Reuveny 2007; Stern 2006; WBGU 2006, 2008.

20 Similar competition for resources can also trigger conflict once migrants return to their regions of origin. Particularly if returnees find their land or property to have been overtaken by others during their absence.

ing states in the Pacific and the Caribbean are worst off in a view even of moderate climate change.

Africa, based on its particular sensitivity with regard to climatic variability combined with socio-economic as well as political stress factors and with very low adaptation capacities, is particularly endangered. Until 2020 the IPCC expects an increase of about 75–250 million people suffering from climate-induced water shortages. In individual countries a fall-off in yields of rain-fed agriculture of up to 50 per cent is also expected. In the Nile delta the regional food production is threatened by rising sea levels as even a small rise leads to the salinization of important agricultural farmland. At the same time, the demand for food, farmland, and freshwater will presumably increase due to the continuing population growth and the immigration from the bordering dryland regions. In the Sahel region and in southern Africa, where a lot of people are dependent on subsistence agriculture and rain-fed agriculture, the already precarious living standards will worsen further due to more frequent and intensive extreme weather occurrences. In combination with the prevailing weakness of state institutions in many countries of the region, as well as complex violent conflicts and large streams of refugees, the risk of a gradual regional destabilization furthermore seems to be quite high. The current endeavours in fighting poverty and regional stabilization would be set back.

In Asia the melting of the Himalayan glaciers is a central problem. Apart from flooding and landslides, this means primarily a shortage of freshwater resources which could affect more than one billion people in 2050, according to the assessment of the IPCC. In large parts of the continent flooding and temperature increases will impede the containment of typical tropical diseases and will probably lead to higher mortality. India, Pakistan, and Bangladesh will be especially hard hit by the foreseeable climatic consequences. The destructive storms and floods that already occur nowadays will take place more and more often, and will also unleash a much larger destructive power due to rising sea levels. In addition, salinization of the soil and changing monsoon patterns are likely to affect the regional food production whose yields could decrease by up to 30 per cent by the middle of the century. In the densely populated and notoriously conflict-ridden Gulf of Bengal the social tensions could eventually escalate in a violent manner (BMU 2002). In China the economically significant southeast coast (tropical storms) and large parts of the hinterland (droughts, heat waves, desertification) will be especially severely exposed. It is hard to tell if the adaptive capacities of the state can match at the same time the challenges of modernization, social crises, environmental stress, and the consequences of climate change.

In South America the accelerated glacier melting in the Andes region together with changing precipitation patterns will most likely lead to a reduction in the available freshwater resources. The water resources in the conurbation of Lima, for instance, depend over 80 per cent on the glaciers of the Andes. These have lost a third of their volume between 1970 and 1997 alone and will disappear within the next decades as warming continues. Hence, a highly populated and continually growing urban agglomeration within a desert-like environment must be supplied with a new water system in the foreseeable future. In other South American dryland areas salinization and desertification will intensify and are thus likely to adversely affect regional food production. In addition, rising temperatures and declining soil humidity in the eastern Amazon region will probably lead to the gradual replacement of rainforest with savannah by the middle of the century (figure 41.1).

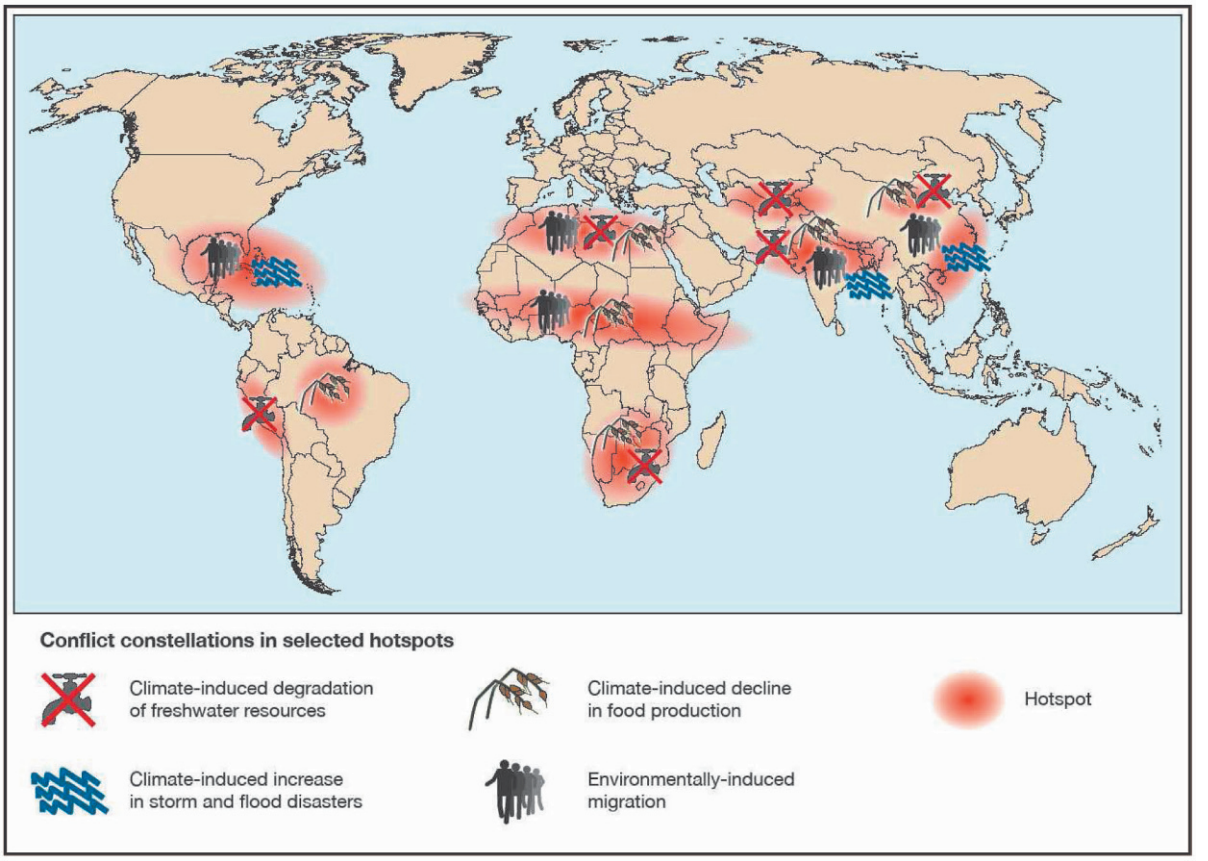
While this selection of examples from the major developing regions is just a scratch at the surface, it should become clear that climate change will intensify the existing development problems in many countries and regions, and will bring forth a multitude of additional constraints for human development and, indeed, human security. Notably, global warming undermines progress towards the Millennium Development Goals even at its current temperature level of less than 1 °C increase in average global temperature.

41.3 New Quality of Threats and Interlinkages

Research on the relationship between changing environmental conditions and violent conflicts began in the 1970's. It was not until the 1990's, however, that scholars entered into systematic inquiry of the causal links between environmental degradation and conflict escalation.[21] Emerging post-Cold War debates on the

21 Seminal pioneering works from this field of research include studies by Homer-Dixon 1990; 1991; 1994; 1999 and by Bächler et al. 1996; 1996a; 1996b; Bächler 1998; for discussions and reviews of the early literature see inter alia Barnett 2000; Brauch 2003, 2005; Brock 1997; Gleditsch 1998, 2003; and Levy 1995.

Figure 41.1: Conflict constellations in selected hotspots. **Source:** WBGU (2008: 163).



concept of human security and about the general 'securitization' (Wæver 1995, 2008, 2008a) of international politics further fuelled this specific research agenda throughout the 1990's. In spite of some fundamental criticism pertaining to the methods and assumptions of this particular research, there is widespread agreement regarding at least three core empirical findings.

- *First*, all approaches to the causality between environmental degradation and conflict emphasize the multi-causality of the conflicts observed. There is thus a strong consensus that environmental degradation is always only one of several complex causes of conflict. Indeed, environmental degradation rarely was considered to be the decisive factor in past conflicts.
- *Second,* there is a consensus regarding the locality of the conflicts with a distinct environmental component. Even when they can be categorized as cross-border conflicts, they are predominantly intrastate conflicts. Generally they do not grow into classical interstate conflicts in the sense of wars between countries but manifest themselves as regionally limited clashes at the sub-national level.
- *Finally*, all approaches emphasize the central role of a state's or society's problem-solving capacity with regard to the emergence and management of conflicts: where political and societal institutions are weak, there is a proportionally higher probability of conflict occurring. Future crisis hotspots in view of environmental degradation intensified by climate change can therefore be assumed to be located in countries and regions with weak capacities for problem-solving.

In the recent past, there has been no evidence that environmental problems are the direct cause of war – that is, there have been no 'environmental wars' manifesting the most extreme form of interstate conflict. However, it can hardly be ruled out that environmental degradation can have destabilizing impacts that may lead to conflict escalation – as can be seen from various conflicts in the recent past, this remains a plausible possibility.

Accordingly, the interconnections between environmental conditions, society, and conflict are ex-

tremely complex due to the diversity of mutual dependencies between political, societal, and economic factors on the one hand and ecosystem factors such as availability of water, soil quality, and climate change on the other. Nonetheless, the key findings of environmental and conflict research suggest that, for the time being, genuine 'environmental conflicts' are unlikely to occur. Yet, environmental degradation may be one significant driver of conflict in combination with predominant socio-economic factors and governance problems. While some of these conflicts may develop a cross-border nature, they generally remain limited to a local area.

However, little can be said about future long-term developments on the basis of these findings. While there is a growing body of scientific evidence about climate change and its potential consequences, knowledge about a resulting tendency towards violent conflicts both within and between countries remains opaque. In order to reach a more accurate assessment of the relevance of climate change and environmental change to security it is necessary to consider that studies on environment and security have thus far focused on environmental changes at local and regional levels, but hardly at large-scale changes as driven by climate change and their potentially destabilizing impact. Moreover, empirical research on environmental conflicts has been concerned with the period from 1980 up to the turn of the millennium (Brauch 2003). Taking a new look through the lens of climate change however requires an extension of the analytical time horizon because the security-relevant disruption that is to be expected as a result of climate change is only likely to occur in the coming decades.

Looking through this lens suggests a need to reconceptualize our current understanding of the environmental conditions of conflict on two counts. First, an intensification of familiar environmental conflict patterns through reciprocal interlinkages; second, a new quality and scale of conflict-relevant environmental changes due to climate change.

41.3.1 Reciprocal Interlinkages between Conflict Constellations

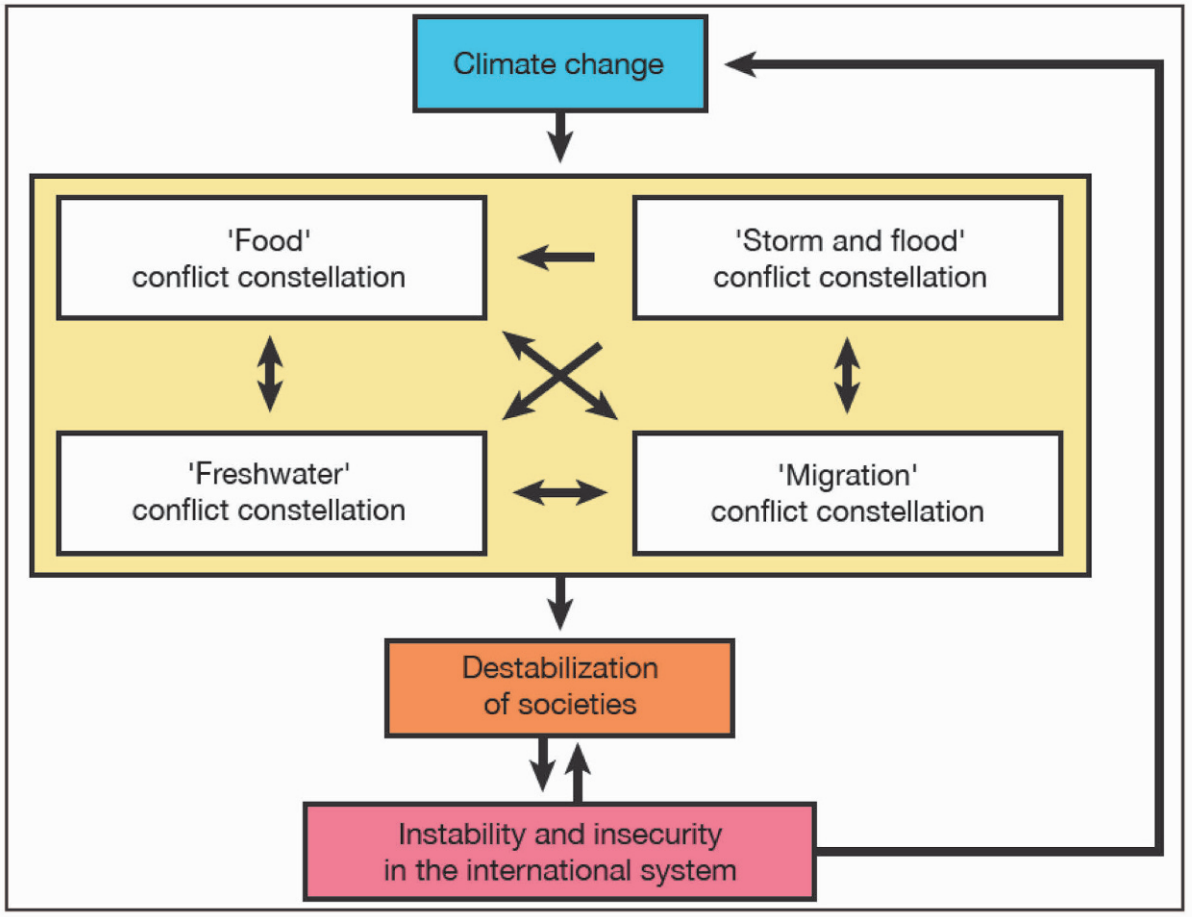
The problems associated with climate change are particularly likely to develop their critical impact when several adverse causal complexes coincide. Societies and regions are particularly vulnerable where unfavourable biogeophysical conditions, such as aridity, converge with poverty, high population density, weak institutions, and political instability. In many cases, the resulting critical constellations can be expected to be amplified by numerous interdependencies and feedback effects among the four constellations described above. Policy challenges to deal with the ensuing security risks would thus grow exponentially.

For instance, there are obvious interlinkages between fresh water scarcity, food production, and migration. With 70 per cent of fresh water being used for farming, it is fundamental to both food security and poverty reduction. Unfavourable climate-related changes in water availability can thus have severe impacts on the conditions for agricultural production and the livelihoods of rural populations. Such trends are again amplified by competition with other forms of resource use such as hydropower, and by pre-existing environmental problems such as soil degradation. In short, where water crises emerge, food crises can be triggered or worsened. Conversely, non-sustainable agricultural practices can contribute to causing water stress and conflict by overexploiting water resources or rendering them unusable through contamination with fertilizers and pesticides. In combination with poverty, weak institutions and political instability, freshwater scarcity and food insecurity can thus concentrate and amplify impacts regionally, thereby overwhelming institutions and causing crises to escalate.

In extreme cases, drought or water stress will force people to leave their homelands and thereby provide a link to migration. Migration, in turn, potentially causes various types of conflicts in transit and target regions. A growth in population and thus in demand for water and food could, for instance, overwhelm local management capacities or lead to further demographic pressure, for instance at risk of storm surges in densely populated coastal conurbations. Poor migration management can then adversely affect water availability and food production as well as disaster risk management structures in the transit and destination regions. In any case, it can be expected that climate change will lead to a considerable increase in the number of migrants, mainly within and between developing countries. An increase of associated conflicts seems therefore likely, in particular as here, too, there exist self-reinforcing feedbacks among the conflict constellations and their concentration in the developing world. They can already be observed today, but will become more frequent and emerge in new regions in the future.

Moreover, the risk for conflict constellations about water, food, and migration to escalate will be driven by the increase and intensification of storm and flood disasters. This will not only inundate and

Figure 41.2: Conflict constellations as drivers of international destabilization. **Source:** WBGU (2008: 160).



erode coasts, destroy settlements and infrastructure and wreak considerable economic damage, for instance in the fisheries and tourism sectors, but it will also force large numbers of people to flee suddenly. This will place major pressures upon disaster risk management systems and upon the coping capacities of the states and regions affected. Moreover, increasing extreme weather events lead not only to sudden disasters. They also trigger gradual processes of environmental degradation, notably through rising sea levels (WBGU 2006). Storm and flood disasters thus have the potential to reduce the availability of fresh water as well as soil quality over the long term, and, in conjunction with other factors, to thus induce water and food crises and to drive large numbers of people to migrate.

41.3.2 Climate Change as a Catalyst of Insecurity

Although conflicts related to environmental degradation have thus far remained relatively uncritical in terms of international security, the phenomena described above suggest, however, that regional risks of destabilization and violence driven by climate change threaten to gain a significantly new dimension. Far-reaching impacts upon national societies, entire continents, and the international system are to be expected unless climate change is effectively mitigated in the near future. It is in this sense that climate change lends a new quality to environmental threats to security, which results from the globality of causation and impacts, the speed and scale of climate-induced environmental effects, the large numbers of people affected, and the reciprocal interlinkages between climate-related conflict constellations about fresh water, food, storm and flood disasters, and migration.

In particular, this new quality is captured by eight distinct characteristics that directly relate to the above described conflict constellations (WBGU 2008):

- *Concentration* of conflict constellations in certain predisposed types of countries. Developing countries and, in particular, those characterized as weak and fragile states will be hit hardest (and often first). The low problem-solving capacities of this group of states makes probable a high potential for violent conflict.
- *Cumulation* of different conflict constellations in one region, which will thus be particularly stressed by resultant feedback effects and interlinkages as described above.
- *Scale* of crisis potential and the number of people affected will both reach unprecedented levels worldwide. Global population amounts to around 6.6 billion people today, and they are exposed in different ways to the consequences of climate change, notably in densely populated coastal communities.
- *Recurrence and a greater frequency* of extreme events can undermine all development efforts and progress in a region. A greater frequency of floods and drought will pose particular risks to people dependent upon subsistence farming (in lower latitudes), i.e. especially in Africa, parts of Asia, and South America (IPCC 2007a).
- *Propagation* of conflict constellations beyond the immediately affected region, with environmentally-induced migration serving as a key mechanism here. It can be assumed that the number of migrants moving away from areas particularly affected by climate change will increase in the future and that this may destabilize neighbouring regions. Moreover, the areas directly affected by severe consequences of climate change can also expand, for instance regarding the occurrence of hurricanes in higher latitudes due to warmer ocean surfaces.
- *Intensification* of crisis situations with problems ultimately resulting from climate change can engender a new dimension of conflict risks resulting from the interplay between increasing frequency and regional propagation of conflict constellations.
- *Disputes* and conflicts of interest between states will become more probable through an altered global balance of power in combination with the new problems driven by climate change. A world characterized by 'power in transition' (Kupchan/Adler/Coicaud/Yuen 2001) is highly likely to be less stable than the unipolar world we know today (see below). Accordingly, the risk of serious confrontation among key players will rise and hamper global governance in areas such as environment, development, and disaster prevention.
- *Time lag* characterizes ongoing climate change and thus poses a particular challenge to efforts to address the problems resulting from it. In order to reduce the risks of major climatic and socio-economic disruption resolute action is required immediately, that is within the next 10–15 years. Political and economic systems, however, are poorly equipped to respond to such global, long-term challenges as posed by climate change. Accordingly, failure to mitigate climate change will lead to considerable further destabilization, crisis, instability, and violence from roughly the mid-century onwards.

41.3.3 Contextual Global Trends and the Cumulative Destabilization of the International System

Of course, none of these developments will occur in isolation but have to be seen in the much bigger picture of world developments and international politics. Here, five macro-trends can be observed, each of which represents a considerable challenge to the current global governance architecture in its own right. Again, climate change will not help to ameliorate the ensuing problems but rather intensify them (Bauer/Messner 2007):

- *A critical impairment of global economics*, that can result, amongst other things, from the necessary adaptation measures which the safeguarding of local and regional production processes and supply structures will require. Thereby the costs for coping with the consequences of climate change will be that much higher, the longer an effective climate policy is procrastinated.
- *An increasing climate-induced threat to existential human rights* (notably access to water, food, security) could undermine the international legitimacy of mainly responsible industrialized nations, but also that of fast-growing anchor countries such as China and India whose emissions are rapidly increasing. Ultimately, this could limit these countries' capacity to act at the global level.
- *An intensification of international distribution conflicts*, especially with a view to the transfer of compensation payments between those mainly

responsible for global warming and those mainly affected by its negative consequences.
- *A drastic increase in migration* both within the regions heavily affected by climate change as well as beyond these regions, for which humanitarian solutions as well as adequate international legal responses must be found in order to cope with these problems.
- *A proliferation of weak and fragile states* that will hardly be able to protect their population from the consequences of climate change and that destabilizes the international order as a result of eroding statehood.

Given the state and capacity of its current multilateral institutional architecture the international community seems ill-prepared to cope with each one of these challenges. If the resulting threats accumulate and intensify each other, which seems probable, it would quickly reach its limits. More than ever, the international community will thus be all but helpless unless governments finally prop up existing multilateral institutions with adequate means. This may require them to venture new ways of international organization altogether and even to transcend persistent notions of national sovereignty that define the present international system.[22]

41.4 Outlook: Reconceptualizing Security for a Hotter World

Security and the question of how it is best conceptualized are among the most controversial issues in international politics. Due to the inherent flexibility of the concept, security can be interpreted in different ways, depending on the interests of security experts, intellectuals, and politicians (Dalby 1992, 2008; Brauch 2008, 2009).[23] In classical terms, security implies the preservation of a nation state's integrity vis-à-vis external threats in an anarchic world of states. In the vein of this paradigm, guaranteeing security is ultimately seen as a military task. In the era of post-Cold War globalization, however, it became ever more obvious that insecurity, instability, and violence are brought about not by military aggression alone, but may have complex political, economic, socio-cultural, and ecological origins, which in turn led to calls for a re-assessment of security and corresponding policy adjustments (Tuchman/Mathews 1989; Lipschutz 1995; UN 2004).

In the particular context of environmental challenges for security policy, proponents of the concept of human security have since stressed that a concept of security which refers to collective actors, such as states and societies, is not capable of encompassing all relevant threats, challenges, vulnerabilities, and risks that can be found on the ground (Brauch 2005, 2009a: 4; Dalby 2002, 2008). Indeed, environmental conflicts do not usually involve longstanding clashes of interest between organized groups, but are rather discrete disputes that occur between people whose intention is to safeguard their means of survival. From the point of view of human security, environmental security would have to be geared not towards the nation state but towards the ecosystem in which humans themselves represent the real threat to security in their role as users and polluters of the environment (Brauch 2005; Dalby/Brauch/Oswald Spring 2009; Oswald Spring/Brauch/Dalby 2009).

However, a range of objections have been raised against the concept of human security. One is that the UNDP approach plays down security risks, such as wars, and the important role of nation states in their significance, and that it blurs the boundary between human security and human development. Clarity can be gained only by restricting the concept of security to 'freedom from direct physical violence'. Even then, there is a danger that the concept of human security, with its positive connotations, could be exploited to construct new sources of legitimacy for military interventions aimed at safeguarding security (from environmental risks, AIDS, migration, etc.). Finally, when the concept of security is watered down in this way, it leads to a loss of analytical clarity from a research perspective as well.

Overall, then, the debates about comprehensive security and its policy implications remain controversial due to the inevitably Janus-faced character of the issues involved. On the one hand, an expanded concept of security could counteract the further militarization of international politics, if the drive to achieve security were increasingly understood to encompass economic, social, and ecological concerns in the context of sustainable development. On the other hand, however, it allows international structural policy to become militarized, as environmental policy and other non-military matters are turned into security concerns.[24] This may lead, among other things, to a situ-

22 See i.a. Newman/Thakur/Tirman (2006); Paolini/Jarvis/Reus-Smit (1998); Kennedy (2006) for general discussions of the state of multilateralism and structural change in the international order.

23 See also Brock (1997); Dalby (2002, 2008); Levy (1995).

ation in which non-civilian actors, such as secret services or police and border protection authorities, are increasingly entrusted with tasks that lie outside their original area of responsibility – as exemplified by the Patriot Act in the USA – or in which resources intended for development cooperation are used to co-finance military operations in the context of humanitarian interventions. Similarly, it is to be feared that the 'colonization' of international environmental policy by the dominant industrialized powers will further reinforce the North-South conflict. Both tendencies – the endeavour to develop non-military supporting measures for security policy and military back-up for global structural policy – are reflected in the more recent debate about development strategies for weak and fragile states (BMZ 2007; Collier 2007; Faust/Messner 2004).

Since the events of 11 September 2001 security discourse in international politics has been dominated by the fight against global terrorism. This is reflected clearly in the new security strategies that have arisen on both sides of the Atlantic (Berenskoetter 2005), with the USA and the European Union setting differing priorities. The National Security Strategy of the USA clearly emphasizes military aspects, even including pre-emptive military action, whereas the European security strategy argues more along political lines and is oriented towards the objective of avoiding conflict. While the strategy of the USA also contains provisions for increasing foreign and development assistance, its overall content and style is oriented towards military offensiveness: 'our best defense is a good offense' (White House 2002).

In contrast to this, the European security strategy, formulated in December 2003 under the supervision of Javier Solana, i.e. the Secretary-General of the Council and High Representative for the Common Foreign and Security Policy of the EU, emphasizes the possibilities of multilateral diplomacy. The strategy calls, above all, for a strengthening of the multilateral world order and of international law; it also calls for conflict prevention measures to be designed for the long term and to be based on both non-military cooperation and political pressure, which in the last resort – as in the case of humanitarian disasters, genocide or acute state failure – is to be complemented by robust military intervention within the framework of the international legal order (EU 2003; Faust/Messner 2004; chap. 6 by Bailes).

The general principles formulated in the European security strategy have been lent greater precision, however, in a European defence paper commissioned by the EU member states and prepared by the Paris *Institute for Security Studies* (ISS 2004). This paper notes that there is an increasing need for expeditionary forces that are flexible and capable of being deployed at short notice, as well as for occupation forces that can be deployed over the long term. The ISS paper bears the unmistakeable trademark of a military policy-based approach, suggesting that the EU's security policy think tank has yet not accommodated the broader, more non-military security approach. Thus the transatlantic differences in approach are no longer quite so pronounced.

In addition to the European defence paper, though, the report commissioned by Solana entitled 'A Human Security Doctrine for Europe' and prepared by the *Study Group on Europe's Security Capabilities* (Study Group 2004) has also become a central component of the debate over European security policy. This report – also known as the 'Kaldor paper' after the group's chairperson Mary Kaldor – makes explicit reference to the concept of human security, which differs markedly from traditional security policy ideas. In particular, the Study Group recommends that foreign and security policy be oriented less towards states and more towards individuals, since territorial defence in the classical sense is no longer effective in the changed global security situation. The Kaldor paper thus calls additionally for a Human Security Response Force that is specialized in humanitarian intervention, to complement the EU Military Rapid Response Force proposed in the ISS paper.

In sum, security risks that could arise as a result of long-term processes of global environmental change are accorded varying degrees of attention in the strategies put forward by the US and other OECD countries; overall, however, they still play a rather subordinate role. Statements about potential linkages between environmental degradation and security often remain vague, unless they are focused on those natural resources whose supply is directly relevant to the interests of the industrialized countries. As another example, the 2005 status report from the Worldwatch Institute, entitled *Redefining Global Security*, stresses the significant role of an oil-based global economy with regard to climate change and calls for a reduction in dependency on crude oil. Yet even the Worldwatch Institute sees the security risks associated with such an economy as being above all a problem of supply shortages and the 'resource curse'; this

24 See, for instance, Brock (1997); Deudney (1991, 1992); Wæver (1995).

means that resource richness can often be associated with negative consequences for the development of a country (Worldwatch Institute 2005).

A similar approach to environmental change also characterizes recent security debates in the United Nations which respond to reports by UN Secretary-General Kofi Annan (UNSG 2005) and by the High-level Panel on Threats, Challenges and Change that was commissioned by Annan (UN 2004). While the high-level panel argues for a more wide-ranging concept of security that regards poverty reduction as an indispensable basis for a new collective security, environmental degradation is mentioned only as a marginal issue in the six categories of global threats to security which the panel defined, namely, as a sub-issue under economic and social deprivation.

Against this background, it is remarkable that, in its security strategy of 2006, which it formulated in the aftermath of Hurricane Katrina, the United States no longer addresses the scarcity of strategically important resources alone, but also explicitly refers to environmental degradation (White House 2006).

Irrespective thereof, the concepts of 'environmental security' and 'ecological security', which relate to environmentally induced security risks, have already been taken on board by important international actors, such as NATO, OECD, and UNEP who have responded to the policy relevance of the issue by setting up working groups and special departments.[25]

The EU, in particular, might be seen as a pioneer in this respect. In March 2008 the EU and the heads of state of the EU member states published an "action plan on climate change and security", emphasizing that the mitigation of global warming should be perceived as a preventive strategy to avoid climate driven conflicts in the future. Furthermore, they emphasize that beyond mitigation initiatives significant adaptation strategies need to be developed in order to avoid destabilizing impacts of climate change in vulnerable countries and regions. Meanwhile, practitioners of international development cooperation, too, have taken up the issue of climate change and security (e.g. GTZ 2008, Smith/Vivekananda 2007; Brauch 2009a; chap. 42 by Scheffran).

A year after the publication of the IPCC's fourth assessment report, it seems, the theoretical and political debates on climate-induced conflicts are actually gaining relevance in international policy-making, as is reflected in the Implementation Paper to the European Security Strategy by the European Council in December 2008 (chap. 6 Bailes; EU 2008, 2008a).

25 See the chapters in the previous volume of the Hexagon Series by Brauch 2009; Dalby/Brauch/Oswald Spring (2009); Matthew/McDonald (2009); Sergunin (2009); Ramakrishnan (2009); Schreurs (2009); Selim (2009); Newman (2009); Twite (2009); Dajani (2009); Ejigu (2009); Moyo (2009); Lopez (2009); Cheterian (2009); Barnett (2009); Hoogensen (2009); Oswald Spring/Brauch/Dalby (2009).

42 Security Risks of Climate Change: Vulnerabilities, Threats, Conflicts and Strategies

Jürgen Scheffran

42.1 The Climate-Security Challenge

With growing indications of climate change, the expected impacts and risks pose a major challenge for society, foreign policy and security (Ott 2001). The issue is complex and covers highly uncertain future developments which preclude simple predictions from previous data. The recent reports by the *Intergovernmental Panel on Climate Change* (IPCC) point to new risks, but do not focus on the linkages between climate change and potential social tensions and conflicts (IPCC 2007a; Nordås/Gleditsch 2009). Worldwide, devastating impacts on food and water availability, flood and storm disasters and large-scale events, such as loss of the monsoon, breakdown of the thermahaline circulation, polar ice melting, or sea-level rise, could affect large populations. It is unclear yet how human beings and their societies will respond to the expected dramatic consequences of climate change and whether the social stress will lead to more security risks and conflicts or to more cooperation.

Since 2007 interest in the climate-security nexus has increased in the international community which contributed to the securitization of climate policy (Scheffran 2008a, 2009; Brzoska 2009; Brauch 2009a). In April 2007, the U.N. Security Council discussed the security risks of climate change for the first time (UNSC 2007), and U.N. Secretary-General Ban Ki-Moon warned that climate change may pose as much of a danger as war (BBC 2007). In June 2009, the UN General Assembly requested a report on climate change and its potential security implications (UNGA 2009). The EU High Representative and the European Commission, in part with a view on the growing tension on Arctic resources, suggested that "climate change acts as a threat multiplier, worsening existing tensions in countries and regions which are already fragile and conflict-prone" (EU 2008).

Several think tanks have published studies that analysed the potential security implications of climate change. A Washington-based panel of experts asserted that climate change "has the potential to be one of the greatest national security challenges that this or any other generation of policy makers is likely to confront" (Campbell/Gulledge/McNeill/Podesta/Ogden/Fuerth/Woolsey/Lennon/Smith/Weitz/Mix 2007). A panel of retired admirals and generals also identified climate change as a 'threat multiplier' that undermines international and human security and aggravates conflict in many parts of the world (CNA 2007). The German Advisory Council on Global Change discussed conflict constellations in climate hot spots and concluded that climate change could overwhelm adaptive capacities of many societies, possibly leading to instability and conflict (WBGU 2008; chap. 41 by Bauer).

Before the year 2000 the research literature sporadically discussed (Brown 1989; Swart 1996; van Ireland/Klaassen/Nierop/van der Wusten 1996; Scheffran 1997; Edwards 1999; Rahman 1999). More recently a number of studies have analysed potential security implications of climate change on the local, regional and global levels (Brauch 2002, 2007f, 2009a; Brown 2007; Maas/Tänzler 2009), without providing sufficient evidence to support a clear causal relationship. A critical analysis raises doubts about over-simplifications (Barnett 2003; Barnett/Adger 2005, 2007; Nordås/Gleditsch 2007) and warns against over-selling the argument before the links are better understood (Dabelko 2009). A systematic and integrated analysis of the climate-security link is still missing, and there is a need to design interdisciplinary and integrated assessment approaches to improve the understanding of how actors are responding to climate change and how potential security implications can be avoided. In particular, indicators are missing that measure key impact dimensions, such as vulnerability, risk, threat, insecurity, instability and conflict that could guide strategies for addressing these problems.

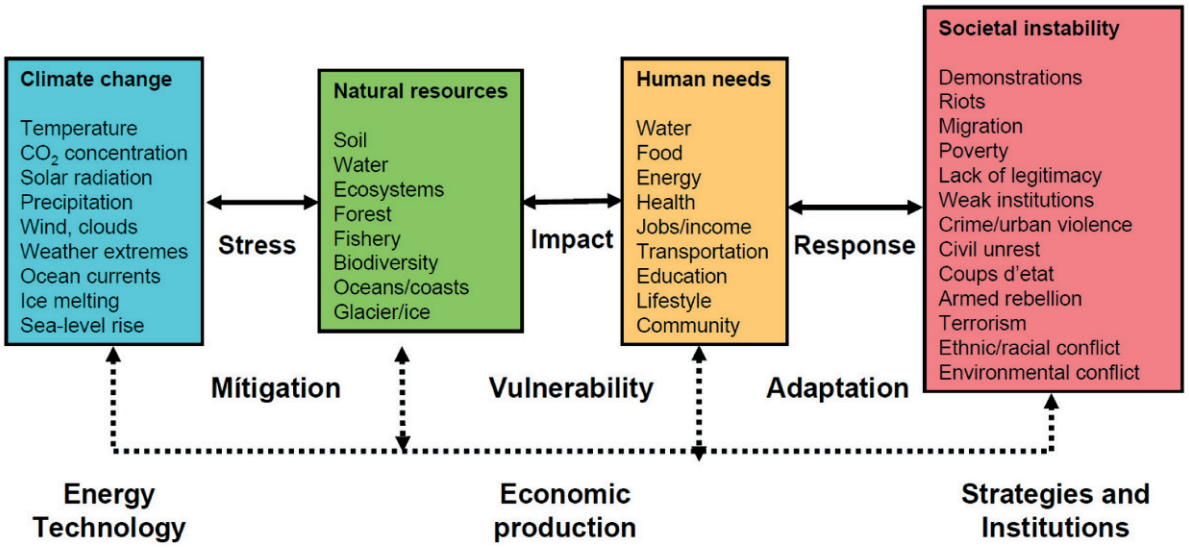
Figure 42.1: Causal relationships between climate change, natural resources, human needs and societal impacts. **Source:** The author.



This chapter will assess these issues by discussing the link between climate change impacts, human responses and societal strategies within an integrated framework of climate-society interaction. An integrated assessment framework will be introduced to analyse the causal chain between climate change, natural resources, human needs and societal stability, with a focus on the sensitivities that couple different systems and variables (42.2). Impacts of and responses to climate-induced stimuli will be evaluated in terms of vulnerabilities and adaptive capacities, threats and security risks, instabilities and conflicts (42.3). This analysis serves as a basis for developing strategies to reduce security risks and conflicts and stabilize the climate-society interaction (42.4).

42.2 Integrated Framework of Interactions Between Climate and Society

42.2.1 Integrated Assessment Framework

Since human societies rest on certain environmental conditions, a changing climate that significantly alters these conditions will cause stress to social systems and has an impact on human life and society. Whether societies are able to cope with the impacts will depend on their responses to change and their abilities to adapt to or solve associated problems. Finding human responses and societal strategies that avoid potential security risks and conflicts of climate change is a major challenge. To analyse these processes more systematically, an integrated assessment framework of climate-security interactions is developed, using concepts and methods rooted both in the social sciences and in complex systems analysis (Cho 2009). To assess the implications for security and conflict that could affect societal and political stability, it is crucial to not only understand the dynamics of systems, but also the perceptions and response patterns of human beings to climate-induced environmental change and how this shapes the social interactions in their respective societies.

Figure 42.1 shows the causal links between climate stress, environmental impacts, human responses and societal consequences, building on related approaches such as the IPAT equation and the Kaya formula (Scheffran/Stoll-Kleemann 2003) or the PEISOR concept, (see Brauch 2005b, 2009a; Brauch/Oswald Spring 2009a; Oswald Spring/Brauch 2009). Changes in the climate system (such as marked changes in temperature and precipitation) affect natural resources (e.g. soil, water, ecosystems, forests, biodiversity), through a sequence of complex interactions. Depending on vulnerability, adverse environmental changes will stress basic human needs and desires (such as the availability of water, food, energy, health and wealth). These impingements on human needs may impair the stability of societies that can appear in violent forms, such as riots, insurgencies, urban violence or war, which in return can aggravate social disruption. Feedback mechanisms allow societies to adapt to the changing situation and mitigate climate stress through

strategies and institutions that apply technology, human and social capital for adjusting the economy, the energy system and human behaviour. To determine the couplings along this causal chain, it is important to identify the sensitivities that measure how variables in one level modify variables in another level. For instance, desertification caused by climate change may undermine food security and force people to migrate or take violent actions. Many more of these linkages are feasible and future research may help to understand the most likely and most significant ones for crisis areas that are most affected by climate change (hot spots). Estimating the sign of these linkages or even the strength may help to sketch impact graphs which can serve as an analytical framework.

42.2.2 The Climate-Environment Link

The interaction between climate change and environmental change is determined by the laws of nature and can be represented by a set of system variables that are mutually interconnected. The degree of environmental change is indicated by the sensitivity of environmental variables, organisms and ecosystems to the stress caused by climate change events, such as global and regional temperature change; a drop in precipitation; the increase in floods and storms; or sea-level rise. The rise of global temperature and its variation alters many natural processes and cycles, including precipitation patterns, ice formation, biological systems and their distribution. Climate change has a multitude of potential impacts on the natural environment which are closely interrelated. For instance, less water affects ecosystems and soil conditions; sea-level rise threatens many coastal regions. Extreme weather events, such as hurricanes, flooding and heat waves, are expected to increase in frequency and strength and can be highly destructive where they hit. Large-scale events such as the loss of the monsoon, the melting of Greenland or West Antarctic ice sheets or the shutdown of the thermohaline circulation can trigger irreversible "tipping points" in the climate system (LentonHeld/Kriegler/Hall/Lucht/Rahmstorf/Schellnhuber 2008).

Where natural resources are in a critical stage, global warming may degrade the environment as a source or as a sink of natural resources. Many natural systems are vulnerable to climate change and have limited adaptive capacity, such as glaciers, coral reefs, mangroves, arctic and mountainous ecosystems, wetlands as well as biodiversity hot spots. Some of the ecosystems may undergo irreversible change, and some may remain intact despite external influences. Adaptive ecosystems are able to preserve their existence through feedback cycles that maintain stability within viable limits. If these feedback cycles are disturbed as a result of climate change, rapid, even catastrophic changes may occur, leading to the loss of valuable functions of the ecosystem. Whether these functions can be preserved against likely disturbances indicates the stability and resilience of the ecosystem (42.3.4).

42.2.3 Human Vulnerability and Responses

The environmental effects of climate change events have multiple impacts on human needs. Potentially affected are systems that provide these needs, including water, food and energy supplies, agriculture and land use, health, urban life and migration patterns, networks and infrastructures, economic activities and political processes. Environmental stress through floods, storms, droughts or heat waves may directly threaten human health and life, others gradually undermine the well-being over an extended period, such as food and water scarcity, diseases, weakened economic and degraded ecological systems. Life-threatening extreme weather events are expected to increase in frequency and strength. Storm and flood disasters could endanger large populations, e.g. in Southern Asia. The melting of glaciers could jeopardize water supply for people in extended areas, e.g. in the Andean and Himalaya regions. The impacts of climate change on human beings and societies depend on their vulnerability and responses. Some responses could help to adapt and minimize the risks, others may cause more problems. For instance, migration is a possible response not only to poverty and social deprivation, but also to environmental hardships. What human actions can do or not do depends on the magnitude of climate change which is a function of the changing temperature. For existential threats the spectrum of responses may be restrained, making non-legal and violent acts more likely, but could also force people to work together to improve the chances for survival.

42.2.4 Societal Impacts, Instabilities and Adaptive Capacities

Environmental changes caused by global warming not only affect the life of human beings, but may also have larger societal effects, either by undermining the infrastructures of society or by inducing destabilizing human responses and interaction patterns of social systems. The associated socio-economic and political

stress can undermine the functioning of communities, the effectiveness of institutions and the stability of societal structures. Societies which depend more on the environment, tend to be more vulnerable to climate stress. The stronger the impact and the larger the affected region, the more challenging it becomes for societies to absorb the consequences. In the worst case, climate change could trigger a cycle of environmental degradation, economic decline, social unrest and political instability that could accumulate to become security threats and aggravate conflicts. For instance, due to water scarcity and soil degradation, agricultural yields could further drop and diminish food supply. Extreme weather events put the economic infrastructure at risk, including industrial sites and production facilities as well as networks for transportation and supply of goods. Each region of the world will be affected differently. In less wealthy regions climate change adds to already stressing conditions – high population growth, inadequate freshwater supplies, strained agricultural resources, poor health services, economic decline and weak political institutions – and becomes an additional obstacle to economic growth, development and political stability (UNDP 2007). The societal implications crucially depend on how human beings, populations and social systems respond to climate change. An increase of forced migration by climate change would create more migration hotspots around the world, each becoming a nucleus for social unrest (WBGU 2008). If multiple systems are affected by multiple impacts, cascading effects could occur (Karas 2003) and overwhelm societies. Large-scale changes in the Earth System, such as the loss of the Amazon rainforest and the Asian monsoon or the shutdown of the thermohaline circulation, could cause disasters on a continental scale.

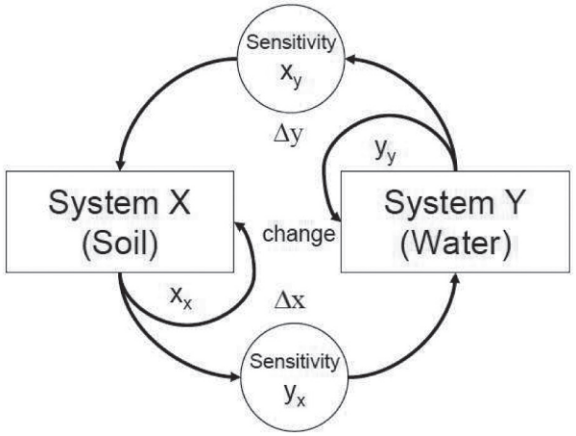
42.2.5 Sensitivity and the Causal Chain from Climate Change to Societal Impacts

The impact of climate change on society depends on the linkages among the various system variables along the causal chain. They can be measured by the pair wise sensitivities between variables, i.e. how much the change of one variable x induces a change in another variable y which is denoted as sensitivity y_x (figure 42.2). According to the IPCC (2007a) sensitivity in the context of climate change is the

> degree to which a system is affected, either adversely or beneficially, by climate variability or change. The effect may be direct (e.g., a change in crop yield in response to a change in the mean, range or variability of temperature) or indirect (e.g., damages caused by an increase in the frequency of coastal flooding due to sea-level rise).

A prominent example is climate sensitivity, i.e. the temperature change induced by a doubling of CO_2 concentration in the atmosphere. Since several intermediate variables are involved, estimates are needed for each of the sensitivities which together multiply to give the overall sensitivity.[1]

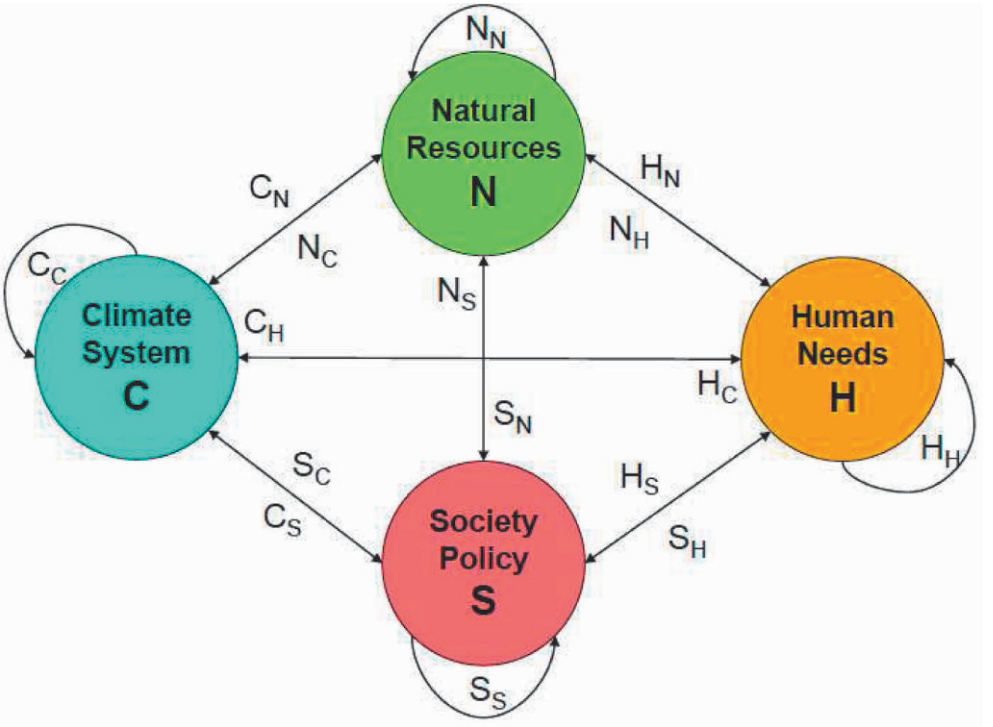
Figure 42.2: System-system interaction (exemplified here by water and soil systems). **Source:** The author.



The possible causal chain from climate stress to societal instability can be constructed through a series of links between them where the couplings between variables are determined by the sensitivities. Changes in the climate system C affect the natural environment and resources, N, through a sequence of complex interactions. Environmental changes will put stress on human needs and desires H (e.g. by reducing the availability of water, food, energy, health and wealth) and ultimately trigger societal impacts and instability events S. The links between variables at each of these levels and the associated variables will be represented by a sensitivity matrix X_Y, which indicates how sensi-

1 The sensitivities determine how a change in one variable x affects either itself (self-impact x_x) or another variable y (mutual impact y_x). The self-impacts determine whether an increase in variable x leads to further growth ($x_x > 0$), which is the case for exponential growth, or to a decline ($x_x < 0$) for exponential decline. The mutual impacts either represent a positive coupling ($y_x > 0$) or a negative one ($y_x < 0$). For human action, the self impacts determine whether someone's action has a positive or negative effect on itself, the mutual impacts represent friendly or hostile relations.

Figure 42.3: Mutual sensitivities in the climate-environment-human-society interaction. Source: The author.



tive a variable in system X is with regard to a variable change in system Y.

Statistical multivariate analysis of data about previous cases allows estimates the entries into the sensitivity matrices: the stress induced to natural resources by climate change (N_C), the impact of environmental change on human needs and living conditions (H_N), and the societal consequences of changes in human living conditions (S_H). The coupling between climate stress and societal instability can be represented by the combined matrix, S_C, which captures both the direct linkages from climate change to societal stability and the indirect linkages through environmental and human impacts. Other linkages are also relevant here, such as the coupling between human needs and climate change, H_C, between societal and environmental change S_N, or the reverse feedback couplings C_N, C_S, N_S and so on. Since there is an internal dynamics in each of these systems, there are internal couplings of variables within the climate system, natural resources, human needs and society, denoted by matrices C_C, N_N, H_H and S_S (figure 42.3).

With these sensitivities the network of interconnections can be constructed between the various system variables. Having this network allows to understand the spread of climate events through the network of connections. Relevant changes in the climate-environment interaction are denoted as events, e.g. an increase or a drop in precipitation, the loss of a species or a natural disaster. With this approach, a stability analysis for the interaction matrix of network linkages can be performed, represented by the sensitivities between system levels (42.3.4). This setup makes it possible study the impact of triggering events (e.g. mass migrations, extreme weather events, social movements), and find cascading sequences and tipping points. With this analysis it is also possible to generate the probability of future destabilizing events occurring under specified conditions, which has implications for developing an early warning system.

Many of the sensitivities are however unknown and depend on other variables. Due to non-linear effects, an increase in average mean temperature above a certain threshold (such as 2 °C) may result in disproportionate impacts, such as a widespread reduction of agricultural output in regions of Africa, South Asia or Central and South America (Hare 2006; Schellnhuber/Cramer/Nakicenovic/Wigley/Yohe 2006). Food insecurity in one country may further increase competition of resources and force populations to migrate into neighbour countries. This chapter addresses the overall sensitivity of security and conflict to global temperature change, i.e. how much do security and conflict increase in particular regions with a particular

rise in temperature. In the following section the focus will be on how human and societal response patterns shape that interaction, where the impacts will be evaluated in terms of vulnerabilities, threats and security risks, instabilities and conflicts.

42.3 Climate Impact Dimensions

42.3.1 Vulnerability and Adaptation

The impact of climate change on systems, persons or social groups depends on their vulnerability to loss (damage, harm, or hazard). According to the *Oxford English Dictionary* (Oxford 2009) a system is vulnerable (from Latin *vulnerare* 'to wound') if it is exposed to being attacked or harmed. This implies that events or acts may interfere with the normal operation of a system in a negative way. Blaikie, Cannon, Davis and Wisner (1994: 275) provide a human-centered definition of vulnerability as the "characteristics of a person or group in terms of their capacity to anticipate, cope with, resist, and recover from the impact of a natural hazard." Thus, vulnerability depends on the person, the type of event and the actions taken against the hazard. Some persons may be more vulnerable to the same event than others, and some may not be vulnerable at all. An event causing vulnerability may be compensated by responses to protect against it or avoid it in the first place.

There is a range of different interpretations of vulnerability (Adger/Lorenzoni/O`Brien 2009, Brauch 2005a, 2007a), partly due to the diversity of the issues involved. A number of studies have discussed conceptual aspects of vulnerability.[2] One approach to present a formal framework (Ionescu/Klein/Hinkel/Kumar/Klein 2009: 3) defines "vulnerability *of* something *to* something" as a relative concept, depending on: (1) the entity that is vulnerable, (2) the stimulus to which it is vulnerable and (3) the preference criteria to evaluate the outcome of the interaction between the entity and the stimulus. In this framework, the classification of vulnerability is a judgement referring to a possible future for a present entity, e.g. a potential event of causing harm. In terms of the preference criteria chosen, vulnerability has a negative connotation and classifies events into desirable and undesirable.

Within the context of climate change, the meaning of vulnerability has evolved over time (Füssel/Klein 2006). The core concept of vulnerability has been defined by the IPCC (2007a) as the "degree, to which a system is susceptible to, or unable to cope with, adverse effects of climate change, including climate variability and extremes." And further: "Vulnerability is a function of the character, magnitude, and rate of climate change and variation to which a system is exposed, its sensitivity, and its adaptive capacity." The operationalization of the IPCC vulnerability concept has proven difficult, partly because of the diversity of potential events associated with climate change, the variety of possible impacts and systems affected, all of which have different sensitivities and adaptive capacities.

The vulnerability concept is complicated because it involves the adaptive activities of the affected systems. For the IPCC (2007a) adaptation is the "adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities". To adapt, a system must be able to respond to a climatic stimulus and take actions that either diminish harm or compensate for it by establishing positive values. The capability to take such actions is the adaptive capacity which is influenced by a number of factors (e.g. poverty, state support, economic opportunities, the effectiveness of decision-making, social cohesion). Each of those factors is affected by other variables, e.g. state support is a function of income and labour support, public education and health, law and (dis)order, credit and protective security (Barnett/Adger 2005: 4).

The overall assessment of vulnerability and adaptation depends on the balance between potential damage, costs and benefits. Implementation of adaptation measures is a costly process which compares with the benefits they produce. Since complete invulnerability against all potential pathways for harm is impossible, the question is where to draw the line between what is tolerated and which further actions are taken that will ultimately depend on whether the additional efforts are worth the potential harm avoided.[3] An insurance may compensate for a loss but this is difficult for

2 See especially: Jones (2001); Turner, Kasperson, Matson, McCarthy, Corell, Christensen, Eckley, Kasperson, Luers, Martello, Polsky, Pulsipher, Schiller (2003); Ribot (2009).

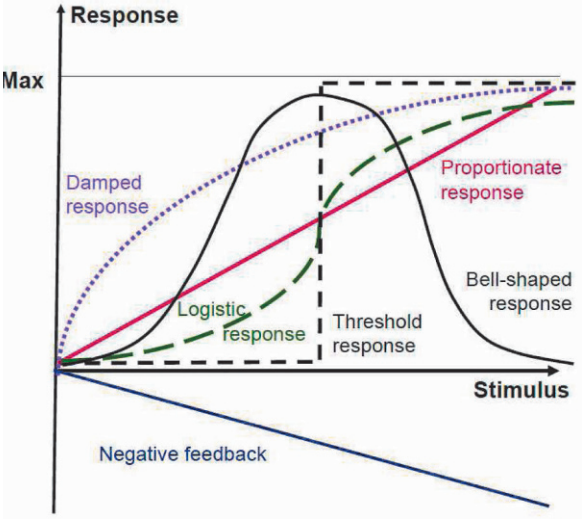
3 It is worth noting here that the limits of invulnerability became a major policy issue in the debate SDI debate of the 1980s when the Reagan Administration was seeking mutually assured survival against nuclear attack and Paul Nitze established a set of criteria to put the SDI program on more practical grounds (see Scheffran 1989).

loss of life. One approach to further operationalize the vulnerability concept is to develop indicators to measure the intensity of climate change, its harmful impact on various systems and the effectiveness of adaption measures to reduce the harm. In this approach vulnerability would be the ratio between net damage and the intensity of climate change which can be reduced by adaptation.[4] An additional question is who will experience the damage and damage reduction and who will pay for it. A global assessment would not distinguish between the different actors but in reality the issue of equity matters considerably (42.4.4).

The relationship between stimuli, losses and adaptive efforts will ultimately depend on the response functions of the respective systems (figure 42.4). For a linear response function the adaptive response is proportionate to the stimulus (positive feedback) or inversely proportionate (negative feedback). In reality, responses can only occur within resource limits, given by a maximum and minimum response. Alternative response functions are dampened with increasing stimulus when approaching the upper limit, or they represent a logistic growth function, starting slowly until they reach a rapid transition point. A special case is a one-step response function where a switch towards the maximum response occurs at a particular stimulus. These response functions can either represent the real action that is taken or a target response to meet a particular objective, e.g. maximizing value, minimizing damage or to guarantee a minimum viability condition for existence (e.g. water and food consumption needed for life or zero profit for a company). Failing to achieve a target response leaves an adaptation gap.

Climate change will affect groups and sectors in society differently. Key variables are location and the group affected. Warming is greater at high latitudes than in the tropics, sea-level rise will have different impacts around the globe and some regions will experience more intense rainfall, others more dry periods. In some regions intense rainfall could lead to devastating floods, in others nobody may be harmed. Heat stress can be more fatal to elderly people than to young people. In South Asia tropical storms can kill tens of thousands of people, at the US Gulf coast they can lead to billions of dollars worth of damage. There are also significant differences in the degree to which regions, groups and sectors are able to prepare for or respond to the effects of climate change. Countries in Northern Europe have more advanced technological capabilities, financial resources and institutional systems to respond to sea-level rise proactively and protect their population than countries in Southern Asia or small island states in the South Pacific. For more frequent droughts, rich farmers will be better able to invest in irrigation technology than poor and less educated farmers.

Figure 42.4: Different response functions to stimuli. **Source**: The author.



4 In mathematical terms, for a system with an expected value W and climate change occurring with intensity X causing an expected loss (damage) Y(X), the net value under conditions of climate change would be V = W - Y(X). Vulnerability could be defined as the ratio y_x = Y(X)/X which is the average value loss to climate intensity. If costs C for adaptation efforts are applied, net value may increase by D(C), either by increasing value to W(C) > W or by reducing damage to Y(C,X) < Y(X). Then adapted net value would be V(C) = W(C) - Y(C,X) - C = V + D(C) - C where the costs for adaptation are diminishing the net value (provided the units are comparable). Adaptation measures would be beneficial for V(C) > V which is the case for D(C) > C. Vulnerability under adaptation would then turn into $y_x(C)$ = (Y(X) - D(C))/X which would be lower for D>0 if the costs for adaptation are not taken into consideration. An extended view could modify this assumption and also specify the functional relationships Y(X) and D(C). For instance, if damage is proportionate to climate change intensity (Y(X) = y X), adaptation costs are proportionate to climate change intensity (C = c X) and avoided damage is proportionate to adaptation costs D(C) = d C, then the net value gain is positive for adaptation efficiency d > 1 (more damage is avoided than cost spent per unit of investment). Vulnerability under adaptation would then be y_x = y - cd, if costs do not count as a loss, and y_x = y - c (d -1) otherwise.

Given the significant impact of climate variability on the natural environment, more affected are agricultural societies which rely more on natural resources and ecosystem services. Due to water scarcity and soil degradation, agricultural yields will further drop. The most serious climate risks and conflicts are expected in poor countries, which are vulnerable to climate change, have less capital to invest in adaptation and thus cannot take the responses needed: "Poor communities can be especially vulnerable, in particular those concentrated in high-risk areas. They tend to have more limited adaptive capacities, and are more dependent on climate-sensitive resources such as local water and food supplies" (IPCC 2007a). A progression of climate change will increase the vulnerability of weak and fragile states and further reduce their adaptive capacities. Some regions such as Bangladesh and the African Sahel are more vulnerable due to their geographic and socio-economic conditions and the lack of adaptation capabilities. According to Nordas and Gleditsch (2005) those with ample resources "will be more able to protect themselves against environmental degradation, relative to those living on the edge of subsistence who will be pushed further towards the limit of survival." Climate change can thus reinforce obstacles to development and heighten poverty, thereby increasing the risk of conflicts in these societies.

The stronger the impact and the larger the affected region, the more challenging it becomes for societies to absorb the consequences. Storm and flood disasters could threaten large populations, e.g. in Southern Asia, China and Central America, the melting of glaciers could jeopardize water supply for people in extended areas, e.g. in the Andean and Himalayan regions. Water and food for about a billion people are already at risk, agricultural areas are overexploited in several world regions. Large-scale changes in the Earth System, such as sea-level rise, the loss of the Amazon rainforest and the Asian monsoon or the thermo-haline circulation (THC) shutdown, could have incalculable consequences on a continental scale.

Wealthier countries are not immune either. While the impacts on some developed countries may be moderate or even positive at small temperature change (greater agricultural productivity, reduced winter heating bills, fewer winter deaths), they will become more damaging at higher temperatures as predicted towards the end of this century. Extreme weather events put the economic infrastructure at risk, including industrial sites and production facilities as well as networks for transportation and supply of goods. Depending on their type and intensity, climate impacts become a major obstacle to economic growth, regionally as well as globally.

The Stern Review concludes that the costs of climate change for developed countries "could reach several percent of GDP as higher temperatures lead to a sharp increase in extreme weather events and large-scale changes" (Stern 2006: 157). Rising temperatures exacerbate existing water shortages on drylands in Southern Europe, California and South West Australia; reduce human security and agricultural output; increase the investment required in infrastructure and the costs of damaging storms and floods, droughts, heat waves and forest fires. During the 2003 heat wave in Europe, 35,000 people died and agricultural losses reached $15 billion (Stern 2006: 150). Abrupt and large-scale changes in the climate system could have a direct impact on the economies of developed countries, ranging from several meters of sea level rise, following the melting of the Greenland ice sheet, to several degrees of cooling in Northern Europe, following the THC-collapse. As impacts become more damaging, they may have severe consequences for developed economies, including population movements and disruption to global trade and financial markets[5].

42.3.2 Risks and Threats

Risk is the "chance of injury, damage, or loss" (Webster's Dictionary 2009). Risk analysis is applied to situations which have multiple, uncertain outcomes, and determines the vulnerability to these events, in terms of estimated losses and their probability (usually risk is the product of these two variables). To estimate the risks of climate change, information would be needed on the expected damage and probability of climate-induced events, as well as their timing and measures for risk reduction. Each of the pathways from climate change to societal impacts comes with a risk that is specific to the persons or systems affected. There is a sequence of probabilities along the causal chain: the probabilities for certain emission scenarios, atmospheric stabilization levels, global temperature change, climate change in each region, type of harm for each affected system, and finally the probability for each of

5 See the report by: Stern, Peters, Bakhshi, Bowen, Cameron, Catovsky, Crane, Cruickshank, Dietz, Edmonson, Garbett, Hamid, Hoffman, Ingram, Jones, Patmore, Radcliffe, Sathiyarajah, Stock, Taylor, Vernon, Wanjie and Zenghel (2006).

the possible responses and societal instabilities. Having reliable estimates for each of these probabilities is a challenging task. A practical approach is to focus on the essential pathways and develop aggregated risk indicators to measure how countries are potentially affected by climate-related stimuli, including the loss of lives, health, money or natural resources, ranging from moderate to catastrophic risk.

The term threat is often used synonymous with risk, but there are differences (Brauch 2005a, 2007a). While risk assessments often deal with systemic contexts regarding technical or natural systems, they claim a certain degree of objectivity, threat perceptions are often based on subjective attitudes towards an event or person. In many definitions threats are related to intentional acts. For instance, the *Compact Oxford English Dictionary* (2009) defines threat as: "1. a stated intention to inflict injury, damage, or other hostile action on someone; 2. a person or thing likely to cause damage or danger; 3. the possibility of trouble or danger." While the first meaning requires a declared intention to impose damage (whether realistic or not), the second evaluates the likelihood of events causing a loss. In the third definition, the mere possibility of danger qualifies as a threat. A threat also implies that those who are threatened feel vulnerable to the threat. A threat by someone is meant to induce fear within someone. To understand and prevent threats, it is important to understand the responsibility of those who cause it.

During an armed conflict, threat assessments and perceptions are concerned with each other's military capabilities and the motivations to use them. Here threats combine the capability to threaten and the motivation to threaten. Without capability a threat is not credible, without motivation it is not likely. Each without the other is only a hypothetical threat. For instance, someone may claim to blow up the world, but to make it a credible threat requires the capability to trigger a major nuclear war. While France and the UK have the capability to attack each other with nuclear weapons, this threat is widely seen as not credible and thus unlikely.

Today the term threat is used excessively. Threats are coming from almost everything, including ethnic groups, criminal gangs, epidemics, terrorism, dangerous food, poverty, economic mismanagement, overpopulation, failed states, refugees, and pollution, to mention a few (Heurlin/Kristensen/Søby 2006). And they are affecting almost everyone, from the single individual to the globe, affecting various dimensions of loss (life, health, money, jobs etc.). The meaning of threat has been extended to events which have no identifiable intention, such as threats by car accidents or natural disasters, as if someone or something (god, fate, misfortune) is responsible for it. This attitude is extended to the animal word, e.g. when a bear is threatening a human being. Threat perception is sensitive to signals indicating a threat (e.g. a statement of threat declaration or a particular body language), assuming that a subject is responsible for sending these signals in preparation or as a warning of real actions.

Various sources have extended the threat terminology to climate change, as exemplified by the phrase 'threat multiplier' (in 42.1) above). In this view, since everyone is contributing to climate change and everyone is affected by it, we all pose threats to ourselves (chap. 94 by Brauch/Dalby/Oswald Spring). Similar phrases have been coined to warn against the threat of nuclear annihilation, putting climate change into the same category of 'common threats' to humanity, although the causes are quite different (Cerutti 2007). In this understanding, nuclear weapons and greenhouse gases would both be indicators for the capability to threaten, making their reduction an important policy goal (Schell 2007). Countries with high per-capita emissions would pose a larger threat to others than countries with low per-capita emissions. On the other hand, developing countries, which are less responsible for global warming, would be affected much stronger and would be less capable to take countermeasures. This asymmetry between those who predominantly cause global warming and those who are largely affected by it, adds to the existing injustice between rich and poor. To solve the problem in a cooperative and sustainable manner, it is important to avoid aggravating threat perceptions between the developed and the developing world, between North and South. Here it is important to make the distinction that global warming is not an intended threat but an unintended risk in the quest for wealth. However, the use of fossil fuels makes the production of wealth and the generation of risk two sides of one coin. The challenge is to decouple wealth and risk by using energy sources and lifestyles that avoid the unnecessary risks of global warming. This does not mean that those who keep high emissions, knowing about the consequences, should not take responsibility for their actions.

The risks and threats of climate change are quite heterogeneous and shaped by a number of factors, including geographical location, the entity affected and the social environment. Risk assessment also depends on the knowledge and perception of people which for real world actors are bound to a window of attention,

using limited information selected in temporal, spatial, social and other dimensions. A spatial window pays more attention to near-distant events while far events are more 'out of view'. Similarly, temporal windows are restrained to the near past and future, and social windows involve close relatives, friends and colleagues while people outside of the own social network have much weaker links. Due to the long delays between emissions and climate impacts, these risks may be out of the temporal window. Impacts on regions and people that are remote receive less attention; they are outside of the 'radar screen'. It is a challenge for education and the media to expand the window of attention regarding climate impacts.

42.3.3 Security Concepts

With the end of the Cold War and increasing globalization the security landscape has fundamentally changed and the debate on climate change contributes to this process. The meaning of security has been transformed and became more comprehensive, including economic, political, social and ecological dimensions (Dalby 2008). The more comprehensive security concepts include not only military capabilities, but human, economic and environmental measures as well, with natural resources becoming a key currency of security.

In a negative sense, security is the ability to protect against danger, threat and doubt, hence the "evil of insecurity" (Wolfers 1962: 153). In a more positive sense, security means the preservation of values, "the assurance people have that they will continue to enjoy those things that are most important to their survival and well-being" (Soroos 1997: 236). Security is future-oriented and not only weighs potential damage but also expected values; in short: it is the difference between chance and risk. Security risks have both an objective and a subjective dimension (Wolfers 1962: 150): "Security, in an objective sense, measures the absence of threats to acquired values, in a subjective sense, the absence of fear that such values will be attacked." Objective security is achieved "if the dangers posed by manifold threats, challenges, vulnerabilities and risks are avoided, prevented, managed, coped with, mitigated and adapted to by individuals, societal groups, the state or regional or global international organizations" (Brauch 2007a: 3). Concerning subjective judgements and perceptions, reasons for fear should be avoided. A system facing threats can take measures to protect its core values and avoid harmful interference with its structure. Broadening the concept implies that security is not only freedom from fear, but also freedom from want.

To operationalize and specify security, it is important to determine the subject whose security is of concern, the values that are affected, the causes of risk, the vulnerability to harm and fear, as well as the capacity to protect against threats. Security may be positive with regard to some values and negative with regard to others. For instance, a prisoner may have secured access to food and housing or be safe from traffic accidents, but would be very insecure regarding freedom of choice and having contact with friends. The degree of insecurity increases if essential core values and basic human needs are affected. Concepts of national and international security are built on the integrity of territorially organized sovereign nation states within the system of international law as represented by the United Nations. National security policy aims at "protecting a nation's people and territories against physical assault and protection of vital economic and political interests" (Anderton 1985: 5). Military security policy deals with actions by determined adversaries who intentionally seek to inflict damage, e.g. by use of military force. During the Cold War, national security was dominated by the bilateral East-West conflict and nuclear force assessments.

If the society's core values change, the security context also changes. In the emerging new world (dis)order, a large number of actors and factors shape the security discourse in a complex way (Scheffran 2008b). Facing a rapidly changing world, security is ultimately linked to the question of identity, i.e. the social entity that individuals predominantly identify with and which they seek to protect. Is it the own person, the family, friends, the nation, the whole of humanity or even future generations? At one end stands the egoist individual who seeks to maximize utility; at the other end it is the global subject seeking to protect all of humanity and nature. If long-established identities are threatened, their defence is often pursued under exclusion of those who are different. With the conflicting tendencies of globalization and fragmentation, social identities are torn between changing and sometimes contradicting roles and relationships. Climate change could support both the tendency towards fragmentation and unification of humanity, between the poles of a Hobbesian struggle of "everyone against everyone" and the development of a world society.

The vulnerabilities, risks and threats posed by climate change have implications for security policy.

New concepts of security are important which could serve as building blocks of climate security:

- *Common security*: Since common threats require common responses, climate security is best realized not against but together with others, addressing the climate problem with joint responses and an unprecedented level of cooperation. In the concept of common security, which was born during the East-West rivalry, "no country can obtain security, in the long run, simply by taking unilateral decisions about its own military forces" (Blackaby/Barnaby/Väyrynen/Bahr/Kaldor/Rothschild/Wiesner/Lodgaard/Sæter/Holst 1986: 203). In the words of the Palme Commission (1982: 139): "States can no longer seek security at each other's expense; it can be obtained only through cooperative undertakings." To face the common threats posed by climate change it is much more effective to work together than against each other.
- *Ecological security* describes environmental problems as security risks, whether self-inflicted or caused by others. The concept was developed in the context of environmental destruction from wars and arms races (Westing 1986, 1989a). Ecological problems often have a trans-boundary effect and cannot be resolved by military instruments. On the contrary, it may often be more beneficial to convert military resources for environmental protection (UNDDA 1991; Scheffran 1992). The problems cannot be resolved by one state alone; they require a global effort. The concept of ecological security was criticized as too broad and inadequate, partly because it would allow the military to expand its instruments into environmental policy (Deudney 1991; Brock 1997).
- *Human security*: Those affected by climate change are in the first place human beings. Thus, it is consequent to develop the concept of 'human security' which is centered on the security and welfare of human beings (UNDP 1994), while national and international security have been largely the domain of governments and the military. One approach to operationalize human security is based on "shielding people from acute threats and empowering people to take charge of their own lives." (CHS 2003: iv). Potential losses of human life from a variety of sources are considered (King/Murray 2001–2002; Owen 2002). Another approach focuses on interpersonal violence in crime, terrorism and armed conflict (Human Security Report 2006). It is increasingly recognized that it makes sense to look at a spectrum of concepts and indicators when studying the security of individuals and societies (Wallensteen 2007). While armed conflict remains relevant because of its potential for destruction and disruption of societies, not all forms of 'downside' risks for lives and livelihoods are covered (Brzoska 2007). This way it is also possible to deal with the argument that human security is a vague concept (Paris 2001).

If the impacts of climate change provoke responses that affect the whole society, the consequences may also become an issue for national, international or global security, and contribute to its securitization (Wæver 1995, 2008; Buzan/Wæver/de Wilde 1998). Some of the climate impacts may indeed force governments and the UN Security Council to take actions, and some could involve the military (e.g. for disaster management, in response to massive refugee flows, or in conflicts induced by environmental stress). That does not imply that global warming is predominantly a threat for national or international security or that it will likely lead to a military confrontation or even climate wars (Welzer 2008). Comprehensive security remains an ambiguous concept which allows to 'soften' security policy by including multiple security dimensions, but it could also 'harden' environmental policy by militarizing it and providing new reasons for intervention, thus leading to more insecurity (Brock 1997).

Security indicators are a quantitative approach to measure the degree of insecurity, conflict or instability of a region to climate change. Risk indicators measure how countries are affected by weather-related loss events. The *Climate Risk Index* developed by Anemüller, Monreal and Bals (2006) uses the number of deaths and the amount of overall losses in US$. For the years 1995 to 2004 the 10 most affected countries are Honduras, Bangladesh, Somalia, Venezuela, Nicaragua, Vietnam, Dominican Republic, France, India and China. Security diagrams couple climate-related environmental stress with the susceptibility of societies and the occurrence of 'crises'. This integrated approach facilitates the interdisciplinary assessment of climate change and the impacts; fuzzy set theory helps to convert expert opinion about critical indicators into numerical values (Alcamo/Endejan 2001; Alcamo 2008).

42.3.4 Stability and Instability

The stability concept is rooted in the natural sciences but is relevant in the social sciences as well (Scheffran 1983, 1989). During the bipolar East-West conflict, sta-

bility was a prominent term in international security and arms control. In the complex world (dis)order that followed the breakdown of the Cold War, which in itself was a major event of political instability, the stability concept has celebrated a revival (Scheffran 2008b). Facing an economic crisis and the spread of destabilizing factors, the world is confronted with an 'axis of upheaval', including states that are "united not so much by their wicked intentions as their instability", as Niall Ferguson (2009: page) notes. In this view, three factors made the location and timing of lethal organized violence more or less predictable in the last century: ethnic disintegration, economic volatility, and the decline of imperial structures. While environmental causes are not considered among those instability factors, it is likely that they will add to them. Besides preliminary attempts to model the link between climate change and international stability (Scheffran/Jathe 1996; Scheffran 1999), there is still a lack of understanding about the implications of global warming for international and societal stability.

In a general sense, stability implies that "minor disturbances will not be magnified into a major disturbance, but on the contrary, dampened so as to have only a small and disappearing impact" (Ter Borg/Tulp 1987: 50). If magnification processes exceed dampening mechanisms, minor causes can have major impacts and instability could lead to a breakdown of essential properties of a system. The question is to identify the essential properties that are to be kept stable, the time and probability for which these are to be maintained, and whether disturbing events can be compensated by mechanisms that prevent magnification. An increase in systems complexity can create possible instabilities which may be compensated by introducing new control variables. If systems complexity grows faster than control complexity, the control mechanisms are overburdened, and the system can get 'out of control'. This could be an issue in the context of climate change when a series of complex interactions is triggered that overwhelm both environmental and social systems, which could combine to complex cascades of instability.

There are similarities and differences of the stability and security concepts. Both evaluate the impact of something to something. Security is judged by a subject that seeks to avoid or counter potential threats; stability takes an outside look on an interaction process among system variables or subjects. Both may evaluate a change of conditions as positive or negative, where stability is mostly dealing with a change in qualitatively different systemic conditions (e.g. a transition from peace to war, from conflict to cooperation or from environmental destruction to sustainability). Although the instability of a threatening regime may be seen as desirable, international or societal instability caused by climate change is widely held as undesirable.

Sensitivity is a key term in the stability concept. If a system is more sensitive to changing conditions, it tends to be unstable if there is no correcting mechanism that maintains its stability. Highly sensitive responses (overreactions) could destroy the structure of a system. The sensitivities between key variables and responses can be combined in the interaction matrix which can be mathematically stable or unstable (similar to the sensitivity matrices in section 42.3.5).[6] If climate change affects the stabilizing mechanisms of systems, they could become unstable and break up. It is possible that for given sensitivities, a climate-related event induces a major instability event in society. But climate change could also modify the sensitivities in one or the other way, triggering a cascading sequence of events.

Depending on the type of systems, disturbances and responses, various meanings of stability can be considered in the climate context.

42.3.4.1 Stability of the Climate System, Ecological and Economic Systems

The *UN Framework Convention on Climate Change* (UNFCCC 1992: 5) in Article 2 demands stabilization of atmospheric greenhouse gas concentrations at levels that "prevent dangerous anthropogenic interference with the climate system." Such a level should be achieved "within a time frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner" (Ott/Klepper/Lingner/Schäfer/Scheffran/Sprinz 2004; Scheffran 2008d). Thus, conditions for ecosystem and economic stability determine tolerable

6 The interaction matrix contains the sensitivities $_{x}y$ between two variables x and y, and its stability is given by its eigenvalues which are indicators of the exponential magnification or dampening of the dynamics. For a two-variable interaction with positive self-impacts $x_x>0$ and $y_y>0$ and negative mutual impacts $y_x < 0$ and $x_y < 0$, the instability condition would be $x_x\, y_y - x_y\, y_x < 0$, which represents the intuitive notion that the negative mutual impacts exceed the positive self impact. With different signs of the impact sensitivities and more variables, the mathematical condition would be different (Scheffran/Hannon 2007).

windows for the admissible speed and magnitude of climate change (Petschel-Held/Schellnhuber/Bruckner/Toth/Hasselmann 1999). Over a short time horizon, ecosystems would be able to adapt to a slowly changing environment. With a longer time horizon and more dramatic changes, ecosystems could become unstable and irreversibly damaged. Ecosystems exhibit adaptive capacities within a viability limit beyond which they can break down (Aubin/Saint-Pierre 2007). These thresholds are often difficult to determine. Similarly, economic processes of production and consumption have a certain stability against disruption, as experienced in major crises and wars in the past. Economic systems can be adjusted to wartime production in a short time and are able to adjust after a war. There are limits of what an economic system and the political stabilization mechanisms may digest, as seen in the Great Depression of the 1930's and in the recent economic crisis. Within these limits, an economic system may be able to adapt to a long-term gradual climate change (despite considerable costs of a transition to a low-carbon society), but regional disasters or abrupt climate change may exceed this capability.

42.3.4.2 Stability Against Escalating Threats

In a multi-actor environment, a perceived loss of security for one actor may provoke reactions leading to a loss of security for other actors whose responses may result in insecurity for all. This notion of stability is reminiscent of the 'security dilemma' which describes a situation where countries build arms to enhance their security but threaten other countries and force them to increase their arsenals as well. This process found its expression in the concept of arms race stability which was a guiding principle for nuclear arms control during the Cold War. The simple version of this concept (two nations building nuclear weapons) needs to be modified in today's multipolar world in which many more threat dimensions and actors are involved, including non-state actors. Nonetheless, as long as actors feel threatened by actions of others and counter them with threatening responses, this logic could drive a destabilizing 'threat race'. Increasing the threat perception could increase the likelihood that a threatening force is actually used, especially in a crisis. The classical example was the Cuban Missile Crisis. The concept of crisis stability attempts to reduce the motivation for the use of violence and the pressure for quick and pre-emptive actions, e.g. through force structures that minimize pre-emptive advantages (e.g. by first strike attack) and technical instability of weapon systems against error or failure. If climate change increases each other's threat perceptions, this could provoke responses adding more threats. For instance, natural resources or agricultural production could be degraded and the affected people seek survival at the cost of others, or they make others responsible for their initial loss. In both cases, to pursue or defend their interests, actors could increase or actually use violent means, including the use of a more threatening language. Non-state actors and non-military threats could trigger conflicts between states and their military forces. To stabilize the interaction, actors could move towards a mutually beneficial cooperation, e.g. by resource sharing and risk management, and abstain from the use of violence. Most important is to avoid a climate crisis that turns into a military crisis.

42.3.4.3 Human, Societal and Political Stability

Societies require structures to make sure that cooperation is beneficial, rules are accepted and social interaction remains effective and predictable. The social contract is based on the consent by a large majority of citizens to rules, regulations and institutions that maintain social order and serve as the glue to keep society together. The stability of societies refers "to the durability of political institutions and to robust social structures", while destabilization "can be understood as a process that (gradually) causes an originally stable political and social situation to break down" (WBGU 2008: 236). Societal structures that loose credibility and support from the citizens become weak and unable to maintain order. Individuals, who experience personal losses (life, income, property, job, health, family and friends) and find their personal identity at stake, may be more tempted to violate established rules and select non-legal actions including violence, even more if these actions offer benefits and low risk of punishment. Along these lines, personal instability caused by loss of human security could trigger societal and political instability, and vice versa. Disruptive climate change could contribute to this process. Especially vulnerable are societies that are already on the edge of instability, such as states in transition from authoritarian to democratic regime, states unable to protect citizens from harm and are lacking legitimacy, and failing states with social fragmentation, w*eak governance structures* and inadequate management capacities. Here the marginal impact of climate change could make a decisive difference, *undermine the ability to solve* the underlying problems, and further dissolve state structures, leading to their collapse.

In this context relevant is the debate on 'failed states' (Milliken/Krause 2003; Rotberg 2003; Schneckener 2004; Starr 2008). Such states cannot guarantee the core functions of government, such as law and public order, welfare, participation and basic public services (e.g. infrastructure, health and education), and the monopoly on the use of force. These core functions are pillars of security and stability, and if any of them is missing, state failure becomes more likely. Weak states may be able to safeguard the monopoly on the use of force, but have severe deficiencies in providing welfare, rule of law and democratic participation. In fragile states, welfare and rule of law are working, but the monopoly on the use of force is severely restricted or absent, affecting the control of state territory and borders (e.g. against separatist forces). In failed states none of the core state functions is effectively performed, making state collapse likely. Whether a state fails is determined by long-term structural factors, such as the endowment with natural resources, the economic infrastructure, power constellations, demographic development and ethnic diversity, which make states sensitive to medium-term processes driving their erosion, e.g. social discontent, ethnic differences, separatist movements, economic crisis or political mismanagement. States are then vulnerable to abrupt changes that trigger the collapse of state structures, including "military intervention, refugee flows, military coups and revolution, massive violent repression of the opposition (e.g. massacres), social unrest, famine, civil war, etc." (WBGU 2008: 43, based on Schneckener 2004). In such states spirals of corruption, crime and violence could erupt, leaving a power vacuum that is filled by non-state actors such as private security companies, terrorist groups and warlords. A prominent example is Somalia, a country controlled by powerful non-state actors (clans). In sub-Saharan Africa about one-third of countries are considered at risk of state failure. Examples for weak states in other world regions are Colombia, Afghanistan, and Kosovo.

Climate change could potentially affect short, medium and long term factors of destabilization along different pathways, although the empirical basis to test these links is weak. In a hypothetical scenario, increased environmental stress and resource scarcity could induce structural changes and make states susceptible to triggering events such as natural disasters. These developments may undercut the ability of governments to satisfy the needs of citizens and to provide opportunities for wealth and prosperity. Combining the pressure from outside with a reduced ability of governments to prevent and cope with the impacts may become a task too big for many societies. Climate risks could add to other problems, such as high population growth and density, inadequate freshwater supplies, strained agricultural resources, poor health services, economic decline and weak political institutions. In climate-security hot spots the erosion of social order, state failure and violence could go hand in hand. In the worst-affected regions, climate change could spread to neighbouring states, e.g. through cross-border migration, ethnic links, environmental resource flows, black markets or arms exports. An increase of forced migration would create more migration hotspots around the world, each becoming a possible nucleus for social unrest. Such *spill-over effects can* destabilize regions and expand the geographical extent of a crisis. With increasing climate impacts, the problem solving capacity could also decline, possibly leading to a tipping point of no return.

It is widely assumed that low-income countries are more vulnerable to instability than wealthy countries, and some countries are more vulnerable due to their natural geographic and socio-economic conditions. At present it seems unlikely that distortions in developed countries will lead to massive security problems or societal instability. However, developed countries cannot ignore the economic impacts, the migratory pressures, the demands for humanitarian assistance, and may be drawn into climate-induced conflicts in regions that are hardest hit by the impacts. Their own infrastructures and networks for energy and water supply, transportation and communication, production and trade are vulnerable to disruption by disasters. Hurricane Katrina, the most costly natural disaster so far, was a vivid signal that, even in highly developed societies, flood disasters could lead to a temporary breakdown of public order. As this example shows, poor and marginalized communities will also be the most vulnerable in developed countries. If the frequency and severity of such disasters increases, they would be more difficult to manage.

42.3.5 Conflict and Cooperation

Conflicts often emerge from incompatible actions, values, and priorities of actors who fail to reduce their differences and tensions to tolerable levels. The actions taken undercut each other's values and provoke responses generating further losses. A conflict escalates if actions by conflict parties aggravate the conflict tension and intensity, which corresponds to an inherently unstable interaction (as discussed in 42.3.4).

If unresolved, conflicts consume a considerable amount of resources, forcing conflict parties to extreme actions and the use of violence, until the capability to act is exhausted, if not replenished by other sources. Conflict resolution can help to reduce the conflict tension and stabilize the interaction by involving actors to learn and adjust their actions until an agreement is reached. Cooperation is a process in which actors adapt their goals and actions in a mutual beneficial way. The transition from conflict to cooperation requires mutual adaptation towards common positions and mutually beneficial actions that stabilize the interaction (Scheffran/Hannon 2007). Whether this succeeds depends on the governance capacity of societies to prevent or manage conflicts.

Whether climate change contributes to conflict is perhaps the most difficult question because it depends on all the factors described above. As the WBGU (2008) notes, climate change could also unite the international community to set the course for a dynamic and globally coordinated climate policy. If it fails to do so,

> climate change will draw ever-deeper lines of division and conflict in international relations, triggering numerous conflicts between and within countries over the distribution of resources, especially water and land, over the management of migration, or over compensation payments between the countries mainly responsible for climate change and those countries most affected by its destructive effects (WBGU 2008: 1).

Four conflict constellations are particularly relevant here: degradation of freshwater resources, decline in food production, increase in storm and flood disasters, and environmentally-induced migration (chap. 41 by Bauer).

Empirical studies do not provide a clear picture so far, which may be due to the fact that climate change is an issue of the future. Some indications can be acquired by looking at historical cases which suggest that the rise and fall of civilizations was indeed affected by a changing climate (Fagan 2003). Recent studies have found significant statistical correlations between a changing average global temperature and the frequency of war, e.g. during the Little Ice Age (Zhang/Brecke/Lee/He/Zhang 2007). But Buhaug, Theisen and Gleditsch (2008) argue that a simple relationship between temperature change and the number of armed conflicts cannot be justified by data over the last two decades because the number of such conflicts has declined after the end of the Cold War, while temperature has increased. One possible explanation is that climate change so far has not directly affected large-scale conflicts such as war but more likely will cause small-scale events of societal instability and low-level conflict which may have increased in recent decades, as suggested by the Heidelberg Conflict Barometer which distinguished five conflict intensities, from latent conflict to war (HIIK 2008). Gathering data about such small-scale events is an important task of on-going and future research.

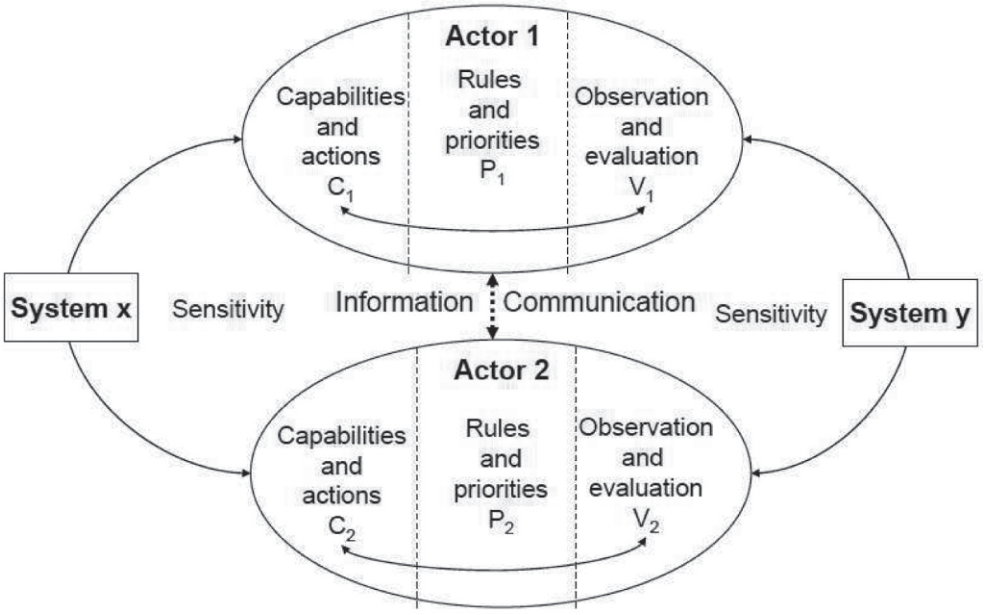
Until more data is available, it is promising to look at regional case studies of environmental conflict which are important to explore the relationships in detail.[7] During the 1990's, several research groups have examined how the scarcity of natural resources, such as minerals, water, energy, fish and land, affects violence and armed struggle. These include the Toronto Project on Environment, Population and Security (Homer-Dixon 1991, 1994), the Swiss *Environment and Conflict Project* (ENCOP; Baechler 1999), the International Peace Research Institute in Oslo (Gleditsch 1997), the Woodrow Wilson Center's Environmental Change and Security Project (Dabelko/Dabelko 1995), and Adelphi, formerly the Institute for International and European Environmental Policy (Carius/Lietzmann 1999; Carius/Tänzler/Maas 2008). The review of 73 empirically recorded 'environmental conflicts' which occurred between 1980 and 2005, showed that these had a regional scope and did not present a serious threat to international security (Carius/Tänzler/Winterstein 2006).

Some scholars have questioned the usefulness of the concept of environmental conflict. According to Gleditsch (1998) the meaning of 'environmental conflict' is often not clear and important variables are neglected. Some models are virtually untestable; the causality of the relationship is sometimes reversed; foreign and domestic conflict is not distinguished. Barnett (2000) argues that the environmental conflict hypothesis is theoretically rather than empirically driven. Some point out that it is not the scarcity of natural resources that is driving conflict but their abundance (Collier 2000; de Soysa 2000; Le Billon 2001; Peluso/Watts 2001), suggesting that the results strongly depend on the type of resource.

The analysis of environmental and climate-induced conflicts can be translated into impact diagrams, incorporating the interaction among multiple

7 See the studies prepared for WBGU (2008) that can be accessed at: <http://www.wbgu.de/wbgu_jg2007_engl.html#jg2007expertisen>; see chap. 26 by Brauch; chap. 27 by Giese and Sehring and chap. 28 by Heberer and Senz.

Figure 42.5: Interaction between two actors and two systems. **Source:** The author.

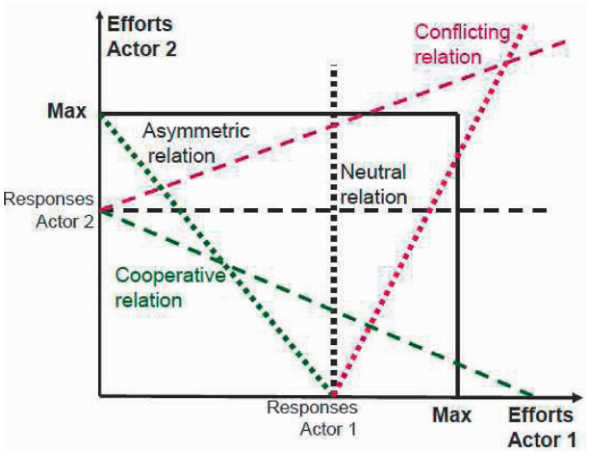


actors into an agent-based model within the integrated assessment framework explained in 42.2 (figure 42.5). Each actor i is represented by its capabilities (C_i) used to make efforts in actions changing the environment (given here by systems x and y). The outcome of the actions is observed and evaluated with a value function (V_i) which guides the change of actions according to internal decision rules and priorities (P_i). The actors are interconnected to each other directly through communication processes that exchange information, or through the impacts of each other's actions on the systems environment. Linkages between the actors are given by the sensitivities which determine how the value of one actor is affected by the efforts of each actor, which depend on the decision rules and action priorities. If the mutual sensitivities are negative, this corresponds to a hostile or conflicting relationship which causes losses to each other; if they are positive, this is a friendly or cooperative relationship which is beneficial to both. In addition, the self impacts have to be considered, i.e. how an effort made by an actor affects his/her own value. With these sensitivities it is possible to construct the social network among multiple actors, which is connected to the environmental system dynamics they are embedded into.

Whether conflict or cooperation prevails in social interaction depends on the responses of each actor, given here by the decision rules and action priorities, and whether they can be changed by learning and adaptation. Figure 42.6 depicts different types of response functions which show how the efforts of one actor to achieve a given value goal are adjusted to efforts of another actor. If the actions are disconnected and independent of each other, effort is kept constant as long as the own goal does not change (neutral relation). In a competitive relationship, effort increases with the effort of the other actor and both experience a loss, while in a cooperative situation the efforts may decrease for the same goal and both benefit from each other. In the mixed cases, one agent cooperates and the other not, which in some cases may still be better than mutual conflict. In a competitive case, a point of mutual agreement is possible, but the question is whether that point is within the admissible range of maximum efforts. If agreement is not possible within admissible efforts, there is an unresolved conflict unless actors add more resources or change their goals. Alternatively, one or both actors change their behaviour by switching to other action rules what makes his or their own actions more efficient and less threatening to the other actor to make the agreement more feasible.[8]

For instance, a case may be assumed where the two actors are a developed and a developing country which invest capital (efforts) into different energy paths to produce goods that contribute to economic wealth (value). Established decision rules and action priorities use only fossil fuels which contribute to climate change and value losses for both, determined by the sensitivities in human-environment interaction. The more they invest into fossil fuel to achieve a given

Figure 42.6: Conflicting and cooperative relationships between two actors making efforts to achieve value goals according to given action rules. **Source:** Modified from Scheffran/Hannon 2007: 82.



wealth, the more they cause losses to each other and to themselves, affecting both mutual and self impacts. With the losses from climate change increasing, the more the agreement point moves further upwards, until value goals are no longer feasible for both within maximum efforts. In this case, actors could switch to military force to acquire a higher share of fossil fuels by violent means, to compensate for climate-induced losses or do harm to the competitor in other ways. As an alternative, actors could switch to alternative energy sources to produce economic wealth with lower carbon emissions and thus less climate losses. In this case, both can cooperate to lower their costs, e.g. by transfer of low-emission technology (Ipsen/Rösch/Scheffran 2001).

Despite the simplicity of this diagram, it is possible to discuss a wide spectrum of possible scenarios with it, based on assumptions of the various sensitivities for action alternatives and involving more than two actors to discuss collective action problems. A degradation of the environment that affects the interests and values of some actors shapes conflicts in one or the other way, i.e. it may increase violent conflict or spur cooperation to resolve common problems. Whether climate risks undermine international security or become a source of major conflicts depends on the responses and learning mechanisms of the actors involved which are shaped by the societal structure, institutional frameworks and political strategies.

42.4 Strategies for Addressing Climate-Security Challenges

Climate change confronts humanity with multiple security risks and major challenges to its problem-solving capacities. The magnitude of the potential risks of climate change requires determined policies to manage global change within a new well-designed global governance architecture that combines sustainable environmental policy, development policy and preventive security policy. Global diplomacy is required to contain climate-induced conflicts, develop compensation mechanisms for those affected by climate change, implement global migration policy, and measures to stabilize the world economy (WGBU 2007). Avoiding climate security risks and mitigating conflicts induced by climate change requires an integrated set of strategies that address both the causes as well as the impacts of climate change.

The conceptual framework described in the previous sections provides guidance to develop such strategies for addressing the climate challenge to society, stability and security (see the key terms and variables in figure 42.7). The approach combines the downward slope towards climate change, security risks, instabilities and conflicts in the lower part of the figure, and the strengthening of economic welfare and human capability via sustainable development, with strategies to reduce vulnerabilities and risk in the upper part of the figure and establish the core functions of a world society through adaptive and participative governance. A set of integrated strategies to address climate security risks is described in the following which affect various parts of the climate-society interaction (figure 42.8).

8 In mathematical terms, let sensitivities $f_{11} > 0$ and $f_{22} > 0$ be the positive efficiencies (self impacts) of the efforts C_1 and C_2 of actors 1 and 2 on their own values V_1 and V_2, and $f_{12} < 0$ and $f_{21} < 0$ be the negative mutual impacts on each other's values. Then this would be a competitive interaction and a switch to cooperation would require that the mutual impacts become positive, thus switching from an adverse to a friendly relationship. Even under conditions of conflict, it may be possible to move the agreement point into the admissible range of efforts by increasing the self impacts, e.g. by improving efficiency. For an unstable conflict, given by the instability condition $f_{11}\, f_{22} - f_{12}\, f_{21} < 0$, an agreement point does not exist and the conflict escalates to utmost efforts, unless actors do not change their goals.

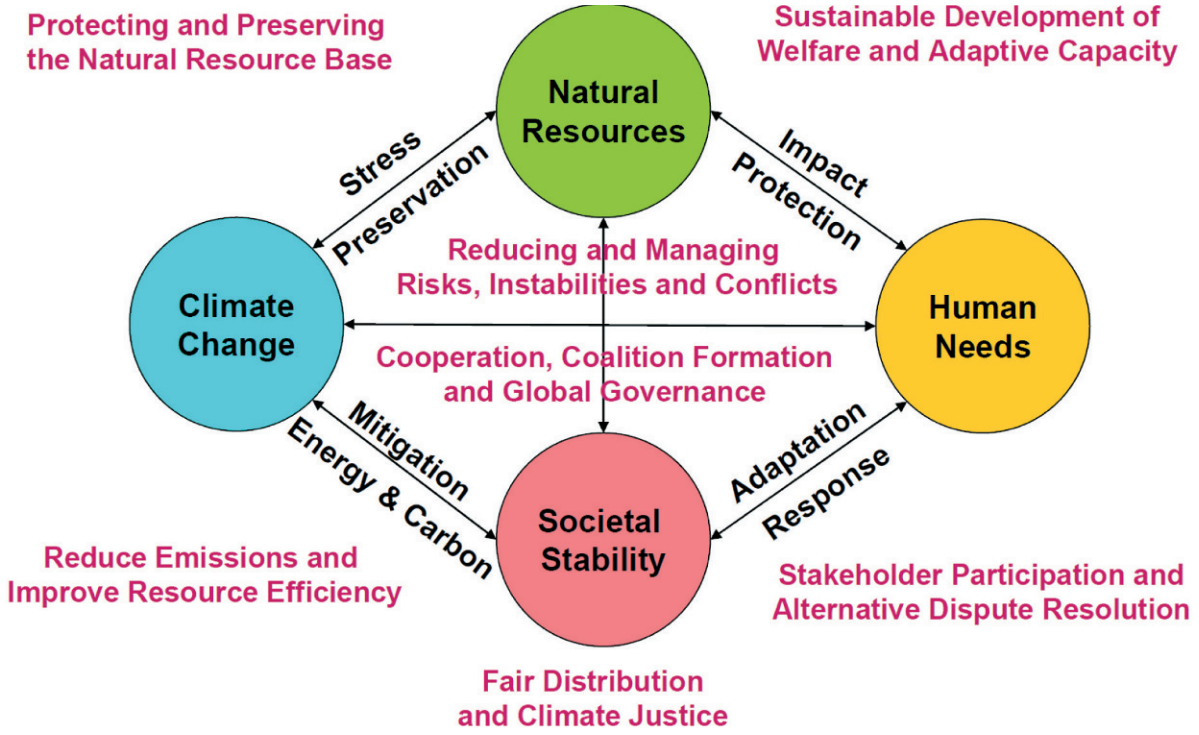
42.4.1 Sustainable Development of Welfare and Adaptive Capacity

Climate change is the result of a non-sustainable economic structure that threatens both the natural resource base and the well-being and capabilities of people. Since wealthy regions are less vulnerable and unstable, and have better adaptive capacities to manage the effects of climate changes, economic development is an important strategy to reduce security risks and stabilize societies. An essential strategy to prevent and minimize harmful climate impacts is sustainable development that "meets the needs of the present without compromising the ability of future generations to meet their own needs" (Brundtland Report 1987: 43). Accordingly, human needs and capabilities of present and future generations are to be satisfied within natural resource limits. Regenerating human capabilities and adaptive capacities in a sustainable manner makes societies more resistant to climate change and allows them to invest into low-carbon energy alternatives and the establishment of institutions. Reducing poverty and establishing human rights would significantly improve the conditions for survival, strengthen human security, and build problem-solving capabilities. Less wealthy countries need development cooperation in various fields (Carius/Tänzler/Maas 2008), going beyond current levels *of* Official Development Assistance funding. Other measures include supplemental international financial assistance, e.g. expansion of microfinance institutions and instruments or an international environmental migration fund.

42.4.2 Reduce Emissions and Improve the Efficiency of Natural Resource Use

Greenhouse gas (GHG) emissions are the main cause of climate change, and their reduction remains a predominant strategy to stabilize carbon concentration at levels that prevent dangerous climate risks and permit societal stability. The task is tremendous, as global greenhouse gas emissions need to be reduced by at least half by the mid 21st century. This requires more efficient and alternative uses of energy and other natural resources to create wealth with less resources. To strengthen international efforts and agreements, a number of instruments are available for this purpose, including taxes, transfer of capital and technology, tradable emission permits and other Kyoto instru-

Figure 42.8: Strategies for climate security within the integrated assessment framework. **Source**: The author.



ments (Clean Development Mechanism, Joint Implementation). In each stage of the life-cycle of goods and products (resource exploration, exploitation, transport, transformation, use and recycling) efficiency improvements can be achieved, by innovative technology, economic instruments such as taxes and investment, behavioural changes and societal reorganization. The transition towards a more efficient and sustainable energy system with less carbon emissions requires new financing instruments and regulatory schemes. In developing countries, multilateral funds (e.g. Global Environment Facility, Carbon Finance Unit) can make important contributions. Subsidies for fossil fuels need to be reduced and channelled into renewable energy sources. Increasing crop yields help to improve agricultural efficiency, reduce carbon emissions from land use and establish agricultural markets that strengthen adaptive capacity in rural areas.

42.4.3 Protecting and Preserving the Natural Resource Base

Consumption of natural resources should not exceed the natural carrying capacity for these resources. Limits are given by the finiteness of non-renewable resources, by the limited regenerating capacity of renewable resources, and by the limited ability of nature to absorb wastes. Sustainability requires that the underlying ecological processes are to be protected against disturbing changes of environmental conditions that could trigger tipping points and cascading breakdowns. To maintain the integrity and adaptive capacity of ecosystems, biodiversity needs to be preserved through building of nature preserves, sustainable land use, limitation of harvest rates, and preservation of endangered species. This would also protect terrestrial carbon stocks, especially tropical forests, against overexploitation and deforestation. Adaptation capacities of ecosystems against climate change need to be strengthened, recognizing their service for human societies. Within limits, ecosystems can be managed to adapt to and survive climate change.

42.4.4 Fair Distribution and Climate Justice

The resources, benefits and risks for each social entity are shaped by allocation and distribution mechanisms, market processes, human rights as well as power and interest structures. Equity strategies seek to achieve a fair distribution between those who have the highest responsibility for climate change and those who are most affected, between north and south, rich and poor, current and future generations. Fair and efficient burden-sharing in a global frame-

work of climate justice would balance responsibilities and impacts among countries, satisfying the 'polluter pays' principle and the 'ability-to-pay' principle. With the formula of 'common but different responsibilities' the UNFCCC assigned different roles for industrialized and developing countries in climate policy. The challenge is to agree on collective emission targets that avoid dangerous climate change and will not be exceeded by all human beings. Several proposals have been made to balance emissions, including the *Triptych* approach to share emission allowances among a group of countries, the *Contraction & Convergence* concept with a joint target of per-capita emissions, and the *Common but Differentiated Convergence* proposal where countries are flexible to select the path appropriate to their development (Höhne/Phylipsen/Ullrich/Blok 2005). As the largest emitters of greenhouse gases, the developed countries have a particular responsibility as well as the power to reach an agreement on reducing emissions to a non-dangerous level. Less-wealthy countries could benefit from adaptation capabilities in wealthy countries which would be liable for compensation of losses in the most affected regions. A global diplomacy could help to contain climate-induced distributional conflicts, as well as the development of compensation mechanisms for the victims of climate change.

42.4.5 Reducing and Managing Risks, Instabilities and Conflicts

To implement the UNFCCC, the impacts of climate change need to be limited to non-dangerous levels. A reasonable and systematic specification of the overall objective with regard to key parameters is still missing. To specify 'danger standards' based in ethical norms would serve as guidelines for orientation to build legitimacy and acceptability of negotiation results. Art. 3.3. of UNFCCC requires "to anticipate, prevent or minimize the causes of climate change and mitigate its adverse effects". Lack of scientific certainty is no sufficient reason to postpone precautionary measures. Concrete measures include disaster relief, protection of refugees, conflict management, among others. Resources from the military, the police and emergency services could be used to protect against the worst effects of disasters, e.g. using troops to contain wildfires or floods, to control crime and looting, evacuate refugees and crisis management (UNDDA 1991; Scheffran 1992). It is important to understand the conditions under which climate-related changes will translate into destabilization and conflict, and find factors that make societies more robust to resist and more able to adapt. Societies need to develop and collaborate on mechanisms to handle conflict and capabilities to manage disasters, including emergency planning and establishment of clear decision-making structures and procedures. Global information systems for early warning could help with timely responses to extreme events and crises. A database would collate information from different sources and UN institutions and address all threats to human security. Arms control, non-proliferation and disarmament would reduce the destructive potential of military forces (especially weapons of mass destruction) that could be used in conflicts. Preventive arms control restrains advanced technical weapons development, for instance of miniaturized vehicles that could be used in terror attacks. Forces need to be restructured towards defensive postures. Regional security concepts would establish conflict resolution mechanisms and confidence-building measures. A high priority should be given to stabilizing fragile and weak states that are threatened by climate change. For instance, the OECD's Development Assistance Committee has set up a Fragile States Group that has defined Principles for Good International Engagement in Fragile States and Situations. The capacity to manage environmental risks must be maintained and reinforced, even under difficult political and economic conditions. Emphasis should be given to crisis prevention which is less costly than crisis management and intervention which often come too late. Critical are strategies that allow human beings and institutions to respond in a constructive and mutually beneficial way and provide alternative venues for grievances and differences.

42.4.6 Stakeholder Participation and Alternative Dispute Resolution

Participation of citizens with their interests and capabilities, knowledge and perceptions, responses and interactions is a key for dealing with the challenges of climate change and managing associated security risks, instabilities and conflicts. Renn, Webler and Wiedemann (1995: 3) define public participation as "forums for exchange that are organized for the purpose of facilitating communication between government, citizens, stakeholders and interest groups, and business regarding a specific decision or problem." Instead of conflicting forms of expression it includes "public hearings, public meetings, focus groups, surveys, citizen advisory committees, referendums and initiatives, and negotiation, among other models." Fo-

cus groups have proven successful in various contexts as a process of group discussion and evaluation of critical societal issues such as climate change (Wibeck/Dahlgren/Öberg 2007). Participation of stakeholders in dialogues is significant in natural resource management (Stoll-Kleemann/Welp 2006). Multi-stakeholder sustainability planning is a social learning mechanism based on the vision of partnership between members of society and their environment, involving stakeholders in the formulation, monitoring and follow-up of sustainable development strategies. It contributes to the formation of social capital, the democratization and stabilization of societies, and can prepare the ground for cooperation, negotiation and conflict resolution (Scheffran/Stoll-Kleemann 2003). Regional participatory assessment will include experts and stakeholders from the regions of concern into a discussion of key links and variables of the climate-society interaction (including gender issues), an evaluation of climate impacts and the design of strategies. Alternative dispute resolution and mediation is an interactive process to reconcile divergent interests and settle environmental and natural resource conflicts.

42.4.7 Cooperation, Coalition Formation and Global Governance

The magnitude of the potential security risks of climate change requires determined policies to manage global change within a new well-designed global governance architecture that establishes rules, regulatory systems and functioning institutions. To master the global and long-term challenges, global governance would create and reinforce multilateral regimes that involve cooperation between states and non-government actors from the local to the global level (Scheffran 2008d; Lempert/Scheffran/Sprinz 2009). Recognizing that anthropogenic climate change constitutes a common problem of humankind, the international community must establish common solutions and cooperative approaches that combine sustainable environmental policy, development policy and preventive security policy into an integrated concept for sustainable peace (Scheffran 1998; Brauch/Oswald-Spring 2009a). To address the climate challenge and its long-term nature with high uncertainties, new concepts of adaptive governance are appropriate that seek to influence the many decision points along the causal chain from climate change to societal instability to avoid cascading risks and prevent the breakup of natural and social systems.

Whether climate-induced pressures upon societies erupt into crisis and conflict depends primarily upon the performance and problem-solving capacity of the states in question. Cooperative approaches include the international transfer of investments and technologies to shift the composition and learning rates of the energy system towards emission reductions. To implement Art. 2 of the UNFCCC, states need binding and verifiable agreements.

The more climate change advances, the more important adaptation strategies in the affected countries will become and these must be supported by international development policy in agriculture, water, food security and disaster prevention. Adaptive governance is arising out of the needs at the state and local level and "involves the evolution of new governance institutions capable of generating long-term, sustainable policy solutions to wicked problems through coordinated efforts involving previously independent systems of users, knowledge, authorities, and organized interests" (Scholz/Stiftel 2005). Adaptive management is essential to adjust to actions and interactions among multiple factors and actors in the complex environment created by climate change and to find the best combination of global mitigation and local adaptation strategies (Scheffran 2008c).

Agent-based approaches allow to represent adaptive agents who follow decision rules based on incomplete knowledge and updated information within a spatial and temporal window of perception, and thus respond to changing circumstances. They are also appropriate to manage the multi-level decision-making process between local and global agents, and the transition between individual and collective action that leads to the formation and breakup of coalitions. This conceptual and analytical framework to global governance is adequate to analyse the conditions for moving from conflict to cooperation.

To overcome diverging interests it is important to build coalitions among those with common interests to establish a regime for sustainable climate security. Win-win solutions among industrialized and developing countries help to avoid a North-South conflict (Ipsen/Rösch/Scheffran 2001). Cooperation becomes feasible if participation is in the developing countries' best interest, e.g. because it supports local environmental goals or provides access to low-carbon investments and advanced technology to fulfil both environmental and economic goals.

Governance capacity is particularly relevant in the context of environmentally induced migration (Biermann/Pattberg 2008). *Migration policy needs to be*

integrated into development cooperation that strengthens the adaptive capacities of people living in poverty and the rights of environmental migrants. Another area is cooperation on transboundary water management which should encourage regional sharing of water resources to avoid water crises and facilitate developing countries' access to current scientific data on regional water availability.

42.5 Conclusions

The climate-society interaction is highly complex and not fully understood. This chapter develops an integrated assessment framework to assess the causal chains of events and impacts from climate change to environmental, human and societal consequences. These are determined by the sensitivities between the key variables and their response patterns to changing conditions. Human and societal responses depend on their vulnerabilities to climate-induced stimuli and their adaptive capacities which determine the threats and risks to security as well as the instabilities and conflicts. Within the introduced framework it is possible to specify conditions for vulnerability, instability and conflict which can help to structure climate change impacts and classify responses into those that affect these conditions in one or the other direction,

The chapter discusses different security concepts (common, ecological and human security) which are adequate as building blocks of climate security, and introduces key stability concepts (economic and ecological stability, escalation stability, societal stability) that are relevant in the climate change context. Whether climate change leads to more conflict or more cooperation depends on the type of resource that is affected and by the adaptive responses selected by the key actors. Based on this analysis we introduce a set of strategies to enhance climate security, prevent environmental conflicts with an early warning system and stabilize societies. These include measures for sustainable development of human and social capital to strengthen adaptive capacities, emission reductions to mitigate the problem, managing and reducing security risks and threats, as well as participatory approaches to involve stakeholders in problem solving and adaptive governance on global and regional levels. Integrating these strategies into a concept of sustainable peace is a key to avoiding, reducing and solving the security problems associated with climate change.

43 New Threats? Risk and Securitization Theory on Climate Change and Water

Anders Jägerskog

43.1 Introduction[1]

Buzan, Wæver, and de Wilde (1998) argue that states and societies 'securitize' issues to highlight their urgency. This has been the case with the environment and particularly water.[2] In this chapter a number of consequences of this phenomenon will be addressed. For example, what are the implications of this securitization on policy formulation both for the security and for the environment sector? Is the securitization process leading to policy priorities that are relevant from a security perspective or is the debate getting blurred? The threat posed to and by the environment differs from traditional threats to state security. Traditional threats deal with military and strategic issues while environmental challenges are seen as incrementally growing threats. The Climate Change issue which has really taken off during the last years, is of course also seen (or indeed branded) as en environmental security issue. The importance of climate change is further elevated as it is seen as affecting, in a destabilizing manner, also food security, water availability, and health issues. It is conceived as a future cause for environmental migrants. Thus, the main importance of climate change as a security issue is that it affects and furthers other environmental scarcities (IPCC 2007a). It is also evident that the issue has gained interest among the defence establishments (US National Security Council Memorandum, 27 March, 1998). And in 2007 the UN Security Council held its first ever debate on climate change and how it affects peace and security.[3]

Similarly, the water problem in the Middle East has also been characterized as an issue with national security implications for the states in the region (Shuval/Dweik 2007). The angle of this chapter is of a multi-disciplinary nature although predominantly related to political analysis (predominantly security focused) as well as sociological perspectives.

The chapter is divided into an introduction followed by aim, background, and theoretical framework (sections 43.1–43.1.4). Then the Israeli-Palestinian water negotiation process is analysed (43.2), especially the risk perception in the negotiation process 43.2.1). Section 43.3 discusses climate change and securitization, and in section 43.4 the findings are discussed and conclusions drawn.

43.1.1 Aim

The chapter has two aims that are interrelated: *first* to discern how climate change has been subject to a securitization within the international community at large. It is assumed that the climate change discourse has been securitized since the end of the Cold War. *Secondly*, to analyse how certain aspects in the water negotiations in the Jordan River Basin have either been emphasized or de-emphasized, drawing on risk theory. Arguably the securitization of an issue area relies on being emphasized by certain actors. By analysing these two concepts they could usefully inform each other.

Furthermore, the risk theory perspective has potentially strong (but not yet very well understood) linkages to securitization. By understanding how certain issues are being stressed or de-emphasized our understanding of why certain issues may become securitized will improve. In addition, climate change will negatively affect water availability in dry areas as the Middle East, what makes the link between climate and water even more urgent.

1 This chapter is partly based on Jägerskog (2003). All copyright permissions have been obtained.

2 For example, Homer-Dixon (1994) argues that environmental issues might be a threat to state security.

43.1.2 Background

During the Cold War the concept of national security was, almost exclusively, defined in military terms (Brauch 2008). Security policy was almost identical with defence policy and was often portrayed as a 'zero-sum game'. After the Cold War ended scientists and professionals have increasingly challenged this narrow perspective (Brauch/Oswald/Mesjasz/Grin/Dunay/Behera/Chourou/Kameri-Mbote/Liotta 2008).

The term 'environmental security' was given significant attention after the end of the Cold War in 1989. Several research projects were launched to analyse links between the environment, national security, and violent conflict. Environmental security issues received much attention as they filled a void in the international security system during its transformation after the end of the Cold War (Brauch 2005; Jägerskog 2004).

Ullman (1983) argued for a wider and more inclusive concept of security. However, he pointed out that environmental 'threats', among them global climate change, have no causal link to national security. They were treated as security issues as they undermine the carrying capacity of the earth, and therefore might lead people and states to take up arms to maintain or gain access to the declining natural resources. Hence, environmental threats are indirect threats as opposed to direct military threats that had dominated the security debate previously. It is argued that increasing pressures on the ecosystems and on renewable resources of the earth impact on people's health and welfare, and in the long run they might pose an equal risk to security as military threats (Jägerskog 2000).

Brauch (2005) has comprehensively reviewed the environment and security debate and further clarified the concepts of 'threats', 'challenges', vulnerabilities', and 'risks' as they are all important facets of the environmental security discussions. In addition, a further development of the security debate continued during the 1990's when the human security concept was launched (including both traditional security aspects as well as new ones such as the environment but also social and economic aspects) primarily by the Commission on Human Security lead by Amartya Sen and Sadako Ogata. Brauch (2005) summarized the human security threats, challenges, vulnerabilities, and risks related to *underdevelopment* (freedom from want), *conflict and human rights violations* (freedom from fear) and *hazards and disasters* (freedom from hazard impact).

In the recent discussions on climate change the economics of the impacts have been dealt with at considerable length in the Stern Review commissioned by the British Government. Among the main predicted repercussions of global climate change are (IPCC 2007a):

- *Human settlements*. When flooding and landslides in combination with a sea-level rise occur it will force people to migrate (environmentally-induced migrants). Climate change will increase the number and intensity of extreme weather events and natural disasters, what will increase both the economic damage and the human toll.
- *Water*. In 2008, some 1.7 billion people live in water-stressed regions. With climate change this figure will rise significantly. It will also negatively affect the availability of freshwater (IPCC 2007a; UNDP 2006).
- *Health*. With a rise in temperatures diseases, such as malaria, will spread to new areas. A decline in biodiversity will lead to a decline in human security as multiplicity of species is an important base for research on new medicines, new crops, etc. (Jägerskog 2000).
- *Food security*. Food security is defined as "having a continuous supply of enough food to be able to live an active and healthy life" (Linnér 2000; FAO 2003). Climate change will negatively affect the agricultural sector (particularly in the South) and thus endanger food security. And in addition the issue of *biofuel*, which is more 'climate friendly' but at the same time consumes a lot of water and thereby is affecting the water scarcity situation negatively, complicates the picture (Falkenmark/Berntell/Jägerskog/Lundqvist/Matz/ Tropp 2007; Lundqvist/Barron/Berndes/Berntell/Falkenmark/Karlberg 2007).

43.1.3 Theoretical Framework

43.1.3.1 Theory of Securitization

Traditional security studies have an objective view of what constitutes a security issue. This approach focuses on military issues and external threats to the security of a state. In contrast, the 'securitization approach' by Buzan, Wæver, and de Wilde (1998) views security as *socially constructed*. They argue that security is not an objective feature of threats. 'Securitization' is seen as an extreme version of politicization. In a securitizing act an issue (or a set of issues) is presented as an existential threat. If the issue is subse-

quently recognized by the public or large parts of the public then the issue has been securitized. Hence the status of an issue depends on the subjective judgements of the public (Wæver 2008, 2008a).

The significance of risk in a negotiation is rarely considered. The risks involved in the water negotiations are of a natural scientific nature and are at the same time politically and culturally determined. As the process of securitization is socially constructed so is risk (or its perception). By using risk theory it may be understood why some risks are emphasized and others are de-emphasized. In the case of the waters of the Jordan River Basin this aspect of the negotiation is particularly important since it pinpoints the ways in which water is subordinated to other political priorities, what results in certain risks being de-emphasized. In addition, it is useful since it helps in identifying constructed realities within the respective societies that influence and effectively 'set the boundaries' for the negotiations.

43.1.3.2 Risk Theory

In the literature there are two main ways of interpreting risks (Beck 1995, 1999). *First*, there is the *natural–scientific objectivism* about hazards that basically identifies risks using scientific techniques of observation, measurement, and calculation. The strength of this perspective is that, through the instruments used, it enables risks to be categorized so that they are definable in terms of probability. However, its inherent weakness is that it fails to recognize that scientific 'facts' are situated and interpreted in cultural and political contexts. The critique of the natural–scientific approach leads to the second approach of *cultural relativism*. This approach emphasizes the contextual aspects of risk but it has an inherent weakness as it fails to recognize the nature of 'real' hazards.

Ulrich Beck argues for a third way to analyse risks – a *sociological perspective* – which combines both. He is interested in the 'cultural disposition' of groups and individuals when they single out certain issues as risks and ignore others. Here it is important to look at the symbols that drive individuals and societies to view certain matters as risks. Symbols that can 'touch a cultural nerve and cause alarm', of which water in the context of the Middle East is a good example that can help people focus on an issue while ignoring others. This is also evident in the debate on climate change and its implications.

Both groups that want to emphasize the risks of climate change as well as those that would like to de-emphasize are best understood in their cultural context, to draw on Beck's concept. In addition, the risks (or the perceived such) are different in the modern world as opposed to the pre-modern era. Beck (1999: 4) highlights that "risk and risk societies combines what once was mutually exclusive – society and nature, social sciences and material sciences, the construction of risk and the materiality of threats."

Another influential thinker on risk is Mary Douglas, who also argues that risk is best analysed through the prism of culture. As an anthropologist she holds that individuals should be seen in their social environment. Douglas argues in her 'cultural theory' that it is possible to understand how some issues which might be perceived as risks are emphasized and others are de-emphasized through looking at the institutions that are created in cultures and which set limits for action (Douglas 1992). The process whereby certain aspects of risk have been emphasized or de-emphasized in the negotiations in the Jordan River Basin is evident. For example, Jordan and Israel in their agreement chose to de-emphasize the provisions in the event of drought.

In order to point out the variable significance of risk it is also necessary to examine both the scientific and the cultural-political discourse. Kopagen (1995) points out the importance of various myths within which issues such as water and territory play a part. To understand risk perceptions in the Middle East it is important to acknowledge the specific cultural and socio-psychological context in which the water issue is situated. There is also a tendency among scientists to downplay uncertainty when communicating scientific results to decision-makers (Wynne 2001).

Another feature that is presumed to be central in the analysis of risk is the notion of 'otherness'. When discussing risks, individuals and societal groups are prone to identify other individuals or societal groups as the source of risk. This is particularly evident in cases where the 'other', in one way or another, threatens to overtake the self – or, in the case of water, claims or uses a water resource which is perceived to belong to oneself (Lupton 1999).

Bar-Siman-Tov deals with the issue of uncertainty and risk while moving from war to peace. He argues that uncertainties pose dilemmas in negotiations as states aim to reach agreements. When a state makes a concession in a negotiation it takes a risk since it cannot be certain what it will gain (or lose) by making that move. Hence, risk management strategies are deemed very important in negotiations. However, Bar-Siman-Tov views risks as largely objective, identifiable, and definable in terms of probability, and his

ideas are thus not as useful for identifying socially constructed risks (Bar-Siman-Tov 1999). This concept relates to culture and identity that are identified as crucial for negotiators dealing with water in the Arab-Israeli context as their identity is rooted in the parties' respective cultures, which largely dictate how they view and react to each others proposals in the negotiations (Fauré/Rubin 1993).

43.2 The Israeli-Palestinian Water Negotiation Process

The opportunities and obstacles in the Israeli-Palestinian water negotiations must be analysed in their context. Thus, what might be seen as an obstacle in the water negotiation could, when linked to other issues, such as refugees or borders, actually be an opportunity. What can be seen as an opportunity and an obstacle can also be seen as a risk.

With the end of the Cold War a 'window of opportunity' opened for the states in the Middle East, as it was no longer an arena for the struggle between the superpowers. The mutually hurting situation – for Israel through the Intifada and for the PLO through the danger of being sidelined by others in efforts to settle the Israeli–Palestinian conflict, felt among the Israeli Labour Party leadership and the PLO leadership, respectively – thus presented an opportunity to start a process aimed at reaching a solution to the conflict.

Clearly, transboundary waters do no fit in the traditional security discourses of international relations (Hurrel 1995). This implies that there is an opportunity for cooperation on water resources. Entering into a joint management institution over a shared water resource does not represent a zero-sum game, in which the loss of one party is a gain to the other, but a positive-sum game where cooperation is something from which both parties can gain (Wolf/Hamner 2000; Sosland 2007). People from both sides emphasize the need for joint management and cooperation. Thus, in the discourse on transboundary waters cooperative management is seen as the best option.

Using a functionalist or idealist approach to international relations one might also hypothesize that water can be a source for future cooperation on other issues. Such a development has not happened so far in the Israeli-Palestinian case. However, using a more realist reasoning, along the analytical lines of Lowi (1993), it can be argued that 'high' politics (such as national security concerns) decides what is agreed upon in areas of 'low' politics (such as water). Indeed, while water cooperation might be the best possible solution for all parties in the basin, it is still Israel, which is in the hegemonic position, that dictates to a great extent what is acceptable and what is not (Nicol/Steenbergen/Sunman/Turton/Slaymaker/Allan/de Graaf/van Harten 2001). Obviously, its hegemonic position is an opportunity for Israel and an obstacle for the Palestinians. The power asymmetry between the parties, with Israel being the stronger on issues such as human resources, military power and economics, is also an obstacle for the Palestinians in obtaining the best possible outcome, while it is an opportunity for Israel to push its interest even harder.

The Palestinians also identified other obstacles. For example, as the Palestinians have repeatedly stated, the parties wanted to discuss and negotiate quite different agendas and issues. While Israel was interested in discussing cooperative ways to find 'new' or additional water, the Palestinians argued that the starting point has to be to identify the water rights. Only after they have been agreed is it possible to discuss other issues. These discussions have also been part of the Joint Water Committee deliberations since the Interim Agreement. A further obstacle for the Palestinians is water data. Since they have not had a functioning measuring system for a long time they need 'raw data' from the Israelis. According to the Palestinians they are only receiving processed data, which makes it difficult for them to make informed decisions and judgements.

In the Interim Agreement signed in Taba in 1995, Israel acknowledges that the Palestinians have water rights, which is partly a victory for the Palestinians. But what these water rights actually imply is not spelled out but is to be negotiated as part of the final status negotiations. The water rights issue was discussed during the negotiations in spite of Israel wanting to postpone it, and according to Uri Shamir these were the hardest issues.

43.2.1 Risk in the Negotiations: Perceived and 'Real'

The risks in the water negotiations are both 'real' and constructed risks. On one level there are the 'real' risks definable by scientific observation and on another level there are the culturally constructed risks (Beck 1995). However, the division between both types of risk is not clear cut: for example, a predominantly culturally influenced risk can be portrayed as a scientific (or real) risk. The problem of diverging risk perceptions, which may all be based on expertise, is

highlighted by Sjöstedt (2001) who shows that in the negotiations between Slovakia and Hungary on the dam on the Danube River the authorities made different use of experts, which led to contrasting perceptions of risk. Furthermore, as is pointed out by Meir Ben-Meir (a former Israeli head of the Joint Water Committee) some issues in negotiations are left vague, thus making it possible to avoid the division of risk, because otherwise it might be impossible to reach an agreement.

The risks primarily perceived by the Israelis in the negotiation with the Palestinians concern water quality and quantity. Some Israelis argue that it might be risky for Israel to rely on water from the aquifers emanating from the West Bank as the Palestinians could pollute the water in these aquifers, thus reducing both quality and quantity. These claims can, of course, be based on hydro-geological science but they might at the same time be influenced by a cultural disposition on the part of the Israelis not to view the Palestinians as trustworthy. In the case of the claim that the Palestinians could pollute the aquifers, the question can be asked why they would be interested in doing so when they rely on the aquifers themselves. The logical answer to this question suggests that the risk that some Israelis are highlighting here has more to do with a lack of trust of the Palestinians and is driven more by cultural dispositions than by natural-scientific arguments. It might be argued that this connects very much to what Lupton (1999) calls the notion of 'otherness', which means that groups are prone to identify other groups as the source of risk. That is particularly true in cases where the 'other' is perceived as threatening to overwhelm the 'self'. As a result of the distrust, the Israelis are reluctant to give up the degree of control that they have over the West Bank waters.

Palestinians, on the other hand, focus on water rights, with a particular emphasis on Palestinian sovereignty over water, as a starting point. They see the main risk to themselves as not achieving what they view as their appropriate water rights. The Palestinian argument is connected to the land issue and is emotionally laden. Control or sovereignty over water is a symbol of importance for the long-awaited Palestinian state. This reflects well the ideas of Kopagen (1995), who emphasizes the cultural attachment to the land and water.

One evident risk of focusing heavily on water rights as the top priority is that the Palestinians will achieve a less favourable deal in terms of water allocation. An agreement with Israel is likely to be based on the level of current use. If, on the other hand, the negotiators' emphasis shifted to the more vague principle of equitable utilization, Palestine could have a better chance of achieving larger allocations. The political-cultural history of the Arab-Israeli conflict is an important factor in understanding why some issues are de-emphasized and others are emphasized. The fact that the Palestinians emphasize water rights can be seen as a result of their long history of having no rights, and the damage to their interests as a result of occupation.

As argued above, water was of less importance in the peace negotiations than issues such as Jerusalem, borders, settlements and refugees. Obviously, this affects risk perceptions on water. Certain risks (loss of water) are de-emphasized by the parties when they stand to gain in areas that are politically more important. Thus a trade-off takes place between issue areas in the negotiations. Consequently, risk perception in the peace negotiations, involving various interlinked issues, is influenced by strategic choice and politics as well as by culture and history.

The water negotiations should not be viewed as isolated events. First, we need to look at the actual agreements and at the various mechanisms that have been created as instruments to deal with the risks and conflict issues that might surface. Second, the water clauses of the agreement need to be put into a wider negotiation context. An awareness that a sacrifice might be made by one party on a certain issue (for example on water) in exchange for a reward in another area is imperative. Thus, some risk issues might be emphasized, de-emphasized, or left out as mutually agreed 'vague' issues because of various complex negotiation linkages.

When a state makes a concession in a negotiation it cannot be certain what it will gain (or indeed lose). The issue of effective risk management strategies and tools is, therefore, very important (Bar-Siman-Tov 1999). Both the Israeli-Palestinian Interim Agreement and the Israeli-Jordanian peace agreement provide for a Joint Water Committee. These committees are useful as both confidence-building measures and conflict resolution mechanisms.

Thus, risks and uncertainties, both those that have been included in the agreements and those that have not been included, can be dealt with within these bodies. Indeed, as Ben-Meir, said: "Both parties acknowledge the importance that it [the JWC] stays in place." This is reiterated by a Palestinian member of the JWC, Ihab Barghouti, who maintains that it is an important body although its work is hampered by being linked to other political issues. A retrospective,

'follow-through' analysis of the water negotiations helps us, as has been shown above, to examine the risks included in agreements as well as those that are not (Zartman 1999). Furthermore, it gives us a view of the joint mechanisms established to deal with the risks. In this regard regime theory is relevant as it focuses on how joint mechanisms can become institutionalized and thereby generate norms and rules for conflict management so that the parties are better able to deal with common issues of dispute. The existence of such mechanisms has been manifested in the Israeli-Jordanian water relations during the recent periods of drought (Jägerskog 2003). Having highlighted the positive aspect of the Joint Water Committee it should be noted that to a large extent Israel uses its hegemonic role to dominate the discourse in the committee and thereby steer the outcome to its liking (Selby 2003a).

43.3 Climate Change and Securitization

In the environmental sector the environment is seen as a referent object that has to survive. If the environment is degraded to the point of no return all other issues will lose meaning. Hence, the security of the environment has to take priority over all other issues. The basic underlying rationale of those who argue for a security concept where environmental security is taken into consideration is that in a global perspective humankind is living beyond the carrying capacity of the earth.

In the environmental sector there is a rather large dependence on scientific authority as a basis for policy decisions. Hence, epistemic communities play a rather large role in setting the agenda. They are, therefore, an important securitizing (or de-securitizing) actor for the environment. The securitizing acts within the security discourse are often a reflection of some tactical rationale employed in order to increase the importance of an issue. While some try to securitize issues there are also those who try to de-securitize issues. This situation has been evident in the debate between the Bush administration and the European Union on the Kyoto Protocol. The Europeans have tried, in the political discourse, to securitize the issue of global warming while the Bush administration has tried to de-securitize it. It has also been evident that there are forces within the US that have tried to securitize the issue. The House democrats managed to get a provision into the State Department bill directing President Bush to continue to negotiate the Kyoto treaty that he rejected. The resolution states that "global climate change poses a significant threat to national security, the American economy, public health and welfare and the global environment."

In the debate on the Kyoto Protocol there are four main securitizing actors: *First*, there are the two political entities, the US wants to de-securitize the issue while the EU wants to securitize it. *Secondly*, there are different epistemic communities. There is one (and by far the largest group) that argues that human controlled emissions contribute to global warming and argue that something needs to be done about it (IPCC 2007a). Then there is the group of scientists that argue that it is not certain that carbon emissions contribute to global warming, at least not the extent of it. They also criticize the methods the first group uses.

If we look at the large political entities they tend to approach the world with rather different mindsets. The member states of the EU emphasize naturally, multilateral agreements and common regimes that tie states together. The European project is not by accident used as a 'definition' of functionalism. Thus, they are interested in things that tie states together and climate control is such an issue. The US, on the contrary, tends to view the world from a pre-dominantly realist perspective – military power, national and economic interests determine international politics. Being in the position of the sole hegemon it is easy to argue like Bush when he said that the cost of the Kyoto Protocol was greater than the United States wanted to bear, and therefore skipped it. It is evident that the EU has its own reasons for attempting to securitize the issue while the US has its reasons de-securitizing it.

The different epistemic communities are composed in different ways. The main body for the scientists dealing with climate change of the governments of the world is the *Intergovernmental Panel on Climate Change* (IPCC). They have been a main securitizing actor in the scientific discourse arguing that the main reason for the global warming is a result of human activities. The other group of scientists is in a minority but they have criticized the IPCC for methodological arrogance and insist that the evidence for global warming is far from certain. Thus, they are attempting to de-securitize the issue. According to risk theory the respective communities are emphasizing and de-emphasizing the issue. Besides the scientists debating climate change, the media are also playing a role in the emphasizing or de-emphasizing of the risks associated with climate change (Oreskes 2004).

There are also linkages between the political entities acting in a securitizing manner and the epistemic group doing the same. This applies also to the groups aiming at a de-securitization. The political entities, quite predictably, reach for the scientific arguments that suit their purpose. For example, in scrapping of the Kyoto Protocol President Bush referred to the "incomplete state of scientific knowledge of the causes of, and solutions to, global climate change."

The French Environment Minister Dominique Voynet, relying on the work of the IPCC, referred to the new US position as "suicidal and irresponsible." Even the sometimes ambivalent UK government that sometimes sided with the USA and not the EU on certain issues, came out harshly, through its Environment Minister Michael Meacher, on the US when he said that global warming is "the most dangerous and fearful challenge to humanity over the next 100 years."

In a much highlighted speech in 2004, the British PM Tony Blair said "our effect on the environment and in particular on climate change is large and growing." UK Foreign Secretary Margaret Becket has furthermore highlighted how she believes climate change will change the security situation stating among other things

> The basic science of climate change is no longer in dispute. But the scale and urgency of the challenge we face is worse than we had feared. Tackling climate change is an imperative, not a choice, a problem for today not tomorrow. I am in no doubt that today being a credible foreign minister means being serious about climate security because the question for foreign policy is not just about dealing with each crisis as it hits us. Our obligation to our citizens is to put in place the conditions for our future security and prosperity in a crowded and interdependent world.

43.4 Discussion and Conclusions

It was hypothesized in the beginning of the chapter that the issue of climate change has been subject to a securitization within the international community. It is found that the issue of global climate change has indeed been securitized by some actors but it is also found that there are actors that have attempted to de-securitize the issue. Perhaps not surprisingly, the willingness to securitize (or de-securitize) the issue of climate change is not only determined on scientific grounds but determined by interests and cultural disposition/context. Hence, when President Bush argues that it is not in the US interest to be a part of the Kyoto Protocol it is because, in his view, it hurts US economic interests. Quite rationally he reaches for the arguments of the epistemic group that argue that there is no clear-cut scientific evidence for global warming, let alone the role of carbon emissions in it. On the other side of the spectre we find the Europeans that argue forcefully that global warming is indeed happening and at a faster rate than ever, and accordingly embrace the conclusions of the IPCC. It is concluded that it is imperative to include an analysis of the politics surrounding the issue of climate change in order to unmask and understand the major forces that are engaging in the discursive battle of securitization and de-securitization respectively of the issue of global warming. A lesson drawn from this exercise is that the concept of security is inherently constructed since it is subjectively defined. From a policy perspective this is important since when creating policies the policymaker would benefit from an increased understanding of the forces that shape a discourse on climate change and the security risks allegedly associated with it. That would help the policymaker not only to adjust his policies to the prevalent discourse but to go beyond it.

The other aim of this chapter has been to analyse how risk perspectives have been incorporated into the water negotiations in the Middle East peace process. Specific attention has been given to why some issues are seen as risks in the negotiations and other issues are not. In particular, what are the decisive political processes in this regard?

It is concluded that when a risk is situated in the wider negotiation context, it may become apparent that some risks are emphasized or de-emphasized as a result of various linkages between different areas of the negotiations. It enables us to understand why some issues that might be termed risks are not part of the negotiations. The reason why measures that would be helpful in this regard are not included is that they are politically stressful. For example, the Palestinians would not agree to work simultaneously to find 'new' water and discuss water rights. Rather, they would like to finalize a division on what there is today first and then move on to discussions on 'new' water. It is also found that the issue of risk in the negotiations cannot be viewed in isolation, as the water issue is subordinate to more salient political issues in the negotiations. One party might overlook a risk in the water negotiations in order to gain something in another area. Hence, the issue of political feasibility and linkages between issues are identified as important. For example, if one party were given the opportunity to gain something on the question of Jerusalem he

would most likely be prepared to compromise on water. Thus a major conclusion seems to be that risk perception is not only culturally informed but also informed by politics, especially in negotiations.

Table 43.1: Risk and Securitization. **Source:** The author.

	Risk Perception	
Referent Object: Climate Change or Water	**Emphasizing Risk**	**De-emphasizing Risk**
	Securitization (Water and/or Climate Change branded as a security issue)	De-securitization (Water and/or Climate Change branded as a non-security issue)

On a final note it is concluded that there are linkages between the two theoretical perspectives employed in the chapter (table 43.1). The referent object in the two cases discussed were water and climate change, and while the processes discussed are rather dissimilar the ways in which the issue of risk is being either emphasized or de-emphasized explains the degree to which the referent object is being securitized or not. In line with a more constructivist approach the risk perception focus is a constructivist approach to the issue.

While the perspectives of Buzan, Wæver, and de Wilde (1998) that deals with securitization processes are useful in analysing the climate change discussions and the perspectives drawn from risk theory are useful in analysing the Israeli-Palestinians water negotiations, one can also discern how the perspectives overlap. The process that drives a securitization is similar and includes comparable facets as those that drive proneness to risk (or vice versa). The actors that argue that climate change is a security issue see this as a high risk and emphasize this. The actors that view climate change as a 'normal' issue try to de-emphasize it. And those that argue that certain aspects in the water negotiations shall be viewed as a risk employ a securitization logic.

In both the securitization process as well as the process of moving describing an issue as a risk or not as a risk through either emphasizing or de-emphasizing, the actors that are active in the processes are informed by their cultural and political circumstances in which they are situated. Thus, the respective processes might look quite apart at first glance but in the process of determining if an issue is a *vulnerability* or a *threat* the interests by the actors that collide (or collude) with a certain scientific (or other idea) is actually one of *knowledge construction.*

44 Dealing With Uncertainties in Climate Change Impacts Assessments: A Case Study on the Nile Basin

Carlo Buontempo, Jens Kristian Lørup, Michael Sanderson, Michael Butts, Erika Palin, Rachel McCarthy, Richard Jones, Richard Betts and Mamdouh Antar

44.1 Introduction[1]

With the publication of the fourth assessment report of the *Intergovernmental Panel on Climate Change* (IPCC 2007, 2007a, 2007b, 2007c) the international scientific community has seen a major shift in priorities. A few years ago the scientific debate was focussed on the detection and attribution of climate change. The emphasis has now shifted towards assessing the impacts of the changing climate on social and economic concerns to inform adaptation and mitigation policies worldwide.

Among other things this change in focus has generated an unprecedented demand for climate projections at the regional and continental level. However making climate projections as the basis of water resource planning, for example, still represents a very challenging task for the scientific community. The study of climate and all the practical challenges associated with it, evolved under the assumption that the climate is stationary. Recent observations not only show this assumption to be untrue, but that emissions from human activity are likely to have been the largest contributor to changes that are potentially threatening the sustainability and diversity of some of the world's greatest ecosystem services, such as the Nile River basin.

Ten riparian countries contribute to and benefit from the Nile's water. 98 per cent of Egypt's freshwater resources come from the Nile and like other countries it also depends on the basin to sustain agriculture and provide power from hydroelectric generation.

Various climate impacts studies have highlighted that the Nile basin is highly vulnerable to the projected changes in temperature, precipitation and sea level we may see by the end of the century. For example, without the building of flood defences, the expected sea level rise in the Mediterranean could submerge a large area of the most fertile lands of the Nile Delta (chap 45 by El Raey). This highlights that countries like Egypt are not only susceptible to impacts within their borders but to those on a larger continental scale as well.

The risks climate change brings to the people of the Nile region will be exacerbated by their low adaptive capacity; the high levels of poverty; poor access to existing water supplies and sanitation; and the low efficiency of water use. Current and future changes in climatic conditions constitute a major environmental risk that may jeopardize Egypt's development gains and efforts for poverty reduction. The *Joint Programme* (JP) on Climate Change Risk Management in Egypt, with participation of six different UN organizations, aims to ensure achievement of the *Millennium Development Goals* (MDGs) in the face of climate change through sustainable energy development strategies and effective management of climate risks in key affected sectors, identified in the *Initial National Communication* (INC) as coastal zones, water resources and agriculture. This programme should help Egypt align its climate risk management and human development efforts in responding to possibly series climate threats. One of the JP components, which is carried out through UNEP, focuses on improving the knowledge of the impacts of climate change, through preparation of *Regional Climate Model* (RCM) pro-

jections and to use these predictions to assess the hydrological impact of climate change on the Nile.

This chapter presents a methodology adopted to address the impacts of climate change on water resources in the Nile Basin using RCMs. The assessment is a joint effort by the UK Met Office, DHI (*Danish Hydrological Institute*) Water, Environment and Health, and the Egyptian *Ministry for Water Resources and Irrigation* (MWRI) and is funded by UNEP and UNESCO.

Starting with a discussion of uncertainties in climate projections (44.2) and how they affect the assessment of climate impacts (44.3), this chapter outlines some common methods used to constrain uncertainty and details the simple yet flexible approach followed in the Nile project (44.4) to identify the impacts of climate change.

44.2 Uncertainties in Climate Projections

There are three commonly recognized sources of uncertainty in climate projections: the uncertainty due to the natural variability of the climate system, the uncertainty in future greenhouse gas emissions (forcings) and that resulting from our incomplete understanding of how to represent important climate system processes in climate models (Stainforth/Allen/Tredger/Smith 2007). All of these are likely to be important in predicting the future climate of the Nile basin.

Natural variability is believed to be the principal source of uncertainty for seasonal to decadal predictions (Cox/Stephenson 2006). Initial condition uncertainty and sampling uncertainty are likely to be particularly relevant in regions, such as part of the tropics, characterized by low frequency processes. The teleconnections between the sea surface temperature in the Pacific and the rainfall in tropical Africa due to ENSO is just one example of the importance of these processes on the seasonal to decadal time-scale.

For centennial projections, the response of the climate system to large modifications in the forcings (greenhouse gases and aerosol concentration) is expected to exceed the natural fluctuations of the system, the point at which this occurs being known as the "time of emergence" (Giorgi/Murphy/Noguer/Keen 2009). Thus, on long timescales the dominant sources of uncertainty are those concerning the forcings, over which we have some control as a society, and the model uncertainty associated with how the climate system is approximated in the numerical model used for the projections (Cox/Stephenson 2006).

On the decision-relevant time-horizon (30–40 years) it is model uncertainty, i.e. our inability to perfectly describe the state of a chaotic system, which forms the largest fraction of the total uncertainty (Cox/Stephenson 2006) suggesting this as the area to be more thoroughly analysed when assessing the local impacts of climate change.

44.3 Impact Studies and Uncertainties

There is strong evidence that in many regions freshwater resources are particularly vulnerable to projected changes in climate, the consequences of which could be wide-ranging (IPCC 2007a). Assessing prediction uncertainty is therefore particularly important for impacts studies. Planning for the worst case scenario may waste money and resources. Underestimating risk may mean infrastructural damage or even loss of life.

Although the study of climate is a very old science, a systematic analysis of the uncertainties inherent in its prediction was only pioneered in the 1990s. The assessment process has been continually refined and the release to the public of the *United Kingdom Climate Projections 2009* (UKCP09) presents both the first systematic evaluation of the uncertainty associated with climate projections and the first attempt to translate such assessment into impacts studies.

The Met Office Hadley Centre, in the project on *Quantifying Uncertainty in Model Predictions* (QUMP) pioneered the use of systematically designed *Global Climate Model* (GCM) ensembles to explore the uncertainties in climate projections (Murphy/Sexton/Barnett/Jones/Webb/Collins/Stainforth 2004). UKCP09 use data from the QUMP ensemble as well as high resolution regional climate models (RCMs) and a complex statistical post-processing technique to derive probabilistic predictions for changes in several meteorological parameters over the UK on climate timescales.

The methodology developed for UKCP09 is in principle available to use for other regions but it would require running further RCMs and is, as of yet, too expensive and complex to be applied worldwide to every situation of interest. Furthermore, it should be recognized that the uncertainty in climate projections represents only a part, albeit significant, of the uncertainty in the impacts assessment.

The extent of hydrological impacts due to climate change will depend on the dominant hydrological

processes and also on the feedbacks between the hydrological system and the atmosphere. In hydrology, several authors (Beven 2000; Butts/Payne/Kristensen/Madsen 2004) classify the sources of modelling uncertainty into the following main groups: model input (boundary or initial conditions), observational data uncertainty used in the calibration process, sub-optimal parameter values and incomplete or biased model structures. In the hydrological community ensemble modelling has focussed mainly on investigating the effect of parametric and input error (Beven/Freer 2001), and more recently on model structure uncertainty (Butts/Payne/Kristensen/Madsen 2004; Georgakakos/Seo/Gupta/Schaake/Butts 2004). However, a comprehensive and systematic ensemble-based study of all sources of hydrological uncertainty is also extremely complex and computationally demanding. Therefore, the initial focus is on the uncertainties in climate projections, arguably the most significant.

44.4 Nile Basin: A Case Study

The Nile is a crucial resource for the economy of eastern and north-eastern Africa (figure 44.1). Agriculture, energy production and livelihoods in general all depend strongly on the river flow (Adly/Ahmed 2009; Kameri-Mbote/Kindiki 2009). For this reason alone, assessing the impacts that climate change may have on water resources in the Nile Basin is of critical importance (chap. 45 by El Raey).

In this project the UK Met Office regional climate model was run several times using different GCM members to provide driving conditions. This enabled the creation of an ensemble of regional (high resolution) projections, likely to be more informative than a simulation based on a single model scenario. This procedure is not country-specific, so this study of Egypt can be considered as testing a pioneering approach that the UK Met Office is likely to apply in other parts of Africa, in South America and in Asia.

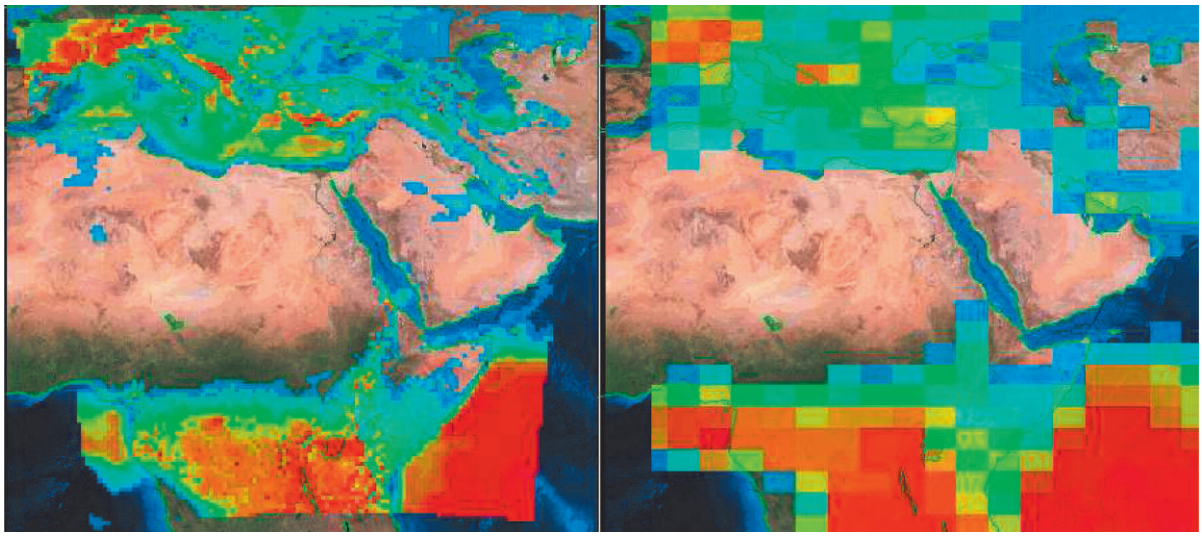
44.4.1 Regional Climate Simulations

Outputs from GCM for a given emissions scenario are provided at a horizontal resolution which is normally too coarse for regional assessments of the impacts of climate change. This is particularly true for water resources, where local effects such as rain shadow and orographic enhancement can be very significant. Therefore different forms of downscaling from climate model scale to hydrological scales are required (Fowler/Blenkinsop/Tebaldi 2007). Here, dynamical downscaling was performed with PRECIS, a modified version of the Met Office Hadley Centre's regional model HadRM3, designed to run on PCs (Jones/Noguer/Hassell/Hudson/Wilson/Jenkins/Mitchell 2004).

Figure 44.1: This satellite image shows the northern portion of the Nile which is being modelled as part of the case study. At the apex of the delta is the Egyptian capital city of Cairo. To the west are the Great Pyramids of Giza. North of here the Nile branches into two distributaries, the Rosetta to the west and the Damietta to the east. Also visible in this image is the Suez Canal, a shipping waterway connecting Port Said on the Mediterranean Sea with the Gulf of Suez. **Source**: courtesy of <nasaimages.org>.

When downscaling dynamically, i.e. with the use of a RCM, particular care needs to be taken with the design of the model domain. If the domain is too small it may prevent the proper internal development of reliable high resolution detail. If the domain is too large it will increase computational expense without adding further information. Over large scales the RCM solution may also diverge from that of the GCM, complicating the interpretation of the climate change projections (Jones/Murphy/Noguer/Keen 1997). In addition, the domain edge should avoid steep topography as the noise generated by interpolation can propagate inside the domain. For this case

Figure 44.2: The rainfall comparison between the regional climate model output and the driving GCM reveals that some significant orographic features are missing in the GCM description. **Source:** Met Office Hadley Centre. ©British Crown Copyright.



study a domain was chosen that extended well beyond the natural border of the Nile basin, (figure 44.2) of the order of 180 x 150 point at 50 km resolution. This was to ensure the area of Blue Nile sources, which account for most of the river runoff, were central to the domain.

44.4.2 Initial Phase: Ensemble Selection and Downscaling

Driving regional climate simulations with different GCM ensemble members is cutting edge technology. As such, the criteria by which to select the most appropriate GCMs is not yet a well-established discipline. Potentially, there are several criteria that could be applied; e.g. maximizing the range of climate change signals, ensuring the best fit to observed climate changes or accurately representing the important aspects of climate variability.

In this project the simplest and most conservative approach was followed. The fit of each GCM member to observations was analysed in a two step process. Firstly a set of climatic processes considered important for the hydrology of the Nile basin were identified. The most important of these were the seasonal cycle of precipitation both over west Africa (west African monsoon) and over the Great Horn of Africa. The Indian monsoon precipitation and temperature along the Nile were also considered. The ensemble members were then ranked according to their ability to reproduce observations of these variables.

The model uncertainty in representing present day climate was sampled as evenly as possible in order to provide the widest possible set of non-discountable alternatives, resulting in five ensemble members being selected to supply boundary conditions to the RCM. This selection process is shown as a flow chart in figure 44.3. Figure 44.4 is a simple comparison between one of the RCM projections and CRU climatology. One of the common problems in assessing the impacts of climate change is the definition of the baseline of past averages against which to compare future projections. It is commonly assumed (Jones/Murphy/Noguer/Keen 1997) that a 30-year period is the minimum needed to capture important aspects of the low frequency variability of the climate. For this study the time-window has been extended to 50 years to better characterisse the natural variability.

In contrast to the UKCP09 which were produced using RCMs with their physics modified to match the GCM they are downscaling, only a single version of the RCM was used for the Nile project. This approach, where different physics are used in the GCM and RCM, corresponds to the standard approach within the international regional modelling community (e.g. as applied in the ENSEMBLES and NARCCAP projects). The advantage of the approach applied here is that it provides a valuable way of assessing the impacts of large scale forcing on the domain of interest. The differences between the five simulations were often large (figures 44.5 and 44.6).

Figure 44.3: Schematic layout of the project: **Source:** Met Office Hadley Centre. ©British Crown Copyright.

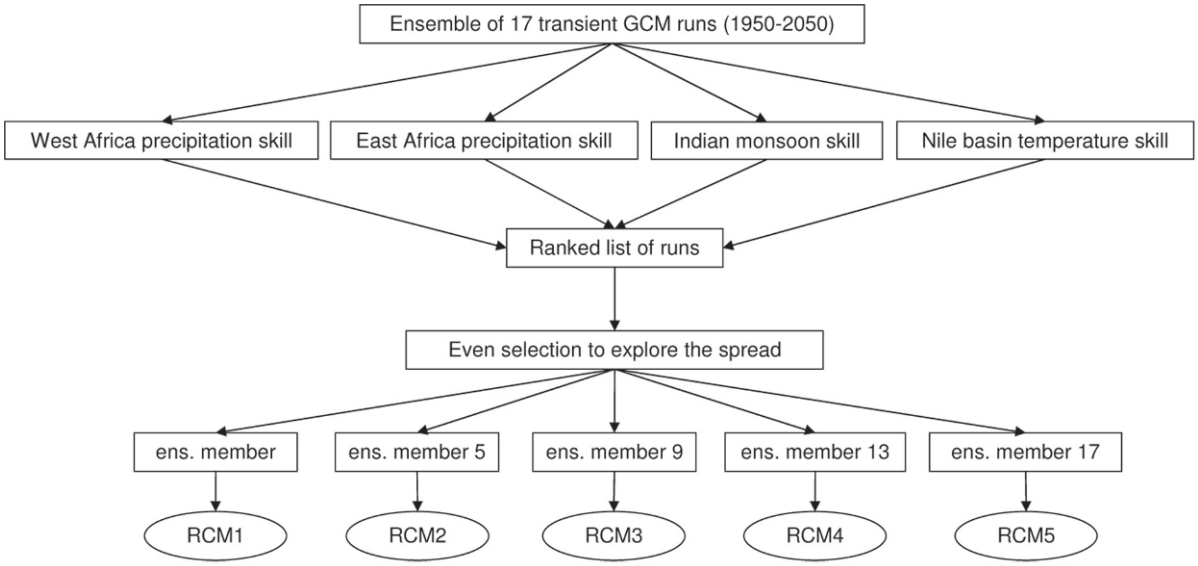


Figure 44.4: Comparison between one of the five regional climate model simulations (left) and the climatology (CRU) for June, July and August. Excluding the sea for which CRU does not provide data the comparison appears to be reasonable. There are two main areas of discrepancies: the Gulf of Guinea and the west Arabic peninsula. In the East African Highlands, where the Blue Nile source is located, the comparison for this specific ensemble member seems to be in very good agreement with CRU datasets. Both datasets, here plotted with the same colour scale, represent a 30-years average: **Source:** Met Office Hadley Centre © British Crown copyright.

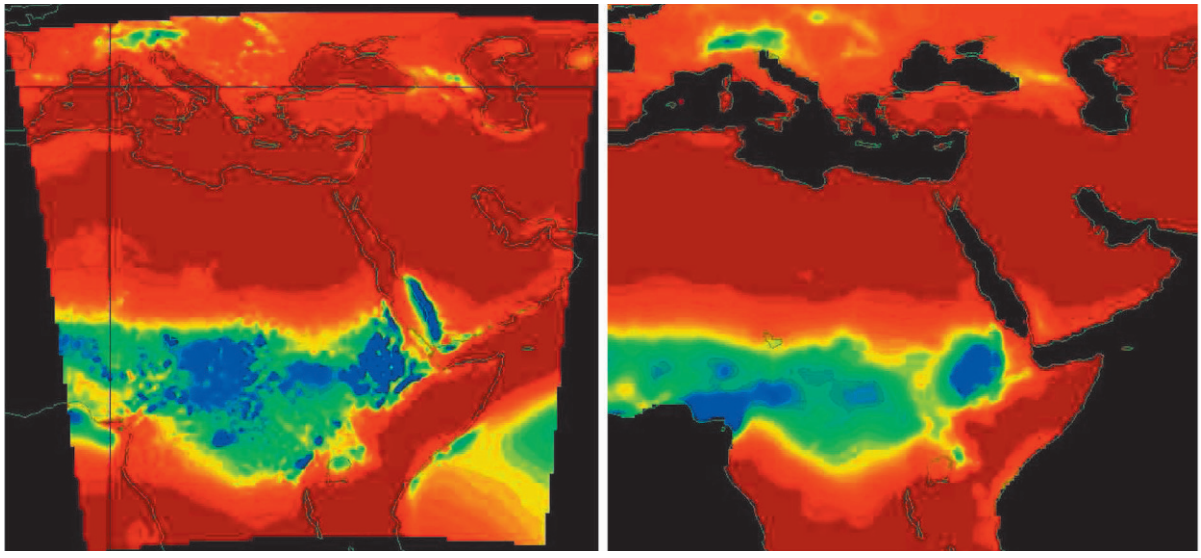


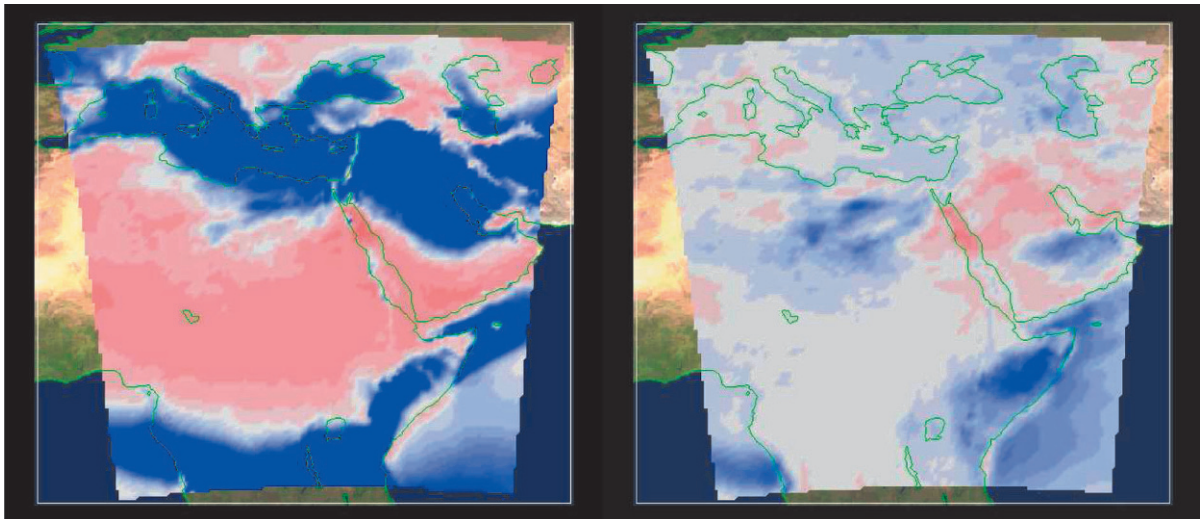
The discrepancies are only attributable to differences in the large scale forcing from the GCM since the processes within the RCM domain are represented in the same way in all experiments. Basing an adaptation strategy on a single run, as on a single model study, is not recommended.

44.4.3 Second Stage: Coupling Regional Climate Projections With a Basin-wide Hydrological Model

While the 50 km resolution used in the regional simulations may provide an accurate representation of the climate processes, the hydrological processes often need to be represented at a smaller scale.

Figure 44.5: Monthly temperature and precipitation for different ensemble members. The symbols and error bars represent the 30-year average and standard deviation of the observations averaged over the entire Nile Basin area, for the period 1961-1990. The coloured lines represent the 30-year average climate data from the 5 GCM ensemble members used in this study, averaged over the same period. **Source:** Met Office Hadley Centre. ©British Crown Copyright.

In certain areas such as southern Africa and the Mediterranean the difference between the two simulations can be as large as a factor of 10. **Source:** Met Office Hadley Centre. ©British Crown Copyright.



In order to provide an estimate of the impact of climate change on the inflow into the High Aswan Dam a basin wide (5 km) gridded model was adopted. This model, currently used operationally at the Nile Forecasting Centre, takes as input the information provided by rain gauges and satellites to calculate the run-off (MWRI, Nile Forecasting System, Version 5.1, 2007).

This case study focuses on uncertainties in the regional climate response to global climate change, not uncertainties in emissions scenarios. Therefore only the SRES_A1B scenario is considered here[2].

To couple the regional climate model with the hydrological model, a simple change factor will be implemented. Using 50 years of data (1950–2000) a baseline reference of monthly precipitation totals and monthly evaporation totals will be calculated. These values will be compared with those obtained by analysing RCM output for the period 2020–2050. For each month, for each ensemble member, a multiplicative change factor will then be calculated. These factors will then be used to modify present day daily time series and consequently generate synthetic time series representative of future conditions. The *Nile Forecasting System* (NFS) can then be run using the modified

2 Anthropogenic climate change is directly controlled by the atmospheric concentration of greenhouse gases. By 2050s A1B and A2 scenario appear to be almost identical.

timeseries as an input. These estimates of Nile runoff will then be compared with those predicted by NFS for present day conditions in order to extract the climate change effect.

44.5 Conclusions

Due to the limited resolution of the current generation of global climate models a downscaling step is often needed in order to assess the impacts of climate change. Different techniques ranging from the statistical to the dynamical can be used to perform this operation. Independent of the particular technique adopted, it is fundamental to take into consideration the uncertainties associated with the climate projections. In the Nile project we followed a new methodology developed at the UK Met Office Hadley Centre to assess the uncertainty associated with the climate model formulation. Five global model runs were selected based on model performance from an ensemble of seventeen transient runs (IPCC A1B scenario) to drive a regional climate model for the Nile basin. The project, which will provide the MWRI of Egypt with an up-to-date assessment of the impacts climate change may have on Nile runoff, has already had influence on the design of other projects. The interim results of the regional climate modelling seem to suggest the existence of very significant differences between different simulations. These differences are solely due to the way the GCM is formulated, already considered to be the main source of uncertainty for near-term (e.g. 2030s-2050s) climate projections (Cox/Stephenson 2006). On longer time scales the forcing uncertainty will be the dominant factor while on the seasonal to decadal range uncertainty due to climate variability is likely to constitute the largest component of the overall uncertainty.

Well-established methods for choosing among the different projections do not yet exist. In the next few years it may become possible to extend the complex statistical techniques developed for the UKCP09 to other countries. At present the methodology adopted for the Nile project represents a simple and effective way of taking into consideration model uncertainty in the assessment of regional climate change impacts.

45 Mapping Areas Affected by Sea-Level Rise due to Climate Change in the Nile Delta Until 2100

Mohamed El Raey

45.1 Introduction

This chapter offers a general survey of the physical characteristics and importance of the Nile Delta region of Egypt and of the vulnerability to potential impacts of climate change. The relatively low land elevation, increasing soil salinity due to salt water intrusion and the low resilience of the communities makes this region highly vulnerable to potential impacts of climate change. A vulnerability assessment based on a mapping of hot spots using remote sensing and GIS technologies is introduced. The main objective is to identify and quantify potential biophysical and socio-economic losses according to various sea-level scenarios taking into consideration the well known delta subsidence rates. Results indicate high risks of direct inundation, salt water intrusion and socio-economic losses and call for proactive integrated planning for development of the coastal zone. The shortage of institutional capabilities, weak law enforcement and low population awareness are additional pressures that need to be addressed.

The large scale implications of climate change impacts on all sectors of human development have been well recognized by most countries and research institutions (e.g. IPCC 2007; Stern 2006; chap. 79 by Parry/Canziani/Palutikof/Hanson). Impacts vary over a wide range of induced changes of the ecosystems. Melting of polar caps, sea-level rise and increase of the intensity and frequency of extreme weather events and their biophysical and socio-economic implications are only few examples. Climatic changes cause a disaster for the global economy and human well-being, however, with some kind of early warning.

According to the studies assessed by the *Intergovernmental Panel on Climate Change* (IPCC), it was realized that human activities have led to a rise in the average earth's temperature by 0.74 degrees C since the late 1800's. It is projected to increase by another 2.0 °C to 4 °C by the year 2100. This rapid and continuous rise in the earth's average temperature has been traced to the increase in greenhouse gases in the earth's atmosphere. This rapid increase of the mean average global temperatures has actually been well observed and is expected to continue for several decades with high levels of certainty. In addition, the increase of temperature is expected to lead to a melting of a large portion of the polar cap as well as a huge expansion of deep ocean water. A world wide sea-level rise between 18 and 59 cm was projected by IPCC (2007) by the end of the present century. According to the synthesis report of the *Copenhagen Scientific Climate Conference* (2009: 10), "new estimates suggest a sea-level rise of around a metre or more by 2100."[1]

The continuous increase of temperature is expected to lead to changes of precipitation levels, which will then lead to shortages of water availability, deterioration of agricultural productivity and loss of coastal sustainability. Global circulation models have been trying to predict expected climatic conditions with reasonable certainty to warrant decisions.

The potential impact of sea-level rise over low elevation deltaic and coastal areas is expected to be very serious and includes direct and indirect inundation of beaches as well as salt water intrusion which is expected to lead to long range damage to urban systems as well as changes of agricultural productivity and public health. It is also predicted that the increases of

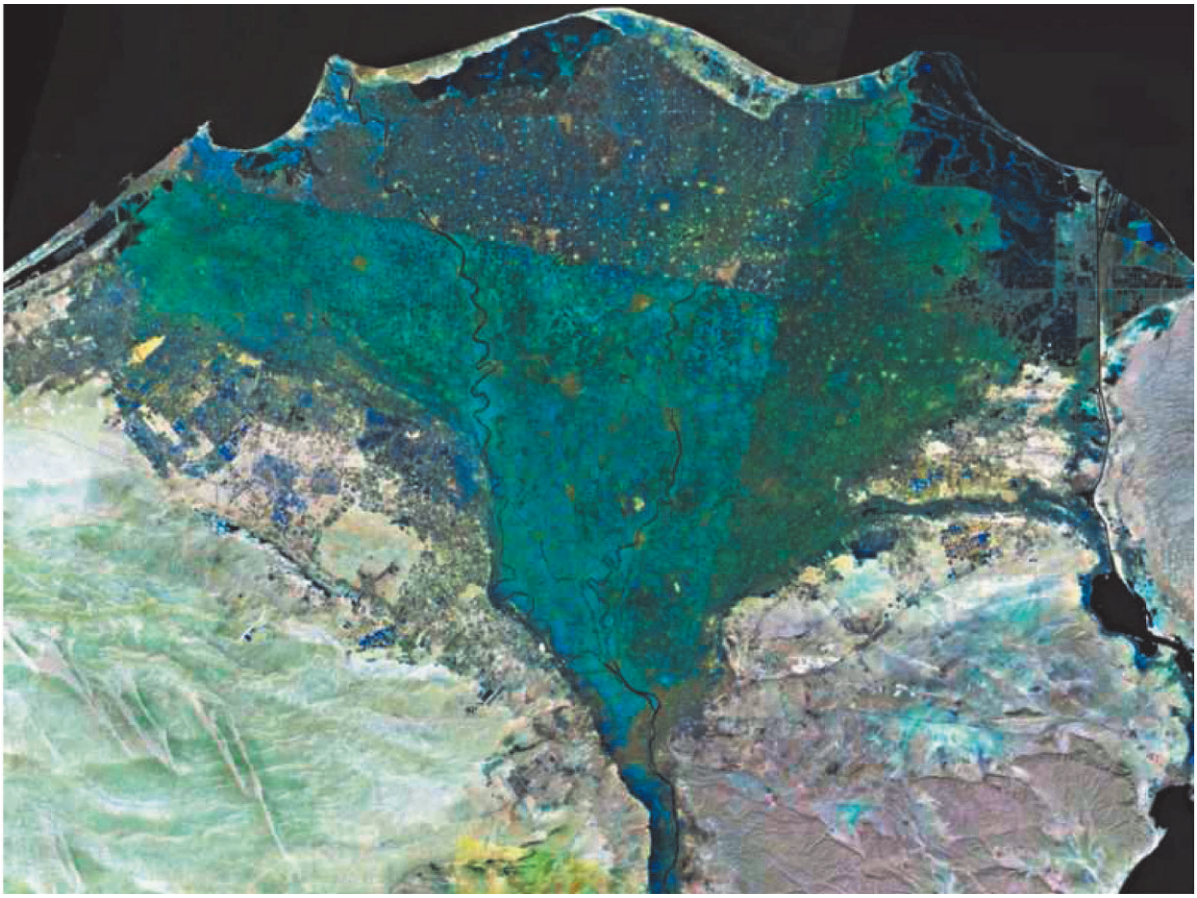
mean average temperatures will be associated with an increase of the intensity and frequency of extreme events such as dust storms, sand storms, heat waves and flash floods. The damage caused by the increase of intensities and frequencies of extreme events will also include agricultural productivity, maritime transport, and damages to property and health.

Egypt is characterized by an arid to semi-arid environment and low community resilience represented by limited water resources and technical capacity. The high population growth rate and the rapid spread of unplanned urbanization are main causes of concern due to the resultant increase in air and water pollution. The rise in temperature is expected to further exacerbate the dearth in water resources, increase the pressure on land resources and lead to a rise in the severity of sand and dust storms. The increased usage of fertilizers and pesticides is also expected to increase the rates of water and food pollution (figure 45.1).

The Nile Delta is 200 km long and 255 km wide, within a coastline of over 1000 km on the Mediterranean Sea. The low sandy coast of the Nile Delta stretches with an arc between Ras Abu Quir to the west and the Bay of Tinah, to the east (figures 45.1 and 45.2). Two branches of the Nile have formed the promontories at Rosetta and Damietta. Egypt's second largest city, Alexandria is located on the northwestern part of the coastal delta zone, with a population of 3.3 million in 1996, and more than 4.1 million in 2006 (CAPMAS 2006 census). Alexandria is the main harbour of Egypt and hosts around 40 per cent of the country's industrial capacity, in addition to being an important summer resort and trading centre. Other large cities in the northern, low-lying delta zone include the rapidly growing city of Damietta and the historic city of Rosetta and Port Said City to the eastern side of the delta.

The northern Egyptian lagoons are among the most productive natural systems in Egypt and they are internationally renowned for their abundant bird life.

Figure 45.2: Satellite Image of Nile Delta. **Source:** Landsat 7 false colour image of the Nile Delta; this image by NASA is in the public domain; at: <http://commons.wikimedia.org/wiki/File:Nile_delta_landsat_false_color.jpg>.



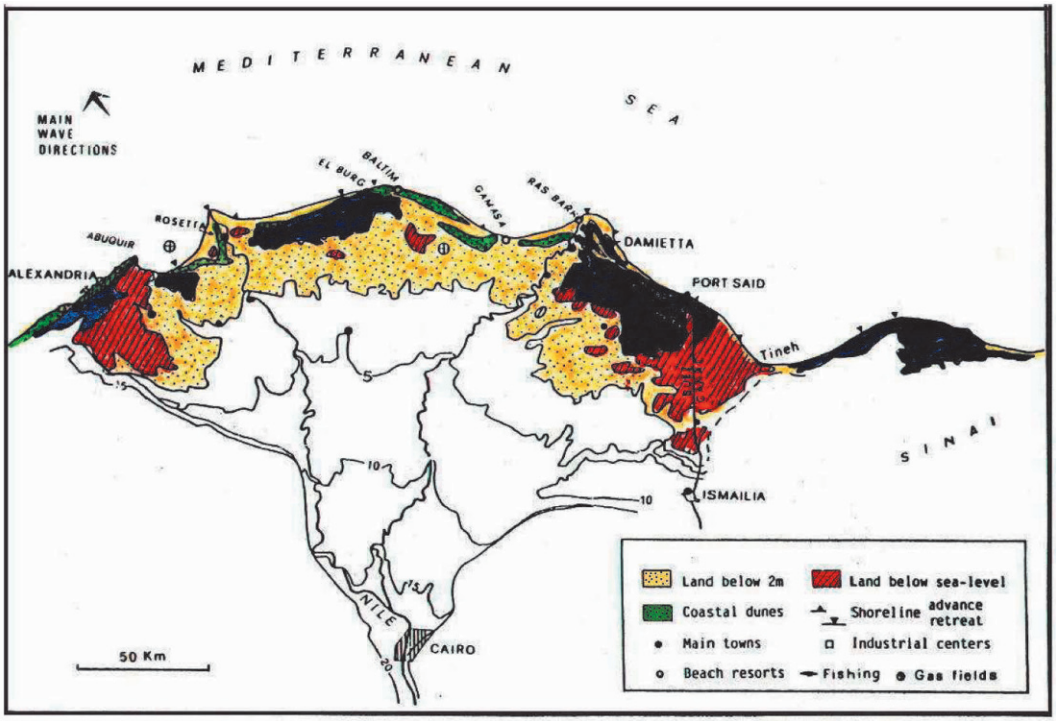
These northern lakes constitute about 25 per cent of the total Mediterranean wetlands and are responsible for the production of over 60 per cent of the fish catch of the country. Since the lakes are relatively shallow, climate change can lead to an increase in water temperature, which could result in changes in the lake ecosystems as well as changes in its yield.

Tourism, industry, agriculture and service sectors are significant contributors to Egypt's economy. Tourism currently represents 11.3 per cent of GDP, 40 per cent of the total of Egypt's non-commodity exports and 19.3 per cent of Egypt's foreign currency revenues. The industrial sector's contribution to the GDP in 2006/07 was around 17.2 per cent. The agriculture sector accounts for roughly 14.8 per cent of the GDP. Agriculture contributes about 30 per cent to Egypt's commodity exports, which makes it a major revenue-generator. Of Egypt's overall labour force, 30 per cent works in the agricultural sector, mostly in the Nile Delta (Egypt Initial National Communication 1999).

Economic conditions in Egypt have improved considerably over the years. In 1990–1991, the real GDP growth rate was 3.7 per cent. By the end of fiscal year of 1998, the growth rate reached 5 per cent, fuelled primarily by private sector investments through a continued rapid privatization and institution-building. Results of the economic and financial performance indicated a great improvement during FY 2006/2007 and first quarter of FY 2007–2008. Egypt's economy achieved a growth rate of 7.1 per cent, which is the highest growth rate in the preceding 10-year period. However, despite these patterns, the failure to raise living standards for the average Egyptian has led to continued government subsidies for basic needs and, consequently, a sizeable budget deficit of roughly 7 per cent of GDP in 2007–2008.

Egypt's Human Development Report (UNDP 2004b) reports a positive response to concerted efforts by the GOE to reduce two major gaps: 1) the gender gap, and 2) the gap between Lower and Upper Egypt. The gender gap reduction is clearly reflected in

Figure 45.3: Contour map of the Nile delta region indicating areas of the delta below sea-level (in red), the 2m contour and below in yellow. **Source:** Sestini (1991) with modifications by El Raey.



improvements in the education index; however, deficits in political empowerment and in economic participation still persist. The gap in the Human Development Index (HDI) values between Lower Egypt and Upper Egypt remains large but has also started to narrow during the last decade.

The objective of this chapter is to survey the methodology used to map vulnerable areas and to assess the potential impacts of sea-level rise and to present results an estimate of the costs of the impacts of the projected sea-level rise based on several scenarios. It identifies gaps of our knowledge and responds to questions on future needs for upgrading institutional capabilities, integrating monitoring and research efforts, transferring technologies and upgrading community resilience.[2]

45.2 The Nile Delta Region

The Nile delta region is fairly unique in the distribution of its population, topography, land-use, agricultural productivity and economic activities, which makes it extremely vulnerable to any potential impacts on its water resources and coastal zone. The River Nile supplies 95 per cent of the country's total water needs, including water intensive irrigated agricultural land along its banks and the delta. Agriculture is quite critical to the national economy as it employs 30 per cent of the work force and contributes 17 per cent to the GNP (IDSC 2009). Major urban centres, commerce, and industrial activities are also confined to the narrow corridor along the Nile and the coast around its delta. The rest of the country (about 95 per cent) is desert and does not support much population or economic activity (figure 45.3).

The Nile Delta region lies within the temperature zone, which is a part of the great desert belt. The average temperatures in January and July in Cairo are 12 °C and 31 °C, respecttively. Minimum and maximum temperatures in Cairo are 3 °C and 48 °C, respectively. Rainfall over the Nile Delta is rare and occurs in winter. Maximum average rainfall along the Mediterranean Sea shore, where most of the rain occurs, is about 180 mm. This amount decreases very

2 For additional publications of this author on this topic see i.a., Agrawala, Moehner, El Raey, Conway, van Aalst, Hagenstad and Smith (2004); El Raey (1991, 1993, 1994, 2000); El Raey, Ahmed and Korany (1997); El Raey, Frihy, Nasr and Dewidar (1998, 1999); El Raey, Nasr, Frihy, Desouki and Dewidar (1995); El Raey, Ahmed and Korany (1997); El Raey, Nasr, Frihy, Fouda, El Hattab, Elbadawy, Shalaby and Mohamed (2005)

Table 45.1: Population and rates of population growth of major coastal cities of the Nile delta. **Source:** Human Development Report (UNDP 2005).

	Population (thousands)			Annual population growth rate		
	1986	1996	2003	1960/86	1986/96	1996/03
Alexandria	2 927	3 339.1	3 755.9		1.3	1.7
Port Said	401	472.3	529.7	1.9	1.6	1.7

Damietta	740	913.6	1 056.4	2.5	2.1	2.1
Egypt	48 254	59 116.8	68 648.0	2.4	2.1	2.2

rapidly inland to about 26 mm in Cairo (Sherif/Al Rashed 2001). The Nile delta region is the most fertile land of Egypt which depends mainly on water that reaches the region through the River Nile with resources on the Ethiopian hills and Lake Victoria some several thousand kilometres to the south (Sestini 1991; Adly/Ahmed 2009; Kameri-Mbote/Kindiki 2009).

The Nile delta coast stretches about 300 km and hosts a number of highly populated deltaic cities such as Alexandria, Port-Said, Rosetta, and Damietta. These cities are also critical centres of industrial and economic activity. In addition, the Nile delta coastal zone includes a large portion of the most fertile low land of Egypt. The topography is generally sloping from the apex at Cairo to the Mediterranean coast at a rate of about 1 m/km with varying sand dunes, ridges and low elevation areas near the coast. The coastal zone of Egypt hosts five northern lakes which constitute about 25 per cent of the wetland of the Mediterranean and are considered main sanctuaries for birds and fish resources.

45.2.1 Population

The population of Egypt has grown 2.0 per cent per year for the past 10 years reaching 72.6 million according to the 2006 census. The growth rate was about 2.1 per cent during the previous decade. In the period from 1976 to 1986 growth reached 2.8 per cent a year. Population growth in urban areas was 22.4 per cent over a decade, only slightly above 22.2 per cent for the growth in rural areas, where 58 per cent of Egyptians still live. Emigration helped to hold down the rate of population growth at home. According to the 2006 census, 3.9 million Egyptians are living abroad. With the Egyptians abroad and those living in Egypt the total population is 76.5 million people, compared with 61.5 million in 1996. The percentage of illiterates among Egyptians aged 10 or older had fallen to 29.3 per cent, from 39.4 per cent in 1996 (CAPMAS 2006).[3]

45.2.2 Land Use

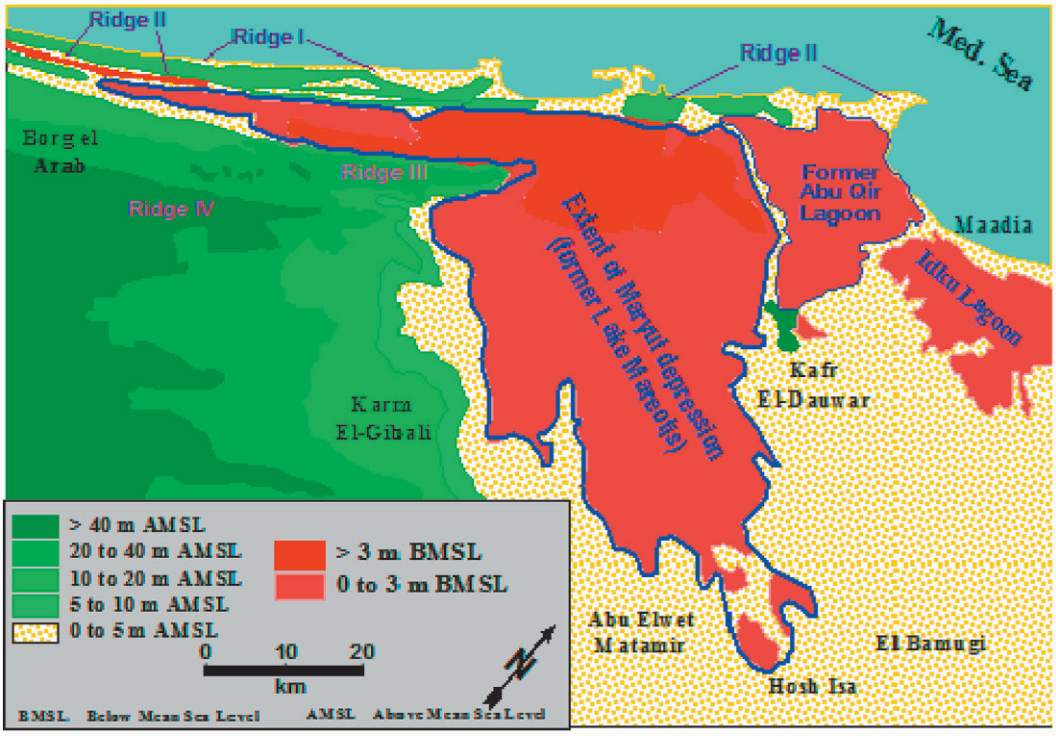
Unplanned urbanization in many coastal and non-coastal cities has been responsible for the creation and expansion of slum areas around major cities. In the absence of strong institutional systems for monitoring, assessment and enforcement of land use regulations, land use plans are not expected to be fulfilled and strong interference of land use is well observed in major coastal cities such as Alexandria, Damietta and Port Said. In fact, most of the land located below sea-level rise is fully occupied by urban settlements, industries and agricultural land.

45.2.3 Topography

The topography of the delta varies from about 200 m elevation at Cairo at the apex of the delta to near zero on the Mediterranean some 200 kilometers to the north. The northern region of the delta hosts several important lakes such as Lake Maryut, Lake Edku, Lake Brullus and Lake Manzala. The wet lands of northern Egypt constitute about 25 per cent of the total wetland of the Mediterranean and provide over 66 per cent of the fish catch of the country. The topography of the northern coast is highly variable. Figure 45.4 shows the major part of the area below sea-level to the south eastern part of Alexandria near Abu Qir Bay. The Mohamed Ali Sea wall with a length of 10 km that was built over 200 years ago protects the low land area from inundation from the water of the Abu Qir Bay.

3 The estimates of Egypt's population and population density (1950–2050) by the Population Division of the UN are accessible at: <http://esa.un.org/unpp>.

Figure 45.4: The topography of the area to the east of Alexandria City indicating areas below sea-level (in red). **Source:** US Defence Mapping Agency (1961, 1973, 1975, 1977).



45.2.4 Subsidence

The eastern part of Lake Manzala (Port Said and the northern part of the Suez Canal) appears to subside at a rate of 4.5 mm yr-1 (Stanley/Warne 1993), faster than any other region along the Nile Delta coast. The *sea-level rise* (SLR) is expected to cause a landward shift of the salt wedge and to increase the rate of saline seepage to the topsoil of the delta. This may have serious impacts on agriculture and drainage conditions, and potentially on available groundwater resources in the upper Nile Delta. Accelerated SLR will enhance the increase in salinity. Combined with the notion that it is unlikely that the lake will expand inland (as protection measures will be taken), this leads to the general prediction that shallow wetland areas will decrease and that the reed beds will become less abundant (due to higher salinity).

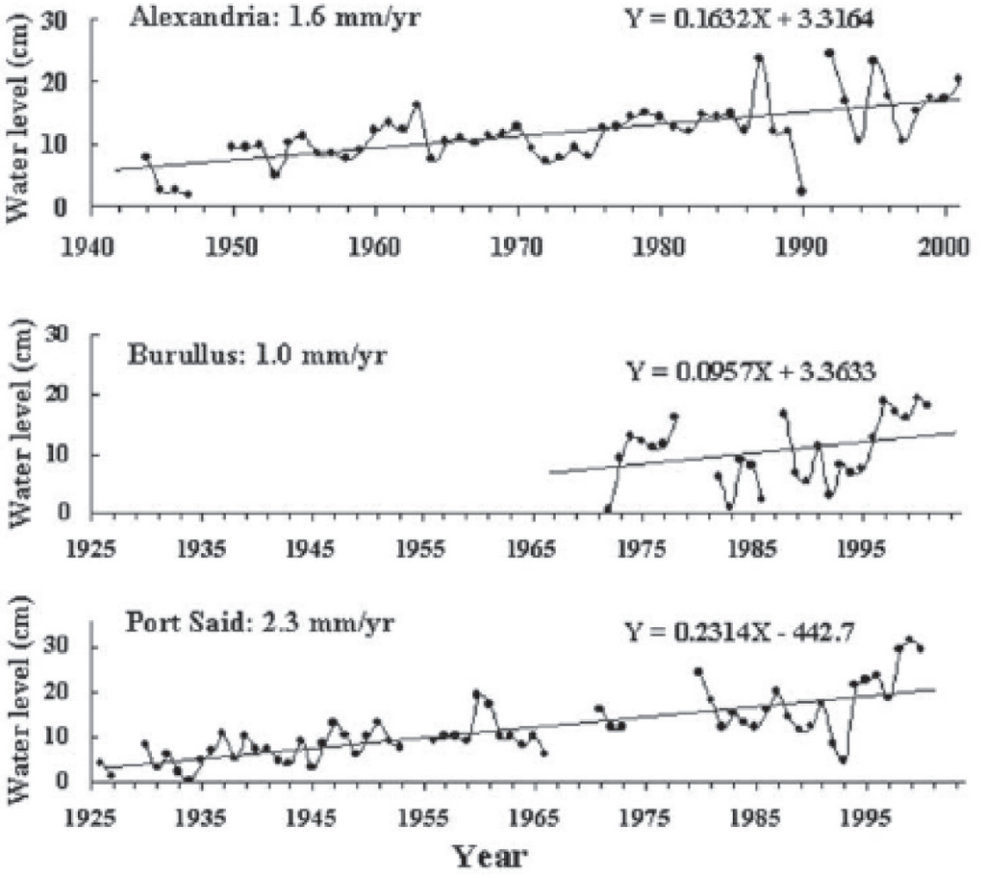
45.2.5 Beach Erosion

The projections of the Nile Delta promontories Rosetta and Damietta are currently undergoing extensive change due to both natural and anthropogenic pressures. The highest rate of erosion occurs along the outer margins of these promontories. This erosion is a result of the combined effects of the cut-off of the River Nile sediment discharge by the Aswan High Dam and prevailing coastal processes. Erosion along the tip of the Damietta promontory has adversely affected homes and condominiums to the east at Ras El Bar, and it has destroyed the old coastal road from Damietta to Port Said and the lighthouse west of the river (Frihy/El Raey/Dewidar 1996). However, a number of protective structures have been constructed by the Egyptian authorities along this projection to reduce shoaling in the river entrance. The *sea-level rise* (SLR) is expected to enhance the rates of erosion.

45.2.6 Pollution

The western and southern sectors of Lake Manzala are supplied by drainage water from 7 main sources. Water from these drains enriches the lake with nutrients, including phosphate, nitrate, and silicate. In addition, some of these drains discharge considerable amounts of sewage and industrial wastes directly into the lake. The Ginka sub basin in the south-eastern sector of the lake is identified as a 'black spot'. SLR is

Figure 45.5: Water level variation at three Nile delta coastal locations indicating land subsidence. **Source**: Frihy (2003: 125) reproduced with permission of the author.



expected to enhance diffusion in the coastal area and magnify the adverse effects of this pollution.

45.2.7 Resilience

The risk associated with the SLR is related to hazard, vulnerability and resilience through:

Risk = Hazard x Vulnerability/Resilience of the community

It is quite clear that to reduce the risks of SLR, it is necessary to upgrade the low resilience of the population in the region. The resilience of the coastal community in the Nile delta region is considered very low not only because of the low education and awareness but also because of the shortage of institutional capabilities and low infrastructure in the region. The vulnerable community consists mostly of farmers, fishermen and industrial workers. The increasing rates of unemployment and low awareness increase the problem further.

45.3 Climate Change and Sea-Level Rise

There are conflicting projections of the future availability of the water of the Nile as a result of climate change. Yates and Strzepek (1998), using a monthly water balance model, reported that five of six *global circulation models* (GCMs) showed for doubled CO_2 levels increased flows at Aswan, with increases of as much as 137 per cent (UKMO). Only one GCM (GFDLT) showed a decline in annual discharge at Aswan (-15 per cent). The variations of the results indicate that more robust studies are needed to provide a more solid base for the design of public policy. However, the more plausible projections seem to point to a reduced availability of Nile water for Egypt in the future. In addition, Elshamy, Seierstad and Sorteberg (2009) confirmed this strong uncertainty using 17 IPCC models. This global sea-level rise combined with local land subsidence in many coastal areas, are expected to cause serious damage to many coastal ec-

osystems especially those of the low land deltaic coasts such as that of the Nile Delta in Egypt.

An overview of uncertainties of climate changes associated with the River Nile is presented in chap. 44 by Buontempo, Lørup, Sanderson, Butts, Palin, McCarthy, Jones, Betts and Antar.

45.3.1 Impacts of Sea-Level Rise on the Nile Delta

The impact of SLR on the Nile Delta can be divided into direct impacts of inundation and salt water intrusion and indirect impacts of loss of productivity, excessive soil salinity, health impacts and socio-economic implications.

45.3.1.1 Direct Impacts on Low Elevation Land in Cities

The IPCC's (1995) *second assessment report* (SAR) has adopted a seven step common methodology for estimating vulnerabilities to sea-level rise which could be summarized as:

1. Choose a case study area and specify climate change boundary conditions;
2. Characterize a case study area (physical, socio-economic);
3. Identify key vulnerabilities (tourism, oil sector development, etc.);
4. Assess physical changes and natural system responses;
5. Formulate response strategies;
6. Assess vulnerability and interpret results;
7. Identify needs and actions.

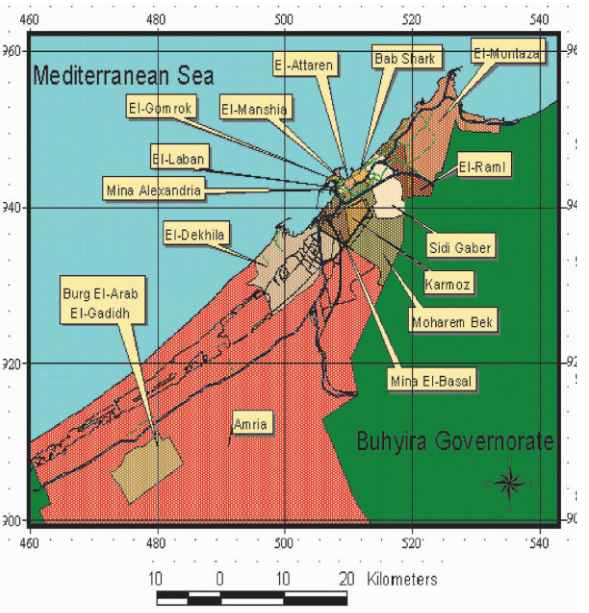
However, the IPCC's (2001, 2001a, 2001b, 2001c) *third assessment report* (TAR) suggested an expanded framework, based on the work of Klein and Nicholls (1999) as well as of Nicholls and Mimura (1998) for sea-level rise assessment that also examines resilience, resistance and adaptation aspects within linkages between natural and socio-economic systems.

45.3.1.2 Methodology of the Assessment

The methodology used by this author's team for estimating the potential impact of sea-level rise is based on using satellite images and GIS and can be summarized as follows for each scenario of sea-level rise:

1. Selecting and characterizing the study area and identifying key vulnerabilities;
2. Carrying out land-use classification of satellite images of the region identifying land cover and land use to the best accuracy available; and building a geographic information system of layers of land cover and land use and population distribution;
3. Building up a *digital elevation model* (DEM) based on the available topographic data on the area with a resolution of 1.0 m or better;
4. Registering and overlaying classified images to the DEM identifying vulnerable areas below the pre-assigned scenario;
5. Extrapolating population growth and distribution in these areas based on the maps;
6. Estimating loss of jobs based on distribution of the work force among sectors for each district; and
7. Identifying options of adaptation and policies and measures for protection and adaptation.

Figure 45.8: A map of Alexandria districts and Lake Maryut. The water surface of the lake is kept at 2.8m below sea-level by a set of pumping stations at El Mex. **Source:** This official map is in the public domain.



(a) Alexandria sub-districts

The output of this process depends on the resolution of the satellite image, the accuracy of available topographic data and the accuracy of the estimated distribution of the work force. The availability of higher resolution satellite imagery and more accurate topographic data will definitely contribute to a better accuracy of estimated impacts. The methodology was applied for several coastal cities, however, in this chapter the case of Alexandria will be considered in somewhat more detail.

45.3.1.3 Alexandria City

Alexandria city is located to the west of the Rosetta branch of the River Nile and is famous for its beaches as well as for its historic and archaeological sites. It has a population of about four million and hosts the largest harbour in the country as well as roughly 40 per cent of the Egyptian industrial activities. During summer, the city attracts over a million tourists. The extension of the city to the south is impeded by the existence of a large water body: Lake Maryut (figure 45.8). The water level in Lake Maryut is kept at 2.8 m below the sea-level through continuous pumping of water into the Mediterranean through the El Mex pumping station.

Figure 45.9: The main topographic features of Alexandria City indicating major ridges or hills (in dark black) and tunnels in between. **Source:** Abdel Hakim, Sobhy (1958); Alexandria City (Alexandria Library 1958).

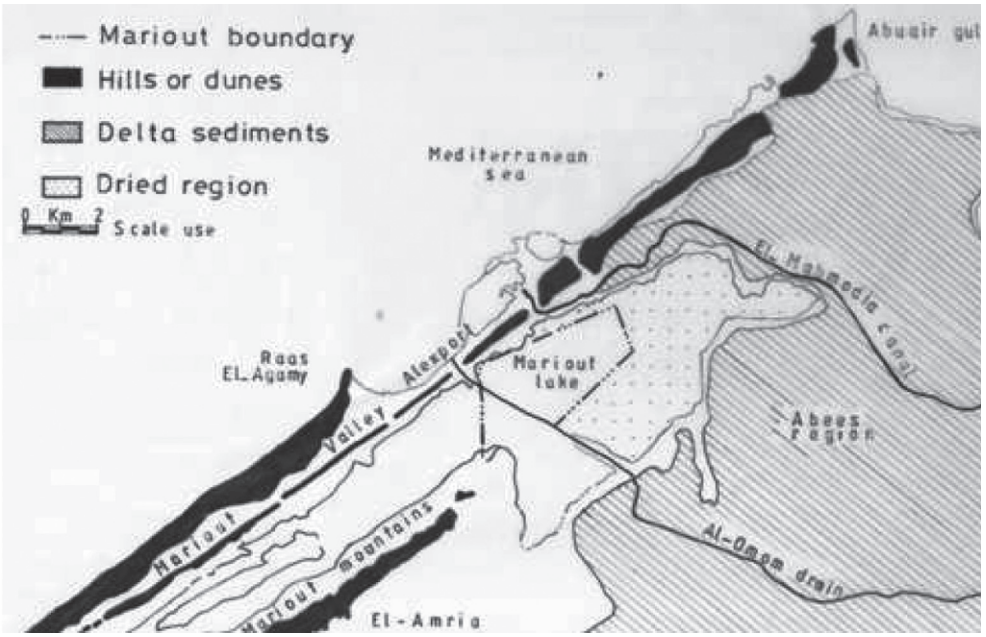


Figure 45.10: Land cover and land use of Alexandria City as observed based on an analysis of satellite images. **Source:** Al Hosaini (2006).

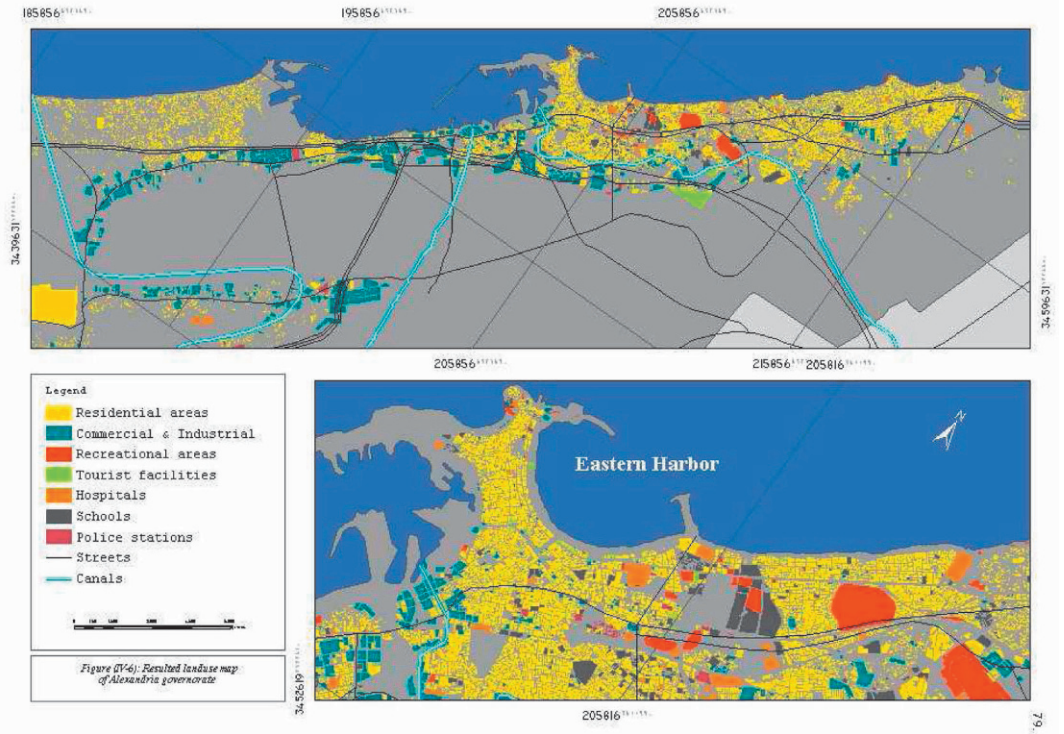
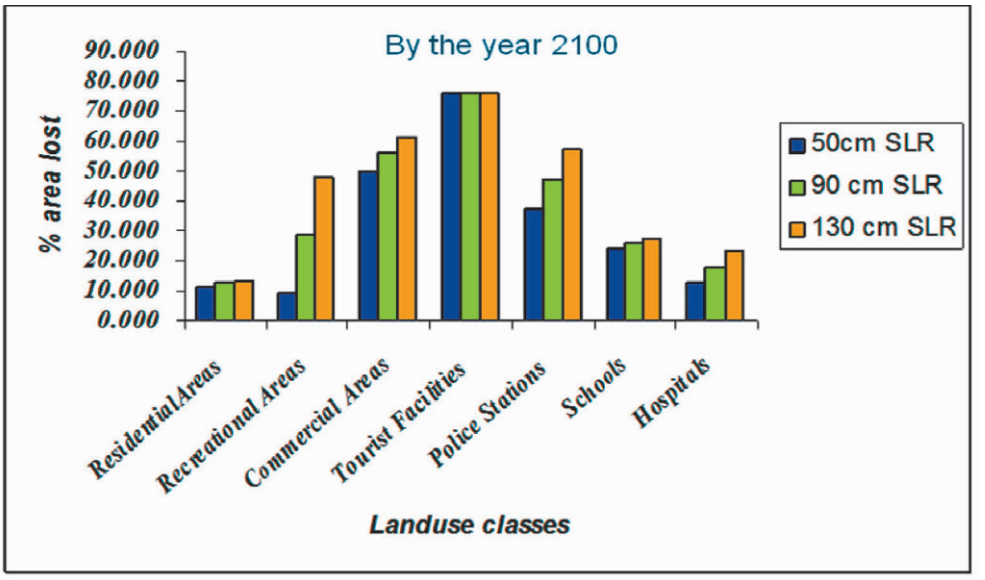


In order to assess the impacts of sea-level rise on Alexandria, a *Geographic Information System* (GIS) was created using the ARC/INFO environment. The GIS included land use layers as obtained from satellite images, a *digital elevation model* (DEM) and extrapolated data on population distribution. To assess the impacts from *sea-level rise* (SLR), a number of scenarios were assumed over the century (0.25, 0.5,

Figure 45.11: Percentage land-use to be affected by scenarios of sea-level rise in Alexandria. **Source:** Al Hosaini (2006).



1.0 m), taking land subsidence (2.0 mm/a) into consideration. Then, the percentage of the population and land use areas at risk for each scenario level were identified and quantified by the GIS analysis.

The outcomes for each SLR scenario in case of a 'business as usual' have been extrapolated to assess the potential loss of employment for each sector for the years 2010, 2025 and 2050, if no action is taken. Analyses of the results indicate that for a SLR of 0.5 m a sizable fraction of the low land inside the city will be inundated unless actions are taken for protection. It will lead to the loss of a number of touristic beaches and flooding of some agricultural and industrial areas. Also, over 1.5 million people will have to be relocated. Other expected losses include 195,000 jobs as well as land, properties and revenues in the range of US$ 30 billion. The loss of the cultural heritage is not being accounted for. These results are based upon an extrapolation of current national statistics, and are only intended as estimates of an order of magnitude. The results in table 45.2 indicate that the most severely affected employment sector will be industry, followed by tourism and agriculture. Fortunately, Alexandria Corniche was built for the purpose of better traffic flow which helped at the same time to protect a major part of the city from the potential impacts of SLR.

Table 45.2: Results of estimation of the impact of sea-level rise over Alexandria based on a scenario of SLR, if no action is taken. **Source:** El Raey, Fouda and Nasr (1997).

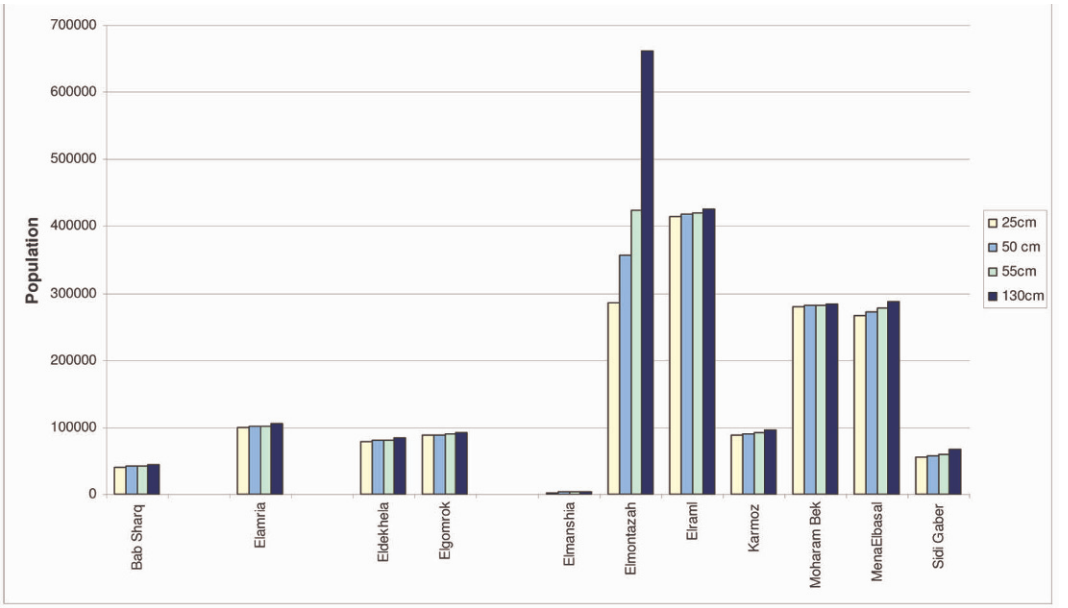
Year / Sector	**Year 2010 SLR = 18 cm**	**Year 2025 SLR= 30 cm**	**Year2050 SLR= 50 cm**
Area loss (km^2)	1.14	19.0	31.7
Population displaced x 1000	252	545	1.512
Loss of employment			
a- Agriculture	1.370	3.205	8.812
b-Tourism	5.737	12.323	33.919
c- Industry	24.400	54.936	151.200
Total loss of Employment	32.507	70.465	195.443

45.3.1.4 Rosetta City and Region

Rosetta city is a well-known Pharaonic and Islamic city located near the intersection of the Rosetta branch of the River Nile with the Mediterranean Sea east of Alexandria. Excessive erosion rates have been observed near the Rosetta promontory, due to the cessation of sediments following the building of the High Dam on the River Nile about 1000 km to the south. The region surrounding the city is well known for its water-logging and water-bogging problems.

Similar to Alexandria, a quantitative vulnerability assessment of the potential impacts of sea-level rise has also been carried out for Rosetta (El Raey/Dewidar/El-Hattab 1999: El Raey/Fouda/Gal 2000). For a sea-level rise of 0.5 m, the study estimated the loss of about one-third of its employment as well as the loss of US$ 2.9 billion (value of 1990) from land and property. As in the Alexandria study, the loss of

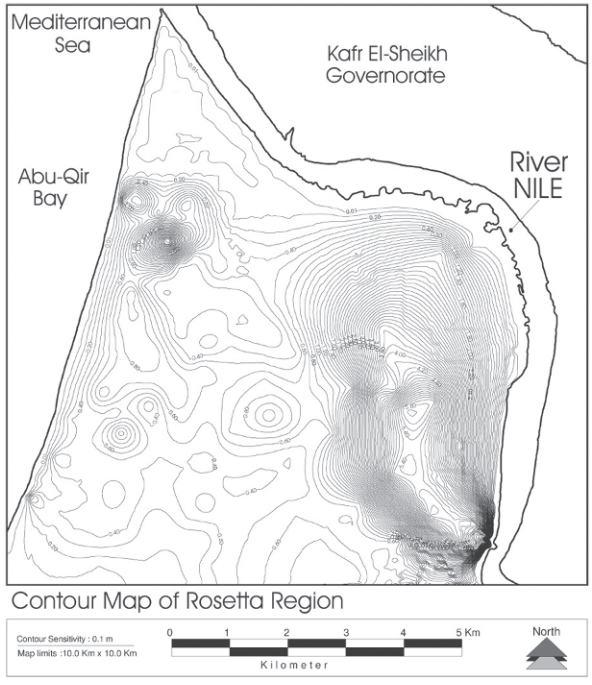
Figure 45.12: Loss of employment in each district of Alexandria City by various scenarios of sea-level rise. **Source:** Al Hosaini (2006).



historic and archaeological sites is unaccounted for. In addition, erosion problems are expected to be exacerbated by sea-level rise. So far, the Government has built a massive sea wall near the tip of the promontory as a protective measure against already existing erosion problems. However, recent observations indicate that this massive hard structure is seriously challenged by coastal erosion. Periodic beach nourishment may be a possible solution. However, plans for the development of the area should consider an approach in which decision-making is based on a detailed assessment of future conditions taking into consideration potential impacts of sea level rise.

A rise of 50 cm in the water level will result in a gradual loss of large coastal areas and a destruction of a large portion of Rosetta's historic Islamic heritage as well as flooding of a large portion of the agricultural land adjacent to the coast and the loss of 30,000 future employment opportunities (figure 45.13).

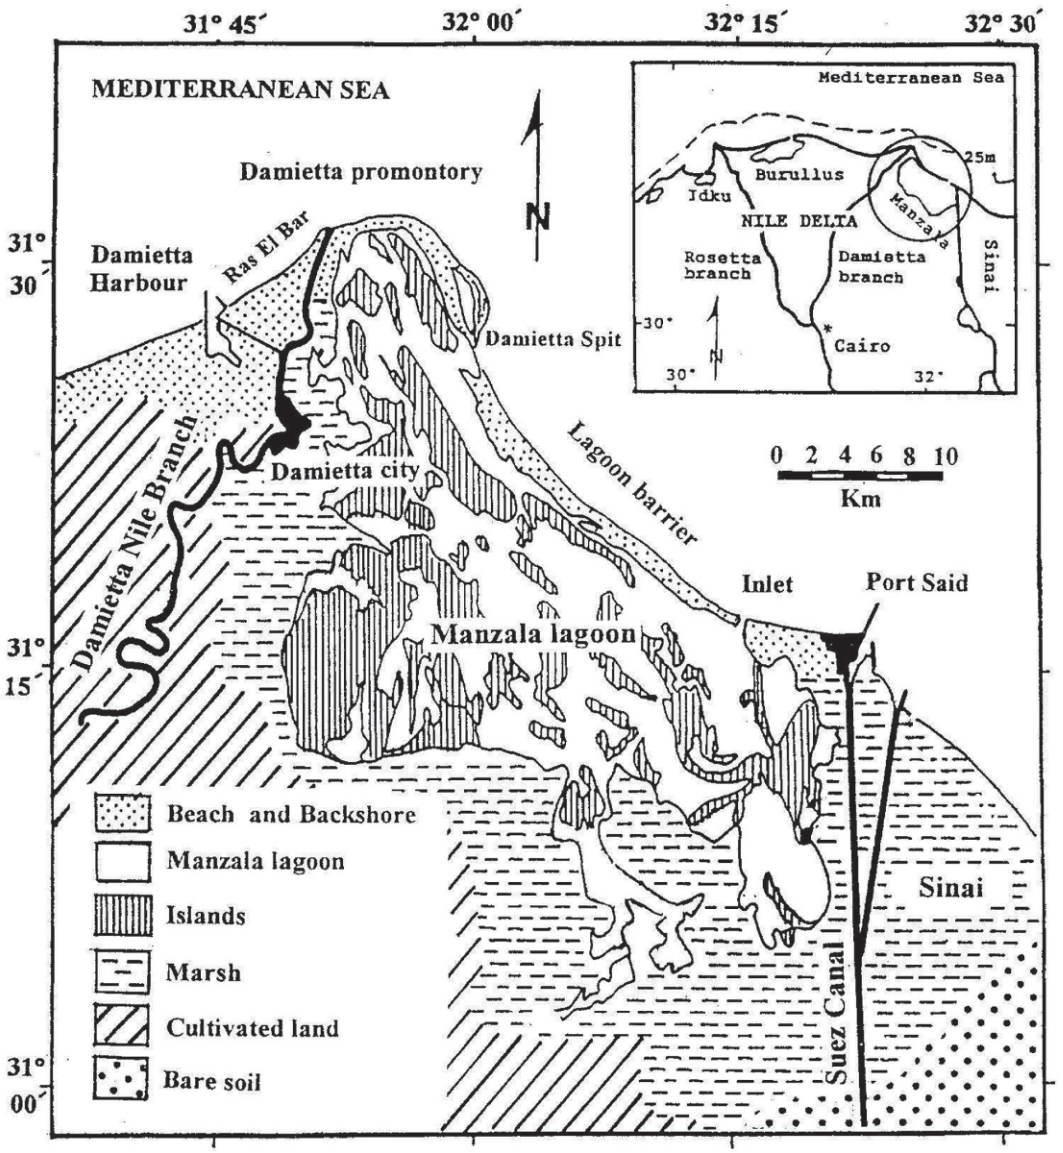
Figure 45.13: Contour maps of the coastal area including Rosetta City indicating high elevation areas where the old city was built on. Natural urban growth is progressing on adjacent the low land area. **Source:** El Raey, Fouda and Gal (2000).



45.3.1.5 Port Said

Port Said is located on the Mediterranean Sea east of the Damietta branch of the River Nile at the entrance or exit of the Suez Canal. In addition to its strategic position, it is the second largest tourist and trade centre of Egypt on the Mediterranean. Lake Manzala, the largest of the Nile delta lakes, is located just to the west of the city and receives a sizable amount of effluent pollution from various sources. Port Said Governorate has a total area of 1,851 km^2 and is divided into five districts: El Shark, El Monakh, El Arab, El Dawahi, and Port Fouad. The coastal zone of Port

Figure 45.14: The location of the city of Port Said on the tip of Suez Canal, surrounded by water bodies and indicating high vulnerability of the city to potential impacts of sea-level rise. **Source:** Sestini (1991: 547).

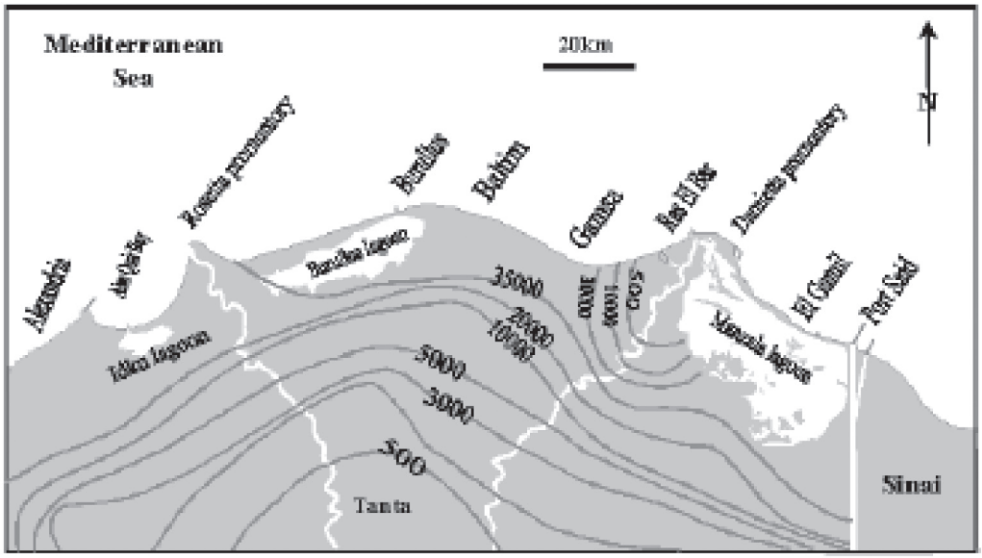


Said is critically important for tourism, which is primarily oriented at beach activities. Most tourism facilities are located within 200–300 metres of the coastline. Besides, there are important archaeological sites along the northern part of the Suez Canal.

The vulnerability of Port Said to sea-level rise is particularly high given the socio-economic importance of its coastline and the fact that it has one of the highest rates of local land subsidence in the Nile Delta (3.5 mm/a), which amplifies the effects of climate change induced sea-level rise. Sea-level rise is expected to cause a landward shift of the salt wedge and increase the rate of saline seepage in the top soil, which may have potentially serious implications for agriculture and drainage conditions as well as available groundwater resources in the upper Nile Delta. Large areas close to the coast near the Suez Canal will be lost if protection measures are not undertaken.

Changes in the salinity of the Lake Manzala may impact on the lake's ecology and fisheries. Further, given that the lake is unlikely to migrate inland, sea-level rise will lead to a decline in shallow wetland areas and less abundant reed beds. The most severely impacted sectors are expected to be industry (12.5 per cent) and transportation (11.7 per cent). In case of a SLR of 0.5 m, a loss of 6,700 jobs (5.3 per cent of the

Figure 45.15: Distribution of groundwater salinity in ppm in the Nile delta region in the year 2000. **Source:** Gaamea (2000) cited in Frihy (2003).



total work force) is expected. In terms of economic losses, the loss of beaches is likely to outweigh losses in other areas, given their high value for tourism. In addition, there are again no assessments to value the loss of historical sites.

It should be noted here that Alexandria, Rosetta and Port Said are not the only vulnerable areas along the coastal zone of Egypt. Beaches and tourist sites at other cities on the Mediterranean such as Matruh City to the west of the delta and Arish City to the east are also vulnerable to a rise of the sea-level. Water-logging and water bogging problems in low lying areas close to the coast have already emerged in many localities. Sand dune movement in the coastal zone is also expected to be more severe in the future. So far, declines in land productivity in the Nile delta region resulting from salt water intrusion as well as declines in fish catch resulting from ecosystem changes in the northern lakes have not been accurately estimated. Besides, the continuous degradation of coral reefs along the coasts of the Red Sea would severely impact biodiversity, fish catch and tourism in that region. The socio-economic impacts associated with these changes are far reaching and include migration, unemployment and possibly political unrest.

45.3.2 Direct Impacts of Salt Water Intrusion

The Nile Delta aquifer system is a complex groundwater system. It is a leaky one, with an upper semi-permeable boundary and lower impermeable boundary. The aquifer is recharged by the infiltration from the irrigation net work, excess of irrigation water and little precipitation through the upper clay layer. It may also be recharged by any possible flow coming from the Upper Egypt aquifer. The increase in demand in the Delta area was covered by intensive pumping of fresh groundwater, causing subsequent lowering of the piezometric head and upsetting the dynamic balance between the freshwater body and saline water body in the aquifer. Like any coastal aquifer, an extensive saltwater flux has intruded the Nile Delta aquifer forming the major constraint against aquifer exploitation.

Climate change and seawater rise will affect the groundwater quality in the Nile Delta aquifer in two ways. First, low lands along the shoreline will be submerged with seawater and the aquifer below these lands will be destroyed. Second, additional pressure heads will be imposed at the seaside causing more intrusion. A dynamic monitoring network for piezometric head and water salinity is needed for better assessment and mitigation of seawater intrusion in the Nile Delta aquifer (Sherif/Al Rashed 2001). A monitoring system must be established to collect data on rates of soil and groundwater salinization.

45.3.3 Direct Impacts of Extreme Events

The region is well known to be exposed to a number of extreme events of sand storms (e.g. Saharan dust and Khamasin which covers the whole region) and marine storms (e.g. Nawwat which hit mainly the coastal areas), as well as a number of heat waves.

These extreme events cause large damage to agricultural productivity, materials and health. Its impact may even cross the Mediterranean and cause damage on the European side. These extreme events are expected to increase in intensity and frequency due to climate changes (e.g. IPCC 2007). It is impossible to exclude the impacts of these storms on sea-level and circulation pattern in the coastal environment. Again a detailed assessment of the impacts of extreme events is still to be carried out. It should be noted here that a lot of data on extreme events is becoming available for downloading from satellites.

45.3.4 Indirect Impacts

Indirect impacts of sea-level rise on the Nile delta region include socio-economic and health impacts due to increased salinity and loss of productivity of the land and consequent migration of population to other areas looking for jobs. Considering scenarios for sea-level rise until 2100, it is estimated that about 6 million people will abandon the saline land in the northern delta and move to southern areas looking for jobs (e.g. Sestini 1991; Dasgupta/Laplante/Meisner/Wheeler/Yan 2007).

45.4 Gaps of Systems and Information

It is now obvious that there are a number of gaps in the institutional systems for identification, assessment and adaptation to climate change. These include:

a.) Shortage of monitoring systems, capacity for monitoring and data bases and redundancy of research;
b.) Shortage of institutional systems to integrate, assess, analyse and for setting up policies for adaptation;
c.) Shortage of capacity for enforcement;
d.) Shortage of awareness among decision-makers and the vulnerable community;
e.) No information is available on the integrated potential impacts of climate changes and extreme events on water resources cultural heritage, agricultural productivity;
f.) The shortage of data and indicators of monitoring of specific parameters such as ground water salinity, sea-level rise and soil salinity;
g.) The shortage of information on infrastructure that is needed to upgrade resilience of the vulnerable community.

45.5 Adaptation Options for Coastal Resources

A number of important economic and commercial centres in Egypt will be exposed to the adverse effects of climate change. Especially the coastal cities of the Nile Delta will be most affected. It is urgent that strategic adaptation policies and plans are put in place and strong institutions and systems of supervision are established to enforce environmental laws. Several criteria are important for the assessment of various options for adaptation in coastal zones, including: net benefits, environmental impacts, robustness and flexibility, chance of success, feasibility and fairness. Using this experience the following generic options have been identified as the most promising adaptation policies and measures for the protection of the coastal zones in Egypt.

Adaptation starts with identifying and assessing vulnerabilities of various sectors to potential impacts of climate change. It then involves determining and assessing available options to deal with the effects of expected climate change through a change in public policies and/or the erection of protective structures such as dams or the like (El Raey/Dewidar/El-Hattab 1999). The Stern Report (2006) stressed the importance of the provision of speedy assistance by the international community to developing countries seriously affected by climate change to help them in their adaptation efforts. The report pointed to the fact that the poorer countries will be the most severely affected even though they are least responsible for greenhouse gas emissions. It also stressed that while addressing climate change today would cost only 1 per cent of the GDP, waiting for the adverse effects to materialize in the future may represent a yearly loss of 10 per cent of GDP. For the Nile delta region the following adaptation measures should be adopted and strictly enforced:

1. A National Institute for Climate Change should be established to build capacity and train human resources, to design the required institutional systems, integrate and coordinate activities among the various sectors. This Institute would focus on the study of possible adaptation policies while also spreading awareness of climate change effects and publicizing success stories on the different sectors.
2. Establishing an institutional capability for coastal monitoring, assessment and follow-up of plans. Activation of the national committee on *Integrated Coastal Zone Management* (ICZM), build-

ing of geographic data bases, developing policies and programmes;
3. Upgrading resilience of the community through upgrading of infrastructure, building capacities and upgrading awareness;
4. Adopting of an *Integrated Coastal Zone Management* (ICZM) for coastal development and enforcing of *environmental impact assessment* (EIA) that take climate change into account:
5. Use of wind and solar energy for water desalinization must be promoted and adequate financing for scientific research in these areas must be provided;
6. Development of local human resource skills in the field of mathematical *Regional Circulation Models* (RCMs) to allow future projections with the high degree of accuracy that is required for policy formulation.
7. Studies should be undertaken to determine possible adaptation options and criteria for the selection of water, agriculture and coastal sectors, which would make use of simple and low cost technologies.
8. Environmental laws should be firmly enforced and environmental assessments of projects must be mandatory. National projects should take expected climate change effects into consideration.
9. A comprehensive institutional setup for the protection of the coastal areas must be established with the aim of coordinating the efforts of the research community and the implementation agencies.
10. Nongovernmental organizations should be encouraged to upgrade the awareness among decision-makers and the public on the dangers posed by climate change and of the necessity to reduce overconsumption.

45.5.1 Specific Adaptation Processes and Policies

According to results of El Shennawy (2009), these general processes and policies are proposed:

- Sand dunes systems should be treated as the first defensive line for the Nile Delta.
- Utmost consideration should be paid to coastal lakes as one of the most appropriate adaptive capacity systems against sea-level rise.
- Coastal international roads should be considered as the second protection measure and studies to support them are urgently required.
- Coastal protection construction need regular maintenance and should be considered in any management plan for coastal zones.
- Decision-makers in coastal governorates as well as concerned ministers should be aware of the importance of sand dunes systems and their role in protecting the coastal zone of the Nile Delta.

45.6 Conclusions and Recommendations

It is concluded that the Nile Delta region is highly vulnerable to potential impacts of climate change especially to sea-level rise and salt water intrusion. The potential impact on water, coastal and agricultural resources is formidable and losses of world cultural heritage cannot be estimated. This calls for immediate and serious action. In particular the following aspects need to be carried out:

1. It is necessary to establish a virtual centre for integrating research activities, carrying out integrated vulnerability assessment, building up a geographic data base of climatic indicators and establishing a regional circulation model.
2. An improvement of the resilience of the population should be carried out through upgrading of infrastructure, building capacities for monitoring and assessment and upgrading awareness of decision-makers, civil society and the population at large.
3. Proactive strategic plans of development should be identified and enforced for all sectors in view of potential impacts of climate change.
4. Introducing policies for adaptation to climate change in various developmental plans, especially in large scale national projects.
5. Recent suggestions of increasing scenarios of sea-level rise will make the situation even worse and call for even faster action.

46 Vulnerability of Tropical Montane Rain Forest Ecosystems due to Climate Change

Hans Juergen Boehmer

46.1 Introduction: Definitions and Key Concepts[1, 2]

Tropical montane rain forests provide important ecosystem services, such as supply, purification and retention of fresh water, regional water and air quality regulation, carbon sequestration, genetic and pharmaceutical resources, natural hazard and erosion regulation, recreation and ecotourism, etc.[3] This type of ecosystem is highly dependent on stable conditions of several climate variables and, therefore, highly sensitive to any changes in those variables. For that reason, these forests provide excellent monitoring sites for detecting threats by climate change and illustrate its potential consequences for natural ecosystems and ecosystem services in an impressive way (Loope/Giambelluca 1998; Foster 2001). Before discussing this topic, however, some principal terms used in this chapter have to be defined.

46.1.1 What is a Tropical Montane Rain Forest?

Like many terms in ecology, the term 'montane rain forest' has different connotations. Also, other terms have been used to describe forests that exist under the conditions outlined below (46.1.2, 46.1.3), like 'cloud forest', 'elfin forest', 'mossy forest', and 'dwarf forest' (Stadtmueller 1987; Richards 1996). This has caused some confusion; for instance, Beard (1955) juxtaposed 'montane rain forest' with 'cloud forest' (Mueller-Dombois/Ellenberg 1974, 2002), while Lamprecht (1977) used the terms synonymously. Bruijnzeel and Hamilton (2000) distinguish between lower montane forest, lower montane cloud forest, upper montane cloud forest, and subalpine cloud forest. 'Cloud forest' has been common for several decades,[4] and is still widely used with a particular focus on *tropical montane cloud forests*.[5] Like Whitmore (1998), the latest analysis of the world's forests[6] distinguishes between tropical upper montane forest and tropical lower montane forest.

This chapter uses the term 'tropical montane rain forest' (van Steenis 1935; Beard 1944; Richards 1996). Its broader connotation includes all types of rain forests in tropical mountain ranges, from naturally open upper montane rain forests at higher elevations (characterized by stunted growth, twisted trunks, and epi-

phytic mosses) to dense lower montane rain forests with tall trees and a closed canopy (Whitmore 1998; Foster 2001). The latter are highly dependent on the frequent presence of clouds, but not on a permanent cloud cover (Stadtmueller 1987). Despite the attempted terminological clarity, it has to be kept in mind that there is a considerable diversity of montane rain forests within the tropics (Vareschi 1980; Kitayama 1995; Bruijnzeel 2001).

Summing this up pragmatically, tropical montane rain forests are the predominating forest type in zones of maximum cloud condensation in mountain ranges of the tropics, and they frequently or permanently receive additional humidity through horizontal precipitation (direct canopy interception of cloud water, so-called cloud stripping).[7]

46.1.2 Structure and Biodiversity of Tropical Montane Rain Forests

Compared to tropical lowland rain forests, tropical montane rain forests have lower nutrient cycling rates and lower overall productivity (Grubb 1977; Whitmore 1989; Bruijnzeel 1998). Thus, trees have a lower stature with an average canopy height of about 15 to 35 meters, and increased stem density (Richards 1996; Whitmore 1998; Bruijnzeel 2001). Generally speaking, above-ground biomass decreases as elevation increases (Bruijnzeel/Hamilton 2000; Kitayama/Aiba 2002; Moser/Hertel/Leuschner 2007). At higher elevations, average canopy height can even be lower than 5 metres and trees have relatively small, thick and hard leaves (Richards 1996; Foster 2001).

The following factors contribute to lower productivity in upper montane forests: reduced photosynthesis due to lower radiation and air temperatures; periodic water shortage on shallow soils; saturated soils and impeded root respiration; high soil acidity and, thus, low decomposition rates, nutrient mineralization and overall fertility.[8]

The complex topography of high mountains provides a large variety of important site factors and disturbance regimes (Boehmer/Richter 1997), thus creating a highly diverse environment with numerous mechanisms that maintain montane forest biodiversity (Zang/Tao/Li 2005). As a result, tropical montane rain forests have high levels of species diversity and endemism[9] (Lewis 1971; Gentry 1995; Kessler 2001); long evolutionary time under relatively constant climatic conditions even made them biodiversity hot spots[10]. Gentry (1986, 1995) emphasizes natural habitat fragmentation and small-scale variation in climatic conditions as decisive triggers for high levels of endemism in tropical uplands. Regarding species composition and diversity, there are continuous elevational changes (Lovett 1998) as well as discrete compositional ecotones at certain altitudes (Martin/Sherman/Fahey 2007; Schmitt/Denich/Frijs/Demissew/Boehmer in press). Ecotonal[11] interactions, e.g. between lower and upper parts of watersheds, further stimulate species richness (Oesker/Dalitz/Günter/Homeier/Matezki 2008).

Due to the high availability of water (which results from high precipitation and high relative humidity), epiphytes[12] are usually the most frequent life forms aside from trees. Trees are covered by dense layers of vascular and non-vascular epiphytes (mosses, liverworts, lichens, ferns, orchids, etc.; Robins/Sugden 1979; Nadkarni 1984; Nadkarni/Matelson/Haber 1995). Moss coverage relative to that of lichens increases with elevation (Frahm/Gradstein 1991). High and largely non-seasonal annual rainfalls appear to be a driving force behind the diversity of epiphytes and terrestrial ferns (Gentry/Dodson 1987, Kessler 2001). Ferns and tree ferns (*Cyatheaceae*) are highly abundant and play an important role as understory species at all altitudes (figures 46.1, 46.2).

In most of the lower montane forests, tree ferns are more common, while the upper montane forests are characterized by high abundances of filmy ferns (*Hymenophyllaceae*), which profit from the relatively

7 Ataroff and Rada (2000), for instance, studied water fluxes in a Venezuelan montane rain forest (2300 m above sea level [a.s.l.] 3124 mm annual rainfall); there, 91 per cent of the incoming water was from rainfall, 9 per cent from cloudwater; in Holder's study (2004) of a Guatemalan montane forest (2550 m), fog perecipitation contributed more than 7 per cent of the total input to the water budget, but was 19 per cent during the dry season.

8 See Stadtmueller (1987), Bruijnzeel and Veneklaas (1998); Sollins (1998); Tanner, Vitousek and Cuevas (1998); Clark, Lawton and Butler (2000); Vitousek (2004).

9 *Endemic species* are restricted to a certain area or ecosystem (*endemism*).

10 See Terborgh (1977); Rohde (1992); Bush, Silman and Urrego (2004); Barthlott, Hostert, Kier, Küper, Kreft, Mutke, Rafiqpoor and Sommer (2008); Beck and Kottke (2008).

11 *Ecotone* refers to a transition zone between two structurally different (plant) communities.

12 *Epiphytes* refers to plants that grow attached to the stem and branches of trees.

Figure 46.1: Montane rain forest on the island of Hawaii, Kilauea area, ca. 1200m above sea level. **Source:** Photograph by Jutta Pscherer (2002).

cool, wet microclimate inside the stands (Richter 2008). In some montane rain forest types, lianas are characteristic features as well (Senbeta/Schmitt/Denich/Demissew/Vlek/Preisinger/Woldemariam/Teketay 2005). The overall richness of vascular plant species usually decreases substantially from lower to upper

elevations (Kitayama 1992; Vásquez/Givinish 1998; Kessler 2001). Tree species composition varies with altitude (Lieberman/Lieberman/Peralta/Hartshorn 1996), but tree species richness does not necessarily decline with elevation (Lovett 1998, 1999).

Tropical montane rain forests harbour highly diverse faunas with numerous co-existing animal species that are limited to certain habitat types within this zone.[13] Habitat specialization of birds, for instance, generates high diversity (Willis/Schuchmann 1993; Watson/Peterson 1999; Jankowski/Ciecka/Meyer/Rabenold 2009).

46.1.3 Distribution of Tropical Montane Rain Forests

The frequent or permanent presence of a dense cloud layer at certain elevation intervals along mountain ranges is a key condition for the existence of tropical montane rain forests;[14] they are strongly linked to regular cycles of cloud formation (Still/Foster/Schneider 1999). In tropical high mountains there is a general correlation between cloudiness and orographic rainfall (Sarmiento 1986). The average rainfall in those areas ranges from 1200 mm to over 7500 mm per year (Evenson 1983; Bush/Hanselman/Hooghiemstra 2007), with a mean annual temperature of 18–20 °C at the lower elevation limit and about 10 °C at the upper limit (Bruijnzeel 2001). However, short periods of drought (infrequent mild droughts) can be considered a normal element of the natural environment (Giambelluca/Nullet/Ridgley/Eyre/Moncur/Price 1991; Werner 2003) that affects or even determines population dynamics of certain foundation plant species.[15]

Exceptionally wet conditions have been described for a wide range of tropical mountains, causing reduced temperature oscillations, solar irradiation, and evapotranspiration of trees (Hedberg 1964; Sarmiento 1986; Stadtmueller 1987; Hamilton/Juvik/Scatena 1995). Here, seasonality is primarily based on fluctuations in horizontal and vertical precipitation (Richter 2008). In many places there are other extreme site factors like insufficient soil drainage (Hamilton/Juvik/Scatena 1995, Mueller-Dombois 2006), nutrient leaching (Vitousek 2004), or strong winds (e.g. along the trade wind belt; Lawton 1982; Sugden 1986).

The band of maximum cloud cover in the humid tropics is highly dependent on the topography of the principal mountain ranges (e.g. Bendix/Rollenbeck/Goettlicher/Cermak 2006). Generally it is located between 1200 and 2500 m *above seal level* (asl; Stadtmueller 1987). Nevertheless, in many regions the belt of montane rain forest begins at lower elevations. Lower extremes tend to be ca. 800 m asl, but can be lower than 500 m, e.g. Seychelles (Flenley 1974) or the tropical Pacific islands (Mueller-Dombois/Fosberg 1998), and, on the high end, Hueck (1978) mentions Andean cloud forests even at 3900 m asl.

A variety of factors affect the intensity, amount, and duration of upslope precipitation, including barrier width, slope steepness, and updraft speed. In addition, other climatic and geographic factors like the direction of the prevailing winds, micro relief, and disturbance regimes determine the distribution of montane rain forests and indicate their limits (Richter 2008). The position of the belt of maximum precipitation in the mountains also depends on the degree of aridity in the adjacent forelands. That means that severe changes in foreland ecosystems (deforestation) can affect nearby montane rain forests (Lawton/Nair/Pielke/Welch 2001, Nair/Lawton/Welch/Pielke 2003).

The distribution of tree ferns is a prominent indicator for the geographical boundaries of montane rain forests in the tropics (Kroener 1967; Troll 1970; Stadtmueller 1987; figure 46.1, 46.2). Troll (1956, 1968) developed a pioneering profile of altitudinal vegetation belts that includes a montane forest belt in the inner tropics, ranging from tropical temperate up to cold altitudes. Numerous case studies have helped to create a clearer picture of tropical montane rain forest distribution (Bruijnzeel 2001). Today, the horizontal extension of tropical montane rain forests is calculated at 924.000 km^2, approximately 15 per cent of the existing tropical rain forest. Among those, tropical upper montane rainforests cover 476.000 km^2, and tropical lower montane rainforests 448.000 km^2.[16]

In the American humid tropics, the principal areas of montane rain forest distribution include Mexico (Hastenrath 1968; Cayuela/Golicher/Rey-Benayas

13 See Orians (1969); Terborgh (1971); Hernández-Baños, Peterson, Navarro-Sigüenza, Escalante-Pliego 1995; Watson and Peterson (1999); Blake and Loiselle (2000); Brehm, Homeier and Fiedler (2003); Herzog, Kessler and Bach (2005).

14 See Grubb and Whitmore (1966); Huber (1976); Nair, Asefi, Welch, Ray, Lawton, Manoharan, Mulligan, Sever, Irwin, Pounds (2008).

15 A *foundation species* is a dominant species in an ecosystem that controls the populations of other species (and overall community dynamics) and modulates ecosystem processes (Ellison/Bank/Clinton/Colburn/Elliott/Ford/Foster/Kloeppel/Knoepp/Lovett/Mohan/Orwig/Rodenhouse/Sobczak/Stinson/Stone/Swan/Thompson/Von Holle/Webster 2005).

2006), Central America (Knapp 1965), particularly Guatemala (Holder 2005), Costa Rica (Zadogra 1981, Nadkarni/Wheelwright 2000), Panama (Myers 1969), Jamaica (Tanner 1977), Puerto Rico (Weaver 1972a, 1972 b), Ecuador (Gradstein/Homeier/Gansert 2008; Beck/Bendix/Kottke/Makeschin/Mosandl 2008), Venezuela (Veillon 1955, 1974), Colombia (Sugden 1982a, 1982b, 1982c), and Peru (Young/León 1995). The high mountains in Southeast Asia, Malaysia, the

16 See Schmitt, Burgess, Coad, Belokurov, Besançon, Boisrobert, Campbell, Fish, Gliddon, Humphries, Kapos, Loucks, Lysenko, Miles, Mills, Minnemeyer, Pistorius, Till Ravilious, Steininger, Winkel 2009a, [2]2009b).

Philippines and Indonesia, in particular, are centres of montane rain forest distribution (Hamilton/Juvik/Scatena 1995). New Guinea and the principal islands of the Pacific region (Hawaii, Samoa) have considerable amounts of tropical montane rain forests as well (Merlin/Juvik 1995; Mueller-Dombois/Fosberg 1998). In Africa, Mt. Cameroon and the high mountains of East Africa are worthy to mention (Hedberg 1951; Friis 1992, Hemp 2006). Even in relatively dry regions such as the Simien Mountains in northern Ethiopia, montane rain forests form a discrete belt on north-eastern escarpments at 2200 to 2500 m a.s.l. (Richter 2008), which again illustrates the major significance of horizontal precipitation in this type of ecosystem.

46.1.4 Climate Change and Specific Vulnerability

Climate change is one of several global processes (including rapid urban development, population growth, etc.) that require special attention because it is affecting the distribution of resources and increasing the vulnerability of ecosystems. In IPCC (2007: 30) terminology, climate change refers to "a change in the state of the climate that can be identified (e.g. using statistical tests) by changes in the mean and/or the variability of its properties, and that persists for an extended period, typically decades or longer." In short, "it refers to any change in climate over time, whether due to natural variability or as a result of human activity." According to Cardona (chap. 3 above), vulnerability of ecosystems is "intrinsically tied to different socio-cultural and environmental processes, but (...) is also related to the fragility, the susceptibility, or the lack of resilience of the exposed elements, both from society and environment" (for overviews on the concepts of 'vulnerability', 'risk', etc. see Brauch 2005a; Birkmann 2006; chap. 2 by Brauch). In the context of climate change, vulnerability is "a function of the sensitivity of a system to changes in climate (the degree to which a system will respond to a given change in climate, including beneficial and harmful effects), adaptive capacity (the degree to which adjustments in practices, processes, or structures can moderate or offset the potential for damage or take advantage of opportunities created by a given change in climate), and the degree of exposure of the system to climatic hazards" (IPCC 2001).

Interestingly, the concepts of disaster, catastrophe, disturbance, perturbation, and resilience are applied differently in the scientific and political discussion on human and environmental insecurity from the way they are commonly understood in ecology (Harper 1977, White/Pickett 1985; Grimm/Wissel 1997; Brand/Jax 2007). This lack of interdisciplinary terminological clarity cannot be discussed here in detail; to give an example, Turner II, Kasperson, Matson, McCarthy, Corell, Christensen, Eckley, Kasperson, Luers, Martello, Marybeth, Polsky, Pulsipher and Schiller (2003: 8074) define hazards as

> threats to a system, comprised of perturbations and stress (and stressors), and the consequences they produce. A perturbation is a major spike in pressure (e.g., a tidal wave or hurricane) beyond the normal range of variability in which the system operates. Perturbations commonly originate beyond the system or location in question. Stress is a continuous or slowly increasing pressure (e.g., soil degradation), commonly within the range of normal variability. Stress often originates and stressors (the source of stress) often reside within the system. Risk is the probability and magnitude of consequences after a hazard (perturbation or stress).

These concepts of perturbation and stress do not fit with the broadly accepted definition of the terms in the natural sciences. There has been a long discussion in ecology about the definitions of terms like perturbation, disturbance, stress, and catastrophe (Harper 1977; White/Pickett 1985; Boehmer/Richter 1997; White/Jentsch 2001; Kammer/Moehl 2002). Widely accepted is the definition of disturbance as "any relatively discrete event in time that disrupts ecosystem, community, or population structure and changes resources, substrate availability, or the physical environment" (White/Pickett 1985: 5ff.). An ecological event is an "abruptly occurring process which significantly affects variables of an ecological unit for a period longer than its own duration. It must have a clear beginning and end, and must be of relatively short duration in relation to the time scale of the organisms considered" (Grimm/Stillman/Jax/Goss-Custard 2007: 60). The term 'perturbation' describes a departure from an explicitly defined normal state, behaviour or trajectory (White/Pickett 1985).

Unfortunately, in the definition by Turner II, Kasperson, Matson, McCarthy, Corell, Christensen, Eckley, Kasperson, Luers, Martello, Marybeth, Polsky, Pulsipher and Schiller (2003: 8074) the term 'perturbation' is used as a synonym for the ecological term 'disturbance', more precisely for what is defined in ecology as a catastrophic disturbance (*large infrequent disturbance* [LID] after Turner/Baker/Peterson/Peet 1998). In ecology, catastrophes or 'catastrophic events' are regarded as special cases of disturbance. Events of this nature are unpredictable and cannot be included in the prevailing regime of

regularly occurring disturbances (Boehmer/Richter 1997; Turner/Baker/Peterson/Peet 1998); accordingly, foundation species cannot become adapted to such events (Harper 1977; Boehmer/Richter 1997).

On the other hand, a 'disaster' recurs so frequently that it becomes relevant for the fitness of successive generations, because it can be expected to occur within the species´ life cycle: "The selective consequence of disasters is therefore likely to be to increase short-term fitness and the consequence of catastrophes is to decrease it" (Harper 1977: 627); so, disasters and catastrophes can – from the viewpoint of ecology – be interpreted as the ends of a continuum. In contrast, a disaster as discussed in the context of human and environmental insecurity implies "loss and damage, and consequential impacts that the affected community is unable to absorb or to cushion the effects and recover using its own resources and reserves" (chap. 3 by Cardona).

Furthermore, the distinction between ecological events (such as disturbance) and continuous processes (such as perturbation) as two fundamental types of ecological processes is central to any ecological research on ecosystem dynamics (Grimm/Stillman/Jax/Goss-Custard 2007). To avoid confusion, the terms 'disturbance' and 'perturbation' will be used here according to White and Pickett (1985), following the introduced and accepted terminology of ecology. 'Stress' is commonly defined as a limitation of dry matter production, while disturbance is connected to the destruction of biomass (Grime 1979; Kammer/Moehl 2002). Another problem with Turner II's definition is the boundary between disturbances originating from 'beyond the system' (commonly named 'exogenous disturbances', not 'perturbation') and those originating from 'within the system' (commonly named 'endogenous disturbances', not 'stress'). This boundary appears to be conceptually precise but is difficult to grasp in terms of structural content (Boehmer/Richter 1997).

The montane rain forests of the tropics are considered – as stated above – fragile exposed elements with a lack of resilience. Bioclimatic models suggest that major impacts to tropical forests will result from climate change (Hannah/Midgley/Andelman/Araújo/Hughes/Martinez-Meyer/Pearson/Williams 2007); complex synergetic effects on essential ecological factors should be expected (see 46.2). Vulnerability is considered for the purposes of this chapter as having the following aspects: 1) destruction of the established ecosystem 'tropical montane rain forest' through substantial changes in the determining climate variables; 2) impact of natural disturbances; 3) enduring disruption of ecosystem processes (irreversible modification of natural long-term dynamics); 4) loss of indigenous biodiversity; and 5) loss of ecosystem services.

Nevertheless, when emphasizing the importance of climatic factors for plant species distribution, it must not be forgotten that most species depend on a much more complex system of factors that describe their ecological niche (Heger/Boehmer 2005; Svenning/Kerr/Rahbek 2009). Non-climatic stresses affecting species survival, exacerbating problems caused by climate change, or limiting species' ability to respond to environmental changes should also be taken into account. Detailed studies of all ecological factors relevant for distribution and spread still do not exist for the vast majority of plant species. Reliable predictions of future distributions are, therefore, hardly possible (Grainger 2008), although attempted frequently (Thullier/Lavorel/Araújo 2005; Thullier/Lavorel/Araújo/Sykes/Prentice 2005). Even so, any assessment of ecosystem vulnerability should consider the full spectrum of possible impacts (Clark 2007; Feeley/Silman 2008), even those not yet quantifiable in detail (e.g. adverse effects of climate change, including climate variability and extremes).

46.2 Climate Change and Tropical Montane Rain Forest Dynamics

The availability of water determines the distribution of plants in terrestrial ecosystems (Larcher 1995). Climatic factors such as temperature, precipitation, and humidity play a fundamental role in the physiology and ecology of plant species (Harper 1977). Changes in those factors can, therefore, cause environmental stress and pose a threat to the regeneration and reproduction of numerous species. To survive such changes, species must be either resilient to climatic extremes, adapt to the new conditions, or migrate to other suitable areas (Davis/Shaw/Etterson 2005; Parmesan 2006). In plant communities, species react individually to climatic change (Hannah/Lovejoy 2007). Alterations in climate affect forest communities by changing the abundance and competitive capacity of different species in the forests (Hannah/Midgley/Andelman/Araújo/Hughes/Martinez-Meyer/Pearson/Williams 2007). Altered rainfall patterns, surface temperatures, and light availability lead to a change in carbon fixation by plants (primary production), higher mortality, and changing regeneration suc-

cess of many plant species (Holmgren/Scheffer/Ezcurra/Gutiérrez/Mohren 2001; Stenseth/Mysterud/Ottersen/Hurrell/Chan/Lima 2002).

Climate change threatens tropical montane rain forests particularly by altering precipitation, humidity, temperature, ultraviolet radiation, storm frequency and duration (Hamilton/Juvik/Scatena 1995, Foster 2001). In tropical high mountains, vascular plant species composition is associated with cloud frequency (Sklenár/Bendix/Balslev 2008). Bush (2002) hypothesized that the elevation of cloud formation will increase due to climate warming, caused by an upslope movement of the cloud base and resulting in a narrower elevational interval supporting the montane rain forest. A prolonged uplifting of the cloud layer can, for example, induce a decline in canopy trees (dieback, see below), enhanced seedling recruitment, population growth among understory plant species, and an increase in fruit production. Increases in air temperature can be linked to community changes of birds and amphibians in montane rain forests (Pounds/Fogden/Campbell 1999). Projected distributions of novel and disappearing climates by 2100 AD show that disappearing climates are concentrated in tropical montane regions (Williams/Jackson/Kutzbach 2007), thus indicating an increased extinction risk for species with narrow geographic distributions.

Climatic extremes, rather than mean values, have crucial impact on the dynamics of vegetation (Condit/Hubbell/Foster 1996). The increase of climatic extremes and fluctuations in recent decades has profound effects on the highly specific conditions outlined above, thus affecting species composition, structure, and dynamics of tropical montane rain forests. Climatic fluctuations such as extreme wet-dry oscillations can act as triggers of forest decline, particularly on marginal sites with shallow soils or poor drainage (e.g. Mueller-Dombois 2006; see below). Rapid changes in climate and atmospheric chemistry threaten sustainability of forests (Wargo/Auclair 2000). Droughts, for instance, have a severe impact on terrestrial vegetation dynamics, particularly in tropical rain forests.[17] Fortunately, tropical mountains are characterized by a variety of local climates; therefore, drought stress does not influence all parts of a montane rain forest in a given region in the same way.

Climatic extremes can arise from the shifts in tropical precipitation patterns, as in the case of El Niño anomalies[18] in the central and eastern Pacific, which have caused droughts in Indonesia (Werner 2003; Slik 2004) and inundated the South American west coast and the islands of the central Pacific with heavy rains (McPhaden/Zebiak/Glantz 2006). Remote effects of such changes are recorded in the North and South Pacific and beyond; strong El Niño and La Niña events have worldwide consequences (McPhaden/Zebiak/Glantz 2006). Severe ENSO-droughts have been increasing in recent decades.[19]

On a local scale, extreme weather events like tropical storms can damage trees by floods, defoliation, and windfall, thereby causing tree fall gaps that affect neighbouring trees as well as understory plants. Landslides, a typical geomorphic process in humid high mountain regions, create large-scale disturbances in montane forests, and become more frequent after extreme precipitation events. These disturbances may lead to a decrease in the connectivity of populations by fostering forest fragmentation.

Nevertheless, there is also evidence from palaeological records that tropical montane rain forests have been a continuous and constant feature, e.g., of the Andean environment throughout the Holocene (Bush/Hanselman/Hooghiemstra 2007). Here, rates of community change were low for thousands of years, despite considerable variability in the climate. Unfortunately, the warming expected in the near future has no physical and biotic analogues in the past (Hannah/Lovejoy 2007).

46.2.1 Climate-Induced Forest Decline

Future warming is expected to exacerbate regional tree species die-off [20] worldwide (Adams/Guardiola-

17 See Lowry, Lee and Stone (1973); Leighton and Wirawan 1986; Oren, Zimmermann and Terborgh (1996); Walsh and Newbery (1999); Nakagawa, Tanaka, Nakashikuza, Ohkubo, Kato, Maeda, Sato, Miguchi, Nagamasu, Ogino, Teo, Abang and Lee (2000); Potts (2003); Williamson and Ickes (2002); Werner (2003).

18 El Niño *or El Niño-Southern Oscillation* (ENSO): periodic change in the atmosphere and ocean temperature of the tropical Pacific; manifested in the atmosphere by changes in the pressure difference between Tahiti and Darwin, Australia, and in the ocean by warming or cooling of surface waters of the tropical Eastern Pacific Ocean

19 See McClure (1983); Loope and Giambelluca (1998); Boehmer and Niemand (2009); Boehmer, Niemand, Gerrish, Jacobi and Mueller-Dombois submitted for publication.

20 Die-off refers to a sudden sharp decline of a population (animals or plants).

Claramonte/Barron-Gafford/Villegas/Breshears/Zou/Troch/Huxman 2009) thereby affecting regional carbon budgets. The suppression or loss of foundation tree species in montane rain forests has acute and chronic impacts on fluxes of energy and nutrients, hydrology, food webs, and biodiversity.[21]

It is well known that climatic fluctuations like ENSO have strong effects on the dynamics of plant populations in a wide range of terrestrial ecosystems (Curran/Caniago/Paoli/Astianti/Kusneti/Leighton/Nirarita/Haeruman 1999; Holmgren/Scheffer/Ezcurra/Gutiérrez/Mohren 2001). El Niño events bring drier, warmer, and sunnier conditions to the wet tropics, resulting, e.g., in a prolonged uplifting of the cloud layer, thus causing stress, e.g., in trees growing on waterlogged substrates. For example, as a result of the 1982–1983 super-El Niño event, which brought record temperatures and severe drought to Indonesia (Leighton/Wirawan 1986), 71 per cent of the canopy trees (>60 cm diameter) died in forest plots on dry ridges and slopes (dieback). 'Dieback' is a special form of forest decline, which affects only canopy trees and is known from several of the world's forest ecosystems (Jane/Green 1983; White 1986; Lawesson 1988; Mueller-Dombois 1988; Stewart 1989; King/Neilson 1992; figure 46.3). The term has been defined as "progressive dying back from the tips of twigs, branches or tops" (Podger 1981; Manion 1981; Ciesla/Donaubauer 1994).

As far back as 1986, it was shown that forests are highly susceptible to dieback under ongoing climate warming (Solomon 1986, Mueller-Dombois 1987, 1988). After a dwindling of interest in the late 1980's, forest dieback resulting from climate change has started to become a major focus of ecological research again (Allen 2009). An important aspect is the assumption that in many forest ecosystems neither floods nor droughts lead to the death of canopy trees. Instead, the combination of both, due for example to more rapid precipitation and irradiation changes, seems to have lethal effects, especially on marginal sites (Auclair 1993; Mueller-Dombois 2006). The phenomenon of stand-level dieback in forests, formerly interpreted as a local symptom of a disease or a pest attack (Petteys/Burgan/Nelson 1972), is nowadays understood as a complicated combination of biotic and abiotic factors that includes generic levels as well as climatic triggers (Mueller-Dombois 1988). According to Auclair (1991), region-wide, persistent episodes of forest dieback are incited by extreme moisture stresses in the Pacific area.

While extreme precipitation events typically are local and short-lived phenomena, the dissolving of the cloud layer during ENSO anomalies may affect large areas over extended periods of time. It is thus assumed that large-scale dieback is triggered by a rapid succession of climatic extremes. For example, high radiation, followed by extreme precipitation and repeated high radiation (Auclair 1991, 1993), may cause lethal cavitation[22] in forest stands. Four types of climatic fluctuations can cause cavitation injury in tropical montane rain forests: 1) wet-dry oscillations; 2) intermittent high pressure or blocking high; 3) extreme rainfall; and 4) extreme drought. Dry-wet oscillations should be considered as dieback triggers as well. The frequency of such fluctuations has been increasing in recent decades.[23]

Usually, forest stands do not die while in full vigour, except from catastrophic disturbances, diseases or insect pests. In the absence of such influences, an endogenous predisposition to decline can be assumed, which may be related to the structure and dynamics of the tree population itself (Mueller-Dombois 1987). For instance, after intensive research on the forest decline on the Island of Hawaii in the early 1970's, it was shown that neither disease nor climatic stress actually caused the mass-dieback of the dominating tree species *Metrosideros polymorpha* (Papp/Kliejunas/Smith/Scharpf 1979; Hodges/Adee/Stein/Wood/Doty 1986). Instead, attention focused on a complex array of demographic factors, namely a uniform age and stand structure ('cohorts'; Mueller-Dombois 1983, Gerrish/Mueller-Dombois 1999), probably resulting from large-scale disturbances, e.g., through volcanic eruptions, leading to the simultaneous aging and finally death of the cohort ('cohort senescence'; Mueller-Dombois 1987).

The concept of cohort senescence, which claims that old cohorts of canopy trees are predisposed to die, due to their low energy potential for recovery from stress, has particular implications for climate

21 See Ellison, Bank, Clinton, Colburn, Elliott, Ford, Foster, Kloeppel, Knoepp, Lovett, Mohan, Orwig, Rodenhouse, Sobczak, Stinson, Stone, Swan, Thompson, Von Holle and Webster (2005).

22 *Cavitation* refers to a catastrophic hydraulic failure in the xylem (water transport tissue) of vascular plants when the tension of water within the xylem becomes so great that dissolved air within the water expands (bubbles), thus blocking the transport of stem water.

23 See Loope and Giambelluca (1998); Boehmer and Niemand (2009); Boehmer, Niemand, Jacobi, Gerrish and Mueller-Dombois (submitted for publication).

Figure 46.3: Dieback of the foundation species *Metrosideros polymorpha*, montane rain forest, Mauna Kea, island of Hawaii. **Sources:** a) aerial photograph by Dieter Mueller-Dombois (1972); b) Jutta Pscherer (2002).

change. It suggests that aging forests are susceptible to synchronized decline under certain demographic conditions (Boehmer/Wagner/Mueller-Dombois submitted for publication). Such weak stages in stand demography increase the vulnerability of forests. Extreme rainfall events or prolonged droughts, or combinations of these factors could generate a physiological shock that may trigger dieback among old,

stressed trees (Mueller-Dombois 1987; Gerrish/Mueller-Dombois/Bridges 1988, Gerrish 1990).

Santiago/Goldstein/Meinzer/Fownes/Mueller-Dombois (2000) propose that poor drainage causes roots to avoid hypoxic[24] soil horizons. This in turn could reduce the leaf area. Dieback symptoms may, therefore, represent an adjustment in leaf area to available resources, primarily in large trees that have a limited rhizosphere, while saplings and smaller trees are frequently established on nurse logs that provide more oxygenated sites. Further research is needed to test the relationship between the age of cohorts and the effect of climatic anomalies on their vitality.

46.2.2 Natural Disturbances

In recent decades natural disturbance has increasingly been recognized as a principal factor controlling the structure and dynamics of ecosystems.[25] Natural disturbances are a major driving factor behind vegetation dynamics in humid high mountain regions at different scales (Boehmer/Richter 1997; Boehmer 1999; Kammer/Moehl 2002). Tropical montane rain forests are subject to numerous natural disturbance factors (e.g. storms, landslides, fires, volcanic eruptions).[26] These factors cause a pattern of coexisting successional stages including moss carpets, herbaceous stands, fern thickets, scrubs, and mature forest. This habitat heterogeneity, e.g., in areas of frequent landslides, explains the high species richness of many tropical montane rain forest ecosystems.

This is especially true for mountain regions characterized by perhumid conditions and frequent earthquakes (Richter 2008). There is a critical threshold for inducing landslides that depends on the following factors in combination: mechanical and hydrological soil parameters and the destabilization of the water-soaked organic layer by the forest load (Asch/Deimel/Haak/Simon 1989). Extreme precipitation events destabilize slopes, particularly where montane forests are already fragmented by wind-induced tree fall or clearing. If larger areas are affected, a change in the local climate and an increase in the invasibility of the ecosystem can result.

Climate change is expected to cause an increase in natural disturbance impact, e.g., from tropical storms (Markham 1996; Elsner/Kossin/Jagger 2008) although there is at present no clear trend in the number of tropical cyclones (IPCC 2007). Such events can alter forest composition and structure for many years. Usually, storms cause more damage on ridges than in valleys and reduce the vegetation in upper height intervals significantly. Average maximum canopy height, for instance, decreased as much as 50 per cent in Puerto Rico's lower montane rainforest after Hurricane Hugo in 1989 (Brokaw/Grear 1991). Nevertheless, local variations in hurricane damage (or disturbance impact, respectively) can increase complexity of forest structure and, in doing so, provide habitats that are essential or favourable for a significant number of plant and animal species (Petraitis/Latham/Niesenbaum 1989). *Coarse woody debris* (CWD), produced when branches fall to the ground, provides important safe sites for seedling establishment on the forest floor (Santiago/Goldstein/Meinzer/Fownes/Mueller-Dombois 2000). In addition, the fine litter fall caused by tropical storms alters nutrient cycling in the forest system (Lodge/Scatena/Asbury/Sánchez 1991).

46.2.3 Range Retractions, Expansions and Biological Invasions

A warming of tropical mountains of 2 to 3 °C (IPCC 2001) might cause an upslope migration of species,[27] thus worsening conditions for the species in montane rain forests that are highly adapted to cloud water (Benzing 1998). Many plant species in the Amazon cloud forest, for instance, may not survive the climate changes forecast to occur within the next 100 years (Bush/Silman/Urrego 2004). Nadkarni and Solano (2002) showed that less cloud water generally has a negative effect on epiphyte growth and leaf production and radically alters the composition of canopy communities. As the mortality of montane rain forest species increases, the competition pressure induced by invasive indigenous lowland species is simultaneously heightened. Short migratory distances from low-

24 *Hypoxic soils* have a lack of oxygen as a result of poor drainage or during short-term flooding.

25 See Levin and Paine (1974); Connell and Slatyer (1977); Connell (1978, 1979); Sousa (1984); Pickett and White (1985); Boehmer and Richter (1997); Turner, Baker, Peterson and Peet (1998); White and Jentsch (2001).

26 See Clark (1990); Waide, Zimmerman and Scatena (1998); Whitmore and Burslem (1998); Chazdon (2003); Cochrane (2003).

27 See Pounds, Fogden and Campbell (1999); Peterson, Ortega-Huerta, Bartley, Sánchez-Cordero, Soberón, Buddemeier and Stockwell (2002); Raxworthy, Pearson, Rabibisoa, Rakotondrazafy, Ramanamanjato, Raselimanana, Wu, Nussbaum and Stone (2008); Sekercioglu, Schneider, Fay and Loarie (2008).

lands to the upper forest line make montane rain forests sensitive monitors of climate change (Bush/Flenley 2007). Such range expansions are widely expected, but have not yet been studied in detail (Colwell/Brehm/Cardelús/Gilman/Longino 2008).

Invasion by non-indigenous species is one of the most important issues in today's applied ecology (Convention on Biological Diversity; United Nations 1993). Some alien species are able to cause fundamental changes in indigenous ecosystems, including the local extinction of native species (SCBD 2001). The weakening of indigenous foundation tree species through climate change increases the invasibility of forests. Declining forests become more vulnerable to biological invasions, for instance, because dying trees can be replaced by invading alien tree species. These occupy available sites before the indigenous species can establish new individuals or a cohort (Boehmer 2005).

The increased invasibility of montane rain forests by canopy decline makes invasive alien species capable of completely changing structure and species composition (Asner/Hughes/Vitousek/Knapp/Kennedy-Bowdoin/Boardman/Martin/Eastwood/Green 2008). An impressive example of the negative potential for a synergetic effect presented by invasive species is Kahili Ginger (*Hedychium gardnerianum*), a 2 metre tall herb native to India's Himalaya region. It was introduced to many tropical regions as an ornamental plant; today it is listed as invasive in most of those regions (CAB International 2005). In its natural range, Kahili Ginger prefers open, well-lighted environments. Nevertheless, in tropical montane rain forests, it also occurs in semi- and full shade beneath the forest canopy (Stone/Pratt 1994). For instance, in Hawaii's montane rain forest, native species cannot compete in the infested sites; no regeneration of indigenous or endemic plant species within Kahili Ginger stands can be observed (Minden/Jacobi/Porembski/Boehmer in press). Furthermore, the colonization by Kahili Ginger provides favourable conditions for the spread of the invasive non-indigenous Strawberry Guava (*Psidium cattleianum*) tree. In the case of climate induced canopy decline, there will be no considerable regeneration of native rain forest plants; an almost total loss of native tree species (including the foundation species *Metrosideros polymorpha*) can be expected, and a new exotic rain forest type, dominated by two alien plant species, is likely to persist (Boehmer 2005; Minden/Hennenberg/Porembski/Boehmer 2009; Minden/Jacobi/Porembski/Boehmer in press).

46.2.4 Negative Synergetic Effects of Human Impact

Humans have inhabited tropical forests for thousands of years (Piperno/Bush/Colinvaux; Roosevelt 1999). Consequently, many tropical montane rain forests have witnessed multiple human impact too (Bruijnzeel/Hamilton 2000), although they did not become subject to intense human disturbance until the mid-20th century (Kellman/Tackaberry 1997). Human disturbances like forest clearing and selective logging directly affect forest structure, leading to widespread fragmentation (Wilder/Brooks/Lens 1998; Laurance 2007; Hemp 2009), thereby entailing complex edge effects[28] within the forest fragments.[29] Recent analyses show a continuous decrease in the area covered by montane rain forests, with a simultaneous increase in fragmentation, e.g., in Mexico between 1976 and 2003 (Cayuela/Golicher/González-Espinosa/Ramírez-Marcial/Rey Benayas 2006a; Cayuela/Rey Benayas/Echeverría 2006b) and East Africa (Schmitt/Denich/Friis/Demissew/Boehmer in press; Hemp 2009).

Even in areas of intact forest cover, indigenous people may have harvested forest products (figure 46.4), introduced useful species, or hunted, thus affecting abundance of important seed dispersers and seed predators.[30] Considerable effects may also have resulted from changes in coffee cultivation from shaded to non-shaded systems (semi-forest coffee systems; Senbeta/Denich/Boehmer/Woldemariam/Demel/Demissew 2007). The complex consequences of such human activities in montane tropical forest areas are still not well understood.

Lawton/Nair/Pielke/Welch (2001) showed that regional deforestation of upwind lowland forest influences cloud patterns in nearby mountains. In a tropical mountain region of southern Mexico, for instance, the agricultural conversion from orchards to dry farming in the coastal lowlands during the 1970's and 1980's resulted in an upward flux of overheated air masses and less cloud frequency in the mountains, thus causing a regional climate change (Richter 2008).

28 *Edge effects* are environmental changes (greater desiccation stress, wind turbulence, litter fall, etc.) associated with the abrupt, artificial boundaries of forest fragments.

29 See Laurance, Nascimento, Henrique, Laurance, Andrade, Ribeiro, Giraldo, Lovejoy, Condit, Chave, Harms and D'Angelo (2006).

30 See Senbeta and Denich (2006); Dietz, Hölscher, Leuschner, Malik and Amir (2007); Gradstein, Kessler and Pitopang (2007).

Figure 46.4: Managed montane rain forest with indigenous coffee shrubs (*Coffea arabica)*, Kayakela Forest, Kafa zone, south-west Ethiopia. **Source:** Photograph by Manfred Denich (2004).

Significant increases in stand precipitation, potential evaporation, and infiltration rates are contrasted by a significant decrease in water holding capacity. One of the consequences is a hundred- to thousand-fold rise in soil loss (compared to land under traditional cultivation) and a dramatic change in stream drainage. The most damaging result is a higher runoff rate during the wet period, with exuberant river discharges, as demonstrated by the floods during hurricane Stan in September 2005. This event led to extended sedimentations in the foreland of the mountain chain and is one of many examples of the consequences of the destruction of the water and soil reservoirs of tropical mountain forest ecosystems. Neither protecting the impacted lowland area by artificial dams and retention ponds, nor securing the slide areas by wire nets can solve the problem in the long term (Richter 2008).

Disturbance and deforestation, in combination with climate change, threaten the regional distributions of endangered tree species in tropical montane forests (Golicher/Cayuela/Alkemade/González-Espinosa/Ramírez-Marcial 2008). Strong forest fragmentation leads, for instance, to disruptions of mutual relationships between plants and animals, of seed disperser-seed interactions (reduced avian visitation of bird-dispersed trees), thus possibly posing long-term effects on tree species abundance and population dynamics (Lehouck/Spanhove/Colson/Adringa-Davis/Cordeiro/Lens 2009). Conservation concepts should, therefore, consider a multi-site approach with several protected areas at different altitudinal levels to cover the diversity of species and communities (Kessler 2001; Schmitt/Denich/Friis/Demissew/Boehmer in press). On abandoned land, regeneration of montane rain forests and de-fragmentation is possible as long as primary forest fragments still exist close to the disturbed sites (Karlowski 2006; Muñiz-Castro/Williams-Linera/Rey Benayas 2006).**t**

46.3 Conclusions

Climate change increases the vulnerability of tropical montane rain forests e.g. by intensifying the frequency of climatic anomalies and extreme weather events, and increasing natural disturbances. A variety of human impacts additionally cause complex synergetic effects. The numerous consequences of these transformations include: changes in species abundances; canopy loss; reduction in wildlife habitat; increased invasibility; the displacement of native species by invasive species; the formation of novel plant and animal communities; biodiversity loss; alterations to the hydrologic cycle; a decrease in water holding capacity; and temporal disruptions or permanent loss of fundamental ecosystem goods and services like regional water and air quality regulation, carbon sequestration, genetic and pharmaceutical resources, and natural hazard regulation. In addition to having a direct impact on montane ecosystems, severe changes in foreland ecosystems (e.g. deforestation) can affect nearby montane rain forests. However, many questions regarding the potential effects of climate change on ecosystem dynamics and species ranges remain unanswered and require further research.[31] Since several key concepts (e.g. of disaster, disturbance, resilience) are applied differently in the discussion on human and environmental insecurity from the way they are understood in ecology, a clarifying interdisciplinary discussion is urgently needed.

47 Securitizing Land Degradation and Desertification: A Proactive Soil Security Concept

Hans Günter Brauch and Úrsula Oswald Spring

47.1 Introduction[1]

This chapter addresses manifold interactions between the natural environment and humankind affecting the land[2] (or often used synonymously as ground[3] and soil[4]) as the provider of ecosystem services, water storage and food for living organisms (plants, animals, micro-organisms, and human beings). As a result of human activities and increased demand due to population growth and climate change desertification has progressed, the land and the quality of the soil have degraded, and the impact of drought has increased.[5] On this background this chapter will:

a.) discuss to which extent the human-nature interactions pose *objective security dangers* and *subjective security concerns* for human beings, the state and the world of states, of the society and of the economy;
b.) introduce the new concept of '*soil security*' – in contrast to the established concept of 'territorial security' – and review the factors contributing to '*soil insecurity*';
c.) review the 'securitizing moves' by international organizations, nation states, and civil society to analyse the three distinct processes of 'land degradation', 'desertification', and 'drought' as issues of 'utmost importance' that 'require extraordinary

1 This chapter emerged from a policy-oriented study for UNCCD that was funded by the Spanish Ministry of the Environment and Rural and Martine Affairs and that was published in English (Brauch/Oswald Spring 2009; at: <http://www.unccd.int/knowledge/docs/dldd_eng.pdf>) and in Spanish (Oswald Spring/Brauch 2009; at: <http://www.unccd.int/knowledge/docs/dldd_sp.pdf>). This chapter, written from a social science perspective, reflects the critique of prominent natural scientists of the combined political concept of DLDD, the UNCCD Secretariat and its officials, as well as diplomats and state representatives have used in many policy documents. The authors are grateful for the recommendations by three reviewers from different scientific disciplines.

2 The term 'land' has multiple meanings. According to the *Shorter Oxford English Dictionary* (McKechnie ^{5}2002: 1534) the noun 'land' stands for "1. the solid part of the earth's surface, as distinguished from the sea or water, or from the air;" it is used synonymously for "2. a) ground or soil, esp. with ref. to its use or properties, b) the land, the (cultivable) earth regarded as a repository of natural resources and the chief source of human sustenance or livelihood, c) an area of ground under cultivation, a field." The second major meaning of 'land' refers to "3. a part of the earth's surface marked off by natural or political boundaries, a country, a nation, a state, also a realm, a domain;" and to "4. ground or territory held as public or private property, landed property ... In pl. territorial possessions; 5. the country, as opp. to the town; 6 a) a strip of arable land or pasture divided from other similar strips by furrows, b) chiefly engineering ...; 7. a tenement building ...; 8. a stretch of country of undefined extent." According to *Webster's New Universal Unabridged Dictionary* (McKechnie ^{2}1983: 1018) 'land' refers to "1. the solid part of the earth's surface: distinguished from sea; 2. a specific part of the earth's surface ...; 3. (a) a country, region, etc.; (b) the inhabitants of such an area; a nation's people;" but it is also used as a synonym for "4. ground or soil in terms of its quality, location; as rich land, high land; 5. ground considered as property; estate...; 6. [pl] specific holdings in land; 7. rural regions as distinguished from urban regions...;" and in economics it refers 10. to "natural resources." As a political concept 'land' refers to territory, besides the people and the system of rule one of three components of national sovereignty. But as a concept in the natural sciences land embraces the soil, its water and its vegetation cover. Many dictionaries in the social sciences do not define 'land' (Kuper/Kuper ^{2}1996: 449 refer to "landscape"; Krieger 1993: 523 to "land reform"). In Schmidt's (^{2}2004: 401) dictionary on 'Politik', the use in political science is limited to the contrast of urban and rural areas, as a synonym for the territory of the state and in German as a 'state' of the federation.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_47, © Springer-Verlag Berlin Heidelberg 2011

measures' (Wæver 1995; 2008) for coping with its consequences to avoid that they result in people's movements, crises, and conflicts.

First the three key scientific concepts of *land degradation, desertification and drought* and the policy-focused DLDD concept[6] – that has recently been used by the UNCCD Secretariat – will be briefly conceptualized (47.2), then the three phases of their evolution will be reviewed (47.3), the securitization of the ground will be discussed (47.4), the causes and impacts of land degradation and desertification will be diagnosed (47.5), a proactive policy for coping with land degradation and desertification will be outlined (47.6), and finally, recommendations will be offered (47.7).

47.2 Conceptualization of Land Degradation, Desertification, and Drought

According to a recent definition in an OSCE Background paper: "Land degradation means loss of the biological and economic productivity of rainfed or irrigated cropland, or range pasture, forests and woodlands resulting from various factors, including climatic variations and human activities such as unsustainable land uses." Within this wider concept "desertification means the land degradation in arid, semi-arid and dry-subhumid areas", where land is defined as "the terrestrial bio-productive system that comprises soil, vegetation, other biota, and the ecological and hydrological processes" (Daussa 2009: 7–8). Accordingly, "combating land degradation requires an integrated approach that takes into account water management and also addresses agricultural and industrial issues. Being a common threat in the region, land degradation calls for transboundary solutions".

For the understanding of 'desertification' the role of nature and human-induced factors has remained controversial. The linkage of human activities, such as the inadequate management of natural resources, and droughts affected in the 1970's many countries in the Sahel. In response, the UN General Assembly organized the *UN Conference on Desertification* (UNCOD) in 1977. During the Earth Summit (1992) desertification was defined as "resulting from various factors, including climatic variations and human activities" (UNEP 1992) and the *United Nations Convention to Combat Desertification* (UNCCD) of 17 June 1994 stated: "desertification is caused by complex interactions among physical, biological, political, social,

3 According to the *Shorter Oxford English Dictionary* ([5]2002: 1158) the term 'ground' has three key meanings: as "I) the lowest or deepest part..."; as "II) base, foundation", and as "III) the earth, land" referring to "8. the earth as distinguished from heaven ...; 9. the earth as distinguished from the sea; dry land...; 10. the earth's surface, on which human, animal, and plant life exists ...; 10. (The) soil, earth, mould, a kind or variety of the soil; 12. a region, a land, a country; ... 14. area or distance ... on the face of the earth; land..." According to *Webster's New Universal Unabridged Dictionary* (McKechnie [2]1983: 804) in American English 'ground' refers to "bottom, foundation, soil" as synonyms for "3. the soil of the earth, earth, land" and as "2. the solid surface of the earth." It is hardly used as a concept in the social and natural sciences.

4 The term 'soil' according to *Webster's New Universal Unabridged Dictionary* (McKechnie [2]1983: 1725) refers either to "any soiled spot, stain, smirch;" or to "1. the surface layer of earth supporting plant life; 2. figuratively, a place for growth or development of any kind; 3. land, country, territory; as native soil; 4. ground or earth, as barren soil." According to the British *Shorter Oxford English Dictionary* ([5]2002: 2910) the term 'soil' points to: "1. the face or surface of the earth, the ground, esp. considered as the source of vegetation or with ref. to composition, quality; 2. a piece or stretch of ground, a site; 3. a land, a country, a region ... now also national territory 4. the material comprising the thin top layer of much of the earth's land surface, composed of fragmented rock particles with humus, water and air, esp. such material as will support the growth of plants, as contrasted with subsoil; b) fragmentary or unconsolidated material occurring naturally at or near the surface of the earth ..." As a scientific concept 'soil' is widely used in the natural and in the soil sciences, especially with regard to specific properties and functions and the sources of erosion and degradation. Wild (1993: 3) defined soil as "the loose material composed of weathered rock and other materials, and also partly decayed organic matter that covers large parts of the land surface of the Earth" that "supports crop growth and can be tilted." He discussed soil "as a component of ecosystems," through geological times and its cultivation by humankind. According to Young (1998: 27) basic stages in soil survey are the description and identification of soil types, classification, and mapping. Soil responds to and influences environmental processes and conditions that is vital for plant growth and food supply (Ellis/Mellor 1995: 1). In soil science, the "term 'soil degradation' denotes a decline in soil quality as a result of anthropogenic factors. .... The concept of soil quality is in turn, based on the soil's capacity to produce biomass and perform environmental services" (Lal 2003: 17).

cultural and economic factors." According to Art. 1 (b) "*combating desertification*" aims at:

> (i) prevention and/or reduction of land degradation; (ii) rehabilitation of partly degraded land; and (iii) reclamation of desertified land." *Drought* is used for "the naturally occurring phenomenon that exists when precipitation has been significantly below normal recorded levels, causing serious hydrological imbalances that adversely affect land resource production systems.

The UNCCD defined four strategic objectives to combat desertification:

1. to improve living conditions of affected populations;
2. to improve the condition of affected ecosystems;
3. to generate global benefits through effective implementation of the UNCCD; and
4. to mobilize resourses to support the implementation of the Convention through building effective partnerships between national and international actors (UNCCD 1994: 36).

Desertification is a highly contested scientific concept (Reynolds/Smith 2002; Mainguet 2003; Safriel 2009), where the controversy focuses "on the causes and consequences of land degradation." For Reynolds and Smith (2002: 3), this problem is

> often attributed to a myriad of human activities, particularly overgrazing, it may be triggered or exacerbated by climate variability... [and] not all such ecological, biogeochemical, and hydrological changes have an immediate or direct economic impact on human activities.

Within their analytic framework they combine meteorological, ecological, and human dimensions and distinguished among the farm or household, the community, regional and international levels as well as social (rural livelihoods) and biophysical factors (state of the ecosystem). They suggested that

> it is crucial to work through the causal links of drylands land degradation, from climate dynamics to ecological impacts to policy response strategies, and to span a wide range of temporal and spatial scales, from small geographical units to larger regions (Reynolds/Smith 2002: 19).

Controversies exist between the different desertification concepts that have been employed in the natural sciences and the *political* DLDD concept[7] as used by the UNCCD Secretariat and some UNCCD member states. Whether desertification occurs only in drylands is a matter of definition. The UNCCD text declares that "desertification is land degradation in ..." and then cites three types of drylands (out of existing four). Thus, the question is not whether or not desertification also occurs outside the drylands, because by definition it can not. However, land degradation surely occurs also outside the drylands but has adverse direct and indirect effects on other ecosystems, such as dust storms due to wind erosion. Land degradation applies to about 33 per cent of the global land surface (UNEP 2008); the productivity loss per year is estimated at 0.5 to 1 per cent, or an accumulated loss of at least 20 per cent during the last 40 years.

In a classification of drought typology Smith (1992) distinguished among four types:

1. Meteorological drought due to precipitation shortage but with no lasting ecological or economic impact and no effective behavioural response.
2. Hydrological drought which depletes water resources and leads to more rigorous management control of supply and demand.
3. Agricultural drought where widespread impact affects farming production and may lead to government compensation,
4. Famine drought, confined mainly to less-developed countries, often wipes out subsistence agriculture and leads to catastrophic mortality and massive international relief programmes (Whittow 2002: 641).

While the first three types have also affected developed nations (e.g. the Dust Bowl in the USA during the 1930's), since 1950 the fourth type has had the highest impact and death toll in developing countries that lack the scientific, administrative, and economic coping capacities. Prince (2002: 24–26) noted that

5 See in this volume: chap. 48 by Safriel; chap. 49 by Adeel; chap. 50 by Galil Hussein; chap. 51 by Arredondo Moreno and Huber-Sannwald; chap. 53 by Mainguet, Dumay, Kabiri and Rémini; chap. 52 by Laureano; with a special focus on the Mediterranean see Mendizábal and Puigdefábregas (2003); Nasr (2003); Kepner, Rubio, Mouat and Pedrazzini (2006); Rubio, Safriel, Daussa, Blum and Pedrazzini (2009); López Bermúdez (2009).

6 The UNCCD Convention (1994) refers to: "Combating desertification and land degradation and mitigating the effect of droughts." More recently, the DLDD concept has been widely used by the UNCCD Secretariat; see at: <http://www.unccd.int/search/search_results.php?query=DLDD>. The DLDD term was criticized by soil scientists, e.g. Safriel (2009). From the perspective of social science theory, 'securitization' is a political process where the vocabulary applies that is used in the policy-focused discourse.

7 Its use is relatively recent and did not exist during the first years of UNCCD in force.

desertification "can be caused either by drought or inappropriate intensity or type of land use, or both" even though both may have different effects due to the fact that some landscapes may be more susceptible than others. While drought events may be temporal, desertification processes may become irreversible.

According to the *Global Drought Monitor* by the Meteorological Hazards and Seasonal Forecasting group at the Benfield UCL Hazard Research, "drought is a deficiency in rainfall over an extended period of time. It is a recurrent feature of climate, which happens almost everywhere." The *Global Drought Monitor* offers a summary of current hydrological drought conditions worldwide where "hydrological drought conditions are displayed based on the two leading drought indices" called the *Standardized Precipitation Index* (SPI) and *the Palmer Drought Severity Index* (PDSI), "a soil moisture algorithm which includes terms for water storage and evapotranspiration".[8]

Loss of yield productivity could produce food scarcity obliging people to migrate from the drylands to better agricultural land, to urban areas or to industrialized countries, but they can also induce inadequate governance, hunger riots, and conflicts. Thus, the three distinct scientific components that were linked in the political DLDD concept[9] pose multiple global, regional, and national security issues related to food, water, climate, livelihood, health, urban, rural and transportation security (Brauch 2003, 2003c, 2006).

A political consensus emerged that land degradation and desertification is primarily a human-induced and drought a natural process with negative effects on land affecting the function of an ecosystem for storing and recycling water, for generating energy, and recycling nutrients. Short-term crop yield increases may threaten the long-term conservation of the agricultural land, which is the main cause of deterioration together with overgrazing, land clearing, deforestation, land-use change, mining, urban conversion, poor irrigation processes, and pollution. All of them create major physical stressors on land such as wind and water erosion, removal of nutrients, increase in acidity, salinization and alkalinization, destruction of soil structure, and loss of organic matter (USDA 2009). Based on these conceptualizations, the political DLDD concept has gradually evolved in three phases from a scientific problem to a policy question and a security danger and concern.

47.3 Evolution of the Scientific Terms of Land Degradation and Desertification, and of the Political DLDD Concept

Three stages of the evolution of the three distinct scientific concepts that were combined by the UNCCD Secretariat in the policy-focused DLDD concept can be distinguished: a) of scientific agenda-setting and research (*scientizing*), b) of political agenda-setting and action (*politicizing*), and c) of upgrading it to a security issue (*securitizing*).

47.3.1 Scientizing by Creating Awareness for Desertification

Global environmental change (GEC) has emerged as a multidisciplinary scientific field of study since the 1970's that has focused on climate change, desertifica-

8 The PDSI "facilitates the quantitative comparison of drought incidence at different locations and at different times of the year," but it "may lag emerging droughts by several months. The empirical relationships used to define the PDSI were determined by observations taken from just nine US climate stations. The limited nature of the original PDSI source training data brings the general applicability of the PDSI into question" (Palmer 1965; Alley 1984).

9 A recent 6-page UNCCD document on "Policies for addressing desertification, land degradation and drought (DLDD) with a focus on strengthening the role of the United Nations Convention to Combat Desertification (UNCCD)" referred 29 times to the DLDD concept; at: <http://www.unccd.int/meetings/global/hlpd/docs/Policy_paper_eng.pdf>. See also the presentation by the UNCCD Executive Secretary, Luc Gnacadja, 4–5 June 2009 in Bonn on: "Framing the issue DLDD into Sustainable Development"; at: <http://www. unccd.int/publicinfo/undp/docs/DLDD%20Priorities%20and%20Principles%20-%20June%2009%20-%20UNDP-UNCCD%20Retreat-%20rev%20LG.pdf>. However, neither UNCCD's 10 year Madrid strategy; at: <http://www.unccd.int/cop/officialdocs/cop8/pdf/16add1eng.pdf> nor the report on the 17th session of the UNCSD in May 2009 used the DLDD concept, what may be an indication that it has not been adopted by UN and UNCCD members. See: United Nations Commission on Sustainable Development Report on the seventeenth session (16 May 2008 and 4–15 May 2009), Economic and Social Council, Official Records, 2009 Supplement No. 9 at: <http://daccess-dds-ny.un.org/doc/UNDOC/GEN/N09/355/72/PDF/N0935572.pdf?OpenElement> (20 December 2009).

tion, water and biodiversity, as well as on the human factors, of population growth, urban and rural systems, and the economic process (figure 47.1). Since the 1990's, scientific networks and projects on global change as well as policy-focused scientific epistemic communities (Haas 1989, 1990, 1992, 1993; see IPCC) have evolved that assess scientific research results, and explain them to the global policy community (*scientific agenda-setting*).

The scientization of 'desertification' started in the 1950's when UNESCO published 30 volumes on drylands in which 200 research institutes were involved.[10] In response to the Sahelian droughts of the 1970's three institutions were established a) the *Inter-States Committee for the Fight against Drought in the Sahel* (CILSS; chap. 63 by Bikienga); b) the *Club du Sahel* within OECD; and c) the *United Nations Sahelo-Sudanian Office* (UNSO) (Mainguet 2003: 645). In 1977, the *United Nations Conference on Desertification* (UNCOD) proposed a *Plan of Action to Combat Desertification* (PACD), and UNEP was tasked to develop it further.

In addition to the work of the *Consultative Group on International Agricultural Research* (CGIAR)[11], specific scientific and policy-focused activities related to land degradation and desertification[12] include:

- The *Global Assessment of Human Induced Soil Degradation* (GLASOD) by the *International Soil Reference and Information Centre* (ISRIC) in 1990 produced a world map of soil degradation for the 1992 *United Nations Conference on Environment and Development* (UNCED) based on expert assessments and input from more than 250 soil and environmental scientists (Kniivila 2004: 4–5).
- The *Global Assessment of Land Degradation and Improvement* (GLADA) identified a programme on *Land Degradation in Drylands* and studied the status and trends of land degradation and established hotspots "suffering extreme constraints or at severe risk", but also areas that have been reversed.[13]
- The Desertification Synthesis of the *Millennium Ecosystem Assessment* (MA 2005) offered an overview of the state of the knowledge and of the knowledge gaps of desertification only, but not of 'land degradation' in general and not of drought.[14]

Besides these scientific assessments several issue-specific scientific networks have evolved:

- *TerrAfrica* is a partnership that aims to address land degradation by scaling up harmonized support for effective and efficient country-driven *sustainable land management* (SLM) practices in Sub-Saharan African countries and NEPAD (Bai/Dent/Olsson/Schaepman 2008).[15]
- *DesertNet* improved research on combating and preventing desertification in Europe and at a global scale, and to support communication with policy-makers and other stakeholders.[16]
- *ARIDnet* is addressing the interaction of meteorological, ecological (*biophysical* factors), and the human dimensions (*socio-economic* factors) of desertification.[17]

Safriel (2009: 36–39) reviewed both the scientific and the conceptual political debate of UNCCD on the linkages between these three concepts of desertification as a "geographical subset of land degradation" or as "extreme land degradation" as well as an "associate of drought and climatic variations". He argues that droughts "constitute an extreme expression of this strong spatio-temporal climatic variability of the drylands" that can be interpreted as "a subset of 'climatic variability'" and that the UNCCD definition implies that drought "is more a driver of desertification than an independent phenomenon to be somewhat associated with desertification", what further implies that "'mitigating the effects of drought' becomes a subset of 'combating desertification', rather than an added action".

10 For a review of the conceptual debate and detailed sources see Mainguet (1994, 1995, 2003).

11 See for details at: <http://www.cgiar.org/>.

12 However, none of these specifically dealt with drought.

13 See for details; at: <http://www.isric.org/UK/Aut+ISRIC/Projects/Current+Projects/GLADA.htm>.

16 See for details at: <http://www.european-desertnet.eu/index.php>.

17 See at: <http://www.biology.duke.edu/aridnet/>. ARIDnet is funded by the U.S. National Science Foundation) with the goal to develop and test a new synthetic Drylands Development Paradigm (DDP).

Within the framework of the *Earth System Science Partnership* (ESSP; chap. 74 by Leemans/Rice/Henderson-Sellers/Noone) and the four related major research programmes[18] issues related to land degradation, desertification, and drought were researched but no specific scientific programme compared with climate change (e.g. WCRP and the *Intergovernmental Panel on Climate Change:* IPCC) and water (e.g. *Global Water Partnership:* GWP) has been set up for land and soil issues (Vlek 2005: 25). So far, the communication of scientific research on land degradation and desertification to policy-makers has been "inadequate" (Bauer/Stringer 2009: 249).

Each of the three key conventions on climate change (UNFCCC), biodiversity (CBD), and desertification (UNCCD) has created a scientific and technological advisory body, with the *Subsidiary Body for Scientific and Technological Advice* (SBSTA) for UNFCCC, the S*ubsidiary Body on Scientific, Technical and Technological Advice* (SBSTTA) for CBD, and the *Committee for Science and Technology* (CST) for UNCCD. With the adoption of UNCCD's 10-year Strategy (2007) at UNCCD's COP 8 the role of the CST was upgraded.

At COP 9 in Buenos Aires (22–24 September 2009) the first UNCCD Scientific Conference[19] addressed "biophysical and socio-economic monitoring and assessment of desertification and land degradation, to support decision-making in land and water management". [20] The participants discussed the wide range of methodologies and underlined the need for *sustainable land management* (SLM). They suggested "an independent, international, interdisciplinary scientific advisory mechanism" for new knowledge creation to DLDD/SLM.[21] While the gap between science and politics was not overcome in Buenos Aires, the *conference of the parties* (COP 9) approved a second Scientific Conference for 2012 to deal with economic factors of desertification, technologies of sustainable land management and the increase of resilience for DLDD regions, including the participation of civil society organizations and the use of traditional technology. But they failed to adopt an "accompanying methodology and data collection strategy".[22]

47.3.2 Politicizing Land Degradation, Desertification, and Drought

Since 1992, international environment policy has resulted in new forms of global governance (climate change, biodiversity, desertification, water regimes) that have moved to the centre of political concerns (*politicization*, e.g. Dessler/Parson 2006, 2008) in the framework of the COPs of UNFCCC, CBD, UNCCD, and the triennial World Water Fora.

With the entry into force of the UNCCD (1996) desertification became an international political issue.[23] At COP 5 the *Committee for the Review of the Implementation of the Convention* (CRIC) was set up[24] and at COP 8 the *10-Year Strategic Plan and Framework (2008-2018)* was adopted. At COP 9 (2009), the existing institutional and "political divisions that the UNCCD has faced since its conception,

18 The four component research programmes are DIVERSITAS (chap. 76 by Walther/Larigauderie/Loreau), the *World Climate Research Programme* (WCRP); chap. 78 by Church/Asrar/Busalacchi/Arndt), the *International Geophysical and Biological Programme* (IGBP; chap. 77 Noone/Nobre/Seitzinger), the *International Human Dimensions Programme* (IHDP; chap. 75 by von Falkenhayn/Rechkemmer/Young).

19 The conference was prepared by the *Drylands Science for Development* (DSD) Consortium consisting of five research institutions and networks: the European DesertNet, the International Center for Agricultural Research in Dry Areas, the International Crops Research Institute for the Semi-Arid Tropics, the European Commission Joint Research Centre - Institute for Environment and Sustainability and United Nations University International Network on Water, Environment and Health. In preparing this SC-1 the DSD consortium convened three global working groups of scientists to analyse and summarize the leading scientific knowledge on the priority theme in order to generate practical recommendations.

20 See: "Summary of the Ninth Conference of the Parties to the UN Convention to Combat Desertification: 21 September – 2 October 2009", in: *Earth Negotiation Bulletin*, 4,229 (5 October 2009): 1, 10–1

21 See: UNCCD: "Report of the UNCCD 1st Scientific Conference", ICCD/COP(9)/CST/INF.2, 25 September 2009; at: <http://www.unccd.int/cop/cop9/menu.php>

22 See: *Earth Negotiation Bulletin*, 4,229 (5 October 2009): 16.

23 COP 1: Rome (1997); COP 2: Dakar (1998); COP 3: Recife (1999); COP 4: Bonn (2000); COP 5: Geneva (2001); COP 6: Havana (2003); COP 7: Nairobi (2005); COP 8: Madrid (2007); COP 9: Buenos Aires (2009).

24 Until September 2009, seven CRIC meetings have occurred: 1) in Rome (November 2002); 2) in Havana (August-September 2003); 3) in Bonn (May 2005); 4) in Nairobi (October 2005); 5) in Buenos Aires (March 2007); 6) in Madrid (September 2007) and 7) in Istanbul (November 2008).

particularly with regard to the relationship between the Global Mechanism and the Secretariat",[25] could not be overcome.

As a suggestion of the *World Summit on Sustainable Development* (WSSD) in 2002 in Johannesburg, the *Global Environment Facility* (GEF) adopted land degradation as a 'focal area' and launched an 'operational programme' on *sustainable land management* (SLM). The *International Year of Deserts and Desertification* (IYDD) in 2006 stressed the urgency of combating desertification and the 17th session of the UN Commission on Sustainable Development (UNCSD) recommended integrating agriculture and rural development with land degradation and desertification.

47.3.3 Securitizing Desertification

With four international conferences and workshops in Almería in 1994 (Puigdefábregas/Mendizábal 1995) and in 2006[26] on desertification and migration and in Valencia in 2003 and in 2007 on desertification in the Mediterranean as a security issue (Kepner/Rubio/Mouat/Pedrazzini 2006; Rubio/Safriel/Daussa/Blum/Pedrazzini 2009)[27], the Spanish government launched a process of securitization of desertification. The security link was taken up by UNCCD at its CRIC 3 meeting (2005)[28] and in UNCCD Issue Paper No. 2 (Brauch/Oswald Spring 2009; Oswald Spring/Brauch 2009). In June 2007, in a workshop on "Desertification: A security threat?", the German development (BMZ) and foreign ministries (AA), and UNCCD reinforced the link between an extended security concept and desertification affecting human and food security at the global, regional, national, and local level. During the *International Year of Deserts and Desertification* (2006) the security linkage was occasionally addressed,[29] but contrary to the intensive securitization of climate change no similar policy debate has emerged on securitizing desertification, and UNCSD 17 referred to 'food' and 'land tenure security' but not to 'soil security', while COP 9 addressed only 'land and food security'.

47.4 Securitization of the Land as Territory and as Soil

47.4.1 Security Concepts, Approaches, and Securitization Theory

Security is a key *concept* in the social sciences and a value and goal of activity of nation states and of supra- and sub-state actors, referring to protection, lack of risks, certainty, reliability, trust and confidence, predictability in contrast to danger, risk, disorder, and fear (Brauch 2003, 2005, 2005a, 2008, 2009).

'Security in an objective sense' refers to specific *security dangers*, *dimensions* and *referent objectives* as well as *sectors* (social, energy, food, water, health, livelihood and also soil), while 'security in a subjective sense' refers to *security concern*s by government officials, media representatives, scientists or 'the people' who securitize[30] perceived 'dangers' as security 'concerns' being existential for the survival of the referent object. Security legitimizes extraordinary measures and means to face and cope with these concerns. Thus, *security concepts* have been used as tools to analyse, interpret, and assess past actions or to legitimize present or future activities in meeting the specified security dangers and concerns.

30 The scientific concept of 'securitization' – as used below – was coined by Wæver (1995) as a specific theoretical concept in political science and international relations. It differs fundamentally from the term 'securitization' as used in the banking sector. While *Webster's New Universal Unabridged Dictionary* (McKechnie ^{2}1983: 1641) does not yet list this term, the *Shorter Oxford English Dictionary* (^{5}2002: 2734) refers to the verb 'securitize' with a different meaning in commerce to "convert (an asset, esp. a loan) into securities, usually for the purpose of raising cash by selling them to other investors. Banker Assets will be growing more slowly ... as the bank securitizes more of its loan." For this different meaning of securitization as a financial technique "that pools assets together and, in effect, turns them into tradable security" see: Fabozzi and Kothari (2008).

The *Copenhagen School* (Buzan/Wæver/de Wilde 1998) posed the attention to the *widened* use of security from the narrow military and political scope to the wider economic, societal, and environmental security 'sectors'. But in their *deepening* of the security concept they focused primarily on state-centred referent objects (international, regional, national), but they did not use or were sceptical (Buzan 2004) of the human security concept. In his conceptual mapping of contemporary security concepts, Brauch (2008, 2009) added the extensive use of sectoral security concepts (*sectorialization*) and integrated the many different meanings of *human security* in policy debates and scientific discourses (Brauch 2009b) while Oswald (2001, 2009) proposed both a combined *human, environmental, and gender security* (HUGE) concept and a related policy strategy.

The 'securitization theory' developed by Wæver (1997) offers a theoretical approach for the analysis of policy declarations ('speech acts') on the security impacts of climate change, food and water issues (Oswald Spring/Brauch 2009) as well as of the three distinct scientific concepts of land degradation, desertification and drought, and of the composite political DLDD concept.[31] By declaring a process a security problem or as an existential threat to sovereignty, the 'state' has been the major securitizing actor.[32] But environmental issues could also be enacted by non-state actors. The emerging policy debate on climate change and land degradation and desertification as well as on the political DLDD concept represents a new subjective security concern whereby the 'securitizing actor' is not solely the nation state but also a transnational epistemic community of natural scientists (e.g. the IPCC). The referent objects are primarily human beings and humankind who are both the cause of global warming and the victims of climate change and land degradation and desertification as well as of the political DLDD concept. However, both actors (those who cause these effects and the primary victims) are not identical, what has created major equity problems (Adger/Paavola/Huq/Mace 2006).

From a narrow national security perspective the 'securitizing actor' and the 'referent object' remains the nation state, while from a 'people-centred' societal or human and gender security outlook the scientific community has become a new securitizing actor, and the referent object are not any longer the state but the vulnerable people that will be hurt by these newly emerging security issues related to climate change and land degradation and desertification as well as to the political DLDD concept.

47.4.2 Two Sides of Securitizing the Land: Territory vs. Soil

Securitizing the 'land' refers to two distinct aspects of 'land' as 'territory' and 'land' as 'soil'. Land as territory covers a key feature of national sovereignty and refers to the protection of the state (territory, people, political institutions); and the land as 'soil' produces the key environmental services, among them the food for living organisms. While 'territorial security' points to the traditional national security concept, the new sectoral 'soil security' concept applies primarily to the economic, environmental, and societal dimensions of security. 'Soil security' can be analysed from both the perspectives of human and gender security and from state-centred perspectives of local, national, regional, and international security.[33]

The 'soil security' concept claims that land degradation and desertification processes relate to a lack of precipitation during periods of drought and an exhaustion of ground water reserves severely challenges the livelihood and often oblige people to migrate to better agricultural land, to urban centres within their country (urbanization) or abroad. 'Soil security' is threatened by a) the degradation of soils and related fertility and biodiversity losses due to processes of geophysical, wind, and water erosion, and b) drought resulting in bad harvests and crop yield declines that have often triggered in developing countries severe and extended periods of famine that affected several hundred millions of people in the 20th century and caused thousands of deaths. In the Sahel drought human factors were involved, and they were decisive.

31 The concept of 'securitization' as used here refers to a specific theoretical approach in political science and international relations. Fabozzi and Kothari (2008) lack any reference to the different earlier use by Wæver (1995).

32 Much of the elaboration of this theory (Wæver/Buzan/Kelstrup/Lemaitre 1993; Buzan/Wæver/de Wilde 1998; Wæver/Buzan/de Wilde 2008) has occurred through exploring the particular dynamics and characteristics of security. Introductions to the theory are at: <http://polforsk.dk/download/securitytheory2006/homepage>."

33 The concept of 'soil security' refers to 'ecosystem' or 'environmental services' offered by the land. It also includes those services that are provided by the 'land', namely through the interaction between the biota, within and on the soil, and the soil and the atmosphere.

But the claim of a spatial expansion of existing deserts is disputed among soil specialists who argue that desertification does not result in the expansion of deserts.[34]

'Soil insecurity' challenges basic ecosystem services, especially due to land degradation but also due to drought,[35] inadequate food production and supply, especially for the poor and marginalized population that cannot afford to purchase food. Since 2008 drastic food price rises increased the number of hungry people by 100 million in 2009, and in the same year one billion people were hungry in countries lacking financial resources and agricultural policy to meet the food demand of their growing population or the capacity to effectively distribute the food aid to the people most in need and affected by famine (FAO 2009; IFPRI 2009).

'Securitzing the land as soil' implies that both policy-makers in national governments and in international organizations, programmes (FAO, WFP, UNDP, UNEP) and environmental regimes (UNFCCC, UNCCD, CBD), networks and knowledge-based epistemic communities succeed in upgrading land issues from environmental, societal, economic and food issues to problems of 'utmost importance' for the highest political level that require 'extraordinary measures' to face their societal and political impacts and cope with their natural and anthropogenic causes.

47.4.3 Securitizing the Land as Soil: Causes and Societal Effects

'Securitizing the land' as soil and 'grounding security' point to different problems:

- *securitizing the land* as soil refers to a process of creating a wider global political awareness for land degradation and desertification by making it a key international issue and upgrading it to the security realm;
- *grounding security* – as we argue below – refers to reactive vs. proactive short-, medium- and long-term strategies for coping with soil insecurity and its consequences.

Addressing both aspects of soil (in)security through a political process of securitization of land degradation and desertification as well as on the political DLDD concept and of the development of effective international strategies, national policies, and local measures requires a diagnosis of the complex interaction between natural and societal causes.

47.5 Diagnosing Land Degradation, Desertification, and Drought

47.5.1 Models on Human-Nature Interactions

Various models were developed to analyse the nature-human interactions. The model of OECD (2001) assumes that human activities put pressure on nature that leads to environmental changes (climate change, water and soil degradation, biodiversity loss) to which the state, the society and the economic sector respond with multiple activities.[36] The PEISOR model (figure 47.1) was developed to securitize GEC issues. This model combines five stages:

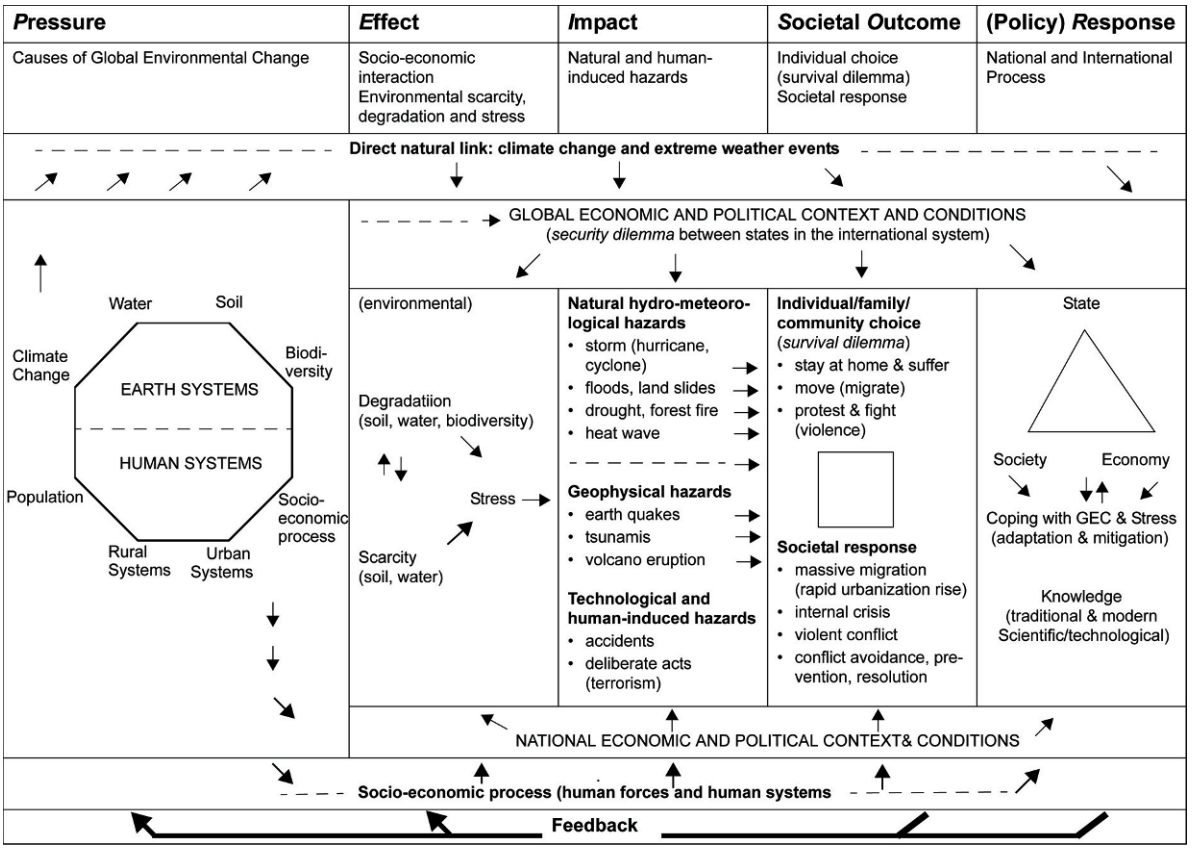
- *P* (*pressure*) refers to eight drivers of global environmental change;

34 The IPCC claimed that anthropogenic climate change may cause an expansion of deserts, but so far we do not really see it yet. Droughts do not expand deserts, because once drought terminate everything gets to where it had been before, unless the drought is linked with human activities. In spite of the UNCCD definition of desertification, 'climatic variations' alone do not cause desertification, which is caused by 'human activities' when there are no climatic variations, or when 'human activities' are coupled with 'climatic variations'.

35 Safriel argued that the soil stores some water as part of its services. But the water stored in the soil, Allen (2009) calls 'brown water', is not available for drinking, sanitation, and irrigation. Also, one gets the impression that the soil is simply a physical entity, but it would not have stored water unless it has a lot of organic matter, and the organic matter is contributed by the above soil biota. Therefore Safriel sees some problems in attributing the flow of ecosystem services to the 'soil', in his view it is the ecosystem, organic matter, microorganisms, evapotranspiration, etc.

36 For details see Brauch (2009a). The *UN Commission for Sustainable Development* (UNCSD) used its DSR (*Driving Force – State – Response*) model and the *European Environment Agency* (EEA 1998) distinguishes *D*riving Force – *P*ressure – *S*tate – *I*mpact – *R*esponse (DPSIR) as a mechanism for analysing environmental problems and for developing environmental indicators. The framework of the *Millennium Ecosystem Assessment* (2003, 2005a) considers security as a key element of human well-being (Leemans 2009).

Figure 47.1: PEISOR-Model. **Source:** Developed further based on Brauch (2005, 2009a) and Brauch and Oswald Spring (2009).



- *E* to the *effects* of the interactions on environmental scarcity, degradation, and stress;
- *I* to extreme *impacts* of human-induced and climate-related natural hazards;
- *SO* to *societal outcomes*: forced migration, slums, crises, conflicts or state failure;
- R to the *response* of all stakeholders.

47.5.2 Environmental and Human Pressures (P)

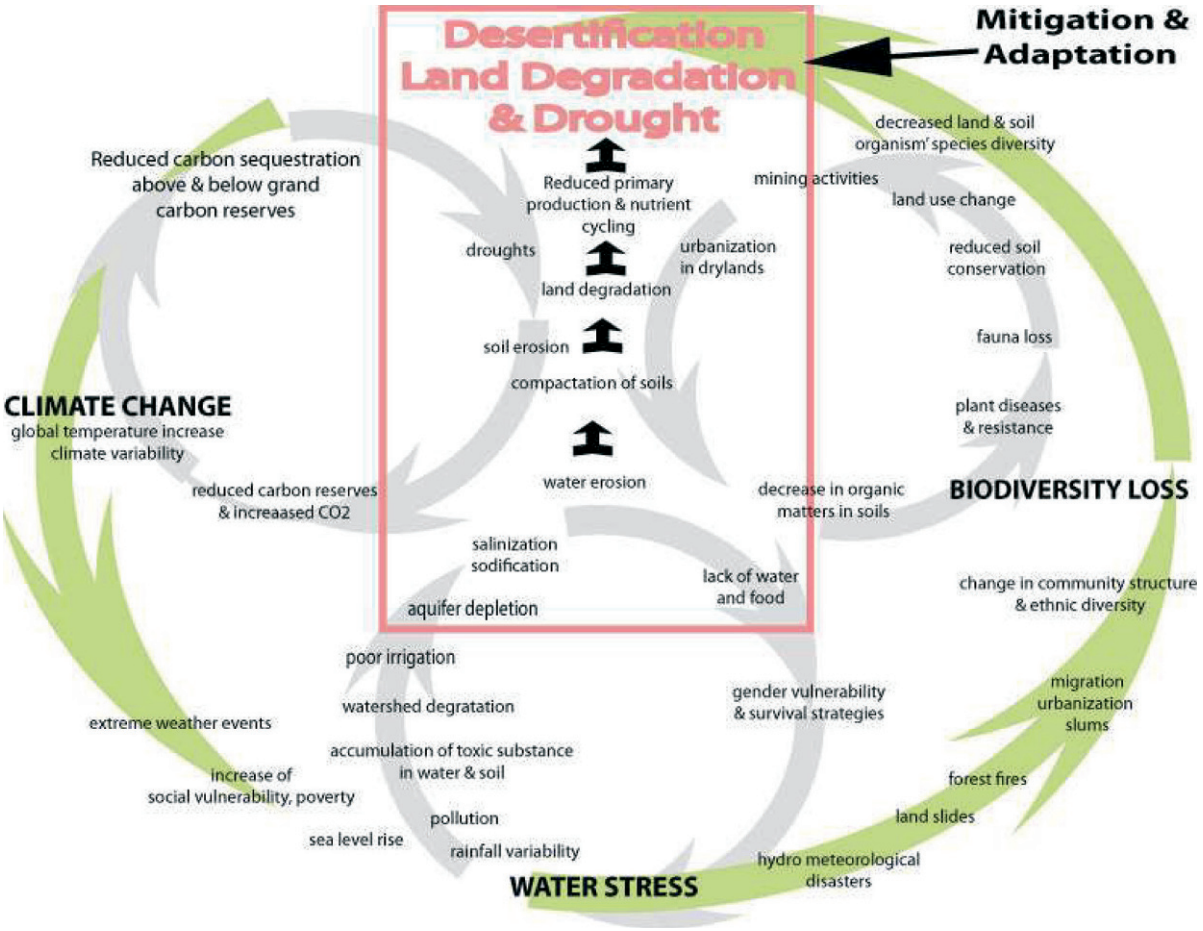
The PEISOR model refers under *pressure* to four supply or environmental factors (land, air, water, and biodiversity) and four demand or human factors (population growth, rural or urban systems and their economic processes). Figure 47.2 illustrates the interactions among the components of the environmental quartet in a non-linear way that pose pressure on the political and societal context where they may cause anthropogenic e*nvironmental degradation* (of water, soil, air, biodiversity) or *scarcity* (water, soil) that may result in environmental stress.

The three small cycles with the factors determining climate change, water stress, and biodiversity loss have each different effects on land degradation and desertification as well as on the political DLDD concept. The wider cycle representing GEC relates the interrelations between the earth and human systems with unpredictable consequences on land degradation and desertification and their societal outcomes.

Biodiversity loss directly affects major drylands services. The inner loops connect desertification to biodiversity loss and climate change through soil erosion. The outer loop interrelates biodiversity loss and climate change. On the top section of the outer loop, reduced primary production and microbial activity reduce carbon sequestration and contribute to global warming. On the bottom of the outer loop, global warming increases evapotranspiration, thus adversely affecting biodiversity; changes in community structure and diversity are also expected because species will react differently to elevated CO_2 levels and its sequestration.

While droughts have existed, especially in drylands, prior to anthropogenic global warming, the IPCC (2001: 4–5) noted that from 1900 to 1995:

Figure 47.2: Environmental Quartet: Land degradation and desertification and the political DLDD concept, Climate Change, Water Degradation and Biodiversity Loss. **Source**: Inspired by MA (2005: 17) and further developed by Brauch and Oswald Spring (2009: 10).



> There were relatively small increases in global land areas experiencing severe drought or severe wetness. In many regions, these changes are dominated by inter-decadal and multi-decadal climate variability, such as the shift of ENSO towards more warm events. In some regions, such as parts of Asia and Africa, the frequency and intensity of droughts have been observed to increase in recent decades.

On the interactions between climate change, land degradation and desertification, the IPCC (1996a: 173) argued that both processes must be considered in parallel. Often it would be impossible to separate the impact of unsustainable land management and climate change but often they interact and produce negative cumulative effects on soil.

- Fundamental soil properties and processes ... will be influenced by changes in climate.
- Desertification arises both from human abuse of the land and from adverse climate conditions. Climate related factors such as increased drought can lead to an increase in the vulnerability of land to desertification and to the escalation of the desertification process.
- Reversing the effects of desertification is not always possible and is more difficult for drier environments with shallower soils.
- Changes in the frequency and intensity of precipitation will have the greatest direct effect on soils via erosion by water. ... Future erosion risk is likely to be related more to increases in population density, intensive cultivation of marginal lands, and the use of resource-based and subsistence farming techniques than to changes in precipitation regimes. ...
- Where conditions become more arid, salinization and alkalization are likely to increase because evapotranspiration and capillary rise will be enhanced. ...
- Predicted warming may give rise to higher evaporation rates, leading to drier soils and more frequent episodes of severe wind erosion.
- Because arid and semi-arid land ecosystems have little ability to buffer the effects of climate variability ... they are particularly vulnerable to climate change. ...

- Adaptation to desertification will rely on conventional strategies (IPCC 1996a: 173).

The fourth IPCC (2007a: 186) assessment report noted that a "warmer climate, with its increased climate variability, will increase the risk of both floods and droughts". Distinguishing among meteorological, hydrological, agricultural and environmental drought, the IPCC claimed:

> The socio-economic impacts of drought may arise from the interaction between natural conditions and human factors, such as changes in land use and land cover, water demand and use. Excessive water withdrawals can exacerbate the impact of drought.

There may also be impacts of climate change resulting in an increase and severity of hydro-meteorological hazards. This aspect has so far only marginally been addressed by the environmental security research (Dalby/Brauch/Oswald 2009) but it is key to the debate on the *securitization* of climate change and land degradation and desertification. While natural hazards (drought) cannot be prevented, processes of land degradation and desertification can be mitigated by proactive human activities. Also, the impact of land degradation and desertification and most particularly of droughts resulting in deaths, affected people, economic and insured damages, can be reduced by linking 'protection' with 'empowerment' of the people (CHS 2003) to become more adapted and resilient. Environmental stress increases the impact of hazards (especially for those with a high degree of social vulnerability (Birkmann 2005) and causes or contributes to internal displacement, urbanization, and forced migration.

Whether these factors result in domestic crises, disasters, and in a few worst cases in violent conflicts, or whether these can be avoided, depends on specific factors and activities resulting from the interaction between the state, the society, and the business community, and on knowledge-based response strategies by governments and international organizations and transnational societal and economic organizations at all levels employing both traditional and modern technical and organizational knowledge (participative governance).

Of the earth system factors, climate change and water have been widely securitized since the year 2000, e.g. by the Ministerial Declaration on Water Security (The Hague 2000) and by the debate on climate change as a security issue in April 2007 in the UN Security Council, in June 2009 in the UN General Assembly, and in the report of the Secretary-General of September 2009.[37] The process of securitization of land degradation and desertification is also emerging, while biodiversity problems have not yet reached the level of securitization.[38]

With regard to the human system, the population has been widely discussed as a key property of national sovereignty. Aspects of socio-economic processes are being analysed in the frame of economic and financial security. The economic, societal, and environmental dimensions of security cover both the productive and consumptive patterns in rural and urban systems.

The *pressure* side are influenced by both *human-induced demand factors* (population change, production, consumption and habitat in rural and urban systems, and the economic process) and *nature-induced supply side factors* (climate change, land, water and biodiversity). Climate change produces at least four impacts: temperature and precipitation changes, rise in sea level, and extreme weather events. Its drivers – the MA (2005) defined these as direct drivers – resulting in an increase in greenhouse gases are influenced by the specific socio-economic development – the MA (2005) defined these as indirect drivers – that affect the direct drivers and their impacts (for ecosystems, water, settlements, human health) that are also affected by the degree of social vulnerability. Besides natural climate variability, human factors have influenced the speed of anthropogenic climate change, especially since 1950. Climate change, land, water, and biodiversity form an 'environmental quartet' with many interactions calling for synergies among the three environmental regimes dealing with climate change (UNFCCC), biodiversity (CBD), and desertification (UNCCD) to which water is an integral part (figure 47.2).

While the sea-level rise and the shrinking of the coastal land and the disappearance of islands due to climate change has a direct impact on 'territorial' and 'national security', the other three effects of climate change (temperature and precipitation change and extreme weather events) directly affect 'soil security'.

37 See: "Climate change and its possible security implications. Report of the Secretary-General" (New York: UN, 11 September 2009); at: <http://www.un.org/esa/dsd/resources/res_docugaecos_64.shtml>.

38 The MA defined security as one of several elements that comprise human well-being. The MA explained how ecosystem services affect human well-being, namely also security. The MA also asserted that biodiversity is actively involved in the provision of ecosystem services, mostly directly but sometimes indirectly. Therefore, loss of biodiversity negatively affects security.

Anthropogenic climate change will directly impact on the precipitation level. The IPCC (2007a, 2007b) concluded that there will be significant precipitation declines in the American Midwest, in Mexico, Central America, Venezuela, Chile and Argentina, in the Mediterranean, in Central Asia, Southern Africa, and in Australia while precipitation levels will increase in most tropical and in higher latitudes in the Arctic Circle (2007c: 47). According to the Fourth Assessment Report, climate change will have many effects on water (IPCC 2007b: 49), and those also directly impact on land degradation and desertification as well as on the political DLDD concept. Climate change will also have multiple negative impacts on biodiversity that will have repercussions on land degradation and desertification (IPCC 2007: 48).

On the social side, population growth and the increasing demand for energy affect global climate change, but most of the additional 2.3 billion people in 2050 are coming from poor countries. According to the 2006 UN Populations Revision, between 2005 and 2010 the population growth will be the highest for Mali and Niger, Congo and Afghanistan (above 3 per cent), and between 2–3 per cent for all countries in the Sahel and for most countries in West and East Africa and for Saudi Arabia, while in all Latin American and in the remaining African countries it was between 1–2 per cent. Thus, the population growth is the highest in drylands. According to the 2008 UN Population Revision many countries with high net emigration rates are also in drylands or are affected by severe drought (Mexico, China, India, Pakistan, and Bangladesh).

Besides desertification, the degradation of soils is a major challenge due to natural developments and anthropogenic factors. WG II of the IPCC (1996a: 95–324, 161) assessed the implications of climate change impacts on forests, rangeland, deserts, land degradation and desertification, mountain regions, non-tidal wetlands, and on coastal zones and small islands. Often it would be impossible to separate the impact of unsustainable land-management and climate change but often they interact and produce negative cumulative effects on soil.

Climate change will impact differently on the five continents and thus also different effects have been projected for the land (territory) and for the ground (soils). The concepts of land and soil degradation and their geographic scope differ significantly from the drylands and the more limited areas that are already desertified. Given the limitations of existing data sets, "the actual extent of the desertified area may lie between 10 and 20 per cent of the drylands that are already degraded (medium certainty). Based on these estimates, the total area affected by desertification is between 6 and 12 million square kilometres" (MA 2005: 7). Due to the number of people threatened, desertification is one of the greatest environmental problems.

Worldwide about one third of the land is threatened by processes of land degradation and desertification due to complex interactions of nature and human activities. Increase in soil temperature dries out the soil and favours wind erosion. Inadequate agricultural and irrigation practices create water losses and erosion, affects soil microbiology by reducing micro-organisms that reduces the natural fertility of the soil, thus increasing soil vulnerability. The high salinity, alkalinity, and sodicity of irrigation water simultaneously change the electrical conductivity and the residual alkalinity. As a result the soil exchange capacity with water can deteriorate and create even more fragile soils. Further, high evaporation draws the salt from the ground and irrigation with brackish groundwater contributes to a salinization process on agricultural land. Land degradation and salinization are the expressions or the symptoms of land degradation.

Some of the most widespread soil depletion occurs in tropical zones with low mineral content of soils. The combined effects of growing population densities, large-scale industrial development, deforestation due to slash-and-burn agriculture, and extensive ranching have depleted soils. The increasing use of sewage waters for irrigation, chemical fertilizers, and pest management increase the contamination of soils and water, which is aggravated by industrial, urban, and human waste. Pollutants may incorporate in the soil, and thus drastically reduce soil fertility. The reduced time for recuperation of the savannah due to overgrazing and the utilization of wood for fuel strengthen land degradation and desertification trends. The thresholds of non-linear response occur beyond the carrying capacity of soils, affecting the yields in almost all grains, threatening the food security of the most vulnerable.

The interactions between the 'environmental' and the 'social quartet' may be non-linear, complex, and dissipative. Human activities have had a major influence on the natural and human interface and trigger environmental tipping points (Marten/Brooks/Suutari 2005).

Societal factors intensify these negative natural outcomes. Rapid population growth and rising water and food demand foster an overexploitation of the

soil. The negative interrelationship between natural and societal factors may produce irreversible effects on soil that may reinforce each other in a chaotic and unpredictable way. Soil deterioration results in processes of salinization, sodification, alkalinity, compactation, surface sealing, and erosion.

47.5.3 Environmental Effect (E): Scarcity, Degradation, and Stress

The interactions between the earth and human systems and among the four factors of the 'environmental quartet' have resulted in environmental scarcity of agricultural land (fertile soils), water, and food. In drylands, the scarcity of land and water often led to an overgrazing and overuse of marginal land. Both brought about environmental stress which further accelerated the processes of desertification.

The possible linkages between environmental scarcity, degradation, and stress and conflicts were analysed during the 1990's by research teams in Toronto (Canada) and in Zürich/Bern (Switzerland) (Homer-Dixon 1991, 1994, 1999; Homer-Dixon/Delingiannis 2009; Bächler/Spillmann 1996, 1996a; Bächler 1999; Mason/Hagmann/Bichsel/Arsano 2009). These environmental security studies applied the concepts of environmental scarcity, degradation, and stress to issues related to land degradation and drought, but they did not consider the impact of climate change. The approaches of both groups influenced the policy debate, e.g. on the environmental dimension of US national security during the Clinton administration (Matthew/McDonald 2009).

After a decade of research a consensus emerged that environmental stress is rarely considered to be the sole factor in precipitating conflict both within and between nations. A major effect of several types of environmental stress is economic decline that will affect the poor more than the rich groups and countries. Environmental stress coupled with rapid population growth contributes to soil insecurity, internal displacement, socially precarious slum formation, and often larger-scale migration sometimes in life threatening conditions. A second pathway from environmental stress to conflict is through forced migration that may also be caused by floods, droughts, loss of natural soil fertility, locusts or famine linked to deteriorated land. Additional related push factors are water and air pollution and deforestation due to lack of wood for fuel. All these phenomena often trigger urban and rural violence. Direct internal conflicts have occurred due to environmental stress, e.g. in the Sudano-Sahelian region where many nomads clashed with peasants.

The human-induced environmental stress has a direct impact on the components of the earth and human systems and reinforces the anthropogenic drivers of GEC. With the progressing 'securitization' of climate change, water, and soil a new policy-focused scientific discourse has emerged that addresses the security implications of climate change and land degradation and desertification from the vantage point of international, national, and human security.

47.5.4 Impact (I) of Climate Change and Stress: Natural Hazards

The pressure posed by global climate change and the local, national, and regional environmental stress have resulted in an increase in intensity and perhaps number of hydro-meteorological hazards, such as drought, heatwaves and forest fires as well as storms, flash floods, and landslides. While drought, forest fires, and heatwaves have contributed to wind erosion, intensive storms (e.g. hurricanes or cyclones), and flash floods have intensified water erosion that directly impact on land degradation and desertification.

On a global level, the impact of extreme weather events differs according to the social, economic, and political system that influences the social vulnerability of the affected people. The largest number of hydro-meteorological hazards and the highest number of killed and affected people occurred in Asia, Africa and in Latin America, while the highest economic damages are recorded in OECD countries (chap. 40 by Guha-Sapir/Vos). While in industrial countries a significant part of the damage is insured, in developing countries poor people cannot afford insurance and lose all their few belongings and are often forced to leave their homes. This ambiguity becomes obvious for India that experienced the highest number of deaths and affected people from drought (table 47.1), but was not even listed among the ten countries that experienced the highest economic damages.

Between 1974 and 2003, about 44 per cent of the reported deaths (2,066,273) and 36 per cent of the affected people (5,076,494,541) from natural disasters were the victims of drought (Guha-Sapir/Hargitt/Hoyois 2004). Thus, drought has become the most deadly and least noted hazard killing some 909,160 people and affecting 1,827,538,000 persons in thirty years, where nearly all 'silent' casualties occurred in developing countries.

Table 47.1: The most severe droughts (1900-2008). **Source:** EM-DAT: The OFDA/CRED International Disaster Database, Université Catholique de Louvain - Brussels – Belgium; at: <www.em-dat.net> (5 January 2009, data version: v12.07).

By the number of people killed on the country base			By the number of people affected on the country base			By the economic damage on the country base		
Country	**Date**	**Killed**	**Country**	**Date**	**Affected (million)**	**Country**	**Date**	**Damage (US$ 1000)**
China P R.	1928	3,000,000	India	1982	300	China P.R.	Jan 1984	13,755,200
Bangladesh	1943	1,900,000	India	2002	300	Australia	1991	6,000,000
India	1942	1,500,000	India	1972	200	Spain	Sep. 1990	4,500,000
India	1965	1,500,000	India	1965	100	Iran	Apr.1999	3,300,000
India	1900	1,250,000	India	Jun 82	100	USA	July 2002	3,300,000
Soviet Union	1921	1,200,000	China P. R.	Jun 94	82	Spain	Apr. 1999	3,200,000
China P R.	1920	500,000	China P. R.	April 2002	60	Canada	Jan 1977	3,000,000
Ethiopia	May 83	300,000	India	April 2000	50	China	May 2006	2,910,000
Sudan	April 83	150,000	China P. R.	June 1988	49	Zimbabwe	Oct. 1982	2,500,000
Ethiopia	Dec 73	100,000	China P. R.	Jan. 2003	48	Brazil	1978	2,300,000

Of the ten most severe droughts since 1900 three occurred in India (4,250,000 deaths), two in China (3.5 million deaths) and Ethiopia (400,000 deaths), and one in Bangladesh (1.9 million deaths), the Soviet Union (1.2 million deaths) and in the Sudan (150,000 deaths). Among the 10 cases with the highest number of persons affected six occurred in India (1,050 million people) and four in China (239 million persons). Of the 10 droughts that caused the highest economic damage since 1900, two occurred in China and Spain, and one in Australia, Iran, in the USA, Canada, Zimbabwe, and in Brazil (table 47.1).

The projected changes in average temperature, precipitation levels, sea-level rise, and in hydro-meteorological hazards directly impact on crop yield and thus on the food security in the 21st century and may lead to an increase of climate related food crises and conflicts. Thus, drought, heatwaves and forest fires directly contribute to soil insecurity, not only in drylands.

The *Potsdam Institute for Climate Change Impacts* (PIK) has visualized drought as well as flood and food security for the past (1975–2004) and has projected these trends into the 21st century to highlight those regions that will be affected most by droughts.[39] While drought and flash floods contributed to wind erosion, intensive precipitation had a major impact on water erosion. Some climate impact models have projected a decline in crop yields due to an increase in temperature and evapotranspiration for some regions for 2020 and 2050, based on different assumptions on a global CO_2 stabilization.

By 2020 a potential decline (-2,5 to -5 per cent) in food security is projected for the USA, Russia and East Central, East European and Central Asian countries and for Nigeria, while an increases in food production are projected for Canada, Bolivia and Argentina, China, Mongolia and Australia, and for countries in North and Central Africa. By 2050 a potential decline in food is projected for the USA, Ecuador, the Balkan countries, Mexico, Brazil, South American countries, Russia, most East Central, East European and Central Asian countries, Pakistan, and for several countries in West, South and East Africa. Increases in food security are projected for Bolivia, Argentina, China, Mongolia and several ASEAN countries, Australia, Spain, France, Germany, and Algeria. Various projections indicate that food security declines in different degrees for Africa and for India, two regions that are at present highly affected by undernourishment that will also experience a high population growth until 2050.[40]

39 These data were prepared for the report on *Security Risk Climate Change* (WBGU 2007, 2008) by Mr. Wodinski. They were used by Brauch (2006c, 2007f); at: <http://www.wbgu.de/wbgu_jg2007_ex01.pdf>.

40 This statement is based on GIS data by Mr. Wodinski that were used by Brauch (2007f).

47.5.5 Societal Outcomes (SO): Famine, Crises, and Conflicts

Land degradation and desertification may trigger different societal outcomes, depending on the level of economic development and the degree of environmental and social vulnerability. The resulting decline in water and food, together with the use of food for biofuels and speculations, has increased hunger and famine primarily in developing countries.

Hunger and famines are among the most extreme outcomes of drought and land degradation, precipitation alteration, failed agricultural policy, but also of conflicts and wars. Famines are documented for the past 4,500 years where climatic factors (droughts and floods) resulted in crop failures that triggered the deaths of people due to hunger. The most severe famines due to droughts in modern history occurred in 1769–1770 in Bengal (10 million deaths), in 1876–1879 in Northern China (19 million deaths), in 1943 in India and Bengal (3 million deaths), and since the late 1970's primarily in Africa (the Sahel, Ethiopia, Somalia, Mozambique).[41]

In many cases crop failures and famines contributed to social unrest, mass protests, hunger riots, and in some cases they even created a revolutionary situation prior to major revolutions in 1789 in France, in 1848 in several European countries, in 1911 in Mexico. Since World War II the most severe food crises occurred in the USSR, Ethiopia, China, India, Biafra, the Sahel region, in Cambodia, Uganda, Somalia, Sudan/Darfur, in the Northeast of Brazil, during the Second Congo War (1998-2004), in Myanmar, North Korea, Afghanistan, Bangladesh, East Africa and Tajikistan; most of them in drylands in Africa, Asia, and Latin America.

The *Global Hunger Index* (GHI) combined three indicators: a) proportion of people who are calorie deficient, or undernourished; b) prevalence of underweight children under the age of five; and c) under-five mortality rate (all in per cent). According to the GHI of October 2009 (IFPRI 2009) the situation was extremely alarming in thirty-three countries among the 84 reviewed developing and transitional countries.

> Of the ten countries that have seen percentage *increases* in their GHI scores since 1990, the Democratic Republic of the Congo has made the least progress in reducing hunger, followed by Burundi, the Comoros, Zimbabwe, Liberia, Guinea-Bissau, North Korea, the Gambia, Sierra Leone, and Swaziland (IFPRI 2009). The Syrian Arab Republic has the best score (lowest level of hunger) on the 2009 GHI, followed by Trinidad and Tobago, Paraguay, Suriname, and China.[42]

Several of these countries (figure 47.3) have also been affected by land degradation and desertification. In a few cases, periods of drought and famines have resulted in public protests, food riots, hunger revolts, small scale clashes between nomads and resident farmers, or between ethnic and religious groups. Most of these small-scale conflicts do not meet the criteria of wars. Since the 1970's several cases of the linkage between drought and food riots have been reported for North Africa (Morocco, Tunisia and Egypt; see Seddon 1986, 1988; Benjelloun 2005), but the reasons may have been the increase of food prices due to requests of IMF to cut food subsidies.

During 2007 and 2008, besides natural (storms, floods, drought) and political (internal conflicts, civil and international wars) causes, several economic factors contributed to an increase in food scarcity, to dramatic food price increases that triggered many events of food unrest with nearly 200 deaths during 2008. Declining global grain reserves and supply due to a shift from food to biofuels, as well as increasing demand due to changing diets, have contributed to massive price increases that were also influenced by crop price speculation at the stock market.[43]

The linkage between the 'environmental quartet' and severe societal outcomes has been addressed for possible security impacts of climate change in a report by the German Advisory Committee on Global Environmental Change (WBGU 2007, 2008: 1) that claimed "climate change could exacerbate existing environmental crises such as drought, water scarcity and soil degradation, intensify land-use conflicts and trigger further environmentally induced migration" as one of several conflict constellations (chap. 41 by Bauer). A more recent report by the UN Secretary-General (UNSG 2009: 10: 1–2) noted:

> Climate change is often viewed as a 'threat multiplier', exacerbating threats caused by persistent poverty, weak institutions for resource management and conflict resolution, fault lines and a history of mistrust between communities and nations, and inadequate access to information or resources. This report identifies several 'threat minimizers', namely conditions or actions that are desir-

able in their own right but also help lower the risk of climate-related insecurity.

Climate change affects human well-being through food security that is "linked to water scarcity, land degradation, and desertification, ... drought and tropical storms" (UNSG 2009: 10). A principal cause of land and soil degradation has been the increased use of drylands for agricultural production that was either poverty-driven in many developing countries or market-driven in several industrial countries (Mendizábal/Puigdefábregas 2003).

The area of Sub-Saharan Africa that has been affected most frequently by extended periods of drought, famine, migration and conflicts has been the Sahel zone (figure 47.3). Besides this high environmental vulnerability of the Sahel zone due to climate change and land degradation and desertification, this region has many weak and fragile states that are among the least developed countries and it experienced many crises, violent internal and international conflicts. The Sahel has also been a major hotspot due to a climate-induced decline in food production and an increase in environmentally-induced migration. Between 1980 and 2006, land and soil and often water related conflicts prevailed in Central America, in the Andean region, in the Amazonas, in Uruguay, Argentina, Mexico and in the Caribbean; in eastern and southern Africa, the Middle East, Central, South, Southeast and East Asia. These regions overlap with the countries that have been prone to the effects of drought, hunger and famine.

The regions and many countries that have been most affected by desertification, drought, hunger, famines, and conflicts, are also the regions that have experienced net emigration rates. Migration is a process that covers different features of people's movements from a) rural to urban livelihoods (*migration from the land to town* or *urbanization*), b) temporary '*internal displacements*' due to a natural hazard, conflict or a complex emergency or c) permanent internal, regional or international South-North migration. Such migration may be *forced* (push factors) or *voluntary* (pull factors). Environmental factors due to GEC (water scarcity, soil degradation, climate change) may force people to leave their homes and traditional livelihoods to survive or to have better prospects for life and economic and human well-being. However, environmental factors are only one of several push factors (economic and political reasons) that contribute to global net migration trends and environmental causes may not be used for granting a refugee status.[44]

The *International Organization of Migration* (IOM 2007) distinguished among four scenarios on the propensity to migrate due to: a) less advanced stages of gradual environmental change (temporary work migration, support of family with remittances);

b) advanced stages of gradual environmental change (permanent often irregular migration, e.g. due to sea-level rise); c) extreme weather events (temporary or permanent movement); d) large-scale development and land conservation (temporary or permanent resettlement). So far, environmental causes have not yet been systematically covered in migration statistics and they are normally interrelated with socio-economic factors.[45]

The trends of the global population, of estimated international migrants and refugees, of the growth of migrants, of international migrants as a percentage of the population and of refugees as a percentage of migrants have been compiled. While the world population and international migrants have increased since 1960, the estimated number of refugees jumped between 1985 and 1990 and has since declined again. With regard to the future, the key findings of the 2008 Revision of the World Population Prospects are:

> In terms of annual averages, the major net receivers of international migrants during 2010–2050 are projected to be the United States (1.1 million annually), Canada (214,000), the United Kingdom (174,000), Spain (170,000), Italy (159,000), Germany (110,000), Australia (100,000) and France (100,000). The major countries of net emigration are projected to be Mexico (-334,000), China (-309,000 annually), India (-253,000), the Philippines (-175,000), Pakistan (-161,000), Indonesia (-156,000) and Bangladesh (-148,000).[46]

Among the key countries of emigration Mexico, China, India and Pakistan are drylands. But a report of the *Global Commission on International Migration* (GCIM) on: *Migration in an interconnected world: New directions for action* as well as a report by the UN General Assembly on migration and development of 18 May 2006 for a high level meeting in September 2006 did not mention environmental factors as a driver. So far no major statistical source (UN, OECD, IOM) has included "environmentally-induced migration" in their database. Thus, no reliable global statistics exist on environmentally triggered migration and even less on people who opt or are forced to leave their livelihood due to land degradation, desertification, drought or famine.

To overcome this deficit and to address coping with environmentally- and climate-induced migration as part of an adaptation strategy, the *International Organization for Migration* (IOM), the *United Nations Environment Programme* (UNEP), *United Nations University* (UNU) and the *MunichRe Foundation* (MRF) have formed the *Climate Change, Environment and Migration Alliance* (CCEMA).[47] Bogardi and Warner (2008) suggested "to identify adaptation pathways that prevent or at least reduce environmental migration flows" with the goal "to mainstream environmental and climate change considerations into the migration management policies and practice, and to bring migration issues into the world's environmental and climate change as well as development discourse."[48]

Nevertheless, environmental change (due to natural and man-made causes) is a recognized cause of migration while migration has also become a cause of environmental change.[49] There are case studies on

specific events (including desertification) that have forced people to leave their livelihood. Case studies on Mexico and on West Africa (Cour 2006) have analysed the specific linkages between land degradation, desertification, and migration.[50]

To summarize, there is an emerging consensus that soil degradation, erosion, desertification, and also drought contribute to distress migration, and that disasters cause, trigger or contribute to migration, while migration may intensify disasters due to a high social vulnerability. There is also agreement that environmental factors, such as desertification, land degradation, and drought are not the sole push factors influencing the decision of people to leave their home and livelihood. Demographic, socio-economic, and ethnic push factors as well as pull factors (family networks) have contributed to people leaving the rural areas. In the Sahel, for centuries, the nomads have moved with their herds to the lands of resident farmers with higher precipitation what has in many cases resulted in violent pastoral clashes between the migrant herders and the farmers (Kahl 2006; Meier/Bond 2007).

Small-scale local and national land and water conflicts are not listed in the war data bases of SIPRI (figure 47.4), HIIK (Heidelberg), and AKUF (Hamburg) as they do not meet their war criteria. In these datasets, environmental factors and hazards (drought) are not listed as causes of conflicts. The conflict definition of the UCDP/PRIO dataset included only the most severe forms of organized violence, and excluded violent clashes between herders and resident farmers, e.g. in the Sahel zone (Kahl 1988, 2002, 2003, 2006; Suliman 1993, 1999, 1999a).

However, the map of armed conflicts (1989–2008) indicates an overlap of countries suffering conflicts and regions highly affected by land degradation and desertification (figure 47.5). The WBGU distinguished four conflict formations defined "as typical causal linkages at the interface of environment and society, whose dynamic can lead to social destabilization and, in the end, to violence". Two conflict constellations are directly related to land degradation and desertification on "climate-induced decline in food production" and on "environmentally-induced migration"

50 See Leighton Schwartz and Notini (1994); Natural Heritage Institute (1997, 1997a); Leighton (1997, 2006); Oswald Spring (2008); Alscher (2001, 2009); Sánchez Cohen; Oswald Spring; Díaz Padilla; Cerano Paredes; Inzunza Ibarra; López López and Villanueva Díaz (2010).

whiles the other two on: "climate-induced degradation of freshwater resources" and on "climate-induced increase in storm and flood disasters" have an impact on water, soil, and food security. Migration is an old coping strategy for dealing with changeable environmental conditions; e.g. in response to periods of drought (Suliman 1994).

Whether climate-triggered, environmentally-induced and forced migration leads to environmental conflicts in the countries of impact or origin depends on many intervening factors, such as the individual attributes, on the specific vulnerability, on the functioning institutions and government structures, and on environmentally-induced conflicts. As a result of migration from region A to B migration-induced conflicts may occur due to many additional factors such as the competition for resources, the change in the ethnic balance, as a result of migration and Diaspora networks, of the reaction of the host country, of the governance capability and the political stability. A political destabilization in regions A and/or B may result in different forms of violent conflicts that may impact on existing conflict constellations in other regions.

Systematic theory and comparative empirical research is needed that collects data on environmental and pastoral conflicts, and analyses the possible linkages between desertification, land degradation, and drought and environmentally-induced peoples movements (rapid and chaotic urbanization processes) and international migration, as well as with small scale violent clashes, e.g. between herders and resident farmers, and often urban food riots due to rapidly growing food prices. It is too early to draw systematic generalizations from the case study literature in anthropology that has been ignored by political scientists and security and peace specialists.

The above nature- and human-induced pressures, their effects, impacts, and societal outcomes require a political strategy to manage the complexity of nature-human interactions in an era of globalization. Such a policy response necessitates the involvement of the state, the society, and of the local, national, and international business community. But a key factor for proactive response strategies, policies, and measures is knowledge development and its use.

47.5.6 Policy Response (R): Three Key Actors and Knowledge

The last aspect in the PEISOR model refers to the policy response by the state, the society, and the economic sector where traditional and modern knowl-

edge and scientific research can lead to new policy solutions that require problem awareness for the new environmental dangers by the people and in the media that can pose multiple security concerns. Scientific recognition and public awareness require processes of anticipatory learning and proactive policies to mitigate against, adapt to, and cope with the impacts of the probable societal effects of these nature-human interactions to prevent that the projected trends become a future reality. The interrelation between the 'environmental' and the 'social' quartet poses many threats to international, national, and human security that may overstretch the security policy and the capacities of the global governance system. The development and transmission of knowledge through policy-relevant research, education, and training of experts and of the population at large become crucial. Thus, science- and knowledge-based policy strategies are an utmost priority for coping with land degradation and desertification.

UNCCD's 10-year strategy that was adopted at COP-8 in Madrid (2007) adheres to the vision: "to forge a global partnership to reverse and prevent desertification/land degradation and to mitigate the effects of drought in affected areas in order to support poverty reduction and environmental sustainability". According to this strategy three of UNCCD's five operational objectives are knowledge-based. The implementation of these goals requires a combination of *top-down* strategies, policies and measures that must be linked with *bottom-up* local initiatives that empower the people affected most by land degradation and desertification.

The state remains the key actor due to its financial and administrative resources to plan, initiate, monitor, and implement knowledge-based strategies to cope with land degradation and desertification and its societal impacts. The specific system of rule and the governance structures matter, but many states in the most affected countries are 'weak' and lack financial and administrative resources to control their territory and to implement the adopted policies and measures. An active involvement of *societal* groups, of social movements, and NGOs matters.

These efforts must be implemented at the local level with the active participation of women to enhance their resilience for coping with drought and for mitigating soil degradation. Women not only suffer harder from land degradation, water scarcity and pollution, crop yield reductions and food shortage, but in poor countries they produce most of the food and care for the livelihood of their families. Special attention must be given to the recovery of fragile drylands, namely salinized, deforested, and eroded land and overexploited aquifers.

Gender programmes are often added to combat land degradation and desertification. A transversal gender line combining all political, institutional, social, and scientific programmes would change the outcomes. Policies on land degradation and desertification, water, and food should take into account that women and men play different social and economic roles, and give more emphasis to small-scale agricultural and survival strategies, basically in the hands of women, such as small business and microcredits. Their income benefits the whole family, above all the children. Their involvement takes advantage of their abilities in resource management and conflict prevention. Climate change and loss of access and control over natural resources through megaprojects reduces their ability to cope with adverse situations. Gender mainstreaming should be included in the planning, legislation, and policies on drylands to consolidate the livelihoods of everyone in the community. Water and energy policies should be gender sensitive and trained women can be excellent agents of change, above all when 'soil security' is declining. For the realization of the Madrid strategy for coping with land degradation and desertification, the involvement and active participation of the most affected economic sectors (agriculture, services, and industry) and of the local business community is crucial. This requires an ethical commitment for a longer-term sustainable management of land and water resources and no exclusive orientation at short-term profits (Oswald Spring 2009b).

47.6 Towards Proactive Policies to Enhance Soil Security

47.6.1 Soil Security in the Anthropocene

The goal of the securitization of land degradation and desertification is to upgrade its political importance. It occurs in other ecological areas beyond subhumid, semi-arid, and arid drylands. Droughts due to a lack or major drop in precipitation lead to a decline in crop yields, in bad harvests that often cause hunger and famine. Among socio-economic factors, droughts result in rising food prices that poor people cannot afford. Also land degradation and desertification often lead to famine and distress migration that cause envi-

ronmental, human, food, health, livelihood and gender security issues.

Relevant policy questions are: How can processes of soil erosion, degradation, and desertification be successfully contained, countered, delayed or stopped? How can the societal consequences of famine, distress migration and conflict constellations be curbed, and the impact be reduced by early warning, rapid action and humanitarian aid? How can the policy implementation be improved and corruption be curbed that the humanitarian aid reaches the most affected people fast whose survival is at stake? And finally, how can local populations and women get involved to mitigate and adapt to land degradation and desertification?

This poses questions of the instruments and actors for dealing with desertification as a security issue, i.e. to reduce violent societal consequences. An early recognition and perception of the urgency of the desertification challenge and its consequences (drought, famine, migration) as security issues partly depends on the mindset and worldview of the observer. This poses different responsibilities for *political* and *military security*: conflict avoidance and prevention with tools of *development* and *environment* to enhance resilience by sustainable development to achieve environmental, human, soil, food, health, and livelihood security.

The dual task is to both focus on the causes and triggers and on violent outcomes. This requires a mainstreaming of activities of coping with environmental hazards and conflict prevention and avoidance. There is no simple strategy to counter desertification and its outcomes but a complex set of strategic components in different action plans by national and international, societal, and economic actors. Knowledge creation and anticipatory learning are crucial tools.

Desertification poses no direct military threats, but as a regional environmental challenge, land degradation and desertification and famine severely undermine the well-being of people. In severe cases desertification may even threaten the survival of individuals of affected local communities, what may in the worst case undermine national and regional stability. From a subjective perspective degradation and desertification and famine contribute to environmental and human, food, health, livelihood, and gender insecurity.

If desertification forces people to leave their home, village and country, internal displacement, urbanization and trans-border migration may contribute to social insecurity with social and ethnic groups as the referent where national identity may be perceived as being at risk and immigrants are often seen as threats that challenge the distribution of scarce resources of water, soil, and food. Whether and when severe social and societal insecurity pose a threat to internal, domestic, national or regional security depends on specific national political circumstances.

National security may be threatened by general strikes and hunger riots, and the value at risk may be regime stability and the survival of governments. The severe droughts and famine in the Sahel during the 1970's and 1980's have repeatedly resulted in violent clashes between nomadic tribes and resident farmers that have also been associated with large trans-boundary environmentally-induced migration what has often triggered ethnic clashes.

In the early 21st century, land degradation and desertification as well as famine and distress migration have been perceived as human security threats by the *Commission on Human Security* (CHS) that have only recently been addressed by the *Human Security Network* (HSN). Drought and famine have been seen as challenges to food security by FAO, the WFP and IFAD, as well as to health security by WHO. Desertification is increasingly being recognized as a critical environmental and human security challenge by academic experts and many UN organizations, but not yet by all governments. Nevertheless, the political agenda-setting has just started.

In the report of the 17th Session of UNCSD (3–15 May 2009) there were 63 references to 'security', but primarily to 'food security' (57), and a few references to land 'tenure security' (4) as well as to 'peace and security' (2) but not yet to 'soil security'.[51] The ENB final report on the COP-9 of UNCCD in Buenos Aires referred 7 times to 'food security' including its 'importance for human security' and once to 'land and food security'.[52] Thus, the concept that was initially introduced by FAO (Oswald Spring 2009b) was widely used in UN deliberations on land degradation and desertification but there were no references to 'water', 'soil', and 'health security' in these two recent documents. In a UNCCD Issue Paper in May 2009 both authors launched the new concept of 'soil' security

51 See: United Nations Commission on Sustainable Development: Report on the seventeenth session (4–15 May 2009), Economic and Social Council, Official Records, 2009, Supplement No. 9 (New York: UN); at: <http://daccessdds.un.org/doc/UNDOC/GEN/N09/355/72/PDF/N0935572.pdf?OpenElement>.

52 See: *ENB*, 4,229 (5 October 2009: 16).

(Brauch/Oswald Spring 2009b; Oswald Spring/Brauch 2009) that is achieved when efforts to combat desertification succeed, when land degradation is successfully contained, and when the consequences of drought are being reduced and famine is being avoided due to countermeasures by governments, and the aid community in close cooperation with the affected people.

A report on *Global Trends 2015* (NIC 2000) only referred to population growth and water scarcity as issues that pose U.S. national security concerns. The most recent update of *Global Trends 2025* recognized 49 times climate change as a 'newer security issue' but it did not yet even mention the concepts of desertification and land degradation (NIC 2008: xi).

The systematic securitization of desertification started with a conference in December 2003 in Valencia (Kepner/Rubio/Mouat/Pedrazzini 2006),[53] and meetings in Almería (1994, 2006) discussed links between desertification and migration as a security issue.[54]

47.6.2 Towards a Proactive Security Policy on Land Degradation and Desertification

Grounding security refers to reactive and proactive short-, medium-, and long-term strategies for coping with 'soil insecurity' and the societal, environmental, and economic security implications of land degradation and desertification on the one hand and drought on the other. The *Desertification Synthesis* of the MA (2005) distinguished four scenarios with a clear preference for proactive global and regional strategies for combating desertification with irrigation, poverty reduction, and coping with climate change (table 47.2). The *MA Desertification Synthesis Study* (2005) noted that

- Understanding the impacts of desertification on human well-being requires that we improve our knowledge of the interactions between socio-economic factors and ecosystem conditions. ...
- There are considerable scientific challenges in detecting thresholds beyond which drylands systems would reach a critical or effectively irreversible change. ...
- The impact of poverty reduction strategies on ecosystem services and desertification has not been fully explored by governments and the international community. ...
- The contribution of drylands urban areas to desertification may be significant but is not known.

Table 47.2: Four scenarios for combating desertification. **Source:** MA (2005: 11).

Ecosystem management	Globalized world	Regionalized World
Reactive	Global orchestration (1)	Order from Strength (2)
Proactive	TechnoGarden (3)	Adapting Mosaic (4)

But the MA did not analyse the impact these complex processes have on political and societal outcomes, whether they triggered and intensified processes of migration, of domestic economic and political crises and conflicts.

UNEP's fourth *Global Environmental Outlook* (UNEP 2007a: 400–401) distinguished in its perspectives towards 2015 four scenarios with different priorities: a) *Markets First*, b) *Policy First*, c) *Security First*, and d) *Sustainability First*. Only the *Sustainability First* scenario offers prospects for reducing global income gaps. The *Security First* scenario comes closest to a neo-realist worldview that focuses on a narrow national military security concept and to a neo-Malthusian standpoint on environmental issues. In contrast, the *Sustainability First* scenario reflects a liberal, pragmatist worldview on security issues based on a widened and deepened security concept including the environmental dimension of human security where cooperation matters and an equity-oriented environmental standpoint where cooperation contributes to solve problems peacefully.

For the needed knowledge-based and scientifically-induced policy response for coping with land degradation and desertification and its potential societal impacts on migration, crises, and conflicts a combination of two scenarios appear to be most promising: of UNEP's *Sustainability First* scenario with the two proactive strategies of MA's *Desertification Synthesis* of a regionalized 'Adaptation Mosaic' with a globalized 'TechnoGarden'. These scenarios pose tasks for the policy response.

53 At the Valencia conference Brauch (2003e, 2006) provided a systematic overview of the manifold conceptual linkages between processes of desertification and their impacts in terms of water, food, and health security that may have repercussions for national and regional security. Other contributions by Kepner (2006), Rubio/Recatala (2006); Yousef/Hegazi (2006); Safriel (2006) discussed security aspects from the perspective of the natural sciences, while López-Bermúdez/García-Gómez (2006) referred to the links with food security.

54 See for the conference documents at: <http://www.sidym2006.org/eng/eng_ponencias_conclusiones.asp>.

Besides these top-down scenarios of the MA and of UNEP the success of these strategies, policies, and measures requires an active involvement of the people affected by land degradation and desertification. Such bottom-up initiatives necessitate an active involvement of all stakeholders, most particularly women, peasants, fishermen, and indigenous people with their traditional knowledge and their expertise of the local soil conditions. To optimize the combat against land degradation and desertification and to guarantee the long-term conservation of fragile soils, an increased representation of women is needed at all decision-making levels and for the prevention, management, and resolution of ground and water conflicts.

Poverty, diseases, and the transformation from marginality into social violence and conflicts cross gender lines and are linked with poor economic achievements, low degrees of economic participation and limited opportunities, a lack of political empowerment and difficult health and survival conditions. There is an inherent link among poverty, disease, and violence that reduce human, gender, and environmental security (HUGE). But proactive and preventive measures are much cheaper than reactive ones. Once the combat against land degradation and desertification has started and impacts on a larger region, small projects can improve the soil conditions and contain the process of deterioration, of which many were developed by women to restore and to recover the environment, as they need these resources for their own survival and that of their families.

47.7 Conclusions: From Knowledge to Action

47.7.1 Proposals by the United Nations Organizations

Several United Nations agencies (FAO, UNESCO, WHO, WMO, UNDP, UNEP, UNU, UNSO, CGIAR) have been involved for decades in the maintenance and recovery of drylands. Many international financial institutions (World Bank, regional development banks, UNDP, IFAD), facilities (GEF), and mechanisms (*Global Mechanisms* for *Sustainable Land Development*) can supply in cooperation with regional organizations (EU) and national donors the financial resources for land and water projects. These international sponsors and national agencies should involve regional and local societal actors in the design, planning, and implementation of concrete measures to combat desertification and land degradation to enhance soil security. Based on its experience a new epistemic community on land degradation and desertification issues may evolve under the leadership of UNCCD. All these activities may contribute to proactive policies to enhance soil security, taking the recommendations of the MA into account.

47.7.2 Proposals by the Millennium Ecosystem Assessment

The *Millennium Ecosystem Assessment* (MA) noted major research and knowledge gaps on the geographical scope of desertification. Its *Desertification Synthesis* suggested "to focus on prevention, because attempts to rehabilitate desertified areas are costly and tend to deliver limited results", while extreme poverty and hunger limits the MDGs. It proposed "major policy interventions and management approaches" what requires "a change in governments' and peoples' attitudes through improved incentives" (MA 2005: 14–15):

- Integrated land and water management are key methods of desertification prevention.
- Protection of vegetative cover can be a major instrument for prevention of desertification.
- In the dry subhumid and semi-arid zones, conditions equally favour pastoral and cropping land use. Rather than competitively excluding each other, a tighter cultural and economic integration between the two livelihoods can prevent desertification.
- Use of locally suitable technology is a key way for inhabitants of drylands at risk of desertification to work with ecosystem processes rather than against them.
- Local communities can prevent desertification and provide effective drylands resource management but are often limited by their capacity to act.
- Desertification can be avoided by turning to alternative livelihoods that do not depend on traditional land uses, are less demanding on local land and natural resource use, yet provide sustainable income.
- Desertification can also be avoided by creating economic opportunities in drylands urban centres and areas outside drylands.

Several of these measures have been taken up in the 10 year strategy of the UNCCD (2008–2018).

47.7.3 Proposals of the UNCCD 10 Year Strategy

In September 2007 at COP-8 the UNCD state parties adopted a 10-year strategy that aims at the following four 'strategic objectives':

- To improve the living conditions of affected populations;
- To improve the conditions of affected ecosystems
- To generate global benefits through effective implementation of the UNCCD;
- To mobilize resources to support the implementation of the Convention through building effective partnerships between national and international actors.

For the implementation of this strategy, UNCCD's *Committee on Science and Technology* (CST) was tasked to implement the first operational objective. With "clear priorities based on the strategic plan" the CST adopts "a focused work programme". Its meetings should "produce sound scientific outputs and policy-oriented recommendations based on the analysis and compilation of peer reviewed and published literature that inform policy formulation and dialogue at the COP". Among its tasks are "to bolster the scientific and technical basis of the UNCCD". Furthermore, it "creates and steers knowledge-management systems aiming to improve the brokering of scientific and technical information from and to institutions, parties and end users". Among its priorities are to develop "tools and methods, biophysical and socio-economic baselines on desertification/land degradation at the national level", and "methodologies and guidelines for monitoring and assessment of desertification/land degradation trends". At COP-9 in Buenos Aires, the debate on the implementation of this 'strategy' did not achieve further advances.[55]

47.7.4 From a Scientization towards a Securitization of Land Degradation and Desertification

The implementation of the UNCCD strategy requires three major activities of *scientization*, *politicization*, and *securitization*.

47.7.4.1 Scientization of Land Degradation and Desertification

The Madrid strategy emphasizes its aim "to become a global authority on scientific and technical knowledge pertaining to desertification/land degradation and mitigation of the effects of drought". The decisions on the CST indicate a new task of assessing peer-reviewed high quality scientific knowledge and to widely disseminate its results. Towards a scientization of land degradation and desertification, the UNCCD secretariat and its CST and CRIC are cooperating with leading universities and research institutes in monitoring research and in disseminating traditional and modern knowledge, the results of scientific research, and adapted technologies to combat land degradation and desertification.

47.7.4.2 Politicization of Land Degradation and Desertification

Since its entry into force in 1996, the UNCCD secretariat and its decision-making fora (COP, CRIC, and CST) have increased political awareness and raised resources for implementing its goals in the most affected countries. In the new context (MDG, WSSD, MA), the Madrid strategy adopted a *policy framework* to achieve five outcomes:

> a) to asses policy, institutional, financial and socio-economic drivers of desertification, land degradation and barriers to sustainable land management, and recommend appropriate measures to remove these barriers; 2) to revise national action programmes (NAPs) into strategic documents with integrated investment frameworks; 3) to integrate the NAPs and sustainable land management and land degradation issues into development planning and relevant sectoral and investment plans and policies; 4) for developed countries to mainstream sustainable land management interventions into development cooperation programmes; and 5) to introduce or strengthen mutually reinforcing measures in desertification, land degradation action programmes and biodiversity and climate change mitigation and adaptation.

Through this strategy resources should be mobilized to increase effective partnerships between national and international actors. Three objectives are to contribute to a political upgrading of land degradation and desertification issues on the policy agendas of affected countries, of IFIs, donors, and of international governmental organizations. The fourth operational objective addresses the need for capacity-building, and the fifth deals with "financing and technology transfer".

47.7.4.3 Securitization of Land Degradation and Desertification

The Spanish government has securitized land degradation and desertification and related migration processes in workshops on desertification and migration in Almería (1994, 2006), and on desertification and security in Valencia (2003, 2007). This chapter introduces the 'soil security' concept besides 'climate' (Ma-

55 See *ENB*, 4,229 (5 October 2009: 15–16); Bauer/Stringer (2009).

bey 2008), 'water' (Oswald/Brauch 2009), 'food' (Oswald 2009a; Salih 2009), 'health' (Rodier/Kindhauser 2009; Leaning 2009), and 'livelihood security' (Bohle 2009). There are many references to land degradation and desertification in policy documents on climate change and international security.

The Report by the UN Secretary-General on *Climate change and its possible security implications* (11 September 2009) refers to 'desertification' as an impact of climate change:

> Climate change's impacts on human well-being can work through several pathways, including impacts on: food production and food security, e.g., linked to water scarcity, *land degradation, and desertification*; health and the incidence of various vector-borne diseases; the frequency and intensity of extreme weather events, including flooding, drought and tropical storms; and sea-level rise. The last two types of impact have particularly severe consequences for human settlements and population displacement. The more dependent are people on climate-sensitive forms of natural capital, the more at risk are they from climate change [emphasis added by the authors].

The UN Secretary-General argued that climate change "can cause a number of economic disruptions" and that "through its effects on nutrition and health, it may diminish human and animal productivity. It may also contribute to land degradation". And in the context of adaptation the report noted that "Critical actions to enhance food security in vulnerable environments include: developing new drought- and heat-tolerant crop varieties; conserving and better managing scarce water resources; combating land degradation and soil erosion; reducing loss of biodiversity and ecosystem services."

In March 2008, a paper by the European Commission and the Council referred to land degradation and desertification among the "conflicts driven by climate change". In the context of land loss and border issues "desertification could trigger a vicious circle of degradation, migration and conflicts over territory and borders that threatens the political stability of countries and regions". The EU paper argued that "in drier areas of Latin America climate change will lead to salinization and desertification of agricultural land and to decreasing productivity of important crops and livestock. This will have adverse consequences for food security. ... In North Africa and the Sahel, increasing drought, water scarcity and land overuse will degrade soils and could lead to a loss of 75 per cent of arable, rain-fed land". It argued that those people "that already suffer from poor health conditions, unemployment or social exclusion are rendered more vulnerable to the effects of climate change, which could amplify or trigger migration within and between countries." The EU paper claimed that "migration may increase conflicts in transit and destination areas. Europe must expect substantially increased migratory pressure".[56]

A paper by the U.S. National Intelligence Council *The world by 2025* (NIC 2008) ignored land degradation and desertification, but it referred 11 times to migration as a security issue, but all NIC reports (2000, 2004, 2008) ignored environmental causes of migration.

47.7.5 Extraordinary Policy Measures for Enhancing Soil Security

The political move by international organizations and governments to securitize land degradation and desertification may upgrade policy measures to enhance 'soil security' that will affect the livelihoods and survival of millions of affected, poor, and marginalized people in developing countries that lack individual means and financial and administrative capacities of a strong state. In this regard specific proposals are suggested below.

47.7.5.1 Demand Side Management and Efficiency Improvements

Combating land degradation and desertification and enhancing soil security is a complex process that involves different activities from river basin management to reforestation. Soils on high slopes tend easily to erode after deforestation. Thus, recovering mountain ecosystem, its trees, shrubs and grasses is crucial for erosion control, water harvesting, and flood protection, but also for maintaining soils and biodiversity upstream. This helps avoiding disasters, landslides, and the destruction of urban infrastructure in the lower-lying areas. In the river plains, where agriculture, livestock, and urbanization are pressuring on

56 In its "Report on the Implementation of the European Security Strategy" of 11 December 2008 (S407/08), the European Council argued that "natural disasters, environmental degradation and competition for resources exacerbate conflict, especially in situations of poverty and population growth, with humanitarian, health, political and security consequences, including greater migration." It requested the Commission and member states "to improve analysis and early warning capabilities" and to "step up our work with countries most at risk by strengthening their capacity to cope" for which "international co-operation, with the UN and regional organizations, will be essential".

soils, a sustainable and participative land planning is required to optimally use existing resources and to avoid further deterioration.

Remote sensing and *geographic information systems* (GIS) have revolutionized data collection on natural resources including land degradation and desertification. They cannot substitute field studies on specific human, societal, cultural, and historic conditions. The lack of reliable information on desertification can increase land degradation and thus the cost of land degradation and desertification. Monitoring desertification indicators is a long-term activity that offers information on land and water degradation trends, but it should not be limited to technical items and it should always analyse the complex interrelationships between human activities and nature. The different sustainable indicators of the UN should be combined: the *Human Development Index* (HDI) and the *Gender Equity Index* (GEI) of UNDP, and the GINI index on income inequality, to monitor in a holistic way the development process, the applied policies and the response of affected people (chap. 91 by Jesinghaus).

As desertification is both a human- and a climate-induced process that may be reversed by human activities, action must counter land degradation and desertification and give nature a chance to recover. Drylands must become a high priority of governments, because the removal of natural vegetation and inappropriate irrigation and cultivation methods are rapidly degrading the limited biological, soil, and water resources. In drylands controlling wind and water erosion, the destruction of infrastructure and farmland and the advance of the dunes are important. Flash floods may be limited by conserving vegetation soil cover. Dried out river basins may be cultivated with terrace systems and flat lake basins could be recovered with traditional or modern protection measures that permit the infiltration of water into the aquifers and the retention of water in small storages. Rain harvesting technologies help also to maintain the vegetation cover of drylands (chap. 59 by Harish/Mullackal).

47.7.5.2 More Environmental Services and Food with Less Resources

On the supply side a major goal is to produce more environmental services and food with fewer resources by an efficiency enhancement that must be implemented at the local level. In semi-arid and subhumid areas, groundwater substitutes the irregular rainfall when plants are growing. Containing and spreading flood water is a key to desertification control in many parts of the world. Infiltration techniques of rainwater reinforce the artificial recharge of groundwater. Adequate soil and watershed management help to enhance or restore the soils for growing food, grass, and fuel wood.

Salinity, sodicity, alkalinity, and water-logging problems are other key issues of land degradation and desertification in irrigated land resulting in crop yield decline. The extension of irrigated lands through dams and water storage, but above all inadequate irrigation processes, can rapidly deplete the aquifer. Through capillary action, water from saline or brackish groundwater may destroy arable lands. Thus, adequate soil drainage, water-saving irrigation techniques (such as drip irrigation, micro tunnels, micro-aspersion, etc.) may avoid a further deterioration of the land and aquifer and also increase crop yields. Improper land use and drought are principle agents of desertification. Reduced groundwater recharge is related to the over-exploitation of a limited natural resource.

To produce enough food for the increasing population with scarce and polluted water requires manifold efficiency enhancement activities in agriculture. This is the most important and first political and societal action. By using more cereals in the human diet, instead of feeding animals, and producing biofuels and industrial products, the reduction of animal proteins cannot only save water and reduce the negative impacts on climate change, but it can also feed more people with less resources.

The second item is related to sustainable agriculture that integrates crop and animal production, appropriate resource management practices with the needs and capabilities of the human population. Some of the needed actions are rangeland rehabilitation, grazing management, farming system development, water harvesting, and on-farm water husbandry practices. Others are related to the increase of crop yields with bio-fertilizers and micro-organisms that are able to fix the nitrogen from the air to the soil or methods for composting organic waste that improve soil quality. A mixed agriculture, policultivation, crop rotation, and enhanced biological productivity are mechanisms to conserve and maintain natural fertility of soils and achieve high crop yields.

The plastic greenhouse technology (chap. 54 by García Lorca) conserves residual humidity, uses dew for irrigation and reduces plagues, while organic fertilizer may enhance crop yields. An interesting aspect of this model is the social organization of cooperatives

at the local level that creates a horizontal and vertical integration of agriculture with the transformation and transportation of the produced crops.

Combating desertification in the field is a local and a regional effort. It must be socially and economically acceptable for indigenous people and peasants, and overcome the interest in short term benefits. Successful approaches combine traditional and modern knowledge accepted by villagers and adapted to local microclimatic conditions (Laureano 2001 and chap. 52).

Many densely populated desertified drylands rely on an agricultural and livestock economy, where land and water rights are privately owned and often divided in small plots, what technical proposals must also consider. While desertification is a regional phenomenon, the control of wind and water erosion, of moving sand dunes involves a mixture of trees, shrubs and grasses, together with improved irrigation and soil management techniques.

To improve the quality and quantity of water, energy efficiency and renewables from solar, wind and waste play a crucial role (Kurokawa 2003; Faiman 2004, 2009; Trieb/Krewitt/May 2009; Safriel 2010). The tropical deserts have the highest solar insolation and could generate in centralized and decentralized systems energy for desalinization of brackish groundwater or sea water. The model suggested by the DESERTEC foundation offers a promising perspective especially for those countries in the sunbelt that lack both fossil fuels and water (preface essay by HRH Prince Hassan of Jordan).[57]

Throughout history, the natural climate variability has resulted in severe droughts, crop failures, bad harvests and famines. Some authors interpreted these events as a systemic ecological collapse[58] resulting from deforestation, siltation, and decline of biological diversity. Due to anthropogenic climate change the number and intensity of extreme weather events is projected to rise (IPCC 2007). Thus, affected governments must ask for timely food aid. Its transparent distribution by international and national humanitarian organizations can avoid famine and social unrest.

47.7.5.3 Transition to Alternative Livelihoods and a Sustainable Economy

Women, peasants and indigenous grassroots movements play an important role in the poor rural areas of developing countries. Their expertise, developed during centuries, may strengthen their strategies for controlling desertification. New technologies that are integrated into traditional management techniques require a prior assessment of natural and social impacts for the population involved. The consolidation of the traditional leadership in the village of old men and women and the integration of young people with technical training and of returning migrants can support the combat against desertification.

Clergymen as spiritual leaders, doctors, and lawyers may play a crucial role as leaders in the efforts to combat desertification. Schools are also important for training and teachers are sources of new knowledge who educate young people, the future labour force for the development of rural society. As the desertification process evolves relatively slowly, these trained young people are the future actors to fight from the grassroots against desertification who understand the complex interaction between human beings and nature. They may also be trained in energy efficiency and renewables to generate a sustainable energy and transport system that may promote drylands ecotourism with low environmental impact and thus generate the financial resources for recovering degraded land and maintaining the soils of fragile drylands. Besides these concrete proposals for coping with the causes of land degradation and desertification and their direct effects and impacts, additional measures are needed to respond to societal outcomes, such as migration.

47.7.5.4 Coping with Environmentally-induced Migration

The *I*IOM (2007: 5–7) suggested as "the most cost-effective and humane" policy response to migration to avoid "the need for environmental migration by intervening at the earliest stage possible. Sustainable development assistance is required to strengthen the coping capacity of communities affected by environmental degradation. Programmes need to engage the most vulnerable". Among them community stabilization initiates should fully involve "diasporas and returning migrants" to optimize the financial resources of migrants and "to prevent further environmental degradation in the migrant sending area" (chap. 53 by Mainguet/Dumay/Kabiri/Lahcen).

57 See for details at: <http://www.desertec.org/> and on alternative livelihood see Adeel and Safriel (2008).

58 Drew (2000); Weiss (1982); Weiss and Bradley (2001); Coe (1999); Webster (2002); Demerest, Rice, and Rice (2004); Sabloff (1990); Gill (2000); Zhang, Cheng, Edwards, Chen, Wang, Yang, Liu, Tan, Wang, Liu, An, Dai, Zhou, Zhang, Jia, Jin and Johnson (2008).

Urban authorities should prevent inflows of environmentally-induced migrants and avoid or limit the negative impact on humans and environment. In the early stages of environmental degradation, efforts to facilitate international labour migration may offer temporary relief. However, if land degradation and desertification reaches an irreversible stage, "permanent migration can be better managed und sustainable resettlement schemes carried out incrementally." With regard to "mitigating forced displacement" policy efforts for "improved disaster preparedness and management" including effective early warning systems, humanitarian assistance and relief efforts are needed that avoid negative environmental impacts of camps and temporary shelter. The expected additional flow of such migrants requires capacity building to reduce irregular migration, and prevent human trafficking and smuggling.

Renaud, Bogardi, Dun and Warner (2007) suggested five steps in implementing a precautionary principle for the relationship between environmental degradation and change and forced migration: 1) the need for a strong scientific basis; 2) increasing awareness; 3) improving legislation; 4) providing means for adequate humanitarian aid; and 5) strengthening institutions and policies.

The WBGU (2008: 193) suggested "the establishment of a transsectoral, multilateral Convention to regulate the legal position of environmental migrants", by adopting supplementary measures outside the existing legal regime (Brauch 2000–2001; Bogardi/Warner 2008). This proposal was developed in detail by Frank Biermann and Ingrid Boas (2008: 51) who suggested a "separate, independent legal and political regime created under a Protocol on the Recognition, Protection, and Resettlement of Climate Refugees to the United Nations Framework Convention on Climate Change".[59]

In his report on the possible security implications of climate change, the UN Secretary-General Ban-Ki Moon had referred 33 times to migration, especially on "population displacement and involuntary migration".

The *Human Development Report 2009* on *Overcoming barriers: Human mobility and development* referred only once to 'desertification' and four times to 'drought' but lacked any reference to 'land degradation' and desertification as a cause of migration. In looking ahead, the UNDP's HDR 2009 referred to three drivers for human mobility a) the economic crisis and the prospects for recovery, b) demographic trends and c) environmental factors. This part concluded on the global trends of human movements:

> First, movement largely reflects people's need to improve their livelihoods. Second, this movement is constrained by policy and economic barriers, which are much more difficult for poor people to surmount than for the relatively wealthy. Third, the pressure for increased flows will grow in the coming decades in the face of divergent economic and demographic trends. Ultimately, how these structural factors will affect the flow of people in the future depends critically on the stance taken by policy-makers (UNDP 2009: 46).

As was argued above, so far no agreement exists on the definition of environmentally-induced migration of which land degradation and desertification has become a major trigger, on the statistical scope and on a legal regime to award to these migrants a refugee status.

47.7.5.5 Preventing Environmentally-induced Conflicts

As issues related to land degradation and desertification may cause, trigger or contribute to societal crises and to low level conflicts by proactively addressing its causes, effects, and impacts the potentially violent societal outcomes may be avoided. A first step is public awareness to recognize the future challenges, and thus to contribute to a process of political learning and cooperation with the goal to revise the projections by jointly defined counteractions. Anticipatory learning as a tool of crisis prevention is more ambitious than crisis management. It remains the domain of long-range and interdisciplinary discourses of academics and of foreign policy planning staffs. As these long-term structural challenges do not require urgent responses, sufficient time exists for conceptually focused and policy-oriented epistemic communities of which UNCCD is a part, and its CST and CRIC offer a framework for dialogue and policy debate.

59 For comments see: Mike Hulme "Commentary - Climate Refugees: Cause for a New Agreement?", in: *Environment*, November-December 2008; at: <http://www.environmentmagazine.org/Archives/Back%20IssuesNovember-December%202008/hulme-full.html>; Dan DaSilva: "'Climate Refugees' Gatecrash the Agenda"; in: *Towards Recognition*, posted on 26 June 2009; at: <http://www.towardsrecognition.org/2009/06/climate-refugees-gatecrash-the-agenda/>; Kayly Ober: "Finding a (Legal) Home for Climate Migrants"; in: *Towards Recognition*, posted on 31 August 2009; at: <http://www.towardsrecognition.org/2009/08/finding-a-legal-home-for-climate-migrants/>.

Joint North-South and South-South anticipatory learning requires a debate on longer-term challenges and a mutual understanding of their relevance, and then a multidisciplinary search for complex strategies to cope both with the root causes and their socio-economic implications. Anticipatory learning must be addressed on three levels: across the boundaries of scientific disciplines; across the North-South divide and between conceptually oriented academics and action-oriented decision-makers. Partnership requires mutual trust and confidence.

47.7.5.6 Ten Conceptual Proposals for Coping with Land Degradation and Desertification

For coping with land degradation and desertification ten conceptual proposals are offered in conclusion:

1. *Partnership building measures* (PBMs) as political tools in the economic and ecological realm may have a positive impact on the societal and cultural level (Brauch 2000). Functional PBMs should aim at:
   - creating awareness on these challenges among decision-makers and in the public;
   - analysing in detail the complex interrelationship among the factors of the environmental and human quartet (figure 47.1);
   - initiating regional climate impact studies and mitigation strategies against land degradation and desertification.

   The global and regional challenges should lead to more active policies of cooperation on sustainable development in agriculture, industry, tourism, and transport. What can PBMs contribute conceptually as a new political tool to a complex anticipatory learning process? In the medium-term, PBMs could become important instruments of preventive diplomacy and of a post-conflict peace-building in parts of the globe with violent conflicts.
2. One example for a *partnership building project* (PBP) to mitigate several impacts of land degradation and desertification could be a 'survival pact' that links 'virtual water' (food exports) with 'virtual sun' (renewable energy exports) based on a longer-term interdependence. Linking both commodities that are crucial for life: cereals and energy requires a high degree of trust and predictability. Such a 'survival pact' could start now with the training of experts for the respective countries in the area of renewable energy (solar and wind power), but above all involving the people that own the land thus increasing their income from exporting renewable energy (Brauch 2002, 2002b, 2006a).
3. The fight against desertification is the task of the parties of UNCCD and of the development programmes of many countries. Sustainable agriculture and food security are a concern of FAO, of the World Bank, of development agencies and national and local governments.
4. Urbanization and urban pollution are the new threats for the majority of the population. Many of these concerns were reflected in the *Declaration by the Millennium Summit* (2000) that relies on a wide security concept, including environmental challenges, and that stresses cooperation on effective countermeasures, but also governance and transparent urban governments, able to create a resilient and participative community.
5. These goals require a longer-term strategy of implementation in a multilateral cooperative framework based on partnership. The societal impacts of climate change, land degradation, and desertification may trigger conflicts that may be negotiated peacefully but they may also escalate into violent clashes. But they are unlikely to produce militarily relevant 'threats' that can be deterred or countered by military means. But the price for not acting now may pose human catastrophes for the victims of climate change and environmental stress (Stern 2006, 2009).
6. The consequences of distress migrants from Central America will impact first on Mexico, and these environmental migrants will certainly have implications for the USA and Canada. Droughts in the Sahel countries will impact on North African countries first and later also on Europe.
7. Active and efficient implementation of climate policies and of measures to cope with land degradation and desertification could become the best security strategy to prevent environmental conflicts from occurring and to contribute to a 'sustainable peace' that combines non-violent conflict resolution, equitable economic relationships, and sustainable policies in the North and South.
8. Long-term oriented proactive policies of sustainable development combating desertification require functional cooperation and non-agricultural employment in rural areas.
9. These initiatives may become the most effective policy of conflict prevention that will enhance both human and societal security in the affected regions but they may also reduce the costs for cop-

ing with the consequences of the missed opportunities that exist for multilateral cooperative policies in the early 21st century.

10. All these measures should enhance water, soil, and food security that will also improve health security of the people most affected by land degradation and desertification. By forward-looking multidisciplinary and policy-relevant research, anticipatory learning and proactive policies, many of the extreme and potentially violent outcomes of GEC and land degradation and desertification may be avoided.

48 Alternative Livelihoods for Attaining Sustainability and Security in Drylands

Uriel N. Safriel

48.1 Introduction[1]

Claims linking desertification with poverty and loss of security are often not supported by hard data (Dobie (2001). This is partly due to loose definitions and indiscriminate use of 'desertification'[2], 'poverty'[3], and 'security'[4] – a result of meagre communication between natural and social scientists addressing phenomena driven by tightly interlinked biophysical and social processes, as well as due to disagreements within each of the two disciplines. As a result, the extent to which conflicts (often resulting in violence) are driven by poverty and poverty is driven by desertification, is controversial and poorly known.

Three issues are addressed in this chapter: (a) the inherent low productivity of drylands can generate low human well-being, with no desertification involved; (b) in the drylands resource sustainability, human well-being, and its security component may represent locally stable states, destabilized by nonlinear, threshold-crossing transition to alternative locally stable states of desertification, poverty and conflicts, respectively; (c) the 'desertification paradigm' (human pressures leading to misuse of land resources, desertification, poverty, and reduced security) and its 'counter paradigm' (challenged by adversity local people mobilize their inherent ingenuity, which generates adaptations and innovations that keep them ahead of desertification, poverty, and conflict) fail to realize that as pressure on resource continues, a point in time is reached when neither technology nor ingenuity would maintain sustainability. This can be avoided by reducing or abandoning land resource use through adoption of dryland 'alternative livelihoods'.

These are of minimal dependence on land primary productivity and generate higher income than traditional drylands livelihoods, even higher than these livelihoods generate when practised outside the drylands. *Dryland afforestation* (48.4), though dependent on the dryland biological productivity, is a potential alternative livelihood, producing fuel wood, biofuel, and sequestered carbon, projected to be of increasing demand. *Controlled-environment protected agriculture* (48.5) is an alternative livelihood dependent on primary productivity, but not on land resources; in spite of high investments, it yields a competitive edge over agriculture within and even off the drylands. *Dryland aquaculture* (48.6), based on biological productivity (though mostly not primary productivity), is of low land use and high water use efficiency and is driven by increasing demands for aquatic, especially marine, food. Increasing *dryland urban growth* (48.7.1) provides urban livelihoods, while *dryland tourism* (48.7.2) as an alternative livelihood is based both on rural and urban dryland resources and is driven by increasing demand. Projected global demands for renewable energy are likely to generate *dryland alternative livelihoods associated with solar energy production* (48.7.3).

Alternative livelihoods can be practised in most drylands, but afforestation has higher prospects in the non-desert drylands, while all other - in desert ones[5].

1 This chapter is partly based on a lecture delivered at the conference "Desertificacion y Seguridad Ambiental: consecuencias y prevención", 9–11 March 2006 under the auspices of Cosmo-Caixa, in Madrid, Spain that was publishe as: "Alternative livelihoods for attaining dryland sustainability", in: Rubio, Jose L.; Andrew, Vincent (Eds.): *Human and socioeconomic consequences of desertification* (Las Palmas: Universidad de Las Palmas de Gran Canaria, Servicio de Publicaciones y Difusion Cientifica de la ULPGC, 2009): 161–190.

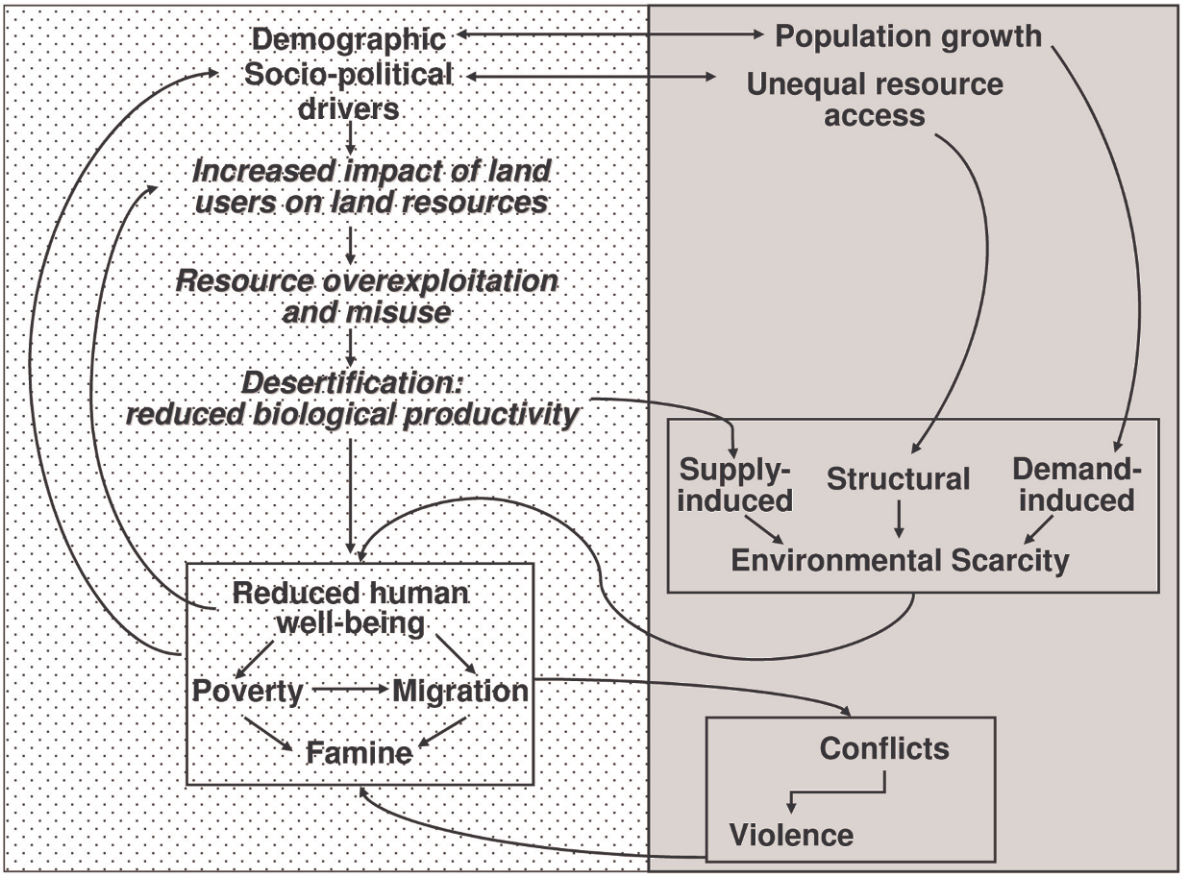
2 'Desertification' is defined here as a persistent reduction in dryland productivity (e.g. Adeel/ Safriel/ Niemeijer/ White 2005).

3 Pleases see section 48.2.4 for discussion of poverty indicators.

4 In this chapter 'security' refers to a component of 'human well-being', which includes personal safety, secure resource access, and security from disasters (e.g. MA 2005; Leemans 2009).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_48, © Springer-Verlag Berlin Heidelberg 2011

Figure 48.1: The rural drylands' 'desertification paradigm': social and policy processes (in conventional font), biophysical processes (*in italics*). **Sources**: The left column is adapted from Safriel/Adeel (2005). The right column introducing the 'environmental security' issue is adapted from Homer-Dixon (1999) and Homer-Dixon/Deligiannis (2009)



For attaining dryland sustainability alternative and traditional dryland livelihoods need to coexist as a mutual back-up, for buffering against uncertainties that affect both the ecological and the human dryland systems. This chapter explores the linkages between poverty and its resulting insecurity, and between these and the currently prevailing land use in drylands, based on land productivity. It then elaborates on the potential of alternative livelihoods in addressing dryland sustainability.

48.2 The Desertification – Security Nexus

48.2.1 The Desertification Paradigm

Desertification, defined by the *United Nations Convention to Combat Desertification* (UNCCD) as land degradation in the drylands is addressed by the *Millennium Ecosystem Assessment* (MA 2005) as a paradigm[6]. According to this 'desertification paradigm' (Safriel/Adeel 2005) demographic and sociopolitical factors drive dryland farmers and herders to overexploit or misuse land resources, which results in desertification, expressed by a persistent reduction of bio-

5 Desert drylands are the hyper-arid and most of the arid drylands, whereas non-desert drylands are the semi-arid and the dry sub-humid drylands (Safriel/Adeel 2005; Ezcurra 2006).

6 A cluster of conceptual and methodological presuppositions embodied in an exemplary body of scientific work, or the predominant worldview in the realm of human thought, e.g. Kuhn 1962).

logical productivity. This leads to interlinked poverty, famine, and migration of the land users (Brauch 2006, 2006d; Boulharouf/Pattie 2008; Rechkemmer 2008). These in turn further amplify the demographic and sociopolitical drivers that had initiated this desertification positive feedback loop (figure 48.1, left column).

This paradigm is often extended to suggest that the desertification-driven reduced human well-being, especially when expressed in poverty that motivates emigration, is prone to become a 'security issue' (Kepner/Rubio/Mouat/Pedrazzini 2006). Since the UNCCD is formally an 'environmental' convention, being designated as a 'Rio Convention' (Bauer 2006), the relevant 'security' is not necessarily associated with armed conflicts, but is alluded to as a 'soft' security issue, often termed 'environmental security'.

The notion that environmental degradation has sociopolitical implications (e.g. Homer-Dixon 1994) and may constitute an emerging security risk, and the term 'environmental security', was coined in the late 1980's (Levy 1995, Brauch 2003, 2005, 2005a). Since then the issue aroused interest but also generated controversy as the term 'environmental security' has not been formally defined, neither scientifically nor legally (Glenn/Gordon/Perelet 1997–1998), yet it has been instrumental in promoting an environmental discourse (e.g. Helm/Sprinz 2000).

'Environmental Security' has been used in the desertification context probably first by Olsson (1993), and was later extensively elaborated on in a 2003 conference on *Desertification in the Mediterranean Region: A Security Issue* (Kepner/Rubio/Mouat/ Pedrazzini 2006; Brauch 2006; Liotta 2006).

The linkage between 'environmental degradation' (including 'desertification' as a special case) and 'environmental security' is one between biophysical and societal-political processes, thus drawing natural scientists and sociopolitical scientists to the same arena. The latter introduced the term 'environmental scarcity' as a mediator between 'environmental degradation' and its expression in reduced human well-being, culminating in conflicts and violence. This scheme, that can be incorporated into the 'desertification paradigm' (figure 48.1, right column), was proposed in the early 1990's (Homer-Dixon 1994, 1999; Bächler 1999; Bächler/Böge/Klötzli/Libiszewski/Spillmann 1996; Bächler/Spillmann 1996a, 1996b) and has become prevalent in the sociopolitical discourse (e.g. Dalby 2004; Brauch 2003, 2005, 2005a, 2006; Liotta 2006). 'Scarcity' in this scheme is generated by each of three mechanisms or their combination: the low supply of the resource due to its degradation ('supply-induced' scarcity), which can be further exacerbated by population growth ('demand-induced' scarcity), and an often emerging inequitable societal distribution of land resources resulting from one segment of the population reducing resource accessibility to the socially and economically weak segments of society ('structural' scarcity). Sociologists often differ from ecologists in the way they perceive these 'scarcity' mechanisms, and an attempt to bridge this gap is presented in the following section.

48.2.2 Scarcity and Degradation – Sociological vs. Ecological Perspectives

Natural scientists practising the discipline of ecology would argue that 'scarcity' is induced by resource limitation, and not necessarily by resource 'degradation'. Using ecology jargon, individual-weighted, density-dependent, intra-population exploitative or interference competition on the finite resource on which the dryland livelihood depends, determines the fraction of the resource available for an individual user (e.g. Puigdefabregas 1995).

Thus, ecologists would claim that the sociologist's 'supply' and 'demand' are interlinked – use of the 'supply' increases the 'demand' through promoting population growth (or wealth), and the increased 'demand' reduces the 'supply' through consumption. Ecologists would also ascribe the sociologists' 'structural scarcity' to the mechanism of asymmetric competition, by which some individuals are affected more than others by intra-specific competition (for terminology see e.g. Begon/Harper/Townsend 1996). Thus, the distinction between supply-induced and demand-induced scarcity is rather artificial, and since at least theoretically any use of finite resource generates competition, i.e. conflict, 'scarcity' is not necessarily a useful term for addressing the 'environmental security' issue, including when the environment is that of a dryland ecosystem.

Furthermore, not only 'scarcity' but also 'degradation' is not required for linking resource use with 'environmental security' and its poverty-conflict nexus. For example, a farmer's income can decrease when his plot loses half of its previous productivity due to desertification. Yet his income can be equally reduced with no desertification, but as a result of losing half of his plot due to social, cultural or policy-driven causes. Moreover, in the dryland context, where productivity is inherently low relative to that of many non-dryland ecosystems, rural poverty can emerge with no land

degradation, i.e. it need not be driven by desertification. In the following section alternatives to the desertification paradigm are brought forward.

48.2.3 The 'Dryland Livelihood Paradigm'

Ecologists have elaborated on several mechanisms that generate nonlinear relations between consumption rates and resource abundance at low resource levels, whereby the cost surpasses the benefit of resource acquisition. These relate to time spent on travelling between low-density resource items or low-density resource patches and the risk and costs involved in this travel (e.g. Optimal Foraging Theory, suggesting that the forager would abandon a resource when the cost of its acquisition surpassed its benefit, see Begon/Harper/Townsend 1996), or to the minimal number of resource items that promote search efficiency (e.g. type 3 functional response, or the Allee effect, see Begon/Harper/Townsend 1996). These mechanisms are relevant to the pastoral livelihood in drylands, whose practitioners' well-being can be reduced by a combination of climate variation and low productivity of non-degraded land. Thus, a herder may become poor not because the range has become degraded, but because plant productivity is too low there, which requires moving with the flocks over an area larger than what is manageable or profitable to cover. Similar considerations apply to a dryland farmer who is poor even though his plot size is large enough to provide for his needs, yet too large for his capacity to make the investments required for its productive cultivation.

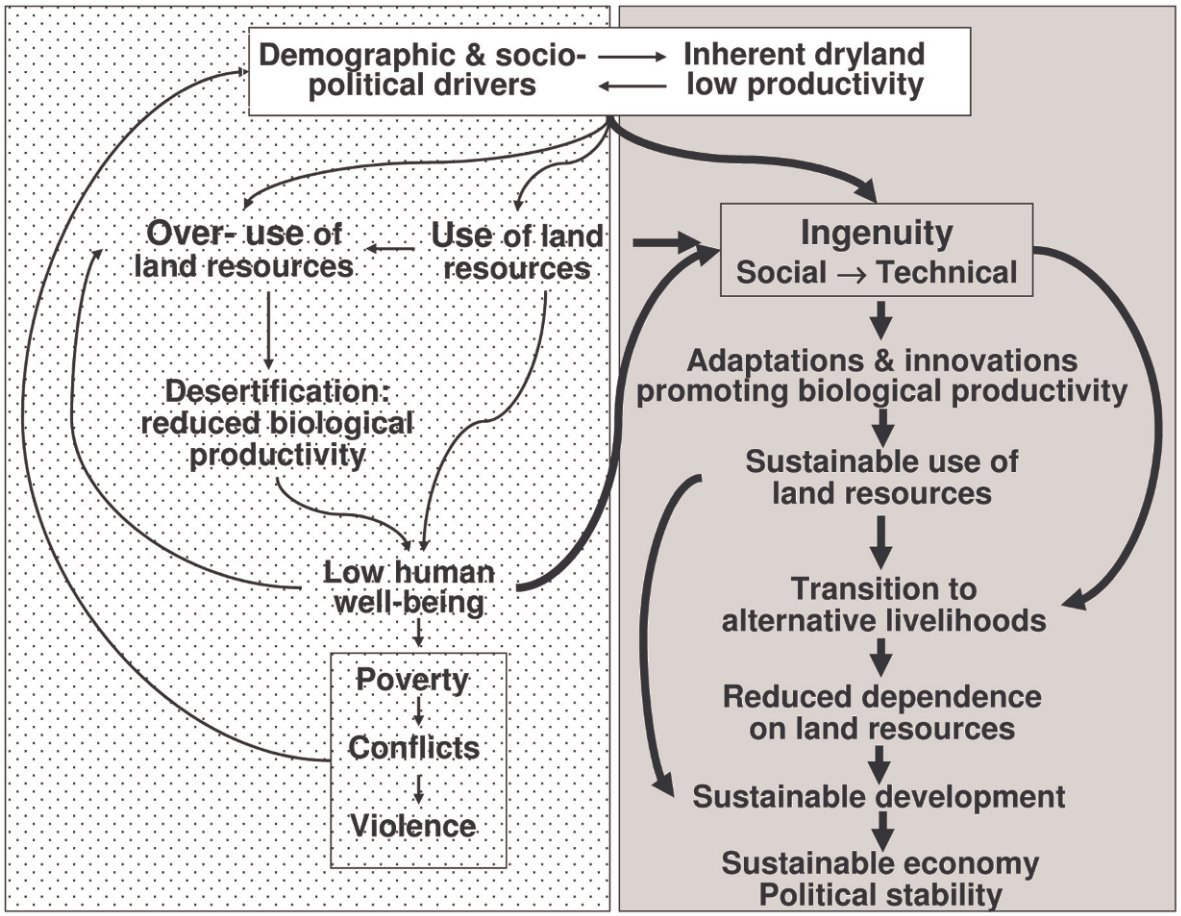
These examples suggest that the dryland practitioner of either pastoral or farming livelihoods can become poor and generate or experience conflict situations without degrading his land. By the same token, the inherently low productivity may motivate the dryland farmer or pastoralist, whether already or not yet poor, to intensify his land use practices (overstocking of rangelands, expansion and intensification of farmlands), thus leading to desertification and poverty. These two scenarios, driven by the drylands' inherently low productivity, call for a '*dryland livelihood paradigm*' which addresses poverty derived from non-degrading dryland use. The '*desertification paradigm*' then becomes a special case in which the inherent low land productivity, and/or the low human well-being of dryland users, motivates them to overuse the dryland, thus leading to its degradation. In both the degrading and the non-degrading track, the low or reduced human well-being generates the downward spiral and feedback loops of poverty, conflict, and their security concerns (figure 48.2, left).

However, increasing evidence suggests that this is not always the case, and that dryland use can also take another, alternative trajectory. Thus, the Millennium Ecosystems Assessment's '*desertification paradigm*' is complemented by an alternative 'counter-paradigm' (Safriel/Adeel 2005). This too can be incorporated in the '*dryland livelihood paradigm*' (figure 48.2, right).

The inherently low dryland productivity and/or the poverty generated by use or overuse of the dryland are a challenge to the land users. Their inherent ingenuity then yields adaptations and innovations that keep them ahead of desertification, poverty, and conflict. This ingenuity is expressed in taking measures such as improving marketing infrastructures, developing financial and extension services ('social' ingenuity, Homer-Dixon 1994) or organization of labour ('induced innovation', Boserup 1965; Tiffen/Mortimore/Gichuki 1994). This implicitly-inherent social and technical ingenuity can be expressed in adaptation of technologies and innovations in cultivation practices, which promote rather than degrade biological productivity (Adeel/Safriel/Niemeijer/White 2005). Hence, in this counter-paradigm, dryland people use the soil and its biological productivity at rates that are within the capacity for renewal, thus practising sustainable use (IUCN/UNEP/WWF 1991) of land resources.

Yet, because land resources remain finite, as long as human pressure increases, ingenuity and adaptive capacity that target biological productivity are bound to be exhausted at some point in time. However, ingenuity and adaptive capacity can also take a different trajectory before land use loses sustainability by turning into livelihoods that 'decouple' from dependence on land resources (Homer-Dixon 1994), or at least reduce the dependence on them (Matthew/Gaulin/McDonald 2003). These are the 'alternative livelihoods' (Safriel 2004, 2006a) that mostly capitalize on non-agricultural dryland assets. Either independently or combined with the attained sustainable use of biological productivity, these alternative livelihoods are likely to lead to a genuine sustainable development – improvement of human well-being which is supported by a sustained flow of dryland ecosystem services (Millennium Ecosystem Assessment 2003). This dryland sustainable development leads to sustainable economy, one which maintains the natural resource base, yet it allows for growth through improvements of knowledge, organization, governance and technical efficiency (IUCN/UNEP/WWF 1991), both enjoying and supporting political stability (figure 48.2, right).

Figure 48.2: The 'Dryland Livelihood Paradigm'. The interaction between people and the inherent low dryland productivity (top) can generate two contrasting development trajectories leading to low human well-being (directly or through desertification), poverty and conflict (left, column, dotted), or through ingenuity and adaptation leading to sustainability and security (right, column, grey). **Source**: The author.



48.2.4 Uncertainties, Loose Terminology, and Controversies

The causal relationships between each of the elements of both the 'desertification paradigm' (figure 48.1) and the 'dryland livelihood paradigm' (figure 48.2), as represented by the arrows in these schemes, are not well understood, and are controversial. It is therefore unknown where, when, and why land use in the drylands leads to conflict and violence, or to sustainable economy and political stability. There are disagreements regarding both the biophysical and the sociopolitical mechanisms involved, and since these are interconnected, the paradigms remain elusive.

Regarding the biophysical processes, the term 'desertification', though defined in a legally-binding international agreement (UNCCD), is loosely and indiscriminately used by stakeholders, implementing parties of this agreement and others (e.g. 'desertification' is used in describing the clearing of sub tidal Mediterranean rocks from algae, caused by fishing of edible, rock-boring marine bivalves; see Guidetti/Fraschetti/Terlizzi/Boero 2004).

This might have led to loss of credibility by sizeable segments of the scientific community, pointing at over-simplification and confusion in describing and addressing dryland processes, and even at deliberate inflation in use of the term as a strategy to attract attention and funding (Warren/Olsson 2003). There is also a disagreement within the scientific community whereby 'desertification' is invoked or refuted depending on whether the context is biophysical or sociopolitical (Herrmann/Hutchinson 2005): a site can be described by social scientists as suffering from severe desertification, whereas biophysical scientists dismiss this claim (Mortimore/Turner 2005).

The definition of the socio-economic terms 'poverty' and 'human well-being' too are not robust. Survey data of consumption and income are used to determine 'poverty lines' set by social norms and expectations that differ between individual countries. For the sake of global aggregation and comparison, the World Bank employs reference lines using two Purchasing Power Parity terms set at $ 1.08 and $ 2.15 in 1993 (Chen/ Ravallion 2001), and the United Nations employs a 'Human Poverty Index' as a composite measure of social, economic, and health parameters (Fukuda-Parr 2003). 'Human well-being', on the other hand is defined as a composite qualitative state, including the above measures as well as others, such as security (e.g. MA 2005). Furthermore, the only available figure to date on dryland poverty ("Of the population living in dry areas approximately 1 billion are poor, which accounts for close to half of the world's poor." UNDP 2008) cannot be substantiated by quantitative data relating to the World Bank's Purchasing Power Parity poverty levels or to values of the Human Poverty Index applied to dryland populations. To conclude, these shortcomings of both the biophysical and the socio-economy disciplines contribute to the difficulties in assessing when and where land use becomes overuse, overused land becomes desertified, and desertification leads to poverty.

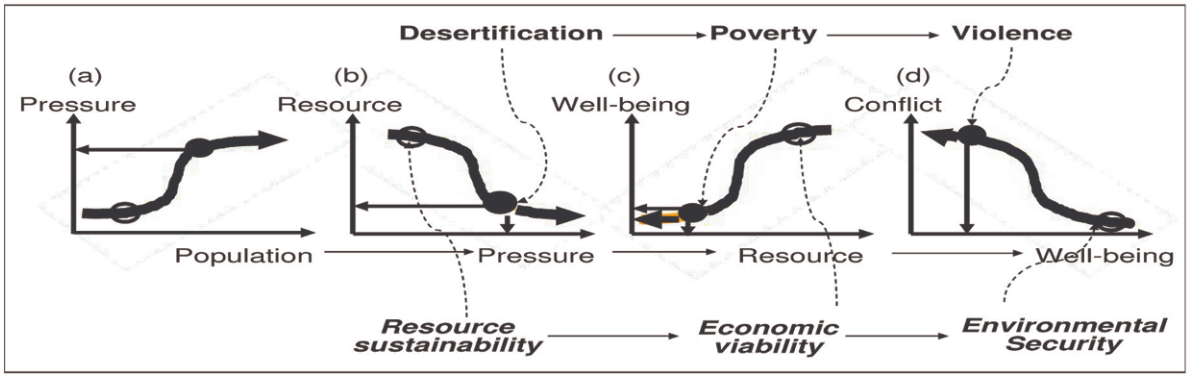
Beside difficulties caused by loose definition of states (e.g. desertification, poverty), social scientists disagree on the relative role of environmental degradation in generating conflicts and violence. The thesis of Homer-Dixon (1994, 1999), that depletion and degradation of renewable 'environmental resources' leading to 'environmental scarcity' contributes to civil violence, was criticized by Hauge and Ellington (1998) as fraught with a shaky theoretical basis and flawed data treatment. Subjecting a wider data set to robust statistical analysis suggested that though degradation of renewable resources, alone or combined with elevated population density, increase the risk of low-level domestic conflict, this degradation is only a marginal driver of violent conflicts (Hauge/Ellington 1998). Analysing the evidence for supporting and refuting Homer-Dixon's thesis, Gleditsch and Urdal (2002) concluded that the existing empirical evidence was still insufficient to demonstrate a tangible effect of population growth and environmental scarcity on conflicts and violence.

Social scientists also disagree on whether population growth, environmental degradation, scarcity and poverty, individually or combined, induce ingenuity and innovation (e.g. Boserup 1965; Tiffen/Mortimore/Gichuki 1994: de Soysa 2002; Dalby 2004), thus leading the drylands onto the sustainability and stability trajectory; or, scarcity and poverty suppress ingenuity by hampering effective social and technological investments (e.g. Homer-Dixon 1994, 1999), hence pushing the drylands into the spiral of desertification and conflict. To conclude, both paths of the *'dryland livelihood paradigm'* are controversial, what calls for a different approach.

48.2.5 The 'Dryland's Alternative Stable States' Hypothesis

The recognition that the processes in the '*dryland livelihood paradigm*' may be nonlinear could contribute to resolving some of the contentions discussed above. It has been hypothesized (Safriel/Adeel 2008) that nonlinear processes characterize the various components of the dryland livelihood paradigm. Accordingly, the paradigm can be collapsed into a chain of variables – population size, population pressure, land resources level, human well-being level, and conflict level. Each of these links in the chain is of a potential to drive the forefront link and to be driven by the preceding link (figure 48.3). It has been further suggested that the functional relations within this chain are nonlinear, such that each of the linked variables can be maintained in two alternative equilibrium states which are locally stable, but each of them can be destabilized once a threshold value is crossed, driving the variable to the alternative locally-stable state. Thus, the effect of a linear population growth on its pressure on land resources may not be linear – when population size is low a low level of pressure is exerted, but when a threshold level of population size is crossed, a strong pressure becomes evident (figure 48.3a). Since the pressure on resources may be buffered under a regime of low population growth rates, resource levels then maintain high, sustainable levels (i.e. its renewal and consumption rates remain similar, figure 48.3b, empty circle), human well-being benefits from economic viability (i.e. the practiced livelihoods generate stable and satisfying income) and only mildly fluctuates around high levels (figure 48.3c, empty circle), thus leading to high 'environmental security' expressed in a low incidence of conflict (figure 48.3d, empty circle). However, when population size reaches a level at which the pressure on land resources steeply climbs to a high state, whereby land resources and their biological productivity sharply drop to a persistent low value, an alternative, relatively stable state of desertification is attained (figure 48.3b, solid circle). Similarly,

Figure 48.3: The 'Dryland's Alternative Stable States' Hypothesis. Nonlinearities in the Dryland Livelihood Paradigm – the desertification – poverty – violence chain (top, bolded) and states (solid circles), and the resource sustainability – economic viability – environmental security (bottom, italics) and states (empty circles). **Source**: The author.



this new, undesirable locally stable state of desertification reduces human well-being in a nonlinear way, to an alternative low state – poverty (figure 48.3c, solid circle). By the same token, the declining human well-being and conflict level may drive conflict level in a nonlinear mode, crossing the violence threshold (figure 48.3d, solid circle).

Note that nonlinearities in the '*dryland livelihood paradigm*' model (figure 48.2, left) can also be then transformed into a feedback loop when the open-ended chain is 'closed'. The prevalence of the security stable state can maintain resource sustainability, or the alternative state of violence can drive the resource level to an acceleration and long-term prevalence of the desertification state.

The conflicting results generated by the different studies of components of the '*dryland livelihood paradigm*' depend on where the studied systems were positioned along the nonlinear curves when observations and data were made and collected, respectively. For example, whereas in a certain area the pressure level is not sufficient to generate desertification the same pressure level under different circumstances does cross the threshold. This also applies to the poverty and security states.

Finally, just as desertification, poverty, and violence result from crossing thresholds by relatively strong perturbations of relatively stable desired states, restoration of security, human well-being, and biological productivity also require a relatively strong perturbation in the opposite direction. This leads to the assertion that desertification, just as poverty and violence, represent a state that is not necessarily irreversible. Rather, it is a locally stable state that moving it to the alternative state, i.e. restoring sustainability would require sizeable investment.

48.2.6 Multiple Stable States in Ecological Systems and in Drylands

The notion that ecological systems can theoretically be maintained at multiple stable states has been deliberated by ecologists for more than three decades; this notion can also be applied to social systems that depend on ecological systems. Evidence for alternative stable states and nonlinearities in ecological and natural resource systems is gradually emerging (Gunderson/Pritchard/Holling/Folke/Peterson 2002). An example that reflects on desertification is, rather paradoxically, that of the Jamaican coral reef, where human-induced increased nutrient input combined with overfishing of herbivorous coral-reef fish drive the coral-dominated reef to algae dominated reef. The latter is a stable, hard to reverse state, with a lower provision of biological productivity, tourism and coast protection ecosystem services as compared to the former state (Janetos/Kasperson 2005; MA 2005).

Two other examples, though controversial, come from the drylands. The first relates to vegetation cover of the semi-arid African Sahel. Much of the rainfall there may be recycled by the vegetation through its effects on *albedo*.[7] It has been claimed that overgrazing and exploitation disrupted this vegetation-related rainfall generation over a long period, leading to reduced productivity (Janetos/Kasperson 2005). This, however, may not be a locally stable state, since the

7 Albedo is the fraction of solar radiation striking earth that is reflected by its surface back to space.

Sahel's productivity recovered following drought years (Safriel/Adeel 2005).

The salient example of a nonlinear, desertification-attributed transition between dryland stable states is that of bush encroachment onto arid and semi-arid grasslands This increase in density of woody plants often unpalatable to livestock reduces the value of the range, though the overall primary productivity is not reduced. Livestock overgrazing is implicated – removal of shallow-rooted grasses enhances water storage in deeper soil layers, thus favouring deeper-rooted shrubs (e.g. in Botswana, Walker/Ludwig/Holling/Peterman 1981). The shrubs are further promoted by the leakage of nutrients from the grass-denuded surfaces into the vicinity of the shrubs, thus a mosaic of 'islands of fertility' in a soil-degraded matrix (e.g. in south-western USA, Schlesinger/Reynolds/Cunninghan/Huenneke/Jarrell/Virginia/Whitford 1990: Schlesinger/Raikes/Hartley/Cros 1996) is established as an alternative stable state, desertification. Bush encroachment in Namibia, however, is not induced by livestock grazing. Rather, the transition between bush-covered and open savannah states is driven by inter-tree competition and patchy rainfall patterns (Wiegand/Ward/Saltz 2005).

Though claims for nonlinear nature of desertification are not yet sufficiently founded, options for nonlinear behaviour of socio-economic states driven by resource nonlinear behaviour can be considered too. It is claimed (Janetos/Kasperson 2005) that at least with regard to fisheries, societies moving from subsistence harvesting to harvesting with improved technology can cause sudden and large changes in the rate of resource exploitation, which often irreversibly pass the threshold of sustainability.

To conclude, though evidence is not conclusive, desertification may be defined as an alternative stable state of the multiple-stable-state dryland ecosystem, as suggested by the '*dryland's alternative stable states*' hypothesis described by the graphical model of figure 48.3. As land use intensifies, soil resources are depleted and biological productivity declines. This leads to a reduced human well-being and even an increase in social conflicts, yet this system remains relatively stable and sustainable. Only when land use intensity reaches a threshold value the system moves to a low-productivity stable state. Once it is in this state, subsequent release of the pressure would not regenerate, let alone restore, biological productivity. Even if the rate of forage use equals the theoretical rate of renewal, the rate of soil degradation or loss is far faster than that of soil renewal, and hence productivity can not be restored. Only input-laden, aggressive management may push the system back to its former, productive stable state.

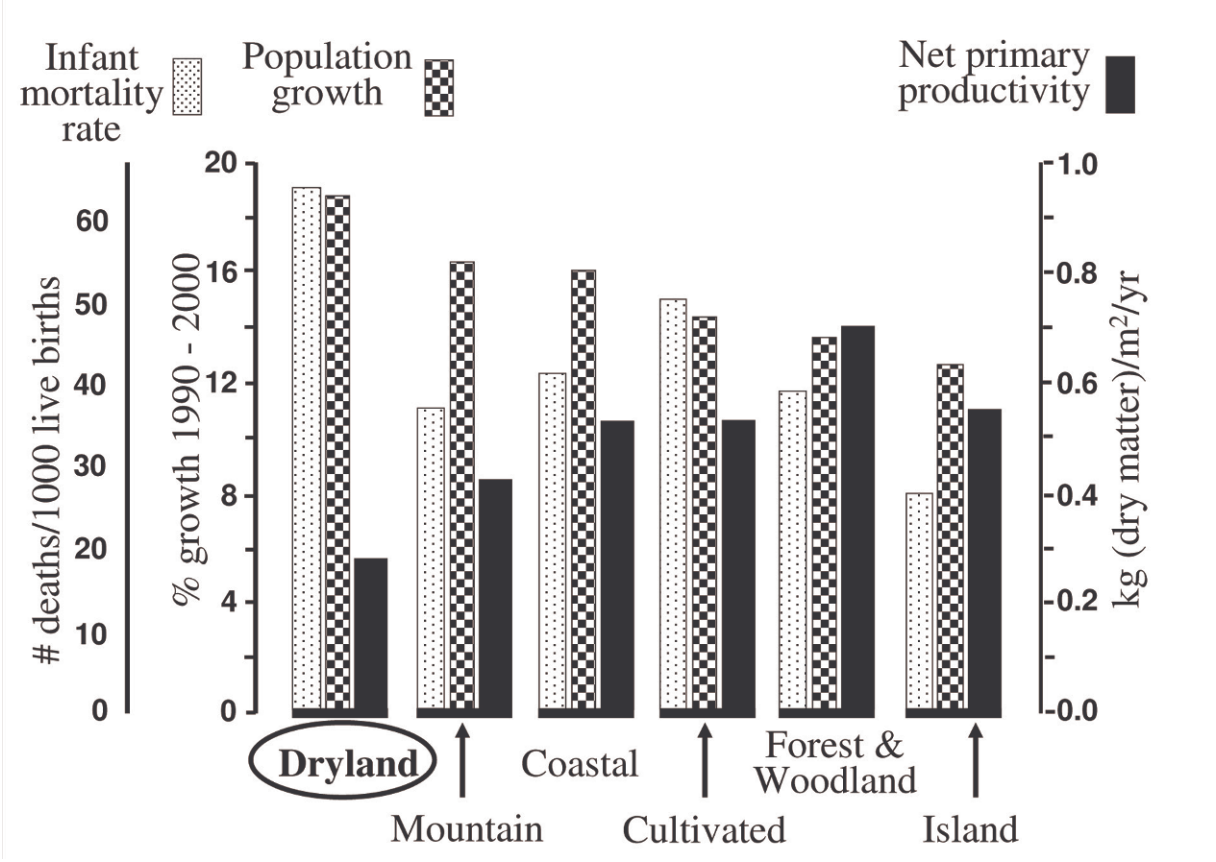
It is likely, however, that the financial resources required for such management are beyond the reach of communities whose land is already desertified. However, a way out can be envisaged whereby another threshold can be crossed, leading to sustainability of the rural drylands. This is based on livelihoods that reduce the dependence on the inherently low dryland productivity through an exploitation of other dryland attributes whose economic potential has not yet been fully recognized. The option of adopting such livelihoods, termed 'alternative livelihoods', is presented and discussed in the following section.

48.3 The 'Alternative Livelihoods' Track

48.3.1 The Imperative of Dryland's Alternative Livelihoods

The '*dryland's alternative stable states*' hypothesis developed in the previous section may support the 'desertification paradigm' section of the 'dryland livelihood paradigm' (figure 48.2). And, there is some evidence to suggest that the alternative track of the latter paradigm, in which crossing the thresholds of population size and population pressures (figure 48.3a, 3b) does not move the system to the desertification alternative state, but instead induces ingenuity, which leads to avoiding desertification and maintaining sustainability (figure 48.2, right). Yet, it is conceivable that this track only pushes the threshold in figure 48.3 further to the right; since resources remain finite, further population increase or increase in demand will eventually lead to crossing the desertification threshold. When approaching the neighbourhood of this new threshold, only another nonlinear change can detract the system from the desertification track – crossing a threshold of moving from land-dependent to land-independent livelihoods. Rather than striving through ingenuity and adaptation for sustainable use of biological productivity, people would divert their ingenuity and adaptive capacity and use them for developing, adapting, or adopting 'alternative livelihoods'. To conclude, as long as population is beyond the threshold (state a in figure 48.3) it is likely that at some point in time the desertification threshold will be crossed too, whether the system as a whole represents the desertification paradigm or its counter-para-

Figure 48.4: Global net primary productivity (black), global population growth rate (coarse dots), and infant mortality rate in Asia (fine dots), in the major global land-human systems. **Sources**: Adapted from the Millennium Ecosystem Assessment (MA 2005) and Adeel/Safriel/Niemejer/White (2005).



digm; the only way out is a gradual, and at least partial shift to livelihoods not based on the land productivity resource.

This shift is likely to be driven by a nonlinear cultural, social, economic or political process, which diverts human endeavour from land productivity-based livelihood, to another, not only non-degrading, but one actually independent of land resources. This option is worth elaboration in face of some sober emerging realities of current dryland uses. Biological productivity and infant mortality, a strong signal of critically reduced human well-being, are lower and higher, respectively, and population growth is higher in the drylands than in any other major human-ecological system on earth (figure 48.4). A decade of implementation of the UNCCD does not seem to have dramatically improved human well-being in the drylands, let alone slowed down population growth rate or increased dryland biological productivity. It is therefore high time to look at livelihoods for the drylands' growing populations which do not further increase the pressure on land resources. These can only be ones with reduced dependency on land productivity.

The notion of alternative dryland livelihoods is not new. More than a decade ago a simple ecological model based on prey-predator dynamics was used to demonstrate that threshold in human pressures on land resources exist, whereby small changes in consumption rates at the neighbourhood of this threshold may lead to destabilization of systems prone to desertification (Puigdefabregas 1995). This analysis suggested that at this point further intensification of land use would increase rather than decrease the per capita consumption rates and lead to desertification. It has been then suggested that this can be avoided by developing the ability to generate income while releasing the pressure on land resources, through increasing economic diversification (Puigdefabregas, 1995). This diversification is expressed in developing and adopting 'alternative livelihoods'.

48.3.2 What is a Dryland Alternative Livelihood?

A dryland livelihood can qualify as an 'alternative livelihood' by complying with one or several of the four following criteria, ordered at an additive, increasing contribution to sustainability: (a) it is of minimal dependence on land primary productivity for producing subsistence products; (b) inasmuch as it does depend on land productivity, it does not impair the provision of other services of dryland ecosystems, which are essential for human well-being (e.g. the provision of water resources and the maintenance of biodiversity, see also MA 2005); (c) it generates more income per investment of local dryland resources, as compared to the traditional, biological productivity-dependent livelihood that it replaced, and (d) it provides its practitioners with a competitive edge over others who practise the same livelihood outside the drylands. These features of alternative livelihoods, and especially when the last one is in place, enable dryland people to be better off than non-dryland people, rather than perpetually lagging behind them in income and well-being.

A common feature of all alternative livelihoods, whether they comply with all four qualifications or only fewer, is that their viability requires capital and trade infrastructures, which in turn depend on compatible policies and governance, attributes that are often deficient in many dryland countries. On the other hand, engagement in these alternative livelihoods does not require particular technological sophistication on the part of the practitioners; science and technology are of course mobilized to generate and support these livelihoods, but their implementation is user-friendly, tailored for the needs of the local people.

Some of several major alternative livelihoods already elaborated on in previous publications (e.g. Safriel 2004; Adeel/Safriel 2005; Safriel/Adeel 2006; Safriel 2006a, Adeel/Safriel 2008) are here reconsidered in order of decreasing dependence on land productivity, and hence of decreasing desertification risks and increasing likelihoods of sustainability. Furthermore, their reduced dependence on land resources determines the dryland type in which their practice will be most sustainable and economically viable.

The four alternative livelihoods to be considered in the following sections are dryland afforestation (generating income from firewood production and from trading the sequestered carbon in the carbon market), controlled-environment dryland agriculture producing cash crops, dryland aquaculture (producing aquatic organisms, mainly fish), and urban-supported dryland alternative livelihoods (such as tourism and industrial energy production based on solar radiation).

48.4 Dryland Afforestation – Land-dependent Alternative Livelihood

Woodlands naturally occur in drylands, and their incidence declines as aridity increases (Safriel/Adeel 2005). Afforestation, i.e. forestry activities in areas that have been naturally devoid of woodlands, also takes place in some drylands (Ginsberg 2002). Dryland afforestation of the least dry drylands (e.g. the dry sub-humid and the semi-arid drylands), though fully dependent on the dryland biological productivity, can have the potential to become an alternative livelihood, by producing fuel wood, biofuel, and sequestered carbon.

48.4.1 Firewood Production

The global fuel wood consumption from sources other than major forest areas increased by 42 per cent between 1961 and 1980, but was down to 38 per cent from 1980 to 2000, apparently due to an increasing shift to fossil fuels. The number of people depending on firewood for heating and cooking is expected to decline by 2030 in China, but to increase in Africa (Arnold/Köhlin/Persson 2003). Though on the local scale, many rural communities experience firewood shortages, both in Africa and in Asia (Sampson 2005), at the global scale firewood supply from reforestation of areas that had been deforested is projected to grow 3- to 5-fold by 2020 (Shvidenko/Barber/Persson 2005). Regarding drylands, an increasing demand is expected, driven by the high population growth rate, coincidental with an increasing decline of firewood provision by dryland ecosystems, caused by livestock grazing and firewood collection at rates faster than those of regeneration (Sauerhaft/Berliner/Thurow 1998).

48.4.2 Biofuel from Forests and Plantations

The elevated awareness of global warming linked to recognizing the need to diversify and increase renewable energy sources on the global energy market (Sampson 2005), draw attention to the option of using the drylands' biological productivity for biomass

Figure 48.5: Landscape manipulation for water harvesting supporting afforestation in an arid dryland (Negev Desert, Israel). **Source**: Photo by Keren Kayemet Le'Israel (JNF). Reprinted with permission.

production. This includes for example 'plantation forestry' in Australia producing wood biomass (Foran 2001; Eco Resource Development 2002) and dryland cultivation of woody perennials for their biodiesel producing seeds in India (Anonymous 2004). Provided that such plantations do not appropriate land used for food production, their sustainability is expected to be higher than that of biodiesel production from agricultural food crops (Hill/Nelson/Tilman/Polasky/Tiffany 2006), a rather unfortunate emerging trend of the first decade of the 21st century. Sustainable dryland biofuel production can be achieved through reforestation in dry sub-humid and semi-arid rangelands and croplands created through woodland clearing. In the dryer arid and hyper arid drylands the required practice is that of afforestation, which is there feasible only through landscape manipulation for runoff harvesting (figure 48.5). Such afforestation may qualify as an alternative livelihood if it can profitably and sustainably replace, or significantly augment, the current traditional livestock production in these drylands.

Furthermore, woodlands and forests in drylands are more effective than rangeland and croplands in preventing soil erosion, and they significantly enhance the soil organic matter contents. Their effect on soil moisture and on dryland water resources, on the other hand, is debatable. Under some circumstances dryland afforestation utilizes local water resources in a non-sustainable manner, and their relatively high evapotranspiration compared to that of the natural ecosystem they replaced, reduces groundwater recharge (Carrere/Lohmann 1996). Yet in other cases dryland afforestation reduces water losses and increases rainfall penetration (Shachanovitch/Berliner/Bar 2008). Furthermore, effective surface cover and optimal viability, growth, and productivity greater than those of rain fed annual crops are achieved by rain fed afforestation (with no supplemental irrigation) even in an arid site, provided appropriate runoff harvesting measures are taken (ICARDA 2007).

48.4.3 Carbon Sequestration

The emerging global carbon trading under the *Clean Development Mechanism* (CDM) of the Kyoto Protocol (TERI 2000) can add much to the qualification of dryland afforestation, as a successful alternative livelihood (UNCCD 1999), on top of its economic value in providing firewood and renewable biomass (Chichilnisky/Heal 1998). At the global scale, about four million hectares of plantations were established with funding for carbon sequestration by the year 2000 (Shvidenko/Barber/Persson 2005). Data on such developments in drylands are not yet available, though conversion of 'marginal agricultural land' to 'woodland' was recommended as a measure for carbon sequestration (Cassman/Wood 2005).

An afforestation project using mostly the Mediterranean, drought-resistant pine *Pinus halepensis* that was initiated in 1964 and extends over 3,000 hectares at the border between the semi-arid and arid region of Israel (270 mm of mean annual rainfall) demonstrates the carbon sequestration potential of arid afforestation. This forest sequesters 165 $gC/m^2/yr$ (as compared to an average of the global monitoring network's dataset [FluxNet] of 270 $gC/m^2/yr$), and its mean annual addition to the carbon reserve since planting is 150 $gC/m^2/yr$, thus storing by now twice as much carbon as the adjacent non-forested rangeland (Gruenzweig/Lin/Rotenberg/Schwartz/Yakir 2003). Though this forest is already more than 40 years old, its carbon sequestration worth is \$18/ha/yr (using the 2005 values of the global carbon market), which augments the \$63/ha/yr generated by the value of the firewood collected by the local Bedouins. At the same time this forest still produces forage valued at \$43/ha/yr (Rueff/Kressel/Schwartz 2004).

Combined, these non-timber products of this afforestation project do not generate ample livelihood and the livelihood of the local population there is totally detached from this forest. Yet, given the projected values of renewable energy and of carbon, similar projects designed for biomass production and for driving CDM contracts or for selling carbon offsets (Aune 2003), are likely to qualify as sustainable dry sub-humid and semi-arid alternative livelihoods.

48.5 Controlled-Environment Protected Agriculture

Under the *desertification paradigm* dryland agriculture is one of the main drivers of land degradation, since the attempt to intensify productivity where it is inherently low brings about reduced rather than increased productivity. Somewhat paradoxically, a high level of agricultural intensification in the drylands is not only non-degrading but also of high economic returns provided it is practised within a confined space that enables manipulation of most environmental variables – that of a greenhouse.

48.5.1 Attributes of Greenhouse Agriculture in Drylands

Figure 48.6: Commercially provided colonies of bumblebees for pollination within a greenhouse in Israel's semi-arid region. **Source:** BioBee (2006); at: <http://www.bchothouse.com/greenhouse-3.html>.

Following the invention of polyethylene in the late 1940's, plastic sheets revolutionized agro-technologies and crop production through an accelerated development of plastic-based protected agriculture. The most advanced component of 'protected agriculture' is the greenhouse and its controlled environment technologies, which transformed farming into industry (see chap. 56 by Garcia Lorca). The plastic cover allows

light penetration and the operation of technologies that manipulate most crop-environment interactions, including the drylands-relevant water use efficiency. The investments required for maintaining an internal favourable environment increase with increasing aridity of the outer environment. Ultimately, in hyper arid areas, the internal environment can be fully detached from the outer environment (Arbel/Segal/Yekutieli/Zamir 1990). While reducing water loss within the enclosed chamber, the internal 'greenhouse effect' also helps in maintaining warm atmosphere, especially during the cold nights or seasons in deserts. In the hot seasons this 'greenhouse effect' is a liability, and cooling is required. Yet, specifically in deserts, evaporative cooling is very effective, though this cooling requires additional water, on top of the irrigation water (Jensen/Malter 1995).

Greenhouses also reduce the use of pesticides and the risk of crop diseases, but once a pest penetrates, it rapidly spreads. Yet, its eradication can be effectively controlled within the confines of the greenhouse. Within a fully-equipped greenhouse temperature, humidity, atmospheric carbon dioxide, light, nutrients and even pollination (figure 48.6) are controlled, and excess water and fertilizer are collected and recycled. This tight management allows for reliable quantity and high and uniform quality of the crop. Production is also independent on seasonality and can be manipulated to take advantage of market needs. Increased number of crops per year, faster growth, longest harvest period, reduced losses due to weather vagaries and pests, and tailoring the internal environment for the specific traits for which each cultivar had been bred, all result in yields four times higher than the nearby open agriculture (Jensen/Malter 1995).

48.5.2 Shortcomings and Advantages of Dryland Greenhouses

The greenhouse intensification of production, which reduces the pressure on local land resources and is independent of the drylands' productivity, requires high investment in infrastructure, inputs, and maintenance as well as research and extension. Yet the operation of the system does not require an outstanding expertise and training. But due to the high input, dryland greenhouse agriculture is sustainable only when the produced crops are of very high value, and are marketed when and where their high value can materialize.

Dryland greenhouse agriculture fully qualifies as an alternative livelihood due to its competitiveness, by virtue of two physical/climatic attributes of many, though not all drylands – high irradiation due to relatively low overcast, and higher ambient winter temperatures relative to those prevailing in the nearest non-dryland areas. Indeed, the gross value added and the cash output per unit area of greenhouse agriculture widely practised in the hyper arid dryland of Israel, are higher than those of all other types of Israeli agriculture, including in the least dry areas of the country (Portnov/Safriel 2004). Yet, though water use efficiency in greenhouses is high, a reliable supply of high quality water resources is imperative, and when this requirement is compromised, this alternative livelihood becomes non-sustainable (Puigdefabregas 1995; chap. 56 by Garcia Lorca).

48.6 Dryland Aquaculture

Drylands are defined as ecosystems whose productivity is water-limited (Safriel/Adeel 2005), hence drylands and aquaculture seem to be at odds. But strange as it may sound, aquaculture in dryland is not only a viable alternative livelihood, but in desert drylands it is even advantageous over dryland agriculture; using a metaphor, whereas fish live in water but don't drink water, dryland plants don't live in water but constantly transpire water. The merits of dryland aquaculture as an alternative livelihood are elaborated on in the following sections.

48.6.1 Higher Water Use Efficiency in Aquaculture than in Agriculture

Aquaculture generated 43 per cent of global fish consumption in 2006 as compared to only 9 per cent in 1980. Between 1994 and 2003 aquaculture increased its share from 1.4 per cent to 1.9 per cent of global agricultural value. Increasing cost of fish indicate increased demand in the developed world, yet the bulk of aquaculture's products comes from developing countries, with projection of further increase and contribution to food security and poverty alleviation in these countries (FAO 2006a).

Since drylands are by definition short of water they are not expected to support a livelihood such as aquaculture, which is apparently one of the most water-dependent livelihoods on earth. However, since unlike terrestrial organisms, aquatic ones do not transpire water, the potential of aquaculture for high water use efficiency in areas of high evaporative losses is higher than that of agriculture. Thus, while most of

Figure 48.7: A fish farm in the arid region of Israel (Kibbutz Mashabe-Sadeh, Negev Desert). **Source:** © Photo by Uriel N. Safriel.

the rainfall and/or irrigation water is lost in drylands through crop transpiration and soil evaporation, aquatic organisms like fish and crustaceans not only do not transpire water, but the evaporative losses of the water in which they live is minimized; since these aquatic organisms do not require light for their production, their containers can be made evaporation-proofed even in ways that compromise light penetration (figure 48.7).

Due to these differences in water conservation, water use efficiency of aquaculture compared with that of agriculture is high in drylands, and even augments with increased aridity. For example, between 0.05 m^3 (Koren/Alon 2004) to 0.03 m^3 (Rothbard/Peretz 2002) are used to produce one kg of fish in fish farms of the Israeli desert, whereas 0.45 m^3 to 1.79 m^3 of water input produces one kg of wheat grains in drylands of Australia (Sadras/Angus 2005) or China (Fan/Stewart/Payne/Wang/Song/Luo/Robinson 2005), with or without supplemental irrigation (values based on water use efficiencies calculated as kg grain/ha/mm rainfall or rainfall equivalent of irrigation).

48.6.2 Avoidance of Potential Drawback of Dryland Aquaculture

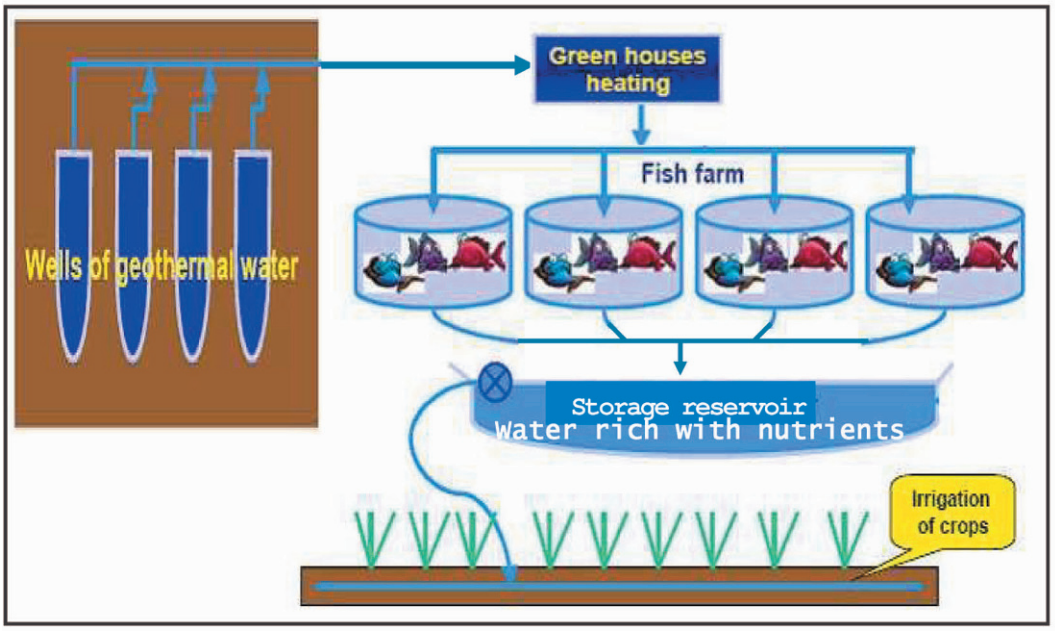
Dryland aquaculture is based on a stable supply of water, and thus may compete with other dryland water uses. However, many aquatic organisms are tolerant or even thrive in water of saline concentrations to which most cultivated crops are sensitive (Koren / Alon 2004). In many dryland regions, aquifers of fossil or partly renewable, brackish water abound, e.g. in Israel (Kolkovsky/Hulata/Simon/Segev/Koren 2003) or Australia (Allan/Banen/Fielder 2001). This water resource is often geothermal, enabling cultivation of tropic and subtropical edible or ornamental fish with no investments in warming during the cold seasons (Rothbard/Peretz 2002). Thus, dryland aquaculture and dryland agriculture differ in the type of water they require and need not compete on water resources. Furthermore, whereas irrigation water can not be reused, aquaculture effluents, enriched by feed residues and fish excrement, can be used for both irrigating and fertilizing crops (e.g. olives, King/McIntosh/Ryder/Fitzsimmons/Collins 2002). Thus, desert aquaculture can be integrated with crop cultivation in controlled-environment greenhouses in drylands (figure 48.8; Kolkovsky/Hulata/Simon/Segev/Koren 2003; FAO 2006a).

Aquaculture may compete with agriculture in the least dry drylands, where population densities are high, land is valuable, and agriculture does relatively well. But in more arid regions with lower population pressures, open agriculture is less successful and land is cheap, providing aquaculture with a competitive edge over agriculture. However, aquaculture may conflict with the livestock sector, since both utilize fishmeal (mostly ocean-derived) for feeds. Furthermore, the dependence of aquaculture on fishmeal may add to the demise of marine fisheries and impinge on the health of marine ecosystems. Greater efficiency in fishmeal use is therefore required in aquaculture (FAO 2006a), and dryland aquaculture need to diversify, in both the spectrum of cultivated fish species (by increasing the use of herbivorous species) and of fish feed sources.

48.6.3 Products of Dryland Aquaculture

Dryland aquaculture can sustainably provide protein-rich edible crops for self-sustenance, local consump-

Figure 48.8: Scheme of aquaculture-agriculture hybrid. **Source:** Adapted from Rothbard/Peretz (2002); permission was granted by the copyright holder.



tion and marketing, but its practitioner can generate a greater return on his investment growing high value crops – ornamental fish and freshwater shrimps. Algae – a crop traditionally associated with oceans, rivers, and lakes – can thrive in dryland conditions, and produced for nutritional, pharmaceutical, or industrial use. Unicellular, or 'micro' algae fare even better than fish and crustaceans under dryland conditions; like cultivated crops, they produce their own carbohydrate food by photosynthesis (and often may require an addition of nutrients), and like fish – live in water but do not transpire it. If cultivated in transparent tubes, they enjoy the abundance of light in the drylands without losing water. Being unicellular they rapidly produce their valuable chemicals, e.g. Astaxanthin produced by *Haematococcus* and used in the food and health industry (Warren 2006). In addition, microalgal aquaculture can be integrated with fish aquaculture since larval stages of many fish species depend on microscopic algae, and highly nutritious microalgae may substitute for fishmeal.

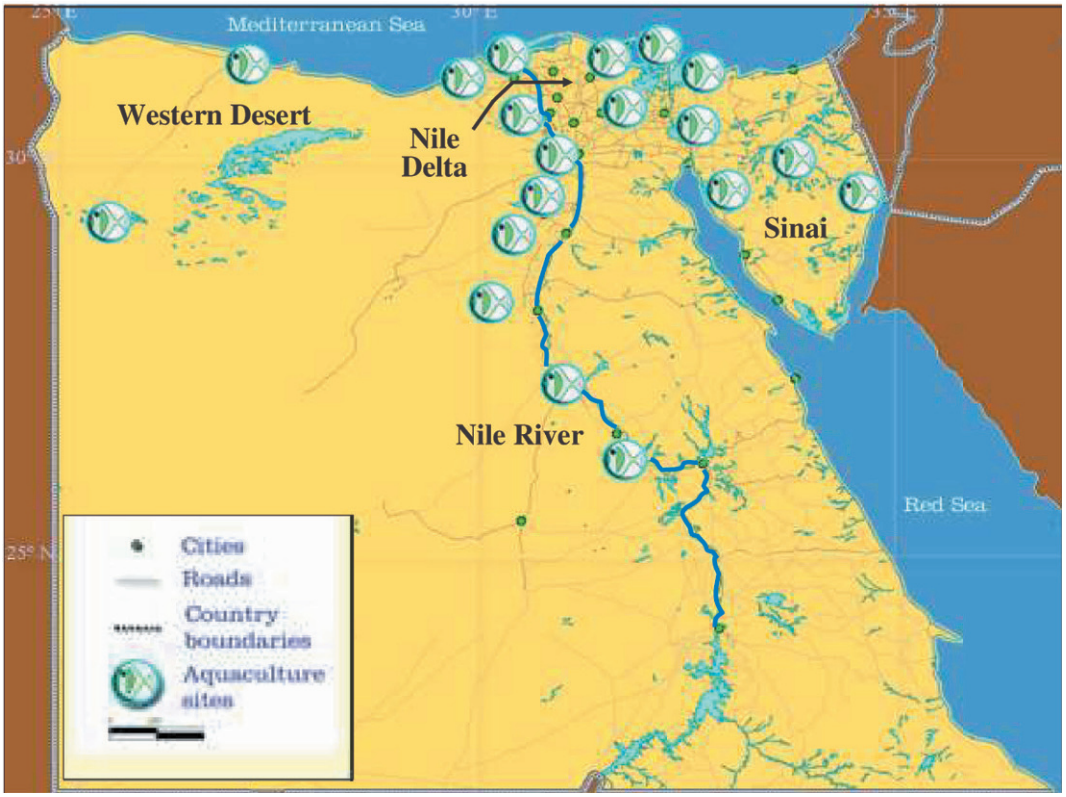
48.6.4 Where Dryland Aquaculture is already practised?

The knowledge, expertise, and investments required to start a modest dryland aquaculture venture are not beyond the means of many farmers in developing dryland countries. In fact, industrial countries such as Israel (Kolkovsky/Hulata/Simon/Segev/Koren 2003), Australia (e.g. Wallace/Barker 2003), and the United States (McIntosh/Baldwin/Fitzsimmons 2003) started dryland aquaculture after it had long been practised in a number of developing countries (FAO 2006a). Dryland aquaculture has been practised in Egypt for thousands of years, along the Nile and its delta, and in recent decades it expanded to the arid and hyper-arid Western and Sinai Deserts (figure 48.9). Currently, a large number of dryland developing countries practise aquaculture, where fish farming rural people are better nourished and have an increased income than others (FAO 2006a, Adeel/Safriel 2008).

48.6.5 Environmental Effects of Dryland Aquaculture

Compared to land cultivation, aquaculture does not have the potential to cause massive land degradation; it is an intensive cultivation that requires relatively little land surface (as compared to traditional agriculture). Land degradation due to soil salinization is often caused by coastal aquaculture of marine organisms (Naylor/Goldburg/Mooney/Beveridge/Clay/Folke/Kautsky/Lubchenco/Primavera/Williams 1998), whereby to avoid accumulation of pollutants (antibiotics, heavy metals, etc.) in the enclosed containers frequent flushing of the containers with seawater (facilitated by the proximity of abundant sea water) is prac-

Figure 48.9: Aquaculture sites in Egypt. **Source:** Adapted from Salem (2006); at: <http://www.fao.org/figis/servlet/static?dom=countrysector&xml=naso_egypt.xml>.



tised. This practice should be avoided, and dryland aquaculture based on brackish water must practise care in maintaining high water quality in the containers and in the disposal of used water. In sum, non-seawater dryland aquaculture does not cause desertification, and its use in the rural drylands as a livelihood alternative to agriculture is a strategy for both avoiding desertification and improving economic viability.

48.7 Urban and Urban-supported Alternative Livelihoods

Whereas the previous sections addressed alternative livelihoods for dryland rural communities, the following section explores the option of dryland urban development that impinges on the overall sustainability of living in drylands, including in the rural areas.

48.7.1 Dryland Urbanization – Trends and Advantages

The accelerated global urbanization trend (UN 2005) has not missed out the drylands, deserts included. Beside their historical functions as commercial and administrative centres, the currently growing dryland cities attract land-consuming military, industrial, and technological installations relocated from overpopulated non-drylands. Within the last thirty years of the 20th century desert cities of both developed (e.g. Phoenix, Arizona) and developing (e.g. Riyadh, Saudi Arabia) countries grew three-fold and seven-fold, respectively. Furthermore, growth of the urban population in drylands is projected to increase to around 52 per cent by 2010 and to 60 per cent by 2030 (Adeel/Safriel 2005).

Interestingly, an inverse relation between the dimension of the agricultural and the urban sectors is evident in dryland countries: the share of arable land, averaged for Pakistan, Uzbekistan, Somalia, and Niger is 12 per cent (CIA 2006), and the share of the urban population averaged for each is only 33 per cent (Herrmann/Hutchinson 2006), whereas these values for Libya, Saudi Arabia, Israel, and Qatar are only 5 per cent for arable land, but 90 per cent for the urban population. Yet, it is not known how much of the current and the projected increase in drylands' urban population is attributable to migration of dryland ru-

ral people, or of non-dryland people attracted by dryland cities. Nevertheless, dryland cities could provide livelihoods to migrants from rural areas, thus releasing pressure on land resource, since urban livelihoods require smaller area per person, as compared to rural livelihoods. Thus, desertification can be avoided by creating economic opportunities in dryland urban centres that would constitute alternative livelihood.

For dryland urban areas to become attractive, services and jobs are imperative (Adeel/Safriel 2005), and dryland-sensitive urban planning (Pearlmutter/Berliner 1999) and architectural design (Etzion/Pearlmutter/Erell/Meir 1999) are required. The low air humidity in the dryer drylands makes summer evaporative cooling efficient and cost-effective adaptation to desert urban life, and the low dryland overcast and the intense solar radiation is projected to provide cheap energy (Faiman 2004, 2008) for cooling and heating buildings or for water desalination for urban domestic use.

Any urban livelihood that is economically viable and can attract rural dryland people qualifies as an alternative livelihood. Yet, there are alternative livelihoods that can be adopted by rural populations and be practised within the rural areas, while being supported by adjacent urban centres. These are the emerging dryland tourist industry that capitalizes on the aesthetic, cultural, and recreational values of many drylands, and the solar energy-generating industry that will capitalize on the forecasted increasing demands for reducing emissions of greenhouse gases coupled with the high potential of drylands to generate economically-viable solar-based alternatives to fossil energy.

48.7.2 Dryland Tourism

Dryland tourism is driven by the increasing affluence, free time and motorization coupled with the growing craving for non-congested, non-polluted, pastoral and pristine landscapes. The scenic, wildlife, biodiversity, historical, cultural, spiritual and therapeutic values unique to many drylands, enrich the quality and appeal of recreation in the drylands (Safriel 2006a). A large segment of the tourist population, however, does not compromise on comforts and other leisure-time amenities, what makes drylands' urban centres a prerequisite for exploiting the recreational values of the dryland rural areas. Dryland tourism is thus an urban-supported alternative livelihood that can be adopted by both rural and urban dryland people.

However, the tourism industry is sensitive to political unrest, corruption, crime, terrorism, recession, and instability in transportation costs (Warren 2006). Therefore this dryland alternative livelihood needs to be backed up by traditional livelihoods. Tourism is also a voracious water user, thus competing with other dryland demands – an issue that may be resolved by desalination and treatment of marginal water resources, including urban wastewater. Tourism often risks the resource on which it depends by littering, eroding soils, and interfering with wildlife, biodiversity, and indigenous cultures. To address this threat, cautiously adopting practices and attitudes of ecotourism, a fast-growing sector of the tourist industry may be appropriate (Warren 2006).

48.7.3 Generation of Solar Energy as an Alternative Livelihood

Drylands are of high potential to become exporters of solar energy to non-dryland areas. The economic value of this clean and renewable energy will gradually increase as the detrimental effects of global warming, coupled with the forecasted depletion of fossil fuel reserves, will become apparent. It is estimated that already by 2025 solar energy may out-compete fossil fuel, and renewables will supply up to one half of global energy by 2050 (Warren 2006). Drylands, and especially deserts, are likely to be competitive in solar energy generation, due to high solar radiation, low cloudiness, and expansive cheap spaces uncontested by other users or objectors, but required for capturing sunlight by photovoltaic cells, mirrors, or their combination (Faiman/Biryukov/Pearlmutter 2002).

The world's drylands are sufficiently large that, in theory, covering a fraction of their landmass with photovoltaic systems could generate many times the current global energy supply. Four per cent of the global desert area can produce an annual energy production by 'very large scale photovoltaic power' (VLPVP) generation plants which would equal world energy consumption (Kurokawa 2003). On the other hand, transportation costs may be forbidding; it was calculated that the cost of installing a power line between a site of a projected small-scale solar power station and the customers in Namibia is three times higher than the cost of installing the solar station itself (Warren 2006). However, developments in the electricity cable industry are likely to reduce these costs. Nevertheless, desert edges would surely be appropriate regions for exported solar power generation, while stations for local uses could be placed at other dryland

sites, which can also include wind energy production as a back-up to solar energy. In both cases, the solar 'farms' of photovoltaic panels, mirrors, and large-scale solar thermal energy devices require much space, and hence will be placed in rural areas.

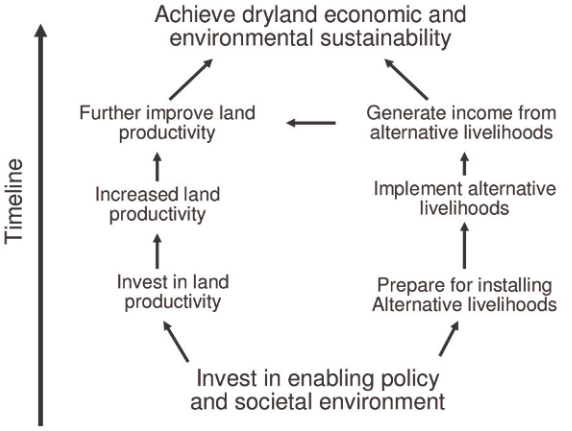
The maintenance of these facilities and the revenue from this land use would augment the income of rural populations, yet the administrative, marketing, and technical backstopping would likely reside in urban centres. Thus, solar energy generation, though not yet practised extensively, has good prospects of becoming an urban-supported dryland alternative livelihood in decades to come (Brauch 2006, 2008).

48.8 Conclusions and Recommendations

Dryland people apply measures for maintaining productivity in face of increasing demands, ranging from adapting local, traditional knowledge to adopting imported technologies. In some cases these combined approaches are successful while in others they fail, resulting in desertification that leads to reduced human well-being of rural people that may generate conflicts and reduced security at both the local and the regional scales. Often the reasons for such failure are not due to flaws in the adopted technologies or to their misuse, but to policy, social, and economic factors that are not conducive for the prescribed implementation (Safriel/Adeel 2005; Adeel/Safriel 2006). But even if and when the social and policy constraints are removed yet pressure on the resources continues to mount, the combination of good practices and supporting policies can be effective only as long as the local resource base is not exploited beyond its capacity for renewal. Therefore, in places where the limit to sustainable land productivity has been already reached, and in others where productivity failure is expected due to projected demographic and social trends, productivity will decline and the risk of desertification and/or consequent local poverty and regional insecurity will increase. When the drylands' inherent limited productivity becomes fully exploited and can not be further increased at a reasonable economic and social cost, maintenance of well-being can be achieved only if the required additional income is generated by livelihoods independent of land productivity, i.e. the "alternative livelihoods".

A promising approach for avoiding degradation and poverty and for achieving resource-use sustainability in the drylands is to adopt both tracks simultaneously – strive for attaining the enabling societal and policy environment, and at the same time (a) apply measures for promoting human well-being through adaptive traditional livelihoods based on land productivity, and (b) invest in preparation for future reduced dependence on land productivity by developing 'alternative livelihoods' often based on introduction of new practices and technologies. Once the enabling societal and policy environment is in place, the alternative livelihood can take off, bringing about both a reduction in the pressure on land and an increase in income. Part of this added income can be reinvested in further promoting the traditional livelihoods based on land productivity (figure 48.10). Coexistence of both tracks can provide a mutual back up, thus buffering against climatic and economic-policy vicissitudes, and conferring stability and sustainability to the rural dryland livelihood (UNCCD 2005). Furthermore, investments in dryland alternative livelihoods such as fish production that can relieve the crisis of global oceanic fisheries, or solar energy development that can reduce dependence on fossil energy sources, can contribute not only to the sustainability of the dryland rural livelihood, but also to regional and even global security in both the environmental and the political sense.

Figure 48.10: Proposed strategy for attaining sustainability in the drylands, through introducing alternative livelihoods. **Source:** Adapted from UNCCD (2005).



49 Societal Vulnerability to Desertification and Policy Response Options

Zafar Adeel

49.1 Introduction

Desertification – land degradation and loss of productivity in drylands resulting from human and climatic factors – is one of the greatest global challenges of our times, and correlates directly to poverty, food insecurity and degradation of human well-being. Desertification directly results in biodiversity changes and a decline in soil fertility, water availability and plant cover, which indirectly affect the livelihoods of dryland populations. Conservative figures estimate the extent of the desertified area ranging from 10 to 20 per cent of all drylands, while a much larger area remains at risk.[1] Measurement of a persistent reduction in the capacity of ecosystems to supply services provides a robust and operational way to quantify land degradation, and thus desertification. Such a quantification approach is robust because these services can be monitored, and some of them are monitored routinely.

This chapter explores the linkages between the desertification process and the vulnerability of dryland populations to environmental and economic shocks of the societies located in water-scarce countries. It argues that the desertification process occurs at a global scale and most of the developing-country societies are ill prepared for its consequences. The chapter addresses the global scope of the desertification and summarizes some of the key impacts already observed (49.2), presents the generic notions of vulnerability (49.3), and how they relate to the impacts of desertification (49.4). It briefly presents the gaps in national and international policies (49.5) which, if unchanged, would lead to exacerbation of the societal impacts. In conclusion (49.6), it proposes that meeting the desertification challenge head on – through significant changes in development and economic policies and in allocation of national and international resources – is critical to meeting the developmental challenges in water-scarce countries. As long as these challenges persist, the societies remain vulnerable to deterioration, conflict and outright collapse.

49.2 The Desertification Challenge

Desertification is now recognized as one of the most pressing global environmental challenges of our time.[2] This recognition has evolved slowly, as the underlying research at a global scale has emerged in the recent years as a by-product of research on global climate change. This recognition has also evolved with a better understanding of the threats desertification poses to the existing achievements in sustainable development as well as their future viability. Nonetheless, conceptual understanding of desertification still remains poor in policy-formulation environments, e.g., national governments, and consequently leads to inadequate or improper responses. Desertification is often equated to encroaching sand dunes (figure 49.1), and is incorrectly considered absent when significant decline in natural productivity exists but there are no moving sand dunes covering roads and buildings.

The policy regime is a very significant reflection of how we perceive and respond to desertification, particularly at the national level. These policies often reflect political perceptions; for example, water scarce areas are seen as derelict and non-productive, and thus not worthy of economic development or investment. Such political marginalization of the dryland communities exacerbates the plight of dryland com-

Figure 49.1: Sand dune encroachment, like this example in an Algerian village, is misconceived to be the only type of desertification, ignoring the broader examples of persistent declining natural resource provisioning. **Source**: Photo by Houcine Khatteli.

munities, which are typically poor. Analysis of economic data in accordance with the level of aridity shows that within developing countries, dryland regions are the worst off in terms of income levels (Safriel/Adeel 2005). The political marginalization also manifests itself through slow growth of health and education infrastructure and the lack of viable livelihood alternatives to the often resource-depleting agricultural practices and natural resource harvesting. It is argued that desertification can destabilize societies in the extreme case, by deepening poverty and creating so-called 'environmental refugees' (Requier-Desjardins 2008) or 'environmentally-induced migrants' (IOM 2007). Some examples exist, particularly in Africa, where population movement patterns as a result of desertification have led to political instability – either armed conflict between rival factions or destabilization of governmental institutions (chap. 92 by Meier; Brauch/Oswald 2009).

The international community has also recognized that desertification is a global process, although a few detractors still remain. Recent dialogue among experts and unpublished work by the author highlights that the political definition of desertification should be expanded to include areas that are not considered drylands but suffer from significant land degradation. Such re-tooling of the definition will lead to an even larger worldwide scope of desertification. On the whole, the global nature of desertification can be understood through three distinct perspectives:

First, the physical process of degradation of natural resources is driven by global climate change (chap. 78 by Church/Asrar/Busalacchi/Arndt) and biodiversity losses (chap. 76 by Walther/Larigauderie/Loreau). In fact, these three processes – desertification, climate change and biodiversity loss – take place at the planetary scale, and inter-connect and amplify the impact of each other.[3] While some may argue that land management and agricultural practices at the local scale are the sole drivers of desertification, such arguments ignore the role of global climate change in re-distributing water resources and significant world-

3 See: Adeel, Safriel, Niemeijer, White, de Kalbermatten, Glantz, Salem, Scholes, Niamir-Fuller, Ehui, Yapi-Gnaore (2005); Bigas, Gudbrandsson, Montanarella, Arnalds (2009).

wide reduction in water availability for drylands (chap. by Leemans/Rice/Henderson-Sellers/Noone).

Second, the biophysical processes triggered by desertification go beyond their local to continental and global scales (Sivakumar/Stefanski 2007). The most common and visible example of such a process are dust storms; the dust from storms in Sahara and Gobi deserts affects the entire Northern hemisphere. Significant increase in dust concentrations from the Sahara and Sahel region has been observed since the 1970s and is projected to get worse with climate change (Prospero/Lamb 2003). Recent data from China show that the frequency and strength of sandstorms affecting eastern China, Beijing in particular, has significantly increased, as limited surface vegetation has been eroded due to land degradation and intensifying human pressure (Gaoming 2008). Downstream flooding is yet another example in which land cover removal due to land degradation can trigger severe flooding events. Destruction of vegetation as a result of desertification also leads to impairment of carbon sequestration capacity and increase in albedo (Sivakumar/Stefanski 2007).

Third, the societal impacts of desertification go beyond the boundaries of drylands. These include migration patterns of people from desertified areas; some experts estimate that the number of people at risk of displacement due to severe desertification will exceed 50 million over the next ten years. Such mass movement of population is not independent of economic influences, social security and ongoing conflicts (Knerr 2004). Nonetheless, it has become a top-level political issue in many countries like Algeria, Morocco, Cote d'Ivoire, the United States, France, Spain and Italy.[4] An indirect indication of the significance of this issue can be derived from the estimated migrant population in these countries (table 49.1).

This three-pronged understanding of desertification is quite critical in devising responses. Such responses must, therefore, lead to policies at national and international levels that include incentives for improved management, provision of resources to improve livelihoods, and political empowerment of dryland communities.

Table 49.1: The number of migrants in selected countries, shown also as a fraction of the global number of migrants and national population. **Source:** Adapted from Renaud, Bogardi, Dun and Warner (2007).

Country	Number of migrants (millions)	Fraction of the total migrants in the world (%)	Fraction of the national population[a] (%)
USA	38.4	20.2	12.9
France	6.5	3.4	10.7
Spain	4.8	2.5	11.2
Italy	2.5	1.3	4.3
Cote d'Ivoire	2.4	1.2	13.2

a) Estimates based on 2004 population figures provided by the UN Population Division. **Sources**: UN (2005a); UN (2006).

It is alarming that the global community has so far failed to adequately understand or respond to the desertification challenge. This failure, in part, relates to our inability to formulate effective, comprehensive, and successful policies. A notable example is the *United Nations Convention to Combat Desertification* (UNCCD), where developed countries have shied away from investing adequate resources and developing countries have been unable to demonstrate any remarkable successes in dealing with desertification. Additionally, some forces of globalization, while ostensibly striving to reduce economic inequality and eliminate poverty, are contributing to the worsening desertification. Studies have demonstrated that trade liberalization, macroeconomic reforms and intensifying agricultural production for exports can contribute to desertification. Perverse agricultural subsidies are one such example, which are estimated at US$300 billion annually for industrial countries, and undermine the ability of food producers in many poorer countries to enter international food markets (box 49.1 for an example of these barriers).[5] This can be compared with an estimated loss of $65 billion annually as a result of land degradation (GEF/GM 2006).

Box 49.1: WTO's Agreement on Agriculture. **Source**: Adapted from the Millennium Ecosystem Assessment (Hassan/Scholes/Ash 2005).

The Word Trade Organization's Agreement on Agriculture has introduced 'green box' provisions as an ostensible mechanism to provide support to producers for improving the landscape and environmental dimensions of farming; these include a number of conservation and countryside stewardship programmes. The espoused intent of these provisions is to introduce less polluting and more environmentally-sensitive practices. However, such provisions have emerged as contentious because most developing countries perceive them as a means to legitimize financial support and subsidies for farmers in rich countries (Wood/Ehui 2005).

49.3 Elements of Societal Vulnerability

The notion of vulnerability[6] can be defined in the context of desertification: It is a way to determine the risks and hazards to communities and societies as a result of losing the provisioning capacity of natural systems in drylands. Societal vulnerability[7] can be measured at a given time, considering the state of the economy and the environment, the level of social and societal support available, and the magnitude of exposure to risk (Cannon/Twigg/Rowell 2005; Birkmann 2006). The examples of how this approach can be used to develop a comprehensive assessment of a community, or a society, has been undertaken through a worldwide project: *Sustainable Management of Marginal Drylands* (SUMAMAD). A number of papers have captured the application of this approach in eight countries (Adeel 2006; King 2007; see below for selected examples).

Societal vulnerability could also be used as a predictive tool in which drivers that impact these state factors are considered in making future projections: population growth, down-turn in economic and agricultural productivity, change to climate patterns, and water availability. For example, water availability when measured on a per capita basis is directly influenced by population growth and change in precipitation patters as a result of global climate change. As the 2007/2008 Human Development Report notes:

> An additional 1.8 billion people could be living in water scarce environments by 2080. Central Asia, Northern China and the northern part of South Asia face immense vulnerabilities associated with the retreat of glaciers – at a rate of 10–15 metres a year in the Himalayas. Seven of Asia's great river systems will experience an increase in flows over the short term, followed by a decline as glaciers melt. The Andean region also faces imminent water security threats with the collapse of tropical glaciers. Several countries in already highly water-stressed regions such as the Middle East could experience deep losses in water availability (UNDP 2007).

Desertification adds to societal vulnerability at several levels, and it exacerbates the situation for highly vulnerable populations already living in drylands countries.

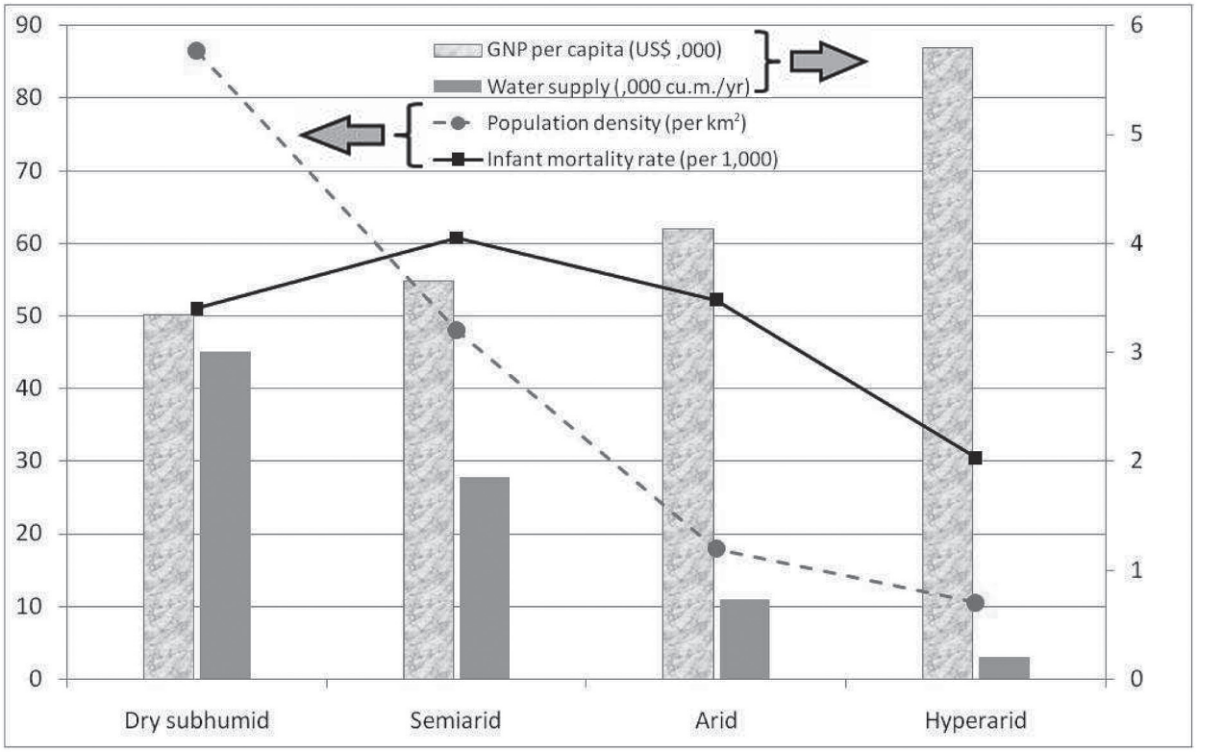
First, it reduces the societal 'resilience' to events that fall outside of the realm of 'norms'. When the social and natural systems are already under stress from desertification, the communities are bound to have great difficulty in bouncing back from adverse events like floods or droughts (Hutchinson/Hermann 2008). Stresses on social systems can include poverty and economic deprivation, poor nutritional status of population, and an inability to continue normal livelihoods. Stresses on the natural system can include shortage or excess of available water, reduction or destruction of natural biological diversity, reduction in crop resilience due to monocropping and soil quality degradation due to poor management and inappropriate introduction of chemicals and nutrients.

The *Millennium Ecosystem Assessment* (MA) charted some of these impacts for the drylands systems in developing countries (figure 49.2). The level of aridity is closely tied to the availability of natural resources, economic development, population stress and their combined impact on human well-being. As dryness increases, water availability also decreases by

6 For an overview of the many different concepts of vulnerability see: Brauch 2005 (with an extensive bibliography); and in this volume: chap. 2 by Brauch; chap. 3 by Cardona; on the notion of social vulnerability: chap. 29 by Pelling; chap. 30 by Nathan; chap. 37 by Tekeli Yeşil; chap. 70 by Villagran; chap. 71 by Warner; chap. 72 by Oswald Spring.

7 This author refers to 'societal vulnerability' as a comprehensive term that encompasses the vulnerability of society as a whole – it includes the resilience of formal and informal social institutions; governance structures and norms; condition of infrastructure related to public welfare, health, transport, and water delivery; financial resources; and environmental conditions and risks. This is a wider definition and includes within itself the more common used terminology of 'social vulnerability'.

Figure 49.2: Key statistics for dryland countries (excluding OECD or developed countries). Drylands are classified according to the climatic conditions as *dry sub-humid, semi-arid, arid* or *hyper-arid*; this classification is based on the values of the Aridity Index, which is the long-term mean of the ratio of an area's mean annual precipitation to its mean annual potential evapotranspiration. **Source:** Safriel and Adeel (2005).



default, whereas all other well-being indicators are driven primarily by population density. Highest population density, in dry sub-humid regions, also leads to lowest GNP per capita and highest infant mortality rates. Safriel and Adeel (2005) thus concluded that the greatest level of vulnerability lies in dry sub-humid and semi-arid regions where population densities are the highest. It should also be stressed that, on average, dryland populations suffer from very low human well-being conditions; this is obvious because the infant mortality rates are greater by a factor of 10 or more when compared with those of OECD countries and by a factor of 2 when compared to that of developing country areas with greater water availability.

Second, desertification nurtures the perception amongst many national policy-makers that drylands are essentially wastelands that can be conveniently forgotten, often with drastic consequences for these dryland dwellers. Political marginalization leads to inadequate allocation of resources and stunted development of fundamental infrastructure, like roads, power and water provisioning, public health facilities, and primary education; the latter two manifest themselves through poor human well-being indicators, like infant mortality rates. The situation of inadequate investments in sustainable land management is similar at the international level where GEF and GM (2006) recommends a 5–15 per cent increase in the annual investments made by the international community to foster sustainable development.

Third, desertification, when coupled with political marginalization and economic deprivation, also leads to gaps in human, technological and institutional capacity. 'Brain drain' often leads to situations where societies can no longer have indigenous human resources to cope with urgent disasters. Lack of appropriate institutions also means that the communities cannot organize themselves to cope with adverse conditions and inherently become dependent on development and emergency aid from elsewhere. Recent studies have also suggested that mass migration of people away from such locations is in part driven by adverse environmental and economic conditions (Renaud/Bogardi/Dun/Warner 2007). Conversely, societies that are well-organized but poor tend to recover from adverse condition much better (Hutchinson/Hermann 2008). An example of this resilience is the Hunshandake Sandland in Inner

Mongolia, China, which is a SUMAMAD project site where significant depletion of the natural grasslands was observed in the recent decade or so (Gaoming 2008). By developing a cohesive community group, provision of appropriate scientific expertise and introduction of livelihood innovations like ecotourism and chicken farming instead of goat herding, led to significant increase in income levels (Adeel/Safriel 2008). Most significantly, this case also demonstrated a rebound of the natural grassland ecosystems, which by default increases the resilience of the communities depending on them.

Fourth, desertification is also intricately linked to the lack of access to safe water for communities. A lack of such a fundamental need leads to disastrous and ongoing consequences for communities, as discussed below. Recent analyses show that communities that are suffering from joint impacts of desertification and lack of safe water are most vulnerable to both chronic (poverty, nutritional status, etc.) and acute (infant and maternal mortality, low resilience to AIDS, etc.) human wellbeing problems (Adeel 2009). Such linkages are discussed next in detail.

49.4 Societal Impacts of Desertification

The societal impacts of desertification are wide-ranging and relate to economics, public health, social welfare, politics and development. Some of these impacts can be quantified, while others manifest over long periods of time and are hard to measure in quantitative terms. Economic and public health impacts are somewhat easier to be treated through commonly used and measured quantitative indicators; typical reporting cycles at national and international level range from quarterly to annual. On the other hand, changes in the political environment and improvements in governance appear to evolve slowly, typically over decades. Increasing land productivity – the opposite to desertification – can also be viewed as the correlation between desertification and societal impacts; for example, GEF and GM (2006) noted:

> Investment in land productivity is a vital engine in development. The rural development strategy documented for the World Bank (2005), for example, shows that for the 35 developing countries in the analysis, a 1 per cent increase in agricultural GDP led to a 1.6 per cent gain in the per capita income of the poorest fifth of the population. A 10 per cent increase in crop yields led to a reduction of 6–10 percent of people living on less than US$1 per day. Thus, if land degradation is allowed to continue, major opportunities for the creation of new wealth and the reduction of poverty will be passed by.

The economic impacts of desertification manifest themselves as loss of income, which is estimated at US$ 65 billion annually (GEF/GM 2006). Table 49.2 shows income levels for six drylands countries (Bolivia, Chad, Mali, Mongolia, Niger, and Sudan), presented as the *gross domestic product* (GDP) per capita in purchasing power parity terms. These countries are considered as drylands in their entirety, and are globally recognized as least developed countries. At the same time, they are also facing significant levels of desertification, as observed through a number of methodologies (Safriel 2007). When comparing the economic status with developed or OECD countries, it is quite obvious that the economies differ by one or two orders of magnitude in per capita terms. This gross disparity can be linked to aridity levels, reduced land productivity and eventual desertification. Yet another manifestation is that almost two-thirds of the population in these countries live below poverty levels, with the exception of Mongolia.

In the public health domain, several key indicators highlight the situation, but perhaps the starkest and most comprehensive indicator is infant mortality. It encapsulates the status of public health support, level of nutrition, access to water and sanitation, exposure to toxins and environmental pollutants, and the level of literacy and education. Shortcomings in any of these services can contribute to increased infant mortality rates. On average, infant mortality in drylands in developing countries averages about 54 children per 1,000 live births, 10 times higher than that in developed countries.[8] Table 49.2 presents the infant mortality rates for the six selected countries and compares them with those for developed countries. Again, there is an order of magnitude difference in infant mortality rates.

The economy and social well-being are not independent of each other. A lack of available financial resources, and often a misguided sense of national priorities, leads to inadequate national investments in the most fundamental infrastructure needed for human well-being; e.g., that for provision of safe water and adequate sanitation. This is further compounded by the inadequate investment in the public health sector which, in turn, is burdened by a disproportion-

8 Adeel, Safriel, Niemeijer, White, de Kalbermatten, Glantz, Salem, Scholes, Niamir-Fuller, Ehui, Yapi-Gnaore (2005).

ately high number of health cases, when compared to OECD countries.

49.5 Policy Gaps

There are some rather fundamental questions related to policy formulation that we need to respond to; these questions can help us in identifying policy gaps:

- What are the most effective policies for combating desertification and how best can we integrate our responses to desertification?
- When we see isolated success stories in dealing with desertification, why are these not propagated at a larger scale and what policies may be serving as stumbling blocks?
- How can we better engage the private sector, which may provide additional financial resources that are neither available within national economies nor through international donors?
- How can globalization be made to benefit developing countries and minimize the adverse impacts of massive public subsidies to agricultural production in developed countries?

In order to respond to the questions, we must realize that major policy gaps exist at the national level; sectoral divisions in policy formulation represent the greatest hurdle to the integration and harmonization of national policies. These can be characterized in terms of gaps within economic policies, agricultural policies, public health and infrastructure development approaches, and policies for management of natural resources. Policy formulation processes in all these realms are also not integrated with each other, often amplifying discrepancies. Underlying problems – lack of scientific knowledge and adequate human resources, shortage of financial capital, and corruption, to name a few – are also persistent and difficult to adjust in countries where stable governance mechanisms are lacking. The economic disparity and shortcomings – as shown in table 49.2 for countries like Mali and Chad – translate to a lack of financial wherewithal to meet the national challenges.

Further, the use of science to inform policy formulation and decision-making remains nearly non-existent. This is in part driven by a lack of relevant scientific information available at the appropriate local or national scale; what little research is done indigenously often fails to focus on emerging issues. Nonetheless, even when scientific information exists or can be brought in from outside, its incorporation into policies, laws, regulations and action programmes to overcome desertification is deficient. This is partly caused by ineffectiveness of the scientific community, which does not ensure that its findings are made available and understandable to decision makers.[9]

The national-scale policy failures are also worsened by a comparable lack of international awareness of the interconnectivity of these developmental and environmental issues, particularly amongst those responsible for designing and implementing develop-

9 Adeel, Bogardi, Braeuel, Chasek, Niamir-Fuller, Gabriels, King, Knabe, Kowsar, Salem, Schaaf, Shepherd, Thomas (2007).

ment aid policies. Very few development and aid policies recognize desertification as the top-most investment priority; most often, governance, gender equity and 'economic development' (often defined as industrial and/or agricultural growth) are considered the top development priorities. Additionally, one may argue that the international trade volumes, particularly those for agriculture, are based on the short-term exploitation of local resources for exports. Such approaches are detrimental to the long-term interests of the people living in developing countries.

The international policy failure is most prominent in how member states relate to environmental conventions and how international development agencies coordinate their own efforts. Most aid agencies rely on a superficial partition between 'environmental' and 'developmental' funding, as if the two are mutually exclusive; the same approach is applied to the UNCCD. It becomes a stumbling block in providing support to developing countries in which developmental needs identified through the UNCCD processes are deemed to be a mismatch with the so-called 'environmental' convention. On the other side, the developing countries have also demonstrated very limited success in developing *National Action Plans* (NAPs) and deploying them effectively within the context of their economic development regimes, such as the *Poverty Reduction Strategy Papers* (PRSPs). Of the 193 countries that have ratified the UNCCD, less than half have developed formal NAPs (GEF/GM 2006); measuring the effectiveness of these plans is difficult in the absence of good benchmarks and baseline data.

Challenges also persist at the international level in how various United Nations conventions are related to each other. In particular, the Secretariats are constrained by their own constitution and procedures, which makes it difficult to focus on areas – like financial, scientific, policy – where substantial synergies exist amongst conventions. More proactive, country-centric efforts may provide a user-perspective that brings together action, reporting and monitoring between key conventions dealing with desertification, climate change and biological diversity.

49.6 Conclusions: What Response Options Exist

On the whole, combating desertification yields multiple benefits at the local and global levels. Addressing desertification is a critical and essential part of adaptation to climate change and mitigation of global biodiversity losses. The *United Nations University* (UNU) has led the argument over the last decade that such interlinkages in policy formulations must be beneficially exploited (Velasquez 2000). Policy- and decision-makers need to understand the critical nature of the desertification challenges and also overcome the incorrect conventional thinking that drylands are a lost cause. There is a need to recognize the opportunities that are offered by drylands, and use them to catalyze investment. Economic arguments about the 'return on investment' are now emerging and can be useful in political contexts. Thorough and detailed research on such cost benefit analysis is still lacking and mostly comprises location-specific and anecdotal evidence (GEF/GM 2006); the SUMAMAD study in Hunshandake Sandland in China is one such example. Achieving effective responses to the desertification challenge requires actions on part of three broad categories of actors: a) the international community, b) governments operating at national and other levels, and c) the research and scientific community.

While there is increasing recognition at the international level of potential synergies between agendas for environmental management and poverty reduction, this must be converted into integration of actions at all levels, and a concurrent decrease in the multiplicity of developmental and environmental frameworks. It is important to enable the capacity of national governments to address their own challenges. Achieving this *inter alia* requires bridging of ministerial and sectoral differences. Development aid should also be directly linked to these integrated responses and efforts to build national capacity. As an example, the *Global Environment Facility* (GEF) is developing Country Partnership Programmes, which promote a 'landscape approach' and focus on system-wide change at both local and national levels.[10] Such approaches give due recognition that desertification affects landscapes and not just single ecosystems.

There has to be a considerable focus on pro-active, cross-linked environmental management at various scales, from national to local. This means that development of agricultural practices, rangeland management approaches, water conversation techniques, soil management practices, alternative livelihoods, economic growth in rural drylands, and removal of perverse subsidies must be considered as part of a comprehensive solution. Enabling policies must provide

10 See Adeel, Bogardi, Braeuel, Chasek, Niamir-Fuller, Gabriels, King, Knabe, Kowsar, Salem, Schaaf, Shepherd, Thomas (2007).

incentives to strengthen land tenure, enhance management of common pool resources, increased access to credit institutions, decentralized government services, and enhancement of research and extension systems. The scope for success of these initiatives can be measured by how well the national investment policies are influenced (Mortimore 2005).

Significant consideration must be given to an effective engagement of the private sector, primarily through economic incentives to invest in efforts to combat desertification. There is a need for measures at governmental level to secure capital investments by the private sector. Such policies, and consequent engagement of the private sector, are essential for the mobilization of technical and financial resources to overcome the shortfall in the public sector.

Several examples of such synergistic approaches are being considered. Some have argued that carbon sequestration in drylands can play a major role in mitigating climate change and providing sustainable livelihoods for drylands people (Niamir-Fuller 2009). Such ideas are of substantial interest when we consider the large surface area of drylands, which is nearly 40 per cent of the global land mass. Recent carbon trading approaches are vehicles through which such approaches can be deployed in dryland countries (Sivakumar/Stefanski 2007).

And finally, one has to recognize that the success of dryland communities can provide tangible benefits to national economies and consequently magnify their significance in national politics. In the same vein, dissemination and advocacy of success stories (or 'bright spots') by stakeholders in affected countries and the international community will further extend the influence of local benefits. These benefits can take the shape of an increase in ecotourism, incremental values of trade and real-estate, and improvements to ecosystem conservation and productivity.

50 Desertification Process in Egypt

Ismail Abd El Galil Hussein

50.1 Introduction

Egypt is one of the most arid lands in the world as 86 per cent of its total area is hyper arid while the remaining area is arid and semi-arid (Meigs 1953). Four agro-ecological zones are distinguished, namely, the Nile Valley, the North Coastal Zone, the Inland Sinai, the Eastern Desert and the Western Desert. As significant variations in ecosystem services are recognized among the four agro-ecological zones, desertification affects each one differently.

However, desertification is strongly affected by population growth (size and density) in Egypt due to the fact that whenever the demand of the population for livelihood exceeds the resource supply, an imbalance is expected to happen for the ecosystem which consequently causes degradation of its services and eventually result in desertification after a long-term failure of such imbalance between demand (human activities) and supply (ecosystem services).

In 2009, the Egyptian population was estimated at 83,082,869 persons with an annual growth rate of about 1.64 per cent. By 2025, Egypt's population is projected to increase to 103,573,056 people. This will further reduce the per capita share of agricultural land and water, as well as increase the pressure and competition for ecosystem services due to the overexploitation of the natural resources. About 20 per cent of Egypt's population lives in Cairo, 6 per cent in the coastal governorates, 40 per cent in the Delta governorates, 33 per cent in the Upper Egypt governorates, and 1 per cent in the remaining areas of the country that amounts to about 95 per cent of Egypt's territory.

Egypt is considered one of the most vulnerable countries to the adverse effects of climate change (loss of agricultural land and production in the Delta, water shortage, and soil salinity) which are expected to exacerbate the desertification process which will eventually result in a substantial increase in food insecurity, poverty, inland migration, and immigration.

This chapter offers background information on Egypt (50.2), it analyses the desertification processes and its multiple drivers (50.3) and discusses the role of traditional knowledge (50.4) and ends with some policy conclusions (50.5) for coping with the challenge of desertification.

50.2 Background Information on Egypt

Egypt is highly diverse due to its location as an African, Asian, and Mediterranean country. It occupies an area of about one million km^2, between latitude 22^o and 32°N and longitude 25° and 35° E. However, 86 per cent of the total area of Egypt is affected by hyper-arid climatic conditions (figure 50.1; table 50.1). The country is endowed with four main agro-ecological zones with specific attributes of resource base, climatic features, terrain and geomorphic characteristics, land-use patterns, and socio-economic implications.

The four agro-ecological zones (figure 50.2) are distinguished as follows:

- The *Nile Valley* (35,000 km^2) encompasses the fertile alluvial land of Middle and Upper Egypt, the Nile Delta region, and the reclaimed desert areas in the fringes of the Nile Valley.
- The *North Coastal Zone* (NCZ) is composed of two major subzones, the north-western coast and north-eastern coast of Sinai. This zone represents the arid province under the maritime influence of the Mediterranean with a shorter dry period.
- The *Inland Sinai* (61,000 km^2) and the *Eastern Desert* (223,000 km^2) with their elevated southern areas.
- The *Western Desert* (681,000 km^2) includes oases and the southern remote areas, including East Uweinat, Tushka and Darb El-Arbian areas.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_50, © Springer-Verlag Berlin Heidelberg 2011

50.2.1 Population Pressure

Egypt's population still grows each year by approximately 1.5 million people. In 2009, the Egyptian population was estimated at 83,082,869 with about 1.64 per cent of annual growth rates while the projected population in 2025 was 103,573,056. However, a demographic imbalance is recognized as about 20 per cent of the current population is squeezed into the capital city of Cairo, 6 per cent live in the coastal governorates, 40 per cent in the Delta governorates, 33 per cent in the Upper Egypt governorates, and 1 per cent is distributed among the remaining areas of the country (in about 95 per cent of the total area of Egypt).

Desertification in Egypt is obviously linked to the demographic pressure due to a high annual population growth accompanied by a continuous increase in population density in the inhabited areas which represent 5 per cent only of the total area of Egypt (table 50.2).

Due to the population increase without any additional water supply to justify the elevated gap between demand and supply, water share per person has significantly declined and is projected to drop further due to future population trends. These projections show that with the current population growth rate, the annual amount of water available per person would decline by 2026 to nearly half of today's levels, by falling from 980 m^2 per person per year in 2010 to 570 m^2 by 2026. However, the available amount would drop only to 670 m^2 if reduced population fertility should be achieved, which would allow each person to consume an additional 100 m^2, or 18 per cent more water per year. The standard yearly requirement for water consumption per person is 1,000 m^2. Given that more than 90 per cent of Egypt's water supply originates outside its borders, reducing water consumption

could also reduce the harmful effects of disruptions in supply.

The results of efforts in the past two decades to increase the amount of cultivated land lagged behind population growth. The average individual's share of cultivated land fell from 3.1 carats[1] in 1981 to 2.7 carats in 1994 and 2.5 carats in 2009. Egypt's strategy for land reclamation aims to increase the area of cultivated land by about 25 per cent during the next 20

1 carat =175 m^2

years but it depends on the future water availability. If fertility remains at its current level, however, the per capita share of cultivated land will also remain at today's level. The projects designed to increase the area of land on which the Egyptian population lives from 5.5 per cent of the total area to 25 per cent in the next 25 years are expected to relieve the high population density in the Nile Valley. However, this relief will not be available in the short term.

The most serious concern of Egypt's population growth is linked to the increase in population density due to the imbalance in the geographic distribution (table 50.2). The Egyptians are squeezed into the Nile Valley which represents less than 5.5 per cent of the total area of Egypt. Most governorates (29) have a population density of more than 1,000 per km^2, while the three largest governorates (Matruh, New Valley, Red Sea) have a population density of less than 2 persons per km^2. Official government statistics estimate the population density of Cairo to be 31,000 persons per km^2.

The high levels of population density (table 50.2) resulted in a fierce competition over the use of land for agriculture and for housing, and have thus overloaded the use of ecosystem services. These facts highlight the danger posed by population density to Egypt's ongoing development efforts. Moreover, high population density along the Nile Valley, especially in Lower Egypt and its urban governorates, will constitute a huge threat to the per capita share of water. For example, in the case of potable water, assuming an annual population growth rate of 1.6 per cent by 2016 (figure 50.3, table 50.3), the water share per capita is expected to sharply decrease during the coming 15 years. This is particularly worrying as Egypt's share of the waters of the River Nile is fixed at 55 billion m^3. Based on that, the per capita share of water sources will decrease as the population grows (figure 50.4).

50.3 Desertification Processes and its Drivers

The main processes involved in land degradation are driven by urbanization (50.3.1), salinization (50.3. 2), pollution (50.3.3), soil fertility depletion (50.3.4), wind (50.3.5) and water erosion (50.3.6), sand encroachment (50.3.7), overgrazing (50.3.8), over pumping (50.3.9), and by the loss of genetic plant resources (50.3.10).

50.3.1 Urbanization

In Egypt, where only 3 per cent of its total territory is fertile land, the encroachment of cities, towns, and random urbanization has been significantly increasing, what has caused serious stress in the Nile Valley and in the Delta. Other types of land degradation evolved, starting with the illegal use of agricultural land to divert it for dwelling purposes and other forms of encroachment.

Also, the skimming layers of the fertile soil surface of agricultural land for the production of bricks, up to an average of one metre deep, has been another reason for the degradation and the shrinking area of productive agricultural land. In 2003 the Ministry of Agriculture and Land Reclamation estimated a total loss of 1,200,000 acres, or of about 16 per cent of Egypt's total irrigated agricultural area.

50.3.2 Salinization

Salinity problems are widespread in Egypt. Almost 30 per cent of the irrigated farmland is salt-affected. It is estimated that 60 per cent and 20 per cent of the northern cultivated land and both the middle and southern Delta regions, in sequence, have salt-affected soils. Meanwhile in the Nile Valley, especially in Upper Egypt, salt affected soils represent about 25 per cent of the cultivated areas. Likewise, many areas of the reclaimed desert land adjacent to the Nile Valley and the Delta, as well as in the Sinai and in oases suffer from waterlogging and high salinity. These soils are characterized by excess soluble salts with sodium chloride in substantial quantity. Consequently, soils accumulate sodium on the exchange of complex causing poor physical and chemical properties, which adversely affect water infiltration, soil tilth, plant growth, and yield. The process of salinization is due to:

- excessive application of irrigation water;
- irrigation with poor quality water, e.g. using low quality mixed drainage water, and increased use of low quality ground water;
- inadequate salt leaching practices;
- inefficient or impaired drainage conditions;
- evaporation from water table especially when it is within 2 metres, significantly contribute to root-zone salinity;
- poor land levelling with consequent localized redistribution of salts can often cause salinity problems of significant magnitude.

50.3.3 Pollution

Chemical degradation of water and land resources, defined as the combined negative effects of the chemicals and chemical processes on the aquatic system and the properties that regulate soil function, has considerably emerged as an important agent of desertification. In most cases the root causes of these problems have been the mismanagement of water and agricultural land as well as the poor implementation of pollution control regulations. The major sources of land and water pollution in Egypt can be summarized as follows:

- The discharge of industrial effluents and agricultural drainage water and navigation activities in the Nile, main canals and drains contaminate the surface water resource. The most important industrial areas that directly affect the water quality of the River Nile system include factories of the Egyptian Chemical Industries (Kima) at Aswan; sugar factories at Kom-Ombo, Edfu and Naga-Hammadi; cement and fertilizer plants at Asyut; iron and steel, coke and chemicals at Helwan; Kafr El-Zayat and Alexandria industrial areas, etc.
- In the rural areas, where 75 per cent of the population (or 45 per cent of Egypt's population) has no access to any sanitary facilities, wastewater and latrine fills are directly absorbed underground or discharged by truckloads in drains, therefore the shallow groundwater, i.e. the Nile aquifer (of less than 50 m) shows signs of pollution. Thus, the use of such contaminated water sources for irrigation progressively undermines not only the quality and quantity of agricultural production but also soil biodiversity.
- The excessive use of fertilizers due to the frequent and intensive cropping pattern, whose rate reaches, on average, 319 kg/ha of basic nutrients N (nitrogen), P (phosphorus) and K (potassium). These rates are very high compared to applied rates worldwide. This overuse has resulted in nitrate pollution of the water table and drainage water. Despite recent significant reductions in the application of pesticides and herbicides that has been observed, excessive amounts of their residues in the soil and in both surface and shallow water tables are reported to create serious impacts on public health and environmental risks for the communities in the rural areas.

50.3.4 Soil Fertility Depletion

Extensive and frequent cropping under the conditions of an unsustainable irrigation water management and of improper agricultural practices in the Nile Valley and in the Delta have resulted in a depletion and a deficiency in many nutrient elements. This situation has been exacerbated after the construction of the High Dam, which sharply decreased the annual additions of the fertile sediments to the soils. Consequently, all Egyptian soils are poor in their content of

organic matter, total nitrogen, and other nutritive elements.

50.3.5 Wind Erosion

The fragile ecosystem in the *North Costal Zone* (NCZ) is subject to soil erosion by wind and water. The most fertile topsoil of rain-fed cultivated areas has been eroded, leaving less productive subsoil to produce crops. Thus, crop yields will continue to decline, providing less protection to the soil surface and putting more pressure on the already fragile ecosystem.

To achieve sustainable rain-fed agriculture, it is essential to control wind and water erosion to minimize its impact. Therefore, it is vital to assess the soil loss due to water and wind erosion, and to develop conservation methods for affected sites to maximize the income of rain-fed agriculture through achieving its sustainable development.

Because of the arid climate, wind erosion is one of the major processes of land degradation in Egypt, as it prevails in the Western desert and in the Eastern Desert and in the agro-ecological zones in the Sinai which are mostly sand textured. Wind erosion also occurs in the coastal zone where coastal sand dunes dominate. Therefore, wind erosion affects about 90 per cent of the total country area, causing its fragility due to deterioration and a distinction of plant cover due to overgrazing, ploughing, and intensive cultivation in the rain-fed areas of the northern coastal zone where the soil is shallow.

The average rate of soil loss via wind erosion in the oases of the Western desert has been estimated as 5.5 ton/ha/year, indicating that the rate of wind erosion is moderate, while the rate of deposition varied from 4.5 to 66.9 ton/ha/year. Data on the percentages of total hours of the active wind speed per year showed that their values varied between 9.4 and 29.0, indicating that wind erosion hazards in this area range between moderate and severe. However, the calculated annual rate of wind erosion in the Omayed area (NWC) based on the *Wind Erosion Equation* (WEQ) reached 100 tons/ha. Meanwhile, the calculated rates in Fuka in the same sub zone have shown to be dependent on the land use, and ranged between 5.2 to 71.3 tons/ha compared with the measured values of 2.43 and 10.63 tons/ha for the same site. In El-Sheikh Zowaied, along the north-eastern coast of Sinai, the amount of airborne materials reached 3.16 tons/100 m spread over 193 days.

50.3.6 Water Erosion

Water erosion is among the major processes of land degradation in the northern coastal zone of the country where abrupt and intense rainstorms cause excessive runoff and considerable soil loss. This process also prevails in the coastal plains, in the hilly and mountain slopes of the Red Sea, in the Gulf of Al Aqaba, as well as in the southern parts of the Sinai and in many wadis in the Eastern Desert. The annual soil loss via water erosion in rain-fed areas along the north-western coastal subzone was related to the number of the effective storms, the amount of rainfall in each storm, the land use, the soil erodibility and slope. The annual water erosion rate has been estimated between 0.8 and 5.3 tons/ha/year. It is also found that the losses of plant nutrients, of nitrogen, phosphorus, and potassium are linearly proportional to the soil loss. In addition, the *Universal Soil Loss Equation* (USLE) was the best for predicting the rate of soil erosion.

50.3.7 Sand Encroachment

Active dunes and sand encroachment cover more than 166,000 km^2, or about 16.6 per cent of the total area due to an ecosystem imbalance caused by erratic rainfall, active winds, soil instability, scarcity of plant cover, overgrazing, and practising of intensive agriculture in marginal land, especially in the coastal area.

- Sand accumulations are located in the north-western coast (5,000 km^2), in the north-eastern coast (4,000 km^2), in the Kattara and Siwa depression (1,000 km^2), in middle and southern oases (4,500 km^2), in the Wadi El-Natron and in the West Delta (500 km^2), in the Great Sand Sea (135,000 km^2), in the East Delta (500 km^2) and in the Fayoum and Wadi El Rayian (3,000 km^2).
- The dominant types of dunes are the longitudinal and barachan in the Western Desert. The traverse, crescentic, star and, longitudinal in the North Sinai and the oolitic sand ridges in the north-western coastal area.
- Shifting dunes are particularly detrimental to agriculture on the two sides of the Nile Delta and along the western windward margin of the Nile Valley between Beni-Suef and Asyut. They also threaten the Western Desert oases and the coastal communities. Shifting dunes threaten many agricultural settlements and socio-economic activities. They also have negative impacts on health and on the environment, in addition to high annual costs

for repairing and maintenance of roads and other elements of the infrastructure.

- The High Dam Lake is exposed at several sectors to sand encroachment, which is blown from the west and north-west. The active winds which have velocities of more than 15 km/hr frequently blow from the north and the north-west. The hazardous impact of such winds and the ensuing sand movement on the lake are accelerated by many environmental factors, among them the favourable morphological setting conditions of the lake for the shifting sands derived from plains.
- The extremely arid conditions (rainfall is almost zero) and the prevalence of high sand dunes and other sand forms in the coastal and inland deserts are the most vulnerable to wind erosion and deposition, consequently they constitute a serious threat to the agricultural development, to rural and urban settlements, to road traffic, and public health.

The characteristics of sand dunes either active or inactive and their potential threatening of the agricultural land in the Nile Delta and in the Valley were studied using a multitude of land satellite images across the area surrounding the cultivated land. The study concluded that there are five discernable areas characterized by serious sand dune encroachment:

a.) The west of the Nile Delta where dunes cover about 255 km^2 with on orientation towards the western and south-western sides of the cultivated land in the Nile Delta.

b.) The Fayoum and Wadi El-Rayan depression, which have three types of active dunes, namely; the longitudinal dunes covering about 480 km^2, sand sheets covering about 240 km^2 and barachan dunes having an area of about 160 km^2. Because of hyper-arid conditions, the activity of the wind and the virtually non-existing desert vegetation, such sand sediments are actively attacking the cultivated land of the western and southern sides of the Fayoum and Rayan depression.

c.) The Nile Valley, where the linear dunes located south-west of the El-Minya governorate cover approximately 350 km^2 and are characterized by steep slip, are actively encroaching on the fertile cultivated land along the western side of the Nile Valley.

d.) The Al Kharga Oasis, which is dominated by longitudinal and linear dunes covering about 400 km^2. The source of the longitudinal mobile dunes is the Great Sand Sea in the Western Desert. As this area is almost rainless, flat in its topography, and has an increasing gradient in wind velocity, such dunes are active and migrate from the north and north-east to the south and south-east. These dunes seriously affect infrastructure and even engulf the villages and palm groves in the area.

e.) The north-western High Dam lake; where longitudinal and barachan dunes located at a distance of about 5 km to the north-west of the lake and extend from the north-west to the south-west cover an area of about 800 km^2. These dunes migrate to the south and south-east, and hence attack the north-west edges of the lake.

There are two major areas characterized by inactive sand accumulations, which can be delineated briefly in the following areas:

a.) East of the Nile Delta, where some longitudinal and barachan dunes are located between east of the Nile Delta and north of the Gulf of Suez. These dunes have low elevation (2–5 metres) with about 2–5 km length and 1–2 km width, and are surrounded with sand sheets. They trend from north to south and do not currently pose any threat to the cultivated land in the Nile Delta.

b.) The Sinai Peninsula, where a zone of inactive sand extends between the east of the Bitter Lakes and north of the Wadi El Arish. These dunes are far from the fertile land in the Nile Valley and the Delta. Nevertheless, at present a new land reclamation project is currently being implemented and a greater canal (El Salam) crossed a part of these dunes, which may disturb the dunes ecosystem, thereby special attention should be focused on the influence of such dunes on the agricultural development in this area.

50.3.8 Overgrazing

The general trend is shrinkage of rangelands coupled with a decline in the quantity and quality of forage production. Adverse changes in range plant composition, i.e. more annuals, less palatable and more unpalatable and noxious species are reported for most range areas. The combined effects of overgrazing, uprooting of woody plants, and extension of rain-fed cultivation have accentuated the decline in native forage production and the deterioration of good native forage species gene pool, thus threatening biodiversity. A recent report indicated that in most areas of the western coastal zone, and of the north Sinai, forage production had declined by 50–60 per cent in less

Figure 50.5: Deterioration of groundwater quality due to an intensive cultivation along the sea shore of Al-Arish/ North Sinai which is causing depletion for the thin lens of sweet water floating over the sea water. **Source**: Photo by Ismail Abd El Galil Hussein.

than 30 years and about 40–50 per cent of the plant cover has been lost. These changes are mainly attributed to ploughing of the most productive range areas to cultivate barley (and sometimes wheat), uprooting of shrubs for fuel, and to increasing grazing pressure.

No real data are available from the actual stocking rate trials to estimate the carrying capacity of the range types. The available data are only some estimates carried by some experts based on their field observation and their long experience in the region. However, the estimated carrying capacity differs from 4 acres/sheep unit/year for the Fuka grazing district to 22 acres/sheep unit/year for the El-Salloum district.

Rangelands deterioration had been accelerated during the last decades of the 20th century by the overuse and improper management practices such as:

- The expansion of rain-fed cultivation (particularly barley and wheat and horticultural crops) in the favourable rangeland areas (especially in the coastal areas, wadis and depressions).
- Increasing uprooting of trees and woody shrubs for fuel.
- Continuous overgrazing due to the rapid increase in the population of small ruminants which was encouraged by the availability of subsidized feed.
- Increased development of stock watering points for grazing herds allow for the extended use of rangelands where grazing was only possible during the rainy season. This increased the proportion of sacrificed areas around water points.
- Increasing use of trucks and water tankers for transporting grazing herds and water to far range areas.
- Neglecting the traditional grazing system as a result of a continuous shrinkage of the common grazing areas due grazing system as a result of the reduction of the common grazing areas due to the appropriation of rangelands by the desert governorates, indivi-duals and families for touristic activities, housing, roads, manufactures, etc.
- The management programme designed by most experts to address the balance in the relationship between animals and carrying capacity in the arid and semi-arid ecosystem is primarily concerned with the long-term production of the resources. On the other hand, the pastoralists are primarily concerned with the survival, first in the short term and then in the long term. Survival for the pasto-

ralist means not only his own personal survival but also the survival of his socio-cultural unit which relies on the productivity of the herds. It is obvious that the two concerns overlap but they are centred on different priorities which are, in turn, based on different values. This conflict between technical experts and pastoralists will not be solved as both of them are not able to provide alternatives to overcome it, but it could be solved in the larger political process.

50.3.9 Overpumping

Serious degradation of water quality has been observed in the north-eastern costal area of Sinai, specifically in Rafah and Shikh Zuwaid due to overpumping of water skimming wells, where lenses of thin fresh water exist. Although these kinds of wells require a high degree of precision in operation and management of the system, the local farmers are overexploiting this water for practising very intensive cultivation. However, the groundwater potential in the Sinai contains shallow groundwater in the Quaternary aquifer and deep groundwater in the fissured carbonate and Nubian sandstone aquifer. The total present usage is about 90 million m^3/yr. A large portion of the water is pumped from the Quaternary aquifer in the northern part of the Sinai (El Arish, Rafah, Bir el Abd). Most of the groundwater is slightly brackish and poses limitations on its use for potable supplies without further treatment. Fresh groundwater is mainly confined to the sand dunes, which are recharged from direct rainfall. Groundwater salinity shows wide values often exceeding 1,000 ppm *Total Dissolved Solids* (TDS). In El Arish and Rafah, the use has already exceeded the potential resulting in a continuous increase in salinity. In Bir el Abd and Sahl el Qaa, on the other hand, small reserves are still available, provided the wells are properly sited. Both the carbonate and sandstone aquifers can be developed, based on the amount of water in the storage and recharge from rainfall. The major portion of available groundwater is found in the middle of the Sinai.

The misuse of groundwater is another serious problem, which minimizes the aquifer capacity or the fresh water potentials. The current trends of population growth, urbanization, and industrialization will substantially increase the pressure on the quantity and quality of water. However, the country's limited water resources will come under further pressure as demand increases with the rapidly growing population. According to the UN survey of Sub-Saharan African countries, eight of 29 countries experienced water stress (less than 1,667 m^3 per capita per yr) in 1990 and will suffer water scarcity (1000 m^3/ capita/yr) in 2025. Egypt has been suffering from water scarcity since 1990.

50.3.10 Loss of Genetic Plant Resources

The Egyptian flora comprises about 2,121 species and 153 infraspecific epithets belonging to 121 families, unevenly distributed over its different agro-ecological zones. The highest species density is in the Mediterranean coastal zone, in the Nile Valley, in the Gebel Elba, and in the mountains of Sinai.

The number of species in proportion to the total surface area of the country (one million km^2) is considered very small. This is evidently due to the arid climatic conditions, where the annual rainfall nowhere exceeds 200 mm but is below 50 mm in most parts of the country. Egypt and Libya (except El-Gebel Al-Aghder) are the only two countries in North Africa where the Saharan climate extends up to the Mediterranean coast, thus preventing the development of any Mediterranean arboreal vegetation.

Due to the very scanty rainfall, most vegetation of Egypt is concentrated primarily in the wadis and depressions (contracted distribution pattern). Although most of the greater part of Egypt is Saharan in vegetation, the proportion of the Saharan plants is relatively small as compared to other phytogeographic regions.

A striking feature in Egypt's flora is the large number of genera in proportion to that of the species, amounting to about 3 species per genus. This is a very low figure compared to the average global proportion which amounts to about 14. The generic index, i.e. the number of genera per 100 species is relatively high, which points to the marginal conditions of Egypt with respect to many genera, and also indicates the lack of accumulation and differentiation centres in Egypt.

50.4 The Role of Traditional Knowledge

Traditional knowledge is a dynamic system which enables local communities to adapt to environmental changes and to create innovative solutions (chap. 52 by Laureano). The *UN Convention to Combat Desertification* (UNCCD) includes the natural and the cultural dimension of development. Therefore, participation of local communities in environmental decision-

making and management has become a valuable means to achieve the environmental objective of several conventions since the *United Nations Conference on Environment and Development* (UNCED) in Rio de Janeiro (1992). The role of traditional knowledge is described in the articles 18 and 20 of the UNCCD convention, in which the parties are asked to protect, promote, and use in particular relevant traditional and local technology, knowledge, know-how and integrating traditional practices with modern technologies (Art 18.d and 19.d). UNCCD endorses a human-centred approach to sustainable development and places the knowledge holders and capacities of the local communities to prevent desertification at the centre.

The role of traditional knowledge has been overlooked in the Egyptian deserts which were historically sustained over centuries by an efficient indigenous system for natural resources management. For instance, *Orf* is an unwritten law adopted by the Bedouin population, which covers several issues, among the items of this law, there are rules regulating the collection and cutting of herbs and wood. It is forbidden to cut the green parts of the tree, and who does so is subject to a penalty of 50 LE. The *Hema* system (Arabic) had been used to conserve the range of plants from extinction through centuries of misuse and communal grazing. No doubt, this system preserved the valuable genetic resources which are unfortunately being overexploited these days. However, *Helf* was also one of the most interesting regulations that the Bedouins in St. Katherine were practising. It is a sort of communal regulation that was arranged by the Bedouins without any interference from governmental authorities for the protection of the plants in certain places against grazing in certain periods of the year to allow proper biomass production and fruit setting in that area. Every year, the sheikhs of the tribes agreed about certain areas to be kept away from grazing in a period starting from the onset of the rainfall in October until the end of the growing season (Batanouny 2000).

The apricot fruit setting was the sign to cease the *Helf* for that season, and then the zoned area was opened first for camels only for one month, thereafter, it was allowed for the other animals; sheep and goats. The selected area was changed every year. The *Helf* was arranged and guaranteed by the sheikhs, who are the wise leaders of the tribes. There were serious penalties for anyone who did not follow these rules.

50.5 Policy Suggestions for Coping with Desertification

Despite informal data indicating that 30 per cent of the drylands in Egypt is actively subject to desertification process, insufficient measures have been taken by policy-makers. The author has experienced as the focal point of UNCCD the lack of awareness by the majority of politicians, as well as the public. The reason behind this might be the nature of the phenomena as its processes occur over a long time period and that makes it invisible. Therefore, the challenge is how to make such invisible phenomena visible to policy-makers and to the public as well, and how to make the desertification definition understandable. For instance, building houses on fertile agricultural land has never been considered by policy-makers in Egypt as a cause of desertification, despite the fact that Egypt is suffering from a growing food gap and very limited agricultural land. Most laws to stop such activities are not properly being implemented due to a lacking political will.

- Accordingly, enhancing all means of mass media, of audio-visual material, and printed sources is of utmost importance by setting up national programmes that focus on social and cultural aspects to raise awareness, helping to mitigate the negative impacts and consequences of desertification.
- Mainstreaming efforts at the cabinet level for combating desertification are required to be proactive in order to minimize risks and costs, to avoid double efforts, and to fulfil obligations adopted by UNCCD. Accordingly, it is needed that the cabinet approves the needed tasks and allocates sufficient funds.
- The role of NGOs to voice their demands and needs is still lacking political support and recognition by the government. Furthermore, the development of a scientific research strategy in cooperation with the private sector that is specifically concerned with desertification will be very helpful.

51 Impacts of Drought on Agriculture in Northern Mexico

Tulio Arredondo Moreno and Elisabeth Huber-Sannwald

51.1 Introduction

Mexico is situated between 14º and 32º latitude North within the tropical and subtropical regions. This wide geographic expansion contributes to the preponderance of arid and semi-arid climates in Northern Mexico covering almost 50 per cent of the country's territory. The Northern region of Mexico is home to close 30 per cent of the total national population (table 51.2), of which more than 6 per cent live in rural areas.

The limiting conditions of drylands both in a biophysical and socio-economic context have favoured the development of rain-fed agriculture, a production system that is increasingly vulnerable to long periods of drought, low crop output, and soil degradation. The declining viability of subsistence production systems forces farmers to opt for alternatives including the exploitation of natural resources; however, future prospects are similarly low. Overexploitation such as overgrazing by livestock often culminates in severe land degradation followed by land abandonment and migration. Since subsistence farming and direct harvesting of natural resources can no longer fulfil the living demands of rural communities, government assistance through self-help programmes or the introduction of technologies may improve the socio-economic situation of some communities or community members in some areas, however, these programmes are rarely sustainable eventually causing the system to convert in unproductive land.

Also, social equity issues related to land tenure and property rights may restrict some community members' access to these assets in turn feeding back on social disparity, exacerbating the exploitation of land, and causing the complex and irreversible process of land degradation. Hence, it is the interaction between biophysical and socio-economic phenomena and their feedbacks that need to be addressed when trying to elucidate the underlying mechanisms of how drought may impact on agriculture and the livelihoods of many rural communities in Northern Mexico.

Over the last decades, Northern Mexico has been greatly affected by climate change with extended periods of drought interrupted by heavy often torrential rainstorms. Recent regional and global scenarios of climate change (IPCC 2007a; Fernández/Martínez/Osnaya 2003) predict decreases in annual precipitation and increases in the frequency of extreme events for arid and semi-arid regions of the world and for Northern Mexico. Unfortunately, it is the rural communities that are at highest risk with respect to these scenarios and directly and indirectly associated environmental problems. Global environmental change and increasing socio-economic constraints for a large proportion of the human population will result in increasing poverty and land degradation. The need to improve our capabilities to forecast future biophysical and socio-economic changes in the aridlands of Northern Mexico simultaneously is more pertinent than ever before. Particularly in the face of non-linear dynamics of global environmental change, new predictive tools will allow us to detect highly vulnerable regions and social groups, and to design flexible adaptation strategies for these regions to cope with drought and desertification.

This chapter is devoted to identifying those factors that may contribute to an exacerbation of land degradation in rural agricultural communities in Northern Mexico. The chapter examines the importance of arid zones in Northern Mexico as well as the agricultural systems in relation to social groups associated to them. We present the possible Global Environmental Change scenarios that may affect the northern aridlands and discuss aspects of vulnerability to natural, agricultural, and social systems. Further, we suggest some adaptation strategies to global change and some mitigation options to reduce desertification. Finally, we present a new framework, the *Dryland Development Paradigm*[1] that allows on the one side identifying the critical socio-economic and biophysical drivers

that lead to desertification and on the other hand offering a holistic approach to mitigate land degradation and/or restore degraded areas; hence a comprehensive tool to tackle this global problem.

51.2 Agriculture in the Arid Zones of Northern Mexico

51.2.1 Characteristics, Extent, and Importance of the Arid Zones of Northern Mexico

Mexico is characterized by a large diversity of ecosystems including alpine, coastal, desert, rain, and temperate forest. The most extended ecosystem types are arid and semi-arid ecosystems, which cover almost 50 per cent of Mexico's territory (Rzedowski 1978). Mexico's arid lands consist of two large regions: i) the *Sonora Desert* in the NW of the country with the states of Sonora, Northern and Southern Baja California, and ii) the *Chihuahua Desert* in the center-north of the country with the states of Chihuahua, Coahuila, Durango, Zacatecas and San Luis Potosí (figure 51.1; 51.2).

The vegetation in Mexico's aridlands is characterized by the desert scrub (*matorral*) and grassland biomes (table 51.1; figure 51.3). The arid and semi-arid regions have one of Mexico's highest species richness (around 6,000) with an extraordinary high number of endemic species (3,600) (CONABIO 2006). The desert scrub is the dominant ecosystem (table 51.1); its complex biota of diverse plant species and life forms including shrubs, subtrees, cacti, succulents (cacti, *Agave* spp., *Opuntia* spp.), and herbaceous perennials covers almost 50 per cent of the region (table 51.1). The grassland formations are less abundant; these are naturally relatively poor species communities; however, they provide the most important provisioning, supporting and regulating ecosystem services for the region.

The importance of these arid regions is related to several often conflicting biophysical and socio-economic factors that include the geographic extent, the enormous biological diversity, and endemism (Rama-

moorthy/Bye/Lot/Fa 1993), exploitation of natural resources, economic and social tensions as a consequence of being the border region to the United States of America, a large expanding human population (up to 20 per cent of Mexico's total population, table 51.2), urbanization, city growth, rural migration, and the high vulnerability of the region to natural and anthropogenic catastrophic events such as decades of droughts, flooding, land use change and abandonment of marginally productive land, expansion of intensive agricultural frontier, environmental degradation, etc.

51.2.2 Agricultural Systems in the Arid Zones of Northern Mexico

As a mega-diverse region, ranked fourth important in the world (CONABIO 2006), Mexico has also developed one of the richest agricultural cultures in the world. In spite of the limiting conditions that arid and semi-arid environments impose on plant growth and subsequently on agriculture development, strong agriculture-based cultures emerged in these environments in the past (e.g. The Pueblo Indian groups from Northern Mexico and Southern U.S.). Ethno-agriculture and traditional extraction of wild plants for food, medicine, fibre, beverages, religious practices, etc. are low-input sustainable production systems based on old traditional knowledge that date back to pre-Co-

Table 51.1: Area (total and per cent) of dominant land cover types in Northern Mexico in 2000 for the states of Northern and Southern Baja California, Chihuahua, Coahuila, Durango, Nuevo León, San Luis Potosí, Zacatecas (Region 1 and 1' in figure 51.2). **Sources:** INEGI (2004); Palacio/Bocco/Velásquez/Mas/Takaki-Takaki/Victoria/Luna-González/Gómez-Rodríguez/López-García/Palma-Muñoz/Trejo-Vázquez/Peralta-Higuera/Prado-Molina/Rodríguez-Aguilar/Mayorga-Saucedo/González-Medrano (2001).

lumbian times (Aguirre-Rivera/Charcas-Salazar/Flores-Flores 2001). Typical examples of extracting plants from natural systems include the use of *Agave* plants for the production of fibre (*Agave lechuguilla*; see Reyes-Agüero/Aguirre-Rivera/Peña-Valdivia 2000), fermented beverages such as pulque or traditionally distilled beverages such as mezcal (*Agave salmiana*; see Aguirre-Rivera/Charcas-Salazar/Flores-Flores 2001). In some places, lack of plant population management and overexploitation could potentially threaten the viability of these plant species. It has been estimated that in a single season 40 million plants of *Agave le-*

chuguilla are harvested to obtain lechuguilla fibre (Reyes-Agüero/Aguirre-Rivera/Peña-Valdivia 2000).

Most of the agricultural systems developed from converting grasslands and desert scrub into cropland. Today, two types of agriculture systems dominate traditional low-input agriculture and intensive, high input farming systems. In the arid zones of Mexico, rain-fed agriculture for corn, bean, and squash production dates back to 5000 BC (Cue 1963). It was primarily adopted for self-consumption. The development of water holding structures such as terraces and retaining furrows (Fortanelli-Martínez/Aguirre-Rivera 2000) was a key aspect contributing to its success. Rain-fed agriculture has either been practised as monocultures or as intercropping where e.g. beans are interspersed with corn. Until now, rain-fed agriculture continues to be a traditional farming technology with tools and management approaches from the beginning of colonization times, and by using a diversity of empirically domesticated plant species adapted to local environmental conditions (Hernández/Inzunza/Solano/Brauer 1977). Producers with access to government cash-based subsidy programmes (like PROCAMPO) have access to modern technology such as mechanization, fertilization, etc. which greatly alter crop residues and soil management, questioning the long-term ecological benefits of this development (Ribeiro-Palacios 2007).

Intensive farming is mostly practised in form of irrigated crops. Paradoxically, the arid and semi-arid regions of Mexico has prime importance for the national production of alfalfa, beans, chilli, cotton, corn, cucumber, garlic, grapes, melon, safflower, sesame, sorghum, soy bean, strawberry, tomato, and wheat. Traditional crop production has been displaced by these highly rentable crops for exportation. These irrigated production systems have contributed up to 48 per cent of the total crop production of the country (Chalita 1974). The largest irrigation districts of the country are located in these regions (Bassols 1970, CNA 2007a). Irrigation technology includes a) open-channel irrigation, b) water tunnels for alluvial water springs (qanat from North Africa), and c) deep pumping from rechargeable aquifers and fossil wells (Fortanelli-Martínez/Aguirre Rivera 2000). Annual water use from surface and subsurface water for irrigation agriculture ranges between 15–20 km^3. Of this, almost 50 per cent is gained from the 318 aquifers occurring in the region, of which 62 are on average overexploited (CNA 2007a, table 51.3).

Irrigation agriculture including high-input agrotechnology have triggered serious environmental disasters in Northern Mexico (Matson/Naylor/Ortiz-Monasterio 1998); among those are soil erosion, soil salinization, soil subsidence, overexploitation of aquifers in addition to the simultaneous biological and ecological devastation. The far reaching environmental consequences of this truly non sustainable agriculture in Northern Mexico trigger also regional socio-economic problems associated with land abandonment, migration, poverty, etc. (Cloudsley-Thompson 1977).

51.2.3 Socio-economic Aspects Associated with Agricultural Practices in Northern Mexico

Historic and current agricultural practices in Mexican drylands have been greatly shaped by a series of complex socio-political phenomena such as the transition from a nomadic to a settled lifestyle, the Hispanic conquest, land ownership, land leasing, conflicts between minifundia and latifundia, agrarian revolution, agrarian reform, communal land structure (ejido), property rights, etc. (Soto-Mora/Fuentes-Aguilar/Coll-Hurtado 1991). Prior to the Hispanic colonization, the arid and semi-arid lands of Northern Mexico were inhabited by semi-nomadic indigenous groups known as the chichimecas (Montejano 1978). These groups were hunter-gatherers that were not familiar with agricultural practices (Clavijero 1979). With the discovery and exploitation of several important silver mines in the central part of Northern Mexico by the Spaniards, the first settlements were established and associated with those, agriculture started. Large landholdings associated with the haciendas promoted crop and livestock production for self-sufficiency and for supplying mining centres in Guanajuato, San Luis Potosì, Zacatecas, Chihuahua and Sonora (Cardoso/Pérez 1979). The feudal type organization of the haciendas allowed the development of semi-intensive, mostly irrigated agriculture. After 300–400 years of social inequalities and land exploitation, the political, economic, and social pressures culminated in profound hacienda criticism and its feudal system, and thus were one of the main causes for the Mexican Revolution in 1910. The agrarian land reforms in 1917 led to shifts in land tenure, when large areas of the country were granted to rural and peasant communities or *ejidos* (Sanderson 1984). In Northern Mexico, there are currently, 7,200 ejidos (table 51.4, INEGI 2004).

These communes were not granted land ownership; however, they had both the rights to exploit the land without restrictions and hereditary privileges. The *ejido* structure consists of small individual farm-

Zacatecas	75300	38443	51.1

ing areas and a large communal land. The small areas are assigned to individual households of the ejido who use them for agriculture. The communal land is a dedicated rangeland area, where any member of the ejido can raise livestock usually without restrictions on stocking density. Because of the collapse of many irrigation systems with the shift of land ownership from Hacienda to ejido, many cropping areas turned into rain-fed agriculture. This, together with the inherently limiting growing conditions in the arid and semi-arid region caused a significant drop in crop productivity.

Ejidos have turned into small-scale subsistence agricultural systems (Assennato/León 2007) and livestock grazing in the communal rangelands has become one of the most important (economically) land use activities in the ejidos. Unfortunately, lack of management policies and regulations by the state has caused vast areas to become heavily overgrazed and degraded (Huber-Sannwald/Maestre/Herrick/Reynolds 2006, Manzano/Návar/Pando-Moreno/MartÌnez 2000). Finally, in 1992 the original law (Consti-

tution Article 27) that once created the 'ejido' was modified by a decree that allows ejido members to be granted land ownership. Consequences of this reform include a return to the concept of private property and likely a change in the agricultural systems of the region. However, we will witness the social, economic, and environmental outcome associated with this reform in the decades to come.

The historical development of ejidos and their agriculture systems are unfortunately tightly linked to a history of subsistence production systems and poverty. Given the close dependence of subsistence farming on summer precipitation, the livelihoods of ejido communities emerge to be one of the most vulnerable to climate anomalies that likely will intensify based on future scenarios of climate change (Conde/Ferrer/Liverman 2003; Fernández/Martínez/Osnaya 2003; Magaña/Conde/Sánchez/Gay 2003; Conde/Ferrer/Orozco 2006).

51.3 Global Environmental Change and Agriculture in the Arid Lands of Mexico

Global environmental change (GEC) is the result of several direct and indirect human drivers with land conversion of natural systems, urbanization, global loss of habitat and biodiversity, change in atmospheric chemistry and climate change being the primary ones. In Northern Mexico in particular, land conversion, inappropriate agricultural practices, overexploitation of rangelands and the associated loss of plant cover, soil organic matter and consequently long-term productivity of the drylands have led to the complex phenomenon of desertification. A phenomenon that tightly links the underlying biophysical and socio-economic dimension (UNFCC 1994; Reynolds/Stafford Smith 2002) of a severe global and regional environmental problem and that encompasses almost all of the above mentioned drivers. Especially, in the semi-arid and arid regions of the world and Mexico, the severe changes in the hydrological cycle are probably the most immediate and hardest to deal with impacts of GEC as they jeopardize the fundamental life-support system in regions, where social and ecosystems have to share freshwater as the survival and longevity of these human-environment systems depends above all on the continuous availability and quality of this key resource (Falkenmark 2003).

51.3.1 Drought and Scenarios of Climate Change in Northern Mexico

Drought is a permanent threat to agriculture in Northern Mexico. Almost 80 per cent of the arid and semi-arid region of Northern Mexico is located in a critical zone (mean annual precipitation less than 350 mm) for rain-fed agriculture, while in less than 5 per cent a favourable precipitation regime is recorded (450–500 mm; Conde/Ferrer/Araujo/Gay/ Magaña/Pérez/Morales/Saturnino 1999). Drought phenomena in this region reoccur every ten years (CNA 2006) and greatly negatively affect agriculture, livestock and forestry. In the past, extreme drought events impacted on food security in the region and in historic times even influenced important socio-political events such as the Independence War and the Mexican Revolution (García-Acosta/Pérez-Ceballos/Molina del Villar 2003; Florescano/Swan 1995; Conde/Ferrer/Orozco 2006). The most recent decade of drought ended in the late 1990's; it affected most of the Chihuahua Desert (Conde/Ferrer/Araujo/Gay/Magaña/Pérez/Morales/Saturnino 1999) causing ecologic, economic, and social collapse (box 51.1).

Box 51.1: Drought periods in Mexico associated with social phenomena**. Source**: The authors.

Although drought[a)] is a periodically recurring climatic phenomenon in large parts of Mexico not many historic records report on its existence. For instance, the *National Meteorological Service* (SMN) has climate records starting only in 1921. A few meteorological stations located next to monasteries and government buildings, as well as historic archives that describe the absence of rain have served as valuable sources to investigate the incidence and patterns of drought in the 19th century. In particular, a historian's perspective on drought such as by Enrique Florescano (1980), has allowed establishing links between historic climate and economic, social and demographic processes. In Mexico, historical drought occurrence suggests that impacts on food production and the subsequent increase in food costs triggered the social upheaval of the Independence War in 1810 and the Mexican Revolution of 1910 (table 51.5, 51.6, and 51.7).

a) Drought may be defined as an extended period, from weeks to years, when a region suffers a deficiency in its water supply. This occurs when a region receives below average precipitation and affect ecosystem functioning and agriculture. Even a short, intense drought can cause significant damage and harm the local economy.

Table 51.5: Years of observed and recorded droughts for the Northern States of Mexico. **Source**: Carrillo-Arronte cited by Contreras-Servín (2005: 123).

State	Years with drought
Nuevo León	1868,1886,1887,1889,1894,1905,1906,1907,1909,1910
Chihuahua	1877,1886,1893,1896,1908,1909
Coahuila	1868,1877,1883,1884,1887,1904,1910
Sonora	1886,1887,1893,1896,1897
Aguascalientes	1868,1895,1905
Durango	1850,1877,1894
San Luis Potosí	1875,1887,1889,1894,1896,1898,1899,1900,1904,1905,1906,1907,1908
Zacatecas	1875,1885,1889,1895,1907
General drought	1808,1809,1810-1811

Historic drought events in Mexico had likely greater social impact because of a higher proportion of the rural population and the characteristic self-sustaining food production system of these human communities. Thus, grain storage and grain importation was limited or not existing, so that even seasonal drought events could produce strong social pressure as the population was trying to satisfy food demands.

In modern times, there has been a switch in the proportion of the population with a drop of the rural population from 57 per cent to 23 per cent in the period between 1950 and 2006 (table 51.6). In 25 years from now there is expected to be a drop in 5 per cent in the rural population. Severe drought as expected under future climate change scenarios (table 51.7) will still hit rural communities, however, greater pressure will occur in urban centres where water availability would have a priority. Between 2006 and 2030 predictions estimate a drop in water availability of 575 m^3/inhab/year (CNA 2007a).

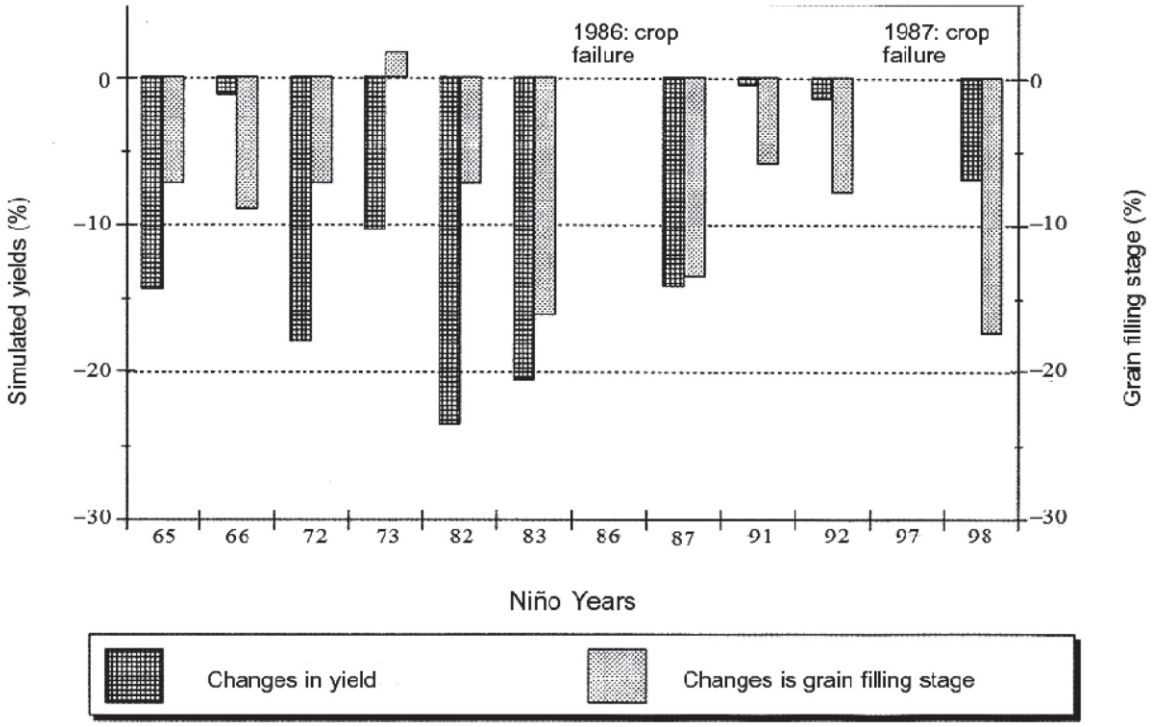
Severity index of meteorological drought	Current proportion (%)	Projections CCC model (%)	Projections GFDL-R30 model
Severe	24.4	30.0	39.4
Very severe	8.1	7.8	7.4
Extremely severe	3.6	3.9	4.3

Figure 51.4: Estimated changes in yield and the stage of grain filling in corn during El Niño years. **Source:** Conde/Ferrer/Araujo/Gay/Magaña/Pérez/Morales/Saturnino (1999).



Large scale drivers of regional precipitation in Northern Mexico include the position of jet streams, the movement of polar-front boundaries, the intensity of summer monsoons, the surface temperature of neighbouring oceans, often regulated by oceanographic events such as *El Niño Southern Oscillation* (ENSO) and by even longer-term ocean cycles of the *Pacific Decadal Oscillation* (Caso/González-Abraham/Ezcurra 2007). From these, ENSO turns out to be a key driver of the climate in Northern Mexico. North of 22° latitude, ENSO brings primarily humidity (Caso/González-Abraham/Ezcurra 2007) while la Niña brings primarily drought (Holmgren/Stapp/Dickman/Gracia/Graham/Gutiérrez/Hice/Jaksic/Kelt/Letnic/Lima/López/Meserve/Milstead/Polis/Previtali/Richter/Sabaté/Squeo 2006). ENSOs are natural phenomena, however, in recent decades they occur with greater frequency, every 3 to 7 years (McPhaden 2004) than they used to (every 10–12 years) causing frequent yet still unpredictable drought events in Northern Mexico (table 51.5). El Niño events are also accompanied by an overall decline of crop yield and incompletion of grain filling in corn (figure 51.4).

In addition to the natural climate variability, the most recent climate change scenarios for the year 2050 simulated with *Global Circulation Models* (GCM) predict an increase in temperature by 2–4 °C. Northern Mexico will be the most affected region of Mexico (Magaña/Conde/Sánchez/Gay 2003). Also, precipitation will decline by up to 20 per cent in the arid and semi-arid regions of Mexico (SEMARNAT 2006), Bur there is still much uncertainty associated with these predictions (Magaña/Conde/Sánchez/Gay 2003; IPCC 2007a). The northern parts of the Chihuahua Desert and the Sonora Desert are the most vulnerable regions according to most recent climate change scenarios (SEMARNAT 2006).

51.3.2 Agriculture and its Vulnerability to Drought in Northern Mexico

Arid and semi-arid ecosystems are characterized by naturally low water availability and by relatively shallow unproductive soils with a general low water holding capacity. The Northern states of Mexico receive on average annual precipitation (for the years 1941–2005) of 260 mm (100–480 mm); 67 per cent of that fall during summer (June – September, CNA 2006). In addition, the onset of summer precipitation varies greatly (between May and August) which may considerably enhance drought effects. As a result, Chihuahua, Coahuila, Durango, Nuevo León, Baja Califor-

Figure 51.5: Distribution of areas suitable for corn production in Mexico. **Source:** Flores/ Araujo/Betancourt (2003).

nia, Sonora, Sinaloa, Zacatecas, San Luis Potosí, and Aguascalientes are the states most affected by pervasive drought (in decreasing order; CNA 2006) and consequently constitute the region with the highest vulnerability to future changes. O'Brien, Sygna and Haugen (2004) attribute vulnerability to the set of attributes generated by social and environmental processes, including climate change, which limit the ability of humans to cope with climatic and other stress types that fundamentally affect their livelihoods.

Rain-fed agriculture is particularly vulnerable to climate change and its predicted strong droughts in Northern Mexico (table 51.7), since it relies on a precise seeding schedule considering a more or less continuous rainfall distribution along the growing season. The vulnerability of rain-fed agriculture to the predicted climatic fluctuations in Northern Mexico is so extremely high that Flores, Araujo and Betancourt (2003) consider a large part of the Sonora Desert and Chihuahua Desert to be non-suitable for corn agriculture (figure 51.5). Modelling studies (Conde/Ferrer/Liverman 2003) on future climate effects on agriculture in more humid Central Mexico suggest that rain-fed agriculture practised in that region will suffer severe reductions in corn production, because of a reduction in the length of the growing season and an overall decrease in total annual precipitation. In Northern Mexico, it is also estimated that even irrigated crops may suffer increasing risks associated with predicted pervasive long-term droughts. These risks may be associated with the overexploitation of superficial and subterranean aquifers (CNA 2004).

51.3.3 Agriculture and its Vulnerability to Desertification in Northern Mexico

Rain-fed agriculture is practiced mostly in plains, at foothills and valley bottoms, where soils are deepest. However, aridisols the dominant soil types in the region are generally shallow and have a relatively low content of soil organic matter (<1.5 per cent). Additionally to rain-fed agriculture almost all subsistence farmers raise livestock on open unmanaged rangelands. Because of the enormous overuse of the rangelands (according to Manzano/Návar/Pando-Moreno/Martínez 2000, the rates of overgrazing in Northern

Mexico range between 182–1,500 per cent over the recommended capacity) many households are forced to feed their animals most of the annual crops as supplementary forage. Thus, upon harvest they remove all plant residuals leaving the soils void of any protecting cover, thereby provoking dramatic soil loss through water and wind erosion (Schoijet 2005; Lal 2004). Another phenomenon that increases the vulnerability of rain-fed agriculture to desertification is associated to a progressive loss in soil fertility as a consequence of inappropriate land management (conventional tillage, removal of plant residuals, crop monocultures, no crop rotation, etc.). Current agricultural practices and land abandonment both alter the biogeochemical cycles of the systems thereby greatly influencing the natural dynamics of hydrology, fertility, and energy balances. Current land use practices increasingly decouple the production systems from their environmental support systems (Naylor/Steinfeld/Falcon/Galloway/Smil/Bradford/Alder/Harold 2005), including the supporting and regulating ecosystem services (MA 2003).[2]

In total, 90 per cent of the area covered by rain-fed agriculture is affected by some sort of land degradation (López Ocaña 1996). According to a recent assessment of human induced soil degradation in Northern Mexico (SEMARNAT 2002), 40 per cent (413,827 km^2) of the soils are degraded, with wind erosion (15 per cent) being the most apparent type followed by chemical erosion (12 per cent; i.e. loss of soil fertility), water erosion (10 per cent), and physical erosion (3 per cent). Soil degradation is in fact the consequence of a more profound problem associated with a multitude of interacting biophysical and socio-economic factors leading to desertification (Reynolds/Stafford Smith 2002).

The UNCCD (1994a) defines desertification as "land degradation in arid, semi-arid, and dry sub-humid regions resulting from various factors, including climatic variations and human activities" and land degradation as the "reduction or loss of the biological and economic productivity and complexity of terrestrial ecosystems, including soils, vegetation, other biota, and the ecological, biogeochemical, and hydrological processes that operate therein" (United Nations 1994). When adopting these definitions, large areas of Northern Mexico must be influenced by desertification, however, to our knowledge there are no compiled statistics on the extent and/or degree of severeness of the land and human populations affected by desertification.

51.3.4 Socio-economic Vulnerability in Northern Mexico

Vulnerability of livelihoods of rural communities to drought and desertification in northern Mexico is directly linked to the susceptibility of subsistence farming and integrity of natural resources to persistent and frequent drought events. For instance, food security for a large proportion of the Mexican population depends on corn production while consumption rates of corn in Mexico approach 250 kg/inhabitant/year. Long-term sustainability of agriculture, particularly of basic grains such as corn and beans, should have high priority in state development plans, and call for innovative policies both to reduce poverty and migration (especially in Durango and Zacatecas; see INEGI 2004) to urban areas and the United States, and to improve the life support system of one fifth of the Mexican population.

However, recent policies associated with food security issues promoted importation rather than the enforcement of a self-sufficient agriculture. For example, in the last decade, Mexico imported food (mostly corn) for US$90,000 million (Perez 2005). Apart from socio-economic aspects this massive corn importation has also threatened the maintenance of the high genetic diversity of Mexican maize (Nadal 2000) which could essentially serve as a key source for adaptation strategies considering future scenarios of global warming. Equally, in 2007 an important increase in the tortilla price due to corn importation, subsidies cut-off and increased use of corn for biofuels, triggered the inflation rate of the Mexican peso. This illustrates how agricultural systems in Northern Mexico may become highly vulnerable and dependent not only on meteorological factors but also on national policies and global markets (Liverman 2000).

51.3.5 Social and Economical Pressures Affecting Dryland Agriculture

Paradoxically, global and national markets and international trade agreements (e.g. NAFTA) have resulted in a marked decline in the competitiveness of traditional crops such as corn produced by a large population in Northern Mexico (table 51.8).

2 This report was written by a team of 5 authors and 10 contributing authors. The MA was coordinated by UNEP and its Secretariat was based at several partner institutions.

Table 51.8: Collapse of corn prices in relation to costs of agriculture inputs between 1981 and 1994. Estimated to corn prices of 1994. **Source**: Becerra-Moreno (1998).

Year	NIP*) agricultural inputs	Real cost of corn N$ t^{-1}
1981	122	1,593
1985	1,097	1,441
1990	16,370	1,153
1994	29,667	749

*) NIP= National Index of Prices for agriculture inputs

With the introduction of NAFTA in 1994, Mexican producers were expected to strongly increase exportation of high rentability crops (Nadal 2000) and to move away from traditional crop production, with the goal that most subsidies for traditional agriculture could be cut back. A decade later, it was only the large-scale commercial farms in Northern Mexico that were able to increase production (forage, vegetables and fruits), however, at a high environmental cost related to high water use for irrigation, excessive fertilizer application and soil contamination through pesticides (Liverman/Vilas 2006). For smallholder farmers, it has become ever more difficult to access credit, water quotas, and technology to participate in the production of goods for exportation.

Among the key outcomes derived from implementing NAFTA in the agricultural sector of Mexico, Henriques/Patel (2004) and Nadal (2000) have mentioned a) international and national decreases in corn prices, b) stable levels of Mexican corn production despite price changes, c) increase in rural poverty, d) increase in out-migration, e) increase in the price of tortillas, f) tariff rate quotas not enforced and revenue foregone, and g) heterogeneity of impact on farmers (worse for small producers). Unfortunately, most of the mentioned outcomes have negatively affected subsistence farming and small agricultural producers (Henriques/Patel 2004).

The high-input production systems in Northern Mexico seem to have traded short-term increases in exportation for long-term sustainability of these highly vulnerable life-support systems (Robertson/Swinton 2005) by sacrificing supporting and regulating ecosystem services and putting economic interests first. Globalization and economic subsidies both in industrialized countries and within the country are also key drivers affecting corn farmers in Northern Mexico (Fitting 2006).

First, Mexican farmers have to compete with imported highly subsidized, low-cost US corn. US corn farmers received between 1993 and 2000 subsidies of up to 18 billion dollars (Henriques/Patel 2004). Secondly, subsidy programmes in Mexico such as PROCAMPO (a national programme for direct assistance to subsistence farmers) offer cash transfer to farmers in form of seed money of one of nine basic crops (corn, beans, wheat, rice, sorghum, barley, cotton, soybean and safflower, Saudolet/Janvry/Davis 2001). The programme was aimed at providing compensatory income for smallholders (targeted towards ejidos) to stimulate the production of low-price crops and to ultimately reduce poverty and out-migration. However, several unintended negative consequences emerged with this programme. Lack of technical support and access to mechanized agriculture resulted in inappropriate agricultural practices (tillaging, monoculture, use of tractors, etc) causing land deterioration and increasing conversion of natural ecosystems to rain-fed agriculture. Huber-Sannwald, Maestre, Herrick and Reynolds (2006) show that in the southernmost part of the Chihuahuan Desert (San Luis Potosí), intensification of farming promoted by PROCAMPO favoured a decline in soil fertility and increased soil compaction in corn, bean, and barley fields. Hence, unfortunately subsidy programmes may in some cases contribute to increased vulnerability of subsistence farmers.

Finally and ironically, environmental problems emerge also from the economical success (remittance) of emigrants and the economical support they provide to their rural regions. This, for instance, has generated a change in the production systems by turning from a low-return cropping system to an intensive livestock production system (Ribeiro-Palacios 2007). Concomitantly with this trend occurs a change in preference for forage crops at the expense of traditional crops. Not to mention an ever increasing grazing pressure in already overgrazed rangelands. These examples illustrate the complex interactions that may arise from coupled socio-economic and agro ecological systems. Additionally, the expectations that arid and semi-arid ecosystems will become unpredictable will contribute to enhanced vulnerability of dryland agriculture, particularly to drought and globalization.

51.4 Strategies for Adaptation and Mitigation to Climate Change in Dryland Agriculture of Northern Mexico

Future scenarios of climate change for arid and semi-arid regions of Northern Mexico include temperature increases between 1–2 °C, decreased rainfall of around 20–30 per cent, as well as changes in rain distribution (fewer but larger events). Potential changes in agricultural systems under the climate change scenarios for the drylands of Northern Mexico include loss of plant cover with increasing soil temperature and reduced precipitation, enhanced soil erosion, and a decline in soil water recharge. The resulting loss in soil fertility will impose more pressure on the land, exacerbating land degradation and poverty. Under these scenarios, regional policies for land management and social welfare should consider the development of strategies of adaptation and mitigation that consider also sustainable alternatives of agriculture to protect the soils against erosion and fertility loss that will contribute to a reduction of GHG emissions.

51.4.1 Adaptation Strategies for Rain-fed Agriculture

Historical accounts of drought events in Northern Mexico report that drought impacts are frequent and severe with on average 10–20 per cent loss of agriculture land and consequent declines in production, export of crops and livestock and increase in importation. Given the high incidence of unpredictable drought events, local communities in arid and semi-arid regions have developed traditional technologies to cope with these limiting conditions (box 51.1). For instance, the installation of sophisticated irrigation systems for water transport and storage in gallery tunnels allowed the collection of subsurface water at foothills and its transport to valley bottoms.

Another irrigation system still in use dates back to colonial times; it is the 'entarquinamiento' or 'water box' approach which was designed to collect and manage run-off water after torrential rainfall events for late fall or winter crops when water is scarce. The technology of entarquinamiento has been implemented extensively in Northern Mexico. For example, the prosperity of agriculture in the 'Comarca Lagunera' region in Coahuila and Durango states has been attributed to this irrigation technology (box 51.2).

Box 51.2: Water boxes in La Comarca Lagunera. **Source**: Eling/López-Pacheco/Palerm-Viqueira/Pimentel-Equihua/Sánchez-Rodríguez (2001); Palerm-Viqueira/Sánchez-Rodríguez (2002).

An 'entarquinamiento' is an irrigation system that consists of a series of crop fields of variable extension which are surrounded by soil furrows and function as 'water boxes' or water deposits for times when water is required weeks or months later. The Comarca Lagunera is a geographic and economic region in the states of Coahuila and Durango characterized by a network of water boxes that extends over 6000 km^2 in valleys with deep and fertile soils to promote winter crops. The volume of water avenues that feed these irrigation systems fluctuates between 177 and 3,157 million m^3. Water from torrential downpours is diverted to fill these boxes up to 0.3 to 1m for a period of 20 to 25 days. The water is then released and moves by gravity to the next box and so on (figure 51.6) and thus serves to flood crop fields prior to planting. The water is directed via natural channels and water avenues. This irrigation method promotes water infiltration and water storage in the soil profile between weeks and months, for the development of fall/winter agriculture (Palerm-Viqueira/Sánchez-Rodríguez 2002). While this system favours mostly winter crops including cotton, wheat, lentils and grapes, recently the system has also been implemented for summer crops including strawberry, some vegetables, sorghum, corn, and beans. Unfortunately, the establishment of ejidos and building of dams negatively affected the use of the entarquinamiento irrigation systems; but they still exist in some parts of this region.

Figure 51.6: Image showing the 'water boxes' of the 'entarquinamiento' system, during the process of being flooded and emptied. **Source**: Photo was taken by Jacinta Pelerm Viqueira/Martin sanchez Rodriguez/ Elvia Lopez Pacheco/Jose lUis Pimentel Equihua/Herb Eling.

Another fundamental strategy to adapt to adverse climatic and environmental conditions is to maintain a high diversity of crop varieties, particularly for maize (Hernandez-Xolocotzi 1987; Muñoz-Orozco 2006). For instance, some Northern (from Matehuala, San Luis Potosí) drought adapted corn varieties now perform better further south (Northern Michoacán state), where reductions in annual precipitation have been observed (Muñoz-Orozco 2000). Other alternatives to adjust to drought include altering the planting ratio of beans and maize or adjusting the planting density of crops (Liverman 2000). In extremely harsh and dry years, some communities rely on traditional sources of food such as cacti, *Agave*, and mesquite fruits (Minnis 1991).

For semi-arid regions some technological programmes recommend the establishment of *Opuntia* orchards to profit from fruit or cladode harvesting. *Opuntia* is a native species in the Chihuahua Desert, adapted to low precipitation and unfertile soils (Mondragón-Jacobo/Fernández-Montes 2000). Additional adaptive alternatives for agriculture in rain-fed agriculture include mixed cropping with diverse seeding arrangements. These systems maintain productivity but help to reduce weed infestation, improve the space use, and reduce water losses compared to mono-specific crops (Arévalo-Valenzuela 2000). It is also advisable as an adaptation strategy to diversify with drought resistant crops such as sunflower, garbanzo beans, lentils, amaranthus, etc.

In addition to all these diversifying alternatives, practices such as organic farming, reduced tillage, and conservation mulching which are devoted to protect the soil surface are becoming the best alternatives to reduce soil erosion, ameliorate other factors such as soil temperature (e.g. soil surface temperatures exhibit up to 15 ºC difference between soil covered by litter and bare soil) and to cut back on CO_2 emission to the atmosphere (Valero-Garza 2000). Agroforestry systems on the other hand, also allow improving soil conditions through increasing soil organic matter inputs, carbon storage, nitrogen fixation, soil water infiltration, reduction of soil compaction, and increase in soil biological diversity, etc. These agroforestry alternatives for arid and semi-arid conditions include the incorporation of traditional crops (i.e. corn, beans, etc) combined with shrubby species (Atriplex, Prosopis, etc.) and the seasonal introduction of grazing animals (Del Rosario y Terrones-Rincón 2000). Finally, government emergency relief and temporary

subsidy programmes should provide temporary support to maintain human welfare in extreme situations.

51.4.2 Mitigation Options to Reduce Desertification in Northern Mexico

For the arid and semi-arid regions of Northern Mexico, government agencies dealing with agriculture are the *Secretaria de Agricultura, Ganadería, Desarrollo Rural, Pesca y Alimentación* (SAGARPA), with social development the *Secretaria de Desarrollo Social* (SEDESOL), and with desertification the *Comisión Nacional de Zonas Áridas* (CONAZA), that have developed mitigation strategies to help withstand drought and ecosystem degradation (box 51.3).

These strategies include planting of windbreak barriers and live fences, cross-slope physical or biological conservation work, agroforestry systems, development of germplasm banks, dam construction, run-off management, planting of drought resistant plants, reduced tillage, conservation mulching, crop rotation, composting, manure application, fallowing, soil salinity control as well as changes in land use patterns (CONAZA 1994; Lal/Kimble/Follet/Cole 1998; Lal 2002). Many of the strategies are designed to control deleterious effects associated with rain-fed agriculture.

However, many of these strategies need to be carefully tested and adapted to local environmental conditions and farmers needs (Hellin 2006). Integrated knowledge on ecosystem function is rarely used as the baseline for the development of mitigation strategies and alternative management options, however by supporting alternative soil management techniques (e.g. zero tillage or conservation tillage vs. conventional tillage) non-provisioning ecosystem services can be encouraged, such as soil C sequestration, that will ultimately benefit soil structure, soil water retention, and overall soil quality (Etchevers/ Prat/Balbontín/Bravo/ Martínez 2006).

When comparing crops with different tillage requirements for weed control, Osuna (1997) observed less soil loss in wheat which does not require weeding compared to corn and bean which require frequent weeding. For crops that incorporate alternative weeding technology such as disc plough a strategy to reduce soil erosion should consider maintaining permanent soil cover i.e. mulching.

Practices of integrated soil conservation are essential to maintain sustainable agriculture in arid and semi-arid regions. Carbon sequestration in form of *soil organic matter* (SOM) is advocated as a profitable win-win strategy for reclaiming degraded lands, particularly in semi-arid regions of the developing world, thereby mitigating global climate change, and improving the livelihoods of resource poor farmers (Tschakert/ Khouma/Séne 2004).

Also, the increasing number of abandoned crop fields in Northern Mexico could be back-converted to grasslands to reduce land degradation (Echavarría-Cháirez/Medina/Gutiérrez/ Serna. 2004) and promote multiple non-provisioning ecosystem services which will eventually positively feed back on the production systems in Northern Mexico.

Box 51.3: The GGAVATT (*Grupo Ganadero para la Validación y Transferencia de Tecnología*) model to implement sustainable farming technology in the aridlands of Northern Mexico. **Source:** Sánchez-Arroyo (2000).

In most small holder production systems in arid and semi-arid Northern Mexico, agriculture and livestock raising are tightly linked. For instance, in many locations basic crop (corn, beans) production for human consumption has been replaced by forage crops allowing the maintenance of large cattle herds which function as saving accounts for smallholder farmers. Under these circumstances peasants invest into increasing the size of cattle herds in spite of surpassing the carrying capacity of the land. Cattle are kept at very low energy-diet by feeding them with traditional forage crops (oat and barley) but also residues or complete crops of corn. During the regional shift from an agriculture-based to an animal-based production system in Northern Mexico most farmers failed to adopt an integrated management approach and to incorporate technology aimed at conservation farming, intercropping, etc. to achieve long-term sustainable productivity.

In 1990, the *National Research Institute of Agriculture, Forestry and Animal Production* (*Instituto Nacional de Investigaciones Forestales, Agrícolas y Pecuarias* (INIFAP)) implemented the model GGAVATT, to facilitate technology transfer to farmers via extension of specialists. The GGAVATT is a participatory approach where governmental institutions help producers to get organized in groups with similar production systems. The group defines production strategies which are revised by technical advisors, tested in demonstration plots and implemented if the technology turns out successful. The model was first introduced and tested in Southern Mexico with successful results in Veracruz and Tabasco. Now, the GGAVATT model is being evaluated in Northern Mexico, mostly in the states of Chihuahua and Durango with promising results. Although GGAVATT is a model to primarily improve animal production systems, the approach is integrated in that agriculture and natural resources are favourably impacted. In addition, the model has recently been adapted for agricultural systems although it has not been transferred yet to the semi-arid regions of Mexico.

Box 51.4: Dryland Development Paradigm. **Source**: Reynolds/Stafford-Smith/Lambin/ Turner II/Mortimore/Batterbury/Downing/Dowlatabadi/Fernández/Herrick/Huber-Sannwald/Jiang/Leemans/Lynam/Maestre/Ayarza/Walker (2007).

The *Dryland Development Paradigm* (DDP) is a framework that builds on earlier efforts to tackle desertification (definition: land degradation in arid, semi-arid, and dry sub-humid areas resulting from various factors, including climatic variations and human activities, UNCCD 1994a). Land degradation is present in 10 to 20 per cent of the drylands affecting an estimated 250 million people. The DDP recognizes those biophysical and socio-economic factors that favour land degradation in regions inhabited by the environmentally, socially, and politically most vulnerable population; this phenomenon has been identified as the 'drylands syndrome' (i.e. high climatic variability, low soil fertility, sparse populations, remoteness, distant voice). The DDP consists of five principles that integrate both earlier experiences and more recent efforts to tackle the dryland syndrome.

Principle 1. Dryland *human-environmental* (H-E) systems are coupled, dynamic, and co-adapting, so that their structure, function, and interrelationships change over time. These systems have no single target equilibrium point.

Principle 2. The critical dynamics of dryland systems are determined by a limited suite of 'slow' variables, both biophysical and socio-economic, that are critical determinants of H-E system dynamics. Slow variables have lengthy turnover times and are thus useful for gaining insights into long-term H-E changes, resource collapses, potential surprises. Fast variables on the other hand, exhibit rapid turnover times that introduce noise, therefore are poor indicators of land degradation or the need for intervention.

Principle 3. Slow variables possess thresholds and define different states of H-E systems that, if crossed, cause the system to move into a new state or condition. Thresholds may change over time, and so may also the underlying controlling processes responsible for thresholds.

Principle 4. The involvement of multiple stakeholders, with highly differing objectives and perspectives illustrates the need to pay attention to the multilevel, nested, and networked nature of H-E systems across multiple spatial and temporal scales.

Principle 5. The key to maintaining functional co-adaptation of coupled H-E systems is an up-to-date body of 'hybrid' environmental knowledge that integrates local environmental knowledge including management and policy experience with science-based knowledge, all of which must be mediated through an effective institutional framework.

There are two principal goals that the DDP pursues; i) one is conceptual and related to providing a holistic synthesis of the diverse lessons learned from previous studies and experiences on desertification and development, and ii) another goal is practical in that the framework can be applied and tested in specific case studies, where each of the five principles can be thoroughly examined for identifying the underlying causes of land degradation, mitigating land degradation, and restoring degraded land.

51.4.3 Decision Support Tools

Currently farmers, producers, and technical support do not have available a comprehensive guidebook or decision support tools for long-term sustainable integrated management of highly vulnerable production systems. However, this is urgently needed considering the increasing number of unpredictable, extreme climatic and land degradation events. In reality, to stop land degradation, poverty and out migration, the complexity of causal interacting biophysical and socio-economic drivers that act at varying spatial and temporal scales, have to be considered simultaneously.

Hence, the *Drylands Development Paradigm*[3] (DDP), an integrated framework, was developed for the holistic analysis and development of highly vulnerable drylands of the world, where drought, poverty and desertification affect the livelihood of their peoples. This DDP addresses precisely this complexity of nonlinear relationships, interactions, and feedbacks between the socio-economic and biophysical dimension of the problem. Hence, it could serve as an excellent tool to first identify the multiple causal interrelationships leading to desertification and then by merging different knowledge systems (box 51.4) to analyse potential long-term solutions and alternatives to substantially improve the livelihoods of people in

3 See for details: Reynolds/Stafford Smith (2002) and Reynolds/Stafford-Smith/Lambin/Turner II/Mortimore/Batterbury/Downing/Dowlatabadi/Fernández/Herrick/Huber-Sannwald/Jiang/Leemans/Lynam/Maestre/Ayarza/Walker (2007).

Northern Mexico who depend on one of the world's most vulnerable farming systems.

51.5 Conclusions

Drylands in Mexico comprise almost half of the country's area. The natural and agricultural ecosystems characterizing these arid regions represent a large proportion of the biological richness of the country. In spite of natural limitations for the development of agriculture, both irrigated and rain-fed agriculture have developed at large scale due in part to the high human population it has to sustain. As an arid environment recurrent drought is one of the challenges farmers have to face with increasing frequency.

The future of agriculture in the drylands of Northern Mexico under current GEC scenarios is uncertain for irrigated and rain-fed agriculture. One principal cause of this uncertainty is linked to the unavoidable and yet highly unpredictable regional effects of climate change as they may be expressed by increasing temperatures, reduced precipitation, and higher frequency of torrential storms and other extreme events (long periods of drought). All of these factors are expected to provoke severe erosion and continuous nonlinear loss in soil fertility, and soil water recharge capacity, and ultimately in the collapse of agricultural systems which are the fundamental life-support systems in the drylands of Mexico.

Impoverishment of agricultural soils and degradation of natural resources trigger poverty, jeopardize food security and human health and consequently exacerbate the downward spiral of degradation of the human environment systems. However, the continuous advance in degradation of natural and social systems in the rural areas of Northern Mexico is not only related to direct effects of overexploitation and climate change. The complexity of these systems is rooted in the dynamics and multilevel interactions within and between biophysical and socio-economic drivers and processes that may be acting at various temporal and spatial scales, and thus be favouring strong yet unexpected feedbacks enhancing degradation at even larger scales.

International, national, regional, and local policies affect agricultural decisions in Northern Mexico. A change in the international livestock market has promoted cattle production even in the marginal ecosystems of arid Mexico. The NAFTA trade agreements have caused the abandonment of traditional crops and the promotion of fewer but more profitable crops (in this case produced with irrigation agriculture) and livestock production. Even well intended national government subsidy programmes (ex. PROCAMPO) for smallholder farmers have accelerated soil degradation. This is an example where environmentally friendly conservation practices derived from traditional agricultural knowledge that helped to protect soil surfaces and incorporate organic matter, have been substituted by the use of tractors, mechanized tillage, and use of chemical fertilizers. At the household level, the economic support from immigrants through remittance has also favoured the adoption of agropastoral production systems, further enhancing land degradation.

Given the high uncertainty with respect to the future outlook of agriculture in the drylands of Northern Mexico, the development of alternative adaptation strategies are paramount as baselines for long-term integrated and sustainable natural resource and ecosystem management plans. For the strategies to be successful und functional, their development has to consider all potentially involved stakeholders from local, community (ejido), municipal, state, national, and international institutions. Thus, strategies for adaptation may include diversification options, strong consideration of traditional or novel local environmental knowledge in addition to expert knowledge, guidelines on how to cope with global markets, how to open regional markets, evaluate the ecological and socio-economic impacts of subsidies, and powerful tools and indicators to identify and combat drivers leading to degradation. Converting desertification in sustainable dryland development in Northern Mexico is an enormous challenge. It has to be tackled as a mutual responsibility by all directly and indirectly involved, and these efforts will hopefully emerge in novel opportunities to secure the long-term livelihood of the people living in this part of the world.

52 Traditional Knowledge in Coping with Desertification

Pietro Laureano

52.1 Rural, Urban and Cultural Desertification

The misuse and the overexploitation of resources are the main causes of desertification which according to the United Nations Convention is defined as: "deterioration of the lands in the arid, semiarid and semi humid dry areas due to different factors including climate changes and human activity" (UNCCD 1994, article 1a, 1995, 1995a). The definition highlights two fundamental aspects of desertification: a) desertification is not the creation of a desert but of soil degradation; and b) human intervention is a fundamental factor besides the role of climate conditions.

Therefore desert and desertification are two very different things. The desert constitutes a precise environmental model that occurs in a specific climatic context with its own laws, biological activities, and an appropriate human use. Desertification produces an environment in full decay and totally devoid of ecological balance. The difference lies in a specific variable: time. The natural establishment of the desert has followed the very long geologic times enabling the species to follow the changes with a process of transformation and evolution, and therefore allowing the creation of environments that in spite of the harsh climate are rich in adaptation and in the biodiversity of the species.

On the contrary, the processes of desertification and the climate changes triggered by human intervention are rapid. The biological and physical structure of the planet has not had time to adapt to them, resulting in desolation and decay. A socio-economic and cultural degradation corresponds to the physical one. Poverty, emigration, and the loss of identity cause the disappearance of the cultural heritage related to the knowledge and management of places.

In order to understand the desertification phenomena the key factor is the soil (Rubio 2002). In geology what is commonly defined as soil is the superficial layer of the earth's crust where the organic and inorganic components mix together, swarmed with bacteria, worms, and other micro-organisms (Bennet 1939). The intense biological activity turns it into humus, a colloidal compound saturated by organic substances deriving from the decomposition of animal and vegetable waste. It is the soil that makes plant life possible, the presence of which is so common in temperate areas that it is taken for granted. Life is instead the complex result of the continuous interaction between chemical, physical, and above all biological factors and, besides protecting the soil, it ensures its constant regeneration. Vegetation, and in general all biological activity related to the availability of water and to climate conditions, determine the soil features and constitute the prior conditions for the existence of topsoil. Seeds can put down roots in the soil and derive sustenance from it. For their part, plants protect the humus and ensure that it is constantly regenerated, thanks to dry cast-off plants. Surfaces which are bare of vegetation are exposed to the harsh atmospheric agents, to the brutality of erosion which crushes the rocks and produces sand. All of this in turn reinforces the erosion factors and worsens the drought in that hard silicon particles are blown away by the wind, thereby becoming an abrasive force which can destroy even the hardest of rocks. Sand contributes to the disappearance of running surface water by settling in and filling up river beds, thus forcing the water to change its course and to become stagnant over vast surface areas where the water can evaporate or seep below ground.

This is how the constantly increasing degradation circuit of desertification is triggered. Soil, water, and vegetation are interconnected in such a close way that the absence of any of these factors can cause the absence of another factor with a multiplying effect. Interfering with each one of these components triggers the desertification process that may occur under all climate conditions, but will variously develop depending on the ecosystems' degree of vulnerability (Safriel 2007).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_52, © Springer-Verlag Berlin Heidelberg 2011

Thus, it may be asserted that even the desert can undergo a process of desertification. Precisely in the environments with a more critical and difficult balance, characterized by a strong interaction between the processes, each intervention from the smallest to the most macroscopic one may produce lasting devastating effects. In the Sahara the traces left by vehicles during the Second World War are still evident on the characteristic microvegetation of the soil that sixty years later has still not recovered. In general the environment reacts to the roughness of the seasonal differences and to the cyclical climate alterations. Once the period of crisis has passed, the environment has the potential to return to its initial situation. Because of overexploitation due to human action, which intensifies its destructive activity against the species and the residual varieties just when the resources are becoming rarefied, any capability of recovery disappears even when the favourable conditions have been re-established.

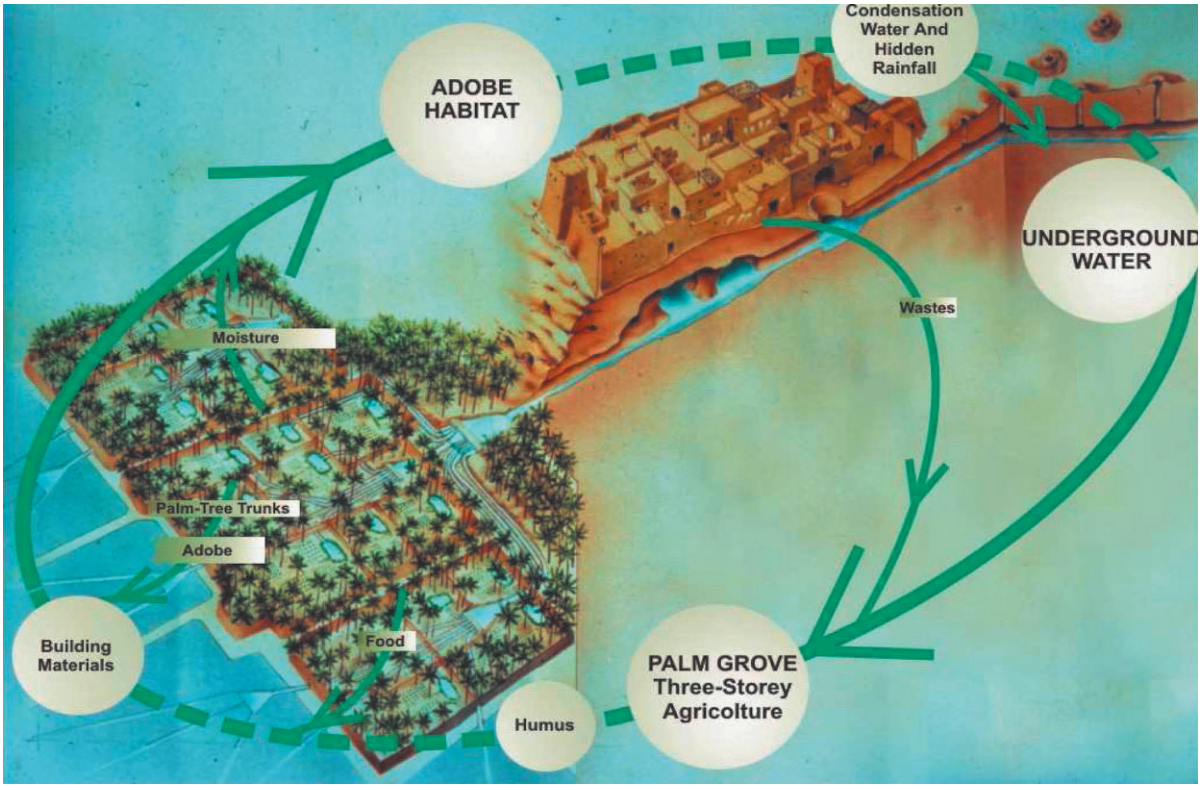
In the agricultural environment the process manifests itself through the following phenomena: water erosion with the creation of cracks and fractures, loss of fertility, alkalization and salinization of the soil; destruction of the humus; disappearance of the plant cover; formation of sand, mud and calcareous layers; exhaustion of the aquifers and drought; decay of the slopes and landslides. The chemical and physical degradation of the soil, induced by biological and physical mechanisms, reduce the vegetation and the original bio-productivity disenabling any kind of use. In the Sahel zone in the Sub-Saharan area, these processes start in a climatic area that receives more than 200 mm of rain per year, and also in a deeper strip in the south where the rains may reach 800 mm per year, i.e. areas that cannot be properly defined as desert. It is estimated that in these countries one million hectares of tropical forests are destroyed and 100,000 hectares of soil are irremediably covered every year with the advance of the sands produced by wind erosion. In Africa, altogether more than one billion hectares have been damaged by this phenomenon. Millions of people have been forced to emigrate elsewhere (Renaud/Bogardi 2006: 24). In Mali and Burkina Faso one sixth of the inhabitants have been forced to abandon their villages. In Senegal two fifths of the population of the upper valley of the homonymous river have been forced to emigrate. Mauritania is invaded by the sands. Here, the population established in the capital, Nouakchott, has increased from 9 to 41 per cent in twenty years, while the nomadic groups have fallen from 73 to 7 per cent (UNCCD 1995). Therefore, non-natural factors trigger an environmental mechanism of degradation which must therefore be ascribed to a single factor: human intervention. The process affects subtropical as well as temperate areas (Brandt/Thornes 1996; Mairota/Thornes/Geeson 1998).

While the traditional landscape with its small plots of land surrounded by dykes and ditches, tree rows or stone and mud walls, constitutes the optimal defensive device against weathering, the industrialization of agriculture based on heavy machinery needs vast homogeneous surfaces. The transformation into a monoculture also involves the slopes, the marginal and karstic areas where the natural harshness and vegetation provided shade, biological richness, and protection from erosion. Chemical addictives like pesticides and fertilizers transform the soil which becomes waterproof. Maintaining the aquifers becomes impossible and agriculture becomes increasingly dependent on artificial irrigation through the construction of big hydraulic basins.

The demographic growth, the abandoning of archaic techniques and social habits even though they were in harmony with the environmental potentials, as well as the imposition of new crops according to the requirements coming from the world market and the dissemination of the monoculture, are only some of the causes of degradation. Above all, the settlement of people gathered in small areas, according to the necessity of the modern economies, causes the increase in energy demand, which is satisfied with a massive devastation of the arboreal and forest heritage. The wounds inflicted on the woods trigger processes of continual and substantial collapse of the biological variety, quality, and productivity. Animals and plants are decreasing and the number of species is falling so much that they are no more able to provide a genetic answer to the altered circumstances, and are therefore destined to disappear.

Also the urban areas are affected by desertification. In fact cities contribute both directly and indirectly to the process. Directly, the massive urbanization may be considered in itself a form of desertification due to the spread of concrete over large natural surfaces; but also indirectly through the absorption from the soil of the natural resources and their destruction in the areas with a high demographic concentration. A close relationship between urbanization and desertification may be found both in the non-industrialized countries and in the most developed ones. In the first case, the process of decay is triggered and extends starting right from the areas undergoing a modern and accelerated urbanization

Figure 52.1: The traditional oasis ecosystem. **Source:** Pietro Laureano (2001: 372). The oasis is a self catalytic system in which the first supply of water condensation and moisture is increased by the installation of palm trees which produce shade, attract organisms, and form humus. The palm grove determines a humid microclimate fed by hidden precipitations, water condensation, and underground drainage through the underground passageways of the foggaras. The adobe habitat does not waste wood for firing bricks, it is kept cool by the underground water passageway and provides waste to fertilize the fields. The system runs the water resource in a cycle of use which is not only compatible with the renewable quantities available but also increases them.



which impoverishes the surrounding territory. In the advanced economies the spread of the process of desertification is directly linked to the crisis of the historic city centres and the traditional arrangement of the landscape. The building systems that have a strong natural component and low consumption of resources have been substituted with a model based on massive building operations that waste energy and pollute the environment.

Thus, a process of physical and social desertification begins with the exodus of the population from the ancient centres and the consequent disappearance of the local systems. The impoverishment of the human resources corresponds to the architectural decay and to the erosion of the mountain, hilltop, and slope systems. Emigration, the loss of identity and values, are associated with the socio-cultural aspects of desertification.

52.2 The Knowledge of the Desert

The aridity of the desert is interrupted in specific cases that create niches and microenvironments that contrast with the general situation. A slight depression collects dampness, a stone shade and seed flourishes. Thus, favourable dynamics develop: the plant generates its protection from sunbeams, concentrates water vapour, attracts insects, produces biological material and the soil which nourishes it. A biological system used by other organisms bringing their contributions is created, and a microcosm is generated as the result of their coexistence. By using these processes people from the Sahara have developed oases. Originally, a single palm tree is planted into a hollow in the ground and surrounded by dry branches, which protect it from sand. As the time goes by, large tilled fields develop along terraced canyons or on green archipelagos among the dunes, thanks to complex and

diversified techniques of water production, territory arrangement, and microclimate formation. An oasis can be defined as a "human settlement living in harsh geographic conditions and exploiting rare local resources, to trigger a growing amplification of positive interactions and fulfil a fertile and self-sustainable environmental niche, contrasting with its hostile surrounding" (Laureano 1995: 24–25).

Therefore not only the palm groves constitute the oasis but the entire landscape formed by the habitat and all the architectural and environmental components. The organization of the ecosystem was realized by the people of the desert through the use of traditional techniques that consist of:

> practical (instrumental) and normative knowledge concerning the ecological, socio-economic, and cultural environment. Traditional knowledge originates from people and is transmitted to people by recognizable and experienced actors. It is systemic (inter-sectorial and holistic), experimental (empirical and practical), handed down from generation to generation, and culturally enhanced. Such a kind of knowledge supports diversity and enhances and reproduces local resources (UNCCD 2005: 109).

The way they are applied differs totally from modern technologies (table 52.1).

Table 52.1: Characteristics of modern and traditional knowledge**. Source:** The author.

Modern Knowledge	Traditional Knowledge
Specific solution	Multifunctional
Immediate efficacy	Functional over a long period
Specialization	Holism
Dominant powers	Autonomy
Separation	Integration
External resources	Internal inputs
Confliction	Symbiosis
Monoculture	Connection and complexity
Uniformity	Diversity
Inflexibility	Flexibility
Costly maintenance	Self-regulation and intensity of work
Internationalization	Consideration of the context
Costliness	Saving
Attention to mere technical details and rationalism	Symbolism and full of significance
Dependence	Autopoiesis

These in fact seek immediate effectiveness through a deep specialization of knowledge managed by dominant structures capable of involving resources external to the environment. Traditional knowledge measures its functionality in the long run using a shared knowledge that was created and passed on from generation to generation through the social practices, and uses internal renewable inputs. Thanks to modern technology, for instance, very deep wells have been dug out to pump water up to the surface. The results have immediately been visible, but have dried up bordering resources, and sometimes by drawing water from fossil pockets, with time they completely exhaust them. On the contrary, traditional knowledge uses systems for harvesting meteoric water or exploits run-off areas by using the force of gravity or water catchment methods, like the drainage galleries, allowing the replenishment and increasing the durability of the resource.

Modern technological methods operate by separating and specializing, whereas traditional knowledge operates by connecting and integrating. According to the usual meaning of words such as *forest*, *agriculture* and *town*, they are completely distinct from each other and meet similarly different needs: *wood*, *food*, and *housing*. They correspond to specialized scientific systems: Silviculture, agriculture, and town planning. Local knowledge does not make an artificial distinction within the world of plants between the forest supplying commercial wood and tilled land supplying food (Shiva 1993a: 18). Forests, fields, and dwellings are unitary ecological systems. Forests and other marginal apparently non-productive areas, such as steppes and marshes, provide large quantities of food and water resources, and fodder and fertilizers for agriculture. They are also convenient to live in. The traditional town, in its turn, integrates with agriculture by replacing the forest in desert areas, by collecting fertilizers produced by the inhabitants' organic waste, and through its production of water collected on the roofs. This principle is so close to the way in which nature works, where everything that remains of a system is reused by other systems and the concept of waste and the possibility of resorting to external resources do not exist. It has allowed human beings to survive throughout history and is today proposed again by the modern theoreticians of sustainability (Pauli 1999).

By this logic, to the strong cohesion among society, culture and the economy, also aesthetic and ethical values are added. Traditional procedures operate a harmonious fusion between the landscape and the tra-

ditional aesthetic canons. A device for collecting or conveying water is never merely a technical structure but also has its own beauty. Fields in the oases are systems of production and relaxing places for contemplation as well. Little agricultural fields in desert areas are called *gardens,* just as in Southern Italy, eliminating the separation between the vegetable garden and the pleasure garden. Often, the works and procedures have a deep symbolic meaning and are a continuous game of suggestions and analogies between techniques, art, and nature. Systems of water distribution in the Sahara are reproduced in carpet drawings and in women's hairstyles. They are part of a complex symbolism linked to life and fertility. Spiritual principles make rules sacred and guarantee their perpetuation as in the case of the African sacred woods with their restricted access and of the whole set of taboo-objects, practices which guarantee the regeneration of forests, the saving of environmental resources and the land as reserves for nature and human communities.

Therefore, traditional techniques are an integral part of a strongly consolidated network of links and relations, supported by a global framework of signs and meanings. They work within a socially shared cultural structure: the historical system of science and local knowledge. It is therefore wrong to isolate each single technology, which is always highly contextualized, not only linked to an environmental situation, but to a precise historical moment and a complex social construction. The totality of traditional practices for managing resources constitutes the mediation through which a certain social form interacts with nature in realizing its technological dimension, an integral part of its cultural complexity, and view of the world. Thanks to this knowledge populations are able to gain greater resources from the environment compared to the ones naturally offered. Both factors, the cultural dimension and the environmental conditions, change continually in time and from place to place, thus creating and amplifying the cultural diversity.

52.3 Validity, Innovative Use, and Integration with Advanced Technology

The validity of traditional knowledge and the use of practices derived from it, variously named as endogenous knowledge, appropriate technologies, local knowledge, indigenous techniques, nature-based knowledge, sustainable knowledge, folk knowledge, and cultural knowledge (Gupta 1989; Warren/Rajasekaran 1993; Tahoun 2003), have been asserted for many years at various levels. In the scientific field, research on traditional knowledge has been implemented for more than twenty years with the specific aim of overcoming the top-down approach to the transfer of technologies as well as the problem of achieving a participatory relationship able to foster sustainability (Brokensha/Warren/Werner 1980). Many international bodies such as the *International Labour Organization* (ILO) (Bhalla 1977; ILO 1985), the *Organisation for Economic Co-operation and Development* (OECD) (Jequier/Blanc 1983), the *Food and Agriculture Organization* (FAO) (Saouma 1993), the *United Nations Educational, Scientific and Cultural Organization* (UNESCO 1994, 1994a, 1994b), the *United Nations Environment Programme* (UNEP) (Dowdeswell 1993) and the *World Bank* (Vernon 1989; Davis 1995) have declared its validity in research and documents. The interest of the United Nations' conventions is clearly highlighted in the report entitled *Building Linkage between Environmental Conventions and Initiatives* (UNCCD 1999).

Despite this full commitment and interest, the fields of application and the innovative dissemination of traditional knowledge are still below their real potential, the reasons may be summarized as follows:

- The lack of awareness that environmental damage, soil degradation, and desertification mostly result from the loss of traditional knowledge;
- The lack of information as to the validity and benefits of traditional knowledge from the experts responsible for national planning;
- The limited understanding of the role to be assigned to traditional techniques and their way of operating;
- The lack of communication and exchange of successful experiences;
- The unawareness of the innovative use of traditional knowledge.

It is necessary to clarify the modalities of use, the validity, effectiveness, the innovative force, and the possibility for integration of the traditional technologies with the modern ones.

52.3.1 Multifunctional Use and Cultural Integration

Traditional knowledge as an integrated learning organization constitutes a complex system with multifunctional characteristics and an integral part of the construction process of the collective identity as well

as of social cohesion. The rice cultivations in the Philippines and Indonesia which cover the mountain sides with an extensive system of terraces constitute a wonderful landscape created by the people. The beauty of these terraces does not result from aesthetic choices but depends on the harmonious application of the traditional engineering techniques in order to organize catchment areas, gather flowing waters and rainfalls, create terraces on which flows are channelled, and preserve the ground from washing away or eroding.

Traditional techniques relating to water management in the Ladakh region in India are another example. These enable fertile mountain oases to be created in otherwise arid lands. The techniques for using the water resources provided by seasonal snow melting are based on a system of rights and rules closely linked to the social structure, to the norms regulating the traditional division of work between sex and age groups, as well as to the ecological situation of each oasis village. The great social cohesion and spiritual motivation has enabled these people to apply modern techniques such as methods for using solar energy, in harmony with their ideals, and to reject others such as chemical fertilizers regarded as harmful for the soils (Wacker 1997).

52.3.2 Technological Effectiveness and Productiveness

Traditional technologies are not less competitive than modern ones. They achieve results differently and consider a series of contextual factors omitted by modern techniques. The procedure is sometimes less immediate and needs more work. However, this is not a negative feature in many countries that face the problem of unemployment. Indeed, the application of a technique determines effects both before and after the use of the necessary resources and has more general consequences on the entire economic, social, and environmental model. These interactions are not taken into account in the application of a modern technique based on specific and immediate yield criteria. On the contrary, traditional techniques are selected and accepted through a process of environmental, historical and social considerations, appraised according to their validity in the long term, their contextual benefits, and their overall sustainability.

Failure to evaluate these aspects has led to unsuccessful projects for development cooperation which have not taken into account the necessity of proposing technologies that could be managed through the local knowledge system and the social categories, mainly women. Within this framework, the case of the irrigated perimeter of Ras Djebel in the northeastern part of Tunisia, 30 km from Biserta, is a significant example. Here a traditional kind of cultivation is applied, following the oasis model and the Maghrebian and Andalusian models of arboriculture and vegetable gardens. Fields are divided into small plots according to complicated procedures of inheritance and marriages that continuously divide and re-compose the properties. In this way, 2,000 hectares of land can be divided into 4,500 plots. Traditional irrigation is carried out through harvesting subterranean waters by means of family-managed wells or irrigation, thanks to superficial channels running all over the agricultural area. A project aiming at modernizing the system created a 15,000-m^3 tank, fed by a lake located on a hill. The agricultural perimeter was then subdivided into larger parts, each supplied by a modern water drawing system that irrigates large areas by sprinkling. Such a perimeter involved the removal of small property boundaries. The peasants distinctly rejected the new division of the plots and the new methods of irrigation on the basis of social, productive, and symbolical reasons which can be summarized as follows:

- The use of family wells enables each owner to manage his own water independently. Such water was previously free whereas there is a charge for the water provided by the project.
- The division of small land plots responds to ancestral structures which extend the domestic space into the agricultural one. In this way, women can work in the fields and at the same time feel at home.
- Irrigation through sprinkling is considered negative since it 'favours the burning of the leaves and the appearance of new diseases'.
- Groundwater is commonly considered as 'alive since it originates from the earth and feeds the plants', in opposition to the water of the project which is held as 'a dead water coming from a stagnant basin and thus harmful to agriculture'.

Despite these oppositions, the project was carried out with disastrous consequences. Indeed, after the project was implemented, a 20-meter lowering of the water table as well as a 3 g/1 increase of salinity were verified (Bouayard-Agha 1997: 22–23).

52.3.3 Validity and Application

Traditional techniques are generally considered valid only for the less developed economies. This stance is contradicted by the fact that situations in which traditional technologies persist, and their role in the economy and society is consolidated and stabilized, can be proved specifically in the more advanced countries. The values of tradition, manufacturing practices, and the craftsmen's skills are the basis on which the great added value of economically important productions for many advanced countries is founded. In particular the typical food production (oil, cheese, wine, etc.) safeguards both the aesthetic and environmental quality of the landscape, since the old production systems are available thanks to the maintenance of traditional soil management techniques, as for instance is the case of the regions of Valais in Switzerland, the Loire Valley in France, and Tuscany in Italy. Thus, it is wrong to consider traditional knowledge as marginal compared to the great economic and technological processes under way. Even from a quantitative point of view, their use still supports most of humankind which is distributed throughout the less industrialized countries. Paradoxically, in these places where traditional techniques are still used in a massive way, these are considered by the modernist thought as a phenomenon of backwardness, whereas, in advanced countries, they create an image and provide added value. Tradition is then a fundamental component of successful modernity and creative industry. Traditional knowledge constitutes a dynamic system capable of incorporating innovation valued through local wisdom: today's appropriate innovation is tomorrow's tradition.

52.3.4 Paleo-technology and High Technology

Traditional technologies do not have less technological consistency than the modern ones. Sometimes they are the most refined technologies, other times they are very simple but still more appropriate, that is ecologically compatible and locally manageable. Furthermore, traditional knowledge is re-proposed through every possible innovative use that is in conjunction with modern technologies, which can operate within the same logic. In the moist areas to the west of Calcutta, the traditional fishing and agricultural practices cover approx. 10,000 ha of territory. Here the world's largest network of urban sewage water re-use is in use. Thousands of peasants convey millions of litres of sewage water from Calcutta towards their land. They consider these waters as an advantageous nutrient supply and not as something harmful they should get rid of. At the same time, they provide an extraordinary contribution to the waste water drainage system of Calcutta completely free of charge.

In Liguria where in the Cinque Terre region there is one of the largest systems of *terraced slopes* in the Mediterranean, this traditional practice that protects the soils, and catches and channels the waters, has been perpetuated through innovative agricultural mechanization. Agricultural work on terraces is hard due to tiring transport systems which are operational only on foot. Traditionally there were techniques of transport by means of sledges drawn up the hill by ropes. Already at the beginning of the century these were substituted with mechanical funicular systems on rails. The same technique is re-proposed today with appropriate *monorail* systems that enable the ascent of the slope without disturbing the landscape or the ecosystem.

In Burkina Faso *zai* is a particular traditional technique able to regenerate highly degraded soils. The soil is dug with holes that fill up with water in the humid season and are used as dump sites for rubbish and manure in the dry season. This practice attracts termites that digest rubbish, thus its absorption by the plants' roots. Furthermore, the tunnels dug by the termites increase the soil's porosity. Seeds are then sown in the holes, giving very high crop yields. Innovative practices which promote original forms of symbiosis between humankind and animals or micro-organisms are today re-proposed to rehabilitate degraded soils or soils made suitable for human living in extreme areas.

52.4 Knowledge from the Past for a Sustainable Future

The enormous hydraulic resources deriving from the river basins of the Nile, Mesopotamia, the Indus, and river systems of China, determined the formation of the great empires that have been defined by Karl August Wittfogel (1957) as *hydraulic societies*. The socio-economic model is the one of an increasingly expanding empire supported by a massive population growth triggered by the agricultural potential and maintained by an imperial conquest, the income coming from the exploitation of a vast quantity of workers and by spending resources on monuments or wars. The long term results of this are the hypertrophy of the population and of the territory, authoritarianism, state cen-

tralization, and the increasing destruction of the environment leading to an ecological catastrophe.

Within the great empires, in marginal areas with scarce resources, or in the fringes of the empires in protected areas, oases and cities were created in inaccessible places and transformed into self-supporting centres. These *autopoietic societies* use the gathered experience of traditional knowledge and become centres of innovation for the amplification and proper use of local resources. This is the way the desert communities were organized and in general those societies often based on hydraulic systems, those which developed in harsh natural conditions (Laureano 2001).

The geographical continuity of the desert areas, extending from China to the Mediterranean and Africa through the three most ancient continents, favours the elaboration of appropriate solutions through the exchange and increase of knowledge.

Complex ecosystems are created based on the use of the local resources, but which assume a larger dimensional scale by exploiting their position to control the trade routes and convey huge economic incomes. This is how the fantastic hydraulic and soil management systems were realized in Petra (Jordan), and in Marib (Yemen), ancient capitals of the Arabic desert now only archaeological remains, and in the Saharan oasis-towns such as Ghardaia that are still intact and vital. The ever increasing effort to organize space depended on the economic benefits ensured by the role undertaken within an international exchange economy: the caravan gold routes in the Sahara, the incense route in Arabia, the silk route in Palestine and in the East.

The community's acceptance of the necessary tasks for preserving the geographic positions depends on delicate environmental, economic, and cultural equilibria. When even only one of the aspects of the holistic conception of the world or a ring in the chain of the resource management is missing, the entire system is destined to collapse. This is the cause for the collapse of various ancient civilizations, a current issue today because of the menace represented for contemporary society by climate change (Mays 2007; Diamond 2007a)

However, the knowledge is not completely lost. It survives among the populations living in the apparently undeveloped areas or the interstices of the advanced society and the places protected for their cultural value. Knowledge is a great potential because the local know-how, which improves under the harshest environmental conditions, and the existence of intact ancient structures are a valuable heritage on which new models of sustainability have to be based. The historical settlements, the traditional landscapes, and the local knowledge provide solutions to be safeguarded and which can be re-proposed, adapted, and renewed by means of the modern technology. It is not a question of reapplying or transforming the single procedures but rather of understanding the logic of those models which have allowed societies to positively advance their status and to make technical, artistic, and architectural implementations, fundamental in the history of the civilizations. Knowledge about the most distant past can lead to the founding of new technological paradigms: the capability of enhancing the inside resources and managing them at a local level; the versatility and the interpenetration of technical, ethical, and aesthetic values; the production not per se but for the good of the community and based on the principle according to which each activity has to start up another one without waste; and energy use based on cycles in constant renewal.

53 Prodromes of Desertification in the Oasis of Tafilalet (Morocco) and Specific Local Solutions

Monique Mainguet, Frédéric Dumay, Lahcen Kabiri and Boualem Rémini

53.1 Introduction

Although a few natural oases exist – for example the tufts of Doum palm trees in the Egyptian desert – the majority of the oases are human creations where humankind adapted to climatic fluctuations and preserved balance between its activities and the environment, until the 1950's. Then climatic fluctuations occurred, which were noted through systematic weather measurements and recurring droughts in the North and the South of the Sahara.

Trying to make an inventory of the specific features of desertification in oases, the authors concluded that it was a hopeless endeavour because the causes, the mechanisms, and the manifestations of desertification seem not to be specific to these areas. Thus, desertification has become a planetary phenomenon in dry ecosystems.

Despite the abundance of more than 150 definitions and confusion between desertification and desertion, the term 'desertification' is used in this chapter with the meaning adopted by the United Nations: "The degradation of the grounds in the arid, semiarid regions and subhumid dry in consequence of various factors, among which climatic variations and human activities." But this definition is insufficient if it is not specified by two other assertions: the adaptability of humankind and the irreversibility of environmental degradation (Mainguet 2003).

Mechanisms of evolution that required several millennia to reach observable thresholds of transition have accelerated in the middle of the 20th century, resulting in a change of scale of time. Thus, within one or two generations a third generation of dunes appeared in the North and South of the Sahara that have been exceeding the capacities of the people in the oases to adapt. The acceleration of these processes requires to replace the concept of desertification in a time scale, by stressing that since the 1950's – thus within half a century – a shift in the speed of evolution processes has occurred. Now desertification refers to inadaptability of human activities with regard to these new geomorphologic rhythms of evolution given these new environmental data.

Starting from a low degree of degradation at the beginning of the 70's, the irreversibility has now become so severe that it is not any more economically profitable to even try rehabilitation as the threshold of desertification has been crossed. When degradation transgresses the stage of a deterioration of the vegetation cover and results in the impoverishment of the soil due to water and/or wind erosion, and chemical impoverishment, the stage of irreversibility has been reached. The soils in the oases are sandy and thus vulnerable. However, after two years of good rains, new feather grasses grew at the top of palm trees that appeared to be dead, thus the degree of irreversibility had not yet been reached, as the new palms indicate.

In this chapter, the authors analyse in a case study the fight against the exodus from the Oasis of Tafilalet in Morocco. After an inventory of environmental degradation which can reach the threshold of irreversible desertification (53.2), the second part will discuss the adopted measures to combat desertification that were developed by the people in these oases (53.3), and it will address those questions which the people in the oases have tried to cure. The conclusions address the difficulties which have to be overcome (53.4).

Our purpose is to bring in these analyses descriptive and objective case studies and to avoid the theoretical and political context and to contribute, with as few interpretations as possible to enlighten, the local perception of the 'prodromes' of desertification (first signs) and the first popular efforts to combat them. We also try to base our first considerations more on up-to-date observations and interviews than on scientific literature.[1]

53.2 The Oases of Tafilalet and Their Many Difficulties

The living conditions have been severely degraded in the oases of Tafilalet within one generation. Some 20 years ago, the situation of the oases of Morocco (figure 53.1) was described as being in 'crisis'; it has now reached the situation of 'dangerous struggle for survival'. An inventory of the many environmental and social difficulties in the oases of Tafilalet (figure 53.2) was made during two missions of three weeks each by relying heavily on the villagers and the village associations.

According to the numerous classifications of desertification and to avoid scattering, we proposed to classify the events producing desertification in three rubrics: 1. natural events (changes in climate, mainly drought); 2. anthropogenic deterioration – overuse, overgrazing and 3. psychological mechanisms.

This chapter is partly a follow-up of the conference organized by the University of Errachidia (Morocco) in September 2006 on "*Avenir des oasis face à la désertification*" [The oases facing desertification]. The combination of these environmental observations and the human data was carried out within the framework of the NATO Programme on: "Use of indicators for desertification in oasian settlements." The first part discusses the three problems of the oases of Tafilalet: a) sand encroachment (53.2.1), b) the severe water deficit (53.2.2), and c) the difficulties of social change (53.2.3).

53.2.1 Sand Encroachment: A Recent New Danger

Statements that were collected in the oases document a recent threat which is not yet perceived as a major danger. Although sand encroachment is omnipresent, it only worries the people in the oases during the genesis of sand dunes when sand is present in their houses and dust causes eye problems.

Figure 53.3: The road from Errachidia to Erfoud crosses the 'corridor of Yerdi', a strip of intense sand transit where the road is regularly covered by sand. **Source**: © Photo taken by the authors, F. Dumay and M. Mainguet.

When the authors drove on the road from Errachidia to Goulmima (figure 53.2) they observed a powdering of sand only 17 kms away from the town of Errachidia on the slopes of small hills, as well as many sand deposits accumulated in the lines of concentrated rill wash. *Sif* (linear dunes), fastened on a slope of hill, worked by the Sahéli wind, appeared at the end of 2004. The *nebkas*[2], another tangible proof of wind transport, directed SW (230°), confirm the effectiveness of the *Sahéli* wind and the extent of the volume of the blowing sand which advances forward on the *hamadas* (limestone plateau), vast surfaces of deflation. These *hamadas* are difficult to take in account in the strategies to combat desertification because they are the grazing areas for the pastoralists who don't wish to see obstacles to their displacements.

In Tafilalet, strips of mobile sand exist, like the so-called '*corridor of Yerdi*' (figure 53.2), where the dunes threaten a portion of the road between Errachidia and Erfoud (figure 53.3).

In 1981, the Moroccan National Forestry Commission launched a project of mechanical fixation of dunes 'by checkerboarding' (squares of palisades) that was accompanied by a biological programme of plantation by tamarix trees. Two phases of reactivation occurred in 1989 and in 1993: sand transported by the wind, from south-west to north-east, filled the checkerboards and during the sandstorm of March 2006 sand covered the roadway within one day. In this sector, our research team identified three wind directions: from NE to SW (*Chergui*), from SW to NE (*Sahéli*) which is the dominant direction, and from NW to SE. These three wind directions build *ghourds* (pyramidal or star dunes) and crescent dunes which have a dynamic of reverse dunes. In the plain of Yerdi (N 31°32' W 04°11'), at the foot of the hamada of Cenomano-Turonian limestone, the pebbles coming from the decomposition of the basic conglomerate allotted to Quaternary have a surface status with aeolian polish

2 Arrow of sand upwind of small obstacles (vegetation or stone).

Figure 53.4: The palisades of asbestos cement set up in 1981 were buried and broken in 2006 (N31°32′ 80 O4°10′ 9).

and vermiculations which is an evidence of the intensity of the past aeolian sand transport of this sector. Asbestos cement palisades of NW-SE direction (figure 53.4), set up in 1981, are presently completely buried with the arrival of abundant sand from SW-NE (*Sahéli*)

On the Rissani-Alnif road, at the foot of *Djebel* Amelane (N 31°16' W 04°20'), mobile barchanic dihedron, with a SW-NE 220 axis and height less than 2 metres, reach the road. The small size of these sand dunes explains their mobility. A set of palisades along the SW-NE 240 direction was built parallel to the road but without a biological fixation. This device is already observed on several locations to protect the roads without paying attention to the principal direction of the wind; in this way it is not very effective to prevent sand encroachment. Due to the absence of biological fixation and the lack of maintenance of the palisades, a great part collapsed and the sand accumulated near the road and thus became an increased threat (figure 53.5). This supports the observation that the majority of the protected sites that were built in 1980 must be rehabilitated.

The sand encroachment increased since a study undertaken for FAO in 1979 (Mainguet/ Chemin 1979). The peasants confirm our observations, in particular in Chtam (N 31°33' W 04°57'), where sand encroachment started 15 years ago and now threatens traditional palm tree plantations, forcing the farmers to move their cultures. The new dunes that are 3.5 metres high are barchans and the responsible wind is *Sahéli* (SW-NE 212°). The aeolian sand originates from the Wadi Sat which, until the 1970's, ran upwind of the cultivable land of Chtam. Today, this wadi is dry and has become a source of sand. The increase in the volumes of sand exported and/or removed by the wind is also obvious in Bouia-Kraïr where, in 2006, the barchanic edifices studied by Kabiri, Boudad, Krimou, Khardi and Elmrani (2003) have disappeared. The palm tree plantations, a major obstacle for the aeolian transport of the sand, suffered from the increased arrival of sandy particles and became the privileged locations for dune genesis. Ait Ben Omar (N

Figure 53.5: The checkerboard of protection of the Rissani-Alnif road is completely filled and in a state of advanced decay. This device, not followed by biological fixation, took part in the accumulation of considerable sandy volumes which are now an immediate danger for the road. **Source:** © Photo taken by the authors, F. Dumay and M. Mainguet.

31°32' W 05°02') oriented NW-SE has walls NW-SE limiting the plot of land at a 90 degree angle to Sahéli. These walls are covered by aeolian sand which already penetrates the most exposed plots of land (figure 53.6).

In the south-west of Ait Ben Omar (figure 53.2), a band of checkerboards of several hundred metres long, directed NW-SE 330° at a 90 degree angle to the *Sahéli* was carried out in feather grasses of palm trees. It comprises three squares leeward of which six to nine lines of tamarix were planted in staggered rows in small holes. Built in 2002, the first square upstream-wind is already filled with sand, proof that this protective strip plays its part and that the volume of sand in transit is high. The plantations leeward of the checkerboards suffered from a lack of watering and the 'dead' seedlings were not replaced, proof of the indifference of the oasians which is regrettable because this system offers an interesting strategy only in the medium term, by biological fixing.

In Boudnib (N 31°56' W 03°37'), the school has been threatened by sand encroachment. A worker clears daily the accumulated sand in front of the main entrance. A perforated palisade of asbestos cement of NE-SW 220°direction, parallel with *Sahéli* wind prevailing in this sector was set up 5 years ago by the ORMVAT "*Office Régional de Mise en Valeur Agricole du Tafilalet*". In bad condition because of lack of maintenance, it has been completely submerged by the accumulated sand on both sides; it acts like a railroad and thus fails to block the sand. A second phase was completed in 2005 by the National Forestry Commission: an impressive length of checkerboards built but, still with a wrong W-E orientation and not at a 90 degree angle to the Sahéli wind. After three months the filling of the system worked badly and sandstrips appeared.

According to the inhabitants of the oases the major problems are the water shortage while the wind risks, probably more pernicious, are taken into

Figure 53.6: Aït Ben Omar. Wall of protection against sand encroachment. The wall plays an effective role in stopping the sand. **Source:** © Photo taken by the authors, F. Dumay and M. Mainguet.

account only when the intervention becomes necessary by sand encroachment of agricultural areas, roads, villages or urban areas. This combat is local and has not been integrated into a regional approach: the source areas are not defined, wind dynamics is not understood. Success and durability require that the mechanical combat is systematically linked to a biological action.

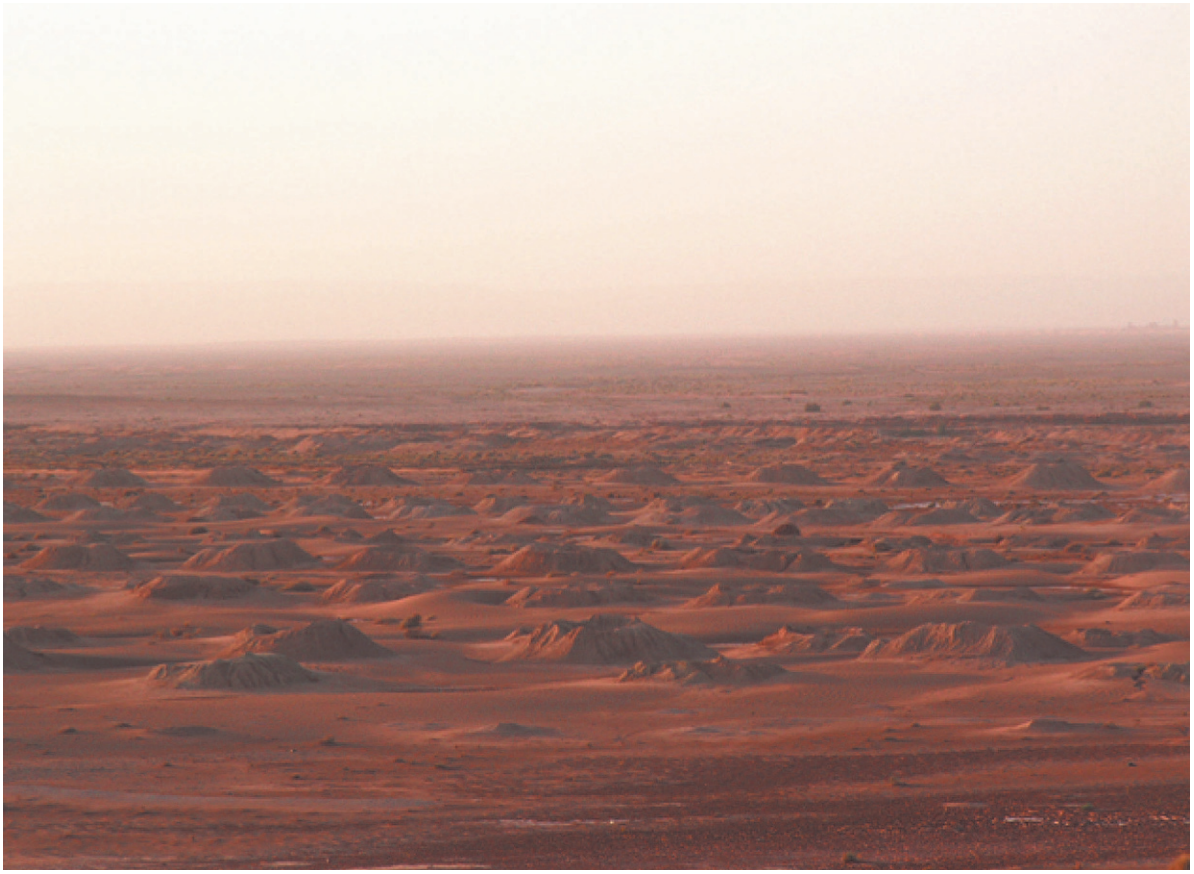
53.2.2 Difficulties Due to the Water Deficit

In the oasis region of Tafilalet, as in the whole semi-arid zone of the Moroccan Sahara, the problems involving water are twofold: water surplus during devastating flash floods, and shortage during the summer heat (June, July, August) and the recurring phases of drought.

The oases between Ouarzazate and Errachidia (figure 53.1) are located in the plains of the wadis, whose floods are violent. On 12 September 2006, intensive precipitations of 50 mm within 30 minutes generated a flood with a speed of 3 m/s and a flow of 500 m^3/s. During these flash floods, the water carries fine and abundant, red material, which increases its competency; a strong 'smell of clay' fills the atmosphere. The flood wave takes on average two days to run out in the wadis of the plain and severe inundation and damages results. The drying out after the floods is fast: in Tinejdad (figure 53.2) on 13 September 2006, after the torrential rains of the day before, water had invaded the road; but on 16 September 2006 the situation became normal again.

The capacity of transport of the wadis is strong: a block of 80 cms was abandoned onto the roadway at the exit of Goulmima (figure 53.2). In May 2005, after large storms, several hotels were destroyed in Merzouga (figure 53.2). In Wadi Rhéris, the width of the floodplain and the abundance of well rounded pebbles in the mean-water channel document the violence of the flood which involves severe undermining of banks, on which are built the ksours surrounded by their cultivated soils. The phases of recurring droughts affect also the oases of Tafilalet; however precipitations of these last years are better: in 2005, it

Figure 53.7: The *khettaras* of Jorf (N31°27′42 O4°25′19). This sector rich in *khettaras* is an area of intense Aeolian sand drift. **Source:** © Photo taken by the authors, F. Dumay and M. Mainguet.



even snowed in Erfoud, which had not occurred since 1965. Since 2005, Tafilalet experienced two annual floods, whereas the previous decades recorded a flood every four to five years.

The recurring droughts of the two last decades of the 20th century contributed to the increase of pumping stations, involving a lowering of the quaternary underground water level and a diminution of the flow of the resurgences collected for irrigation. Droughts and excessive pumping are responsible for the drying up of many *khettaras*[3], as in the oases of Ferkla, 80 kms south-west of Errachidia.

The *khettaras* which supply palm plantations in the South of Morocco suffer from the decline in underground water and sand encroachment (figure 53.7).

In Jorf (51 kms west of Erfoud), 4,000 ha are still irrigated by *khettaras*. After the recurring droughts of 1980 to 2000, they dried up and sand covered a total of 68 khettaras, and only 16 remained active. The palm tree plantations of Jorf, located upstream of the catchment area, suffers from lack of water. Only 50 per cent of the palm plantation benefits from irrigation. As in many villages, an association manages flood water and the collective clearing out of the underground channels. To combat sand encroachment of the *khettaras* locally, a mechanical fixation was achieved on four hectares. On the other hand, the inhabitants of the ksar of Ouled Ali (figure 53.2) informed us that the tamarix, planted to create a green barrier, caused a drop in the flow of the *khettaras*, which shows that no simple solution exists.

The irrigation water comes also from small permanent dams, like that of Tifounassine supplied with resurgence in Turonian limestone. From the dam, water is conveyed by an underground channel towards the palm tree plantations located downstream. The major problem of these dams is the fall in storage capacity due to silting.

After the flood of 1965 which caused large damage for palm tree plantations of Wadi Ziz, the Moroccan state set up the Hassan Haddakhil's Dam. According

3 Underground canal surmounted by open wells

Figure 53.8: The palm tree plantation of Aoufouss on three levels: palm trees, fruit trees, cereals and gardens. **Source:** © **Source:** © Photo taken by the authors, F. Dumay and M. Mainguet.

to the inhabitants of Jdid Mdaghra (figure 53.2), located downstream of Ziz, the dam played a positive part regarding water erosion, putting an end to undermining banks which existed on the affluents of Wadi Ziz and taking part in the refill of the underground water level. Two days after the flood the level goes up in the wells. The irrigation water comes from the dam by a principal irrigation channel from where it is forwarded to the fields. The release of water from the Hassan Haddakhil Dam (on the Wadi Ziz upstream of Tafilalet) should be undertaken in dialogue with the farmers. It is the *Jemaa* (the council of wise men) that manages the distribution of water. Downstream, the palm tree plantation of Aoufouss is located (figure 53.8), one of the large palm tree plantations of Morocco, made up to 100 per cent of palm trees, especially *Mejhoul* (a type of dates of high quality), whose harvest of one palm tree can support the life of a family for a year; dense, this palm tree plantation is composed of three levels of vegetation, irrigated by the dam water, the oasis is luxuriant. Only a central strip of the bed is unoccupied to manage the violence of the flow during the floods. The habitat is located at the base of the slopes in the vicinity of surfaces managed for drying harvest. There is no water problem; the limiting factor here is the availability of arable land. The surfaces of the lower part of the slopes of the wadi are not divided yet; new extensions are envisaged there... whereas it would be necessary to manage the water of the rill wash on the slopes.

Downstream, in the oasis of Erfoud, the irrigation by release of water from the Hassan Addakhil Dam (1 to 2 per year) remains insufficient: it is achieved field by field, the palm tree plantation cannot be irrigated in its entirety and the upstream has priority, times of irrigation are too short, and there is not enough release of water. The release take place in July and high heat is responsible for intense evaporation. The peasants wish for them in April and September. The irrigation is also achieved directly with flood water; it is, however, not organized, the upstream has priority and can keep whole or part of the water, contrary to the release from the dam which has a strongly organized distribution. The upstream part of the palm tree plan-

tation of Ouled Ghanen Essaouia (figure 53.2) is irrigated by flood water; the downstream part, which does not benefit from flood water, is dying (figures 53.9 and 53.10.

In Rissani, cultivation can be achieved only when the flood water reaches the palm tree plantation, approximately every five years. In this oasis, the poor drainage of the palm tree plantation led to intense salinization. Near Goulmima, four ksours also practise this possible opportunist agriculture every three or four years. In Goulmima, underground water level in the infra-Cenomanian rocks has a salinity from 0.7 to 2 mg/l and 14 mg/l at Erfoud, which makes it unsuitable for irrigation of palm trees. The palm tree plantation of Tinejdad suffers from the insufficiency and bad quality of the water.

The vice-president of the association Ouled M' Bareck for the Rural Development of Erfoud estimates that the lack of water is the main difficulty of the oasis, before both sand accumulation and salinity; the drinking water comes from Errachidia; the underground water, formerly 6 metres deep, is now 20 metres deep in the paleozoic schists and water is strongly mineralized (salted water). There are other underground water levels to 70 and 500 m of depth: the disadvantage is the cost of drilling.

The lack of water is mainly a result of the drying up of *khettaras*, which where a collective access to water and irrigation is remplaced nowdays by motor pumps, individual, irrational and devastating management of the resource. The dispersion (wide distribution) of the fields increases the difficulties of irrigation and leads to the multiplication of motor pumps. The president of the *Bougafr* association for the cultural, social development and the environment of Alnif told the authors that the use of the water is the problem rather than the lack of water and the dryness. He referred to the overexploitation of groundwater and the abusive use of motor pumps. Water was formerly 6–7 metres deep and *Oughrour*, wells with animal traction, were used; the water is now deeper and the roots of the palm trees do not manage any more to reach it: in some fields, it irrigates only 2 or 3 palm trees, from where arises the complaints of oasians who would wish to see a distribution according to the effective needs. The muddy deposits of floods cause a serious rising in fields compared to the irrigation channels, where water runs out by gravity. However, there is unanimity for saying that flood water is the best for irrigation.

53.2.3 Social Transformations

Facing the increasing environmental difficulties, the society in the oases has opposed the ancestral practices which became insufficient and must seek for new solutions for which it very often lacks the power and the financial means. The improvement of rainfall in the last years did not reactivate the traditional organization of the oasis. In spite of these difficulties, all local markets abound in fruits and vegetables produced in the palm tree plantations. In this oasian system, agriculture accounts for 90 per cent of the activity and employs 60 per cent of the population. The demographic pressure is alarming, more especially as the population in the oases is young: 40 per cent are between 0–14 years and in this region the fertility rate was 4.3 per year compared with an average of 3.2 in Morocco (El Meskine 2006).

The strict state control during the past three decades has weakened the traditional *Djemaa* (the council of wise men), the only authority that is respected by the population in the oases. The *khettaras*, which remain an effective means for water harvesting for irrigation, are not yet definitively abandoned but for their maintenance and their use the *Djemaa* must restore its authority and consolidate it with the rational use of modern means of water access.

The irrigation canal of the Djam Djama (figure 53.11) that is 10 kms long and 1.5 metres deep and was built in 2000 costing more than 3 billions dirhams (265.000.000 €), has never functioned, it rapidly silted up to half of its height (80 cm) within six years. It was built to recover 300–400 ha of degraded soils and to irrigate several thousands of palm trees in the palm tree plantation of *Moungara*. These particles must be removed but this cannot be done without the support of the *Djemma*. It will be equipped with bypass valves to convey water to the fields by respecting the right distribution from upstream to downstream. On the edges of this channel, the palm trees are in good shape. Recently a test was made to release water (during a flood) and to try to clean the canal with its hydraulic force. This clearing will required about thirty people; its cost and maintenance will be supported by a tax on the seeds of 1 dirham for each kg of seeds. The protection of this channel against sand encroachment is a major problem, but the upwind area is a grazing land and the nomads are opposed to a grazing interdiction, which makes the installation of biological protection difficult. In 1999, after localized rain in this area, the nomads came with their herds and within two months the pastures were totally exhausted. The state aid of some barley bags was consumed by the nomads. The efforts to combat sand encroachment become more difficult because the nomadic grazing areas are often located on the sur-

Figure 53.11: Djam Djama irrigation canal that is 1.5 metres deep and two metres wide. **Source:** © Photo taken by the authors, F. Dumay and M. Mainguet.

faces which should be treated, and this has made the situation more difficult.

To these problems of authority other questions of land rights are added. Many peasants do not have property rights and the fields are divided among the children. The people in the oases told the authors: "because of the problems of heritage in the oases there will be no more fields but only limits.. The common law has been an obstacle for the current well-being of palm tree plantations. Associations have tried to combine traditional with modern operations of palm tree plantations. The division of the fields was worsened by the numerous houses in breeze-blocks that were set up in the palm tree plantations at the expense of arable lands. These constructions are often the property of migrants who have returned for their retirement to the village. An emigrant supports the survival of four people who remain in the 'village'. In each family there are one or two soldiers, who also contribute to the family mutual aid. In fact, this extra income from the civil service, emigration, and begging sustains the survival of the oases.

Tinejdad experienced high emigration rates during the last decade because of the aridity and the lack of work for young people who did not know the prosperity of the oasis since this disappeared during the 1970's. Each family had beforehand two to three cows, a donkey and some sheep, whereas, in the '*ksar*' (traditional village) of 1,260 houses, only two cows remained and more nomads lived in the sector – the majority were settled during the drought in the 1990's. Only some shepherds remained who sold their herds and settled in the oasis. In the village, there have been more new inhabitants than departures as a result of these settling processes. The newcomers are not adapted to the life of the oasis, their concern is that of daily subsistence: they are farm workers and receive 50 per cent of the harvest; the children are provided education at little cost.

Despite these difficulties, the village associations play a major part. The association of *Gourama* organ-

ized the collection of household waste every Wednesday evening. In the oasis, the inhabitants got rid of their waste by throwing it into the bed of the wadi, which was cleared during the next flash flood, but this waste has polluted the ground water. The people thus solve a problem without worrying about the people living downstream and about the future. The current waste collections have been insufficient and result in a multiplication of the rat population, which has an impact on diseases. It is a problem that must be solved if ecotourism should suddenly develop; this is what the people in the oases are looking for. Many associations were created to combat the disappearance of community practices for the benefit of individual practices incompatible with a civic management of the problems in the oases. In Ifri, the people in the oases replaced unproductive palm trees with olive trees, what indicates that they do not wish to leave the oasis.

An investigation on the development of the Association of Achbarou reflects the current psychology of Oasian people. The drought discouraged them so much that when they had sufficient rain for two years and increasing water in the wells, they lack the will to return to their agricultural activity. Quantified values were given to the authors, for example that the palm tree plantation of Achbarou (figure 53.2) has died by 90 per cent, that of Alnif by 50 per cent, but these values are debatable because the people refer to the values that were recorded during the drought and they ignored the successive years with good rainfall that permitted the rejuvenation of many palm trees.

53.3 Countermeasures of the Oases Against Desertification

The oasian population is not passive in facing oasian degradation. They always try to improve the water collection, to develop associations, and unfortunately solve also their difficulties by emigration. Emigration is certainly the main problem because the young people do not benefit from the knowledge of palm trees cultivation. Unfortunately, the new technologies mainly for water collection are very expensive and beyond what the local population can afford. More modest solutions the farmers can afford are unable to solve the problems, given the drastic environmental changes.

Desertification has been introduced above as a threat, but it is also a challenge for improving traditional technology and introducing modern technology. For humankind it is a strong opportunity to think about a new relationship between a vulnerable environment and a growing population that negatively affects the environment.

53.3.1 Research on New Water Supplies

Since the 1970's, the recurring droughts and the decline in the level of underground water has been the cause of the desiccation of the khettaras. The available water resources enabled a cultivation of the alluvial soils of Tafilalet in the basins of Guir, Ziz, Rhéris and Maïder (figure 53.2).

Each area has its specific water conditions. In these dry areas, the underground water is the most secure due to the scarce rainfall. In the oases of Tafilalet, the water deficit had various forms. The volume of water used in the basin of Tafilalet is calculated at 572 millions m^3/yr, 352 millions m^3/yr is surface water and 220 millions m^3/yr underground water (Kelly/Mahboub 2006).

In Morocco, the surface water which feeds the oases comes from the mountains; thus, with less precipitation the surface water declines. The management of the hydrological basins by creating benches and small dams on the slopes of the hills by gabionnage[4] with local material, is not yet envisaged nor the combat against erosion, which must also be combatted by improvements of the slopes. It is also necessary to consider the storage of the water, making it possible to have reserves of water for periods of water shortage.

Two types of irrigation coexist in the palm tree plantations: a) the traditional one by irrigation channels, and b) a modern one using motor pumps. Taking the tensions into account due to the decline of the underground water level and the needed conservation of the water resource, a third technique of irrigation – drip irrigation – is used in the region between Tilouine (figure 53.2) and the South of Tinejdad (figure 53.2). To introduce these new techniques, the farmers asked for support.

The achievements supported by the association of the Oases of Ferkla are manifold: a) a hill dam at 25 kms from Tinejdad provides 30 per cent of the irrigation water for the palm tree plantation; b) the construction of an irrigation channel on the foot of the slope which collects the surface waters; c) the building of a small dam on the foot of the slopes to create

4 Anti-erosion structure composed of blocks or rocks enclosed in a wire mesh form

Figure 53.12: The peasants of the oasis of Has Ouali set up a system of derivation of water of the Wadi Ziz after the flood. (see figure 11 sketches of interpretation). **Source:** © Photo taken by the authors, F. Dumay and M. Mainguet.

basins and small terraces to limit water erosion; and d) finally the recovery of rainwater with less acidity than the water of the wells, in particular for the irrigation of alfalfa. Pumping techniques have been created but the subdivisions of the fields complicate the water distribution. The refilling of the *khettaras* requires basins such as that built in *Rissani*, with a dam that collects the flood of the Wadi Ziz, where water is retained for 2 to 3 months. There are also 13 dams of derivation in Rissani, which rise about 40 cms every 40 years, but the inhabitants of the downstream community of *Tinrheras* have opposed them.

For refeeding of the underground water level, the *Sarata* (natural hole of infiltration of water in the sand) was suggested as a model and the digging of wells into the flood plain of the wadis. These 10-metres-deep wells would be covered with air bricks to support side infiltration and to avoid their filling; they should be placed at the bottom of a small diversion canal at the opposite side of the current of the wadi. The cost for this is estimated to be from 5,000 to 10,000 dirham (440–800 €).

Along the road of Errachidia-Rich towards Gourama, the authors observed the digging by people from the oases of a derivation of the water of the Wadi Ziz near the oasis of Has Ouali. After each flood, water thus derived is forwarded to an irrigation channel dug in the bed of the wadi to benefit from the flow related to last precipitations (figures 53.12 and 53.13). Nine groups participated in the irrigation work undertaken by a chief, helped by parents and volunteers from outside the oasis, which is spread out over 11 kms, and the water access returns every 15 days; each family irrigates two parcels of land.

Despite these activities, there is water shortage in the summer (from June to August), without a motor pump and drip in this oasis; only three irrigation channels irrigate the olive plantations. The problems that were stressed by the inhabitants are: harmful effects due to the rodents and undermining of banks. A

1 : Oasis Ait Ouali south of Rich; 2 : Main water diversion to the oasis; 3 : Bags alignment to partialy stop flow; 4 : Small pebble dikes to create small balancing; 5 : Part of the river not harnessed; 6 : Major bed with pebbles; 7 : Two levels of canals are perched as a result of bed hemming

wall in breeze-blocks was built but the inhabitants preferred *gabionnage*. During this time the women wash the carpets for the end of Ramadan.

In Erfoud, thirty-three ksour (traditional villages) met to carry out projects to combat desertification and to benefit most from available water resources. They proposed: a) the protection of underground water and monitoring of motor pumps, b) the drilling of artesian wells, c) the creation of artificial lakes like water tanks to refill the underground water levels, d) the derivation of the Wadi Rhéris to the Wadi Ziz at Douirat, and to avoid that the four to five annual floods are lost in the desert, e) the development of the infrastructure: bridges, roads, and d) the improvement of cleaning.

The inhabitants of Erfoud also wanted the installation of diversion canals of flood water of the Rhéris. The authorities opposed the passing of water of the Wadi Ziz by modern channels, even when the flood of Ziz involves serious inundations of Merzouga before being lost in a closed basin. There the inhabitants underline a problem of management of the floods. The only large irrigation channel, the '*Chabourat*' which is 1,200 metres long, 3.5 metres deep and wide and feeds Erfoud is full of sand and vegetated. The inhab-

itants claim mechanical means to carry out its clearing.

When the quantity of water from a well of 60 metres depth became insufficient; a second well of 103 metres was carried out, but the available pumps were too weak and the water was salty. Currently the Association of Erfoud wants an old tank to be rehabilitated to practise drop irrigation. The *metfia is* the traditional basin that was used since antiquity to collect the water of the flood and to use thereafter for various domestic needs of the population. This basin and the channels which flow there will be rehabilitated to store the water brought back by motor pumps of the Paleozoic underground water level of poor quality, and to treat it before using it for drip irrigation. This project has been developed in 2007 by a subdivision of Erfoud (ORMVAT), in partnership with the beneficiaries and the association users.

It is also a question of creating AGR (generating actions of income) like small ovine cooperatives, developing apiculture, benefiting better from the production of dates and developing the stone cut. In Erfoud, every year in September a market of dates is organized where many companies of conditioning and transformation of this fruit are present. The association also tries to train users not to waste water, what is too often regarded as a gift of God, and thus: 'I do with it what I want'.

53.3.2 Efficient Development of Associations in the Oases of Tafilalet

The field investigations in the oases of Tafilalet conclude that in the oasis the associations are an interesting response to the effects of desertification or its first steps. This will be shown by a few examples.

The ORMVAT of Erfoud and the *Association of Combating Desertification and Environmental Protection* of Jorf in partnership with the IFAD (International Fund for Agricultural Development) created an experimental station where four farms buy water stored in an artificial plastic sheet basin. In the winter, when the flow to the *khettaras* is increasing, a portion of this water is stored in this basin and sold in the summer to four plantations that practise drip irrigation. The disadvantage of this system is the loss by evaporation.

In the valley of Guir, in Gourama, the *Association Oasis of Guir for the Development and the Environmental Protection of Gourama, Rich, and Errachidia* participated in 2005 to construct a wall to fight against the undermining of the river banks. It organized meetings to sensitize women and the children for the environmental protection, and it distributed bags to collect waste. The Association rented a truck which collects the domestic waste previously thrown into the Wadi Guir downstream of the village. The association also participates in campaigns for planting and protecting trees. According to its president, the new extensions and the abusive development of the motor pumps threaten the underground water level. The governor was alerted and a meeting was organized as a sign of protest.

There is no problem with drinking water in Gourama that is distributed by the *National Office for Drinking Water* (NODW). The major problem is the processing of the waste water. About 15 per cent of the families are connected to the system collecting waste water that is delivered to the wadi downstream from Gourama, the others have pits. The president of the association said that between 2005 and 2006 the precipitation was good. The floods usually take place in November, December and January, but in 2006 there was an exceptional flood in September. The president pointed to these most urgent problems: 1) water erosion and the undermining of the banks along the high and middle Guir Valley; 2) the first indices of sand encroachment which start to appear in the streets of the village, carried by a south wind (exceptional in 2005–2006); and 3) the bad management of domestic waste what resulted in cases of leishmaniose in connection with the increase of rats.

In Jorf, the khettaras are still under the responsibility of a voluntary *Sheik* who manages all questions related to water (water turns, maintenance of khettaras, and management of conflicts). Each tribe is represented by the *Mazal* or the council of the wise men. The *sheik* is elected every year by the group of *Mazal*. The Association of khettaras of Jorf takes part in the life of the palm tree plantation in several ways: the development of drip irrigation, combating desertification, improvement of the breeding in the oasis, diffusion of information in the ksar.

The badly conceived water processing pollutes the underground water. A collection system for waste water is under construction. The Association of Jorf intervenes in the collection of domestic waste, including the idea to reward the children of the village that participate with tickets for access to the sports ground and the library. It asked for monthly meetings with the municipality to solve the problems of everyday life, e.g. to fight against the smuggling of palm trees.

In Tinejdad, the *Association of the Ferkla Oasis for the Environment and the Inheritance* tries to set up projects to find complements of resources for the young people: 1) the creation of a dairy cooperative and incentives for bovine breeding; the incomes of which are subject to less fluctuations in the market than those of ovine breeding. In Errachidia and Tineghir, the people living in apartments buy fodder to be able to have their own cow; 2) the building of a small factory for date jam; 3) the sale of garlic powder instead of garlic cloves.

The Association of the Oases of Ferkla also participates in the development of citizens' education by organizing ecological meetings for sensitizing schools and families, in particular for saving water, helping with planting trees in the villages, and helping with the maintenance of the khettaras. As a result 1,200 trees were planted, parks were built, sheep and chicken were distributed, and scientific workshops on topics of development were organized. Foreign students find accommodation in the buildings of the association.

In the province of Errachidia, the well developed association does not take over from the Djemaa because they do not have the same authority to manage natural resources, especially water, irrigation, land distribution, grazing .... These associations propose modern functions and profits from the wisdom of the old men of the Djemaa, and they participate in the education and information of the people in the oases.

53.3.3 Emigration: The Worst Solution

Rural migration started in 1960, and it has increased since 1973. By 1971, 87,000 rural people left the Tafilalet, and from 1975 to 1982 100,000 departures were recorded with a high of 20,000 in 1980. The towns of Fez and Meknes attracted 43 per cent of the migrants. The first migrants were young men. Thus, in Jdid Mdaghra during the difficult periods of the end of 1970 and from 1983 to 1989, many inhabitants were fascinated by the urban lures and left for Meknes, Fez and Casablanca (figure 53.1). The cities of the North are perceived as golden cities; the return of the pensioners to their village who earlier emigrated to work in Europe induced many young people in the oases to give up agriculture and participate in the loss of transmission of knowledge of the oases. The young rural people prefer emigration to farming because they consider the work too difficult with poor financial results.

53.3.3.1 Emigration in the Oasis of Achbarou

The palm tree plantation is in a bad state but there are some signs of improvement after the good rainfall during 2005 and 2006. An interview with Hassan Benelmadani, a teacher, and Mohammed Boumdiene, also a teacher and treasurer of the *Association of Achbarou for the Development*, starts with this sentence: "the oasis does not go well." Approximately 1,800 persons live in Achbarou. The old ksar that was abandoned in 1968 is already strongly damaged. The inhabitants suffer from lack of water. Three decades ago the ground water was 16 metres deep, it is now 60 metres. In 1987 soldiers built a small dam near the village on the Wadi Gaiz, which now makes it possible to obtain drinking water from 40 metres.

Before the drought the primary activity of the oasis was the cultivation of palm trees. The irrigation was provided by a system of four *khettaras*, the last was active in 1991. Then the villagers used underground water but the motor pumps exhausted the groundwater. Of the 125 families, 20 per cent had a motor pump that was bought with the money of emigrants.

The traditional family unit consists of three or four women at the house who deal with the domestic tasks in turn. An association was founded in 1998 to create work for women who are not any longer collecting wood and grass. A house for women will be completed where weaving and embroidery will be done. Although the khettaras are now dry, the Djemaa always exists and collects the money to pay the Imam. Nowadays, almost all the motor pumps have stopped and agriculture is non-existent any longer.

Many people left the oases for North Morocco and Europe, in France primarily to Nancy, Montpellier, Saint-Etienne and Mulhouse. Now, marriages are arranged in the month of August with the French children of the first wave of emigration, thus allowing the inhabitants of Achbarou to obtain French nationality by marriage. This is organized in France by the Association of Chabraoui.

The drought discouraged so many people who do not react any more to the return of good rainfall. It seems that the idea of cultivating the land has been abandoned. While the palm tree plantation is still in a reversible status, the problem is a mental one. The inhabitants live in the palm tree plantation but without practising agriculture there, what in the province of Errachidia has been their first vocation. The only resource is the money coming from outside. "Here it is

like an hotel" one of our interviewees told us. There is no local answer to desertification.

53.3.3.2 Emigration and Its Noxious Consequences for Jorf

In Jorf the emigration to Europe has been high and irregular because generally the young children are sent there where a majority is waiting to get naturalized; then they return to marry 'in the village' to allow the spouse to qualify for naturalization. The migrations concern especially the rich families and they are related to the subdivision of the fields among the next generation. The migrants leave to work on construction sites in Fez, Meknes and Casablanca but the women and the children remain in the *Ksar*. With the money of the emigrants, houses in breeze-blocks are built in the palm tree plantations. These constructions constitute an aesthetic damage and an environmental trauma because they require sand whereas the traditional houses were built with silt and clay. Jorf assumes that until 2025 about 60 hectares will be used for the construction of these new houses within the palm tree plantations.

Presently, the bed of the Wadi Ferkla in Tinejdad is emptied of its sand; this has lowered the bottom of the bed of the wadi. The flash flood of 1979, with the sand covering the bed of the wadi, reloaded the underground water level. In 2006, the flash flood was stronger but the refill of the underground water level was deficient due to the thinning of the fluvial sand sheet that was collected for construction. In 2007 there was a sand shortage, a cubic metre cost more than 150 dirham (13 €), whereas a few years ago it was only 50 dirham. A regulation is essential: to create sand pits and gravels far from the wadis and to prohibit that they are taken from the beds of wadis.

53.3.3.3 Emigration from Alnif

The region of Alnif has been most affected by illegal emigration to Spain from Ait Atta. In Barcelona a quarter/neighbourhood is called Nighreme which means 'door of the village' in the Tamazight language. All *ksour* lost between 150 and 300 persons, primarily to Spain. People live here from the remittances of the emigrants, and from the income of cumin, henna, and the dates which are sold abroad. Emigration is a response to the lack of water and the difficulty to deepen the wells. The area of Alnif used much dynamite for drilling wells.

While the recurrent droughts since the 1970's have been push factors for emigration, the arranged marriages during the holiday season in France (in August) are pull factors. Emigration is an individual topic without links with the necessary participative behaviour of the population and collective actions to reach a better standard of living. Emigration does not allow poor people to work for their own and to integrate at a regional and national level.

53.4 Conclusion

The situation of the oases has become difficult in the world in general, in the southern part of Morocco, and in the Tafilalet in particular both for human and natural causes. The first have accelerated and intensified the effect of the second due to recurring droughts and intensive rainfall that was worsened by the degradation of the vegetation cover.

The oasis system combines two ways of life: the palm tree plantation (which is being substituted in Tafilalet with olive trees on the lower slopes of the mountains) and breeding. This combination has resulted in advantages and disadvantages, for example in the combat against the negative effects of the wind where the grazing areas should be controlled, what is unacceptable for the nomads. Competition for vital space is linked to questions of authority. The obsolete practices combine a) the non-existence of property rights, b) the dispersion of the field by the system of heritage, and c) new concrete constructions on the arable lands of the palm tree plantations. The excessive division of the fields due to an ancestral right leads to the dispersion of scraps of fields of which only the borders remain.

The oases do not have any longer an oasian function: the people do not live there any more from their own work. The recurring droughts discouraged them and led to massive emigration. When the climatic situation temporarily improved and the level of underground water rose (during the last few years) the people in the oases no longer responded as farmers. Due to the recurrence of droughts since the 1970's, many young people whose parents were not working any longer as farmers lost the traditional knowledge, and for them it has become difficult to work the soil.

During the last decades, state control replaced the traditional capacity of the Djemaa which gradually lost its authority. Today, the state has pulled out with the rise of the difficulties and has become conscious of the weight of the traditions and the necessary reactivation of the local Djemaa. The associations whose role is of primary importance have tried to reconcile

the tradition and the modern evolution in the oasis. The major problem has been the lack of water and drying up of many khettaras, the collective form of water collection. The increasing development of irrigation with motor pumps and thus to individual means of access to the resource has resulted in a fast exhaustion of the aquifers due to an irrational management. The disappearance of community practices for the benefit of individual practices is unsuitable for the oasis. Due to the lack of water, the over deepening of the wadis and the raising of fields compared with the irrigation channels has become a major danger that will have to be considered soon. The silting of small dams, such as that of Tifounassine, remains a problem.

The general decline in the underground water level, which does not any longer permit the roots of the palm trees to reach it, was instrumental in making many people in the oases become discouraged and inactive. Several responses should allow for survival in the oasis without external assistance and offer opportunities for development. The case of Achbarou referred to a bad option of an unsustainable development. The NGO 'AGIR' of Epinal participated in the financing of a socio-cultural home with the goal of keeping occupied the women considered to be idle. But much of the embroidery and knitting work produced in this framework was out of fashion and thus non-marketable. It would have been better if these women would have again taken up gardening, especially when the rainfall conditions were good in 2005 and 2006. It is deplorable to occupy people artificially and to lean on the benevolence of charity organizations, in a complete socio-economic shift and without links to basic needs. The craft industry cannot be an activity in response to local needs.

In addition, all development solutions aiming at promoting ecotourism must be moderate as the oasis has been by definition a fragile area. Efforts must be improved, like a) the collection of the waste and its treatment, as waste often pollutes the oasis, b) the combat against diseases like leishmaniose, rage, and their vectors due to rats and dogs. To improve the quality of the drinking water in all oases, it is now necessary to develop effective systems of water treatment, and not to reintroduce the waste water directly into the wadis.

Among the main changes in the oasian system is the loss of insularity due to new developments that affected the oasis: 1) electricity, telephone, computer, roads with bus and car traffic; 2) new structures of market from a closed market to a regional and open global market. The consequence is also too often an anarchic urbanization with houses of breeze-blocks instead of clay houses.

Migration from the oases is only one aspect of global population mobility. A review of the economic reasons for migration reveals many positive individual results: discovering a new world, new lifestyles, escaping family conflicts, new apprenticeships, and a possible return to the homeland when getting old, but fewer collective results in support of the local economy and for the maintenance of the fields by a part of the family. It appears doubtful that migration can be a sustainable solution for combating desertification and helping the development. Does migration allow them to reinforce their livelihood with non-agricultural activities?

Giving up agriculture means for the oases the collapse of the whole ecosystem. Sustainability of the oasis requires making the agricultural activity sustainable by developing activities and all natural resources of the dry areas: mixed agriculture, controlled rural ecotourism, water storage and management, flood prevention, control of water and aeolian erosion, and a better marketing of their products.

54 Agriculture in Drylands: Experience in Almeria

Andrés Miguel García Lorca

54.1 Introduction Justification[1]

The fundamental basis for security and peace in a territory is linked to the absence of internal and external conflicts. Situations of internal conflicts in modern societies normally have their immediate origin in social inequalities and are expressed in an unjust distribution of wealth. The causes that determine these inequalities may be derived from environmental situations, as is the case with the exhaustion of natural resources which assured the existence of a community; they may also be due to the abandonment or isolation of social groups who are then deprived of the possibility of developing their own capacities to access resources, as a result of administrative or political irredentism. They may even derive from the installation of external models of socio-economic exploitation, as is the case of 19th century colonialism, which drained the resources of territories without promoting the socio-economic development of their inhabitants.

These causes have all been present in recent centuries in the area of Almeria, and were responsible for the poverty of this province until the mid 1970's. Historically, this situation has been improving due to emigrations which served as an escape valve, with occasional violent episodes, the highest expression of which was the Spanish Civil War of 1936/1939. The geo-strategic position of Almeria, on the northern shore of the Mediterranean Sea opposite the coast of Africa, involved the province in external conflicts, sometimes due to direct conflicts, i.e. of colonial wars in Africa in the first 30 years of the 20th century, and as a region of tension during the Cold War.[2]

In the post-Cold War era, among the external tensions are the processes of clandestine inmigration and drug trafficking originating from North Africa, for which a main entry to Europe is the coast of Almeria. This province is a buffer as the first place of contact between two highly differentiated socio-economic worlds. In the region of Almeria many immigrants initiate their process of integration and assimilation into the new host socio-economic space. This reality is not without tensions and problems, which may result in potential and actual conflict situations. The historic process of the territory of Almeria began from a situation of inequality, poverty, and marginality within Spain, not exempt of external risks, which might have increased territorial differences.

The Almeria model offers a reference for tackling security problems in a globalized world. It is becoming a space for reflection which allows the sensing of opportunities for development that enable greater social adjustments with access to a higher income for many countries where the rate of human development is not only low, but of a middle level. It favours social stability and more efficient management of natural resources.

Thus, the land development that has been induced by the Almeria agricultural model has already become a referent for the whole planet. It is based on intensive agriculture under plastic covers. This model stresses the development capacity of a society in a financially depressed and poor land, and in an arid natural environment. Within the course of a few decades it has been able to catch up socially and financially with advanced territories of the European Union.

1 This chapter contains part of the results of the Ministry of Science and Technology Research Project, REF.SEC2001-3776, of the National Research + Development + Innovation Plan. It was co-financed with European Regional Development Funds.

2 The incident of the thermonuclear bombs that were dropped by accident in Palomares (Almería) in 1965 comes to mind. For background on the circulation of Russian nuclear submarines in the Alborán Channel, see: García Lorca (1985): 267–296.

Figure 54.1: Map of the Almeria province in Andalusia, Spain. **Source**: Elaboration of the autor.

It is indeed an endogenous development model, derived from the effective mobilization of local productive factors, natural resources, work and capital; although the latter has been of reduced importance given the low relationship between capital and labour. With the necessary adaptations this model may be applied to other countries without an industrial transition. This is confirmed by the continued and increasing interest this model has elicited in many American, Asian, and African countries.

This model of productive development has achieved a very high level of social redistribution of wealth that has reached the whole population and allowed overcoming poverty, marginality and the cultural delay of its people, while simultaneously integrating a large number of immigrants from all continents.[3]

54.2 Territorial Context

The territorial sphere of development of the intensive agriculture model is the province of Almeria in Andalucía (Spain) between the 37º latitude and the Mediterranean Sea. This is the Southeast of the Iberian Peninsula, and it is one of the most arid regions of the Mediterranean basin, with a sub-desert environment equivalent to regions of North Africa, the Middle-East or the Aral and Caspian basins (figure 54.1).

Physiographically it comprises the alluvial belts of the hydrographical systems and a set of neogenous plains, which are bordered by a system of alpine mountain chains, with important limestone formations which enable the accumulation of subterranean waters. In its origin, no agricultural aptitude was seen in the scarce and undeveloped land, which was stony and largely affected by a limestone exudation crust, only allowing for scarce herb or bush vegetation.

3 This chapter is based on the following sources: Analistas Económicos de Andalucía (2005); COCA (2006); Consejo Económico y Social de Andalucía (2006); Ferraro García (2000); Fundación Cajamar (2006); García Lorca (1977, 1995, 1998, 1999, 2002, 2003, 2005); García Lorca/García Fernández (2005); García Lorca/Márques Ibáñez (2003); Hernández Porcel/García Lorca (1999); Instituto Cajamar (2004); Instituto de Estudios de Cajamar (2002); Pizarro (2005); Rivera Menéndez (2000); Ruíz Rodríguez (2005); Uclés Aguilera (2005).

From the point of view of its climate, the area has a very severe pluviometric deficit, below the 300 millimetres isohyet, with annual and inter-annual periods of extreme drought. Rainfall appears as intense cloud bursts which favour strong and rapid surface runoffs. It exhibits an exceptionally benign average annual temperature from 17 °C to 21 °C, the coldest month of the year reaches average values of 12 °C. Winds are fairly constant throughout the year. Solar radiation is very high, with approximately 3,200 sun hours yearly. The correct manipulation of these climatic factors is one of the keys of the development process. In general terms, the territorial environment was that of an arid, desertic zone with scarce agricultural use, and mainly goat husbandry. Irrigation was limited to the few wells in the area, while use of runoff water was problematic due to its variability and intermittence.

These climatic circumstances implied a very depressed socio-economic situation with a low household income, and territorial resources that were incompatible with its demographic development, resulting in emigration pressures.

54.3 Origin and Development of the Model

Although in the mid 19th and early 20th century attempts were made to promote agricultural development in these territories, it was not until the end of the 20th century that the process began. Its origin can be traced back to the 1939 agricultural policy after the Spanish Civil War when the INC was created to promote and initiate an agricultural reform aiming at the transformation into irrigation with the final goal to increase agricultural productivity and raise the level of income of peasants. Thus began an important process of agricultural development which was expressed legally in the *Law of Foundations* (Ley de Bases) of 26 December 1939 for "the colonization of large areas" and its subsequent development in legislation by means of a set of regulations like the "Colonization of local interest" Law of 20 November 1940. Both laws were instrumental for furthering the agricultural transformation. Among their objectives was an effort to stimulate private initiatives in the development of agricultural structures.

Since initially no adequate response occurred, the state took over the management and promotion of development through the INC. In order to facilitate the action of the new institution and finally initiate the colonization, the Law on the "Colonization of areas with irrigation potential and distribution of property in areas with irrigation potential" was adopted in 1949. These legal instruments launched the process which rapidly fostered private initiatives.

Actions occurred in two zones, in the *Campo de Dalias* and in the *Campo de Nijar* that basically aimed at: a) the transformation of soil for agricultural activities with legal instruments that facilitated, in cooperation with owners, the purchase or compulsory expropriation; b) the construction of an electricity network and communication structures; c) the probing for drilling wells to guarantee sufficient water, and elevation of water storage and its distribution, and d) the construction of new villages. A total of 13 villages were founded with 970 houses where 967 settlers selected from nearby villages came to live with their families. Initially, settlers were given plots of 3.5 to 5 hectares and later of 1 hectare, once 'cultivation on sand' was introduced. The real surface of these actions reached 6,947 hectares in *Campo de Dalias* and 3,346 ha in *Campo de Nijar*. The settlers were offered a low interest 20-year loan that paid for the house, the land, and the proportional part of the road works, general irrigation infrastructures and probing. The public administration offered them counselling and tutoring during the first five years in agricultural matters.

The efficient and honest work of state technicians enabled the success of the model which initially had two important features, the introduction of the system of cultivation on sand, and protection of crops with traditional structures and plastics.[4] Both developments took place very early, cultivation on sand in 1957 and the first plastic protected crops in 1960. Since then, agricultural development has been continuous, paired with constant structural transformations and technological changes (figure 54.2).

4 The 'cultivation on sand' technique consists of creating a soil basis out of vegetable earth, organic fertilizer and sand. This soil allows for irrigation with brackish water, and improves the root temperature, thus enabling better performance and earlier crops, which means a better market option. Traditional grape cultivation in grapevines (a wooden structure with wire-supported crop) already existed in the area. These structures were covered with transparent plastic supported by a wire network. Results were impressive, increasing performance and precocity of production.

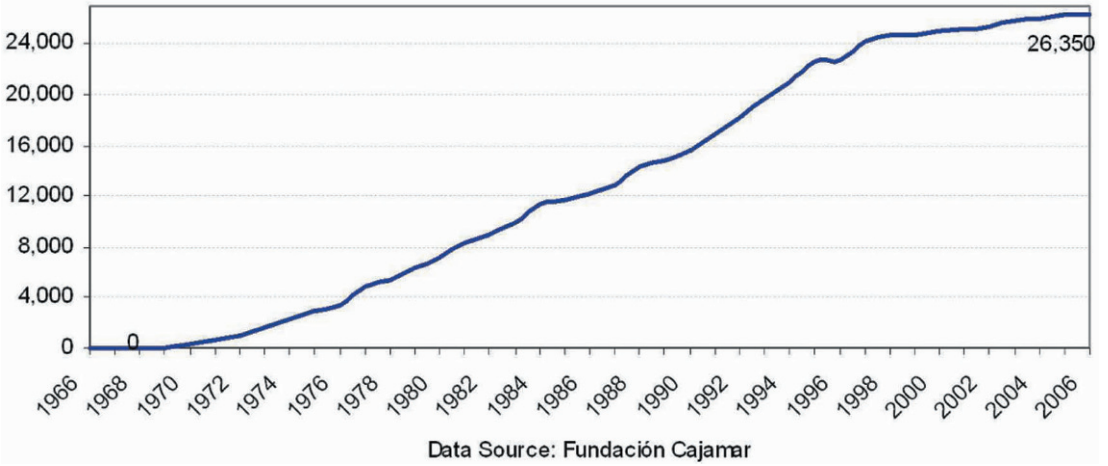
54.4 Features of the Intensive Agricultural Model

From the start, this productive model was defined by several features that still apply.

- It is a very intensive work model, also known as *'delicate agriculture'* due to the constant and continuous attention required in the production process. Although at present one hectare requires at least 2.5 manpower units per agricultural campaign, previously the rate was even higher, what was solved by the inclusion of all members of the family into the activity, including whole family networks for some operations.
- Another important aspect is the socialization of the model, both from the point of view of landowner structure and of *association* and *cooperatives*: In a registered surface of 31,932 hectares, there are 32,581 owners[5], and the number of cooperatives in the area under study is 309, with 38,995 members. These cooperatives have focused on promoting productive efficiency, reduction of costs by an economy of scale, concentration and standardization of production and technical counselling, as well as servicing.
- *Moderate capitalization*. Large investments were not necessary in order to initiate production activity, as land and also the crop protection systems were inexpensive. In the early 1980's, the price for starting a crop, including the purchase of the land, was around 3 million pesetas per hectare (18,000 €). This aspect explains the growth and territorial expansion of the greenhouse, and also the social mobility from employees to shared farmers and later to landowners.[6] This is now also happening with immigrants, although the costs for developing a greenhouse are much higher, reaching approximately 200,000 €.

5 These figures for surface and owners differ from official figures. They have been obtained by direct evaluations applying different more complex methods than those used for the census, together with the analysis and photointerpretation of the orthophotos of the Regional Environmental Authority.

Figure 54.3: Evolution of greenhouse surface in Almeria (in ha). **Source:** Elaboration of the autor.



54.5 Evolution Process of the Model

In 1979 a Spanish financial company publication alerted about what it called the 'Almeria miracle'; analysing a number of national, regional, and provincial economy indicators, it verified that the agricultural income of Almeria changed between 1955 and 1975 from being the last to the first in the region, with a growth rate seven times higher than the average in Spain. Then its consolidated development process was confirmed and it evolved as a consequence of stimuli of different origins and intensities. The most significant case was the difficulty with tariffs for exports to the European Common Market. This forced farmers to improve their efficiency to compete and to overcome the price increase due to customs. When Spain joined the EEC in 1981, the Almeria horticulture grew rapidly despite the international crises and regional problems. This required a constant process of evolution and transformations in order to respond to market demands and improve benefits.

54.5.1 Structural Transformations

They affected the entire productive model both in the production phase and also in post-crop and commercialization; but it is very significant that they appeared in the most stable structures as the cultivation surfaces, plotting structure, property regime, and plot size. Cultivation size throughout the time period under study has experienced substantial qualitative and quantitative changes.[7]

The *first* transformation, as mentioned above, was from dry farming to irrigation, a transformation which continues at present in marginal lands inadequate for farming, mainly heaths and practically dry grassland. Obtaining water has varied and diversified; initially water came from superficial aquifers, today it is obtained from deep aquifers, and also from desalination of seawater and re-use of recycled residual town waters, as well as from surface runoff water. The *second* great transformation was the protection of crops with windbreaks and cultivation on sand; this entailed an increase in crop productivity and security. The *third* transformation was the development of 'greenhouses'; the plastic protected surface has systematically increased from 0.5 ha in 1963 to 26,350 ha in 2006. These transformations in crop surface have been accompanied by other technological transformations (figure 54.3).

6 An employee learns the growing techniques in a few years and with that knowledge he associates with a landowner, contributing his manpower and part of the production costs. Benefits are shared, normally 40/60 per cent or 50 per cent each. With the capital gained in a few years and with bank credits he purchases his own land, normally marginal land, transforms it, and begins his own activity as a new landowner.

Figure 54.4: Evolution of agricultural production. **Source:** The author

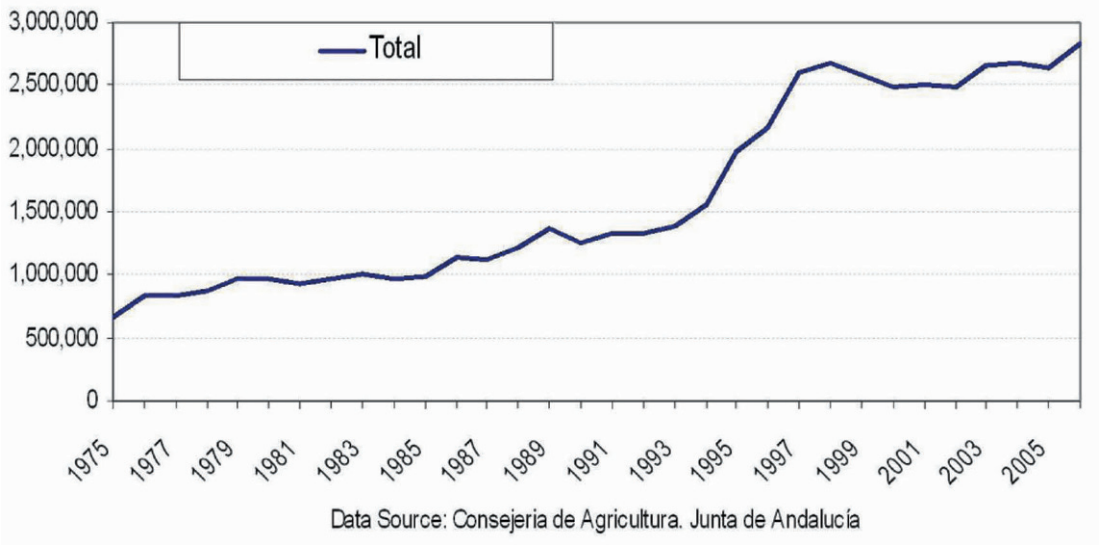

Figure 54.5: Evolution in agricultural exports. **Source**: The author.

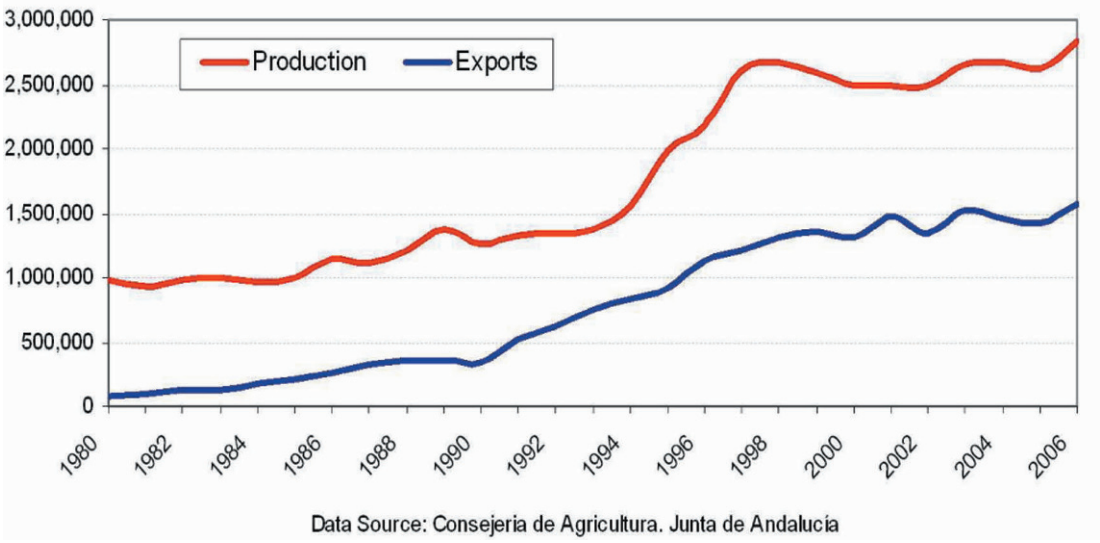


Change in property structure is a very complex phenomenon, given the territorial reality from which it started. The INC developed a number of agricultural structures with a given size of plots, but was soon overcome by the conditions of the model. It should not be forgotten that it is an intensive agriculture with regard to production but also for manpower and capital employed. This resulted in a fragmentation of property to unsuspected levels.

In 2005, 28 per cent of the farms under study were still below 0.5 ha. Obviously this situation of small property accounted for a reality which was the conversion of many employee farmers into property holders, since with a 5,000 square metres surface greenhouse it was possible to maintain a family unit. Changes in economy, new possibilities offered by technology, and the transformation in the agricultural society together with a constant arrival of immigrant manpower, generated a tendency towards a more professional business model without abandoning the basis of the agricultural family company. This has determined a change in the structure of property, which although it continues to be based on family farms, which at present account for 63 per cent of the farms, a new type of middle-size company with employees is appearing, accounting at present for 32 per cent of the farms. At the same time another model of capitalist companies is emerging with strong investments

and with a cultivation area above 10 ha, accounting for 4.5 per cent of the agricultural companies, a paradoxical situation, as attempts to create large companies in the 1980's were unsuccessful (García Lorca 1983).

54.5.2 Technological Transformations

The constant innovation process and the capacity of the model to incorporate self-developed or third-party low cost technologies, or which substantially improve production efficiency, production quality and consolidation or widening of market areas, constitute the objectives of the model. But these innovations have always been incorporated following very pragmatic criteria. The Almeria model has its own *know-how* based on observation, knowledge of technology, possibilities for their incorporation, and common sense. The main process may be summarized in the following features:

- *Intensification of Production*: A higher performance per surface unit has been fundamentally reached by means of control of the vegetable development of the plants, using crop protection systems and also new methods and technologies of organic irrigation and pesticide treatment. The average performance varies from 120,000 to 160,000 kg/ha (figures 54.4, 54.5).
- *Improvement of vegetable genetics*: New varieties of fruit and vegetables were introduced to reach better performance and resistance to diseases. These varieties are the result of the application of research using Mendel's genetic techniques, together with micro-grafting of the varieties which are most resistant to the action of pathogenic elements; they have enabled said increases in production and their adaptation to environmental conditions of the different crop zones, improving the safety protection of the production avoiding pesticide treatment.
- *Improvement in crop practices*: Cropping methods and agricultural manipulation are fundamental for quality and production, such as pruning techniques, irrigation timetabling and pesticide application, together with the manipulation of wastes and the environment health control, have led to a significant improvement in production quality, performance, and hygiene – the latter is of important commercial significance. This improvement in crop techniques is supplemented with the use of new and more efficient tools for farming labour which also enable mechanization of certain activities, with the consequent decline in expenditure for manpower and an improved process control. This has been the case of irrigation automation or environmental control.
- *Introduction of pest control systems*. The need to control plagues and diseases, with the consequent avoidance of pesticides plant protection products and the improvement of product safety, is imposing the use of biological depredators. This also includes the use of pollinating insects, with the consequent disappearance of auxins for fructification development.

Table 54.1: Technological additions to the productive process in Almeria. **Source:** The author.

Year	Introduced Technology
1950	Sand culture
1970	Almeria-type greenhouse
1980	Hybrid seed
1981	Drip irrigation
1984	Thermal plastic
1986	Integrated drip-line
1990	Soiless culture
1991	Bumblebee pollination
1992	New seed variation
1997	Invernadero industrial
1999	Automatic drip head
2000	Automatic climate control
2005	Biological culture

- *Efficient water management*: Agricultural growth could not be understood without the constant innovation and improvement of irrigation networks and devices, such as the modernization of the irrigation network with constant pressure tubes, and the extension and automation of drip irrigation. During the 1970's, over 8,000 cubic metres of water/ha/year produced between 50,000 and 60,000 kg/ha/year; while in 2008 the average production is between 120,000 and 160,000 kg/ha/year using 3,500 to 6,000 cubic metres/ha/year.

As for the technological development of the post-crop process, i.e. from fruit recollection to the final consumer, transformations have signified an important challenge for cultural adaptation and farmers' responsibility, the most significant ones being standardization of production according to market standards

and traceability, the assignment of a code which enables identification of the product and the producer until the product reaches the final consumer. At the same time an extensive system for vegetable health has been developed. It would not be an exaggeration to say that this may possibly be the territorial sphere in which the highest number of analytical controls has been performed in the whole world.[8]

54.6 Impact of the Model on the Territorial System

The territory is a system where all elements interact. The capacity to impact on the territorial system of the model is manifest if each and all subsystems of the territorial system interact. Only its most significant dimensions will be discussed next.

54.6.1 Environmental Problems

The struggle for natural resources, especially of water and land, had multiple negative impacts, among them are increased salinity in aquifers due to excessive pressure from water consumption, severe alterations of hydrological systems due to the occupation and modification of the riverbeds, and alteration and pollution of soils due to an intensification of crops using chemical fertilizers. As a consequence of the territorial expansion of the model, natural resorts were lost which, although they may have had little or no agricultural value, were rich in biodiversity.

From a positive perspective, the concentration of the agricultural activity on the coast has reduced the human pressure on the entire territory, favouring natural recuperation of forest areas and marginal crops which had been under severe desertification risk. At the same time, other areas in the territory have recuperated their traditional agricultural activity although in a different sense, i.e. as recreation areas, not as production zones as they had been. The reasons are fundamentally sociological and are based on the benefits generated by the intensive system which are transferred to the traditional model; the traditional agricultural areas have transformed into leisure and recreation areas. Also the contribution of the model to the reduction of atmospheric CO_2 has been significant as it is a high consumption system, given the extension of chlorophyll mass.[9]

These technological transformations initiated by water and land management have reduced the pressure on resources due to market and production efficiency, eliminating many of the previous actions which had important negative impacts.

Water management produced significant progress for the use economy, and also for its diversification and re-use. Water supply has diversified, thus reducing the pressure on aquifers and balancing the water deficit within the zone. Regulations require the harvesting of rainwater in greenhouses, which takes advantage of runoff water. The present tendency is to promote water supply by desalination – the capacity already installed in the intensive culture zone reached 60 hm^3 (cubic hectometres) per year by the end of 2006 – and to re-use urban residual waters using depuration and ozone processes, with 15 hm^3 per year from plants already installed in Almeria, and new plants are under construction.

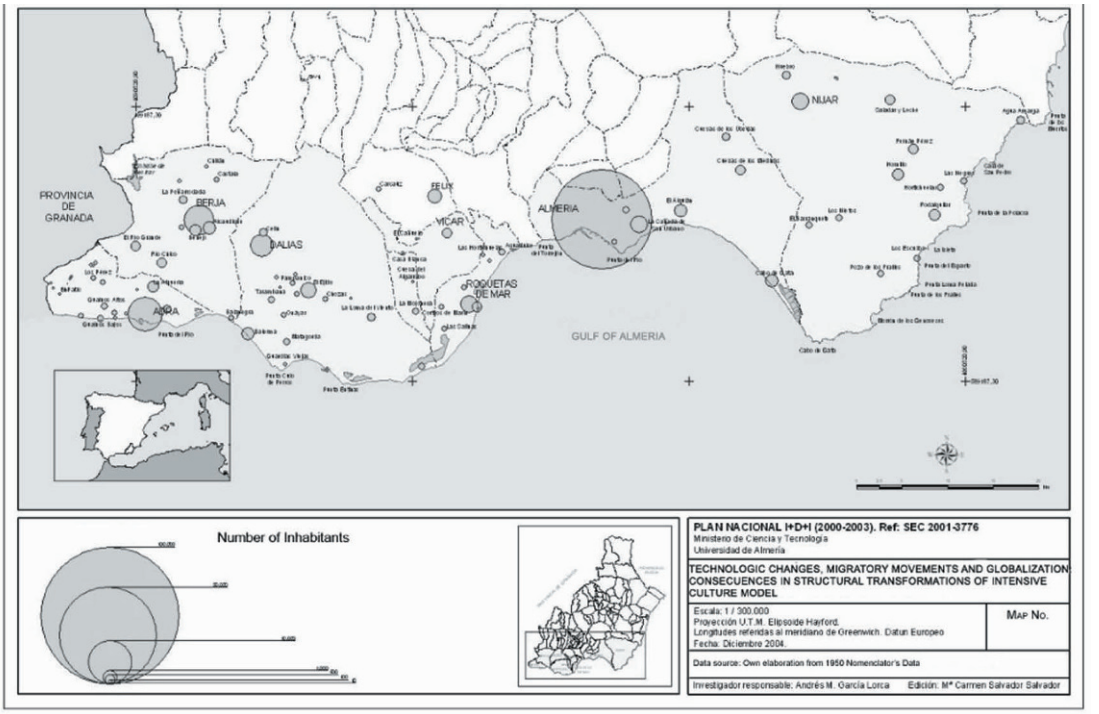
So far land management offers an uneven balance. While the model has created agricultural lands in desert areas, at the same time, and to a lower degree, it has degraded other land by an irrational use of agrochemical and plant protection products, particularly in the earliest greenhouses due to the accumulation of residues. This situation has improved, in some cases by abandoning the cultivating surface, changes in land-use (from agricultural to urban), and in others by the adoption of soil-free (semi-hydroponic) production, and finally by the incorporation of environmentally correct practices. At present more than one third of all the agricultural exploitations comply with regulation UNE.155.001 (European quality control norm), to which those of integrated production and ecological production may be added[10], which guarantee quality maintenance of the land. This concern is the result of a commercial competition for maintaining market positions. During the first decades of development the use of chemical fertilizers and plant protection products reached inadmissible levels, generating problems in land pollution and for human health. Market vegetable health requirements provoked a favourable

8 In 2005, the number of residue analyses of vegetables by laboratories in the province of Almeria was 36,000.

9 One square metre of vegetables consumes an average of 30 g of CO_2/day.

10 A field study performed by the author at the beginning of the 2006/07 agricultural campaign detected 1,100 ha with biological control using depredator insects to fight against plagues, avoiding the use of chemical plant protection products. A total of 9,000 ha were considered to have passed census at the beginning of the 2007/08 campaign, according to the journal F&H: *Frutas y Hortalizas* No. 155, year VIII, pages 18–25.

Figure 54.6: Population of the area under study in 1950. **Source:** Census 1950. Designed by the author.



reaction towards more sustainable models like the present ones.

Environment hygiene and residue management are other significant aspects expressed in the disciplined application of legal regulations, with recollection, treatment, and recycling of plants for both vegetable and inorganic residues But there are still some problems related to these residues, so a number of lines of Research+Development+Innovation are being developed to transform residues into organic fertilizers.

54.6.2 Demographic Impact

Based on census data, the increase of population in Almeria was higher than the average in Andalusia and in Spain as a whole due to the higher vegetative growth and a positive balance in migration. There has been a sustained demographic evolution due to the young age of the settlers and to the migration phenomenon, both aspects arse closely interrelated. In 2004/05 the population growth rate in Almeria was 5.3 per cent, while it was 2.11 per cent both in Andalusia and in the whole of Spain, according to I.N.E. data (figure 54.6, 54.7)

The data for 2005 show a very significant migratory balance, with 4 per cent in Almeria, compared with 1.2 per cent in Andalusia and 1.5 per cent in Spain as a whole (National Census, I.N.E. 2006). This increase of immigrants has accelerated in recent years, with figures above 100,000 that were very unevenly distributed territorially (figures 54.8, 54.9).

From a descriptive analytic perspective this immigration process can be summarized in three phases according to the origin of the immigrants.

- Phase 1: *Intermunicipal movement*: 1954–1970. This coincides with the colonization phase, i.e. the settlement of new farmers in the plotted land and in the new villages. These settlers proceeded from the same town or from neighbouring villages, and were gradually joined by friends and other settlers as a result of the development of the production model. The settling process extended to the end of the 1960's.
- Phase 2. *Interprovincial and regional movement: 1971–1989.* In the context of the Spanish economy the recognition of the success of the agricultural model in Almeria raised investment expectations in the area. Also emigrants returned to Almeria from Catalonia and Europe with their savings and settled around intensive cultivation, together with new residents from other Spanish regions.
- Phase 3. *Intercontinental movement* in the era of globalization (1990–2008). During this period immigration from abroad grew very intensely, at

Figure 54.7: Population of the area under study in 2006. **Source**: Census 2006. Designed by the author.

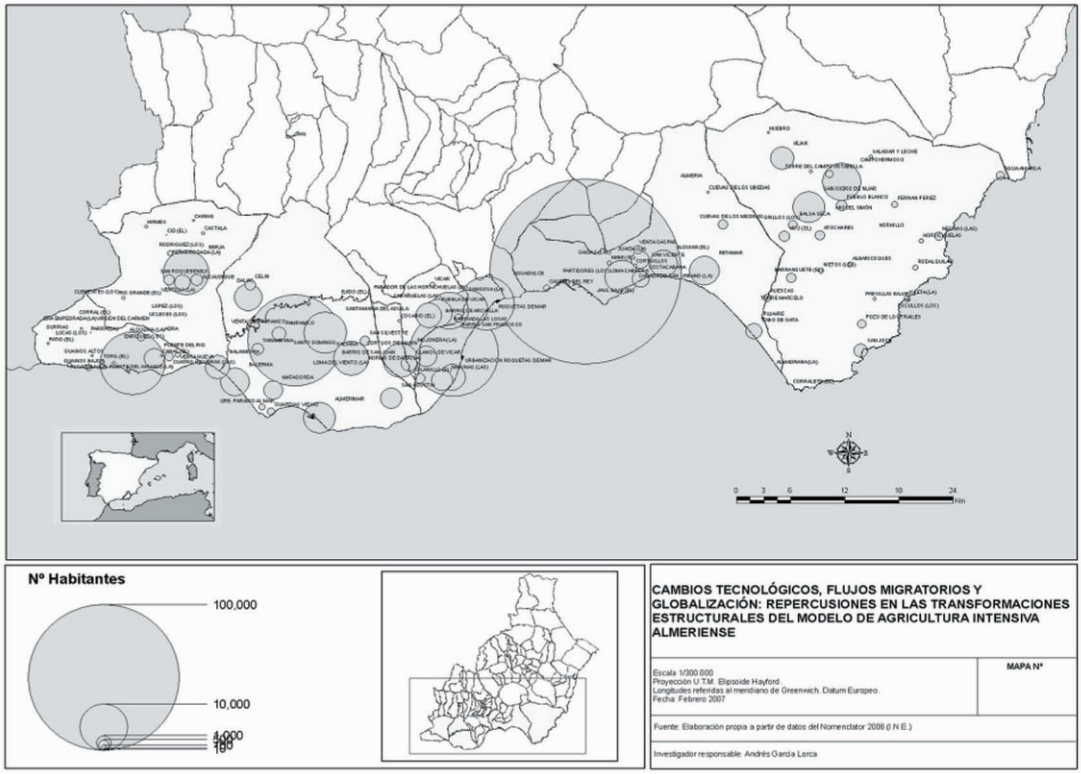


Figure 54.8: Increase of foreigners in Almeria. **Source:** Census-Foreign Yearbook.

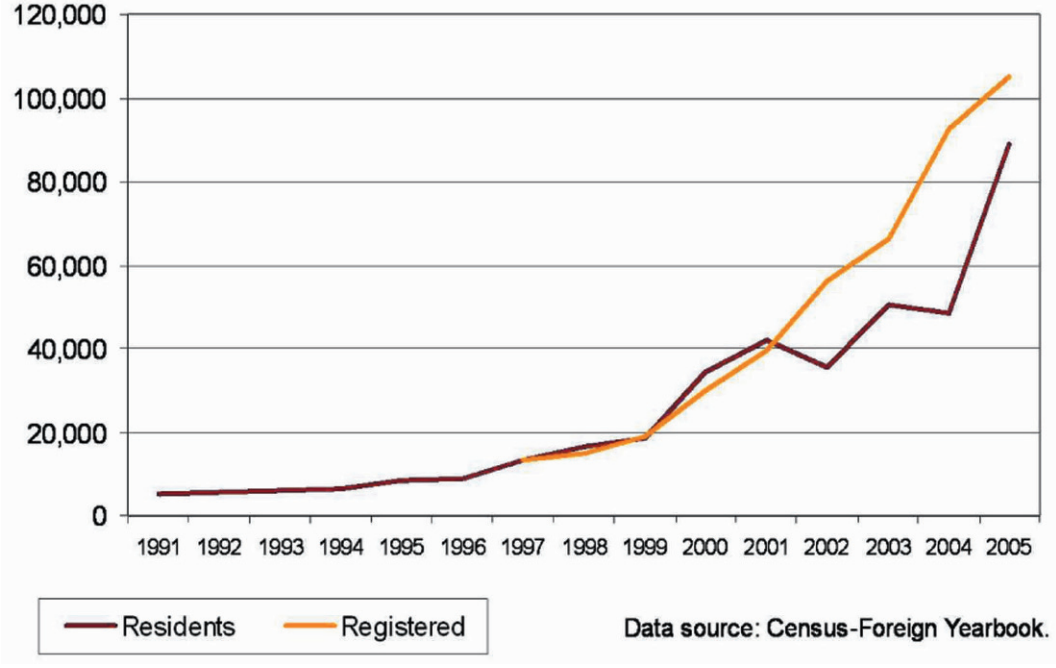
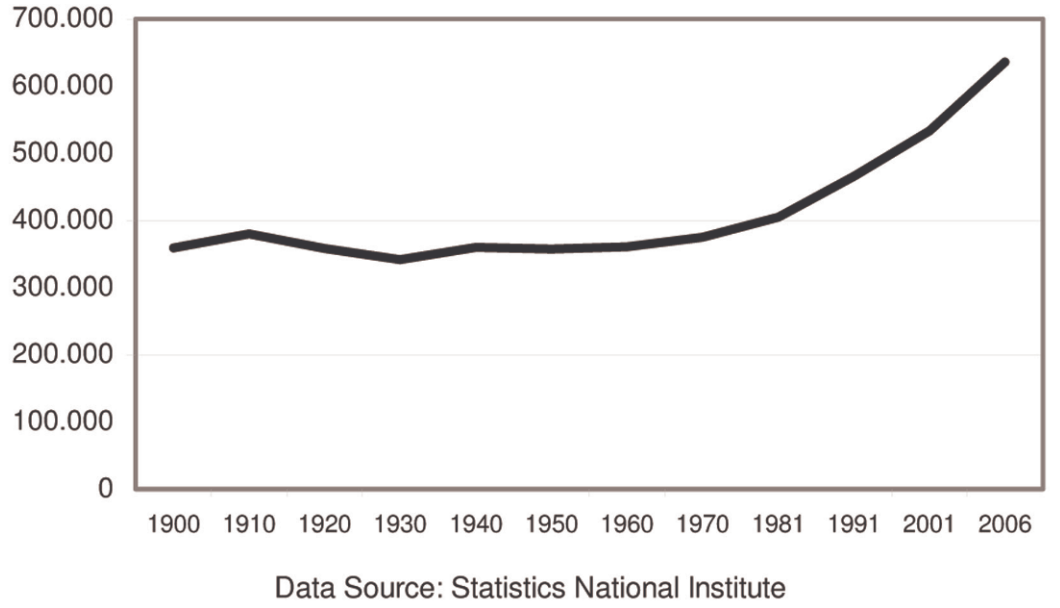


first mainly from neighbouring Morocco, but today it comprises 118 nationalities.

Two types of immigrants can be distinguished: a) *labour immigrants* who come to Almeria to earn their living; and b) those who want to improve their quality

Figure 54.9: Demographic growth in Almeria. **Source:** National Institute of Statistics of Spain.



of life by moving to areas with better environmental quality; this group could be called *environmental immigrants*. The former come from Africa, Latin America, Asia, and Eastern Europe, while the latter come from developed countries in the European Union.

For *labour immigrants,* the migratory process in the zone has very specific features. Immigration is based on the demand for manpower in agriculture, but also on opportunities to find a first job which may open the doors to the EU labour market. This explains the constant renewal of personnel which complicates the development of stable and trained staff, and has also developed an informal manpower which makes real control of immigration extremely difficult (figures 54.10, 54.11).

The case of the *environmental immigrants* presents a very complex problem linked to the environment of the territory where they settle and their cultural origin. This has provoked environmental tensions in the consumption of natural resources, water and land (they want to settle in the countryside, in single-family houses with swimming-pool and garden), and if possible close to a golf course, apart from other territorial tensions, as they do not follow territorial and city planning criteria, thus generating problems in pollution, territory disarticulation, and also not contributing to the development of general territorial planning systems, road networks, water supply and sanitation, and public services. This has accelerated land speculation and produced severe losses of natural heritage. For example in towns like Arboleas, in the year 2006, of 3,042 inhabitants, the foreign population is 1,829 people, of which the English community with 1,477 people reaches 48.55 per cent of the total population.

Statistics distinguish between residents – legally documented foreigners – and those who are only municipally registered, who only appear in the municipal census, although many of them appear in the census but do not have a legally recognized status, either because they have no identity card, pending repatriation, or have entered the country illegally; in any case they are recognized subjects with respect to the access to welfare services, but they cannot sign work contracts. In order to understand this reality, and bearing in mind that young people emigrate, the welfare data offered by the S.A.S. indicate that during the 2000/2005 period 111,505 health cards were issued, 824,808 health actions were performed, and there were 99,540 hospital day cases.[11]

This model of immigration, with a constant increase in uncontrolled human flows, provokes a social conflict which is not exempt of a certain level of violence, given the precarious conditions of immigrants prior to their access to the labour market. There are also socio-cultural adaptation problems which complicate the integration processes.

According to the 2006 census, the structure of the immigrant population is quite revealing with regard to

11 Data from: Immigration Attention Programme, Health Authority, Regional Government in Andalusia (2006).

Figure 54.10: Increase of registered foreigners in Spain, Andalusia and in Almeria**. Source:** Census 2006.

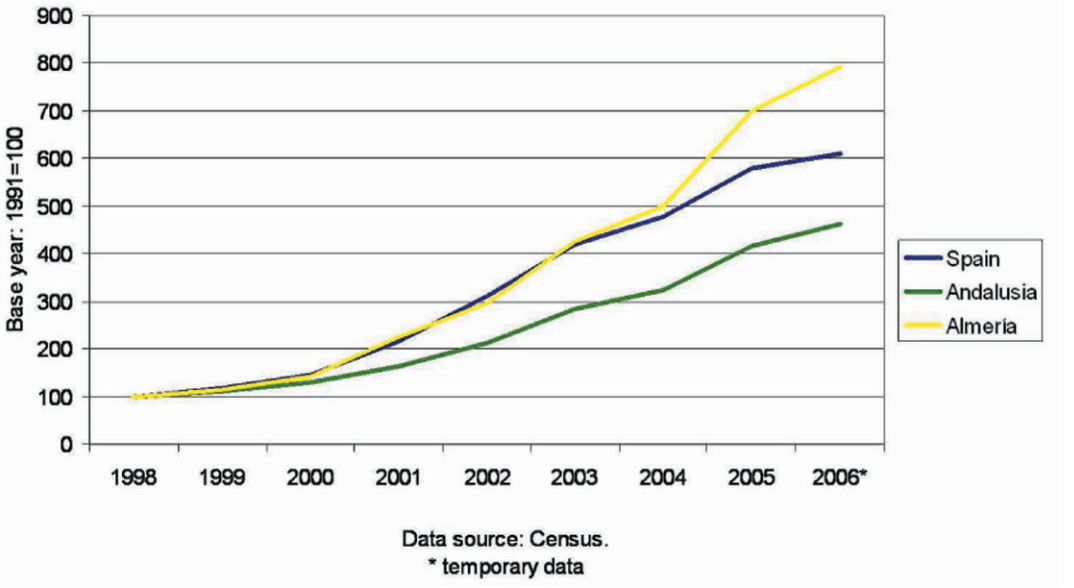


Figure 54.11: Increase of resident foreigners**. Source:** Ministry of Interior.

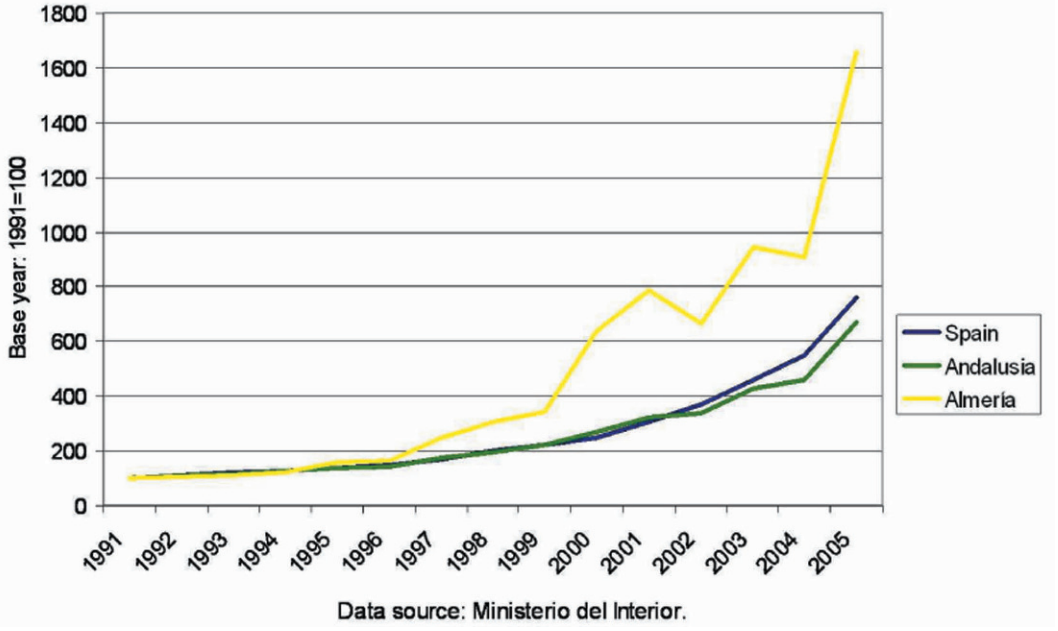
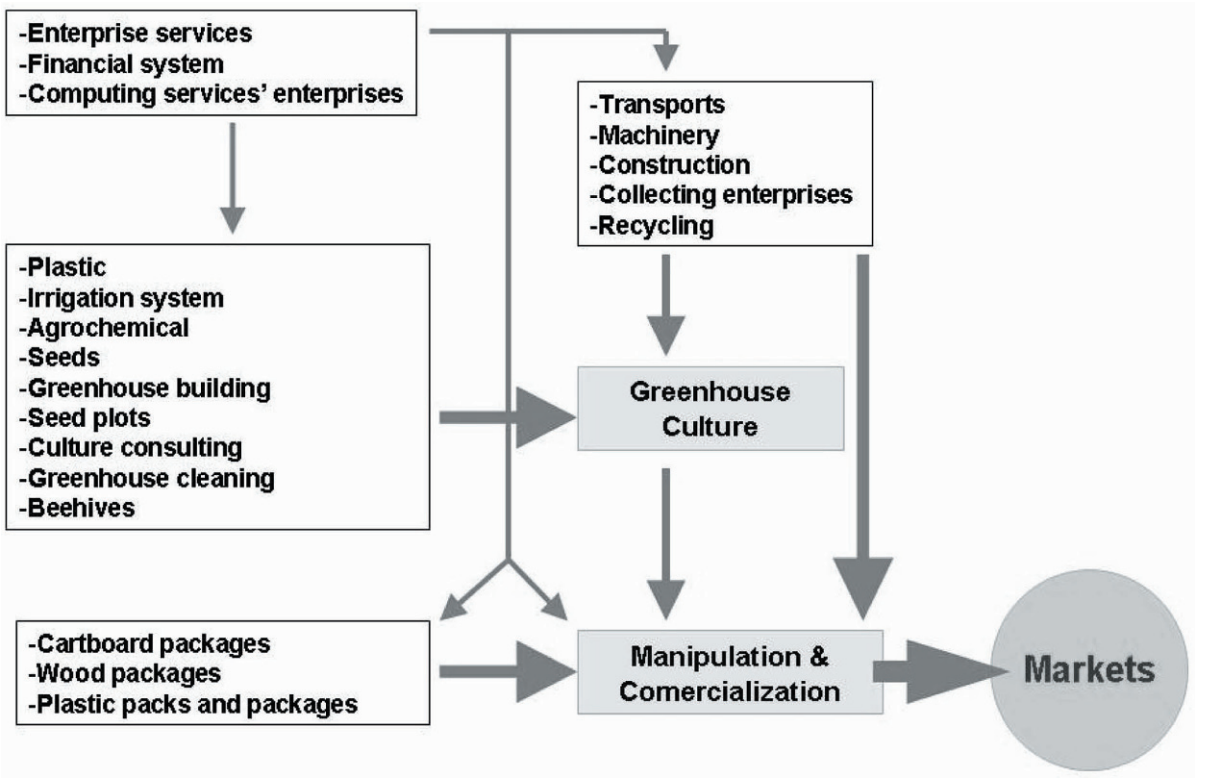


their origin. In 2006, 44,991 people came from Africa, of which 35,634 were Moroccans. The second largest group with 38,602 people come from EU countries, of which 16,540 are Romanians looking for work, while British immigrants reached 10,071 people, moist of them being 'environmental immigrants'. Latin America immigrants account for 17,205 people, of which 8,212 people come form Ecuador. About 1,715 people come from Asia, of which the Pakistanis are the most numerous group, with 812 people.

The migration policies of different governments have not produced satisfactory results. The constant flow of illegal immigrants combined with the lack of an administratively regularized work force, are responsible for an alteration of the labour market which has important consequences for the productive system and social stability. While the fact that many immigrants are Moslems has not provoked cultural clashes, it has generated the development of parallel societies. Some immigrant organizations are considered as dan-

Figure 54.12: Cluster of the agricultural model of Almeria. **Source:** Cajamar Foundation (2004: 25).



gerous for the security and stability of the host country. In Almeria some immigrants belong to '*Justice and Charity*', '*Tablig Al Dawa*', '*Moslem Brothers*', '*Former Salafista Group for Liberation and Combat*', while others are members of other associations aligned with *Salafía Jihadía,* which is known to be under *Al-Qaeda*. [12]

54.6.3 Socio-economic Development

In general, the intensive agriculture model has served as an impulse for all economic sectors of Almeria and its proximities. It has even generated endogenous business behaviour and methods in management and commerce. The existing demand in services and the equipment generated by the development of intensive agriculture led to the emergence and subsequent expansion of a business structure which has developed a leading role during the last decade, not only covering local demand but also extending to the regional and international sphere.

This business cluster may be defined as a self-developed model. Ferraro and Aznar (2005: 303) called it a *Local Productive System* (LPS) which they defined as

> ...a set of economic activities in a territory with commercial and cooperation links, with a shared labour market and a common know-how, which provides external economies for the territory, which are competition factors added to those pertaining to each company.

There were no technological or business precedents in the territory where the process has evolved. The model emerged and grew due to the impulse of the territorial needs, and as a result of the agricultural productive model. Although it is true that in the initial phases and even in those of the development of the agricultural model, some input was provided by local agents, the rest was marketed by foreign companies. As technological and equipment needs increased, there was a similar increase in the development of a locally based auxiliary industry, although it was unorganized and followed market impulses. It reached its present configuration and presence in the economic system during the 1990's. Now the sector is constituted by 250 companies from 14 productive sectors which may be grouped in four types of activities: in-

12 FLORES, F. *Foco Sur* nº128 October 2007 , pages 20–22.

dustrial, commercial, services, and research (figure 54.12).

Labour and production is important locally, as some 20,500 direct jobs have been generated, from which 12,000 are in the handling sector and the remaining 8,500 jobs are in other activities, the average productivity per worker being 145,000 €, although it varies much according to the specific activities. In 2007, 47.1 per cent of the economic activity focused on the local market, 44.3 per cent on the national market, and 8.6 per cent on the foreign markets. Its main clients are Morocco, Kenya, and Latin American countries, like Mexico and Chile that need non-complex and inexpensive technologies.

The Almeria economy is now based on services, agriculture, construction, and industry. For its population of 630,000 inhabitants, there are 57,208 business licenses for different sectors. Some sectors are highly consolidated, like tourism with hotel availability of 49,751 beds and close to 3 million visitors coming per year.[13] These data summarize the strength of the productive and financial system and indicate that the commercial balance in Almeria is positive. In 2005, Almeria had an export surplus of 272 per cent, compared with 81 per cent for Andalusia and 68 per cent for the whole of Spain.

54.7 Concluding Remarks

The primary challenges facing the agricultural model are not the environmental physical constraints, i.e. of water and land, but the human limitations, i.e. of transport policies and manpower. The increasing dependence on waged manpower, with a low level of efficiency due to its mobility and training, and also due to cultural differences and slow integration, has hampered productivity compared with the competition from nearby third countries with lower social and labour costs. The difficulties in using alternatives to road transport for vegetables, in light of transport restrictions and regulations for road transport in Europe, have increased transport expenses that reached 100 per cent from Almeria to European markets, what has reduced the competitiveness in production.

Despite the power of the productive sectors, and magnitude of the services (57 per cent of GVA [Gross Value Added], agricultural activity has been and continues to be the real leader in regional development, and has been responsible for the financial figures for Almeria that have been higher than those of Andalusia, equal to those in Spain, and close to those of the most developed EU countries.

The environmental and territorial risks mainly originate from the demand-driven town planning development model which often ignores the fragility of the environment although it bases its settlement criteria on 'environmental quality'. The environment has been preserved thanks to the absence of anthropic pressures. The housing and tourism sectors need extra resources to ensure higher standards of living, which endangers those very standards and the whole territorial model.[14]

55 Land-use Changes, Desertification, and Climate Change Impacts in South-eastern Spain

Jorge García Gómez, Francisco López-Bermúdez and Juan Manuel Quiñonero Rubio

55.1 Introduction

The south-east of Spain is a semi-arid area suffering marked rainfall seasonality, with frequent and long dry seasons. Inappropriate human activities and developments in unsuitable areas have caused soil erosion and degradation that are expected to increase due to negative effects of climate change ranging from moderate to severe depending on the specific scenario. This chapter reviews current land-use changes and their effects on desertification[1] taking a specific regional climatic change scenario into account from the *National Ministry of Rural and Marine Environment* (MARM 2007, 2008) and the *fourth assessment report* (AR4) of the *Intergovernmental Panel on Climate Change* (IPCC 2007, 2007a, 2007b) on agriculture and urbanization.

These two issues are studied and their economic impact on the area and their role as driving forces and pressures that affect land-use changes and desertification processes. Both are studied in the Campo de Cartagena in the surrounding coastal area in Murcia (Spain) where very intensive agriculture and marginal dry farming coexist, and where water availability is under risk. Moreover, a further intensive land-use change has occurred from natural or agricultural areas to urban settlements, changing the economic and social structure and increasing the need for water. The evolution of land-use changes, its causes and consequences are reviewed, together with the projected climate change for Murcia and the interactions among these factors. The conclusions suggest that the role of government in managing territories must be stressed since it is the only key actor that can manage in a coordinated way the different approaches of agriculture, urban development, and the environment.

55.1.1 South-eastern Spain Facing Desertification

The landscape of south-east Spain is a product of its geographic location, of its climatic and geo-morphological conditions, and of human history. These complex and functional territorial systems are the result of interactions of factors that vary greatly in nature and intensity, due to physical (weather, terrain, soil, water...), biological (wildlife), and human (culture, use, and management of land and its resources in history) drivers. In Murcia the physical environment heavily impacts on humans. But irrespective of the impact of physical factors on these ecosystems, for millennia human action has profoundly influenced landscapes, systems of land-use, and ecosystem degradation, particularly of soil and vegetation (López Bermúdez 1996, 1999).

The south-eastern part of the Iberian Peninsula offers a large variety of geo-morphological and bioclimatic landscapes, due to its location in a transition region between North Africa and the rest of Europe, between the Mediterranean coasts and the continental mainland, and its terrain features and climate history. In this region a large variety of landscapes exists that are defined by a constant dualism of coastal plains vs. coastal mountains, of river valleys vs. highlands, of topographical depressions vs. mountains above 2000 metres, of sharp contrasts between shady or sunny exposures and upwind and downwind orientations. There are also strong contrasts between irrigated and dry rural landscapes as well as densely and scarcely populated areas.

Many ecosystems and agrosystems are seriously degraded or are at risk of degradation due to a combination of drought recurrence, soil and water degra-

1 According to the UNCCD convention, 'desertification' is defined as "land degradation in arid, semi-arid, and dry sub-humid areas, resulting from various factors, including climate variations and human activity."

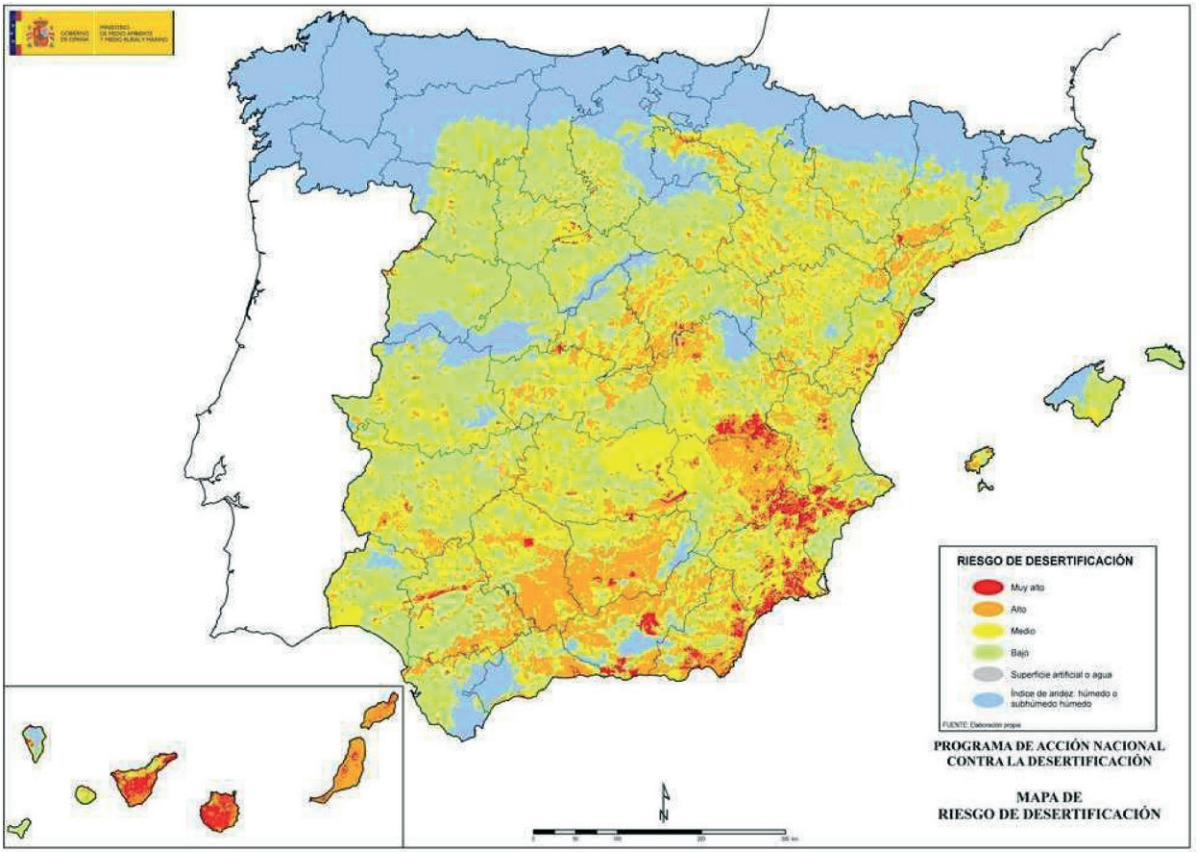
dation, wildfires, land clearance for cultivation, groundwater overexploitation, soil and water salinization, wetland drainage, abandonment of traditional practices of soil conservation, littoralization of greenhouse-based intensive agriculture and of population, discharge of dangerous chemicals, reclassification of land for speculative housing developments, etc. The result has been a worrying increase in ecosystem degradation at several scales. This complex process is known as desertification, and it prevents the preservation of basic resources in terms of quantity and quality, as well as sustainable development.

The south-east of Spain is a climatic region (Vilá 1971; Geiger 1973; Font Tullot 1989) that is mainly determined by its aridity. It is the driest and most arid region in Europe, where most of the territory obtains between 170 and 350 mm in precipitation. The strong and long summer drought can be observed in the annual totals. However, rainfall is best defined by its strong variability, about 50 per cent, with the highest volumes recorded in autumn, sometimes concentrated on a few hours. This strong intensity causes important water erosion in bare or sparsely covered soils, water course overflow and floods, with heavy economic and environmental impacts (chap. 90 by Quiñonero-Rubio/López-Bermúdez/Alonso-Sarría/Gomariz-Castillo). Extension, frequency, intensity, and duration of wet and dry periods are key factors in south-eastern Spain. Other features of this climate are: strong solar radiation and albedo, average annual temperatures between 15 °C and 19 °C, high potential evapotranspiration and highly negative moisture balances during most of the year.

The dry nature of most of the region severely constrains the development of vegetation and rain-fed agriculture. In the south-east, there are clear limits to the development of a continuous tree layer, as well as a mosaic structure of vegetation determined by orientation, exposure, soil, and lithology (Barberá/López Bermúdez/Romero Díaz 1997). It is the broad extension of soft lithologies, unfavourable soils, and centuries of human activities that have hampered plant development and facilitated the effectiveness of erosion processes, by both rainfall impact (splash) and surface runoff, as evidenced by the profusion of rills, gullies, ravines, and wadis. These processes have created a landscape that prevails throughout the Mediterranean region: the 'badlands'. Since the 1950's a process of environmental change has occurred where the impacts of climate change and desertification processes can increasingly be observed.

Figure 55.2: Desertification risk in Spain. **Source:** *National Ministry of Rural and Marine Environment* (MARM): PAND National Action Plan against Desertification; at: <http://www.mma.es/portal/secciones/biodiversidad/desertificacion/>. Colour range goes from very high (red) to low (green) and humid and sub-humid areas (blue).



55.1.2 Historical Evolution of the Environmental Crisis

South-east Spain has been under ecological stress for centuries, as most dry Mediterranean regions. However, the present economic system that has favoured certain types of inappropriate farming (clearance of forest land, irrigation with poor quality water, frequent abuse of agrochemicals), overexploitation of groundwater, forest fires, and discharges from industry and tourism, have caused more ecological changes and damage than has previously occurred during human history. An increasingly strong interaction between human activities and geo-ecological equilibria can be observed that have degraded large areas where almost sub-desert conditions prevail. This is defined as desertification, a process of environmental change due to the alteration of the ecobalance by excessive or inadequate human pressures on ecosystems that have been weakened by drought and aridity, i.e. an imbalance between the natural resource system and the economic system using them (López Bermúdez/García Ruiz 2008; López Bermúdez/Barberá 2000; Puigdefábregas 1995; Puigdefábregas/Mendizábal 1998).

Many studies show that degradation of ecosystems by human activities has been neither linear nor irreversible over time, but that they are related to factors like climatic fluctuations, population density, level of social organization, and the systems used for resource exploitation (Dregne 1983; Ibáñez/Valero/Machado 1997; Brandt/Thornes 1998; López Bermúdez 2001). To address the respective impacts related to natural processes or human activities has been a difficult task due to the complexity of the process and the similarity of the impacts, which are not easily identifiable in the landscape.

In the Mediterranean regions of the Iberian Peninsula, pollen diagrams have shown significant changes in the vegetation structure and a growing presence of xeric plants from the Holocene up to modern times

(Gilman/Thornes 1985; Follieri 1996; Burjachs/Febrere/Rodríguez/Buxó/Araus/Julia 1997). The causes have been attributed to climatic fluctuations towards a more arid climate and to pressures from Neolithic populations on vegetation cover due to the emergence of agriculture and domestic livestock. At this early age of human technological progress, the evolution of landscapes was more conditioned by climatic fluctuations than by human action. The Roman colonization modified heavily the plant landscapes through abusive logging and extensive land clearance for agriculture (for cereals, vines and olive trees), grazing and mining.

The Muslim and medieval times seemed relatively stable and allowed the recovery of Mediterranean ecosystems in south-east Spain. Muslims introduced new agrarian systems and modes of land development and management. The introduction of new hydraulic systems for irrigation and of new species grown in irrigated conditions meant a profound break with previous agricultural traditions that were based on extensive rain-fed cultivation of cereals and implied deforestation and use of large spaces (García Latorre/Sánchez Picón 1998). Between 1501 and 1812, the livestock institution known as La Mesta enjoyed great privileges granted by the Kings. The millions of sheep and goats, moving along trails called *cañadas, veredas,* and *cordeles* appear as critical determinants of forest degradation and meant a return from irrigated agriculture to rain-fed cultivation of cereals, and vineyards, and to wool sheep ranching. Land clearance for pastures and cereals were conducted at the expense of plant cover. In addition, the boom in shipbuilding and mining caused the clearing of large forested areas covering the mountains of the south-east. Naked soils, stripped of protective vegetation, were exposed to severe water erosion processes (López Bermúdez 2001).

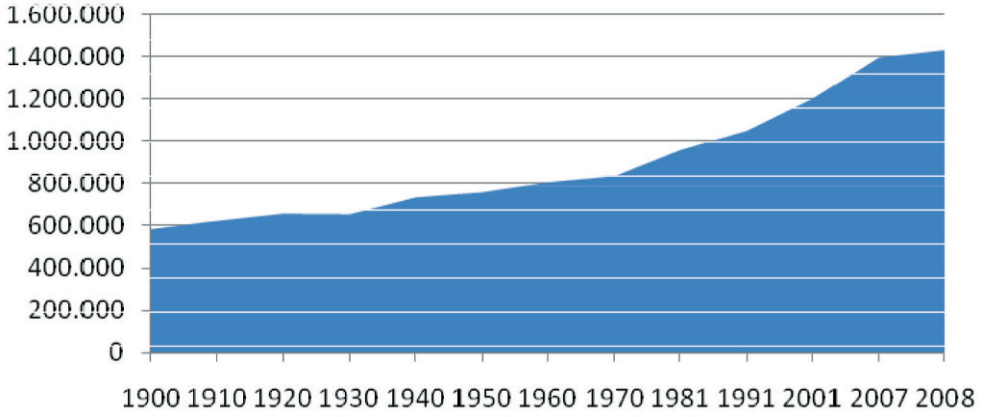
The demographic crisis of the 17th century slowed the clearing of forest land and allowed some recovery of the vegetation cover, however, deforestation was already well advanced in the 18th century and most of the land had become barren with little or no fertility. The degraded soil, devoid of vegetation, and the heavy rains recorded in this century activated, once again, the mechanisms of erosion and increased surface runoffs and flooding risk – severe floods hit the land and the populations. In the mid 19th century, the disentailment laws had serious environmental consequences because of the sale of public and church forests to individuals. This privatization resulted in the loss of more than four million hectares of forest in Spain (a considerable amount in the south-east) with dire consequences for forest soils. Intense rain and strong runoff mobilized millions of tons of soil that went to the bottom of valleys, lowlands, and the sea. The loss of vegetation cover left the soil unprotected and produced, once again, an acceleration of water erosion and the development of large bare areas, which, in turn, increased the risk of extensive inundations and flash floods (López Bermúdez/Navarro Hervás/Montaner Salas 1979; Canales 1989; Molina Sempere/Vidal-Abarca/Suárez 1994). The forests, providers of public goods (not entering the market) and environmental and recreational functions, were subjected to unsustainable exploitation by private owners. This has been described as the most tragic event in the history of Spanish forests (Bauer 1991).

During the second half of the 19th century and the first half of the 20th century, population growth and its food needs generated a strong demand for cereals that contributed to the expansion of clearings for rain-fed crops at the expense of marginal lands and forests. The consequences of this process became soon manifest: erosion processes were aggravated, with rills, gullies, and ravines thereby increasing their size and density, extending badlands landscapes. In conclusion, the centuries-old deforestation that occurred in the south-eastern part of the Iberian Peninsula and its implications (the alteration of the hydrological cycle, activation of erosion processes, significant loss of soil, degradation of ecosystems, increased risk of flooding, and other environmental impacts) have transformed this region into one of the most threatened by desertification and climate change in Europe.

55.2 Land-use Changes in the South-east of Spain

Land-use changes have increased in speed and intensity during the last three decades, which had a special effect on the Mediterranean (Margaris/Koutsidou/Gioura 1996). These human-induced changes have been more severe than nature-induced changes. Among all human activities many changes were triggered by regional policies that were often influenced by external factors, such as the EU's *Common Agricultural Policy* (CAP), which is linked to other processes due to economic activities and dynamics. These processes have introduced new driving forces and effects that need to be taken into account (like rural abandonment).

Figure 55.3: Evolution of the Population in the Region of Murcia (1900-2008). **Source:** *National Institute of Statistics* (INE) of Spain (1900-2008).



All these social, legal, political, and economic aspects have determined in recent years changes in land-use, and thus a large imbalance between the economic, social, and environmental sectors, leading to greater unsustainability of the system. This unsustainability has led, in many cases, to the emergence or acceleration of processes of land, environmental, and social degradation and, therefore, poses a serious problem that affects large areas of the Mediterranean region. For instance, the abandonment of dry farming cultivations (cereals, almonds...) or their conversion into irrigation farming, especially in slope areas, has led to an increase of runoff, soil degradation, and severe impacts on the value of the landscape.

The south-eastern part of Spain has experienced great changes during the last two decades. The strong population increase (from 2001 to 2007 the population grew from 1,190,000 to 1,392,000 inhabitants, or by 16 per cent) has been also associated with an increased use of resources, far greater than that of GDP (INE 2003). Therefore, the growth has occurred at the expense of a disproportionate use of resources, especially of the land, one of the most valuable resources (OSE 2007, 2008), which has faced strong irreversible processes. The two major developments in land-use change are:

- The intensification of agricultural crops, with the transition from rain-fed cultivation to irrigation, and the intensification of existing irrigation systems;
- The changes to an urban use of land derived from the unprecedented increase in the property business.

Another important phenomenon related to changes of land-use has been the abandonment of land. However, in the areas studied here (i.e. of coastal or intensive agriculture) this phenomenon is irrelevant due to the high potential of land-use, since the irrigation infrastructure had already been built or the demand for recreational uses offered an alternative use for the existing land. These possibilities and demands act as true driving forces. Also, rain-fed crops tend to be the first to be abandoned, but in these coastal and intensive farming areas, the transition from rain-fed to irrigation cultivation date back to the 1970's and 1980's, with the water transfer between the rivers Tagus and Segura and the modernization of irrigation.

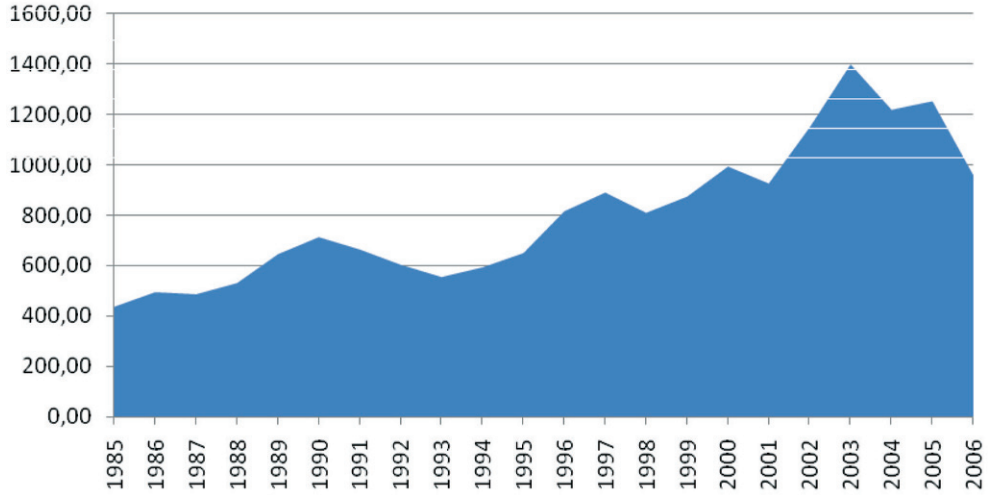
The Corine Land Cover 2000 project (EEA 2000) and the *National Action Plan against Desertification* (PAND) have summarized the changes in land-use (MARM 2008).

For *artificial areas* these changes were observed:

- accelerated development of urban areas and infrastructure from agricultural areas that were, in some cases, very productive; (In the case of Murcia this development is due to the arrival of immigrants and the increase of residential tourism).
- accelerated and intense artificialization of the coastal strip, especially in the first kilometre of the coastline;
- taxing artificialization because of the deterioration of wetlands;
- development of highly visible open cast mining areas from forest areas;
- smaller but highly significant development of urban areas from forest areas.

For *forest and agricultural areas* these changes were noted:

Figure 55.4: Evolution of the GVA (Gross Added Value) at market prices for the agricultural sector in the Region of Murcia. (1985-2006). **Source:** National Institute of Statistics (INE) of Spain (2009).



- continuous and uncontrolled development of permanent irrigation areas from rain-fed areas;
- development of forest areas from agricultural areas, usually due to their abandonment (marginal land) or afforestation;
- development of forest areas as a result of new forest crops;
- development of areas of scrub from burnt forest areas; and
- loss of high-quality forest areas due to wildfires and ecosystem fragmentation.

These land-use changes have produced these phenomena that can be summarized as follows:

- *Increase of artificialization:* there is an expansion of the artificial surface largely due to urbanization, which creates a mostly discontinuous urban fabric. The artificialization is especially intense in the first kilometre of the coastline and around urban areas, and it means also the loss of natural areas, which means the loss of quality and functionality in the ecosystems.
- *Increase of intensive irrigation:* from rain-fed or traditional irrigation areas. This increase implies greater pressure on resources and greater environmental stress, because humans modify it to fit to cultivation necessities instead of adapting cultivations to the soil and climate conditions. This, together with the increase of population, leads to an increase of water needs and water shortage.
- *Changes in the runoff and water retention and circulation patterns* and, in general, the hydrologic cycle.
- *Alteration of forest ecosystems*: the abandonment of marginal agricultural areas favours the spread of forest areas through colonization. This phenomenon occurs mainly in agricultural areas that were previously reclaimed from the forest. It is important to bear in mind that, in many cases, the abandonment of agricultural land (profoundly altered by man) does not automatically lead to the recovery of the forests but, on the contrary, may accelerate the processes of soil degradation, erosion, and desertification.

There is an area in Murcia where land-use changes have been really intense during the last 40 years: the 'Campo de Cartagena' along the coast. The arrival of water from the river Tagus (water transfer Tagus-Segura rivers) led to the development of an intense irrigation farming from the ancient dry farming, covering currently more than 40,000 ha in 7 municipalities (for a total area of 116,000 ha). In the same area an intense population increase and tourist development occurred during the last 25 years, with the construction of many new settlements and holiday homes. This example of human-induced land-use changes applies to many Mediterranean areas. This development is illustrated below (figures 55.5, 55.6, 55.7, 55.8), where it is possible to see the most common processes of changes in land-use in Murcia. The land-use changed from more sustainable and less resource demanding use to less sustainable and more resource demanding use.

Figure 55.5: New urban settlements in traditional farming or forest areas. Here it is possible to see the whole process of land change: dry farming to irrigation farming and then to housing development. The satellite images of the *Campo de Cartagena* coastal agricultural area were taken in 1956, 1997, and 2007. **Sources**: The 1956 aerial photo, taken from a USAF flight, is the property of the Instituto Geográfico Nacional de España; the photo of 1997 is from the Ministry of Environment and Rural and Marine Affairs. Figure 55.6: In this case, the images (1956, 1997 and 2007) are located in the coastal area near the city of Cartagena. The house development process started at the end of the 1980's and continues until present. **Sources:** The 1956 aerial photo is from a USAF flight and is the property of the Instituto Geográfico Nacional de España; the photo of 1997 is from the Ministry of Environment and Rural and Marine Affairs. Olive GIS mapping (SIG oleicola); and the photo of 2007 is from Ministry of Development (Ministerio de Fomento) PNOA (National Plan of Aerial Ortophotography).

55.3 Climate Change Scenarios for Murcia in the 21st Century

The climate change scenarios that were assessed by the IPCC (2003, 2007a, 2007b, 2007d) and developed by MMA (2006, 2007a, 2007b) show, despite their different numerical values, a clear qualitative trend in the south-eastern part of Spain for this century. In short, their basic characteristics are:

Figure 55.7: Intensification of farming activities in traditional dry-farming areas. In this sequence (1956, 1997 and 2007), located near the town of Fuente Álamo, the change to more intensive farming activities is shown. **Sources:** The 1956 aerial photo is from a USAF flight and is the property of the Instituto Geográfico Nacional de España; the photo of 1997 is from the Ministry of Environment and Rural and Marine Affairs. Olive GIS mapping (SIG oleicola); and the photo of 2007 is from Ministry of Development (Ministerio de Fomento) PNOA (National Plan of Aerial Ortophotography).

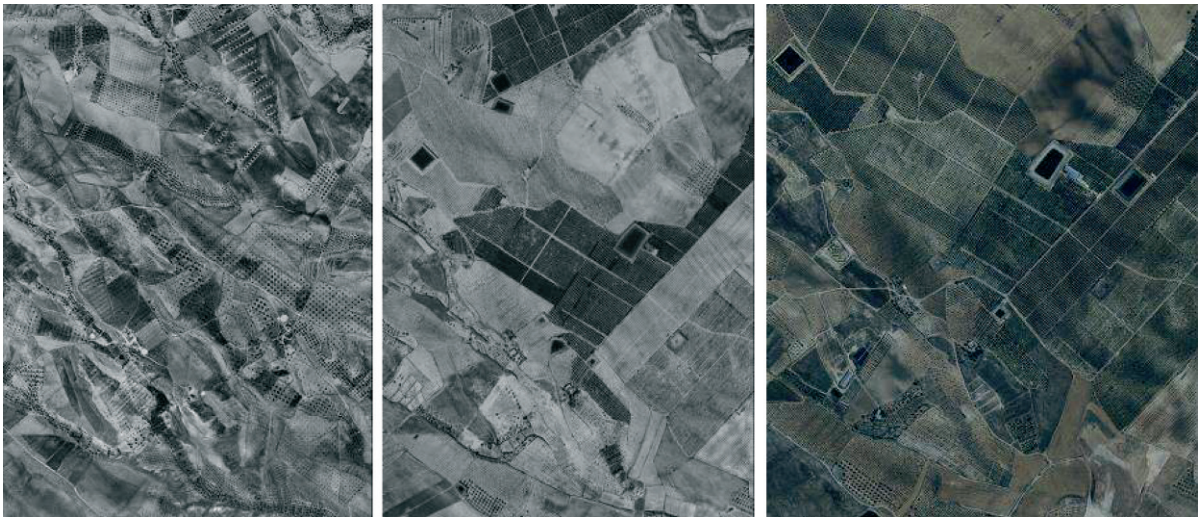

Figure 55.8: Irrigation development. Development of irrigation farming in Rambla de *Las Moreras*, Murcia (1956, 1987, 2003) **Sources:** The 1956 aerial photo is from a USAF flight and is the property of the Instituto Geográfico Nacional de España; the photo of 1987 is from the Ministry of Environment and Rural and Marine Affairs. Olive GIS mapping (SIG oleicola); and the photo of 2003 is from Regional Ministry for Agriculture and Water based on "Quickbird" satellite images.

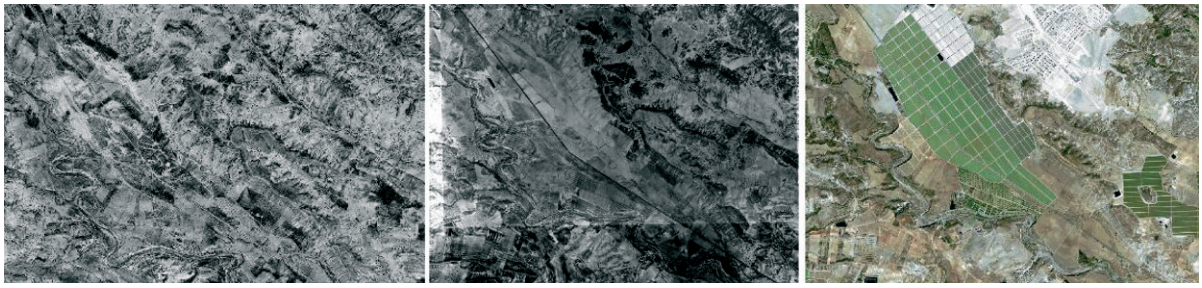

- A gradual increase in surface temperature throughout the century, which is accelerating very sharply since the mid century in the case of scenarios of higher global emissions, with very significant differences in the average annual or seasonal warming between the various emission scenarios (differences of up to 3 °C), most noticeable in summer and less severe in winter. Spring is the season where the warming would tend to be higher.
- There is a trend for the daily thermal oscillation (difference between maximum and minimum temperature) to increase in various climate change scenarios, especially in those assuming high emissions. This trend would be lighter in winter and more pronounced in spring.

For the region of Murcia other studies (López-Bermúdez/García 2004, 2005) show that, for the period between 1863 and 2002, the annual mean temperatures show a growing trend of around 2 °C, based mainly on the rise of the minimum mean temperatures, which show a significant increase (of 2.1 °C for the studied period). These data differ from averages reported in IPCC reports, but are based on data obtained from measurements of temperature since 1863.

The scenarios on the change in annual precipitation present a less regular trend than for temperatures. A progressive declining trend is projected, which will be more pronounced after the mid century and even higher for the high emission scenarios. For 2011 to 2040, the projections show a similar reduction

in the total annual precipitation for the different emission scenarios, with values around 5 per cent. However, between 2070 and 2100, the contrast between high and low emissions scenarios is much higher, with reductions that would exceed 30 per cent in the A1 scenario and around 20 per cent in the B1 scenario. The seasonal mean values of relative humidity tend to decline in general and in all seasons, but with higher rates in the summer than in the winter.

Average insolation is projected to rise in all regions due to a lower cloud cover. In spring and autumn, the reduction rates are higher in the southern half of the peninsula, while in the winter the changes are less significant with regard to the current climate.

The regions most prone to an increase in the drought hazard are the Mediterranean regions, where the river flows decrease significantly, especially in the summer. However, other factors such as land-use changes, water management practices, and extensive water withdrawals have considerably changed the natural flows of water, making it difficult to detect climate change-induced trends in hydrological variables. In general, annual river flows have been observed to decrease in the south of Europe, a difference projected to intensify. Strong changes in seasonality are projected, with lower flows in the summer and higher flows in the winter. As a consequence, droughts and water stress will increase, particularly in the south and in the summer (European Commission 2008a).

Another very important aspect of the climate projections is the possible change in the intensity and frequency of extreme weather events. The Iberian Peninsula and especially its south-east have been affected by several major droughts during the last century and more recently a catastrophic drought was linked to a heat wave in the summer of 2005. The concern is that the impacts due to changes in climate extremes are usually more severe than those associated with the change of the average climate, because, although the frequency with which such events occur is relatively small, the damage they produce for the environment, socio-economic activities, or human health are often quite serious. In this regard, all projections indicate that there will be a marked increase in the intensity and frequency of extreme events related to temperature in all Spanish regions, which will be significantly greater in the highest emissions scenarios.

55.4 Interactions of Climate Change, Desertification, and Land-use Changes

Due to its geographical situation and its socio-economic characteristics, the south-east of Spain is highly vulnerable to both climate change and desertification that are closely linked and are both a source of risk. Moreover, both are influenced by (albeit at different scales) and also determine medium- and long-term changes in land-use. In this dry area climatic conditions and desertification feed each other positively and affect the land-use. Many ecological, economic, and social sectors and systems are vulnerable to climate change and desertification, such as biodiversity, agricultural and forest soils, water resources, forests, agro systems, mountain areas, river and marine ecosystems, tourism, urban development, industry and energy, transport and insurance.

The assessment of desertification and climate change is complex due to uncertainties. So is the prediction of land-use changes in the future. The forces driving these changes are highly dependent on human activities, rather than climatic conditions: the legislative and regulatory policy, the economic situation and external factors (that affect both agricultural markets and the housing demand for recreational use) have been central to the changes in land-use, its influence being more important as the level of economic development gets higher. In south-eastern Spain the economic situation (sustained growth and recurring positive future prospects) and the housing boom (also used as a safe way to invest and a saving by many people), supported by a favourable attitude of the authorities, created a situation that has provoked a profound change in land-use and a very important alteration of the landscape.

The current diametrically opposite economic situation and the exhaustion of the urban model, allow at least ensuring that in the near future, urbanism will not be a significant driving force, and if so, it will not be a global phenomenon but rather a local feature. As for the intensification of agricultural activity, with increases in water demands by 50–70 per cent in the Mediterranean areas (and this is projected to continue), there is an increasing competition for water between sector and use. Farming (at least with regard to intensive irrigation) is conceived at present as a conventional economic activity, increasingly disconnected from its social component, and thus increasingly subject to market forces, so that future decision-making will be analysed from a purely economic point

of view, taking production options, costs, and profitability into account. It can cause the migration of these activities to areas with fewer conflicts over resources and lower costs (e.g. in North African countries), a process that has already started.

Desertification contributes to global climate change through the loss of capacity for carbon sequestration and the increased albedo on the Earth's surface. The land can be degraded by frequent and intense droughts and by high-energy rains because of these extreme events associated with climate change. With a reduced availability of water and increased temperatures, the water balance will be substantially modified and water stress will increase in many areas that are threatened by desertification, such as the Mediterranean countries, in particular Spain and its south-eastern region. This will necessarily affect decision-making on land-use changes at the local level, what in turn can cause a worsening of environmental conditions.

The impacts of climate change on soil can be very important. Changes in the bio-physical nature of the soil are likely, due to projected rising temperatures, changing precipitation intensity and frequency, and more severe droughts. Such changes can lead to a future decline in soil organic carbon stocks and a substantial increase in CO_2 emissions. Adapted land-use and management practices could be implemented to counterbalance these impacts. Projected increased variations in rainfall pattern and intensity will make soils more susceptible to water erosion. Projections show significant reductions in summer soil moisture in the Mediterranean, and increases in the north-eastern part of Europe (European Commission 2008a). Soil degradation is already intense in parts of south-eastern Spain, and with prolonged drought periods it is already contributing to an increased risk of desertification. In many cases, desertification has become irreversible, leading to adverse social, economic, and environmental effects.

The projected climate-induced changes in the hydrological cycle will aggravate the impact of other stresses (such as land-use and socio-economic changes) on water availability, freshwater ecosystems, energy production, navigation, freshwater supply and use (in agriculture, households, industry) and tourism. Adaptation actions will be needed, such as improving water efficiency to mitigate water stress and enhance retention to reduce flood risk.

In agriculture, climate change affects the growing season and average yields while also key relevant land-use and management changes occur, making it difficult to detect climate change-induced trends. There is a need for adaptation of farm practices and land management to reduce or avoid adverse impacts. Some of the adaptation options such as irrigation may however increase emissions because of increased energy consumption.

55.5 Conclusions and Recommendations

All major changes in land-use in southern Spain in recent years have always evolved into situations where pressure on the environment and natural resources increased. On the other hand, the different options for climate change always involve a more complicated availability of natural resources and more fragile ecosystems. All this happens in a geographical area that is extremely vulnerable to desertification, with great dependence on water resources due to the economic and social importance of agricultural activities (about 8 per cent of regional GDP) and tourism (the building sector accounts for more than 11 per cent of GDP). Therefore all possible future situations seem to become more difficult for humans and for their development, and it appears that climatic conditions will be in the future more important in decision making processes related to land-use. The main resource for much of the current economic activity (water) will become increasingly limited, which will cause conflict among potential users that can affect decision-making in several ways.

To limit adverse impacts, adaptation is needed. Adaptation involves all levels of decision making, from municipalities to national levels. It is a cross-sectoral and transboundary issue which requires comprehensive integrated approaches. Economic sectors that are particularly concerned with adaptation include energy supply, health, water management, agriculture, tourism, and transport. Integration of adaptation into sectoral policies at the European and national levels is important in order to reduce, in the long term, the vulnerability of ecosystems, economic sectors, landscapes, health, and communities to climate change impacts. Future land-use change decisions will include in the future land abandonment (if no alternative use to intensive agriculture can be found) and other major changes in the economic activities (with, probably, initial unemployment and economic crisis stages). Administrations must be ready for this problem, designing measures for alleviating and supporting changes in the area. Currently the European regulations are the

main driving force that induces Regional Administrations to act. It is necessary that these Administrations, as key managing actors of the territories, develop their own territorial management, adapted to each specific area and taking into account the expected scenarios for the future. There have been positive management practices developed in Murcia during the last years that can be useful for coping strategies. On the other hand, it is also possible to remark negative practices that do not help to solve the problem and that can worsen the effects of land and resource use on degradation processes. Regarding positive actions to avoid or reduce land degradation in the future, it is possible to mention:

- *Environmental regulations in the agricultural activity*: the programme for fighting erosion (2007–2013) developed by the Regional Ministry of Agriculture and Water in Murcia. This action relates agricultural subsidies to conservation practices and, for the first time, includes also constraints for certain activities that have a negative effect on the environment. It includes compulsory soil covering in dry cultivations (almond, olive...) and limitation of the cultivation in slope areas (by eliminating subsidies for these cultivations if they are developed in plots on higher slopes than accepted but giving also the possibility to receive subsidies if farmers change the land-use to forests). Compulsory actions and limitations on subsidies on cultivations managed in non-appropriate areas are new in these regulations. It can be necessary when market and traditional driving forces are, often, more powerful than voluntary environmental regulations.
- *Development of plans for improving water efficiency*: Water for agriculture means 80 per cent of the water use in Murcia. A major effort was supported by Regional and National Administrations to modernize the agriculture and increase the use of drip irrigation. While the total irrigated area declined by about 10,000 ha from 2001 to 2008 (from around 163,000 ha to 153,000 ha) the area irrigated with drip irrigation increased from 74,500 ha to more than 122,000 ha (of which ca. 25,000 ha are in the *Campo de Cartagena* area), which means an increase of 63 per cent and represents 80 per cent of the total irrigated area. This improvement in the irrigation efficiency is essential to cope with fewer resources available in the future and to prevent conflicts among water users.
- *Development of clear protection and regulation programmes in areas of environmental interest*: The development of management plans for protected areas (areas of Community interests) are providing these sites with planning tools that include forest management and agricultural regulations that will protect the areas and avoid soil degradation. This action, necessary for EU protected areas, is the first territorial management practice that includes all activities and can help to avoid conflicts and to better manage these areas.
- *Afforestation measures*: There is a large tradition in afforestation activities in semi-arid regions like Murcia. These have evolved from aggressive interventions on the landscape (affecting shapes and using hard machinery) to activities that are more adapted to the area, taking real possibilities of development of afforested areas into account. This, together with a better management of forest areas to avoid forest fires (a major challenge and a severe damage to Mediterranean ecosystems) has led to an increase in the forest area by more than 17 per cent in 12 years between 1987 and 1999 (National Forest Inventory 2002).

But there are still significant gaps. There is no clear and adopted territorial management policy. Agricultural regulations are not enough in these economically dynamic areas, with other sectors affecting the environment. The regional authorities must be the key actor managing future resource conflicts but this has not yet been determined. The experience with the bad management of the building boom (where the economic profit was the driving force) must be used to improve the role of the regional administration in an area where many competencies of territorial management are developed by local administrations but ruled and controlled by the regional bodies.

56 Reconsidering Integrated Water Resources Management: Promoting Economic Growth and Tackling Environmental Stress

Jakob Granit

56.1 Introduction

Integrated Water Resources Management (IWRM) is today widely advocated by natural resources managers and the scientific community as the preferred approach to manage water. IWRM stresses the river basin as the single management unit and the integration of freshwater using sectors and stakeholders across society.

No doubt, effective water resources management and development are fundamental to achieve sustainable growth and to meet environmental objectives in all societies. Underinvestment in water management and storage in developing regions increases the vulnerability to rainfall variability and floods and droughts cause water related shocks to the society and the economy. In industrialized regions, on the other hand, where water resources have been extensively utilized for economic development through agriculture, hydropower, and industrial production, freshwater and marine ecosystems are showing increasing signs of environmental stress. This is clearly demonstrated by the spreading of dead zones in coastal seas. An underlying cause is water quality degradation due to euthrophication caused by excess nutrient runoff from intensive agriculture production and the burning of fossil fuels for transport and energy production.

Two case descriptions of the Nile and Baltic Sea Basin regions illustrate the dual challenge of both the need to develop water resources to contribute to economic growth and the need to manage water quality degradation because of development. This chapter asserts that IWRM needs to be re-considered and be broadened to better meet development and water quality concerns in the economy as a whole.

To verify this thesis, this chapter will offer an analysis of scientific, policy and development literature. *First*, it will assess water resources in an economic development context and illustrate tradeoffs from regional development. *Second*, it will discuss the evolution of IWRM and the emerging critique of its usefulness. *Finally*, it will suggest how the IWRM paradigm could be re-considered in three ways to meet economic growth and environmental management objectives at the regional level.

56.2 Water Resources in Economic Development and Environmental Trade-offs

56.2.1 Water as a Public and Private Good

Transboundary water resources management is considered a public good as well as a source of public goods (Jägerskog/Granit/Risberg/Yu 2007). Typical use of water resources as a public good include recreation, aesthetics, biodiversity, flood risk reduction and water quality improvement. These goods and services are 'public' because they benefit all and the consumption and quality of water to produce these goods and services does not limit the availability of water to other users.[1] At the same time, water transforms from being a public good to a private good when the use of water resources moves to the private domain and contributes to generate private goods and services. Examples of this include electricity generated from hydropower, agriculture products and water supply for drinking water and industrial production (GWP 2000; Jägerskog/Granit/Risberg/Yu 2007). When water is

1 The International Task Force on Global Public Goods describes public goods as goods that address issues which: (i) are deemed to be important to both the developed and developing countries that make up the international community; (ii) typically cannot, or will not, be adequately addressed by individual countries or entities acting alone, and, in such cases (iii) are best addressed collectively on a multilateral basis. See at: <http://www.gpgtaskforce.org/bazment.aspx> (19 March, 2009).

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_56, © Springer-Verlag Berlin Heidelberg 2011

returned to the recipient according to agreed standards and regulations, it is again in the public domain.

Water resources cross boundaries within countries and between countries. There are an estimated 261 river basins globally that cross international boundaries. These international river basins cover about 45 per cent of the earth's surface (Wolf/Natharius/Danielsson/Ward/Pender 1999). Managing and developing these transboundary water resources is in itself a public good (Jägerskog/Granit/Risberg/Yu 2007).

56.2.2 Water and Economic Development

Effective water resources management and development are preconditions of sustainable growth and poverty reduction (e.g. Grey/Sadoff 2007; UN Water 2009; Winpenny 2003). Growing demand for public and private goods and services is increasing the pressure and competition for water and natural resources at the regional and local levels (UN Water 2009). Water is a fundamental input for many businesses and services creating important employment opportunities (Granit/Berntell 2008; Merret 2008; UNEP FI 2007; Winpenny 2003). During the past 100 years the world's population has tripled but the use of water has increased six fold (GWP 2008).

How to best allocate water for different purposes to optimize the generation of both public and private goods and services is debated in water policy, customary and modern law at the national and international level (see e.g. Hooper 2006; EU 2000; McCaffrey 2001; Newson 2004; Salman/Bradlow 2006; Tropp 2007; Turton/Hattingh/Gillian/Roux/Claassen/Strydom 2007). The debate centres on the issue of how to prioritize water use in a given context, whether to use market or state controlled mechanisms to optimize water allocation and use, and how to share benefits accrued from water management and development in the society (GWP 2000, 2009).

In developing regions, underinvestment at the national level in water management institutions, capacity building and water infrastructure has led to mismanagement of water resources and competition among user groups (UN Water 2009; World Bank 2003b). This in turn blocks the development potential in several key sectors and has a negative impact in meeting poverty alleviation objectives (Grey/Sadoff 2007). Broad-based water service interventions in water supply and energy utilities, water and sanitation and irrigation services benefit everyone including the poor and play a major role in reaching some of the *Millennium Development Goals* (MDG, see UN Water 2009; Winpenny 2003). Many countries and regions are off track towards meeting the water supply and sanitation target of the MDG (WHO 2004). This policy target (number three) states that by 2015, the proportion of people without sustainable access to safe drinking water and basic sanitation should be halved.[2] Following current trends, the targets for water supply would be met by 2040 and for sanitation not until 2076 (WHO 2004). It is argued that US$1 invested in improved water supply and sanitation yields gains of US$4–US$12, depending on the type of intervention (SIWI 2004). Without means to capture rainfall in the landscape or in artificial storage, a high degree of rainfall variability will turn into high output volatility and increased risk coverage against water shocks to the economy from the devastating impacts of floods and droughts (Grey/Sadoff 2007).

The World Bank (2003b) asserts in its Water Resources Strategy that countries must take action on several fronts to build sustainable societies. This includes increasing their capacity to manage water resources and provide security against rainfall variability, floods, and droughts. This entails broad based interventions, including major infrastructure projects such as dams and inter-basin transfers, which provide local, national and regional benefits (Grey/Sadoff 2007). Chenoweth (2008) states that it is effective human organization that is critical in ensuring sufficient water availability for domestic needs and for facilitating economic development. Extreme water scarce states that also lack petroleum assets such as Malta, the Maldives and Israel, can achieve good social and economic development even though plentiful water resources is more beneficial to societal development (Chenoweth 2008). From a management and development perspective, a combination of weak institutional frameworks and lack of hydrological and meteorological observation systems are obstacles for effective water resources planning and development at the regional, national and local level (CAPNET 2008; GWP 2009).

While industrialized countries have invested significantly in major water management capacity and water infrastructure, many developing countries have not. In hydropower development, for example, industrialized countries use most available hydroelectric potential as a source of renewable energy. Many developing countries, on the other hand, harness only a small fraction of available hydropower potential. In Africa only 7 per cent of the technical and economic hydropower po-

2 See at: <http://www.un.org/millenniumgoals/environ.shtml> (13 March, 2009).

tential is exploited compared to 22 per cent in Asia, 69 per cent in North America and 75 per cent in Europe.[3]

In the case of Mozambique, the World Bank (2007b) claims that high variations in rainfall, combined with limited storage facilities and underdeveloped flood control infrastructure are the main factors contributing to the high variability in the river flows. This variability results in water shortages in a number of basins during dry seasons and a high risk of water related shocks to the economy and the society. Mozambique's economic performance is significantly affected by the frequency of floods and droughts. Analysis suggests that the GDP growth in Mozambique is cut by 5.6 per cent, on average, when a major water shock to the society from drought or floods occur (World Bank 2007b). Similarly, in Tanzania the World Bank (2006c) notes that the 2003 GDP growth rate of 5.6 per cent was less than the projected rate of 6.5 per cent. It is argued that this is largely because of the impact that drought had on the agriculture, manufacturing, livestock and energy sectors (World Bank 2006c).

Grey and Sadoff (2007) introduce the concept of water security which summarizes the development challenges in the water resources sector in developing regions. Water security is defined as the "availability of an acceptable quantity and quality of water for health, livelihoods, ecosystems and production, coupled with an acceptable level of water-related risks to people, environments and economies." Water security can be enhanced if the capacity to harness the productive potential of water and limit its destructive impact is increased.[4] This means adjusting the structure of the economy of a country to move it out of a water dependent low-equilibrium poverty trap through significant investment in the sector (Grey/Sadoff 2007).

The *Nile Basin Initiative* (NBI) is an example of how developing countries that share a river basin can explore development options and work cooperatively towards greater water security (box 56.1). The country partners in the NBI jointly identify necessary investments in institution building, human capacity, infrastructure and the environment and explore options to sharing benefits derived from the utilization of the Nile Basin water resources. It is also an example of how countries can work in a collaborative framework without having a formal agreement of water allocation in place that is recognized by all riparian countries.

56.2.3 Environmental Trade-offs From Water Management and Development

In industrialized regions and in countries in economic transition the external effects of poor water management and development are evident. The Baltic Sea Basin (box 56.2) clearly illustrates this situation. While point-source pollution from industry and urban areas has been largely addressed, diffuse pollution from land-based anthropogenic activities, such as from agriculture production, road and air transport, and energy production has not yet been managed (Lääne/Kraav/Titova 2005).

Dead zones in the coastal oceans and seas have spread exponentially since the 1960's and provide evidence of the long-term environmental stress caused by the intensive use of water for different purposes (Diaz/Rosenberg 2008). The formation of dead zones has been exacerbated by the increase in primary production and consequent worldwide coastal euthrophication fuelled by riverine runoff of fertilizers and the burning of fossil fuels. Diaz and Rosenberg (2008) report that dead zones have been found in more than 400 marine systems affecting a total area of more than 245,000 square kilometres and are generally located in areas with major population centres and watersheds that deliver large quantities of nutrients. The increased use of industrially produced nitrogen fertilizer that began in the late 1940's is also highly likely to have lead to the spread of dead zones (Diaz/Rosenberg 2008). The *Swedish Environmental and Protection Agency* (SEPA 2006) concludes that nitrogen input to the Baltic Sea has increased fourfold and phosphorus input eight times since the mid 19th-century. This has resulted in massive algae blooms of Cyanobacteria and other toxin producers resulting in dead zones in bottom waters in deep basins (Diaz/Rosenberg 2008).

Box 56.1: The Nile Basin Initiative (NBI): Management and development efforts in a transboundary basin. **Sources:** See at: <http://www.nilebasin.org/> (23 March, 2009).

The Nile river basin encompasses an area of about 3 million square kilometres. Ten countries, with a total estimated population of 300 million people share the Nile river basin: Burundi, Democratic Republic of Congo, Egypt, Ethiopia, Eritrea, Kenya, Rwanda, Sudan, Tanzania, and Uganda. The population in the basin countries is expected to reach 600 million by 2025 (Adly/Ahmed 2009; Kameri-Mbote/Kindiki 2009).

Human security is strongly linked to poverty reduction. In the Great Lakes region in East Africa at the head waters of the White Nile, poverty is fuelling civil strife at the local and sub-regional scale (Falkenmark/Folke/Granit/Jägerskog/Mathews/Molden/Rajagopal/Scanlon/Schulze/Sendama 2002). The rationale for improved water resources management is to contribute to sustainable economic growth and poverty alleviation. The total potential annual direct gross economic benefits of Nile water utilization in irrigation and hydroelectric power generation are estimated to be on the order of US$7–11 billion (Whittington/Wu/Sadoff 2004).

The Nile riparian countries took a major step to establish the NBI in 1999, an initiative that includes all Nile countries and provides an agreed basin-wide framework to fight poverty and promote socio-economic development in the region. The NBI follows a set of institutional arrangements supported by international organizations and technical cooperative frameworks on hydrometeorology and environmental protection since 1960 (McCaffrey 2001). The initiative is guided by a shared vision "to achieve sustainable socio-economic development through the equitable utilization of, and benefit from, the common Nile Basin water resources."

The Nile riparian countries seek to realize their shared vision through a strategic action programme, comprising basin-wide projects and joint investment projects at the sub-basin level. This programme seeks to exchange experience, build capacity and trust and create an enabling environment for investments (Whittington 2004). Seven basin-wide projects address issues that are common for all the riparians. This includes: transboundary environmental concerns, regional power trade, agricultural production, water resources planning and management, communication, applied training, socio-economic development and benefit-sharing (World Bank 2008e).

To unlock the development benefits, the riparian countries are exploring investment opportunities in multipurpose water management and development by collaborating in two Subsidiary Action Programmes. The two programmes are the *Eastern Nile Subsidiary Action Programme*, which includes Egypt, Ethiopia, and Sudan and the *Nile Equatorial Lakes Subsidiary Action Programme* (NELSAP), which includes Burundi, Democratic Republic of Congo, Kenya, Rwanda, Tanzania, Uganda, Egypt and Sudan. The two downstream countries, Egypt and Sudan, are directly affected by developments upstream and hence also members of NELSAP (Falkenmark/Folke/Granit/Jägerskog/Mathews/Molden/Rajagopal/Scanlon/Schulze/Sendama 2002). Approaches taken to increase joint investments include pre-investment studies, such as *Strategic/Sectoral Social and Environmental Assessments* (SSEA), and the design of far-reaching multi-purpose programmes in areas such as IWRM, flood management, power generation and interconnection, and irrigation and drainage (King/Noël/Granit 2008).

The NBI is closely linked to other cooperative frameworks including the *East African Community* (EAC). Modelled on the EU, the EAC is *a Regional Economic Community* (REC) that provides a broader framework linking natural resources management with regional economic development. Currently, EAC has five member countries in the upstream part of the Nile Basin (Burundi, Kenya, Rwanda, Tanzania, and Uganda). EAC manages through regional regulations move the member countries into legislative compliance that would be difficult to achieve on a voluntary basis[5].

The NBI provides a forum to explore water security and promotes a cooperative process with the stated objective of bringing tangible benefits to the basin (Song/Whittington 2004). The alternative would be unilateral actions which could lead to tensions and conflicts (Falkenmark/Folke/Granit/Jägerskog/Mathews/Molden/Rajagopal/Scanlon/ Schulze/Sendama 2002). The decision-making process is strong with the Nile Council of Ministers for Water Affairs serving as the highest decision-making body of the NBI. The core cost of this arrangement is supported by the Nile Basin countries through payment of annual dues (World Bank 2008).

Box 56.2 below details the situation in the Baltic Sea Region, the impacts of large scale euthrophication and the response by the basin countries and the *European Union* (EU).

Box 56.2: The Baltic Sea - the ecosystem that 'flipped'. **Source:** The author.

The summer of 2005 served as a wake-up call for all citizens around the Baltic Sea. Alarming reports in the local newspapers about toxic algae blooms, dead sea zones caused by anoxic conditions, and the loss of fish species resulted in heated debates about the 'flip' of the Baltic ecosystem.[6] The citizens, believing that the scientists had a clear picture of the reasons for the current state of affairs, were shaken by the fact that the root causes threatening the Baltic ecosystem were not known. An open conflict between different scientific disciplines on the root causes of euthrophication ensued (SEPA 2006).

The political and economic geography of the Baltic drainage basin is complex. Fourteen riparian countries fully or partly lie in the basin: Belarus, Czech Republic, Denmark, Estonia, Finland, Germany, Latvia, Lithuania, Norway, Poland, Russia, Slovakia, Sweden, and Ukraine. Nine of these states border the Baltic Sea directly and only Russia is a non EU littoral state.[7]

There are a multitude of complex linkages and feedbacks between the land-based ecosystems of the drainage basin, the sea-based ecosystems and the human economic systems (Lääne/Kraav/Titova 2006; Lundqvist/Granit/Rahm 2007. Subsequent studies have made an attempt to assess these and put an economic value on the cost of euthrophication. The benefits of accomplishing a Baltic Sea undisturbed by excessive inputs of nutrients are calculated to be about 5 billion Euro annually (SEPA 2008).

At the policy level, the UN Conference on the Human Environment in Stockholm (1972) was the first global conference highlighting the linkages between human well-being, the environment and economic growth.[8] The next major regional step in the Baltic Sea Region was the establishment of the *Helsinki Convention on the Protection of the Marine Environment of the Baltic Sea* (HELCOM; Räsänen/Laakkonen 2007). It became the first international management regime on the protection of a regional sea (Joas/Jahn/Kern 2008). In 2007 HELCOM agreed on a *Baltic Sea Action Plan* that sets clear but voluntary ecological objectives to realize the joint vision of a healthy marine environment.[9] However, in spite of the work through HELCOM evidence indicates that this form of traditional cooperation and coordination have been inadequate (Joas/Jahn/Kern 2008).

With the EU enlargement process in 2004 there has been a strong Europeanization process (Joas/Jahn/Kern 2008) offering new management opportunities of the Baltic Sea as a public good. The EU has developed different forms of regulations and laws to link freshwater and oceans management that address the management challenges at each stage from source to sea. The EU Water Framework Directive (EU 2000) addresses freshwater resources and the *Integrated Coastal Zone Management* (ICZM) principles seeks, over the long term, to balance environmental, economic, social, cultural and recreational objectives within the limits set by natural dynamics (European Commission 2000). The Marine Strategy Directive takes the marine environment as the starting point and directs that each Member State shall, in respect of each marine region or sub-region concerned, develop a strategy for its marine waters (EU 2008). The agreed objectives of achieving a good water status should be reached by 2015 for freshwater systems and by 2020 for marine water systems.

In the three pieces of legislation integration of management objectives and coordination of sectors are stressed. The EU has through these and other environmental legislation managed to ensure compliance by the member states in the area of environmental policy which has never occurred before in the history of the Baltic Sea Region (Joas/Jahn/Kern 2008). The water resources management concept is moving towards a more broad based system analysis and improved understanding of the water management continuum[10] on land, at the coastal zone and in the open sea (Granit 2008).

During 2008 and 2009, the EU Commission is developing a Baltic Sea Region Strategy in consultation with the member states and Russia.[11] This is the first regional strategy the EU Commission is developing to address the environment with a focus on making the Baltic Sea Region a prosperous, accessible, attractive, safe and secure place.[12] With the new integrated governance regime provided by the EU there is a good opportunity to tackle the challenge of legal compliance and integrate the environment into mainstream regional economic planning. Existing management regimes such as HELCOM will need to fit into the coming EU Baltic Sea Region Strategy.

56.3 Evolution and Critique of IWRM

IWRM has been actively promoted as the preferred approach to manage water for the past 15 years (Dombrowsky 2007; GWP 2000, 2008, 2009) at both the national and transboundary level. The concept of IWRM was first developed during the International Conference on Water and the Environment in Dublin in 1992. The Dublin Statements on Water and Sustainable Development highlight four principles of managing water. These are that water is a finite and vulnerable resource, essential to sustain life; water development and management should be based on a participatory approach; women play a central part in the provision, management and safeguarding of water and; water has an economic value and should be recognized as an economic good.[13] Later that year these principles were reinforced during the *United Nations Conference on the Environment and Development* (UNCED)[14] and detailed in Agenda 21.[15] The subsequent four World Water Forums (ibid) and the annual World Water Week organized by the *Stockholm International Water Institute* (SIWI) since 1991 have reinforced the IWRM concept.

The *Global Water Partnership* (GWP 2008) defines IWRM as "a systematic process for the sustainable development, allocation and monitoring of water resource use in the context of social, economic and environmental objectives." GWP notes that IWRM departs from traditional natural resources management approaches in three ways (GWP 2000, 2008):

1. The multiple goals and objectives are crosscutting and depart from the traditional sectoral approach in natural resources management.
2. The spatial focus is the river basin with multiple water resources instead of single water courses.
3. It incorporates participatory decisionmaking of all stakeholders (inclusion vs. exclusion).

GWP (2000) argues that IWRM is a problem-solving approach to address key water challenges in ways that balance *economic efficiency*, to make scarce water resources go as far as possible; *social equity* in the allocation of water across different social and economic groups; and *environmental sustainability* to protect the water resources base and the ecosystems upon which it depends. The GWP has played an important role promoting IWRM through its action network of water management actors including government agencies, public institutions, private companies, professional organizations, and multilateral development agencies.

There is a growing global trend towards decentralized governance that supports the IWRM principles (Tropp 2007). This provides opportunities for governments to more actively engage citizens, and corporate and public institutions in the decisionmaking process to tap their creative and innovative capacity. As decentralized governance gains ground, the three clusters of actors in the trialogue (government, scientific community, civil society) need to be engaged and involved in management and development actions (Turton/Hattingh/Gillian/Roux/Claassen/Strydom 2007). In spite of the decentralization trends, water decision-makers and managers are not prepared to fully realize the development potentials of these new forms of governance options and impacts (Tropp 2007). This would include facilitating inclusive decision-making processes emphasizing the management of people and processes, diversity of organizations and knowledge sharing (Tropp 2007).

As illustrated in the case on the Baltic Sea Basin, the EU has encoded IWRM into the EU Water Framework Directive (European Union 2000). This directive expands the scope of water protection to all waters at both the national and transboundary level and establishes management and environmental objectives. The EU has effectively been able to promote IWRM amongst countries with different interests and negotiated a new water management regime valid throughout Europe.

The development of water resources and building capacity to achieve it is a long term process and requires long term support (Jägerskog/Granit/Risberg/Yu 2007). This is true in both in-country and in transboundary contexts. Consistent central government support for basin management, stakeholder involvement and water policy reform is one of the most important factors behind successful water development cases (Kemper/Dinar/Blomquist 2005). The authors continue to argue that while the level of economic development of the nation and the basin matters there is no reason to believe that improvements in water resource management are limited to wealthy basins (ibid). On the contrary they demonstrate that notable

14 Chapter 18 on the protection of the quality and supply of freshwater resources: application of integrated approaches to the development, management and use of water resources.

15 See at: <http://www.un.org/esa/sustdev/documents/agenda21/english/agenda21chapter18.htm> (24 March 2009).

improvements have been realized in a variety of settings, and sometimes very early in the life of basin organizations and stakeholder participation initiatives (ibid).

Despite the wide uptake of IWRM in both developing and industrialized regions its contribution to economic growth and meeting environmental objectives is being questioned. A growing critique asserts that it is amorphous and questions its track record in the actual provision of development outcomes (Biswas 2008). Further, Newson (2004) argues that IWRM has helped to define a new scientific agenda that is hard to comprehend outside the IWRM epistemic community and has had difficulty creating valuable tools for effective management and development of water. The perception for its failure lies mainly in the inappropriateness of basin management institutions and styles (Biswas 2008) that do not have a clear strategy for engagement with the broader economy.

Allan (2003) argues in a similar fashion that the IWRM approach will not serve the needs of water policy-makers unless it escapes the assumption that the river basin is the fundamental management system. Sustainability is about social and economic processes and integration and management are political processes (Allan 2003). To broaden water issues outside the water sector itself, it is critical to treat politics as both part of the problem and the solution (Granit/Berntell 2008). The two case studies on the Nile and the Baltic basins illustrate clearly how governments at both the national and regional level struggle with the politics of demonstrating development and environmental outcomes from IWRM policy.

56.4 Ensuring Water Resources Development and Management Outcomes - Minimizing Negative Trade-offs

Water experts define the physical drainage basin as the geographical framework and natural unit for water management (GWP 2000; Kemper/Dinar/Blomquist 2005). Socio-economic and political systems, however, are not and will likely never be, confined within these geographic boundaries. Many times IWRM policy is owned by a Ministry for Water or by a *River Basin Organization* (RBO) that has little influence on the policies of a Ministry for Planning or Finance, or key water dependent sectors such as energy, agriculture and the environment. Water experts and managers must therefore adapt to this situation and provide recommendations and management strategies that fit the basin as well as the political, administrative and economical context beyond the river basin. This will ensure that benefits from management and development of water resources are recognized and valued within the broader society.

At the transboundary level, the absence of common frameworks for sharing information and exploring common development options can hinder the exploration of broad based collaborative benefits from water development and the comparative advantage of countries' water endowment from being utilized (McCaffrey 2001; Dombrowsky 2007). In regions with weak cooperative frameworks, collaboration around a shared water body can be the starting point for partnerships in several other associated areas, such as energy markets, transport, and trade of agricultural products as illustrated in the Nile Basin case. In countries in economic transition and in industrialized economies, expectations from cooperation may be slightly different and the outcome of cooperation will in some cases be geared more towards meeting environmental quality objectives and aesthetical values as in the case of the Baltic Sea Basin.

Sharing water is a complex and highly political process (Philips/Claassen/Granit/Jägerskog/Kistin/Patrick/Turton 2008). Simple negotiating strategies among countries are based on perceptions of acquired rights, harm from water development and poor management, and territorial sovereignty that do not tackle the broader political and economic gains that could be gained from cooperation (Grey/Sadoff 2002, Song/Whittington 2004). To develop an appropriate water sharing regime entails negotiations among sovereign states. The skills and preparedness for negotiating regimes that benefit all may differ and be an object for tension and dispute (McCaffrey 2001; Dombrowsky 2007). The capacity to undertake effective negotiations at the transboundary level is determined by the institutional capacity at the country level.

For IWRM to be relevant, it needs to support the delivery of management and development outcomes in the broader economy and geographic context. SIWI (2004) argues that the greatest economic benefits of improved water resources management and water supply and sanitation will be felt in those countries with the greatest water challenges. The role of water in development is stressed by Stern (2002) when he notes the importance of building an investment climate that facilitates growth and empowers poor people to participate in that growth. The quality of infra-

structure including water is a prerequisite for growth along with good governance and strong institutions and macroeconomic stability (Stern 2002). Sachs[16] further notes the linkages between water and development aid and claims that international aid resources should target *inter alia* food production and clean water and sanitation.

To promote the exploration of political and economic gains Phillips, Claassen, Granit, Jägerskog, Kistin, Patrick and Turton (2008) introduces the *Transboundary Waters Opportunity* (TWO) Analysis. The TWO is a simple conceptual framework that can be used by stakeholders concerned with the management and development of shared freshwater resources in a country or between countries. The concept assists in analysing potential benefits in a transboundary river basin to optimize economic growth, political stability and regional integration intended to be used by basin state governments, RECs, and financing entities. The concept stresses four key development opportunities and associated benefits: 1) hydropower production and power trading; 2) primary production; 3) urban and industrial development; and 4) environmental and ecosystem services. To realize these opportunities, countries sharing water bodies need to cooperate and jointly explore opportunities and tradeoffs from development. Such an approach can contribute to overall economic growth and resource sustainability.

Practical examples of benefit sharing beyond the river include the interconnection of electricity transmission networks, the development of power pools for energy markets (King/Noël/Granit 2008) and water transfer schemes developed between basins to meet water demand in water scarce areas (Philips/Claassen/Granit/Jägerskog/Kistin/Patrick/Turton 2008). Such practical ways of distributing benefits through market mechanisms benefit citizens beyond the actual watershed and whole regions. The United Nations General Assembly (GA 2009) highlights the role of reliable and stable transit of energy in ensuring sustainable development and points to the importance of international cooperation in developing transportation systems and pipelines to reach regional benefits. In this context, REC frameworks, such as the *Southern Africa Development Community* (SADC) and the *European Union* (EU), are critically important to ensure the integration of markets and free movement of goods, services and labour that can materialize from water management and development. Where a REC exists, as in the case of the Baltic Sea Basin, the management and development of transboundary water resources can be designed so that it meets and supports the strategic objectives of the REC.

The findings by Diaz and Rosenberg (2008) and of SEPA (2006) indicate the strong *linkages between freshwater use and its impacts on coastal and marine ecosystems*. Beyond the creation of dead zones, poor water management can have numerous negative impacts on coastal regions, such as salt water intrusion into freshwater areas and changes in sedimentation patterns (SEPA 2006). Euthrophication is a clear symptom of stress from water quality degradation that is threatening not only the water ecosystem, biodiversity and the water resources themselves but also other ecosystem services providing added value such as recreation, tourism, and spiritual values.[17] To reduce and reverse costly degradation of the marine environment, the impacts of land-based activities along the coast and further inland that impact water resources must be considered and incorporated into water resources management planning (Gonzalo/Clement/Jønch-Clausen 2008). The IWRM concept needs to be broadened and incorporate tools and methods to address issues on management of water from the source to the sea.

56.5 Conclusions

Transboundary water resources management is a public good that contributes to the achievement of private goods and services. Effective water resources management and development are essential to achieve sustainable growth and to meet environmental objectives in all societies and at all levels. This chapter highlights the dual challenge of the need to both develop water resources for economic growth and the need to manage environmental tradeoffs from water resources development at the regional level.

The concept of IWRM has been developed over the past 15 years as the preferred management response to water challenges in the society. This chapter asserts that IWRM is not effectively delivering much needed development outcomes and also does not effectively provide good integrated management tools

16 Jeffrey Sachs: "A new system of development finance", in: *Financial Times*, 27 November 2008; at: <http://blogs.ft.com/wolfforum/2008/11/a-new-system-of-development-finance/>.

to achieve environmental objectives in regions where water resources have been developed.

It is concluded that the IWRM approach needs to be re-considered in three ways to better meet water management and development challenges at the regional level.

- *First*, it should include the broader political and economical context beyond the river basin. This is to ensure that benefits generated from water management and development are properly valued and become part of the broader economic development planning. RECs provide useful vehicles to ensure a broader integration of IWRM objectives in economic planning.
- *Second*, IWRM should more strongly promote investments in hydraulic infrastructure for multipurpose water use to ensure real development outcomes in developing regions. The promotion of hydropower development and power trading to achieve direct benefits illustrates such opportunities.
- *Third*, IWRM needs to define tools and approaches to better manage the full water cycle along the continuum from freshwater management on land, to coast and sea. The spreading of dead zones in coastal seas, as in the Baltic Sea Basin, illustrates water quality degradation and euthrophication because of development.

57 Coping with Population Growth, Climate Change, Water Scarcity and Growing Food Demand in China in the 21st Century

Zhanyi Gao and Yaqiong Hu

57.1 Introduction

China is a developing country with the largest population in the world. Food security is not only important for the sustainable social and economic development of China, but also for its food security and for stable global food prices. According to the guideline for food and nutrition development by the State Council of the People's Republic of China, the average grain holdings in 2000, 2010 and 2020 should be 400, 415 and 420 kg per capita per year, respectively (General Office of the State Council PRC 2001). In China food security will be achieved when the average grain holdings reach these levels. However, with the rapid social and economic development the people's living standard and their meat consumption are significantly increasing, why more grain will be needed.

China is also a large country in terms of irrigation, which is crucial for agricultural production. In the year 2000, the yield of irrigated paddy was 6900 kg/ha, and the average yield of other irrigated grain crops was 5250 kg/ha while the average yield of rain-fed grain crops was only 2100 kg/ha. This means that the yield of irrigated land can be increased by 1 to 3 times compared with rain-fed land (Shi/Lu 2001). In 2008, the irrigated area in China covered 57.8 million ha, accounting for 47.38 per cent of the total farmland. The irrigated area produced 75 per cent of the total grain production, and more than 90 per cent of cotton and vegetable production (Li 2009).

With the recent economic development more water and land resources are converted from agricultural production to other sectors. Furthermore, extreme drought and flood disasters occur more frequently due to climate change impacts. Thus, agricultural production is facing a challenge. It is a key research area how to cope with population growth, climate change, water scarcity and the growing food demand in China in the 21st century. This research analyses whether available water resources can meet the growing agricultural demand and how an increasing irrigated area and grain production can be realized without a significant increase in water consumption for agriculture. This chapter reviews the major results of related research, planning and practice.

57.2 Population Increase and Grain Demand

The total population and its growth rate are two key factors that affect the demand for cereals in China. Table 57.1 offers the most recent UN data on China's past and projected population size, density and urbanization range from 1950 to 2050. Table 57.3 compares the projections of China's population by the UN Population Division (UN 2001) and China's Population and Development Research Center (2000). The average of both projections is used below.

Based on this near-term population projection (table 57.3) and the average grain holding required by the guideline for food and nutrition development, the Chinese grain demands in target years is listed in table 57.4.

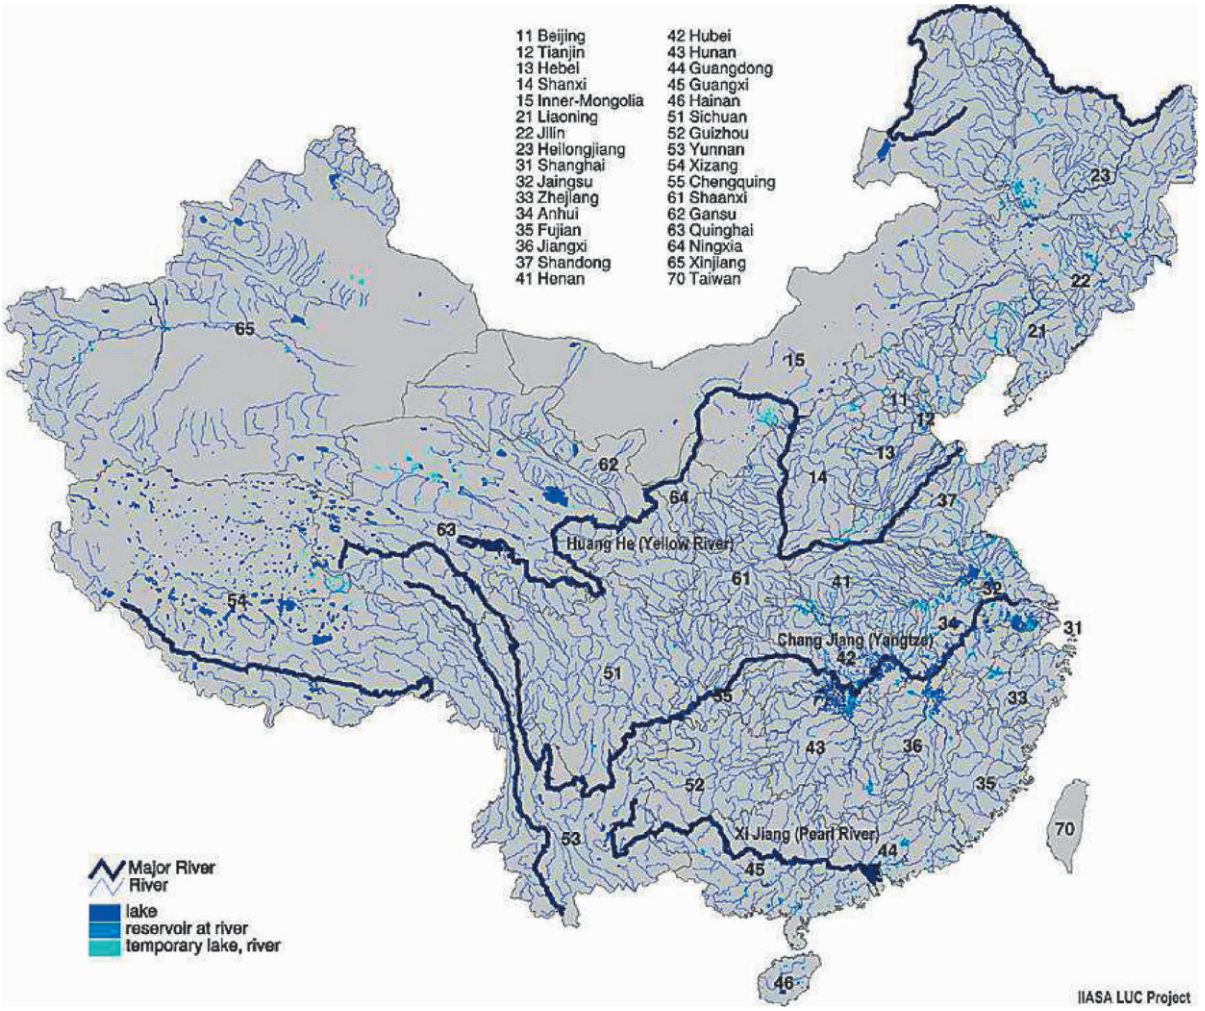
Table 57.5 lists the requirement of domestic grain production and needed grain imports under self-sufficiency rates of 92, 95 and 98 per cent respectively.

57.3 Irrigation Requirement for Grain Production

The total size of grain production depends on the following factors: farmland area, crop index, proportion of land for grain crops and cash crops, irrigated area and its yield, rain-fed area and its yield, etc. Irrigation has played an important role in grain production in China. Figure 57.2 shows that grain production has been increased with the increase of irrigated area in China.

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_57, © Springer-Verlag Berlin Heidelberg 2011

Figure 57.1: Rivers of China. **Source:** © Heilig, G.K. (1999): *ChinaFood. Can China Feed Itself?* (Laxenburg: IIASA, 1999) [CD-ROM Vers. 1.1].



The areas and their yields of both irrigated and rainfed cereals can be estimated by analysing the development trends and considering major determining factors. Based on the above estimates and on the potential water resources the irrigation requirement for an efficient irrigation in agricultural production can also be estimated. A framework for the analysis is provided in figure 57.3 (Gao/Wang 2008).

The year 2000 is used as the base year for the analysis. In the year 2000 the irrigated area was 55 million ha. The grain crop yield has been increased due to the development of irrigation and the improvement of farming practices, seeds, fertilizers, etc. By considering all of these factors, a study was carried out to analyse the requirements for irrigation development for 2010 and 2020 under different self sufficiency rates for cereals (Gao/Wang 2008). The results of the study are provided in tables 57.5 and 57.6.

Therefore, to maintain the grain self sufficiency rate at a level of 95 per cent the irrigated area should reach 58.69 million ha in 2010 and 59.97 million ha in 2020.

57.4 Irrigation Area and Distribution

Influenced by climate conditions of the monsoon, the average annual precipitation in China decreases from 1600 mm in the southeast to less than 200 mm in the northwest (figure 57.5) and 80 per cent of precipitation occurs in four months (June- September).

Further, 80 per cent of the water resources are in the south of China where the land resources represent only 38 per cent of the total. But only 20 per cent of the water resources are in northern China where land resources account for 62 per cent of the Chinese ter-

Table 57.1: Changes of the population size (in thousand), population density and of the urban population in China (1950-2050) for the medium variant. **Source:** UN (2009, 2008); at: <http://esa.un.org/unpp/p2k0data. asp>.

Year	Population Size	Population density	Urban population	Percentage urban
1950	544 951	57	72 119	13.0
1955	598 226	62	86 363	14.2

2050	1 417 045	148	1 027 294	72.

ritory. These differences in water and land resources highlight the importance of irrigation and drainage for agricultural production. According to the irrigation demand of crops, China may be divided into three irrigation zones, a) an intensive, b) a supplementary and c) a rice paddy irrigation zone (PRC 1998).

a.) The *intensive irrigation zone* includes northwest China and parts of north and northeast China, where annual precipitation is below 400 mm. Here the precipitation and its distribution do not meet crop water requirements, why there is hardly any agricultural production without irrigation.

b.) The *supplementary irrigation zone* covers the plain area of the Yellow River, the Huaihe River and the Haihe River and most parts of northeast China. The annual precipitation in this zone varies

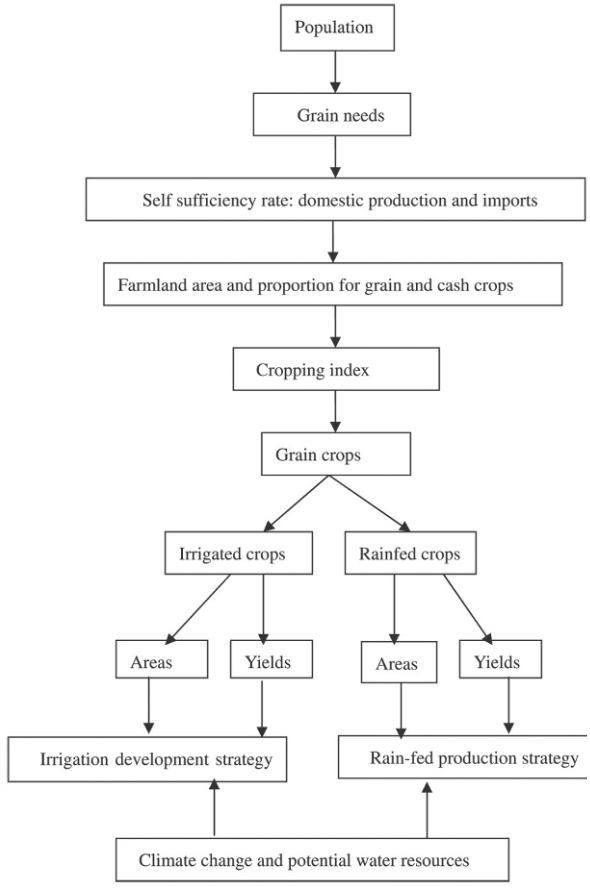
from 400 to 1000 mm. Influenced strongly by the monsoon, the precipitation in this zone is distributed extremely uneven. Here crop water requirements change sharply in different years, why drainage is extremely necessary. Therefore, both irrigation and drainage are highly needed for a stable and high yield agricultural production.

c.) The *paddy irrigation zone* covers south and part of southeast and southwest China. The annual precipitation in this zone is more than 1000 mm. Paddy rice is the main crop in this zone and irrigation is needed although precipitation is here very high. Irrigation is unnecessary for other crops during the rainy season, but it is necessary during the drought season. Here drainage and flood protection facilities are the basic condition for stable agricultural production during the rainy season.

Due to the uneven distribution of precipitation in both time and space, irrigation and drainage are the life blood of agricultural production. Up to 2008, approximately 85,400 reservoirs were constructed with a total capacity of 634.5 billion m^3. The current annual total water supply capacity of various projects

Figure 57.3: Framework for grain production and the analysis of the development of irrigation. **Source:** Developed by the authors.



reached 659.1 billion m^3. In 2007 the total volume of water used was 581.9 billion m^3, whereof 12.2 per cent, 24.1 per cent, 61.9 per cent and 1.8 per cent were

used by the households, the industry, the agricultural sectors, and by the ecological system. Up to now, there are 402 large irrigation schemes each with an irrigated area of more than 20,000 ha. For China the construction of small rain water harvesting projects is of utmost importance (PRC 2007).

57.5 Effects of Climate Change on Water Resources

Due to global warming annual average temperature and precipitation varied significantly over several years. Extreme weather events have also increased, and the regional variation of precipitation and river run-off rose significantly. During the past two decades, the annual average temperature has risen, especially for northern China. Since 1985, China has experienced 21 warm winters. Due to climate change the relationship between precipitation and water resources has changed in some river basins. Particularly, in the Yellow River, the Huaihe River, the Haihe River, and the Liaohe River basins, the average surface runoff has declined by 17 per cent of which a six per cent decline occurred during the past 20 years.

Among these four river basins, the Haihe River Basin experienced the largest change with a 41 per cent reduction in surface water resources due to a 10 per cent decline in precipitation.

For the past decade, the climate and hydrological changes and their effects on water resources in China were summarized by Liu (2008):

- In most parts of China, temperature has been rising, except in the southwest region. The temperature increase in the north has been higher than in the south; the areas with the highest temperature increase are in the northeast and in Xinjiang, where temperature has increased by more than 1°C.
- Annual precipitation in south China with latitudes below 30° has significantly increased. However, precipitation in the area north of the Huaihe River decreased, except in the northwestern part of Xinjiang and in the west of the northeast region.
- Water surface areas are shrinking and water levels are falling in the lakes in the northwest of Inner Mongolia and in the central and western part of he Qinghai-Tibet Plateau.
- The runoff in the Huaihe River and in major rivers north of the Huaihe River has declined. The frequency of floods in the main stream of the Yangtze River and its tributary as well as for rivers south of the Yangtze have increased.

Since 1990 both drought-affected areas and drought disaster areas have expanded. The reduction of grain production caused by drought accounted for more than 60 per cent of the total reduction of cereal production caused by various natural disasters. Taking the extreme drought of the year 2000 as an example, the total disaster area caused by drought was 40.53 million ha and the total losses were 60 billion kilogrammes for grain production and 51.1 billion RMB Yuan for cash crops. The total drought-hit grassland area in the north, northeast and northwest of China was 78 million ha, accounting for more than 65 per cent of total usable grassland. In the year 2006, a serious drought hit Sichuan and Chongqing and resulted in 9.75 billion kilogrammes losses in grain and about 310,000 ha of orchards were destroyed. According to preliminary estimates, since 1990 the average annual loss caused by drought is about 1.1 per cent of the Chinese national GDP, this figure can reach up to 2.5 ~3.5 per cent in extreme drought years (Lu/Gao 2008). Drought and flood affected areas in China from 1950 to 2008 are listed in table 57.8.

57.6 Measures for Coping with Climate Change

57.6.1 Establishing a Legal Framework

In China the laws and regulations for coping with climate change effects include: a) the water law (box 57.1), b) the law on agriculture (box 57.2), c) the law on the popularization of agricultural technologies, d) the regulation for the management of irrigation schemes, e) the regulation for the calculation, collection and management of water fees, and f) the regulation for the management of subsidies for small irrigation and water and soil conservation projects.

The Law on the 'popularization of agricultural technology' encouraged the extension of techniques of irrigation and water conservation, soil improvement and water and soil conservation; techniques of water supply and energy utilization in rural areas and agricultural environmental protection; techniques of agricultural meteorology, and techniques of agricultural management and administration (PRC July 1993).

57.6.2 Implementing Integrated Water Resource Management

The *integrated water resources management* (IWRM) at the basin level has become a new model for water resources management. In China irrigation is the largest water user and consumes more than 60 per cent of the water resources of each basin. There is a significant difference in irrigation efficiency and water productivity among the irrigation districts located at the upper, middle and lower parts of river basins because of the variation of natural, economic and social conditions. Usually, the irrigation efficiency and water productivity of the irrigation districts downstream is higher than those of the upstream irrigation districts. However, compared with those downstream the upstream irrigation districts usually receive more water with better quality. Thus, it is necessary to optimize the allocation of water resources at the basin level in order to increase the general water use efficiency and productivity in the whole basin.

57.6.3 Enhancing Infrastructure for Irrigation and Drainage

During the past five decades, China has made tremendous achievements in water conservation. Currently, there are 57.8 million ha of irrigated area, accounting for 47.38 per cent of the total farmland of 122 million ha. However, most of the existing irrigation schemes were built before the 1970's with low design standards and mismatching facilities. After more than 30 years of operation, serious aging problems have emerged, which resulted in low efficiency and reliability. Since 1998, the rehabilitation and modernization of large-scale irrigation schemes has been carried out with the objective to upgrade 402 large irrigation schemes by the year 2020. The main purpose of the rehabilitation and modernization of large irrigation schemes is to increase its water efficiency and productivity. The rehabilitation of more than 260 large-scale pumping stations for irrigation and drainage is scheduled to be completed until 2012 to 2014 within. The reinforcement of 6240 large, medium and small-sized reservoirs will be completed by 2010. In the mean time, the amelioration of low-yield farmland will be implemented in large scale (Chen 2009).

Box 57.1: Modifications of the Chinese water law. **Source**: PRC (1 October 2002).

China's modified 'water law' entered into force on 1 October 2002, highlighting the following aspects:

- Article 3: Water resources shall be owned by the state. The State Council shall exercise ownership of water resources on behalf of the state. Water in the ponds of rural collective economic organizations and in the reservoirs constructed and managed by rural collective economic organizations shall be used by those organizations.
- Article 4: The development, utilization, preservation, and protection of water resources and the prevention and control of water disasters shall be carried out through comprehensive planning, with all factors taken into consideration. The planning shall seek both a temporary solution and a permanent cure, with emphasis on multipurpose use and achieving maximum benefits to take advantage of the multiple functions of water resources and harmonize water use in production and the environment.
- Article 5: The governments at and above the county level shall strengthen the construction of infrastructures for water conservation that shall be included in plans for national economic and social development.
- Article 6: The state shall encourage entities and individuals to develop and utilize water resources according to law, and to protect their legal rights and interests. The entities and individuals developing and utilizing water resources shall bear an obligation to protect water resources according to law.
- Article 7: The state shall apply the systems of water licensing and paid use of water resources according to law, excepting collective economic organizations and their members' use of the water in the ponds and reservoirs owned by those organizations. The department of the water administration under the State Council shall be responsible for organizing the water license system and its implementation as well as the nationwide paid use of the water resource system.
- Article 8: The state shall require strict economy in the use of water, vigorously promote measures for water saving, spread of new technology and techniques to conserve water, develop the water conservation industry and agriculture and service industry, and establish a water conservation society.
- Article 10: The state shall encourage and support the research, distribution, and application of the advanced technology for the development, utilization, preservation, protection, and management of water resources and the prevention and control of water disasters.
- Article 11: The people's governments shall award the entities and individuals that have made outstanding achievements in the development, utilization, preservation, protection and management of water resources and in the prevention and control of water disasters, etc.
- Article 21: The development and utilization of water resources shall first satisfy the needs of the urban and rural inhabitants in their domestic use of water and give overall consideration to the agricultural, industrial and ecological need for water as well as to the needs of navigation.
- Article 25: The local governments at various levels shall improve the leadership over the work of irrigation, draining saturated fields, and water and soil conservation, thus promoting the development of agricultural production. In areas where brackishness or saturation is likely to take place, the governments shall take actions to control and lower the level of groundwater. In dry and semi-dry areas, the development and utilization of water resources shall take into full consideration the ecological water needs for the environment.
- Article 47: The state shall apply a system that combines the control of the total amount that is to be managed on a quota basis.
- Article 49: The used water shall be measured, and the water shall be used according to the approved plans. Measurements of water use shall be adopted charging progressively fees for the water use above the granted quota.
- Article 50: The governments at various levels shall promote water saving irrigation modes and water saving technology, and shall take necessary measures

Box 57.2: References to irrigation in the law on agriculture. **Source**: PRC (1 March 2003).

In the 'law on agriculture' these articles address irrigation development and management (PRC 1 March 2003)

- Article 17: People's governments at all levels shall take measures to strengthen the agricultural development and the construction of infrastructures for agriculture and the rural areas, such as irrigation and water conservation, protection of the agricultural ecological environment, rural roads, rural energy and electric networks, storage and circulation of agricultural products, fishing ports, grassland enclosures and bases of original and fine breeds and improved strains of animals and plants, improve the conditions for agricultural production, and protect and increase the comprehensive production capacity of agriculture.
- Article 19: Governments at all levels and agricultural production and operation organizations shall strengthen the construction of irrigation and water conservation facilities, establish a sound system for the management of such works, economize on the use of water, develop a water-saving agriculture, con-

trol strictly in accordance with the law the use of irrigation water resources by non-agricultural construction projects and prohibit all organizations and individuals from unlawfully occupying or damaging irrigation and water conservation facilities. The state gives priority to water-deficient regions in supporting the development of a water-saving agriculture.

- Article 20: The state encourages and supports farmers and agricultural production and operation organizations to use advanced, applicable farm machines and it improves the safety control over such machines to raise the level of agricultural mechanization..

The state also supports farmers and agricultural production and operation organizations in purchasing advanced farm machines.

- Article 21: Governments at all levels shall support the development of the meteorological undertakings in the service of agriculture and enhance their abilities for monitoring and forecasting meteorological calamities.
- Article 40: The state, through taxation, pricing, credit and other means, encourages and guides farmers and agricultural production and operation organizations to increase investment in agricultural production and operation and in capital construction such as small irrigation and water conservation projects.
- Article 59: The governments at all levels shall take measures to improve the comprehensive rehabilitation of small river basins, and to prevent and control soil erosion. Units and individuals engaged in the production or construction which may cause soil erosion shall take preventive measures, and shall be responsible for the control of soil erosion caused by production or construction.

57.6.4 Adopting Water-saving Irrigation Practices.

Currently in China the annual water shortage in agricultural irrigation is about 30 billion m^3. Due to social and economic development the demand for water will further increase. To cope with the water shortage and to increase the irrigated area technologies and measures for water saving in irrigation have been introduced and extended with the objective to improve the efficiency and productivity of water use.

The efficiency and productivity of irrigation are improved at two levels, at the farm and the irrigation district level (Gao 2005). The technologies and measures for improving the efficiency and productivity of water use for irrigation differ at both levels because the beneficiaries, the incentives and goals of water saving may be different.

At the farm level small basin, furrow, sprinkler and drip irrigation and land levelling and other measures can be used. For cash crops, micro sprinkler irrigation and drip irrigation can be applied. For field crops, such as wheat and maize the main water saving measures include land levelling, optimal size of basin and furrow, and use of low pressure pipelines. The end users of these water-saving technologies and measures are farmers. They can benefit from water savings by reducing irrigation and labour costs, improving irrigation uniformity, increasing production and labour intensity by adopting water-saving irrigation technologies and measures. Across China on-farm water saving practices were tested in pilot projects in 300 counties and the extension of water saving practices is currently being carried out nationwide.

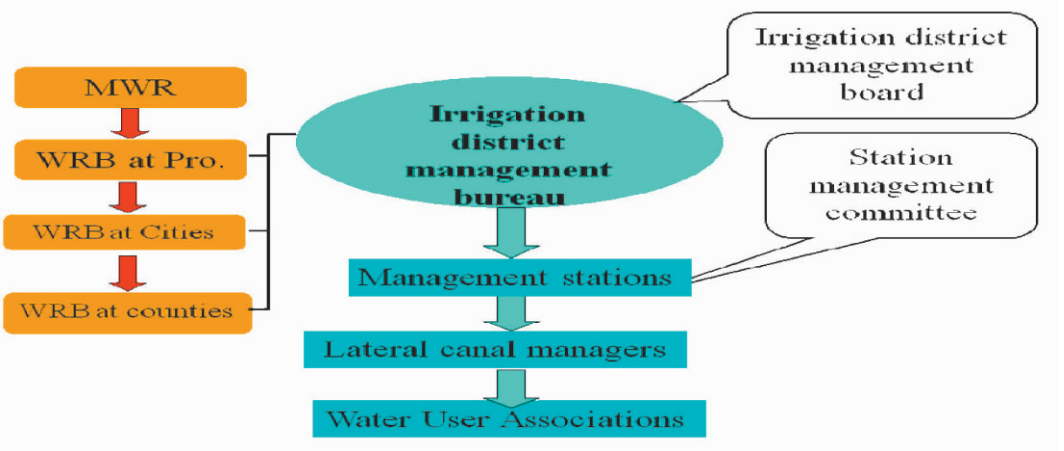
At the irrigation district level, the technologies and measures adopted for increasing water use efficiency include canal lining, application of pipelines and improvement of control structures and facilities for water measuring, automation and other technologies for operating irrigation systems. These technologies have been tested in 30 large irrigation districts. The recycling and reuse of water resources in irrigation districts is also practiced at the irrigation district level. It has been proven that recycling and reusing water at the irrigation district is a cheaper and more effective way to increase the water for irrigation by using efficiency and productivity.

57.6.5 Reforming Irrigation Management Institutions.

In China the administration of the irrigation management is handled by water resource departments at various levels (Gao 2009). The structure of the irrigation management system is shown in figure 57.6.

At the central level, the *Ministry of Water Resources* (MWR) takes the responsibility to work out national irrigation development planning, stipulate and modify related regulations, and supervise the implementation of planning and regulations. The *Water Resources Bureaus* (WRBs) at the province, city and county levels take the responsibility to work out local irrigation development planning and supervise the implementation of planning and regulations and the management of irrigation schemes. To promote sustainable development and to increase the productivity and profitability of irrigation systems, institutional reforms in irrigation and drainage system management

Figure 57.6: Structure of the irrigation management system. **Source:** Li Daixin (2002).



towards a stakeholder-involved management have been introduced.

The major stakeholders include the government, the professional irrigation management agency, *water use associations* (WUAs) and farmers. In China most of large and medium irrigation schemes are jointly managed by professional agencies and farmer's collectives or WUAs. Usually, as a professional agency the irrigation management bureau and its management stations takes the responsibility to operate and maintain the main structures, and the main and branch canals of the irrigation system. The canals below the tertiary canal and small irrigation projects are operated and managed by *Water User Associations* (WUAs) or farmer's collectives. Different roles of the three key stakeholders of the government, of irrigation management agents and of WUAs must be distinguished.

The role of the *government* is to provide leadership, to design national development planning, to stipulate and modify modifying policy and legal arrangements and related regulations, to supervise the implementation of planning and regulations, to stipulating and, to make and modify institutional arrangements, to strengthen capacity building, to making financial arrangements and to asess existing irrigation systems.

The tasks of *irrigation management agents* are to evaluate and benchmark the operation of irrigation systems, to conduct feasibility studies and designs for rehabilitation, to carry out the rehabilitation of the main canals and structures of irrigation systems, to implement institutional reform, to operate and maintain the main structures and canals systems, to bridge the gap between the government and WUAs, to provide technical support to WUAs, to supervise and monitor irrigation systems, to document the operation of irrigation schemes and to test and introduce new technologies and materials.

The *responsibility of WUAs* is to carry out the rehabilitation as well as to operate and maintain on farm canals and structures and to provide irrigation services to individual water users.

57.6.6 Collection of Water Fees

Since 1995, when the first farmer WUA was established in the Zhanghe irrigation district of Hubei province, participation of irrigation management has been adopted in 30 provinces and autonomous regions in China. Currently, there are more than 20,000 such water user associations and cooperative organizations which involve 60 million farmers. The irrigated area managed by water user associations has reached to 6.67 million ha (Pie 2009). It has been proven that participatory irrigation management is an effective measure to increase the water efficiency and productivity of irrigation, especially for China's specific conditions of many small land plots per household. The collection of water fees has been improved since the introduction of WUAs.

57.6.7 Strengthening Protection and Proper Groundwater Use

In China groundwater has played an important role in irrigation, in domestic and industrial water supply, especially in dry years. Groundwater will play an even more important role under climate change. To achieve a sustainable exploitation and use of groundwater, it is important to protect the groundwater through a reasonable exploration and use and adequate recharge measures. The new 'Water Law' high-

lights the integrated surface and groundwater management.

57.6.8 Strengthening the Construction of Small-scale Water Conservation Projects and the Use of Poor Quality Water

To cope with problems of water shortage and climate change, the construction of medium, small and micro-size projects, including rainwater harvesting and utilization projects, have been developed in China, especially in the northwest and southwest. The treatment and application of poor quality water is also practiced in line with local conditions. Currently, there are 4.2 million small water storage ponds and rainwater harvesting wells for supplying drinking water and 7 million small water storage ponds and rainwater harvesting wells for irrigation purposes.

57.6.9 Encouraging International Cooperation

Facing the floods, droughts and water shortages caused by climate change, the research on adaptation strategies and long-term development planning are being carried out with the support of the governments at different levels. Much experience and progress has been gained with integrated water resources management and through the application of advance technologies. China has attached great importance to international cooperation on research to cope with climate change.

57.7 Conclusions

The food demand in China is continually going up due to population growth. Irrigation has played a significant role in agricultural production and food security due to the uneven distribution of precipitation in both time and space. Climate change has and will have a big impact on the supply and demand of water resources, as floods and droughts have occurred more frequently. Extreme droughts and floods caused by climate change have a major impact on agricultural production. Thus, measures must be undertaken to cope with climate change. To maintain food security at a self sufficiency rate of 95 per cent, the irrigation area in China should reach 58.69 million hectares in 2010 and 59.97 million hectares in 2020.

To solve the problem of water shortage and to cope with climate change, measures are undertaken to improve the use of irrigation water by enhancing the efficiency at the farm, irrigation district and river basin levels with a different focus at diverse levels. Related laws and regulations have been passed and modified. Integrated water resource management will be an effective measure to cope with climate change and water shortage.

Most of China's existing irrigation schemes were built before the 1970's, the rehabilitation of these irrigation schemes is an effective measure for coping with climate change and ensure food security. China has launched the rehabilitation and moderation of large irrigation schemes, and this rehabilitation work is scheduled to be completed by 2020. Reform of the irrigation management institutions is an important component of the modernization of these irrigation schemes and has been successfully adopted in China.

Measures have been undertaken to strengthen the protection and reasonable exploitation and utilization of groundwater. Medium and small projects, including rainwater harvesting and utilization projects, have been developed to cope with water shortage and climate change in China.

58 Ensuring Water Security in Rural Areas of Bangladesh under Climate Change and Non-climatic Drivers of Change

Mohammed Rahman Zillur and Kuntala Lahiri-Dutt

58.1 Introduction

This chapter addresses the question of security[1] and sustainability[2] of *water resource management* (WRM) in Bangladesh due to climate change and complex social and political factors including weak governance. It suggests that social networks should play an important role in ensuring security at the micro levels, and the promotion of people-centred water management. Bangladesh, a highly populated country located on the floodplains of the Ganges-Brahmaputra-Meghna Rivers, receives abundant monsoonal rain which is concentrated between June and September. Rapid population growth, economic growth imperatives, changing farming practices and the weak coordination of WRM have increased the gap between the demand and supply of water leading to a water crisis that threatens the stability of the country. It is increasingly being understood that climate change poses a serious challenge for future water resource management in South Asia as a whole and exacerbates existing environmental problems. Babel and Wahid (2008) showed that Bangladesh is highly vulnerable to declining freshwater supplies. Mirza and Ahmad (2003) showed that the melting of the Himalayan glaciers will change the volume and frequency of monsoonal floods due to changed river regimes and affect Bangladesh more severely than other parts of South Asia. Other changes in the country's water resources include large-scale sedimentation, changing water quality, saline intrusion in coastal areas, land-use conversion and degradation of water ecosystems.

Threats to the security of water resources and vulnerabilities,[3] however, are not caused only by climate change; there are a number of non-climatic drivers or human-induced activities involved. For instance, discharging household and industrial sewage and wastewater into canals and rivers without any treatment, illegal encroachment of river course and construction inside river channels, imbalanced use and control of water by upstream users causing a reduction on the volume of flow, are important human-driven factors. These affect water availability in major rivers causing water resource pollution and posing threats for human health throughout the rural areas in Bangladesh.

Sustainable economic development and poverty reduction still remain top priorities for Bangladesh, while the effects of climate change and impacts of non-climatic drivers on its water resources affect human activities and settlements, making farmers in rural areas in particular and poor people in general highly vulnerable. Increased water insecurities have the potential to undermine the nation's development goals, in particular to erode its sustainability.

Although the predictive power of water resources and climate change models has improved significantly, so far little has been done to link climate change to rural social factors, which are crucial in determining

1 Environmental security is an increasing issue in world affairs. Currently there is little coherence around the world on its definition, threats, and policy responsibilities. For the present purpose of this chapter, we use Barnett's definition: environmental security is the proactive minimization of anthropogenic threats to the functional integrity of the biosphere and thus to its interdependent human component (Barnett 2001).

2 For the purposes of this chapter, we follow the definition of sustainability or sustainable development by the World Commission on Environment and Development (1987), defining sustainability as "forms of progress that meet the needs of the present without compromising the ability of future generations to meet their needs."

3 The best, pro-poor, definition of vulnerabiulity has been proposed by Wisner, Blaikie, Cannon and Davis (1994: 16): "By vulnerability, we mean the characteristics of a person or a group and their situation that influence their capacity to anticipate, cope with, resist and recover from the impact of a natural hazard."

H.G. Brauch et al. (eds.), *Coping with Global Environmental Change, Disasters and Security*, Hexagon Series on Human and Environmental Security and Peace 5, DOI 10.1007/978-3-642-17776-7_58, © Springer-Verlag Berlin Heidelberg 2011

water resources management practices in Bangladesh. In linking both, this chapter assumes that the study applies to WRM and security issues by enhancing our knowledge of sustainability under changing climatic and non-climatic conditions. Given its weak governance structures this chapter may have some policy relevance for Bangladesh and could be used by other countries whose water resources are also severely affected.

58.2 Background

Local to global water resources, environment and ecosystem are being heavily influenced by both climate change and non-climatic drivers such as human activities. In the following sections we shall discuss how climate change (*climatic drivers*) and human activities (*non-climatic drivers*) impact on water resource and increase the vulnerabilities of the environment, of human beings and society in Bangladesh.

58.2.1 Climatic Drivers: Impacts and Vulnerabilities

Alam and Murray (2005: 3) observed that climate change would impose significant stress on resources throughout Asia, but "water resources, coastal ecosystems and human settlements" are amongst those that are "thought to be highly vulnerable to climate change." The *fourth assessment report* (AR4) of the *Intergovernmental Panel on Climate Change* (IPCC 2007a) indicates that one of the most important challenges for Bangladesh's potential for sustainable development is the impact of climate change on its wa-

Figure 58.2: Flood types in Bangladesh. **Source:** Ahmad, Warrick, Ericksen and Mirza (1996: 13). Permission was granted.

ter resources. Hydro-geological, human health and socio-economic factors in Bangladesh are highly vulnerable to the severe impacts of climate change. In coastal zones, for example, there would be a combined effect of climate change, sea level rise, subsidence and changes of upstream river discharge, cyclone and coastal embankments. Bangladesh's dynamic coastal morphological processes would experience change in the tidal and seasonal variations as well as experience increased frequency and intensity of extreme events (World Bank 2000). According to Ahmed (2006), a number of factors are contributing to the increase of these vulnerabilities, such as the geographical location of the country, the low elevation of the land and the deltaic and tidal landscape, concentrated and heavy monsoon rains within a short period, high population density and a high dependence on agriculture that is dependent on monsoonal water supplies. The key impacts of climate change on water resources in Bangladesh and the increased vulnerabilities raise the question(s): who or what is vulnerable to climate change and how and why they are vulnerable? We discuss these questions this next section.

In short, the key climate change impacts in Bangladesh are:

- increases of rainfall leading to an unusual flow of abundant water between June and September and very limited water flows from November to May;
- increases of water temperature and evapotranspiration rates lead to a decline in water quality in most parts of country;
- increased temperatures in the Himalayan glaciers lead to water shortages in Bangladesh;
- acceleration of the ice discharges from Greenland and Antarctic ice sheets contribute to a rise in sea-level, posing threats to costal areas in Bangladesh.
- which impact on aquatic ecosystems raising concerns on water-related biodiversity.

58.2.1.1 Important Vulnerabilities

People living in rural and costal areas in Bangladesh are more vulnerable to the impacts of climate change on water resources. Urban livelihoods and national economic activities directly and indirectly rely on the production (agriculture, fishing, cattle) in rural areas. Thus, the climate change impacts on water resources increase the vulnerabilities not only in rural areas, but also of urban livelihoods and the economic development of the country. For instance, if less rice is pro-

duced, the government must spend public resources for imports. Below, we discuss how and why people in rural and costal areas and national economic development are vulnerable to the impacts of climate change.

Water quality: According to Longfield and Macklin (1999), climate change increases the vulnerabilities of many geomorphic processes in water infrastructures, such as slope stability, soil moisture, erosion and sediment transportation. The usual infrastructures of most rivers, canals and agricultural lands in Bangladesh are becoming endangered by the unusual water flows. This further increases the vulnerabilities from floods, droughts and water quality in most parts of Bangladesh, posing threats to human health and ecosystems. Heavy rainfall and floods bring additional suspended solids and increase the turbidity in lakes, ponds, reservoirs and introduce pollutants (pesticides, organic matter, heavy metals) and promote algal blooms and increase bacteria content. Moreover, Schindler (2001) argues that volatile and non-volatile compounds such as ammonia, mercury, dioxins and pesticides will spread with surface water bodies to the atmosphere, putting rural people's living conditions at risk.

Key human vulnerabilities are for:

- *rural people*, especially farmers (using contaminated water for irrigation), children and poor men and women who are directly affected by water quality (from lack of pure water for drinking and other household purposes);
- *urban people* who are indirectly vulnerable, because many sick people in rural areas move to urban areas and spread diseases. Food supply in urban areas could decline and urban livelihoods could thus also be affected.

Coastal areas: Ericson, Vˆrˆsmarty, Dingman, Ward and Meybeck (2006) have noted that the Ganges, Brahmaputra and Meghna rivers are highly sensitive to sea-level rise, where the largest segment consists of deltaic plains. This unique physical property of the region presents great risks to coastal water resources and for the population, particularly for the poorer communities (Woodroffe/Nicholls/Saito/Chen/Goodbred 2006). Allison, Khan, Goodbred and Kuehl (2003) argue that salinization of surface water in the coastal regions in the south of Bangladesh increases through seawater (saltwater) incursion into surface or freshwater sources, costal aquifers and costal river systems and that is attributed by a rising sea level in the Bay of Bengal.

Key human vulnerabilities: Coastal farmers will lose agricultural lands and its productivity due to sea level rise and saltwater intrusion.

Agricultural productivity: Agriculture and agri-food production sectors in Bangladesh are most vulnerable due to conditions such as heavy rains, flood conditions, weak quality of water and severe drought. Faisal and Parveen (2004) point out that rice and wheat productions are more vulnerable than other crops because of their requirement of water for cultivation. They argue that about 8 per cent of rice and 32 per cent of wheat production will drop in Bangladesh by 2050 due to climate change and its implication on water sector. From past experiences, almost every year, all floods had submerged huge agricultural cultivated lands and damaged large amount of crops. On the contrary, during the summer season, rural farmers face challenges to cultivate rice and wheat crops due to severe drought in the northern part of Bangladesh.

Key human vulnerabilities:

- Because the rural people will not have the means to access the commercial market to buy products

that they could produce, less agricultural productivity will pose direct threats to their livelihoods.
- Urban people are indirectly vulnerable because food supply in urban areas will decline and urban livelihoods would be affected.
- National economic development is directly vulnerable because of its agro-based economy.

Water related biodiversity: The impacts of climate change on inland aquatic ecosystems in Bangladesh are quite large. Water-related biodiversity across the country remain highly vulnerable because of the effects of rise in water temperature that lowers water quality; alter mixing patterns of water compounds of lakes, ponds and rivers. Production of planktonic communities and their food web, species composition will change with higher water temperature. As a result fish yields in many lakes, ponds and rivers in Bangladesh have declined and many other species are threatened with extinction (MA 2005). On the other hand, coastal vegetated wetlands and water-based species also face this risk due to saline intrusion and erosion through extreme events such as seal level rise, tornados and cyclones in coastal areas.

Key human vulnerabilities: Less fish production poses threats to rural people in terms of lack of protein with their intake. Less fish in rivers and canals means rural people can not access the commercial market to buy fishes.

Risk of human health: Human beings are directly and indirectly vulnerable to climate change through changes in the poor quality of water. Floods, considered to be one of the most frequent natural weather disasters in the country, have large impacts on the water quality[4] and on health ranging from injuries to deaths (Ahern/Kovats/Wilkinson/Few/Matthies 2005). In addition, floods, storms, cyclones and tornados destroy many infrastructures including the sanitation sys-

4 See EM-DAT: The OFDA/CRED International Disaster Database; at: <http://www.em-dat.net> (10 April 2009).

tems of the rural poor. They also contaminate water supplies with faecal bacteria, with dangerous chemicals, pesticides, metals and hazardous waste. All these affect human health through diseases such as vector-borne (e.g. malaria) and water-borne (e.g. cholera). One indirect result of poor public health is that the productive efficiency of rural agricultural activities and non-farm economic activities are affected by the shortage of labour and waste of man days.

Livelihood vulnerabilities in the Charlands: The river systems in the Bengal delta, are in the final stages of formation. They bring large amounts of silt from upstream parts in the Himalayas which give rise to riverine islands within the river beds and channels that are locally known as the *char*lands. People living in *char*lands are among the poorest and the most vulnerable to sudden floods. Baqee (1998: 1–2) has shown that the large number of *choura*s, the inhabitants of the chars, constitute "some of the most desperate people in the country," who live in a most uncertain and fragile environment. Thus, *chars* have been at the epicentre of resource management and of policy debates in Bangladesh because of the importance of the riparian zones to the country's life and economy and the large number of people living and using these lands (Chowdhury 2000). Lahiri-Dutt and Samanta (2006) noted that people who live in *char*lands and who are coping with perceived insecurities, due to certain livelihood benefits as well as lack of alternative opportunities, and social capital play an important role in mobilizing community support and enhancing resilience to cope with sudden disasters. The impacts of climate change on water resources, in particular the seasonal floods, riverbank erosion and shifting river channels, are expected to make these large numbers of *choura*s physically, socially and economically more vulnerable and displace many of them, forcing them to become environmental migrants unless people-oriented water management practices are promoted.

Socio-economic vulnerabilities due to climate change can occur in different forms in Bangladesh; for instance, damages can occur in an inequitable manner leading to even permanent displacement of the rural poor due to floods, droughts (or perceived droughts, such as the lack of water in Padma River), tornados and cyclones. Rural and coastal communities in Bangladesh are mostly victims of these changes because of their limited resources, opportunities and protection. Traditional livelihoods of local people are threatened by their lacking ability to irrigate crops due to water shortage or their lacking resources to buy other products due to the crop damages from natural hazards. Affected people are mentally stressed losing crops, property, infrastructures and livestock. But certain segments of the population, especially children, the elderly, daily paid workers (working for other farmers) and marginalized groups are even more vulnerable Further, diseases emanating from the poor quality of water make some local people socially vulnerable because they do not get proper treatment due to a lack of money. As a result, social stability will be affected because most rural people will lose their income, become unemployed and live with high mental stress. The education of children and of the young from affected families will be interrupted and they will be socially vulnerable due to lower economic productivity. Finally, the national economic development is directly affected by these changes.

58.2.2 Human-induced Drivers, Impacts and Vulnerabilities

Water resources in Bangladesh are not only threatened by the impacts of climate change, but also by non-climatic drivers or human-induced activities, such as:

- Household sewage and wastewater are discharged untreated into canals and rivers causing water pollution.
- Due to a lack of tight regulations and effective monitoring systems water sources are at risk from industrial effluents discharged into rivers. Textiles, tanneries, pulp and paper mills, fertilizer, chemical industry and refineries are the most harmful industries for the water sector in Bangladesh. According to Cegis (2003) these industries also discharge hazardous chemicals, both organic and inorganic, without treatment.
- Imbalanced use and control of water by upstream users (e.g. India) are affecting water availability in major rivers in Bangladesh (e.g. in the Padma River).

58.2.2.1 Important Vulnerabilities from Non-climatic Drivers

The quality of water is depleting due to industrial effluents, household sewage and wastewater discharged into rivers. As a result, fishes and other aquatic species are becoming vulnerable to water pollution. Direct or indirect effects of these pollutions are also contributing to people's health and livelihoods. Loss of biodiversity, reduction of fisheries (a major source of pro-

tein for the people) and reduction of agricultural production near river banks also increase the vulnerability of local poor farmers for sustenance.

The water flow of small rivers, canals and lakes distributing the waters from or depending on the Ganges becomes vulnerable due to the diversion and unbalance use of water resource by upstream users in India. The construction of the Farakka barrage over the Indian part of the distributaries of the Ganges River has undoubtedly worsened the water availability during the winter months in Bangladesh. Moreover, the chronic reduction over the recent years in the flows of rivers falling into the Bay of Bengal has unduly created misunderstanding between the upper and lower riparian countries in this part of South Asia. The physical effects have also led to further socio-economic vulnerabilities in the rural areas of the Ganges-Padma basin in Bangladesh. Finally, due to increasing industrialization and urbanization, agricultural lands are shrinking in all over the region, and it is feared that reduced availability of farming land is making the poor more vulnerable. This was apparent from the recent outburst of public anger across the border in West Bengal in India over the acquisition of cultivable land for industrial use, leading to widespread public perception of a looming decline in food security.

58.2.2.2 Weak Governance

According to UNESCAP (2007), most developing societies are facing enormous challenges due to inefficiency and poor accountability which are symptoms of weak governance. Pande, Tropp, Sharma and Khatiwada (2006), in their report on human development and good governance on Nepal, argue that ignoring the interest and priorities of the people in the execution of plans by the government reflects weak governance. This challenges principles of human dignity (inclusiveness, liberty, equality and cooperation) and at the end societies become vulnerable to weak policies. Weak governance is a key non-climatic driver with adverse impacts on WRM. Although climate change impacts are also related to governance issues, the direct impacts of weak governance on the sustainability of water resources in Bangladesh are obvious.

For the WRM in Bangladesh, the influence of weak regulations, lack of cooperation and monitoring systems are acknowledged when major industries (textiles, tanneries, pulp and paper mills, fertilizer, chemical industrial and refineries) ignore their environmen-

Figure 58.6: The central or national (top-down) control system and influences on the local level of government. **Source:** Zillur (2007).

tal consequences that affect the people's livelihood by polluting water resources through industrial effluents. An example of weak governance is the well-known common occurrence of encroachment and illegal constructions on rivers.

The security of water resources in Bangladesh is not only threatened by industrial pollution, but also from the narrowing-down of the water system by illegal encroachment of river channels and river banks for building activities. A recent report in the *Daily Ittefaq* of 16 June 2009 suggests that the Buriganga River in Dhaka will no longer be considered a legitimate river with a regular flow if the construction activities around it are not immediately stopped. Such a dramatically reduced water flow does not only undermine environmental sustainability but also threatens the security of the water resources. One may question the legitimacy of such constructions on common property resources or on public lands, but more importantly, the excessive demands for land are threatening the natural river flows with long-term consequences for human well-being. One may argue that the lack of accountability, transparency and responsiveness of the public authorities are responsible for the failure of the protection of water systems in Bangladesh.

The influence of the national government on local governments is another aspect of weak governance and of poor WRM. Although there is a great demand from civil society organizations, from non-governmental organizations (NGOs) and academics for a decentralization of governance, little progress towards a real decentralization of administration and political power has so far taken place. A reduced control of the central government over local authorities would lead to a loss of power to interfere in local matters.[5]

Unfortunately, the lack of accountability encourages many central administrators to use their authority for personal benefits (figure 58.6). This systematic top-down control is a reflection of weak governance and the process directly and indirectly impacts negatively on the country's water resources. However, there are certain aspects contributing to this prevailing weak governance and affecting the paradigm of WRM (figure 58.7).

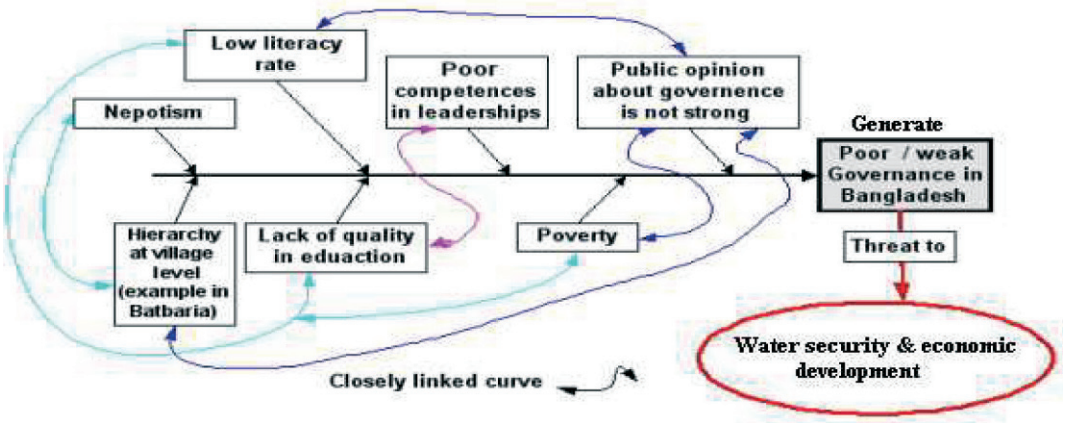
Figure 58.7 illustrates the close linkages among these factors and how these factors are contributing to the risk of water resources due to the formulation of weak governance. For instance, to put pressure on the authorities for certain legal issues, a strong public opinion is necessary. However, it is difficult to consider these public issues given the low literacy rate (ca. 41 per cent) and as many people live below poverty line.

The sensitive politics of transboundary water sharing is another aspect of water security for the rural areas of Bangladesh. Different policies on the water use in international river basins by one country, e.g. by India, Nepal and China affect the water availability in Bangladesh. The Dublin principles[6] emphasize the importance of upstream and downstream users of water as:

5 S. Kazi and K Alam, 2006: "Empowering Local Government in Bangladesh"; at: <http://nation.ittefaq. com/artman/publish/article_29731.shtm> (30 June 200?).

6 Four principles for IWRM were developed in Dublin (1992) by a conference on water and environment
Principle No. 1: Fresh water is a finite and vulnerable resource, essential to sustain life, development and the environment;
- *Principle No. 2*: Water development and management should be based on a participatory approach, involving users, planners and policy-makers at all levels;
- *Principle No. 3*: Women play a central part in the provision, management and safeguarding of water;
- *Principle No. 4*; Water has an economic value in all its competing uses and should be recognized as an economic good (<www.gwpforum.org>).

Figure 58.7: Interlinked factors behind weak governance posing threats for water security in Bangladesh. **Sources:** Zillur (2007).



> Upstream users must recognize the legitimate demands of downstream users to share the available water resources and sustain usability. Excessive consumptive use or pollution of water by upstream users may deprive the downstream users of their legitimate use of the shared resource (Jonch-Clausen 2000: 15).

Bangladesh has complained about declining water flows during the dry season (November to May) due to the construction of Farakka Barrage on the Ganges by India. India has started to build barrages upstream to use the waters of two other large rivers, the Brahmaputra and Meghna. These rivers comprise the main sources of water for many small rivers and canals in Bangladesh and such constructions may impede their natural flows with dire consequences for the downstream ecology (Rahman 2005). The first and second Dublin Principle on *Integrated Water Resource Management* (IWRM) emphasize that a "holistic management approach"[7] and effective participation by all countries – Bangladesh, India and Nepal – are required for an efficient management of transboundary rivers. The geopolitics of the region is undoubtedly dominated by India and water issues continue to provoke strong tensions (Hill 2008). The impacts of reduced flows are far-reaching downstream. Samarakoon (2004) has shown that besides the environmental effects, some social and economic challenges in Bangladesh can sometimes be traced to decreased water flows in the Padma River, particularly during the dry season when other canals and rivers also become vulnerable to reduced flows.

58.2.2.3 Crisis of Water Availability or Governance

Experts have referred to weak governance as the main problem in South Asia. For Moench, Dikshit, Rathore and Srinivas (2003: 3–4) governance is the "core water challenge in South Asia." The fundamental challenge posed by the water crisis in South Asia is not about the capacity of key stakeholders (governments, NGOs or communities) to select technical solutions or planning mechanisms. Since water challenges heavily depend on the 'constitutional foundations' to which all decisions are linked, the authors argue for a deeper analysis of such foundations and if necessary the rethinking of these constitutions. Major questions exist as to who does the integration of water resources planning, whose interests are reflected in the integration process and how this process is governed to ensure that the interests of all stakeholders are equitably reflected, how disputes are resolved, and above all, which issues must be addressed through integrated approaches (Lahiri-Dutt 2008: xxxvii). Similar opinions are voiced by completely different schools of thought. For example, whilst Shiva (2002: 1) argued that "the water crisis is the most pervasive, most severe, and most invisible dimension of the ecological devastation of the earth" and she stressed that the wa-

7 According to the EU, a holistic approach of water resources management that is combined, 'environmentally-sound water management; food security especially for the poor; private sector involvement; reduction of subsidies; decentralization of decision-making to the lowest appropriate administrative level; user participation in services; institutional reform and regulatory frameworks; and cost recovery and pricing' (EU 1999). The definition has been taken from the paper of "Wetlands: water, life, and culture", 8th Meeting of the Conference of the Contracting Parties to the Convention on Wetlands (Ramsar, Iran, 1971), Valencia, Spain, 18–26 November 2002.

Figure 58.8: Water crisis and poor governance relationship. **Source:** Zillur (2007).

ter crisis is mostly a human-created crisis or water *management* crisis instead of a natural crisis.[8] From a more technocentric perspective, Biswas[9] (2006) argued similarly that the South Asian region faces "a crisis of bad water management." The *Asian Development Bank* (ADB) also argued that "the concept of governance is concerned directly with the management of the development process" (ADB 2005).[10]
